ESE Geoffrey Harris Prize 2020 – Biography
Annamaria Colao

Authored 500+ peer reviewed publications. Her current areas of research include molecular basis and clinical treatment of tumors in the region of the hypothalamus-pituitary and neuroendocrine tumors. Consequences of deficiency and excess of GH and IGF-I on the cardiovascular system. Endocrine consequences in survivors of malignant neoplasia. Insulin resistance and cancer. Secondary osteoporosis. Endocrine consequences of bariatric surgery in obesity. She is affiliated with numerous medical societies, including Italian Society of Endocrinology; Italian Society of Andrology and Sexual Medicine Medical Association Doctors Endocrinologists, Endocrine Society; European Neuroendocrine Association, European Neuroendocrine Tumors; European Society of Endocrinology.

EJE Award 2020 – Biography
Davide Calebiro

Davide Calebiro is a Professor of Molecular Endocrinology and Wellcome Trust Senior Research Fellow at the Institute of Metabolism and Systems Research (IMSR) and the Centre of Membrane Proteins and Receptors (COMPARE) of the University of Birmingham.

He leads a multidisciplinary research team comprising biologists, chemists, physicists, engineers and computer scientists focusing on the basic mechanisms of G protein-coupled receptor (GPCR) signalling and their alterations in endocrine and metabolic diseases. To study GPCR signalling in cells and tissues, they develop and use innovative optical methods based on FRET and single-molecule microscopy, which allow them to directly observe signalling events in living cells with unprecedented spatiotemporal resolution.

His major scientific contributions include the discovery that GPCRs are not only active at the plasma membrane but also at intracellular sites and that these receptors interact among themselves and with other membrane proteins to form dynamic nanodomains at the plasma membrane.

Davide has published 60 research papers, many of which in prestigious scientific journals, attracting several prizes and awards. He is serving on multiple panels and committees, including the Programme Committee of the Society for Endocrinology and the MRC Molecular & Cellular Medicine Board.

The *European Journal of Endocrinology* Prize Lecture
AP2

Shining light on membrane receptors

Davide Calebiro
University of Birmingham, Birmingham, United Kingdom

G protein-coupled receptors (GPCRs) are the largest family of membrane receptors and major drug targets. They play a fundamental role in the endocrine system by mediating the effects of several hormones and neurotransmitters. Alterations of GPCR signalling, for instance due to genetic mutations, are responsible for a variety of endocrine diseases ranging from congenital hypothyroidism to Cushing's syndrome. My group develops innovative optical methods such as fluorescence resonance energy transfer (FRET) and single-molecule microscopy, which allow us to investigate GPCR signalling directly in living cells with unprecedented spatiotemporal resolution. Using this innovative approach, we are investigating some of the most fundamental mechanisms at the basis of GPCR signalling and their involvement in human disease. This led us to discover that GPCRs are not only active at the plasma membrane, as previously strongly believed, but also at intracellular sites. Moreover, our work has contributed to the identification of new genetic alterations responsible for endocrine diseases, including the recent discovery that mutations in the catalytic α subunit of protein kinase A cause cortisol-producing adrenocortical adenomas. Altogether, our findings indicate that GPCR signalling is much more complex and dynamic than previously thought. This not only has major implications for understanding the functioning of this important family of receptors, but might also lead to the development of innovative drugs for common diseases such as diabetes or heart failure.

European Hormone Medal 2020 – Biography
Olle Kämpe

Olle Kämpe is professor and senior consultant in endocrinology at the Karolinska Institutet in Stockholm, Sweden. He holds the Torsten and Ragnar Söderberg endowment professorship in clinical endocrinology since 2014 and was before that professor of molecular medicine at Uppsala University between 1999 and 2014. He is fellow of the Royal Swedish Academy of Sciences (www.kva.se/en), and member of the Nobel Assembly at the Karolinska Institutet. He was adjunct member of the Nobel Committee for the Prize in Physiology or Medicine 2017-2019 and a member of the Nobel Committee since 2020. He has participated in several EU-projects of which he coordinated one, EurAPS, dealing with APS-1/APECED. He has identified a number of the autoantibodies in clinical use for Addison's disease and APS-1 and initiated the Swedish national registries and biobanks (www.addisonregistret.se) for these disorders.

European Hormone Medal Lecture
AP3

The cause of autoimmune endocrine diseases

Olle Kämpe
Department of Endocrinology, Karolinska University Hospital (Solna), Karolinska Institutet, Stockholm, Sweden

Autoimmune endocrine diseases such as type 1 diabetes and autoimmune adrenal insufficiency (Addison's disease) are disorders that often aggregate in families. Despite being universally lethal before the 20th century, the predisposing genetic variants have remained in the population, probably conferring advantages even at the price of an enhanced risk of developing autoimmunity. With carefully phenotyped patients and geographically matched controls, strong signals can be obtained in genome wide associations studies (GWAS) even with small cohorts in rare diseases. In patients with autoimmune adrenal insufficiency positive for 21-hydroxylase autoantibodies genetic variants of MHC, BACH2 and AIRE have emerged as the most important risk genes.

Monogenic disorders such as Autoimmune Polyendocrine syndrome (APS-1) and Immune Dysregulation Polyendocrinopathy, Enteropathy, X-linked (IPEX) have proved invaluable for our understanding of the events eventually leading to endocrine autoimmunity. These rare syndromes have helped us identify the genes AIRE and FOXP3, critical for important tolerance mechanisms. They also represent good examples of how research on rare disorders translate into novel diagnostic tools and better understanding of more common autoimmune disorders, and at the same time improve clinical care practices for patients with APS-1 and IPEX.

Clinical Endocrinology Trust Award 2020 – Biography
Richard Eastell

I received a clinical fellowship from the Medical Research Council to study osteoporosis at the University of Edinburgh in 1978. I furthered my clinical research training by working at the Mayo Clinic under the supervision of Dr B L Riggs where I worked for five years. I developed a number of new approaches for studying osteoporosis while at the Mayo Clinic including the use of stable (non-radioactive) isotopes to measure the absorption of calcium from food, the use of an infusion technique to measure the production of the active form of vitamin D, the measurement of bone density at the site in the wrist where fractures commonly occur (the ultradistal radius) and a height ratio approach to identifying vertebral fractures on radiographs of the spine. I began my training in endocrinology and diabetes at the Western General Hospital in Edinburgh in 1980 and continued it at Northwick Park Hospital in Harrow in 1982 and at the Mayo Clinic in 1987.

I joined the Department of Human Metabolism and Clinical Biochemistry at the University of Sheffield in 1989 as a Senior Research Fellow. I set up a metabolic bone service at the Northern General Hospital and am an Honorary NHS Consultant. I became Professor of Bone Metabolism in 1995 and received funding from the Arthritis Research Campaign to use biochemical tests of bone turnover to better understand the way in which older men and women develop osteoporosis and propensity to fracture.

My studies on the cause, diagnosis, prevention and treatment of osteoporosis have been conducted with the support of many colleagues; I have supervised the study for 37 doctoral degrees over the past 30 years. I have published over 550 research papers.

I am currently Director of the Mellanby Centre based at the University of Sheffield. I became an NIHR Senior Investigator in 2009. Some of my recent contributions have been authorship on key papers describing new treatments for osteoporosis, such as tibolone, zoledronic acid, denosumab and lasofoxifene as well as addressing issues about safety of medications and provide guidelines to diagnose primary hyperparathyroidism, a common disorder resulting in high levels of blood calcium.

My work as a clinical investigator was recognised in 2014, by the Frederick C Bartter Award from the American Society for Bone and Mineral Research.

Postmenopausal osteoporosis: balancing the risks and benefits

Richard Eastell
Director, Mellanby Centre for Bone Research, University of Sheffield, Sheffield, United Kingdom

The fractures that result from postmenopausal osteoporosis have a major public health impact. We have a number of drugs we can use to reduce the risk of these fractures. Most of these drugs are anti-resorptive, such as the bisphosphonates (alendronate, ibandronate, risedronate and zoledronate), raloxifene, oestrogen, and denosumab. Until recently the only anabolic agent available was teriparatide. However, in the last couple of years two new agents have been approved in some countries, namely abaloparatide (an analogue of parathyroid hormone related protein) and romosozumab (an antibody against sclerostin). Important questions arise such as should the anabolic drugs be given early in the course of osteoporosis or just to patients with severe disease? What treatment should be given after these anabolic treatments? The anti-resorptive drugs are very safe. However, it has become common practice to take 'drug holidays' in patients taking bisphosphonates for 3–5 years in order to prevent rare side effects such as atypical femur fracture. Thus, the indications for treatment, the order of treatment and the individualisation of treatment are all important considerations for optimal patient care. We highlighted these issues in a recent guideline from the Endocrine Society[1], endorsed by the European Society for Endocrinology.

Harnessing the Microbiome in Metabolic Disease
PL3

Harnessing the microbiome in metabolic disease

Sonia Fernandez Veledo
Head of Diabetes and Metabolic Associated Diseases Research Group, Pere Virgili Institute - Rovira i Virgili University, University Hospital Joan XXIII, Tarragona, Spain

Communication between microbiota and the host is critical to sustaining the vital functions of the healthy host, and disruptions of this homeostatic coexistence are associated with a range of diseases including obesity and T2D. Microbiota-derived metabolites act both as nutrients and as messenger molecules to shape host pathophysiology. Succinate, which has the distinction of being produced by both the host and microbiota, is quickly becoming a poster child for these metabolites. Succinate is a by-product of some bacteria and a primary cross-feeding metabolite essential for the maintenance of a healthy resident gut microbiota. In this sense, the increase in succinate in some pathological conditions would be reflective of dysbiosis. For many years succinate has been considered as a danger signal via its intracellular and extracellular signaling properties. Nonetheless, unexpected pleiotropic functions, such as a positive regulator of intestinal gluconeogenesis and thermogenesis, have been ascribed to this metabolite. In this context, we have demonstrated that succinate via its cognate receptor SUCNR1 is a key mediator of the resolution of inflammation– a physiological mechanism that is not working properly in obesity. Thus, similar to what happens with other hormones as insulin and leptin, obesity and T2D is associated with higher circulating levels of succinate but impaired SUCNR1 signaling, which we have termed a succinate-resistant state. We have also proposed circulating succinate as a surrogate marker of metabolic control and an excellent predictive biomarker for diabetes remission after bariatric surgery. An important unanswered question concerns the source of circulating succinate. Along this line, we recently provided the first demonstration of a close relationship between circulating succinate and gut microbiota signature. To establish the contribution of gut microbiota to circulating levels of succinate as well as the use of probiotic interventions directed to decrease the higher circulating succinate and thus recover the physiological functions of succinate are our current research focus.

Mechanisms for SARS-CoV-2 Cell Entry
PL4

SARS-CoV-2 entry into cells and its inhibition

Stefan Pöhlmann
Infection Biology Unit, German Primate Center – Leibniz Institute for Primate Research, Göttingen, Germany

The coronavirus disease 2019 (COVID-19) has devastating consequences. The establishment of antiviral intervention targeting the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the causative agent of COVID-19, is urgently needed. However, such approaches require the identification of virus-host cell interactions essential for viral spread and pathogenesis. The viral spike protein (S) mediates the first step in SARS-CoV-2 infection, viral entry into target cells, and is the key target for neutralizing antibodies. In this presentation, I will discuss the cellular factors engaged by the SARS-CoV-2 S protein for entry and will outline strategies for intervention. One focus will be on the S protein activation by host cell proteases. I will discuss why the serine protease TMPRSS2 plays a central role in this process whether auxiliary S protein-activating proteases might impact extrapulmonary spread of SARS-CoV-2. Further, I will discuss how S protein activation can be blocked and whether such strategies are successful in COVID-19 patients.

It Takes Thyroid Hormone to Make Sense
PL6

Maternal thyroid hormone and child brain development

Tim Korevaar
Erasmus University Rotterdam and Harvard TH Chan School of Public Health

During this presentation, I will share my views on the effects of maternal thyroid hormone on child brain development. I will discuss the physiology of maternal thyroid function during pregnancy and how this relates to time-dependent processes of fetal brain development. I will also discuss the various aspects of assessing fetal brain development. This is particularly important because we can only assessments fetal brain development in the children after birth, and we have to use proxy measurements such as child IQ or developmental disorders. I will share an overview of recent clinical studies that have used different approaches to identify and quantify the relevance of maternal thyroid hormone for fetal brain development. I will discuss common pitfalls in the setup and interpretation of such studies and share my views on what is needed in the future. Finally, I will discuss the interpretation of current available randomized trials and provide insights into the potential harms associated with levothyroxine overtreatment.

DOI: 10.1530/endoabs.70.PL6

Effects of EDCs on Neuro-Endocrine Systems and Behaviour

PL7

Endocrine disruption of neuroendocrine development, function, and behavior

Andrea Gore
Professor and Vacek Chair of Pharmacology, The University of Texas at Austin, United States

Environmental endocrine-disrupting chemicals (EDCs) are exogenous chemicals that perturb hormones and their actions. Exposures to EDCs during critical periods of life, especially in the developing fetus and infant, are particularly problematic due to the high sensitivity of the perinatal hypothalamus to endogenous hormones and exogenous compounds. Our lab has been using a rat model of prenatal exposure to two classes of EDCs: a polychlorinated biphenyl (PCB) mixture used previously in industry, the fungicide vinclozolin, in current agricultural use, or the vehicle. These chemicals are administered to the dam during the period of prenatal brain sexual differentiation in the developing offspring. These latter female and male rats are phenotyped for effects on development, hormones and behavior in adulthood, and functional behavioral outcomes. Protein, gene expression, and epigenetic changes to the brains of these animals are also determined. Our results show that sociosexual and anxiety-like behaviors are changed by EDCs in a sexually-dimorphic manner. Gene expression profiling of brains from these animals has identified suites of genes differentially affected by EDCs compared to vehicle rats, with sex-, age-, and brain-region specific differences. Recent results have focused on the implications of these changes induced by EDCs for mate choice behavior and underlying neural pathways involved in conveying information about the attractiveness of a mate and transducing it into a behavioral choice. As a whole, our work indicates that gestational exposure to PCBs has lifelong effects on the developing brain, neuroendocrine systems, and reproductive and social behaviors in exposed individuals. These data are highly relevant to humans and wildlife, as all individuals are exposed to environmental chemicals due to their persistence and ubiquity.

Combination targeted therapies for malignant tumours – towards precision medicine

Svenja Nölting
Specialist in internal medicine, endocrinologu and diabetology, Endocrine oncology, adrenal gland, Medical clinic and polyclinic IV, Munich, Germany

For metastatic phaeochromocytomas (PCCs) and paragangliomas (PGLs), there are currently no highly effective therapies available. We therefore investigated multiple novel molecular-targeted drug combinations in murine PCC cell lines and, most importantly, in human PCC/PGL 2D and 3D primary cultures ($n=18$). Additionally, we analysed signalling pathway alterations as well as somatic mutations in the patients' tumours in order to correlate these data with drug responsivity of individual patient tumours. In a large cohort of 16 human PCC/PGL 2D primary cultures, we confirmed that the mTORC1 inhibitor everolimus in combination with the PI3K inhibitor BYL719 was highly effective at low clinically-relevant doses via strong inhibition of mTORC1/p70S6K signalling and significant attenuation of everolimus-induced AKT activation. Everolimus in combination with other targeted drugs such as the tyrosine kinase inhibitor sunitinib also additively decreased primary culture growth ($n=16$), while combination therapy of BYL719 with the MEK inhibitor trametinib even synergistically decreased PCC/PGL primary culture viability ($n=3$). Additionally, we discovered that the BRAF inhibitor dabrafenib promoted PCC/PGL primary culture survival through a paradoxical MAPK activation ($n=13$). Combination therapy of the HDAC inhibitor entinostat with the PARP inhibitor niraparib showed antagonistic effects in PCC/PGL cultures ($n=15$). In one patient primary culture, extraordinarily high SSTR2 expression was found by Western blot analyses. This patient is currently being treated with SSTR2-guided radionuclide therapy and responded very well to the first 2-cycles. We further verified drug efficacy in human PCC/PGL 3D tumour spheroids and murine PCC cell lines. Moreover, we have engrafted two different human PGL primary cultures into R2G2 immunodeficient mice to serve as relevant experimental models for *in vivo* drug screening of human PCCs/PGLs. Utilising patient-derived 2D/3D primary cultures we have established models to generate highly clinically relevant data, emphasizing combinatorial therapy, providing further insight and evidence for personalised therapy (precision medicine) of PCCs/PGLs.

Osteoporosis and Fracture Prediction

S2.1

Risk of fractures following discontinuation of denosumab – and how to handle it

Bente L Langdahl
Endocrinology and Internal Medicine, Aarhus University Hospital, Denmark

Denosumab (DMAB) discontinuation is characterized by an increase in bone turnover and a rapid bone loss. These changes are associated with an increased risk of multiple vertebral fractures (VFx). Prevalent VFx, longer duration of therapy, greater gain in hip BMD during DMAB, and greater loss of hip BMD after DMAB were identified as risk factors for multiple VFx following DMAB cessation in a retrospective analysis of the FREEDOM Extension Study. Case series have indicated that prior bisphosphonate therapy may mitigate the increase in bone turnover after DMAB discontinuation. Current evidence indicates some efficacy of subsequent antiresorptive treatment depending on the duration of DMAB treatment. The ZOLARM-AB study investigated if transitioning to zoledronate can prevent the bone loss following DMAB discontinuation. The study included 61 patients with osteopenia, discontinuing DMAB after 4.6 ± 1.6 years. Zoledronate was administrated 6 or 9 months after the last DMAB injection or when bone turnover had increased. BMD decreased significantly in all groups. Incident vertebral fractures were seen in two women in the 9 months group. In conclusion: In case of DMAB discontinuation, alternative antiresorptive treatment should be given and the effect monitored using bone turnover markers or BMD. In patients who have been treated for only a few years, oral bisphosphonates for 1–2 years may prevent the bone loss, however, in patients treated with DMAB for a longer period of time, it is recommended to use zoledronate. In patients at high fracture risk continuing DMAB should be considered given the favourable efficacy and safety profile.

Abstract unavailable

S2.3

The role of bone turnover markers in the diagnosis and management of osteoporosis

Elena Tsourdi
Dresden, Germany

During the last years, bone turnover markers (BTMs) have gained importance as surrogate markers to monitor both anti-resorptive and anabolic treatment, and may be used in conjunction with bone mineral density (BMD) measurements in clinical practice. The two most widely utilized BTMs are pro-collagen type 1 N-terminal propeptide (PINP), which reflects osteoblast activity, and C-terminal-cross-linking telopeptide of type 1 collagen (CTX), which corresponds to the osteoclastic function. BTMs can be measured on several occasions in one individual with good precision. However, these markers are subject to several sources of variability; including feeding (resorption decreases) and recent fracture (all markers increase for several months). BTMs are not used for diagnosis of osteoporosis and do not improve prediction of bone loss or fracture within an individual. In people with osteoporosis, BTMs might be useful to evaluate the response to anabolic and antiresorptive therapies, to assess compliance to therapy, or to indicate possible secondary osteoporosis. While prior treatment with bisphosphonates results in smaller BMD and BTMs changes in patients transitioning to denosumab as compared to treatment-naïve patients beginning denosumab therapy, it has also been proposed to blunt enhanced bone turnover and/or attenuate BMD loss after denosumab discontinuation. On the contrary, postmenopausal women switching from teriparatide (TPTD) to denosumab depicted a continued increase in BMD, with bone resorption maximally suppressed after 1-month of denosumab and a delayed suppression of bone formation with maximal effects after 12–24 months of denosumab treatment. More studies are needed to investigate the use of bone turnover markers for assessment of the bone safety of new medications.

Controversial Issues in Bariatric Surgery

S3.1

Abstract unavailable

S3.2

Abstract unavailable

S3.3

Relapse and prediction of relapse

Erik Stenberg
Department of Surgery, Faculty of Medicine and Health, Örebro University, Örebro, Sweden

Background
Over the last decade, bariatric and metabolic surgery has been recognized as an important step in the treatment algorithm for type-2 diabetes (T2DM). Despite early suggestions of surgery providing a potential cure for T2DM, only a small proportion of all patients who could benefit from surgery are ultimately considered for this treatment. Furthermore, the long-term effects on T2DM still remains somewhat controversial.
Methods and results
A review of the current literature as well as data from the Scandinavian Obesity Surgery Registry (SOReg) were considered. Remission of diabetes occurred for 58–89% of patients with T2DM. A higher chance of remission was reported for patients with shorter duration and a less severe disease. Age, surgical method, postoperative weight-loss, sex and socioeconomic status may also influence the chance of reaching remission. Relapse of disease was reported to occur in 19–50% of those who initially experienced remission. Longer duration and a more severe disease, as well as female sex, weight-regain, and type of surgery are associated with higher risk for relapse. Patients who eventually relapse still experience reduction in the risk for diabetes complications.
Conclusion
The chance of reaching diabetes remission after metabolic and bariatric surgery is high. While relapse is common, patients still experience long-term metabolic benefits from this type of surgery.

Unveiling Signatures in Pituitary Neuroendocrine Tumours

S4.1

Circulating microRNAs: from PitNET pathogenesis to diagnostics

Henriett Butz[1,2]
[1]Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary; [2]Department of Molecular Oncology, National Institute of Oncology, Budapest, Hungary

Introduction
MicroRNAs are short, single-stranded, protein non-coding RNA molecules which can be secreted into the circulation by mammalian cells. Their altered expression pattern has been described in many different physiological and pathological conditions. In the extracellular compartments they are encapsulated within vesicles, associated to proteins or apoptotic bodies. Due to their stability they are suggested as promising circulating biomarkers. Regarding pituitary adenoma several studies have been published describing the different expression pattern of miRNAs and their role in adenomagenesis on tissue level, but only a few publications investigated circulating miRNAs.
Aim
To identify pituitary tissue-specific miRNAs in circulation comparing tissue and blood miRNA profiles reported in literature.
Methods
Data mining of available serum or plasma miRNAs detected in patients with pituitary adenomas. Reevaluation of expression data and correlation with tumor biology.
Results
Overall, a global downregulation of miRNA expression was reported in plasma samples obtained from patients with pituitary adenoma compared to healthy controls. Pituitary adenoma tissue-specific miRNAs have low abundance in plasma, minimizing their role as biomarkers. To date, only miR-143-3p was reported as plasma maker for non-functioning adenomas which level decreased following surgery.
Discussion
Circulating miRNAs in pituitary adenoma would help patient care especially in non-functioning adenoma as minimally invasive biomarkers of tumor recurrence and progression. However, technical difficulties may challenge the clinical use of miRNAs as potential biomarker and the application of standardized protocols could help their clinical utility. MiR-143-3p may predict tumor recurrence but it needs further investigation.

S4.3

Unravelling the PitNET methyloma

Antonio Pico[1,2]
[1]Department of Endocrinology & Nutrition, Hospital General Universitario de Alicante, Spain; [2]University Miguel Hernández, Spain

Context
Pituitary tumorigenesis does not fit into the most common model of cancer development driven by gene mutations. Instead, epigenetic mechanisms have been widely involved. Among them, aberrant DNA methylation at CpG sites is one of epigenetic hallmarks of tumour cells. There are several methods to study the epigenetic regulation of genome activity, from DNA methylation arrays to more specific DNA methylation analysis such as pyrosequencing, Methylation-Specific PCR (MS-PCR) or MS-multiplex ligation-dependent probe amplification (MS-MLPA) of selected genes.
M & M
We studied the DNA-promoter methylation and gene expression of 35 tumour suppressor genes in 105 pituitary neuroendocrine tumors (PitNETs) by MS-MLPA and quantitative real-time PCR techniques, looking for differences among subtypes and between functional and invasive behaviour of tumors. Moreover, I revised the most relevant results published in the literature.
Results
We observed different methylation patterns among PitNET subtypes. The methylation status correlated negatively with its gene expression in some but not all methylated genes. Moreover, some genes appeared more frequently methylated in macro and invasive tumours than in micro or non-invasive ones. Finally, we found significant differences between functioning and

non-functioning corticotroph tumours. The revision of the literature showed contradictory results related to invasion and functionality, mainly due to the sample studied and the techniques used.
Conclusions
It seems clear that aberrant DNA methylation of several genes play an important role in the behaviour of PitNETs. However, as pituitary tumours come from different cell lineages which can show different patterns of methylation, it is necessary to consider the pituitary subtypes as different entities.
DOI: 10.1530/endoabs.70.S4.3

Hyperthyroidism Across the Lifespan

S5.1

Hyperthyroidism in pregnancy
Stine Linding Andersen
Department of Clinical Biochemistry, Aalborg University Hospital, Denmark

Hyperthyroidism in pregnancy should be adequately managed to prevent maternal and fetal complications. The diagnosing of hyperthyroidism in pregnant women is challenged by the physiological alterations in thyroid function tests. Furthermore, the distinction between gestational hyperthyroidism and the hyperthyroidism of Graves' disease presents a clinical challenge. Graves' disease is an autoimmune disorder associated with the presence of thyroid stimulating hormone-receptor antibodies, and the immunological alterations in and after a pregnancy affect the incidence and the manifestation of the disease. An important clinical focus is on the treatment of hyperthyroidism caused by Graves' disease in women of fertile age who are or may in the future become pregnant. Antithyroid drugs (ATDs) constitute a recognized treatment of hyperthyroidism in non-pregnant and pregnant individuals, and a general risk of side effects is known. Severe side effects such as agranulocytosis and liver failure are in general considered rare, but for the use of ATDs in pregnancy there is an additional concern about teratogenic adverse effects. The initial concern emerged from case reports and case series half a century ago and more recently, large observational studies have added new evidence and quantified the risk of birth defects associated with different types of ATDs. The findings that all clinical available ATDs have been associated with birth defects challenge the clinical recommendations on the treatment of hyperthyroidism in an around the early pregnancy period and have led to considerations on the timing and dosage of treatment as well as the role of maternal thyroid function per se.

S5.3

Hyperthyroidism in adolescents
Marek Niedziela
Department of Pediatric Endocrinology and Rheumatology, Poznan University of Medical Sciences, Poland

The term "hyperthyroidism" is a form of thyrotoxicosis due to inappropriately high synthesis and secretion of thyroid hormone(s) by the thyroid. The leading cause of hyperthyroidism in adolescents is Graves' disease; however, one should also consider other potential reasons such as toxic adenoma (TA) or a toxic multinodular goiter (TMNG), and other rare disorders leading to excessive production and release of thyroid hormones. The term "thyrotoxicosis" refers to a clinical state that results from inappropriately high thyroid hormone action in tissues generally due to inappropriately high tissue thyroid hormone levels. Thyrotoxicosis is a condition having multiple etiologies, manifestations, and potential modes of therapy. By definition, the extrathyroidal source of excessive amounts of thyroid hormones such as iatrogenic thyrotoxicosis, factitious ingestion of thyroid hormone, or struma ovarii does not belong to hyperthyroidism. The etiology of hyperthyroidism/and thyrotoxicosis should be determined. If the diagnosis is not apparent based on the clinical presentation and initial biochemical evaluation, diagnostic testing is indicated. It should include (1) measurement of TRAb, (2) determination of the radioactive iodine uptake (RAIU), or (3) analysis of thyroidal blood flow on ultrasonography. A 123I or 99mTc pertechnetate scan should be obtained when the clinical presentation suggests a TA or TMNG. A question arises whether diagnostic workup and treatment (antithyroid drugs, radioiodine, surgery, others), should be the same in adolescents as in adults, whether there are the same goals of treatment in adolescents as in adults, in females vs. males, in reproductive or post-reproductive age. In this aspect, different treatment modalities may be preferred, to avoid potential risks.

Recent studies have reported that tissue micro-environment including tumor infiltrating lymphocytes (TILs) as well as neo-angiogenesis played pivotal roles in biological and clinical behavior of various human malignancies. In adrenal neoplasms, TILs are far more frequently detected in cortical than medullary tumors. In adrenocortical adenomas, we have recently demonstrated that enhanced angiogenic chemokines, especially CXCL12, in cortisol producing adenoma (CPA), induced TILs, especially CXCR4 positive T cells, which are involved in removing tumor cells of CPA harboring DNA damages inflicted by excessive cortisol through promoting cell senescence from tumor microenviroment. In adrenocortical carcinoma (ACC), PD-1 receptor and its ligand, PD-L1 have been considered to play pivotal roles in immune checkpoint mechanism and to serve as potential markers responding to immunotherapy in various human cancers. In ACC, however, conflicting results have been reported and recent clinical trials of the agent targeting PD-L1 also provided lukewarm results in terms of therapeutic outcome of ACC patients. In TILs, recent study demonstrated the better clinical outcome in the pediatric ACC patients harboring a high CD8+-CTL count. In our recent study of adult ACC cases, CD8 count was significantly correlated with TILs but also with CD4 and Treg or FOXP3 counts. PDL-1 status in carcinoma cells of ACC , was also significantly correlated with TILs and CD8 counts but also with CD4 count in the tumor and PD-L1 positive carcinoma cells were less than 1% in all 15 cases examined. In pheochromocytoma, results of our recent study in 39 cases revealed that TILs were not as abundant as other malignancies but CD8 counts as well as vascularity examined by CD31 positive endothelial cells served as the prognostic factors in well differentiated pheochromocytoma. In addition, as previously reported, CD68/CD163 positive macrophages appeared to play roles in biological behavior of well differentiated pheochromocytoma.

Circulating microRNAs in the differential diagnosis of benign and malignant adrenocortical tumours
Peter Igaz
Chair of Endocrinology, Department of Internal Medicine and Oncology, Faculty of Medicine, Semmelweis University, Budapest, Hungary

MicroRNAs, the endogenous mediators of RNA interference have been shown to be helpful as markers of malignancy and prognosis in various neoplasms. The use of microRNAs as biomarkers has been greatly expanded with findings showing their secretion into body fluids (liquid biopsy). Mi-

croRNAs are released both passively due to necrosis and inflammation, and actively in extracellular membrane vesicles (exosomes, microvesicles) or in macromolecular complexes. Circulating microRNA can be determined both from unfractionated plasma/serum samples or from extracellular vesicles.
The preoperative diagnosis of adrenocortical cancer (ACC) is difficult and relies mostly on imaging. The applicability of circulating microRNA for the differential diagnosis of benign and malignant adrenocortical tumours has been investigated in some studies. The most reliable circulating microRNA for the diagnosis of adrenocortical cancer appears to be miR-483-5p. Overexpressed miR-483-5p showed a specificity approaching 100 %, and sensitivity of almost 90 % for ACC diagnosis in different studies on both unfractionated serum and extracellular vesicles. However, miR-483-5p was not significantly different in ACC compared to adrenal myelolipoma. Other microRNAs, such as underexpressed miR-195 might be promising markers. Circulating microRNAs can be exploited for the follow-up of ACC that could be of major clinical relevance. The circulating microRNA expression profiles in cortisol-secreting and hormonally inactive adrenocortical tumours are also different. Circulating microRNA markers for the two major forms of primary aldosteronism (unilateral adenoma and bilateral adrenal hyperplasia) have also been identified. Circulating microRNAs are promising markers, but there are still major differences among the findings on circulating microRNA by different research groups and therefore uniform methodologies and larger cohorts are needed to reduce interassay variability and to increase their reliability.

ACC - what's new today; where is hope tomorrow

Gary Hammer
University of Michigan Rogel Cancer Center

Adrenocortical Carcinoma (Adrenal Cancer or ACC) is a rare malignancy. It requires multidisciplinary care to manage the multiple endocrine and oncologic manifestations of the disease. We will use the recently published international ACC Guidelines to illustrate essential components of the standard of care work-up, diagnosis, and management of ACC. As an understanding of genetics is becoming increasingly mainstream in cancer biology and care including adrenocortical carcinoma (Adrenal Cancer or ACC), we will discuss the burgeoning work in endocrine genetics and current efforts to translate such work into better strategies for diagnosis and for the development of targeted therapies for the treatment of adrenal cancer. Additional goals of this talk are to understand the role of genetics in the pathobiology of adrenal cancer and to discuss how such knowledge is transforming how we care for our patients.

Endocrine Disruptors, Just a Hype or Not?

S7.1

The environment and male fertility, will we disappear?

Aleksander Giwercman
Department of Translational Medicine; Lund University; Malmö, Sweden

From an evolutionary point of view, reproduction is one of the key events. Thus, any potential threat to human fertility, needs to be taken seriously by researchers as well as the general public. In 1992 a meta-analysis of 63 published papers, indicated almost 50% reduction of sperm counts during the period 1940 to 1990. Since then, the discussion on whether the sperm numbers are decreasing or not has divided the scientific world into believers and non-believers. A concomitant rise in the incidence of testicular cancer and, possibly, even congenital malformations of male genitalia, has been claimed as support to the hypothesis of negative secular trend in male reproductive function. The rapidity by which these changes have occurred has pointed to non-genetic causes – life style changes and/or environmental exposure to so called *endocrine disrupters (ED)*. Whereas animal studies have shown that ED given in sufficiently high doses, may possess a negative effect on male reproduction we are still looking for a "smoking gun" in the context of human exposure. So far, relatively weak associations between exposure to ED – at doses normally found in humans – and semen parameters, have been reported. However, it has been hypothesized that male reproductive organs are mostly vulnerable to the negative effect of ED, during early fetal period. Human studies, linking fetal exposure to male reproductive function are still very scarce and, therefore, not yet conclusive. During the next few years we can expect more robust data based on utilization of several biobanks of maternal blood obtained during early pregnancy. However, recent research has indicated the impaired male fertility may be associated with increased risk of long-term comorbidity including metabolic and cardiovascular diseases, osteoporosis as well as cancer. With up to 40% of men having – from fertility point of view – suboptimal sperm counts, the threat to the human race may not only be related to suboptimal fertility rates but also to reduced life expectance and unhealthy aging.

The bad cocktail of endocrine disruptors

Andreas Kortenkamp
Brunel University London, College of Health, Medicine and Life Sciences, Division of Environmental Sciences, Uxbridge, Middlesex, United Kingdom

Several lines of evidence fuel concerns about endocrine disruptors and human health: First, there are increasing trends of endocrine-related disorders such as endocrine cancers, neurodevelopmental disorders, diabetes, thyroidal diseases, and congenital malformations. Second, several widely used chemicals have been linked to such disorders in epidemiological studies and experiments with laboratory animals. Although human exposures involve many endocrine disruptors simultaneously, these efforts have largely focused on single chemicals. Using the example of declines in male reproductive health, this presentation summarises the state of the art of experimental mixture studies with chemicals known to disrupt male sexual development. These studies show that risk assessments should consider combined exposures to bisphenols, polychlorinated dioxins, polybrominated diphenyl ethers, analgesics, parabens, phthalates, triclosan and azole pesticides together. The first mixture risk assessment with focus on declines in semen quality which considers all these chemicals together is presented. It shows that current exposures of the general population are several-fold higher than levels judged to be tolerable. Bisphenols, dioxins and analgesics make the largest contribution to combined risks to semen quality. This analysis calls for substantial reductions in exposures to several chemicals to protect the developing foetus and childhood, life stages vulnerable to impacts on semen quality. It helps prioritise those chemicals that should be targeted to achieve the greatest impact on risk mitigations. The findings provide explanations for reports of substantial declines in semen quality in Western countries.

Micro(nano) plastics, a real threat or not?

M Ramiro Pastorinho
Biology Department and CHRC (Comprehensive Health Research Centre), University of Évora, Portugal.

Environmental pollution by microplastics has been transcending usual stakeholders (such as policymakers and scientists) to become a public concern. The conspicuous, widespread occurrence of (micro)plastics together with the publicization by the media of its potential impacts on wildlife and human health have contributed for this state of affairs. Microplastics, typically defined as plastic particles smaller than 5 mm, have been detected throughout the marine, freshwater and terrestrial environment, as well as in many items commonly consumed by/in contact with humans. This pervasive presence makes Human exposure certain (but exposure-dose has yet to be established). Some microplastic fibers and particles are small enough to become internalized and transported within the body. Moreover, they include added chemicals (from the production process) and can act as "chemical sponges" that sequester and, subsequently, release toxic xenobiotics. However, critical data are lacking to accurately estimate human exposure and effects: small sized microplastics (<100 μm) are seldom measured (and some sources are

virtually ignored); the methods for identifying and measuring the particles is highly variable between studies rendering their comparison difficult and leading to under or overestimations; most studies do not identify the polymers present in the analyzed samples, which constitutes a problem since each polymer has different additive chemicals and affinities for contaminants; sample analysis results seldom include mass measurements; studies of human and animal health effects are too few and too limited, and those available test for unrealistic doses; most human exposure media are not sampled, while others are over studied (i.e., seafood ingestion). This leads us to inevitably conclude that, despite the acceleration in scientific research into the effects of microplastics exposure, no broad conclusions toward human health can, at this point, be drawn. However, "absence of evidence is not absence of presence" and further research is binding.

Estroprogestins and female sexuality

Linda Vignozzi[1,2]
[1]Associate Professor of Endocrinology, Head of SOD "Andrology, Female Endocrinology and Gender Incongruance" – AOU Careggi; [2]Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence

Estroprogestins (EP) are the short-acting hormonal contraceptives most commonly used in Europe, and include combined oral contraceptives (COCs), the patch, and the vaginal ring. Although the safety and efficacy of EP have being extensively investigated, scarce and controversial evidence is available on their impact on female sexuality. The potential negative effects of EP on female mood and desire are hypothesized to derive from sex steroids altering the interplay between neurotransmitters in specific brain areas. Detrimental effects on arousal, lubrication and orgasm have been attributed to changes peripheral concentration in both androgens and estrogens. In fact, EP suppress ovarian synthesis of androstenedione and testosterone and also reduce free androgen levels by increasing the hepatic production of sex hormone binding globulin (SHBG). The progestin component may influence such increase in SHBG, since progestins with androgenic activity induce a less pronounced increase than those with antiandrogenic activity. However, all available EP reduce androgen levels, independently of estrogen dosage and progestin type. As for estrogens, in the last years COCs containing low and very-low doses of ethinyl estradiol have been developed, in order to reduce the risk of side effects, but potentially leading to hypoestrogenism. Despite this strong pathogenetic background, in the vast majority of studies the use of oral EP did not significantly affect sexual desire, whereas data on non-oral forms of EP are scarce. On the other hand, EP seem to change female perception of male attractiveness with a weaker preference for cues of genetic fitness. Low-level evidence also suggests that EP induce a reduction in orgasm frequency. While the effect of oral EP on vaginal lubrication and vulvovaginal atrophy are controversial, no negative effects with the vaginal ring have been reported on these aspects. Finally, oral EP have been associated with an increased risk of painful bladder syndrome.

Current insights into the genetics of polycystic ovary syndrome

JA Visser
Department of Internal Medicine, Erasmus MC, University Medical Center Rotterdam, 3000 CA Rotterdam, the Netherlands

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder, affecting 10–18% of women of reproductive age. Based on the Rotterdam consensus, PCOS is diagnosed by at least two of the following three criteria: oligo- or anovulation, hyperandrogenism, and polycystic ovaries on ultrasound. Thus, four different phenotypes can be recognized. In addition, PCOS is also a metabolic disorder since many affected women present with obesity, insulin resistance and associated metabolic comorbidities. This makes PCOS a very heterogeneous disease and explains why, despite its prevalence, the pathophysiology is still not understood.

Genetic predisposition and environmental exposure are thought to play a major role in the pathophysiology of PCOS. Recent genome-wide association studies (GWAS) in women of Han Chinese and Western European descent have identified several genetic loci associated with PCOS. Importantly, these PCOS-susceptibility loci account for maximally 10% of the estimated heritability, suggesting that there is missing heritability. It will be important to determine whether the different diagnostic criteria for PCOS account for different biological subtypes with a distinct genetic architecture. Studies are ongoing to address this question.

In addition, variants with a lower allele frequency, not detected by GWAS, may contribute to this missing heritability. Recent studies have identified rare PCOS-specific variants in anti-Müllerian hormone (*AMH*) and its receptor (*AMHR2*). This strongly suggests that serum AMH is not only a marker for the polycystic morphology in PCOS, but that aberrant AMH signaling may also contribute to the pathophysiology of PCOS.

In conclusion, the technical advancement in sequencing techniques allows for improved genotype-phenotype studies. Combined with functional studies, this will aid in deciphering the potentially different biological mechanisms involved in PCOS.

Endocrine Targets Related to COVID Infection
CS1.1

Endocrine targets related to COVID19 infection

Daniel J Drucker
Tanenbaum Research Institute, Mt. Sinai Hospital, Canada

SARS-CoV-2 infection produces greater morbidity and mortality in people with cardiovascular disease, diabetes, and obesity, raising the possibility that the consequences of viral infection are modulated directly and indirectly by the endocrine system. Hospitalization and severity of illness is more common in males, further suggesting that sex, possibly male and female sex hormones, modifies the host response to coronavirus infection. SARS-Co-V-2 cellular infection requires ACE2, as well as associated proteases, including TMPRSS2. These molecules are widely expressed in cardiometabolic organs, and the gastrointestinal tract, and to a lesser extent, in the endocrine and exocrine pancreas. Notably, TMPRSS2 is regulated by sex steroids, and clinical trials are examining whether disruption of steroid control of TMPRSS2 expression might be therapeutically useful in SARS-CoV-2 infection, Viral infection may also modify the host susceptibility to autoimmune disease, through dysregulation of humoral and cellular immunity and cytokine expression. Although SARS-CoV-2 infection has not been associated with widespread endocrine dysfunction beyond that commonly seen with critical illness, case reports of automimmune endocrine disease, including type 1 diabetes, have been described. The use of dexamethasone in severely ill individuals with SARS-CoV-2 prompts evaluation of potential endocrine consequences ensuing from sustained high dose glucocorticoid administration. Herein I will review the endocrine consequences of SARS-CoV-2 infection, highlight key knowns and unknowns, and discuss principles for linking coronavirus infection to disorders of the endocrine system.

How Strong is Obesity as a Risk Factor for COVID-19 Patients
CS1.3

How strong is obesity as a risk factor for COVID-19 patients?

Matteo Rottoli
Surgery of the Alimentary Tract, Sant'Orsola Hospital, Alma Mater Studiorum University of Bologna, Italy

Objective
Specific comorbidities and old age create a greater vulnerability to severe Coronavirus Disease 19 (COVID-19). While obesity seems to aggravate the course of disease, the actual impact of the body mass index (BMI) and the cutoff which increases illness severity are still under investigation. The aim of the study was to analyze whether the BMI represented a risk factor for respiratory failure, admission to the intensive care unit (ICU) and death.
Research Design and Methods
A retrospective cohort study of 482 consecutive COVID-19 patients hospitalised between March 1 and April 20, 2020. Logistic regression analysis and Cox proportion Hazard models including demographic characteristics and comorbidities were carried out to predict the endpoints within 30 days from the onset of symptoms.
Results
Of the 482 patients included in the study, 202 (41.9%) had a BMI <25 kg/m^2, 176 (36.5%) had a BMI between 25 and 29.9 kg/m^2, and 104 (21.6%) were obese (BMI ≥ 30 kg/m^2). In the group with obesity, 20 patients (4.1%) had a BMI ≥ 35 kg/m^2. A total of 18 patients (3.7%) had a BMI <20 kg/m^2. Hypertension and type 2 diabetes were reported in 76 (72.8%) and 27 (26%) patients with a BMI ≥ 30 kg/m^2, respectively. Among patients with obesity, 54 (51.9%) experienced respiratory failure, 38 (36.4%) were admitted to the ICU, 26 (25%) required mechanical ventilation, and 31 (29.8%) died within 30 days from the onset of symptoms. At logistic regression analysis, a BMI between 30 and 34.9 kg/m^2 significantly increased the risk of respiratory failure (OR: 2.32; 95% CI: 1.31–4.09, $P=0.004$), and admission to the ICU (OR: 4.96; 95% CI: 2.53–9.74, $P<0.001$). A significantly higher risk of death was observed in patients with a BMI ≥ 35 kg/m^2 (OR: 12.1; 95% CI: 3.25–45.1, $P<0.001$).
Conclusions
Obesity is a strong, independent risk factor for respiratory failure, admission to the ICU and death among COVID-19 patients. Whereas a BMI ≥ 30 kg/m^2 identifies a population of patients at high risk for severe illness, a BMI ≥ 35 kg/m^2 dramatically increases the risk of death.

Pheochromocytoma/paragangliomas (Pheo/PGL) are rare neuroendocrine cancers with strong genetic background. Mutations in the *SDHB* subunit of succinate dehydrogenase (SDH) predispose to malignant disease with limited therapeutic options and poor prognosis. Novel prognostic markers and therapeutic targets are required to decrease the high mortality rate. Glutaminases play a crucial role in the metabolism of SDH impaired tumor cells. By using a host of cellular and molecular biology techniques in 2D and 3D cell culture formats we show that the proliferation of rat Pheo cell line PC12 is not affected negatively by the inhibition of SDH either by siRNA directed against *SDHB* or treatment with SDH inhibitors (itaconate and atpenin A5). BPTES, a specific glutaminase-1 (GLS1) inhibitor successfully decreased proliferation of SDH impaired PC12 cells. BPTES also significantly increased the ratio of dead cells in the 3D model of SDH impaired PC12 cell line. The role of GLS1 was assessed in 35 Pheo/PGL tumor tissues. Higher GLS1 expression was associated with lower SDHB expression. In summary, our data suggest that the SDH-associated malignant potential of Pheo/PGL is strongly dependent on GLS-1 expression and glutaminases may serve as novel prognostic and therapeutic targets.

[1]NIH, United States; [2]University of Birmingham, United Kingdom; [3]Hopital Femme Mere Enfant, France; [4]Karolinska Institute, Sweden; [5]Rigshospitalet, Denmark; [6]University of Sheffield Medical School, United Kingdom; [7]University of Glasgow, United Kingdom; [8]University of Cardiff, United Kingdom; [9]University of Munich Hospital, Germany; [10]Radound University, Netherlands; [11]Sorbonne Université, France; [12]Diurnal Ltd, United Kingdom; [13]Peter Treasure Statistical Services, United Kingdom

Background
Patients with classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21-OHD-CAH) have poor health outcomes due to failure of currently available glucocorticoid preparations to control adrenocorticotropic hormone-driven androgen excess. We investigated whether modified-release hydrocortisone (MR-HC), which mimics the physiological circadian cortisol rhythm, could improve androgen control.
Methods
122 patients with 21-OHD-CAH were randomized to receive either MR-HC or standard glucocorticoid therapy (hydrocortisone, prednisolone, prednisone and dexamethasone). Patients underwent 24-hour profiling of serum 17-hydroxyprogesterone (17-OHP) at baseline and for dose titration at 4 and 12 weeks. The change in mean 24-hour serum 17-OHP standard deviation score (SDS) at 24 weeks was defined as the primary outcome.
Results
Both groups achieved better hormonal control at 24 weeks compared to baseline. The change from baseline in 17-OHP SDS was significantly greater in MR-HC patients at 4 ($P=0.007$) and 12 ($P=0.019$) weeks, but not at 24 weeks. In post-hoc analyses at 24 weeks, a greater reduction was observed in the MR-HC group for the 17-OHP SDS score between 07:00 h and 15:00 h ($P=0.044$) and 17-OHP AUC ($P=0.025$). Good disease control (17-OHP <36 nmol/l (<1200 ng/dl) measured at 09:00 h), was achieved more often in the MR-HC group than the standard glucocorticoid group (90% vs 71%, $P=0.0018$). The variability of 17-OHP over 24 hours was reduced in the MR-HC group compared to standard glucocorticoid therapy ($P=0.0001$). Serum androstenedione 24-hour AUC demonstrated a greater reduction in the MR-HC arm (ratio of geometric LS means of MR-HC divided by standard glucocorticoid: 0.636; 95% CI: [0.450, 0.900]; $P=0.0110$). At 24 weeks, the MR-HC and standard glucocorticoid groups were on similar glucocorticoid hydrocortisone equivalent doses (30 vs 31 mg). There were no safety concerns during the study. There were no adrenal crises in the MR-HC group compared with three (4.9%) in the standard glucocorticoid group. Glucocorticoid stress dosing was reported by 26 patients (42.6%) in the MR-HC group and 36 patients (59.0%) in the standard glucocorticoid group. Resumption of regular menses occurred in 5 patients (4 MR-HC, 1 standard glucocorticoid). The partners of two patients in the MR-HC group became pregnant during the study; one had a history of testicular adrenal rest tissue with documented sperm count improvement on MR-HC.
Conclusion
Six months of MR-HC therapy improved the biochemical control of 21-OHD-CAH in the morning and early afternoon with lower circadian variability and increased patient-reported benefits.

Tumor microenvironment adipose stem cells modulate adrenocortical carcinoma progression

Giulia Cantini[1], Roberta Armignacco[2], Diego de Assis Goncalves[1], Daniele Guasti[3], Gabriella Nesi[4], Paolo Romagnoli[3], Massimo Mannelli[1], Mario Maggi[1,5] & Michaela Luconi[1,5]
[1]University of Florence, Endocrinology Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Florence, Italy; [2]Descartes University, Institut Cochin, INSERM, Paris , France; [3]University of Florence, Histology & Embryology Unit, Department of Experimental and Clinical Medicine, Florence, Italy; [4]University of Florence, Division of Pathological Anatomy, Department of Experimental and Clinical Medicine, Florence, Italy; [5]Istituto Nazionale Biostrutture e Biosistemi (INBB), Rome, Italy

The metabolic interplay occurring between the tumor microenvironment and cancer cells may represent a potential target for novel anti-cancer approaches. Among stromal components, adipocytes and adipose precursors have been shown to actively participate in tumor progression in several solid malignancies. In adrenocortical carcinoma (ACC), a rare endocrine neoplasia with a poor prognosis, cancer cells often infiltrate the fat mass surrounding the adrenal organ, enabling a possible crosstalk with the adipose cells. The molecular biology underlying adrenocortical carcinoma (ACC) development and growth remains to be fully elucidated.
We set up an *in vitro* co-culturing system to study the effects of human white adipose stem cells (ASCs) on the ACC H295R cell line, in order to investigate the role of the adipose microenvironment on ACC evolution. Cell proliferation rate significantly increased in both ASCs (2.6-fold, $P<0.001$) and H295R cells (1.4-fold, $P<0.005$) after 9 day co-culture compared to the mono-culture condition, with a parallel increase in glucose uptake (2.1-fold, $P<0.001$ and 1.2-fold, $P<0.001$, for ASCs and H295R respectively).
When co-cultured with ASCs, H295R cells showed a significant increased cell migration rate (1.8-fold, $P<0.05$ at 48 hours) and expression of migration-related protein (i.e. FAK, RhoA and Fascin-1), as well as a higher invasion ability (1.6-fold, $P<0.001$). A reciprocal influence of the two cell types was further demonstrated by assessing H295R cells ability to influence ASC differentiation, resulting in a significant decrease in the expression of stem genes, such as Bmi1, Nanog and Oct-4 (2.8, 3.1 and 1.3-fold, respectively) and an increased expression of the myofibroblast-like marker α-SMA. Furthermore, *in vitro*-induced differentiation of ASCs in the presence of H295R cells resulted in an impaired adipocyte maturation, as indicated by the significant decrease observed both in the expression of specific markers, such as Adiponectin, FABP4 and HSL (0.28, 0.25 and 0.27-fold, respectively) and intracellular lipid content (0.58-fold, $P<0.001$).

In conclusion, our results support the occurrence of a specific crosstalk between ACC and its adipose microenvironment, leading to cancer cell reprogramming associated with increased invasiveness, opening new perspectives for the development of more effective therapeutic approaches.

Immune infiltrate and PD-1 / PD-L1 expression in adrenocortical carcinoma: who can predict patients´ outcome?

Laura-Sophie Landwehr[1], Iuliu Sbiera[1], Jochen Schreiner[1], Isabel Weigand[1], Matthias Kroiss[1,2], Martin Fassnacht[1,2,3] & Silviu Sbiera[1,2]
[1]University Hospital, University of Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]Comprehenssive Cancer Center Mainfranken, University of Würzburg, Würzburg, Germany; [3]Clinical Chemistry and Laboratory Medicine, University Hospital, University of Würzburg, Würzburg, Germany

Context
Adrenocortical carcinoma (ACC) are endocrine malignant neoplasms associated with severe aggressiveness. Tumour-related glucocorticoid excess occurs in 60% of patients and is associated with poor prognosis. First clinical trials using immune checkpoint inhibitors are quite unsatisfactory and treatment advancements are urgently needed.
Recently, we characterized tumour-infiltrating lymphocytes (TILs) in ACC and identified the detrimental dependency of immunosuppressive effects of glucocorticoids. In this study, we analyse the impact of the checkpoint markers programmed-death 1 (PD1) and its ligand PD-L1 on patients´ outcome and treatment response as additional factor on resistance to immunotherapy.
Methods
We performed immunofluorescence analysis quantifying the expression of the checkpoint marker PD-1 and PD-L1 in 58 primary ACC. Furthermore, we correlated its presence with clinical data.
Results
Most ACCs show infiltrates of T-cells (86.3%, 7.65 cells/HPF) both cytotoxic (84.3%, 5.70 cells/HPF) and helper cells (74.0%, 6.68 cells/HPF) and Tregs (49.3%, 0.75 cells/HPF). Interestingly, the $CD3^+$, $CD4^+$ and $CD8^+$ ACC-infiltrating immune cells were associated with better overall survival (HR for death: 0.45, 95% CI : 0.25–0.87, $P=0.016$; 0.47; 95% CI : 0.23–0.67, $P=0.001$; 0.39; 95% CI : 0.26–0.85, $P=0.013$; respectively). Moreover, T helper cells were negatively correlated with glucocorticoid excess in localized, non-metastatic ACC and even in local recurrences and metastases ($P=0.049$ and $P=0.006$; respectively). In addition, 36% of ACC show intra-tumoral expression of PD-1 positive tumour-infiltrated lymphocytes (15 ± 30 cells/HPF), while 83% (34 ± 82 cells/HPF) of ACC tumour cells were positive for PD-L1. Interestingly, all tumours with PD-1/PD-L1 expression correlated with immunosuppressive glucocorticoid excess and thus were in the poor prognosis group characterized by immune depletion.
Conclusion
First, tumours of ACC patients are characteristically infiltrated by $CD3^+$, $CD4^+$ and $CD8^+$ T cells that positively influence patients' overall survival. However, ACC were less infiltrated by $CD4^+$ T cell in presence of glucocorticoids. Second, ACC tumours often have increased, but heterogeneous expression of immune checkpoint molecule PD-1/PD-L1 on tumoural and infiltrating immune cells predominantly under glucocorticoid excess conditions. Hence, examine the molecular checkpoint markers considering glucocorticoid secretion may be an option in order to predict patients´ outcome and treatment response to immunotherapy.

The utility of salivary cortisol and cortisone measurement in the assessment of cortisol secretion in adrenal incidentalomas

Basil Issa[1], Brian Keevil[1], Neethu Graham[1], Grace Ensah[1], John Belcher[2], Anthony Fryer[3] & Fahmy Hanna[3]
[1]Wythenshawe Hospital, Wythenshawe, United Kingdom; [2]The University of Manchester, United Kingdom; [3]University hospital of north Midlands, United Kingdom

Backgound
Adrenal incidentalomas (AI) are lesions that are incidentally identified while scanning for other conditions. The European Society of Endocrinology guidelines recommend that all patients with AI should undergo an overnight dexamethasone suppression test (ONDST) for the evaluation of autonomous cortisol secretion as defined by failure of suppression of cortisol to <50 nmol/l. The reported prevalence of this is high (50% of patients in a recent publication) and may be linked to an increase risk of cardiometabolic complications in these patients. The ONDST requires attendance to a health care facility and venepuncture. Cortisol and cortisone measurements can also be taken on salivary samples which can be easily collected and posted to the laboratory offering convenience to the patient. We therefore aimed to assess the utility of these measurements in patients with AI.
Methods
We retrospectively analysed the data of 112 patients with AI who underwent an ONDST with measurement of post dexamethasone (0900 h) serum cortisol and salivary cortisol and cortisone and serum and salivary cortisol and salivary cortisone at around midnight the night before. Both serum and salivary samples were analysed with liquid chromatography-tandem mass spectrometry. Statistical analysis was done using SPSS.
Results
There were 64 female and 48 male patients mean age 64, 31 with bilateral adenomas. 48 (43%) failed to suppress there cortisol to <50 nmol/l. There was a strong correlation between salivary cortisone and serum cortisol post 1 mg dexamethasone (R^2 Linear 0.907). No correlation was observed between, serum and salivary cortisol post dexamethasone, or midnight salivary cortisol and cortisone and serum cortisol post dexamethasone.
Discussion
In an ONDST for AI patients, post dexamethasone, salivary cortisone correlates very strongly with serum cortisol and could therefore be used as an alternative sampling method in the ONDST as a simple test (when available) for the evaluation of cortisol secretions in patients with AI which does not require venepuncture or attendance to hospital. We have demonstrated that the prevalence of autonomous cortisol secretion in patients with AI is high and is in line with data that has been reported in the literature recently.

Background
Adrenocortical carcinoma (ACC) has an aggressive but heterogenous behaviour. ENSAT stage and Ki67 proliferation index are used to predict clinical outcome but are limited in distinguishing patients with best outcome. We aimed to validate the prognostic role of clinical and histopathological parameters alone or combined by applying a previously proposed points-based score (mGRAS, Lippert JCEM 2018) to a large multicentre cohort of ACC patients.

Methods
International multicentre retrospective study including ACC patients who underwent adrenalectomy from 2010–2019. Acquired covariates include age at diagnosis, presence of steroid- or mass-related symptoms, ENSAT stage, tumour resection status, Ki67, progression-free survival (PFS), and disease-specific survival (DSS). Each parameter's prognostic value was tested by univariable analysis and PFS and DSS were the primary and secondary endpoints, respectively. Additionally, we evaluated the prognostic performance of mGRAS calculated as follows: age (<50 yr=0; ≥50 yr=1), symptoms (no=0; yes=1), ENSAT stage (1–2=0; 3=1; 4=2), resection status (R0=0; RX=0.5; R1=1; R2=2), and Ki67 (0–9%=0; 10–19%=1; ≥20%=2 points), generating four mGRAS groups: 0–1, 2–3, 4–5, and 6–9. Survival curves were plotted via the Kaplan-Meier method. The discriminative performance of mGRAS and its components were compared using the Harrell's C-index and Royston-Sauerbrei's R^2_D statistic.
Results
We screened 1075 patients from 14 centres; 946 patients met the inclusion criteria (median age 50 years; 61.9% females). Univariable cox regression showed that mGRAS and its components significantly influenced both PFS and DSS. With PFS, mGRAS showed superior prognostic discrimination (C-index 0.71, R^2_D 0.29) compared to its components: symptoms (C-index 0.57, R^2_D 0.08), ENSAT stage (C-index 0.67, R^2_D 0.21), resection status (C-index 0.60, R^2_D 0.18), and Ki67 (C-index 0.65, R^2_D 0.21). mGRAS divided the cohort into four groups with median PFS of 181.6, 33.0, 9.8, and 6.0 months. Similarly, with DSS, mGRAS showed superior discrimination (C-index 0.76, R^2_D 0.44) compared to symptoms (C-index 0.60, R^2_D 0.15), ENSAT stage (C-index 0.72, R^2_D 0.35), resection status (C-index 0.64, R^2_D 0.25), and Ki67 (C-index 0.68, R^2_D 0.31). Median DSS for the mGRAS groups were 248.8, NR, 66.0, and 18.1 months.
Conclusion
The prognostic performance of mGRAS is superior to that of individual clinical and histopathological parameters. This simple score will be valuable in guiding personalised treatment decisions in patients with ACC, e.g. the need for adjuvant mitotane and frequency of monitoring.

Comparative proteomic analysis of different bilateral adrenocortical hyperplasia

Annabel Berthon[1,2], Stephanie Cologna[3], Paul Blank[2], Fady Hannah-Shmouni[2], Jerome Bertherat[1], Forbes Porter[2] & Constantine Stratakis[2]
[1]Institut Cochin , Endocrinology, Metabolism and Diabetes, Paris, France; [2]National Institutes of Health, National Institute of Child Health and Development, Bethesda, United States; [3]University of Illinois at Chicago, Chicago, United States

Bilateral Adrenal Hyperplasias (BAH) are responsible for approximately 10% of ACTH-independent Cushing syndrome and are classified as either micronodular or macronodular. Whereas Primary Pigmented Nodular Adrenocortical Disease (PPNAD) and isolated Micronodular Adrenal Disease (iMAD) are two types of micronodular hyperplasia, Primary Macronodular Adrenal Hyperplasia (PMAH) is a macronodular BAH. These tumors are classified differently based on clinical, histological and genetic features but they all share a dysregulation of the cyclic AMP/protein kinase (PKA) pathway, a molecular signaling system that is essential for the synthesis and secretion of glucocorticoids. We investigated the molecular differences between the various types of BAHs using a proteomic approach on normal tissue, iMAD, PPNAD and PMAH. In total, we identified 37 proteins differentially expressed between these diagnostic groups. Most of these proteins are involved in metabolism and mitochondrial function, which is consistent with prior transcriptomic data as well as the secretory status of BAH. We are currently comparing all "-omics" for consistency and/or important differences. Interestingly, each BAH (iMAD, PPNAD and PMAH) has its own proteomic signature and can be separated by primary component analysis highlighting differences in molecular pathways. We propose that the 37 proteins identified here may provide new clues for the formation of these neoplasms, how they link to the PKA pathway, and importantly assist in their clinical diagnosis.

Background/Aim
X-linked hypophosphatemia (XLH) is a rare disease caused by *PHEX* mutation, leading to elevated FGF23, renal phosphate wasting, hypophosphatemia, insufficient $1,25(OH)_2D$ synthesis. Clinically, it manifests with rickets including leg deformities, poor growth, dental abscesses, craniosynostosis, and hearing loss. Beyond conventional treatment (phosphate supplements+active vitamin D), burosumab is pathogenetic anti-FGF23 therapeutic approach, whose efficacy was demonstrated in clinical trials on 1−12 years-old children affected with XLH. Here, we prospectively assessed the efficacy and safety of burosumab on a large cohort of children in clinical practice, including adolescents ≥13 years of age at moment of treatment.
Patients/methods
57 XLH-children (36 girls/21 boys; 9.1±8.9 years; including 10 adolescents ≥13 year-old, 14.5±1.2 years) were switched from conventional therapy to burosumab.
Objectives
The primary end-point was the change from baseline (M0) to 12 months (M12) in the rachitic lesions evaluated through knee MRI by measuring of the maximum width of physis and the transverse extent of widening. The secondary end-points were the changes in biochemical (serum phosphate (sP), TmP/eGFR, ALP, $1,25(OH)_2D$, PTH), clinical parameters (height-SDS, function evaluated through 6-minutes walking test [6MWT]), incidence of dental-hearing-neurological manifestations and safety (incidence of any adverse events, nephrocalcinosis, hyperparathyroidism). In France, the target sP was >1.2 mmol/l (>3.7 mg/dl).
Results
1-year treatment with burosumab significantly reduced the disease activity, as shown by reduction of the transverse extent of widening and the maximum width of medial physis by 50% and 44% (M0→M12: 62±34 → 31±20%; 5.5±2.1 → 3.2±1.4 mm, $P=0.00$ for all, respectively). This was associated with significant reduction in ALP (M0 → M12: 418±150 → 299±146U/l, $P=0.006$) and improvement in physical ability expressed as age-adjusted 6MWT-SDS (M0 → M12: −3.3±1.3 → −2.8±1.3, $P=0.03$). As expected, we found a rescue of phosphate wasting (M0→M12:sP 0.73±0.12 → 1.19±0.15 mmol/l, TmP/eGFR 0.62±0.12 → 1.07±0.17) and $1,25(OH)_2D$ synthesis (M0 → M12: 25±15 → 79±22 pg/ml); $P=0.00$ for all. There were no significant changes in height-SDS and incidence of complications after 1 year. The most common side effects were bone-muscular-abdominal pain, headache, reactions at sites of injection. Adolescents showed higher baseline PTH levels, however, upon burosumab, PTH reduced overtime (M0 → M6 → M12: PTH 85±43 → 57±27 → 66±39 ng/l, $P=0.7$). Secondary hyperparathyroidism in adolescents was associated to a slower restoration of phosphate metabolism.
Conclusion
Our findings on efficacy and safety of burosumab confirm those of clinical trials. Restoration of phosphatemia and endogenous calcitriol synthesis by

burosumab leads to healing of rickets, reduction of disease activity and improvement of physical function. XLH-adolescents show slower restoration of phosphate wasting under burosumab likely due to secondary hyperparathyroidism; noteworthy, the use of burosumab seems to control PTH in adolescents.

STOPFOP: A european phase II clinical trial using saracatinib to prevent FOP

Bernard Smilde[1], Richard Keen[2], Clemens Stockklausner[3], Dong Liu[4], Alex Bullock[5], Annette Von Delft[6], Natasja Van Schoor[7], Paul Yu[8] & Elisabeth Eekhoff[9]
[1]Amsterdam UMC, location VUmc, Internal Medicine Section Endocrinology, Amsterdam, Netherlands; [2]Royal National Orthopaedic Hospital, Department of Rheumatology, Middlesex and London, United Kingdom; [3]Klinikum Garmisch-Partenkirchen GmbH Abteilung für Kinderklinik, Department of Paediatrics, Garmisch-Partenkirchen, Germany; [4]Astrazeneca, Boston, United States; [5]University of Oxford, Nuffield department of Medicine, Oxford, United Kingdom; [6]University of Oxford, Nuffield department of Medicine, Oxford, United Kingdom; [7]Amsterdam UMC, locatie VUmc, Epidemiology and biostatistics, Amsterdam, Netherlands; [8]Brigham and Women's Hospital - Department of Cardiovascular Medicine, Department of Medicine, Boston, United States; [9]Amsterdam UMC, location VUmc, Internal Medicine section Endocrinology, Amsterdam, Netherlands

Background
Fibrodysplasia ossificans progressiva (FOP) is a rare, genetic and devastating disease characterized by progressive heterotopic ossifications (HO) in muscles, tendons, ligaments and fascia. The formation of HO leads to severe contractures and early death. There are no approved medications yet. The STOPFOP team identified AZD0530 (saracatinib) as a potent, low nanomolar inhibitor of the mutant ALK2 kinase which is the unique genetic driver of this rare bone disease. AZD0530 was proven to be effective in representative FOP mouse models. The European Union's Innovative Medicines Initiative (IMI) has provided funding to investigate the repurposing of this drug, originally designed for ovarian cancer treatment, to treat patients with FOP.
Methods
This is a phase 2a study, designed as an European multicentre 6-month double blind randomized controlled trial (RCT) of AZD0530 vs placebo, followed by a 12 month trial comparing open-label extended AZD0530 treatment with historical control data. In total 20 FOP patients, aged 18 to 65 years, will be included with the classic FOP mutation (R206H). Endpoints are objective change in heterotopic bone volume measured by low-dose whole body computer tomography (CT) , [18F] NaF PET activity and patient reported outcome measures (PROMS).
Discussion
Drug repurposing – using existing clinical molecules for new disease indications - presents an ideal solution for limiting risks in early clinical studies where there is a supporting genetic rationale for the drug in question. This is especially useful in rare diseases, as the study population is limited. Using existing assets and investments, may also allow more affordable pricing once an indication is approved. AZD0530 would represent a rapidly translatable therapy for FOP, having the significant advantage of extensive safety data from over 28 registered clinical trials with AZD0530 involving over 600 patients. Trial registration EudraCT number 2019-003324-20

Prediction algorithm for persistent primary hyperparathyroidism after parathyroidectomy

Andrea Repaci[1], Valentina Vicennati[1], Nicola Salituro[1], Giulia Vandi[1], Guido Zavatta[1], Paola Altieri[1], Guido Di Dalmazi[1], Alessandra Gambineri[1], Carla Pelusi[1], Luca Burgio[2], Ottavio Piccin[2], Ottavio Cavicchi[2] & Uberto Pagotto[1]
[1]Endocrinology and Prevention and Care of Diabetes Unit, S.Orsola Policlinic, Department of Medical and Surgical Sciences, Alma Mater University of Bologna, Bologna, Italy; [2]Otolaryngology Head and Neck Surgery Unit, S. Orsola Policlinic, University of Bologna, Bologna, Bologna, Italy

Background
Primary hyperparathyroidism (PHPT) is characterized by an excessive secretion of the parathyroid hormone (PTH) with normal or high calcium levels. The gold standard therapy involves minimally invasive parathyroidectomy with intraoperative PTH (ioPTH) monitoring. Different criteria have been identified when predicting cure rates using ioPTH values.
Objective
To evaluate the percent ioPTH drop (ΔioPTH), the post-excision ioPTH, the first post-operative day PTH/calcium ratio and their possible combinations to predict persistent PHPT (PPHPT) after parathyroidectomy.
Methods
We retrospectively analyzed 211 patients who underwent parathyroidectomy with ioPTH for Primary hyperparathyroidism between 2008 and 2017 at the Department of Otolaryngology of S. Orsola Policlinic of Bologna. Vienna Criteria were used to evaluate the PTH drop during the procedure. By ROC curve we calculated ΔioPTH cut-off, the post-excision ioPTH cut-off, the first post-operative day PTH/calcium ratio cut-off. We compare these values with the Vienna Criteria.
Results
At the last follow-up, 16.4% of patients had normocalcemic PPHPT (NormoPPHPT) and 6% had hypercalcemic PPHPT (HyperPPHPT). ΔioPTH < 69.7% was associated with PPHPT with 66.7% sensitivity and 67.5% specificity. A post-excision ioPTH value ≥55 ng/ml was associated with PPHPT, with 80.0% sensitivity and 77.0% specificity. A first post-operative day PTH/calcium ratio ≥3.58 was associated with PPHPT, with 62.5% sensitivity and 79.8% specificity. PPHPT was more effectively identified with the combination of ΔioPTH < 69.7% and ioPTH post-excision ≥55 ng/ml than with the Vienna Criteria (Area under curve, AUC, 0.832 vs 0.620; $P < 0.001$). When added to the combination, the first post-operative day PTH/calcium ratio slightly but not significantly improved AUC (0.916; $P = 0.187$).
Conclusions
ΔioPTH < 69.7% and post-excision ioPTH ≥55 ng/ml combined are able to predict PPHPT and show a better accuracy than the Vienna Criteria. The combination can thus be a useful tool in post-surgical PHPT follow up.

Loss of glucocorticoid rhythm induces an osteoporotic phenotype in mice

Elizabeth M Winter[1], M Schilperoort[1], J Kroon[1], S Kooijman[1], K Mletzko[2], B Busse[2], AM Pereira[1], NM Appelman-Dijkstra[1], N Bravenboer[1], PCN Rensen[1] & OC Meijer[1]
[1]Leiden University Medical Center, Department of Internal Medicine, Division of Endocrinology, Leiden, Netherlands; [2]University Medical Center Hamburg-Eppendorf, Department of Osteology and Biomechanics (IOBM), Hamburg, Germany

Introduction
Glucocorticoid (GC)-induced osteoporosis is a widespread problem that is accompanied with increased fracture risk. Currently, it is unknown whether detrimental effects of GC therapy on bone are simply the consequence of supraphysiological GC doses, or whether absence of the endogenous GC rhythm also plays a role. In this study, we aimed to elucidate the importance of the presence of a diurnal corticosterone (CORT) rhythm, the primary GC in mice, for bone quality.
Methods & Results
We implanted female C57Bl/6J mice with slow-releasing corticosterone (CORT) pellets to blunt the rhythm in CORT levels without inducing hypercortisolism. Flattening of the CORT rhythm for 7 weeks reduced cortical and trabecular bone volume (−8%; $P < 0.001$ and −26%; $P < 0.05$, respectively), as determined by micro-CT analysis. Furthermore, tartrate-resistant acid phosphatase (TRAP) levels were increased (+42%; $P < 0.01$) while procollagen type 1 N-terminal propeptide (P1NP) levels were decreased (−37%; $P < 0.001$) in plasma of mice with a flattened CORT rhythm, indicative of a negative balance in bone remodeling. Double calcein labeling of bone *in vivo* revealed a reduced bone formation, as reflected by a reduced mineral apposition rate (−20%; $P < 0.05$), mineralizing surface per bone surface (−23%; $P < 0.05$) and bone formation rate per bone surface (−39%; $P < 0.01$). Collectively, these perturbations in bone turnover and structure decreased bone strength and stiffness (−15%; $P < 0.01$ and −11%; $P < 0.01$, respectively), as determined by mechanical testing.
Conclusion
We demonstrate for the first time that flattening of the GC rhythm results in an osteoporotic phenotype in mice. Our findings indicate that at least part

of the fracture risk associated with GC therapy may be the consequence a disturbed GC rhythm, rather than an excess in GC dose alone. Thus, reintroduction of a trough and/or peak in GCs could be a promising novel strategy to prevent GC-induced osteoporosis.

Effect of nine months of vitamin D supplementation on areal and volumetric bone mass density and bone architecture in graves' disease: a double-blinded, randomized clinical trial

Diana Grove-Laugesen[1], Eva Ebbehoj[1], Torquil Watt[2], Klavs Würgler Hansen[3] & Lars Rejnmark[1]
[1]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark; [2]Gentofte Hospital, Department of Internal Medicine, Hellerup, Denmark; [3]Silkeborg Regional Hospital, Department of Internal Medicine, Silkeborg, Denmark

Background
Vitamin D is important to skeletal health and is standard care in conditions with low BMD. Thyrotoxicosis caused by Graves' disease (GD) leads to increased bone turnover and reduced BMD. We aimed to test the hypothesis that vitamin D supplementation would improve bone recovery in GD.
Methods
Using a double-blinded design, hyperthyroid patients with a first time diagnosis of GD were randomized to supplementation with vitamin D3 70 mg/day or placebo as add-on to standard therapy with anti-thyroid drugs (ATD). At baseline and nine months, we measured bone mass density, body composition and bone architecture using DXA and HRpqCT. Between-group differences in change and response to ATD treatment were analyzed using linear mixed modelling. In subanalysis, we tested for interaction between the intervention and baseline vitamin status (insufficient (<50 nmol/l or replete). (The DAGMAR study clinicaltrials.gov #NCT02384668).
Results
86 GD patients were included (86% females, mean age 41 ± 14). Compared with placebo, nine months of vitamin D3 did not significantly improve bone density or architecture. However, vitamin D3 tended to reduce gain in lean body mass (−24%, $P=0.08$), fat mass (−49%, $P=0.21$) and body weight (−33%, $P=0.09$). Vitamin D3 did not affect changes in plasma levels of thyroid hormones or TRAb. In response to ATD, BMD increased significantly in hip 2% (95% CI : 1–4). Cortical porosity decreased, tibia −7% (95% CI : −12 to −2) and radius −14% (95% CI : −24 to −3), and trabecular thickness increased, tibia 5% (95% CI : 2–9) and radius 4% (95% CI : 1–7). Stiffness and estimated failure load did not change significantly. Lean body mass increased 10% (95% CI : 8–12). In subanalysis of all outcomes, the effect of intervention did not differ between patients with a baseline insufficient as opposed to replete vitamin D status.
Conclusion
In newly diagnosed GD, nine months of high dose vitamin D3 supplementation does not offer benefit in improving skeletal health but may adversely affect restoration of body composition. Treatment of thyrotoxicosis is of major importance to restore bone density and microarchitecture.

Superior efficacy of calcifediol soft gelatin capsules vs cholecalciferol independently of bmi, for the management of vitamin d deficiency in postmenopausal women: a treatment to be considered in therapeutic guidelines

Esteban Jódar[1], José Luis Pérez-Castrillón[2], Antonio Dueñas-Laita[3], Gonzalo Hernández[4], Nieves Fernández-Hernando[4] & Paula Arranz-Gutiérrez[4]
[1]Hospital Universitario Quironsalud Madrid, Endocrinology and Nutrition Service, Pozuelo de Alarcón, Spain; [2]Hospital Universitario Rio Hortega and Universidad de Valladolid, Internal Medicine Service, Valladolid, Spain; [3]Hospital Universitario Rio Hortega and Universidad de Valladolid, Clinical Pharmacology Service, Valladolid, Spain; [4]Faes Farma S.A., R&D+i Department, Leioa, Spain

Background
Vitamin D deficiency is a worldwide health issue that affects more than one billion people. Few guidelines assess optimal dosing of vitamin D in general population, and although there is no international consensus, the optimum dosing for vitamin D3 and mainly calcifediol is not known.
Objective(s)
To assess the efficacy of calcifediol in the treatment of vitamin D deficiency, compared with therapeutic guidelines recommendations for cholecalciferol in postmenopausal women.
Material and Methods
Phase III–IV, double blind, randomized, controlled, multicentre superiority clinical trial approved by the corresponding Ethics Committees and Health Authorities. Postmenopausal women with baseline levels of 25(OH)D < 20 ng/ml were randomised to calcifediol 266 µg /month for 4 or 12 months (standard and test regime), or to cholecalciferol 25 000 IU/month (as per therapeutic guidelines) for 12 months. Results from an interim analysis - performed upon completion of month 4 visit by 100% of evaluable patients - are presented and reported without unblinding subjects' study treatments. Both calcifediol groups are summarised for analysis.
Results
298 women were included in the ITT analysis. All demographic characteristics were balanced amongst groups. Regarding analysis based on World Health Organization classification for BMI (kg/m^2), 41.3% were obese, 32.6% were overweight, 25,2% were normal weight and 1% were underweight. Due to limited sample size, underweight group is not considered for analysis. When treatments are compared for BMI groups at Month 4, mean change versus baseline and % subjects achieving 25(OH)D > 30 ng/ml resulted statistically significant (Table 1). When analysing per treatment group,13.5% and 35% of women in the calcifediol group reached 25(OH)D > 30 ng/ml at 1 and 4 months when compared to 0% and 8.2% respectively in the cholecalciferol group ($P<0.001$). No relevant safety issues reported for the present analysis.

Table 1

	NORMAL		OVERWEIGHT		OBESE	
	Calcifediol ($n=58$)	Cholecalciferol ($n=17$)	Calcifediol ($n=59$)	Cholecalciferol ($n=38$)	Calcifediol ($n=80$)	Cholecalciferol ($n=43$)
Mean Change (ng/ml)	16.6*	12.6	15.6***	9.8	13.4***	8.9
% Subjects with 25(OH)D > 30	51.7*	17.6	33.9**	7.9	25**	4.7

*$P<0.05$; **$P<0.01$; ***$P<0.001$.

Conclusions
Calcifediol shows a greater efficacy than cholecalciferol (as recommended in therapeutic guidelines), for the treatment of vitamin D deficiency in postmenopausal women independently of their BMI. A significant percentage of patients on cholecalciferol group failed to reach recommended levels.

Surgery alone or surgery in combination with postoperative zoledronic acid for the treatment of osteoporosis in primary hyperparathyroidism: a 2-year double-blind randomized placebo-controlled study

Eeva Ryhänen[1], Anna-Mari Koski[2], Loyttyniemi Eliisa[3], Kiviniemi Ulla[4], Camilla Schalin-Jantti[5] & Välimäki Matti[1]
[1]Helsinki University Central Hospital, Department of Endocrinology, Helsinki, Finland; [2]Central Finland Central Hospital, Department of Internal Medicine, Finland; [3]University of Turku, Department of Biostatistics, Finland; [4]Tampere University Hospital, Department of Internal Medicine, Finland; [5]Helsinki University Hospital and University of Helsinki, Endocrinology, Helsinki, Finland

Background
Osteoporosis is common in primary hyperparathyroidism (PHPT). It is also an indication for parathyroidectomy in PHPT. Bone mineral density (BMD) measured by dual-energy x-ray absorptiometry (DXA) increases after successful surgery. Alendronate significantly increases BMD in PHPT patients not undergoing surgery. It is not known whether surgery alone or in combination with postoperative zoledronic acid more efficiently improves bone health in PHPT.
Objective
To compare the effects of surgery alone with surgery in combination with zoledronic acid on bone turnover and BMD in PHPT.
Methods
Randomized, double-blind, placebo-controlled study of PHPT patients with osteoporosis including DXA and bone marker measurements at baseline, 1- and 2-year follow-up.
Patients
1–3 months after parathyroidectomy, 56 patients with PHPT were randomized to zoledronic acid (ZOL; f/m (25/3), mean age 67.9 yrs) or placebo (PBO; f/m (22/6), mean age 69.0 yrs).
Results
BMD significantly improves 2 yrs after parathyroidectomy, with significantly better scores at the femoral neck (FN) and lumbar spine (LS) in the ZOL compared to the PBO group (Z-score in FN; $P=0.045$ and T- and Z-scores in LS; $P=0.039$ and 0.017, respectively). Bone turnover markers (P1NP, CTX, ALP) decrease significantly more in the ZOL compared to the PBO group ($P<0.001$ for all markers). Of the 18 patients who before surgery had received bisphosphonates for >1 yr, BMD improved significantly in the femoral neck and lumbar spine in the ZOL ($n=10$; $P<0.001$–0.01 for all) but only in the lumbar spine in the PBO ($n=8$, $P=0.03$) group.
Conclusion
BMD increases after parathyroidectomy both with and without zoledronic acid. However, BMD improves significantly more when combined with postoperative zoledronic acid.

Twenty-two years results of the israeli-georgian program diabetes in pregnancy

Natalia Asatiani, Ramaz Kurashvili, Ekaterine Inashvili, Elena Shelestova & Mzia Dundua
National Center for Diabetes Research, Tbilisi, Georgia

Background
The Israeli-Georgian Program Diabetes in Pregnancy was initiated at the Georgian Diabetes Center in 1997, with the aim to provide care for women with diabetes. The Program has become possible as a result of Twinning between Union of Diabetes and Endocrine Association and Israeli Diabetes Association. It was initiated in 1997, and since then it successfully works, being the longest and most sustainable Twinning program in Europe. The aim to assess the efficacy of treatment in women with pre-GDM and GDM.
Methods
In total, 407 women with type 1 preexisting diabetes (mean age 23+6 yrs, diabetes durations 12.4+7.5 yrs) and 119 women with gestational diabetes (GDM) were enrolled in the study. The patients were divided into 4 groups (Gr.):
Gr.1 – 223 patients who received specialized pre-conception care;
Gr.2 – 118 patients enrolled in the program at < 10 weeks of gestation;
Gr.3 – 66 patients enrolled in the program at > 10 weeks of gestation;
Gr.4 – 119 women with GDM.
Results
At entry HbA1c(%) levels for Gr.1, 2, 3 and Gr.4 were: 8.12 (0.05), 9.08 (0.6), 8.09 (1.6), 6.7(0.9) respectively; By the end of preconcetion care HbA1c levels in Gr.1 – 6.0(0.65)% were statistically lower in Gr.2 and 3 ($P=0.000$). By term HbA1c levels statistically decreased in all the groups ($P=0.024$, $P=0.000$, $P=0.000$, respectively). The rate of spontaneous abortions was lower in Gr.1 (2.24%), than in Gr.2 (8.4%) $P=0.000$. In Gr.1 patients percent of pre-eclampsia (0.44%) was lower, than in Gr.2 (8.4%) and Gr.3 (10.6%) (P1 – 2 = 0.0005; P1 – 3 = 0.0002). No statistical difference between Gr.1 and Gr.4 was revealed. In Gr.1 patients percent of preterm deliveries was lower, than in Gr.2 and Gr.3 (P1 – 2 = 0.0014; P1 – 3 = 0.0001). No statistical difference between Gr.1 and Gr.4 was revealed. In Gr.1 patients percent of macrosomia was lower, than in Gr.2 and Gr.3 (P1 – 2 = 0.0074; P1 – 3 = 0.0101); and in Gr. 1 and 4 (10.47 – 11.7%) – no statistical difference was observed. Perinatal mortality was observed in Gr.1 – 1.79%, in Gr.2 – 4.23% in Gr.3 – 7.5% and in Gr.4 – 1.68% (P1-2 = 0.0944; P1 – 3 = 0.0129; P1 – 4 = 0.7265).
Conclusion
In patients with Pre-GDM and GDM good glycemia control during pregnancy significantly reduces the risk of spontaneous abortions, pre-eclampsia, preterm delivery, and perinatal deaths. This program shows that proper approach to pregnancy management in diabetes can be successfully implemented even in low-to-middle income countries.

Influence of obesity in the miRNome landscape: miR-4454, a tissue-specific regulator of insulin response

Prudencio Sáez-Martínez[1,2], Vicente Herrero-Aguayo[1,2], Juan M Jiménez-Vacas[1,2], Juan L López-Cánovas[1,2], Lourdes Garrido-Sánchez[3], Manuel Macías-González[3], José López-Miranda[2,4,5], Enrique Gómez-Gómez[4,6], Justo P Castaño-Fuentes[1,2], Manuel D Gahete-Ortíz[1,2] & Raúl M Luque-Huertas[1,2]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Department of Cell Biology, Physiology and Immunology, University of Cordoba, Córdoba, Spain; [2]Carlos III Health Institute, CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Madrid, Spain; [3]Biomedical Research Institute of Malaga (IBIMA), Clinical Management and Endocrinology and Nutrition Unit; Hospital (Virgen de la Victoria), University of Malaga, Malaga , Spain; [4]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [5]Reina Sofia University Hospital, Lipids and Atherosclerosis Unit, Córdoba, Spain; [6]Reina Sofia University Hospital, Urology Service, Córdoba, Spain

Obesity is a major health problem commonly associated with severe comorbidities, including insulin resistance and type 2 diabetes mellitus (T2DM). Emerging evidence suggests that production and secretion of certain micro RNAs (miRNAs) are dysregulated under adverse metabolic conditions and might exert a key role in the development and progression of different metabolic-related pathologies. However, the alteration of the plasma miRNA profile under obesity condition and its pathophysiological implication in insulin resistance and T2DM has not been fully explored. Here, we aimed to explore the dysregulations of the miRNome landscape in human obesity and to unveil the putative role/association of key altered miRNAs with basic clinical characteristics in obesity. Specifically, an Affymetrix-miRNA 4.1 array was implemented in a pilot cohort of plasma samples from normoweight and obese patients (BMI < 25 vs >30), and the main changes were further validated in two independent cohorts of patients ($n=221/n=20$). Moreover, different *in vitro* (using cell models derived from metabolic-tissues) and *in silico* approaches were performed. Our results demonstrated a profound dysregulation in the human miRNome under obesity conditions. Interestingly, miR-4454 was consistently elevated in plasma of obese patients compared to control patients in all the cohorts, and was positively associated with key clinical parameters related to insulin resistance (i.e. insulin levels, HOMA-IR and HbA1b). We found that miR-4454 is mainly expressed in liver and prostate tissues. Consistent with this, *in vitro* treatment with high-dose of insulin induced an overexpression of miR-4454 in liver and prostate cell-line models (HEPG2 and RWPE-1, respectively). Moreover, forced overexpression of miR-4454 led to a marked downregulation in the expression of insulin response-related genes (i.e. *INSR*, *IRB*, *GLUT4)* and to a reduction in the activity of key proteins involved in insulin-signaling pathways (i.e. AMPK and AKT). Additionally, miR-4454 overexpression resulted into a clear alteration of several key splicing factors and spliceosome components associated with the development of T2DM (i.e. *ESRP1*, *ESRP2*, *RBM45* and *RNU2*). Finally, our data showed that bariatric surgery and the treatment with anti-diabetic/obesity drugs (biguanides or statins) led to a reduction in plasma level of miR-4454, which is consistent with a putative role and implication of miR-4454 in obesity. Altogether, our results suggest that miR-4454 could be considered as a novel diagnostic and/or therapeutic target for obesity and its associated comorbidities such as insulin resistance and T2DM.

Circulating follistatin predicts type 2 diabetes risk

Chuanyan Wu[1], Yan Borné[1], Rui Gao[2], Maykel López Rodriguez[3], William Roell[4], Jonathan Wilson[4], Emma Ahlqvist[1], Cheng Luan[1], Andreas Peter[5],

Jürgen Machann[5], Mun-Gwan Hong[6], Jochen Schwenk[6], Peter Nilsson[1], Angela Shore[7], Faisel Khan[8], Andrea Natali[9], Olle Melander[1], Marju Orho-Melander[1], Jan Nilsson[1], Erik Renström[1], Claes Wollheim[1], Ewan Pearson[8], Paul Franks[1], Morris White[10], Kevin Duffin[4], Allan Vaag[11], Markku Laakso[3], Norbert Stefan[5], Leif Groop[1] & Yang De Marinis[1]
[1]Lund University, Dep. of Clinical Sciences, Malmo, Sweden; [2]Shandong University, China; [3]University of Eastern Finland; [4]Lilly Research Laboratories; [5]University of Tübingen; [6]KTH Royal Institute of Technology; [7]University of Exeter; [8]University of Dundee; [9]University of Pisa; [10]Harvard Medical School; [11]University of Copenhagen

Follistatin is a hepatokine found to be elevated in patients with type 2 diabetes (T2D) and promotes hyperglycemia in mice. We report that elevated baseline circulating follistatin levels predict future T2D incidence in longitudinal cohorts including up to 5274 individuals. Individuals with elevated circulating follistatin had higher risk of developing type 2 diabetes during follow-up of 4 years (IMI-DIRECT-METSIM, $n=1079$, Finland), 5 and 19 years (MDC-CC, $n=4195$, Sweden). The hazard ratios (HRs) for incident T2D adjusted for multiple risk factors by quartiles of follistatin were 2.26 (95% CI: 0.98-5.22; P for trend=9.00E-16) for 4 years; 4.22 (95% CI: 1.38-2.94, P for trend=0.012) for 5 years; and 1.36 (95% CI: 1.06-1.74, P for trend=0.014) for 19 years. K-means clustering on 4-year follow-up cohorts (IMI-DIRECT and its four sub-cohorts, in total $n=1701$, Denmark, Finland, Sweden and the Netherlands) identified a fast glycemia progression subgroup with higher follistatin and C-peptide levels. Circulating follistatin, adipose tissue insulin sensitivity and liver fat content were studied in a TDFS cohort ($n=210$, Germany); and follistatin levels associated significantly with adipose tissue insulin resistance and circulating follistatin was elevated in non-alcoholic fatty liver disease (NAFLD). In human stem cell-induced adipocytes, follistatin dose-dependently attenuated insulin-inhibited lipolysis and increased free fatty acid release. To identify genetic factors that influence plasma follistatin levels, genome-wide association studies (GWAS) was performed on MDC-CC ($n=4239$), and identified 13 genetic variants, including rs780094 ($P=1.11E-11$), rs780093 ($P=1.91E-11$) and rs1260326 ($P=2.77E-11$) in strong linkage disequilibrium (LD) within the glucokinase regulatory protein (*GCKR*) gene to be associated with plasma follistatin. The results were replicated on SUMMIT-VIP cohort ($n=885$, UK, Italy and Sweden). Regulation of follistatin production in liver cells by GCKR in addition to insulin and glucagon was confirmed in HepG2 cells *in vitro*. Thus, we present a new aspect and mechanism in the development of type 2 diabetes (T2D) which involves hepatokine follistatin. Elevated circulating follistatin predicts T2D, and may predispose to diabetes risk and NAFLD by promoting adipose tissue insulin resistance and adipocyte free fatty acid release. Liver follistatin secretion is regulated by insulin, glucagon and GCKR. Our study suggests that follistatin predicts and mediates type 2 diabetes, and play an important role in the pathogenesis of T2D.

Dietary intake of fat and oil are associated with expression of miR-143 and miR-34a in visceral and subcutaneous adipose tissues: A nutriepigenetic study

Behnaz Mahmoodi[1], Emad Yuzbashian[1], Golaleh Asghari[1], Maryam Zarkesh[2], Mehdi Hedayati[2], Parvin mirmiran[1] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran

New evidence indicated that miRNAs may contribute to the regulation of energy balance and metabolic homeostasis, by controlling a wide range of metabolic pathways. miR-143 and miR-34a are the best studied among the miRNAs linked to adipose tissue regulation. Dietary intake, among many other environmental factors, is a key player that can induce epigenetic changes. The aim of the study was to investigate the association of the miR-143 and miR-34a expression in visceral and subcutaneous adipose tissues with habitual fat and oil intakes. Visceral and subcutaneous adipose tissues were obtained from 97 subjects (41 non-obese, 18 obese, and 38 morbid obese), who underwent open abdominal surgery with minimal impact on dietary intake. Intake of hydrogenated and non-hydrogenated vegetable oils and butter were collected by using a valid and reliable food frequency questionnaire. The expressions of miR-143 and miR-34a in visceral and subcutaneous adipose tissues were analyzed by Real-Time PCR. Linear regression models were used to estimate the association of dietary hydrogenated and non-hydrogenated vegetable oils and butter intake with miR-143 and miR-34a expression after adjustment for potential confounding variables. The gene expression of miR-34a was more increased in morbid obese than obese subjects in both subcutaneous (13.3 vs 11.3, $P<0.002$) and visceral (13.4 vs 9.2, $P<0.001$) adipose tissues. There was no association of the miR-143 and miR-34a expression in both adipose tissue in total population. After adjustment for total energy intake, insulin, triglycerides, and age, visceral adipose tissue miR-143 gene expression was positively with total fat and oil intake ($\beta=0.334$, $P=0.024$) in the total population. The expression of miR-143 in visceral adiposity among morbid obese participants was negatively associated with non-hydrogenated vegetable oils ($\beta=-0.317$, $P=0.036$), and directly associated with butter ($\beta=0.503$, $P=0.002$) intake. The miR-34a expression among morbid obese participants was associated with total fats and oils ($r=0.534$, $P<0.001$) and non-hydrogenated oil ($\beta=0.443$, $P=0.008$) in visceral adipose tissue. Moreover, we found significant association of miR-143 expression in subcutaneous adipose tissue with butter in both morbid obese and non-obese participants. An increase in miR-143 and miR-34a expression by total fats and oils, may explain development of obesity through high fat diet. A decrease in expression of miR-143 by non-hydrogenated oils would justify a lower adipogenic capacity and, would therefore contribute to the decrease of fat stores observed in adipose tissue with higher intake of fatty acids contains of non-hydrogenated oils.

Supplementation with Bifidobacterium breve BR03 and Bifidobacterium breve B632 favoured weight loss and improved insulin metabolism in children and adolescents with obesity in the BIFI-OBESE cross-over, randomized placebo-controlled trial

Arianna Solito[1], Iderina Hasballa[2], Matteo Calgaro[3], Nicole Bozzi Cionci[4], Roberta Ricotti[1], Marina Caputo[2], Giulia Genoni[1], Alice Monzani[1], Francesca Archero[1], Simonetta Bellone[1], Gianni Bona[1], Emanuela Agosti[5], Gianluca Aimaretti[2], Angela Amoruso[6], Marco Pane[6], Nicola Vitulo[3], Diana Di Gioia[4] & Flavia Prodam[7]
[1]SCDU Pediatrics, University of Piemonte Orientale, Department of Health Sciences, Novara, Italy; [2]SCDU Endocrinology, University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]University of Verona, Department of Biotechnology, Verona, Italy; [4]University of Bologna, Department of Agricultural and Food Sciences, Bologna, Italy; [5]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [6]Probiotical Research Srl, Novara, Italy; [7]University of Piemonte Orientale, Department of Health Sciences, Novara, Italy

Background
Variations in gut microbiota might impact metabolic functions like caloric intake and energy expenditure leading to body weight excess. Microbiota modulation may be a potential approach for obesity management, especially in subject characterized by specific microbial enterotypes.
Objective
We aimed to assess the impact of probiotic treatment in obese children and adolescents, under diet control, on weight loss, glucose, and insulin homeostasis, gut microbiota composition and SCFAs.
Methods
This was a cross-over, double-blind, RCT on 100 children and adolescents (6–18 years) affected by obesity with insulin-resistance (NCT03261466). The subjects on dietary training were randomized to treatment with 2×10^9 CFU/AFU/die of *Bifidobacterium breve* BR03 (DSM 16604) and *Bifidobacterium breve* B632 (DSM 24706) or placebo for 8 weeks with a 4-weeks wash-out period. Clinical, biochemical and stool sample analyses were carried out at each time (T0–T3).
Results
At baseline, there were no differences in clinical and metabolic parameters between treatment and control group, except *Escherichia coli* concentration, which was higher in the placebo group. A mixed-effect model analysis revealed a carry-over effect on most of the variables, suggesting that the probiotic treatment had a prolonged effect over the washout period. Due to this event, only the results of the first phase (T0–T1) were deeply analyzed. For all the subjects (active and placebo) we observed significantly decreased BMI, BMI Z score, waist circumference (WC), systolic and diastolic blood pressure, insulin after OGTT, and *E. Coli* concentrations at T1. Probiotics further decreased WC (–3.51 cm, $P<0.05$), BMI Z score (–0.17 kg/m^2, $P=0.07$), fasting insulin (–4.57 mcUI/ml, $P=0.06$), HOMA IR (–1.1, $P<0.05$), *E. Coli* concentrations ($P<0.02$), and increased nearly

to significance insulin sensitivity after OGTT. No differences were observed in inflammatory cytokines and GLP-1 levels at fasting. Of twenty-five SCFAs, probiotics decreased the 2-methyl- propanoic acid relative abundance ($P<0.02$). The PCoA analysis of SCFAs allowed defining four clusters of patients. Two clusters identified subjects that were healthier and had better responses in BMI Z score, WC, insulin resistance and sensitivity during probiotics.
Conclusions
Probiotic supplementation with *B. breve* BR03 and B632 has determined beneficial effects on weight and insulin metabolism in obese children and adolescents undergoing dietary training. Moreover, the microbiome-host configuration could be a predictor of the obesity phenotype and the efficacy of treatment with *B. Breve* strains.

OC3.6

11β-Hydroxysteroid dehydrogenase type 1 inhibition protects against the development of adverse metabolic and bone effects of prednisolone: A randomized, double-blind, placebo-controlled trial

Nantia Othonos[1], Riccardo Pofi[2], Anastasia Arvaniti[1,3], Andrew Whittaker[4], Paul Stewart[5], Ruth Coleman[6], Olorunsola Agbaje[6], Joanne Milton[6], Rury Holman[6] & Jeremy W Tomlinson[1]
[1]University of Oxford, Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom; [2]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [3]Oxford Brookes University, Department of Biological and Medical Sciences, Oxford, United Kingdom; [4]Astrazeneca, Cambridge, United Kingdom; [5]University of Leeds, School of Medicine, Leeds , United Kingdom; [6]University of Oxford, Diabetes Trial Unit, Oxford, United Kingdom

Glucocorticoids (GC) are commonly prescribed, but their use is associated with significant adverse metabolic and bone effects. 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) regenerates active GC within tissues, tightly controlling the availability of GC to bind and activate the GC receptor; Our preclinical data have shown that 11β-HSD1 knock out mice resist the adverse effects of exogenous GC excess. We have now conducted a randomized, double-blind, placebo-controlled clinical study to determine if pharmacological inhibition of 11β-HSD1 (using AZD4017) can prevent the adverse effects of prescribed GC without compromise to their anti-inflammatory actions.
30 healthy male volunteers (age; 38±12 years, BMI; 25.2±2.3 kg/m^2) were recruited and underwent metabolic assessments including a 2-step hyperinsulinemic euglycemic clamp incorporating stable isotopes to measure glucose and fatty acid flux and adipose tissue microdialysis. Immune-inflammatory responses were measured using an OX40 (CD134) assay. All participants received prednisolone 20 mg once daily for 7 days, and, in addition, were randomized to treatment with either AZD4017 (400 mg twice daily) or matched placebo. After 7 days, all investigations were repeated. The primary endpoint was assessed using a general linear model adjusting for baseline measures. Secondary endpoints were assessed using Wilcoxon (paired), and Mann-Whitney (unpaired) tests, where appropriate.
The predefined primary end-point (change in glucose disposal (Gd)) was threefold lower in the AZD4017 group, but this failed to reach statistical significance (–0.58±2.12 vs –1.56±1.99, AZD4014 vs placebo $P=0.17$). As expected, prednisolone+placebo worsened metabolic phenotype; Gd decreased ($P=0.004$), circulating triglyceride ($P=0.018$) and glycerol levels ($P<0.0001$) increased, as did adipose tissue interstitial fluid glycerol release ($P=0.011$). Osteocalcin (as an index of bone formation) also decreased significantly ($P<0.0001$). In contrast, when prednisolone was co-administered with AZD4017, there were no significant changes in any of these variables. Importantly, the OX40 (CD134) assay demonstrated a robust response to prednisolone (1.4±0.3 vs 0.6±0.2%, $P=0.011$), which persisted in the prednisolone+AZD4017 treated group (1.1±0.3 vs 0.6±0.1%, $P=0.016$). Circulating prednisolone and prednisone levels were not different between the 2 groups.
We have demonstrated that 11β-HSD1 inhibition limits the adverse metabolic and bone effects of prednisolone. Oral prednisolone (an *'active'* GC) is reliant upon tissue-specific regeneration (from inactive prednisone) for many of its biological actions and these appear independent of circulating levels. In addition, we have provided the first clinical evidence to show that 11β-HSD1 inhibition has potential as a strategy for selectively limiting the adverse side effects of prescribed GC.

