#### Abstract

The inclusion of a tetrahedral $\mathrm{XY}_{4}$ molecule (or ion) in a crystal is, very often, followed by a lowering of its symmetry. In order to describe the apparent distortions of the tetrahedron, second-rank tensors were constructed. It was shown that the characteristic surface of such a tensor is always an ellipsoid. The relative lengths of the axes of the ellipsoid and their position with respect to the symmetry elements of the $\mathrm{XY}_{4}$ group can be used to determine the effective symmetry of the molecule, as well as the degree of its distortion. Some of the spectral properties of the studied compounds can also be predicted. $36 \mathrm{SO}_{4}$ ions with accurately refined structures were investigated and the results obtained by this method were compared with the results ${ }^{1}$ obtained by other ${ }^{2-4}$ methods. A correlation of rather high significance ( $r^{2}=$ $=0.97$ ) was found between the main components of the tensor and the frequencies of the components of the antisymmetric stretching vibration $\left(\nu_{3}\right)$ of the molecule.

## INTRODUCTION

In a number of solid state studies of molecules, a lowering of symmetry is observed. In most cases, the local symmetry of such molecules is $C_{1}$ - the lowest one possible (see e.g. Baur ${ }^{2}$ ). Despite this, it may be important to determine the so-called »effective« symmetry (the term "co-kernel" symmetry is sometimes used in the same sense ${ }^{3}$ ), since it often seems that the latter is higher than the local crystallographic one. ${ }^{5,6}$ Unfortunately, it is not altogether clear how the effective symmetry can be exactly determined. One of the possible approaches is based on the use of symmetry coordinates, as shown by Murray-Rust et al. ${ }^{3,4,7}$.

Several methods have so far been used to describe the distortions of tetrahedral molecules in crystals. ${ }^{2-4,7,8}$ Baur ${ }^{2}$ uses distortion indices, Murray--Rust et al. ${ }^{3,4}$ employ displacement vectors and Dollase ${ }^{8}$ defines the degree of distortion as the average distance between corresponding atoms of the
given molecule and the reference one, the latter being chosen as the »... least--squares bestfit polyhedron with optimum location, orientation, size parameters and prescribed symmetry«. ${ }^{8}$

The intention of the present work is to show that the degree of distortion and the effective symmetry of the tetrahedron can be quantitatively expressed by the use of tensors. In addition to this, some spectra-structure correlations are also pointed out.

## MATHEMATICAL METHOD

Let us consider a second-rank tensor with components constant with respect to some space-fixed coordinate system. If we denote the components as $\mathbf{T}_{\mathrm{ij}}$ ( $i, j \in\{1,2,3\}$, the tensor will define a second-order surface in the tridimensional space, given by:

$$
\begin{gather*}
\mathbf{T}_{11} \cdot x^{2}+\mathbf{T}_{22} \cdot y^{2}+\mathbf{T}_{33} \cdot z^{2}+\left(\mathbf{T}_{12}+\mathbf{T}_{21}\right) \cdot x \cdot y+\left(\mathbf{T}_{13}+\mathbf{T}_{31}\right) \cdot x \cdot z+ \\
+\left(\mathbf{T}_{23}+\mathbf{T}_{32}\right) \cdot y \cdot z=1 \tag{1}
\end{gather*}
$$

or

$$
\begin{equation*}
\mathbf{\Sigma} \mathbf{T}_{\mathrm{ij}} \cdot x_{\mathrm{i}} \cdot x_{\mathrm{j}}=1 \quad i, j \in\{1,2,3\} \quad x_{1} \equiv x \quad x_{2} \equiv y \quad x_{3} \equiv z \tag{2}
\end{equation*}
$$

In the domain of orthogonal transformations, it can be proved (see Appendix 1) that the surface does not depend on the choice of the coordinate system. This allows us to use only Cartesian orthogonal coordinates in which case the covariant and contravariant vectors and tensors coincide and we decide on writing their indices as subscripts.

Let $\mathrm{XY}_{4}$ be the molecule of interest. The following notation is used:

$$
\begin{aligned}
& \overrightarrow{X Y}_{1}=\mathbf{p}=\left\{p_{1}, p_{2}, p_{3}\right\} \\
& \overrightarrow{X Y}_{2}=\mathbf{q}=\left\{q_{1}, q_{2}, q_{3}\right\} \\
& \overrightarrow{X Y}_{3}=\mathbf{r}=\left\{r_{1}, r_{2}, r_{3}\right\} \\
& \overrightarrow{X Y}_{4}=\mathbf{s}=\left\{s_{1}, s_{2}, s_{3}\right\}
\end{aligned}
$$