Efficacy and safety of volanesorsen for the treatment of metabolic complications in patients with familial partial lipodystrophy: results of the BROADEN study

Louis O'Dea[1], Joseph Tami[2], Veronica Alexander[2], Lynnetta Watts[2], Eunju Hurh[1], Brant Hubbard[1], Hartmut Schmidt[3], Anatoly Tiulpakov[4], Ann Mertens[5], Abhimanyu Garg[6] & Elif Oral[7]
[1]Akcea Therapeutics, Boston, United States; [2]Ionis Pharmaceuticals, Carlsbad, United States; [3]Universitaetsklinikum Muenster, Gastroenterology, Hepatology, Endocrinology, Diabetology, and Infectology, Münster, Germany; [4]Moscow, Moscow, Russian Federation; [5]KU Leuven, Department of Chronic Diseases, Metabolism, and Ageing, Leuven, Belgium; [6]University of Texas Southwestern Medical Center, Internal Medicine, Dallas, United States; [7]University of Michigan, Metabolism, Endocrinology, and Diabetes Division, Ann Arbor, United States

Introduction
Familial Partial Lipodystrophies (FPLD) are rare genetic disorders characterized by marked loss of subcutaneous fat from the extremities with variable fat loss from the face and trunk. Patients with FPLD develop metabolic abnormalities including hypertriglyceridemia, insulin resistance, and diabetes mellitus, which are difficult to manage with conventional therapies including fibrates, statins and insulin. The BROADEN study evaluated the efficacy and safety of volanesorsen, an antisense inhibitor of apolipoprotein C-III, to improve the metabolic abnormalities of patients with FPLD consuming a low-fat diet.
Methods
BROADEN was a 52-week phase 2/3 study of volanesorsen in 40 patients (11 males, 29 females) with FPLD, randomized 1:1 to weekly administration of volanesorsen (300 mg) or placebo. Enrollment criteria included FPLD by genetic, familial or phenotypic criteria; fasting plasma triglycerides ≥2.3 mmol/l (200 mg/dl) and diabetes mellitus. The primary efficacy endpoint, mean percent change in fasting plasma triglycerides from baseline, was evaluated at 3 months and other secondary endpoints were evaluated at 12 months.
Results
The median age of the participants was 49 years (range 28 – 68), and they had a BMI of 29.8 kg/m^2 (range 21.0 – 44.2), fasting plasma triglycerides of 8.6 mmol/l (range 2.4–60.4) and HgbA1c of 8.2 % (range 4.8–10.5) at baseline. Volanesorsen treatment resulted in an 88% reduction in fasting plasma triglycerides as compared to 22% reduction in placebo-treated patients ($P=0.0009$) and this reduction remained significant for the entire duration of the study. As compared to placebo, volanesorsen treatment significantly reduced hepatic fat fraction at 12 months (+1.5% vs –51.9%, respectively; $P=0.004$) but did not improve HgbA1c levels (–0.2% vs 2.3%, respectively; $P=0.77$). The most common adverse event for volanesorsen-treated patients was injection site reactions, which were predominately mild in severity. While reductions in blood platelet count were seen in volanesorsen-treated patients, no one developed severe thrombocytopenia (platelet count <50,000/mm^3). Five patients treated with volanesorsen discontinued treatment due to a mild or moderate adverse event, while no patient on placebo treatment discontinued treatment.
Conclusions
In patients with FPLD, as compared to placebo, volanesorsen therapy results in significant reductions in serum triglycerides and hepatic fat fraction but glycemic control remains unchanged. The prevalence of side effects of volanesorsen was comparable to that reported previously in patients with familial chylomicronemia syndrome, but without any reports of severe thrombocytopenia.

Quantitative mRNA expression of PROK2, DUSP6, and WDR11 in peripheral blood as diagnostic criteria for central hypogonadism

Anna Loktionova[1], Irena Ilovayskaya[1] & Lidia Nefedova[2]
[1]MF Vladimirsky Moscow Regional Scientific Research Clinical Institute, Department of Endocrinology, Moscow, Russian Federation; [2]Lomonosov Moscow State University, Biological Faculty, Moscow, Russian Federation

Central hypogonadism (CH) is a syndrome that can be diagnosed in women with hypoestrogenic amenorrhea and a lack of normal response of gonadotropins to hypoestrogenemia in the absence of other reasons. To date, about

50 genes were reported as a possible reason for this condition, but the genetic basis is still unknown for approximately a half of CH cases.
Patients and methods
Some of the CH-related genes are expressing in leukocytes of peripheral blood: *GNRHR* and *GNRH1* (necessary for the adequate biological effect of GnRH); *PROK2* and *CHD7* (responsible for the GnRH neurons migration), *WDR11* and *DUSP6* (involved in normal sexual development). 15 female patients with CH (age from 18 to 50 y.o.) were examined; 6 of them have amenorrhea I and the rest 9 – amenorrhea II. Risk factors of amenorrhea II were: stress, excessive physical exercises, rapid weight loss, past use of oral contraceptives. The control group: 21 healthy women (age from 19 to 37 y.o.) with the regular ovulatory menstrual cycle, some of them have children. A quantitative determination of mRNA expression of genes *GNRHR*, *GNRH1*, *PROK2, CHD7*, *WDR11* and *DUSP6* was completed in the fresh peripheral blood sample by PCR in real-time. Measurement results were normalized to the reference primer beta-actin expression.
Results
Expression patterns of examined genes differed from normal in each case of CH. Changes in neurodevelopmental genes *PROK2*, *DUSP6* and *WDR11* expression were statistically significant: $U_{emp}=75$ vs $U_{cr}=83$ for *PROK2*, 77 vs 88 for *DUSP6* and 66 vs 77 for *WDR11* ($P<0.05$ for all genes; Mann-Whitney U-test). After ROC-analysis diagnostic clipping points were determined: *PROK2* expression >0.009356 and *DUSP6* expression >0.01478 showed sensitivity 60.0% and 60.0% and specificity 82.0% and 83.3%, respectively, for CH diagnosis. *WDR11* expression > 0.002224 pointed to the central genesis of hypogonadism with sensitivity 66.7% and specificity 75.0%.
Conclusion
According to our results, quantitative mRNA expression measurement of neurodevelopmental genes *PROK2*, *DUSP6*, and *WDR11* (which are responsible for CH) can be considered as diagnostic criteria for central hypogonadism with sensitivity 60.0%, 60.0%, 66.7% and specificity 82.0%, 83.3%, 75.0% respectively.

Both ghrelin deletion and unacylated ghrelin overexpression preserve muscles in aging mice

Emanuela Agosti[1], Marilisa De Feudis[2], Elia Angelino[3], Roberta Belli[4], Maraiza Alves Teixeira[2], Ivan Zaggia[2], Tommaso Raiteri[2], Andrea Scircoli[2], Andrea Graziani[3], Flavia Prodam[1], Maurilio Sanpaolesi[5,6], Paola Costelli[7], Elisabetta Ferraro[8], Simone Reano[2] & Nicoletta Filigheddu[2]

Sarcopenia, the decline in muscle mass and functionality during aging, might arise from age-associated endocrine dysfunction. Indeed, muscle wasting follows the general decline in trophic hormones and the establishment of a chronic mild inflammatory status characteristic of aging. Ghrelin is a gastric hormone peptide circulating in both acylated (AG) and unacylated (UnAG) forms that have anti-atrophic activity on skeletal muscle. AG is the endogenous ligand of the growth hormone secretagogue receptor (GHSR-1a), and it is involved in metabolic regulation and energetic balance through induction of appetite, food intake, and adiposity. UnAG does not induce GH release and has no direct effects on food intake, but it shares with AG several biological activities on cell types lacking AG receptor. In particular, both AG and UnAG have direct biological activities on skeletal muscle, including promotion of myoblast differentiation and protection from atrophy, in all likelihood by activating a common receptor. Also, UnAG promotes muscle regeneration, stimulation of muscle satellite cell activity, and activates autophagy and mitophagy at higher extent than AG in muscles of nephrectomyzed mice. Age-dependent hypoghrelinemia could participate in the establishment of sarcopenia by facilitating the progression of muscle atrophy and limiting skeletal muscle regeneration capability. Here, we show that both the deletion of the ghrelin gene (Ghrl KO) and the lifelong overexpression of UnAG (Tg) in mice attenuated the age-associated decline in muscle mass and functionality, seen as larger myofiber areas, lower levels of Atrogin-1, an increased mitochondrial functionality compared to old WT animals. Also, both Ghrl KO and Tg animals displayed reduced systemic inflammation and maintenance of brown adipose tissue functionality. While old Tg mice apparently preserved the characteristics of young animals, Ghrl KO mice features deteriorate with aging. However, young Ghrl KO mice show more favorable features compared to WT animals that result, on the whole, in better performances in aged Ghrl KO mice. Altogether, the data collected suggest that, in Ghrl KO mice, it is the lack of AG the major determinant factor of their overall better conditions and advocate for the design of analogs to UnAG rather than AG to therapeutically treat sarcopenia in humans.

Clinical implications of Pan-genomic classification of pituitary neuroendocrine tumours

Chiara Villa[1,2,3], Mario Neou[2], Roberta Armignacco[2], Anne Anne Jouinot[2], Marie-Laure Raffin-Sanson[4], Amandine Septier[2,2], Karine Perlemoine[2], Michèle Bernier[1], Bertrand Baussart[5], Jerome Bertherat[2,6], Stéphan Gaillard[5] & Guillaume Assié[2,6]
[1]Hopital Foch, Pathology Departement, Suresnes, France; [2]Institut cochin, U1016, Paris, France; [3]Chu De Liege, Endocrinology Departement, Liege, Belgium; [4]Hopital Ambroise Pare, Endocrinology Departement, Boulogne-Billancourt, France; [5]Hopital Foch, Neurosurgery Departement, Suresnes, France; [6]Hopital Cochin, Departement of Endocrinology, Paris, France

Recently, we provided the first integrated genomic classification of pituitary neuroendocrine tumors (PitNETs), on a series of 134 tumors. This series covered all histological, secretion, invasion and growth speed types. This molecular classification supports the importance of pituitary lineage as proposed by the World Health Organization 2017 classification, but also individualizes new entities. Indeed, corticotroph tumors are split into three distinct molecular groups. In addition sparsely granulated somatotroph tumors cluster with thyrotroph and pluri-hormonal-PIT1 tumors. Finally, "null-cell" are gonadotroph tumors.
Aim
To explore the clinical implications of this new molecular classification;
Method
For the series of 134 tumors with genomic characterization (transcriptome, exome, miRnome, methylome, SNParray), extensive data were collected, including clinical (size, sphenoid and cavernous invasion), hormonal, pathological (WHO2017) and outcome (aggressiveness) features.
Results
-Immunohistochemistry thresholds:
Based on molecular classification, immunopositivity thresholds could be determined for prolactin, GH and ACTH in lacto-, somato- and corticotrophs.
-Aggressiveness:
On the whole cohort, aggressiveness did not appear as a major driver of genomic classification. The number of chromosomal alterations was not related to aggressiveness either, but rather to secretion type. Subgroup analyses revealed, for corticotrophs, an association between USP8 mutation status and aggressiveness. Indeed, USP8-mutated corticotrophs seemed less aggressive.
-Response to Temozolomide:
Temozolomide is currently recommended for treating aggressive tumors not responding to other treatments. Temozolomide is degraded by MGMT. The association between MGMT expression and response to temozolomide was evaluated in three patients. Expression level was high in one not responding, intermediate in one with partial response, and low in one with complete response. No negative correlation was found between MGMT expression and DNA methylation in MGMT locus on the whole cohort, including its promoter (median correlation coefficient 0.55; range: –0.27 to 0.76).
- Expression of somatostatin receptors:
Somatostatin receptor subtypes showed variable expression between molecular groups (Kruskal-Wallis test, $P<10–13$ and $P<10–15$ for SSTR2 and SSTR5, respectively). Notably, for corticotroph PitNETs, expression of SSTR5 was higher in USP8-mutated PitNETs compared with USP8-wild-type (Wilcoxon's $P<10–4$), supporting a potential value of USP8 mutation status for predicting response to pasireotide. Finally SSTR5 expression was also high in the group of thyrotroph tumors.
Conclusion
USP8-wildtype corticotroph adenomas with overt Cushing are more aggressive. MGMT promoter methylation is not correlated to MGMT expression. MGMT expression level may be associated to Temozolomide response.

mRNA expression level could be a predictor of temozolomide. SSTR5 expression is high in USP8-mutated corticotroph tumors.

Thyrotropin/Thyrotropin receptor signaling deficiency impairs spatial learning and memory

Sisi Luan, Xu Hou, Zhao He & Jiajun Zhao
Shandong Provincial Hospital affiliated to Shandong University, Department of Endocrinology

Purpose
Subclinical hyperthyroidism is associated with cognitive impairment, but the mechanism has remained unclear. As subclinical hyperthyroidism is characterized by significantly decreased thyrotropin (TSH) levels, this study aimed to investigate whether TSH regulates cognitive function.
Methods
The correlation between TSH and cognitive impairment was investigated in a cross-sectional population study including 382 participants with ages ranged from 21 to 82 years old. The role of TSH/TSH receptor (TSHR) signaling in spatial learning and memory was further examined by behavior tests in *Tshr*$^{-/-}$ mice. Dendritic spine, synaptic density and structure of hippocampal CA1 pyramidal neurons were detected by Golgi's method and electron microscopy. The mRNA and protein expression levels of learning and memory-related genes were assessed by RNA sequencing, real-time PCR, immunoblotting and immunofluorescence approaches.
Results
Serum TSH level correlated inversely with cognitive impairment in the current population. Consistently, *Tshr* deletion in mice led to significantly compromised performance in hippocampus-dependent tasks, reduced dendritic spine density and excitatory synaptic density as well as altered synaptic structure in CA1 subfield of the hippocampus. Furthermore, the mRNA levels of learning and memory-related genes were altered, and protein levels of CREB-regulated genes were downregulated in the hippocampus of *Tshr*$^{-/-}$ mice.
Conclusions
These findings reveal that TSH/TSHR signaling ablation impairs spatial learning and memory, indicating a decline in TSH level might contribute to the increased prevalence of cognitive impairment in subclinical hyperthyroidism patients.

Introduction
In a Phase II study, osilodrostat, a potent oral 11β-hydroxylase inhibitor, normalized mean urinary free cortisol (mUFC) in most patients with CD. We report the efficacy and safety of osilodrostat in a large CD patient population (NCT02180217).
Methods
In this study, open-label osilodrostat was initiated at 2 mg bid in 137 adults with CD and mUFC > 1.5×ULN, with dose adjustments every 2 weeks (range 1–30 mg bid) up to W12. At W26, patients achieving mUFC ≤ ULN at W24 without a dose increase after W12 ($n=71$) were randomized to continue osilodrostat ($n=36$) or matching placebo ($n=35$) for 8 weeks, followed by open-label osilodrostat until W48. Patients ineligible for randomization continued open-label osilodrostat ($n=47$). The primary endpoint was mUFC ≤ ULN at the end of the randomized withdrawal phase (W34) without a dose increase after W26.
Results
At baseline, median (range) mUFC was 3.5×ULN (0.3–69.6). At W34, significantly more patients in the osilodrostat group maintained mUFC ≤ ULN (without a dose increase after W26) than in the placebo group (86% vs 29%; OR 13.7, $P<0.001$). At W24, 53% of enrolled patients had mUFC ≤ ULN without a dose increase after W12. At W48, 66% of enrolled patients had mUFC ≤ ULN and 96% of enrolled patients had mUFC ≤ ULN at least once during the study, with a median time to first mUFC ≤ ULN of 41 days and no differences observed between males and females. In addition, 64/97 (66×0%) patients maintained normal mUFC for ≥6 months after the first mUFC normalization. By week 24, 72·2% were receiving an osilodrostat dose of ≤5 mg bid, irrespective of mUFC elevation at baseline. Median (range) duration of osilodrostat exposure was 75 weeks (1–165). By W48, 24 (18%) patients had discontinued the study, 15 (11%) because of adverse events (AEs). Overall, the most common AEs were nausea (42%), headache (34%), and fatigue (28%). AEs related to hypocortisolism and adrenal-hormone-precursor accumulation occurred in 51% and 42% of patients, respectively. No males experienced signs or symptoms related to increases in androgens or oestrogens. In females, AEs of hirsutism (8·8%), acne (8·8%), and hypertrichosis (0·7%) were reported, all grade 1–2, and none leading to study discontinuation.
Conclusion
Osilodrostat was significantly superior to placebo at maintaining mUFC ≤ ULN after randomized withdrawal, and normalized mUFC in two-thirds of enrolled patients at W48, with few patients discontinuing treatment because of AEs. This study demonstrates osilodrostat to be a highly effective treatment for CD, with good tolerability.

Results from the phase 3, randomized, double-blind, placebo-controlled OPTIMAL study of oral octreotide capsules in adult patients with acromegaly

Susan Samson[1], Lisa Nachtigall[2], Maria Fleseriu[3], Murray Gordon[4], William Ludlam[5], Gary Patou[5], Asi Haviv[5], Mark E Molitch[6], Nienke Biermasz[7], Christian J Strasburger[8], Laurence Kennedy[9] & Shlomo Melmed[10]
[1]Baylor College of Medicine, Houston, United States; [2]MGH Neuroendocrine and Pituitary Center; [3]Oregon Health & Science University; [4]Allegheny General Hospital; [5]Chiasma; [6]Northwestern University, Evanston, United States; [7]Leiden University Medical Center; [8]Charite Campus Mitte; [9]Cleveland Clinic Foundation; [10]Cedars Sinai Medical Center

Background
Many patients with acromegaly report limitations of long-acting somatostatin receptor ligand (SRL) injections, including ongoing disease symptoms near cycle-end and injection-site pain. Oral octreotide capsules (OOC) may provide an alternative to monthly injections. The phase 3 CHIASMA OPTIMAL study assessed efficacy and safety of OOC in patients with acromegaly controlled on injectable SRLs.
Methods
A multinational, randomized, placebo-controlled study was conducted in 56 patients ≥18 years of age with active acromegaly (IGF-I ≥1.3 ×ULN) and average IGF-I ≤ 1.0 ×ULN on stable dose of SRL injections (octreotide or lanreotide, ≥3 months). At baseline (1 month after last injection), patients were randomized to OOC or placebo (28/group) for 36 weeks, followed by an optional open-label extension (OLE). The primary endpoint was proportion of patients maintaining biochemical response, defined as IGF-I ≤ 1.0 ×ULN (2-value average at weeks 34 and 36). Secondary endpoints included need for rescue with injectable SRLs, GH response (GH < 2.5 ng/mL), and time to loss of IGF-I response (IGF-I > 1.0 and $1.3 ×ULN for 2 consecutive visits). Safety and tolerability were assessed.

Results
The primary endpoint was met, as 58% of patients receiving OOC maintained IGF-I response vs 19% receiving placebo ($P=0.008$). Mean IGF-I levels in patients receiving OOC were within the reference range at treatment end (0.97 × ULN) vs patients receiving placebo (1.69 × ULN). All secondary endpoints were met. Of patients receiving OOC, 75% completed 36 weeks without need for rescue therapy. However, 68% of the placebo group required rescue therapy. GH response was maintained at week 36 in a significantly larger proportion of patients receiving OOC than placebo (78% vs 30%; $P=0.001$). Median time to loss of IGF-I response was not reached by the end of the study for patients receiving OOC vs 16 weeks for the placebo group ($P<0.0001$). Five patients in the placebo group had IGF-I levels in the reference range at the end of 36 weeks. Only 2 (7% of placebo group) did not meet loss of response criteria anytime throughout the study. OOC were safe and well tolerated; no new/unexpected safety signals were observed. Most patients (55/56) experienced at least one treatment emergent adverse event; most were mild or moderate in intensity. Overall, 90% of patients who completed the trial on OOC opted to enter the open label extension phase.
Conclusion
These phase 3 data demonstrate OOC to be potentially safe and effective for treating adults with acromegaly.

OC4.7

Fluid restriction results in a modest rise in plasma sodium concentration in chronic hyponatraemia due to SIAD; results of a prospective randomised controlled trial

Aoife Garrahy[1], Iona Galloway[1], Anne Marie Hannon[1], Rosemary Dineen[1], Patrick O'Kelly[1], William Tormey[2], Michael O'Reilly[1], David Williams[3], Mark Sherlock[1] & Chris Thompson[1]
[1]Academic Department of Endocrinology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [2]Department of Chemical Pathology, Beaumont Hospital, Dublin, Ireland; [3]Department of Stroke and Geriatric Medicine, Beaumont Hospital and RCSI Medical School, Dublin, Ireland

Fluid restriction (FR) is the recommended first-line treatment for chronic hyponatraemia due to syndrome of inappropriate antidiuresis (SIAD) in expert guidelines, despite the lack of prospective data to support its efficacy. We aimed to test the hypothesis that FR was more effective than no treatment. 46 patients with chronic SIAD were randomised to either fluid restriction (1 litre/day, FR) or no specific hyponatraemia treatment (NoTx) for one month. Inclusion criteria were euvolemia, plasma sodium (pNa) 120–130 mmol/l, urinary sodium (UNa) ≥30 mmol/l, urine osmolality (UOsm) $100 mOsm/kg and normal cortisol secretion. Patients with symptomatic hyponatraemia, alcohol dependence, diuretic therapy, and recent discontinuation of medications causing hyponatraemia, were excluded. The primary endpoints were change in pNa at day 4 and day 30, chosen to match the endpoints reported in the SALT trials. A rise in pNa of <5 mmol/l was defined as treatment failure. Data are expressed as median (IQR). The two groups were matched for age (74 yrs (68–80) in FR and 72 yrs (54–80) in NoTx, $P=0.55$), baseline pNa (127 (126–129) mmol/l FR and 128 (126–129) mmol/l NoTx, $P=0.36$) and urine osmolality (459 (345–604) mOsm/kg FR and 457 (287–556) mOsm/kg NoTx, $P=0.86$). Idiopathic SIAD accounted for 39% of FR, and 26% of NoTx, $P=0.15$. PNa rose by 3 (2–4) mmol/l by day 4 in FR ($n=23$), compared with 1 (0–3) mmol/l NoTx ($n=23$), $P=0.005$. There was minimal additional rise in pNa by day 30; pNa increased from baseline by 4 (2–6) mmol/l in FR ($n=17$), compared with 1 (0–1) mmol/l NoTx ($n=15$), $P=0.04$. By day 4, 17% of FR had a rise in pNa of ≥5 mmol/l, compared with only 4% NoTx, $P=0.35$. By day 30, 47% of FR had a rise in pNa of $5 mmol/l, compared with only 6.7% NoTx, RR 7.1, $P=0.02$. There was no statistically significant difference in the proportion of patients reaching pNa $130 mmol/l by day 4, 61% FR compared with 39% NoTx, $P=0.24$, or by day 30, 71% FR and 40% NoTx, $P=0.15$. FR results in a modest rise in pNa after three days in patients with chronic SIAD, with minimal additional rise thereafter. Less than half of patients achieve a target rise in pNa ≥5 mmol/l after 30 days of FR, emphasising the clinical need for additional therapies for SIAD.

TSH-Independent upregulation of thyroid-specific gene expression in dehal1 knockout mice

Pouya Alikhani[1,2], Cristian Gonzalez-Guerrero[1], Xiao-Hui Liao[3], Marco Borsò[4], Teresa Peluso[1,5], Riccardo Zucchi[4], Samuel Refetoff[3] & Jose Carlos Moreno[1,2]
[1]INGEMM, Madrid, Spain; [2]Autonomous University of Madrid, Madrid, Spain; [3]The University of Chicago Department of Medicine, Chicago, United States; [4]Department of Pathology, University of Pisa, Pisa, Italy; [5]Universita' Degli Studi Del Sannio - Dipartimento di Scienze e Tecnologie, Benevento, Italy

Background
Most thyroid specific genes are transcriptionally regulated by TSH-TSHR signalling and T4-driven negative feedback of TSH secretion at the pituitary. However, local autoregulation of transcription has been described from IGF-IGFR, follicular thyroglobulin, or iodine. We aimed to investigate the TSH dependency of thyroid transcriptional regulation in the *Dehal1* knockout, devoid of iodide-recycling capacity from iodotyrosines.
Methods
Dehal1 knockout (KO) and wild-type (WT) mice were fed with a diet containing high iodine (5.6 µg/l/day, to secure iodine sufficiency) for 28 days. Plasma TSH and T4 were determined on days 0 and 28 by radioimmunoassay and LC/MS-MS, respectively. After sacrifice, RNA from thyroids were isolated and cDNA-qPCR were used to determine expression levels of genes involved in basal/apical iodide transport (*Slc5a5*, *Slc26a4*, *Slc26a7*), nuclear transcription (*Pax8*, *Nkx2-1*, *Foxe1, Glis3*) and thyroid hormone synthesis and secretion (*Tshr*, *Tg*, *Tpo*, *Duox2*, *Duox2*, *Dehal1*, *Slc16a2, Dio1*).
Results
Under sufficient iodine, TSH was equal in both genotypes (logTSH: 1.45±0.1 vs 1.45±0.4 mU/l, $P>0.05$). Plasma T4 (58.5 vs 59.9 ng/ml) and T3 (0.5 vs 0.47 ng/ml) were normal in both genotypes respectively ($P>0.05$). However, despite complete euthyroidism, *Dehal1*-KO mice showed a dramatic increase of overall gene expression at baseline, as compared to WT mice (mean 8.7-fold upregulation, 14 genes studied) including hormone-synthetic *Tshr* (8.7-fold), *Tg* (10.2), *Tpo* (5.8), *Duox2* (8.4), *Duoxa2* (4.5), *Slc16a2* (8.2) and transcriptional factors *Nkx2-1* (6.4), *Pax8* (28), *Foxe1* (7.5) and *Glis3* (11). Interestingly, basal and apical iodide transporters showed opposite modulation: *Slc5a5 (Nis)* was maximally overexpressed in KO mice (20-fold) while expression of apical *Slc26a4* and *Slc26a7,* exceptionally, remained unchanged.
Conclusion
A TSH-independent mechanism of transcriptional regulation is active in the thyroid glands of *Dehal1* knockout mice, which are fully euthyroid. This mechanism is not indiscriminate but gene-specific, since apical iodide transporters pendrin and Slc26a7 are preserved from regulation. Our data suggest that intrathyroidal, yet unspecified signals, may regulate specific gene expression to compensate for the deficient iodide recycling before hypothyroidism occurs.

DOI: 10.1530/endoabs.70.OC5.1

OC5.2

Overtreatment of papillary thyroid microcarcinoma: a snapshot from the italian thyroid cancer observatory

Valeria Ramundo
On behalf of ITCO, Italy

Background and Aim
The incidence of papillary thyroid microcarcinoma (mPTC) has dramatically increased in the last decades. The majority of these tumors remain small and clinically silent, only small number progress. Clinical practice guidelines currently suggest avoiding the cytological examination of subcentimeter nodules and reducing surgeries for mPTC. Several risk factors have been identified as strongly associated with a high-risk phenotype for mPTCs (e.g. gross nodal metastasis, extranodal extension). This study aims to evaluate the prevalence, the risk of recurrence and the management of mPTCs in different Italian thyroid clinical centers.
Methods
The Italian Thyroid Cancer Observatory (ITCO) was established in 2013 to collect prospective data on thyroid cancers consecutively diagnosed in member centers. We collected data of all histologically confirmed mPTCs present in the database at the end of December 2019. The risk stratification

was classified according to the 2015 ATA guidelines after surgery and it was re-classified after radioiodine treatment.
Results
A total of 7747 patients, enrolled by 48 centers were included in the initial cohort. Overall, 3172 cases were mPTCs (40.9%). No significant difference in the prevalence of mPTC was detected over time. The initial risk stratification (after surgery) included: 2115 (66.7%) low-risk PTCs, 989 (31.2%) intermediate-risk mPTCs and 68 (2.1%) high-risk mPTCs. 991 patients (31.2%) underwent radioiodine treatment. Among these, the initial (after surgery) risk stratification was as follows: 385 (38.8%) low-risk PTCs, 550 (55.5%) intermediate-risk mPTCs and 56 (5.7%) high-risk mPTCs. After radioiodine treatment, the risk stratification was re-classified as follows: 360 (36.3%) low-risk PTCs, 522 (52.7%) intermediate-risk mPTCs and 109 (11%) high-risk mPTCs.
Conclusions
Despite the efforts to reduce the number of surgeries for mPTCs, these interventions are still very common. The optimal management of low-risk microPTC represents a major clinical issue. Furthermore, in recent years, in spite of the updated guidelines and scientific literature data, no relevant differences were measured in real-world clinical practice in Italy. In this large and contemporary cohort of patients, radioiodine treatment allows us to re-classify risk stratification for about 5% of mPTC patients.

Acute pancreatitis associated with methimazole treatment: A retrospective analysis of administrative health databases conducted in the Piedmont Region, Italy

Marina Caputo[1], Alessandro Pecere[2], Andrea Sarro[2], Angelica Zibetti[2], Paolo Marzullo[1,3], Gianluca Aimaretti[1] & Francesco Barone-Adesi[2]
[1]Università del Piemonte Orientale, Endocrinology, Department of Translational Medicine, Novara, Italy; [2]Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]I.R.C.C.S. Istituto Auxologico Italiano, Ospedale San Giuseppe , Division of General Medicine, Verbania, Italy

Purpose
Methimazole (MMI) is a widely used antithyroid agent for first-line treatment of hyperthyroidism. A warning has been recently issued by the European Medicine Agency (EMA) regarding a potential increased risk of acute pancreatitis (AP) in MMI users, based on evidences from published case reports and post-marketing surveillance. The aim of this study was to investigate the association between MMI treatment and the diagnosis of AP in drug users.
Materials and methods
Retrospective analysis of administrative databases: inhabitants registry, hospital discharge records (HDRs) and the drug claims registry of the Piedmont Region, Italy. In the study period 2013–2018, MMI users were identified using the drug claims registry (ATC H03BB02) and cases of AP through HDRs (ICD-9-CM 577.0). General population (non-users) was used as comparative group. To investigate the association between MMI treatment and AP risk, we identified hospitalizations for AP occurring in each trimester comprised in the first 18 months following the first prescription of MMI. Poisson regression was used to estimate the age- and sex-adjusted ***Rate Ratios*** (adjRRs), and the relative 95% confidence intervals (CI), comparing rates of AP between MMI users and non-users. The absolute risk of AP in MMI users was also calculated.
Results
A total of 23,087 users of MMI were identified. Among these, 13 hospitalizations for AP were recorded within the first trimester of treatment, for a total of 61 hospitalizations occurring within the first 18 months. The crude RR for AP in the first trimester of treatment was 270 per 100,000 person-year [95% CI 170–428] in MMI users and 60 per 100,000 person-year [95% CI 59–61] in the general population. Values of adjRRs according to trimesters of observation were 3.40 [95% IC 2.12–5.48] for the first, 2.40 [95% IC 1.36–4.23] for the second, 2.80 [95% IC 1.66–4.73] for the third, 1.20 [95% IC 0.54–2.68] for the forth, 1.60 [95% IC 0.80–3.21] for the fifth and 0.80 [95% IC 0.30–2.14] for the sixth trimester. The absolute risk for AP in MMI users was less than 0.39%, considering both sex and different ages.
Conclusions
AP should be considered as a rare-uncommon adverse drug reaction in MMI-users; further studies are warranted to identify subgroups at higher risk.

Drug repurposing identifies inhibitors of the proteostasis network to augment radioiodine uptake in combinatorial approaches targeting thyroid cancer

Martin Read[1], Katie Brookes[1], Alice Fletcher[1], Caitlin Thornton[1], Mohammed Alshahrani[1], Rashida Khan[1], Hannah Nieto[1], Holly Adcock[2], Jamie Webster[3], Liam Cox[2], Luke Alderwick[4], Kristien Boelaert[5], Vicki Smith[1] & Christopher McCabe[1]
[1]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [2]University of Birmingham, School of Chemistry, Birmingham, United Kingdom; [3]University of Birmingham, Protein Expression Facility, College of Medical and Dental Sciences, Birmingham, United Kingdom; [4]University of Birmingham, Institute of Microbiology and Infection, School of Biosciences, Birmingham, United Kingdom; [5]University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom

New combinatorial drug strategies are urgently needed to improve radioiodine (RAI) uptake and efficiently ablate thyroid cancer cells, thereby reducing the risk of recurrent disease. Drug repurposing offers the promise of identifying already approved compounds capable of inducing sodium iodide symporter (NIS) function to enhance iodide uptake. However, a lack of thyroid cell-based assays amenable to high-throughput screening has limited progress. We utilised the mutated yellow fluorescent protein (YFP) as a surrogate biosensor of intracellular iodide and screened the Prestwick Chemical Library (1200 drugs; 95% approved) for quenching of YFP fluorescence. This allowed us to identify putative candidate drugs which increased iodide uptake >2 SD above mean. Categorisation of these revealed a high proportion of drugs that modulate the proteostasis network (19/48; ~40%), including key processes in protein homeostasis such as endoplasmic reticulum-associated protein degradation (ERAD) and autophagy. Secondary screening validated the activity of proteostasis modulators in enhancing iodide uptake after ranking 73 leading compounds based on their pharmacologic (AUC, E_{MAX} and EC_{50}) and specificity of response (NIS+ve vs NIS-ve YFP-thyroid cells) at ten different drug doses (0.1 to 50 μM). Of importance, several repurposed drugs (e.g. ebastine, Prestwick N, Prestwick C and clotrimazole) in combination with the HDAC inhibitor vorinostat induced a robust enhancement in RAI uptake in thyroid cancer cells (TPC-1 and 8505C NIS+ve cells, up to 11-fold vs DMSO, $P<0.001$), which was significantly greater than using vorinostat alone (up to threefold, $P<0.01$). For clotrimazole, we designed 7 new chemical derivatives, 3 of which showed enhanced aqueous solubility and retained the ability to significantly enhance RAI uptake. TaqMan RT-PCR revealed that, in contrast to vorinostat, our repurposed drugs failed to alter NIS mRNA expression, highlighting post-transcriptional mechanisms. Critically, 11 repurposed drugs induced significant gains in RAI uptake in human primary thyroid cells (up to 4.1-fold; $P<0.05$), the most physiological setting for NIS function. In conclusion, we performed high-throughput screening and identified proteostasis modulators, as well as other repurposed drugs, that markedly enhance radioiodine uptake. Further clinical investigation of these drugs might offer new combinatorial approaches, especially with existing therapies, to improve the treatment of thyroid cancer.

Thyroid dysfunction induced by immune checkpoint inhibitors is associated with a better progression-free-survival and overall survival in non-small cell lung cancer: an original cohort study

Philippe Thuillier[1], Claire Joly[1], Nathalie Roudaut[1], Geneviève Crouzeix[1], Renaud Descourt[2] & Véronique Kerlan[1]
[1]CHRU de Brest, Endocrinology, Brest, France; [2]CHRU de Brest, Oncology, Brest, France

Objective
Immune checkpoint inhibitors (ICI) are used for treatment of non-small cell lung cancer (NSCLC) and are associated with immune-related adverse events (irAEs), especially thyroid dysfunction. Few studies found an association between thyroid dysfunction and response to Nivolumab in the NSCLC The objective of this retrospective cohort study was to investigate the association between the occurrence of thyroid dysfunction in patients treated with Nivolumab for a NSCLC and treatment efficacy and to assess whether this association is function of severity and type of thyroid dysfunction.
Materials and methods
This study was performed at a referral oncology center between July 20, 2015 to June 30, 2018. Inclusion criteria were patients with histologically

confirmed stage IIIB/IV NSCLC and progressive disease who initiated anti-PD-1 blockade (Nivolumab). The exclusion criteria were: patients whose primary tumor was not from bronchopulmonary origin; patients with a history of thyroid disease; patients not having any thyroid monitoring before/ during Nivolumab treatment. Thyroid function (TSH ± fT4, fT3) was monitored and patients were classified according to thyroid dysfunction occurrence (TD(+) vs TD(−)) and according to severity (moderate thyroid dysfunction: TSH level between 0.1–0.4 or 4.0–10 mIU/l, and severe thyroid dysfunction: TSH ≤ 0.1 or ≥10 mUI/l) and subtypes (isolated hypothyroidism, isolated thyrotoxicosis or thyroiditis (thyrotoxicosis then hypothyroidism)). The primary clinical endpoints were the overall survival (OS) and progression-free survival (PFS). The secondary clinical endpoints were the objective response rate (ORR), the disease control rate (DCR) and the duration of response.
Results
Among 194 eligible patients, 134 patients (median age, 63 yo; 70.1% male) were included. Forty (29.9%) patients were classified in TD (+) and had a longer OS of 29.8 months (15.2-not reached) vs 8.1 months (3–20.4) in TD (−) group ($P<0.001$). PFS was also longer (8.7 months (2–27.1) in TD (+) vs 1.7 months (1.6–3.6) in TD (−) group ($P<0.001$). Treatment response was also higher in TD(+) group vs TD(−) group : ORR was of 47.5% vs 12.8% ($P<0.001$), PRR was of 20% vs 7.4% ($P=0.04$), DCR was of 70% vs 27.7% ($P<0.001$). In Cox proportional hazards analysis, thyroid dysfunction remained an independent prognostic factor associated with OS/PFS. Severity and subtypes of thyroid dysfunction were not correlated with survival outcomes.
Conclusions
This study found a high prevalence of thyroid dysfunction under Nivolumab, which appears to be an independant prognostic factor regardless of thyroid dysfunction severity and subtypes.

Patients with APECED have increased early mortality due to endocrine causes, malignancies and infections

Joonatan Borchers[1,2,3], Eero Pukkala[4,5], Outi Mäkitie[1,2,3,6] & Saila Laakso[1,2,3]
[1]University of Helsinki, Children's Hospital, Pediatric Research Center, Helsinki, Finland; [2]Folkhälsan Research Center, Helsinki, Finland; [3]University of Helsinki, Faculty of Medicine, Helsinki, Finland; [4]Tampere University, Faculty of Social Science, Tampere, Finland; [5]Finnish Cancer Registry, Institute for Statistical and Epidemiological Cancer Research, Helsinki, Finland; [6]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden

Context
Autoimmune polyendocrinopathy–candidiasis–ectodermal dystrophy (APECED) is an autoimmune endocrinopathy with severe and unpredictable course. Previous studies have reported increased mortality in patients with APECED. However, the impact of APECED on mortality has not been previously determined.
Objective
To systematically study overall and cause-specific mortality in patients with APECED. Design and Setting: A follow-up study of Finnish patients with APECED in 1971–2018. The clinical picture of the disease was studied from the patient records. Causes and dates of death were collected from Finnish registries using the Finnish personal identity codes as patient identifiers. Overall and cause-specific standardized mortality ratios (SMRs) were determined by comparing the observed numbers of death and those expected on the basis of respective population death rates in Finland.
Patients
Cohort of 91 Finnish patients with APECED. Main outcome measure SMR.
Results
Of all patients 29 (32%) had deceased during the follow-up period. The overall disease mortality was significantly increased [SMR 11; 95% confidence interval (CI) 7.2–16; $P<0.001$]. Altogether 21 patients (72%) had deceased before 45 years of age. The relative risk (SMR) was highest in the youngest age groups but the absolute excess risk was similar (about 10 per 10,000 person-years) in all age categories. The highest SMRs were seen for endocrine and metabolic diseases (SMR 570; 95% CI 270–1000; $P<0.001$) and for oral and esophageal malignancies (SMR 170; 95% CI 68–360; $P<0.001$). Mortality was also increased for infections, diseases of digestive system, alcohol-related deaths, and for accidents. No significant differences in SMR were found between subgroups of patients divided according to number of clinical manifestations or patients with or without hypoparathyroidism or adrenal insufficiency in the beginning of follow-up.
Conclusions
Patients with APECED have significantly increased mortality already at an early age and mortality is similarly increased in all age groups. Highest SMRs are found in causes that are directly related to APECED. In addition, our results suggest increased mortality due to previously unreported causes, such as infections. Increased alcohol- and accident-related deaths may be influenced by psychosocial factors.

Triiodothyronine (T3) use in hypothyroidism and effects on cancer and mortality

Tereza Planck[1,2], Fredric Hedberg[3,4], Jan Calissendorff[3,4,4] & Anton Nilsson[5]
[1]Skåne University Hospital, Department of Endocrinology, Malmö, Sweden; [2]Lund University, Department of Clinical Sciences Malmö, Malmö, Sweden; [3]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [4]Karolinska University Hospital, Department of Endocrinology, Metabolism and Diabetes, Stockholm, Sweden; [5]Lund University, EPI@LUND, Division of Occupational and Environmental Medicine, Lund, Sweden

Background
The prescription of triiodothyronine (T3) for hypothyroidism is increasing worldwide, however, long-term effects of its use are largely unknown. Previous studies have suggested possible association between T3 use and breast cancer. The aim of the study was to examine the effects of T3 use on cancer incidence and mortality.
Material
Our sample included the full adult population of individuals living in Sweden with at least three purchases of thyroid replacement hormones between July 2005 and December 2017. Individual-level data on drug purchases were linked to register data on cancer incidence and mortality. There were 575,461 individuals with at least three purchases of thyroid replacement hormones, of which 11,147 had at least three purchases of T3 including combinations of l-thyroxine (T4) and T3. Individuals were followed for 7.4 years on average.
Methods
We applied Cox-regression with a time-varying exposure variable, comparing "T3 users" (individuals with at least 3 cumulative purchases of T3) with "T4 users" (the rest). Outcomes included breast cancer incidence, any cancer incidence, all-cause mortality, any cancer mortality, and breast cancer mortality. We adjusted for age, gender, previous thyroid cancer, previous other cancer, use of antithyroid preparations, use of sex hormones, and dosage in multivariate analyses.
Results
Multivariate analyses comparing T3 and T4 users produced a hazard ratio of 1.03 (95% CI 0.83–1.29) for breast cancer incidence (only women), 0.96 (0.85–1.07) for any cancer incidence, 0.92 (0.81–1.05) for all-cause mortality, 0.85 (0.66–1.10) for any cancer mortality, and 1.23 (0.69–2.22) for breast cancer mortality (only women), none of which was significant. Analyses focusing only on new thyroid replacement users (after July 2006) and analyses stratified by sex yielded similar results, with insignificant estimates that were close to one.
Conclusion
In this large Swedish long-term register-based study, the use of T3 compared to T4 did not lead to increased breast cancer incidence, any cancer incidence, all-cause mortality, any cancer mortality, and breast cancer mortality. Other possible negative effects of T3 use were not analyzed in this study and cannot be excluded.

Effects of nonpeptide orally bioavailable ACTH antagonists on adrenal gland size and function in rats

Stacy Markison, Melissa Fowler, Jon Athanacio, Taylor Kredel, Agnes Antwan, Michael Johns, Oleg Tsivkovski, Shirley Cruz, Rosa Luo, Greg Reinhart, Ana Kusnetzow, Ajay Madan, Stephen Betz & R Scott Struthers
Crinetics Pharmaceuticals Inc, San Diego, United States

Cushing's disease (CD) and Ectopic ACTH syndrome (EAS) stem from excess circulating adrenocorticotropic hormone (ACTH) and resulting hypercortisolemia. In CD, excess ACTH is secreted from pituitary tumors, whereas excess ACTH in EAS arises from nonpituitary tumors. ACTH acts on the adrenal melanocortin type 2 (MC2) receptor to control the synthesis and secretion of adrenal hormones, including the stress hormone cortisol (corticosterone in rats) which accounts for the comorbidities of CD and EAS. Availability of a potent ACTH antagonist that can normalize cortisol in patients with diseases of excess ACTH will be a major advance in endocrinology. Additionally, an ACTH antagonist will have utility in congenital adrenal hyperplasia (CAH) because of its ability to block production of excess adrenal androgens. Crinetics is evaluating and developing ACTH antagonists for the treatment of diseases of excess ACTH. To our knowledge, these compounds represent the first potent nonpeptide ACTH antagonists to demonstrate *in vitro* potency and *in vivo* efficacy. As a result, the direct effects of sustained MC2 receptor blockade on the structure and function of the adrenal gland have never been able to be assessed. We examined the effects of several orally bioavailable ACTH antagonists across a range of doses on Sprague-Dawley rat adrenal gland weight, histology, and hormone levels in repeat dosing (7–14 days) studies. Sustained MC2 receptor antagonism dose dependently blocked activity of ACTH at the level of the adrenal gland and reduced plasma corticosterone levels. In the normal rat, this resulted in dose-dependent atrophy of the adrenal gland as assessed by organ weights and microscopically. The atrophy was primarily observed in the cortisol producing zona fasciculata, as well as in the zona reticularis, with smaller reductions noted in the aldosterone producing zona glomerulosa. Additionally, hypertrophy of the adrenal glands caused by continuous subcutaneous administration of exogenous ACTH was reversed by treatment with an ACTH antagonist. The adrenal effects were accompanied by expected changes in corticosterone levels. These preclinical findings demonstrate the therapeutic potential of ACTH antagonism and provide a strong rationale for development of an orally bioavailable drug that can be used to combat CD, EAS, and CAH.

Spiridon'' County Hospital, Endocrinology, IASI, Romania

Experimental autoimmune thyroiditis (EAT) has been used to simulate human autoimmune thyroid disease for decades. EAT can be easily induced in genetically susceptible strains of mice by excess iodine ingestion or by immunization with mouse thyroglobulin. Excess iodine may induce and exacerbate autoimmune thyroiditis (AIT) in humans and animal models. In order to assess the potential protective mechanisms of selenium (Se) in thyroid autoimmunity, we evaluated the effects of inorganic Se (sodium-selenite) administration on thyroid morphology and follicular cytology in adult Wistar rats with iodine-induced AIT. Forty-eight adult Wistar rats (24 females, 24 males) were allocated to one of four dietary regimens: C0: control; C1: only potassium-iodine (KI); C2: concomitant KI and Se; C3: only KI initially, followed by Se administration. For AIT induction, the rats were fed with 0.05% KI for 56 days. Se-treated rats received 0.3 mg/l sodium-selenite in drinking water. Thyroid tissue for pathologic diagnosis was collected after 7 days in C0, 56 days for C1 and C2, and 112 days in C3. In C1, moderate to severe thyroiditis was observed in 83% males and 50% of female rats ($P=0.223$). In C3 only, 16.7% of male rats developed mild thyroiditis and none in C2, while no females were identified with moderate to severe thyroiditis in both C2 and C3. The male rat thyroid morphology showed that the C1 group had higher mean values of thyroid follicles compared to C0, the control group (73.82 μm vs 50.13 μm, ×100), and to the C2 (73.82 μm vs 53.74 μm,×100). In female rats, the highest mean value of thyroid follicles was recorded in C1 group (57.56 μm,×100), and the lowest in C2 (47.32 μm, ×100). Thus, the administration of Se was proved to have protective effects against thyroiditis cytology in both male and female Wistar rats.

Introduction
The majority of adrenal neoplasms are benign while adrenocortical carcinomas (ACC) are rare with poor prognosis. Previous studies indicated that estrogens play important role in the etiology and progression of adrenocortical tumors. Estrogens exert genomic activities trough the estrogen-receptor (ER) subtypes α and β, while the non-genomic effects are mediated by membrane-bound-G-protein-coupled-ER-30 (GPR30). Although estrogens induce cancer cell proliferation through ERα, ERβ appears to exert a protective effect. In vitro experiments showed that treatment with ERα antagonist as well as GPR30 agonist reduces proliferation in H295R cells. However, data on the expression profile of ERs in normal and human adrenocortical neoplasms are limited. Epidermal growth factor receptor (EGFR) found to be highly expressed in ACC. The expression of EGFR has been negatively correlated with expression of ER in other cancers, while data regarding the correlation between ERs and EGFR expression in adrenocortical neoplasms are missing.
Aim
We aimed to investigate the expression profile of ERs and EGFR in adrenocortical neoplasms and correlate it with their biological behavior.
Material and methods
Total RNA was extracted from fresh frozen tissue of: eight non functional adenomas (NFA), eight cortisol producing adenomas (CPA), their adjacent normal adrenal tissues (NAC) AND eight adrenocortical carcinoma (ACC). The expression of ERα, ERβ, GPR30 and EGFR genes was evaluated by qPCR. The Immunohistochemistry (IHC) was performed to evaluate the EGFR and GPR30 protein levels.
Results
The expression of both ERα and GPR30 were higher in the CPA as compared to their adjacent normal tissue ($P<0.05$) while there was no significant difference in ERβ and EGFR mRNA levels between CPA, NFA and their adjacent normal tissues. The expression of GPR30 was significantly higher in ACC compared to either NFA or NAC groups ($P<0.05$), and marginally higher in ACC compared to CPA. The expression of ERα and EGFR was higher in ACC compared to either CPA or NFA ($P<0.1$). IHC confirmed the higher expression EGFR in ACC compared to the adrenal benign tumors. A marginal positive correlation between EGFR and GPR30 expression was observed in ACC.
Conclusion
To our knowledge this the first study to evaluate the expression of membrane-bound GPR30 in human adrenocortical neoplasms. Our preliminary data suggest a possible role of GPR30 and EGFR in adrenocortical malignancy, while ERα may play a role in functional adenomas. Further studies with larger number of samples are required to elucidate the role of ERs and EGFR on the adrenal tumorigenesis.

High-dose Vitamin D supplementation reduces inflammation and improves microcirculation in patients with diabetic peripheral neuropathy – a randomized control trial

Anna Stepanova[1], Tatiana Karonova[1,2], Anna Bystrova[1,2] & Edward Jude[3]
[1]Pavlov First Saint Petersburg State Medical University, Internal Medicine Department, Saint Petersburg, Russian Federation; [2]Almazov National Medical Research Centre, Institute of Endocrinology, Saint-Petersburg, Russian Federation; [3]Tameside and Glossop Integrated Care NHS Foundation Trust, Diabetes Centre, Manchester, United Kingdom

Background
In recent years, the role of vitamin D in improving the profile of inflammatory markers in order to prevent and treat diabetic neuropathy and microcirculation disorders has been actively studied.
Aims
The research goal was to study the dynamics of inflammatory markers, clinical manifestations of diabetic peripheral neuropathy and laser Doppler flowmetry of skin microcirculation during treatment with various doses of cholecalciferol in patients with type 2 diabetes and DPN.
Materials and methods
A single-center, open, randomized trial included patients with type 2 diabetes with DPN. Sixty-seven patients were randomized into 2 groups, where Group I took cholecalciferol in a dose of 5,000 IU/week for 24 weeks, and Group II took a dose of 40,000 IU/week. At the start and the end of the trial, the body mass index (BMI), glycated hemoglobin level (HbA1c), 25(OH)D, PTH, interleukins-1β, −6, −10 (IL), C-reactive protein (CRP), and tumor necrosis factor α (TNFα) levels were determined; the survey was conducted on the NSS, NDS and visual analog scales. Using laser Doppler flowmetry, one compared the initial and final indicators of the baseline blood flow and microcirculation (MC) against functional samples (postural and occlusal). Control measurements of LDF parameters were performed on 16 subjects without diabetes mellitus (eight men/eight women, 51.8±3.7 years).
Results
Sixty-two patients completed the study. Group I ($n=31$, W16) and Group II ($n=31$, W15) were initially comparable by age, gender, BMI, HbA1c level, NSS, NDS, and VAS. Initially, LDF indicators were significantly lower compared to the group without T2DM. Vitamin D deficiency was detected in 78% of patients with T2DM. After 24 weeks of taking cholecalciferol in Group II, there was a significant decrease in BMI, in the levels of HbA1c and IL-6, and an increase in the level of IL-10, as well as the improvement of cutaneous MC and functional test parameters, while in Group I these changes were not detected. A correlation was established between the final level 25(OH)D and IL-6 ($r=-0.378$, $P=0.036$), IL-10 ($r=0.483$, $P=0.006$), BMI ($r=-0.388$, $P=0.031$) and HbA1c ($r=-0.388$, $P=0.031$).
Conclusion
Receiving cholecalciferol in a dose of 40,000 IU/week over the course of 24 weeks is associated with a decrease in BMI, an improvement in glycemic control and the profile of pro-inflammatory markers, a decrease in the severity of diabetic peripheral neuropathy, and an improvement in the LDF parameters of cutaneous MC and functional tests in patients with type 2 diabetes and DPN

[1]Aarhus University Hospital, Aarhus, Denmark; [2]Bone Research & Education Center, Oakville, Canada; [3]Rigshospitalet, Copenhagen, Denmark; [4]University of Chicago, Chicago, United States; [5]Mayo Clinic, Rochester, United States; [6]Colombia University, New York, United States; [7]Universitätsklinikum Dresden, Dresden, Germany; [8]Oslo University Hospial, Institue of Clinical Medicine, Oslo, Norway; [9]Campus Bio-Medico University, Rome, Italy; [10]Alma Mater Studiorum University of Bologna, Balogna, Italy; [11]University of Pisa, Pisa, Italy; [12]Thomas Jefferson University, Philadelphia, United States; [13]Ascendis Pharma Inc., Palo Alto, United States

Background
Hypoparathyroidism (HP) is characterized by low serum calcium (sCa) and high serum phosphate (sP). Standard of care (SoC), active vitamin D and calcium, raises sCa and sP and increases burden of illness on HP patients by worsening hypercalciuria and the CaxP product. Parathyroid hormone (PTH)(1–84)($t_{1/2}$ ~2–3 hrs) is approved and can raise sCa and allow partial withdrawal of SoC, but does not sufficiently control urine calcium or symptomatic hypo- or hypercalcemia. [NATPARA Package Insert; Khurana M *et al*. 2019] TransCon PTH, an investigational prodrug of PTH(1–34) transiently bound to an inert carrier via a linker, is under development for the treatment of HP. Linker auto-cleavage occurs under physiologic conditions, releasing active PTH at a controlled rate with a $t_{1/2}$ ~60 hrs.
Methods
PaTH Forward is a phase 2, double-blind, placebo-controlled trial evaluating TransCon PTH in adult HP patients treated with SoC. Subjects received fixed-dose TransCon PTH 15, 18, or 21 μg/day or placebo for 4 weeks, followed by an open-label extension period during which subjects could titrate their individual TransCon PTH dose (6–30 μg/day). The primary composite endpoint at Week 4 required 1) normal sCa, 2) normal (or ≥50% decrease from baseline) fractional excretion of calcium (FECa), 3) not taking active vitamin D, and 4) taking ≤1000 mg/day of calcium.
Results
At Week 4, significantly more subjects (50%) on TransCon PTH achieved the primary endpoint vs (15%) subjects on placebo (Table). sP decreased from baseline by 20% in subjects on TransCon PTH vs 1% on placebo. Increase from baseline in subjects meeting FECa endpoint was 42% on TransCon PTH vs 0% on placebo. Free PTH showed stable levels in the lower half of the normal range at both 2 and 4 weeks. TransCon PTH was well-tolerated; no subjects discontinued treatment or withdrew from the trial during the 4-week period, and no SAEs or severe AEs were reported. No subjects on TransCon PTH showed symptomatic hypocalcemia vs 7% on placebo.
Conclusions
Results from the initial 4 weeks of the PaTH Forward Trial demonstrated the TransCon PTH met the primary endpoint without increased incidence of symptomatic hypocalcemia despite a fixed dose. This trial will help inform the starting dose and SoC titration schedule for the phase 3 trial.

Week 4

	TransCon PTH ($n=44$)	Placebo ($n=13$)	*P*-value
Off active vitamin D and ≤ 500 mg/day calcium	82%	15%	$P<0.0001$
Off active vitamin D and calcium	50%	0%	$P=0.0008$
Primary Endpoint	50%	15%	$P=0.0305$

Low serum 25-hydroxyvitamin D (25[OH]D) levels in patients hospitalised with COVID-19 are associated with greater disease severity

Su Tee[1], Grigorios Panagiotou[1], Yasir Ihsan[1], Waseem Athar[2], Gabriella Marchitelli[3], Donna Kelly[4], Christopher S Boot[5], Nadia Stock[3], James Macfarlane[2], Adrian Martineau[6], Graham Burns[2] & Richard Quinton[1,7]
[1]Newcastle upon Tyne NHS Foundation Trust, Department of Endocrinology, Newcastle upon Tyne, United Kingdom; [2]Newcastle upon Tyne NHS Foundation Trust, Department of Respiratory Medicine, Newcastle upon Tyne, United Kingdom; [3]Newcastle upon Tyne NHS Foundation Trust, Department of Acute Medicine, Newcastle upon Tyne, United Kingdom; [4]Newcastle upon Tyne NHS Foundation Trust, Department of Anaesthetics & Critical Care, Newcastle upon Tyne, United Kingdom; [5]Newcastle upon Tyne NHS Foundation Trust , Department of Blood Sciences, United Kingdom; [6]Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom; [7]University of Newcastle upon Tyne, Translational & Clinical Research Institute, United Kingdom

Background
The pandemic of Coronavirus Disease 2019 (COVID-19) caused by Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2) is associated with higher fatality in respect of male sex, advancing age, obesity, diabetes, hypertension, climatic factors and, in the UK and North America, with darker-skinned ethnicities; in all of which circumstances vitamin D deficiency (VDD) is more common. 25(OH)D levels reach their nadir at the end of winter and have been associated with increased risk of acute respiratory tract infections, which is mitigated by vitamin D supplementation. As seasonal VDD is highly prevalent in North-East England, physicians in Newcastle-upon-Tyne Hospitals (NuTH), a large tertiary NHS centre, decided to measure admission serum 25(OH)D levels in patients with COVID-19, to inform a treatment protocol adjusted according to the severity of baseline deficiency.
Objectives
To evaluate implementation of a local protocol for treatment of VDD among inpatients with COVID-19; to assess the prevalence of VDD, and examine potential associations with disease severity and fatality.
Methods
We performed a retrospective interim audit of a local care pathway for hospitalized patients with COVID-19-related illness. 134 patients with documented COVID-19 infection were included. We determined the prevalence of VDD, implementation of the local treatment protocol and relationship of baseline serum 25(OH)D with markers of COVID-19 severity and inpatient fatality vs recovery.
Results
55.8% of eligible patients received Colecalciferol replacement, albeit not always loaded as rapidly as our protocol suggested. No cases of new hypercalcaemia occurred following treatment. Patients admitted to ITU were younger than those managed on medical wards (61.1 years ± 11.8 vs 76.4 years ± 14.9, $P < 0.001$), with greater prevalence of hypertension, higher baseline respiratory rate, National Early Warning Score-2 and C-reactive protein level. While mean serum 25(OH)D levels were comparable [ITU: 33.3 nmol/l, 95% Confidence Interval (CI) 28.0–38.5 nmol/l vs Non-ITU: 48.2 nmol/l, 95% CI 40.3–56.0 nmol/l, $P = 0.2$) only 19% of ITU patients had 25(OH)D levels greater than 50 nmol/l vs 39.1% of non-ITU patients ($P = 0.02$). However, there was no association with fatality, potentially due to small sample size and prompt diagnosis and treatment of VDD.
Conclusions
Patients requiring ITU admission were more frequently vitamin D deficient than patients on medical wards, despite being significantly younger. These data suggest an important association between VDD and COVID-19 severity. Larger prospective studies and/or clinical trials are urgently needed to elucidate the role of vitamin D as a preventive and/or therapeutic strategy for mitigating the effects of COVID-19 infection.

Hypocalcemia is highly prevalent and predicts hospitalization in patients with COVID-19

Luigi Di Filippo[1], Anna Maria Formenti[2], Patrizia Rovere-Querini[2], Carlucci Michele[2], Caterina Conte[2], Fabio Ciceri[2], Alberto Zangrillo[2], Mauro Doga[2] & Andrea Giustina[3]
[1]Università Vita-Salute San Raffaele, Italy; [2]San Raffaele Scientific Institute, Italy; [3]Univesrity of Brescia, Italy

Coronavirus disease 2019 (COVID-19), may lead to a severe acute respiratory syndrome requiring hospitalization and assisted ventilation with high lethality. Replication of SARS-CoV, MERS-CoV and Ebolavirus is calcium-dependent and hypocalcemia has been frequently reported in all these infections. Despite already many studies reporting on clinical and laboratory presentation of COVID-19 patients, including inflammatory and organ injury biomarkers, only one case report has so far described hypocalcemia in COVID-19. The aim of our study was to investigate the incidence of hypocalcemia in a large single center population of COVID-19 patients and evaluate its clinical implications. We retrospectively included 531 COVID-19 patients (aged ≥ 18 years) with serum ionized calcium (Ca^{2+}) evaluation from arterial blood gas test (ABG) performed at initial evaluation in our Emergency Departments (ED). We collected two different Ca^{2+} levels, a real level (“actual calcium (AC)”) and a corrected for a pH 7.4 (“standardized calcium (SC)”). Hypocalcemia was defined as a calcium levels below 1.18 mmol/l. We excluded patients with comorbidities and concomitant therapies influencing calcium metabolism. Hypocalcemia was found in 462 patients (82%) with AC levels and in 414 (78.6%) patients with SC levels. Severe hypocalcemia (below 0.99 mmol/l) was found in 18 (AC, 3.4%) and 10 (SC, 1.9%) patients. Hypocalcemic patients were more frequently males (AC, 69% vs 57% $P = 0.06$; SC, 70% vs 60% $P = 0.046$) and older (AC, 59 yr [51–69] vs 53 [45-67] $P = 0.01$). LDH and PCR levels were very significantly higher in hypocalcemic vs normocalcemic patients (AC, LDH: 372 U/l [287–466] vs 271.5 [202.25–347.5] $P < 0.001$; PCR: 71.55 mg/dl [31.22–132.4] vs 24 [4.65–77.65] $P < 0.001$; SC, LDH 70.25 mg/dl [30.87–130.35] vs 38 [11.2–105.9] $P < 0.001$; PCR 377 U/l [289–467] vs 307 [236–399] $P < 0.001$). In univariate and multivariate analyses hypocalcemia was an independent risk factor associated with hospitalization. Fifty-eight patients died (11.5%) and 62 (11.7%) were admitted in ICU. Hypocalcemia at admission was significantly associated to these two outcomes only in univariate but not in multivariate analyses. To our knowledge this is the first study that reports very high incidence of hypocalcemia in a large monocentric population of COVID-19 patients at initial hospital evaluation. Since hypocalcemia is highly incident in COVID-19 patients, predicts the need for hospitalization and may be life threatening if severe potentially worsening the COVID-19 morbidity at the cardiovascular level we suggest that ionized calcium should always be assessed at initial hospital evaluation, monitored and eventually adequately treated in all COVID-19 patients.

Introduction
Carney Complex (CNC) is a rare genetic syndrome, with multiple endocrine and non-endocrine neoplasia, mostly due to inactivating mutations of the *PRKAR1A* gene. CNC has a wide spectrum of manifestations : most frequently skin lesions, cardiac myxomas and primary pigmented nodular adrenocortical dysplasia (PPNAD), but also thyroid nodules, schwannomas, breast tumors (mainly myxoid fibroadenomas and ductal adenomas)… The present study was designed to describe the characteristics of breast lesions diagnosed in CNC patients and their association with other manifestations of CNC and *PRKAR1A* genotype. Since breast cancer is the most frequent cancer in women and the leading cause of death from cancer worldwide, malignant breast lesions were carefully analysed.
Methods
This cohort comes from a 3 years follow-up multicenter French prospective study of 70 CNC patients (Espiard, *et al*., JCEM 2020). The 50 included women here were analyzed for CNC manifestations and particularly breast lesions, with systematic mammography, genotype and hormonal settings, in order to characterize breast lesions, look for association with other CNC manifestations and assess the frequency and average age of breast cancer in this population.

Results
Among the 38 women with breast imaging, 14 (28%) had breast lesions, half of them bilateral. Ten women (20%) presented with benign lesions: fibroadenomas (70%), bilateral polyfibromatosis (30%), diffuse myxomatosis (20%)… Six women had breast carcinomas (12%) : five had invasive cancer before 50 years old (10%) and one had ductal carcinoma *in situ* at 54 years old. One patient presented with recurrent contralateral breast cancer. The average age of breast cancer was 44.7 years old, 17 years younger than in the general population, and relative risk of breast cancer in women less than 50 years old was threefold higher in CNC patients compared to general population. Breast cancer had good prognosis factors: all lesions were N0M0, hormonal receptor positive, HER negative, except for one at metastatic stage at diagnosis. All the participants were alive at the end of the study, the observation period ranging from 7 to 14 years. All Breast carcinomas occurred in *PRKAR1A* mutated patients. The occurrence of carcinomas was associated neither with conventional risk factors for breast cancer, nor with any other CNC manifestations.
Conclusion
Breast lesions are frequent in women with CNC and breast carcinoma might be considered a "new" manifestation of this disease. As CNC could predispose to breast carcinoma, an adequate screening strategy and follow up should be discussed in affected women.

Introduction
Angiogenesis is regulated by different components of the tumour microenvironment (TME) including cytokines and immune cells. Although angiogenesis has been studied in pituitary adenomas (PAs), the role of individual TME components in PA angiogenesis remains largely unknown. We aimed to characterise the role of the TME components in determining the angiogenesis of PAs, focusing on PA-infiltrating immune cells and the PA-derived cytokine network.
Methods
Different immune cells were studied by immunohistochemistry in 24 human PAs (16 non-functioning PAs (NFPAs) and 8 somatotrophinomas): macrophages (CD68), M2-macrophages (CD163), M1-macrophages (HLA-DR), cytotoxic T lymphocytes (CD8), T helper lymphocytes (CD4), T regulatory cells (FOXP3), B cells (CD20) and neutrophils (neutrophil elastase); endothelial cells were assessed with CD31. Five normal pituitary samples (NP) were included for comparison. Microvessel density and vascular morphological parameters were estimated with *ImageJ* software. Cytokine secretome from these same 24 human PAs were assessed on primary cell culture supernatants using a multiplex immunoassay panel with 42 cytokines.
Results
PAs contained 4× more CD68+macrophages than NP, with a 3-fold increased M2:M1 macrophage ratio, as well as more CD4+T cells but fewer CD8+T cells or neutrophils. Microvessel density and microvessel area were higher in NP than PAs, which also had more round and regular vessels. NFPAs had vessels of increased caliber (higher perimeter and Feret's diameter), occupying an increased area comparing to somatotrophinomas. PAs with more macrophages tended to have higher microvessel density and area, as well as a higher perimeter and Feret's diameter. The M2:M1 macrophage ratio correlated with microvessel density ($P=0.015$) and microvessel area ($P<0.001$) in PAs. PAs with more CD4+T cells had higher microvessel area ($P=0.035$), while PAs with more FOXP3+cells were associated with lower microvessel density ($P=0.021$). PAs with more B cells had more rounded vessels ($P=0.021$). Of the studied PA-derived cytokines and growth factors, only FGF-2 and CXCL10 were significantly associated with microvessel architecture, namely vessel perimeter ($r=-0.407$; $P=0.048$) and area occupied per vessel ($r=0.407$; $P=0.049$), respectively.
Conclusions
Our data suggest that different TME components may influence the angiogenesis of PAs: M2-macrophages appears to play a relevant role in PA angiogenesis, and B, CD4+and FOXP3+lymphocytes may also have a modulatory role in the PA neovascularisation.

Adrenocortical carcinoma (ACC) is a rare endocrine malignancy with an unfavorable prognosis. Despite the poor prognosis in the majority of patients, no improvements in treatment strategies have been achieved. Therefore, the discovery of new prognostic biomarkers is of enormous interest. Sterol-O-acyl transferase 1 (SOAT1) is involved in cholesterol esterification and lipid droplet formation. Recently, it was demonstrated that SOAT1 inhibition leads to impaired steroidogenesis and cell viability in ACC. To date, no studies have addressed the impact of *SOAT1* expression on ACC prognosis and clinical outcomes. We evaluated *SOAT1* expression by quantitative real-time PCR and immunohistochemistry in a tissue microarray of 112 ACCs (Weiss score ≥ 3) from adults treated in a single tertiary center in Brazil. Two independent pathologists evaluated the immunohistochemistry results through a semiquantitative approach (0–4). We aimed to evaluate the correlation between *SOAT1* expression and clinical, biochemical and anatomopathological parameters, recurrence-free survival (RFS), progression-free survival (PFS) and overall survival (OS). SOAT1 protein expression was heterogeneous in this cohort; 37.5% of the ACCs demonstrated strong SOAT1 protein expression (score $ 2), while 62.5% demonstrated weak or absent protein expression (score < 2). Strong SOAT1 protein expression correlated with features of high aggressiveness in ACC, such as excessive tumor cortisol secretion ($P=0.01$), an advanced disease stage [ENSAT 3 and 4 ($P=0.011$)] and a high Ki67 index ($P=0.002$). In multivariate analysis, strong SOAT1 protein expression was an independent predictor of a reduced OS (HR 2.15, CI 95% 1.26 – 3.66; $P=0.005$) in all patients ($n=112$), and a reduced RFS (HR 2.1, CI 95% 1.09 – 4.06; $P=0.027$) in patients with localized disease at diagnosis ($n=83$). Our findings demonstrated that SOAT1 protein expression has prognostic value in ACC and reinforced the importance of investigating SOAT1 as a possible therapeutic target for patients with ACC.

Increased E2F1 mRNA and miR-17-5p expression may predict aggressiveness of pituitary neuroendocrine tumours

Araceli García-Martínez[1], Sebastián Martínez-López[1], Beatriz López-Muñoz[2], Rosa Cámara[3], Carmen Fajardo[4], Cristina Lamas[5], Sandra Silva-Ortega[6], Ignacio Aranda[6] & Antonio Picó[2]
[1]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Research Laboratory, Alicante, Spain; [2]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Endocrinology Department, Alicante, Spain; [3]La Fe University and Polytechnic Hospital, Endocrinology Department, Valencia, Spain; [4]La Ribera Hospital, Endocrinology Departmen, Alzira, Spain; [5]Albacete University Hospital Complex, Endocrinology Department, Albacete, Spain; [6]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Pathology Department, Alicante, Spain

Introduction
E2F1 regulates the expression of genes required for cell cycle progression and apoptosis. miR-17-5p regulates expression of *E2F1*. Both miR-17-5p and *E2F1* have been described deregulated in cancer but they have been scarcely studied in human pituitary neuroendocrine tumours (PitNETs).
The aim of the present study was to find biomarkers of aggressiveness in PitNETs and report the correlation between *E2F1* and miR-17-5p in the regulation of the pituitary tumorigenesis.
Methods
In this cross-sectional descriptive study, we evaluated the expression of *E2F1*, c-myc and two microRNAs of miR-17~92 cluster (miR-20a and miR-17-5p) by qRT-PCR in 60 human PitNET samples: 29 gonadotrophs (GT), 15 functioning somatotrophs (fST), 8 functioning corticotrophs (fCT) and 8 silent corticotrophs (sCT). Clinical, radiological and pathological data were recovered to determine the pre-operative behavior of the tumour. We defined invasiveness if the tumour invaded one of the cavernous or sphenoid sinus. We defined aggressiveness depending on the invasiveness of the tumours and the Ki-67 expression.
Results
E2F1 and c-myc demonstrated different expression in PitNETs depending on subtypes ($P=0.000$ and 0.004 respectively). Specifically, GT and sCT showed overexpression of E2F1 compared to the functioning variants (fST and fCT). In the whole series, *E2F1* was more expressed in invasive than in non-invasive tumours ($P=0.004$). Moreover, *E2F1* ($P=0.001$) and miR-17-5p ($P=0.011$), were overexpressed in tumours with high grade of aggressiveness in the whole series.
Conclusions
We confirm the deregulation of *E2F1* and c-myc in the pathogeneis of PitNETs, with different behavior depending on their subtypes. Moreover, *E2F1* and miR-17-5p could be good markers of PitNET aggressiveness.

Background
Mitotane is the only approved treatment for advanced adrenocortical carcinoma and was shown to inhibit Sterol-O-Acyl transferase 1 (SOAT1) which leads to the depletion of cholesterol esters and increase of free cholesterol in the ACC cell line H295R. Downstream activation of the endoplasmic reticulum stress (ER-stress) pathway results in decreased adrenocortical cell viability.
Aim
To better characterize the effects of SOAT1 inhibition in ACC, four human cell lines (H295R, MUC-1, CU-ACC1 and CU-ACC2) were treated with the SOAT1 inhibitors SOATi) mitotane, nevasimibe, AZD 3988 and Sandoz 58-035.
Methods
SOAT1 inhibition was quantified *in vitro*, ER-stress marker expression by qPCR and WB, cell viability by cell titer glo-assay, SOAT1 knockdown (KD) by siRNA and steroid hormone synthesis by LC-MS/MS.
Results
Mitotane, nevasimibe, AZD 3988 and Sandoz 58-035 inhibited SOAT1 in NCI-H295R cells with IC_{50} of 1.3 µM, 3.1 nM, 0.9 nM and 13 nM, respectively. Expression of ER-stress markers was activated by mitotane, nevasimibe, only poorly by AZD 3988 and not at all by Sandoz 58-035. Sandoz58-035 did not impair viability of any ACC cell line. H295R cells were most responsive to SOAT1 inhibition, while MUC-1 cells were least responsive, with EC_{50}>100µM for all inhibitors. Only mitotane efficiently blocked cortisol secretion in the two highly cortisol-secreting cell lines H295R and CU-ACC1. KD of SOAT1 in NCI-H295R cells did not affect the response to mitotane treatment.
Conclusion
Although SOAT1 inhibition was confirmed for all compounds, downstream effects on ER-stress markers and cell viability exhibit marked differences. SOAT1 expression does not affect mitotane responsiveness in H295R cells, suggesting targets different from SOAT1 are relevant for *in vitro* cytotoxicy. Their identification may lead to novel ACC treatments.

Llaser ablation vs radiofrequency ablation for benign non-functioning thyroid nodules: six-month results of a randomised, parallel, open-label, trial (LARA trial)

Roberto Cesareo[1], Claudio Maurizio Pacella[2], Valerio Pasqualini[3], Giuseppe Campagna[4], Angelo Lauria Pantano[5], Paolo Pozzilli[6], Roberto Cianni[7], Silvia Manfrini[6], Anna Crescenzi[8] & Andrea Palermo[9]
[1]"SM Goretti" Hospital, Unit of metabolic diseases, Latina , Italy; [2]Regina Apostolorum Hospital, Department of Diagnostic Imaging and Interventional Radiology, Italy; [3]Department of Radiology, "SM Goretti" Hospital, Latina, Italy; [4] "SM Goretti" Hospital, Department of Internal Medicine, Latina, Italy; [5]University Hospital Campus Bio-Medico, Rome, Italy, Department of Internal Medicine; [6]Campus Bio-Medico University, Unit of Endocrinology and Diabetes, Rome, Italy; [7]S Camillo Hospital, Department of Interventional Radiology, Rome, Italy; [8]University Hospital Campus Bio-Medico, Pathology Unit, Rome, Italy; [9]Campus Bio-Medico University, Unit of Endocrinology and Diabetes , Rome, Italy

Background
No direct prospective studies comparing laser ablation (LA) and radiofrequency ablation (RFA) for debulking benign non-functioning thyroid nodules (BNTNs) exist. We aimed to compare the efficacy and safety of both techniques in patients with solid or predominantly solid BNTN.
Methods
This six-month, single-use, randomized open label parallel trial compared the following primary endpoints between the RFA and LA groups six months after treatment: (1) nodule volume reduction expressed as a percentage of nodule volume at baseline; (2) proportion of nodules with more than 50 % reduction (successful rate). We enrolled subjects with a solitary BNTN or dominant nodule characterized by pressure symptoms/cosmetic problems or patients without symptoms who experienced a volume increase >20% in one year. Nodules underwent core needle biopsy (CNB) for diagnosis. Patients were randomly assigned (1:1) to receive LA or RFA. Safety was assessed in all randomly assigned participants.
Results
Sixty patients were randomly assigned to receive either RFA or LA (1:1) between January 2016 and November 2018. Both groups were similar in basal nodule volume, thyroid function, histology, symptoms/cosmetic score, and procedure time. At six months, the nodule volume reduction was 64.3% (95% confidence interval 57.5 – 71.2%) in the RFA group and 53.2% (47.2 – 95.2%; $P=0.02$) in the LA group. This effect was also confirmed in the linear regression model adjusted for age, baseline volume, and proportion of cellular component (LA vs RFA percent change Delta=−12.8, $P=0.02$). No significant difference was observed in success rate 6-month after treatment (RFA vs LA: 86.7% vs 66.7%, $P=0.13$) or in thyrotropin level between the groups. Although improved, no significant

difference was observed between RFA and LA for compressive symptoms (RFA: 2.13 vs 3.9, $P<0.001$; LA: 2.4 vs 3.87, $P<0.001$) and cosmetic score (RFA: 1.65 vs 2.2, $P<0.001$; LA: 1.85 vs 2.2, $P<0.001$). The adverse event rates (local pain, dysphonia, thyrotoxicosis, fever, hematoma) were 37% ($n=11$) and 43% ($n=13$) for RFA and LA, respectively, with no requirement for hospitalization.
Conclusion
While the success rate was similar in the RFA and LA groups, RFA achieved a significantly larger nodule volume reduction at six months.

A rare case of lynch syndrome in a patient with metastatic malignant paraganglioma with SDHA mutation

Jessica Ares Blanco, Pedro Pujante, Raul Rodriguez, Soraya Lanes, Elías Delgado & Edelmiro Menéndez-Torre
Hospital Universitario Central de Asturias, Endocrinology and Nutrition, Oviedo, Spain

Paragangliomas (PGLs) and pheochromocytomas (PCCs) are rare tumors that arise from the neuroendocrine tissue along the paravertebral axis with the ability to secrete cathecolamines. Up to 33% of these tumors may be hereditary either alone or as a component of a multiple tumor syndrome. Germline *SDHA* mutations are relatively frequent (7.6%) in patients with genetically unexplained PGL, even in the absence of familial or clinical indications for inherited PGL. Most of *SDHA* mutation carriers presented with an apparently sporadic head and neck PGL and extra-adrenal PGL. Lynch Syndrome (LS) is one of the most common cancer susceptibility syndromes. Individuals with Lynch syndrome have a 50%–70% lifetime risk of colorectal cancer, 40%–60% risk of endometrial cancer, and increased risk of several other malignancies. It is caused by germline mutations in the DNA mismatch repair genes MLH1, MSH2, MSH6 or PMS2. We present the case of a woman who underwent surgery in 2008 for retroperitoneal paraganglioma removal. No previous medical history was reported. Ten years later, she presented with mechanical-back pain and headaches. Initial imaging included MRI of the abdomen and lumbar spine and showed bone metastasis in T10-T11-T12. Laboratory investigations included 24-h fractionated urinary catecholamines and metanephrines supporting a functional tumor (plasma normetanephrine 425 mg/24 h and urine normetanephrine 976 mg/24 h). She was treated initially with phenoxibenzamine 20 mg daily in 2 doses and stereotactic body radiation therapy (SBRT), completing a course of 57 Gy in 8 fractions. Genetic testing was also performed. It revealed the expression of 2 mutations in heterozygosis, in both genes SDHA (v481fs* R31) and PMS2. The patient had not suffered from any disease associated with Lynch syndrome until now. It is not common to find these 2 mutations in the same person; in fact, there is not any case described before in the literature. This case report enhances the importance of clinical follow-up in pheochromocytomas and paragangliomas and encourages us to perform genetic testing to prevent the development of malignancies in people who carries oncogenic mutations.

The mosaic effects of endocrine disrupting chemicals mixtures on thyroid hormone levels: experimental study

Aleksandra Buha, Vesna Milovanovic, Zorica Bulat & Biljana Antonijevic
Faculty of Pharmacy, University of Belgrade, Department of Toxicology, Belgrade, Serbia

The lifelong exposure to mixtures of endocrine disrupting chemicals raises serious concerns about their deleterious effects on human health. Polychlorinated biphenyls (PCBs) had widespread use in numerous industrial applications, and were massively produced for several decades. After the discovery of the adverse effects of PCBs in the 1970s, brominated flame retardants (BFRs) were established as the major chemical flame retardant. Both chemicals persist in the environment and biomagnify in the food chain, hence their cocktail effect on thyroid gland can be assumed.
This experimental study was aimed to assess effects of repeated relatively low doses (corresponding low to high environmental human exposures) of these persistent organic pollutants on thyroid homeostasis in adult animals. Rats were randomized into control and treatment groups. Animals were treated by oral gavage for 28 days with either PCBs solution in corn oil or polybrominated diphenyl ether (BDE-209) suspension in dimethyl sulfoxide, or their combination. Animal groups were receiving BDE-209 suspension or commercial mixture of Aroclor 1254 at five different dose levels for each chemical. Nine groups were receiving different combinations of BDE-209 and PCBs. Treatment of all animals was performed by oral gavage, each day, during 28 days. Thyroid hormones were investigated in serum samples obtained from blood samples collected at necropsy.
Applied doses of PCBs induced dose dependent decrease in T4, while BDE 209 caused increase in T4 and decrease in T3 levels, compared to respective controls. However, no interaction at tested dose levels of PCBs and BDE-209 were observed implying that PCBs and BDE-209 as chemicals which act by similar modes at the level of thyroid homeostasis, exert additive effects in mixture.
The study implicates that exposure to low, environmental doses of these chemicals interferes with thyroid function and raises an issue of their additive thyroid toxicity in mixtures.

Introduction
The metabolic risk associated with air pollution could vary according to the specific pollution levels of each area, as well as factors related to lifestyle (diet, activity physical, socioeconomic status, tobacco), other exposures, comorbidities etc.. and has been insufficiently evaluated in our country.
Objective
To study the association between long term exposure to air pollution (measured as PM concentrations) and the incidence of hypertension in a disease free sample representative of the adult population of Spain (di@bet.es).
Methods
The study population was composed of 1103 individuals, participants in the nation-wide population based cohort study di@bet.es, free of hypertension at baseline (2008–2010) who completed the follow up exam of the cohort (2016–2017) with complete clinical information and blood pressure measurements available for analyses. Mean follow up time was 7.4 ± 0.6 years.
Exposure Assessment
Cohort participants were assigned air pollution exposures for particulate matter $<10\,\mu m$ (PM10) and $<2.5\,\mu m$ (PM25) during follow-up (2008–2016) obtained through modeling combined with measurements at air quality stations (CIEMAT).
Diagnose of Hypertension
Hypertension was considered if there was a previous clinical diagnose of hypertension and/or systolic blood pressure was ≥140 mmHg and/or diastolic blood pressure was ≥90 mmHg.
Results
In the table we present crude and multivariate adjusted Odd Ratios for developing Hypertension during follow up according to PM10 and PM2.5 cuartiles.

	PM 10 (μg/l)				
	12.21–16.95	16.96–20.00	20.01–22.79	22.80–30.18	*P* for trend
Number at risk	278	280	279	266	
Number developing HT	63	61	74	84	
OR crude (95% CI)	1 (reference)	0.95 (0.64–1.42)	1.23 (0.84–1.81)	1.58 (1.08–2.31)	0.008
OR multivariate (95% CI)	1 (reference)	1.08 (0.70–1.67)	1.36 (0.88–2.12)	1.86 (1.19–2.91)	0.005
	PM 2.5 (μg/l)				
	7.25–9.31	9.32–10.77	10.78–11.79	11.80–16.49	
Number at risk	280	275	279	269	
Number developing HT	68	60	68	86	
OR crude (95% CI)	1 (reference)	0.87 (0.59–1.29)	1.00 (0.68–1.48)	1.47 (1.01–2.13)	0.032
OR multivariate (95% CI)	1 (reference)	0.96 (0.63–1.49)	1.00 (0.64–1.56)	1.67 (1.07–2.59)	0.029

Multivariate ORs were calculated by logistic regression adjusted for age, gender, ethnicity, education level, MedScore, SF-IPAQ BMI and municipality population.

Conclusions

Our study shows an association between PM concentrations and the incidence of Hypertension in Spain even with pollution levels below the air quality levels currently established. These data reinforce the need for measures to improve air quality in our country.

Comparative histopathology of endocrine glands in phthalate exposed male Wistar rats unveil the vulnerability of adrenal gland and augmented by molecular docking

Shahzad Ahmad, Sheikh Raisuddin
Jamia Hamdard, Department of Medical Elementology & Toxicology, New Delhi, India

Limited research has been conducted on adrenal gland as target of endocrine disrupting chemicals (EDCs). Moreover, studies on steroidogenesis as the target of EDCs has also attracted lesser attention compared to other metabolic pathways. We studied the effects of two extensively used phthalate esters viz., di-ethyl hexyl phthalate (DEHP) and di-butyl phthalate (DBP) on the adrenal gland in Wistar rats and checked its susceptibility against the exposure of these extensively used phthalates categorized as EDCs. Male rats were divided into seven groups ($n=6$). Group I (control) received only corn oil (as vehicle). Group II, III and IV were treated daily with DEHP at the dose of 250, 750 and 1500 mg/kg-BW respectively *per os* for 14 days. Group V, VI and VII were treated with daily dose of DBP 100, 500 and 1000 mg/kg-BW respectively *per os* for 14 days. The comparative histological observation of endocrine glands i.e., pituitary, pineal, thyroid, parathyroid, adrenal gland and testes unveil that changes in adrenal gland towards the DEHP and DBP were more remarkable compared to other endocrine glands. Glucocorticoid biosynthesis pathway in adrenal gland was analyzed by molecular docking of DEHP and DBP with the enzyme proteins involved in the pathway using Maestro Schrodinger 9.4 software. It showed the potential of DEHP and DBP to inhibit these proteins comparable to the known inhibitors of enzymes involved. The present study used a novel approach of *in silico* and *in vivo* to elucidate the sensitivity of adrenal gland towards EDCs through the analysis of the sensitivity of adrenal steroidogenesis on exposure to two widely distributed phthalates with environmental and human health risk potential.

Keywords: glucocorticoid biosynthesis pathway, endocrine glands, phthalate esters, molecular docking.

Cigarette smoking and the risk to develop symptoms of Hashimoto's thyroiditis

Agata Jabrocka-Hybel, Anna Skalniak & Alicja Hubalewska-Dydejczyk
Uniwersytet Jagielloński Collegium Medicum, Kraków, Poland

Introduction

Hashimoto's thyroiditis (HT) is a complex disease which is caused by genetic as well as environmental factors. While the genetic predisposition to HT has been extensively investigated, the influence of most environmental factors still needs to be evaluated. Based on our previous study, we did not find any correlation between HT and the fact of cigarette smoking or the number of pack-years. We did, however, find a significant correlation between the age of smoking discontinuation and the age of HT onset. However, in this previous study, the number of patients for which we have obtained data on smoking discontinuation, was very sparse; therefore, no unequivocal conclusions could have been made.

Aim

The aim of our study was to verify the correlation between the age of smoking discontinuation and HT diagnosis.

Methods

In our first study, we included 35 HT patients who have declared to have stopped smoking in the past. The verification study included 48 patients. Stepwise regression analysis was used to predict the dependence of the age of HT diagnosis with gender, age of smoking discontinuation, TSH at diagnosis, and anti-TPO at diagnosis.

Results

In patients who had discontinued smoking at the age of 39 years or more, the diagnosis of HT was predominantly made after the discontinuation of smoking. No such regularity was observed for patients who had stopped smoking before the age of 39 years. In their case, the diagnosis of HT was made similarly often before and after the discontinuation of smoking. The patients' gender and biochemical parameters at diagnosis were not significantly correlated with the age of HT onset.

Conclusions

We concluded that neither smoking nor its discontinuation has a significant impact on the onset of HT symptoms in patients aged less than 39 years before smoking discontinuation. However, in the vast majority of our HT patients who had stopped smoking at a later timepoint, it seemed as if stopping smoking was a trigger of HT symptoms that would be indicative of the disease. It remains to be evaluated whether this is a straight-forward correlation or whether other factors like hormonal changes or the ability to deal with stress in the older patients might have been involved in the observed correlation.

Effects of perinatal exposure to triclosan on neuronal development and behavior of mice

Sunhwa Jeong, Dinh Nam Tran, Seon Myeong Go, Thi Bich Thuy Vo, Eui-Man Jung & Eui-Bae Jeung
Chungbuk National University, College of Veterinary Medicine, Cheongju, Korea, Represent of South

There have been raising concerns in the effects of endocrine disrupting chemicals like triclosan (TCS) on the embryo development. Triclosan (TCS) is commonly present in household and personal wash products We hypothesize that exposure to TCS during early stage of development could alter brain development affecting behavior. To test this hypothesis, primary cortical neurons were exposure to TCS with/without estrogen antiestrogen ICI 182780 from day in vitro 1 to 4. We also address whether maternal TCS-exposure at dose 10 mg/kg and 100 mg/kg during pregnancy and lactation, affects neurobehavioral development in the offspring generation. We found that TCS impaired to growths of dendrite and axon by reducing the average

dendrite lengths and number of both axon and dendrite. In the present of ICI, the effects of TCS on neurite growth are recued. At six weeks of age, the spatial learning and reference memory in offspring derived from dams exposed to TCS were impaired. Furthermore, TCS-treated groups displayed cognition dysfunction in novel test and impairments in sociability and social novelty preference in three-chamber social test. In addition, TCS-treated groups increased anxiety-like behavior in open field test. Moreover, TCS-treated groups exhibited deficits in nesting behavior. However, there was no significant difference in depression-like behavior in tail suspension test and forced swimming test. Our data demonstrate that perinatal exposure to TCS induces the neurodevelopment disorder, causes abnormal in social behavior, cognitive impairment, and deficits in spatial learning and memory in offspring.

Temporal and spatial trends of operated cryptorchidism in France and environmental hypotheses: a nationwide study from 2002 to 2014

Joëlle Le Moal, Sarah Goria, Agnès Guillet, Annabel Rigou & Julie Chesneau
Santé publique France, Saint Maurice, France

Introduction
Santé publique France develops a national epidemiological monitoring program to study health indicators related to endocrine disruptor exposure. Based on the weight of evidence, cryptorchidism was selected for this purpose. In this study, we aimed to analyze temporal, spatial and spatio-temporal trends of cryptorchidism during the period 2002–2014 in France, and explore and/or generate environmental hypotheses.
Methods
We built an indicator reflecting incident operated cryptorchidism in boys under the age of 7, using the data of the French National Hospital Discharge Database (PMSI). We fitted temporal, spatial and spatio-temporal models to describe trends of the risk of cryptorchidism at the department and at the postal code scale. We used Kulldorff's spatial scan statistic and Tango's flexibly shaped spatial scan statistic to identify spatial clusters at the postal code scale. We studied all types of cryptorchidism and bilateral cases separately. We searched for demographic, economic and environmental shared characteristics within clusters to discuss environmental hypotheses.
Results
We identified 91400 new cases of operated cryptorchidism in boys under the age of 7 years, including 9799 (10.7%) bilateral cases. The observed incidence was equal to 2.14 /1000 in 2002 and to 2.81/1000 in 2014. In the study period, the estimated increase of operated cryptorchidism incidence was equal to 37.1% (31.5%; 42.9%), especially among boys under 2 years and bilateral cases. An increase was observed in all departments, including ultramarine territories. The risk of cryptorchidism presents structured spatial heterogeneity. We detected 24 spatial clusters scattered in Metropolitan France. Low socio-economic levels were often observed in the cluster areas. Potential environmental exposures included mining activities (8/24 clusters), metallurgy (17/24 clusters) and mechanics (16/24 clusters). We also detected 21 spatial clusters of bilateral operated cryptorchidism, in the same areas and in a few agricultural areas.
Discussion, conclusion
To our knowledge, this is the first descriptive study on cryptorchidism addressing the issue of environmental exposure nationwide, with a large sample. As regards environmental hypothesis, this is an exploratory study, with limits due to the indicator built from hospital discharges and lack of individual data. Among some of the identified, environmental exposures related to mining and metallurgy could have induced persistent environmental pollution to metals, metallurgy inducing in addition dioxins and PCBs. This study analysis should be considered as a hypothesis-generating process for future research studies.

Identification of a novel hypothalamic miRNA/Kisspeptin pathway as pathophysiological mechanism and putative target for management of obesity-induced hypogonadism

Cecilia María Perdices López[1,2,3], María Soledad Avendaño Herrador[1,2], María Jesús Vázquez Villar[1,2,3], Alexia Barroso Romero[1,2], Francisco Ruiz Pino[1,2,3], Rosario Morrugares Carmona[1,2], Alejandro Correa Sáez[1,2], Marco Antonio Calzado[1,2], Juan Manuel Castellano Rodríguez[1,2,3], Ana María Briones Alonso[4] & Manuel Tena-Sempere[1,2,3]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain; [2]Cordoba University, Cell Biology, Physiology and Immunology Department, Córdoba, Spain; [3]Institute of Health Carlos III (ISCIII), CIBER Fisiopatología de la Obesidad y Nutrición, Madrid, Spain; [4]Autonomous University of Madrid , Madrid, Spain

Among its numerous comorbidities, obesity is often linked to central hypogonadism in men, i.e., low circulating levels of gonadotropins and testosterone. While this condition of obesity-induced hypogonadism (OIH) is frequently neglected, it has been suggested to contribute to the metabolic complications of male obesity. However, the mechanisms of OIH, and even its actual role in the metabolic alterations of obesity remain ill defined. Our recent data suggest that OIH is bound to suppression of the hypothalamic Kiss1/kisspeptin system, which would lower gonadotropin levels and, thereby, testosterone in obese males. Yet, the mechanisms for Kiss1 suppression in obesity remains unknown. Our recent findings suggest that microRNAs might operate as putative regulators of Kiss1. Here, we identify a novel miRNA pathway regulating kisspeptin expression, and assess its potential contribution to OIH. Bioinformatic prediction of miRNA regulators of the *KISS1* gene were conducted with several algorithms, searching for putative seed regions at the 3' untranslated region (3'UTR) of *KISS1*. For selection, miRNA candidate(s) had to meet the following criteria: 1) to be identified in at least two databases; 2) to display evolutionary conservation of its seed regions; and 3) to be sensitive to metabolic regulation, according to previous literature. Based on these criteria, miR-A (*anonymized due to ongoing patent protection*) was selected as a robust putative modulator of *KISS1*. Luciferase reporter assays confirmed a repressive interaction of miR-A at the 3'UTR of *KISS1*. Hypothalamic expression of miR-A was increased in obese male rats displaying OIH. Moreover, in vivo administration of a target-site blocker (TSB), tailored to specifically prevent the repressive interaction of miR-A at the 3'UTR of *Kiss1*, significantly ameliorated the reproductive and metabolic alterations observed in a rat model of OIH. Thus, while OIH rats showed severe suppression of T and gonadotropin (LH) levels, together with notable metabolic alterations (glucose intolerance, insulin resistance), elevated systolic blood pressure and severe inflammation, TSB administration not only restored T and LH levels, and enhanced hypothalamic kisspeptin, but improved also the metabolic alterations seen in OIH rats, even more effectively than pharmacological treatments with either kisspeptin or T. In sum, we provide herein preclinical evidence for a major role of a central miR-A/kisspeptin pathway in the generation OIH. This pathway might be a suitable target for the management of central hypogonadism linked to obesity, and its major metabolic complications.

Kisspeptin as a biomarker for pregnancy complications

Maria Phylactou[1], Ali Abbara[1], Pei Chia Eng[1], Maya Al-Memar[1], Alexander Comninos[1], Rans Nadir[1], Chioma Izzi-Engbeaya[1], Sophie Clarke[1], Edouard Mills[1], Mark Sykes[1], Ewa Pacuszka[1], Lisa Yang[1], Hanine Fourie[1], Paul Bech[1], Tom Kelsey[2], Tom Bourne[1] & Waljit Dhillo[1]
[1]Imperial College London, United Kingdom; [2]University of St Andrews, United Kingdom

Background
Placentation (invasion of the placenta into the maternal endometrium of pregnancy known as the decidua) is hypothesised to be critical for healthy placental function and is abnormal in two thirds of miscarriage. Kisspeptin has emerged as a putative regulator of physiological placentation; it is highly expressed in placental syncitio-trophoblasts, whereas its receptor is expressed in both syncitio- and cyto-trophoblasts, such that kisspeptin is hypothesized to play an important paracrine role to regulate placentation. Circulating kisspeptin levels are considerably raised during healthy pregnancy and are reduced in women with miscarriage.

Aim
We aimed to investigate the utility of circulating kisspeptin levels in the assessment of pregnancy complications and determine whether kisspeptin provides additional diagnostic information compared to beta human chorionic gonadotropin (βhCG) alone.
Methods
This study was performed in collaboration with the Early Pregnancy Outcome Study (EPOS), which aims to identify novel pregnancy biomarkers. Women were invited to attend every fortnight for blood-sampling, clinical and ultrasound assessment during the first trimester, and repeated during the second and third trimesters. Asymptomatic women with healthy pregnancy ($n=265$) provided 960 blood-samples. Women with pregnancy complications including miscarriage ($n=95$), pre-eclampsia (PET; $n=24$), pregnancy induced hypertension (PIH; $n=14$), gestational diabetes (GDM; $n=41$), preterm birth (PTB; $n=14$) and intrauterine growth restriction (IUGR; $n=24$) provided 569 blood-samples.
Results
Gestation-adjusted circulating kisspeptin and βhCG levels were lower, by 66% and 57%, respectively, in women with miscarriage compared to healthy pregnant controls ($P<0.0001$). Area under ROC curve for diagnosis of miscarriage was greater for the combination of both kisspeptin and βhCG together (0.92) than for either measure alone (βhCG 0.859, kisspeptin 0.874). An adjusted logistic regression model revealed that every 100 pmol/l increase in plasma kisspeptin levels reduced the odds of miscarriage by 42%. Gestation-adjusted kisspeptin levels were lower in women with GDM ($P=0.002$), or IUGR ($P<0.0001$), and higher in women with PTB ($P=0.004$). Kisspeptin increased with gestation greater in PET ($P=0.008$) and PIH ($P<0.0001$) than in healthy controls.
Conclusions
Plasma kisspeptin is a promising biomarker for pregnancy complications and provides additional diagnostic capability over that provided by βhCG alone.

Association between an AMH promoter polymorphism and serum AMH levels in PCOS patients

Loes Moolhuijsen[1], Yvonne V Louwers[2], Cindy Meun[2], Linda Broer[1], Andre G Uitterlinden[1], Ryan K Sisk[3], Andrea Dunaif[4], Joop SE Laven[2] & Jenny A Visser[1]
[1]Erasmus MC, University Medical Center Rotterdam, Department of Internal Medicine, Rotterdam, Netherlands; [2]Erasmus MC, University Medical Center Rotterdam, Division of Reproductive Endocrinology and Infertility, Department of Obstetrics and Gynaecology, Rotterdam, Netherlands; [3]Northwestern University Feinberg School of Medicine, Division of Endocrinology, Metabolism, and Molecular Medicine, Department of Medicine, Chicago, United States; [4]Icahn School of Medicine at Mount Sinai, Division of Endocrinology, Diabetes and Bone Disease, New York, United States

Introduction
Polycystic ovary syndrome (PCOS), the most common endocrine disorder in women of reproductive age, is diagnosed based on three criteria, including a polycystic ovarian morphology. Moreover, women with PCOS have elevated serum Anti-Müllerian Hormone (AMH) levels, a hormone known to correlate with follicle number. In addition, AMH production per follicle is suggested to be higher in PCOS. Little is known about AMH gene regulation. Hence, this study aims to investigate the regulation of AMH gene expression in PCOS patients. We have taken a genetic approach through association analysis and performed *in silico* analysis of common variants in the human AMH promoter. Associated variants were analyzed *in vitro* to assess the functional impact.
Methods
A cohort of 700 Caucasian PCOS women, diagnosed by the Rotterdam criteria, were included. All common two-allelic single nucleotide polymorphisms (SNPs), located in the region Chr19:2,245,353–2,250,827bp, were selected. AMH levels were measured with the picoAMH assay (Ansh Labs, Houston, Texas, USA) and presented as median (first–third quartile). The association between SNPs and serum AMH levels was analyzed by regression and allele carrier model analyses. KK1 cells were used to assess the functional effects of associated variants.
Results
We assessed 11 SNPs in 700 Caucasian PCOS patients. Polymorphism rs10406324 was associated with AMH levels in the regression analysis. This effect remained present when adjusted for age, BMI, and follicle count ($\beta=-0.52$, $P=6.08e-07$). Similar results were obtained in a carrier model analysis [AA: $n=645$, 8.29 ng/ml (5.20–12.81) vs AG/GG: $n=54$/n=1, 5.57 ng/ml (3.40–9.98), $P=1.47e-03$]. Results were replicated in an independent cohort of 321 PCOS patients of European ancestry ($P=2.59e-03$ and $P=6.2e-03$, respectively). Stratification by BMI in lean (<25 kg/m^2) and obese (>30 kg/m^2) patients showed that the association was only present in obese PCOS patients [$P=0.01$ (AA: $n=162$, AG/GG: $n=14$)], but not in lean PCOS patients [$P=0.11$ (AA: $n=322$, AG/GG: $n=22$)]. *In silico* analysis suggested a decreased binding affinity of the transcription factor SF1 to the minor allele G variant. Subsequently, functional analysis showed a significant decrease in basal activity of the AMH promoter construct containing the G variant ($P=0.04$), and a lower SF1-induced activity compared to the A variant ($P=8.7e-03$).
Conclusion
We have identified a functional AMH promoter polymorphism rs10406324 that is associated with lower serum AMH levels in obese PCOS women. These findings suggest that the genetic context should be taken into consideration when establishing an AMH cutoff value to diagnose PCOS.

Introduction
The developmental stages of the ovarian follicle are characterized by changes of gonadotropin and steroid hormone receptor expression and their potential interactions on the surface of granulosa cells. In this study *in vitro*, we aim to evaluate whether the co-existing follicle-stimulating hormone receptor (FSHR) and G protein-coupled estrogen receptor (GPER) form heteromers, which may play role in selecting the dominant ovarian follicle.
Methods
FSHR-GPER interactions was evaluated in transfected HEK293 cells by bioluminescence resonance energy transfer (BRET) and photo-activated localization microscopy using photoactivatable dyes (PD-PALM). Molecular modelling of FSHR-GPER heterodimers identified the sixth and seventh transmembrane segments (T6, T7) of both receptors as a potential heteromer interface. Seven T6 and eight T7 GPER putative interaction amino acid residues were mutated to alanine (mutGPER). Intracellular Ca^{2+} levels were measured by aequorin-dependent calcium assay (AEQ-GFP) and BRET.
Results
In order to evaluate its functionality and compare it to the wild-type receptor (wtGPER), wt or mutGPER were transiently expressed in HEK293 cells and demonstrated to both mediate estradiol (E_2)-induced intracellular Ca^{2+} increase (two-way ANOVA; $P<0.0001$; $n=8$; mean±S.E.M). FSHR-wtGPER dimerization was demonstrated by BRET in HEK293 cells transiently transfected with a fixed amount of Rluc8-tagged FSHR and increasing doses of wtGPER-Venus. The BRET signal logarithmically increased together with the acceptor concentration (non-linear regression; $r^2=0.876$; $n=4$; mean±S.E.M), revealing a specific heretomeric interaction between the two receptors. Further confirmation of the FSHR-wtGPER complexes at the cell surface was obtained by super-resolution PD-PALM imaging in cells co-expressing HA-tagged FSHR and FLAG-tagged wtGPER. We found FSHR and wtGPER both form monomers and homomers in equivalent amounts, however, while FSHR formed both dimers and a range of low to higher order homo-oligomers, GPER-GPER associations were primarily homodimer. FSHR-wtGPER heteromers were also observed with heterodimers as the predominant form (15% +/− 2.2, Mean±S.E.M; $n=8$). The ability of mutGPER to associate with FSHR was first determined by BRET, which demonstrated no specific BRET interaction (linear regression; $r^2=0.014$; $n=4$; mean±S.E.M). Furthermore, a fourfold decrease in the percentage of

heterodimeric structures in the cell surface were found by PALM ($n=3$), indicating the failure of heteromeric assembly between FSHR and mutGPER at the plasma membrane.
Conclusion
We demonstrated for the first time the physical interaction of FSHR-GPER *in vitro*, and identified a molecular heteromer interface, which could be exploited to understand the role of this heteromer in granulosa cell physiology.

Genetic dissection of spermatogenic arrest through whole exome analysis: Clinical implications for the management of azoospermic men
Antoni Riera_Escamilla[1], Daniel Moreno-Mendoza[1], Kaylee Holleman[2], Elena Casamonti[3], Francesca Cioppi[3], Sara Pietroforte[3], Eduard Ruiz-Castané[1], Willy Baarends[2] & Csilla Krausz[3]
[1]Fundacio Puigvert , Barcelona, Spain; [2]Erasmus MC University Medical Centre, Rotterdam, Netherlands; [3]University of Florence, Firenze, Italy

Background
Non-obstructive azoospermia affects about 1% of men and has a multifactorial etiology with heterogeneous testicular histology. Pure spermatogenic maturation arrest (MA) is a relatively rare NOA phenotype but its clinical relevance is high, since patients affected by MA should not undergo invasive testis surgery. A clear-cut distinction between MA and other spermatogenic disturbances leading to azoospermia is not possible with the currently available clinical tools. Consequently, testis biopsy (TESE), is offered to all NOA patients as the only treatment option to recover spermatozoa for subsequent in vitro fertilization. MA is of polygenic nature and in >60% of cases the etiology remains unknown.
Methods
We aimed to identify the underlying genetic cause of MA in 17 patients using whole exome analysis.
Results
Rare or novel LoF mutations (homozygous or compound heterozygous) were identified in 5 novel genes (*TERB1, MSH4, ADAD2, SHOC1* and *RAD21L1*) for which mouse KO models are concordant with the human phenotype. Our meiotic studies in the testis biopsy of the mutation carriers provided detailed characterization of the functional consequences of the variants, supporting their causative role in MA. In addition, 8 patients carried pathogenic variants in 7 previously reported genes - *TEX11, TEX14, MEIOB, MEI1, DMRT1, STAG3* and *SYCE1*. Thanks to our study, the clinical significance of these genes can now be upgraded to strong or definitive level, therefore they can be proposed for diagnostic purposes. In four cases, infertile or fertile brothers were available, and the recessive genotype segregated with azoospermia. Interestingly, both of our patients with variants in *MSH4* and *SYCE1* had at least one infertile sister with suspected premature ovarian insufficiency (POI).
Conclusions
The diagnostic yield of our exome analysis was 76%. This data is unique in this field and have implications for the understanding of human meiosis and its defects. In addition, we report novel genetic links between azoospermia and POI and propose three novel MA genes (*ADAD2*, *RAD21L1* and *TERB1)* as potential candidates for POI. Since the reported gene defects were all associated with pure MA (no mature spermatozoa found in the testis), our study contributes substantially to the development of a pre-testis biopsy gene panel with prognostic value for sperm retrieval.

Testosterone replacement therapy of opioid induced male hypogonadism improved body composition but not pain perception A double-blinded, randomized and placebo-controlled trial
Dorte Glintborg[1], Henrik Bjarke Vægter[1], Louise Lehmann Christensen[1], Emma Bendix[1], Thomas Graven-Nielsen[2], Per Grunwald Andersen[1] & Marianne Andersen[1]
[1]Odense University Hospital, Odense, Denmark; [2]Aalborg University, Aalborg, Denmark

Background
Hypogonadism is prevalent during opioid treatment, but the effect of testosterone replacement treatment (TRT) on body composition, pain perception, and adrenal function is unclear.
Purpose
To measure changes in body composition, pain perception, quality of life and adrenal function after TRT or placebo in opioid treated men with chronic non-malignant pain.
Methods
Double-blinded, placebo-controlled study in 41 men (>18 years) with total testosterone <12 nmol/l were randomized to 24 weeks TRT (Testosterone undecanoate injection 3 times/6 months, $n=20$) or placebo (placebo-injections, $n=21$).
Outcomes
Body composition (lean body mass and fat mass assessed by DXA), clinical pain intensity (numerical rating scale), and experimental pain perception (quantitative sensory assessment), quality of life (SF36), and adrenocorticotrophic hormone (ACTH) test. Data were presented as median (quartiles). Mann Whitney tests were performed on delta values (24–0 weeks) between TRT and placebo.
Results
The median age was 55 years (46; 59) and total testosterone before intervention was 6.8 (5.0; 9.3) nmol/l. TRT was associated with change of testosterone levels 12.3 (7.0; 19.8) nmol/l ($P<0.001$ vs placebo), increased lean body mass 3.6 (2.3; 5.0) kg vs 0.1 kg (−2.1; 1.5) during TRT vs placebo and decreased total fat mass −1.2 (−3.1; 0.7) kg vs 1.2 kg (−0.9; 2.5) kg, both $P<0.003$. Changes in pain perception, SF36, and ACTH stimulated cortisol levels were non-significantly changed during TRT compared with placebo.
Conclusions
Six months TRT improved body composition in men with opioid induced hypogonadism without significant changes in outcomes of pain perception, quality of life or adrenal function.

A mixed nutrient preload attenuates glucose-induced endothelial dysfunction in individuals with abnormal glucose tolerance
Domenico Trico[1,2], Lorenzo Nesti[3], Alessandro Mengozzi[3], Simona Baldi[3] & Andrea Natali[3]
[1]University of Pisa, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy; [2]Scuola Superiore Sant'Anna, Institute of Life Sciences, Pisa, Italy; [3]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy

Background
Postprandial hyperglycemia is an independent risk factor for cardiovascular disease and all-cause mortality. This excess cardiovascular risk may be partly explained by the impairment in endothelial function that typically follows an acute increase in plasma glucose levels. Recently, nutritional interventions focused on the sequence of macronutrient consumption within the meal have been proposed to normalize postprandial glycemia in subjects with abnormal glucose tolerance (AGT). We therefore aimed to establish whether and by which mechanisms a protein- and fat-rich nutrient preload attenuates glucose-induced endothelial dysfunction in individuals with AGT.
Methods
In this randomized controlled trial, the endothelial function was assessed by the reactive hyperemia index (RHI) using an EndoPAT device at fasting, 60 min and 120 min during two 75 g oral glucose tolerance tests (OGTTs) preceded by either a mixed nutrient preload (one boiled egg, 50 g parmesan cheese, 300 ml water) or a water preload (500 ml water; control OGTT). A total of 30 volunteers were recruited, including 22 patients with impaired glucose tolerance (IGT, $n=13$) or diet-controlled type 2 diabetes (T2D, $n=9$), who were classified as AGT. A group of 8 subjects with normal glucose tolerance underwent the control OGTT and was used as reference. Plasma glucose, insulin, glucagon-like peptide-1 (GLP-1), glucose-dependent insulinotropic polypeptide (GIP), glucagon, free fatty acids (FFA), arginine, branched chain amino acid (BCAA), and total amino acids (AA) were measured during the tests.

Results
The RHI negatively correlated with fasting plasma glucose ($r=-0.29$, $P=0.04$). During the control OGTT, the RHI decreased by 9% ($P=0.02$) and its deterioration was associated with the time-course of plasma glucose levels ($\beta=-0.03$, $P=0.015$). In individuals with AGT, the nutrient preload attenuated the decline in the RHI ($P=0.04$) and markedly reduced postprandial glycemia ($P=0.0003$) compared with the control OGTT. The beneficial effect of the nutrient preload on the RHI was proportional to the improvement in glucose tolerance ($r=0.52$, $P=0.02$). Furthermore, it was associated with the increase in plasma GLP-1 ($r=0.47$, $P=0.04$) and arginine levels ($r=0.64$, $P=0.04$).
Conclusions
A mixed protein- and fat-rich nutrient preload attenuates postprandial endothelial dysfunction in individuals with AGT by lowering plasma glucose excursions and by increasing GLP-1 and arginine levels, both of which are known upregulators of the nitric oxide vasodilator system.

Transcriptomic response of mouse thyroid to iodine by upregulating Nrf2-dependent and independent pathways

Dionysios Chartoumpekis[1,2], Panos Ziros[2], Ioannis Habeos[1], Venetsana Kyriazopoulou[1], Adam Smith[3], Ana Claudia Marques[3] & Gerasimos Sykiotis[2]
[1]University of Patras, Department of Internal Medicine, Division of Endocrinology, Patras, Greece; [2]Lausanne University Hospital (CHUV), Service of Endocrinology and Diabetology, Lausanne, Switzerland; [3]University of Lausanne, Department of Computational Biology, Lausanne, Switzerland

Introduction
Nrf2 (Nfe2l2) is a transcription factor that regulates a series of cytoprotective and antioxidant enzymes. Upon exposure to oxidative or electrophilic stress, Nrf2 enters the nucleus and induces its target genes expression. Follicular thyroid cells have physiologically high levels of reactive oxygen species as oxidation of iodine is essential for iodination of thyroglobulin and thyroid hormones synthesis. We have shown previously that Nrf2 pathway is active in thyroid and regulates the transcription of thyroglobulin.
Hypothesis
We thus hypothesized that the response of thyroid to iodine excess should comprise Nrf2-dependent and -independent pathways.
Methods
To this end, 3 months-old male C57Bl6J wild-type (WT) or Nrf2 knockout (Nrf2KO) mice were exposed to 0.05% sodium iodide in their water for 7 days. Thyroids were used for RNA extraction; RNA-seq was performed by Exiqon, with a fold-change cutoff set at 2. Representative genes of the enriched pathways were quantified by qPCR to validate RNA-seq results. Pathway analysis of the differentially expressed genes was performed using the Ingenuity Pathway Analysis (IPA) software. Pathways that were enriched with a p-value <0.05 were considered significant.
Results
828 genes were differentially expressed in response to iodine exposure; 66% were upregulated, as were most of the highly enriched pathways (related to inflammatory-immune response, antioxidant response, xenobiotic metabolism, platelet activation and calcium signaling). About 300 genes were differentially expressed between WT and Nrf2KO mice; highly enriched pathways were related to glutathione and xenobiotic metabolism, Ahr signaling and Nrf2 signaling and were all downregulated in Nrf2KO mice. Analysis of the potential upstream regulators of these highly enriched pathways revealed that Nrf2 and NfkB are main regulators of the antioxidant and inflammatory response induction upon iodine exposure and that fibrosis signaling is downstream to Tgfβ-Smad cascade. Last, we performed an analysis limited to already known thyroid pathways. A few genes were enriched following this method. Specifically, Duoxa1 (hydrogen peroxide generator) and Nis (sodium iodide symporter) were upregulated upon iodine exposure, which are expected responses. Thyroglobulin was decreased and Duoxa1 was increased in Nrf2KO mice confirming our previous findings.
Conclusions
In conclusion, Nrf2-driven cytoprotective response and inflammatory pathways are upregulated after iodine overload. Nrf2 regulates transcriptomic responses in the thyroid, including a small but significant part of the response to iodine challenge. Hence, Nrf2 can be considered a novel player bridging thyroid antioxidant response and thyroid economy.

Background
Genetic alterations underlying the pathogenesis of autonomous cortisol secretion and early adrenocortical tumorigenesis have been identified in 40% of adrenocortical tumors (ACT). Nonetheless, the molecular events leading to development of ACT and steroid secretion remain obscure for a large proportion of patients.
Aim
Aims of our study were to investigate the relationship between transcriptome profile and genetic background in a large series of ACT and to identify novel potentially pathogenic molecular event by deep RNA-sequencing.
Methods
We collected snap-frozen tissue from patients with ACT and known genetic background among centers of the European Network for the Study of Adrenal Tumors (ENSAT). Details about somatic mutations were available from previous targeted Sanger sequencing or whole-exome sequencing (WES). We included in the study 52 adenomas (26 associated with Cushing syndrome [CS-CPA], 17 with mild autonomous cortisol secretion [MACS-CPA], and 9 endocrine-inactive, EIA) and 7 early-stage adrenocortical carcinomas (ACC). We performed deep RNA-sequencing for the analysis of gene expression, long non-coding RNA (lncRNA), and gene fusions. We investigated the correlation between RNA-sequencing results and genetic background (i.e. presence of mutations in driver genes - PRKACA, GNAS or CTNNB1, or no mutations in driver genes).
Results
Transcriptome analysis identified two major clusters for adenomas: cluster 1 with EIA and MACS-CPA with CTNNB1 mutations or no drivers and cluster 2 with CS-CPA and MACS-CPA with PRKACA or GNAS mutations and CS-CPA with no drivers. In cluster 2, FATE1 was among most common overexpressed genes. Overall, three CS-CPA with CTNNB1 mutations clustered close to ACC. The analysis of the lncRNA expression showed similar results, confirming the clusters identified in transcriptome profile. ACC showed a higher number of gene fusions per sample (average 8.14) than adenomas (0.79), whereas CTNNB1-CPA had an intermediate number of gene fusions per sample (1.7). We identified novel gene fusions, including an AKAP13-PDE8A fusion in a CS-CPA sample with no previously identified driver mutations.
Conclusions
MACS and EIA showed a similar transcriptome profile, independently of the genetic background. Still unrevealed molecular alterations might be involved in the pathogenesis of adrenocortical tumors associated with cortisol excess. CT

Evidence for increased SSTR5 expression and improved pasireotide response in USP8 mutant corticotroph tumours

Adriana Albani[1], Luis Gustavo Perez-Rivas[1], Tang Sicheng[1], Michael Buchfelder[2], Roman Rotermund[3], Jörg Flitsch[3], Marco Losa[4], Günter Stalla[5], Martin Reincke[1] & Marily Theodoropoulou[1]
[1]Medizinische Klinik und Poliklinik IV, Ludwig Maximilian University Munich, Munich, Germany; [2]Neurochirurgische Klinik, Klinikum der Universität Erlangen, Erlangen, Germany; [3]Klinik für Neurochirurgie, Universitätskrankenhaus Hamburg-Eppendorf, Hamburg, Hamburg, Germany; [4]IRCCS San Raffaele, Vita-Salute University, Milan, Milan, Italy; [5]Medizinische Klinik und Poliklinik IV, Ludwig Maximilian University Munich; Medicover Neuroendocrinology, Munich, Munich, Germany

The somatostatin analogue pasireotide is approved for the treatment of Cushing's disease, where it achieves biochemical normalization in ~40% of patients. Predicting pasireotide resistance would help avoid unnecessary treatment. Pasireotide mediates its antisecretory action by binding to somatostatin receptor 5 (SSTR5). Almost half of corticotroph tumours carry mutations in the ubiquitin specific protease 8 (*USP8*) gene that encodes for a deubiquitinase. Previous analysis has suggested a correlation between USP8 mutational status and SSTR5 expression. In the present study, we determine the impact of *USP8* mutational status on pasireotide's antisecretory response in vitro and propose a potential mechanism through which USP8 may control *SSTR5* expression. We treated 17 consecutive human corticotroph tumours with 10 nM pasireotide and determined ACTH secretion with a radioimmunoassay, arbitrarily setting physiologically relevant suppression 20% (compared to vehicle control). We assessed 50 archival human corticotroph tumours for *USP8* mutational status by Sanger sequencing and SSTR5 expression by immunohistochemistry (UMB4 rabbit monoclonal antibody). We detected *USP8* mutations in the mutational hotspot of exon 14 in 9/17 (59%) fresh and 21/50 paraffin-embedded corticotroph tumours (42%). Pasireotide treatment suppressed ACTH secretion beyond the 20% cut-off in 11 out of 17 cases (3 *USP8*wt and 8 mutant). We observed more than two-fold inhibitory action in mutant corticotroph tumours (overall % ACTH suppression *USP8*mut 42.6±24.7 vs wt 18.9±10.9; independent *t*-test $P=0.032$). The SSTR5 immunoreactivity score was significantly higher in *USP8* mutant corticotroph tumours compared with wt (mean 0.543±0.338 vs 0,228±0.263, *t*-test $P=0.001$). AtT-20 cells overexpressing the most frequently found in Cushing's disease USP8 mutants p.Pro720Arg, p.Ser-718del and Ser718Pro, showed improved response to pasireotide's inhibitory action on *hPOMC* promoter activity and increased endogenous *Sstr5* -but not *Sstr2*- transcript levels two-fold. The murine *Sstr5* promoter has two binding sites for the activating protein 1 (AP-1). USP8 mutants stimulate AP-1 transcriptional activity, indicating an unexpected mechanism through which activated USP8 regulates SSTR5 levels at transcriptional level. In conclusion, the present study shows that USP8 mutant corticotroph tumours have higher SSTR5 expression and are more prone to respond favourably to the antisecretory action of pasireotide.

Craniopharyngiomas are rare benign epithelial tumors derived from remains of Rathke's pouch. They are more prevalent in childhood, adolescence, and adults <50 years, and, commonly, are usually diagnosed after being associated with serious comorbidities when the development of the tumor is already advanced. To date, first-line therapy is usually surgery, but frequently the resection is not complete, causing high rates of recurrence. Therefore, the identification of new diagnostic and prognostic biomarkers as well as therapeutic tools to improve the management of patient with craniopharyngiomas is necessary. In recent years, a growing evidence indicates that defects in the splicing process are frequent in tumor pathologies, leading to the appearance of altered spliceosome components (SCs), splicing factors (SFs) and/or aberrant splicing variants (SVs; generated by alternative splicing), which are associated to the development, progression and aggressiveness of various cancer types. Based on the information described above, the aim of this study was to establish the expression profile of key splicing machinery components [major and minor spliceosome machinery ($n=13$ and 4, respectively) and 28 relevant SFs] in craniopharyngiomas (primary and recurrent tumors; $n=36$) compared with control samples [normal pituitary glands (NPs, $n=11$)] using a microfluidic qPCR-array, to explore their potential dysregulation and identify specific components of this machinery that could serve as diagnostic and/or prognostic biomarkers as well as therapeutic targets for this pathology. Expression of a substantial number of components of the splicing machinery and SFs were drastically altered in craniopharyngiomas vs NPs, and, also when primary vs recurrent craniopharyngiomas were exclusively compared. Bioinformatic analyses identified RAVER1, RBM22, FBP11 and PRP8 as the most discriminating diagnostic factors of craniopharyngiomas vs NPs. These results were corroborated in two external cohorts (i.e. human and ACP-like mouse model). Furthermore, expression levels of some of these components were associated with key clinical parameters suggesting a potential patho-physiological role of these splicing components in craniopharyngiomas. Finally, the *in vitro* modulation of *RAVER1* and *PRP8* (the most relevant splicing component identified) in primary craniopharyngiomas-derived cell cultures revealed a critical role of these factors in craniopharyngiomas proliferation. Altogether, the expression of key splicing machinery components and associated SFs is dysregulated in craniopharyngiomas, which provides an original approach to identify novel diagnostic and/or prognostic biomarkers and new targets with therapeutic potential in this poorly known disease with multiple endocrine comorbidities.

Development and progression of liver diseases, from non-alcoholic fatty liver disease (NAFLD) to steatohepatitis (NASH), and hepatocellular carcinoma (HCC), seem to be accompanied by a dysregulation of the expression of alternative splicing variants (SVs) and appearance of aberrant SVs. The splicing factor 3B subunit 1 (SF3B1) represents a crucial player for the functional assembly of the spliceosome, the core machinery that controls the splicing process, and its activity can be specifically blocked using pladienolide-B. Here, we explored the putative dysregulation and pathophysiological role of SF3B1 and the potential therapeutic utility of pladienolide-B in liver disease. To this end, SF3B1 expression (mRNA and protein levels) and clinical implications were assessed in patients with liver diseases from two retrospective ($n=154$ and $n=172$) cohorts, and five *in silico* cohorts of HCC patients [TCGA ($n=369$), Wurmbach ($n=45$), Roessler ($n=43$), Roessler 2 ($n=445$) and Mas ($n=57$)]. Functional and molecular consequences of *SF3B1* silencing (using specific siRNAs) and/or pharmacological blockade (using pladienolide-B) were evaluated in normal-like hepatocyte-derived (THLE-2) and liver cancer (HepG2, Hep3b and SNU-387) cell lines. In addition, Hep3b-induced xenograft tumors treated with pladienolide-B were developed *in vivo*. Results showed that SF3B1 expression levels were consistently elevated (at mRNA and protein levels) in transformed livers (NASH/HCC) compared to normal liver in all cohorts studied. Moreover, *SF3B1* expression levels were associated with clinical (histologic differentiation, overall survival) and molecular parameters of aggressiveness (expression of oncogenic SVs, including KLF6-SV1, BCL-XL, etc). Furthermore, *SF3B1* silencing *in vitro* resulted in reduced proliferation and migration capacity of liver cancer cell lines. Consistently, pladienolide-B

strongly inhibited proliferation, migration, as well as tumorsphere- and colony-formation in liver cancer cells, whereas its effects on the proliferation of normal-like liver cells (THLE-2) were negligible. Remarkably, intratumor injection of pladienolide-B was able to markedly reduce the growth rate of xenograft tumors. Finally, silencing and blockade of SF3B1 both *in vitro* and *in vivo* clearly modulated the expression levels of cancer-associated genes (e.g. *CDK4*, *CD24*) and oncogenic SVs (e.g. *KLF6-SV1*). Altogether, these results demonstrate that SF3B1 expression increases with the pathological transformation of the liver and that its pharmacological inhibition using pladienolide-B may represent a promising novel therapeutic approach worth to be explored through randomized controlled trials, alone or in combination with existing therapies.

Congenital isolated follicle-stimulating hormone deficiency due to the FSHB gene mutation in a female patient – a rare case report

Katarzyna Paczkowska[1], Monika Kolanowska[2,3], Beata Wikiera[4], Marek Bolanowski[1], Krystian Jażdżewski[2,5] & Jacek Daroszewski[1]
[1]Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw, Poland; [2]Medical University of Warsaw, Genomic Medicine, Poland; [3]Warsaw Genomics Inc., Poland; [4]Wroclaw Medical University, Department of Endocrinology and Diabetology of Children, and Adolescents, Poland; [5]University of Warsaw, Laboratory of Human Cancer Genetics, Poland

Introduction
Mutations in FSHβ gene leading to isolated follicle-stimulating hormone (FSH) deficiency are very rare and the disorder is inherited in an autosomal recessive manner. Up to date, only few case reports have been described in the literature.
Case report
25-years old woman was admitted to the Endocrinology Department with a suspicion of FSH deficiency. She was firstly diagnosed with primary amenorrhoea and impaired pubertal development at the age of 17. Hormonal tests were performed and low concentrations of FSH and estradiol were found. Pelvic ultrasound and pituitary MRI did not reveal any pathology. Treatment with hormonal replacement therapy was started and continued for 8 years. It was withdrawn 7 days before admission to our department. During hospitalization hormonal function tests were performed and there were found undetectable concentrations of FSH and estradiol, while LH level was mildly elevated. In the gonadotropin-releasing hormone stimulation test there was no response in FSH concentration. Anti-Mullerian hormone (AMH) concentration was within the normal range and inhibin B level was undetectable low. Next-generation sequencing was performed and homozygotic mutation in FSHB gene was found (ENST00000417547c.236-237delTG, protein p.Val79fs). Isolated FSH deficiency was diagnosed.
Conclusion
Hypogonadism and primary amenorrhoea may present a clinical picture of isolated FSH deficiency in women. However, it is worth to notice that a severe deficiency of FSH was not related with AMH deficiency. Patients with isolated deficiency of single gonadotropin give us a new, important insight into its role in human fertility processes, which are still under investigation.

Towards the development of an *in vitro* 3D human thyroid model

Özlem Vural[1], Ugarit Daher[1], Shirin Kadler[1], Martina Mogl[2], Peter Goretzki[2] & Roland Lauster[1]
[1]Technical University Berlin, Medical Biotechnology, Berlin, Germany; [2]Charité – Universitätsmedizin Berlin, Department of Surgery Campus Charité Mitte/Campus Virchow Klinikum, Berlin, Germany

Human and animal health has been exposed to endocrine disruptors (EDs) which are chemicals found in pesticides, food or personal care products. The main concern about these disruptors is caused by their interference with the endocrine system causing adverse effects, such as altered reproduction, abnormal neurological development in newborns and children or an elevated susceptibility to hormone-related cancers. The thyroid gland and its hormones belong to major targets that are primarily affected by EDs. Studies on endocrine disrupting effects as well as general endocrine research has been primarily conducted in animal studies due to the lack of representative human models. The importance of the thyroid gland accentuates its role already during embryonic development and organogenesis by secreting thyroid hormones T3 and T4. It further controls the metabolism of various adult organs, the well-being, and the cardiovascular system. The architecture of the characteristic units of the thyroid gland, the thyroid follicles, is a prerequisite for its functionality. A human thyroid test system is urgently needed to evaluate the effects of new substances on endocrine organs. Therefore, the aim of this study was dedicated to advance the field of *in vitro* three dimensional (3D) thyroid research using primary human adult thyrocytes. The hypothesis is based on the importance of a 3D environment and the concomitant cell-cell/cell-matrix interactions to mimic *in vitro* thyroid follicles. In vitro expanded adult thyrocytes, derived from macroscopically normal tissue, were cultured as single 3D culture or in co-culture with endothelial cells (ECs). Adult human thyrocytes dedifferentiated in long-term *in vitro* culture and lost their transcriptional thyroid-phenotype. The results of 3D cultures, independent from the co-culture with another cell type, demonstrate that the 3D environment exerted a beneficial effect on the transcriptional status of thyrocytes by upregulating thyroid-specific markers. It became obvious that 3D culture approaches without supplying additional extracellular matrix were not sufficient to emulate the native thyroid follicle morphology. A reorganization of thyrocytes was finally induced by the co-culture and the addition of Matrigel™. These 3D constructs showed follicular-like structures and are a promising culture strategy for in-vitro test systems of endocrine disruptors. All in all, this study presents for the first time in thyroid research, the successful co-culture of adult human thyrocytes with ECs that induces a reorganization to follicle-like structures *in vitro*.

[1]IRCCS Ca Granda Policlinico of Milan, Endocrinology, Milano, Italy; [2]Policlinico of Milan, Endocrinology, Milano, Italy; [3]Policlinico of Milan, Ophthalmology, Milano, Italy; [4]Italian Institute Auxologico, Endocrinology, Milano, Italy; [5]Policlinico of Milan, Milano, Italy; [6]Policlinico of Milan, Otolaryngology, Milano, Italy

Background
BAFF is a Serum B cell stimulating factor shown elevated in Graves' disease, compared to controls (Vannucchi 2012). BAFF and its receptor are expressed on lymphocytes infiltrating the thyroid in Graves' disease as well as on thyrocytes themselves (Campi 2015).
Aims
A single-blind randomized controlled trial (EudraCT 2015-002127-26) has been conducted to test the efficacy of the anti-BAFF monoclonal antibody belimumab (BMB) in active moderate-severe Graves' Orbitopathy (GO) compared to iv methylprednisolone (MP).
Methods
We studied the first 20 of the planned 40 patients with active, moderate severe GO and detectable serum TSH receptor antibodies (TRAb), euthyroid for at least 3 months, whether untreated or previously treated with iv steroids (relapsing GO). They received iv belimumab at 0,14, 28 days and then every four weeks for five cycles of infusion or iv MP, 833 mg/ weekly for 6 cycles, followed by one cycle of 425 mg/week. The first dose of belimumab was associated to a full dose (833 mg) of MP. Patient were studied at 12, 24 weeks (primary end point) and followed-up for 48 weeks. In addition to the CAS (primary end point), Gorman diplopia score and proptosis (secondary end points) were also measured.
Results
In both groups CAS decreased significantly at 24 weeks ($P<0.0001$). At 12 weeks patients on MP had a significantly lower CAS than those on BMB (4.8–1.4 vs 4.18–2.45, $P<0.02$). At 24 weeks 9/10 patients had inactive disease (mean CAS with MP 1.33 and with BMB 1.5). No differences were observed in the proptosis and the Gorman score for diplopia with either treatment ($P=$NS). Only one patient (BMB) developed optic neuropathy after the first infusion. In addition, among patients treated with BMB, we

observed one with increased blood pressure, one with headache and dizziness, one with nausea and bile vomiting. Among patients treated with MP, two developed fasting hyperglicemia, one headache, one insomnia, one increased nervousness. Two patients trated with BMB developed epigastralgy, but they were not on pump inhibitor, unlike all patients treated with MP.
Conclusions
The interim analysis suggests that BMB is as effective as iv MP in the treatment of active GO, inducing inactivation in approximately 90% of subjects. Its effect is slower than MP, but its tolerability is very good. If the data is confirmed, BMB is suggested to be a good alternative to MP. Finally, the side-effects profile of BMB is better than MP.

Association of dietary and plasma fatty acids with adipose triglyceride lipase (ATGL) and hormone-sensitive lipase (HSL) gene expression in human adipose tissues

Emad Yuzbashian[1], Golaleh Asghari[1], Maryam Zarkesh[2], Parvin mirmiran[1], Mehdi Hedayati[2] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran

Adipose triglyceride lipase (ATGL) and hormone-sensitive lipase (HSL) are key enzymes involved in intracellular degradation of triacylglycerols. The environmental factors and circulating biomarkers can affect the expression of ATGL and HSL in adipocytes among rats. To our knowledge, however, no information is known about the dietary and plasma fatty acids composition on gene expression of ATGL and HSL in human adipose tissue. We aimed to determine how fatty acid species measured in plasma and dietary intake associate with HSL and ATGL gene expression in subcutaneous and visceral adipose tissues. In this study, 97 participants aged ≥18 years were selected from patients admitted to the hospital for abdominal surgeries. Visceral and subcutaneous adipose tissues were obtained during the operation those with minimal impact on dietary intake. Habitual dietary intake of participants was collected using a valid and reliable food frequency questionnaire (FFQ), from which the intake of fatty acids was quantified. Plasma fatty acids were assessed by gas-liquid chromatography. The gene expressions ATGL and HSL in visceral and subcutaneous adipose tissue were assessed by Real-Time PCR. After adjustment for total energy intake, sex, HOMA-IR, and age, visceral adipose tissue ATGL and HSL gene expression was associated with total fatty acids concentration ($\beta=0.373$, $P=0.032$ and $\beta=0.411$, $P=0.006$, respectively). Furthermore, visceral adipose tissue ATGL and HSL gene expression was significantly associated with plasma PUFAs ($\beta=0.421$, $P=0.002$ and $\beta=0.395$, $P=0.026$, respectively). Moreover, in visceral adipose tissue, HSL mRNA levels had a significant association with dietary PUFA intake ($\beta=0.471$, $P<0.001$). There was no significant association of dietary intake and plasma fatty acids with ATGL and HSL expression in subcutaneous adipose tissue. Expression of adipose tissue ATGL and HSL positively associated with total fatty acids and PUFA concentration in visceral fat. Besides, dietary PUFA has an association with only HSL in visceral fat. It seems that fat quantity along with quality may be most important for modulating visceral adipose tissue ATGL and HSL gene expression.

Growth hormone-releasing hormone (GHRH) antagonists increase the sensitivity to radiotherapy in lung cancer cells

Iacopo Gesmundo[1], Alessandro Dematteis[1], Alessandro Fanciulli[1], Francesca Romana Giglioli[2], Renzhi Cai[3,4], Wei Sha[3,4], Umberto Ricardi[5], Ezio Ghigo[1], Andrew V Schally[3,4] & Riccarda Granata[1]

Città della Salute e della Scienza, Turin, Italy; [3]University of Miami Miller School of Medicine, Division of Endocrinology, Department of Medicine, Miami, Florida, United States; [4]University of Miami Miller School of Medicine, Division of Medical Oncology, Department of Medicine, Miami, Florida, United States; [5]University of Turin, Department of Oncology, Radiation Oncology, Turin, Italy

Growth hormone-releasing hormone (GHRH), apart from stimulating GH secretion in the pituitary, exerts many extrapituitary functions, including stimulation of cell proliferation and survival. GHRH and its receptor splice variants (SVs) are expressed in different cancer cell types, where they modulate cell growth. It has been shown that GHRH antagonists exert anticancer activities in a variety of tumors, including malignant pleural mesothelioma and lung cancer, one of the leading causes of cancer death worldwide. Radiotherapy with ionizing radiation (IR) is currently the first-line treatment for advanced stage lung cancer; however, IR is not always resolutive and is often associated with serious side effects. To date, the role of GHRH antagonists in sensitization of lung cancer to IR remains unknown. Thus, we aimed to verify the antitumor effect of last generation GHRH antagonists, MIA-602 and MIA-690, in human A549 non-small cell lung cancer (NSCLC) cells, in combination with IR. We found that, as previously reported, 24 h treatment with MIA-602 and MIA-690 reduced cell survival and growth in A549 cells NSCLC cells. Interestingly, both antagonists potentiated the inhibitory effect of IR (at 2 and 5 Gy) on cell survival and proliferation, and increased IR-induced apoptosis. Furthermore, MIA-602 and MIA-690 enhanced the IR-induced increase in p53 tumor suppressor protein and the inhibition in Bcl-2 antiapoptotic protein. These effects were paralleled by elevation in expression of genes involved in tumor progression (c-Myc, cyclin B1 and cyclin D1/2), angiogenesis [vascular endothelial growth factor (VEGF)], and invasion [(metalloproteases (MMP)-2, MMP-9 and E-cadherin)]. Ongoing experiments will assess the role of GHRH antagonists in human primary lung cancer cells, along with the regulation of pathways involved in DNA repair (Ku70, Ku80 and DNA-dependent protein kinase). Overall, these results suggest that, in addition to the previously reported inhibitory effects in lung cancer, MIA-602 and MIA-690 may enhance the sensitivity to radiotherapy, thereby increasing the IR-induced antitumor response.

Background
Adrenocortical cancer (ACC) is an aggressive tumor with heterogeneous prognosis. Previous genomic studies have demonstrated the importance of molecular classification for the prognostic assessment. Among molecular markers, transcriptome profiles "C1A" (steroid and proliferative signature) and "C1B" (immune signature) show the strongest association with outcome. However these markers are determined so far only from frozen tissue samples, since paraffin-induced RNA degradation prevents the determination of transcriptome profiles using standard technologies on paraffin samples. This limitation hampers the integration of such markers in the routine of pathology departments. The aim of this study was to determine transcriptome profiles from paraffin samples, using a dedicated protocol of RNA-sequencing.
Methods
Tumor RNA was extracted both from frozen (Qiagen) and paraffin (Promega) tissues in 48 ACC patients from Cochin hospital. For 5 patients, several samples (2 to 4) from macroscopically different primary tumor regions were analyzed, including 2 with one area presenting a high Weiss score (> 3) like an ACC and another area with a low Weiss score (< 3) like a benign adenoma. Transcriptome was determined using RNA-sequencing of 3'-end transcripts -that are more resistant to RNA degradation- in paraffin samples

(QuantSeq, Lexogen and Illumina). An unsupervised non-negative matrix factorization consensus clustering was performed on the top most variable genes to classify the transcriptome profiles. These transcriptome profiles were then compared with known prognostic expression marker (*BUB1B-PINK1* differential expression assessed by RT-qPCR) obtained from frozen samples. Association between groups was assessed with Fisher's test. Association with overall survival (OS) and disease-free survival (DFS) was tested using log-rank test.

Results

Sufficient quality of RNA-sequencing (>1 000 000 reads, Q30 > 85%) was obtained for 54/55 paraffin samples (98%). Unsupervised clustering identified 2 main subgroups: one (26 patients, 55%) enriched in proliferative genes was characterized as "C1A", and the other (21 patients, 45%) showing immune and inflammatory signature was characterized as "C1B". Transcriptome profiles were strongly associated with *BUB1B-PINK1* marker ($P < 10^{-5}$), DFS (5-year DFS of 45% and 95% in "C1A" and "C1B" subgroups respectively, $P < 10^{-3}$) and OS (5-year OS of 55% and 95% in "C1A" and "C1B" subgroups respectively, $P = 0.007$). Transcriptome-based classification was stable in different tumor regions from the same patient.

Conclusion

The 3' RNA-sequencing protocol successfully classified "C1A" and "C1B" transcriptome profiles and represents a convenient solution for the determination of gene-expression-based prognostic classification from paraffin samples.

Background
Previous research show that autoimmune adrenal insufficiency develops gradually over time and inexorably results in a total inability to produce adrenal steroids. However, growing evidence suggest that a few patients preserve some steroid producing capacity.
Aim
To explore the frequency of residual cortisol production and possible clinical consequences in patients with autoimmune Addison´s disease (AAD).
Material and Methods
We performed a two-staged clinical multicenter study. Study subjects submitted a medication-fasting morning blood sample for analysis of adrenocortical steroids by liquid chromatography-tandem mass spectrometry (LC-MS/MS) method. Before sampling, patients abstained from cortisone acetate or hydrocortisone and fludrocortisone for at least 18 and 24 hours, respectively. Residual glucocorticoid (GC) production was defined as quantifiable serum cortisol and 11-deoxycortisol, and residual mineralocorticoid (MC) production as quantifiable serum aldosterone and corticosterone. Clinical variables included demographics, replacement therapy, frequency of adrenal crises, clinical biochemistry, and quality of life. Peak cortisol response was evaluated by a standard 250 µg cosyntropin test.
Results
Fifty-eight of 192 patients (30.2%) had residual GC production, more common in men ($n=33$, $P<0.002$) and in shorter disease duration (median 6 [0–44] vs 13 [0–53] years, $P<0.001$). Residual MC production was found in 26 (13.5%) patients and associated with shorter disease duration (median 5.5 [0.5–26.0] vs 13 [0–53] years, $P<0.004$), lower fludrocortisone replacement dosage (median 0.075 [0.050–0.120] vs 0.100 [0.028–0.300] mg, $P<0.005$), and higher plasma renin concentration (median 179 [22–915] vs 47.5 [0.6–658.0] mIE/l, $P<0.001$). None had a normal cosyntropin response, but peak cortisol strongly correlated with unstimulated cortisol ($r=0.753$, $P<0.000$) and plasma ACTH ($r=–0.694$, $P<0.001$). No differences in HRQoL or other clinical parameters were seen.
Conclusion
In patients with AAD one-third have residual production of glucocorticoids, more common in men and patients with shorter disease duration. In the future, these patients could be candidates for regenerative therapy.

Ovarian adrenal rest tumor in congenital adrenal hyperplasia: Is medical treatment the first line option?

Ronit Koren[1,2], Shlomit Koren[2,3,4], Alla Khashper[2,5], Carlos Benbassat[4], Marina Pekar-Zlotin[2,6] & Zvi Vaknin[2,6]

[1]Shamirmedical center, Department of Internal Medicine A, Zerifin, Israel; [2]Tel-Aviv University, Sackler faculty of medicine, Tel Aviv, Israel; [3]Shamir medical center, Diabetes unit, Zerifin, Israel; [4]Shamir medical center, Endocrine Institute, Zerifin, Israel; [5]Shamir medical center, Diagnostic Imaging, Zerifin, Israel; [6]Shamir medical center, Obstetrics and Gynecology, Zerifin, Israel

Introduction
Ovarian adrenal rest tumors (OARTs), in contrast with testicular adrenal rest tumors, are very rare. Up to date, 13 cases were reported in the literature; all treated surgically.
Aim
We describe a case of a young female with uncontrolled classical congenital adrenal hyperplasia (CCAH), presenting with bilateral OARTs, successfully treated with steroid replacement.
Methods
Data on clinical history and biochemical work-upwas obtained from medical records.
Case presentation
A 20 years old women presented with severe abdominal pain, vomiting, diarrhea,and fever. She was known to have 21OH-CCAH. As a result of poor compliance, 6 months before her admission hirsutism worsened and amenorrhea, hyperpigmentation,and weakness developed. ACTH levels were 278< pmol/l and 17OHP 91.3 nmol/l. She was admitted for parenteral antibiotics and high dose hydrocortisone treatment. CT revealed bilateral juxta-ovarian masses (6.2×3.6×7.4 cm left and 5×2.2×3.2 cm right) that on MRI were iso-intense in T1 and hypo-intense in T2, with early enhancement and rapid washout. Trans-abdominal US found the same masses with no ovarian torsion. One week of high dose hydrocortisone resulted in significant clinical and laboratory improvement,and a multidisciplinary teem decided to continue conservative management. The patient was discharged with 2 mg dexamethasone per day. One-month later US revealed shrinkage of the masses and dexamethasone dose was decreased to 1 mg/day. At three months from discharge, she has resumed regular menses,and a repeated MRI (Figure 1) revealed the para-ovarian masseshaveshrunk to 2.7×2.4×5 cm on the left and 1.6×1.4×2.3 cm on the right. Dexamethasone levels were decreased to 0.25 mg/day. One year after the diagnosis, the paraovarian masses shrunk to 2.8×1.9×4.3 on the left (down from 4.6×3.3×7 cm) and 2.1×0.9×1.2 on the right (down from 2.5×1.6×3.9) with less contrast enhancement in comparison to previous test possibly due to fibrotic changes of the tissue
Conclusion
OARTs are rare tumors with a poorly known natural history, and surgery has been the first option in the few reported cases. We demonstrate here that medical treatment is a good alternative, leading to significant tumor shrinkage over a short period.

Is there an epithelial to mesenchymal transition (EMT) in adrenocortical tumours?

Iuliu Sbiera[1], Stefan Kircher[2], Annette Feuchtinger[3], Kerstin Höfner[1], Axel Karl Walch[3], Martin Fassnacht[1,4,5], Matthias Kroiss[1,4,5] & Silviu Sbiera[1,4]

[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University of Würzburg, Institute for Pathology, Würzburg, Germany; [3]Helmholtz Zentrum München, Research Unit Analytical Pathology, München, Germany; [4]University of Würzburg, Comprehenssive Cancer Center Mainfranken, Germany; [5]University Hospital Würzburg, Clinical Chemistry and Laboratory Medicine, Würzburg, Germany

Introduction
Adrenocortical carcinoma (ACC) is an aggressive tumour with unsatisfactory treatment options in advanced disease. Activation of epithelial to mesenchymal transition (EMT) has been described as causative of metastatic spread in human cancers. New drugs were developed targeting EMT with a focus on FGF/FGFR signalling. We here asked whether EMT is relevant in ACC.
Methods
We analysed 6 normal adrenal glands (NAG), 40 adrenocortical adenomas (ACA) and 55 ACC. Epithelial and mesenchymal markers were analysed

by IHC. Expression of FGFR1-4 was quantified using RNAscope and qRT-PCR was employed to quantify expression of 92 FGF-FGFR pathway genes. Isoform switching between FGFR isoforms IIIb (epithelial) and IIIc (mesenchymal) was assessed by qRT-PCR.
Results
Surprisingly, all adrenal tissues lacked E-cadherin expression while N-cadherin was present in both normal and neoplastic adrenal tissues but was significantly lower in malignant vs benign tissues (0.88 vs 1.64, $P=0.007$). SLUG had a uniformly high nuclear expression in all adrenal tissues. FGFR2 mRNA was expressed at lower levels in ACC compared to ACA (3.1 vs 5.2 mRNA copies/cell, $P=0.005$) whereas FGFR1 (8.2 vs 1.7, $P=0.0001$) and FGFR4 (5.5 vs 2.1, $P=0.0004$) were significantly higher in ACC. FGF/FGFR pathway analysis confirmed differential FGFR expression and revealed decreased expression of FGF7, FGF17 and mitogen associated protein kinases in tumors compared with NAG. Again surprisingly, all adrenal tissues had higher expression of IIIc vs IIIb isoform for FGFR. A brief comparison between adrenocortical tissues versus known epithelial tumors as well as mesenchymal tumors shows that in terms of the common markers, adrenal tissues are more mesenchymal than epithelial.
Conclusions
Normal but also tumoral adrenocortical tissues exhibit consistent expression of proteins considered to reflect mesenchymal differentiation. However, significant changes in expression of mesenchymal markers suggest their relevance in adrenocortical tumorigenesis and progression. Receptor tyrosine kinases FGFR1 and 4 may be also a suitable treatment target for advanced ACC.

Copy number determination of steroid 21-hydroxylase gene for the genetic testing of congenital adrenal hyperplasia using real-time quantitative PCR

Marton Doleschall[1], Otto Darvasi[2], Peter Igaz[1,3] & Attila Patocs[2]
[1]Eotvos Lorand Research Network - Semmelweis University, Molecular Medicine Research Group, Budapest, Hungary; [2]Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary; [3]Semmelweis University, 2nd Department of Internal Medicine, Budapest, Hungary

Congenital adrenal hyperplasia (CAH) is usually caused by the mutations of steroid 21-hydroxylase gene (*CYP21A2*). *CYP21A2* resides in RCCX copy number variation (CNV), and the genomic structure of RCCX CNV creates difficulties in the genetic testing of CAH. An RCCX CNV allele on one chromosome can carry *CYP21A2* in various numbers. Homozygous deletion of complete *CYP21A2* results in most severe form of CAH, whereas an additional and intact *CYP21A2* copy can replace the lost function of the other *CYP21A2* on the same chromosome. Therefore, the copy number determination of *CYP21A2* has got a profound impact in genetic testing of CAH.
The clinical chemistry validation of duplex real-time quantitative polymerase chain reaction (RT-qPCR) based on hydrolysis probes for the determination of *CYP21A2* copy number was performed on 18 genomic DNA samples from European reference population of HapMap project (CEU), 19 samples with good DNA quality and 12 samples with bad DNA quality. The validation of RT-qPCR for steroid 21-hydrosylase pseudogene and the verifications of RT-qPCRs for complement component genes, HERV-K(C4) CNV alleles and RCCX CNV breakpoint region were also achieved. Estimated limit of detection for *CYP21A2* RT-qPCR was lower than measurement concentration by two order of magnitude, and nonspecific PCR product was not detected by melting curve analysis and microcapillary electrophoresis. PCR efficiency was 1.019 ± 0.077, and linearity was $R^2=0.988\pm0.008$. Repeatability was 0.35 CV% and reproducibility was 0.57 CV%. Accuracy was 7.23 ± 4.28% of the *CYP21A2* copy number, however it was 15.15 ± 7.53% in samples with bad DNA quality. Both clinical sensitivity and specificity were 100%, however, a relatively small number of samples was examined ($n=49$). Robustness was not influenced by the smaller changes of PCR conditions, but different instrument and inadequate RT-qPCR reagent could diminish it. The validation and verification of RT-qPCR for the copy number of other genetic elements of RCCX CNV had got some flaws, however, their performance were reasonable.
The validation of RT-qPCR assay for the copy number determination of *CYP21A2* is fitted for the genetic testing of CAH. In case of need, ambiguous finding in *CYP21A2* copy number can be solved by the consideration of the copy numbers of other RCCX CNV elements.

Cytochrome P450 (CYP) 2W1 affect steroid secretion in adrenocortical cell line and tumor tissues

Barbara Altieri[1], Silviu Sbiera[1], Isabel Weigand[1], Marco Volante[2], Sonja Steinhauer[1], Antonia Lorey[1], Sabine Kendl[1], Max Kurlbaum[1], Sabine Herterich[3], Silvia Della Casa[4], Annamaria Colao[5], Massimo Terzolo[6], Matthias Kroiss[1], Martin Fassnacht[1] & CristinaRonchi[1,7]
[1]University Hospital of Würzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine I, Würzburg, Germany; [2]University of Turin, San Luigi Hospital, Department of Oncology, Turin, Italy; [3]University Hospital of Würzburg, Central Laboratory, Würzburg, Germany; [4]Catholic University of the Sacred Heart, Division of Endocrinology and Metabolism, Rome, Italy; [5]Federico II University, Department of Clinical Medicine and Surgery, Naples, Italy; [6]University of Turin, San Luigi Gonzaga Hospital, Division of Internal Medicine I, Turin, Italy; [7]Institute of Metabolism and System Research, University of Birmingham, Birmingham, United Kingdom

Background
The human cytochrome P450 (CYP) 2W1 is involved in the metabolism of several endogenous substrates, including lysophospholipids and fatty acids. Using a polyclonal antibody, we previously demonstrated a high CYP2W1 immunoreactivity in adrenocortical tumors, particularly in those secreting steroids. The aim of the study was to better elucidate the relationship between CYP2W1 and steroid secretion in adrenocortical carcinoma (ACC) H295R cell line and in a larger series of ACC tissues associated with different steroid secretion patterns.
Methods
H295R cells were stably transfected in order to achieve CYP2W1 overexpression, which was confirmed both at mRNA and protein levels. Mock-transfected H295R cells were used as controls. Steroid secretion was evaluated by liquid chromatography tandem-mass spectrometry (LC-MS/MS) using a panel of 13 steroids both at baseline (t0) and after 48h of 1 ∝M forskolin treatment (t1). For the immunohistochemistry (IHC) analysis 203 ACC tissue samples were collected, most of which pertained tumors that secreted cortisol and/or aldosterone alone ($n=64$, 31.5%), followed by endocrine inactive tumors ($n=49$, 24.1%), multiple secreting tumors, including cortisol in combination with other steroids ($n=46$, 22.7%), and androgen-secreting ACC ($n=44$, 21.7%). IHC was performed using a new highly specific monoclonal CYP2W1 antibody (sc374426, Santa Cruz). The relationship between cytoplasmic CYP2W1 immunoreactivity, measured by semi-quantitative H-score, and the steroid secretion pattern at the time of diagnosis was evaluated.
Results
In vitro, aldosterone levels were significantly higher in CYP2W1-transfected cells than in controls both at t0 (21.5 ± 9.2 fold change (FC), $P=0.02$) and t1 (18.3 ± 6.8 FC, $P=0.04$). Cortisol was significantly increased at t0 (3.9 ± 1.1 FC, $P=0.01$), whereas cortisone was higher at t1 (2.4 ± 0.6 FC, $P=0.01$). On the contrary, androgen levels were significantly lower in CYP2W1-cells, including DHEA (-2.1 ± 0.9 FC, $P=0.01$ at t0), DHEAS (-4.1 ± 0.1 FC, $P<0.001$ at t0; -2.00 ± 0.0 FC, $P<0.001$ at t1), androstenedione (-3.3 ± 0.1 FC, $P=0.04$ at t0; -3.7 ± 0.1 FC, $P=0.03$ at t1), and DHT (-2.0 ± 0.2 FC, $P=0.02$ at t1). At IHC analysis, the majority of ACC tissues (56.3%) had CYP2W1 immunoreactivity of H-score = 1. Particularly, CYP2W1 staining was lower in androgen-secreting tumors than in multiple-secreting cases ($P=0.003$), whereas a trend to lower immunoreactivity was observed compared to only cortisol- or aldosterone-secreting ones ($P=0.11$). No significant difference was found between inactive and secreting-ACC.
Conclusion
CYP2W1 may induce cortisol and aldosterone secretion and inhibit androgens secretion both in vitro and in ACC tissues. Further experiments investigating the steroidogenic pathway are needed to confirm our results.

Integrated genomics reveals different subgroups of primary bilateral macronodular adrenal hyperplasia (PBMAH)

Anna Vaczlavik[1,2], Lucas Bouys[1], Eric Letouze[3], Karine Perlemoine[1], Laurence Guignat[2], Franck Letourneur[1], Mathilde Sibony[1,4], Fidéline Bonnet[1,5], Victor Heurtier[1], Stéphanie Espiard[6], Guillaume Assié[1,2], Bruno Ragazzon[1] & Jerome Bertherat[1,2]
[1]Cochin, Paris, France; [2]Cochin hospital, Endocrinology, Paris, France; [3]Integragen, Paris, France; [4]Cochin hospital, Pathology, Paris, France; [5]Cochin hospital, Hormonology, Paris, France; [6]Lille Hospital, Endocrinology, Lille, France

Introduction
Primary bilateral macronodular adrenal hyperplasia (PBMAH) are benign adrenocortical disease responsible for benign tumors and cortisol autonomous secretion. There is a broad spectrum of clinical, imaging and hormonal presentations. Aberrant membrane receptor expression is frequent, the most characteristic example being the food dependent Cushing syndrome due to ectopic expression of the GIP receptor (GIP-R). In 20 to 25 % of these patients, inactivating heterozygous germline mutation of *ARCMC5* explains the development of the disease. The aim of this study was to characterize the molecular alterations in PBMAH and to see whether integrated genomics could identify molecular groups explaining this disease heterogeneity.
Methods
Nucleic acids were extracted from macronodules of adrenal frozen tissue collected in the COMETE tumor bank for 36 PBMAH operated patients. 15/36 patients had a germline *ARMC5* mutation. RNA and micro RNA have been sequenced using Illumina technology/Genomic platform, Cochin Institute. We used Illumina HumanCore BeadChips (306,702 SNPs) to analyze copy-number alterations in these samples, and Illumina MethylationEPIC BeadChip array (866,895probes) to profile DNA methylation.
Results
Half of the tumor samples did not show any chromosomal alterations. A copy neutral LOH of 16p (ARMC5 locus) was observed in 6 patients who carried an ARMC5 mutation. Gain at 1q was observed in 5 patients and gain at 9q21.11–9q34.3 (SF1 locus) in 3 patients. Using the 5000 more differentially methylated positions (SD based classification), we identified two clusters including one corresponding to the *ARMC5* mutated PBMAH. Similarly a specific miRNome profile is observed in the *ARCM5* PBMAH. Transcriptome analysis showed two main clusters: one containing the *ARMC5* mutated PBMAH and one with the WT PBMAH. Interestingly two sub-groups with different gene expression profiles were observed in the WT cluster, suggesting molecular heterogeneity in *WT* PBMAH. The GIP-R was over expressed in one of these two sub-group (fold change 5.8, $P = 5.7E-09$) suggesting a specific molecular profile for food-dependent Cushing PBMAH.
Conclusion
This is the first integrated genomic analysis of PBMAH. It demonstrates molecular heterogeneity of this disease. Three molecular classes of PBMAH determined by gene expression profile, methylome and miRNome are identified: one driven by *ARMC5* mutation and one characterized by GIP-R overexpression. The third one needs to be further investigated. This clusterisation will help to better understand PBMAH pathophysiology and to improve its classification.

Investigation of angiotensin II induced gene expression changes in vascular smooth muscle cells

András Balla[1,2], Laura Szalai[1,2], Janka Gém[1], Kinga Kovács[1], Gyöngyi Szakadáti[1] & László Hunyady[1,2]
[1]Semmelweis University, Department of Physiology, Budapest, Hungary; [2]Semmelweis University, MTA-SE Laboratory of Molecular Physiology, Budapest, Hungary

The angiotensin II (AngII) hormone exerts a number of biological effects through the type 1 angiotensin II receptor (AT1R). One of the main targets of AngII are vascular smooth muscle cells, their stimulation activates many signaling pathways and results in gene expression changes.
Affymetrix Gene Chip experiments were performed to analyze the effects of AngII stimulation on gene expression. For the determinations, aortic thoracic aorta from young male Wistar rats were usedto obtain primary vascular smooth muscle cells (VSMCs).In our experimental set-up more than 200 genes were upregulated in response to AngII stimulation in smooth muscle cells. In our further experiments, we investigated several genes whose transcription were significantly enhanced by AngII in primary VSMCs (DUSP5, DUSP6, DUSP10, Lmcd1, HbEGF, and endothelin). Our aim was to investigate the kinetics of the gene-expression changes, and to reveal the possible signal transduction processes which lead to the altered expression changes after AngII stimulation. The results of the quantitative PCR measurements also confirmed the increased expression of selected genes upon AngII stimulation. Transcription of most genes was largest two hours after AngII stimulation. Based on our results obtained with different inhibitors, several parallel signaling pathways, e.g. MAPK/ERK signaling may play an important role in the observed gene expression changs. We also investigated the role of epidermal growth factor receptor (EGFR) transactivation in AngII-induced gene expression changes. According to our data, EGFR transactivation does not play a significant role in the gene expression changes in response to AngII stimulation, since genetic silencing of EGFR did not significantlyabolish the AngII induced changes. In our experiments with kinase inhibitors, dasatinib, which acts primarily on the soluble tyrosine kinases ABL and Src, significantly inhibited the induced gene expression changes, suggesting that soluble tyrosine kinases may play an important role in AngII-induced long-term cellular responses. Our results suggest that not only one but parallel signal transduction pathways are responsible for the AngII induced gene expression changes and their effects may be synergistic. Our results may provide important data for understanding the molecular background of various cardiovascular diseases and may even identify novel therapeutic targets. This work was supported by the National Research, Development and Innovation Fund (NKFI K116954 and NVKP_16-1-2016-0039).

Structural instability of mutant variants of 21-Hydroxylase

Nicolas Meese[1], Pallabi Sil Paul[1], Martin Haslbeck[2], Angela Huebner[3] & Nicole Reisch[1]
[1]Klinikum der Universität München, LMU München, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Technical University of Munich, Department of Chemistry, Garching, Germany; [3]Universitätsklinikum Carl Gustav Carus, Technische Universität Dresden, Division of Paediatric Endocrinology and Diabetes, Dresden, Germany

Congenital adrenal hyperplasia (CAH) summarizes a group of genetic disorders of enzymes involved in cortisol biosynthesis. The most common causes detrimental mutations in the steroidogenic cytochrome P450 enzyme 21-hydroxylase (CYP21A2). Patients are dependent on a lifelong oral cortisol replacement therapy to ensure survival but quality of life is often reduced and co-morbidities are substantially increased. Also, the administered supraphysiological glucocorticoid dosescannot ideally mimic the circadian rhythm and stress adaption of cortisol secretion. Therefore, the goal of our research is to better understand the specific biophysico-chemical pathomechanism of functional 21-hydroxylase deficiency in order to develop new causative therapeutic approaches. In this work, we investigated the structural and stability properties of six clinically relevant mutant variants of CYP21A2 (V282G/L, P31L, D323G, R484Q/W).Structural and thermal stability were assessed by circular dichroism (CD) spectroscopy. Wild type enzyme showed high α-helical content (65% α-helix) as well as mutants at the position 282 (V282G: 60.6 %, V282L: 57.6%).The α-helical organization in other variants (P31L, D323G, R484Q/W) was more disrupted (42 – 48%) in exchange for mainly random coil. Thermal stability of all mutant variants was reduced (Tm: 41.5 – 45.1°C) compared to the WT (Tm: 47.6°C) in temperature dependent CD spectroscopy. Tryptophan fluorescence experiments to assess denaturant stability of mutant variants also showed higher susceptibility to local unfolding (3.42 – 4.30 M urea) at the hydrophobic core compared to WT using urea as denaturant. Furthermore, in UV/Vis spectroscopy at 280 nm and 418 nm we could demonstrate that all mutant variants had a reduced heme incorporation (A418/A280: 0.20 – 0.63) compared to WT (A418/A280: 0.88). Our results show that correct structural folding and stability pose a major problem in specific mutations involved in CAH. Therefore we propose that structural protein instability plays a key role in the pathophysiology of CAH and thus might constitute a novel tailored therapeutic target for the treatment of affected patients.

Introduction
Chronic hypercortisolemia during Cushing Syndrome (CS) determines significant changes in the plasticity and function of metabolic tissues like visceral adipose tissue (VAT). Persistence of alterations in VAT function after CS remission is under debate, as data of clinical studies is not consistent

due to confounder factors and limited availability of VAT. Animal model of reversible CS presents long-term alterations on VAT after remission. We investigate VAT alterations at transcriptional and epigenetic level during active and after CS remission employing a translational approach in a reversible CS animal model and CS patients.
Methods
VAT was obtained during abdominal laparoscopic interventions from 6 patients with active ACTH-independent CS due to adrenal cortical adenoma and from 12 controls (CTR) with benign non-inflammatory abdominal pathology matched by sex, age, BMI, metabolic and vascular comorbidities. VAT from C57BL/6 mice with active CS induced by chronic oral GC administration (5 weeks) and mice with cured CS (10 weeks after treatment) was compared to that of CTR mice. RNAseq and ChIPseq were used to analyze gene expression profile and histone mark H3K4me3, H3K27me3 and H3K27ac at both time points in the animal model and human VAT. Differentially expressed genes (DESeq2 algorithm, adj. $P<0.1$; fold-change ≥ 1.5) and putative histone marks associations present in patients were compared with those altered during active and cured CS in the animal model.
Results
Transcriptional analysis of mice VAT revealed 464 up and 366 significantly down-regulated genes persistently altered in active CS and after remission. Gene ontology analysis of the disrupted genes at both times resulted in several pathways and biological process including lipid metabolism, circadian rhythm and inflammation. Moreover, the H3K4me3 and H3K27ac peak- associated genes were commonly maintained at both time points and correlated well with alterations present on gene expression. RNAseq of human VAT showed 69 up and 76 significantly down-regulated genes in CS patients compared to CTR from which 14 genes were commonly altered in the animal model at both time points. Overall analysis of human H3K4m3, H3K27ac and H3K27me3 peaks revealed different profiles between CTR and CS patients. Correlation analysis of commonly altered genes and histone marks signature between mice and human is under process.
Conclusion
Chronic hypercortisolism induces persistent transcriptional disruption in mice VAT long term after remission, from which some are commonly altered in patients with active CS. Potential stable histone marks signatures associated to these persistent altered genes are under study.

Cortisol rhythm in patients with adrenal insufficiency switched from conventional glucocorticoids to dual release hydrocortisone: Impact on metabolic profile

Chiara Simeoli, Marina Iacono, Rosario Ferrigno, Mariarosaria Negri, Claudia Pivonello, Renata Simona Auriemma, Maria Cristina De Martino, Annamaria Colao & Rosario Pivonello
Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy

Background
Several evidences suggested that conventional glucocorticoids (CGCs) used as replacement treatment in adrenal insufficiency (AI) are inadequate to mimic physiological cortisol circadian rhythm (CCR), and that CCR disruption, represented by non-physiological pattern of peaks and troughs and elevated evening GC levels, might be responsible for the increased metabolic and, consequently, cardiovascular risk. It has been demonstrated that once daily dual-release-hydrocortisone (DR-HC), which better reproduces physiological CCR, significantly improves metabolic parameters in primary AI (PAI) and secondary AI (SAI) patients.
Aim
The aim of the current study was to evaluate CCR and metabolic profile in PAI and SAI patients switched from CGCs, particularly cortisone acetate and immediate-release hydrocortisone, to DR-HC.
Methods
Thirteen AI patients (7 SAI and 6 PAI, nine females and four males, 20–66 yrs) were enrolled. CCR ($AUC_{0\text{-}24\ hrs}$) was explored by collecting cortisol blood samples at selected time points (0700–1000 h, 1300–1600–1900–2100 h, 0100–0400–0700 h), at baseline (CGCs) and 12 months after switching to DR-HC. Anthropometric and metabolic parameters were evaluated with standard procedures in a fasting status (1900 h) in the entire cohort;glucose and insulin at fasting and during oral glucose tolerance test (OGTT) were evaluated in a subgroup of nine patients; surrogate indexes of insulin sensitivity/resistance, derived from OGTT, were calculated according to homeostasis model assessment-insulin resistance (HOMA-IR) and Insulin Sensitivity Index (ISI) Matsuda.
Results
Cortisol AUC (1900 h–0100 h) was significantly lower with DR-HC than with CGCs ($P=0.033$), and particularly, cortisol levels measured at 1900 h appeared lower with DR-HC than with CGCs ($P=0.042$). After 12 months of treatment, DR-HC induced a significant improvement in waist circumference ($P=0.004$), and a trend to a significant improvement in body mass index ($P=0.07$); in the subgroup of patients evaluated with OGTT, DR-HC induced a significant reduction in fasting insulin levels ($P=0.039$) and a significant increase in $ISI_{0'}$ ($P=0.012$) and $ISI_{120'}$($P=0.027$).However, no significant correlation was found between cortisol secretion pattern and metabolic changes.
Conclusions
The switch from CGCs to DR-HC in AI patients induces a significant decrease of late evening GC overexposure associated with a significant improvement of visceral obesity and insulin sensitivity. Therefore, this change might induce a beneficial effect on cardiovascular risk in AI patients treated with GCs.

Adrenal cortex is responsive to human chorionic gonadotropin stimulation in patients with adrenal incidentalomas

Antoan Stefan Sojat[1], Ljiljana Marina[1,2], Miomira Ivovic[1,2], Milina Tancic-Gajic[1,2], Zorana Arizanovic[1], Aleksandra Kendereski[1,2], Natalija Antic[2], Jelena Milin Lazovic[3], Sladjana Mihajlovic[2,4], Dragana Mitrovic[1] & Svetlana Vujovic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Department for Obesity, Metabolic and Reproductive Disorders, Serbia; [2]Faculty of Medicine, University of Belgrade, Serbia; [3]Institute of Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, Serbia; [4]University Hospital Centre Dr Dragisa Misovic

Introduction
It is well documented that adrenal tumor tissue is responsive to human chorionic gonadotropin (hCG) as well as to luteinizing hormone (LH) with both hormones sharing a similar physiological role and a mutual receptor.
Objective
The objective of our study was to assess the adrenal steroid response to acute, exogenous hCG stimulation in patients with adrenal incidenatalomas (AI) and for the first time, in a healthy control group.
Methods
Our study group consisted of 39 subjects, 34 patients with AI and 5 age matched healthy controls (63.54 ± 6.91 vs 65.8 ± 3.71 years, $P>0.05$). All patients underwent standard AI endocrinological evaluation. The morning after 1mg dexamethasone suppression test (1 mg DST), 10.000 IU hCG was administered intramuscularly to all subjects, starting at 0800 h with measurements of cortisol, dehydroepiandrosterone-sulfate, testosterone and aldosterone every 30 minutes for 3 hours. The partial response to hCG stimulation was considered as a hormone level raise for at least 25% and the full response for at least 50% during the test.
Results
Based on the cortisol level after 1 mg DST, AI patients were divided in two groups: 15 patients withnonfunctional AI (NAI) and 19 patients with (possible) autonomous cortisol secretion ((P)ACS). There was no difference in age nor in sex distribution between the groups. The only hormone which showed response was cortisol in 20 AI patients: 7 with NAI and 13 with (P)ACS. The cortisol response AUC was significantly higher in (P)ACSthen in NAI patients (15075 (9280.5–31224) vs 4134 (3361.5–4894.5), $P<0.001$).In the NAI group, 3 patients had partial and 4 had full cortisol response to hCG stimulation, while in the (P)ACS group, 6 patients had partial and 7 had full cortisol response. Although more patients with (P)ACS had a response in cortisol then patients with NAI (13 vs 7), there was no significant difference inthe frequency of partial or full cortisol response between the two groups. This suggests that both patients with NAI and (P)ACS are responsive to hCG stimulation in comparison to healthy controls who showed no response at all in all of the measured hormones.
Conclusion
Our results imply that hCG contributes to the cortisol secretion in both NAI and patients with (P)ACS but not healthy individuals. Patients with (P)ACS showed significantly higher cortisol response than NAI. These findings suggest a possibility of cortisol secretion modulation or control through a suppression of luteinizing hormone secretion or action in patients with (P)ACS.

Introduction

PBMAH is a rare but heterogeneous disease, characterized by multiple benign adrenal macronodules with variable levels of cortisol excess. In 2013, our team discovered germline heterozygous inactivating mutations of *ARMC5*, acting as a tumor suppressor gene. *ARMC5* mutation rate is 50% in patients with PBMAH treated by adrenalectomy for severe hypercortisolism, 80% in familial cases and 20% in sporadic cases according to the current literature. The aim of this study was to identify predictive criteria for *ARMC5* mutation.

Methods

Since 2014, 454 French and European index PBMAH cases have been genotyped for *ARMC5* in Cochin Institute or in the Genetic Department of Cochin Hospital. To date, among these 454 patients, we have reviewed the 264 consecutive index cases referred from five endocrinology French departments belonging to the COMETE network. A retrospective analysis of the clinical, radiological and biological data was done with a central review of the adrenal CT-scans.

Results

Sixty-five out of the 454 index cases (14.3%) present a germline inactivating *ARMC5* mutation. Similarly, 40 (15.2 %) out of the subgroup of the 264 reviewed patients had a germline *ARMC5* mutation. Patients with *ARMC5* mutations have a more severe disease than wild-type patients, in terms of cortisol excess (UFC 1.92 [0.2 −12.1] vs 0.84 [0.08 − 10.1] fold ULN, respectively, $P=0.017$), adrenal morphology (10.8 [2–27] vs 3.4 [1–13] nodules, respectively, $P<0.001$) and complications (87.5 vs 68.3% of patients treated for hypertension, respectively, $P=0.013$). 100% of the mutated patients have bilateral adrenal nodules AND plasma cortisol after dexamethasone 1 mg suppression test above 50 nmol/l, only 61.6% of the non-mutated patients have these two associated criteria. Therefore, the 100% negative predictive value of the association of bilateral nodules and autonomous cortisol secretion allows to exclude *ARMC5* mutation when both are absent. Using more stringent criteria improved the specificity for *ARMC5* mutations : among the mutated patients, 75.9% had at least 4 and 65.5% had at least 6 adrenal nodules, vs 18.0 and 6.8% of wild-type patients respectively, improving the mutation rate to 37.3% and 57.6%, respectively. However by using these criteria some mutated patients would be missed (24.1 and 34.5%, respectively).

Conclusion

Restricting the indication of *ARMC5* sequencing to patients with bilateral adrenal nodules and a cortisol above 50 nmol/l after 1 mg dexamethasone suppression test could avoid useless genotyping in a third of patients, and would allow a cost and time economy and earlier results, without missing any mutated patient.

Prevalence and incidence of atrial fibrillation in a large cohort of adrenal incidentalomas: A long-term retrospective study

Guido Di Dalmazi, Valentina Vicennati, Carmine Pizzi, Cristina Mosconi, Lorenzo Tucci, Caterina Balacchi, Eugenio Cosentino, Pasquale Paolisso, Flaminia Fanelli, Alessandra Gambineri, Carla Pelusi, Andrea Repaci, Silvia Garelli, Nazzareno Galiè, Claudio Borghi, Rita Golfieri & Uberto Pagotto

University of Bologna, Bologna, Italy

Background

Chronic glucocorticoids excess leads to morphological and functional cardiac alterations, a substrate for arrhythmias. Autonomous cortisol secretion (ACS) from adrenal incidentalomas is a model of chronic endogenous hypercortisolism, leading to severe cardiovascular diseases.

Aim

To investigate prevalence and incidence of atrial fibrillation in a large cohort of patients with adrenal incidentalomas and ACS.

Methods

After excluding pheochromocytoma, primary aldosteronism, Cushing syndrome, congenital adrenal hyperplasia, and adrenal malignancy, we included 632 patients with adrenal incidentalomas evaluated between 1990 and 2018, aged 18-90 years old. Cortisol after 1 mg-dexamethasone suppression test (DST) < or >50 nmol/l defined non-secreting tumors (NS, $n=420$) and ACS ($n=212$), respectively. We evaluated the prevalence of atrial fibrillation at the time of first evaluation for the adrenal mass. We calculated the incidence of atrial fibrillation during a mean follow-up of 8.6 years (range 6 months-23 years), by retrospective data analysis of 357 patients (249 NS, 108 ACS). Contributing factors associated with prevalence and incidence of atrial fibrillation were analyzed by regression models.

Results

The prevalence of atrial fibrillation was higher in patients with ACS (8.5%) than NS (3.1%, $P=0.003$) and the general population (1.7%; $P<0.001$ vs ACS, $P=0.034$ vs NS). The age-adjusted rate ratio was 1.0 for NS and 2.6 for ACS, compared to the general population. Atrial fibrillation was associated with ACS (Odds ratio 2.40; 95% confidence interval [CI] 1.07–5.39; $P=0.035$). The proportion of patients with atrial fibrillation at the end of follow-up was higher in ACS (20.0%) than NS (11.9%; $P=0.026$). Patients with ACS showed a higher risk of incident atrial fibrillation than NS (HR 2.95; 95% CI 1.27–6.86; $P=0.012$). Post-DST cortisol was associated with risk of atrial fibrillation (HR 1.15; 95% CI 1.07–1.24; $P<0.001$).

Conclusion

Patients with adrenal incidentalomas and ACS are at risk of atrial fibrillation. Electrocardiographic monitoring may be recommended during follow-up.

Background
LC-MS/MS is recommended for accurately measuring circulating steroids. However, laboratories using LC-MS/MS adopt various pre-analytical and analytical strategies, and little is known about comparability of results. Whether different blood derivatives impact LC-MS/MS measurements is unclear, and the benefit of unifying the calibration system among laboratories was not tested.
Aim
Comparisons of LC-MS/MS measurements of circulating aldosterone (Al), corticosterone (B), cortisone (E), cortisol (F), 11-deoxycortisol (11S), 17OH-progesterone (17OHP4), androstenedione (A4), testosterone (T) and DHEAS among 9 European centers. Analysis of the impact of different blood specimens. Assessment of potential benefit of unifying the calibration system.
Methods
Thirteen female and 13 male adult patients in fasting state provided blood between 0800–0900 h into gel separator (gel-serum), beads clot-activator (beads-serum) and Li-heparin (plasma) tubes. Each laboratory analyzed two aliquots of 78 total samples according to laboratory specific procedures. Quantitation was obtained using in house, EUM01041 (BSN, Italy) (external set 1) and 6PLUS1 (Chromsystems, Germany) (external set 2) calibrators. Data were analyzed as inter-laboratory CV.
Results
Median (min-max) CV% were: female range-T, 6.2 (3.0–12.5); E, 6.4 (2.9–12.6); male range-T, 7.0 (4.1–10.9); DHEAS, 7.7 (4.3–14.0); B, 10.9 (4.2–26.5); A4, 11.0 (6.5–21.6); F, 13.0 (6.4–27.3); 11S, 13.5 (5.4–39.0); 17OHP4, 13.8 (6.3–34.0) and Al, 14.4 (6.0–24.1). Samples showing CV > 15% were 0.0% for T, E and DHEAS, and 16.7, 43.6 and 44.9% for B, 17OHP4 and Al, respectively, with minimal differences among specimens. When gel-serum, plasma and beads-serum were separately analyzed, cases with CV > 15% were 38.5, 7.7 and 0.0% for A4, 61.5, 30.8 and 26.9% for 11S, and 61.5, 30.8 and 30.8% for F, respectively. When changing in house calibration with external sets 1 and 2, samples showing CV > 15% were 15.4, 3.8 and 6.4% for A4; 16.7, 32.1 and 26.9% for B; 39.7, 38.5 and 73.1% for 11S; 41.0, 0.0 and 0.0% for F; 43.6, 66.7 and 24.4% for 17OHP4; 44.9, 47.4 and 28.2% for Al; and overall < 5% for T, DHEAS and E.
Conclusions
Inter-laboratory variability was good for T, DHEAS and E, moderate for A4 and B, and poor for 11S, Al, 17OHP4 and F. A4, 11S and F variability worsened with the gel-serum specimen. Unifying the calibration system dramatically improved A4 and F, worsened B, and variably impacted 11S, 17OHP4 and Al measurement comparability. Our data suggest that blood derivatives should be carefully evaluated by each procedure. Caution is required when adopting external calibration as it may not result in improving the harmonization of results.

Multiple hormonal deficiency in heart failure with preserved ejection fraction: Prevalence and role in modulation of antioxidant levels and myocardial dysfunction indexes

Carmine Bruno[1], Edoardo Vergani[1], Rodolfo Calarco[1], Maria Anna Nicolazzi[1], Angela Maria Rita Favuzzi[1], Claudia d'Abate[1], Andrea Silvestrini[2], Elisabetta Meucci[2], Alvaro Mordente[1] & Antonio Mancini[1]
[1]Fondazione Policlinico Universitario A Gemelli IRCCS, Università Cattolica del Sacro Cuore, Dipartimento di Medicina e Chirurgia Traslazionale, Rome, Italy; [2]Fondazione Policlinico Universitario A Gemelli IRCCS, Università Cattolica del Sacro Cuore, Dipartimento di Scienze biotecnologiche di base, cliniche intensivologiche e perioperatorie, Rome, Italy

In heart failure with reduced ejection fraction, catabolic mechanisms have a strong negative impact on mortality and morbidity. The relationship between anabolic hormonal deficiency and heart failure with preserved ejection fraction (HFpEF) has still been poorly investigated. On the other hand, oxidative stress is recognized as a player in the pathogenesis of HFpEF. Therefore, we performed a cohort study in HFpEF in order to: 1) define the multi-hormonal deficiency prevalence in HFpEF patients; 2) investigate the relationships between hormonal deficiencies and echocardiographic indexes; 3) explore the modulatory activity of anabolic hormones on antioxidant systems.
Methods
84 patients with diagnosis of HFpEF were enrolled in the study. Plasma levels of N-terminal pro- brain natriuretic peptide, fasting glucose, insulin, lipid pattern, insulin-like growth factor-1, dehydroepiandrosterone-sulfate (DHEA-S), total testosterone (T, only in male subjects) were evaluated. Hormonal deficiencies were defined according to T.O.S.C.A. multi-centric study, as previously published[1]. An echocardiographic evaluation was performed. Plasma total antioxidant capacity (TAC) was measured using the system metmyoglobin -H2O2 and the chromogen ABTS, whose radical form is spectroscopically revealed; latency time (LAG) in the appearance of ABTS•is proportional to antioxidants in sample.
Multiple deficiencies were discovered. DHEA-S deficiency in 87% of patients, IGF-1 in 67% of patients, T in 42%. Patients with DHEA-S deficiency showed lower levels of TAC expressed by LAG (mean ± SEM 91.25 ± 9.34 vs 75.22 ± 4.38 sec; $P < 0.05$). No differences between TAC in patients with or without IGF-1 deficiency were found. A trend toward high level of TAC in patients without hormonal deficiencies compared with patients with one or multiple deficiencies was found.
Regarding echocardiographic parameters, Left Atrial and Left Atrial Volume Index were significantly higher in patients with low IGF-1 values (mean ± SEM 90.84 ± 3.86 vs 72.83 ± 3.78 ml; 51.03 ± 2.33 vs 40.56 ± 2.46 ml/m^2, respectively; $P < 0.05$).
Our study showed high prevalence of anabolic deficiencies in HFpEF. DHEA-S seems to influence antioxidant levels; IGF-1 deficiency was associated with alteration in parameters of myocardial structure and dysfunction. These data suggest a role of anabolic hormones in the complex pathophysiological mechanisms of HFpEF and could represent the basis for longitudinal studies and investigations on possible benefits of replacement therapy.

Introduction
The management of patients with adrenal incidentaloma (AI) and possible subclinical hypercortisolism (SH) is debated. This randomized study was aimed to evaluate the effects of adrenalectomy on arterial hypertension (AH).
Methods
We consecutively evaluated 590 AI patients (referred to 3 Italian Centres between 06/2016 and 12/2019). Among these, 134 patients showed a possible SH (i.e. 1 mg DST between 1.8 and 5 µg/dl). Based on the exclusion criteria we enrolled 56 SH patients (42 F). Patients were randomized in two groups: surgery (Group 1, $n = 23$) or conservative follow up (Group 2, $n = 30$) (3 patients withdrew their consent). Presence of AH was evaluated at baseline and at 6–12 months in the two groups.
Results
So far, 23 patients (9 in Group 1 and 14 in Group 2, mean age 65.1 ± 8.2 years, adenoma diameter 3.0 ± 0.65 cm, 1 mgDST 3.0 ± 2.1 µg/dl) have completed the 6 months follow up. At baseline, the main clinical and biochemical characteristics of the two groups were comparable. In particular, 4/9 patients from Group 1 and 11/14 from Group 2 were hypertensive.
After 6 months, in Group 1 AH improved in all 4 hypertensive patients (1 patient stopped therapy, 2 patients passed from a grade 1 AH to an high-normal blood pressure –BP- without therapy changing, and 1 patient maintained adequate BP despite reducing therapy dose). All non-hypertensive patients ($n = 5$) presented steady BP. In Group 2, 4 patients (28%) worsened the BP control (2 hypertensive patients worsened AH grade and 2 not hypertensive patients at baseline became hypertensive). However, 2 patients (14%) passed

from a grade 1 AH to a high-normal BP without therapy modifications. The remaining8 patients maintained a stable BP control.
Currently,15 patients (5 in Group 1 and 10 in Group 2) have completed the 12 months follow up. The patient from Group 1, who improved AH at 6 months, maintained stable BP levels, while among the remaining patients, including the other hypertensive one, BP remained unchanged vs baseline. Among patients from Group 2, 2 hypertensive patients (20%) worsened BP control, 1 patient (10%) ameliorated the BP control thanks to the increase of the AH therapy, whereas the other 5 hypertensive and the 2 non-hypertensive patients remained stable.
Conclusion
These preliminary data suggest that adrenalectomy has a beneficial role on hypertension in SH patients.

A double-blind, randomized, placebo-controlled phase 3 study to assess the efficacy and safety of relacorilant, a selective glucocorticoid receptor modulator, in patients with hypercortisolism due to cortisol-secreting adrenal adenoma(s)/hyperplasia

Iacopo Chiodini[1], Andreas Grauer[2], Andreas Moraitis[2] & Massimo Terzolo[3]
[1]University of Milan, Milano, Italy; [2]Corcept Therapeutics, Menlo Park, United States; [3]University of Turin, Torino, Italy

Relacorilant is a highly selective glucocorticoid receptor modulator that antagonizes the effects of excess cortisol while showing no significant affinity for the mineralocorticoid and progesterone receptors. In a Phase 2 study in patients with endogenous hypercortisolism, relacorilant demonstrated improvements in glycemic and hypertension control with no treatment-related hypokalemia or antiprogesterone effects. An international, multicenter, Phase 3 clinical trial, using randomized withdrawal after 22 weeks (22 wk) of open-label treatment, is currently underway to evaluate the efficacy and safety of relacorilant in hypercortisolism of various etiologies (GRACE Study: NCT03697109). In this study, evidence of hypercortisolism must be documented through 2 independent biochemical tests and at least 2 clinical signs and symptoms. Here, we introduce GRADIENT, a double-blind, randomized, placebo-controlled Phase 3 study in approximately 130 patients with less-severe hypercortisolism secondary to adrenal adenoma(s) or hyperplasia. Clinical entry criteria for patients 18–80 years old include a radiologically confirmed adrenal lesion, a biochemical diagnosis of autonomous cortisol secretion, and either impaired glucose tolerance/diabetes mellitus (IGT/DM) and/or hypertension. Participants will receive relacorilant (100 mg/day, titrated to 400 mg/day, as tolerated) or placebo over 22 wk. Biochemical criteria for entry into the study include serum cortisol >1.8 µg/dl after dexamethasone suppression testing and low (<15 pg/dl) or suppressed morning ACTH levels. Patients must be stable on their antidiabetic and/or antihypertensive agents for at least 4 weeks prior to the first dose of relacorilant. The primary efficacy endpoints are the mean change in $AUC_{glucose}$ from baseline to 22 wk for the IGT/DM group and mean change in systolic blood pressure (based on ambulatory blood pressure monitoring) for the hypertension group. Secondary endpoints include changes in weight, waist circumference, quality of life, trabecular bone score, and coagulation markers. The safety analysis will be performed for all patients who received at least one dose of study drug. GRADIENT will be the first double-blind, randomized, placebo-controlled study to test if patients with less severe hypercortisolism secondary to cortisol-secreting adrenal adenoma(s) or hyperplasia benefit from medical treatment.

Aetiology, clinical presentation and mortality of Addison's disease in India: A retrospective follow-up study over 14 years

Eesh Bhatia[1], Gunna Sri Harsha[1], Rungmei SK Marak[2], Rakesh Pandey[3] & Liping Yu[4]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Microbiology, Lucknow, India; [3]Sanjay Gandhi Postgraduate Istitute of Medical Sciences, Pathology, Lucknow, India; [4]Barbara Davis Centre fro Childhood Diabetes, Denver, United States

Background
Autoimmune destruction is the most common aetiology of primary adrenal insufficiency (PAI) in Europe and north America. In contrast, tuberculosis is a common cause of PAI in developing countries. More recently, adrenal histoplasmosis (AH) is being increasingly reported from India
Aims
To study the aetiology, clinical presentation and mortality in adults with PAI who were diagnosed between 2006-2019 and to determine the changes in aetiology since an earlier study conducted between 1991–1999.
Materials and methods
We conducted a retrospective study of 89 patients (age 15–83 years), diagnosed with PAI between 2006– 2019. An infective pathology was suspected if adrenals were enlarged ($n=65$). Adrenal biopsy was performed in 60 patients. AH was diagnosed by demonstrating *Histoplasma* on staining/culture; adrenal tuberculosis (AT) by granulomas, culture/GeneXpert positive for *M. tuberculosis*, or clinical response to anti-tuberculous therapy (ATT); autoimmune aetiology by normal adrenal size, 21-hydroxylase (21-OH) antibody positivity and/or presence of other autoimmune disorders. Patients received anti-fungal/ATT as per guidelines.
Results
Median duration of symptoms prior to presentation was 6 months. Common presentations were anorexia (97%), weight loss (97%), hyperpigmentation (89%), abdominal pain (36%), and fever (48%). Forty-two (47%) patients presented with acute adrenal crisis. The most frequent aetiologies were AH (45%), tuberculosis (19%) and autoimmunity (25%). Forty-five percent of patients with AH were initially misdiagnosed as AT. Patients with AH were similar to those with AT in their clinical presentation, except for shorter duration of symptoms before follow-up. 21-OH antibody was noted almost exclusively in patients with autoimmune aetiology (41%) and only 1/41 (2%) with infective aetiology. Overall mortality was 18%, over follow-up of 38 (range 1–158) months. Mortality was significantly greater among AH (30%), compared with AT (6%) and autoimmune PAI (5%) ($P<0.001$ between 3 groups) patients. As compared with our earlier report of patients seen in 1991-99[1], where AH was not diagnosed in any patient, AH was now the most common aetiology of PAI.
Conclusions
A recent appearance of AH was noted over the last 15 years. AH was difficult to differentiate from AT on clinical features alone. Despite appropriate therapy, patients with AH had a worse prognosis compared to other aetiologies of PAI.

Genes mediating cell growth in aldosterone-producing adenomas

Yuhong Yang[1], Martina Tetti[2], Paolo Mulatero[2], Holger Schneider[1], Martin Reincke[1] & Tracy Ann Williams[1,2]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, LMU München, Munich, Germany; [2]Division of Internal Medicine and Hypertension, Department of Medical Sciences, University of Turin, Turin, Italy

Objective
Aldosterone-producing adenomas (APA) are a major cause of primary aldosteronism. Somatic mutations explain the excess aldosterone production in the majority of patients with APA with mutations in *KCNJ5* encoding a potassium channel the most prevalent in most reported populations. Mechanisms driving cell proliferation are largely undefined.
Design and method
Quantitative transcriptome analysis using RNA-seq was used to identify differentially expressed genes between macro-APAs ($n=9$, diameter ≥30 mm) and micro-APAs ($n=12$, diameter ≤10 mm). Validation of RNA-seq data by TaqMan real-time PCR was performed for 14 genes in a broader cohort of APAs (NMD, no mutation detected, $n=28$; *KCNJ5*-mutated, $n=43$).
Results
Hierarchical cluster analysis of the 500 genes with largest coefficient of variation indicated sample clustering based on genotype (*KCNJ5* or NMD) and APA diameter. Differential expression of 155 and 348 genes was found between micro- and macro-APAs with *KCNJ5* mutations and NMD, respectively. Among the top 5 overrepresented Gene Ontology terms (biological process), cell death was exclusively enriched in NMD micro- vs

NMD macro-APAs. The expression levels of 10 genes were validated with a potential function related to cell growth. Expression of *BEX1* (a reported tumour suppressor) was 2.8-fold down regulated in macro-APAs relative to micro-APAs ($P<0.001$), and a linear negative correlation of *BEX1* expression with APA diameter was observed in NMD APAs ($r=-0.501$, $P=0.007$). A human adrenocortical cell line with stable expression of *BEX1* was established and showed that *BEX1* induced a reduction in cell viability (difference $P<0.01$ from control cells) and an increase in aldosterone production (2.9-fold increase, difference $P<0.0001$ from control cells).
Conclusions
PA display distinct transcriptome profiles according to adenoma diameter and we show a potential dual function for *BEX1* in APA pathophysiology in adrenocortical cell growth and aldosterone production.

Transcriptomic profiling of canine adrenocortical tumors

Karin Sanders, Frank van Steenbeek & Sara Galac
Faculty of Veterinary Medicine, Utrecht University, Clinical Sciences, Utrecht, Netherlands

Adrenocortical carcinoma (ACC) is an aggressive cancer, with, in its advanced stages, a median 5-year survival rate of less than 15%. ACC is rare in humans, but in dogs the incidence is at least 100 times higher. Because these dogs receive medical care, have an intact immune system, and have inter-individual and intratumoral heterogeneity, the dog is a unique spontaneous animal model to study new treatment options for ACC. However, to determine similarity of canine and human ACCs, a more in-depth analysis is required. We therefore sequenced the whole transcriptome of 36 canine cortisol-secreting adrenocortical tumors. Bulk RNA was sequenced with the CEL-seq method to produce paired-end 75 base long reads, and reads were aligned to the canFam3 reference genome. After quantification, reads were converted to reads per kilobase of transcript per million reads sequenced (RPKM). Statistics included the Log Rank test for survival analysis and the independent t-test for differences between groups. The tumors were previously classified as either low risk of recurrence tumors (LRT; $n=13$) or moderate-high risk of recurrence tumors (MHRT; $n=23$) based on our newly developed histopathological Utrecht score (a canine variant of the Weiss score). However, in principal component analysis, these groups did not cluster apart. Unbiased clustering analysis divided the tumors into two main groups: 1 and 2. Survival analysis showed that group 2 had a significantly shorter estimated median survival time after adrenalectomy (30 ±5 months) than group 1 (74 ± 7 months) ($P<0.0001$). Significantly upregulated genes in group 2 included several genes also known to be upregulated in human ACCs when compared to adrenocortical adenomas, e.g., TOP2A, PTTG1, CDC2, and ASPM. In addition, genes differentially expressed between the groups included genes important in adrenocortical development such as SHH, but also genes not previously linked to adrenocortical development or tumorigenesis such as CCDC33, HK2, and CYP26B1. The results of this study greatly increase our understanding and improve the classification of canine adrenocortical tumors. This brings valuable insight into how comparable canine ACCs are to human ACCs, and for which treatment targets dogs with spontaneous ACC are a suitable animal model. In addition to previously identified factors in adrenocortical tumorigenesis, these results identify new factors that not only improve our understanding of ACC, but could also be targeted therapeutically.

Psychosocial determinants of body acceptance and quality of life in women with congenital adrenal hyperplasia

Lea Tschaidse[1], Marcus Quinkler[2], Anna Nordenström[3,4], Hedi Claahsen van der Grinten[5] & Nicole Reisch[1]
[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany; [2]Endokrinologie Charlottenburg, Berlin, Germany; [3]Karolinska University Hospital, Astrid Lindgren Children's Hospital, Pediatric Endocrinology Unit, Stockholm, Sweden; [4]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden; [5]Radboud University Medical Center, Radboud Institute for Molecular Life Sciences, Amalia Children's Hospital, Department of Pediatric Endocrinology, Nijmegen, Netherlands

Background
Women with congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency have a poor Quality of Life (QoL) compared to the general population and are less satisfied with their body appearance. Data indicates that psychosocial determinants such as good professional and general support could be associated with an improved QoL. Since there is only little data available that has been deduced from samples of small size this effect should be further examined.
Methods
Data of 203 women with CAH aged from 15 – 68 was collected as part of the multicenter dsd-LIFE study performed in 14 specialized centres in 6 European countries. To assess psychosocial determinants, we performed an explorative factor analysis including items of the PRO Questionnaire concerning the participants' satisfaction with their treatment and support in childhood and adolescence, as well as in adulthood. We then built multiple regression models to examine the influence of these psychosocial determinants on the participants' body acceptance and QoL, using the Body-image-Scale (BIS) and the WHOQOL-BREF.
Results
The factor analysis revealed two psychosocial factors which were both significant predictors for all four WHO domains of QoL (physical health, psychological health, environment, social relationships). One of these factors contained items describing the participants' satisfaction with care in the last 12 months and was the most important predictor for the QoL domains psychological health, environment and social relationships. The other factor represented satisfaction with care in childhood and adolescence as well as satisfaction with general support in childhood, adolescence and adulthood. Of these two only this factor was a predictor for body acceptance.
Conclusion
These results show that psychosocial factors such as general and family support, or social interactions with professionals have a significant impact on QoL and body acceptance in adult CAH females. This should be taken into account regarding long-term follow up and multimodal therapy.

The study of cell senescence in cortisol-producing adrenocortical adenoma

Xin Gao[1], Yuto Yamazaki[1], Jacopo Pieroni[2], Yuta Tezuka[3], Kei Omata[3], Yoshikiyo Ono[4], Ryo Morimoto[4], Yasuhiro Nakamura[5], Fumitoshi Satoh[3] & Hironobu Sasano[1]

Introduction
Aging is associated with the pathogenesis of many endocrinological disorders, especially for functioning adrenocortical disorders. In addition, mitochondria DNA abnormalities have been reported to be correlated with aging through ROS which eventually resulted in cell senescence. We previously reported that cortisol-producing adenomas (CPA) expressed more abundant cell senescent markers including p16 and p21, compared to other hormone-producing adenomas. However, the detailed pathophysiology of cell senescence and its association with histological features (compact and clear cells) in CPAs have remained unknown. Therefore, we analyzed cell senescent markers examined their correlation with clinicopathological factors in CPA including compact and clear cells respectively. *In vitro* study was performed with exposure to cortisol using H295R cell lines to explore the pathogenesis of cell senescence caused in cortisol-producing lesions.
Materials and methods
We immunolocalized p16, p21,p53 and ki67 in 20 CPAs. mtDNA abnormalities were examined in 20 CPAs, 10 adjacent ZF of CPA and 6 non-functional adenoma (NFA). mtDNA deletion was evaluated by nested-PCR, mtDNA copy number was studied by the relative ratio of copy number compared with diploidy of nuclear-coding genes using real-time PCR. *In vitro* study was performed in H295R cell lines with 10 nM hydrocortisone treatment.
Results
mtDNA copy number of CPA and tumoradjacent ZF were significantly lower than that of NFA. On the other hand, 4977bp mtDNA deletion was more frequently detected in CPA (53%) and adjacent ZF (50%) than in NFA (17%) and CPAs with 4977bp mtDNA deletion harbored higher serum cortisol level than those without 4977bp mtDNA deletion. p53 and Ki-67

were significantly higher in clear than compact tumor cells. However, immunoreactivities of CYP11B1, CYP17A1 and p16 as well as mtDNA copy number were significantly higher in compact than in clear tumor cells. *In vitro* study demonstrated that cortisol could increase p53 and p21 mRNA level, resulting in subsequent suppression of CDK4/6 and cell proliferation in H295R cells.
Discussion
We firstly demonstrated that excessive cortisol did induce cellular and mitochondrial senescent phenotype in CPA as the results of lower mtDNA copy number, frequent mtDNA deletion and higher expression of p21. GR could be involved in the regulation of cell senescence and could possibly control the cell cycles in adrenocortical cells. This study also firstly demonstrated that compact tumor cells harbored high hormonal activity but low proliferative ability while clear cells harbored relatively quiescent but relatively high proliferative ability than compact cells resulting in marked biological intratumoral heterogeneityof CPA.

Mortality in patients with adrenal incidentalomas and autonomous cortisol secretion

Albin Kjellbom[1,2], Henrik Olsen[1,2], Ola Lindgren[1,2] & Magnus Löndahl[1,2]
[1]Skane University Hospital, Department of endocrinology, Lund, Sweden; [2]Lund University, Faculty of medicine, department of clinical sciences, Lund, Lund, Sweden

Background
Autonomous cortisol secretion (ACS) in patients with adrenal incidentalomas (AI) has been associated with increased mortality in previous small studies. Our aim was to evaluate if ACS is a risk factor for mortality in a large population of patients with AI.
Methods
Consecutive patients examined for adrenal adenomas, found as AI, without catecholamine or aldosterone hypersecretion between 2005 and 2015 were included and followed for up to 14 years (Clinicaltrials.gov, NCT03919734). Patients were grouped according to predefined levels of cortisol after 1-mg dexamethasone suppression test (DST) (< 50, 50–83, 84–138 and >138 nmol/l). Controls matched for sex and age were randomly selected from the general population (3:1 ratio). Mortality data were collected from the National Registry. Mortality rates were adjusted for age, sex and cardiovascular risk factors.
Results
3980 individuals were included, 995 patients and 2985 controls, of which 170 and 429 died (mean follow-up-time 6.9 years). Mortality rates were similar between controls and patients with DST < 50 ($n = 561$) and DST50-83 ($n = 267$), hazard ratio (HR) 0.98 (0.73–1.30) and HR 0.96 (0.70–1.32). Compared to DST < 50, mortality was similar in the DST50–83 group, HR 1.26 (0.86–1.85).
DST84-138 ($n = 105$) and DST > 138 ($n = 62$) had increased mortality both compared to controls, HR 1.80 (1.19–2.74) and HR 4.06 (2.31–7.15) respectively, and to DST < 50, HR 2.13 (1.38–3.29) and HR 2.91 (1.73–4.89) respectively.
Conclusion
In patients with an AI, a cortisol after DST > 83 nmol/l seems to be a clinically significant risk factor for mortality, while a lower value indicates a risk comparable to the general population.

Real life experience of 8 people with adrenal insufficiency using subcutaneous hydrocortisone infusion in continuous and pulsatile regimens recruited through hydrocortisone pump support group

Phillip Yeoh[1,2] & Jennifer Kenworthy[3]
[1]King's College London - Waterloo Campus, London, United Kingdom; [2]The London Clinic, London, United Kingdom; [3]UK cortisol pump group, United Kingdom

Real life experience of 8 people with adrenal insufficiency using subcutaneous hydrocortisone infusion in continuous and pulsatile regimens recruited through hydrocortisone pump support group

Background
Subcutaneous hydrocortisone (HC) infusion using continuous (CSHI) and pulsatile (PSHI) regimes are treatment options for adrenal insufficiency. It is an off-labelled treatment in UK for patients with adrenal insufficiency (AI). Both treatment aim to mimic natural body circadian rhythm of cortisol production. Continuous regimes deliver a consistent rate of hydrocortisone using an Insulin Pump, programmed to mimic a circadian rhythm. Pulsatile regimes use a pump developed specifically for hydrocortisone and aim to more closely replicating circadian rhythms by delivering extra hydrocortisone at mealtimes.
We surveyed 8 cohorts via Cortisol Pump UK support group in Facebook to capture their data in the following area:
Quality of Life AddiQoL scores
24 hours infusion doses & type of regimens
HC doses according to body surface area (BSA)
A&E, hospital admission before & after starting on HC pump
Improvement since started on HC pump
Challenges with HC pump.
Survey Monkey conducted in February 2019
Results
Mean age 47 (31–51); All female; Mean AddiQoL score 87.5/120 with 2 primary AI, 2 unknown, 4 secondary AI. 6 on continuous subcutaneous hydrocortisone infusion and 2 on pulsatile subcutaneous hydrocortisone infusion. Mean length of time on infusion 12 months (10 days - 22 months); mean body surface area dose per day 17.425 mg.
Conclusion
Those with daily dose between 20- 25mg has a higher mean AddiQoL score compare to those with a daily dose above 30mg (100/120 vs 80/120).
Mean daily rate per body surface area is higher than previous studies. A&E visits and hospital admissions in this cohort has reduced from 38 visits to 2 visits for the first 6 months or since started on pump.
Larger studies are needed to look of the effects of these 2 regimens.