If we write

$$
\begin{equation*}
\mathbf{T}_{\mathrm{ij}}=\frac{p_{\mathrm{i}} \cdot p_{\mathrm{j}}}{|\mathbf{p}|^{\delta}}+\frac{q_{\mathrm{i}} \cdot q_{\mathrm{j}}}{|\mathbf{q}|^{\delta}}+\frac{r_{\mathrm{i}} \cdot r_{\mathrm{j}}}{|\mathbf{r}|^{\delta}}+\frac{s_{\mathrm{i}} \cdot s_{\mathrm{j}}}{|\mathbf{s}|^{\delta}} \quad i, j \in\{1,2,3\} \tag{3}
\end{equation*}
$$

it is obvious that the right-hand side of equation (3) is a tensorial quantity and so it is independent of the choice of the coordinate system which can, therefore, be chosen quite arbitrarily. The quantity $\delta$ is a constant and will be discussed in more detail later.

Let us now briefly examine some characteristic cases:
a) Let the atoms $Y_{1}, Y_{2}, Y_{3}, Y_{4}$ be at the corners and the atom $X$ in the center of a regular tetrahedron. The $X-Y_{1}$ distance is fixed as a unit of length and the $x, y, z$ axes of the coordinate system are chosen to coincide with the $C_{2}$ axes of the molecule. The coordinates of the atoms are:

$$
X-(0,0,0)
$$

$$
\begin{aligned}
& Y_{1}-(0, \sqrt{3} / 3, \sqrt{2} / 3) \\
& Y_{2}-(0, \sqrt{3 / 3},-\sqrt{2 / 3}) \\
& Y_{3}-(\sqrt{2} / 3,-\sqrt{3 / 3}, 0) \\
& Y_{4}-(-\sqrt{2} / 3,-\sqrt{3 / 3}, 0)
\end{aligned}
$$

Substituting these coordinates (since they are, at the same time, the components of the four vectors) into (3), one obtains

$$
\left(\mathbf{T}_{\mathrm{ij}}\right)=\left[\begin{array}{ccc}
\frac{4}{3} & 0 & 0  \tag{4}\\
0 & \frac{4}{3} & 0 \\
0 & 0 & \frac{4}{3}
\end{array}\right]
$$

This tensor defines the surface:

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=\frac{3}{4} \tag{4a}
\end{equation*}
$$

and it can, thus, be concluded that the characteristic surface of a tensor adjoint to a regular tetrahedron is a sphere.
b) Let the atoms $Y_{1}, Y_{2}, Y_{3}, Y_{4}$ be at the corners of a regular trilateral pyramid with $X$ and $Y_{4}$ lying on the $C_{3}$ axis. If the coordinate system is chosen in such a way that the $z$-axis coincides with the $C_{3}$-symmetry axis and $Y_{1}$ lies in the $y z$ plane, the coordinates of the atoms would be:

$$
\begin{aligned}
& X-(0,0,0) \\
& Y_{1}-(0, \sqrt{8} / 3, \mu) \\
& Y_{2}-(\sqrt{6 / 3},-\sqrt{2} / 3, \mu) \\
& Y_{3}-(-\sqrt{6 / 3},-\sqrt{2} / 3, \mu) \\
& Y_{4}-(0,0, \nu)
\end{aligned}
$$

where $\mu$ and $\nu$ are arbitrary parameters. It follows from (3) that

$$
\left(\mathbf{T}_{\mathrm{ij}}\right)=\left[\begin{array}{ccc}
\frac{4}{3 \omega} & 0 & 0  \tag{5}\\
0 & \frac{4}{3 \omega} & 0 \\
0 & 0 & \frac{3 \mu^{2}}{\omega}+v^{2-\delta}
\end{array}\right]
$$

with $\omega=\left(\frac{8}{9}+\mu^{2}\right)^{\delta / 2}$.
This tensor defines the surface:

$$
\begin{equation*}
\frac{4}{3 \omega} \cdot x^{2}+\left(\frac{4}{3 \omega} \cdot y^{2}+\frac{\left(3 \mu^{2}\right.}{\omega}+v^{2-\delta}\right) \cdot z^{2}=1 \tag{5a}
\end{equation*}
$$

Hence, for $X Y_{4}$ molecules with $C_{3 v}$ symmetry the characteristic surface of the tensor is an ellipsoid of revolution, the $C_{3}$-axis being the axis of revolution.
c) Let $D_{2 d}$ be the symmetry of the molecule; the $y$-axis is set to coincide with the $S_{4}$-axis, while the atoms $Y_{1}$ and $Y_{2}$ are placed in the $y z$-plane and the atoms $Y_{3}$ and $Y_{4}$ - in the $x y$-plane, respectively. If, as earlier, the $X-Y_{1}$ distance is chosen as a unit of length, the coordinates of the atoms would be:

$$
\begin{aligned}
& X-(0,0,0) \\
& Y_{1}-(0, \cos \varphi, \sin \varphi) \\
& Y_{2}-(0, \cos \varphi,-\sin \varphi) \\
& Y_{3}-(\sin \varphi,-\cos \varphi, 0) \\
& Y_{4}-(-\sin \varphi,-\cos \varphi, 0)
\end{aligned}
$$

( $\varphi$ is the angle between $\vec{X} Y_{1}$ and $y$-axis). The characteristic surface is again ellipsoid of revolution

$$
\begin{equation*}
2 \sin ^{2} \varphi \cdot x^{2}+4 \cos ^{2} \varphi \cdot y^{2}+2 \sin ^{2} \varphi \cdot z^{2}=1 \tag{6}
\end{equation*}
$$

the axis of revolution coinciding, in this case, with the $y \equiv S_{4}$-axis.
d) Suppose $D_{2}$ is the local symmetry of the molecule (for $C_{2 v}$ symmetry the discussion is analogous). If the axes of the coordinate system are chosen to pass through the $C_{2}$ axes of the molecule and $X-Y_{1}=1$ is taken for convenience, one can write the coordinates of the atoms as

$$
\begin{aligned}
& X-(0,0,0) \\
& Y_{1}-(\chi, \nu, \zeta) \\
& Y_{2}-(-\chi, \nu,-\zeta) \\
& Y_{3}-(-\chi,-\nu, \zeta) \\
& Y_{4}-(\chi,-\nu,-\zeta)
\end{aligned}
$$

where $\chi^{2}+\nu^{2}+\zeta^{2}=1$. Substituting these coordinates into (3), one obtains a tensor for which the characteristic surface is

$$
\begin{equation*}
4 \chi^{2} \cdot x^{2}+4 \nu^{2} \cdot y^{2}+4 \zeta^{2} \cdot z^{2}=1 \tag{7}
\end{equation*}
$$

The axes of the corresponding ellipsoid are: $a=\frac{1}{2 \chi}, b=\frac{1}{2 \nu}, c=\frac{1}{2 \zeta}$, and thus this ellipsoid is not an ellipsoid of revolution.
e) In fact, it can be proved (see Appendix 2) that the characteristic surface of the tensor is always an ellipsoid, even if the distortion of the tetrahedron is quite arbitrary.

From the arguments given so far, it can be concluded that the symmetry of the $X Y_{4}$ molecule may be also described by the properties of the adjoined tensor (i. e. the properties of its characteristic surface). Therefore, if the molecule possesses some non-trivial symmetry, at least some of the axes of the
ellipsoid will lie on some symmetry-elements. For $C_{3 v}$ and $D_{2 d}$ symmetry, the ellipsoid is a solid of revolution, i. e. two of its axes have equal lengths. Hence, the axes $a, b, c$ and their position with respect to the symmetry elements of the tetrahedron may be used to determine (strictly or approximately, depending on the local symmetry) the effective symmetry of the $X Y_{4}$ group.

Now, we turn back to the value that should be assigned to the constant $\delta$. It is easy to prove that $\delta$ has to be greater than 2 - otherwise the ellipsoid would not be »well-behaved«*. The crucial assumption was that there should be some interdependence between the components of the tensor and the vibrational energy levels in the molecule (see below). Therefore, it was necessary to assign $\delta$ such a value that the components of the tensor should properly reflect the changes in the energy levels (caused by varying the $X-Y_{i}$ distances). It seemed resonable to us to suppose that the covalent forces depend on the distance between the atoms in the same way as the overlap forces (except for the sign). From the reasons mentioned above, a value of 12 was assigned to $\delta$ - by analogy to the $r^{12}$ term in the Lennard-Jones potential (it is this term that is believed to reflect, the existence of overlap forces).

When the distortion is arbitrary, all the components of the tensor are non-zero. Using an orthogonal-similarity transformation, it is possible ${ }^{9}$ to transform the tensor ( $\mathbf{T}_{\mathrm{ij}}$ ) into another - diagonal tensor ( $\mathbf{T}_{\mathrm{ij}}^{\prime}$ ):

$$
\boldsymbol{\Gamma} \times\left[\begin{array}{ccc}
\mathbf{T}_{11} & \mathbf{T}_{12} & \mathbf{T}_{13}  \tag{8}\\
\mathbf{T}_{21} & \mathbf{T}_{22} & \mathbf{T}_{23} \\
\mathbf{T}_{31} & \mathbf{T}_{32} & \mathbf{T}_{33}
\end{array}\right] \times \mathbf{\Gamma}^{-1}=\left[\begin{array}{ccc}
\lambda_{1} & 0 & 0 \\
0 & \lambda_{2} & 0 \\
0 & 0 & \lambda_{3}
\end{array}\right]
$$