The glucocorticoid receptor in macrophages protects against inulin resistance and promotes homeothermy

Giorgio Caratti[1], Ulrich Stifel[1], Bozhena Kozak[1], Alexander Rauch[2] & Jan Tuckermann[1]
[1]Ulm University, Ulm, Germany; [2]Syddansk Universitet, Odense, Denmark

Insulin resistance and obesity are a global health problem and directly linked to macrophage-driven inflammation of the adipose tissue. Glucocorticoid therapy, used to treat inflammatory conditions, increases adiposity and insulin resistance. It is unknown however, whether anti-inflammatory actions of glucocorticoids at physiological levels can have beneficial effects on adipose tissue inflammation, potentially limiting insulin resistance. Using a macrophage specific deletion of the glucocorticoid receptor (GR), we show that the glucocorticoid signalling in macrophages protects against obesity related insulin resistance. We found that obese mice lacking the glucocorticoid receptor in macrophages have increased adipose tissue inflammation along with a diminished anti-inflammatory polarisation of adipose tissue macrophages. Macrophages deficient for GR show diminished IL-4 signalling which consequently leads to diminished maintenance of body temperature during cold exposure, linking glucocorticoid action in macrophages to homeothermy. Unexpectedly, this was only attributed to limited browning in subcutaneous but not brown adipose tissue. Similarly, loss of macrophage GR reduced inflammation regulated adipose tissue browning, which increases the drop in body temperature during endotoxin shock. Our results demonstrate that glucocorticoids play an important homeostatic role in macrophages during obesity to limit adipose tissue inflammation and promote insulin sensitivity. We also identify a cooperation of glucocorticoid signalling and IL-4 signalling in macrophages to promote alternative activation, in turn assisting in homeothermy.

Introduction
Pheochromocytomasand paragangliomas are tumors derived from chromaffin cells which result from mutations of at least six different genes as autosomal dominant disorders.
Aim
To evaluate the existence of correlations between genetic alterations and clinical data in 16 patients with pheochromocytomas and/or paragangliomas.
Methods
From 2007 to 2009, 13 patients with pheochromocytoma [3 men, medium age 39 years (14–61)] and 3 with paraganglioma [1 men, medium age 33 years (22–35)] were evaluated from 2007 to 2019 regarding the presence of genetic mutations and possible correlations between the latter and some clinical features. Besides the mutations, tumor size, symptoms and signs present by the time of the diagnosis were studied.
Results
Four patients had pathogenic mutations (SDHB deletion encompassing the promotor and exon 1, C98Y in the SDHB gene, N78S in the VHL gene, and C634R in the RET gene) and one subject had a V90M variant in the TMEM127 gene. Two patients did not present mutations and nine had nonpathogenic mutations. Regarding the presence of clinical features before treatment, there was a predominance of arterial hypertension (75.0%), while the prevalence of tachycardia, abdominal pain and headaches was respectively 12.5%, 12.5% and 6.25%. There was no significant difference between the age of patients with pathogenic mutations and that of the other patients (31.2 vs 38.6 years, $P=0.3952$). Moreover, there were no differences regarding the prevalence of pheochromocytoma ($P=0.2143$) or clinical features (p: hypertension = 0.6346, tachycardia = 0.4583, abdominal pain = 0.5417, headaches = 0.6875), or tumor dimensions ($P=0.4578$) when the two groups were compared. However, the prevalence of paragangliomas was higher in patients with pathogenic mutations ($P=0.0179$).
Conclusion
In patients with pheochromocytoma and paraganglioma, the absence of correlations between pathogenic mutations and clinical features increases the importance of the genetic studies in the determination of treatment and prognosis of these tumors. Furthermore, subjects with germline mutations associated with pheochromocytoma and paraganglioma should undergo lifelong clinical, biochemical and imaging surveillance and their families should receive genetic counseling.

Peritoneal implantation of pheochromocytoma – two cases of pheochromocytomatosis

Gergő Csitári[1,2], Judit Tőke[2], Nikolette Szücs[2], János Horányi[3], Zsolt Varga[4], Gabriella Dabasi[4] & Miklós Tóth[2]
[1]Saint Imre Teaching Hospital, Metabolic Center, Budapest, Hungary; [2]Semmelweis University, 2nd Department of Medicine, Budapest, Hungary; [3]Semmelweis University, 1st Department of Surgery, Budapest, Hungary; [4]Semmelweis University, Division of Nuclear Medicine, Department of Radiology, Budapest, Hungary

Introduction
Peritoneal implantation of benign pheochromocytomas – also known as pheochromocytomatosis – is a rare event caused by tumour rupture during surgical intervention. In our tertiary referral centre, we managed over two hundred patients with adrenal pheochromocytoma in the past 27 years. Now we report on the two cases diagnosed and followed with pheochromocytomatosis.
Case 1.
A 33-year-old man presenting with paroxysmal hypertension and palpitation was diagnosed with a left adrenal pheochromocytoma (60 mm largest diameter). Laparoscopic adrenalectomy was carried out in 2011. Difficulties manipulating the tumour required deliberate fragmentation to insert it into the entrapment bag. Hypertension and vasomotor symptoms resolved after surgery. Five years later, the patient presented with clinical and biochemical recurrence. During a second surgical exploration in 2017, multiple 2-3 mm nodules were found on the peritoneum forming a tumour-like mass in the left hypochondrium. Debulking tumorectomy with distal pancreatectomy and splenectomy were performed. Metanephrine and normetanephrine excretions remained elevated but non-progressive, 3-metoxitiramin excretion is within the reference range. On the most recent 123I-MIBG SPECT-CT, multiple radiotracer uptaking nodules were visualised on the peritoneal surfaces, around the left kidney and on the lower surface of the liver, however, distant metastases were not described. On doxazosin, the patient has rare mild symptoms of catecholamine excess, however; he is normotensive.
Case 2.
A 34-year-old woman presented with hypertension, palpitation, tremor, headaches, and muscle cramps. She had elevated urinary metanephrine, and abdominal MRI showed a 46 mm pheochromocytoma in the left adrenal. Laparoscopic tumour removal was performed in 2006. Upon dissection, both the capsule and the tumour were found to be ruptured. Urinary metanephrines dropped to normal after surgery. Four years after the primary resection, a non-progressive metanephrine excretion wasdetected, while normetanephrine and 3-metoxitiramin excretions were within normal limits. The patient remained asymptomatic for the next nine years; successfully carried out a pregnancy. Repeated CT, MRI and 123I-MIBG imaging showed multiple nodules in the left adrenal bed and on the peritoneal surfaces, considered to be unresectable. Distant metastases were not visualised. Fourteen years after the primary surgery, the patient is normotensive on prazosin monotherapy.
Family history and genetic testing for hereditary pheochromocytoma/paraganglioma syndromes were negative in both cases.
Conclusions
Benign pheochromocytoma may recur because of tumour capsule rupture and local spillage of tumour cells during surgical resection, with subsequent peritoneal dissemination and implantation. Consecutive pheochromocytomatosis can account for difficult diagnostic and therapeutic challenge.

The role of cytotoxic chemotherapy in adjuvant treatment of radically resected adrenocortical carcinoma

Otilia Kimpel[1], Sara Shokry Daniel Bedrose[2], Felix Megerle[1], Marilyne Daher[2], Matthias Kroiss[1], Mouhammed Amir Habra[2] & Martin Fassnacht[1]
[1]Division of Endocrinology, University Hospital Würzburg, Würzburg, Germany; [2]Department of Endocrine Neoplasia and Hormonal Disorders, MD Anderson Cancer Center, Houston, United States

Background
The recent ESE-ENSAT guidelines on adrenocortical carcinoma (ACC) indicated new treatment options for patients with “high risk for recurrence” as one of the major research topics for the field. However, since almost no data were available on the use of cytotoxic drugs in an adjuvant setting, no clear recommendation could be given. Here we report our experience with adjuvant platin-based therapy since 2002 at the University of Würzburg and MD Anderson.
Methods
22 presumably high risk patients (12 female, 10 male, median age 38.5 years) after radical resection (R0 $n=16$, RX $n=4$, R1 $n=2$), ENSAT stage (II $n=9$, III $n=10$, IV $n=3$) and with median Ki67 of 30%, who were treated with adjuvant platin-based chemotherapy (initiated < 3 months after primary surgery) were matched to patients without adjuvant chemotherapy (using the following criteria: ENSAT stage, resection status, Ki-67, other adjuvant therapies, age and cortisol excess). 19 patients in both group have been treated with concomitant mitotane, none with adjuvant radiotherapy. Primary endpoint was recurrence-free survival (RFS), secondary overall-survival (OS).
Results
Twelve of 22 patients with adjuvant platin-based therapy experienced recurrence, whereas this was the case in 20/22 matched controls. Patients with adjuvant chemotherapy had a significant longer median RFS than matched controls (639 vs 336 days; multivariate adjusted HR: 0.33 (95% CI 0.14-0.79; $P=0.012$). At last follow-up, 4 patients in the chemotherapy group and 12 patients in the control group have been died leading to a trend toward improved overall survival (HR 0.39; 0.09-1.55; $P=0.173$). Neither the highest mitotane blood level in the first three months (12.2 mg/l vs 9.6 mg/l;

$P=0,37$) nor the highest mitotane blood level until progress or end of therapy (17.8 mg/l vs 16.3 mg/l; $P=0,67$) were significantly different between the two groups.
Conclusions
Our retrospective cohort study provides first evidence that adjuvant platin-based chemotherapy may lead to a prolonged recurrence-free and overall survival. The retrospective nature and the size of the study are major limitations. A prospective study (like the just started ADIUVO-2 study) is needed to prove the value of adjuvant platin-based therapy.

Introduction
Adrenocortical carcinoma (ACC) is a rare entity, usually associated with a poor prognosis. There are still many areas of uncertainty regarding its approach.
Methods
A Portuguese ACC register was established in 2020, including information from 24 endocrine centres. Kaplan-Meier was used to calculate overall survival and recurrence; log- rank test to assess survival and progression free survival (PFS) differences between groups; cox-regression analysis to assess predictors of survival and PFS. Alfa level of significance was 0.05.
Results
198 patients (63% female) with a mean age at diagnosis of 51.96±15.1 years old presented with constitutional symptoms in 62.8%, hormonal hypersecretion in 47.2% and incidentally in 31.82%. The mean tumour size was 11.1 cm±5.09 with evidence of adenopathy in 21.8%, local invasion in 41.6% and distant metastasis in 47.9%. Surgery was performed in 88% of patients with negative resection margins in 61.44%. Mean Weiss score was 4.94±1.6 and mean ki67 17.5%.ENSAT staging was: I – 1.6%; II – 30%; III – 20%; IV – 47.9%. Mitotane was used in 71% of patients, adjuvant radiotherapy was employed in 11%, and different modalities of chemotherapy in 19%. During follow-up: 32% remained disease-free; 27% recurred (63% at the adrenal bed, followed by lung and liver metastasis in 37% and 29%) and 42% progressed (the majority in the lungs and liver 56%, followed by the adrenal bed in 30%). One and five-year survival was 72.7 and 35.7%. One and five-year survival was 92.8/59.5% for ENSAT stage 2; 74.5/34.6% for ENSAT stage III and 35.8/9.9% for ENSAT stage IV. One and five-year PFS was, for stage II, 89.5%/56.5%; for stage III, 54.6/31.9%, and for stage IV, 33.0/0%. Patients with incidentally discovered tumours, lower ENSAT stages, R0 surgery, ki67<20%, low-grade tumours, stage IV patients treated with mitotane irrespective of other chemotherapy, and patients treated with radiotherapy had better survival and PFS in univariate analysis ($P<0.05$). Tumour stage III and IV (HR 4.65 and 13.59, $P<0.001$), age at diagnosis (HR 0.25, $P=0.031$) and incidentally discovered tumours (HR 0.44, p=0.034) were the only independent predictors of survival. Adrenal bed radiotherapy showed a trend towards improved survival (HR 0.25, $P=0.061$). Stage IV was the only independent predictor of PFS (HR 18.36, $P<0.001$).
Conclusions
This is the first characterisation of treatment outcomes of the Portuguese ACC population. Overall survival and its predictors are consistent with published literature, except for age, which impact is still uncertain.

Excess glucocorticoid activity may suppress tumor immune activity in adrenocortical carcinoma

Andrew Greenstein[1], Mouhammed Amir Habra[2], Marzena Mura[3], Paweł Biernat[3], Marek J Piatek[3], Andreas Grauer[1] & Stacie Peacock Shepherd[1]
[1]Corcept Therapeutics, Menlo Park, United States; [2]The University of Texas, MD Anderson Cancer Center, Houston, United States; [3]Ardigen, Kraków, Poland

Introduction
Excess glucocorticoid (GC) activity has been implicated in the pathophysiology of multiple cancer types. For instance, approximately half of adrenocortical carcinoma (ACC) patients exhibit excess GC (GC+). This provides a unique opportunity to study correlates of GC activity, such as a possible suppression of tumor immune response and immune checkpoint inhibitor (ICI) efficacy due to the broad immunosuppressive effects of GC. ACC multi-omics data can be used to identify the molecular consequences of GC activity and assess the rationale for combining relacorilant, a selective glucocorticoid receptor (GR) modulator, with an ICI in GC+ ACC.
Methods
GC status, mRNA expression, DNA mutation, and DNA methylation data from distinct adrenal resections ($n=71$) were accessed via The Cancer Genome Atlas (TCGA). To deconvolute immune cell type abundance, xCell was applied to the mRNA data. Random forest was used to derive gene signatures.
Results
A significant difference in the expression of858 genes was observed between GC- and GC+ ACC cases. In the GC+ cases, KEGG pathway analysis showed higher gene expression of 7 pathways involved in steroid synthesis and secretion, as well as lower expression in 19 pathways, most of which were related to natural killer cells, T-cells, and immune activity. Hypomethylation was primarily observed in the steroid-synthesis pathways. Tumor-infiltrating $CD4^+$ memory ($P=.003$), $CD8^+$ memory ($P<.001$), and NKT-cells ($P=.014$) were depleted, while tumor-associated neutrophils were enriched ($P<.001$). Moreover, higher tumor mutation burden (TMB) was observed in the GC+ cases ($P=.029$). A gene signature predictive of GC status in ACC was derived and applied to other cancer types to identify tumors with GC+-like transcriptional profiles.
Conclusions
By reducing the abundance of immune cells and immune-related transcripts in GC+ ACC, GC may limit response to ICI therapy. Selective GR modulators such as relacorilant may be able to increase immune related transcripts, thus promoting tumor immune response in GC+ ACC and other malignancies with elevated GC activity. This hypothesis will be tested in a Phase 1 trial of relacorilant+ICI.

AEP31

Functional ectopic adrenocortical carcinoma; A case report

Sarah Craus[1], Carol Cardona Attard[1], Miriam Giordano Imbroll[1], Simon Mifsud[1], Mark Gruppetta[1,2] & Stephen Fava[1,2]
[1]Mater Dei Hospital, MSD2090, Malta; [2]University of Malta, Msida, Malta

Background
Adrenocortical carcinomas (ACC) are rare malignant tumours, with a quoted incidence of 0.7–2.0 cases/million habitants/year, with ectopic ACC being exceptionally rate. Diagnosis is based on clinical and biological assessment supplemented by imaging. Patients commonly present with features secondary to steroid excess, but around 15% of patients are diagnosed incidentally.
Case Report
A 54-year old lady, presented to clinic for assessment of possible polycystic ovarian syndrome (PCOS). The patient gave a few months history of facial hirsutism accompanied by excessive weight gain and new onset hypertension. On further questioning, she had more sinister symptoms including easy bruising, proximal myopathy and insomnia. Initial investigations revealed a 0900 h cortisol of 867 nmol/l, testosterone 6.73 nmol/l, oestradiol of 129 pmol/l, DHEAS 2.50 umol/l, Androstenedione 9 (0.35-2.49) ng/ml,

17-hydroxyprogesterone of 24.8 ng/ml. 0900 h Cortisol post over-night Dexamethasone suppression test was 1482 nmol/l, ACTH was undetectable and 24-hour urinary cortisol >4138 nmol/24 hr (<806.8 nmol/24 hr).An abdominal CT revealed a 6 cm solid and irregular retroperitoneal mass, in the right iliac fossa, that was separate from the kidney. The lesion increased in size from 6.3 cm to 10.3 cm in 4 months. She had a surgical resection and histology revealed an adrenocortical carcinoma, with a Ki-67 score of 25% and 20 mitoses per high power field. On immunohistochemistry, the tumour cells were positive for melanin A, synaptophysin and inhibin. Post-operatively, the patient was given 6 cycles of etoposide, doxorubicin and cisplatin as Mitotane was locally unavailable, however it was agreed that this is initiated if there is evidence of metastatic disease during follow up. 0900 h Cortisol level on Day 3 post-operatively was 20 nmol/l. She was started on Hydrocortisone 20 mg-10 mg-10 mg peri-operatively, which was tailed down and eventually stopped 7 months later, once Synacthen test showed normal cortisol response. The patient has remained well and is under regular surveillance with the most recent imaging showing no evidence of disease recurrence.

Conclusion

Ectopic adrenocortical carcinomas are exquisitely rare tumours and can constitute an exceptional cause of ACTH-independent Cushing's syndrome. Our case highlights such a functional tumour occurring in a very unusual location, secreting cortisol, androgens and other metabolites. Although very rare, it is an important condition to recognise because of the significant and sinister clinical sequalae that may develop.

A rare case of functioning adrenocortical oncocytoma of uncertain malignant potential in a young female diagnosed with type 1 neurofibromatosis

Isabela Gaita[1], Radu Iorgulescu[2], Dana Cristina Terzea[1], Razvan Danau[3], Catalina Poiana[1] & Serban Radian[1]
[1]CI Parhon National Institute of Endocrinology, C Davila University of Medicine and Pharmacy, Pituitary and Neuroendocrine Diseases, Bucharest, Romania; [2]Sf. Ioan Emergency Hospital, Surgery, Bucharest, Romania; [3]Professor Doctor Theodor Burghele Hospital, Urology, Bucharest, Romania

Background

Adrenocortical oncocytoma is a veryrare adrenal tumor type, usually non-functioning and benign. Neurofibromatosistype 1 (NF1) is an autosomal dominant disease caused by mutations of the NF1 gene encoding neurofibromin, a tumor supressor gene that acts by activating a RAS GTP-ase which negatively regulates RAS activity. NF 1 is usually associated with pheocromocytoma, rarely with adrenal carcinoma, and no association with adrenal oncocytoma has been reported.

Aim

To report a case of a functioning adrenal oncocytoma in a young patient diagnosed with NF1.

Case report

A 22 years-old-female, with a family history of possible NF1 (father with cafe-au-lait spots) presented in July 2019, following the CT diagnosis of a $9.2 \times 9.6 \times 7.3$ cm right adrenal tumor after a pregnancy loss at week 21. The tumor was apparently encapsulated and homogeneous, without evidence of local invasion or lymphadenopathy. Physical examinationrevealed signs of Cushing's syndrome, hirsutism, acne and multiple cafe-au-lait spots, axillary freckles and Lisch nodules on ophtalmological examination. Hormonal assessment revealed: 0800 h cortisolemia=16.84 mg/dl, unsupressed on LDDST (15.27 mg/dl), ACTH=1.91 pg/ml, DHEA-S=1151 ug/dl (18-391), testosterone=2.06 ng/ml (<0.75), while aldosterone/renin ratio and serum metanephrines were normal. A right open adrenalectomy was performed for the suspicion of adrenocortical carcinoma and the patient was started on prednisone replacement for adrenal insufficiency. On microscopical examination, tumor cells were large, polygonal, with eosinophilic granulated cytoplasm, suggestive of oncocytoma. The mitotic activity was low, without evidence of capsular and vascular invasion and large areas of necrosis were present. Immunohistochemical analysis showed positivity for calretinin and inhibin, confirming an adrenocortical origin. Cytokeratin staining was negative, vimentin was positive. Ki-67 index was 10 %. The Lin-Weiss-Bisceglia score was low (2 minor criteria: large size and tumor necrosis), supporting a diagnosis of functioning adrenocortical oncocytoma of uncertain malignant potential. Postoperatively, on glucocorticoid replacement (due to contralateral adrenal suppression), we observed an improvement of signs of hypercortisolism and androgen excess, paralleling the normalisation of androgens and restauration of cortisol diurnal rhythm and normalisation of ACTH. No signs of local recurrence were observed on the 3 months follow-up CT scan.

Conclusion

Functioning adrenocortical oncocytoma has rarely been described and its association with NF1 is novel. Careful monitoring is required for adrenal tumor relapse and for other NF1-associated tumors.

Adrenocortical cancer mimicking lymphoma on magnetic resonance scan

Murat Calapkulu, Muhammed Erkam Sencar, Hakan Duger, Muhammed Kizilgul, Bekir Ucan, İlknur Ozturk Unsal, Pinar Akhanli & Erman Cakal
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Turkey

Background

Adrenocortical carcinoma (ACC) is a rare cancer that originates from the cortex of the adrenal gland. Although its exact etiology is not clear, it has been found to be associated with some hereditary cancer syndromes. Sometimes patients present with hormonal excess symptoms (virilization, Cushing's syndrome) or local symptoms consistent with an abdominal mass. In ACC, computed tomography (CT) and magnetic resonance imaging (MRI) are preferred imaging modalities for the localization of the tumor, and the determination of metastases. Myelolipoma, Metastases, lymphoma, and pheochromocytoma should be considered in the differential diagnosis of adrenal carcinoma. Herein, we aimed to present a case of ACC that initially mimics lymphoma with clinical and imaging findings.

Case report

A 42-year-old female presented to our outpatient clinic with a 3-month history of fever (38°C), night sweats, malaise, amenorrhea, abdominal pain, proximal muscle weakness, and deepening of the voice. She was receiving antihypertensive medication therapy. Physical examination revealed peripheral lymphadenopathy and central obesity. Abdominal ultrasonography showed a 164×72 mm mass lesion on the paraaortic area. To define the lesion more accurately, we performed abdominal contrast-enhanced MRI which revealed a $200 \times 130 \times 90$ mm conglomerate solid mass with diffusion restriction that mimic bulky lymphadenopathy. On imaging, the appearance of mass was not clearly distinguishable from adrenal glands. Laboratory tests were found to be compatible with Cushing's syndrome (Table-1). Urinary catecholamines levels were found within normal limits. Thoracic and cervical CT was performed and detected 41×34 mm conglomerate lymphadenopathy at the subcarinal and supraclavicular area. An ultrasound-guided percutaneous tru-cut biopsy was performed from the supraclavicular lymph node to confirm the diagnosis. The patient was diagnosed with metastasis of ACC by histopathology and referred for chemotherapy.

Conclusion

Since complete surgical resection is one of the most important factors which prolong survival, it is very important to make an early diagnosis in ACC. When an intra-abdominal mass is detected, a careful examination should be performed to exclude signs and symptoms of pheochromocytoma, hyperaldosteronism, hyperandrogenism, and Cushing's syndrome. ACC should be kept in mind in case of symptoms of Cushing's syndromeand/or virilization.

Table 1 Laboratory analysis of patient at the time of admission

	Values	Reference Ranges
ACTH (pg/ml)	< 5	0-46
Cortisol (mg/dl)	29,95	6,7-22,6

Cushing's syndrome during pregnancy - case presentation and follow-up.

Mervat Hassan[1], daniela-georgiana amzar[2], Ioana Golu[2], Vrinceanu Luminita[3], Craina Marius[3], Bernad Elena[3], Neamtu Radu[3] & Mihaela Vlad[2]
[1]"Pius Brânzeu" Emergency Clinical County Hospital Department of Endocrinology, Timisoara, Romania; [2]Faculty of Medicine, "Victor Babes" University of Medicine and Pharmacy Timisoara (Romania), Department of Endocrinology, Timisoara, Romania; [3]Faculty of Medicine, "Victor Babes" University of Medicine and Pharmacy Discipline of Obstetrics and Gynecology, Department of Obstetrics and Gynecology, Timisoara, Romania

Background
Cushing's syndrome is a rare condition in pregnancy, because infertility is one of the main features of this pathology. Association between pregnancy and cortisol excess involves a high rate of mortality and morbidity for mother and fetus. Hypertension, preeclampsia, diabetes, miscarriage, preterm delivery or sudden intrauterine death can occur. We describe a case of a pregnancy in a patient with a history of Cushing's Syndrome, diagnosed during the previous pregnancy.
Case presentation
A 31 years old patient was diagnosed in 2018 with Cushing's syndrome, during the 19th week of pregnancy. Clinical examination revealed weakness, inspiratory dyspnea, high blood pressure, lower limbs bilateral edema, truncal obesity, moon facies, hirsutism, buffalo hump, purple striae; the paraclinical investigations revealed a right adrenal adenoma (30/35/28 mm) on MRI, proteinuria (0,1 g/l/24 hours), hypoalbuminemia (2,4 g/dl), hypokalemia (2,9 mmol/l). Blood pressure ranged between 160-180/100-120 mmHg despite therapy. Hormonal analyses performed confirmed the diagnosis of adrenocorticotropic hormone (ACTH-) independent CS. The obstetrical ultrasound showed a single, live fetus. The patient's condition deteriorated, developing severe preeclampsia with multiple complications, and a medical board took the decision to terminate the pregnancy for mother's interest. Three weeks later, she underwent laparoscopical right adrenalectomy followed by hydrocortisone replacement.
Results
Evolution was favourable. Her current status in January 2020 reveals regression of all cushingoid features; blood pressure was 110/60 mmHg. Hormonal analyses revealed a normal level for morning serum cortisol (5.74 mg/dl). At the moment, the patient is 26 weeks pregnant, with a good evolution, a single, live fetus, with normal growth and anatomy, according to gestational age and a normal placenta. Her clinical and paraclinical profiles are closely monitored.
Discussion
The serum cortisol increases normally during pregnancy and the screening for Cushing's syndrome is more difficult, particularly in the second and third trimester. The management for such cases is complex and sometimes difficult, especially when a termination of pregnancy is necessary due to severe complication. It requires multdiciplinary approach, with quickly implemented measures. Fertility and overall wellness of the patient could and should be fully reobtained, like in this case.
Conclusion
Pregnancy in a patient with Cushing syndrome induces multiple complications, requiring sometimes termination of pregnancy for mother's interest. Surgical treatment of Cushing syndrome restores the fertility and allows a normal evolution of upcoming pregnancies for such patients.
Keywords: Cushing's syndrome, pregnancy, preeclampsia, laparoscopical adrenalectomy, fertility.

AEP35

A rare presentation of salt wasting in congenital adrenal hyperplasia with 11β-hydroxylase deficiency.

Rym Belaid, Ibtissem Oueslati, Anaam Ben Chehida, Nadia Khessairi, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
La Rabta hospital, Department of endocrinology, Tunisia

Introduction
Steroid 11β-hydroxylase deficiency (11-OHD) is the second most common causeof congenital adrenal hyperplasia (CAH),characterized by the overproduction of adrenal androgens and deoxycorticosterone (DOC).It usually presents with virilization of the female fetus, precocious puberty in male infants and hypertension with or without hypokalemia in both genders. Because of high levels of mineralocorticoids, patients rarely present with salt wasting (SW). We herein report a case of a patient with 11-OHD presenting with SW adrenal crisis.
Case report
A 10-year-old male was admitted to our department for the management of acute adrenal insufficiency. He was born at term to healthy consanguineous parents and had a history of severe dehydration, hyponatremia and sexual ambiguity at birth which was initially diagnosed as 21-hydroxylase deficiency. He was raised as a male but had absent testicles since birth. The patient was irregularly followed up. At the age of 4 years, precocious puberty and arterial hypertension were discovered. At the age of 10 years, the patient was admitted for management of acute adrenal insufficiency due to an abrupt withdrawal of hydrocortisone. On physical examination, he had a body weight of 37 kg (± 2 s.d.), a body height of 1.42 m (± 2 s.d.), a blood pressure of 130/60 mmHg, a masculine morphotype, a sexual ambiquity stage V of Prader and a pubertal development S4 P3 of Tanner. Laboratory examination revealed hypokaliemia of 2.1 mmol/l, normal LH, and FSH levels and high levels of testosterone, 17-OH-progesterone, 11-deoxycortisol, 11-deoxycorticosterone and DHEA-S. Basal 11-deoxycortisol and cortisol levels were 29.6 µg/l [nr: 0.2–1.4] and 0.9 µg/dl respectively and raised to 31.4 µg/l and 1.2 µg/dl at 60th minute, respectively, after ACTH stimulation test. Chromosome analysis revealed a 46XX karyotype. Pelvic ultrasonography showed normal uterine cavity with two ovaries. He was diagnosed as congenital adrenal hyperplasia due to 11-OHD and treated with hydrocortisone and spironolactone. After psychiatric expertise, phenotypic sex was chosen and the patient underwent surgical reparation at the age of 16 years.
Conclusion
Salt wasting crisis is rare in patients with 11-OHD. In newborns, there is a resistance to mineralocorticoids which could contribute to moderate and transient salt loss. However, the combination of both 21-hydroxylase and 11 β-hydoxylase has been reported in literature and it is unclear whether such association is due to a random occurrence of two different mutations or to a single mutation.

Identification of the genetic signature of vascular calcification in patients with type 2 diabetes mellitus by a computational approach

Francisco Andújar-Vera[1,2,3], Cristina García-Fontana[1,2,3,4], Sheila González-Salvatierra[1,2,3,5], Manuel Muñoz-Torres[2,4,5,6] & Beatriz García-Fontana[2,3,4]
[1]Fundación Pública Andaluza para la investigación Biosanitaria Andalucía Oriental (FIBAO), Granada, Spain; [2]Instituto de Investigación Biosanitaria de Granada, Granada, Spain; [3]Hospital Universitario San Cecilio de Granada, Granada, Spain; [4]Instituto de Salud Carlos III, CIBERFES, Madrid, Spain; [5]University of Granada, Department of Medicine, Granada, Spain; [6]Hospital Universitario San Cecilio de Granada, Endocrinology and Nutrition, Granada, Spain

Introduction
The analysis of the signaling pathways involved in vascular calcification is difficult due largely to the limitation in obtaining vascular tissue samples. Therefore, the use of bioinformatics tools for the identification of potential biomarkers associated with vascular calcification is an advantage for the advancement in the knowledge of the molecular pathways involved in this pathology.
Objective
Increase understanding of the molecular mechanisms involved in vascular calcification processes and to identify potential molecular targets for diagnostic and therapeutic use through the use of bioinformatic resources.
Methods
Calcified femoral artery sections from 7 patients diagnosed with type 2 diabetes mellitus and critical ischemia were used for the study of the proteome by liquid chromatography and mass spectrometry. The set of identified proteins was faced with the set of proteins of 19 similar vascular pathologies described in other studies. In this way, a biological network of proteins associated with vascular calcification was created. The use of bioinformatic tools such as Cytohubba and String allowed to identify a potential genetic signature on which proteins of high degree of centrality and possible subrogated markers were determined.
Results
751 proteins were identified in the characteristic proteome of calcified femoral artery. Seventy one of themwere common proteinsof similar pathologies. The centrality analysis of the common proteins showed that APOE, HP, CAT, MPO and ACTB proteins had the highest value in the centrality ranking. The study of the protein-protein interaction network determined that HSPD1, HSP90B1, SERPINC1, HADHB and PDIA3 could be potential subrogated markers of vascular calcification.

Conclusions
The identified proteins with involvement in vascular pathologies play an important role in processes related to bone mineralization. Therefore, the study of these proteins could be a therapeutic strategy for the joint treatment of vascular and bone pathologies.

Physiologically based pharmacokinetic modelling to inform dosing in adrenal insufficiency and congenital adrenal hyperplasia

Martin J Whitaker[1], Jennifer J Bonner[2], Howard Burt[2], Trevor N Johnson[2], John Porter[1] & Richard JM Ross[3]
[1]Diurnal Limited, Cardiff, United Kingdom; [2]Certara UK Limited, Simcyp Division, Sheffield, United Kingdom; [3]University of Sheffield, The Medical School, Sheffield, United Kingdom

Background
Replacing physiological cortisol levels is important for the long-term health of patients with adrenal insufficiency and congenital adrenal hyperplasia (CAH). Modified-release formulations of hydrocortisone are one strategy being used to replace the cortisol circadian rhythm in adult patients but there is no data in children. Physiologically based pharmacokinetic (PBPK) modelling is a valuable tool for paediatric drug development[1]; however, there are no examples of PBPK simulations for hormone replacement.
Objective
To develop a PBPK model for hydrocortisone.
Methodology
The PBPK model was developed using the Simcyp Simulator population-based PBPK software (Certara UK Ltd., UK; version 16.1). The model includes systems information to account for non-linear binding to cortisol binding protein, metabolism by 11β-HSD2 and 5α-reductase, and how these parameters develop with age. The model was developed and verified using published literature and cortisol pharmacokinetic data measured by LC-MS/MS in healthy adults and adults and children with CAH in trials of an immediate release formulation of hydrocortisone granules (Alkindi, Diurnal Ltd, UK) and a modified-release formulation of hydrocortisone (Chronocort, Diurnal Ltd, UK).
Results
The model predicted immediate-release hydrocortisone PK in adults across the dose range 0.5 to 20 mg, with predicted/observed AUCs within 0.8 to 1.25-fold – defined as a good prediction of the observed FDA bioequivalence criteria based on ± 20% difference - for both the published literature and test cohorts. The model predicted pharmacokinetic parameters for the modified-release formulation, with AUCs within 0.8 to 1.25-fold after single and multiple (representing an 8-hour interval between doses) dosing. After calculation of mg/kg and mg/m^2 modified-release doses roughly equivalent to 20 mg and 10 mg in adults, simulations were performed in a virtual paediatric population aged 12 to 18 years and results compared to equivalent doses simulated in adults. The results showed minimal difference in C_{max}, T_{max}, and AUCs between adults and adolescents.
Discussion
The PBPK model predicted PK parameters in adults and children acrosshydrocortisone dose ranges 0.5 to 20mg and captured the adult modified-release data after single and multiple dosing. Predictions in adolescents aged 12 to 18-years were aligned with current guidelines which recommend hydrocortisone dosing for adolescents with CAH of 10–15 mg/m^2 per day[2]. This PBPK model will provide an invaluable tool in refining dosing regimens for patients who require hydrocortisone replacement therapy and allow prediction of dose for different populations and age groups.

An unusual case of Cushing's syndrome secondary to ACTH producing prostate adenocarcinoma

Wanling Zeng[1] & Joan Khoo[2]
[1]Singhealth, Endocrinology, Singapore; [2]Changi General Hospital, Endocrinology, Singapore

Introduction
Cushing's syndrome (CS) secondary to ectopic adrenocorticotrophic hormone (ACTH)–producing prostate cancer is rare with less than 30 cases reported. We report a case of Cushing's syndrome secondary to prostate adenocarcinoma with recurrent hypokalemia, sepsis and rapid disease progression. A 61-year-old man presented in January 2019 with 3-week history of lower limb swelling and weakness. Past medical history is significant for metastatic prostate cancer diagnosed in December 2018 for which he was started on gonadotropin-releasing hormone (GnRH) analogue. His other co-morbidities include hypertension and diabetes. On examination, he had ecchymoses of the upper limbs and proximal myopathy but no other features of Cushing's syndrome. Blood investigations showed hypokalemia with metabolic alkalosis (potassium 2.5 mmol/l, bicarbonate 36 mmol/l) and 0800 h cortisol of 1229 nmol/l. Cushing's syndrome was diagnosed after cortisol failed to suppress after a 1 mg overnight dexamethasone suppression test (cortisol 1327 nmol/l), and 48-hour 2 mg dexamethasone suppression test (cortisol 1447 nmol/l). This was likely to be ACTH-dependent as ACTH was 57.4 (normal range NR 10 – 60) ng/l and high dose 8mg dexamethasone did not suppress cortisol to less than 50% of baseline (cortisol 1424 nmol/l). His 24-hour urine free cortisol was 20475 (NR 59-413) nmol/day. MRI pituitary did not show any pituitary mass. 68Ga-DOTA-NOC PET-CT scan revealed an area of increased DOTA-NOC-avidity in the inferior aspect of the right side of the prostate gland. Review of his prostate biopsy done in December 2018 showed adenocarcinoma with no features of small cell carcinoma, but immunostaining positive for synaptophysin, CD 56 and ACTH. He was initiated on potassium replacement, ketoconazole and spironolactone with improvement of hypokalemia, blood pressure and glucose. Ketoconazole was switched to somatostatin analogue octreotide in view of progressive liver dysfunction. He eventually succumbed to by parainfluenza, varicella and bacterial bronchopneumonia with septic shock, 2 months after diagnsosis.
Conclusion
Adenocarcinoma of the prostate with neuroendocrine differentiation is a rare cause of ectopic Cushing syndrome. It is imperative to recognize and treat ectopic Cushing's syndrome as it has an aggressive course with poor prognosis and limited treatment options.

Background and Aims
Higher cortisol levels are associated with cardiovascular mortality in the elderly resulting from potential angiostatic effects of glucocorticoids (GCs). These features are replicated in patients with endogenous GCs excess (Cushing's syndrome) as well as with exogenous hypercortisolism due to excessive pharmacological GCs usage. Both groups present the augmented cardiovascular disease event rate. GCs may also adversely influence remodeling after myocardial infarction via inhibition of angiogenesis. Despite new advances in our understanding of GCs pathophysiology over the past decades, the mechanisms that account for glucocorticoid-related control of vessel generation remain a subject of investigation. Recently, it was proposed that microRNAs (miRNAs), the small noncoding RNAs functioning as antisense regulators of gene expression by targeting mRNA, may have a central role in regulating endothelial function through multiple mechanisms. Thus, the purpose of this study was to evaluate the effects of chronic GC excess on the expression of selected angiogenesis-related miRNAs, called Angio-miRs, expressed in nucleated cells circulating in peripheral blood (PBNCs) of patients with endogenous hypercortisolism either due to corticotrophin-dependent or corticotrophin-independent Cushing's syndrome (CS).

Material and methods
Cells were isolated from circulating peripheral blood collected from 35 healthy subjects and 31 patients with endogenous hypercortisolism as a source of miRNAs. A self-validated individual quantitative RT-PCR study was then performed to evaluate the expression levels of selected Angio-miRs in isolated cells. Additionally, using Western blot technique, the endothelin-1 (ET-1) expression in plasma of peripheral blood was assessed to detect endothelial dysfunction in vasculature.
Results
The performed analysis of selected Angio-miRs revealed a significantly increased intracellular expression of angiogenesis-related miRNAs in patients with CS, including miRNA-150-5p and miRNA-223-3p transcripts compared with healthy subjects. To the contrary, three other potent angiogenic miRNAs, such as miRNA-17-5p, miRNA-126-3p, and miRNA-126-5p, were significantly down-regulated in patients with endogenous hypercortisolism in comparison to healthy volunteers. Besides, the ET-1 expression levels in CS were higher than in healthy subjects, thus, indirectly confirming endothelial dysfunction developed in the CS cohort.
Conclusion
Cardiovascular events related to hypercortisolism remain a challenging problem in clinical endocrinology. This study has demonstrated that the chronic excess of GCs in endogenous CS might induce significant dysregulation of selected Angio-miRs involved in the biologic activity of endothelial cells in peripheral vasculature. Indeed, dysregulated miRNAs seem to be promising targets for further research, especially to search for potential therapies for several GC-induced cardiovascular complications.

Association of the subclinical hypercorticism and BclI glucocorticoid receptor polymorphism with bone mineral density in women with adrenal incidentalomas

Sanja Ognjanovic, Djuro Macut, Jadranka Antic, Bojana Popovic, Tamara Bogavac, Tatjana Isailovic, Ivana Bozic Antic, Dusan Ilic, Valentina Elezovic Kovacevic & Svetozar Damjanovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Department for neuroendocrine tumors and hereditary cancer sy, Belgrade, Serbia

Most of adrenal incidentalomas (AI) are nonfunctional, although some of those demonstrate an autonomous subtle cortisol hypersecretion that could lead to increased risk for osteoporosis. Several polymorphisms of glucocorticoid receptor (GR) gene have been found to alter glucocorticoid tissue sensitivity. The aim of this study was toinvestigate whether subclinical hypercortisolism (SH) and *Bcl*I variant of the GR gene have an impact on bone mineral density (BMD) in women with AI. In 106 women with AI, we evaluated BMD with dual-energy X-ray absorptiometry at lumbar spine (LS) and hip. The hypothalamic-pituitary-adrenal axis activity was evaluated using ACTH, midnight cortisol level, 24-h urinary free cortisol, and dexamethasone suppression *tests*. DNA was obtained from peripheral blood leucocytes. The polymorphism was detected using PCR, RFLP and DNA sequencing. Patients with SH had increased frequency of osteoporosis (61.1% vs 22%, $P=0.002$). They had significantly lower BMD at the LS (0.83 ± 0.15 vs 0.93 ± 0.13, $P=0.005$), and total hip (0.79 ± 0.13 vs 0.72 ± 0.11, $P=0.022$). Femoral neck BMD was also lower but the difference did not reach statistical significance (0.66 ± 0.12 vs 0.72 ± 0.11, $P=0.069$). Presence of osteoporosis was associated with SH [odds ratio (OR)=5.775, 95% confidence interval (CI) 1.423-23.426, $P=0.014$] and lower body mass index (OR=1.226, 95% CI 1.071-1.405, $P=0.003$), after adjusting for age, menopause and vitamin-D. Carriers of the C allele of *Bcl*I had significantly less suppression of cortisol levels after 0.5 mg dexametasone (126.4 ± 111.4 vs 80.9 ± 75.7 nmol/l, $P=0.026$). Osteoporosiswas more prevalent in carriers than non-carriers (26.5% vs 7.7%, $P=0.031$). The present study shows that women with AI and SH have higherprevalence of osteoporosis. Although individual bone sensitivity to glucocorticoid is not only influenced by polymorphism, carriers of the longer C allele of *Bcl*I polymorphism exhibit increased sensitivity with enhanced risk of bone density reduction.

Somatostatin receptors 2A and 5 expression in adrenocortical cancer

Anna Roslyakova, Lilia Selivanova, Arina Tarasova & Dmitry Beltsevich
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Adrenocortical carcinoma (ACC) is a rare malignant tumor with heterogeneous prognosis. The median overall survival of all ACC patients is about 3-4 years. Complete surgical resection provides the only cure [Fassnacht M, et al., 2018]. In cases of advanced ACC, therapeutic options are limited. No effective second-line therapies are recommended for patients with disease progression to EDP chemotherapy scheme and Mitotane. It is essential to study alternative drugs, their combinations and tumor biological targets.
Objectives
The aim of the study is to evaluate somatostatin receptor (SSTR) types 2A and 5 expression in ACC.
Materials and methods
Formalin-fixed paraffin-embedded tissues from 69 patients were investigated. All the cases were reviewed according to the Weiss criteria to confirm the presence of ACC. Immunohistochemistry (IHC) staining was performed on 3 μm sections using the Leica Bond Max stainer. The primary antibodies anti-somatostatin receptor types 2A (UMB-1, Epitomics) and 5 (UMB-4, Epitomics) were incubated at the concentration 1:100. Only membranous staining was considered. The IHC results were evaluated through a semi-quantitative approach as negative (0), weak (1+), moderate (2+) or strong (3+) in accordance with intensity of staining. The staining intensity was analysed using the following system: 1+=faint staining at 100× magnification; 2+=strong staining at 100× magnification, not entire circumference of tumor cell membranes stained at 400× magnification; 3+=strong staining at 100× magnification, entire circumference of tumor cell membranes stained at 400× magnification [].
Results and Discussion
We identify moderate or strong staining intensity of SSTR types 2A and/or 5 expression in 49% of ACC spices. The detection of SSTR 2A and/or SSTR 5 expression in tumor tissue may be a promising marker of prolonged somatostatin analogs in the complex therapy of patients with advanced ACC, however, further research is required. There is no ability to evaluate effectiveness of their monotherapy, as well.

Prognostic value of Ki-67 and ENSAT stage on recurrence-free survival and overall survival in patients with adrenocortical carcinoma

Ivana Kraljevic[1,2], Nikola Knezevic[2,3], Luka Kakrigi[2], Marko Kakarigi[2], Tina Dusek[1,2], Mirsala Solak[1], Tanja Skoric Polovina[1], Annemarie Balasko[1], Karin Zibar Tomšić[1], Ana Marija Alduk[4] & Darko Kastelan[1,2]
[1]UHC Zagreb, Department of Endocrinology; [2]School of Medicine, University of Zagreb, Croatia; [3]UHC Zagreb, Department of Urology; [4]UHC Zagreb, Department of Radiology

Background
The adrenocortical carcinoma (ACC) is a rare malignancy with poor outcomes and overall survival of less than 40%. Different prognostic factors were evaluated in patients with ACC. We analyzed overall survival (OS) and recurrence-free survival (RFS) in patients with ACC depending on Ki-67 and ENSAT staging.
Methods
We performed a retrospective study on 62 ACC patients treated at the Croatian Referral Center for adrenal gland disorders from 2005 to 2019. Six patients (10%) had ENSAT stage I disease, 30 patients (48%) stage II, 14 patients (23%) stage III and 12 patients (19%) stage IV. RFS was analyzed in 47 patients with the ACC ENSAT stage I-III and R0 resection. Based on Ki-67 patients were stratified in two groups: Ki-67≤10% and Ki-67>10%.
Results
The mean age of patients was 49.1 ± 15.5 years and 70.9% were females. During the study, 15 patients died of whom 10 deaths were related to ACC. The mean OS was 83.3 ± 14.3 months, 153.7 ± 11.3 months, 77.1 ± 14.5 months and 19.7 ± 4.9 months for ENSAT stage I, II, III, and IV, respectively ($P<0.001$). Disease recurrence was observed in 9 patients (19%) of whom two patients had Ki-67≤10%.The mean RFS was 68.3 ± 9.5 months, 109.9 ± 9.4 months and 82.4 ± 16.4 months for ENSAT stage I, II and III, respectively ($P=0.916$). Ki-67>10% was associated with poorer survival ($P=0.04$).

Conclusion
Our data confirmed that the ENSAT stage and Ki-67 are major predictors of ACC patient's survival. However, in our cohort of patients, Ki-67 has not been associated with the ACC recurrence.

CYP11B2 DNA methylation pattern is discordant in aldosterone-producing adenomas and in concurrent aldosterone-producing cell clusters

Guido Di Dalmazi[1], Luca Morandi[1], Beatrice Rubin[2], Catia Pilon[2], Valeria Maffeis[2], Sofia Asioli[1], Valentina Vicennati[1], Uberto Pagotto[1], Ambrogio Fassina[2] & Francesco Fallo[2]
[1]University of Bologna; [2]University of Padua

Background
Previous studies have shown an association between low CYP11B2 DNA methylation levels and high CYP11B2 mRNA levels in aldosterone-producing adenoma (APA), suggesting that epigenetic mechanisms play a pivotal role for regulating CYP11B2 function in primary aldosteronism. It has been proposed that aldosterone-producing cell clusters (APCCs) may become a source of autonomous aldosterone production when evolving into APA.
Aim
Our aim was to determine whether the CYP11B2 DNA is differentially methylated in APAs and in their concurrent APCCs, and to assess the relationship with CYP11B2 tissue expression.
Methods
A series of 12 formalin-fixed paraffin-embedded (FFPE) adrenal tissues from patients with APA were studied. Immunohistochemical staining was performed using anti-CYP11B1 and anti-CYP11B2 monoclonal antibodies, and anti-CYP17A1 polyclonal antibody. Staining was quantified by the McCarty's H-scoring system. APA, APA-adjacent adrenal cortex, and satellite APCCs identified by immunohistochemistry were microdissected using manual core drilling, and genomic DNA was extracted and assessed for CYP11B2 methylation analysis. CYP11B2 DNA methylation level was measured by quantitative Bisulfite Next Generation Sequencing. Bioinformatic analysis was performed in a GalaxyProject environment and processed by BSPAT (Bisulfite Sequencing Pattern Analysis Tool). The equation 2^-ddCt was used to calculate the fold changes in gene expression between the different intra-adrenal cell structures. Analysis of DNA mutations in aldosterone-driver genes KCNJ5, ATP1A1, ATP2B3 and CACNA1D was performed by Sanger sequencing.
Results
9/12 APA specimens showed at least one concurrent APCC. A wide range of CYP11B2, CYP11B1 and CYP17A1 immunohistochemical expression was detected in tumor cells of APA, while positive CYP11B2 and negative CYP11B1/CYP17A1 staining was uniformly found in APCCs. H-score of CYP11B2 expression in 3/9 APAs was lower than in their satellite APCCs and was generally negative or very low in APA-adjacent adrenal cortex. CYP11B2 DNA methylation levels were significantly lower in APA than in concurrent APCCs and APA-adjacent adrenal cortex ([mean ± standard deviation] 0.51 ± 0.25 vs 0.87 ± 0.11 vs 0.70 ± 0.27; $P < 0.05$ in all but one CpG island considered). Five KCNJ5 and one ATP2B3 mutations were found overall in 12 APAs, including four KCNJ5 and one ATP2B3 mutations among the 9 APAs with concurrent APCCs. No somatic mutations were found in APCCs.
Conclusion
Lower CYP11B2 methylation levels in APA than in concurrent APCCs may sustain the hypothesis of a progressive demethylation process of APCCs, causing their switch to an autonomous aldosterone production. Somatic aldosterone-driver gene mutations do not affect the CYP11B2 DNA methylation rate in APA.

Background
Patients with Cushing's Syndrome (CS) suffer from a variety of neuropsychiatric and cognitive problems. Following remission, some, but not all of these symptoms resolve. Recent cross-sectional studies in patients with CS show persistent structural and functional brain abnormalities. However, longitudinal studies using magnetic resonance imaging, and a detailed neurocognitive assessment, performed before and after treatment, are not available.
Trial objective
To investigate the extent and time-course of restoration of physical and neurocognitive symptoms, as well as functional and structural brain abnormalities in patients with CS.
Methods
The IQFACE-CS study is an investigator-initiated, multicentre, international, prospective observational cohort study (ClinTrial.gov:NCT03211624). Thirty-six patients with active CS and 36 age-, sex-, and education-matched controls will be included. Neurocognitive tests, general and disease specific QoL questionnaires, and functional task-based and structural MRI are performed before treatment and 1 and 2 years after treatment. Currently, 25 patients and 4 controls have been included. Twenty patients were female, mean age at inclusion was 50 years. Ten patients had adrenal Cushing, while 14 had pituitary source. At baseline, mean 24 hour UFC was 723 nmol, mean midnight salivary cortisol was 16.0 nmol/L, and serum cortisol after 1-mg dexamethasone suppression test was 375 nmol/l. Fifteen patients received presurgical treatment with ketoconazole, while 5 patients used metyrapone. Elevated liver enzymes were observed in 5 patients. Mean preoperative 24-hour UFC decreased to 167 nmol. Remission was achieved in 14/17 (82%) operated patients, recurrence was observed in 1 patient during the study period. Four patients have completed the trial.
The study is financially supported by an unrestricted grant fromHRA Pharma.
Conclusion
This study discusses the rationale, design, and progress of the IQFACE-CS study. Inclusion is still ongoing, and final results are expected at the end of 2022.

Regression of the adrenal X-zone controlled by JAK pathway in SF1/SOCS3 KO mice

Thais Barabba Auricino, Eduarda Correa Bento & Claudimara Ferini Pacicco Lotfi
University of São Paulo, Department of Anatomy, São Paulo, Brazil

Our previous data showed that histological markers of the X-zone in mice adrenal (fetal zone in human adrenal) were still present in adult males and postpartum SF1/SOCS3 KO females. This change led to a distinct distribution of lipid droplets along the adrenal cortex and a blunted ACTH-induced corticosterone secretion in SF1/SOCS3 KO mice. Here we have examined the morphological and functional adrenals of SF1/SOCS3KO male mice adrenals at 3, 8 and 15 weeks through histochemical, immunohistochemical and molecular approaches. The hematoxylin-eosin stains showed retention of X-zone in SF1/SOCS3KO mice adrenals at all ages analyzed. Also, CYP17A1-positive cells were found in X-zone of SF1/SOCS3KO mice. The gene expression analysis by RT-PCR of fetal adrenal enhancer (FAdE) and Pik3c2g genes showed augment, whereas CYP11B1 gene expression was decreased in microdissected X-zone of SF1/Socs3 KO mice adrenals when compared to control male mice, both at 8 weeks age. Taken together, these results showed retention of X-zone in the SOCS3KO mice up to the age of 15 weeks and define the involvement of JAK/STAT/SOCS3 signaling pathway in the X-zone retention and therefore differentiation process of mice adrenal cortex. Supported by FAPESP, CNPq and CAPES.

Fertility testing in patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency

Nikolette Szücs[1], Judit Tőke[1], Péter Reismann[1], Márton Doleschall[2], Attila Patócs[3], Péter Riesz[4] & Miklós Tóth[1]
[1]Semmelweis University, 2nd Department of Medicine, Budapest, Hungary; [2]Semmelweis University, ELRN-SE Molecular Medicine Research Group; [3]Semmelweis University, Department of Laboratory Medicine; [4]Semmelweis University, Department of Urology and Urooncology

Introduction
Congenital adrenal hyperplasia (CAH) is an autosomal recessively inherited disorder resulting from the mutations of one of Seven genes involved in adrenal steroidogenesis. The consequent enzyme defects lead to defects of varying severity of steroid biosynthesis. Patients require lifelong substitution treatment and endocrine care.
Objectives
One of the many consequences of CAH is reduced fertility. The aim of this study was to investigate the fertility parameters of 36 patients with 21-hydroxylase deficiency (21-OHD).
Patients and methods
The study included 36 patients (19 women, 17 men) suffering from salt wasting (24) and simple virilizing (12) forms of 21-OHD followed at our endocrine centre. The mean age was 34.5 years (20–48 years). Serum hormone levels essential to follow for optimal treatment were analysed. In males, spermatogram and testicular ultrasound were performed. In women, regularity of menstrual cycles were recorded.
Results
Serum androstenedione (AD) levels were below the lower limit in 5 patients (ref. range: .70-250 ng/dl) while in 2 patients they were above the upper limit of normal. Twenty-four patients had normal serum androstenedione level. Low, normal and elevatedserum 17-hydroxyprogesterone (17-OHP, ref. range: 40-250 ng/dl) concentrations were measured in 2, 13 and 21 patients, resp. ACTH levels were low, normal and increased in 1, 22 and 13 patients, resp. (ref. range: .7.2-63.3 pg/ml). Testicular ultrasound examinations confirmed epididymal cyst in 1 patient, testicular adrenal rest tumors (TART) in 10 patients. Semen analysis was performed in 11 men. Azoospermia, oligozoospermia (<39 million/ejaculations) and normal sperm counts were recorded in four, one and six males, resp. However, considering the sperm concentration (> 15 million/ml), only 4 subjects had adequate results; all of them had satisfactory (> 4%) sperm morphology. Examining the progressive movement of the spermatozoa, reduced movement (asthenozoospermia, less than 32%) was observed in 9 subjects. Overall, considering the number, morphology, and movement of spermatozoa, only 2 (27%) patients had normal values. Among the 19 female patients, 12 underwent feminizing genitoplasty in childhood, and almost all patients still use regular manual vaginal dilation. Nine female patients are using oral contraceptive pills. Four female patients gave birth after spontaneous conception, and two male have children.
Conclusion
Our results confirm that patients with 21-OHD have reduced fertility parameters and conditions in both genders. A multidisciplinary approach including endocrinologist, andrologist and gynecologist is necessary for adequate treatment

Relationship between the hypothalmic-pituitary-adrenocortical axis activity and the characteristics of aldosterone-producing adenomas

Moe Thuzar[1,2], Yu-Chin Lo[1,3], Zeng Guo[1], Warrick J Inder[2,4] & Michael Stowasser[1,3]
[1]The University of Queensland Diamantina Institute, Endocrine Hypertension Research Centre, Brisbane, Australia; [2]Princess Alexandra Hospital, Department of Endocrinology & Diabetes, Brisbane, Australia; [3]Princess Alexandra Hospital, Hypertension Unit, Brisbane, Australia; [4]The University of Queensland, Faculty of Medicine, Brisbane, Australia

Objective
Aldosterone production can be regulated by adrenocorticotrophic hormone (ACTH) which normally controls cortisol secretion. Some cases of aldosterone-producing adenoma (APA) display features which may suggest increased sensitivity to the stimulatory effects of ACTH. The aim of this study was to investigate if there is any relationship between the hypothalamic-pituitary-adrenocortical (HPA) axis activity and the characteristics of APAs.
Methods
This is a retrospective review of the HPA axis activity of 41 histologically-confirmed APA cases which were characterised with regards to clinical, biochemical and somatic mutation status. HPA axis activity was assessed from morning plasma cortisol, ACTH and 1mg overnight dexamethasone (DEX) suppression test. Correlation was analysed by Pearson's correlation coefficient, and the HPA axis activity between APAs with KCNJ5 mutation and those without was compared using Mann Whitney U-test.
Results
Twelve out of 41 patients (29.3%) were women, median age was 49 years and 85.4% were overweight/obese. All except 2 had somatic mutations within APA. Fourteen (34.1%) were KCNJ5 mutation. Only one patient (APA not KCNJ5 mutated) had post-DEX cortisol > 50 nmol/l. Upright morning plasma aldosterone concentration (PAC) correlated with tumour size ($r=0.347$, $P=0.026$), plasma cortisol ($r=0.425$, $P=0.006$) and plasma ACTH ($r=0.446$; $P=0.056$). Plasma ACTH and cortisol were positively correlated ($r=0.511$, $P=0.025$). Higher PAC, cortisol and ACTH concentrations were in turn associated with the need for higher defined-daily-dose (DDD) of anti-hypertensive medications ($r=0.466$, $P=0.002$ for PAC; $r=0.315$, $P=0.045$ for cortisol; $r=0.449$, $P=0.054$ for ACTH). Higher PAC was also predictive of higher BMI ($r=0.348$, $P=0.026$). Plasma cortisol, ACTH, post-DEX cortisol, BMI and DDD of anti-hypertensives were not significantly different between those with KCNJ5 mutation vs those without.
Conclusions
HPA axis activity correlated with clinico-biochemical characteristics in patients with APAs, but the prevalence of autonomous hypercortisolism was low. The findings suggest a potential role of ACTH in the pathophysiology of APAs. There was no significant difference in HPA axis activity between those with somatic KCNJ5 mutation compared to those without.

[1]Ribeirao Preto Medical School - University of Sao Paulo, Internal Medicine, Ribeirao Preto, Brazil; [2]Ribeirao Preto Medical School - University of Sao Paulo, Surgery and Anatomy, Ribeirao Preto, Brazil; [3]Ribeirao Preto Medical School - University of Sao Paulo, Pedriatrics, Ribeirao Preto, Brazil

Background
Low plasma aldosterone after adrenalectomy due to aldosterone-producing adenoma (APA) and postoperative hypoaldosteronism recovery have been well described. However, prospective time course comparing simultaneously aldosterone and renin levels is still lacking.
Aim
We prospectively studied clinical and biochemical findings emphasizing aldosterone and renin levels, in a cohort of patients with APA who underwent adrenalectomy in a single tertiary center.
Patients and Methods
Of 38 patients diagnosed with primary aldosteronism (PA) from 2016-2019, eighteen patients were diagnosed with APA (11M,7F)and underwent unilateral adrenalectomy. Among them, five were excluded by lost or short follow up, kidney disease, cortisol co-secretion, and aldosterone secreting carcinoma. Blood pressure and antihypertensive requirement as well asserum potassium, aldosterone and direct renin (DRC)concentrations were evaluated before and after 1, 3, 5, 7, 15, 30, 60, 90, 120, 180, 270 and 360 days of adrenalectomy. Aldosterone and DRC postoperative recovery was arbitrary defined as ≥ 5 ng/dl and ≥ 5 mU/l, respectively.
Results
Hypertension was diagnosed at the mean age of 32 years (range 17–52). PA diagnosis was performed with a delay of sixteen years (25–64). The majority of patients had hypokalemia (83%). Post-operatively, median systolic and diastolic blood pressure decreased from 149 to 129 mmHg ($P=0.01$) and

from 91.6 to 81.6 mmHg ($P=0.04$), respectively. Anti-hypertensive daily requirement was decreased and 16% of patients were normotensive with no medications. Median potassium levels increased from 2.8 to 4.7 mmol/l ($P<0.0001$). The median aldosterone and DRC at diagnosis and at last follow up after surgery were 41 vs 5.5 ng/dl and 2 vs 9.1 mU/l ($P<0.0001$).
Renin recovery was observed at median of 15 days (range 3-720) and aldosterone recovery at median of 120 days (5–720). The median difference between renin to aldosterone recovery was 52 days (2–263). In 77% of the patients the renin recovered earlier than aldosterone while in 23% they recoveredsimultaneously. No association was observed between these hormones recovery and age at diagnosis, time of disease, or potassium serum. However, patients with higher aldosterone levels at diagnosis (>41 ng/dl) presented later renin (>15 days; $P=0.03$) and aldosterone (>120 days; $P=0.008$) recovery.
Conclusion
This is the first report, using a prospective protocol, comparing simultaneouslythe short and long-term time-course of aldosterone and renin levels recovery in APA after adrenalectomy. In spite of early renin recovery in most patients, the hypoaldosteronism remained elongated indicating that renin deficiency is not the main cause of postoperative hypoaldosteronism in patients with APA.

Comparison of incidence and characteristics of non-functioning and autonomous cortisol secreting adrenal incidentaloma across different BMI and age distribution

Ana Podbregar[1], Andrej Janez[2], Katja Goricar[3] & Mojca Jensterle[2]
[1]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia Slovenia; [2]University Medical Center Ljubljana, Ljubljana, Slovenia, Department of Endocrinology, Diabetes and Metabolic Disease, Ljubljana, Slovenia; [3]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, Pharmacogenetics Laboratory, Institute of Biochemistry, Slovenia

Background
The relationship between obesity, metabolic traits and adrenal incidentaloma (AI) in clinical studies have been discussed mainly in one direction: as the consequences of mild autonomous cortisol secretion in autonomous cortisol secreting AI (ACS) and as possible consequences of minimal hormonal secretion not detectable by current diagnostic methods in non-functioning (NF) AI. However, the observed anabolic and mitogenic effects of insulin on adrenal cortex from preclinical models led to the hypothesis of the potential existence of bilateral relationship between obesity and AI. In clinical studies, obesity as a primary cause of AI and as a main risk estimator of metabolic burden in patients with AI remained largely unaddressed.
Purpose
We compared the incidence and characteristics of non-functional (NF) and autonomous cortisol secreting (ACS) adrenal incidentaloma (AIs) after cohort was stratified by different body mass indexes (BMI) and age groups.
Methods
Cohort study comprising of 432 patients (40,6% male, 59,4% female) with NFAI ($n=290$) and ACS ($n=142$), of median age 63.4 (54.0–71.6) years and median BMI 28.6 (25.5–31.7) kg/m^2. The data collection contained 11.132 points including demographic, anthropometric, radiologic, hormonal and metabolic parameters.
Results
We observed 68-87% higher incidence of AI across different age groups in NFAI and ACS if BMI was >25 kg/m^2 compared to BMI ≤25 kg/m^2 (Figure1). Patients with ACS were older ($P=0.008$), with higher basal cortisol ($P<0.001$), lower basal DHEAS ($P=0.001$), lower suppression DHEAS ($P=0.027$) and higher aldosterone ($P=0.039$). AIs with ACS were larger than NFAI. Interestingly, ACS group had lower body mass ($P=0.023$) and did not differ in BMI, blood pressure, heart rate, lipid profile, fasting glucose and presence of diabetes mellitus type 2 when compared to NFAI. By contrast, some components of metabolic profile were rather associated with higher BMI and older age, in particular in NFAI.
Conclusion
The incidences of NFAI and ACS were significantly higher in overweight/obese subgroup across the age distribution. Incomplete post-dexamethasone cortisol suppressionwas not a reliable predictor of metabolic alterations, whereas stratification by age and BMI displayed significant differences in some metabolic traits, in particular in NFAI.

Prevalence of primary aldosteronism and association with cardiovascular complications in patients with resistant and refractory hypertension

Mirko Parasiliti Caprino[1], Chiara Lopez[1], Nunzia Prencipe[1], Barbara Lucatello[1], Fabio Settanni[2], Giuseppe Giraudo[3], Denis Rossato[4], Andrea Benso[1], Ezio Ghigo[1] & Mauro Maccario[1]
[1]University of Turin, Endocrinology, Diabetes and Metabolism, Turin, Italy; [2]City of Health and Science University Hospital, Clinical Biochemistry Laboratory;, Turin, Italy; [3]City of Health and Science University Hospital, Surgery, Turin, Italy; [4]City of Health and Science University Hospital, Radiology Unit, Turin, Italy

Background
Primary aldosteronism (PA) is the most frequent form of secondary hypertension, with a high prevalence in resistant hypertension (RH), a condition of insufficient blood pressure (BP) control despite a 3-drug based treatment at full dose, including a diuretic. The prevalence of PAin refractory hypertension (ReH), a condition of persistently elevated BP values despite therapy with 5 drugs, is not known.
Objective
To investigate the prevalence of PA in RH and ReH and its association with cardiometabolic complications, atrial fibrillation (AF) and aortic ectasia.
Subjects and Methods
We enrolled consecutive patients with RHand without previous cardiovascular events, referred to our Center for Hypertension, Division of Endocrinology, Diabetes and Metabolism, University of Turin, between 09/2011 and 09/2019. PA was diagnosed when the following conditions were met: PAC >150 pg/ml, PRA <1 ng/ml per hour, ARR >400 and PAC after SIT >100 pg/ml.
Results
110 patients with RH were enrolled. PA was diagnosed in 32 cases (29.1%). In univariate analysis, PA patients was associated to male gender, hypokalemia, worse hypertensive profile, single and cumulative organ damage (OD) (microalbuminuria, chronic kidney disease, carotid Intima Media Thickness andLeft Ventricular Hypertrophy), aortic ectasia and atrial fibrillation. The multivariate analysis showed that PAis a strong factor associated with left ventricular hypertrophy (OR=13.13, 95% CI 3.79-62.70; $P<0.001$), microalbuminuria (OR=3.77, 95% CI 1.45–10.21; $P=0.007$), carotid intima-media thickness (cIMT)≥0.9 mm (OR=2.81, 95% CI 1.02–8.19; $P=0.049$), aortic ectasia (OR=7.93, 95% CI 2.09–52.36; $P=0.008$) and atrial fibrillation (OR 8.54, 95% CI 1.53–70.77; $P=0.022$). Moreover, PA was independently associated with the presence of at least one type (OR=8.60, 95% CI 1.73–69.88; $P=0.018$) and at least two types of OD (OR=3.08, 95% CI 1.19–8.24; $P=0.022$). 13 patients (11.82%) were affected by ReH. This group was characterized by higher valuesof cIMT (1.20, 1.00–1.40 vs 0.70, 0.60–0.90 mm; $P=0.002$), higher rate of aldosterone producing adenoma (23.08% vs 6.19%; $P=0.041$) and atrial fibrillation (23.08% vs 5.15%; $P<0.049$), if compared to the other subjectswith RH.

Conclusions
The present study indicates that primary aldosteronism is a frequent cause ofsecondary hypertension andcardiovascular complications among patients with resistant andrefractory hypertension, suggesting acrucial role of aldosterone in the pathogenesis of severe hypertensive phenotypes and cardiovascular disease. Physicians should not stigmatize the relevance of an ineffective multiple drug antihypertensive therapy and should refer patients with RH to hypertension reference centers, because specific treatment of PA improves OD and reduces the incidence of cardiometabolic complications.

Isolated acquired hypoaldosteronism as a cause of hypovolemic hyponatremia with urinary sodium loss

Jorge Gabriel Ruiz Sánchez[1,2], M Cuesta[1], P De Miguel[1], X Perez[1], I Moraga[1], MV Sáez de Parayuelo[1], L Fernández[1], LA Calle-Pascual[1] & I Runkle[1]
[1]Hospital universitario Clínico San Carlos, Endocrinología, Madrid, Spain; [2]Hospital universitario Fundación Jimenez Díaz, Endocrinología, Madrid, Spain

Isolated acquired hypoaldosteronism (HA) is considered to be a cause of hypovolemic hyponatremia (HH) with urinary sodium loss (UNaL) and hyperkalemia/upper-limit serum potassium (SK). However, some authors question the presentation of hyponatremia of these characteristics in the absence of Addison's disease (AD).We present a series of patients with HA.
Methods
Aretrospective study of 70 cases of HH with UNaL (UNa > 25 mmol/l) and SK ≥ 5 mmol/l or in upper limits (≥ 4.8 mmol/l) with inadequately low urinary potassium (UK), in absence of oliguria. Patients were assessed for hyponatremia by the Endocrinology Department of a tertiary hospital, from 2012–2019. All presented a low central venous pressure (indicated by the internal jugular vein pulse). AD was ruled out as follows: basal cortisol > 15 µg/dl, or basal cortisol between 10-15 µg/dl with ACTH < 40 pg/ml or use of pharmacological doses of glucocorticoids (GC) during the episode. Reference aldosterone (RIA) values: 90-200 pg/ml.
Results
44/70 (62.9%) were women, mean age: 75.5 years (SD: 12.7). Mean values at diagnosis:serum Sodium 128.5 mmol/l (SD: 5.80), SK 5.5 mmol/l (SD: 0.4), UK 28.8 mmol/l (SD: 11.3), bicarbonate 21.5 mmol/l (SD: 3.2), trans-tubular potassium gradient 4.2 (SD: 1.2). 66/70 (94.3%) presented hyperkalemia with a mean zenith SK of 5.8 mmol/l (SD: 0.5), 67.9% presented metabolic acidosis (MA) with normal anion GAP, 66% hyperkalemia with MA. Morning serum cortisol was available in 54 cases, mean cortisol without GC: 17.2 µg/dl (SD: 5.2). AD was diagnosed in 3/70 cases (4.3 %), AD was ruled out in 43/70 cases (61.4%). 24/70 cases were "indeterminate", requiring further testing and follow-up, during which no additional cases of AD were diagnosed. In 29/43 patients with AD ruled out, serum aldosterone was measured during the episode, permitting differential diagnosis of HA. 16 cases were secondary to aldosterone deficit, with low aldosterone levels: median aldosterone 52 pg/ml [IQR: 21.5 – 82.5]. 7 cases were due to mineralocorticoid resistance, with elevated aldosterone levels: median aldosterone 258 pg/ml [IQR:223 – 293]. 6 cases presented a combination of aldosterone deficit and resistance, with inadequately "normal" aldosterone levels for hyperkalemia: median aldosterone 153.5 pg/ml [IQR: 129.35 – 177.65].
Conclusion
Isolated acquired hypoaldosteronism, due to aldosterone deficit and/or mineralocorticoid resistance, can induce hypovolemic hyponatremia. Furthermore, it is a more frequent cause of hypovolemic hyponatremia with urinary sodium loss and hyperkalemia than is Addison's Disease, in patients studied for hyponatremia.

Ambulance alert system enabling pre-hospital parenteral steroids for patients with adrenal insufficiency

Sam Westall[1], Heather Sullivan[1], Emma Rawsthorne[1], Carl Beesley[2], John Collins[3], Niall Furlong[1], Steven McNulty[1], Sumudu Bujawansa[1] & Ram Prakash Narayanan[1]
[1]St Helens and Knowsley Teaching Hospitals NHS Trust, Diabetes and Endocrinology, St Helens, United Kingdom; [2]St Helens and Knowsley Teaching Hospitals NHS Trust, Information Governance, St Helens, United Kingdom; [3]North West Ambulance Service NHS Trust (NWAS), United Kingdom

Background
For patients in an adrenal crisis, the timely administration of parenteral hydrocortisone can be life-saving. Data from the Addison's Disease Self-Help Group found that a large proportion of adrenal crises occur out of hospital, with many patients relying on the emergency services for initial parenteral hydrocortisone administration. Despite regular patient education (including parenteral hydrocortisone self-administration) and recommendations to wear steroid alert jewellery or carry steroid alert cards, it is not uncommon for patients with primary or secondary adrenal insufficiency to experience delays in the administration of potentially life-saving hydrocortisone injections when unwell often due to health care services being unaware of their diagnosis.
Aim
The aim of this project was to identify the current local rates of emergency attendance of steroid-dependent patients and the rates of pre-hospital parenteral hydrocortisone administration to help guide service-development.
Methods
STHK is a large secondary care hospital in the North West of England with over 800 beds and up to 450 emergency department presentations per day. A list of steroid-dependant patients was obtained from the endocrine outpatient department, and using the hospital electronic records a search was performed on all hospital attendances over the 3-year audit period (2015–2018). Following collection of this data, we worked extensively with our local information governance team and North West Ambulance Service NHS Trust (NWAS) to set up a data-sharing agreement for patients with adrenal insufficiency. Following patient consent, we securely upload patient details to the NWAS Electronic Referral and Information Sharing System (ERISS).
Results and Outcomes
More than 50% of our steroid-dependent patients attended hospital as an emergency within the time period. 78% of patients arriving by ambulance did not receive pre-hospital parenteral hydrocortisone. 56% of patients arriving by ambulance did not receive parenteral hydrocortisone upon attendance to AED. With the ERISS upload and through collaboration with NWAS, following a 999 call, NWAS paramedics and call-handlers are automatically notified that the patient involved requires parenteral hydrocortisone upon emergency service contact.
Conclusions
For patients with adrenal insufficiency, a delay in parenteral hydrocortisone in an emergency can be fatal. A high proportion of steroid-dependent patients within the St Helens and Knowsley region do not receive parenteral hydrocortisone in a timely fashion when becoming significantly unwell. Through an information-sharing arrangement with the ambulance service, we have set up this safety net to ensure that no patient of ours with adrenal insufficiency misses out on this potentially life-saving treatment during an ambulance-callout.

Trends in the incidence of adrenal incidentaloma diagnosed by CT abdomen in 2002 and 2015: Preliminary data from a retrospective study in regional sweden

Fredrik Sahlander[1,2,3], Sophie Bensing[1,4] & Henrik Falhammar[1,4]
[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [2]Falun Hospital, Department of Medicine, Falun, Sweden; [3]Center for Clinical Research Dalarna, Falun, Sweden; [4]Karolinska University Hospital, Department of Endocrinology, Metabolism and Diabetes D2:04, Stockholm,

Background
Adrenal incidentalomas (AI) are common and reported at frequencies of 2-10% at CT-scans of the abdomen. It is established that the number of diagnosed and investigated cases of AI have increased over the last decades. This increase is closely related to the development of modern radiology. General access of CT scanners with higher performance have led to an improved capacity and consequently more performed investigations. Other contributing factors are improved imaging technique with higher resolution images and other effects that can enhance the possibility to detect adrenal masses. Increased knowledge and attendance of AI among radiologists are other important factors that probably also entail a more structured and clear reporting

of the findings, which increases the likelihood that the diagnosis is recorded and that an adequate investigation is conducted.
Aim
To describe the development of the absolute numbers in relation to frequency of AI diagnosed with CT abdomen 2002 and 2015 in Regional Sweden.
Method
Retrospectively we reviewed all digital imaging reports of CT-scans of the abdomen performed on patients >18 years at four hospitals in Regional Sweden in 2002 and 2015. To identify missed cases, images were reviewed if the adrenals were not mentioned in the report. Adrenal masses were subdivided into three classes, AI > 10 mm (according to regening definition of AI; adenoma >10 mm), hyperplasia/ general enlargement and suspected malignancy (metastasises/ adrenocortical cancer).
Results
3467 imaging reports from 2939 individuals performed in 2002 were reviewed. In 2015 > 14000 investigations were performed, of which 5434 CT-scans of 5018 individuals were reviewed (only first 5 months in 2015). The median age in 2002 was 64 years (18–97) and in 2015 66 years (18–101). Adrenal masses were found in 3.0% in 2002 and 4.9% in 2015 ($P<0.05$). 0.6% respectively 0.3% were classified as metastasises. The incidence of AI according to reigning definition (> 10 mm) was 2.0 resp 4.1% ($P<0.05$).
Conclusion
A fourfold increase of performed investigations was observed comparing 2002 to 2015. Consequently, there was an increase of the absolute number of diagnosed AI. In parallel the incidence increased significant from 2.0 to 4.1%, which is relatively low in relation to reports from other cohorts. A direct comparison is though difficult to make due to differences in definition of adrenal masses and the types of CT exams used. The increased incidence is probably an effect of improved image technique in combination with enhanced awareness of AI among radiologists.

Sympathoadrenal system function in patients with multiple sclerosis

Miroslav Vlcek[1], Adela Penesova[1], Zofia Radikova[1], Andrea Havranova[1], Peter Turcani[2], Branislav Kollar[2], Monika Sivakova[2] & Richard Imrich[1]
[1]Biomedical Research Center, Slovak Academy of Sciences, Institute of Clinical and Translational Research, Bratislava, Slovakia; [2]Faculty of Medicine, Comenius University, 1st Department of Neurology, Bratislava, Slovakia

Background
Multiple sclerosis (MS) is a chronic inflammatory autoimmune and neurodegenerative disease of the central nervous system typically affecting young adults. Autonomic dysfunction is commonly detected in patients with multiple sclerosis. Lower response of sympathoadrenal system to various stressors is mainly connected with more developed disease. However, data evaluating sympathoadrenal system function in early MS are limited. Present study investigates stress response in newly diagnosed MS patients, at the time of the first attack of MS.
Methods
We examined 15 MS patients and 15 age, sex, and body mass index matched healthy controls. MS patients were newly diagnosed, untreated, in the time of the first occurrence of the symptoms. Two stressors were used to evaluate the sympathoadrenal response: Stroop word-color interference mental stress test and orthostasis. Plasma levels of epinephrine and norepinephrine, blood pressure (BP), and heart rate were evaluated.
Results
The MS patients have higher heart rate during the first two minutes of orthostasis compared to controls ($P=0.034$). Norepinephrine levels were lower ($P=0.027$) in MS patients in the supine position before the orthostasis, however the following rise was similar to healthy controls. Epinephrine levels were similar in both groups before and during orthostasis. At the end of Stroop test MS patients showed trend to have lower systolic BP ($P=0.055$) and lower epinephrine ($P=0.064$) compared to healthy controls. Norepinephrine response during the Stroop test was unaffected by MS.
Conclusions
We were not able to find clinically significant dysfunction in sympathoadrenal system in newly diagnosed untreated MS patients. The results are supporting the findings that autonomic dysfunction in MS is connected with progression of the disease.
Grant support
The study was supported by the grants APVV-15-0228 and Ministry of Health of the Slovak Republic 2018/37-LFUK-11.

[1]Instituto de Patologia e Imunologia Molecular da Universidade do Porto (IPATIMUP), Porto, Portugal; [2]Instituto de Investigação e Inovação em Saúde (I3S), Porto, Portugal; [3]Instituto de Ciências Biomédicas Abel Salazar, Department of Anatomy, Porto, Portugal; [4]Unit for Multidisciplinary Research in Biomedicine (UMIB), Endocrine, Cardiovascular & Metabolic Research, Porto, Portugal; [5]GV (Sonny) Montgomery VA Medical Center and University of Mississippi Medical Center, Endocrinology Section, Jackson, United States; [6]Hospital S João, Department of Endocrinology, Porto, Portugal; [7]Faculty of Medicine of the University of Porto, Department of Biomedicine, Porto, Portugal

Introduction
The majority of adrenocortical carcinomas (ACC) autonomously produce steroids. However, urinary steroid profile of patients with ACC revealed that these tumors secrete and release predominantly intermediate metabolites. This steroid secretion pattern could be attributed to the undifferentiated status of the tumor cells expressing an incomplete pattern of enzymes involved in the steroidogenic cascade.
Aims
Our study aim was to analyze the expression profile of key proteins involved in the steroidogenesis cascade, in different adrenocortical tumors.
Methods
Expression of proteins involved in steroidogenesis, namely steroidogenic acute regulatory protein (StAR), 11β-hydroxylase (CYP11B1), aldosterone synthase (CYP11B2) and 17α-hydroxylase (CYP17A1), were analyzed by immunohistochemistry in ACC ($n=14$), adrenocortical adenomas presenting with Cushing syndrome (ACAc) ($n=11$) and non-functioning adrenocortical adenomas (ACAn) ($n=15$). The percentage of the stained area for each protein was analyzed through a computerized morphometric quantification, the ImageJ software.
Results
CYP11B1, StAR and CYP17A1 expressions were significantly lower in ACC when compared to ACAc. Besides that, ACC presented co-staining cells for CYP11B1 and CYP11B2. CYP11B1 expression has a high discriminative power to distinguish ACC from ACAc with a sensitivity of 100% and specificity of 92%. CYP11B1 and CYP11B2 dual negativity presented a specificity of 100% for the differential diagnosis between ACC and ACAc.
Conclusion
ACC present an incomplete pattern of steroidogenic protein expression, with decreased CYP11B1 and CYP17A1, which could explain the predominant secretion of predominantly intermediate metabolites in ACC patients. In addition, in cortisol secreting tumors, CYP11B1 positivity alone is highly specific for benign lesions.
Funding
This study was funded by the Foundation for Science and Technology (FCT) (PTDC/MEC-ONC/31384/2017).

Crinecerfont (NBI-74788), a novel CRF1 receptor antagonist, reduces adrenal androgens and precursors in patients with classic congenital adrenal hyperplasia: Results from a phase 2, multiple-dose study

Richard Auchus[1], Kyriakie Sarafoglou[2], Patricia Fechner[3], Maria Vogiatzi[4], Nagdeep Giri[5], Eiry Roberts[5], Julia Sturgeon[5] & Robert Farber[5]
[1]University of Michigan Medical School, Ann Arbor, United States; [2]University of Minnesota Masonic Children's Hospital, Minneapolis, United States; [3]University of Washington School of Medicine, Seattle Children's Hospital, Seattle, United States; [4]The Children's Hospital of Philadelphia, Philadelphia, United States; [5]Neurocrine Biosciences, Inc., San Diego, United States

Introduction
Classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21OHD CAH) is a rare genetic disorder resulting in impaired cortisol biosynthesis, increased steroid precursors, and excess androgen production. Inhibition of adrenocorticotropic hormone (ACTH) release via antagonism of the corticotropin-releasing factor-1 (CRF1) receptor could reduce adrenal

androgen production, thereby reducing the amount of exogenous glucocorticoids required for androgen control. This Phase 2 study evaluated the pharmacodynamic effects of a novel, non-steroidal, and selective CRF1 receptor antagonist, crinecerfont (NBI-74788), on adrenal androgens and precursors in adults with 21OHD CAH.
Methods
In a sequential-cohort design, 16 subjects (18–50 yrs) with 21OHD CAH received crinecerfont open-label for 14 consecutive days in one or more of 4 oral dosing regimens: 50 mg QHS (Cohort1); 100 mg QHS (Cohort2); 100 mg QPM (Cohort3); and 100 mg BID (Cohort4). ACTH, 17-hydroxy-progesterone (17OHP), and androstenedione (A4) were measured Q2H during the peak morning period (0600, 0800, 1000 hrs) and averaged at baseline and Day14.
Results
Demographics are provided in the table. Substantial reductions from baseline in peak-morning ACTH, 17OHP, and A4 after 14 days of crinecerfont treatment were observed across Cohorts 1 through 4 (Table). A dose-response in A4 was observed with 100 mg dosing regimens showing superiority over the 50mg dose cohort. Adverse events were mostly mild. There were no clinically significant findings from routine laboratory tests, vital signs, or electrocardiograms.
Conclusions
This study ofcrinecerfont, a novel, selective CRF1 receptor antagonist, demonstrated clinically meaningful reductions of elevated ACTH, 17OHP, and A4 and was well tolerated after 14 days of treatment in adults with 21OHD CAH. Further studies are warranted to evaluate the effects of chronic crinecerfont therapy on adrenal steroid production, clinical endpoints of disordered steroidogenesis, and reduction of supraphysiologic glucocorticoid dosing in adult and pediatric patients with 21OHD CAH.

Possible protective influence of KCNJ5 and CACNA1D gene polymorphisms on lipid profile in primary aldosteronism and essential hypertensive patients

Weronika Korzynska[1], Grzegorz Mazur[1], Katarzyna Bogunia-Kubik[2] & Anna Jodkowska[1]
[1]Wroclaw Medical University, Department and Clinic of Internal and Occupational Diseases, Hypertension and Clinical Oncology, Wrocław, Poland; [2]Polish Academy of Sciences, Laboratory of Clinical Immunogenetics and Pharmacogenetics, Institute of Immunology and Experimental Therapy, Wrocław, Poland

Introduction
Primary hyperaldosteronism (PHA) is the most common hormonal cause of secondary hypertensionconnected with substantially higher cardiovascular morbidity and mortality than essential hypertension (EH). The association between aldosterone excess in PHA and mutations in KCNJ5 and CACNA1D genes has been previously described and the possible relation with gene polymorphisms was to consider. The present study is to assess possible association between polymorphisms of ion channel genes with PHA and cardiovascular risk factors.
Methods
68 hypertensive patients (mean age: 47.57±14, 68 y, 29 men, 39 women) with clinical suspicion of PHA were evaluated for PHA and EH according to the aldosterone concentration before and after the salt loading test. In the whole group cardiovascular risk factors including blood lipid profile and the KCNJ5 rs2604204 A>C and CACNA1D rs312481 C>T polymorphisms were determined. Statistical analysis was performed. Statistical significance was set at P-value<0.05.
Results
PHA was confirmed in 30 patients. In PHA patients and in the the entire studied group the CACNA1D 312481C allele was associated with lower total and LDL cholesterol concentration compared to 312481TT (P=0,0030 and P=0.0067). In the EH group the KCNJ5 2604204C allele was associated with lower LDL cholesterol concentration compared to 2604204AA (P=0.0311). No significant differences in the incidence of studied alleles between PHA and EH groups were observed, however a tendency towards more common occurrence of CACNA1D rs312481T allele in EH than in PHA patients has been noted (P=0.0673).
Conslusion
We postulate (1) possible protective influence on lipid profile of the KCNJ5 2604204C and CACNA1D312481C polymorphism variants. The results suggest that (2) PHA and EH do not differ strong in terms of the incidence of investigated gene polymorphisms, however (3) the occurence of rs312481 T allel of CACNA1D gene appears to be more common in patients with EH. Observations need to be confirmed on larger studies.

Steroid hormones influence systemic sclerosis prevalence

Valentina Biasin[1,2], Petra Kotzbeck[1], Ines Foessl[1], Anna Birnhuber[2], Leigh M Marsh[2], Andrea Olschewski[2,3], Barbara Obermayer-Pietsch[1] & Grazyna Kwapiszewska[2,4]
[1]Department of Endocrinology, Medical University of Graz, Graz, Austria; [2]Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria; [3]Department of Experimental Anaesthesiology, Medical University of Graz, Graz, Austria; [4]Otto Loewi Research Center, Medical University of Graz, Graz, Austria

Introduction
Systemic sclerosis (SSc) is a connective tissue disorder with higher prevalence in females which is characterized by vascular damage, pulmonary hypertension, inflammation and progressive fibrosis of skin and other internal organs such as lung. In the skin it has been shown that dermal adipose tissue atrophy and microangiopathy drive fibrosis development, however which is the underlying mechanism and whether this mechanism is responsible for the female prevalence of the diseases needs to be investigated. Here, we addressed these questions by using fra-2 over-expressing mice as a model of SSc.
Material and Methods
Female and male fra-2 overexpressing mice and wild type littermates were characterized at the age of 16-20 weeks. Ovariectomy was performed at the age of 6-8 weeks and the phenotype was analysed at 20 weeks of age. Lung function was measured using Flexivent system (SCIREQ), immunohistochemical staining for alpha-smooth muscle actin (αSMA) and von Willebrand factor (vWF) was performed to assess vascular remodelling. Inflammatory cell count was performed on bronchioalveolar lavage (BAL) of the mice and the right ventricular systolic pressure was acquired by closed chest hemodynamic measurement.
Results
Characterization of fra-2 over-expressing mice, showed that female transgenic mice have a worse phenotype compared to male, suggesting an influence of sex steroid hormones in the development of the phenotype. Female fra-2 over-expressing mice had worse lung function, higher inflammation and stronger vascular remodelling compared to male, however no differences in right ventricular systolic pressure was detected. Ovariectomy did not influence the phenotype, suggesting that female steroid hormones do not play a role in disease development and progression.

Conclusion
Female fra-2 over-expressing mice develop a more severe phenotype compared to male mice. Which is not influenced by ovariectomy. Further analyses are necessary to elucidate the male steroid hormones contribution to the phenotype of fra-2 over-expressing mice. Additionally, the underlying mechanism, the contribution and regulation of hormonal imbalance in these mice will be elucidated.

Algorithm of staged perioperative hemodynamic management (SPOHM)

Sergii Dubrov[1], Sergii Tarasenko[2], Mikhailo Kunatovskiy[3], Natalia Zelinska[3], Kateryna Maslii[3] & Olena Yefimova[3]
[1]Bogomolets National Medical University, Ukraine; [2]Bogomolets National Medical University, anesthesiology and intensive care, Kyiv, Ukraine; [3]Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine organs and tissues of MoH of Ukraine

Aim
The introduction of modern pheochromocytoma anesthetic management in a specialized endocrinology center with using of the algorithm of SPOHM.
Materials and methods
The implementation of pheochromocytoma anesthetic management in 65 women during surgical intervention by video assistant laparoscopic adrenalectomy. All patients were used an algorithm of SPOHM: preoperative tableted hypotensive therapy before admission (outpatients); preoperative infusion controlled hypotensive therapy by urapidil and correction of hipovolemia by balanced crystalloid solutions and a colloid solution 4-6 mg/kg were applied on the 2nd stage; intraoperative infusion controlled antihypertensive therapy by urapidil on the 3rd stage under the control of non-invasive hemodynamic monitoring (NIHM) and prevention of adrenal insufficiency with final hypovolemia correction on the last 4th stage.
Results and Discussion
All patients had significantly (P=0,0087) increased levels of daily urine metanephrines up to 3080.8±295.7 mg/24 h (control of 169.3±12.7 mg/24 h). According to SPOHM doxazosin 9.72±0.96 mg twice-daily or urapidil 144.0±11.2 mg twice-daily were used at the first stage. On the second stage performed haemodilution by 6-10% solution of HES or 4% Gelatine and controlled infusion antihypertensive therapy by urapidil in anaverage speed 9.7±1.9 mg/hr. During the third stage infusion rate of Urapidil was 1.25±0.08 mg/min (additionaly, in time of the pheochromocytoma surgical separation, urapidil bolus was administered in dosages 25–50 mg IV when the slightest increasing of blood pressure was detected by NIHM, especially cardiac output changes). On the fourth stage was conducted the prevention of adrenal insufficiency by hydrocortyzon replacementtherapy and hypovolemia. No mortality cases were observed.
Conclusions
The introduction of SPOHM has ensured high efficiency and safety of laparoscopic adrenalectomy under general anesthesia and an absence of lethal cases.

16 year-old woman with abdominal paraganglioma secondary to SDHB mutation

Javier Bodoque Cubas, Elena Mena Ribas, Guillermo Serra Soler, Carlos Antich Barceló, Iñaki Argüelles Jiménez, Santiago Tofé Povedano, Mercedes Codina Marcet, Honorato García Fernández & Vicente Pereg Macazaga
Hospital Universitary Son Espases, Endocrinology, Palma de mallorca, Spain

Introduction
Catecholamine-secreting tumours derived from the adrenal medulla and the nodes of the autonomic nervous system are known as pheochromocytomas or paragangliomas, respectively. Although their clinical manifestations are similar, their differentiation is important from an epidemiological and prognostic point of view and their possibility of being associated with genetic syndromes.
Case Report
We present a case of a 16 year old patient, with no pathological history of interest, who was admitted to our centre after finding elevated levels of 24-hour urine fractionated metanephrine, as well as elevated dopamine, noradrenaline and methoxytyramine. A three-year history of evolution based on repeated cases of holocranial headache, diaphoresis, and skin pallor accompanied, especially in the last months before admission, by typical angina chest pain. In the month prior to admission, she had consulted her family doctor due to the increase in symptoms, and in medical consultation she noted high blood pressure. There was a family history of hypertension in a well-controlled maternal grandmother with 2 antihypertensive drugs.
The metanephrine elevation was confirmed after a second determination made during hospitalization. Likewise, imaging tests (abdominal MRI) were performed for tumour location, which showed the presence of a right para-aortic mass compatible in clinical and biochemical context with an abdominal paranganglioma. An extension study was performed with MIBG-123. The patient was operated by laparotomy after medical treatment with phenoxybenzamine and subsequent beta blocking with atenolol for 20 days prior to surgery. The results of the pathological anatomy were compatible with poorly differentiated paraganglioma with associated lymph node metastases. The levels of ki 67 in the sample was >3%. A genetic study was also requested which was positive for the SHDB enzyme mutation.
After the intervention the patient is asymptomatic. Post-surgical determination of fractionated metanephrines without elevation was requested demonstrating a decrease in levels of fractionated methanephrines and methoxytyramine, with persistence of dopamine elevation.
Conclusion
The study and management of catecholamine-secreting tumours is complex. It is well established that surgery is the treatment of choice but there are controversies about the pre and post-operative management of these patient. With this review we want to clarify the more complex data related to the management of these tumours that not only represent a diagnostic challenge but also a therapeutic challenge.

Pheochromocytoma multisystem crisis presenting with cardiogenic shock and Tako-tsubo cardiomyopathy.

Modesta Petravičiūtė[1,2], Dovilė Šilinskienė[1,2], Monika Laukyte-Sleniene[2] & Zydrune Visockiene[1,2]
[1]Vilnius University, Vilnius, Lithuania; [2]Vilnius university hospital Santaros klinikos, Vilnius, Lithuania

Introduction
Pheochromocytoma is a rare catecholamine secreting neuroendocrine tumor. We describe a rare case of Tako – Tsubo cardiomyopathy as first manifestation of pheochromocytoma, which later developed into PMC.
Case report
A 39-year-old woman, with no history of arterial hypertension, was admitted to the emergency room with acute headache, severe chest pain radiating to the back, nausea and vomiting. At presentation, patient was in cardiorespiratory distress, tachycardic, tachypneic, with signs of pulmonary edema. Electrocardiogram showed supraventricular tachycardia with minor ST-segment depressions at V_5 through V_6 leads. Transthoracic echocardiography revealed akinesis of the middle segments of the left ventricle (LV), excessive apical and basal LV segments contractions and significantly impaired LV ejection fraction of 35–40%. Blood test analysis showed elevated troponin, significantly elevated brain natriuretic peptide (BNP), metabolic acidosis, together with increased hepatic enzymes. Chest and abdominal CT scan was performed and a massive left adrenal mass of 107×93×137 mm was found, so catecholamine – induced stress related (Tako-Tsubo) cardiomyopathy was highly suspected. Blood samples for plasma metanefrin and normetanefrin were taken to confirm the diagnosis of pheochromocytoma. During first 24-hours sepsis, acute renal failure and hypotension developed, thus intravenous infusion of vasopressors was started. However, patient's hemodynamics became unstable, cardiac function deteriorated – troponin I and BNP increased, hypotension and tachycardia remained despite maximal doses of vasopressors. Intra-aortic balloon pump was implanted and α-blocker labetolol 20 mg per hour intravenously and ß-blocker metoprolol 25 mg orally was started. Hemodynamics was stabilized and oral phenoxybenzamine 10 mg bid was prescribed. On day 9th the intra-aortic balloon pump was removed, the dose of phenoxybenzamine was increased to 40 mg per day. Laboratory analyses showed improvement in renal and liver, echocardiography showed transient previously noted wall motion abnormalities with a normal ejection fraction of >55%. On the 15th day of hospitalization, patient under-

went an exploratory laparoscopy, due to bleeding, turning into a laparotomy and excision of the large left adrenal mass. The pathological analysisand elevated plasma metanefrin and normetanefrin confirmed pheochromocytoma. After operation, patient was stable, her vitals were normal, renal, liver and heart function normalized. During follow-up, serum metanephrines were normal. Also abdomen CT scan showed no tumor recurrence.
Conclusion
Our case showed, that despite the rarity of the tumor, it is important to consider pheochromocytoma in any patient with unexplained cardiogenic shock or left ventricular failure, multi-organ failure, hypertensive crisis or unexplained lactate acidosis, especially, if also febrile.

Reducing short synacthen tests by deriving a novel baseline and 30 min cortisol level for a scottish population

Pauline McAleer, Joy Johnston & Saket Gupta
NHS Fife, United Kingdom

Introduction
The Short Synachten Test (SST) is the gold standard test for assessing adrenal insufficiency, however these can be time and resource consuming. Improved cortisol assays (Scottish consensus) currently advise a cut-off of 430 nmol/l at 30 minutes . However, there is no clarity about the optimum baseline cortisol level and recommendations range varies from 300 – 500 nmol/l. The aim of this study was to establish a single baseline cortisol concentration cut-off which could reliably exclude adrenal insufficiency for this Scottish sub-population. We also assessed if both 30 minute and 60 minute SSTs have clinical necessity.
Method
188 SSTs performed over a 1 year period (2016–2017), at the Victoria Hospital in Fife, were retrospectively analysed for indications, results (baseline, 30 and 60 minutes) and if on long term (LT) steroids. Receiver-operating characteristic (ROC) curve analysis was then performed to assess the optimalserum cortisol level and cut-off for the SSTs.
Results
Out of the 188 patients, 77% ($n=145$) passed the SST at 30 minutes, 6% (11) passed only at 60 minutes and 17% (32) failed at both time cut-offs. A total of 47% (87) patients were on LT steroids. These accounted for 70% (22) that failed overall but represented 80% of those that required the 60 minute test to pass. ROC curve analysis identified a cut-off level of 350 nmol/l (94% specificity and 28% sensitivity) for 30 minute cortisol. This excluded 2 patients who failed the SST. A further cut-off level of 250 nmol/l increased specificity and sensitivity to 91% and 57% respectively, but excluded 3 patients that failed.
Discussion
This study showsthat only a 30 minute SST is required in most cases to identify adrenal insufficiency. This reduces the time and financial costs associated with SSTs. However, 60 minute SSTs should be considered in patients on LT steroids, acutely unwell or with a pituitary disorder. This study suggests that a novel cortisol cut-off level of 350 nmol/l at 30 minutes in a SST can be safely used to identifypatients with adrenal insufficiency in a Scottish population. It also suggests a novel morning baseline cortisol level of <250 nmol/l can be used to classify SST requirement. Limitations to this study include the small population sample, the large number on steroids and unknown timings of the SSTs. Further studies in a larger population size shall be performed to confirm these results.

Surgical outcomes of adrenalectomy for primary hyperaldosteronism after using novel diagnostic tests

Krystallenia Alexandraki[1], Athina MARKOU[2], Labrini Papanastasiou[2], Ernestini Tyfoxylou[2], Chara Kapsali[2], Christos Gravvanis[2], Gregory Kaltsas[1], Giorgos Zografos[3] & George Piaditis[2]
[1]Laiko University Hospital, Medical School, National and Kapodistrian University of Athens, Endocrine Unit, 1st Department of Propaedeutic Medicine; [2]G Gennimatas Hospital, Department of Endocrinology and Diabetes Center; [3]Athens General Hospital "G Gennimatas", Third Department of Surgery

Background
Primary hyperaldosteronism (PHA) is the most frequent type of endocrine hypertension with a prevalence that is continuously rising. Following the introduction of diagnostic tests that consider both the adrenocorticotropic hormone effect andrenin–angiotensin–aldosterone system (RAAS), the post-dexamethasone saline infusion test (D-SIT) and the overnight dexamethasone, captopril, valsartan test (DCVT) using pharmaceutical RAAS blockade, a higher prevalence of PHA was found.
The aim of the study
To validate in the utility of the newly introduced diagnostic tests in pre- and post-surgical setting. The normal cutoffs values post-D-SIT were for aldosterone 67.59 pmol and for aldosterone-to-renin-ratio (ARR) 9.74 pm/mU/l, whilst post-DCVT for aldosterone 85 pmol/l and for ARR 9 pmol/IU.
Results
We studied 41 patients (16 males), with median (IQR, range) age 50 (16, 35–74) years. The median size of the adenoma resected was 2.1 (2.5, 1–6.5) cm, and in 21 patients was left-sided. Twenty-nine out of 31 were cured by the D-SIT, with aldosterone suppression; 4 patients had ARR >9.74 pm/mU/l but with suppressed aldosterone levels. In 6 patients PHA was diagnosed by DCVT criteria and one by both DSIT and DCVT; 2 patients were found cured post-adrenalectomy by DCVT criteria whereas the rest of the patients displayed low blood pressure measurements post-surgery. Overall, only 2 patients failed to be cured post-surgery implying an adrenalectomy success rate of 95.1%. In 40 patients post-adrenalectomy, 12 (30%) did not change their therapeutic anti-hypertensive status (remained without treatment if not previously treated or retained the same drugs and doses), 23 (57.5%) showed improvement (discontinued their anti-hypertensive treatment or reduced number and doses of anti-hypertensive drugs) and 5 (12.5%) had deterioration (anti-hypertensive treatment or drugs dose increase). A subset of 15 patients out of 32 diagnosed by D-SIT criteria did not suppressed cortisol levels post-dexamethasone suggesting a high percentage of mixed adenoma. The majority 9 patients had cortisol levels between 51 and 138 nmol/l whilst 6 patients had>150 implying autonomous cortisol secretion. Post-surgery, all 33 patients submitted on D-SIT suppressed cortisol levels.
Conclusion
The present study is a proof of concept for the validity of the newly introduced diagnostic tests for PHA in the clinical practice. The novel tests show a similar rate of clinical and biochemical response post-adrenalectomy, but may better discriminate the cases that may recur.