where $\Gamma$ is some orthogonal matrix.
One can easily calculate the axes of the ellipsoid by use of the components of ( $\mathbb{T}_{i \mathrm{ij}}^{\prime}$ ), which are usually called the main components of ( $\mathbf{T}_{\mathrm{ij}}$ ):

$$
\begin{equation*}
a=\frac{1}{\sqrt{\lambda_{1}}} \quad b=\frac{1}{\sqrt{\lambda_{2}}} \quad c=\frac{1}{\sqrt{\lambda_{3}}} \tag{9}
\end{equation*}
$$

In practice, the main components are calculated as solutions of the determinantal equation:

$$
\begin{gather*}
\mathbf{T}_{11}-\lambda  \tag{10}\\
\mathbf{T}_{21} \\
\mathbf{T}_{31}
\end{gather*}
$$

$$
\begin{gathered}
\mathbf{T}_{12} \\
\mathbf{T}_{22}-\lambda \\
\mathbf{T}_{32}
\end{gathered}
$$

$$
\left.\begin{gathered}
\mathbf{T}_{13} \\
\mathbf{T}_{23} \\
\mathbf{T}_{33}-\lambda
\end{gathered} \right\rvert\,=0
$$

In the above equations, the $\lambda_{i}$ - components were chosen in such a way that $\lambda_{1} \leq \lambda_{2} \leq \lambda_{3}$ and hence $a \geq b \geq c$. The excentricities of the ellipsoid - $b / a$, $c / a$ and $c / b$ - are proportional to the degree of distortion of the molecule. Going one step further, we define the total distortion as:

$$
\begin{equation*}
D_{\mathrm{t}}=\left[\left(1-\frac{b}{a}\right)^{2}+\left(1-\frac{c}{a}\right)^{2}+\left(1-\frac{c}{b}\right)^{2}\right] / 3 \tag{11}
\end{equation*}
$$

(as defined above, $D_{\mathrm{t}}$ is scaled between 0 and 1 ).

[^0]
## RESULTS AND DISCUSSION

The distortions of a series of sulfate-ions, taken from compounds with precisely refined structures $(\sigma(\mathrm{s}-\mathrm{o}) \leq 0.005 \AA)^{+}$and calculated by use of the method of Baur ${ }^{2}$, Murray-Rust et al. ${ }^{3,4}$ and our method, are comparatively presented in Table I. Although it can be seen that for the vast majority of compounds there is some correspondence between the measures of distortion obtained by various methods, a direct comparison is not possible since it is not clear which of the quantities $D I(T O), D I(O T O), D I(O O)$ on the one hand, and $\mathbf{D}_{2}(E), \mathbf{D}_{3}\left(F_{2}\right), \mathbf{D}_{4}\left(F_{2}\right)$ on the other, should be compared with $D_{\mathrm{t}}$. Moreover, the relative differences in the $D_{\mathrm{t}}$ - values are, in some cases, much larger than e.g. the differences in the distortion indices. Because of these differences and the inability to make direct comparisons, it is natural to question the possible advantages of the present method over the existing ones.

We think that our method has indeed some advantages, some of the reasons being outlined below:
a) The tensor adjoined to $X Y_{4}$ reflects in a simple way the local or effective symmetry of the molecule. Such an information is not obtainable from either the distortion indices, or the $\mathbf{D}_{3}\left(F_{2}\right)$ and $\mathbf{D}_{4}\left(F_{2}\right)$ displacement vectors in molecules with $D_{2 d}$ or $D_{2}$ symmetry (see e.g. the results for $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and $\mathrm{BeSO}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ in Table I).
b) In some cases, such as $\mathrm{BeSO}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}, \mathrm{Cu}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{SO}_{4}\right)_{2}$. $\cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\left(\mathrm{NH}_{4}\right)_{3} \mathrm{H}\left(\mathrm{SO}_{4}\right)_{2}$, two of the ellipsoid axes are almost equal in length (for $\mathrm{BeSO}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ they are equal by symmetry). This finding is consistent with $C_{3 \mathrm{v}}$ or $D_{2 \mathrm{~d}}$ approximate (effective) symmetry. On the other hand, in all cases cited above, two components of the $\nu_{3}$ mode are found in the vibrational spectra, which is in ideal agreement with the $T_{d} \rightarrow C_{3 v}$ and $T_{d} \rightarrow D_{2 d}$ correlation diagrams ${ }^{10}$ for descent of symmetry. It should be mentioned again that $D I(T O), \mathbf{D}_{3}\left(F_{2}\right)$ and $\mathbf{D}_{4}\left(F_{2}\right)$ are all equal to zero, for both $\mathrm{BeSO}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Na}_{2} \mathrm{SO}_{4}$. If some of these parameters should be correlated* with the spectroscopic ones, it could only be concluded (incorrectly!) that there is no splitting at all of the $\nu_{3}$ modes in these compounds, which is in discrepancy with the existing doublet - for $\mathrm{BeSO}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ and triplet - for $\mathrm{Na}_{2} \mathrm{SO}_{4}$, in this spectral region.**
c) The total distortion of the sulfate ions in $\mathrm{CsAl}\left(\mathrm{SO}_{4}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O}$ is very small (cf. Table I), two of the axes of the ellipsoid being, in addition, equal