Subtyping of primary aldosteronism in patients with partially successful adrenal vein sampling

Karin Zibar Tomšić[1], Vilim Molnar[2], Tina Dusek[1,2], Ivana Kraljevic[1], Tanja Skoric Polovina[1], Annemarie Balasko[1], Mirsala Solak[1], Hrvoje Popovac[1], Nino Matas[3] & Darko Kastelan[1,2]
[1]Department of Endocrinology, University Clinical Hospital Center Zagreb; [2]School of Medicine, University of Zagreb; [3]Department of Internal Medicine, General Hospital Dubrovnik

Introduction
Adrenal vein sampling (AVS) is a gold standard in the assessment of the cause of primary aldosteronism (PA). It is technically demanding procedure having the high rate of failure, even in expert centres. Our study aimed to investigatewhether the data on aldosterone and cortisol concentration from successfully cannulated adrenal vein could determine the subtype of PA in certain patients with partially successful AVS.
Materials and methods
The study included 36 AVS procedures performed in 35 patients (one patient undergone AVS twice). Unilateral aldosterone secretion was confirmed in 12 patients who were all surgically treated and achieved biochemical remission of the disease. In the remaining 23 patients, AVS results were consistent with bilateral adrenal hyperplasia. In all patients aldosterone/cortisol ratio between the peripheral and adrenal veins, as well as aldosterone/cortisol ratio in adrenal veins were analysed.
Results
Statistical analysis, using ROC curve, showed that peripheral/adrenal vein aldosterone/cortisol ratio>2.3 (100 % sensitivity, 88% specificity) OR aldosterone/cortisol ratio in adrenal vein<0.64 (92% sensitivity, 93% specificity) indicate unaffected adrenal gland.

Conclusions
Aldosterone/cortisol ratio in adrenal vein of <0.64 and aldosterone/cortisol ratio between the peripheral and adrenal vein of >2.3 are consistent with unaffected adrenal gland indicating that excess aldosterone secretion originates from the opposite side.

Patients with adrenal insufficiency have cardiovascular features associated with hypovolemia

Daniela Esposito[1,2], Gudmundur Johannsson[2,3], Oskar Ragnarsson[2,4] & Daniela Pasquali[5]
[1]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden; [2]Sahlgrenska University Hospital, Department of Endocrinology, Gothenburg, Sweden; [3]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Gothenburg, Sweden; [3]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Gothenburg, Sweden; [5]University of Campania "Luigi Vanvitelli", Department of Advanced Medical and Surgical Sciences, Naples, Italy

Context
Patients with adrenal insufficiency (AI) have excess mortality and morbidity, mainly due to cardiovascular diseases. The mechanisms for this is unclear.
Objective
To assess cardiovascular structure and function in AI patients on conventional replacement therapy and after switching to once-daily, modified-release hydrocortisone (OD-HC).
Methods
The analysis included 17 adult AI patients (11 with primary AI, 7 with secondary AI)on stable replacement with cortisone acetate [median (minimum, maximum) 33.5 (12.5–50) mg] and, if needed, fludrocortisone [0.1 (0.05–0.2) mg], and 17 healthy matched controls. Ten patients switched to an equivalent dose of OD-HC. Echocardiography, 24-hour Holter-ECG and 24-hour blood pressure monitoring were performed at baseline and 6 months after the switch to OD-HC.
Results
At baseline, AI patients had smaller left ventricular diastolic diameter (47.1±4.2 vs 51.6±2.3 mm; $P=0.001$) and left atrial diameter (34.9±4.7 vs 38.2±2.6 cm; $P=0.018$), and a higher ejection fraction (62.5±6.9% vs 56.0±4.7%; $P=0.003$) than controls. AI patients had lower nocturnal systolic and diastolic blood pressure than controls (108.3±14.7 mmHg vs 117.2±8.3 mmHg; $P=0.038$ and 65.1±9.4 vs 72.9±6.6 mmHg; $P=0.008$, respectively). After the switch to OD-HC, nocturnal diastolic blood pressure normalised. No significant changes were observed in echocardiographic and Holter-ECG parameters following the switch.
Conclusions
AI patients on conventional treatment display cardiovascular abnormalities that could be related to hypovolemia. Switch to OD-HC seems to have beneficial effect on blood pressure profile, but no effect on cardiovascular structure and function.

Indications for aldosterone/renin screening presented by patients later diagnosed with hyperaldosteronism in a general endocrinology outpatient clinic

Elvira Ramos, Elvira Barrio, Inmaculada Moraga, Martin Cuesta, Mario Pazos, Raquel Pallares, Victoria Saez de Parayuelo, Luzdivina Fernandez, & Alfonso Calle Pascual, Isabel Runkle
Hospital Clínico San Carlos, Servicio de Endocrinología y Nutrición, Madrid, Spain

Introduction
Endocrine Society guideline indications for screening (EGS) of hypertensive patients for hyperaldosteronism are not universally followed in clinical Endocrinology. We present a series of patients with hyperaldosteronism, diagnosed following strict EGS compliance.
Methods
Retrospective. Following compliance with EGS in all patients attended in a general Endocrinology outpatient clinic, 70 hypertensive patients were diagnosed with hyperaldosteronism over an 8-year period. Screening, with determination of the Aldosterone (RIA)/direct renin (RIA) ratio (ARR), was considered positive when ≥20 in patients on hypertension medication, excluding spironolactone, eplerenone, amiloride. The 2-hour 25 mg captopril test was performed following a minimum of 2 weeks solely on doxazosin, slow-acting verapamil, and/or hydralazine, at least 6 weeks off spironolactone, eplerenone, amiloride. Hyperaldosteronism was diagnosed when the 2-hour aldosterone level (in pg/ml) was ≥130, and/or the 2-hour ARR was ≥50. Interquartile Range in brackets.
Results
40/70 (57.1%) women, mean age: 63.01 (SD:11.9). Hypertension diagnosed 12.6 (SD: 10.8) years earlier.
Reasons for Referral
Thyroid disease: 19/70 (27%), Diabetes 14/70 (20%), normokalemic hypertension 10/70 (14.3%), obesity 5/70 (7.1%), first-degree relatives (FDR) of hyperaldosteronism patients 5/70 (7.1%), adrenal incidentaloma 4/70 (4.7%), hyperparathyroidism 4/70 (5.7%), hypokalemic hypertension 2/70 (2.8%), others 7/70 (10%).
Indications for screening
Severe hypertension 35 (50%), moderate hypertension 31 (44.3%), resistant hypertension 17 (24.3 %), spontaneous hypokalemia 6 (8.6%), diuretic-induced hypokalemia 13 (18.6 %), hypertension <40 years of age 10 (14.3 %), FDR 6 (8.6%), Incidentaloma 5 (7.1 %). 35/70 (50%) presented 1 indication for screening, 22 (31.4 %) had 2, and 13 (18.5%) had ≥3. The latter presented a higher 2-hour median serum aldosterone: 214 [169.3-350.8] versus those with 2:174 [139.5-245.5] or 1 indication: 147 [120-181.5] $P=0.008$. Moderate hypertension was the sole indication in 16/70 (22.9%). The median screening ARR was higher in patients with resistant hypertension: 109 [41.5-232] than in the rest: 55 [35.15-92.13], $P=0.047$. Median aldosterone screening levels were higher in patients with severe hypertension: 248[152-338] than in the rest:190[132-245], $P=0.028$, as was 2-hour serum aldosterone: 201 [141-279.5] versus 151 [121-186.5], $P=0.016$.
Conclusions
Almost half the patients diagnosed with hyperaldosteronism in Endocrine Clinic had been referred for treatment of thyroid disease or Diabetes. Only 8.6% of patients presented spontaneous hypokalemia. Given the elevated morbimortality associated with hyperaldosteronism, Endocrinologists should study ALL their hypertensive patients presenting indications for screening, regardless of the reason for referral. Screening should not be limited to patients with adrenal incidentaloma or hypokalemia.

Hyperparathyroidism in patients with overt and mild primary aldosteronism: Epidemiological data from a tertiary centre

Christos Gravvanis, Labrini Papanastasiou, Spyridoula Glikofridi, Nikolaos Voulgaris, Ernestini Tyfoxylou & Theodora Kounadi
General Hospital of Athens G Gennimatas, Unit of Endocrinology and Diabetes Centre, Athens, Greece

Introduction
Primary aldosteronism (PA) is the most common cause of endocrine hypertension. In recent studies, increased prevalence of hyperparathyroidism (HP) has been observed in PA patients. However, the prevalence of HP in overt or milder forms of PA has not been evaluated yet.
Objectives
To estimate the prevalence of HP in patients with PA (overt and milder forms) and investigate the effect of treatment (eplerenone or surgery) on PTH secretion.
Patients and methods
We included prospectively 60 (39 men) PA patients (mean age 58.4±11 years) with normal renal function. The diagnosis of PA was based on the combination of valsartan, captopril and dexamethasone suppression test (DCVT)[1]. The patients were divided in two groups: overt (based on basal aldosterone/renin ratio (ARR)>84 pmol/mU[2] and positive DCVT) and mild PA (based only on positive DCVT). Mean systolic (SBP) and diastolic (DBP) blood pressure, iPTH, 25OHD, serum and 24 h-urinary calcium, potassium and phosphate levels at time of PA diagnosis and after surgical or medical treatment with eplerenone were evaluated.

Results
Primary HP was found in 5% (3/60) and secondary HP in 51.6% (31/60). Overt and mild PA was found in 40% (24/60) and 60% (36/60) respectively. Fifty one out of 60 PA patients were followed-up for 11 ± 6months, without receiving supplementary vitamin D treatment. After treatment, there was a significant decrease of mean SBP and DBP ($P<0.001$), iPTH ($P<0.001$) and 24 h-urinary calcium ($P<0.001$) and a significant increase of serum potassium ($P<0.001$), corrected Calcium ($P=0.01$) and 25OHD ($P<0.001$) levels in both primary and secondary HP patients. Furthermore, there was no significant difference between patients with overt and mild PA, concerning the iPTH, serum calcium and 25OHD levels, neither prior or after treatment. Aldosterone levels before treatment were positively correlated with serum PTH levels ($P=0.04$).
Conclusions
The prevalence of HP was found to be particularly high in PA patients, both in overt and mild cases. Treatment has a significant impact equal in overt and mild PA on serum calcium, 25OHD and iPTH levels, suggesting an association between mild or overt PA and primary or secondary PH.

Does adrenal vein sampling really improve the final approach for treating prymary aldosteronism? a retrospective study.
Josep León Mengíbar[1], Ismael Capel Flores[1], David Subias Andujar[1], Juan Perendreu Sans[2], Jaume Almirall Daly[3], Eugenio Berlanga Escalera[4] & Mercedes Rigla[1]
[1]Hospital Parc Taulí de Sabadell, Endocrinology and Nutrition, Sabadell, Spain; [2]Hospital Parc Taulí de Sabadell, Radiology, Sabadell, Spain; [3]Hospital Parc Taulí de Sabadell, Nefrology, Sabadell, Spain; [4]Hospital Parc Taulí de Sabadell, Laboratory, Sabadell, Spain

Introduction
Primary aldosteronism (PA) causes 15–25% of cases of drug-resistant hypertension (RBP). Adrenal vein sampling (AVS) is considered the gold standard for diagnosis of aldosterone aberrant secretion origin. The distinction between unilateral and bilateral disease dictates the targeted therapeutic approach, with surgery for aldosterone producing adenomas and medical therapy for patients with bilateral hyperplasia. As AVS is an invasive, not well standardized procedure and it is restricted to few specialized centers, several attempts have been made to simplify diagnostic algorithms by using abdominal imaging only. We aimed to compare how AVS changed the approach firstly chosen by CT-scan at our hospital.
Methods
A retrospective study in a single referral center was performed. All cases diagnosed with PA and in which CT scan and AVS were carried out, between 2006 and 2019, were included. We compare the CT scan-AVS concordance and we analyze the clinical decision that was taken and its result in terms of blood pressure control. For asses sampling quality we used an index cutoff of 1.1.
Results
We included 36 patients. 21 men/15 women. Mean age 60.8 y.o.. Diagnosis of PA was made due to suspicion of secondary RBP in 34 patients and due to an adrenal incidentaloma in 2 patients. CT-scan showed unilateral adenoma in 28 patients and hyperplasia or bilateral adenomas in 8 patients. In AVS, left AV was adequately sampled in 97% and right AV in 78%. In 20 patients (55,5%) AVS and CT-scan agreed, thus, initial therapeutic achievement did not change. In 12 patients, CT-Scan showed unilateral adenoma but AVS displayed no lateralization. All these patients were treated successfully with medical therapy except 2 patients who underwent surgery. One was cured but in other HBP persisted. In 3 patients, CT-scan showed bilateral disease but AVS displayed lateralization. One was treated with surgery and was cured. Other was treated successfully with drugs and other is waiting for surgery. Finally, one patient presented with a right adenoma and AVS displayed left lateralization. She was treated medically. Overall, 18 (50%) patients have been operated, and RBP has been cured in 8 and the rest has significantly reduced the number of antihypertensive drugs.
Conclusion
In 55% of patients, AVS confirms the abdominal imaging and the initial approach would not change. However, in 43% of patients AVS and CT-scan did not correlate. Thus, AVS can significantly improve the choice of treatment modality.

Pulsatile subcutaneous hydrocortisone replacement in primary adrenal failure, a proof of concept pilot trial
Katerina Simunkova[1,2], Marianne Øksnes[1,2], Paal Methlie[1,2], Nevena Jovanovic[3], Nebeyaet Selemon Gebreslase[1], Kristian Løvås[3] & Eystein Sverre Husebye[1,2]
[1]University of Bergen, Department of Clinical Science, Bergen, Norway; [2]Haukeland University Hospital / Health Bergen, Departments of Medicine and Centre for Clinical Research, Norway; [3]Haukeland University Hospital/Health Bergen, Endocrinology Department, Norway

Background
The pulsatile endogenous cortisol secretion is crucial for ultradian rhythmicity in blood and this rhythmicity triggers pulses of gene signaling in tissues. Disturbances in cortisol pulsatility can lead to cognitive, metabolic and cardiovascular dysfunction, and could explain why patients with primary adrenal insufficiency on conventional glucocorticoid replacement have reduced quality of life, increased mortality and are at risk of cardiovascular complications. Pulsed subcutaneous cortisol administration could be a means reversing and preventing these complications.
Objective
Comparison of three treatment regimen: conventional tablet treatment, continuous subcutaneous hydrocortisone infusion (CSHI), and pulsatile subcutaneous hydrocortisone infusion (USHI).
Study design
An open labelled, two weeks crossover, clinical trial
Participants
Two participants with Addison's disease, one adrenalectomized and two with congenital adrenal hyperplasia . All participants signed informed consent before entering the study.
Intervention
All underwent treatment with standard oral hydrocortisone, USHI and CSHI for two weeks in each treatment arms. USHI delivered hydrocortisone in seven bolus doses every three hours. Microdialysate from adipose tissues was obtained continuously and collected in fractions, each covering 20 minutes. Blood samples were taken every 20 minutes in the morning, hourly in the afternoon hourly and every other hour at night. Samples were assayed for glucocorticoids by liquid chromatography mass spectrometry.
Results
We restored the pulsatile oscillation of cortisol in serum and in subcutaneous tissue in the morning hours, the maximum levels of cortisol were between 350–495 nmol/l. The midnight maximum levels of cortisol were between 90–45 nmol/l. ACTH levels were in normal range during day time during both USHI and CSHI treatments compared with large oscillation on oral treatment. ACTH-levels started to raise about 0100 h and were significantly lower on USHI treatment from 0330 h compared to CSHI and oral treatment. Levels of androgens oscillated in the same pulsatile fashion as cortisol.
Conclusion
We show that mimicking the physiological ultradian cortisol rhythm is possible with pulsatile hydrocortisone treatment, resulting in reduction of ACTH levels.

CAH-X Syndrome in a german cohort of patients with 21-hydroxylase deficiency
Andrea Sappl[1], Christian Lottspeich[1], Katharina Vill[2], Monika Morak[1,3], Martin Bidlingmaier[1] & Nicole Reisch[1]
[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Dr. v. Hauner Children's Hospital, LMU - University of Munich, Department of Pediatric Neurology and Developmental Medicine, Munich, Germany; [3]Medizinisch Genetisches Zentrum, Munich, Germany

Congenital adrenal hyperplasia due to 21-hydroxylase deficiency (CAH) is encoded by the CYP21A2 gene. The CYP21A2 gene is partially overlapped by the TNXB gene encoding an extracellular matrix protein called Tenascin-X. Deficiency of Tenascin X can cause the Ehlers-Danlos Syndrome (EDS). Deletions of CYP21A2 extending into TNXB rarely cause CAH combined with EDS. CAH associated with mild hypermobility form of EDS due to TNXB haploinsufficiency caused by heterozygous mutation has been named CAH-X syndrome. We genetically investigated a cohort of 81 patients (31 males, mean age 37.8 years ±9.8) with classic CAH for CAH-X. Patients genetically positive for CAH-X and unaffected CAH

control patients matched for sex, age and BMI underwent a thorough clinical investigation including joint examination by Beighton 9-point scale, skin and neurological examination, by a standardised protocol of thransthoracic echocardiography and muscle ultrasound. In addition serum tenascin-X has been measured. We identified one patient with CAH and EDS and 4 patients with CAH-X. All CAH-X patients had concentrations of tenascin-X below the normal range, but not different from 35 unaffected CAH patients. All 4 patients with CAH-X showed some associated clinical symptoms. Two had joint hypermobility detected by Beighton 9-point score. Two CAH-X patients showed cardiac abnormalities. The patient with CAH and EDS showed cardiac abnormalities and typical EDS symptoms. All affected patients complained about back pain and showed foot malposition. Profound changes in muscle ultrasound were found in 60 % of patients with CAH-X syndrome (3/5) and in none of the controls (0/5). In conclusion, our data confirm the previously described prevalence of CAH-X. Beighton-score seems to be a quick and cheap screening instrument for CAH-X and should be performed in all patients with classic CAH, since protein level in serum cannot be used for screening for CAH-X-Syndrome. A stronger focus needs to be made on back pain and foot malposition as symptoms of CAH-X and echocardiography should be performed in all CAH-X patients. Therapy should depend on clinical symptoms.

DOI: 10.1530/endoabs.70.AEP70

Cardiovascular risk and metabolic profile in adult patients with congenital adrenal hyperplasia

Mattia Barbot, Filippo Ceccato, Ilaria Patelli, Daniela Regazzo, Laura Lizzul & Carla Scaroni
University of Padova, Endocrinology Unit, Department of Medicine-DIMED, Italy

Background
Classic congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency is characterized by impaired cortisol synthesis, requiring life-long glucocorticoid (GC) replacement therapy. Given the detrimental systemic effects of GCs in the long term, the aim of our study was to assess whether CAH patients have increased metabolic and cardiovascular alterations compared with age-matched controls.
Materials and methods
For this cross-sectional study 29 patients with CAH were submitted to biochemical and hormonal testing, oral glucose tolerance test (OGTT), intima-media thickness (IMT) evaluation and compared to 21 controls matched for age, sex, BMI and smoking-habits. The effects of different GC regimens (dexamethasone, DEX vs dual-release hydrocortisone, DR-HC) on metabolic parameters and quality of life were also assessed.
Results
IMT was higher in CAH than in controls at right and left common carotids (0.8±0.3 vs 0.68±0.12 mm, $P<0.001$ and 0.8±0.35 vs 0.68±0.17 mm, $P<0.001$) and carotid bulbs (0.8±0.2 vs 0.64±0.18 mm, $P<0.0001$ and 1±0.35 vs 0.62±0.13 mm, $P<0.0001$). Patients on DEX treatment had taken lower cumulative GC dose during the last 3 years compared to those on DR-HC and daily dose normalized for body surface area (7.18±4.18 and 10.77±2.76 mg/m^2, $P=0.045$). Despite lower equivalent doses, patients taking DEX showed better disease control with lower 17-hydroxyprogesterone (respectively, 40.5±230.76 vs 741±893.5 nmol/l, $P=0.008$) and ACTH (respectively, 32±58 vs 652.5±855.25 ng/l, $P=0.016$). However, DEX therapy was associated with higher glucose levels during OGTT with an overall more elevated $AUC_{-glucose}$ (32.9±9.58 vs 21.45±6.77, $P=0.005$) than DR-HC without differences in insulin curves. To add, DEX induced an increase in clotting factors II (143.95±35.55% vs 109.55±25.5%, $P=0.039$) and X (106±6.24% vs 96.5±8.2%, $P=0.05$), followed by a compensatory increase in antithrombin (106±6.24% vs 96.5±8.2%, $P<0.005$), protein C (113.8±23.99% vs 92.35±27%, $P=0.006$) and plasminogen (108.9±17.04% vs 89.5±28.03%, $P=0.025$) compared to DR-HC.
Conclusions
Patients with CAH have a higher cardiovascular risk which is probably due to both chronic GC treatment and the disease itself. The negative effects of GCs on glucose metabolism and coagulative cascade depend not only on the total GC dose, but also on the type of drug taken and probably on its time of administration. DEX proved to be effective in suppressing adrenal androgen secretion to the detriment of a less favourable glucose profile. Conversely, DR-HC, even administered at higher equivalent dose, did not guarantee a comparable disease control, but showed a lower metabolic impact. Our results pinpointed the need to individualize GC therapy in CAH on the basis of each patient's characteristics.

Adrenal incidentalomas and renal cysts – the definitive sign of aging?

Ljiljana Marina[1,2], Miomira Ivovic[1,2], Milina Tancic-Gajic[1,2], Zorana Arizanovic[1], Aleksandra Kendereski[1,2], Antoan Stefan Sojat[1], Aleksandar Filipovic[3], Dragan Vasin[3], Andja Cirkovic[4], Dragana Rakovic[1], Milan Radovic[2,5], Ana Bontic[5], Kristina Nedic[2], Tijana Petkovic[1], Isidora Petkovic[2], Sladjana Mihajlovic[2,6], Marija Stevanovic[2] & Svetlana Vujovic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Department for Obesity, Metabolic and Reproductive Disorders, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia; [3]Centre for Radiology and Magnetic Resonance Imaging, Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia; [4]Institute of Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia; [5]Clinic for Nephrology, Clinical Centre of Serbia, Belgrade, Serbia; [6]University Hospital Centre Dr Dragisa Misovic, Belgrade, Serbia

Introduction
The prevalence of adrenal incidentalomas (AI) and renal cysts increase with age. Depending on the study population age and sex, on average, both are prevalent with about 8 to 10% in subjects older than 50 years of age.
Aim
We aimed to investigate the co-occurrence of AI and simple renal cysts.
Methods
Our study included 970 subjects, 494 with AI – all evaluated in single centre, and 476 control group (CG) patients (not harboring AI) enrolled from trauma patients admitted to the emergency room with performed CT scan of abdomen. Patients with polycystic kidney disease, end-stage kidney disease, hydronephrosis and known malignant diseases were not included in the study.
Results
There was no significant difference in age (AI: 60.79±10.26 years, CG: 61.80±9.59 years, $P>0.05$) nor gender (male/female, AI: 163/330, CG: 181/295, $P=0.107$) between AI and CG. Simple renal cysts were significantly more prevalent in patients with AI than in CG, 33.1% vs 19.5%, $P<0.001$. In both groups patients with cysts were significantly older than those without them (AI: 62.45±9.00 vs 56.99±10.38 years, $P<0.001$ and CG: 64.20±9.26 vs 61.22±9.59 years, $P=0.007$, respectively). Gender distribution was the same between patients with and without cysts in both study groups. Among AI patients the presence of cysts was not dependent on the level of cortisol suppression in 1mg dexamethasone suppression test (cortisol: <50 nmol/l, $P=0.661$ and <140 nmol/l, $P=0.248$). The prevalence of renal cysts among unilateral and bilateral tumours was the same ($P=0.814$) and it was not dependent on the size of the adrenal tumour.
Conclusion
Patients with AI are more likely to harbor a renal cyst(s) then patients without AI. Also, our study points to the significance of aging to occurrence of both AI and renal cysts.

Major barriers exist in the diagnosis and management of addison's disease in africa

Ian Louis Ross[1], Thabiso Mofokeng[2], Kwazi Ndlovu[2] & Salem Beshyah[3]
[1]University of Cape Town, Department of Medicine, Cape Town, South Africa; [2]University of the Free State, Department of Medicine, Bloemfontein, South Africa; [3]Dubai Medical College, Dubai, United Arab Emirates

Background
The burden and management of Addison's disease (AD) in Africa have not been well documented. We aimed to identify specific disease characteristics, patient demographics and patterns of clinical management in established AD in Africa, hypothesizing that deficiencies in diagnosis and management exist.

Methods
An on-line survey of a large pool of medical practitioners' experience from Africa and Middle East, relating to AD was conducted, using a commercial database.
Results
Respondents: Of the 1334 responses received, 589 provided complete data and of these, 332 respondents confirmed that they manage patients with hypoadrenalism. Patients: Data obtained referred to 5787 patients with hypoadrenalism (2746 females, 3041 males), of whom 2302 had primary hypoadrenalism (AD). The likely causes of AD in sub- Saharan Africa (SSA) vs Middle East North Africa (MENA) included autoimmune disease (20% vs 60.3%; $P<0.001$), tuberculosis (34% vs 4.1%; $P<0.001$), AIDS (29.8 % vs 1%; $P<0.001$). Most patients 83.7% presented with typical AD symptoms, however 376 patients (16 %) presented in an Addisonian crisis in both regions. Non-availability of diagnostic tests across both regions included tetracosactide in at least 45.7%, serum cortisol 50.7% adrenal antibodies (64.1%), and adrenal CT scans (49.1%). They were managed using hydrocortisone alone in SSA 588 (39.9%), compared with MENA 780 (94.2%); $P<0.001$, whereas fludrocortisone was only available in 36% of the entire cohort. Some form of medical emergency identification was used in only 241 patients in SSA (16.4%) vs 493 (59.6%) MENA patients; $P<0.001$.
Conclusions
Significant hurdles in diagnosing AD in Africa include poor availability of tetracosactide by plasma cortisol as a surrogate, adrenal autoantibodies and CT scans of the adrenal glands, all proven diagnostic utility. Fludrocortisone is also poorly available. It is expected that these findings may account for inadequate diagnosis, management of AD with potential fatal consequences.

AEP74

Acute adrenal failure as presenting feature of antiphospholipid syndrome

Mohamad Mustafa, Sanval Warriach, Denis O'Keefe & Michael Watts
University Hospital Limerick, Limerick, Ireland

Introduction
Anti-phospholipid syndrome is characterised by the presence of arterial or venous thrombosis, it is autoimmune in nature and manifests as a systemic disease. Adrenal vein haemorrhagic infarction which is a sequel of adrenal vein thrombosis ultimately leads to loss of adrenal function, it is one of the presentations of anti-phospholipid syndrome especially with catastrophic type. In one analysis adrenal involvement was reported in only 13% of the reported cases of a catastrophic type of anti-phospholipid syndrome.
Case report
A 64-year-old man presented with generalised fatigue, dizzy spells nausea, vomiting, and vague abdominal pain. His past medical history includes previous admission with pneumonia complicated with right leg deep venous thrombosis. At that time a thrombophilia screen was performedand revealed positive anticardiolipin (serum level of >120 U/ml) and anti-B-2 glycoprotein antibodies (268 RU/ml). Hence the patient was diagnosed with antiphospholipid syndrome secondary to pneumonia. At the time of admission, he looked plethoric, his blood pressure was 90/45 mmHg, and no significant systolic drop in blood pressure was noted. The blood sugar level was 4.0 mmol/l. Initial investigations revealed serum sodium 129 mmol/l (136–145 mmol/l) potassium t 5.7 mmol/l (3.6–5.1). APTT of 72 seconds (28–40). ESR 73 mm/hr (1–14). Given the clinical presentation, the low sodium, and the high potassium, synacthen test was performed. Pre synacthen serum cortisol was 41 nmol/l (119–618 nmol/l) and post synacthen cortisolwas 43 nmol/l (> 450 nmol/l), indicating no significant response to ACTH. Adrenal antibodies were negative. Abdominal ultrasound revealed a left kidney cyst measuring 3 cm in maximum diameter. This led to a CT scan of the abdomen that showed enlarged adrenal glands bilaterally. Urinary catecholamines and VMA were requested and werewithin the normal range. A PET CT was done to rule out malignant enlarged adrenal gland and showed no FDG avid macroscopic disease. Serum QuantiFERON sample was requested as TB remains an important cause and revealed strongly positive result. Anti-tuberculosis treatment was started in view of evidence at hand. Regular follow up plan put in place. Five months after the initial scan, a repeat scan showed a significantly reduced size of adrenal glands to 1.3 cm .After reviewing the serial scans at MDT discussion the initial diagnosis was revised and the MDT Consensus washaemorrhagic infarcts secondary to anti-phospholipid syndromeas the final diagnosis.
Conclusion: APS should be considered as a cause of hypoadrenalism even though it is a very rare cause.

Differential diagnosis of primary adrenal insufficiency in a young male with mental retardation and axonal sensorimotor polyneuropathy

Maria Cristina Baleanu[1], Simona Galoiu[1,2], Lavinia Popa[1], Emma Margarit[1], Mihai Constantin Marinescu[1], Andra Caragheorgheopol[1] & Catalina Poiana[1,2]
[1]CI Parhon National Institute of Endocrinology, Pituitary and Neuroendocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania

Introduction
Primary adrenal insufficiency (PAI) is a rare disease with a prevalence of 82–144 cases/milion. The etiology of PAI is represented primarily by autoimmune adrenalitis, followed by tuberculosis and less common by fungal infections, HIV, hemorrage in adrenal glands, certain drugs and by some genetic disorders such as Triple A syndrome (AAA), Adrenoleukodystrophy (ALD), congenital adrenal hypoplasia, congenital adrenal hyperplasia, etc.
Case presentation
A 19-years old male diagnosed with moderate mental retardation is admitted to our clinic complaining about the appearence of few dark spots on his tongue and chronic dysphagia for both solids and liquids. He has a sister with subclinical hypothyroidism and his mother, with type 2 diabetes mellitus, suffered a myocardial infarction at 40 years old. Clinical findings included: BMI = 17.9 kg/m^2, generalized hyperpigmentation of teguments and darken patches on the dorsal surface of his tongue, normal body and facial hair, important muscular hypotrophy on lower limbs, bilateral pes cavus and hammer toes. Blood pressure was 100/60 mmHg with no postural variation. Adrenal insufficiency was confirmed by low 0800 h serum cortisol (1.92 µg/dl; normal values: 6-22 µg/dl) with high ACTH (1320 pg/ml; normal values: 16-65 pg/ml), low-normal aldosterone level in upright position (25.3 pg/ml) and normal renin. Thyroid function, antithyroglobulin and anti-TPO antibodies, 17-OH progesterone, testosterone, LH, FSH, PTH and electrolytes were in the normal range. Abdominal computed tomography revealed enlarged left adrenal gland. The patient started replacement therapy with 20 mg hydrocortisone and 0.1 mg fludrocortisone per day. We excluded tuberculosis. Neurological examination revealed peripheral axonal sensorimotor polyneuropathy. The MRI of the brain showed a 9.5 mm arachnoid cyst, no signs of demyelination and no imagistic arguments for leukodystrophy. Further investigations, 21-hydroxylase antibody, very long chain fatty acids (VLCFA) levels and esophageal manometry, are needed in order to establish the etiology of PAI.
Conclusion
Even though the primary etiology of PAI is autoimmune, in some patients additional testing should be performed in order to exclude genetic causes. Early diagnosis of these conditions may reduce morbidity and improve quality of life in these patients.

Bronchogenic cyst mimicking adrenal mass

Derya Köseoğlu
Erol Olçok Education and Research Hospital, Department of Endocrinology and Metabolism, Çorum, Turkey

Introduction
Primary retroperitoneal bronchogenic cysts are rarely seen. Bronchogenic cysts are mostly benign which originate from the remnants of the primitive foregut during the embryonic development.
These lesions can be seen near or inside any organ that originates from the embryonic foregut. Bronchogenic cysts are most often found in the thoracic cavity, especially in the mediastinum. Except this many distant sites, such as abdomen, retroperitoneum, left ventricle have been reported. A bronchogenic cyst, which was defined in the retroperitoneal region, was first described

by Miller et al. in 1953. No specific diagnostic imaging modality is present for the preoperative diagnosis of retroperitoneal bronchogenic cysts. This is why a bronchogenic cyst may be misdiagnosed as an adrenal tumor or other retroperitoneal lesions. Definite diagnosis requires histopathological examination. Here, we report a case of a 28-year-old male with a bronchogenic cyst mimicking as an adrenal mass.
Case
A 28-year-old male was admitted to the hospital after having intermittent left flank pain. There was no significant findings in his physical examination, and in the laboratory analysis kidney and liver function test values were within normal limits. Abdomen computed tomography was performed and in the left surrenal gland a 42 × 36 mm large lesion with 38 HU density without contrast enhancement was observed. The patient was tested for hypercortisolism and pheochromocytoma. Primary hyperaldosteronism was not examined because he had no history of hypertension. After the test results the adrenal mass was considered as nonfunctional. Because of the size of the mass, the patient was operated and left adrenelectomy was performed. Macroscopically, the specimen consisted of a regular, cystic mass measuring 50 × 40 × 35 mm. It was observed that the mass was attached to the adrenal gland but not infiltrated into the adrenal parenchyma. After histopathological analysis the concise diagnosis was made as bronchogenic cyst.
Conclusion
We present an uncommon bronchogenic cyst mimicking adrenal mass in a 28-year-old male who admitted with left flank pain. Bronchogenic cysts are rare and often benign lesions. Like most adrenal lesions, bronchogenic cysts are frequently asymptomatic and diagnosed incidentally. Bronchogenic cysts should be considered in the diagnosis of lesions located in the retroperitoneal region.

Primary aldosteronism : Study of 09 cases

Abainou Lahousssaine, Idrissi Ayoub, Hamza El Jadi, Sanae Elhadri, Azelarab Miftah & Hicham Baizri
Avicenna Military Hospital Marrakech, Morocco

Introduction
Primary aldosteronism (PHA), also known as primary hyperaldosteronism or Conn's syndrome, refers to the excess production of the hormone aldosterone from the adrenal glands.
Study objectives
To show clinical, biochemical, and morphological data of 09 patients with primary hyperaldosteronism as well as the therapeutic choice for each patient
Mehtods
it is aretrospective and descriptive study of 09 cases with primary hyperaldosteronism, which were admitted between 2014 and 2019.
Results
Our series included 5 women and 4 men. The mean age of our patients was 44 years. All had severe blood pressure at the time of diagnosis with a median of 190/101 mm Hg varying between 240 and 150 mm Hg for systole and between 120 and 80 for diastole. The mean age of onset of hypertension was 32 years. The context of screening of PHA was severe and resistant hypertension in 89% of the cases followed by the association of hypertension and hypokalemia in 67% of the cases. Sixty-seven percent of our patients had hypokalemia at the time of diagnosis, while 33% had normal serum potassium.
PAH was mentioned and then confirmed by a high aldosterone / renin ratio in 89% of patients with values varying between 63 and 195 (122.42 on average) when standing and then lying down with values varying between 25 and 840 (178 on average). CT scan showed bilateral adrenal hyperplasia in 4 cases, Conn's adenoma in 3 cases, and unilateral hyperplasia in one case. Four patients had an adrenalectomy under laparoscopy while 5 patients were put on medical treatment. Seventy-five percent of our operated patients had complete remission with normalization of blood pressure while only 40% for patients on medical treatment. The serum potassium level normalized for all patients.
Conclusion
At the end of this work, concerning the management of the 9 cases of PAH treated at the Avicenna Military Hospital in Marrakech, it seems important to insist on the methods of management of this pathology, which must be multidisciplinary including endocrinologists, cardiologists, radiologists, urologists and biologists.

Adrenal necrosis caused by streptococcus constellatus infection

Chun-Hsien Lin & Wan-Chen Wu
National Taiwan University Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Taipei, Taiwan

A 49-year-old man who has diabetes mellitus and alcoholic cirrhosis presented to the emergency department due to left upper quadrant abdominal pain and left back soreness for three days. He received sclerotherapy and endoscopic band ligation twice for gastric varices few months prior to admission. On physical examination, he had rebound tenderness at left upper abdomen. The computed tomography (CT) of abdomen revealed diffusely enlarged left adrenal gland with rim-enhanced multi-cystic components and necrosis in pararenal space. One of the two peripheral blood culture yielded streptococcus constellatus. The adrenal hormones were all within normal limits. CT-guided biopsy of the left adrenal gland was performed. The pathology revealed only necrosis with reactive change, and the results of special stains and culture were both negative. The symptoms were resolved after intravenous broad-spectrum antibiotic agents and he continued 6-month course of oral cefixime at outpatient department. During the antibiotic treatment, the Gallium scan showed grossly normal and no definite gallium accumulation at the suprarenal/perirenal soft tissue. The follow-up CT scan showed partial resolution of infiltrative left adrenal lesion after 2-month treatment, and smaller size of left adrenal lesion after 5-month treatment. However, fever with chills and abdominal fullness developed three months after discontinuation of the antibiotic treatment. The CT scan showed enlargement of left adrenal lesion, and recurrent infection or inflammation was suspected. Antibiotic treatment was given again. The peripheral blood culture revealed negative finding. He received CT-guided drainage, and 5 ml yellowish pus was drained. The culture from CT-guided aspiration this time yielded streptococcus constellatus. The patient then received laparoscopic left adrenalectomy, and the pathology revealed chronic inflammation. He was totally recovered uneventfully and no adrenal insufficiency developed during follow-up. Adrenal infection is a rare cause of adrenal disorder in adults. The adrenal gland can be infected by a myriad of pathogens, and Mycobacterium tuberculosis was the most common causative agent. Streptococcus constellatus infection was likely cause abscess, but no report as adrenal abscess. Immunocompromised individuals are at greatest risk for adrenal infection. Antibiotic treatment or surgical intervention remains debate.

Endothelial vascular adrenal cyst with unusual presentation

Gavriel Lichewitz[1], Marina Pal[2], Atlan Karine[3], & Haggi Mazeh[4]
[1]Meuhedet HMO, Endocrinology, Israel; [2]Meuhedet HMO, Diabetic Clinic; [3]Hadassah-Hebrew University Medical Center, Pathology; [4]Hadassah-Hebrew University Medical Center, Mount Scopus, Endocrine and General Surgery

Primary adrenal cysts are a relatively rare form of lesions with incidence of 0.06% in general population and higher prevalence in women (female-to-male ratio 2.3:1). Adrenal endothelial cysts are the most common form of adrenal cysts subtypes (45%) and they usually present with abdominal or flank pain, or nonspecific symptoms . Adrenocortical carcinomas are a rare condition as well, with an incidence of 1–2 per million per year. The typical clinical presentation may include symptoms of glucocorticoid excess and systemic symptoms such as weight loss, anorexia, leukocytosis, and fever.
We describe a case of a 51-year-old female with poorly controlled hypothyroidism. She presented to endocrinology clinic with a history of fever for three months. The clinical evaluation of fever of unknown origin was unremarkable. A CT scan demonstrated a 3.6×2.6 cm heterogenic mass in the leftadrenal. Endocrine blood tests revealed no abnormalities besides overnight dexamethasone (1 mg) suppression test that demonstrated partial suppression of cortisol levels (126 nmol/l). As malignancy was suspected, the patient was referred to surgery and the adrenal was removed laparoscopically. Surprisingly, histology confirmed endothelial/vascular cyst. During multiple follow-up visits over a period of 18 months, the fever has completely resolved. This demonstrates the first known case of endothelial/vascular adrenal cyst presenting with persistent fever.

DOI: 10.1530/endoabs.70.AEP79

AEP80

Less common form of adult secondary hypertension

Iconaru Laura, F Baleanu, Taujan Georgiana, Ichiche Malika, & Karmali Rafik
CHU Brugmann, Endocrinology, Bruxelles, Belgium

Introduction
Patients with clinical clues suggesting the possible presence of secondary hypertension should undergo a more extensive evaluation, because in this case some of these disorders can be cured, leading to partial or complete normalization of the blood pressure.
Case description
We report a case of a 43-year-old man, who suffered for years of hypertension despite concurrent use of adequate doses of three antihypertensive agents from different classes. He presented a heart failure, diffuse hypokinesia and a reduction of his ejection fraction to 40%. In the blood tests he had hypokalemia, low cortisol (117 mmol/l) with high ACTH (1013 ng/l), low aldosterone (21.8 ng/l) and renin at 9 µUI/ml. In this context we tested testosterone (30.4 nmol/l), androstenedione (31 ng/ml), DHEAS (17,8 µmol), 17OH progesterone (8 ng/ml) and the 11 deoxycortisol (>30 ng/ml). The abdominal scan showed bilateral adrenal hyperplasia and on testicular ultrasound the patient presented bilateral intra-testicular lesions compatible with intra-testicular adrenal inclusions. The genetic test confirmed the suspicion of the congenital adrenal hyperplasia by 11-hydroxylase deficiency. It showed a homozygous mutation in the CYP11B1 gene, chromosome 8, exon 8, pArg448His. The patient didn't have the adrenal crisis before despite the cortisol deficiency. We started the treatment by Dexamethasone 0.5 mg per day and 6 months later we obtained a normalization of the blood pressure and a decrease of adrenals hyperplasia and intra-testicular adrenal inclusions.
Discussions
CYP11B1 deficiency affects 1 in 100,000 live births and accounts for up to 5% of adrenal steroidogenic defects. The frequency of no classic disease is far less common for 11hydroxylase. Patients do not have adrenal crisis due to accumulated adrenal steroid precursors that can activate the glucocorticoid receptors, especially for hydroxylation at position 11 which enhances glucocorticoid activity.
Conclusions
We report a case with a late diagnostic of congenital adrenal hyperplasia by 11-hydroxylase deficiency, with proven cortisol deficiency without adrenal crisis, but good treatment response.

Behavior of adrenal incidentalomas with density computed tomography scan > 10 HU

Ines Modrego Pardo, Sandra Garzón Pastor & Carlos Morillas Ariño
Hospital Universitario Doctor Peset, València, Spain

Background
The prevalence of adrenal incidentalomas has increased. The malignancy is determined by radiographic appearance and, secondly, by the size. Adenomas manifest a low attenuation on computed tomography (CT) (<10 Hounsfield Units(HU)).The cut-off point of 10 HU has been proposed to discriminate benign and malignant lesions.
Objective
To determine if the cut-off point of 10 HU is useful in clinical practice to discriminate benign and malignant incidentalomas. Determine if there are other discriminatory characteristics.
Methods
Retrospective serie of patients referred for adrenal incidentaloma in imaging test between 2015–2019.The characteristics of incidentalomas by CT and other tests were evaluated and associated with the final diagnosis.
Results
Baseline characteristics are shown in Table 1. Of the 139 patients,3 were diagnosed of adenoma by magnetic resonance (MR). In the remaining 136,CT without contrast was performed and the results are shown in Table 2. Of the 27 lesions with CT>10 HU:9 were adenomas (false negatives of CT), 9 other diagnosis and 10 were lesions with uncertain malignant potential (UMP).
Finally, 8 patients (6%) were operated: 3 functioning adenomas and the rest corresponding to the UMP group: 1 pheochromocytoma (17UH), 1 hematoma (16UH), 1 cyst (>10UH), 1 metastasis (22UH) and 1 bleeding adenoma(>10UH). Of the 5 that were not operated,2 died during follow-up,1 decided not to continue the study and 2 are keeping under observation by PET-CT without hypermetabolism. No differences were observed depending on the size between the different lesions. Finally, there were 116 adrenal adenomas:12% were false negatives on CT without contrast using a 10 HU cut-off point. The sensitivity to detect adenomas was 88%.
Conclusions
CT without contrast is an adequate tool to typify adrenal lesions and confirm or rule out malignancy.
The 10 HU cut-off pointdiscriminates properly benign lesions from malignant/uncertain behavior.
The size was not discriminatory to differentiate benign or malignant lesions.
It should be considered not to request metanephrines in patients with a characteristic image of adenoma on CT because image's diagnosis excludes that of pheochromocytoma.

Malignant collision tumour in left adrenal gland- A rare tumour

Ma'en Al-Mrayat & Sing Yang Sim
University Hospital Southampton, Endocrinology, Southampton, United Kingdom

We present a 41 years old lady who presented with non specifc symptoms-lethargy, general myalgia, memory impairment. She also complained of hot flushes, sweats and had a brief episode of panic attacks hence was commence on Sertraline by the GP. She has a past medical history of appendicectomy. Her mother had lymphoma and mother died from lung cancer. She is a smoker, however is teetotal. She has 3 children and works in a laundry. She was initially referred to the haematologist for investigation of lympho-

cytosis and neutrophiliawho subsequently discovered a 51mm left adrenal mass (not typical of an adenoma) raising the possibility of a phaeochromocytoma or adrenal cortical carcinoma through a CT scan subsequently characterised byfurther MRI scans. On clinical examination, her blood pressure was 126/73 sitting and 125/84 standing with a regular pulse of 82bpm. She has no cushingoid features and no proximal myopathy. Her investigations showed a normal cortisol 18 nmol/l post overnight dexamethasone suppression test. Raised Metanephrines 6.8 umol/24 h (0-3 umol/24 hr), Raised Normetanepherine 7.35 umol/24 h (0-1.14 umol/24 h), 3-methoxytyramine 2.11 umol/24 h Normal. Aldosterone renin ratio, DHEA 3.70 umol/l normal, Aldosterone renin ratio 25.3 pmol/mU Normal She was alpha and beta blocked prior to surgery. She had a left laparoscopic adrenalectomy where her histology results showed a mixed composite of phaeochromcytoma/paraganglioma with neuroblastic elements. Immunohistochemistry showed some areas staining strongly with chromogranin and synaptophysin while other areas are weaker. The Ki67 proliferation index is <1%. Post operatively, she had a 123I-mIBG scintigraphy scan which show physiological tracer distribution with no abnormal focal mIBG avidity. She consented for genetic testing and undergone the pheochromocytoma and paraganglioma gene paneltesting (FH, MAX, RET exons 10&11, SDHA, SDHAF1, SDHB, SDHC, SDHD, TMEM127, VHL) with no alteration identified. Her RET gene testing (exons 5, 8, 10, 11, 13, 14, 15 and 16) is also normal. She was offered entry into the molecular pathology of human genetic diseasese Post operatively, she recovered well, her subsequent 24 hour metanephrines normalised. Serial CT scans show no disease recurrence so far. Adjuvant chemotherapy was also discussed with the oncology team. However, this wasn't deemed necessary and surveillance was advocated. This is a very rare tumour with few case series reported. This case adds to the sparse literature on this type of tumour and uncertainties regarding longterm management.

JIL-O: Establishment of a new steroidogenic human adrenocortical carcinoma cell line

Laura-Sophie Landwehr[1], Schreiner Jochen[1], Sabine Herterich[2], Silke Appenzeller[3], Martin Fassnacht[1,2,3], Matthias Kroiss[1,3] & Isabel Weigand[1]
[1]University Hospital, University of Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital, University of Würzburg, Clinical Chemistry and Laboratory Medicine, Würzburg, Germany; [3] University of Würzburg, Comprehensive Cancer Center Mainfranken, Würzburg, Germany

Adrenocortical carcinoma (ACC) is a rare malignancy with heterogeneous but dismal prognosis and despite numerous efforts to improve patient care, effective treatment options are still lacking. ACC *in vitro* research faces for decades one major obstacle - the unavailability of different ACC cell line models. Here, we present a newly established human ACC cell line that was directly transferred to and now proliferates in cell culture. JIL-O cell line was derived from a primary adrenal tumor of a female, fifty-year-old patient with ENSAT stage IV. The patient presented with clinical symptoms of hypercortisolism and androgen excess and was treatment-naïve at the time of surgery. Subsequently, she received palliative mitotane and cytotoxic chemotherapy. Short tandem repeat (STR) profiling confirmed matches between the tumour and the derived cell line. Both tumour tissue and JIL-O cells were exome sequenced and a hemizygous TP53 mutation (NM_000546.5: c.859G>T: p.Glu287*) in the cell line excluded contamination with healthy cells. JIL-O cells stained positive for steroidogenic factor 1 (SF-1) by western blot. Hormone profile panels were determined by LC-MS/MS and those of the cell line matched to the secretion of the tumour in the patient, withexcessive secretion of cortisol, 11-deoxycortisol and androgens (androstendione, DHEA, testosterone). JIL-O cells adhere on plastic and started to proliferate after being in cell culture for more than one year with a doubling time of approximately 39 hours. To our knowledge, this is the first ACC cell line since the establishment of the NCI-H295R cell line that was directly transferred into *in vitro* culture without implantation into mice. JIL-O cells hence present another new tool to study ACC *in vitro* and hopefully help to reflect heterogeneity of this rare malignancy.

[1]Semmelweis University, 2nd Department of Medicine, Budapest, Hungary; [2]Semmelweis University, 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary; [3]Semmelweis University, Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary, Budapest, Hungary; [4]Semmelweis University, 1st Department of Surgery, Budapest, Hungary; [5]Semmelweis University, 2nd Department of Pathology, Budapest, Hungary; [6]Semmelweis University, Division of Nuclear Medicine, Department of Radiology, Budapest, Hungary

Introduction
Adrenocortical cancer is a rare malignant tumour with a poor prognosis. The incidence is 0.7–2.0/million/year.
Objectives
The aim of this study was to characterise the clinicopathological features and prognostic factors of a large cohort of patients with adrenocortical cancer diagnosed between 1974–2019.
Patients and methods
The study included eighty patients (22 men and 58 women) with histologically confirmed adrenocortical cancer in our single tertiary referral endocrine unit. Sixty-two and forty-three of the patients were diagnosed after years 2000 and 2010, resp. Descriptive statistics were performed, providing summaries of selected clinical and pathological parameters at the time of diagnosis. The results are given in median (minimum-maximum). Factors contributing to overall survival were analysed. A p value of less than 0.05 was considered statistically significant.
Results
The median age of patients was 52 years (18–84 years) at diagnosis. The majority of cases was diagnosed at ENSAT stage II (41.4%) and stage IV (34.3%), the median tumour size was 9.5 cm (4–30 cm) at diagnosis. In 57 patients (76%) the tumour was hormonally active. Primary surgical tumour resection was performed in 70 patients (87.5%), in 30 patients R0 resection was achieved. The median overall survival and the 5-year survival rate were 23 months (0–274 months) and 20%, respectively. In univariate Cox regression model, older age (>57 years), tumours with stage III-IV, high mitotic activity of the tumour cells (Ki67-index >20%) and R1-R2 surgical resection state were associated with poorer survival. The overall survival of patients achieving therapeutic mitotane plasma concentration ($n=21$) was significantly better comparing to those who failed to achieve the therapeutic serum mitotane concentration ($n=22$) (38 (13–193) months vs 18 (2–101) months). The time needed to reach the therapeutic range of serum mitotane was 4 (2–12) months. The median age, the distribution of gender, ENSAT stage, resection stage and Ki67-index stratified to 20% did not differ between these two groups. In patients with stage III-IV disease, there was no significant difference in overall survival between those who were treated with mitotane monotherapy compared to those with combined (mitotane plus chemo- therapy (19 (2–193) months, $n=8$ vs 18.5 (4–76) months, $n=18$).
Conclusion
Our results confirmprevious data that age, disease stage, mitotic activity and the resection stage are the most critical factors influencing the prognosis of adrenocortical cancer. The rapid achievement of therapeutic mitotane concentration has a significant and independent effect on overall survival.

Introduction
Adrenocortical carcinoma (ACC)is a rare disease with an unfavourable prognosis. Complete surgical resection of the tumour provides the only chance for long-term cure. The aim of this study was to compare long term outcomes in patients with ACC referred to surgery in an expert adrenal centre (EC) versus nonspecialised centres (NSC).
Materials and methods
This retrospective study included 48 patients with ACC, ENSAT stage I-III. All of study participants underwent complete tumour resection of whom 35 (73%) were operated in a high-volume centre by a dedicated surgeon, whereas 13 (27%) patients were operated in nonspecialised centres. The study analysed the differences between the two groups in terms of recurrence free survival (RFS) and overall survival (OS).
Results
Median duration of follow-up was 51 months (5–174) in EC group and 46 months (3–165) in NSC group. Disease recurrence was observed in 5 (14.3%) patients in the EC group and in 5 (38.5%) patients in the NSC group ($P=0.067$). Patients in the EC group had longer PFS but the difference did not reached the level of statistical significance (28 (11–45) month vs 19 (3–43) months; $P=0.083$). Overall, seven patients died during follow-up (5 EC, 2 NSC). ACC was the cause of death in two EC patients (5.7%) and in two NSC patients (15.4%; $P=0.16$).
Conclusion
The above-mentioned results show thatACC recurrence is less likely to occur in patients operated by a dedicated surgeon in an expert adrenal centre.

VDR-GR complex reduces apoptosis in acute myeloid leukemia cells via reduction of GR transcriptional activity

Angeliki Karapanagioti[1], Narjes Nasiri-Ansari[1], Vasiliki Kalotychou[2], Panayiotis Lembesis[3], Harpal Randeva[4], Athanasios G Papavassiliou[1] & Evanthia Kassi[1]
[1]National and Kapodistrian University of Athens, Medical School, Department of Biological Chemistry, Athina, Greece; [2]National and Kapodistrian University of Athens, Medical School, 1st Department of Internal Medicine, "Laiko" Hospital, Athina, Greece; [3]National and Kapodistrian University of Athens, Medical School, Department of Physiology, Athina, Greece; [4]Warwick Medical School, Division of Translational and Experimental Medicine- Metabolic and Vascular Health, United Kingdom

Introduction
Glucocroticoids (GCs) which are routinely used in the treatment of Acute Lymphocytic Leukemia (ALL), found recently to be beneficial in a subset of AML patients resistant to chemotherapy, by promoting leukemia cells apoptosis. Current studies indicate that vitamin D (VitD) deficiency is highly prevalent among AML patients, posing vitamin D as a therapeutic supplementation. Our previous study demonstrated that VitD exerts inhibitory effect on Dexamethasone-induced apoptosis in AML cells via altering Bcl2/Bax ratio, and inhibits GC-mediated cell cycle arrest through reduction of p21.
Aim
In the present study, we aimed to clarify if 1) these actions are mediated through formation of GR-VDR complex and 2) this complex is driven by VitD (1,25 (OH)2D3) in the promoter of Bax and p21 or not.
Methods
Kasumi-1 cells were incubated for 72 hours with dexamethasone (Dex-10–6M and 10–7M) alone or pre-incubated with VitD (10–8M) for 24 h following by co-incubation with Dex. MTS assay was performed to quantify viable cells whereas apoptosis was evaluated by Annexin V/PI based flow-cytometry assay. The mRNA levels of apoptotic and anti-apoptotic markers such as Mcl-1, Noxa, Bcl-2, Bax, p21 was measured by quantitative real time PCR. Immunoprecipitation was performed in order to examine the formation of GR-VDR complex, while ChIP assay was employed in order to evaluate GR-VDR occupancy at the Bax and p21 promoters.
Results
MTS and FACS analysis indicated that Dex induces apoptosis in Kasumi-1 cells dose-dependetly, while this effect was reduced significantly when cells were pre-incubated with VitD. Bax and p21 mRNA expression was significantly decreased in cells pre-incubated with VitD (24h) following by co-incubation with Dex for further 72 h as compared to cells incubated with Dex alone. Immunoprecipitation showed that GR forms a stable complex with VDR in cells preicubated with VitD . Moreover, ChIP analysis showed that preincubation with VitD increased the formation ofGR-VDR complex. Additionally, pre-incubation ofcells with vitamin D decreased the binding of this complex in p21 promoter.
Conclusions
VitD inhibits Dex induced-apoptosis and induces cell survival in AML cells, at least in part, via formation of VDR-GR complex and attenuation of GR transcriptional activity.

Cortisol response to acute stress is dependent on previous stress exposure and sex of the examined humans

Bojana Popovic[1,2], Djuro Macut[2], Dejana Popovic[2], Marko Banovic[3], Tatjana Isailovic[2], Ivana Bozic Antic[2], Sanja Ognjanovic[2], Tamara Bogavac[2], Valentina Elezovic Kovacevic[2], Dusan Ilic[2] & Svetozar Damjanovic[2]
[1]Clinic for Endocrinology, Diabetes, and Metabolic Diseases, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes, and Metabolic Diseases, Belgrade, Serbia; [3]Clinic for cardiology, Belgrade, Serbia

Introduction
Prolonged exposure to stress has a modifying effect on activity of hypothalamo-pituitary-adrenal (HPA) axis. This is a protective adaptation aimed to diminish potential deleterious effects of chronic hypercortisolism, and to diminish effects of acute exposure to heterotypic forms of stress. Our aim was to analyze modes of cortisol response to acute physical stress in groups of different stress categories and sex.
Subjects and methods
Study group consisted of 17 healthy males (23 ± 1 years old) exposed to current psychological stress (medical students during exams) – SM (stressed males). Two age matched control groups were: 1) 20 males (22 ± 3 years old) currently not exposed to stress – NSM (nonstressed males), and 2) 17 females (23 ± 2 years old) currently exposed to psychological stress (medical students during exams) – SF (stressed females). All subjects were exposed to acute physical stress by performing cardiopulmonary exercise test on a treadmill. Cortisol response was measured at 4time points: B at baseline (during rest), S at the start of the test (the moment of stepping on a treadmill), and MAX at the point of maximal effort, and R at the 3rd minute of recovery period. Statistical analysis was performed using SPSS software. Specifically, ANOVA for repeated measures was used to analyze difference in cortisol response during stress test.
Results
Stressed males had significantly higher cortisol levels than NSM at all time points ($P<0.001$, $P<0.001$, $P=0.007$, $P=0.015$ for B, S, MAX and R respectively), but the pattern of response was significantly different ($F_{1}=9.75$, $P=0.004$); SM had attenuated cortisol response compared to NSM, with significantly smaller percent of change between S and MAX ($P=0.04$) and between MAX and R ($P=0.039$). Similarly, cortisol was higher in SM than in SF ($P=0.004$, $P=0.002$, $P=0.001$ and $P=0.001$, for B, S, MAX and R respectively), but the pattern of stress response was similar ($F_{2,1}=1.605$, $P=0.208$). Stressed females had higher baseline cortisol levels than NSM ($P=0.015$), but the difference was lost throughout the test ($P=0.125$, $P=0.752$, and $P=0.283$, for S, MAX and R respectively). This was due to a fact that NSM had a more pronounced cortisol response compared to SF ($F_{1,9}=13.649$, $P<0.001$), with significantly greater percent of change between P and MAX ($P=0.001$) and MAX and R ($P=0.039$).
Conclusion
Lasting psychological stress exposure modifies the pattern of acute cortisol response to physical stress, but overall HPA axis activity is strongly dependent on the sex of examined subjects.

Introduction
Despite the fact that CS is widely employed, further investigation on the topic of the physiology vis a vis this type of delivery is required, especially regardingstress related hormonal response during this practice. The aim of this study is to provide data regarding stress related hormonal response during Vaginal Delivery (VD) and elective CS evaluating levels of Cortisol, Interleukin 6 (IL-6), Growth Hormone (GH) and Insulin-like Growth Factor 1 (IGF-1).
Materials and methods
The sample size of this study ($n=50$) was divided in two groups, namely the VD ($n=26$) and the CS ($n=24$)groups. The inclusion criteria were the following: healthy women aged 20–43 years, with hitherto uncomplicated singleton pregnancies who underwent spontaneous VD or elective CS, at a gestational age ranging from 37–40 weeks. Peripheral blood samples were collected at three different time-points. Time-Point 1 (TP1): samples collected at the first stage of labor for VD or 30 minutes following admission to the hospital for CS. Time-Point 2 (TP2): samples collected 120 minutes following placenta delivery. Time-Point 3 (TP3): samples collected 48 hours following placenta delivery. Umbilical cord blood samples were collected following placenta delivery. Evaluation of hormonal levels were performedvia standard ELISA.
Results
No significant difference could be established between the two groups regarding all hormones in the TP1. Cortisol levels did not differ at TP3 between the VDG and the CSG. The CSG presented with lower levels compared to the VDG (129.93 ± 63.10 vs 299.58 ± 74.00, P-value <0.001) at TP2. IL-6 levels were lower in the CSG at TP2 (20.15 ± 7.25 vs 48.70 ± 7.45, P -value <0.001) and higher at TP3 (21.85 ± 6.35 vs 6.86 ± 5.86, P –value <0.001) compared to the VDG. IGF-1 levels were higher at TP2 in the CSG (230 ± 80.63 vs 173.15 ± 38.12, P -value $=0.004$) in comparison to VDG, but were similar between the two groups at TP3 (101.38 ± 80.63 vs 88.19 ± 18.89, P -value $=0.94$). Cortisol and IL-6 levels in the umbilical blood did not present with a statistically significant difference between the two groups. IGF-1 and GH levels in the umbilical blood were statistically significantly higher in the CSG.
Conclusion
Data presented indicate that CS is a less stressful procedure for mothers in comparison to VD, and is further associated with less intense inflammation with an albeit longer inflammatory response period. From the infants' perspective, GH and IGF-1 appear to be increased in the umbilical cord blood of CS born neonates. Nonetheless, whether this may be attributed to mode of delivery remains unanswered.

Apparent mineralocorticoid excess (AME): Finding the "root" cause

Ma Pyeh Kyithar, Tomasz Blasiak, Srinivasachar Kodandapani, Meena Kumari & Joseph McHugh
Midland Regional Hospital Portlaoise, Diabetes & Endocrinology, Portlaoise, Ireland

Liquorice is a sweetener found in many food products, soft drinks, snacks and herbal medicines. Liquorice ingestion is an uncommon cause of AME or pseudohyperaldosteronisim. The mechanism involves the inhibition of 11-beta-hydroxysteroid dehydrogenase type-2 by the active ingredient called glycyrrhizin, which leads to the uninhibited activation of mineralocorticoid receptors by cortisol. Confectionary products that contain liquorice are readily available in the European Union.
We report a case of severe refractory hypokalaemia due to excessive liquorice consumption. A 79-year-old female presented to the emergency department following a road traffic accident secondary to collapse. She described feeling weak in the preceding weeks and was managed by her GP for hypokalaemia. Investigations revealed hypertension (BP 180/69 mmHg), severe hypokalaemia (K 2.2 mmol/l), normal renal function (Na 143 mmol/l, urea 3.4 mmol/l, creatinine 54 umol/l), normal magnesium (0.79 mmol/l) and calcium (2.24 mmol/l) levels with metabolic alkalosis (pH 7.537, bicarbonate 33.5 mmol/l). Spot urinary potassium was 22 mmol/l. The patient denied taking medications including over-the-counter or herbal medicines that can cause hypokalaemia. Hypokalaemia persisted for six days despite aggressive IV and oral potassium replacement. She later developed hypertensive emergency (BP 239/114 mmHg) with pulmonary oedema and required admission to intensive care unit for emergency management of hypertension with intravenous furosemide infusion and isosorbide dinitrate infusion. Further discussion with the patient revealed that since she quitted smoking, she was taking liquorice sweets excessively for the past 3 months to manage her nicotine cravings. Suppression of plasma renin [4.4 pg/ml (reference range <20 pg/ml)] and aldosterone levels [<26 pg/ml (reference range 42–209 pg/ml)] also supported the diagnosis of AME. Her symptoms and hypokalaemia resolved since discontinuing liquorice. This case highlights the life-threatening and refractory nature of severe hypokalaemia and hypertensive emergency caused by pseudohyperaldosteronisim secondary to excessive liquorice consumption. This case also emphasizes the importance of comprehensive history taking including the dietary habits to identify the root cause. Increased awareness among the public is required regarding the potential health hazards of excessive liquorice consumption.

Hypertensive crises related to the defecation strain, what's the diagnosis?

Agnieszka Kuzior[1], Paula María Fernández-Trujillo Comenge[1], Manuel Esteban Nivelo Rivadeneira[1], Alba Hernández Lázaro[1], Ana Delia Santana Suárez[1], Carmen Acosta Calero[1] & Francisco Javier Martínez Martin[2]
[1]Endocrinology & Nutrition Dpt., Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria., Las Palmas de Gran Canaria, Spain; [2]Outpatient Hypertension Clinic, Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria

Introduction
The defecatory strain in constipated people can raise the blood pressure and occasionally trigger cardiovascular events.
Methods
Review of the patient's clinical records and the relevant literature.
Results
Clinical Case: A 53-year old woman with history of breast surgery for adenocarcinoma and chronical constipation had severe resistant hypertension in the previous three years; she had hypertensive crises with SBP up to 260 mmHg with headache but no vegetative symptoms; often these crises had been elicited by the defecation strain. In a extension study five years after breast surgery the CT showed a heterogeneous, dense (mean density 110 UH) right adrenal mass measuring 39–43 mm suggestive of metastasis; she was referred to our Hypertension Clinic for evaluation. Under treatment with amlodipine and doxazosine lab tests were obtained, with normal cortisol, ACTH, LH, FSH, aldosterone, renin activity and A/RA ratio (10.5); plasma metanephrine was 104 pg/ml and normetanephrine >2400 pg/ml. A 125-I-MIBG SPECT-CT showed intense activity in the right adrenal without additional findings. After routine presurgical preparation with doxazosine followed by bisoprolol, a 24 h ABPM was performed showing a diurnal mean BP of 127/65 mmHg, HR 87 bpm, and nocturnal 120/64 mmHg, HR 83 bpm (non- dipper) without any SBP data >130 except for a peak (148/76 mmHg) at 21:34 coincident with strained defecation. The right adrenal was laparoscopically removed without complications. The pathology diagnosis was a 6 cm pheochromocytoma without apparent malignancy (Ki-67 <2%). After the surgery the patient remains normotensive without medication and her plasma metanephrines are normal (32/64 pg/ml) but remains constipated.
Conclusions
The defecation strain associated to chronic constipation might squeeze a large non-metastatic pheochromocytoma and cause hypertensive crises. Although raised blood pressure in connection with constipation has often been reported, the triggering of hypertensive crises by defecation strain in a patient with pheochromocytoma had not been previously reported in our knowledge.

Composite pheochromocytoma of the adrenal gland: Case report

Andreea Nicoleta Dumitrascu[1], Teodora Dumitru[1], Cristina Preda[1,2] & Maria Christina Ungureanu[1,2]
[1] Sf. Spiridon' Emergency Hospital, Iaşi, Romania; [2] Grigore T Popa' University of Medicine and Pharmacy, Iasi, Romania

Introduction
Composite pheochromocytoma is a rare tumor composed histologically of pheochromocytoma and other neurogenic tumor components such as neuroblastoma, ganglioneuroblastoma, ganglioneuroma, peripheral nerve sheath tumor, or other types of neuroendocrine carcinoma. The frequency of composite adrenal tumors reportedly ranges from <3% of all adrenal gland neoplasms to 1–9% of pheochromocytomas. The clinicopathological diagnosis of composite pheochromocytoma is, at times, a clinical dilemma because it is not known whether the nonpheochromocytoma component has any therapeutic and/or prognostic implications as compared to the standard pheochromocytoma.
Case report
A 82-year-old male presented with gastrointestinal complaints (abdominal pain and diarrhea) for 2 months along with facial flushing, sweating and 10 kg weight loss. He had a history of mild hypertension with orthostatic hypotension. Hemogram reports revealed anemia. Abdominal ultrasonography and computed tomography showed the presence of a large heterogeneous mass 118×135×108 mm with well-defined boundaries in the left suprarenal region. In view of adrenal tumors, 24-hr urinary metanephrine was further evaluated, with high levels 1674,17 mg/24-hrs (reference range, 25–312), plasma free metanephrines levels: 707,5 ng/l (reference range, 7,9-88,7), cortisol level was 1,76 ug/dl after overnight dexamethasone suppression test showed normal suppression, plasma level of chromogranin A was 746,3 ng/ml (reference range <76,3). Left adrenalectomy was performed. The anesthetic team confronted with intraoperative complications: arrhythmia. Postoperative period was uneventful and plasma levels of free metanephrines and normetanephrines normalized: 74,8pg/ml (reference range, <65), respectively148,1 pg/ml (reference range, <196). Pathological diagnosis was composite pheochromocytoma / ganglioneuroma.
Conclusions
Composite pheochromocytomas are rare catecholamine-producing tumor which has the propensity to large size which is unlikely when it is classical pheochromocytoma. Clinical manifestations unique to the tumor are occasional and atypical and non-specific symptomatology and its association with autoimmune disorders. A multidisciplinary approach involving anesthesia, endocrinology, and surgical expertise is the gold standard in maximizing patient care.

Cystic pheochromocytoma, a diagnostic challenge: A case report

Cvetanka Volkanovska Ilijevska[1,2], Taner Hasan[2], Liljana Malinovska-Nikolovska[3], Brankica Krstevska[1] & Ance Volkanovska Nikolovska[4]
[1]University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia; [2]8th September General City Hospital, Department of Endocrinology, Skopje, Macedonia; [3]8th September General City Hospital, Department of Anesthesiology, Skopje, Macedonia; [4]University Clinic of Gatstroenterology, Skopje, Macedonia

We describe a case of cystic pheochromocytoma (PCC) with negative biochemical evaluation, diagnosed on the basis of hypertensive crises during operative management and histopathologic findings. A 57-year-old woman complained of several episodes of stabbing right upper abdominal pain accompanied by tachycardia, headache, lack of breath, elevated blood pressure and vomiting in the preceding three years. At presentation, blood investigations were significant only for mildly elevated transaminases and serum amylase. An abdominal ultrasound was performed and revealed large right adrenal incapsulated and heterogenous mass, 7×7 cm in size, with mass effect. Computed tomography imaging confirmed incapsulated adrenal mass with internal septations and unenhanced attenuation of >30 Hounsfield units. Based on imaging appearance and patient's history, a suspicion of PCC was established, and the patient was referred to endocrinologist. Laboratory exams for Cushing's syndrome were unremarkable and urinary vanilmandelic acid, metanephrines and serum chromorgranin A were within normal range on several occasions. Further evaluation with iodine-123 (123I)-labeled metaiodobenzylguanidine (MIBG) scintigraphy would have been useful to differentiate the mass, but it was not available at the moment of investigations. Despite negative biochemical diagnosis,strong clinical suspicion for PCC was established and the patient was preoperatively prepared with α-adrenoreceptor and beta blockers. Initial attempt for laparoscopic adrenelectomy was unsuccessful due to early intraoperative occurrence ofhypertensive crises with blood pressure 300/150 mmHg. Three months later a successful open adrenelectomy was performed with nonsignificant intraoperative hemodynamic instability. Histopathologic evaluationconfirmed cystic benign PCC with dominance of multnuclear giant, foamy macrophages, presence of hemosiderin deposition and hemolyzed erythrocytes. Although cystic adrenal lesions comprise several types of non-functionating benign lesions, the differential diagnosis should include cystic form of PCC, an entity that is rarely reported. In cystic PCC the number of cateholamin-producing cells are low, especially when an extensive necrotic cystic regions are present. Furthermore, catecholamines stored in the capsular mass may not be released into the blood circulation until surgical attempt for isolation of PCC is made. Therefore, high clinical suspicion for PCC is necessary since negative biochemical diagnosis is possible. As demonstrated by our case, clinical presentation was crucial in the diagnosis and preoperative management. Preoperative optimization with antihypertensive drugs and blood volume expansion fluids is obligatory in PCC surgery in order to prevent detrimental intraoperative hemodynamic instability. Albeit laparoscopic adrenelectomy is becoming a first line surgical option for PCC, still it's not always feasible as shown in our case.

Type 1 neurofibromatosis and malignant pheochromocytoma

Inês Vieira[1], Diana Catarino[1], Lúcia Fadiga[1], Diana Silva[1], Joana Guiomar[1], Mariana Lavrador[1], Sara Pinheiro[2], Carolina Moreno[1], Dírcea Rodrigues[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Endocrinology, Coimbra, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Endocrinology, Lisbon, Portugal

Introduction
Neurofibromatosis type 1 is a disease caused by mutations in the tumor suppressor gene NF1.
Although pheochromocytoma is a rare manifestation in these patients (~0.1–5.7%), the incidence is significantly higher than that of the general population.
Results (case description)
A 50 years old female patient had a clinical diagnosis of neurofibromatosis type 1 since she was 5 years old. She received follow-up in internal medicine appointments since 1999 after a paroxistic episode of headache, palpitations, dizziness and pre-cordial discomfort in the postpartum period, initially attributed to anxiety. The episodes were repeated in the following years and coincided with hypertensive peaks. In 2002 she was admitted to the hospital, and the complementary diagnosis exams revealed: increase in metanephrines and vanillmandelic acid; heterogeneous nodular formations on the left and on the right adrenal glands(~5.2×4.9 cm and ~5.4×8.9 cm, respectively) in abdominal computerized tomography; bilateral adrenal masses intensely fixating the radiopharmaceutical contrast in the MIBG scintigram. She underwent a bilateral adrenalectomy (after α and β block). The anatomopathological result reported a "bilateral pheochromocytoma" - PASS score 3 on the right and 6 on the left. In the subsequent years, she underwent follow-up in endocrinology and internal medicine appointments at different hospitals, however some appointmentswere missed. In 2015 a chest magnetic resonancerevealed an hyperintense 16×19 mm right-hilar nodular lesion in T1 and T2. Between 2016–2018, slightly elevated metanephrines were detected - maximum metanephrine 185,7 ng/ml (<60) and normetanephrine 247,9 ng/ml (<120). In 2019, DOPA-F18positron emission tomography (PET) revealed right bronchociliary nodular formation with intense DOPA-F18 uptake, suggesting a neuroendocrine tumor /pheochromocytoma ganglion metastasis. The patient underwent excision of the right hilar lesion (after α and β block) and the anatomopathological result reported a pheochromocytoma metastasis, PASS 5 score, ki67 <1%. Currently, sheis under regular clinical, biochemical and imagiological follow-up at the endocrinology department.
Conclusions
Although pheochromocytoma is a rare manifestation of neurofibromatosis type 1, the presence of arterial hypertension in these patients should lead to suspicion of the diagnosis. The hypertensive crisis recorded in the postpartum period was one of the first manifestations of the tumor.
Patients with neurofibromatosis type 1must be monitored regularly by professionals specialized in the various manifestations of the disease. The irregular follow-up of this patient, hindered an adequate evaluation and delayed the diagnosis of metastatic disease.

Results of biochemical testing in suspected primary hyperaldosteronism – a retrospective study

Andreea Vladan[1], Iuliana Baranga[1], Anda Dumitrascu[1], Dan Hortopan[1], Radu Iorgulescu[2], Ruxandra Jurcut[3,4], Adrian Zugravu[5], Catalina Poiana[1,4] & Serban Radian[1,4]
[1]CI Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Sf Ioan Emergency Hospital, Surgery, Bucharest, Romania; [3]CC Iliescu Institute of Cardiology, Bucharest, Romania; [4]Carol Davila University of Medicine, Bucharest, Romania; [5]Carol Davila Nephrology Hospital, Bucharest, Romania

Background
PA is a frequent cause (5–13%) of secondary hypertension (HT), yet diagnostic work-up of PA remains challenging.
Aim
To describe the characteristics of a series of hypertensive patients diagnosed with PA compared to those with negative biochemical screening (aldosterone-to-renin ratio/ARR)
Methods
Clinical, hormonal and imaging evaluation.
Results
We have screened for PA 34 patients diagnosed with HT, using as screening criteria: 1. HT+hypokaliemia,2. early-onset HT, 3. drug-resistant HT, 4. HT+sleep apnea, 5. HT+adrenal incidentaloma. 15 patients (7M/8F), aged 39.5 yo (17–58, median/range) at HT onset had a diagnosis of PA confirmed by biochemical testing. Twelve patients (80%) with PA and 14 patients (73.7%) with primary HT had stage 3 HT. Systolic and diastolic BP were significantly higher in PA confirmed group (median SBP 140 mmHg vs 125 mmHg and median DBP 90 mmHg vs 80 mmHg). There was a higher prevalence of drug-resistant HT in PA patients (60% vs 10%). Hypokaliemia history was documented in 6 patients (40%) with PA and in 2 patients (10.5%) with primary HT. ARR on RAAS-interfering drugs (ARRon) was 87 (1.04–426.6) in PA group and 17.28 (0.47–63.44) in primary HT group. Repeated ARR after RAAS-interfering drugs discontinuation in 10 patients (ARRoff) was 59.85 (1.21–926). We performed 20 confirmatory tests in 14 patients (17 tests for PA pts and 3 for primary HT pts): 14 saline infusion tests (SIT), 5 captopril challenge tests (CCT) and one oral salt loading. 13 patients were SIT-positive (aldosterone>5 ng/dl), 2 patients were CCT-positive (aldosterone suppression <30%), one CCT-negative patient (2 h suppression = 25.6%) was SIT-positive. Adrenal CT identified unilateral adenomas in 8 patients (53.3%), 5 of whom associated a diffusely enlarged contralateral adrenal. One patient underwent unilateral adrenalectomy and he was biochemically cured, the 14 remaining received mineralocorticoid receptor antagonists. Target organ complications were present in 6 pts with PA (40%) patients: 5 presented cardiomiopathy, 4 had CKD and 3 patients had retinopathy.
Conclusions
PA was a frequent cause of severe secondary HT in our cohort. Systolic and diastolic BP were significantly higher in PA patients compared with those with primary HT and drug-resistant HT prevalence was higher in hypertensive patients with confirmed PA. ARR in patients taking RAAS-interfering medication decreased after drug discontinuation. There were no significantly differences in target organ complications between PA and primary HT patients.

Body composition, insulin sensitivity and blood pressure in patients with congenital adrenal hyperplasia

Ruta Navardauskaite[1], Kristina Liesionyte[2], Indre Petraitiene[2], Aurika Vanckaviciene[3] & Rasa Verkauskiene[1]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Nursing and Care, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Management of patientswith congenital adrenal hyperplasia (CAH) is a challenge to find a right balance of glucocorticoid doses and long-term consequences of overtreatment isassociated with increased risk of cardiometabolic disorders.

The aim of our study was to evaluate body mass index (BMI), body composition, blood pressure (BP) and insulin sensitivity in children and youth with CAH in comparison with healthy control subjects.
Methods
Data from 29 patients with CAH (13 males; median age 16.9 ± 6.8, years (10.2–30.9)) were collected retrospectively and compared to 29 healthy controls (14 males; median age 20.2 ± 0.9 years (17.7–21.3), $P = 0.13$). 21 patient had salt-wasting (SW 11 males) and 8 patients - simple virilising (SV, 71 male) form of CAH. Median dose of hydrocortisone (HC) was calculated from CAH diagnosis until last examination. Prednisolone and dexamethasone doses were converted to equivalent HC doses in mg/m^2 per day using standard GC equivalencies (20 mg of HC = 5 mg of prednisolone = 0.4 mg of dexamethasone). Body composition was evaluated in both groups with DXA (Hologic Inc., Bedford, MA, USA). Hypertension was defined as BP >95 percentile in children and adolescents and >140/90 mmHg in adults). Comparisons between two groups were adjusted for age, gender and height. Oral glucose tolerance test (OGTT) was performed and fasting insulin level were evaluated in the CAH group. Insulin sensitivity was determined using homeostasis model assessment of insulin resistance index (HOMA-IR).
Results
Mean BMI was significantly higher in subjects with CAH (1.18 ± 1.3 SDS and 0.18 ± 1.05 SDS, respectively, $P = 0.002$). Total body fat (TBF) mass Z-score was significantly higher in CAH patients vs controls (0.629 ± 0.80 vs –0.04 ± 0.76, $P = 0.003$). Mean total daily dose of HC in the SW group was 15.4 ± 2.3 (11.03–21.41) and in the SV group 14.32 ± 1.29 (12.45 – 15.95) mg/m^2 per day, $P = 0.22$. Hypertension was identified in 24.1% of CAH patients (7 SW and 1 SV) and 13.8% ($n = 4$) of controls ($P < 0.0001$). Impaired glucose tolerance was found in 2 CAH patients (13.3 and 30.1 years-old). In the CAH group, significant association was found between HOMA-IR and visceral adipose tissue in grams ($r = 0.636$, $P = 0.011$) and HOMA-IR and waist-to-hip-ratio ($r = 0.543$, $P = 0.045$). HC dose was not related to BMI, TBF, BP or HOMA-IR.
Conclusions
CAH patients had higher BMI, TBF and frequency of hypertension compared to controls. Doses of glucocorticoids were not associated with body composition and BP in CAH patients.

Confirmatory testing of primary aldosteronism with saline infusion test and LC-MS/MS

Carmina Teresa Fuss[1], Katharina Brohm[1], Max Kurlbaum[1,2], Anke Hannemann[3], Sabine Kendl[1], Martin Fassnacht[1], Timo Deutschbein[1], Stefanie Hahner[1] & Matthias Kroiss[1,2]
[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Germany; [2]University Hospital Würzburg, Central Laboratory, Core Unit Clinical Mass Spectrometry; [3]University Medicine Greifswald, Institute of Clinical Chemistry and Laboratory Medicine, Germany

Objective
The saline infusion test (SIT) is a standard confirmatory test for primary aldosteronism (PA) and based on impaired aldosterone suppression in PA compared to essential hypertension (EH). In the past, aldosterone was quantified using immunoassays (IA). Due to the more widespread use of liquid chromatography tandem mass spectrometry (LC-MS/MS) in clinical routine, we aimed at a method-specific aldosterone threshold for the diagnosis of PA during SIT and explored the diagnostic utility of other mineralocorticoids and glucocorticoids.
Design
Cohort study of 187 paired SIT samples at a single tertiary endocrine center 2009–2018. Diagnosis of PA ($n = 103$) and EH ($n = 84$) was established based on clinical routine workup without taking LC-MS/MS values into account.
Methods
LC-MS/MS using a commercial steroid panel with a lower limit of quantification for aldosterone of 10 ng/l. Receiver operator characteristics analysis was used to determine method-specific cut-offs.
Results
Aldosterone measured by IA was on average 31 ng/l higher than with LC-MS/MS. Cut-offs were comparable with 64 ng/l for IA (sensitivity: 93%, specificity: 90%, area under the curve (AUC) 0.955) and 69 ng/l for LC-MS/MS (80%, 89%, 0.902). Other steroids did not provide additional diagnostic value.
Conclusions
Quantification of aldosterone with LC-MS/MS and IA yields in comparable SIT-cut-offs for PA. Lower AUC for LC-MS/MS is likely due to the large

spectrum of disease in PA and previous decision making based on IA results. Until data of a prospective trial with clinical endpoints are available, the suggested cut-off can be used in clinical routine.

Clinical and histopathologic phenotype of a single-center patient cohort operated for unilateral primary aldosteronism

Lucie Meyer[1], Martin Reincke[1] & Tracy Ann Williams[1,2]
[1]Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; [2]Division of Internal Medicine and Hypertension, Department of Medical Sciences, University of Turin, Turin, Italy

Objective
Clinical and histopathological assessment of a consecutive series of Munich patients operated between 2016 and 2018 for unilateral primary aldosteronism (PA).
Background
Unilateral PA is the most common surgically curable form of hypertension mainly caused by an aldosterone-producing adenomas (APA). Somatic mutations in *KCNJ5, CACNA1D, ATP1A1* or *ATP2B3*drive the aldosterone excess in the majority of APAs. Genetic variants in *CLCN2* have been described in a familial form of PA.
Design and method
The study included 60 surgical adrenal specimens from patients diagnosed with unilateral PA at a single referral center over a 3-year period (2016 to 2018). Clinical and biochemical outcomes were determined according to the PASO criteria. Histopathology of all resected adrenal was assessed by hematoxylin and eosin and aldosterone synthase (CYP11B2) staining. Aldosterone-producing adenomas were genotyped for known somatic mutations by CYP11B2-immunohistochemistry-guided Sanger sequencing of formalin-fixed adrenals or exome sequencing of fresh-frozen tissue.
Results
The cohort (29 males and 31 females) displayed a mean age at surgery of 51 ± 13 years and a median duration of hypertension of 103 [39–171] months. Complete biochemical success after surgery was observed in 84% of 54 patients with follow-up and complete clinical success was achieved in 19% ($n=10$) with a further 57% ($n=31$) displaying significant clinical improvements (partial clinical success). Histopathologic assessment demonstrated an aldosterone-producing adenoma in 78% (47 of 60) with the remaining 13 adrenals showing multiple micronodules or diffuse hyperplasia. In patients with follow-up, complete biochemical success was achieved in 84% of the 43 patients with an aldosterone-producing adenoma compared with 45% of the 11 patients with diffuse hyperplasia or multiple micronodules. Of 40 genotyped aldosterone-producing adenomas, 22 (55%) had a *KCNJ5* mutation, 4 carried mutations in *ATP1A1* and 4 had *CACNA1D* mutations. Exome sequencing of an aldosterone-producing adenoma identified a *CLCN2* variant (encoding a C244Y mutation).
Conclusions
These findings may contribute to a better understanding of the clinical, histopathologic and genetic correlates of the pathophysiology of unilateral PA.

Introduction
The majority of adrenal neoplasms are benign while adrenocortical carcinomas (ACC) are rare with poor prognosis. Previous studies indicated that estrogens play important role in the etiology and progression of adrenocortical tumors. Estrogens exert genomic activities trough the estrogen-receptor (ER) subtypes α and β, while the non-genomic effects are mediated by membrane-bound-G-protein-coupled-ER-30 (GPR30). Although estrogens induce cancer cell proliferation through ERα, ERβ appears to exert a protective effect. In vitro experiments showed that treatment with ERα antagonist as well as GPR30 agonist reduces proliferation in H295R cells. However, data on the expression profile of ERs in normal and human adrenocortical neoplasms are limited.
Epidermal growth factor receptor (EGFR) found to be highly expressed in ACC. The expression of EGFR has been negatively correlated with expression of ER in other cancers, while data regarding the correlation between ERs and EGFR expression in adrenocortical neoplasms are missing.
Aim
We aimed to investigate the expression profile of ERs and EGFR in adrenocortical neoplasms and correlate it with their biological behavior.
Material and methods
Total RNA was extracted from fresh frozen tissue of:eight non functional adenomas (NFA), eight cortisol producing adenomas (CPA), their adjacent normal adrenal tissues (NAC) AND eight adrenocortical carcinoma (ACC). The expression of ERα, ERβ, GPR30 and EGFR genes was evaluated by qPCR. The Immunohistochemistry (IHC) was performed to evaluate the EGFR and GPR30 protein levels.
Results
The expression of both ERα and GPR30 were higher in the CPA as compared to their adjacent normal tissue ($P<0.05$) while there was no significant difference in ERβ and EGFR mRNA levels between CPA, NFA and their adjacent normal tissues. The expression of GPR30 was significantly higher in ACC compared to either NFA or NAC groups ($P<0.05$), and marginally higher in ACC compared to CPA. The expression of ERα and EGFR was higher in ACC compared to either CPA or NFA ($P<0.1$). IHC confirmed the higher expression EGFR in ACC compared to the adrenal benign tumors. A marginal positive correlation between EGFR and GPR30 expression was observed in ACC.
Conclusion
To our knowledge this the first study to evaluate the expression of membrane-bound GPR30 in human adrenocortical neoplasms. Our preliminary data suggest a possible role of GPR30 and EGFR in adrenocortical malignancy, while ERα may play a role in functional adenomas. Further studies with larger number of samplesare required to elucidate the role of ERs and EGFR on the adrenal tumorigenesis.

Assessment of serum adropin concentrations in primary aldosteronism

Agnieszka Łebek-Szatańska, Piotr Glinicki, Karolina Nowak, Wojciech Zgliczynski, & Lucyna Papierska
Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
Primary aldosteronism constitutes the most common form of hormonal hypertension. However, it is often mistreated and widely underdiagnosed. Despite the great progress in laboratory technics of adrenal diseases, in the field of primary aldosteronism there is still a need for novel biomarkers that would clarify the diagnosis in equivocal cases. Adropin is a newly discovered protein that may play a role in glucose metabolism and the development of cardiovascular diseases connected to endothelial dysfunction. Lower adropin concentrations has been discovered in patients with primary arterial hypertension in comparison to healthy volunteers. No difference has been yet observed between patients with or without target organ damage related to hypertension, which is most pronounced in primary aldosteronism and refractory hypertension.
Objective
The aim of our studywas to evaluate the differences in adropin levels in hypertensive patients depending on their hormonal status.

Methodology
Adropin, aldosterone and renin concentrations from 80 hypertensive patients were analyzed. 20 patients were diagnosed with primary aldosteronism, 60 patients had primary hypertension. From the whole group, 17 patients had refractory hypertension – only 5 of them had primary aldosteronism. 45% of patientswith primary aldosteronism and 51.6% with primary hypertension had glucose metabolism disorders, including type 2 diabetes and pre-diabetes. Adropin was measured by ELISA method.
Results
Median adropin concentrations in primary aldosteronism were not statistically different from primary hypertension group: 33.2 ng/l versus 45.1 ng/l ($P=0.3$). What's interesting, adropin concentrations were the lowest in patients with refractory hypertension (independently of aldosterone secretion status): median 32.1 ng/l comparing to median 58.6 ng/l ($P=0.0545$) in the group of patients with no refractory hypertension. There was significant difference between the youngest patients (under 40 years of age) in comparison to the older population – 1042.8 ng/l versus 34.9 ng/l ($P=0.04$), respectively. Patients with glucose metabolism disorders had lower, but not statistically different, adropin levels versus patients with normal glucose levels – 34.6 vs 240.1 ng/l ($P=0.07$), respectively.
Conclusions
To our knowledge, this is the first study to assess adropin concentrations in primary aldosteronism. Because of the small sample, the role of adropin needs further evaluation in larger population.

Radiological and functional analysis of a cohort of adrenal adenomas

Miriam Giordano Imbroll[1,2], Sarah Craus[1,2], Josanne Vassallo[1,2], & Mark Gruppetta[1,2]
[1]Department of Medicine, University of Malta Medical School, Mater Dei Hospital, Msida, Malta; [2]Neuroendocrine Clinic, Mater Dei Hospital, Msida, Malta

Aim
A cohort of adrenal incidentalomas which had radiological or histological characteristics in keeping with an adrenal adenoma was analysed in terms of the radiological and functional characteristics.
Methods
A retrospective cross-sectional analysis of a cohort of adrenal adenomas was carried out. Lesions were followed up for a median of 8.2months (IQR 1.4 – 34.6). In the majority of patients (69.95%), the diagnosis of a benign adrenal adenoma was made via an unenhanced CT scan (density of lesion <10HU in keeping with a lipid rich adenoma). In those patients where the adrenal lesion was lipid poor (density >10HU on an unenhanced CT scan) or had a contrast scan in the first instance, the absolute or relative washouts were calculated in 11.0% and 13.5% respectively. MRI was the imaging modality of choice in 1 patient. 3 patients had an adrenalectomy, with histology confirming an adrenocortical adenoma.
Results
209 patients with adrenal adenomas were included. Out of the whole cohort, 111 patients were females (53.1%). The mean age of patients at diagnosis was 62.3 years (± 12.1SD). Left sided lesions were noted to be the commoner lesions, being present in 61.2% and bilateral lesions in 6.2%. The median longest radiological diameter (on CT or MRI) was 19.0 mm (IQR15.0–25.0). During this follow up period, practically no change in size of the adenomas was identified (median change in size 0 mm (IQR 0 – 1).
Morning cortisol following 1mg overnight dexamethasone suppression was >50 nmol/l in 34.2% in keeping with possible autonomous cortisol secretion. 4 out of these patients had cortisol above 138nmol/l in keeping with autonomous cortisol secretion. 0900 h cortisol post ODST correlated positively with age ($P=0.003$) and longest radiological diameter of adenoma ($P<0.001$) and negatively with DHEAS ($P<0.001$). Multiple logistic regression analysis maintained the positive correlation between 9am post ODST cortisol with age (OR 1.066 $P=0.004$) and longest radiological tumour diameter (OR 1.168 $P<0.001$).
A high aldosterone renin ratio was found in 36% of patients. Out of these patients, 22% also had a level of cortisol following overnight dexamethasone suppression of more than 50 nmol/l.
Conclusion
Interesting correlations between biochemical and radiological parameters in patients with adrenal adenomas have been established. The correlation between 0900 h cortisol following the overnight dexamethasone suppression test and age is not documented in the literature.

Aetiological diagnosis of Cushing's syndrome : A trap for the unwary

Safa Khaldi, Haythem Jenzri, Maria Abouloula, Hanène Sayadi & Inès Khochteli
University Hospital Fattouma Bourguiba Monastir, Departments of Internal Medicine and Endocrinology, Monastir, Tunisia

Introduction
Cushing's syndrome denotes pathologic hypercortisolism as a result of excessive adrenocorticotropic hormone (ACTH) production or autonomous adrenal production of cortisol according to the ACTH levels. However, 30% of the patients with CS have ACTH levels in the 'grey zone' (5–20 pg/ml), thereby posing a challenge in establishing the aetiological diagnosis.
Case presentation
A 20-year-old woman presented to our departement with the complaint of weight gain, facial plethora and spaniomenorrheaof 6 months duration. There was no previous medical or surgical history, no family history for endocrine disease. On examination, she had facial plethora, moon facies, centripetal obesity and purple striae on the abdomen and the four limbs. The rest of the exam was within normal limits. Investigations showedno suppression of cortisol after low dose dexamethasone confirming hypercortisolism. Early morning ACTH was 17,9 pg/ml. MRI of sella showed lesion on the left side of the pituitary measuring 5 mm. Since the ACTH level was in the gray zone, the dosage was controlled showing a low level (1,1 pg/ml) confirmed by a third ACTH sample (5,38 pg/ml). Computed tomography for adrenal gland showed a left adrenal mass, 4.4 cm in diameter (arrow), with a density of 30 Hounsfield units and a washout of contrast about 62% at 15 minutes. The diagnosis of pituitary ACTH-independent Cushing's syndromewith pituitary incidentaloma was considered. The patient was subjected to surgery. The resected mass measured 5 cm. Histopathological examination was suggestive of adrenocorticaladenoma with modified Weiss score of 2/7.Postoperative hormonal evaluation showed 08:00 hours serum cortisol at 43.6 nmol/l and hydrocortisone supplementation was continued.
Discussion-conclusion
Cushing's syndromeis a challenging disease to diagnose. The most common cause is Cushing's disease accounting for 70–80% of the cases. Adrenal causes contribute 15–20%.The ACTH value of <5 pg/ml is suggestiveof ACTH-independent Cushing's syndrome, while ACTH value of >20 pg/ml is suggestive of ACTH-dependent, and the levels between 5 and 20 pg/ml arein the 'grey zone'. In this case, testsshould be repeated multiple times and clinicians should be cautious about the possibility of technical errors in any measuring systems. The presence of a pituitary microadenoma, if <6 mm in size, may be an incidental finding in this scenario and can be present in 3–27% of the healthy population. Therefore,multiple samplings for ACTH and adrenal imaging should be performed to exclude ACTH-independent CS.

Is glucocorticoid replacement therapy in adrenal insufficiency a risk factor for liver steatosis?

Gesine Meyer, Madeleine Gruendl, Florian Schlereth, Ludmila Gerber, Klaus Badenhoop & Joerg Bojunga
Goethe-University Hospital, Medical Clinic 1, Endocrinology, Frankfurt, Germany

Introduction
Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease affecting up to 30% of the population in western countries. Previous studies have demonstrated that increased glucocorticoid levels play an important role in the development of obesity, hyperglycemia, dyslipidemia, insulin resistance, as well as NAFLD. However, the effects of glucocorticoid substitution on the liver in patients with primary or secondary adrenal insufficiency have been rarely examined.
Objective
To investigate the impact of glucocorticoid replacement therapy in patients with primary or secondary adrenal insufficiency on developing NAFLD or liver fibrosis
Methods
Association between the grade of hepatic steatosis and the dose of hydrocortisone replacement therapy was investigated in $n=96$ patients suffering from primary or secondary adrenal insufficiency. The grade of liver steatosis was determined by using an ultrasound-based vibration-controlled transient elastography device called controlled attenuation parameter (CAP). CAP was adjusted for body weight, body mass index and waist circumference.

Additionally, we examined the association between HOMA-Index, hypertension, hyperglycemia and dyslipidemia and the dose of glucocorticoid replacement therapy.
Results
There was no significant correlation between the grade of liver steatosis measured with CAP and the daily dose of glucocorticoid replacement therapy. There was also no significant correlation between the CAP value and the product from the duration of glucocorticoid intake in years and the daily dose of glucocorticoid replacement in mg hydrocortisone equivalent as a marker for cumulative glucocorticoid dose. However, CAP showed a strong correlation with waist circumference ($P<0.001$), BMI ($P<0.001$) and body weight ($P<0.001$). There was a moderate relationship between CAP and the metabolic syndrome ($P<0.001$), hypertension ($P=0.031$) and the level of triglycerides ($P=0.008$). On multiple regression analysis, only waist circumference ($P<0.001$) and dyslipidemia ($P=0.012$) remained significantly associated with CAP. HOMA-Index, hypertension, hyperglycemia and dyslipidemia showed no association with the dose of glucocorticoid replacement therapy.
Conclusion
Glucocorticoid replacement therapy in a physiological daily dose of 15 mg to 30 mg hydrocortisone equivalent seams not to raise the risk of developing NAFLD. Patients suffering from liver steatosis mostly have metabolic risk factors such as obesity, dyslipidemia or hypertension.

Evaluation of clinical and functional differences between unilateral and bilateral adrenal incidentalomas. A spanish multicentric study.

Marta Araujo Castro[1], Cristina Robles Lázaro[2], Paola Parra Ramírez[3], Rogelio García Centeno[4], Paola Gracia Gimeno[5], Mariana Tome[6], Miguel Antonio Sampedro Núñez[7], Mónica Marazuela[7], Héctor F Escobar-Morreale[1] & Pablo Valderrábano Herrero[1]
[1]Hospital Universitario Ramón y Cajal, Endocrinology, Madrid, Spain; [2]Hospital Clínico Universitario de Salamanca, Endocrinology, Salamanca, Spain; [3]Hospital Universitario de la Paz, Endocrinology, Madrid, Spain; [4]Hospital Universitario Gregorio Marañón, Endocrinology, Madrid, Spain; [5]Hospital Royo Villanova, Endocrinology, Zaragoza, Spain; [6]Hospital Universitario Nuestra Señora de Valme, Endocrinology, Sevilla, Spain; [7]Hospital Universitario de la Princesa, Endocrinology, Madrid, Spain

Purpose
To evaluate differences in the prevalence of autonomous cortisol secretion (ACS) and related comorbidities between patients with unilateral and bilateral adrenal incidentalomas (AI).
Methods
Seven Spanish institutions participated in this institutional review board-approved retrospective study for patients with AI. 342 patients with one or more AI ≥1 cm evaluated by participating physicians between 2001 and 2019 were subject to inclusion. Patients with adrenal lesion detected in the study of extension of an extra-adrenal cancer, with predisposing adrenal hereditary syndromes, manifest functioning AI or missing values in the 1mg dexamethasone suppression test (DST) were excluded. ACS was defined as lack of cortisol suppression after DST in the absence of Cushing Syndrome data. Different cortisol DST thresholds were evaluated: 1.8, 3.0, and 5.0 µg/dl. Diabetes, hypertension, dyslipidemia, cardiovascular and cerebrovascular disease, and obesity were considered ACS related comorbidities.
Results
A total of 256 patients (155 females, 60.6%) were enrolled in the study. 209 (81.6%) had unilateral and 47 (18.4%) bilateral AI. Prevalence of ACS using 1.8 µg/dl, 3.0 µg/dl and 5.0 µg/dl DST threshold was 40.6%, 18.8% and 9.4%, respectively. The prevalence of ACS was significantly higher for bilateral AI (3.0 µg/dl) (31.9% vs 15.8%, $P=0.010$). Bilateral ACS AI presented higher risk of diabetes vs unilateral ACS AI (53.3 vs 18.2%, $P=0.013$) (3.0 µg/dl) and of obesity (71.4% vs 29.4%, $P=0.058$) (5.0 µg/dl). ACS (1.8 µg/dl) was associated with diabetes (OR=1.8, 95% CI=1.01–3.13) and cerebrovascular disease (5.0 µg/dl) (OR=5.3, 95% CI=1.24–22.78) but not with other comorbidities regardless of DST threshold. Patients with ACS (1.8 µg/dl) had lower DHEAS (54.9 vs 121.7 µg/dl, $P=0.009$) and ACTH levels (13.9 vs 21.8 pg/ml, $P=0.001$); higher 24-hour urinary free cortisol (77.5 vs 45.3 µg/24 h, $P=0.056$) and were larger (25.0 vs 20.0 mm, $P=0.002$). Tumor size was negatively correlated with DHEAS ($r_2=-0.16$, $P=0.051$); and positively with DST ($r_2=0.18$, $P=0.014$). However, no analytical or radiological differences were found between bilateral and unilateral AI ($P>0.05$), except for DHEAS (162.0 vs 78.6 µg/dl, $P=0.009$). During follow-up (mean=57.9 months), 6 (6.7%) AI grew (>10 mm); 3 (2.0%) non-functioning AI developed ACS (1.8 µg/dl); and 18.4% developed new comorbidities, being significantly more frequent in patients with ACS (1.8 µg/dl) (28.9% in ACS vs 11.2% in non-functioning, $P<0.001$). Bilaterality was not associated with tumor growth, or development of ACS or comorbidities.
Conclusion
We found higher prevalence of ACS in bilateral compared to unilateral AI, and an increased risk of diabetes and obesity in AI, but not of growth or development of new comorbidities during follow-up.