(the local symmetry of $\mathrm{SO}_{4}{ }^{2-}$ is $C_{3 \mathrm{v}}$ ). Therefore, a doublet is expected in the $\nu_{3}$ region, the splitting of which should be considerably smaller than that observed in $\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (compare the values of $D_{\mathrm{t}}, a, b$ and $c$ in Table I). The appearance of a single peak in the infrared spectrum of $\mathrm{CsAl}\left(\mathrm{SeO}_{4}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O}$ containing isomorphously isolated $\mathrm{SO}_{4}{ }^{2-}$ ions is, in fact, consistent with these expectations (a splitting of about $25 \mathrm{~cm}^{-1}$ was found ${ }^{5}$ in the case of $\mathrm{SO}_{4}{ }^{-{ }^{-}}$ doped $\mathrm{CaSeO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ ).

We considered the above findings as encouraging enough to search for a correlation between the values of the main components of the tensor ( $T_{\mathrm{ij}}$ ) and the wavenumbers of the $\nu_{3}$ vibrational bands. Eleven sulfate-ions (from compounds with accurately refined structures, available spectroscopic data and unequivocal assignment) were included in the regression analysis. An ideal $\mathrm{SO}_{4}{ }^{2-}$ tetrahedron and $\mathrm{SO}_{3}$ (as an example of sulfate-tetrahedron with extremely large distortion) were also included. The data for all these compounds are presented in Table II.

We tested several two-parameter functions. The highest value ( $r^{2}=0.97$ ) for the correlation coefficient was found for the function of the type:

$$
Y=k \cdot X^{1}
$$

(see Figure 1). This is, it should be noted, the only function (linear, logarithmic, explonential and $Y=k / X+1$ - type functions were also tested) that retains its physical significance throughout the whole range of possible X -values, a fact that should no the ignored.

The scatter of the points (see Figure 1) seems to be larger for small distortions, contrary to the expectations. There are several possible reasons for this finding: (i) the uncertainties of the atomic positions are more relevant for small than for large distortions; (ii) the structural data were not corrected for thermal motion; (iii) the effect of the surrounding on the sulfate frequencies is, also, more relevant for small distortions; (iv) the number of pairs (35) of values included in our regression analysis is not too large; (v) finally, it might be possible that there is no simple relation between the value of the constant $\delta$ (taken as should be recalled, to be equal to 12) and the

Figure 1. Regression of $\mathbf{T}_{\mathrm{ii}}{ }^{\prime}$ vs. $v_{3}$ - best curve fit.

exponent of the $r^{12}$ term of the Lennard-Jones potential and that some other, empirically found, value of $\delta$ would result in an even better correlation. It thus seems worthwhile to study, in an analogous way, other oxoanions $\left(\mathrm{PO}_{4}{ }^{2-}\right.$, $\mathrm{AsO}_{4}{ }^{3-}, \mathrm{SeO}_{4}{ }^{2-}$ etc.) and to compare the results obtained in such studies with the present ones.

## APPENDIX 1

Let $x_{1}, x_{2}, x_{3}$ and $x_{1}{ }^{\prime}, x_{2}{ }^{\prime}, x_{3}{ }^{\prime}$ be the axes of two orthogonal Cartesian coordinate systems with a common origin. The primed coordinates may be expressed as

$$
x_{\mathrm{i}}^{\prime}=\Sigma a_{\mathrm{ij}} \cdot x_{\mathrm{j}} \quad i, j \in\{1,2,3\}
$$

where [ $a_{\mathrm{ij}}$ ] is an orthogonal matrix. Using the equality

$$
\mathbf{T}_{\mathrm{ij}}{ }^{\prime}=\Sigma a_{\mathrm{ik}} \cdot a_{\mathrm{j} 1} \cdot \mathbf{T}_{\mathrm{kl}} \quad i, j, k, l, \in\{1,2,3\}
$$