How innocent are nonfunctioning adrenal incidentalomas?

Akrivi Savelli[1], Fani Athanassouli[1], Fotini Petychaki[1], Nikos Asonitis[1], Ilias Giovanopoulos[1], Michalis Samarkos[1], Olga Benopoulou[2], Irene Kourbeti[2], Mina Psichogiou[1], Marina Mantzourani[1], Evangelos Cholongitas[1], Helen Gogas[1], Eva Kassi[1] & Anna Angelousi[1]
[1]National and Kapodistrian University of Athens, Athens, Greece. [2]Laiko Hospital, Athens, Greece.

Context
Adrenal incidentalomas (AI) can be found in 3–10% of the general population. The vast majority of them (70%) represents nonfunctioning adrenal incidentalomas (NFAI). Although several comorbidities have been studied in patients with autonomous cortisol secretion (ACS) there are limited data for those with NFAI.
Aim
To study metabolic disorders frequency in patients with AI and especially NFAI.
Design
Retrospective study.
Methods
Seventy AI and 50 controls were recruited from the 1st Department of Internal Medicine in "Laiko" Hospital, Athens (Greece). NFAI were selected based on current guidelines. The control group was selected based on normal adrenal imaging exams (Computerized Tomography (CT)). Patients and controls were matched forage, sexand menopausestatus. Patients receiving any medication that could affectcortisol levels were excluded.
Results
Sixty patients (86%) presented NFAI and 10 patents ACS AI (14%). The 27% of the patients were diagnosed with bilateral AI and were more commonly classified as ACS compared to NFA ($P=0.005$). Adrenocorticotropic hormone (ACTH), urinary free cortisol levels (UFC) and cortisol levels after (1 mg-ODST) differed significantly between NFAI and ACS AI ($P<0.05$) as it was expected,in contrast with morning cortisol levels ($P=0.48$). AI size was higher in ACS compared to NFAI ($P=0.009$). The patients bearing NFAI and ACS AI had higher Body Mass Index (BMI) ($P=0.048$ and 0.02 respectively), higher fasting blood glucose ($P=0.009$ and 0.03) and Hb1Ac compared to controls ($P=0.04$ and $P=0.05$, respectively). The presence of NFAI was correlated with higher incidence of diabetes mellitus and hypertensioncompared to controls (33% vs 10%,and 37% vs11%, respectively). Serum cortisol levels in 1-mg ODST in NFAI group although normal (<1.8mg/dl) were positively correlated with Hb1Ac levels ($r=0.66$, $P=0.05$). No other metabolic disorders (i.e. dyslipidemia, osteoporosis) were correlated with the presence of AI.
Conclusions
The frequency of ACS among patients with AI is not negligible. Patients with NFAI exhibitmore commonly glucose metabolism disorders and obesity as compared to controls. Further investigations with larger sample are necessary to elucidate the aetiopathogenesis of metabolic disorders in this population.

Human centered design in co-creation of tool-kit for care of patients with adrenal insufficiency- an iterative quality improvement approach

Kevin Hamming[1], Guillermina Noel[2], Denise Campbell-Scherer Campbell-Scherer[2], Mahua Ghosh[1], Anna Lam[1], Laurie Mereu[1], Andrea Opgenorth[1] & Roseanne O Yeung[1]
[1]University of Alberta, Division of Endocrinology and Metabolism, Department of Medicine, Edmonton, Canada; [2]University of Alberta, Physician Learning Program, Edmonton, Canada

Background
The high prevalence of chronic disease urges for new ways of working with our patients as active members of the health care team to better design processes for ongoing supportive treatment. Our Division of Endocrinology & Metabolism at the University of Alberta prioritized the need to improve care for those living with adrenal insufficiency (AI). We have worked with AI patient partners to address learning needs and priorities of our patients, their caregivers, and health professionals.
Methods
We created a Divisional Quality Improvement (QI) team and trained members in theEvidence-based Practice for Improving Quality program (www.epiq.ca). For needs assessment and to better understand our local clinical context, we surveyed local endocrinologists on their current management approach for AI patients. In order to check provider assumptions and to ensure patient-centred care, we partnered with Human-Centred Design team and started AI patient engagement in a workshop series. We reviewed resources available in Canadian and international societies as a group, and used human-centred design methods to co-create new educational materials for improved AI shared decision making.
Results
15 endocrinologists filled the survey, revealing that existing endocrinologist practice and materials provided are variable and inconsistent. Five patient partners from the Canadian Addison Society joined our QI team. Using human centred design methods to review reported endocrine practice and explore needs and wants from the patient perspective. Our QI team prioritized development ofemergency room (ER) AI material and created an emergency card and emergency letter. We incorporated feedback from ER physicians and nurses to ensure end-user clinical acceptability.
Conclusion
The goal of these human-centred co-creations is to ensure that the AI resources support the educational needs of both patients living with chronic disease and clinicians during a clinical encounter. We believe materials developed from our collaborative approach incorporating cumulative experience and expertise from all stakeholders will result in improved care for our patients. Our QI team is working on a resource dissemination plan.

Study of effect of whitening creams on serum basal cortisol level in egyptian females

Hany Khairy, Yara Eid, Iman Zaky, Merhan Samy & Mohammed Omar
Ain Shams University Faculty of Medicine, internal medicine, Cairo, Egypt

Background
Topical corticosteroids (TCs) are widely used as depigmenting agents alone or in combination with other fairness creams. However, its use may cause secondary adrenocortical insufficiency.
Objective
The aim of the present study is to evaluate the relationship between practice of whitening creams (Topical Corticosteroids) and serum cortisol level in a sample of healthy females at Ain- shams University hospital.
Methods
We recruited 45 subjects practice whitening creams (TCs) for three months or more; matched with a healthy control group consists of 45 participants. Blood pressure BMI and early morning basal serum cortisol level (0800 h). Blood glucose, serum Na, and serum K were measured.
Results
Early morning serum cortisol level was statistically insignificant among subjects practice whitening creams with TCs vs healthy controls (*P* value 0.307). However, there were 7 out of 45 participants in the study group (15.6%) while none (0%)of the control group had low serum cortisol level (< 5 mg/dl) with highly statistically significant difference (*P* value <0.001). In comparison and data analysis between subjects of the study group regarding practice duration, used quantity, application frequency, and method of exposure, there was high statistically significant difference between subjects with normal cortisol level vs subjects with low cortisol level (*P* value <0.001). There were, no significant difference found regarding BMI, and arterial blood pressure between study group and controls.
Conclusion
Whitening creams abuse especially high potency TCs among Egyptian females may induce adrenal gland insufficiency.
Keywords: Serum cortisol level, Whitening creams, TCs.

AEP107

A congenital adrenal hyperplasia patientpresented with myocardial infarction due to inadequate glucocorticoid therapy

Meliha Melin Uygur & Ali Dogan
New Century University Hospital Gaziosmanpasa, Turkey

Congenital adrenal hyperplasia (CAH) refers to an autosomal recessive condition due to 21 hydroxylase (21OHD) deficiency, is characterized by impaired biosynthesis of glucocorticoid and mineralocorticoid. The consequent increase in the ACTH leads to bilateral adrenocortical hyperplasia and hyperandrogenism. Nonclassic CAH (NCCAH) manifests with a less severe clinic that presents later in life with the sympthoms of excessive androgen production. Clinical features include premature pubarche,acne, accelaration in bone age. Although this group often does not require continuous glucocorticoid (GC) replacement, most of the patients with NCCAH receive GCs for different range of durations. Overtreatment with GCs might lead to increases in cardiovascular risk factors. In contrast, insufficient GC therapy can lead to androgen excess,infertility,development of adrenal crest tumors. Our case, a thirty-seven year old male, presented with acute chest pain in the emergency room. Electrocardiographic evidence of ST-segment elevationin leads II, III and elevation in cardiac biomarkers correlated with acute inferior ST-elevated miyordial infarction. Coronary reperfusion was performedwith primary percutaneous coronary intervention to the infarct-related circumflex artery. In his medical history,he was diagnosed CAH at the age of ten but he gave up the glucocorticoid therapy four years ago. He was married with two children, both daughters (eight years old and five yerars old). His weight was 92 kg, height was 150 cm. Waist circumferencewas 112 cm. His body mass index was 40.8 kg/m² and his waist to height ratio was 0.74 kg/cm which were shown to be associated with an increase in insuline resistance. Theresults of the biochemical evaluations of the patient are presented in Table-1 which were more consistent with NCCAH according to moderate elevation in 17-OH progesterone levels. We planned genetic consultation. Low dose GC treatment and metformin was started along with antithrombotic therapy, regular endocrinologic follow-up was arranged. The increased cardiovascular risk in CAH patients mainly attributed to GC overtreatment in studies. In our case cardiovascular morbidity may be consistent with adrenal hypofunction and androgen excess, which may both lead to insulin resistance. It is essential to follow-up patients with CAH in terms of cardiovascular morbidity whether on GC treatment or not.

Table 1 The biochemical results of the patient.

Glucose	87 mg/dl
Triglyceride	411 mg/dl
Troponin T	1,34 ng/ml (0-0,014)
17-OH Progesterone	251,47 ng/ml
ACTH	112,7 pg/ml
Cortisol	3.42 µg/dl
Total Testosterone	1.19 ng/ml
DHEA-SO4	198 µg/dl

Paradoxical hypertension: The hidden risk of beta blockade

Alba Hernández Lázaro[1], Ana Falcon-Suarez[2], Valeria Gazzaneo[3], Paula Maria Fernandez-Trujillo-Comenge[1], Agnieszka Kuzior[1], Manuel Esteban Nivelo-Rivadeneira[1], Ana Delia Santana-Suarez[1], Carmen Acosta-Calero[4], Claudia Arnas-Leon[4] & Francisco Javier Martinez-Martin[5]
[1]Hospital Dr Negrín, Endocrinology, Las Palmas de GC, Spain; [2]Centro de Salud Escaleritas, Las Palmas de GC, Spain; [3]Consultorio Local, Bañaderos, Consultorio Local, Bañaderos, Arucas, Spain; [4]Hospital San Roque, Endocrinology, Las Palmas de GC, Spain; [5]Hospital Dr Negrín, Outpatient Hypertension Clinic, Las Palmas de GC, Spain

Introduction
Betablockers are not a first-line antihypertensive therapy, although they have specific cardiological indications. The use of betablockers, especially the non-selective ones, may be associated with paradoxical hypertension, due to unopposed alpha-adrenergic peripheral vasoconstriction.

Methods
Review of the patient's Clinical Record and of the relevant literature.
Results
Clinical Case: A 66 year old woman was referred to our Outpatient Hypertension Clinic for evaluation of severe hypertension. She had no known allergies, did not smoke, her plasma glucose andlipid profile were normal, had underwent surgery of varicose veins in both legs. Her treatment included calcium plus vitamin D for osteopenia and alprazolam for anxiety (she was the main caretaker of her husband who had severe cognitive impairment). She did not take SSRI or MAO inhibitors. In the last two years she complained of uncontrolled hypertension in spite of multiple treatments, weight loss of about 3 kg, anxiety, tachycardia and tremor. She had consulted a private cardiologist, who ordered a transthoracic echocardiogram and a 24 hour ABPM. Both were reported as normal and she was prescribed propanolol. With this treatment she hads severe hypertensive episodes with SBP up to 250 mmHg with holocraneal headache, with pallor and nausea. Her blood pressure in our clinic was 136/81 mmHg, heart rate 77 bpm, her body mass index was normal and the physicalexamination was unremarkable. Lab tests (including plasma aldosterone and renin) were normal except for very high plasma normetanephrine (481.2 pg/ml, range 18–111) and slightly elevated metanephrine (64.9 pg/ml, range 12–60) The presuntive diagnosis is phaeochromocytoma/paraganglioma, as plasma normetanephrine was very high and the paradoxical hypertensive response to propanolol is characteristic. Abdominal CT and MIBG gammagraphy have been ordered and treatment with doxazosine has been instaured.
Conclusion
Betablockers should not be used in patients with uncontrolled hypertension in the absence of specific cardiological indication, until phaeochromocytoma/paraganglioma is ruled out. In the absence of alpha blockade, beta blockade may trigger severe hypertensive crisis.

Case study of family performing pheochromocytoma and paraganglioma (PPGL)

Ewa Tywanek[1], Agnieszka Zwolak[1], Magdalena Wozniak[2], Marcin Lewicki[3] & Beata Matyjaszek-Matuszek[2]
[1]Medical University of Lublin, Chair of Internal Medicine and Department of Internal Medicine in Nursing, Lublin, Poland; [2]Medical Univerity of Lublin, Chair and Department of Endocrinology, Lublin, Poland; [3]Medical Univerity of Lublin, Chair and Department of Epidemiology and Clinical Research Methodology, Lublin, Poland

Introduction
Phaeochromocytomas are mostly benign tumours with origin from chromaffin tissue of adrenal glands, whereas paragangliomas aretumours located along the sympathetic or/and the parasympathetic chain. Generally they are quite rare neoplasms with ability of producing, storing and secreting of catecholamines. Predominatingly they are sporadic, but in some cases they may develop in progress of particular genetic syndromes, such as multiple endocrine neoplasia type 2 (MEN II), neurofibromatosis type 1 (NF-1), Von Hippel-Lindau disease or Carney's Syndrome. Different defects in succinate dehydrogenase gene (SDH A, B, C, D) may be also detected. In this paper we would like to present a case of familiar PPGLs.
Case study
28-year-old woman with history of hypertension diagnosed during pregnancy, persistent after childbirth, was admitted to Chair and Department of Endocrinology of Medical University of Lublin (Poland) with suspicion of phaeochromocytoma. About 28 × 22mm lesion was visualised in right adrenal gland in routine ultrasonography imaging. In CT scannning performed in further stage of diagnostics, focal lesion of right adrenal gland about 37 × 31 mm in diameter and density about 37j.H. was detected, what aroused suspicion of pheochromocytoma. In diurinal urine collection elevated concentration of metanephrines, especially normethanephrine was detected. Patient was successfully operated after pharmacological preparation with doxazosin. Diagnosis of phaeochromocytoma was histopathologically confirmed. Simultaneously, 18-year-old man, the brother of above woman, was diagnosed with the presence of paraganglioma 56 × 26 × 28 mm in size of left side of his neck. Again elevated concentration of metanephrines, especially normethanephrine were detected in urine. Histopathological assessment after operation confirmed diagnosis of paraganglioma. At contiuous clinical and biochemical observation remain lesions in abdominal cavity of the patient.
Multiple neoplastic lesions originate from chromaffin tissue, present in siblings raise suspicion of familial PPGLs.
Conclusions
Pheochromocytomas and paragangliomas are extremely rare lesions derived from chromaffin-tissue with or without hormonal activity. In about 40 percent of cases, PPGLs are caused by a single driver germ line mutation. According to this data, patients with confirmed genetic mutations not only require more intensified follow-up, but also screening of family members is needed.

Pheochromocytoma with subclinical cushing's syndrome: A case report

Jenzri Haythem, Bilel Ben Amor, Hanene Sayadi, Hela Marmouch & Inès Khochteli
Monastir, Internal Medicine-Endocrinology Department, Monastir, Tunisia

Introduction
Pheochromocytoma is a functional catecholamine producing tumor that originates from adrenal chromaffin cells and is an extremely rare cause of ectopic Cushing syndrome. We report clinical case of adrenal incidentaloma with the evidence of both pheochromocytoma and sub-clinical Cushing's syndrome.
Observation
A fifty-two year-old female patient was referred to our institution because of an incidentally discovered right adrenal mass. Although she had mild hypertension, she had no signs of excessive production of either catecholamines or adrenocortical steroids. Abdominal computed tomography revealed right adrenal solid mass with the diameter of 6 cm. The tumor was visualized as a heterogeneous mass with a central area of necrosis. Left adrenal gland was normal. The laboratory data demonstrated three times raised twenty four hours urinary fractionated metanephrines with non-suppressible serum cortisol after two-day low-dose dexamethasone suppression test. Her basal corticotrophin concentration was nineteen pg/ml. Pituitary magnetic resonance imaging (MRI) did not reveal any lesion. After pre-operative management with alpha blocker, she underwent laparoscopic right adrenalectomy. The pathologist concluded that the lesion was pheochromocytoma . The patient developed adrenal insufficiency after surgery and required glucocorticoid replacement therapy for eight months.
Discussion
Patients with ACTH-secreting pheochromocytoma are seen in five per cent of patients with the ectopic Cushing syndrome, and pose distinctive diagnostic and management challenges, but if diagnosed early and managed intensively they should be curable by surgery.
Conclusion
This case represents a very rare cause of ectopic Cushing syndrome caused by an ACTH producing pheochromocytoma. Extensive hormone profile evaluation should be carried out in all adult patients presenting with an adrenal mass independent of their clinical presentation.

AEP111

A rare case of spontaneous adrenal haemorrhage from an adrenal haematoma

Lily Mae Dacay & Wann Jia Loh
Changi General Hospital, Endocrinology, Singapore, Singapore

Introduction
Severe haemorrhage from an adenoma is rare and potentially fatal. We report an unusual case of idiopathic unilateral severe adrenal haemorrhage from a non-functioning adrenal adenoma which was incidentally discovered 12 years earlier.
Case Presentation
A 59-year-old female was admitted to the hospital for a severe sudden onset of abdominal pain associated with vomiting. About 12 years ago, she was found incidentally to have a left adrenal adenoma of 2×1.7 cm of 8 Hounsfield Unit when she underwent CT abdomen investigating for anaemia. The adrenal hormonal work up of 24 h urine catecholamine and metanephrine, 24 h urine free cortisol and aldosterone-renin were unremarkable.

A repeat CT scan at 8 months later showed a stable adrenal lesion and she was discharged to her general practitioner. Her only other past medical history was diet-controlled hyperlipidaemia. She did not have hypertension, diabetes or obesity and did not take any medications. She did not have any symptoms to suggest pheochromocytoma. She denied any weight changes, fever or trauma. An urgent CT scan revealed a 9.7 × 7.2 cm acute haematoma in the left upper quadrant of the abdomen, likely related to a ruptured adrenal nodule. Her blood pressure inpatient was raised at 142–189/70–80 mmHg, likely due to the catecholamines release from adrenal haemorrhage. She was started on doxazosin to maintain normotension. 24 h urine catecholamines and metanephrines collected at 2nd day of admission were mildly raised which was appropriate for that level of stress (<1.5 times upper limit of normal). Her plasma free metanephrine (<0.20 nmol/l) and free normetanephrine (0.5 nmol/l) were normal. She did not have biochemical evidence of Cushing syndrome, hyperaldosteronism or hyperandrogenism. MRI adrenals performed on day 7 confirmed the enhancing left adrenal mass as the source of haemorrhage. Her abdominal pain resolved within the week and she was discharged well. Serial imaging of the adrenals using CT scan at 4 weeks and 5 months showed that the left adrenal size became progressively smaller, at 7 × 3.3 cm and 2.1 × 2 cm respectively. Her blood pressure control improved and she required only a low dose nifedipine 30 mg for control of hypertension at 5 months of follow up.

Conclusion

Idiopathic unprovoked adrenal haemorrhage from a non-functioning adrenal adenoma 12 years later can occur, suggesting that a longer follow up of adrenal adenoma should be considered before discharge.

A patient with seizures and adrenal failure as systemic manifestations of miliary tuberculosis: A case report

Davina Jugnarain[1,2], Shirin Patel[2], Bashir Mahamud[2], Swetha Reddy Kotha[2] & Gideon Mlawa[3]
[1]Barts and the London Medical School, London UK, London, United Kingdom; [2]Queen`s Hospital, London, United Kingdom; [3]Queen`s Hospital, Diabetes and Endocrinology/Acute Medicine, London, United Kingdom

Introduction

Extrapulmonary manifestations of tuberculosis can cause a diverse range of atypical presentations, depending on the system involved. Involvement of lymph nodes, pleura, central nervous system and bone are some of the organs that are well-described in the literature. This leads to a diverse range of presentations which can misguide diagnosis unless there is a high index of suspicion. Endocrinological manifestations are rare, but can occur uponhaematogenous dissemination of *Mycobacterium tuberculosis* in miliary tuberculosisto well-vascularised organs such as the adrenals, presenting with adrenal insufficiency or Addisonian crisis acutely.

Case description

We present the case of a 59-year-old man of South Asian origin, who presented in adrenal Addisonian crisis with a history of a significant, unintentional weight loss. He presented with classical signs of hyperpigmentation of the skin, hyponatraemia, hyperkalaemia and hypotension. A diagnosis of miliary tuberculosis was made based upon imaging, with suspected involvement of the adrenal glands. The patient improved with anti-tuberculosis chemotherapy and corticosteroid supplementation. The patient also later experienced tonic-clonic seizures and an altered personality, and magnetic resonance imaging later revealed several tuberculomas. The seizures were managed with levetiracetam, and corticosteroids were used to control tuberculoma development. Weaning of corticosteroids was necessary to conduct a short synacthen test. However, this repeatedly led to the patient being admitted on further occasions, presenting with similar signs of adrenal insufficiency. Eventually when a short synacthen test was conducted, it was able to demonstrate a lack of a cortisol response, which combined with high levels of adrenocorticotrophic hormone and bilaterally enlarged adrenals, suggested the patient was experiencing primary adrenal insufficiency secondary to extrapulmonary tuberculosis of the adrenals.

Discussion

The systemic manifestations of tuberculosis are complex, with little literature available regarding the involvement of adrenal glands. This case report describes the progression of possibly long-standing miliary tuberculosis to cerebral tuberculoma and adrenal tuberculosis, likely through lymphohaematogenous spread. Immunosuppressive therapies and the HIV/AIDS pandemic is likely to increase the incidence of unusually presenting extrapulmonary manifestations of tuberculosis. Therefore, it is important to acknowledge adrenal insufficiency and seizures as potential presentations of tuberculosis, particularly in the context of disseminated miliary tuberculosis.

Misdiagnosis of phaeochromocytoma with multiple cerebral infarcts and complex arrhythmias, failure "to think of it"

Genevieve Tellier[1], Simeon Head[1], Ffion Wood[2] & Anthony Wilton[1]
[1]Betsi Cadwaladr University Health Board, Endocrinology, Bangor, United Kingdom; [2]Betsi Cadwaladr University Health Board, Clinical Chemistry, Bangor, United Kingdom

The classic episodic triad of headache, sweating and palpitations facilitates the diagnosis of phaeochromocytoma. The absence of these symptoms can lead to misdiagnosis in patients with uncommon symptoms attributable to phaeochromocytoma. We present such a case.

Case report

A 64 year old man was referred to endocrinology having been coincidentally found to have a right adrenal mass with features of a phaeochromocytoma. He was asymptomatic and engaged in regular formal exercise. Hypertension diagnosed seven years earlier was treated with bisoprolol, amlodipine and losartan. Five years earlier multiple cerebral infarcts were found on presentation with sequential neurological deficits. Our biochemical and imaging investigations confirmed a diagnosis of solitary phaeochromocytoma.24 hour blood pressure monitoring revealed extreme lability exceeding the normal limits of cerebral autoregulation of blood flow.24 hour electrocardiography revealed episodes of asymptomatic trigeminy and ventricular tachycardia. Alpha blockade with doxazosin improvedblood pressure lability with resolution of arrhythmias prior to laparoscopic adrenalectomy. At the time of diagnosis of multiple cerebral infarcts the stroke team initially found mild weakness and reduced sensation in the right arm. A diagnosis of cervical myelopathy was supported by finding degenerative changes on x-ray. One week later he developed visual disturbance and was found to have a left homonymous hemianopia. CT brain confirmed infarction in areas perfused by the middle cerebral artery. MRA was normal but MRI confirmed right parietal, occipital and cerebellar infarcts. These findings led to extensive investigations with involvement of cardiologists, haematologists and neurologists. Such investigations excluded vasculitis, thrombophilia, diabetes, HIV and sarcoid.4-D cerebral CT angiography, transthoracic and transoesophageal echocardiography were normal. Seven day electrocardiography detected asymptomatic episodes of atrial fibrillation and complex ventricular tachycardia. Repeat MRI confirmed a new large pontine infarct. Throughout the investigations blood pressure ranged from 108/61 mmHg to 130/80 mmHg. He was discharged to primary care following anti-coagulation with warfarin with a putative diagnosis of multiple cerebral infarcts secondary to embolic events.

Discussion

This case confirms the presentation vagaries of phaeochromocytoma, it remains "the great mimic".Colleagues who managed him previously confirmed a failure to "think of it", particularly in view of the apparently normal blood pressure levels. It behoves endocrinologists to highlight the protean manifestations of phaeochromocytoma, particularly in patients with unexplained cerebrovascular events and arrhythmias.

Can you diagnose drug-induced bilateral adrenitis before clinical and analytical manifestations are present?

Paula Maria Fernandez-Trujillo-Comenge, Alba Hernández Lázaro, Agnieszka Kuzior, Manuel Esteban Nivelo-Rivadeneira, Ana Delia Santana-Suarez & Francisco Javier Martinez-Martin
University Hospital Doctor Negrin of Las Palmas de Gran Canaria, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain

Introduction

The introduction of immunotherapy with checkpoint inhibitors for oncologic diseases has improved the survival and quality of life of our patients; however, these therapies are frequently associated with autoimmune endocrine disease.

Methods
Revision of the patient's clinical record and the related literature.
Results
Clinical Case : An 88-year old woman was referred to our Endocrinology Clinic because of a PET image suggestive of bilateral adrenitis. Her history included essential hypertension and dyslipidaemia, treated only with enalapril 20 mg and atorvastatin 20 mg daily. She had been diagnosed in 2015 of melanoma with primary lesion in the right foot and extensive systemic metastases. She was treated with stereotactic body radiation therapy (I-SRBT) and conventional chemotherapy, plus eight cycles of pembrolizumab. Afterwards her melanoma was in complete remission, and the patient was asymptomatic except for asthenia and right malleolar oedema. A control PET was performed, showing bilaterally enlarged non-nodular adrenals (SUVmax 4.1 right adrenal, 5.8 left), suggesting bilateral adrenitis elicited by immunotherapy. Lab tests showed normal adrenal axis function, with glomerular filtration rate (CKD-EPI) 52 ml/min 1.73 m², Na^+ 142 mEq/l, K^+ 5.5 mEq/l, cholesterol 211 mg/dl, triglycerides 113 mg/dl, ACTH 12.6 pg/ml, cortisol basal 17.3 µg/dl. At this point she was referred to our Endocrinology Clinic. The presumptive diagnosis was bilateral adrenitis attributable to immunotherapy, without clear clinical or analytical manifestations. We ordered new lab tests. 2 months later the patient had very low fasting plasma cortisol (2.90 mg/ml) and aldosterone (3.7 ng/dl) with normal plasma ions, but her asthenia had improved, and she remained without treatment. A new lab control 2 months afterwards showed full recovery of her adrenal function (aldosterone 31.5 ng/dL, test ACTH → cortisol: 19.6, 25,10 and 24.7 mg/dl at 0', 30' and 60', while a new PET scan showed lower adrenal activity (SUVmax 2.74 left, 2.24 right).
Conclusions
The new checkpoint inhibitors such as pembrolizumab unleash an autoimmune aggression against the neoplastic cells, but collateral damage is frequent and autoimmune disease affecting the thyroid, the adrenal glands, the hypophysis and/or the endocrine pancreas is a common occurrence. The peculiarity in our patient was that there was evidence of drug-induced adrenitis before the biochemical and clinical manifestations were apparent.

Severe hypoaldosteronism after unilateral adrenalectomy for aldosteronoma: Case report

Lilit Egshatyan
Moscow, The Loginov Moscow Clinical Scientific Center of Moscow Health Department; Endocrinology Research Centre, Ministry of Health of Russia; AI Evdokimov Moscow State University of Medicine and Dentistry, endocrinology, Moscow, Russian Federation

Introduction
Primary aldosteronism is characterized by hypertension and accounts for about 10% of hypertensive patients. Post-operative hypoaldosteronism is well documented in cases within the past 3 years of unilateral adrenalectomy for aldosterone-producing adenomas.
Case report
We present the case of a 46-year-old patient with a 10-year history of hypertension and hypokalaemia (1.9 mmol/l) with normal renal function. Serum aldosterone was high with low renin activity leading to high aldosterone to renin ratio. Serum creatinine was 67 umol/l. CT abdomen showed 1.5 cm hypodense left adrenal mass. Post unilateral adrenalectomy he had reduction in the blood pressure, became eukalemic. After 8 weeks of adrenalectomy patient developed hyperkalemia (6.4 mmol/l) and increased serum creatinine (161 umol/l). Nephrology was recommended furosemide 80 mg daily. After furosemide, his kalium dropped to 5.8 mmol/l, creatinine to 149 umol/l. After 9 weeks, he presented to our department with muscle cramps, weakness, intermittent cardiac arrhythmia, and hyperkalemia (6.2 mmol/l), hypocalcaemia (1.82 mmol/l), hyperphosphatemia (1.9 mmol/l), the serum creatinine (158 umol/l) and parathyroid hormone (135 pg/ml) were high, aldosterone (16.3 pg/ml) and 25(OH)D (11.4 ng/ml) were low. After fluid resuscitation he was started on fludrocortisone 0.1 mg, calcium carbonate 1500 mg daily, and cholecalciferol 50.000IU weekly. His furosemide was reduced to 20 mg in a day. Two weeks later his creatinine was 126 umol/l,kalium 5.3 mmol/l, calcium 2.2 mmol/l, phosphat 1.6 mmol/l. His blood pressure was 138/85;therefore, he was switched to furosemide 20 mg once daily. Two months later his serum creatinine was 109 umol/l, kalium 4.8 mmol/l, calcium 2.31 mmol/l, phosphat 1.35 mmol/l, parathyroid hormone 83 pg/ml, 25(OH)D 29.1 ng/ml and so a dose reduction in fludrocortisone was attempted but at 0.05 mg per day, her kalium promptly rose to 5.2 mmol/l with creatinine 118 umol/l. The furosemide was stopped and fludrocortisone dose increased again with similar normalization of kalium and creatinine. Two months later off of the fludrocortisone 0.1 mg, his blood pressures were 145/85 and a dose reduction in fludrocortisone was attempted again. During the last 5 weeks on fludrocortisone 0.05 mg daily andcholecalciferol 10.000 IU weekly, his blood pressures (120–130/70-75), kalium (4.9–5.0 mmol/l),-calcium (2.34 mmol/l),parathyroid hormone (54 pg/ml) have been normal with stable renal function (creatinine 100–103 umol/l).
Conclusion
Screening of developing post-operative hypoaldosteronism with hyperkalemia should be actively considered in high-risk patients.

Adjuvant mitotane therapy: Predictive factors of response in adrenocortical carcinoma

Diana Alexandra Festas Silva[1], Joana Reis Guiomar[1], Diana Catarino[1], Carolina Moreno[1,2], Leonor Gomes[1,2], Cristina Ribeiro[1], Lúcia Fadiga[1], Inês Vieira[1], Mariana Lavrador[1], Rui Caetano[3], Arnaldo Figueiredo[4] & Isabel Paiva[1]
[1]Coimbra Hospital and University Centre, Endocrinology Department, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Endocrinology Department, Coimbra, Portugal; [3]Coimbra Hospital and University Centre, Pathological Anatomy Department, Coimbra, Portugal; [4]Coimbra Hospital and University Centre, Urology Department, Coimbra, Portugal

Introduction
Adrenocortical carcinoma (ACC) is a rare and aggressive tumor, with a poor prognosis and median survival of 3–4 years. Complete surgical resection is the only possibility of cure. The rate of post-surgical recurrence is high, so adjuvant treatment with mitotane plays a key role.
Objectives
To evaluate predictive factors of response to adjuvant treatment with mitotane in monotherapy in patients that underwent surgical resection of ACC.
Material and methods
Retrospective study of medical records of ACC patients from March/1991 to May/2019. Analysis of clinical, biochemical, imaging and anatomopathological variables (Ki-67 and Weiss score) and their predictive role in response to adjuvant treatment with mitotane. Some patients did not have a description of all Weiss criteria. Results with $P<0.05$ were considered statistically significant.
Results
Of the 34 patients, 22 were excluded (4 were not operated and 18 received mitotane in combination with chemotherapy and/or metyrapone and/or radiotherapy). Twelve patients were included. The average age at diagnosis was 50.5±14.6 years, with 83.3% being female. At presentation 50.0% of patients had symptoms of hormonal hypersecretion, 25.0% had constitutional symptoms and 25.0% were diagnosed as incidentaloma. The laparotomy was the preferred surgical approach ($n=7$; 58.3%). Complete tumor resection occurred in 8 patients (72.7%). The initial median dose of mitotane was 1.5 g/day (IQR:1.5), with an average maximum dose of 4.4±2.6 g/day (minimum: 2.0; maximum: 8.0). The average time interval to reach the maximum daily dose of mitotane was 4.7±3.9 months, with an average maximum mitotanemia of 14.5±7.7 mg/l. 83.3% of patients reported treatment-limiting adverse effects, with a predominance of gastrointestinal effects. The median duration of therapy was 12 months (IQR:38.0; minimum: 1.0/maximum: 68.0). 25.0% had a complete response, without evidence of disease until the present time. The median survival was 18 months (IQR:38.3; minimum: 4.0/maximum: 113.0). In the univariate analysis, only the presence of atypical mitoseswas significant. The disease persisted in all cases with it vs 33% in the absence of atypia ($P=0.023$). Gender, age, other imaging and anatomopathological characteristics, hormonal statusin the preoperative period, initial dose of mitotane, level of mitotanemia, and time to maximum dose or duration of therapy, were not predictive of the response.
Conclusions
In this study, the presence of atypical mitoses was the only significant survival predictor. Mitotanemia at the lower limit of the therapeutic window or even lower and the small sample size conditioned by the rarity of the pathology may have contributed to the results.

Diagnosis, treatment and survival of adrenocortical carcinoma: 28 years of experience

Diana Catarino[1], Diana Silva[1], Joana Guiomar[1], Carolina Moreno[1], Critina Ribeiro[1], Leonor Gomes[1], Lucia Fadiga[1], Mariana Lavrador[1], Inês Vieira[1], Rui Caetano[2], Arnaldo Figueiredo[3] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra EPE, Coimbra, Portugal, Endocrinology, Diabetes and Metabolism Department; [2]Centro Hospitalar e Universitário de Coimbra EPE, Coimbra, Portugal, Pathologic Anatomy Department; [3]Centro Hospitalar e Universitário de Coimbra EPE, Coimbra, Portugal, Urology Department

Introduction
Adrenocortical carcinoma is a rare endocrine disease characterized by an aggressive behaviour with a poor prognosis. Clinical experience, even with a little number of patients, has enhanced knowledge about this malignancy, in most cases challenging.
Objective
Characterization of patients with adrenocortical carcinoma followed at the endocrine department of a hospital centre, between 1991 and 2019.
Methods
Retrospective cohort study, based on clinical records of patients with histopathologic confirmed result of adrenocortical carcinoma. Statistical analyses with SPSS v.25.
Results and conclusion
We obtained 34 patients: 79.4% female, mean age at the diagnosis 50.03±13.02 years. Clinical presentation: 50% (n=17) - symptoms of adrenal hormone excess, 32% (n=11) - low back/abdominal pain or weight loss, 18% (n=6) - adrenal incidentalomas. Computerized tomography scan (CT) data: mean tumour size - 10.5±4.2 cm, necrosis imaging- 80%, CT density >10UH - 100%, additional invaded organs – 35.3% (mainly kidney and inferior cava vein), metastases at the diagnosis – 26.5%. Laboratory analysis: functional tumours (71%, n=24); hypercortisolism – n=11; hypercortisolism and androgen excess – n=9; androgen excess – n=3, hypercortisolism, androgen and mineralocorticoid excess – n=1. Surgery treatment was performed on 88.2% (n=30) of patients. Surgical approach: open surgery – 67% (n=20), laparoscopic adrenalectomy – 32% (n=10). Resection: R0 – 72.4%, R1 – 24.1%, R2 – 4.4%. ENSAT stage: 66.7% (n=20) in the stage II, 20% (n=6) in stage III, 13.3% (n=4) in stage IV. Histopathologic analysis: median of weight tumour – 260.5 g(680 g), between 71-2600 g; mean Weiss-score – 5.36±1,55; mitotic rate (>5 per 50 high-power fields) – 73.3%, abnormal mitoses – 68.4%, cytoplasm with clear cells comprising 25% or less of the tumour – 84.6%, necrosis – 91.7%, capsular invasion – 62.5%, mean Ki-67 index –26.2±22.8. Medical adjuvant therapy was performed on 70.6% (n=4) patients: mitotane monotherapy (n=12), mitotane and chemotherapy (n=5), mitotane and metyrapone (n=5), mitotane, chemotherapy and metyrapone (n=2). Radiotherapy was performed only on one patient. Relative to mitotane therapy: median initial dose – 1.5 g/day (1.5), median of maximum dose –5.4 g/day (3.0); mean of mitotane plasma level – 14.8±7.9 mg/l. Therapeutic mitotane plasma level was reached at 60% of patients. The mean overall survival was 52.2±79.1 months and was higher in youngers patients (r=-0.09; P=0.596). Actually, 12 patients are alive, 11 of them with complete remission. Despite the poor prognosis of this malignancy, the high survival rate and the high number of patients on complete remission found in this series (32.4%) is highlighted.

CT signs and parameters of vascularization of pulmonary neuroendocrine tumours and their relationship with the development of ACTH ectopic syndrome

Svetlana Buryakina[1], Natalya Tarbaeva[2], Natalya Volevodz[3] & Michael Pikunov[4]
[1]Endocrinology Research Centre, radiology, Moscow, Russian Federation; [2], Radiology; [3]Endocrinology Research Centre, Clinical and diagnostic center, Moscow, Russian Federation; [4]Vishnevsky Institute of Surgery, Thoracic surgery, Moscow, Russian Federation

Purpose
To analyze CT signs and parameters of vascularization of pulmonary neuroendocrine tumours (PNT) and their relationship with the development of ACTH ectopic syndrome.
Materials and methods
23 patients with PNT were evaluated with contrast-enhanced MDCT. Arterial and venous phases were obtained at 10 and 35 seconds after the attenuation of 200 HU at the descending aorta, a delayed phase was at 6–8 min after the start of injection of contrast media. The final diagnosis was established after histological and immunohistochemical analyses. "Typical carcinoid" (16 patients), "atypical carcinoid" (7) were revealed. ACTH ectopic syndrome was in 9 (56,3%) patients with TC and in 2 (28,6%) with AC. The following qualitative signs were analyzed at CT scans: localization of PNT, shape (round, oval, irregular), contours (smooth, tuberous, spiculate), its relationship with bronchus/vessel (stenosis, invasion, intimate adherence, presence of a feeding vessel), structure (necrosis and calcifications (localization and size). The surrounding parenchyma (ground glass opacity, lymphangitic carcinomatosis, areas of fibrosis, atelectasis, infiltrative changes), pleural thickening, bronchiectasis, pleural effusion were analyzed. The following quantitative signs were analyzed: the size of the PNT and the largest regional lymph node, patterns of the time-density curves (TDC). The precontrast density, peak height in density (PH: the maximum value of the TDC) and S/A ratio (the ratio of the PH of lesion to aorta) were recorded. Precontrast density and enhancement patterns of lesions were recorded. Perfusion of the lesions was calculated.
Results
The moderate relationship between ACTH ectopic syndrome and following CT features was revealed: perfusion (r=0.567, P=0.007), S/A ratio (r=0.504, P=0.02) and size of lesion (0.540, P=0.008). A very good quality of predictive model for the perfusion of the lesion and its size was determined (AUC 0.827, P=0.011, AUC 0.811, P=0.012). Perfusion rate 0.86 ml/min per ml and tumor size 12.5 mm ware the cut-off value (sensitivity 72.7%, specificity 80%, sensitivity 100%, specificity 54.5%). A good quality of predictive model for S/A ratio (AUC 0.791, P=0.024) was determined. S/A ratio 36.8% was the cut-off value (sensitivity 54.5%, specificity 100%).
Conclusions
The following findings: small size of the lesion (less than 12.5 mm) and low parameters of perfusion and S/A ratio allow us to suspect a hormonal activity of carcinoid tumor and, consequently, a more malignant nature of tumour, which should be taken into account in treatment strategy.

A retrospective review of radiological and endocrine characteristics of adrenal incidentalomas,in an Irish regional hospital

Awanish Shukla, Pooja Pathak, MaPyeh Kythar & Jayant Sharma
HSE, Midlands Regional Hospital, Endocrinology, Portlaoise, Ireland

Objective
To identify the radiological characteristics of adrenal abnormalities as reported on CT abdomen;To identify functional characteristics of adrenal incidentalomas; To identify 12 month outcomes of adrenal incidentalomas
1500 consecutive unselected computerised Tomograms(CT abdomen) done for non-adrenal indication, reviewed for adrenal abnormalities to identify, the incidence size, radiological density, those with abnormalities underwent endocrine work-up and re-imaging as advised in the European endocrine society guidelines.1500 scan were reviewed, Total abnormalities identified in the adrenal in 60 scans. Adrenal Adenomas wereidentified in 55, of which 1 was >4 cm, 1 were 3-4 cms in size, 5 in the 2-3 cm range, 18 in the 1-2 cm range and 30 in the sub centimetre range. 5 non-specific abnormalities were also identified.75% of all lesions were non-functioning adenomas. 12% had non-suppressed cortisol on overnight 1 mg Dexamethasone suppression. 2% patients had features of aldosterone over secretion, and 1 percent had phaeochrochromocytoma. Repeat scanning at 12 months was done on 25 of these adenomas that were ≥1 cm and no significant interval change in their size or appearance was identified in any of the adrenal incidentalomas on re-imaging. Our study is the first study of adrenal incidentalomas in the Irish midlands and broadly confirms the accepted European prevalence of adrenal incidentalomas of 0.04% for CT abdomen. Furthermore, it demonstrates that functionally 1 out of every 5 of the adrenal incidentaloma may have features of adrenal autonomous secretion. And cortisol oversecretion was the commonest endocrine abnormality detected in this cohort.

A 17-year-old Takotsubo cardiomyopathy patient exhibiting SDHB (+) PPGL and hypersecretion of insulin at 15 minutes after glucose loading

Sumie Okahata[1], Toshino Suzuki[1], Yuko Kondo[1], Takako Mitsumatsu[1], Teruo Shiba[1,2] & Hajime Ueshiba[1]
[1]Toho University Ohashi Medical Center, Tokyo, Japan; [2]Tokyo General Hospital

A 17-year-old woman was hospitalized emergently after suffering sudden palpitations and losing consciousness. On admittance she was in a state of shock, with a pulse rate of 140/min and systolic blood pressure of 70 mmHg. Echocardiography revealed a diffuse wall hypokinesis with decreased left ventricular ejection fraction. Acute heart failure was diagnosed. Coronary angiography, LV imaging, and myocardial biopsy suggested fulminant Takotsubo cardiomyopathy due to catecholamine hypersecretion, with urine normetanephrine 1350 ng/mg/Cr and urine noradrenaline 728 µg/day (noradrenaline dominant). Other endocrine hormones were in the normal ranges. Paraganglioma (PPGL) was suggested by an abdominal-CT showing a well-defined 33 × 22 mm tumor in the right retroperitoneum and by MRI showing hypointensity on T1-weighted image and a high intensity on T2-weighted image. Scintigraphic and PET-CT evidence of accumulated MIBG confirmed solitary PPGL in the right retroperitoneum. The tumor was surgically removed, and clear evidence of the SDHB mutation was confirmed. The 75 g OGTT test was performed before and after the surgery. Blood glucose (mg/dl) was normal high before resection, and improved after resection. The patient's IRI value, an all rose sharply at 15 minutes after the preoperative glucose loading. Improvements over the initial secretion expressed by the insulinogenic index (I.I.), the secretion expressed by HOMR-β (significant), and the resistance expressed by the HOMA-IR and Matsuda index were observed.[Discussion] This case has been presented as acute catecholamine cardiomyopathy, Takotsubo cardiomyopathy due to PPGL. Among the various genetic mutations that influence PPGL, those in genes encoding subunits of succinate dehydrogenase are the most relevant. As a mechanism of impaired glucose tolerance in catecholamine-producing tumors, noradrenaline dominance has been reported to lower insulin sensitivity and promote hepatic gluconeogenesis. In our case, hypersecretion of insulin was observed 15 minutes after the glucose loading before resection of the catecholamine-producing tumor, and improvements in the hypersecretion of insulin and insulin resistance were obtained after the tumor was excised. The catecholamine-producing tumor did not appear to impair early insulin secretion in our case. In this case exhibiting insulin hypersecretion at 15 minutes after glucose loading before tumor resection, the insulin secretion seemed to increase in a blood glucose-dependent manner.

Melatonin inhibits vascular smooth muscle cell proliferation and apoptosis through upregulation of Sestrin2

Kwi Hyun Bae[1], Mi Kyung Kim[2] & Keun-Gyu Park[3]
[1]Daegu Fatima Hospital, Internal Medicine , Daegu, Korea, Rep. of South; [2]Keimyung University School of Medicine , Internal Medicine , Daegu, Korea, Rep. of South; [3]Kyungpook National University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of South

Melatonin inhibits vascular smooth muscle cell proliferation and apoptosis through upregulation of Sestrin2

Excessive vascular smooth muscle cell (VSMC) proliferation contributes to the development of atherosclerosis and restenosis. On the other hand, apoptosis of VSMCs accelerates plaque rupture in the atherosclerotic vessels. Therefore, a strategy that regulates both VSMC proliferation and apoptosis is essential for the development of new pharmacological tools for the treatment of atherosclerosis. Despite mounting evidence supporting the benefits of melatonin in diverse metabolic diseases, the role of melatonin in VSMC growth remains largely unknown. In this study, we found that melatonin inhibited both proliferation and apoptosis of primary cultured rat VSMCs. Melatonin induced mitochondrial energetic stress in VSMCs and subsequent induction of Sestrin2 via C/EBPβ. Melatonin-induced Sestrin2 suppressed mTORC1 activity in VSMCs, contributing to suppression of VSMC proliferation. Moreover, melatonin-induced upregulation of Sestrin2 blocked apoptosis by preventing excessive ROS generation. Our results show that melatonin controls both VSMC proliferation and apoptosis via Sestrin2-mediated inhibition of mTORC1 and ROS scavenging. Therefore, melatonin should be considered as a lead compound for therapies aimed at preventing vessel lumen constriction during the course of atherosclerosis and restenosis.

Introduction

Burosumab, a fully human monoclonal antibody to fibroblast growth factor 23 (FGF23), is the only approved treatment for XLH, a rare genetic disorder characterized by renal phosphate wasting and substantial cumulative musculoskeletal morbidity. BUR02 (NCT03920072) is a European phase 3b open-label study monitoring the long-term safety and efficacy of burosumab in adults with XLH from sites who participated in the CL303/CL304 studies (NCT02526160/02537431).

Objective

To describe the patients in the open label follow-up and the first 12 weeks data from BUR02.

Methods

Forty-eight adults with XLH who participated in CL303/CL304 studies from EU sites were invited to take part in BUR02 and continue to receive burosumab every 4 weeks. Thirty-seven patients are expected to be recruited in total. Patients attended the clinic at baseline and week 12 for measurement of serum phosphate (primary endpoint) and patient-relevant secondary endpoints, and collection of safety data.

Results

Baseline and Week 12 data from BUR02 are available for 27 subjects (median age 46 years [range 22–63 years]; 66.7% female).At BUR02 baseline their median height was 150 cm, height z-score -2.2, BMI 25.6 kg/m^2 and 96.3% had a pathogenic *PHEX* gene variant, 52% were taking pain medication, 81% had joint pain and 67% had received prior orthopaedic surgery. Median serum phosphate was 0.7 mmol/l (2.3 mg/dl) at baseline and 0.8 mmol/l (2.4 mg/dl) at Week 12. Median Brief Pain Inventory (BPI) scores at baseline and Week 12 were 5.8 and 6.0 for worst pain, and 3.0 and 3.6 for pain interference. Median Brief Fatigue Inventory (BFI) scores were 5.8 and 6.0 for worst fatigue, and 2.7 at both timepoints for fatigue interference. Median Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores were 45.6 and 36.8 for physical functioning, 50.0 at both timepoints for stiffness, 45.0 at both timepoints for pain, and 46.9 and 41.7 for total score respectively. Median Short-form-36 v2 scores at Week 12 were 39.0 for the physical component score (PCS) and 49.3 for the mental component score (MCS).Median 6-minute walk test (6MWT) distance was 412 m at baseline (58.8% predicted) and 423 m (62.9%) at Week 12. There were no serious adverse events in the first 12 weeks of BUR02.

Conclusion

Early analysis of the first 12 weeks of BUR02 data demonstrates that continuation of burosumab from the CL303/304 studies into BUR02 sustains the correction of serum phosphate levels and maintains clinical benefits in patients.

Usefulness of parathormone (PTH) needle washout measurement vs MIBI scintiscan in localization of parathyroid adenoma- a single-center based preliminary study

Dorota Filipowicz, Ewelina Szczepanek-Parulska & Marek Ruchala
Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland

Introduction
An accurate identification of affected parathyroid is crucial for implementation of mini-invasive surgery techniques and therefore reduction of complication rate. A few centers postulate measuring washout parathormone (PTH) concentrationin suspected lesions, despite lack of established cut-off point for concentration values and validated measurement methods. Thisprospective study aimed to compare washout PTH assessment vs MIBI scintiscan in terms of efficacy in localization of parathyroid adenoma (PTA) in patients with hyperparathyroidism (HPT).
Material and methods
55 consecutive HPT patients (including seven males) aged 59±12 years were included. Median serum PTH was 133 mg/dl (range 83–148; normal 15–57), total calcium 11.2±1 mg/dl, ionized calcium 6.1±0.7 mg/dl, phosphates 2.8±0.6 mg/dl. Median maximum diameter of the lesion was 8 mm (range 3–40) on ultrasound. The most common location was left lower thyroid pole ($n=18$). The needle washout was performed in 1ml 0.9% NaCl. PTH concentration was measured by electro-chemiluminescence third-generation immunoassay Elecsys PTH 1–84 using cobas e 801 analyzer. Thyroid and parathyroid ultrasound was performed by an AIXPLORER system (Supersonic Imagine, Aix en-Provence, France).
Results
Median PTH washout concentration was 1493 pg/ml (range 17.2–5000). Positive PTH washout result (≥3 times above serum PTH value), was obtained in 76% of subjects. In lesions with ultrasound picture typical of PTA ($n=45$), PTH washout was positive in 82%. PTH values were significantly higher in typical than atypical lesions ($P=0.026$). Among patients with negative PTH washout ($n=13$), 85% had nodular goiter and/or autoimmune thyroid disease (AITD). MIBI performed in 53 patients, provided localization of PTA in 68%. In subgroup with negative MIBI, 13 subjects (76%) had positive PTH washout (location confirmed surgically in 3, 8 awaiting surgery, 2 followed-up).According to clinician, more useful in terms of PTA location was PTH washout alone in 30% of cases, especially in lesions <1 cm (33% vs 25% for MIBI), MIBI alone in 21% of cases, for the rest both methods were equivalent.
Conclusions
PTH washout assessment using the same method as for serum PTH measurement isa reliable method of PTA localization,particularly useful for lesions <1cm, with typical ultrasound features of PTA, without concomitant nodular goiter or AITD and negative MIBI results, although is not yet widely validated by lab technicians. Despite slight preponderance of PTH washout above MIBI alone, combination of both methods seems to be the most valuable. The study will be continued to reach relevant endpoint after surgery.

«Angio Scan-01» for extraskeletal calcification assessment in patients with mineral and bone disorders in chronic kidney disease

Irina Maganeva, Victoria Volodicheva, Anna Eremkina, Alina Aynetdinova & Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russian Federation

Background
Mineral and bone disorders in chronic kidney disease (CKD-MBD) is a systemic disorder of mineral metabolism due to CKD, which is manifestedby abnormalities of calcium, phosphorus, parathormone (PTH) and vitamin D; renal osteodystrophy; extraskeletal calcification. In patients with CKD, vascular calcification occurs 10–20 years earlier than in the general population, and is highly prevalent (40–92%) in the hemodialysis population. «AngioScan-01» is a professional diagnostic device for assessment of arterial function state and seems promising as a screening method for calcification detection in CKD patients.
Aim
To evaluate the diagnostic value of «AngioScan-01» device for theextraskeletal calcificationdetection in CKD patients compared totraditional noninvasiveimaging tools.
Methods
22 patients with secondary hyperparathyroidism (SHPT) were includedin the study, and 19 of them received hemodialysis. Calcification was estimated using echocardiography, doppler sonography of peripheral arteries, plain lateral lumbar X-rays, AngioScan-01 device. Laboratory tests included serum phosphorus, calcium, albumin, PTH, triglycerides, cholesterol (total, high-density lipoprotein, and low-density lipoprotein).Data analysis was performed with the Statistica 13 package (StatSoft, USA) and SPSS (IBM, USA).Quantitative data were assessed for normal distribution using the Shapiro – Wilk's W-test. Multiple and logistic regression were used to detect calcification predictors. A prognostically significant model was considered at $P<0.05$.
Results
Calcification was found in all examined patients: calcification of arterial and mitral heart valves in 54.5% (12/22 in both cases), in total femoral artery in 45.4% (10/22), and in common carotid artery in 36.4% (8/22), the thoracic aorta in 45.4% of cases (10/22), the abdominal part in 54.5% (12/22). Calcification according to «AngioScan-01» device was detected in 68.2% (15/22). The sensitivity and specificity of «AngioScan-01»compared to echocardiography was defined as 68% and 33%, with Doppler scanning as 80% and 57%, with X-rays as 86% and 71%respectively. Thelogistic regression analysis confirmed a statistically significant relationship of calcification with serum phosphorus level and calcium-phosphorus products ($P<0.05$, average for phosphorus 1.87±0.49 mmol/l,for calcium-phosphorus products 4.53±1.44 mmol/l), but did not indicate this for calcium, parathyroid hormone levels, the severity of anemia and dyslipidemia, which may be associated with a small number of patients.
Conclusion
The «AngioScan-01» method showed diagnostic value in the vascular calcification detection in patients with SHPTin CKD and could be introduced as a simple screening method into clinical practice.
Keywords: secondary hyperparathyroidism, chronic kidney disease, vascular calcification.

Impaired bone health at cancer diagnosis in paediatric patients

Maria Nikita[1], Artemis Doulgeraki[2], Christina Kanaka-Gantenbein[3], Kyriaki Karavanaki[4], Marina Servitzogloy[1], Helen Athanasopoulou[2], George Polyzois[2], Charalampos Tsentidis[5], Margarita Baka[1] & Lydia Kossiva[4]
[1]"P.&A. Kyriakou" Children's Hospital, Athens, Greece, Oncology Department, Goudi, Greece; [2]Institute of Child Health, Athens, Greece, Department of Bone and Mineral Metabolism, Goudi, Greece; [3]"Aghia Sophia" Children's Hospital, Athens, Greece, Division of Endocrinology, Diabetes and Metabolism, 1st Department of Paediatrics, Medical School, National and Kapodistrian University of Athens, Goudi, Greece; [4]"P.&A. Kyriakou" Children's Hospital, Athens, Greece, 2nd Department of Paediatrics, Medical School, National and Kapodistrian University of Athens, Goudi, Greece; [5]Nikaea-Piraeus General Hospital "Agios Panteleimon", Greece, Department of Endocrinology, Metabolism and Diabetes Mellitus, Goudi, Greece

Objectives
To evaluate the skeletal profile of paediatric patients with cancer at diagnosis.
Methods
Children diagnosed with cancer in our Oncology Centre were recruited during a two-year period and underwent metabolic bone profile and dual-energy X-ray absorptiometry (DXA) at the time of diagnosis.
Results
88 children were evaluated (51 boys, 53 prepubertal), aged 7.6±4.6 years. Of those, 50 were diagnosed with haematological malignancies and 37 with solid tumours. 21 out 69 patients had bone pain, (15 had a limp pain) and one sustained a femoral fracture. 43.2% (38/88) of the patients were vitamin D insufficient (25-OH-D: 12–20 ng/ml) and 5.7% (5/88) were deficient (25-OH-D <12 ng/ml). Hyperparathyroidism was present in 11.4% and hypercalciuria in 30% of all patients. One patient with hepatoblastoma had rickets. Bone turnover was also affected, particularly bone formation, because the patients had lower levels of osteocalcin (OC, $P<0.001$) and procollagen type I propeptide (PICP, $P=0.001$), compared to controls. Subgroup analysis revealed lower bone formation markers in the haematological subgroup i.e. OC and PICP ($P=0.001$ for both markers), whereas the solid tumour subgroup had higher bone resorption markers: tartrate-resistant acid phosphatase and urine deoxypyridinoline/urine creatinine ($P=0.002$ for

both markers).
DXA scan was performed in 47 patients; 21,2% (10/47) of them had low-normal bone mineral density (BMD) of the lumbar spine (LS BMD Z-score between –1 and –2) and only one patient had low BMD Z-score <–2 at the same site. Two patients had low/normal BMD of total body less head scans.
Conclusion
Skeletal health is already affected at the time of diagnosis in paediatric cancer patients. Low vitamin D levels are common. Bone turnover is disturbed and follows different patterns, depending on the type of cancer. These observations support bone health surveillance and early intervention at the time of diagnosis.

Familial hypocalciuric hypercalcemia in a young man: Grey zones of the differential diagnosis in 10-year clinical follow up

Katerina Zajickova, Jitka Moravcova & Josef Včelák
Institute of Endocrinology, Prague, Czech Republic

Herein, we report currently a 39-year old male with a 13-year history of asymptomatic hypercalcemia (mean 2.88 mmol/l; reference range 2.15–2.55 mmol/l) and mildly elevated parathyroid hormone (mean 68.7 ng/l; reference range 15–65 ng/l). Initially, in years 2007–2010 his laboratory picture was compatible with the diagnosis of Familial hypocalciuric hypercalcemia (FHH) with calcium-to-creatinine clearance ratio (Ca/Cr) between 0.008–0.009.Genetic testing was not available at that time. The differential diagnosis from primary hyperparathyroidism (PHPT) was complicated by the fact that there was no other family member with documented hypercalcemia. Between years 2014–2016 his follow up was interrupted. When he came in 2017, his Ca/Cr has almost doubled (0.014–0.019), whereas serum calcium has remained at a constant and moderately elevated level. To rule out a parathyroid adenoma, the patient underwent Tc-sestamibi scintigraphy (negative) and PET-CT with fluorocholine revealing an active focus bellow the left thyroid lobe. The neck ultrasound did not find any lesion corresponding to an enlarged left lower parathyroid gland. The Calcium-sensing receptor gene sequencing was finally carried out and identified a heterozygous missense mutation in exon 6 (c.1670G>A, p.Gly557Glu). This mutation has been previously reported in a Japanese family. Unlike our proband, all family members with G557E mutation had Ca/Cr lower than 0.01 in line with FHH. Although bone densitometry showed normal bone mineral density (BMD) in our male patient, there was a significant decrease in BMD between years 2009–2017 (22% at the femoral neck, 14% at total hip and 4.5% at lumbar spine). The documented bone loss corresponded to annual BMD % change of 2.75 at the femoral neck, 1.75 at total hip and 0.6 at lumbar spine. The patient did not have any other obvious reasons for bone resorption (no medication, normal body mass index, no endocrinopathy, vitamin D sufficiency) and it remains to be elucidated.
The biochemical profile of FHH and PHPT may overlap. The present FHH patient illustrates that the differential diagnosis can be difficult in an index case with (false) positive parathyroid imaging. Moreover, his Ca/Cr fluctuated in a large range (0.007–0.0198).Calcium intake, vitamin D status and bone resorption might have contributed to the patient Ca/Cr variations in 10-year clinical follow up.

Ultrasound-guided laser thermal ablation for parathyroid adenomas - preliminary report

Magdalena Kochman, Misiorowski Waldemar & Zgliczyński Wojciech
Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
The curative therapy of primary hyperparathyroidism (pHPT) is surgery. Data about ultrasound-guided laser ablation (LA) of parathyroid tumor are limited, however it could be a solution for patients with high surgery or anesthetic risk. We report our experience on LA of parathyroid tumors in 11 patients with pHPT with high surgery or anesthetic risk.
Methods
LA was performed under ultrasound guidance with an output power of 3W. Total energy and time of ablation was set individually, to make the ablation zone (monitored with real-time ultrasound and power Doppler) cover the entire parathyroid tumor.
Results
At baseline, serum calcium and iPTH concentrations were above normal range in all patients (2.62–3.34 mmol/l and 66.58–875 pg/ml, respectively). At day 1 after LA serum calcium normalized in 7/11, was under the normal range in 3/11 treated. Serum iPTH was low in 6, normal in 2 and elevated in 3 subjects (2 of them with hypocalcemia). At 3 months after ablation serum calcium and iPTH normalizedin 10/11. In one patient with large parathyroid tumor (3 ml) only partial improvement (decrease of calcium and iPTH concentrations) was achieved. Vocal cord palsy was observed in one of the subjects treated.
Conclusion
LA may be a valuable alternative treatment for patients with primary hyperparathyroidism and high surgery or anesthetic risk.

The picture of primary hyperparathyroidism in Italy: Proceeding from hyperparanet survey

Federica Saponaro, Filomena Cetani, Laura Mazoni, Matteo Apicella, Elena Pardi, Simona Borsari & Claudio Marcocci
Endocrinology Unit, University of Pisa, Pisa, Italy

This is a multicentre retrospective observational study, with the aim to characterize the presentation, management and cure rate of Primary Hyperparathyroidism (PHPT) in Italy. Sixty-one Italian Centres of Endocrinology participated in the study. Clinical, biochemical and instrumental records of 2173 patients with diagnosis of PHPT were collected on a specific online platform (Hyperparanet). Patients were 1808 females (83.2%) and 365 males (16.8%). Diagnosis of PHPT was made at the same centre which followed the patient in 1888 cases (86.9%). PHPT was sporadic in the majority of patients ($n=2044$ patients, 94%), in the remaining a familial form was diagnosed including 69 cases of MEN1, 34 cases of FIHP, 3 of HPT-JT, 2 MEN2A and 20 cases of FHH. The age at diagnosis was 61 ± 15 in the whole group and 45 ± 15 in familial patients. Clinical manifestation of the disease were: nephrolithiasis (either symptomatic or imaging detected) in 687 patients (31.6%), osteoporosis (T score <–2.5 at any site) in 1071 patients (49.2%) complicated by clinical fragility fractures in 282 cases (12.9%), symptoms of hypercalcemia in 104 patients (0.04%). Neuropsychiatric symptoms were detected in 244 (11.2%) cases and cerebrovascular accidents in 60 (0.02%). Only 432 patients were considered completely asymptomatic according to the latest guidelines. Mean serum calcium adjusted for albumin was 12 ± 0.1 mg/dl, PTH 129 ± 117 pg/ml, 25OHD 33 ± 20 ng/ml, 24-hours urinary calcium 291 ± 117 mg, without significant differences between sporadic and familial patients. Parathyroid imaging was performed in all centres in the majority of patients, independently of the indication for surgery. Ultrasound was positive in 833/1414 (58.9%), MIBI scintigraphy in 646/1143 (56.5%) and imaging was concordant in 638 cases. 689 (31.7%) underwent parathyroidectomy, performed at the same centre in half of the cases. At histology a single parathyroid adenoma was found in 554/689 cases (80.4%), a double adenoma in 36 (0.05%), a multiglandular disease in 48 (0.07%), an atypical adenoma in 16 (0.02%), a parathyroid carcinoma in 17 (0.02%). In 18 cases no parathyroid tissue was found at neck exploration. The rate of cure was 88.9: a persistence of the disease occurred in 71 cases and recurrence in 5 cases. Seven cases of persistence/recurrence occurred in

familial forms, the remaining cases in apparently sporadic disease. PHPT is a common endocrinopathy in Italy, presenting mostly as a sporadic disease, still burden by common even if silent bone and kidney involvement. The cure rate in patients who undergo parathyroidectomy is high, in centres with parathyroid surgery experience.

Phase II study of the impact of AZD4017, a selective 11β-HSD1 inhibitor, on osteocalcin in post-menopausal osteopenia

Afroze Abbas[1], Richard Eastell[2], Rachel K Crowley[3], Gemma Ainsworth[4], Sarah Brown[4], Louise M Flanagan[4], Rebecca J Fairclough[5] & Paul M Stewart[1]

[1]University of Leeds, School of Medicine, Leeds, United Kingdom; [2]Mellanby Centre for Bone Research, Academic Unit of Bone Metabolism, Sheffield, United Kingdom; [3]St Vincent's University Hospital, Dublin, Ireland; [4]University of Leeds, Clinical Trials Research Unit, United Kingdom; [5]Emerging Innovations Unit, Discovery Sciences, R&D, Astrazeneca, Cambridge, United Kingdom

The causative link between circulating glucocorticoid excess and osteoporosis is established. Although circulating cortisol levels do not change significantly with age, local tissue metabolism may be implicated in age-related bone loss. The enzyme11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) increases local cortisol production, is expressed in human osteoblasts and its activity increases with age leading to a decrease in bone formation. We hypothesised that selective 11β-HSD1 inhibition may enhance post-menopausal bone formation. A UK phase II randomised, double-blind, placebo-controlled trial of 90 days treatment with AZD4017 (a selective 11β-HSD1 inhibitor) was conducted across 2 centres. 55 post-menopausal women with osteopenia on bone density criteria were recruited. Participants received 400 mg twice daily of oral AZD4017 (active) compared to matched placebo over 90 days. The primary outcome measure was impact of AZD4017 on the bone formation marker, osteocalcin. Secondary objectives included correlation with 11β-HSD1 activity, safety, tolerability and reversibility. Baseline characteristics (age, BMI, blood pressure, bone density, cortisol secretion or metabolism) were matched between the active and placebo groups. At 90 days absolute osteocalcin measurements did not differ between active group (mean (SD): 22.3 (SD 8.59) ng/ml, $n=22$) versus placebo (21.7 (SD 9.21) ng/ml, $n=24$). Similarly, linear regression analysis of osteocalcin at 90 days adjusted for baseline osteocalcin demonstrated an estimated treatment effect of 0.95 (95% CI (–2.69, 4.60), not significant). Selective 11β-HSD1 inhibition was inferred through a large reduction in the urinary [THF+alloTHF]/THE ratio at 90 days (active group (mean 0.1 (SD 0.12), $n=19$) versus placebo (mean 0.6(SD 0.26), $n=22$). This returned to baseline by 180 days. Importantly urinary free cortisol/cortisone ratio as a surrogate marker of 11β-HSD2 activity, was unchanged at 90 days (estimated treatment effect –0.054 (95% CI (–0.21, 0.10)). 5α/5β reductase activity was also unchanged (estimated treatment effect –0.19 (95% CI (–0.34, –0.039)). Linear regression analysis of osteocalcin adjusted for change from baseline at 90 days in 11β-HSD1 activity, suggests that degree of 11β-HSD1 inhibition was a poor predictor of osteocalcin at 90 days. This phase II randomised controlled trial demonstrates that AZD 4017 selectively inhibits 11β-HSD1 activity *in vivo* in a safe and reversible manner. However, at 90 days there is no treatment effect on bone formation as measured by osteocalcin. Therefore, the relative impairment of bone formation in post-menopausal women, is not improved by changes to the intracellular production of cortisol, at least in subjects with normal glucocorticoid levels.

Changes in the relative expression of circulating microRNAs linked to bone metabolism in HIV-infected Individuals with low bone mass

Maria Yavropoulou[1], Artemis Kolynou[2], Polyzois Makras[3], Lemonia Skoura[2], Sideris Nanoudis[4], Maria Pikilidou[5], Olga Tsave[3], Simeon Metallidis[4] & Dimitris Chatzidimitriou[4]

[1]Medical School, National and Kapodistrian University of Athens, Endocrinology Unit, 1st Department of Propedeutic Internal Medicine, Athens, Greece; [2]Aristotle University of Thessaloniki, Medical School, Department of Microbiology, Thessaloniki, Greece; [3]251 Hellenic Air Force & VA General Hospital, Laboratory of Biomedical Research, Athens, Greece; [4]Medical School, Aristotle University of Thessaloniki, Division of Infectious Diseases, 1st Department of Internal Medicine, Thessaloniki, Greece; [5]Medical School, Aristotle University of Thessaloniki, 1st Department of Internal Medicine, Thessaloniki, Greece

Objective
Human immunodeficiency virus (HIV)-infected patients demonstrate an increased risk of osteoporosis and fractures. The pathophysiology of HIV-induced bone loss is complex and remains largely unknown. Recent studies have identified a molecular signature of small non-coding RNAs (microRNAS) in patients with osteoporosis, but data are lacking in HIV-infected patients. The aim of the present study was to investigate the expression profile of microRNAs related to bone metabolism in HIV infected (HIV+) patients with osteoporosis.
Methods
This was a cross-sectional study of one single centre. Thirty HIV+ male patients on anti-retroviral treatment (ART) with low bone mass and 30 male HIV+ patients matched for age and ADT duration with normal bone mass were included in the analysis. Twenty matched for age not –HIV infected (HIV-) and otherwise healthy individuals, from whom 10 had low bone mass and were drug-naive at the time of enrollement were also included as controls. All participants had measurements of bone mineral density, vertebral fracture assessment and complete biochemical work up. In our study cohort we evaluated changes in the serum relative expression of selected miRs linked to bone metabolism.
Results
Mean age of the enrolled HIV+patients and mean duration of ART were 55 ± 8 years and 11 ± 7 years, respectively. None of the participants had a prior history of a fragility fracture. Three miRs were significantly deregulated in HIV+ patients with osteoporosis compared to HIV+patients with normal bone mass. In particular miR-24 was significantly increased (fold change 2.34, $P=0.03$), and miR21 and miR-23a were significanlty decreased (fold changes 0.49, $P<0.001$ and fold change 0.75, $P=0.04$, respectively). The relative expression of miR-124 was significantly decreased (fold change 0.432, $P=0.02$) in the serum of HIV+patients compared to controls. In a subgroup analysis between osteoporotic patients with and without HIV-infection, the relative expression of miR-124 and miR-29a were also significantly decreased in the serum of HIV+ patients compared to HIV- individuals (fold regulation 0.12, $P=0.01$ and fold regulation 0.07, $P=0.02$)
Conclusion
The serum expression profile of miRs linked to bone metabolism is significantly deregulated in HIV+ osteoporotic males compared to HIV+ patients with normal bone mass, in line with what has been shown in non HIV infected osteoporotic patients.

Denosumab associated risk of malignancy- systematic review and meta-analysis of randomized controlled trials

Talia Diker-Cohen[1,2,3], Dana Rosenberg[2,3], Tomer Avni[2,3], Gloria Tsvetov[1,3] & Anat Gafter-Gvili[2,3]

[1]Rabin Medical Center, Beilinson Campus, Institute of Endocrinology, Metabolism and Diabetes, Israel; [2]Rabin Medical Center, Beilinson Campus, Medicine A, Israel; [3]Tel Aviv University, Sackler Faculty of Medicine, Israel

Context
Possible increased risk of malignancy in patients treated with denosumab has been concerned due to inhibition of the immune modulator receptor activator of nuclear factor κ-B ligand.
Objective
To assess the risk of malignancy associated with denosumab treatment.
Data Sources
PubMed and Cochrane Central Register of Controlled Trials were searched up to May 27, 2019.
Study Selection
All randomized controlled trials of denosumab (60 mg every 6 months) versus any comparator. Trials using higher drug doses for prevention of skeletal-related events were excluded.

Data Extraction
Data were independently extracted by two reviewers. We used a fixed effect model to pool risk ratios (RR) with 95% confidence intervals (CI).
Data Synthesis
Twenty-five trials (21,523 patients) were included. The risk of malignancy was comparable between denosumab and other comparators (absolute risk difference 0%, RR 1.08 [95% CI, 0.93–1.24], I2=0%). Sensitivity analysis based on adequate allocation concealment showed similar results. The risk of malignancy did not differ between groups in any of the subgroup analyses, including stratification by race, individual comparators, indications for treatment and longer drug exposure (≥ 24 months, 9 studies). The risk ratio of cancer-related death was comparable between groups.
Conclusions
Early concerns about a potential increased risk of malignancy resulting from an immune modulatory effect of denosumab are not supported by evidence from 25 RCTs with drug exposure of up to 48 months.

Prevalence and determinants of radiological vertebral fractures in a cohort of patients with Klinefelter syndrome

Walter Vena[1,2], Alessandro Pizzocaro[1], Myriam Amer[1], Rita Indirli[2,3], Filippo Maffezzoni[4], Emanuele Ferrante[3], Andrea Delbarba[4], Luca Balzarini[5], Alberto Ferlin[4], Giovanna Mantovani[2,6], Andrea Lania[5,6] & Gherardo Mazziotti[1,6]
[1]Humanitas Research Hospital, Endocrinology, Diabetology & Medical Andrology Division, Rozzano (MI), Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Italy; [3]Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [4]University of Brescia, Endocrine and Metabolic Unit, Department of Clinical and Experimental Sciences, Brescia, Italy; [5]Humanitas Clinical and Research Center, IRCCS, Department of Radiology, Rozzano, Italy; [6]Humanitas University of Milan, Department of Biomedical Sciences, Italy

Klinefelter syndrome (KS) is a frequent form of male hypogonadism that may be associated with a series of comorbidities potentially affecting quality of life and survival. As a matter of fact, KS was shown to negatively impact skeletal health. However, the studies so far published on this topic were mainly focused on evaluation ofbone mineral density (BMD) and bone microstructure, whereas data on fracture risk are still lacking. In this cross-sectional study, we evaluated for the first time the prevalence and determinants of vertebral fractures (VFs), i.e. the hallmark of osteoporosis, in KS. Eighty-seven patients with KS(mean age 41 years, range 18–64) were consecutively evaluated for radiological VFs (by quantitative morphometry) and lumbar spine and femoral neck BMD (by DXA). Fifty KS patients with age ≥40 were also evaluated by the Fracture Risk Assessment (FRAX) tool. Seventy-three patients were undergoing testosterone replacement therapy (TRT; 45 with testosterone undecanoate, 25 with transdermic formulation and 3 with testosterone enanthate). Seventy-four patients were taking vitamin D (cholecalciferol and calcifediol in 54 and 20 patients, respectively; 17 patients in combination with calcium). Low BMD was found in 22 patients (12 with osteopenia, 3 with osteoporosis and 7 with "low BMD per age"), whereas no one resulted to be at increased risk for either major (> 10%) or hip fracture (>3%) by the FRAX algorithm. Thirteen patients presented VFs with a median spine deformity index (SDI) of 2 (range 1–9). Prevalence of VFs was similar between normal vs low-BMD patients (15.9% vs 13.6%; $P=0.80$). Noteworthy, patients with VFs had significantly higher age at diagnosis of KS as compared to patients who did not fracture (33 years, range 15–47 vs 20 years, range 0–48; $P=0.03$), without significant differencesin age at the time of observation ($P=0.16$), body mass index ($P=0.25$), TRT ($P=0.43$), vitamin D therapy ($P=0.43$), calcium supplementation ($P=0.69$) and serum testosterone levels ($P=0.34$). Moreover, patients with VFs were more likely to complain back pain in comparison to those without VFs (33.3% vs 7.4%; $P=0.03$). In conclusion, this study provides a first evidence that KS may be associated with high risk of VFs in close relationship with delay in disease diagnosis and independently of BMD values and serum testosterone levels. Moreover, the association between VFs and back pain would suggest that VFs may have a clinical impact in KS, such as already reported in patients with primary male osteoporosis

Radiofrequency Echographic Multi Spectrometry (REMS) evaluation in patients with primary osteoporosis and primary hyperparathyroidism

Giorgia Grassi[1], Serena Palmieri[1,2], Elisa Cairoli[2,3], Iacopo Chiodini[2,3], Maura Arosio[1,2] & Cristina Eller Vainicher[1]
[1]IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy; [2]Department of Clinical Sciences and Community Health University of Milan, Italy; [3]Unit for Bone Metabolism Diseases and Diabetes & Labaratory of Endocrine and Metabolic Research, Istituto Auxologico Italiano IRCCS, Italy

Background
Radiofrequency Echographic Multi Spectrometry (REMS) is a new ultrasound-based tool for bone mineral density (BMD) measurement, recently approved by FDA for the use in clinical routine to diagnose osteoporosis (OP) and to monitor bone changes. However, data on patients with secondary OP are not available. The aim of our study was to compare REMS and DXA ability in identifying clinical (cFX) and morphometric vertebral fractures (VFx) in patients with primary OP (pOP) and with primary hyperparathyroidism (PHPT).
Methods
We enrolled 99 consecutive postmenopausal women referred to our Unit for pOP ($n=52$) or PHPT ($n=47$), who underwent REMS, DXA and spine X-ray to detect possible VFx. We excluded subjects with history ofbone-active therapy. The same operator executed REMS lumbar spine (LS) and total femural (TF) scan in all patients.
Results
Age, body mass index and BMD at any site, prevalent cFX (18.6% and 20.8%, respectively, $P=0.793$) and VFx (21.4% and 22.4%, respectively, $P=0.907$) were comparable between pOP and PHPT. The concordance between DXA and REMS in diagnosing osteopenia or OP was below 70% and comparable in pOP and PHPT patients (LS 64% and 58%; TF 66% and 51%, $P=$ns for all comparisons). The prevalence of OP according to REMS (REMS-OP) was lower than according to DXA (DXA-OP), although not significantly, in both pOP and PHPT groups (26.9% and 65.4%, $P=0.06$; 28.6% and 64.3%, $P=0.103$ respectively). Altogether, patients with DXA-OP had a higher prevalence of all (cFX+VFx) fractures (42.4% and 21.4%, $P=0.05$) and a trend for a higher prevalence of VFx (28.8% and 10.7%, $P=0.06$, respectively) as compared with patients without DXA-OP. Conversely, patients with and without REMS-OP had a similar prevalence of all fractures (32.0% and 39.1%, $P=$ns) and VFx (20.0% and 23.4%, $P=$ns). Similar results were obtained in both groups. Considering both the whole sample and the pOP and PHPT patients separately, REMS and DXA values were significantly associated, however the strength of correlation was low (LS all $r=0.373$, $P=0.001$; LS pOP $r=0.371$, $P=0.008$; LS PHPT $r=0.389$, $P=0.14$; TF all $r=0.48$, $P=0.001$; TF pOP $r=0.435$, $P=0.02$; TF PHPT $r=0.544$, $P=0.001$; respectively).
Conclusions
In our real life study, REMS seems to overestimate BMD values compared to DXA in both pOP and PHPT patients. REMS reliability in identifying patients with both cFx and VFx, seems to be lower than DEXA, in both pOP and PHPT patients. Future studies are needed to understand how to optimize this however promising technique.

Melatonin affects hypoxia-stressed cardiomyocyte differentiation of mouse embryonic stem cells

Eui-Bae Jeung, Jae-Hwan Lee, Seon Mi Park, Sunhwa Jeong & Yeong-Min Yoo
Chungbuk National University, College of Veterinary Medicine, Cheongju-si, Korea, Republic of South

Hypoxia causes oxidative stress and is known to affect cardiovascular dysfunction and the programming of cardiovascular disease. Melatonin is the hormone released primarily from the pineal gland and has been proven to be an antioxidant. Melatonin promotes the expression of antioxidant enzymes such as superoxide dismutase and catalase. To confirm the effect of hypoxia on the differentiation of mouse embryonic stem cells (mESCs) into cardiomyocytes, hypoxia condition induced during the differentiation period. mRNA expressions of cardiac-lineage markers (*Brachyury, Tbx20, and Ctn1*) decreased at differentiation 2-10day. The expression of hypoxia marker, Hif-1α, was increased in the hypoxia condition-plus mESC differentiation 2–10,

6–10, and 2–10 day, but melatonin receptor *Mtnr1a* mRNA expression was reduced in the hypoxia condition-plus mESC differentiation 6–10 and 2–10 day. To confirm the effect of melatonin against the hypoxia condition, melatonin was treated. Beating ratio and the mRNA expression of cardiac-specific marker (*Ctn1*) restored in 500 μM melatonin-plus hypoxia condition. The level of Hif-1α protein decreased in melatonin (100, 500 μM)-plus hypoxia, but the *Mtnr1a* mRNA expression was increased. In these conditions, the expressions of p-ERK and Bax proteins decreased, but the levels of p-Akt, PI3k, and Bcl-2 proteins increased. Melatonin has been shown to mitigate hypoxia via the ERK pathway in the differentiation of mESCs into cardiomyocytes. The expression of *Mtnr1a* mRNA was increased during the differentiation of mouse stem cells into cardiomyocytes, indicating that melatonin may affect cardiomyocyte differentiation. These results suggest that melatonin may protect against hypoxia in cardiomyocyte differentiation of mouse embryonic stem cells.

Hypercalcaemia in pregnancy due to parathyroid adenoma – would you recognise it?

Asma Bitar[2], Davina JUGNARAIN[3], Ahmed Al-Khayfawee[1], Bashir Mahamud[1,1], Belayet Hossain[1], Shirin Patel[1], Swetha Reddy Kotha[4], Aruna Ramineni[4] & Gideon Mlawa[4]
[1]Queen's Hospital, London, United Kingdom; [2]King George Hospital, London, United Kingdom; [3]Barts and the London Medical School, London, United Kingdom; [4]Queen's Hospital, London, United Kingdom

Introduction
Primary hyperparathyroidism (PHPT) is the third most common endocrine disorder in the general population, with a prevalence of 0.1 to 0.4%, caused by a solitary parathyroid adenoma in 80 to 85% of cases. In pregnancy, however, it is rare and usually manifests with non-specific symptoms leading to the delay in diagnosis A 33-year-old female patient who wasreviewed in obstetrics clinic at 15/40 weeks gestation. She complained of body aches, intermitted nausea and vomiting, and feeling generally unwell. She visited her GP who performed blood tests including serum bone and thyroid profiles. This revealed a high adjusted serum calcium of 3.27 millimoles/litre (mmol/l), borderline-low phosphate of 0.79 mmol/l, a high PTH of 9.4 pmol/L, and normal vitamin D level at 83. Thyroid profile showed a free T4 (FT4) level of 35.1 pmol/l and a suppressed thyroid-stimulating hormone (TSH) of less than 0.01 mU/l. 24-hour urine calcium result was elevated at 11.1 millimoles. She was admitted to the hospital and was managed conservatively with IV fluids. She was also started oncarbimazole 5 mg daily. The calcium level improved after IV hydration to 2.88 mmol/l and discharged home. Three weeks later,a repeat blood test showed persistent hypercalcaemia of 2.96 mmol/l andsymptomatic requiring admission for IV hydration. Initial neck ultrasonography was performed and did not show parathyroid adenoma. It did however detect a total of three benign-appearing nodules in both lobes of the thyroid gland. The patient also underwent urinary tract ultrasonography and nephrolithiasis was ruled-out. She had parathyroictomy at 19th week of gestation, after which calcium and PTH levels returned to normal. The patient did not suffer from any post-operative complications.
Discussion
Primary hyperparathyroidism in pregnancy(PHPT) rare and probably underdiagnosed. This is partly due to the large overlap between symptoms of hypercalcaemia and symptoms commonly attributed to pregnancy itself, such as nausea and vomiting. It is necessary to recognise symptoms of hypercalcaemia, when present, during pregnancy and establish the diagnosis of primary hyperparathyroidism to prevent both foetal and maternal complications associated with hypercalcaemia.
Conclusion
Serum bone profile is not routinely performed during pregnancy check-ups; however, we would highly recommend screening for primary hyperparathyroidim in the presence of any symptoms known to be associated with hypercalcaemia. This would lead to early diagnosis Diagnostic and therapeutic options are more limited for PHPT in pregnancy than in the non-pregnant patient. Parathyroidectomy is strongly advised as a first-line curative measure,in the second trimester.

Are young primary hyperparathyroidism patients differ from older ones regarding clinical and biochemical features?

Şefika Burçak Polat, Berna Evranos Ogmen, Didem Ozdemir, Oya Topaloglu, Reyhan Ersoy & Bekir Cakir
Ankara Yildirim Beyazit University, Endocrinology, Ankara, Turkey

Introduction
Primary hyperparathyroidism (PHPT) is a prevalent endocrinologic disease and the most common cause of hypercalcemia. PHPT usually affects the elderly. PHPT younger than 40 years of age is less frequent. In young patients especially for ones younger than 30 years of age, screening for familial syndromes such as MEN 1 and MEN 2A is recommended. However, in most of the cases genetic tests are negative and evidence for other endocrine components are absent. Herein this study we retrospectively evaluated the data of 322 patients with asymptomatic PHPT patients who were operated and compared the biochemical and clinical features of young patients (<40 years old) with older ones.
Method
This study had a retrospective design. We evaluated the data of the patients who admitted to our university hospital's endocrinology clinics and diagnosed with PHPT between September 2015-may 2018. According to the clinical guidelines all symptomatic patients and asymptomatic ones who had at least one indication for surgery were operated. There were 346 adenomas belonging to 322 patients in total. The patients were classified into 2 groups regarding age (<40 years or >40 years old as Group 1 and 2, respectively). Two group was compared according to clinical, biochemical and histopathologic features.
Results
There wasn't any statistically significant difference between groups according to histopathology (adenoma, hyperplasia and carcinoma) ($P=0.065$). In both groups there was female predominance, but number of male patients was significantly higher in Group 1 compared to Group 2 ($P=0.004$). Serum Ca levels were similar whereas PTH level was higher in Group 1. According to ultrasonographic features, Group 2 had higher prevalence of accompanying thyroid nodules or thyroiditis ($P<0.001$).Interestingly T scores on femur and total vertebra and prevalence of osteoporosis were similar in between two groups. The percentage of preoperative localization with US and mean size of adenomas were similar. However positive result on MIBI scan was higher in Group 2. median Urinary Ca excretion was higher in Group 1 despite similar vitamin D levels ($P=0.0012$).
Conclusion
The phenotype of PHPT in young adults is different from older patients. In our cohort number of male patients, serum PTH, urinary Ca excretion were higher in younger patients.

A new and valuable predictor for the diagnosis of primary hyperparathyroidism: Ca/P Ratio

Nagihan Bestepe[1], Neslihan cuhaci[2], Burcak Polat[2], Berna Ogmen[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Primary hyperparathyroidism (PHPT) is a common endocrine disorder that is characterized by hypercalcemia and elevated or normal levels of parathyroid hormone (PTH). Most PHPT cases are incidentally discovered when routine laboratory analysis reveals hypercalcemia. PHPT should be considered in any person with elevated serum calcium (Ca) levels and no clear evidence of malignancy. Serum phosphorus (P) is low due to the phosphaturic effects of PTH and mostly in the lower half of the normal range. As serum Ca and P are inversely related in PHPT, we examined the diagnostic value of the serum Ca/P ratio in the diagnosis of PHPT.
Method
A total of 364 patients followed at our clinic with a diagnosis of PHPT were retrospectively analyzed. As a control group, we selected 98 patients who attended the clinic in the same time period, presenting serum PTH, Ca and P within the normal range. The main outcome measures were: serum Ca, P, albumin, PTH, 25-OH vitamin D and creatinine. Both patients with normocalcemic PHPT and hypercalcemic PHPT were included. The diagnostic accuracy of Ca/P was investigated using receiver operator

characteristic (ROC) curve analysis. The resultant cut-off was verified using the independent set of data containing 100 patients and 50 control cases.
Results
There were 317 (87%) females and 47 (13%) males in patients group, and the mean age of the cohort was 53.9±11.4 years (range: 20–82). Ca and PTH were significantly higher in PHPT than in controls ($P<0.0001$). The Ca/P ratio was also significantly higher in PHPT than in controls ($P<0.0001$). ROC curves analyses identified a cutoff value as 3.23 (mg/dl) for Ca/P ratio with a sensitivity and specificity of 94% and 93%, respectively ($P<0.0001$). This cut-off value was confirmed by an independent group of cases (100 PHPT and 50 control cases) with 91% sensitivity and 80% specificity.
Conclusion
Ca/P is a precious predictor for the diagnosis of PHPT and it can be used instead of evaluating serum Ca and P levels solely. As Ca/P ratio is easily accessible and inexpensive, it will be useful for PHPT diagnosis and provide simplicity especially for thepractitioners with limited resources.

Comparative efficacy of parathyroidectomy and conservative management in patients with mild primary hyperparathyroidism: A systematic review and meta-analysis of randomized-controlled studies

Panagiotis Anagnostis[1], Konstantina Vaitsi[1], Stavroula Veneti[2], Theodosios Papavramidis[2], Eustathios Kenanidis[3], Michael Potoupnis[3], Eleftherios Tsiridis[3] & Dimitrios Goulis[1]
[1]Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, 1st Propedeutic Department of Surgery, AHEPA University Hospital, Thessaloniki, Greece; [3]Aristotle University of Thessaloniki, Academic Orthopedic Unit, General Hospital Papageorgiou, Thessaloniki, Greece

Objective
Whereas parathyroidectomy (PTx) has an established benefit in patients with symptomatic primary hyperparathyroidism (PHPT), its efficacy in patients with mild (asymptomatic) PHPT has not been proven. The aim of this study was to systematically investigate and meta-analyze the best available evidence from randomized-controlled trials regarding the efficacy of PTx on fracture risk (primary endpoint), as well as bone mineral density (BMD), serum calcium concentrations, nephrolithiasis risk and quality of life (QoL) (secondary endpoints) compared with conservative management (non-PTx; pharmaceutical intervention or active surveillance) in patients with mild PHPT.
Methods
A comprehensive literature search was conducted in PubMed, Scopus and Cochrane, from conception to January 11th, 2020. Data were expressed as percentage mean differences with 95% confidence intervals (CI). The I2 index was employed for heterogeneity.
Results
Five studies (four with active surveillance, one with etidronate) fulfilled the eligibility criteria [334 patients, mean age 66.5±5.6 years, mean follow-up time 25.2 (range 6–60) months]. There was no difference in fracture incidence between non-PTx and PTx patients [relative risk (RR) for total fractures 2.93 (95% CI 0.91, 9.49), I2=0%; RR for vertebral fractures 5.66 (95% CI 0.68, 47.31), I2=0%; RR for non-vertebral fractures: 1.32 (95% CI 0.31, 5.67), I2 not applicable)]. Lower BMD values were demonstrated in non-PTx compared with PTx patients [mean difference in lumbar spine BMD –4.53% (95% CI –6.25, –2.81), I2=98%; femoral neck BMD -2.89% (95% CI -5.71, –0.06), I2=100%; total hip BMD –3.44% (95% CI –5.49, –1.39), I2=99%; forearm BMD: no difference]. With respect to serum calcium concentrations, PTx patients demonstrated a mean reduction of 10.8% (95% CI 9.1, 12.6, I2=98%) compared with non-PTx patients. No difference was observed between the groups in the risk for kidney stone formation or the QoL indices (physical and social function, physical and emotional role function, mental health, vitality and bodily pain; general health higher in the non-PTx group).
Conclusions
PTx is not a first-line treatment option in patients with mild PHPT, as it does not improve fracture, nephrolithiasis risk or QoL, compared with conservative management; however, PTx does improve BMD and serum calcium concentrations.

Prevalence of hypoparathyroidism in the EU: A systematic review and meta-analysis

David Karpf[1], Chelsea Catsburg[2] & Alden Smith[1]
[1]Ascendis Pharma Inc, Palo Alto, United States; [2]BluePrint Orphan, New York, United States

Background
Hypoparathyroidism (HP) is caused by a group of heterogenous conditions that result in deficient secretion of parathyroid hormone. Due to this heterogenous nature, information on HP prevalence is highly variable and studies can be difficult to compare. This study aims to estimate the true prevalence of HP within the EU via comparison of available literature and analyses of sub-populations.
Methods
MEDLINE and EMBASE were systematically searched for peer-reviewed English-language studies involving population-based European HP prevalence estimates. Studies were assessed for rigor of methodology, suitability of study population, and were also reviewed for possible biases. In total, five prospective studies qualified via these criteria and were comprehensively evaluated for estimates of HP prevalence. Some studies presented prevalence results based on less stringent criteria than others, thus wherever possible criteria were standardized across studies, and where necessary, prevalence results were reevaluated. In addition, any estimates of temporal and geographical trends across the EU were collected.
Results
The most common division within adult HP is between non-surgical and post-surgical cases. All resulting data from the qualifying studies were entered into separate meta-analyses for both non-surgical and post-surgical HP. Based on these analyses the best prevalence estimate for non-surgical HP in the EU was 1.2/10,000 (95% CI : 0.6–1.6 per 10,000) and the best prevalence estimate for post-surgical HP in the EU was 2.0/10,000 (95% CI : 1.6–2.3 per 10,000). To evaluate temporal trends, use was made of detailed information available in the literature regarding change in rates over time. Post-surgical HP has been increasing at a faster rate (growth of approximately 0.03 cases per 10,000 annually) than non-surgical HP (growth of approximately 0.01 cases per 10,000 annually).
Conclusions
The overall prevalence of HP in the EU was estimated at 3.2 per 10,000 population in 2020 with a growth rate of approximately 0.04 cases annually. Although study criteria and geographies of the included studies were disparate, once separated into non-surgical and post-surgical, results were more consistent. These results help inform the epidemiology of both non-surgical and post-surgical HP within the EU.

Identifying clinical characteristics of hypoparathyroid patients in turkey: The 'HIPOPARATURK-NET Study'

Ceyla Konca Degertekin[1], Dilek Gogas Yavuz[2], Zafer Pekkolay[3], Kader Ugur[4], Arzu Or Koca[5], Ömercan Topaloğlu[6], Nilufer Ozdemir Kutbay[7], Yasemin Aydoğan Ünsal[8], Nusret Yilmaz[9], Tülay Omma[10] & on behalf of the HIPOPARATURK-NET Study Investigators[11]
[1]Ufuk University Faculty of Medicine, Department of Endocrinology, Ankara, Turkey; [2]Marmara University Faculty of Medicine, Department of Endocrinology, Turkey; [3]Dicle University Faculty of Medicine, Department of Endocrinology, Turkey; [4]Firat University Faculty of Medicine, Department of Endocrinology, Turkey; [5]Kecioren Training and Research Hospital, Department of Endocrinology, Turkey; [6]Kocaeli Derince Training and Research Hospital, Department of Endocrinology, Turkey; [7]Manisa Celal Bayar University Faculty of Medicine, Department of Endocrinology; [8]Bursa Uludag University Faculty of Medicine, Department of Endocrinology, Turkey; [9]Akdeniz University Faculty of Medicine, Department of Endocrinology; [10]Ankara Training and Research Hospital, Department of Endocrinology, Turkey; [11]Turkey

Hypoparathyroidism is a rare endocrine disorder whose epidemiologic characteristics regarding the cause, clinical course, acute and chronic complications have not been well defined. There is also a substantial geographic variability regarding those parameters, and country-specific local data is scarce. This study was conducted to assess the baseline characteristics, including the demographics, etiologic distribution, disease severity, medications used, frequency of acute and chronic complications, and treatment/follow-up patterns of patients with chronic (>6 months) hypoparathyroidism in Turkey.

The 30 centers that participated in the study filled out the data of their registered adult hypoparathyroid patients, retrospectively, through detailed questionnaires using their patient records. Overall, 738 hypoparathyroid patients were included in the analysis. The mean age of the patients was 48.5±13.3 years, and the majority were female (83.9%). The most common etiology of hypoparathyroidism was surgical damage to the parathyroid gland (postsurgical group; $n=661$, 89.6%) following a complete/partial thyroidectomy, parathyroidectomy and/or neck dissection with an indication of Graves disease in 31 (5.5%), multinodular goiter in 282 (49.6%), thyroid cancer in 155 (27.3%) and toxic nodular/multinodular goiter in 100 (17.6%). The nonsurgical cohort included 77 (10.4%) patients. The patients had a mean disease duration of 9.5±6.9 years. The majority ($n=593$, 81.6%) were diagnosed shortly after the operation that caused hypoparathyroidism while 19 (2.6%) patients had a diagnosis since childhood, another 89 (12.2%) were diagnosed as outpatients with mild symptoms of hypocalcemia, 18 (2.5%) withemergency department admission due to hypocalcemic tetany, and 8 (1.1%) were asymptomaticduring the routine blood tests that led to the diagnosis. Of all patients in our cohort, 117 (15.9%) had serum calcium measurements <7.5 mg/dl, 111 (15.1%) between 7.5–8.0 mg/dl, 200 (27.1%) between 8.0–8.5 mg/dl, 304 (41.3%) between 8.5–10.5 mg/dl and 5 (0.7%) >10.5 mg/dl under their current treatment. The postsurgical and the nonsurgical groups did not differ in terms of age, BMI, and duration of disease. The nonsurgical group had a lower nadir plasma PTH concentration than the postsurgical group (2.28±2.77 vs 10.08±7.92, $P<0.0001$) while their current daily dose of calcitriol and corresponding serum calcium levels on treatment were similar. In conclusion, the etiology of hypoparathyroidism is predominantly surgery-induced in our cohort. Most patients are under 1–2 times yearly follow-ups, and their serum calcium levels are in an acceptable target range. Rates of screening for chronic complications are below desired levels and need to be improved.

The prevalence of postoperative (PO) chronic hypoparathyroidism (HypoPTH) in bilbao, northern spain

Amelia Oleaga[1], Fernando Goñi[1], Cristina Moreno[1], Natalia Iglesias[1], Laura Calles[1], Andoni Monzon[1], adela martinez[1], ignacio merlo[1], Teresa Gutierrez[2], Elena Ruiz de Velasco[3] & Miguel Paja[1]
[1]Basurto University Hospital, Endocrinology and Nutrition, Bilbo, Spain; [2]Basurto University Hospital, Surgery, Bilbao, Spain; [3]OSI Bilbao Basurto, Pharmacy Primary Care, Bilbao, Spain

Introduction
HypoPTH is an uncommon disorder, mostly due to anterior neck surgery. The prevalence of HypoPTH has been studied in surgical series and registries, (USA, Denmark and Hungary) where only a minority of patients has HypoPTH due to non-surgical causes. In Spain data on PO HypoPTH in endocrinologist clinical practice has been published recently. The aim of this study was to establish the prevalence of chronic PO HypoPTH in Bilbao area, with a population 2019: 346,843.
Subjects and methods
In Spain, patients who have been prescribed a drug in the public Health Service are recorded in a regional prescription database. Data were obtained by searching for patients on both calcitriol and levothyroxine between 2012 and 2019. For all identified patients the individual medical record was reviewed. Only patients who underwent neck surgery (mainly total thyroidectomy) were included in the study. For the analysis, chronic PO HypoPTH was defined as hypocalcaemia with inadequate low PTH levels following neck surgery that necessitated treatment with calcitriol for more than 1 year.
Results
436 out of 489 patients met inclusion criteria. 110 patients were found to have chronic POHypoPTH, giving a prevalence of 31.7/100,000 inhabitants. Among patients operated on in our center before 2012, 56 developed chronic HypoPTH. No data is available on the total number of surgeries performed during this period of time. 119 thyroid surgeries performed before 2012 are on record. 63/119 patients develop transient HypoPTH. Some of them were taking calcitriol although calcium and PTH levels were normalized. Between 2012 and 2019, 1096 patients underwent thyroid surgery (1,021 total thyroidectomy, 214 central/lateral lymphadenectomy additionally) in our center. Among those, 317 (31%) resulted in HypoPTH, with 269 (26.3%) of these cases being transient, and 48 (4.7%) chronic.
Conclusion
– The estimated prevalence of chronic PO HipoPTH in the population of Bilbao is similar to other areas related in the literature.
– The prevalence of PO hypoPTH in our center since 2012 is high 31% but in line with other surgical series, being chronic in 4.7%.
– No differences were found between surgeries for benign or malignant disease.
– Data published in endocrinologist clinical practice show higher rates: 48.3% transient and 14.5% chronic. These differences are due to the methodologies used.
– Although recovery from chronic HypoPTH is rare, patients should be monitored forserum PTH levels so that unnecessary treatments can be avoided.