one obtains

$$
\begin{gathered}
\boldsymbol{\Sigma} \mathbf{T}_{\mathrm{ij}}{ }^{\prime} \cdot \mathrm{x}_{\mathrm{i}}^{\prime} \cdot \mathbf{x}_{\mathrm{j}}^{\prime}=\Sigma a_{\mathrm{ik}} \cdot a_{\mathrm{j} 1} \cdot \mathbf{T}_{\mathrm{k} 1} \cdot a_{\mathrm{ir}} \cdot x_{\mathrm{r}} \cdot a_{\mathrm{j} \mathrm{~s}} \cdot x_{\mathrm{s}}= \\
=\Sigma \delta_{\mathrm{kr}} \cdot \delta_{\mathrm{ls}} \cdot \mathbf{T}_{\mathrm{k} 1} \cdot x_{\mathrm{r}} \cdot x_{\mathrm{s}}=\Sigma \mathbf{T}_{\mathrm{k} 1} \cdot x_{\mathrm{k}} \cdot x_{1} \quad i, j, k, l, r, s \in\{1,2,3\}
\end{gathered}
$$

which proves that the surface defined by equality (2) does not depend on the choice of the orthogonal Cartesian coordinate system.

## APPENDIX 2

To prove that equation (3) always defines an ellipsoid, we consider the vectors $\mathbf{p}^{\prime}, \mathbf{q}^{\prime}, \mathbf{r}^{\prime}, \mathbf{s}^{\prime}\left(\mathbf{p}^{\prime}=\mathbf{p} /|\mathbf{p}|^{8 / 2}\right.$ and similarly for $\mathbf{q}^{\prime}, \mathbf{r}^{\prime}$ and $\left.\mathbf{s}^{\prime}\right)$. Then the tensor is:

$$
\mathbf{T}_{\mathrm{ij}}=p_{\mathrm{i}}^{\prime} \cdot p_{\mathrm{j}}^{\prime}+q_{\mathrm{i}}^{\prime} \cdot q_{\mathrm{j}}^{\prime}+r_{\mathrm{i}}^{\prime} \cdot r_{\mathrm{j}}^{\prime}+s_{\mathrm{i}}^{\prime} \cdot s_{\mathrm{j}}^{\prime}
$$

The surface will be an ellipsoid if and only if the following three conditions are satisfied:

$$
\begin{align*}
& \Delta_{1}=\mathbf{T}_{11}>0  \tag{i}\\
& \Delta_{2}=\left|\begin{array}{ll}
\mathbf{T}_{11} & \mathbf{T}_{12} \\
\mathbf{T}_{21} & \mathbf{T}_{22}
\end{array}\right|>0  \tag{ii}\\
& \Delta_{3}=\left|\begin{array}{lll}
\mathbf{T}_{11} & \mathbf{T}_{12} & \mathbf{T}_{13} \\
\mathbf{T}_{21} & \mathbf{T}_{22} & \mathbf{T}_{23} \\
\mathbf{T}_{31} & \mathbf{T}_{32} & \mathbf{T}_{33}
\end{array}\right|>0 \tag{iii}
\end{align*}
$$

The inequality (i) obviously holds.
To prove the inequality (iii) we consider the tensor ( $\mathbf{T}_{\mathrm{ij}}$ ) as a contravariant one. A coordinate system $x_{1}^{\prime}, x_{2}{ }^{\prime}, x_{3}^{\prime}$ is chosen so that $\mathbf{p}^{\prime}=(1,0,0), \boldsymbol{q}^{\prime}=(0,1$, 0 ) and $\mathbf{r}^{\prime}=(0,0,1)$. In a quite general case, the coordinate system may not be orthogonal. Using the transformation formula

$$
\mathbf{T}^{i j}=\Sigma \frac{\partial x_{\mathrm{i}}}{\partial x_{\mathrm{k}}{ }^{\prime}} \cdot \frac{\partial x_{i}}{\partial x_{\mathrm{i}}{ }^{\prime}} \cdot \mathbf{T}^{/ k 1} \quad k, l \in\{1,2,3\}
$$

or

$$
\mathbf{T}^{\mathbf{i j}}=\mathbf{\Sigma} \frac{\partial x_{\mathrm{i}}}{\partial x_{\mathrm{k}}{ }^{\prime}} \cdot \mathbf{T}^{\text {k1 }} \cdot\left(\frac{\partial x_{1}}{\partial x_{\mathrm{j}}^{\prime}}\right)^{t} \quad k, l \in\{1,2,3\}
$$

we obtain:

$$
\operatorname{det}\left(\mathbf{T}^{\mathrm{ij}}\right)=\left[\operatorname{det}\left(\frac{\partial x_{\mathrm{i}}}{\partial x_{\mathrm{k}^{\prime}}}\right)\right]^{2} \cdot \operatorname{det}\left(\mathbf{T}^{\mathbf{k l}^{\prime}}\right)
$$

and it is necessary to prove that $\operatorname{det}\left(\mathbf{T}^{\mathbf{k l}}\right)>0$. If the vector $\mathbf{s}^{\prime}$ has components ( $a, b, c$ ) in the new coordinate system, then

$$
\operatorname{det}\left(\mathbf{T}^{k k 1}\right)=\left|\begin{array}{ccc}
1+a^{2} & a b & a c \\
a b & 1+b^{2} & b c \\
a c & b c & 1+c^{2}
\end{array}\right|=1+a^{2}+b^{2}+c^{2}>0
$$

and (iii) is proven.
It may be shown that the proof of inequality (ii) may be treated as a pure two-dimensional problem. Therefore, we identify the vectors $p^{\prime}, q^{\prime}, r^{\prime}, s^{\prime}$ with their projections on the $x y$-plane. Similarly as in the previous proof, the components may be chosen as: $p^{\prime}=(1,0), q^{\prime}=(0,1), r^{\prime}=(a, b), s^{\prime}=(c, d)$. In this case, the inequality (ii) takes the form:

$$
\Delta_{2}=\left|\begin{array}{cc}
1+a^{2}+c^{2} & a b+c d \\
a b+c d & 1+b^{2}+d^{2}
\end{array}\right|=1+a^{2}+b^{2}+c^{2}+d^{2}+(a d-b c)^{2}>0
$$

This finishes the proof.

## APPENDIX 3

The compound $\mathrm{Te}(\mathrm{OH})_{6} \mathrm{~K}_{2} \mathrm{SO}_{4}$ is worked with in the numerical example given below. According to the structural data ${ }^{32}$ the compound is triclinic, space group $P 1$. The unit cell parameters are: $a=6.243 \AA, b=6.647 \AA, c=13.405 \AA$, $\alpha=73.14^{\circ}, \beta=103.05^{\circ}, \gamma=116.97^{\circ}$. The fractional coordinates of the five atoms of the $\mathrm{SO}_{4}{ }^{2-}$ ion are:

| Atom | $x / a$ | $y / b$ | $z / c$ |
| :---: | :---: | :---: | :---: |
| S | 0.7488 | 0.2845 | 0.2516 |
| 01 | 0.6034 | 0.3692 | 0.1593 |
| 02 | 0.5835 | 0.1201 | 0.3314 |
| 03 | 0.8650 | 0.1638 | 0.2179 |
| 04 | 0.9394 | 0.4777 | 0.2938 |

The values of the calculated orthogonal coordinates are:

| Atom | $X / \AA$ | $Y / \AA$ | $Z / \AA$ |
| :---: | ---: | ---: | ---: |
| S | 3.810 | 0.749 | 3.208 |
| 01 | 3.131 | 1.365 | 2.031 |
| 02 | 2.777 | 0.435 | 4.225 |
| 03 | 4.504 | 0.513 | 2.778 |
| 04 | 4.810 | 1.654 | 3.746 |

The components of $\mathbf{p}(\overrightarrow{\mathrm{SO}} 1)$ are calculated as differences of the $X, Y$ and $Z$ coordinates of the atoms 01 and $S$ :

$$
\mathbf{p} / \AA=(-0.679,0.616,-1.177)
$$

And similarly for $\mathbf{q}(\overrightarrow{\mathrm{S} 02}), \mathbf{r}(\overrightarrow{\mathrm{S} 03})$ and $\mathbf{s}(\overrightarrow{\mathrm{S} 04})$ :

$$
\begin{aligned}
\mathbf{q} / \AA & =(-1.033,-0.314,1.017) \\
\mathbf{r} / \AA & =(0.694,-1.262,-0.430) \\
\mathbf{s} / \AA & =(1.000,0.905,0.538)
\end{aligned}
$$