Osteocalcin may participate to the bone-parathyroid crosstalk through activation of the calcium-sensing receptor in human parathyroid adenomas

Chiara Verdelli[1], Giulia Stefania Tavanti[1], Riccardo Maggiore[2], Gilberto Mari[2], Veronica Sansoni[3], Silvia Perego[3], Leonardo Vicentini[4], Paolo Dalino Ciaramella[5], Giovanni Lombardi[3,6] & Sabrina Corbetta[7,8]
[1]IRCCS Istituto Ortopedico Galeazzi, Laboratory of Experimental Endocrinology, Milan, Italy; [2]Endocrine Surgery, IRCCS Ospedale San Raffaele, Milan, Italy; [3]Laboratory of Experimental Biochemistry & Molecular Biology, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [4]Endocrine Surgery, IRCCS Istituto Auxologico Italiano, Milan, Italy; [5]Endocrinology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [6]Poznań University of Physical Education, Poznan, Poland; [7]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [8]University of Milan, Department of Biomedical, Surgical and Dental Sciences, Milan, Italy

Parathyroid glands regulate bone metabolism through PTH, while bone modulates parathyroid function through calcium and FGF23. Bone releases the matrix protein osteocalcin (OC), whose hormone function is increasingly evident. We tested the hypothesis that OC may modulate parathyroid function. The 6 hours-stimulation of human parathyroid cells derived from adenomas (PAds) ($n=5$) with γ-carboxylated OC (GlaOC; 40–60 ng/ml) increased the expression levels of the *PTH*, *CASR* and *CCND1*genes, as well as of WNT/β-catenin member *AXIN2*. In PAds-derived cells ($n=4$), GlaOC (60–80 ng/ml) incubation for 10 min, inhibited the basal phosphorylated ERK/total ERK ratio (pERK/ERK) and increased the basal phosphorylated AKT/total AKT ratio (pAKT/AKT) and active β-catenin. PhosphoERK/ERK, pAKT/AKT and active β-catenin were similarly modulated by the incubation with 60–80 ng/ml undercarboxylated OC (GluOC). OC is known to exert its biologic effects through the activation of the putative membrane receptor GPRC6A. GPRC6A transcripts and proteins were variably detected in human PAds ($n=10$). Immunohistochemistry showed specific GPRC6A cytoplasmic staining in some cells and membrane staining in other cells scattered throughout the parenchyma, both in normal and tumor parathyroids. Immunofluorescence detected colocalization of GPCR6A with PTH and GCM2. GPCR6A is a homolog of the calcium sensing receptor (CASR). CASR was variable expressed in the present series of PAds and it did not correlate with the GPRC6A expression. We investigated whether OC activates CASR, using HEK293 cells transiently transfected with GPRC6A (GPRC6A-HEK293) and with CASR (CASR-HEK293). Increasing GlaOC and GluOC (20–80 ng/ml) induced significant increases of pERK/ERK, decreases of pAKT/AKT, while active β-catenin was unaffected in GPRC6A-HEK293 cells. By contrast, GlaOC and GluOC inhibited the basal pERK/ERK levels and increased basal pAKT/AKT in CASR-HEK293 cells, resembling the effects detected in PAds-derived cells and suggesting that OC activates CASR in parathyroid cells. These patterns of response to OC were observed in presence of 1.5 mM extracellular calcium ($[Ca^{2+}]_o$). When CASR-HEk293 cells were cultured in presence of 5.0 mM $[Ca^{2+}]_o$, pERK/ERK levels were inhibited by GluOC, but not by GlaOC. By contrast, in $[Ca^{2+}]_o$-deprived medium, basal pERK/ERK levels were unaffected by both GlaOC and GluOC in both PAds-derived and CASR-HEK293 cells, while GlaOC and GluOC reverted their stimulatory effects on pERK/ERK, exerting inhibitory effects in GPRC6A-HEK293 cells, consistent with modulation of the biologic effects of OC by $[Ca^{2+}]_o$. These new data add OC to the bone-parathyroid cross-talk and suggest that CASR can be activated by OC with different intracellular signaling responses depending by $[Ca^{2+}]_o$.

Long-term effectiveness of asfotase alfa in adults with pediatric-onset hypophosphatasia in routine clinical practice

Lothar Seefried[1], Ulrike von Hehn[2], Dominik Rak[1], Anna Petryk[3] & Franca Genest[1]
[1]Julius-Maximilians-Universität, Orthopaedic Clinic King-Ludwig-Haus, Würzburg, Germany; [2]medistat GmbH, Kiel, Germany; [3]Alexion Pharmaceuticals Inc., Global Medical Affairs Lead, HPP & Amyloidosis, Boston, United States

Hypophosphatasia (HPP) is a rare, inherited, metabolic disorder caused by deficient tissue-nonspecific alkaline phosphatase activity. A heterogeneous presentation in adults includes musculoskeletal symptoms, impaired physical function, and reduced health-related quality of life (HRQoL). Asfotase alfa is the only approved treatment for pediatric-onset HPP. We evaluated, in a real-world setting, the long-term effectiveness of asfotase alfa on physical function and HRQoL among adults with pediatric-onset HPP (NCT03418389). Data were analyzed from adults who had pediatric-onset HPP, were aged >18 years, and received care at the Orthopedic Institute of the Julius-Maximilians-University of Würzburg. They had received asfotase alfa for ≥24 months. Physical function evaluation included the 6-Minute Walk Test (6MWT), Timed Up-and-Go (TUG) test, Lower Extremity Functional Scale (LEFS), and Short Physical Performance Battery (SPPB). HRQoL was assessed with the 36-item Short-Form Health Survey, version 2 (SF-36v2); prevalence and intensity of pain were evaluated. Safety data were collected throughout the study. The study included 14 (11 women, 3 men) patients, with a median (min, max) age of 53 (20, 78) years for women and 46 (19, 57) years for men at asfotase alfatreatment initiation. All 14 patients had compound heterozygous *ALPL* gene variants, ≥1 HPP bone manifestation, and history of ≥1 fracture. We previously reported on the score changes for each tool from baseline to 12 months; here we report changes from 12–24 months. Improvements on treatment were observed over the first 12 months and maintained over another 12 months. Median (min, max) distance, according to 6MWT, was similar at 12 (320 [0, 605] m) and 24 (316 [60, 600] m) months ($n=13$; $P=0.115$). A slight increase in median time to complete the TUG test from 11.3s–13.75s was not statistically significant ($n=7$; $P=0.382$). Specific SPPB component results were stable. Slight decreases seen in median 4m usual gait speed from 1.12 m/s–1.02 m/s ($n=9$; $P=0.61$) and in median repeated chair rise time from 12.53 s–12.48 s ($n=8$; $P=0.398$) were not statistically significant. Improvements in LEFS ($n=10$) and SF-36v2 Physical Component Summary ($n=9$) scores were observed early at 3 and 6 months and remained stable over 24 months. Changes in pain level ($n=5$) were variable between 12 and 24 months. No new safety signals were identified. These data suggest adults who have pediatric-onset HPP treated with asfotase alfa in real-world settings have marked improvements in clinical and functional outcomes, which were observed early and sustained over 24 months of treatment.

Prevalence of osteoporosis, vertebral fractures and hypogonadism in HIV-infected men.

Letizia Chiara Pezzaioli[1], Teresa Porcelli[2], Filippo Maffezzoni[3], Paolo Facondo[1], Elena Di Lodovico[1], Andrea Delbarba[3], Martina Properzi[4], Carlo Cappelli[1], Francesco Castelli[4], Maria Eugenia Quiros Roldan[4] & Alberto Ferlin[1]
[1]Department of Clinical and Experimental Sciences, Unit of Endocrinology and Metabolism, University of Brescia, Brescia, Italy; [2]Endocrinology, Montichiari Hospital, ASST Spedali Civili Brescia, Montichiari, Italy; [3]Unit of Endocrinology and Metabolism, Department of Medicine, ASST Spedali Civili Brescia, Brescia, Italy; [4]Department of Clinical and Experimental Sciences, Unit of Infectious and Tropical Diseases, University of Brescia, Brescia, Italy

With HAART (Highly Active Anti-Retroviral Therapy) introduction, HIV infection history has radically changed. Increased survival has led to new complications, including osteoporosis. The pathogenesis of osteoporosis in HIV patients is multifactorial: virus, HAART, smoking, alcohol, physical inactivity, comorbidities, and hypogonadism can interact in bone depletion. Aim of this study was to evaluate the prevalence of osteoporosis, vertebral fractures (VF) and hypogonadism in 189 HIV men. Spine and femoral mineral density (BMD) were acquired by DXA. Vertebral fractures were assessed by quantitative morphometric analysis; VF were defined as mild, moderate and severe based on a height ratio decrease of 20–25%, 26–40% and more than 40%, respectively. For the assessment of gonadal status, total testosterone (TT), calculated free testosterone (cFT), SHBG, LH and FSH values were obtained. Hypogonadism was defined as overt with low TT or cFT levels, and classified in primary, secondary or normogonadotropic based on LH levels. The prevalence of subclinical hypogonadism (TT and cFT normal values, with high LH levels) was assessed. Possible risk factors, and bone turnover markers levels were also collected. Osteoporosis was found in 32.8% of patients (62/189), 30.2% (57/189) showed at least one VF, 11.1% (21/189) had an overt hypogonadism, and 9.5% (18/189) subclinical hypogonadism. Among the patients with overt hypogonadism, 4 showed a primary form, 2 secondary and 12 normogonadotropic. Compared to non-osteoporotic patients, those with osteoporosis had longer infection duration (17.9 vs 13.6 y, $P=0.0034$), had been on HAART for more years (14.6 vs 10.9, $P=0.0049$), and showed higher SHBG values (78.9 vs 64.5, $P=0.049$). With respect to VF, years of HIV-positivity (18.2 vs 13.6, $P=0.0028$), HAART duration (14.7 vs 10.9, $P=0.0056$), SHBG (84.2 vs 62.7, $P=0.0092$) and FSH (12.01 vs 8.21, $P=0.049$) values differed significantly between fractured and non-fractured patients. No significant difference was found between hypogonadal and eugonadal patients in terms of BMD (0.954 vs 0.968), vertebral T-score (–1.8 vs –1.5) and VF (29.4% vs 27.2%), whereas it was achieved for BMI (26.3 vs 24.7, $P=0.017$) and FSH (15.4 vs 7.7, $P<0.001$). This study included a large number of HIV+ men in which testicular function was fully assessed, in contrast to most of the published studies. These data show a high prevalence of osteoporosis, VF and hypogonadism in HAART treated HIV-infected men. The role of hypogonadism in osteoporosis and VF pathogenesis is unclear, even if a correlation between FSH and SHBG levels and skeletal fragility was found in these patients.

Bone metabolism in patients with extreme insulin resistance (IR) syndromes

Yevgeniya Kushchayeva[1], Idri Abdullah[2], Sergiy Kushchayev[3], Sungyoung Auh[2], Megan Startzell[2], Elaine Cochran[2] & Rebecca Brown[2]
[1]University of South Florida, USF Diabetes and Endocrinology Center, Tampa, United States; [2]NIDDK, NIH, Diabetes, Endocrinology, and Obesity Branch, Bethesda, United States; [3]Moffitt Cancer Center, Diagnostic Imaging and Interventional Radiology, Tampa, United States

Introduction
Diabetes is associated with increased fracture risk both in patients with type 1 (T1D) and type 2 diabetes (T2D) despite differences in bone mineral density BMD (decreased in T1D and increased in T2D). In T2D, insulin resistance (IR) is selective, with some insulin signaling pathways impaired, while others are overactive due to hyperinsulinemia. It is not clear how different insulin signaling pathways might contribute to the bone phenotypes observed in diabetes. To understand the role of insulin signaling in bone metabolism, we studied patients with severe impairment of all insulin signaling pathways (insulin receptor, INSRmutation) versus severe, selective IR (lipodystrophy, LD). *We hypothesized*differences in insulin signaling in INSR vs LD might lead to differing bone phenotypes.
Patients and methods
116 LD and 27 INSR. BMD of the spine, total hip (TH), femoral neck (FN), and 1/3 radius by DXA (age 18–30y); kidney ultrasonography; PTH, serum calcium, phosphorus, magnesium, alkaline phosphatase, osteocalcin, vitamin D 25-(OH), vitamin D 1,25-(OH), HbA1c, and 24-hour calcium excretion were analyzed.
Results
There were no difference in HbA1c in INSR vs LD. BMD was higher in LD vs INSR at the spine (1.167±0.06 vs 0.808±0.07, $P<.001$), TH (1.120±0.08 vs 0.783±0.07, $P<.001$) and FN (0.986±0.08 vs 0.687±0.05, $P<.001$). No difference was found in 1/3 forearm. Kidney stones and nephrocalcinosis were found in 40 and 46.7% of INSR vs 0% and 2.2% of LD patients ($P=.0001$).
Conclusion
Similar to T1D vs T2D, patients with severe IR due INSR mutation vs lipodystrophy have opposing phenotypes for BMD (low in INSR, high in LD) and renal calcium deposition (high in INSR, normal in LD). These findings are consistent with a model in which insulin action in bone is needed to

prevent bone resorption. In the absence of insulin signaling (INSR), there is increased bone resorption, thus increasing Ca filtration by the kidneys and causing renal Ca deposition. In the selective IR with hyperinsulinemia due to LD, enhanced insulin signaling in bone prevents bone resorption, leading to high BMD. Fracture risk for our patients has not been established, thus the clinical significance of the differences in BMD is not known. Further research is needed to clarify the long-term effect of insulin signaling on bone and mineral metabolism.

Core muscles trainig for muscle strength improvement in patients with osteoporotic compression vertebral fractures

Ekaterina Makarova[1], Larisa Marchenkova[1] & Mikhail Eryomushkin[2]
[1]FSBI "National Medical Research Center of Rehabilitation and Balneology" Ministry of Health of Russian Federation, Somatic Rehabilitation, Anti-Aging and Reproductive Health Department, Moscow, Russian Federation; [2]FSBI "National Medical Research Center of Rehabilitation and Balneology" Ministry of Health of Russian Federation, Moscow, Russian Federation

Aim
To estimate the effect of new complex physical rehabilitation program on core muscles strength in patients with osteoporotic vertebral fractures (VFs).
Materials and methods
Study comprised of 90 osteoporotic patients aged 50–80 (65.4±9.1 years) with low-traumatic VFs who were randomized as 2:1 into intervention group (group1, $n=60$) and control group (group2, $n=30$). Patients in group1 received an intensive rehabilitation course including back muscle training with mechanical loads #10; sensorimotor training on double unstable platform #10; kinesohydrotherapy in a pool #15; physical exercises in a gym #10. Group2 was prescribed only physical exercises in a gym #15. All patients undergo tenzodynamometry on BackCheck diagnostic unit (Dr. Wolff, Germany) at baseline, at the end of rehabilitation course and in a month after the rehabilitation as follow-up.
Results
After a rehabilitation course muscle strength increased significantly in trunk extensors (TE) from 15.8±10.1 to 21.7±13.1 kg ($P<0.0001$), trunk flexors (TF) from 14.5±9.1 to 18.9±10.2 kg ($P<0.001$), left lateral flexors (LLF) from 12.8±7.2 to 17.5±9.6 kg ($P<0.01$) and right lateral flexors (RLF) from 13.2±7.1 to 17.8±9.2 kg ($P<0.01$). The maximal improvement of muscle strength was registered in TF +6.5±57.5% above recommended values ($P<0.001$). TE strength deficiency significantly decreased ($P<0.001$), but did not reach the recommended values –15.8±25.8%. After the 1-month follow-up muscle strength in all examined muscles didn't significantly diminished vs results just after rehabilitation course completion ($P>0.05$). The strength of all the studied muscles were higher ($P<0.01$) and the muscle deficiency was less in TE ($P<0.05$) and TF ($P<0.001$) in group1 vs group2 in a month of follow-up after rehabilitation course.
Conclusions
A new complex physical rehabilitation program leads to increase of muscle strength and elimination of muscle strength deficiency in patients with osteoporotic VFs, and these effects are not attenuate for at least a month after the treatment completion.

Successful quantification of symptom load by a disease-specific questionnaire HPQ 40/28 and analysis of influencing biochemical parameters in patients with postsurgical hypoparathyroidism

Deborah Wilde[1], Lara Wilken[1], Bettina Stamm[2], Christina Heppner[3], Andreas Leha[4], Martina Blaschke[1,3], Christoph Herrmann-Lingen[5] & Heide Siggelkow[1,3]
[1]University Medical Center Goettingen, Clinic for Gastroenterology and Endocrinolgy, Goettingen, Germany; [2]MVZ Endokrinologikum Saarbrücken, Saarbruecken, Germany; [3]MVZ Endokrinologikum Goettingen, Goettingen, Germany; [4]University Medical Center Goettingen, Institute for Medical Statistics, Goettingen, Germany; [5]University Medical Center Goettingen, Department for Psychosomatic Medicine and Psychotherapy, Goettingen, Germany

In hypoparathyroidism (HypoPT), patients suffer severely from reduced quality of life. The complexity of HypoPT demands a disease-specific control instrument to characterize symptom load. We employed a newly developed disease-specifichypoparathyroid patient questionnaire (the HPQ 40/28) to investigate and quantify HypoPT patients' complaints and contributing factors. In this cross-sectional, two-center study, patients with postsurgical HypoPT ($n=49$) were matched for sex and age and compared to patients having undergone thyroid surgery without HypoPT (ThySu, $n=39$)) and patients with primary hyperparathyroidism (pHPT, $n=35$). The HPQ 40/28 was filled in when patients visited the respective center. Clinical background information, blood tests,as well as current medication were documented by the physician. Serumcalcium laywithin the reference range in 87% of HypoPT patients, serumphosphate in 95.7%, and calcium-phosphateproduct in 100%. HPQ 40/28 scores for the scales "pain and cramps" (PaC), "neurovegetative symptoms" (NVS), "numbness or tingling", and "heart palpitations" were significantly elevated in comparison with control groups. Correlations between complaints and laboratory parameters could be demonstrated in the HypoPT group, with serumcalcium correlating with NVS ($r=0.309$, $P<0.05$) and serumphosphate with loss of vitality ($r=0.349$, $P<0.05$). Calcium-phosphate product was the main contributor to symptom load with an influence on PaC ($r=0.295$, $P<0.05$), loss of vitality ($r=0.498$, $P<0.001$), numbness or tingling ($r=0.328$, $P<0.05$), and memory problems ($r=0.296$, $P<0.05$). In conclusion, the newly developed HPQ 40/28 successfully identified and quantified symptoms typical in HypoPT patients. Using the HPQ 40/28, the calcium-phosphateproduct was identified as the predominant factor in the severity of complaints in HypoPT

Investigation of total- and free-25OHD levels by different methods in pregnant women

Ágnes Tüttő[1], Gellért Balázs Karvaly[2], Dóra Gerszi[3], Szabolcs Várbiró[4], Zoltán Lőcsei[5], Judit Konderak[6] & Erzsébet Toldy[7,8,9]
[1]Pécs University of Pécs Faculty of Health Science, Institute of Diagnostics, Pécs, Hungary; [2]Budapest, Faculty of Medicine, Institute of Laboratory Medicine, Semmelweis University, Budapest, Hungary; [3]Budapest, Faculty of Medicine, Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary; [3]Budapest, Faculty of Medicine, Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary; [5]Szombathely, DepartmentDepartment of General Internal Medicine, Markusovszky University Teaching Hospital, Szombathely, Hungary; [6]Budapest, Diagnostic Centre, Clinical Chemistry and Immunology Laboratories, Budapest, Hungary; [7]Szeged, QualiCont In Vitro Diagnostic Quality Control Nonprofit Ltd., Szeged, Hungary, Szeged, Hungary; [8]Pécs, Institute of Diagnostics, Faculty of Health Science, University of Pécs, Pécs, Hungary; [9]SYNLAB Hungary KFT Diagnostic Centre, Budapest, Hungary, Clinical Chemistry and Immunology Laboratories, Budapest, Hungary

Avoiding vitamin D deficiency can be beneficial in prevention of adverse maternal, fetal and neonatal outcomes. Because of increasing level of vitamin D-binding protein (DBP) in pregnancy, the determination of free-25OHD should be required, whose adequate measure is a challenge for the analytics. Literature data are contradictory whether total-or free-25OHD fraction is more reliable taking into consideration the methods of measurement. Data of publications on free or total, bioavailable 25OHD are quite discrepant. Our study started in connection with gestational diabetes (GDM) we aimed to evaluate the correlation of 25OHD-fractions measured by different assays.
Methods
88 sera of pregnant women (31.4±5.0 years; gestational age: 26.6±1.3 weeks; out of them 25 suffered from GDM; 62 cases were on 665±742 IU_D3/day) were investigated. Measured biochemical markers were: calcium, t-25OHD by three methods; liquid chromatography/mass spectrometry (t-25OHD_MS) chemiluminescence immunoassay (t-25OHD_CLIA, Liaison, DiaSorin) and protein binding assay (t-25OHD_PBA, Cobas Roche), as well as albumin and DBP (immunoturbidimetry Roche and Dako, Integra, Modular) to calculate free levels (c-f-25OHD_MS; c-f-25OHD_CLIA ; c-f-25OHD_PBA). Direct measured free-25OHD (dm_f-25OHD) was determined by ELISA (DiaSource, Future Diagnostics) method. To evaluate the agreement of different methods Passing & Bablok regression and Bland & Altman analysis were used.
Results
The levels of t-25OHD_MS were significantly higher ($P<0.001$) than the routinely used methods (MS: 76±31 vs CLIA: 59±24; PBA: 60±25 nmol/l;

both biases: -24%). Tests of linearity were excellent (MS-CLIA: $P=0.939$ and MS-PBA $P=0.634$). Mean of dm-f-25OHD level was lower compared to c-f-25OHD_MS (7.5±2.1 vs 8.3±3.2 pmol/L; $P<0.05$; bias:-5.3% and linearity: $P=0.808$).But the c-f-25OHD_CLIA and c-f-25OHD_PBA levels are lower (both: 6.5±2.1 pmol/l; $P<0.01$;) than dm_f-25OHD. The biases of both methods are: +18%; the linearities with dm_f-25OHD are by CLIA: $P=0.934$ and by PBA method: $P=0.634$. The markers of 25OHD didn't show any significant differences between GDM and GDM-negative cases.

Conclusion

Our results confirm the acceptable dissimilarity of the routinely, frequently used methods (CLIA and PBA). They diverge from LC-MS method but show an excellent linearity with that. It should be recommended to define cut-off points depending on assay method for monitoring vitamin D supply in pregnant women. Unfortunately, we have few data to suggest to the sole measure of free-25OHD. Although our results indicate that calculated free levels are not consistent because the one underestimated, the other two overestimated the direct measured levels.

DOI: 10.1530/endoabs.70.AEP149

AEP150

Analysis of 25OHD levels in chronic renal failure depending on the methods

Erzsébet Toldy[1,2,3], Judit Konderak[1], László Kovács[4,5], Ágnes Tüttő[3], Gellért Balázs Karvaly[6] & Zoltán Lőcsei[4]

[1]Budapest, SYNLAB Hungary Ltd., Budapest, Hungary, Diagnostic Centre Clinical Chemistry and Immunology Laboratories, Budapest, Hungary; [2]Szeged QualiCont In Vitro Diagnostic Quality Control Nonprofit Ltd., Szeged, Hungary; [3]Pécs University of Pécs Faculty of Health Science, Institute of Diagnostics, Pécs, Hungary; [4]Szombathely Markusovszky University Teaching Hospital, Department of General Internal Medicine, Szombathely, Hungary; [5]Szombathely, B. Braun Avitum Hungary Dialysis Center No 6, Szombathely, Hungary; [6]Budapest, Faculty of Medicine, Institute of Laboratory Medicine, Semmelweis University, Budapest, Hungary

Vitamin D deficiency is common in patients with chronic renal failure (CRF) based on routinely determined total-25-hydroxyvitaminD (t-25OHD) levels. The present knowledge is contradictory whether the direct measured free-25OHD (dm_f-25OHD) or the calculated free-25OHD (c_f-25OHD) is the best indicator of the vitamin D supply for CRF patients. Adding methods to our previously described first experiences on this subject, in this study we aimed to serve newer data to make this question clearer.

Method

95 patients [39 men; 56 women; 69±12 years: 30 on peritoneal dialysis (PD) 34 on haemodialysis (HD), both on 3000 IU D_3/day; 31 pre-dialysis (preD) on 1400 IU D_3/day] were investigated. Their sera were analysed for vitamin D-binding protein (DBP) (Dako), albumin (immunoturbidimetry, Integra), Ca, PTHi (Roche) dm_f-25OHD (ELISA, FutureDiagnostics), t-25OHD [using two methods: liquid chromatography/mass spectrometry (t-25OHD_MS) and chemiluminescence immunoassay (t-25OHD_CLIA; DiaSorin]. The c_f-25OHD levels were calculated from both t-25OHD (c_f-25OHD_MS; c_f-25OHD_CLIA). Differences between the methods were evaluated by Passing&Bablok regression and Bland & Altman analysis.

Results

Albumin levels were the lowest (PD:33±4 vs HD:37±4; preD:39±4 g/l; $P<0,001$) and DBP concentrations the highest (PD:351±39 vs HD:307±48 mg/l; $P<0,001$) in PD group. The t-25OHD_CLIA levelswere lower compared to t-25OHD_MS t-(73.4±22.4 vs 106.2±30.5 nmol/l; $P<0,0001$) in all groups, but the greatest bias was in PD patients (37%; test of linearity: $P=0.660$). Free 25OHD levels obtained by calculation were overestimated compared to dm_f-25OHD concentrations in all three groups (all groups: dm_f-25OHD: 13.2±4.5 vs c_f-25OHD_MS: 26.4±11.4 and c_f-25OHD_CLIA: 20.0±8.2 pmol/l; $P<0.001$). The negative biases were significantly higher in case of c_f-25OHD_MS in all groups compared to c_f-25OHD_CLIA (preD: –53% vs –35,2%; PD: –67% vs –31%; HD: –45% vs –66%) but the test of linearity showed the best correlation between direct measured and c_f-25OHD_MS in PD ($P=0,999$). All 25OHD fractions were significantly lower ($P<0,010$) in PD compared to HD (t-25OHD_CLIA:73.4 vs 94.8 nmol/l; t-25OHD_MS:106 vs 122 nmol/l; dm-f-25OHD: 11.9 vs 14.9 pmol/l; c_f-25OHD_CLIA:24.2 vs 31.3 pmol/l) though the patients received the same dose of vitamin D3. Out of the five obtained 25OHD levels only dm_f-25OHD showed significant positive correlation ($r=0.39$) with Ca and only in preD patients.

Conclusions

Our results highlight that determination of cut-off values that reflect the appropriate vitamin D supply should be defined according to the diseases and the methods as well. Calculated free levels overestimate the 25OHD supply. The dm_f-25OHD promises to be the most reliable marker in preD. All five methods certify that patients on PD need much higher doses of cholecalciferol.

Cardiovascular status in chronic hypoparathyroidism – a single-center analysis in 133 patients compared to the general german population

Carmina Teresa Fuss[1], Karen Gronemeyer[1], Franca Hermes[1], Marcus Dörr[2], Ann-Cathrin Koschker[1], Peter Nordbeck[3], Anke Hannemann[4] & Stefanie Hahner[1]

[1]University Hospital Würzburg, Department of Medicine I, Division of Endocrinology and Diabetes, Germany; [2]German Centre for Cardiovascular Research (DZHK), Greifswald, Germany; [3]University Hospital Würzburg, Department of Medicine I, Division of Cardiology; [4]University Medicine Greifswald, Institute of Clinical Chemistry and Laboratory Medicine, Germany

Introduction

Even though it is well known that long-term complications, such as renal insufficiency and brain calcifications can occur in patients with hypoparathyroidism (HPT), the risk of cardiovascular diseases still remains unclear.

Objective

To perform a systematic assessment of cardiovascular function in a well-characterized cohort of patients with HPT compared to population-based controls.

Methods

133 patients with chronic HPT (disease duration >6 months) were included and systematically examined regarding cardiovascular comorbidities. All participants were assessed by blood pressure measurement, electrocardiogram (ECG), cardiac ultrasound and laboratory analyses. We performed 1:3 propensity score matching with individuals from the German population-based Study of Health in Pomerania (SHIP-TREND, $n=2682$) for age, sex, body-mass-index, smoking status, diabetes mellitus, dyslipidemia and TSH. Group differences were tested with Wilcoxon signed rank sum test (continuous variables), McNemar-test (dichotomous variables) or Friedman's Chi-Square test (categorical variables).

Results

Patients with HPT showed significantly higher diastolic blood pressure levels than controls (median 86 mmHg vs 78 mmHg, $P<0.01$), whereas systolic blood pressure was comparable (126 mmHg vs 127 mmHg, $P=0.19$). Intake of diuretics (24% vs 6%, $P<0.01$), calcium channel blockers (13% vs 6%, $P<0.01$), as well as angiotensin receptor antagonists (36% vs 27%, $P<0.01$) was significantly more frequent in patients with HPT. QTc intervals were markedly prolonged in HPT patients (438 ms vs 423 ms, $P<0.01$) in ECG. Interestingly, cardiac ultrasound revealed significantly lower interventricular septum thickness (0.8 cm vs 1.0 cm, $P<0.01$), as well as lower E/A ratio (1.0 vs 1.1, $P<0.01$) in HPT. Left ventricular ejection fraction was comparable between patients and controls ($P=0.05$). Regarding valvular dysfunctions HPT patients less frequently presented with insufficiencies of the mitral (20% vs 40%, $P<0.01$) and aortic (1% vs 7%, $P<0.01$) valve, whereas aortic stenosis was more prevalent in HPT compared to controls (7% vs 1%, $P<0.01$).

Conclusion

Here we report more frequent treatment with calcium channel blockers and angiotensin receptor agonists, as well as higher diastolic blood pressure in HPT patients compared to matched controls. Furthermore, QTc intervals remain prolonged in HPT despite established replacement therapy which should be taken into account when treating patients with compounds additionally prolonging QTc. Cardiac ultrasound revealed comparable left ventricular ejection fraction, thinner interventricular septum, as well as lower E/A ratio. Additionally, prevalence of aortic stenosis was higher in HPT, most likely due to valvular calcification. In general, HPT is not associated with striking cardiovascular disease burden in our cohort compared to matched controls.

Renal complications in chronic hypoparathyroidism – a german single-center analysis in 169 patients

Karen Gronemeyer, Carmina Teresa Fuss, Franca Hermes, Armin Plass, Ann-Cathrin Koschker & Stefanie Hahner
University Hospital Würzburg, Department of Medicine I, Division of Endocrinology and Diabetes, Germany

Introduction
Although long-term complications such as nephrocalcinosis and renal insufficiency are well-known in chronic hypoparathyroidism (HPT), standardized investigations of their prevalence and causes are still lacking.
Objective
To systematically investigate the prevalence of renal calcifications and dysfunction and their predictors in a well-characterized cohort of patients with HPT.
Methods
Cross-sectional assessment of comorbidities in 169 patients with chronic HPT (disease duration >6 months). Further examinations included renal ultrasound and laboratory analysis of serum- and urine samples. Logistic regression analysis with backward selection was performed to identify risk factors for the development of nephrocalcinosis.
Results
Out of 169 patients (55±13 yr, 76% female, disease duration 17±15 y), 88% had postoperative HPT. Prevalence of eGFR <60 ml/min/1.73m^2 was 21%, hypercalciuria 29%. Significant correlation between 24-h urine calcium excretion and spot urine calcium (r=0.61, P<0.0001) was observed. Renal ultrasound performed in 151 patients revealed renal calcifications in 9%, nephrocalcinosis in 7% and calculi in 3%. Significant differences between patients with renal calcifications (defined as nephrocalcinosis and nephrolithiasis) and without were found for 24-h urine calcium excretion (8.4±5.9 mmol/d vs 6.1±3.9 mmol/d, P<0.05), albumin-corrected serum calcium (2.1±0.2 mmol/l vs 1.99±0.2 mmol/l, P<0.02), serum phosphate (1.2±0.3 mmol/l vs 1.3±0.2 mmol/l, P<0.05) and serum magnesium (0.73±0.08 mmol/l vs 0.78±0.07 mmol/l, P<0.02). In contrast, no significant difference was found for prevalence of renal dysfunction and eGFR<60 ml/min/1.73 m^2, serum calcium-phosporus product, serum 25-hydroxyvitamin D, 24 h urine calcium-to-creatinine ratio, daily calcium intake or duration of disease (24±20 y vs 16±14 y). In logistic regression analysis only serum calcium could be identified as potential risk factor, in contrast to 24-h urine calcium, serum phosphate, disease duration, as well as dosage of calcium and active vitamin D.
Conclusion
Here we report a high prevalence of eGFR <60 ml/min/1,73 m^2 and hypercalciuria but a low prevalence of renal calcifications. This reduction of eGFR is independent of type of HPT, daily calcium intake and disease duration. In our study, only fasting serum calcium represented a risk factor for the development of nephrocalcinosis. Further studies are warranted to elucidate the pathomechanism behind nephrocalcinosis in patients with HPT.

AEP153

Risk of fractures in primary hyperparathyroidism: A systematic review and metaanalysis

Henriette Svensson[1], Lars Rolighed[2], Torben Harsløf[1] & Lars Rejnmark[3]
[1]Aarhus University Hospital, Internal Medicine and Endocrinology, AARHUS N, Denmark; [2]Aarhus University Hospital, Otorhinolaryngology, Head and Neck Surgery, AARHUS N, Denmark; [3]Aarhus University Hospital And Aarhus University, Internal Medicine and Endocrinology, AARHUS N, Denmark

Background and objective
An increased risk of fractures in Primary Hyperparathyroidism (PHPT) has been reported in a number of relatively small studies. Performing a systematic literature search we identified available studies and calculated common estimates by pooling results from the individual studies in a meta-analysis.
Methods
Searching EMBASE and PubMed using both free text word search and Mesh terms we identified published studies reporting the risk of fractures in PHPT compared to a control group or compared to the expected fracture rates from the general population. We calculated odds ratio (OR) with 95% confidence interval (CI).
Results
A total of 804 studies were identified of which 13 studies and a total number of 5457 PHPT patients and 13633 controls were included. Overall, risk of any fracture was increased compared to controls (OR 2.01; 95% CI, 1.61–2.50; I^2 46%, 5 studies). Analysis of fracture risk at specific sites showed an increased risk of fracture at the forearm (OR 2.36; 95% CI, 1.64–3.38; I^2 0%, 4 studies) and spine (OR 3.50; 95% CI, 1.66–7.89; I^2 87%, 10 studies). Risk estimate for hip fractures was also increased although non-significantly (OR 1.27; 95% CI, 0.97–1.66; I^2 0%, 3 studies). Risk of vertebral fractures (VFx) was also increased if analyses were restricted to only studies with a healthy control group (OR 5.76; 95% CI, 3.86–8.60; I^2 29%, 6 studies), studies including only patients with mild PHPT (OR 4.22; 95% CI, 2.20–8.12; I^2 57%, 4 studies), or studies including only postmenopausal women (OR 8.07; 95% CI, 4.79–13.59; I^2 0%, 3 studies).
Conclusions
Overall, PHPT is associated with an increased risk of fractures. Although number of studies are limited – it seems that the risk is increased across different skeletal sites including patients with mild PHPT. Of notice, relative risk of VFx seems to be extraordinarily high in postmenopausal women.

Psychiatric Comorbidities in Chronic Hypoparathyroidism – a German Single-Center Analysis in 107 Patients

Carmina Teresa Fuss[1], Franca Hermes[1], Ann-Cathrin Koschker[1], Stefan Unterecker[2], Jürgen Deckert[2] & Stefanie Hahner[1,1]
[1]University Hospital Würzburg, Department of Medicine I, Division of Endocrinology and Diabetes, Germany; [2]University Hospital Würzburg, Department of Psychiatry, Psychosomatics and Psychotherapy, Germany

Introduction
Reduction of quality of life in patients with chronic hypoparathyroidism (HPT) has been reported by several studies. Additionally, self-report data point to a higher prevalence of anxiety disorders in HPT compared to patients after thyroidectomy.
Objectives
To characterize psychiatric diseases in a systematically reviewed cohort of patients with chronic HPT.
Methods
We systematically assessed psychiatric comorbidities in a well-characterized cohort of patients with chronic HPT (n=107) using standardized questionnaires (depression: Patient Health Questionnaire (PHQ9), Beck Depression Inventory (BDI2), anxiety: State-Trait Anxiety Inventory (STAI)) and further performed a diagnostic interview using the Mini-DIPS (n=103).
Results
Out of the 103 interviewed patients 69% were female. 72% presented with postoperative HPT. The STAI provides a screening tool to assess both state (X1) and trait (X2) anxiety separately. Scores range from 20–80 with higher scores being positively correlated with higher levels of anxiety. In the STAI X1 21% of the patients scored between 40 and 50 and 25% of patients had a score above 50 (mean 40±13). Regarding trait anxiety (STAI X2) 24% of patients had values between 40 and 50, whereas 20% scored above 50 points (mean 39±12). In contrast, most patients with chronic HPT did not show markedly elevated scores in PHQ9 (81% with scores below 9), as well as BDI2 (72% with scores below 13). No significant correlations could be observed between serum calcium, parathyroid hormone or 25-OH-Vitamin D levels and scores of STAI X1, X2 and PHQ, whereas BDI2-scores significantly correlated with serum calcium levels (Pearson's r=0.386, P<0.001). In the diagnostic interviews, anxiety disorder was found in 36% of patients. The kinds of anxiety disorders according to the Mini-DIPS were: Agoraphobia (31%), specific phobia (21%), panic syndrome (16%), generalized anxiety disorder (16%), social phobia (10%), and posttraumatic stress disorder (9%).
Conclusion
The performance of systematic screening as well as diagnostic interview for psychiatric disorders in HPT showed a high prevalence of anxiety disorders despite established treatment of HPT. However, the pathophysiology still remains unclear.

Do near-infrared intra-operative findings by the use of indocyanine green correlate with post-thyroidectomy parathyroid function? - the ICGPREDICT study

Thedosios Papavramidis[1], Panagiotis Anagnostis[2], Angeliki Chorti[1], Ioannis Pliakos[1], Stavros Panidis[1], Dimitris Koutsoumparis[3] & Antonios Michalopoulos[1]

[1]Aristotle University of Thessaloniki, 1st Propedeutic Department of Surgery, AHEPA University Hospital, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Thessaloniki, Greece; [3]Department of Minimal Invasive Endocrine Surgery, Interbalkan Medical Center, Thessaloniki, Greece

Background/Aims
Post-operative hypoparathyroidism still remains a significant complication after thyroidectomy. Intraoperative imaging modalities, such as near infrared fluorescence by the use of indocyanine green (ICG), may assist to identify and preserve the parathyroid glands (PGs). The purpose of this study was to test the association between intra-operative ICG staining scoring system and 24-h post-operative parathyroid hormone (PTH) levels, as well as its capability of intra-operative PG identification.
Methods
This was a prospective study, recruiting patients scheduled for total thyroidectomy by the same surgical team, from December 2018 to April 2019. Intraoperative angiography was performed, after infusion of ICG solution (5 mg). Two minutes later, images were acquired by the near-infrared system.
Results
Sixty patients fulfilled eligibility criteria. The percentage of temporary post-operative hypoPT (defined as PTH <14 pg/ml) was 11.66%. No association between intra-operative ICG staining score (expressed as the number of PGs scoring <2 per patient) and 24-h post-operative PTH ($r=0.011$, $P=0.933$) or serum calcium concentrations ($r=0.127$, $P=0.335$). There was also no correlation between the location of PGs scoring ≤2 and post-operative PTH ($P=0.257$) or serum calcium levels ($P=0.950$). Moreover, with regard to secondary endpoint, ICG correctly identified parathyroid glands in 98.3% of cases. ICG score was not affected by age, gender, duration of operation or thyroid gland pathology. No allergic reactions attributed to ICG administration were observed.
Conclusions
Intra-operative ICG staining scoring system did not predict 24-h post-operative PTH and serum calcium levels. This modality does not seem to assist in intra-operative parathyroid identification during a total thyroidectomy.

DXA scanning in primary hyperparathyroidism: Should forearm DXA be performed routinely?

Hamide Piskinpasa[1], Sema Ciftci Dogansen[1], Duygu Metin[2], Nuri Alper Sahbaz[3], Husnu Aydın[3], Ayse Esen[1], Evin Bozkur[1], Seda Turgut[1], Naim Pamuk[1], Ilkay Cakir[1] & Meral Mert[1]

[1]Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Department of Endocrinology and Metabolism; [2]Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Department of Radiology; [3]Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Department of General Surgery

Introduction
Primary hyperparathyroidism (PHPT) is a disease associated with a decrease in bone mineral density (BMD), especially in cortical bones such as distal radius. Therefore, the BMD measurement of forearm is valuable in the detection of cortical bone loss by PHPT. However, forearm measurement is not routinely recommended for the diagnosis of osteoporosis in PHPT. In this study, we aimed to evaluate the importance and priority of forearm BMD measurement in PHPT.
Material and Methods
286 (249 female/37 male) patients with PHPT and eGFR>60 ml/min, whose BMD was measured at lumbar spine, femur and forearm by dual-energy X-ray absorptiometry (DXA) wererecruited to the study. The patients were divided into two groups as group 1 ($n=139$) with forearm osteoporosis and group 2 ($n=147$) without forearm osteoporosis. Age, sex, creatinine, eGFR, alkaline phosphatase (ALP), corrected calcium, phosphorus, magnesium, parathormone, 25 OH vitamin D, 24-hour urine calcium levels were recorded and compared between the groups. Additionally, patients with osteoporosis at any site, forearm osteoporosis, and the other two regions were normal but only with forearm osteoporosis were evaluated as three groups. The effect of the isolated forearm osteoporosis on surgical criteria was evaluated in patients without other surgical indications.
Results
The mean age at diagnosis of PHPT was 55.9±12.1 years. Our patients in group 1 were older than in group 2 ($P=0.001$). 151 (53%) patients have osteoporosis at any site, 139 (49%) have forearm osteoporosis, and only 76 (27%) patients have osteoporosis at forearm while the other two sites were normal. ALP, corrected calcium and parathormone levels in group 1 were significantly higher than patients in group 2 ($P=0.005$, $P=0.005$, $P<0.001$, respectively). The groups were similar in terms of other variables. Only the isolated forearm osteoporosis was determined as the surgical indication in 22 patients who did not meet any other surgical criteria. In the light of these findings, additional operation indication was established by evaluating the forearm BMD in 7% ($n=22/286$) patients of the study group.
Conclusion
Although forearm BMD measurement is not routinely recommended in patients with PHPT, only spine and femur evaluation may not be adequate since cortical bone loss is more expected in this disease course. In our study, the frequency of diagnosis of osteoporosis and operation indication increased with BMD measurements, including forearm site. Therefore we suggest forearm BMD measurement to be performed routinely in PHPT.

Burden of illness in patients with chronic hypoparathyroidism not adequately controlled with conventional therapy: A survey of physicians in belgium and the Netherlands

Neveen AT Hamdy[1], Brigitte Decallonne[2], Pieter Evenepoel[3], Damien Gruson[4], Claudio Marelli[5] & Liza van Vlokhoven-Verhaegh[6]

[1]Leiden University Medical Center, Department of Medicine, Division of Endocrinology, and Centre for Bone Quality, Leiden, Netherlands; [2]University Hospitals Leuven and KU Leuven, Department of Endocrinoogy, Leuven, Belgium; [3]University Hospitals Leuven and KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium; [4]Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Department of Medical Biochemistry, Brussels, Belgium; [5]Shire International GmbH, a Takeda company, Global Medical Affairs, Zurich, Switzerland; [6]Shire Netherlands BV, a Takeda company, Department of Medical Affairs, Amsterdam, Netherlands

Patients with hypoparathyroidism are at risk of short-term and long-term complications and comorbidities, such as renal, cardiovascular, metabolic or cognitive manifestations. The purpose of this study was to determine the burden of illness (BOI) in patients with not adequately controlled chronic hypoparathyroidism receiving conventional therapy (oral calcium supplements and active vitamin D) in Belgium and the Netherlands. Data werecollected from a cross-sectional, 2-part online survey for which all endocrinologists from the two countries, and nephrologists from Belgium, were invited by telephone to participate. Part 1 included collecting data on general management of patients with hypoparathyroidism. In part 2, physicians were requested to provide data of ≤2 unique cases of patients with chronic hypoparathyroidism not adequately controlled on conventional therapy. Data collected included aetiology of hypoparathyroidism, clinical manifestations, comorbidities, results of laboratory and other investigations used for diagnosis and screening for complications, therapy received, and physician's perception of impaired quality of life (QoL) rated on a visual analogue scale. A total of 93 physicians - 29 nephrologists and 36 endocrinologists from Belgium and 28 endocrinologists from the Netherlands - provided data for 97 patients treated with conventional therapy (60 cases were from Belgium and 37 from the Netherlands). The average age of patients was 48.5±16.8 years, the majority (66%) were women, and neck surgery (67%) was the most common cause of hypoparathyroidism. At the time of the survey, 96% of patients were receiving calcium supplementation and 97% active vitamin D: 51% alfacalcidol and 46% calcitriol. Mean duration of hypoparathyroidism was 4.5±4.9 years (median, 2.2; range, 0.17–20.00). The majority of patients had neuromuscular (85%) and/or neurological (67%) symptoms,

71% had abnormal biochemical parameters, and 10% were overweight. Most frequently reported comorbidities included hypertension (25%), renal comorbidity (20%), diabetes mellitus (12%), and dyslipidaemia (11%). Amongtreating physicians, 71% subjectively perceived a deterioration in QoL (degree of change, –1.4) in their patients since disease onset. Among patients who were hospitalised in the 12 months before the survey because of inability to control chronic hypoparathyroidism(17%), the median number of hospitalisations was 2.0 with a median duration of hospitalisation of 5.0 days. Patients with chronic hypoparathyroidism not adequately controlled on conventional therapy experienced a substantial BOI, mainly because of persistence of symptoms and presence of multiplecomorbidities. These findings highlight the need for general awareness of the BOI associated with inability to adequately control hypoparathyroidism.

Burden of illness in patients with chronic hypoparathyroidism not adequately controlled with conventional therapy: European subanalysis of a global patient survey

Heide Siggelkow[1], John Germak[2], Claudio Marelli[3], Kristina Chen[4], Helen Dahl-Hansen[5], Elizabeth Glenister[6], Nawal Bent-Ennakhil[7], Davneet Judge[7], Katie Mycock[7] & Bart L Clarke[8]
[1]University of Göttingen, Clinic of Gastroenterology and Endocrinology, Göttingen, Germany; [2]Shire Human Genetic Therapies, Inc., a Takeda company, US Medical Affairs, Massachusetts, United States; [3]Shire International GmbH, a Takeda company, Global Medical Affairs, Glattpark-Opfikon (Zurich), Switzerland; [4]Shire Human Genetic Therapies, Inc., a Takeda company, Global Outcomes Research Epidemiology Data Sciences Institute, Research and Development, Massachusetts, United States; [5]hypoPARA NORGE, Vettre, Norway; [6]Parathyroid UK, Yorkshire, United Kingdom; [7]Adelphi Real-World, Bollington, United Kingdom; [8]Mayo Clinic Rochester, Division of Endocrinology, Diabetes, Metabolism, & Nutrition, Minnesota, United States

Although chronic hypoparathyroidism is known to negatively affect health-related quality of life (HRQoL), burden of illness is less well defined in patients whose disease is not adequately controlled on conventional therapy. We report burden of illness for the European subset of a patient survey in 13 countries globally. 398 adults with chronic hypoparathyroidism not adequately controlled on conventional therapy (recruited by treating physician or patient association) completed the survey online anonymously between October 2017 and March 2018. Health status/HRQoL were evaluated using the 36-item Short Form Health Survey version 2.0 (SF-36 v2.0)/EuroQoL 5 Dimensions Five-Level (EQ-5D-5L). Employment status/productivity were evaluated using the Work Productivity and Activity Impairment (WPAI) questionnaire. Symptom severity was self-rated as well as assessed using a hypoparathyroidism symptom diary (7-day recall period). This subanalysis includes 203 patients (Denmark; $n=11$; France, $n=13$; Germany, $n=31$; Italy, $n=35$; Norway, $n=16$; Spain, $n=35$; Sweden, $n=17$; UK, $n=45$). Self-rated symptom severity was mild (25%), moderate (61%), or severe (14%); no one self-reported as symptom-free. Mean SF-36 summary scores (0–100), EQ-5D-5L utility scores (0–1), and EQ-5D-5L visual analogue scale (VAS) scores (0–100) according to self-rated symptom severity are summarised in the Table; health status and HRQoL decreased with increasing self-rated symptom severity. According to the hypoparathyroidism symptom diary tool, moderate/severe/very severe symptoms were reported by 41%/24%/8% of patients for physical fatigue, 43%/12%/2% for muscle cramps, and 48%/13%/1% for heaviness in the limbs; moderate/severe/very severe cognitive symptoms (ie, slow/confused thinking) and mood symptoms of anxiety and sadness/depression were reported by 30%/13%/4%, 31%/14%/1%, and 13%/10%/3% of patients, respectively. Impact on personal relationships, work, sleep, and ability to exercise were reported by 68%, 77%, 83%, and 86% of patients. Mean (SD) percent overall impairment at work score was 51.5% (25.67%) and increased with self-rated symptom severity (Table). These results demonstrate a burden of illness on HRQoL, symptoms, and functioning at work in European patients with not adequately controlled chronic hypoparathyroidism. Degree of burden reflected self-rated symptom severity. These results are consistent with those from the global population.

Clinical features and management of primary hyperparathyroidism discovered by parathyroid incidentaloma

Vlatka Pandzic Jaksic, Ana Majic, Jelena Andric, Maja Cigrovski Berkovic & Srecko Marusic
Dubrava University Hospital, Endocrinology, Zagreb, Croatia

Primary hyperparathyroidism (PHPT) is nowadays usually diagnosed as an asymptomatic disease but it might be related with advanced end-organ damage. Parathyroid incidentaloma (PI) is the term describing enlarged parathyroid nodules that are unexpectedly discovered on surgery or by imaging performed for nonparathyroid disorders. The recognition of PI might uncover a clinically significant PHPT with the potential for surgical cure. We retrospectively reviewed patients' records with a newly diagnosed PHPT in the last 5 years in our hospital. Among 74 retrieved patients we found 14 (18.9%) diagnosed with PHPT following the discovery of PI. Nonparametric statistical tests were used for the comparison between this PI PHPT group and the rest of our cohort. Overall thirteen PHPT patients with PIs were discovered on neck ultrasound. The median volume of these PIs was 403.2 mm^3 (117–1570 mm^3). One PI was found during the surgery in a patient referred for thyroidectomy at our institution. The previous presence of PHPT in this case was suggested by development of transitory hypocalcemia due to hungry bone syndrome after the surgery. The rest of PHPT patients were mostly identified by incidental laboratory findings of hypercalcemia (36.5%) or during the osteoporosis work-up (32.4%). The comparison of the PI PHPT group with other PHPT patients found a statistically similar level of PTH, calciuria and eGFR. The highest serum calcium level measured before treatment was lower in PI PHPT patients ($P=0.037$), but rates of normocalcemic PHPT were comparable in both groups. The PI PHPT group had more often positive scintigraphy ($P=0.027$). Differences in the occurrence of osteoporosis and urolithiasis did not reach statistical significance. The PI PHPT group was less likely to meet the international consensus criteria for surgery ($P<0.01$), but the frequency of surgical management did not differ between groups. The surgical cure for PHPT was achieved in all PI PHPT patients and pathohistology of all operated PIs confirmed adenomas. PIs are still an uncommon but relevant way of revealing PHPT. In our institution the radiological suspicion for enlarged parathyroid glands is further investigated only after the positive biochemical screening for parathyroid hyperfunction. This certainly introduces a bias in our clinical data because silent PIs are disregarded, similar to bias which exists in other circumstances of discovering asymptomatic PHPT. We emphasize that all relevant laboratory parameters are checked not to miss the normocalcemic PHPT. An appropriate follow up for suspicious silent nodules should be suggested.

Background
Epigenetic changes appear to be implicated in the development of parathyroid tumors. In this study we investigated the microRNA expression profile in the serum and tissue samples from patients with primary hyperparathyroidism (PHP) due to sporadic parathyroid adenomas (SPAs).
Methods
Our study cohort consisted of 40 patients with PHP due to SPAs that underwent parathyroidectomy (PTX).
MicroRNA extraction was performed from a) 40 FFPE samples of sPA, b) 10 FFPE samples of normal parathyroid tissue (NPT) from patients that underwent total thyroidectomy for benign multinodular goiter, c) serum samples from the 40 cohort patients with PHP at two time points (before and 2 months post PTX), d) serum samples from 10 healthy individuals that served as controls, also at two time points (t1=baseline and t2=2 months after). Nine microRNAs (miRs) were selected based on their interaction with genes related to the pathogenesis of sporadic parathyroid adenomas (namely, miR-17-5p, miR-24, miR-29b, miR-31, miR-135b-5p, miR-186, miR-195, miR-330-3p, and miR-483-3p)
Results
The microRNA expression profile of SPAs at tissue level differed significantly compared to NPT. In particular, the relative expression of 4 miRs, namely miR-17-5p, miR-31, miR-135 and miR-186 was significantly decreased in SPAs compared to NPT (fold change 0.17, fold change 0.034, fold change 0.01 and fold change 0.09, respectively, all P values<0.001). On the other hand, the relative expression of 2 of the tested miRs was significantly increased in SPAs (miR-24, fold change 12.4, $P<0.001$; miR-29b, fold change 18.5, $P=0.011$). Similar to the microRNA profile in the tissue the relative expression of miR-135 was also significantly decreased in the serum of patients with PHP compared to controls (fold change 00.7, $P<0.001$), while no significant differences were found in the serum of PHP patients before and after parathyroidectomy.
Conclusion
MicroRNAs that regulate genes linked to the pathogenesis of SPAs, such as menin 1 (miR-24 and miR-29b), cyclin D1 (miR-17-5p) and CaSR (miR-31 and miR-135) are significanlty deregulated in SPA samples compared to NPT, suggesting a role for epigenetic changes in the development f SPAs.

The use of PET/CT with 11C-methionine for the diagnosis of a patient with renal hyperparathyroidism

Maciej Kolodziej[1], Marek Saracyn[1], Dorota Brodowska-Kania[1], Stanislaw Niemczyk[2] & Grzegorz Kaminski[1]

[1]Military Institute of Medicine, Department of Endocrinology and Isotope Therapy, Warsaw, Poland; [2]Military Institute of Medicine, Department of Internal Medicine, Nephrology and Dialysis, Warsaw, Poland

Background
Renal hyperparathyroidism (rHPT) may affect up to 30% of dialysispatients with end-stage renal disease (ESRD). rHPT is associated with an increased risk of cardiovascular events (CE) and bone diseases such as pain or renal osteodystrophy. Total or subtotal parathyroidectomy may be a chance to reduce the severity of the symptoms and decrease the risk of CE and death. Pre-operative scintigraphy and ultrasound diagnostics in rHPT may be insufficient at even up to 60% of the patients. PET/CT examinationusing the new tracers may be helpfulto localize parathyroid glands in such cases.
Clinical Case
We present the case of a 46-year-old woman with ESRD who underwent a kidney transplant in 2002, in whom ESRD relapsed in the mechanism of chronic antibody mediated graft rejection. Patient was on dialysis since 2014. Time of dialysis was 12 hours per week and the dialysis was adequate. Due to persistent high level of PTH, the occurrence of pathological fracture of the tibia, and presence of the brown tumors of the pelvic bones, the patient received cinacalcet (90 mg/d). During cinacalcet treatment minimal concentration of PTH was 1223 pg/ml and patient reported bone and joints pain, fatigue and pruritus. US of the neck and parathyroid scintigraphy with ^{99m}Tc-MIBI revealed no pathological features. In February 2019 PET/CT with ^{11}C-methionine (^{11}C-MET) was performed, showing high tracer accumulation in the left lower parathyroid gland and in the numerous brown tumors of the ribs. In June 2019 patient underwent subtotal parathyroidectomy and parathyroid adenoma in histopathology examination was reported. On the first day after the surgery PTH serum level drop to 236 pg/ml, but then started to rise again till 823 pg/ml and hypocalcemia occurred. Hungry bone syndrome (HBS) was suspected. Patient received calcium oral supplementation and 6-week post-operative follow-up ^{11}C-MET PET/CT examination revealed no foci of pathological marker accumulation in the parathyroid glands what allowed to exclude rHPT recurrence, giving confirmation of the HBS. Significant reduction in the size and number of brown tumors in the bones was observed additionally. Eight weeks after surgery, the PTH concentration was 281 pg/ml with normocalcemia and slightly elevated phosphate concentration, and the patient reported a significant improvement in well-being.
Conclusion
1. ^{11}C-MET PET/CT examination was a useful tool for setting best surgical treatment and postoperative follow up of a patient with rHPT
2. The HBS after successful surgical treatment of rHPT can be a potent parathyroid stimulating factor and mimic rHPT recurrence.

Oncogenic osteomalacia – from diagnosis to recovery in 7 days

Ewa Zalewska[1], Monika Płoszaj-Neć[1], Anna Orzechowska-Pawiłojć[2], Maciej Śledziński[3], Wojciech Biernat[4], Sonia Kaniuka-Jakubowska[1] & Krzysztof Sworczak[1]

[1]Medical University of Gdańsk, Endocrinology and Internal Medicine, Gdańsk, Poland; [2]Copernicus, Gdansk, Poland, Outpatient Endocrinology Unit, Gdańsk, Poland; [3]Medical University of Gdańsk, General, Endocrine and Transplant Surgery, Gdańsk, Poland; [4]Medical University of Gdańsk, Pathology, Gdańsk, Poland

Introduction
Oncogenic Osteomalacia (OO) is a rare paraneoplastic syndrome, resulting from fibroblast growth factor 23 overproduction. The rarity of the disease and nonspecific symptoms often cause delay in diagnosis by months, or even years. There are two cornerstones in the diagnostic process. The first concerns clinical identification, where awareness of this uncommon ailment combined with hypophosphatemia and clinical signs may be sufficient to identify OO. The second involves imaging procedures to anatomic localisation of the tumor, which can be complicated as the lesions are usually small, and may occur at various sites.
Aim
We present a case of OO where the whole diagnostic process and treatment took one week, in a patient misdiagnosed during the previous three years. We would like to emphasise that such a fast diagnosis is possible without sophisticated imaging tools. Awareness of this rare disease, coupled with conscientious physical examination can be enough for diagnosis, resulting in efficient treatment.
Materials and methods
Day 1. Physical examination and clinical features:
Patient's main complaints included severe bone pain, general fatigue, muscle weakness, as she required walking assistance. Upon physical examination she exhibited a waddling gait, had pain on palpation of the bones and joints; a flat, cohesive lesion in the subcutaneous tissue in the region of the right scapula was notable.
Day 2. Laboratory diagnosis:
Mild hypophosphatemia and increased activity of alkaline phosphatase were documented (FGF-23 and 1,25(OH)2D3 in process).
Day 3. Imaging diagnosis and surgery:
Soft tissue US of the right scapula region revealed subcutaneous tissue 21x6x27mm, with heterogeneous decreased echogenicity, smooth contours, and increased vascularity.

Surgical removal of the lesion in the right scapula region was performed.
Day 4. Observation:
Neither clinical nor biochemical improvement was noticed.
Day 5. Discharge from the hospital:
MR of the whole body was planned as part of out-patient diagnosis continuation.
Day 7. Histopathological result:
Phosphaturic mesenchymal tumour with small fusiform cells, which focally undergo chondroblastic-like differentiation.
Gradually, phosphate increase and alkaline phosphatase decrease were observed; subsequently the patient began to walk without aid, the waddling gait ceased, general fatigue and pain ended.
Conclusion
By presenting this case we would like to remind clinicians about OO as a rare cause of hypophosphatemia. Prompt diagnosis and treatment can prevent a patient from becoming disabled. Based on our experience, we assume that removing easily accessible lesions before performing sophisticated imaging studies for its localization should be recommended.

Case report: Refractory hypercalcemia due to a pancreatic neuroendocrine tumor misdiagnosed as adenocarcinoma

Mirella Hage[1], Ségolène Hescot[2], Amani Asnacios[3], Sophia Bakopoulou[1], Laure Cazabat[1,4], Pascal Houillier[5], Emile Jean Francois[6] & Marie-Laure Raffin-Sanson[1,4]
[1]Centre Hospitalier Universitaire Ambroise Paré, Service d'Endocrinologie de Diabétologie et de Nutrition, Boulogne Billancourt, France; [2]Hopital René Huguenin – Institut Curie, Service de Médecine Nucléaire, Saint Cloud, France; [3]Hopital René Huguenin – Institut Curie, Service d'Oncologie Digestive, Saint Cloud, France; [4]EA4340, Université de Versailles Saint-Quentin-en-Yvelines, UFR des sciences de la santé Simone Veil, Montigny-le-Bretonneux, France, France; [5]Hôpital Européen Georges Pompidou, Département de Physiologie, Paris, France; [6]Centre Hospitalier Universitaire Ambroise Paré, Service d'Anatomo-Pathologie, Boulogne Billancourt, France

Background
Hypercalcemia is a well-described paraneoplastic manifestation encountered in a variety of malignancies. However, it is rarely the initial feature of a neuroendocrine tumor.
Herein we report a caseof metastatic pancreatic neuroendocrine tumor (NET)presenting with a refractory hypercalcemia and initially misdiagnosed as an adenocarcinoma of the pancreas.
Objective
The aim of this case report is to illustratesome of thecomplexities pertaining to the diagnosis of a pancreatic NET and the challenges in the management of an associated hypercalcemia caused by parathyroid hormone related protein (PTHrP) hypersecretion.
Clinical case and results
A 67-year-old woman presented with asthenia and weight loss and was found to have severe hypercalcemia. Laboratory evaluation demonstrated high calcium levels associated with low serum parathyroid hormone (PTH) levels. Despite an initial low PTHrP level, nephrogenous cAMP was elevated consistent with PTHrP related hypercalcemia. Work up revealed a pancreatic tumor associated with liver and splenic metastases but no bone metastases. Biopsy of the liver metastasis concluded to an adenocarcinoma and appropriate chemotherapy was initiated. Despite the stability of the pancreatic tumor, the associated hypercalcemia was refractory to various supportive therapy and chemotherapeutic regimens including corticosteroids, bisphosphonates, calcitonin and denosumab. Because of the indolent progression of the tumor and in view of the persistent hypercalcemia, slides of the pancreatic tumor were reviewed, and complementary immunohistochemistry was performed. The results contradicted the initial diagnosis and were compatible with a well differentiated pancreatic NET. Additional staining was positive for PTHrP confirming the secretion of this hormone by the tumor. Chemoembolization of the liver metastases was performed and treatment with somatostatin analogues (SSA) was introduced allowing a good but transient control of the hypercalcemia. This phenomenon of tachyphylaxis, occurring after a few months of therapy with SSAs, has been described in some patients with NETs. Due to the rise of calcium levels, the patient was referred for vectorized internal radiation therapy.
Conclusion
We report a case of pancreatic NET with hypercalcemia as a presenting feature initially misdiagnosed as adenocarcinoma. Hypercalcemia was refractory to all symptomatic therapies and was transiently controlled with SSA. This case highlights the challenges in diagnosing and controlling hypercalcemia due to PTHrP hypersecretion in patients with NETs. Furthermore, it underlines the importance of reconsidering the initial diagnosis in front of an unusual course of the disease.

Increasing incidence of parathyroid carcinoma according to russian registry of the primary hyperparathyroidism

Julia Krupinova[1], Julia Veretennikova[2], Irina Maganeva[1], Anna Eremkina[1], Alina Aynetdinova[1], Svetlana Mirnaya[1] & Natalia Mokrysheva[1]
[1]Endocrinology research center, pathology of the parathyroid gland, Moscow, Russian Federation; [2]Endocrinology research center, Moscow, Russian Federation

Introduction
Parathyroid carcinoma (PC) occurs in 0.005% of all malignant tumors and in less than 1% in primary hyperparathyroidism (PHPT), but recent reports indicate increasing incidence of PC.
Aim
To estimate the prevalence of PC in Russia and to identify its distinctive characteristics relevant as preoperative markers.
Material and methods: We conducted a retrospective study based on the on-line Russian Registry of 3061 patients with PHPT. The analysis included patients with PC ($n=74$), atypical adenomas (AA, $n=23$) and adenomas (A, $n=1540$). The demographic, clinical and laboratory features were compared between groups. Statistical analysis was performed with package Statistica 13 (StatSoft, USA) and SPSS (IBM, USA) and Bonferroni correction was used for multiple comparisons.
Results
PC was identified in 2,4% and AA in 0,8%. Most of the cases were reported in last 9 years of study ($n=52$). Age of PHPT manifestation in the PC group was 53 year [43; 62], in AA 61.5 [43; 72] and A 56 [48; 62] ($P=0.0092$). The ratio of men to women in PC was 1:4, AA 1:3.6, A 1:10 ($P=0,001$). Levels of intact parathyroid hormone (iPTH, 15–65 pg/ml) were significantly higher in PC compared to AA and A (1024 [356; 1772] vs572 [3544; 1569] vs 174 [115; 305.5] respectively, $P<0$, 001). Surprisingly the total calcium (Ca, 2.15–2.55 mmol/l) and ionized calcium levels (Ca+, 1.03–1.29 mmol/l) were higher in AA compared to PC and A: Ca 3.24 [3.01; 3.51] vs 3,18 [2.82; 3.6] vs 2.78 [2.63; 2.97], Ca+ 1.69 [1.59; 1.91] vs 1.55 [1.39; 1.69] vs 1.39 [1.29; 1.51], $P<0.001$). The most frequently localization of the PC was a right lower PG (32.4%). PC patients had more often bone fractures than AA and A (30% vs 22% vs 18% vs $P<0.001$). However, AA patients compared to PC and A had a higher frequency of osteoporosis (65% vs 62% vs 45%, $P<0.001$), nephrolithiasis (52% vs 43% vs 0.4%) and GFR reduction (48% vs 28% vs 9%, $P=0.002$). The prognostic significance for PC was excess of PTH more than 538 (sensitivity 80%, specificity 84%, AUC=0.866) and Ca more than 2.97 (sensitivity 67%, specificity 75%, AUC=0.713) according to ROC analysis. Recurrences of PC were reported in 16 cases (22%).
Conclusions
Our results demonstrate the increased incidence of PC in Russia. Malignant parathyroid tumors are associated with more severe clinical manifestations PHPT compared to A.

AEP165

Primary hyperparathyroidism in multiple endocrine neoplasia type 1 (MEN-1) according to the online russian registry

Anna Eremkina, Svetlana Mirnaya, Irina Maganeva, Alina Ajnetdinova & Natalia Mokrysheva
Department of parathyroid pathology, Moscow, Russian Federation

Objective
Primary hyperparathyroidism (PHPT) is one of the most frequently diagnosed endocrine disorders. The Russian Registry of PHPT is an on-line web-based database with the aim to estimate the prevalence and main features of disease. PHPT in Multiple Endocrine Neoplasia type 1 (MEN-1) is associated with polyglandular and early involvement of parathyroid glands.

Material and methods
The database from The Russian Registry of PHPT was used for retrospective analysis. We compared MEN-1 and sporadic PHPT cohorts regarding clinical and biochemical parameters, differences in preoperative features, operative strategies and outcome. Statistical analysis was performed with the STATISTICA 7 (DELL, USA), the significance levels in the range from critical to 0.05 were considered.
Results
Of a total 3010 patients from Registry, 128 patients meet the clinical and genetic criteria of MEN-1 and MEN-2A syndromes. Summary genetic testing was performed in 89 patients, mutations in MEN1 gene were verified in 60 patients (2%, 6/3010), inRET gene - in 2 (0.07%), in CDC73 gene - in 6 (0,2%). As expected, the PHPT manifestation in MEN-1 group was observed earlier 39,5 [26; 51] compared to sporadic disease 59 [53; 67] years ($P<0,001$), average duration of disease before diagnosis was 13.2 [9;13] vs 6 [3; 11] years respectively ($P<0.001$). The presence of 2 or more MEN-1-associated neoplasia's was determined in 42%. The most frequent components were pituitary adenoma (71.9%), pancreatic tumors (40.4%) and adrenal adenoma (38.6%), while isolated PHPT was diagnosed in 3% (2/60). We did not find any differences in the PTH, phosphorus and creatinine levels, but suddenly more severe hypercalcemia was observed in MEN-1 group (2.85 ± 0.26 mmol/l vs 2.74 ± 0.28, $P=0.011$), possibly due to delayed diagnosis. 68% of MEN-1 patients had symptomatic PHPT more often with bone manifestation (38.6%). Multiple parathyroid involvement on the time of primary diagnosis was found in 15 patients with MEN-1. Primary surgical treatment was performed in 42/57 patients with MEN-1, but only 55% of them underwent initially subtotal or total parathyroidectomy. We found a greater frequency of relapses compared to sporadic form ($P<0.0001$), reoperations for recurrent PHPT occurred in 35/57.
Conclusion
PHPT is the most common and earliest endocrinopathy in patients with MEN-1. According to the Russian registry, the average age of MEN-1 associated PHPT diagnosis is shifted by 10 years, and the symptomatic course with severe hypercalcemia is dominant. Thus indicates a late diagnosis and insufficient awareness on the PHPT diagnosis in the context of MEN-1.

Neural network algorithm to determine the optimal range of PTH level for patients with end-stage chronic kidney disease to maintain bone metabolism

Natalia Karlovich[1], Olga Spiridonova[2] & Tatiana Mokhort[2]
[1]Republican Center of Endocrinology, Minsk, Belarus; [2]Belorussian State Medical University, Minsk, Belarus

Secondary hyperparathyroidism is highly prevalent in patients with end-stage chronic kidney disease (CKD). Optimal range of PTH level for this cohort of patients is still controversial. The aim of the study was to use a neural network algorithm to determine the optimal point value and confidence interval for the average PTH value for patients with end-stage chronic kidney disease to maintain bone metabolism.
The study included 190 patients with end-stage CKD receiving renal replacement therapy. Blood levels of parathyroid hormone, total calcium (Ca), phosphorus (P), levels of markers of bone metabolism: alkaline phosphatase (ALP), osteocalcin (OK), C-terminal telopeptides of type I collagen (CTx) were evaluated in patients. Bone mineral density (BMD) was determined by double x-ray absorptiometry. For clustering patients into groups, a neural network algorithm (auto-encoder) was used, consisting of an encoder and a decoder. Four clusters were obtained, one of which determined optimal indicators of BMD status, markers of bone metabolism, and also the best patient survival. The optimal value of PTH in terms of supporting bone metabolism and better survival rates of dialysis patients is in the range of 114–490 pg/ml. The point estimate of the average PTH value is 234 pg/ml, the variance is 188 pg/ml. Both a decrease and an increase in PTH can lead to a critical imbalance in bone metabolism and an adverse outcome, including loss of BMD and shortened life expectancy. In addition to the level of PTH, an adaptive increase in osteocalcin and CTx, and an age-associated decrease in BMD are important in determining the prognosis of bone tissue and patient survival. These factors must be taken into account when diagnosing secondary hyperparathyroidism and determining the tactics of its treatment and observation.

The trabecular bone score predicts vertebral fragility fractures and decrease in volumetric bone mineral density in postmenopausal women

Keunyoung Kim, Injoo Kim, Kyoungjune Pak, Eunheui Kim & Yun Kyung Jeon
Pusan National University Hospital, Korea, Republic of South

Background
Osteoporosis frequently occurs in elderly people and is commonly associated with fall and fractures which leads the increase of morbidity and mortality. Therefore, precise prediction of osteoporotic fracture is important in clinical setting. The objective of this study was to investigate the association between baseline compression fracture and trabecular bone score (TBS) and was to assess the ability of TBS to predict vertebral fragility fracture and changes of volumetric BMD (vBMD) in postmenopausal women.
Materials and Methods
We enrolled 270 postmenopausal women aged over 46 who visited our hospital for a health check-up between Sep, 2013 and Sep 2017. TBS was calculated from dual energy X-ray absorptiometry and vBMD was generated from central quantitative computed tomography (cQCT). Both baseline and follow-up X-ray images were reviewed for the evaluation of thoracolumbar vertebral compression fracture which were defined according to the Genant criteria.
Result
At baseline, 76 (28.1 %) compression fractures were identified in 270 participants and the additional or progressive fractures occurred in 21 participants (7.8 %) for the median 19.5 month of the follow-up period. The median TBS was significantly higher in participants without vertebral fracture (median: 1.326, interquartile range [IQR]: 1.264 – 1.372) compared with that of those with vertebral fracture (median: 1.246, IQR: 0.169 – 1.308, $P<0.001$). During the follow-up, the deteriorated TBS value (≤ 1.31) were significantly associated with osteoporotic change of BMD assessed by cQCT using Kaplan-Meier analysis (Hazard ratio [HR]; 2.423, confidence interval [CI]: 1.708–3.438, $P<0.001$). Lower TBS (Hazard ratio [HR]; 2.505, confidence interval [CI]: 1.062– 5.911, $P=0.036$) was also revealed as a significant risk factor for the future vertebral fragility fracture.
Conclusion
The patients who had the deteriorated status of TBS showed more frequent predisposing compression fracture. In addition, it was suggested that TBS has the potential to predict future vertebral fractures in patients.

Inactivation of diabetoporosity-associated miRNAs in human mesenchymal stem cells

Ines Föß[1], Christoph Haudum[1,2], Olivia Trummer[1], Harald Dobnig[1], Astrid Fahrleitner-Pammer[1], Moustapha Kassem[3], Barbara Obermayer-Pietsch[1] & Jeroen van de Peppel[4]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinoligy and Diabetology, Graz, Austria; [2]CBmed – Center for Biomarker Research in Medicine, Graz, Austria; [3]University Hospital of Odense, Department of Endocrinology and Metabolism, Laboratory for Molecular Endocrinology (KMEB), Odense, Denmark; [4]ErasmusMC, Department of Internal Medicine, Bone and Calcium Metabolism, Rotterdam, Netherlands

Introduction
Osteoporosis is a disease characterized by the loss of bone density and deficits in bone microarchitecture. "Diabetoporosity" is a new term for osteoporosis in diabetes mellitus type 2 (T2DM) patients, where classical tools for the assessment of bone properties like dual x-ray absorptiometry or bone turnover markers are lacking prognostic accuracy for the determination of bone quality and fracture risk.
MicroRNAs (miRNAs) are getting into the focus of research not only for their importance in the development of osteogenic lineage cells, but also as biomarkers for bone related diseases. Sequencing of serum samples of elderly T2DM patients with prospective fractures identified differentially expressed miRNA compared to control serum samples. Here we have removed some of the identified microRNAs by CRISPR/Cas and examine the function of these microRNAs upon osteoblast differentiation of immortalized human mesenchymal stem cells (hMSC-TERTs).
Materials and methods
Serum samples of patients with T2DM who developed fractures within two years of follow-up were compared to serum of T2DM patients without

fractures. miRNA sequencing was performed in serum of 10 non-fracture and 6 fracture patients. Immortalized human bone marrow derived mesenchymal stem cells expressing Cas9 (MSC-TERT ^{Cas9}) were used to delete selected miRNAs. Guide RNAs were designed, cloned into the plasmid phU6 and transfected in MSC-TERT^{cas9} cells. Individual cells lacking miRNAs were clonally expanded.
Results
miRNA sequencing analysis of serum samples revealed 16 miRNAs (FDR < 0.05) that correlated with prospective fractures in elderly diabetic patients. miRNAs with average relative counts between 100 and 10000 were chosen for further analysis. 8 of the selected 9 were expressed in MSC-TERTs and considered for functional analyses and deletion. Successful creation of three microRNA deletion strains, namely miR140-KO, miR25/93/106b KO and miR-363/19b-KO, could be confirmed by PCR and sanger-sequencing.
Discussion
The establishment of cells lacking our target miRNAs is the first step for the examination of their importance during osteoblast differentiation of hMSCs. Further experiments will reveal the function of these miRNAs in the context of the differentiation potential of the created cell lines.

Fracture risk in patients with acute poliomyelitis§ going through late adulthood

Rutie Mamlok Sherf[1], Dror Cantrell[2], Keren Or[3], Efrat Marcus[3], Carlos Benbassat[3], Sofia Ish Shalom[4], Alex Shapira[5] & Ronit Koren[6]
[1]Shamir medical center, Internal medicine A, Tzrifin, Israel; [2]Shamir medical center, Internal Medicine C, Endocrine institute, Tzrifin, Israel; [3]Shamir medical center, Endocrine Institute, Tzrifin, Israel; [4]Lin Endocrine Research Center, Haifa, Israel; [5]Shamir medical center, Polio Clinic Department of Orthopedics, Tzrifin, Israel; [6]Shamir medical center, Internal Medicine A, Endocrine institue, Tzrifin, Israel

Objective
While osteoporotic fractures are reported in up to 40% of post-poliomyelitis adults, clinical guidelines regarding bone mineral density (BMD) testing and best timing for initiating treatment in this population are scarce. We assessed the characteristics of post-poliomyelitis patients, focusing on fracture and osteoporosis as the primary outcomes.
Methods
We conducted a cross-sectional retrospective data analysis from medical records of 204 post-poliomyelitis patients regarding their clinical characteristics, acute poliomyelitis disease and bone metabolism status.
Results
Our cohort included 53% females, mean age was 65 years (yrs.) at study entry and 1.7 yrs. at diagnosis of acute poliomyelitis. The lower limb was involved in 97.5% of patients, and the BMD in the affected limb was lower than the unaffected one (T score (Tsc) –1.64 vs –1.19, respectively; $P=0.06$). This difference was more evident in males than females (Tsc-1.85 vs –1.02, respectively; $P=0.07$), and in the fracture vs the non-fracture group (T-1.9 vs –1.25, respectively; $P=0.09$). Recurrent falls were documented in 39.2% of patients. Osteoporosis was diagnosed in 20.6% of patients and was more frequent in females ($P=0.003$) and patients with fractures ($P=0.002$). At least one fracture occurred in 52.2% of patients, and more than one in 40.3%, with a mean age of 57 yrs. at the first fracture. Most patients fractured their affected limb (73.1%).
Conclusion
Despite the high fracture risk, osteoporosis in late-adulthood post-poliomyelitis patients appears●to be underdiagnosed and undertreated. A comprehensive bone health assessment and early initiation of treatment, including anabolic agents, should be considered in this population.

AEP170

Long term effect on trabecular bone score but not BMD is preserved in GH-deficient adults only when sufficient vitamin D levels are maintained

Martin Kužma, Juraj Smaha, Daša Stojkovičová, Peter Jackuliak, Zdenko Killinger & Juraj Payer
Comenius University Faculty of Medicine, Comenius University Bratislava, 5th Department of Internal medicine

Introduction
Adult growth hormone deficiency (AGHD) is associated with lower bone mass and likely with increased risk of fragility fractures. GH replacement leads to increase in bone mineral density (BMD) and trabecular bone score (TBS). The effect of adequate levels of vitamin D during GH replacement is important to provide effect on TBS.
Aim
To assess long–term effectof recombinant GH replacement on BMD and TBS with regards to vitamin D levels during period of 8 years.
Patients & Methods
Prospective follow-up of AGHD patients at one single center. Allpatients with adult GHD followed at single center. All participants were replaced with daily injection ofrecombinant human (rh) GH in IGF-1 normalizing regimen according to Endocrine Society Guidelines. From total number of 63 patients, 31 patients ended 8 years follow-up period with BMD measurement [at lumbar spine (L-spine) and total hip (TH)] and TBS performed at year 8. Deficiencies of other pituitary axes were treated if necessary. All patients were supplemented with 800 IU /day of cholecalciferol and 1000–1200 mg/day of calcium as recommended by International Osteoporosis Foundation. The study cohort was divided based on 25(OH)D levels into two groups with the cutoff defined as the median at each time-point of follow up.
Results
Study group consisted of 16 males and 15 females (14 with adult onset (AO) /17 with childhood onset (CO); mean age at diagnosis 25.03 yrs) AGHD patients. Average dose of rhGH was 0.4 mg/day and after six month of treatment IGF1 levels stayed in reference range (±2 SDs for age). After 8 years of GH replacement, increase of 8.7% and 8.2% (both $P<0.05$) for LS and TH BMD but not TBS was observed. TBS decrease of 2,2% in patients with 25(OH)D levels below median (24.1 mg/l) and slight increase +0,8% ($P=0.05$) in group with 25(OH)D levels above median was observed. BMD in both groups increased similarly.
Conclusion
Long-term GH replacement in adult GHD led to increase in BMD, but not TBS. However, after adjustment for vitamin D levels, patients with vitamin D below median showed significant decrease in TBS but no difference in BMD at both sites. In addition slight TBS increase was observed in patients with vitamin D above median. This study has shown that adequate vitamin D levels in GH-replaced have beneficial effect on bone quality, as measured by TBS.

AEP171

Does real-life time spent within the therapeutic range affect degree of improvement in bone mineral density in men receiving testosterone therapy for hypogonadism?

Stephen Osei-Osafo[1], Dushyant Sharma[2] & Deepa Beeharry[2]
[1]University of Liverpool, School of Medicine, Liverpool, United Kingdom; [2]The Royal Liverpool University Hospital, Endocrinology, Liverpool, United Kingdom

Background
Hypogonadism in males is associated with a reduction in bone mineral density (BMD). It is known that the reversal of this is achievable through adequate hormone replacement; however, the degree to which this is dependent on the proportion of time patients spend within the recommended therapeutic range (>15 nmol/l) in real-ife has not yet been established.
Aim
To evaluate the degree to which the proportion of time that a hypogonadal patient's testosterone levels are maintained within the target range affects the magnitude of their BMD improvement.
Methods
This retrospective, longitudinal observational, study included 115 patients aged 25–87 (±15.1) treated ata regional tertiary centre between 2006 and 2019. BMD measurements were performed using Bone Densitometry (DXA).The target range of testosterone >15 nmol/l was used as per nationalguidelines. Proportion of time spent within target range (TST) was expressed as a percentage of the treatment duration and grouped into 4 ranges; <25, 25–50, 50–75, >75%. Between-groups differences were analysed using the Kruskal-Wallis test.

Results
Mean percentage of treatment duration spent within target range was 44.2±27.2 with 43 (42%) of patients exhibiting an increase in *t*-score values for both Femoral Neck (FN) and L2-L4 measurements during their treatment period. The median change in bone mineral density for FN BMD was 0.2 and for L2-L4 it was 0.4. Median improvement in FN BMD for <25%=–0.05; 25–49%=0; 50–75%=0.1; >75%=0.2 showing a linear increase across groups, however differences lacked statistical significance ($P=0.64$). For L2-L4 BMD measurements, the median improvement values were <25%=–0.4; 25–49%=0.5; 50–75%=0.3; >75%=0.3. These scores between groups were also not statistically significant ($P=0.92$).
Conclusion
The results of this real-life longitudinal, retrospective observational study did not show a significant association between time spent in recommended target range of testosterone and an increase in BMD. Whilst a relationship is evident for the FN scores, the absence of a statistically significant difference potentially implies the influence of multiple confounders in practice. Cofounders, such as low sample numbers, should be explored and other modalities of bone protection should also be considered for BMD improvement in these patients.

Primary hyperparathyroidism diagnosis with 18-F-fluorodioline Pet/CT (FCPCT) in a routine endocrinology praxis: Need of the new guidelines

Luc Schroeder[1], Svetlana Smorodova[2], Stefan Meilinger[1], Sven Münks[1], Maria Yaneva[3], Michel Doat[4], Florence Jonard[4], Christian Picard[4] & Maria Tikhomirova[3]
[1]Centre Hospitalier du Nord, ORL, Ettelbruck, Luxembourg; [2]Privolzhsky Research Medical University, student, Nizhny Novgorod, Russian Federation; [3]Centre Hospitalier du Nord, endocrinology, Ettelbruck, Luxembourg; [4]Centre Hospitalier du Nord, nuclear medicine, Ettelbruck, Luxembourg

Background
Primary hyperparathyroidism (pHPT) is a common disease in a routine endocrinology praxis, but the biggest challenge is a localization of the adenoma and the further correct management of the disease. First FCPCT was reported in 2014 as the additional method of diagnosis of pHPT and in some centers has been already used as a first line diagnostic modality. However, FCPCT is still lacking in the European or International guidelines for the diagnosis of pHPT.
Methods
Patients with biochemical and clinical pHPT between January 2017 and august 2019 were included in the study. Baselines characteristic, clinical data, scan results and type of treatment were recorded.
Results
A total 39 patients (32 F) were included in the study, mean age at diagnosis 57.6 ± 11.7 (31–81), 21 patients were asymptomatic 54%. Osteoporosis was diagnosed at 45% of 11 patients by DEXA. One patient had previously diagnosed multiply fractures. 17 patients 45 % had positive Sestamibi scintigraphy and/or echography and/or Dual-isotope 99mTc-MIBI/123 Iwere successfully operated. 22 patients with inconclusive echography, Sestamibi scintigraphy and Dual-isotope 99mTc-MIBI/123 I received FCPT, 18 (81%) were positive and 16 later operated with positive outcome (100% specificity). Two patients refused the operation. Four negative: two patient did not receive any treatment, two remaining are clinically controlled under Mimpara.
Conclusion
In our little retrospective study we showed high detection rate per patient of FCH PT scan (81%) with operation after positive scan and Mimpara treatment by negative patient. We conclude that FCHPT should be included in the diagnosis and the treatment choice of pHPT. Moreover, the current guidelines should be added FCPT as diagnostic possibility by inconclusive other modalities.

Patients with hypoparathyroidism may have sypmptoms consistent with physical, emotional and cognitive dysfunctions which may cause impaired quality of life (QOL). We included 266 patients (20–79 years; 231 women/35 men) who were being treated for hypoparathyroidism. They were taking conventional therapies for hypoparathyroidism; calcium, active vitamin D and magnesium when needed. We applied Beck Depression Scale, Anxiety Scale and SF-36 QOL scale to the patients. The etiologic factors were thyroid surgery ($n=198$), autoimmune ($n=41$) and surgery for thyroid cancer ($n=27$). The etiologic cause of hypoprathyroidism did not show any correlation with questionnare scores. As thyroid cancer might be an additional stress factor we evaluated it as an independent factor but it had no impact on parameters. Duration of hypoparathyroidism had no effect on parameters ($P=0.662$). Serum calcium, and magnesium had a negative correlation with anxiety and depression scores (anxiety; $P=0/r=–0.336$, $P=0.001/r=–0.210$, depression; $P=0/r=–0.258$, $P=0.001/r=–0.210$, respectively). SF-36 parameters did not have any correlation with serum calcium and magnesium. Serum phosphorus and vitamin D levels did not have any correlation with depression, anxiety or SF-36 parameters. Frequency of admission to the emergency unit with hypocalcemic crisis did have a positive correlation with anxiety and depression scores ($P=0.001/r=0.202$; $P=0.004/ r=0.171$, respectively) and a negative correlation with general health status ($P=0.001/r=–207$). Compliance to the therapy (skipping calcium, magnesium or active vitamin D preparations) affected patients' scores. Anxiety and depression scores were higher among noncompliant patients (anxiety; 25.6±14.9 vs 18.6±12.7, $P=0$, depression; 18.4±12.7 vs 13.7±11.6, $P=0.001$, respectively). As expected SF-36 scores were lower among noncompliant patients (vitality; 39.1±21.6 vs 49.3±22.1, $P=0$, mental health; 54.1±18.7 vs 59.3±20.2, $P=0.027$, social function; 59.1±25.6 vs 67.5±25.4, $P=0.004$, bodily pain; 49.8±28 vs 56.9±27.7, $P=0.031$, general health; 43.2±20.9 vs 49.4±19.6, $P=0.012$). Conventional therapy does not meet the needs of patients with hypoparathyroidism. It has been shown thatnewly discovered parathyroid hormone therapy may improve QOL of patients. Further studies are needed.

Colour doppler ultrasound: Preoperative location of parathyroid adenomas in primary hyperparathyroidism

Sara Amaral[1], Teresa Rego[1], Miguel Vasques[1], Olga Gutu[1], Ana Cláudia Martins[1], Ana Palha[1], Teresa Sabino[1], Luísa Cortez[1], António Afonso[1], Fernando Fonseca[1], Nuno Carrilho[2], José Mário Coutinho[3], Paula Tavares[3] & Ana Agapito[1]
[1]Centro Hospitalar Universitário Lisboa Central, Endocrinology, Diabetes and Metabolism, Lisboa, Portugal; [2]Centro Hospitalar Universitário Lisboa

Central, Radiology, Lisboa, Portugal; [3]Centro Hospitalar Universitário Lisboa Central, Endocrine Surgery, Lisboa, Portugal

Introduction
Parathyroid adenoma is the most frequent cause of primary hyperparathyroidism (PHPT). In recent years minimally invasive surgical techniques have challenged the traditional bilateral neck exploration. There are different imaging techniques for preoperative location of parathyroid adenomas. In this study the authors review the role of Doppler ultrasound focusing on its safety, availability and affordability.
Aim
To evaluate the role of Doppler ultrasound on preoperative location of parathyroid adenomas in patients with PHPT.
Methods
Retrospective study based on data from patients with PHPT that underwent parathyroidectomy between 2013 and 2019. Statistical analysis with Excel and IBM SPSS Statistics 20.
Results
Parathyroidectomy was performed in 135 patients (78,5% females) with PHPT between January 2013 and January 2019. The median age at diagnosis was 66 years old (22–89 years old). The median serum calcium and PTH were 11 mg/dl and 188 pg/ml respectively. The median follow up time was 2 years. Most patients performed 2 exams in order to detect the enlarged parathyroid(s). Cervical ultrasound without Doppler was the most performed exam (77%) and detected the lesion in 26% of the patients. The second most performed exam was sestamibi parathyroid scintigraphy (63.7%) and lesion was found in 62.8%. Doppler ultrasound was the third most requested exam (57.8%) and detected parathyroid adenoma in 88.5%. Parathyroid 4D computed tomography was performed in 37.8% of the patients and was diagnostic in 76.5%. In the group of patients that performed Doppler ultrasound ($n=78$), the median adenoma size was 18 mm (5–34 mm). Preoperative location of the parathyroid adenomas based on Doppler ultrasound was compared to the surgical and histological findings. 90.9% were accurately located on the superior poles and 63% on the inferior. 82.4% were correctly located on the right side of the neck and 88.2% on the left. Diagnosis accuracy was not affected by the presence of thyroid nodules ($P=0.728$). In 9 patients Doppler ultrasound did not find lesion and bilateral neck exploration was needed in 4 of them.
Conclusions
In this study Doppler ultrasound showed high diagnostic accuracy even in patients with nodular thyroid disease. Furthermore, its safety, affordability and availability should favor its use as a first line exam on preoperative location of parathyroid adenomas in PHPT.

Normocalcemic primary hyperparathyroidism in patients with elevated parathormone (PTH) in a regional health area. A laboratory based approach.

Borja Santana[1], Luis Alberto Vázquez[2], Bernardo Alio Lavín Gómez[3], Carlos Pesquera[3], María Piedra[4] & María Teresa García-Unzueta[3]
[1]Universidad de Cantabria - Facultad de Medicina, Santander, Spain; [2]Marqués de Valdecilla University Hospital, Endocrinology and Nutrition, Santander, Spain; [3]Marqués de Valdecilla University Hospital, Biochemistry, Santander, Spain; [4]Marqués de Valdecilla University Hospital, Endocrinology, Santander, Spain

Normocalcemic primary hyperparathyroidism (nPHPT) is still a poorly understood entity, characterized by increased circulating parathormone (PTH) and normal total and ionic calcium, excluding secondary causes.
Aim
To characterize the cases of nPHPT detected for a whole year from laboratory records of PTH in a tertiary referral centre, with the purpose of assessing a preliminary estimation and describing their main features.
Material and methods
Retrospective study of a database from the Biochemistry laboratory at "Marqués de Valdecilla" University Hospital (Santander, Spain) including the results of all PTH requests throughout 2018 coming from Primary Care and Hospital departments in Cantabrian health areas I-II (population 420,000).
Results
From 13,201 PTH determinations performed during 2018 in our lab, 4,746 showed an increased iPTH level (>65 pg/ml). Amongst them, 386 samples from 350 patients met the following criteria: normal corrected total calcium (8.1-10.4 mg/dl), normal renal function (eGFR >60 ml/min) and vitamin D sufficiency (>20 g/ml). Then, their electronic records were reviewed and secondary causes of hyperparathyroidism were excluded according to the 4th International Workshop guidelines. Eventually, 31 patients met the diagnostic criteria for nPHPT based on 2 normal values of corrected total calcium, but only 10 had a concomitant determination of ionic calcium, considered as mandatory to confirm nPHPT by the 4th International Workshop. At last, 6 of these 10 patients showed a normal ionic calcium level (1.18-1.30 mmol/l). Regarding the main clinical features of these 6 patients, 2 subjects had been diagnosed of osteopenia/osteoporosis, another one had had previous bone fractures and 3 of them urological findings (only one with confirmed renal lithiasis). In 2 of these 6 patients parathyroid scintigraphy was requested; in one of them a parathyroid adenoma was suggested.
Conclusions
Very few cases of nHPTP were found amongst PTH determinations performed upon suspicion in our health area, suggesting a low prevalence of this entity. Ionic calcium determination is still underused to confirm its diagnosis.

NGS sequencing proves as a powerful method to perform differential diagnosis in patients with inactivating PTH/PTHrP signaling disorders (iPPSD)

francesca marta elli[1], maria antonia maffini[2], Jole Costanza[3], Laura Fontana[4], Maura Arosio[1,2] & Giovanna Mantovani[1,2]
[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Endocrinology, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Endocrinology, Milan, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Facility di Bioinformatica, Milan, Italy; [4]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, UO coordinamento laboratori di ricerca, Direzione Scientifica, Italy

The impairment of the parathyroid hormone (PTH) signaling pathway determines a group of related and highly heterogeneous disorders associated or not with the Albright's hereditary osteodystrophy (AHO) phenotype, classified as inactivating PTH/PTHrP signaling disorder (iPPSD). iPPSD features are rather difficult to be identified in some casesbecause manifestations are somewhat variable and some AHO characteristics are not specific to a specific disorder. Actually, besides *GNAS*defects causing pseudohypoparathyroidism (PHP), additional genes of the PTH pathway have been associated to other disorders, that should be considered for establishing a correct diagnosis in patients with no *GNAS* alterations. The aim of the present work was to discovermolecular alterations in iPPSD patients withno GNAS defects by NGS target sequencing and, afterreview of available clinical data, to identify manifestations useful for an early classification of patients. We investigated by NGS target sequencingof iPPSD associated genes (*GNAS*, *PRKAR1A*, *PDE4D*, *PDE3A*, *PTH1R*, *PTHLH*, *HDAC4*, *HOXD13* and *TRPS1*) 58 patients referred to our laboratory with a clinical diagnosis of iPPSD, in whom previous genetic testingfailed to identify any *GNAS* molecular defect. Deleterious variants were filtered and prioritized according toACMG/AMP pathogenicity scoresby the eVai v0.6 tooland potentially causative rare variants were confirmed by Sanger sequencing. By the bioinformatic analysis we discovered 5 novel highly damaging genetic variants, 3 in the *PTHLH* gene and 2 in the *TRPS1* gene, and, after re-evaluation of available clinical data, patients were re-diagnosed as suffering from brachydactyly with short stature (BDE2) and tricho-rhino-phalangeal syndrome (TRPS), respectively. All mutated patients presented both frequent and rare features commonly observed in PHP, BDE2 and TRPS. In particular, TRPS patients were mistakenly identified as PHP because they presented ultrarare signs, PTH resistance in one case and intellectual disability, obesity and subclinical hypothyroidism in the other one, that were already reported in the literature for single cases. In conclusion, our work allowed, by using a NGS gene panel for iPPSD-associated genes, to establish a correct genetic diagnosis, follow-up and genetic counseling in 5 patients misdiagnosed as PHP and to discover novel mutations in *PTHLH* and *TRPS1* genes. No genotype-phenotype correlations were observed and, unfortunately, we did not identify distinctive phenotypic features that could be exclusively associated to a specific syndrome different from PHP and could help in an early classification of patients.

Incidence of hypercalcemia and its causes in spain in a fifteen years period (2001–2015)

Guillermo Ropero-Luis[1,2], Jaime Sanz-Cánovas[3], Almudena López-Sampalo[3], Ricardo Gómez-Huelgas[2,3] & Alberto Ruiz-Cantero[1,2]
[1]Hospital de la Serranía de Ronda, Internal Medicine Department, Ronda, Spain; [2]Universidad de Málaga, Málaga, Spain; [3]Hospital Regional Universitario de Málaga, Internal Medicine Department, Málaga, Spain

Background and aims
Hypercalcemia is a rare ionic disorder and is often overlooked. The aim of this study was to describe the annual incidence of hypercalcemia in the adult population in Spain during a period of fifteen years, using the International Classification of Diseases, 9th Revision Clinical Modification (ICD-9). The diseases and procedures associated with this condition were also assessed.
Materials and methods
Data from the Minimum Basic Data Set of discharged patients older than 14 years old from the Spanish National Health System (Ministry of Health Affairs) between 2001 and 2015 were analyzed to describe the profile of patients with diagnostic codification of hypercalcemia (ICD-9: 275.42).
Results
41,075 unique patients were identified. The annual incidence is shown in Table 1. 22.3 % of the patients had no identifiable cause of hypercalcemia. 91 % of patients with known causes of hypercalcemia had one reported, 8 % had two, and 1 % had three or more. The most common identifiable causes were: neoplasia 87.8 %, hyperparathyroidism 15.3 %, thyrotoxicosis 2.1 %, parenteral nutrition 1.5 %, sarcoidosis 0.9 %, A-D vitamin poisoning 0.4 %, adrenal insufficiency 0.4 %, thiazide poisoning 0.3 %. Among the neoplastic causes, the most common were: lung cancer 19.8 %, multiple myeloma 14.7 %, breast cancer 6.9 %, gastrointestinal duct cancer 5.1 %, lymphoma 3.9 %, kidney cancer 3.7 %, bladder cancer 3.6 %, hepatobiliopancreatic cancer 3.6 %, prostate cancer 2.8 %. Among cancer patients, 50.6 % had metastatic spread: bone 53.5 %, liver 39 %, lung 27.4 %, serosa 15.1 %, central nervous system 9 %, other 46.7 %. Others conditions associated with hypercalcemia were: acute kidney failure 18.4 %, delirium 6.7 %, lithiasis 1.6 %, phosphorus disorders 0.9 %, magnesium disorders 0.9 %. In-hospital mortality was 26.9 %.

Year	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
×10,000 admissions	7	6.9	7	6.6	7.7	7.2	7	7.3	8.1	8.5	9.3	10.1	10.3	10.7	11.7
×100,000 inhabitants	5.9	5.8	6	5.7	6.5	6.1	6.1	6.3	6.9	7.3	7.9	8.5	8.7	9.2	10.1

Conclusions
The annual incidence of hypercalcemia among the admitted patients in the Spanish National Health System had a notable and constant increase between 2007 and 2015. The actual incidence is probably higher as this condition is underreported. The most common etiologies are neoplastic disorders, followed by hyperparathyroidism.

Management of severe hypercalcemia secondary to primary hyperparathyroidism: The efficiency of saline hydration, furosemide, and bisphosphonates.

Seifeddine Mellassi, Ibtissem Oueslati, Rym Belaid, Nadia Khessairi, Meriem Yazidi, Wafa Grira, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Severe hypercalcemia is a life-threatening condition which should be managed urgently. Its pharmacological treatment consists of intravenous saline hydration, loop diuretic and intravenous administration of bisphosphonates. However, data evaluating these treatments are very limited.
The aim of this study was to assess the efficiency of saline hydration, furosemide, and bisphosphonates in the management of severe hypercalcemia secondary to a primary hyperparathyroidism (PHPT).
Methods
We conducted a retrospective analysis in 50 patients with severe hypercalcemia (≥120 mg/l) secondary to a PHPT. Clinical, biological and treatment data were collected regularly. The efficiency of each therapeutic agent was evaluated according to the variation of calcium levelcalculated as: □ calcium = Baseline calcium level –minimal calcium level after the administration of each agent.
Results
The study population included 41 women and 9 men with a mean age of 58.9 ± 12.9 years. At baseline, they had a mean serum calcium level of 133.2 ± 14.5 mg/l [extremes: 120–180] and a mean parathormone level of 682.4 ± 600.9 ng/l. Acute renal failure was diagnosed in 15 patients (30%). Thirty six patients received normal saline hydration alone with a mean duration of 5.9 ± 1.1 days with an infusion of 3-4 liters/24 h. The calcium level decreased to 120.1 ± 13.1 mg/l ($P < 10^{-3}$) with a □ calcium of 13.1 ± 14.5 mg/l. Normalization of calcium level occurred in only one patient (3%). Furosemide was prescribed in 36 patients with a mean dose of 60 mg/day [extremes: 20–120]. It resulted in a calcium decline of 12.1 ± 11.3 mg/l (before: 132.5 ± 15.1 mg/l, after: 120.4 ± 9.3 mg/l, $P < 10^{-3}$). Normalization of calcium level occurred in only one patient (3%). Twenty one patients received intravenous bisphosphonates. The mean maximal reduction in serum calcium level was 24.2 ± 8.9 mg/l [extremes: 6–44] reached 5.2 ± 3.2 days after the administration of bisphosphonates (before: 132.1 ± 8.8 mg/l, after: 107.85 ± 9.75 mg/l, $P < 10^{-3}$). Normalization of calcium level occurred in 8 patients (38%).
Serum creatinine level significantly decreased in all patients ($P < 10^{-3}$).
Conclusion
Our results demonstrated the absence of a significant additional effect of furosemide on calcium level in patient with severe hypercalcemia as compared to the effect of saline hydration alone. However, bisphosphonates were more potent. Thus, appropriate normal saline hydration and immediate intravenous bisphosphonates infusion should be considered in the pharmacological management of severe hypercalcemia in patients with PHPT.