The lengths of these vectors are:

$$
\begin{gathered}
|\mathbf{p}|=1.491 \AA,|\mathbf{q}|=1.484 \AA,|\mathbf{r}|=1.503 \AA,|\mathbf{s}|=1.452 \AA \\
\mathbf{T}_{11} / \AA^{-10}=\frac{(-0.679) \cdot(-0.679)}{1.491^{12}}+\frac{(-1.033) \cdot(-1.033)}{1.484^{12}} \\
\\
+\frac{(0.694) \cdot(0.694)}{1.503^{12}}+\frac{(1.000) \cdot(1.000)}{1.452^{12}}
\end{gathered}
$$

etc. The results for all components are given below:

$$
\left(\mathbf{T}_{\mathrm{ij}} / \AA^{-10}\right)=\left[\begin{array}{lll}
0.02817 & 3.113 \cdot 10^{-3} & 1.226 \cdot 10^{-3} \\
3.113 \cdot 10^{-3} & 0.02525 & 7.947 \cdot 10^{-4} \\
1.226 \cdot 10^{-3} & 7.947 \cdot 10^{-4} & 0.02522
\end{array}\right]
$$

To calculate the main components of the tensor, the determinantal equation (10) must be solved. The following cubic equation is obtained:

$$
\lambda^{3}-7.8647 \cdot 10^{-2} \cdot \lambda^{2}+2.0471 \cdot \lambda-1.7649 \cdot 10^{-5}=0
$$

The solutions of this equation (the components of the diagonal tensor ( $\mathbf{T}^{\prime}{ }_{i \mathrm{ij}}$ ) can be obtained by using Cardano's method (or numerically) to get:

$$
\lambda_{1}=0.02327 \quad \lambda_{2}=0.02482 \quad \lambda_{3}=0.03055
$$

The lengths of the axes and the total distortion are, finally, calculated from (9) and (11) to have:

$$
\begin{array}{lll}
a=6.555 \AA^{5} & b=6.347 \AA^{5} \quad c=5.721 \AA^{5} \\
& D_{\mathrm{t}}=0.00897 &
\end{array}
$$

The calculation of the axes ( $a, b, c$ ) and the total distortion $\left(D_{t}\right)$, in the present work, were performed on a COMMODORE 64 microcomputer with a program written in Basic. The input data were the unit cell parameters and the fractional coordinates of the five atoms forming the $X Y_{4}$ group. (A listing of the program is available upon request, from the authors. The program was written in standard Basic and, with only minor changes, should work on any microcomputer equipped with a Basic interpreter).

## МЗВОД

Примена на тензори за опишување на деформациите кај молекулите.
I. Тетраедарски молекули
В. Петрушевски и К. Тренчевски

Вклопувањето на една тетраедарска $\mathrm{XY}_{4}$ молекула (или јон) во кристал е поврзано, практички во сите случаи, со снижување на нејзината симетрија. За опишување на деформациите на тетраедарот до кои доаѓа при ова, конструирани се тензори од втор ранг. Покажано е дека карактеристичната површина на ваквиот тензор е секогаш елипсоид. Полуоските на елипсоидот и неговата положба во однос на елементите на симетрија на групацијата, може да послужат за определување на ефективната симетрија и степенот на деформираност на тетраедарот. Врз основа на овие податоци, можно е да се претскажат некои од спектралните карактеристики на испитуваните соединенија. За група од $36 \mathrm{SO}_{4}$ јони. со прецизно определени структури, споредени се резултатите добиени со примена на оваа метода и резултатите ${ }^{1}$ добиени со примена на други методи ${ }^{2-4}$. Со доста висок коефициент на корелација ( $r^{2}=0,97$ ) утврдено е постоење на заемна зависност помеѓу главните компоненти на тензорот и фреквенциите на лентите од антисиметричната валентна ( $\nu_{3}$ ) вибрација.

[^0]:    * The ellipsoid must collapse into an ellipse, if one of the $X-Y_{i}$ distances becomes infinitesimal. If, on the other hand, the $X-Y_{i}$ bond is infinitely stretched, the corresponding axis of the ellipsoid will increase in length and becomes infinitely long as the rest of the molecule becomes complanar.

[^1]:    + The convention of crystallographers to use ångström ( $\AA$ ) as a unit of length, rather than picometer ( pm ) or nanometer ( nm ) is adopted in this work.
    * In fact, we do not see any possibility of correlating the frequencies of the $\nu_{3}$-mode bands with some of the distortion indices or displacement vectors. The method of Dollase ${ }^{8}$ has the same shortcoming, although it has the adventage of giving a single parameter as the measure for the distortion of a coordination polihedron.
    ** We mention here that in all cases where it was known that there are selenate compounds isostructural with sulfate ones, the spectra were recorded from selenates containing a small amount ( $\sim 1 \%$ ) of isomorphously isolated $\mathrm{SO}_{4}{ }^{2-}$ ions. As a consequence of the restricted resonant interactions (Davydov-splitting and similar crystal effects) it is believed ${ }^{11,12,5,6}$ that the spectra of such samples reflect the effective $\mathrm{SO}_{4}{ }^{2-}$ symmetry better than the spectra of pure sulfate compounds.