Modeling to estimate the prevalence of chronic hypoparathyroidism in the absence of population-based studies

Olulade Ayodele[1] & Nicole Zhang[2]
[1]Shire Human Genetic Therapies, Inc., a Takeda company, Global Outcomes Research and Epidemiology, Data Sciences Institute, Massachusetts, United States; [2]Decision Resources Group, Epidemiology, Massachusetts, United States

Hypoparathyroidism is a rare endocrine disorder characterized by insufficient parathyroid hormone levels in the blood, low serum calcium and elevated serum phosphate. Studies evaluating the prevalence of chronic hypoparathyroidism (cHypoPT) are limited, and it is challenging to compare prevalence estimates owing tothe rarity of the disease and the difficulty of differentiating transient from permanent or cHypoPTin secondary data analyses. PublishedcHypoPTprevalence is between 9–37/100,000 from population-based studies in five countries. The objective of the study was to develop and evaluate two models that can estimate the prevalence of cHypoPTfor countries where population-based data are unavailable. We developed a thyroid surgery-derived model using data on thyroid cancer prevalence and probability of cHypoPT following thyroid surgery for countries where the relevant inputs were available from publishedliterature. We estimated the lifetime prevalence of thyroid cancer using historical cancer incidence data from cancer incidence registries and assumed most thyroid cancer cases undergo surgical resection. Using country-specific ratios of cancer-related versus non-cancer-related thyroid surgeries, we calculated lifetime prevalence of thyroid surgery. The proportions of thyroid surgeries leading to cHypoPT were applied to estimate the prevalence of surgical-related cHypoPT. Lastly, we summed up estimates of the prevalence of non-surgical and surgical-related cHypoPT. We considered gross domestic product (GDP) as a proxy for important risk factors for cHypoPT: healthcare quality and access, surgeon technique/skill, follow-up care and complication rates. We identified published population-based estimates for cHypoPTprevalence for five countries; the corresponding country-specific GDP data were collected from the World Bank. We evaluated the correlation between GDP and chronic hypoparathyroidism prevalence using R^2 and exponential coefficient values. We used this correlation to model country-specific prevalence and compared estimates from both models with published prevalence estimates. cHypoPTprevalence strongly correlated with GDP ($R^2 = 0.86$; $P < 0.001$). Prevalence estimates obtained from both modelswere comparable. For the United States, the thyroid surgery-derivedprevalence was 22.8 per 100,000, comparable to the prevalence of ~23.2 that was calculated from published population-based estimates and 20.6 for the GDP-based model. In the absence of population-based studies, thyroid surgery-derived and GDP-based

models can be used to estimate the prevalence of cHypoPT. These two methods yielded comparable US prevalence estimates and accurately predicted US prevalence as reported in the literature. Further validation is required, but preliminary data suggest that these models can be used to predict prevalence in countries without population-based studies.

PARADIGHM is an actively recruiting, prospective, observational registry (NCT01922440/EUPAS16927). The primary objective is to evaluate the safety and effectiveness of recombinant human parathyroid hormone, rhPTH(1-84), treatment in patients with chronic hypoparathyroidism under routine clinical care. The secondary objective is tocharacterize the clinical course of chronic hypoparathyroidism under conditions of routine clinical practice. At enrollment, registry inclusion criteria are patients having a hypoparathyroidism diagnosis >6 months and receiving conventional therapy (CT; eg, calcium supplements and active vitamin D), rhPTH(1-84) plus CT, or rhPTH(1-84). We present baseline characteristics of patients as of a June 30 2019 data cut. Baseline was defined as the value entered at the time of enrollment (Visit 1). Baseline symptom data exclude patients who initiated rhPTH(1-84) prior to enrollment ($n=68$) and are herein presented as two groups: those subsequently prescribed with rhPTH(1-84) after enrollment or those treated with CT. All data are summarized descriptively. Patient data from 64 centers in Europe and North America were analyzed. In the analysis population ($n=737$), 587 patients (79.6%) were female, 620 (84.1%) were white, and the mean (SD) age was 49.1 (16.45) years. The mean (SD) BMI was 19.3 (5.73) kg/m^{2}and 30.0 (7.72) kg/m^{2}in patients aged <18 ($n=25$) and ≥18 ($n=587$) years, respectively. The primary cause of hypoparathyroidism was thyroid surgery ($n=547$ [74.2%]; of these, 281 [60.0%] underwent surgery for thyroid cancer). Endocrinologists were the prescribing specialists for most patients ($n=660$ [89.6%]). Vitamin D and analogs were prescribed for 90.1% of patients (calcitriol, 74.2%, native vitamin D, 47.4%, alfacalcidol, 7.9%), calcium for 81.0% (calcium carbonate, 57.9%, calcium citrate, 27.1%), and thyroid hormones for 71.2% (levothyroxine, 73.4%; liothyronine, 5.8%). Symptoms reported at enrollment for the rhPTH (1-84) ($n=66$) and the CT groups ($n=603$), respectively, included fatigue (53.0%, 39.3%), paresthesia (48.5%, 29.2%), muscle twitching (48.5%, 21.1%), muscle cramping (40.9%, 33.0%), headaches (33.3%, 17.6%), anxiety (28.8%, 20.1%), muscle pain (28.8%, 19.2%), tetany (28.8%, 12.1%), and brain fog (27.3%, 16.3%). The baseline data for the overall population appear to be representative of patients with chronic hypoparathyroidism. Baseline data suggest that at enrollment patients prescribed rhPTH(1-84) after enrollment appear to have an increased burden of disease than patients receiving CT based on symptoms. PARADIGHM will be a valuable resource of real-world longitudinal data for patients with chronic hypoparathyroidism.

Clinical presentations of patients receiving PTH-therapy among the referral population with hypoparathyroidism.

Sofia Gronskaia[1], Tatiana Grebennikova[1], Ekaterina Pigarova[1], Luidmila Rozhinskaya[1], Galina Melnichenko[1], Maria Luiza Brandi[2] & Zhanna Belaya[1]
[1]Endocrinology Research Center, Moscow, Russian Federation; [2]University of Florence

This study aims to evaluate patients who require PTH-treatment among the referral population with hypoparathyroidism.
Methods
The information was collected from the registry database of chronic hypoparathyroidism, which was initiated by the National Medical Research Centre for Endocrinology (NMRCE).
Results
Among 194 cases of hypoparathyroidism referred to our clinic over 2 years (2017–2019), eight patients required PTH replacement treatment and six patients (3,09%) received treatment with teriparatide due to complete resistance to conventional therapy with alfacalcidol and calcium supplementation. The mean age of these 6 patients at evaluation was 52 ± 12 s.d. years (minimum 31 and maximum 71 years); the female-to-male ratio was 5:1. In 4 cases the subjects had postsurgical hypoparathyroidism (in 3 cases after thyroid surgery ($n=2$ thyroid cancer and $n=1$ thyroid goiter) and in 1 case after parathyroid surgery). Additionally 1 patient had autoimmune polyglandular syndrome and one male patient suffered from idiopathic hypoparathyroidism. In 3 cases of postsurgical hypoparathyroidism patients suffered from osteoporosis diagnosed before thyroid or parathyroid surgery. The longest duration of teriparatide treatment was 5 years at a dose of 20–60 mg/day with periodically used pump therapy. Treatment with teriparatide was cancelled after achieving remission of candidiasis which led to improved gastrointestinal absorption. Other patients continued treatment with teriparatide. The next longest treatment duration was three years at a dose of 40 mg in a patient with gastric resection due to ulceration; 2.5 years at a dose of 20 mg in a patient with colon pseudomelanosis; one subject received 40 mg over 12 months and two patients only started treatment with teriparatide at a dose of 20 mg over 6 and 7 months. The daily dose of calcium and active vitamin D were reduced and calcium levels within the reference range were achieved in all subjects. Serum phosphate was decreased in 3 subjects out of 6. Bone mineral density (BMD) was increased in all patients with osteoporosis.
Conclusion
Severe malabsorption is the most frequent requirement of PTH treatment. Teriparatide was effective in all subjects to alleviate symptoms and to achieve calcium levels within the reference range.

Background
Treatment of vitamin D deficiency orinappropriate vitamin D supplementation may cause side effects associated with hypercalcemia. We observed a tendency to use very high single dose cholecalciferol for treatment of vitamin D deficiency.
Aim
The primary aim of this study was to examine the clinical characteristics of patientswith very high serum 25OHD levels of vitamin D toxicity in Turkey.
Materials and methods
An invitation was sent to all tertiary endocrinology clinics of Turkey to complete a retrospective survey for the diagnosed high serum 25OHDlevels (>88 ng/dl) and/or vitamin D toxicity, between January 2019 and December 2019. Twenty-threecenters responded from 19 cities. Subjects evaluated according to the presence of signs and or symptoms of hypercalcemia. The evaluation also is doneaccording to 25OHD levels >150 ng/dl (Group 1), 149–100 ng/dl (Group 2), 99-88 ng/dl (Group 3).
Results
Two hundred and fifty-three patients included in the final analysis (female/male: 215/38,: 51.5±15 yrs). Serum 25OHD level:119.9±33 (min-max 88-259) ng/dl, and serumcalcium level was 9.8±0.7 (min-max 8.1–13.1) mg/dl. Most ofthe patients were asymptomatic ($n=201$, 75.4%)despite high vitamin D and calcium levels. Serum 25OHD levels was significantly higher in the symptomatic group(138.6±64 ng/dl) compared to asymptomatic group (117.7±31 ng/dl) ($P<0.05$). Serum calcium levels were10.36±1.0 mg/dl vs 9.7±0.6 mg/dl ($P<0.01$) for symptomaticand asymptomatic groups, respectively. The symptomatic group was older than others ($P<0.05$). Serum intact PTH level was similar between groups. There was no significant difference in terms of age,serum calcium and iPTH levels in group 1,2 and 3. Inappropriate prescribed high dose oral vitamin intake (600.000-1.500.000 IU) in short term (1–3 months) for treatment ofdeficiency/insufficiencyis to the most common reason (73%) associated with high serum 25OHD levels.75.9% of patients who developed toxicity(serum 25OHD >150 ng/dl) used the vial form (300.000 IU/1 vial=1 ml) twice consequently.
Conclusions
High serum 25OHD levels were associated with very high dose vitamin D intake. To avoid vitamin D toxicity and related complications need to avoidusing very high dose of cholecalciferol. Clinical guidelines recommendations for the treatment of vitamin D deficiency are effective and safe.

The bone density and trabecular bone score in patients after solid organ transplantation

Jana Brunova & Simona Kratochvilova
Institute for Clinical and Experimental Medicine, Diabetes centre, Prague, Czech Republic

Introduction
Organ transplant recipients are at increased fracture risk compared to general population. Bone mineral density (BMD), predictive of fracture in general population, does not reflect impaired bone quality frequently present in patients with advanced organ failure. Trabecular bone score (TBS) provides surrogate measures of bone microarchitecture and therefore helps to identify persons at risk for fracture among transplant recipients.
Methods
Our retrospective study comprises 186 persons (115 M, 71 W, age 54.4±12.0 y), 34 simultaneous pancreas and kidney (SPK) recipients, 60 kidney and 92 liver recipients, transplanted in 2018. Dual energy X-ray absorptiometry scans (DXA) and TBS measurement were performed with the Lunar Prodigy apparatus within the year of transplantation (Tx). Standard TBS was calculated from DXA images of the lumbar spine.
Results
Osteoporosis of L-spine (T score ≤–2.5) was present in 29/186 persons (16%), osteopenia (T score>–2.5 <–1.0) in 58/186 (31%). Proximal femur osteoporosis was diagnosed in 24/186 (13%), and osteopenia in 71/186 (38%) patients. Mean T score of spine was –0.9±1.5 and T score of hips –1.02±1.2. The lowest values of L spine T score among all were found in liver graft recipients mean-1.2±1.5 vs SPK recipients –0.7±1 ($P<0.05$) and for kidney recipients –0.5±1.7 ($P<0.05$). SPK recipient had the lowest T score of hips –1.7±1 vs the kidney Tx group (T score –1.0±1.3) ($P<0.01$) and for liver graft recipients (T score –0.8±1.2) ($P<0.001$). The total group TBS was decreased (mean 1.18±0.1) which corresponds to high risk values <1.23. The worst TBS was found in liver Tx patients 1.13±0.2, which differs significantly from SPK recipients cohort TBS 1.26±0.1 ($P<0.001$) and kidney recipients TBS 1.22±0.1 ($P<0.001$).
Summary
Bone density of L spine was decreased in 48% and proximal femur in 51% in patients after solid organ transplantation. The low TBS values in comparison with relatively preserved T score point to more prevalent bone microstructure damage present in transplant recipients.

Background
Total 25 hydroxyvitamin D (25(OH)D) and total 1.25 dihydroxyvitamin D ($1.25(OH)_2D$) are associated with all-cause mortality. The free hormone hypothesis postulates that only the free vitamin D fraction can exert its biological function. Recently some studies suggested that free 25(OH)D levels might be a better predictor for clinical outcomes, including mortality.
Objective
To study the association between total and free 25(OH)D and $1.25(OH)_2D$ with all-cause mortality in a prospective cohort of community-dwelling European men.
Methods
1970 community-dwelling men, aged 40–79, participated in the European Male Ageing Study (EMAS) between 2003–2005. In 5 of 8 EMAS centres, survival status was available until 1 April 2018. Total 25(OH)D levels were measured by radioimmunoassay and recalibrated to NIST standard reference material. Total 1 $25(OH)_2D$ was measured by mass spectrometry and vitamin D binding protein (DBP) by immunodiffusion. Free 25(OH)D and free $1.25(OH)_2D$ were calculated from the total hormone and DBP concentration. Vitamin D measurements and DBP were divided into quintiles. Cox proportional hazard models were used to study the association between

vitamin D status and all-cause mortality. Because of the wide age range at inclusion, age was used as time scale instead of years since inclusion adjusting for age. Results were expressed as hazard ratios (HR) with 95% confidence intervals, adjusted for centre, BMI, smoking and self-reported health.
Results
524 (26.6%) men died during a mean follow-up of 12.3±3.4 years. Men who died had a higher BMI ($P=0.002$) and lower physical activity level ($P<0001$), but there was no difference in smoking status. Men in the lowest total 25(OH)D and the lowest total $1.25(OH)_2D$ quintile (cutoff <9.3 µg/l and <46 ng/l respectively) had increased mortality risk (HR compared to men in the highest quintile (HR 1.83 (95% CI 1.34–2.50); $P<0.001$ and 1.41 (1.04–.90); $P<0.05$ respectively). Likewise, men in the lowest three free 25(OH)D quintiles (levels <4.43 ng/l) had a higher mortality risk compared to men in the highest quintile (HR 1.91 (1.34–2.73); $P<0.001$ for the lowest quintile). However, mortality risk was similar for across all free $1.25(OH)_2D$ and DBP quintiles.
Conclusions
Low total 25(OH)D levels and low total $1.25(OH)_2D$ levels in community-dwelling middle-aged and elderly men have an increased future mortality risk. However, only low free 25(OH)D but not free $1.25(OH)_2D$ levels predict all-cause mortality. Vitamin D deficiency is associated with a negative impact on general health and is predictive of a higher mortality risk.

Calcium-sensing receptor gene polymorphisms and their effect on response to cinacalcet treatment in patients with secondary hyperparathyroidism in chronic kidney diseases

Lilit Egshatyan[1,2,3], Tamara Filippova[4], Sevda Nuralieva[4], Diana Svetlichnaya[4], Aliy Asanov[4] & Maria Litvinova[1,4]
[1]The AS Loginov Moscow Clinical Scientific Center, endocrinology, Moscow, Russian Federation; [2]Endocrinology Research Centre, Ministry of Health of Russian Federation, Moscow, endocrinology, Moscow, Russian Federation; [3]AI Evdokimov Moscow State University of Medicine and Dentistry, Moscow, Endocrinology, Moscow, Russian Federation; [4]Federal State Autonomous Educational Institution of Higher Education IM Sechenov First Moscow State Medical University under the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background
Secondary hyperparathyroidism (SHPT) is an adaptive process that develops in response to declining kidney function, impaired phosphate excretion, and failure to bioactivate vitamin D. The signal transduction via the calcium-sensing receptor (CaSR) is a key determinant of parathyroid gland hyperplasia.
Aims
To examine the polymorphisms rs1801725 (p.Ala986Ser, G>T), rs1042636 (p.Arg990Gly, A>G), rs1801726 (p.Glu1021Gln, G>C) of *CaSR* gene as a possible cause of the different responses to cinacalcet.
Materials and methods
In study were enrolled 25 patients undego chronic hemodialysis with SHPT (parathyroid hormone (PTH) levels greater than 800 pg/ml). The mean age of patients was 47 (21–77) years old. Patients were genotyped for rs1801725, rs1042636, rs1801726 of *CaSR* gene by Sanger sequencing. The initial dosage of cinacalcet was 30 mg/day. All patients were also tested for calcium-phosphate metabolism parameters.
Results
The baseline levels of albumin-corrected calcium were significantly lower in patients with polymorphisms rs1801725, rs1042636, rs1801726 of *CaSR* gene compared to the patients with wild type genotype ($P=0,01$). In 3 months cinacalcet treatment patients homozygous and heterozygous for the rs1801725 polymorphism did not demonstrate significant reduction in PTH from baselinecompared to the patients without this polymorphism in the genotype. The same situation was found for rs1801726 polymorphism carriers. The heterozygous patients for the rs1801726 polymorphismshowed-significant reduction in PTH andcalcium * phosphate product (Ca*P), while patients without this polymorphismshowed reduction in PTH,ionized calcium, albumin-corrected calcium,phosphate and Ca*Pfrom baseline. After 3 months treatment the homozygous and heterozygous patients for the rs1042636 showed significant reduction of PTH levels, while the patients without this polymorphism showed reduction in PTH, ionized calcium, albumin-corrected calcium, phosphate and Ca*P.
Conclusions
This study shows that polymorphisms rs1801725, rs1042636, rs1801726 of *CaSR* geneinfluence the effectiveness of cinacalcet treatment. The patients without this polymorphism showed a significantly higher sensitivity to cinacalcet compared to the patients who were carriers of *CaSR* polymorphisms.

An extremely rare cause of severe primary hyperparathyroidism due to intrathyroidal parathyroid cyst.

Jorge Monroy Sánchez[1], Ana María Delgado Lucio[1], Estefanía Santos Mazo[1], Marta Baraia-Etxaburu[1], Pablo Herguedas Vela[1], Simón Gundin Menéndez[2], Ana Ruiz de la Parte[3] & Johanna Beatriz Palacios Ball[3]
[1]Burgos University Hospital, Endocrinology and Nutrition, Burgos, Spain; [2]Burgos University Hospital, Clinical analysis laboratory, Burgos, Spain; [3]Burgos University Hospital, Pathological anatomy, Burgos, Spain

Introduction
Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia, most cases with parathyroid adenoma as the underlying pathology. However, when blood and urine calcium levels and PTH are higher than normal in PHPT, t's important to suspect an ectopic PTH secretion or a parathyroid carcinoma. Intrathyroidal parathyroid cysts are extremely rare cause of severe PHPT.
Clinical case
A 36-year-old male presented with dizziness and weakness for several weeks. Osmotic polyuria and nocturia with thirst were also impairing his quality of life. He had no history of renal lithiasis or hypertension. Biochemical features were suggestive of PHPT (Ca^2:12.9 mg/dl; iPTH:>300 pg/ml; $Ca_{u:}$11.5mg/kg/24 h). Physical exploration shows normal thyroid palpation and there were no lipomas or facial angiofibromas. BMD was reduced and skull X-ray revealed a brown tumor. US also showed bilateral renal microlithiasis. No family background of MEN 1. CT showed a right thyroid nodule and a possible left parathyroid adenoma but Tc99m sestamibi scintigraphy revealed radio tracer uptake in the right lobe of thyroid. In ultrasonography no parathyroid lesions were located, but a solid-cystic nodule in the right lobe was observed. US-FNA of the thyroid nodule followed by cyst iPTH measurement (2,170,000 pg/ml) confirmed intrathyroidal parathyroid gland. Treatment with 30 mg of cinacalcet was initiated, but without calcium decrease until 210 mg daily dose. After sharing our clinical suspicion with the surgeon, an hemithyroidectomy was performed, checking that PTH dropped to normal levels. Twenty-four hours after surgery, the patient started with paresthesias and positive Trousseau sign, PTH level was of 5 pg/ml with normocalcemia. After resolution of symptoms with IV calcium, oral calcitriol and calcium carbonated were initiated. Two weeks after surgery both medications were stopped without symptoms at all.

Biochemical parameter	Baseline	Cinacalcet 120 mg	Cinacalcet 210 mg	24 hours after surgery	2 months after surgery (without treatment)
Albumin corrected calcium (mg/dl)	12,2	12,2	11,4	10,7	9,8
Phosphorus (mg/dl)	1,8	2,4	2,8	3,1	3,6
PTH(pg/ml)	258	257	332	5,7	20
25OH VitaminD (ng/ml)	42	16,8	18	×	20
Urine calcium (mg/kg/24 h)	11	7,5	4,3 (incomplete)	7,2	4,4
Glomerular filtration (ml/min/1.73m^2)	115	110	110	110	110

Conclusions
1. Intrathyroidal parathyroid cystic adenoma is an extremely rare cause of PHPT.
2. FNA-iPTH is a helpful tool to make an accurate diagnosis when an intrathyroidal parathyroid adenoma is suspected.
3. Elevated levels of PTH and bone disease before parathyroidectomy, are risk factors for hungry bone syndrome.

AEP187

Skeletal manifestations of hypoparathyroidism mimicking ankylosing spondylitis; a rare clinical presentation: A case report

Sonali Gunatilake & Uditha Bulugahapitiya
Colombo South Teaching Hospital, Diabetes and Endocrine Unit, Kalubowila, Sri Lanka

Introduction
Idiopathic hypoparathyroidism is a rare endocrine disorder with varying clinical manifestations ranging from acute hypocalcemic symptoms to asymptomatic soft and skeletal tissue calcifications/ossifications. Patients may present with wide spectrum of rheumatological manifestations, which are under-recognized, thus delaying timely treatment. This results in chronic disability.
Case presentation
A 47-year-old male with past history of convulsions and non-specific musculoskeletal symptoms presented with chronic backache for 10-years duration, with clinical findings of spinal stiffness and kyphosis suggestive of ankylosing spondylitis. He was initially managed with non-steroidal anti-inflammatory drugs and disease modifying anti-rheumatoid drugs with poor response. He was also treated with sodium valproate for adult onset seizure disorder. Further, he had intermittent numbness of hands and positive Trousseau's and Chvostek's signs. Radiological evaluation revealed multiple anterior osteophytes in the spine, mainly in the lumbar region and prominent end plates with shiny corners. Left iliolumbar ligament was calcified with sclerotic changes in the left sacro-iliac joint and joint space reduction mimicking spondyloarthropathy. However, HLA B27 was negative. He also had bilateral cerebral, cerebellar and basal ganglia calcification on non-contrast computed tomography of head. Biochemical evaluation confirmed hypocalcemia secondary to hypoparathyroidism. Following treatment with calcium and vitamin D, patients' symptoms improved but skeletal changes mimiking spondyloarthropathy remained unchanged.
Conclusion
Long standing untreated hypoparathyroidism may lead to ligamental/joint ossification and calcifications resulting in spinal stiffness mimicking ankylosing spondylosis-like clinical picture. It is important to consider hypoparathyroidism as a differential diagnosis in the background of atypical spondyloarthropathies to avoid delay in diagnosis and to prevent chronic disability.

Hypercalcemia and primary hyperparathyroidism case progressing during the treatment of dapagliflozin

Pinar Akhanli[1], Sema Hepsen[1], Bekir Uçan[1], Güleser Saylam[2] & Erman Çakal[1]
[1]University of Health Sciences, Diskapi Yildirim Beyazit Training and Reseach Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]University of Health Sciences, Diskapi Yildirim Beyazit Training and Reseach Hospital, Department of Otolaryngology, Head and Neck Surgery, Ankara, Turkey

Introduction
Hypercalcemia associated with the use of a SGLT-2 inhibitor is a very rare adverse effect. Herein we reported a case of apparent primary hyperparathyroidism that occurred while applying the treatment of dapagliflozin in a patient with asymptomatic primary hyperparathyroidism.
Case report
A 49-year-old male patient with 5 years of diabetes mellitus history admitted for his routine control and Hba1c level was observed 7.9%. Dapagliflozin (1 × 10 mg) was started to the patient who has been using metformin (2 × 1000 mg) and gliclazide (1 × mg). At 6 months of dapagliflozin therapy, calcium level was detected 11.28 mg/dl, creatinine level was 1.21 mg/dl, and phosphorus level was 3.73 mg/dl, parathormone level was 70.8 ng/l, 25-(OH) vitamin D level was 33.16 ng/ml. A 4 × 9 × 14 mm-sized hypoechoic lesion located inferior to the right thyroid lobe, which was compatible with a parathyroid adenoma was detected on the neck ultrasonography. Because 99m-MIBI scintigraphy does not show an uptake compatible with parathyroid adenoma, four-dimensional computed tomography and magnetic resonance imaging were performed to clarify the localization of parathyroid adenoma. A 15 × 10 × 9-mm nodular lesion, which was compatible with the parathyroid adenoma was observed adjacent to lower part of the right thyroid gland. A 24-hours urine calcium level was 492 mg/day. The patient underwent lower right parathyroidectomy. Histopathological findings confirmed the diagnosis of parathyroid adenoma. After three months of the surgery, the patient is still asymptomatic and followed up with normal calcium levels.
Conclusion
Thiazide use and excessive calcium intake have been previously reported in the in the development of hypercalcemia while using SGLT-2 inhibitors. In response to increased absorption of phosphorus from the kidney, FGF-23 and parathormone levels increase. Another reason why SGLT-2 inhibitors cause moderate increase in calcium levels is the inhibition of both SGLT-1 and SGLT-2 receptors and the increase in calcium absorption in the intestines. Volume depletion caused by SGLT-2 inhibitors may also contribute to hypercalcemia. As the result of these mechanisms, calcium level may be seen increased with the use of SGLT-2 inhibitors. SGLT-2 inhibitors are medicines which lead to hypercalcemia and to reveal parathyroid adenoma that is not symptomatic. İt should be considered that calcium following-up might be needed while using SGLT-2 inhibitors.

Radioiodine, hyperparathyroidism and schwannoma... coincidence or consequence?

Emin Mammadov[1], Andrei Goldstein[2] & Ruxandra Vladescu[3]
[1]Sanador Oncology Centre, Endocrine Oncology, Bucharest, Romania; [2]National Institute of Endocrinology CI Parhon, Nuclear Medicine, Bucharest, Romania; [3]Sanador Oncology Centre, Nuclear Medicine, Bucharest, Romania

Background
Primary hyperparathyroidism (PHPTH) refers to overproduction of PTH (parathyroid hormone) which leads to hypercalcaemia and hypophosphataemia. Preoperative imaging aims identification of a solitary parathyroid adenoma (PTA) or multiple gland hyperplasia. However, it is not always possible to identify the lesions, and in some situations imaging findings could be misleading.
Case report
A 48-year old male, with personal history of differentiated thyroid cancer in 1998 (at age 27), underwent total thyroidectomy and multiple radioactive iodine (RAI) treatments (cumulative dose 610 mCi). During follow-up, there was no evidence of recurrent disease. He was lost for follow-up for several years.
In August 2018, he presented with signs and symptoms of hypercalcaemia, and was diagnosed with primary hyperparathyroidism (PHPTH). The neck ultrasound revealed a 3-cm hypoechoic heterogeneous mass in the left suprasternal region, suggestive of PTA. In April 2019, he underwent a resection of the mass with lateral neck lymph node dissection, the pathology report described the 3–cm mass as schwannoma, all other lesions resected as reactive lymphadenopathy. Postoperatively, he had persistent PHPTH. In May 2019, a 99mTc-Sestamibi scintigraphy with SPECT-CT identified two lesions with high uptake: one in the sternocleidomastoid muscle, with uptake on early imaging (10 minutes), with almost complete washout on late imaging (3 hours); and the other one in the right upper thyroid bed, with persistent uptake on late imaging. These lesions were excised, and the former one was reported as a reactive lymphadenopathy, while the latter one was confirmed as a PTA. Postoperatively, PTH levels immediately dropped from 267 pg/ml to 50.1 pg/ml. However, during follow-up, we identified persistently high PTH and Ca levels (92.9 pg/ml and 12.8 mg/dl in Jul 2019, 76.5 pg/ml and 11.7 mg/dl in Jan 2020). He repeated scintigraphy in Jan 2020, with no unusual uptake identified.

Discussion
Our case emphasises the importance of scintigraphy for differential diagnosis in PHPTH, even if the neck ultrasound identifies a suspicious lesion. Both schwannoma and lymphadenopathy could have a high uptake on scintigraphy, however the washout pattern is different compared to PTA. On the other hand, it reminds of higher incidence of PHPTH in patients treated with RAI, previously reported in literature. Also, hyperparathyroidism was reported as a possible aetiological factor of schwannoma. Hence, we could hypothesise that the lesions identified in our patient represent a linked sequence of events rather than a simple coincidence, with RAI for thyroid carcinoma causing hyperparathyroidism, and the latter contributing to development of schwannoma.

Multiple endocrinopathies associated with myotonic dystrophy type 1 – case report

Tanja Miličević & Anela Novak
University Hospital Center Split, Endocrinology Department, Split, Croatia

Introduction
Myotonic dystrophy type 1 (DMT1) is the most prevalent muscular dystrophy that affects 1 in 8000 individuals. Disease is caused by CTG repeat expansion of the DMPK gene located on chromosome 19. Beside neuromuscular involvement, studies have found an increased prevalence of endocrinopathies such as diabetes, hyperparathyroidism and hypogonadism. The exact underlying mechanism of endocrine dysfunction remains unclear. Moreover, endocrine dysfunction is progressive in nature as is the muscle affection. We illustrate the problem with following clinical case.
Case report
47-year old women, complaining of chronic fatigue, muscle weakness and anxiety was admitted to our department for an evaluation of low TSH, T4, T3, hypercalcemia, hypophosphatemia, and elevated PTH level. We performed pituitary MRI, neck ultrasound, ^{99m}Tc sestamibi SPECT/CT and all results were unremarkable. Other pituitary hormone testing showed normal findings. We diagnosed patient with secondary hypothyroidism and primary hyperparathyroidism, introduced levothyroxine along with hidration and furosemide and decided to do regular check-ups. However, patient was not feeling better with therapy. In the meantime, she underwent genetic testing for myotonic dystrophy type 1 as her son was diagnosed with severe form of disease after suffering cardiorespiratory insufficiency during influenza. Later on, her son developed primary adrenal insufficiency and primary hypogonadism. In further monitoring, our patient´s calcium and PTH levels where persistently elevated. Given the inability to locate hyperactive parathyroid tissue and an increased perioperative risk due to neurological disease itself, we decided to treat patient conservatively rather than surgically. Despite hidration, furosemide, pamidronate and cinecalcet, calcium levels did not decrease.^{18}F choline PET/CT is not a routine diagnostic method for this indication in our country. We performed it for the first time in this patient and found 6 mm large hyperactive tissue in the projection of the left lobe of the thyroid gland. Patient underwent surgery and finally calcium, phosphorus and PTH levels normalized. Couple of years later we noticed elevation in fasting glucose and HbA1c levels, so we started metformin therapy. She is well now but we keep monitoring the rest of the endocrine function, especially adrenal function.
Conclusion
Myotonic dystrophy type 1 and associated endocrinopathies are one more proof of neuroendocrine connection. In all patients suffering from it, endocrine evaluation and monitoring is obligatory. Although Consensus-based Recommendations from Myotonic Dystrophy Fundation do not mention screening of the parathyroid gland function, it is one of the most common endocrinopathy and should be evaluated in these patients as well.

Remission of disseminated parathyroid cancer after multiple surgical interventions because of recurrences in the neck lymph nodes, left lung and liver in a young patient with hyperparathyroidism-jaw tumor syndrome

Julia Krupinova & Natalia Mokrysheva
Endocrinology research center, pathology of the parathyroid gland, Moscow, Russian Federation

Background
Parathyroid cancer (PC) is a rare tumor associated with poor prognosis particularly when disseminated. Currently, the only effective treatment is a surgical intervention.
Case
Starting from the age of 19 a woman had been suffering from bone pains and change in gait. A low-energy right humerus fracture with displacement occurred when she was 23. At the same time, primary hyperparathyroidism (PHPT) was diagnosed for the first time (PTH 569 pg/ml (15–65), Ca total – 3.30 mmol/l (2.15–2.55)) and the right lower parathyroid gland (PG) was removed that led to a remission of the diseases. Histological examination showed PC. The first recurrence of PC with metastases in the neck lymph nodes developed in a year. The subtotal resection of the thyroid gland, a removal of pre- and paratracheal tissue, nerve-sparing lymphadenectomy on the right of the neck was performed with achievement of a remission of PHPT (PTH 4 pg/ml, Ca total 1.82 mmol/l). After 3 years (at the age of 29), there was a second recurrence of PC (Ca total 4 mmol/l, PTH 2 186 pg/ml) with metastases in S3 of the left lung (17 mm) and in the liver SII-III (17 × 17mm and 24 × 2.7 mm). A resection of the upper lobe of the left lung and liver resection (bisegmentectomy II -III with resection of the IV) was successfully performed in two stages. The metastases of PC verified by histological analysis and immunohistochemistry (IHC) of the removed distant lesions. The remission of the disease has been observed for the last two years (PTH 6 pg/ml, Ca total 2.08 mmol/l). Considering that the manifestation of the PHPT began at an early age and mothers' PHPT (parathyroid adenoma) a hereditary form of PHPT was suspected. Next-generation sequencing identified a germline mutation in the *CDC73* (c.355C>T:p.Q119X).
Conclusion
Patient with PC associated with a germline mutation in the *CDC73* has a poorer disease prognosis. In some cases, it is possible to achieve a remission of the disease by a surgical removal of distant metastases, but future studies must focus on searching a new effective treatment option.

Sequencing of the gnas gene in hungarian patients with pseudohypoparathyroidism and mccune-albright syndrome

Gábor Nyirő[1,2,3], Attila Patocs[3,4,5] & Péter Igaz[1,2]
[1]Semmelweis University and Hungarian Academy of Sciences, Molecular Medicine Research Group, Budapest, Hungary; [2]Semmelweis University, 2nd Department of Internal Medicine, Budapest, Hungary; [3]Semmelweis University, Institute of Laboratory Medicine, Budapest, Hungary; [4]National Institute of Oncology, Department of Molecular Genetics, Budapest, Hungary; [5]Semmelweis University and Hungarian Academy of Sciences, Hereditary Tumours Research Group, Budapest, Hungary

Introduction
The human GNAS gene is coding for the alpha stimulatory subunit of the guanine nucleotide-binding protein. This G protein stimulates the activity of the adenylate cyclase enzyme which is in control of the production of various hormones in endocrine glands and also regulates bone development. Mutations in GNAS can lead to McCune Albright syndrome, progressive osseous heteroplasia or pseudohypoparathyroidism.
Aim
Our aim was to find the genetic background of the disease.
Materials and methods
In this study we screened 24 people, 20 index patients and 4 relatives, 9 with preliminary McCune Albright indication and 11 with pseudohypoparathyroidism. For genetic testing peripherial blood was collected. In two cases tumor tissue samples were also available. Genomic DNA was isolated with Qiagen DNAeasy Blood and Tissue kit. PCR products were directly Sanger sequenced. Sequence data obtained were compared to NCBI and ENSEMBL databases.
Results
Out of 9 samples only one tissue (11%) tested positive for somatic mosaic (level 25–30%) mutation, p.MET703_ARG704del, thus for McCune Albright syndrome. In the case of pseudohypoparathyreosis 6 germ line mutations out of 11 index patients could be detected (54%). Inheritance of the mutations within families could be observed. In our samples one GNAS

c.2277delC frameshift mutation was found in heterozygotic form possibly causing truncated protein. The heterozygous Leu706Pro probably damaging (Polyphen2 score 1.0) variant, was found in the index patient but absent in the parents, likely originated de novo. The GNAS Arg231Cys known pathogenic mutation was found in three cases, one mother and two siblings. The c.432+1G>A splice mutation could be detected in one index patien and her mother, The known pathogenic heterogeneous 4 bp deletion rs587776829 was also detected.
Discussion
Six different mutations in 6 index patients (54%) were found and symptomes could be matched to pseudohypoparathyreosis type 1a. McCune Albright syndrome found in one case only shows the importance of testing somatic DNA samples is of critical importance here.

Mineral density of bone tissue, parathyroid hormone and vitamin D in children and adolescents with thyrotoxicosis
Shakhlo Muratova & Anvar Alimov
Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician E.Kh.Turakulov of the Ministry of Health of the Republic of Uzbekistan, Thyroidology, Tashkent, Uzbekistan

Thyroid hormones have an important role in bone metabolism. In this case, hyperthyroidism causes secondary osteoporosis and osteopenia. There is very little information in the literature about the state of bone metabolism in children and adolescents with thyrotoxicosis. Thus, our work aimed to study the state of bone mineral density and levels of calciotropic hormones in children and adolescents with thyrotoxicosis. The study was conducted in a group of 19 children and adolescents with thyrotoxicosis at the age of 9–18 years. The control group consisted of 23 healthy children and adolescents. All studies were conducted in the RSSPMCE. Levels of TSH, fT4 and fT3, PTH and vitamin D were determined using a closed-type immunochemistry analyser Cobas e 411 Hitachi company HoffmanLeRoche (Switzerland) and its reagents. Bone mineral density was evaluated by dual-energy absorptiometry on a Stratos X-ray densitometer from DMS, France. The results of the study showed that the average value of the level of vitamin D in the control group was 20.4±6.2 ng/ml, in the group with thyrotoxicosis – 12.3±1.1 ng/ml, P <0.05. At the same time, vitamin D deficiency was detected in 43.4% of children and adolescents without endocrine pathology. In the group with thyrotoxicosis, vitamin D deficiency was diagnosed in 84.2%, and its deficiency in 15.8% of pediatric patients. The average level of parathyroid hormone in the control group was 49.2±2.3 ng/ml, whereas, in the group with thyrotoxicosis, the average level of parathyroid hormone was significantly lower and amounted to 45.1±3.9 ng/ml, P<0.05. In the group with thyrotoxicosis, hypoparathyroidism occurred 4.9 times more often than among healthy children, 21.1% showed an increase in PTH levels of more than 65 ng/ml. According to the results of dual-energy X-ray absorptiometry in children and adolescents with thyrotoxicosis, the mean valuesand median of the Z-index of femoral neck, lumbar vertebrae and the total body were significantly lower than in the control group. In this control group, 4.2% of adolescents were diagnosed with juvenile osteoporosis. At the same time, in the group with thyrotoxicosis, 36.8% registered osteoporosis, P≤0.01.Thyrotoxicosis in children and adolescents causes a decrease in BMD and increases the development of osteoporosis by almost nine times. Thus, thyrotoxicosis in children and adolescents causes a decrease in bone mineral density and is accompanied by hypoparathyroidism and vitamin D deficiency.

Assessing risk factors and predictors of mortality in patients with fragility hip fracture
Joana Lima Ferreira[1], Joana Teixeira e Silva[2], Francisco Simões de Carvalho[1], Francisca de Brito Marques[1], Ana Paula Marques[1] & Rosa Maria Príncipe[1]
[1]Hospital Pedro Hispano, Endocrinology, Matosinhos, Portugal; [2]USF Lagoa, General Practice, Matosinhos, Portugal

Introduction
Fragility fractures are the main consequence of osteoporosis. It results in increased morbidity and mortality. The incidence of fractures has been increasing steadily in Portugal. Hip fragility fractures have been estimated to occur in up to 572/100,000/year in women and up to 232/100,000/year in men.
Methods
A retrospective study of hospitalized patients for femoral neck fracture in our institution in 2018 was performed to evaluate their previous risk of fracture and the predictive factors of one-year mortality. We excluded patients without a fragility fracture or absence of relevant clinical data. The previous absolute risk of fracture was calculated using FRAX-Port. High ten-year fracture risk (without BMD) was considered from 11% for major osteoporotic fracture and from 3% for hip fracture, according to 2018 Portuguese recommendations for the prevention, diagnosis and management of primary osteoporosis. Logistic regression was performed to evaluate factors associated with the occurrence of death and included also other risk factors not assessed in FRAX.
Results
We included 193 patients, with a median age of 84.0 years old (IQR 10) and 76.2% were female. Most patients (95.3%) underwent surgery after hospital admission. Globally they were hospitalized for a median of 9 days (IQR 8). They presented a median BMI of 24.44 kg/m^2 (IQR 6.18), 42% had a previous fragility fracture, 4.1% were smoker at the time, 5.2% had alcohol abuse, 4.7% were under therapy with glucocorticoid, 2.6% had rheumatoid arthritis and 4.7% had a disorder associated to secondary osteoporosis according to FRAX. The majority of patients (77.7%) did not perform previous dual-energy x-ray absorptiometry, even the ones with risk factors for fractures not included in FRAX. Median FRAX was 15.0% (IQR 11) for major osteoporotic fracture and 6.8% (IQR 7) for hip fracture. High absolute risk of fracture without BMD was found in 84.5% of patients. Only 14 patients were under osteoporosis treatment at the time of the fracture and other 14 were under calcium and vitamin D supplementation alone. All-cause mortality was 4.1% in the first 30 days and 19.2% in the first year. The risk of death was 3 times higher in men versus women (OR=3.223, 95% CI=1.281-8.107, P<0.013). It was also positively correlated with age (OR=1.082, 95% CI=1.019-1.149, P<0.011).
Conclusion
Fragility fractures are a dramatic public health problem. This study highlights the importance of the risk fracture evaluation, institution of preventive measures and close follow-up of patients suffering a fracture, given the high rate mortality.

Bone quality is associated with perinatal nutritional manipulation in adult Wistar rats offspring
Areti Augoulea[1], Nikolaos Syggelos[1], Eleni Armeni[1], George Kaparos[2], Homeira Vafaei[3], Ismene Dontas[4], Katerina Marinou[5], George Vaggos[6], Panagiota Raptou[4], Irene Lambrinoudaki[1], Makarios Eleftheriades[1,7] & Kypros H Nicolaides[7]
[1]National and Kapodistrian University of Athens, Aretaieio Hospital, 2nd Department of Obstetrics and Gynecology, Athens, Greece; [2]National and Kapodistrian University of Athens, Aretaieio Hospital, Hormonal and Biochemical Laboratory, Athens, Greece; [3]Faghihi Hospital, Shiraz University of Medical Sciences, Department of Obstetrics and Gynecology, Shiraz, Iran; [4]National and Kapodistrian University of Athens, Laboratory for Research of the Musculoskeletal System, Th. Garofalidis, KAT Hospital, Athens, Greece; [5]Greek Ministry of Rural Development and Food, Department of Animal Welfare for farm and laboratory animals, Athens, Greece; [6]General Hospital of Arta, Department of Obstetrics and Gynecology, Arta, Greece; [7]King's College Hospital, Harris Birthright Research Centre for Fetal Medicine, London, United Kingdom

Introduction
Prenatal and perinatal food manipulation might be related with bone quality in offspring of Wistar rats. This study aimed to assess the impact of different dietary patterns provided before delivery to the mothers on the skeletal characteristics of newborn rats and the levels of insulin.
Materials and methods
We randomized 67 timed-pregnant rats into control diet (CD), high-fat (FD) and food-restricted (FR) on the 12th day of gestation. The pregnant Wistar rats delivered 618 pups on the 21st day. We classified pups born to FR-mothers, based on their birthweight, into fetal-growth restricted (FGR) and non-FGR. Following delivery, we enforced postnatal food manipulation

for all pups; the pattern of cross-fostering consisted of the offspring of CD-mothers being now lactated by FD, FR or CD fed dams. A similar process was applied for offspring of FR and FD-mothers. All pups were weaned to the diet of their fostered mother, starting from the 26th postnatal day until their 1st year of age, when they were sacrificed. We measured biochemical parameters and skeletal properties, using peripheral quantitative computed tomography.
Results
FGR-pups that received CD after birth had better skeletal properties compared to FGR-offspring that were starved postnatally and lower values of total/subcortical area compared to controls. Offspring fat-restricted postnatally had better skeletal properties if born to mothers who received high-fat diet compared to mothers who were food restricted during gestation. Higher levels of insulin were evident in pups born to mothers who received high-fat diet during gestation, provided pups received high-fat diet rather fat-restriction after birth.
Conclusion
The results of this study confirm the significance of intrauterine diet for the establishment of appropriate skeletal properties of the neonate. Islet dysfunction and predisposition towards raised insulin production during lifetime is linked with high-fat intake both before and particularly after birth.

Epidemiology of osteoporotic hip fracture in the largest urban area of Romania

Ramona Dobre[1], Niculescu Dan Alexandru[1,2] & Poiana Catalina[1,2]
[1]Parhon Hospital Bucharest, Pituitary and Neuroendocrine Pathology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania

Background
Osteoporotic hip fracture remains a problem of public health concern. Different studies highlighted the existence of a particular epidemiology derived from local differences. We aimed to evaluate the epidemiology of osteoporotic hip fracture in the capital city of Romania plus city suburban area.
Methods
We collected data from over 95 % of fractures from hospitals with an Orthopedic Surgery Department in the area of interest. Patients were selected using the hip fracture codes (S72.0, 1, 2, 3, 7, 8, 9) and age >40 years old, during a 12 months period (09/01/2017 – 08/31/2018). We included only osteoporotic hip fracture (fall from a standing height or less) after a careful review of all the patients' medical records.
Results
We included a total of 1896 patients with fragility hip fracture (86.6% in the capital city and 13.4 % in the suburban area). 73.68% were female (mean age of 80.16±9.8 years old) and 26.14 % males (mean age of 75.85±12.2 years). The median body mass index was 23.87 kg/m^2 with only 21.5 % of the patients being overweight or underweight. Fractures in the femoral neck comprised 36.33 % of the total, intertrochanteric ones 55.74 %, atypical 6.8 % and 0.5 % nonspecific. Out of the total number, only 80.74 % were surgically treated (71.9 % of the femoral neck fracture, 86% of the intertrochanteric fractures and 90.7 % of the atypical ones). The median day of surgery after admission was 3±3.42 days (3.93±4 days for neck fractures and 2±2.94 days for intertrochanteric). 10.91 % of the patients had a history of one or more osteoporotic hip fracture.
Conclusion
This is the first study to describe the epidemiology of osteoporotic hip fracture in Romania after singly reviewing all patients' charts. Compared with literature data we discovered a very high rate of conservative treated fractures, and also a delayed time of surgery. We need further studies to evaluate the impact of this factors on the mortality rate.

The osteoporosis and hormonal status of our thalassemia patients

Iffet Dağdelen Duran[1] & Neşe Ersöz Gülçelik[2]
[1]Denizli Devlet Hastanesi, endocrinology and metabolic diseases, denizli, Turkey; [2]ankara gülhane education and research hospital, endocrinology and metabolic diseases, ankara, Turkey

Introduction
Thalassemia manifests clinically as anemia requiring life-long blood transfusions and the chronic iron deposition . Iron overload can lead to decreased functioning of the respective systems. Thalassemia-associated osteoporosis constitutes a majorproblem. Weinvestigated the bone mineral density scores of the thalassemic patients and correlated the scores of themwith some parameters including the transfusion frequency, levels of ferritin and pituitary hormones.
Subjects-materials
We recruited 54 thalassemic patients who were under follow-up in our hospital.26 of them were male, 28 were female. The mean of their age was 27.0±8.4 years, body weight 52.1±8.6 kg, transfusion frequency every 3.07±0.71 weeks, calcium (Ca) corrected for albumin 8.9±0.42 mg/dl, 25-0 h-vitamin D 321.9±10.5 ng/ml, total bilirubin (tot bil) 3.00±1.8 mg/dl, magnesium (Mg) 2.00±0.1 mg/dl, free triiodothyronine (f T3): 3.13 (OR:0.41, P=0.003) 0.62 ng/dl, prolactin 13,6±6.0 ng/ml, cortisol 11.2±2.9 mg/dl, Luteinizing hormone (LH): 2.5±1.7 IU/l, alkalen phosphatase 91.6±35.7 U/l, hemoglobin 9.3±0.7 g/dl, ferritin 1918.8±2188.3 ng/ml, mean corpuscular volume(MCV): 80.4±4.4 femtoliter/cell (fL), mean platelet volume (MPV) 7.39±1.88 fL, low density lipoprotein (LDL) 50.4±27.8mg/dl, high density lipoprotein (HDL):32.1±10.7 mg/dl, total cholesterol :107.9±33.5 mg/dl, Lumbar spine1-4 (L1-L4)T score –2,1±1.2, femoral total T score -0.7±1.4, femoral neck T score -0.7±1.5. When correlation analysis was attempted L1-L4 T score was correlated with Mg level [Odd's ratio (OR): 0.35 (P=0.021)], cortisol level (OR: –0.74, P=0.00), ferritin (OR: –0.38, P=0.007) and body weight (OR: 0.73, P =0.036). Femoral total T score was correlated with tot.bil. (OR: 0.41, P=0.003), MCV:f T3 (OR: 0.77, P =0.014), LH (OR: 0.73, P=0.033), LDL (OR: –0.42, P=0.003), total cholesterol (OR: –0.44, P=0.002), MCV (OR: –0.38, P=0.008). Seven (25%) female described amenorrhea,while one male (3.8%) had azospermia, one had decreased (3.8%) and two (7.7%) had increased total testosterone levels. Three (5.5%) patients had low IGF1 levels whose growth hormone levels showed normality after insulin tolerance test. Two patients experienced lumbar vertebralheight loss (3.7%) while one developed (1.8%) clavicle fracture. One patient (1.8%) had hypothyroidism under hormonal treatment while two (3.7%) had type1 diabetes mellitus.
Conclusion
The frequent endocrine complications reported in the literature in thalassemia are growth retardation, delayed puberty, hypogonadism, diabetes, impaired thyroid functions, and dyslipidemias. Early recognition and treatment of endocrine complications is important. A decrease in bone mass alsocan occur due to increased bone resorption or decreased bone formation which can lead to osteopenia/osteoporosis in thalassemia . The bone mass would be affected from several types of variables differing for separate parts of the skeleton thatconstitutesof L1-L4 vertebra and femur in our study . Transfusionnormalizing hemoglobin levels, iron chelation, and adequate hormonal,Vitamin D and calcium replacement therapy would reduce progressive bone disease.

Follow-up report: A case of FGF23-related tumor-induced osteomalacia with pulmonary adenocarcinoma

Hiroshi Arai[1], Yugo Kanai[2], Yuji Nakamoto[3], Yuichi Sakamori[4], Ichiro Yamauchi[2], Toshihito Fujii[2], Daisuke Taura[2], Masakatsu Sone[2], Akihiro Yasoda[2] & Nobuya Inagaki[2]
[1]Kyoto Institute of Technology, Health Administration Center, Kyoto, Japan; [2]Kyoto University Graduate School of Medicine, Department of Diabetes, Endocrinology and Nutrition, Kyoto, Japan; [3]Kyoto University Graduate School of Medicine, Department of Diagnostic Imaging and Nuclear Medicine, Kyoto, Japan; [4]Kyoto University Graduate School of Medicine, Department of Respiratory Medicine, Kyoto, Japan

Tumor-induced osteomalacia (TIO) is a rare paraneoplastic syndrome caused by the abnormal production of fibroblast growth factor 23 (FGF23) in the tumor. We havereported a case of TIO with pulmonary adenocarcinoma at ECE2018. Here we present the follow-up report of the case. A 61-year old woman suffering from severe polyarthralgia and bilateral limb weakness was referred to our hospital. Her blood chemistry revealed high alkaline phosphatase, low phosphate, low calcium, and low 1,25-$(OH)_2D_3$. Bone-scintigraphy revealed multiple accumulations, suggesting small fractures and systemic arthritis. Endocrinological analyses exhibited elevated iPTH and markedly high FGF23 level of 3900 (reference: 14.7–40.5) pg/ml.

These findings suggest that the FGF23-producing tumor induced osteomalacia. DOTATOC-PET/CT showed a major uptake in a nodular lesion of the left lung and several minor uptakes in the supraclavicular, hilar and mediastinal lymph nodes. An ultrasound-guided fine needle aspiration biopsy of the left supraclavicular lymph node revealed metastatic adenocarcinoma with a mutation in Exon19 of the EGFR gene. She was diagnosed as stage IV A (cT1cN3M1b) pulmonary adenocarcinoma, and the chemotherapy with afatinib maleate (EGFR tyrosine kinase inhibitor) was started. Simultaneously, alfacalcidol and menatetrenone were prescribed for osteomalacia. Five months later, the primary tumor and metastatic lesions gradually shrinked. The bone metabolism was almost normalized, the bone mineral density measured by DXA was improved, and FGF23 level was markedly decreased to 42 pg/ml. The arthralgia was ameliorated and controlled with minimal dose of analgesics. After the partial remission for 16 months, the metastatic lesion progressively enlarged and FGF23 was slightly elevated to 66 pg/ml. The anticancer agent was switched to osimertinib mesilate. Three months later, the lesion contracted again and FGF23 level was decreased to 34.7 pg/ml. At present, 35 months after the first visit, she is still in partial remission and working as a housewife. This is a rare case of TIO associated with pulmonary adenocarcinoma.

Biochemical and clinical findings distinguishing between the genetic and the acquired conditions in osteoporotic patients with low serum alkaline phosphatase levels

Federica Sileo[1,2], Vito Guarnieri[3], Rita Indirli[2,4], Gregorio Guabello[5], Matteo Longhi[5], Giorgia Dito[1] & Sabrina Corbetta[1,6]
[1]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]Medical Genetics, IRCCS Ospedale Casa Sollievo Sofferenza, San Giovanni Rotondo (FG), Italy; [4]Endocrinology Unit, IRCCS Fondazione Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]Reumatology Unit, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [6]Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy

Background
Hypophosphatasia is a rare genetic disease with low serum alkaline phosphatase (ALP) activity and hypophosphatasemia. It is caused by loss-of-function mutations and deletions of the tissue-nonspecific isoenzyme of alkaline phosphatase (*TNSALP*) gene; it has a wide range of severity in its phenotype, from death in utero to asymptomatic disease accidentally diagnosed in adult life. Furthermore, some diseases and drugs may induce hypophosphatasemia. Thus, the genetic and acquired etiology can be hardly distinguishable. Aim of the present study was to identify clinical and/or biochemical parameters predictive of genetic disease.
Materials and methods
This is a retrospective study. Biochemical analyses, including serum vitamin B6 and urinary phosphoethanolamine, DXA results and genetic analyses (NGS, MLPA and direct sequencing) were performed in 21 adults (0.9%) with at least two values of ALP below the reference levels out of 2319 osteoporotic patients referred to our third level Bone Unit. Hypophosphatasemic patients with diseases and therapies known to reduce ALP levels were excluded.
Results
Eight patients harboring mutations and/or polymorphic variants of the*TNSALP* gene (two males, six females; median age 55.0 years, range 50.9–65.6: group A) were detected. Thirteen patients (three males, Ten females; median age 51, range 45.4–62.2) had a negative genetic molecular analysis (group B). The two groups were similar for most of the investigated biochemical parameters, including vitamin B6 levels, though urinary levels of phosphoethanolamine showed the trend to be higher in the group A patients [median values 5.25 (3.22–6.10) vs 3.0 (2.30–4.85) mmol/mol of creatinine; $P=0.056$]. On the other hand, anamnestic data appear more indicative of the genetic origin of hypophosphatasemia: dental anomalies, musculoskeletal symptoms and familiarity for skeletal and extra-skeletal manifestations of the disease occurred more frequently in group A with respect to group B ($P=0.056$, $P=0.032$, and $P=0.032$, respectively). It is note of worth that 7 out of the 13 patients harboring the wild type *TNSALP* gene experienced low levels of ALP during treatment with tamoxifen, a drug whose hypophosphatasemic effect is uncertain.
Conclusions
Urine levels of phosphoethanolamine may be a useful tool in distinguishing between genetic and acquired forms of hypophosphatasemia, though anamnestic data such as dental anomalies, musculoskeletal symptoms and familiarity for the skeletal and extra-skeletal manifestations of the disease may be even more relevant in the selection of the patients deserving of genetic analysis. Moreover, our data suggested that tamoxifen should be considered as a hypophosphatasemic drug.

Multiple vertebral fractures in a real-life denosumab-treated cohort: Patient level data

Liana Tripto-Shkolnik[1], Naama Yekutiel[2], Gabriel Chodick[2], Varda Shalev[2] & Inbal Goldshtein[2]
[1]Sheba Medical Center, Tel Hashomer, Division of Endocrinology, Diabetes and Metabolism, Ramat Gan, Israel; [2]Maccabi Healthcare Services, Maccabitech Institute of Research and Innovation, Israel

Introduction
Denosumab discontinuation rapidly reverses bone turnover inhibition and eliminates anti-fracture protection. Multiple vertebral fractures (MVF) were reported in this scenario. Previously, we reported a retrospective real-life analysis designed to estimate fracture risk following denosumab discontinuation. Here we report a patient-level data of a subgroup with MVF.
Methods
Via computerized database of Maccabi Healthcare Services, persistent denosumab users (PU) and denosumab discontinuers (DD) were detected. MVF were adjudicated by an expert's chart review. Patients' baseline characteristics, osteoporosis therapy, variables related to denosumab treatment and discontinuation, and post-MVF treatments were retrieved.
Results
In the core study, 12 female patients with MVF were identified among 1500 DD (MVF-DD) and 2 among 1610 PU (MVF-PU), $P<0.01$. The MVF patients were comparable in age (71 ± 12 vs 68 ± 11), BMI (26.4 ± 2.9 vs 22.6 ± 2) and eGFR (73 ± 27 vs100 ± 7.7) among DD and PU, respectively. Osteoporotic fractures prior to denosumab treatment were prevalent in 41.6% MVF-DD and 100% MVF-PU ($P=0.4615$). Femoral neck T-scores were -2.7 ± 1 vs -3.5 ± 0.56 ($P=0.33$) in the MVF-DD and MVF-PU, respectively. 75% of MVF-DD versus 100% of MVF-PU received osteoporosis medications prior to denosumab. MVF occurred 134 ± 76 days post DD and 57 ± 35 days from the last dose in PU. Two patients in the MVF-DD passed away. One patient suffered from additional VF. Denosumab, teriparatide, oral and IV bisphosphonates were prescribed in various sequences post-MVF and two patients underwent vertebroplasty/kyphoplasty.
Conclusions
MVF occurred in high-risk individuals in both groups. There is no consistency in post-denosumab discontinuation management and studies are urgently needed to reveal the safest approach. Denosumab discontinuation should be avoided, especially in patients with high-risk profile.

Body composition and bone mineral density in craniopharyngioma patients: A longitudinal study over 10 years

Selvetta S Van Santen[1,2], Daniel S Olsson[3,4], Casper Hammarstrand[3,4], Mark Wijnen[1], Marta Fiocco[2,5,6], Marry M van den Heuvel-Eibrink[2], Gudmundur Johannsson[3,4], Aart Jan Van der Lely[1] & Sebastian Neggers[1,2]
[1]Erasmus University Medical Center, Department of Medicine, Endocrinology, Rotterdam, Netherlands; [2]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands; [3]Sahlgrenska University Hospital, Department of Medicine, Endocrinology, Göteborg, Sweden; [4]Sahlgrenska University Hospital, Department of Internal Medicine and Clinical Nutrition, Göteborg, Sweden; [5]Leiden University, Mathematical Institute, Leiden, Netherlands; [6]Leiden University Medical Center (LUMC), Department of Biomedical Data Sciences, Leiden, Netherlands

Introduction
Patients with craniopharyngioma (CP) suffer from pituitary deficiencies and hypothalamic damage, resulting in obesity and impaired bone health. Little is known about long-term changes in body composition and bone mineral density (BMD).
Methods
Dutch and Swedish patients were included in this retrospective longitudinal study if they had DXA-scan (body composition/BMD) data available at

age of 18 years or older. Linear regression modelswereestimated for change of Z-score of total body, L2-L4 and femur neck. Age- and sex-specific standardized deviation scores (SDS) were calculated. Data is provided as mean±standard deviation unless stated otherwise.
Results
There were 112 CPincluded [58 (52%) male, 50 (44%) childhood-onset] witha median age at first presentation of 25 years (range 0–73) and median age at last documented visit at the clinic of 49 years (range 16–82). All patients had one DXA-scan available, 86 CP had at least two DXA-scans. The mean time between first and last DXA-scan was 10.8±6.7 years. Hypopituitarism occurred in 96%. Values of body composition measures were high and increased: BMI at first DXA-scan was 30.0±4.8, the mean difference from first to last DXA-scan 1.95±3.39, P<0.001. Fat mass index (FMI) at first DXA-scan was 10.7±3.4, the mean difference to last DXA-scan was 0.86±2.41, P=0.002; fat free mass index (FFMI) at first DXA-scan was 18.3±3.2; the mean difference to last DXA-scan was 18.3±3.2, 1.15±1.86, P <0.001. However, corresponding SDS did not increase, except for FFMI SDS (from 0.26±1.63 to 1.11±2.14, P<0.001). Fat percentage (SDS) did not change. Predictors in a linear regression model for Z-score models were hydrocortisone dose (total body Z-score: beta –0.07, P=0.002), medication to improve BMD (L2-L4 Z-score: beta -1.07, P=0.008), radiotherapy (femur neck Z-score: beta –0.64, P=0.04); the estimated regression coefficient for growth hormone replacement therapy was not significant but showed a strong trend (femur neck Z-score: beta 0.81, P=0.06).
Conclusions
Patients withCP remain stable in BMI SDS, fat percentage SDS and FMI SDS and increase in FFMI SDS and BMD Z-scores. Hydrocortisone dose, radiotherapy and medication to improve BMDwere significantly associated to change in BMD (Z-score).Growth hormone replacement therapy showed a trend towards association with Z-score.

Body composition and adipokines influence upon bone mineral density and bone metabolism in renal transplant receivers

Anca Matei[1,2], Stefana Bilha[1,2], Daniela Constantinescu[3,4], Petru Cianga[3,4], Adrian Covic[5,6] & Dumitru Branisteanu[1,2]
[1]"Grigore T Popa" University of Medicine and Pharmacy, Endocrinology Department, Iaşi, Romania; [2]»St. Spiridon» Hospital, Endocrinology Clinic, Iasi, Romania; [3]»Grigore T Popa «University of Medicine and Pharmacy, Immunology Department, Iasi, Romania; [4]»St. Spiridon» Hospital, Immunology Department, Iasi, Romania; [5]»Grigore T Popa «University of Medicine and Pharmacy, Nephrology Department, Iasi, Romania; [6]»CI Parhon»University Hospital, Nephrology Clinic, Dialysis and Renal Transplant Centre, Iasi, Romania

Introduction
Renal transplant receivers (RTR) have a higher risk for osteoporosis, obesity and sarcopenia, which all seem to be interrelated. FGF23 and adipokine disorders, often recognized in RTR, might be involved in the fat-muscle-bone crosstalk. The current study aims to evaluate the influence of body compartiments and adipokines on bone mass in RTR.
Methods
Thiscross-sectional study investigates the predictive role of body composition, adipokines (leptin, adiponectin, resistin) and FGF23 upon bone mineral density (BMD) and bone metabolism parameters (osteocalcin, C-terminal telopeptide of type I collagen (CTx), calcium, phosphate) in 59 RTR and 59 age, sex and BMI-matched healthy controls, using correlation and multiple linear regression analysis.
Results
Comparative analysis of the two groups confirmed lower BMD in the RTR group at the hip, neck, forearm and whole body locations (P<0.005). In the RTR group, mean GFR was 53.93±23.98 ml/min/1.23 m^2, 86% have osteoporosis, 13.6% have sarcopenia and 47.5% are overweight.
Total lean mass (TLM), lean mass index (LMI) and appendicular lean mass index (ALMI) were mildly positively correlated with all bone parameters (P<0.001 for all). Fat mass percentage (FM%) was a negative predictor for BMD at the level of forearm (Coef R2=0.152, P=0.002) and whole body (Coef R 2=0.098, P=0.016).
Negative correlations were found between adiponectin, resistin, and lumbar and forearm BMD, respectively (P<0.05). Adiponectin is also positively correlated with osteocalcin (r=0.540, P<0.001), but negatively associated with CTx (r=–0.375, P=0.007). Leptin negatively impacts forearm (r=–0.449) and whole body BMD (r=–0.419) (P<0.005 for all) and is positively correlated with osteocalcin (r=0.280, P<0.05). No relationship was observed between serum FGF-23 or klotho levels and BMD values.
TLM and FM% remained the only independent predictors of forearm, hip and whole-body BMD inmultiple regression analysis (P<0.001) after adjusting for confounders such as age, sex, cumulative dose of corticosteroids, dialysis time period, smoking, adipokines levels, graft function.
Conclusions
This is the first study confirming the predictive role of TLM on BMD after renal transplantation, with predilection at the forearm level. Adipokines interfere with bone remodeling, both leptin and adiponectin being associated with higher levels of bone formation markers andlower level of bone resorbtion markers. Their overall negative effect on bone mineral density implies a compound effect yet to be determined.

Hip spine discordance in bone mineral density: Prevalence and potential significance

Karthik Balachandran, Shriraam Mahadevan & Adlyne Reena Asirvatham
Sri Ramachandra Institute of Higher Education and Research, Endocrinology, Chennai, India

Introduction
The WHO recommends that osteoporosis be diagnosed based on the lowest T score in hip, spine or distal 33% radius. Indian guidelines emphasize T score based diagnosis and treatment of osteoporosis..One of the reasons for measuring bone density is to account for differences in bone density between sites. The data on discordance in bone density between the hip, spine and distal radius is scarce in India - despite DXA scanning being available in India for the last 20 years. If there's a significant discordance between hip and spine, this can potentially have impact on the diagnosis of osteoporosis. With the currently available options for treatment of osteoporosis, such discordance would raise the question of selective targeting of hip or spine, depending on bone density. Thus it is important to know the prevalence of clinically meaningful discordance and its predictors in Indian patients.
Materials and methods
This was a retrospective study in which individuals who underwent BMD measurement and FRAX scoring at Sri Ramachandra Medical Centre, Chennai during the time period July 2016 to July 2018 were included. Those who have already received treatment with US Food and Drug Administration (USFDA) approved drugs for osteoporosis were excluded. Height and weight were measured using standard medical scales. Femoral neck BMD and T-score were obtained from the DXA scanner. DXA was done using the same machine for all the subjects (GE Lunar Prodigy Advance enCORE™ Version 13.60).
Discordance in the classification between hip and spine was noted. Minor discordance was defined as one step classification difference (Normal in one site and osteopenia in the other or Osteopenia in one site and osteoporosis in the other). Major discordance was defined as maximum difference in classification between sites – normal in one site and osteoporosis in the other. The analysis was repeated with ICMR normative data. Ordered logistic regression, with all the variables used in FRAX calculation, was used to identify predictors of discordance.
Results
The study included 808 adults, both men and women, above the age of 50. The mean age(sd) was 58.7 (6.2) years. The group had 56.8% men. None of the patients were taking any osteoporosis medications. In 58.2% of patients, no discordance was seen. In 2% of patients major discordance was seen and 39.9% of patients had minor discordance.
Conclusion
Hip spine Discordance is seen in 4 out of 10 patients undergoing DEXA scan.

High serum FSH is not a risk factor for low bone mineral density in infertile men

Leen Antonio[1,2], Lærke Priskorn[3,4], Inge A Olesen[3,4], Dirk Vanderschueren[1,2] & Niels Joergensen[3,4]
[1]KULeuven, Department of Chronic Diseases, Metabolism and Ageing (CHROMETA), Laboratory of Clinical and Experimental Endocrinology, Leuven, Belgium; [2]University Hospitals Leuven, Department of Endocrinology, Leuven, Belgium; [3]Rigshospitalet, University Department

of Growth and Reproduction, Copenhagen, Denmark; [4]Rigshospitalet, International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark

Background
Male infertility is associated with a higher long-term morbidity and mortality risk. However, it is not clear which diseases are contributing to this risk. Osteoporosis is a possible factor, as it is a frequent disease and sex steroids regulate both fertility and bone health. Furthermore, there are data indicating that high FSH levels in women are related to low bone mineral density (BMD), independent of estradiol levels. As infertile men often have increased FSH, already from a young age, this could be a risk factor for impaired bone health in later life.
Methods
One hundred and thirty-seven men with a history of male factor infertility due to spermatogenic failure (SgF men) as well as a control group of 70 men from couples treated with IVF for female factor infertility (non-SgF men) were included in a long-term follow-up study. Men with explained infertility, including testosterone deficiency, were excluded. Data from baseline fertility investigations were retrieved from the patient files of the SgF men. At follow-up, hormonal and semen analysis was performed and axial, femoral and total body BMD was measured by dual X-ray absorptiometryin all men. Multiple linear regression was used to assess differences between SgF and non-SgF men and to study associations between FSH levels and BMD.
Results
Median follow-up time was 14.8 years (5th-95th percentile 11.3–18.2) after fertility assessment for SgF men and 15.6 years (12.1–18.5) for non-SgF men ($p=0.033$). When comparing the two groups, no significant differences in total T, free T or E2 levels were apparent at follow-up. As expected, LH and FSH were higher in SgF men (median (5th–95th percentile)) for LH (IU/l): 4.3 (2.2–13.6) for SgF men and 3.0 (1.4–5.8) for non-SgF men ($P<0.001$); FSH (IU/l): 9.8 (2.8–35.5) vs 3.7 (1.6–8.7); $P<0.001$). Inhibin B and semen parameters were lower in SgF men.
There were no differences in BMD between the two groups. Furthermore, both groups had median Z-scores close to zero at all sites, indicating that BMD is not different when compared to age-matched healthy men. In SgF men, neither baseline FSH, nor FSH at follow-up, was associated with BMD at the different sites at follow-up.
Conclusion
Men with spermatogenic failure are not at increased risk for impaired bone health later in life. Furthermore, infertile men with high FSH levels do not have lower BMD.

Denosumab-induced hypocalcemia: Does gender play a role?

Talia Diker-Cohen[1,2], Oren Amitai[2,3], Tzippy Shochat[4], Ilan Shimon[1,2] & Gloria Tsvetov[1,2]
[1]Institute of Endocrinology, Diabetes and Metabolism, Rabin Medical Center - Beilinson Hospital, Petah Tikva, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel; [3]Clalit Healthcare Services, Dan-Petah-Tikva district, Petah-Tikva, Israel; [4]Rabin Medical Center - Beilinson Hospital, Statistical Consulting Unit, Petah-Tikva, Israel

Introduction
The recognition that disease presentation, treatment and outcomes may differ betweenmen and women has become established. We have recently reported a-7.4% rate of denosumab-associated hypocalcemia in community-dwelling osteoporotic patients.
Aim
To investigate the role of gender in this complication.
Methods
A retrospective analysis of medical records (2010–2018) from a large HMO. An albumin-adjusted serum calcium concentration ≤8.5 mg/ml was defined as hypocalcemia.
Results
A total of 1871 women and 134 men were included. Men were older (median 81 vs 77 years, $P=0.004$), more likely to receive denosumab as first-line treatment (22% vs 6%, $P<0.001$), were treated less with calcium supplements (42% vs 53%, $P=0.024$) and had a lower median eGFR level compared to women (66.1 vs 79.9 ml/min/1.73m^2, $P<0.001$).Denosumab-associated hypocalcemia developed in 133 women (7.1%) and in 16 men (11.9%) ($P=0.04$). The strongest predictors of hypocalcemia in women were pretreatment levels of albumin-adjusted serum calcium (OR 0.08, 95% CI [0.04, 0.14]) and creatinine (OR 2.43, 95% CI [1.45, 4.05]). There were no predictors for hypocalcemia in men, probably due to the small cohort. Gender was not a predictor for hypocalcemia after propensity matching of 126 men versus 126 women.
Conclusion
Contrary to previous reports, male gender *per se* is not a risk factor for denosumab-associated hypocalcemia. Despite increasing recognition of male osteoporosis, there was a considerable difference in the number of treated men and women. Men who received denosumab were significantly older with lower GFR, therefore are probably more prone to develop hypocalcemia.

Parathyroid carcinoma: An italian multicenter retrospective analysis

Laura Gianotti[1], Elena Castellano[1], Corrado Lauro[2], Alessandro Piovesan[3], Massimo Procopio[3], Marco Barale[3], Nicola Palestini[4], Francesco Quaglino[5], Luca Manfrino[5], Valentina Bullara[6], Marco Volante[7] & Giorgio Borretta[1]
[1]Santa Croce & Carle Hospital, Department of Endocrinology, Diabetes and Metabolism, Cuneo, Italy; [2]Santa Croce & Carle Hospital, Department of Surgery, Cuneo, Italy; [3]AOU Città della Salute della Scienza di Torino, Department of Endocrinology, Turin, Italy; [4]Candiolo Cancer Institute I.R.C.C.S, Thyroid and Parathyroid Surgery, Candiolo, Italy; [5]"Maria Vittoria" Hospital ASL Città di Torino, Department of General Surgery, Turin, Italy; [6]Ospedale Maggiore di Novara, Novara, Italy; [7]San Luigi Gonzaga University Hospital, Sanatorio San Luigi, Italy

Parathyroid carcinoma (PC) is a rare neoplasia responsible for about 1% of primary hyperparathyroidism (PHPT). Differently from patients with its benign counterpart, the phenotype of these patients is characterized by severe PHPT and hypercalcemia. The aim of this study was to describe a series of PC casesrecorded in the regional cancer network of Piedmont and Valle d'Aosta, Italy (Rete Oncologica del Piemonte e della Valle d'Aosta) from 2007 to 2017, including 25 patients (11 males and 14 females, mean age 59 yrs) from four hospitals (AO S. Croce e Carle in Cuneo, AOU Città della Salute e della Scienza and ASL Città di Torino in Turin and AOU Ospedale Maggiore della Carità in Novara). Disease incidence, gender, age at time of diagnosis, presence of renal and bone symptoms, serum calcium and PTH levels, surgical technique performed and percentage of recurrence were analysed. A PC incidence of 0.05 cases per 100.000 inhabitants was found in this region. PC occurred equally in males and females and affected patients mostly in their fifties. Concomitant hypercalcemia and increased PTH were present in all patients. Typical PHPT symptoms were reported in 92% of PC cases. In this series, en-bloc resection showed a 13 times lower risk of relapse compared to all the other surgical techniques. A not-radical surgical resection is associated with a higher recurrence rate. In conclusion, this series confirms that PC is equally gender distributed, with average age at diagnosis earlier than benign PHPT. A meticulous pre surgical evaluation of PHPT patients who show evocative features of PC is mandatory in order to adopt an appropriate approach and treatment of this disease.

18Fluoro-choline PET/CT is a useful tool for patients with primary hyperparathyroidism negative at first-line imaging localization tecniques

Matteo Apicella[1], Stefano Bola[2], Duccio Volterrani[2], Laura Mazoni[1], Gianluca Frustaci[3], Gabriele Materazzi[3], Claudio Marcocci[1] & Filomena Cetani[4]
[1]Endocrinology, Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Nuclear Medicine, Translational Research and New Tecnologies in Medicine, University of Pisa, Pisa, Italy; [3]Endocrine Surgery, Surgery, University of Pisa, Pisa, Italy; [4] Endocrine Unit 2, University Hospital of Pisa, Pisa, Italy

Primary hyperparathyroidism (PHPT) is a common endocrine disease mainly caused by a single parathyroid adenoma. Although the localization of the parathyroid adenoma is not a surgical criteria for parathyroidectomy, this is known to increase the cure rate of PHPT and reduce the complication rate. Neck ultrasound and MIBI-scintigraphy are the first-line localization techniques to detect parathyroid adenomas, however, they have some

limitations including the operator-dependent sensitivity and limited utility in case of a deep-laying or ectopic parathyroid. Scintigraphy is better for ectopic localizations but its sensitivity remains suboptimal. Evidence has recently emerged that parathyroid adenomatous cells are capable of capturing choline similarly to what occurs in prostate cancer, making this molecule a potential tracer in parathyroid. We conducted a monocentric study at theUniversity Hospital of Pisa in order to evaluate the utility of ^{18}Fluoro-choline PET/CT in 20 patients with PHPT candidates for surgery and with negative or inconclusive conventional imaging. All patients underwent a neck ultrasound performed by an expert physician in parathyroid disease and a double tracing MIBI SPECT/CT. Neck ultrasoundwas negative in 15/20 patients and uncertain in 4. SPECT/CT was negative in 18/20 and uncertain in 2 patients. Therefore, 18F-choline PET/CT (with early and late scans and without iodinated contrast) was performed in the whole group. A dosimetric study was done: 18F-choline PET/CT effective dose was 8.09 mSv. Twelve patients (60%) were positive, 4 (20%) inconclusive and 4 negative. Eleven patients underwent surgical removal of the lesion detected at PET/CT, of which eight with mini-invasive approach and three with an open cervicotomy due to a concomitant thyroidectomy for non toxic multinodular goiter. In all cases histology showed a parathyroid adenoma (mean size 7,3 cc, range 0.4–33.5 cc). An intraoperative PTH assay was performed in 9 cases and in all demonstrated a reduction greater than 50% of PTH levels from the highest basal value. Disease cure was confirmed in all patients after 1 month post-surgery and no surgical complications were recorded. In our experience, therefore, 18F-coline PET/TC has demonstrated a good diagnostic performance and a valid alternative in patients having negative/inconclusive conventional imaging. Furthermore, it has allowed us to avoid bilateral cervical exploration in the patients. Finally, compared to four dimensional (4D) CT, another emerging imaging method for parathyroid glands, 18F-coline PET/CT exposes the patients to less radiation (CT 4D effective dose is at least 27 mSv) and does not require the use of iodine contrast.

Effect of vitamin D supplementation on carotid intima media thickness in overweight and obese schoolchildren: A single blind randomized clinical trial

Golaleh Asghari[1], Emad Yuzbashian[1], Carol Wagner[2], Parvin Mirmiran[1] & Farhad Hosseinpanah[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Department of Pediatrics, Division of Neonatology, Shawn Jenkins Children's Hospital, Charleston, United States; [3]Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, United States

Previous observational studies suggest that low 25(OH)D concentrations in childhoodmight have deleterious effects on vasculature. The present study addresses this key knowledge gap with the use of a dose-response randomized clinical trial (RCT) aimed to determine the effect ofone-year vitamin D supplementationon carotid intima media thickness (cIMT) in overweight and obese school children. The current study was a single-blind RCT. A total of 378 children and adolescents, 6–13 y of age, with age- and sex-specific body mass index (BMI) Z-score ≥ 1 (according to the World Health Organizationcriteria)were recruited into the study. Participants were allocated to receive 600, 1000, and 2000 IU/d for 12 months. We measured cIMT at baseline and end of 12 months. In this intention-to-treat analysis, to estimate the effect size of 1000 and 2000 IU/d vitamin D in comparison to 600 IU/d, we fit a linear mixed effect model adjusted for sex, season of recruitment, and baseline cIMT, smoking exposure, physical activity, puberty status, and BMI. Participants' mean (SD) age was 9.3 (1.7) y; 52.3% wereboys with BMI z scores of 2.55(0.73). The mean (SE) for 25(OH)D were 13.7 (0.79), 14.8 (0.86), 14.8 (0.79) ng/ml at baseline (P=0.792) and 22.7(0.57), 26.1 (0.70), 30.2 (0.78) ng/ml at the end of 12 months (P<0.0001) in 600, 1000, and 2000 IU/d, respectively. The standardized mean difference (95% CI) after adjusting covariates was 0.36 (0.07, 0.65) and 0.97 (0.67, 1.28) for 1000 and 2000 IU/d vitamin D, respectively. The mean (SE) for cIMT were 0.396 (0.005), 0.403 (0.005), 0.406 (0.005) mm at baseline (P=0.389) and 0.400 (0.008), 0.405 (0.009), 0.407 (0.007) mm at the end of 12 months in 600, 1000, and 2000 IU/d, respectively (P=0.821). The cIMT change during one-year follow-up was not significant between three groups. The standardized mean difference (95% CI) after adjusting covariates was –0.0003 (–0.294, 0.293) and 0.081 (–0.207, 0.370) for 1000 and 2000 IU/d vitamin D, respectively. In conclusion, children with excess weight did not benefit from daily supplementationof 1000 and 2000 IU/d for one year compared with 600 IU/din decreasing subclinical atherosclerosis; although 25(OH)D increased.

Can serum calcium, phosphorus and parathyroid hormone levels predict histopathological diagnosis in patients with primary hyperparathyroidism?

Ahmet Dirikoc[1], Husniye Baser[1], Fatma Neslihan Cuhaci Seyrek[1], Burcak Polat[1], Berna Ögmen[1], Abbas Ali Tam[1], Cevdet Aydın[1], Aylin Kilic Yazgan[2], Mehmet Kilic[3], Didem Ozdemir[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Endocrinology and Metabolism; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Pathology; [3]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of General Surgery,

Aim
While the histopathological diagnosis is parathyroid adenoma in majority of patients with primary hyperparathyroidism (PHPT),parathyroid hyperplasia, atypical parathyroid adenoma or parathyroid carcinoma can be seen in others. Although it is known that serum calcium (Ca) and parathyroid hormone (PTH) levels are higher in patients with parathyroid carcinoma, there are not any cut-off value for serum Ca, phosphorus (P) and PTH levels defined for different histopathological parathyroid lesions. In this study, we aimed to determine cutoff levels for serum Ca, P and PTH in different histopathological PHPT lesions.
Materials and Methods
The data of 392 patients operated for PHPT were evaluated retrospectively. Patients were grouped as parathyroid hyperplasia, parathyroid adenoma and atypical parathyroid adenoma according to histopathological results. Three way ROC analysis was used to evaluate the performance of serum Ca, P and PTH to determine the three groups. It was shown that Volume Under Surface (VUS) higher than 0.17 was giving information beyond chance. Cut-off levels and correct classification rates (CCR) were calculated when the VUS value was significantly higher than 0.17.
Results
There were 19 patients with parathyroid hyperplasia, 343 with parathyroid adenoma and 31 with atypical parathyrod adenoma. Serum Ca, P and PTH levels were significantly different between groups (P=0.026, P=0.003 and P≤0.001, respectively). Serum Ca was significantly lower in parathyroid hyperplasia group compared to other two groups (P=0.032 and P=0.036, respectively). Serum Ca was similar in patients with parathyroid adenoma and atypical parathyroid adenoma (P=0.999) (Table 1). The performance of serum P and PTH to determine groups were not sufficient significantly (P >0.05). In determining the groups, only the VUS value of serum Ca was statistically significantly higher than 0.17 (P=0.005). The cut-off values for the variable were determined as C_1=10.73 mg/dl and C_2=11.40 mg/dl, respectively.
Conclusion
In this study, we found that serum Ca levels can be predictive for the histopathological diagnosis in patients with PHPT. Serum Ca lower than 10.73 mg/dl, 10.73–11.40 mg/dl and >11.40 mg/dl were determined to predict parathyroid hyperplasia, parathyroidadenoma and atypical parathyroid adenoma, respectively.

Table 1 Serum calcium, phosphorus and parathyroid hormone in patients with primary hyperparathyroidism according to histopathological diagnosis.

	Parathyroid hyperplasia (n=19)	Parathyroid adenoma (n=342)	Atypical parathyroid adenoma (n=31)	P
Calcium (mg/dl)	10.98±1.31	11.39±0.98	11.56±1.24	0.026
Phosphorus (mg/dl)	3.83±2.08	2.62±0.69	2.35±0.59	0.003
Parathyroid hormone (pg/ml)	806.71±923.07	229.82±311.67	402.54±383.46	<0.001

Is the assessment of clinical risk factors for vitamin D deficiency sufficient?

Ekaterina Pigarova[1], Svetlana Vorotnikova[1], Andrey Korolenko[2], Larisa Dzeranova[1] & Liudmila Rozhinskaya[1]
[1]Endocrinology Research Centre, Neuroendocrinology and bone diseases, Moscow, Russian Federation; [2]School № 1210, Moscow, Russian Federation

Introduction
Extremely low levels of vitamin D usually include levels < 4 ng/ml, which is almost the same as undetectable. The risk groups for vitamin D deficiency have been identified, but do they allow such patients to be identified based solely on clinical presentation.
Objective
To identify risk factors and their actual clinical determination in patients with 25(OH)D serum levels <4 ng/ml.
Materials and methods
The study included electronic medical record information of 72 individuals (mean age 43 ± 3, 59 women and13 men) with a vitamin D level of < 4 ng/ml found among 5449 patients (1,3%) tested in 2019. Total 25(OH)D was determined using the immunochemiluminescent method. The laboratory participates in the DEQAS program.
Results
No clinical information was available for 20 patients so they were excluded from further analysis. Of the clinical risk factors among the rest 52 patients: 0 – had a dark skin tone, 0 had liver failure, 0 were pregnant, 13 – BMI more than 30 kg/m^2, 12 had diseases of bones or complaints of diffuse bone pain, 6 – GFR less than 60 ml/ml, 5 – primary hyperparathyroidism, 5 patients took drugs that distirb the metabolism/absorption of vitamin D. Nineteen of 52 (37%) patients did not have any risk factor for vitamin D deficiency according to their medical record.
Conclusions
Clinical evaluation of risk factors for vitamin D deficiency does not allow to correctly identify such patientswhich may necessitate thereview of the predisposing factors or be the basis for a wider biochemical screening.

First results of an austrian prospective hypoparathyroidism registry – the HypAus study

Stefan Schatzl[1], Adelina Tmava[2], Mario Scherkl[2], Susanne Kaser[1], Astrid Fahrleitner-Pammer[2], Julia Mader[2], Maximilian Zach[3] & Karin Amrein[2]
[1]Medizinische Universität Innsbruck, Innsbruck, Austria; [2]Medical University of Graz, Graz, Austria; [3]Lkh Hartberg, Hartberg, Austria

Background
Permanent hypoparathyroidism is the most common complication of thyroid surgery with a reported incidence of 2-10% depending on the observation time, extent of surgery and underlying disease, with higher risk for total thyroidectomy and Graves disease/thyroid cancer. European data on chronic hypoparathyroidism have been reported from several countries, especially Scandinavia. We therefore aimed to add more information from Central Europe.
Methods
In this ongoing prospective Austrian multi-center observational registry at the Medical University of Graz and the Medical University of Innsbruck, we include adult patients with hypoparathyroidism of all etiologies. Routine clinical and laboratory data is collected for all patients. Extensive neurocognitive assessment with comparison to a normative collective is performed in a subgroup of patients and will be reported separately, including the Trail Making Test A and B (TMT-A and TMT-B).
Results
So far, we included 47 patients. 39 are women (83%), and the average age is 61 ± 17 years. 13% have nonsurgical etiologies (ie. AIRE or 22q11 mutations, "idiopathic"), and 87 % had postsurgical hypoparathyroidism. Both hypercalcemia and hypocalcemia were common. Paresthesia and tetany was reported by most patients. In postsurgical hypoparathyroidism, the median time between surgery and diagnosis of hypoparathyroidism was 5.5 years (range: 0–67 years). Treatment included calcium, active vitamin D, vitamin D, hydrochlorothiazide, magnesium and teriparatide. Three patients were started on rhPTH 1–84 (Natpar) since early 2018. TMT-A and TMT-B were performed in 15 patients and showed slower task resolution for TMT-A: 32 (IQR: 22–38) vs 29 seconds (IQR: 24–37), $P = 0.233$ and TMT-B (median = 78; IQR: 72–109 vs 58 seconds, IQR: 51–89, $P = 0.001$).
Conclusion
In this prospective registry, we report and continue to collect real-world data of hypoparathyroid patients in Austria with the goal to increase awareness and facilitate optimization of care of this rare disease.

Renal complications in patients with chronic hypoparathyroidism receiving conventional therapy: A systematic literature review

Elvira Gosmanova[1], Pascal Houillier[2], John Bilezikian[3], Claudio Marelli[4] & Lars Rejnmark[5]
[1]Albany Medical College, Division of Nephrology, Department of Medicine, New York, United States; [2]Georges Pompidou European Hospital and Paris University, Department of Physiology, Paris, France; [3]Columbia University, Division of Endocrinology, College of Physicians and Surgeons, New York, United States; [4]Shire International GmbH, a Takeda company, Medical Affairs, Zurich, Switzerland; [5]Aarhus University and Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark

Conventional therapy for chronic hypoparathyroidism is oral calcium and active vitamin D; despite treatment, chronic hypoparathyroidism may be associated with increased risk of renal complications. Without the effect of parathyroid hormone on renal tubular reabsorption, calcium-conserving and phosphaturic effects are lost, serum calcium levels are reduced and serum phosphate levels are increased. This may lead to hypercalciuria and hyperphosphataemia, which may be associated with long-term renal complications. A systematic literature review was performed to summarise the frequency and nature of renal complications in patients with chronic hypoparathyroidism managed with conventional therapy. Abstracts with specified MeSH terms were identified using the PubMed, EMBASE, and Cochrane databases. Pre-defined outcomes were nephrolithiasis, nephrocalcinosis, and chronic kidney disease (CKD). Papers that described estimated glomerular filtration rate (eGFR) were also selected. The search yielded 1200 articles; following screening and assessment for eligibility, 21 articles reported data for nephrolithiasis/kidney stones, nephrocalcinosis, and/or CKD. Data were extracted from 13 manuscripts with renal outcomes for ≥10 adult ($n = 11$ manuscripts) or paediatric ($n = 2$ manuscripts) patients. Some articles contributed to ≥1 outcome category. Due to the heterogeneity of the studies, a meta-analysis could not be conducted. The reported rate of nephrolithiasis was ≤36%, including 0% in the Levy et al paediatric study, with low rates in other studies reporting shorter duration of disease (Table). Nephrocalcinosis was ≤ 38%, with 2 studies reporting rates of 0% (Table). Nephrolithiasis and/or nephrocalcinosis was 19%–31%, and CKD/kidney failure/renal insufficiency 2.5%–41% (Table). Chronic hypoparathyroidism is a rare disease, which likely contributed to the heterogeneity in reported renal complications in this systematic literature review. Overall, however, patients with chronic hypoparathyroidism who receive conventional therapy had an increased risk of renal complications. Limitations of this systematic literature review are the differences in study design, heterogeneity in imaging methods, which may have affected detection/differentiation of small stones/parenchymal calcinosis, and heterogeneity in the methods of reporting renal outcome data. Additional large-scale studies are needed to understand how the disease pathophysiology and/or conventional treatment may increase the risk of renal complications in patients with chronic hypoparathyroidism.

Renin-angiotensin-aldosterone system in patients with primary hyperparathyroidism

Ekaterina Dobreva, Ekaterina Bibik, Anna Eremkina, Julia Krupinova, Svetlana Mirnaya, Alina Ajnetdinova & Natalia Mokrysheva
Endocrinology Research Centre, Parathyroid pathology department, Moscow, Russian Federation

Background
Hypertension is one of the widespread cardiovascular pathology in patients with primary hyperparathyroidism (PHPT).The renin-angiotensin-aldosterone system (RAAS) is a key system in the regulation of blood pressure and its interactions with mineral metabolism are described. Our previous study* of PHPT patients revealed a significant decrease in plasma renin activity (PRA) and serum aldosterone levels in the early postoperative period and also positive correlations of calcium and PTH with RAAS parameters.
The aim of this study was to investigate follow-up changes of the RAAS activity in PHPT patients one year after surgery.
Material and Methods
We have examined 27 patients with PHPT (24 women, 3 men; median age 55 years [37; 59]) within a year (12±1.3 months). All patients underwent biochemical and hormone evaluation before, in 3 daysand 1 year after surgical treatment for PHPT. The exclusion criteria were the glomerular filtration rate <75 ml/min/1.73 m², severe cardiovascular pathology, obesity, diabetes mellitus, using drugs affected calcium balance before and in 12 month after radical surgery. Control group was sex- and age-matched without cardiovascular pathology and any mineral disturbances (median serum calcium 2.45 mmol/l [2.42; 2.49], PTH 32.94 pg/ml [27.2; 41.6]).
Results
All patients initially had symptomatic PHPT (median serum calcium level 2.74 mmol/l [2.66; 2.9], PTH 123.8 pg/ml [85.8; 203]). Hypertensionwas observed in 37% and corrected with ACE-inhibitors or angiotensin II receptor blockers. PHPT patients had lower plasma renin activity (PRA) and higher serum angiotensin II (AT II) level comparing to control group (0.49 [0.11; 1.8] vs 1.23 [0.74;2.24] ng/ml*h, $P=0.02$ and 38 [30;42.2] vs 25.64 [20.14;35.44] pg/ml, $P=0.04$ respectively). At the 3rd day after surgery the blood evaluation revealed a significant decrease in PRA ($P=0.001$), whereas at 12th month there were decrease in AT II ($P=0.03$) and increase in PRA ($P=0.018$). Serum aldosterone level did not show any significant changes ($P=0.62$). There were no differences in the RAAS components between PHPT and control groups. However wefound a positive correlation of intact PTH with aldosterone in 3 days ($P=0.04$) as well as intact PTH with AT II levels at 12th month ($P=0.03$) after parathyroidectomy in non-therapy subgroup.
Conclusion
Our resultsdemonstrated the interaction between RAAS activity and PHPT, but further studies are required.

Gene expression of claudins in NCKX3 knockout mouse

Seon Myeong Go, Donglin Yi, Jae-Hwan Lee, Yeong-Min Yoo & Eui-Bae Jeung
Chungbuk National University, College of Veterinary Medicine, Cheongju-si, Korea, Republic of South

Potassium-dependent sodium/calcium exchanger (*NCKX3*) is expressed in the brain, smooth muscle, the uterus, and intestine. NCKX3 gene plays a role in transporting intracellular calcium and potassium ions across the cell membrane in exchange for extracellular sodium ions. This gene is also associated with calcium metabolism in bones. Tight junctions have functional barriers for material transport and osmotic balance, which are regulated by calcium metabolism. Claudin, one of the tight junction protein members, take a part in a barrier preventing free diffusion and generate the paracellular pore pathway with unique cation- or anion-selectivity. The study has investigated the expressions of intestinal epithelial claudin genes in the duodenum of 6 week-aged Nckx3 knockout (KO) mice. The mRNA and protein levels of claudin-2, -5, and -15 were increased in Nckx3 KO mice compared to wild-type mice. However, mRNA and protein levels of claudin-12 were decreased in Nckx3 KO mice. We also found that *Ifit1, Zbp1, Oasl1, Oasl2, H2-DMb1* and *H2-Aa* genes were up-regulated in Ncxk3 KO mice, and *Gkn2, Gkn3, Tff2* and *Tff1* genes were down-regulated in Ncxk3 KO mice in gene expression profiles using an Affymetrix GeneChips. These results suggest that the *NCKX3* gene may be involved in tight junction and calcium metabolism in duodenum.

Progression of vertebral fractures in long-term controlled acromegaly: A 9-year follow-up study

Iris Pelsma[1], Kim Claessen[1], Alberto Pereira[1], Wouter van Furth[2], Natasha Appelman-Dijkstra[1], Margreet Kloppenburg[3,4], Herman Kroon[5] & Nienke Biermasz[1]
[1]Leiden University Medical Center, Department of Endocrinology and Metabolism, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Neurosurgery, Leiden, Netherlands; [3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [4]Leiden University Medical Center, Department of Epidemiology, Leiden, Netherlands; [5]Leiden University Medical Center, Department of Radiology, Leiden, Netherlands

Objective
Growth hormone (GH) and insulin-like growth factor 1 (IGF-1) excess results in both reversible and irreversible damage to the skeleton, and includes increased vertebral fracture (VF) risk in the presence of normal BMD. The prevalence of VFs is approximately 60% in controlled acromegaly patients, and these VFs can progress during short-term follow-up. We aimed to identify the course of VFs and their associated risk factors in a cohort of acromegaly patients in long-term remission during long-term follow-up.
Methods
Thirty-one patients with acromegaly (49% female, median age 60 yrs (IQR 53 – 66)), who were in biochemical disease remission for a median of 12 years (IQR 7 – 17) following uni- or multimodality treatment, were included in this longitudinal, prospective, follow-up study. Spine radiographs of vertebrae Th4 to L4 were assessed for VFs using the Genant score, at baseline, after 2.6 yrs and 9.1 yrs of follow-up. Progression was defined as either a new fracture, or a ≥1-point increase in the Genant score.
Results
The prevalence of VF at the baseline visit was 87.1% (27/31 patients), and the number of VFs was associated with active disease duration ($r=0.462$, $P=0.009$). Progression of VFs was observed in eleven patients (35.5%),

during the 9.1-year follow-up period, with a total incidence rate of 65.5 per 1,000 PY (Males 59.8/1,000 PY vs females 71.6/1,000 PY). VF progression occurred more frequently between baseline and the first follow-up visit, with an incidence rate of 86.9/1,000 PY, compared to the period between the first and second follow-up visit (incidence rate of 57.7/1,000 PY). Patients treated with surgery or radiotherapy had a higher risk of VF progression in this cohort in comparison with medical treatment (OR 17.3 (95% CI 1.5 – 203.7), $P=0.023$).
Conclusions
In this cohort of long-term well-controlled acromegalic patients, the prevalence and progression of VFs was high, showing that deleterious effects of the transient GH and IGF-1 excess persist despite achievement of long-standing remission. Therefore, there is a clinical unmet need for strategies to prevent fractures in newly diagnosed and chronic patients with acromegaly.

Assessment of physical fitness after bariatric surgery and its association with protein intake and type of cholecalciferol supplementation

Hendrika Smelt[1], Sjaak Pouwels[2], Alper Celik[3], Adarsh Gupta[4] & Johannes Smulders[1]
[1]Catharina Ziekenhuis, Eindhoven, Netherlands; [2]St. Elisabeth Hospital, Tilburg, Netherlands; [3]Metabolic Surgery Clinic, Istanbul, Turkey; [4]Rowan University School of Osteopathic Medicine, Stratford, United States

Background
Several studies showed that there is a relationship between vitamin and mineral status and muscle strength. In particular this is the case for handgrip strength (HS) and vitamin D deficiency. In bariatric surgery there is a risk of decrease in muscle strength after surgery and also vitamin and mineral deficiencies are not uncommon. The aim of this study is to assess the effect of low vitamin 25 (OH) cholecalciferol levels, high dose cholecalciferol supplementation regime and protein intake on physical fitness, measured using handgrip strength (HS) and the shuttle walk run test (SWRT).
Methods
For this retrospective study, 100 patients who have had bariatric surgery were included. Group A ($n=50$) used 800 IU oral cholecalciferol per day. Group B ($n=50$) used 800IU oral cholecalciferol daily and 50000 IU liquid colecalciferol monthly lifelong. Both groups were matched on common variables. To measure physical fitness we used the HS manometer of Jamar and the Shuttle Walk Run Test (SWRT) to assess physical capacity.
Results
No significant differences in HS and SWRT outcomes were found between patients with serum 25 (OH) cholecalciferol <75 nmol/l or >75 nmol/l. The postoperative HS is significantly influenced by protein intake ($P=0.017$) and no significant influence was seen in outcomes of the SWRT ($P=0.447$).
Conclusion
We have found that serum 25 (OH) cholecalciferol and different cholecalciferol supplementation regimes do not have a significant effect on HS and SWRT before, three and 6 months after surgery. It seems that protein intake plays a more important role in maintaining adequate muscle strength.

The Burden of chronic hypoparathyroidism in canada: A retrospective study using the institute for clinical evaluative sciences (ices) database

Aliya A Khan[1], Kristina Chen[2], Claudio Marelli[3] & Lidia Demchyshyn[4]
[1]McMaster University, Department of Medicine, Divisions of Endocrinology and Metabolism and Geriatric Medicine, Ontario, Canada; [2]Shire Human Genetic Therapies, Inc., a Takeda company, Global Outcomes Research Epidemiology Data Sciences Institute, Massachusetts, United States; [3]Shire International GmbH, a Takeda company, Medical Affairs, Zurich, Switzerland; [4]Shire Pharma Canada ULC, a Takeda company, Internal Medicine, Ontario, Canada

Hypoparathyroidism is a rare disorder characterised by hypocalcaemia and hyperphosphataemia in the presence of low or inappropriately normal parathyroid hormone levels. Currently there are limited data on the burden of illness and healthcare resource utilisation (HCRU) associated with chronic hypoparathyroidism in Canada. A retrospective cohort analysis with matched controls was conducted to examine HCRU in patients with chronic hypoparathyroidism in Ontario, Canada. Data were extracted from the ICES database, which includes 7 integrated sources of clinical information. Patient selection included the following 3 stepwise criteria for hypoparathyroidism: (1) Hypoparathyroidism diagnosis based on 5 hypoparathyroidism diagnosis codes, (2) inferred hypoparathyroidism based on ≥1 procedure associated with the development of hypoparathyroidism in combination with a Ca^{2+} metabolism disorder, and (3) inferred hypoparathyroidism in the presence of disorders associated with hypoparathyroidism in combination with a Ca^{2+} metabolism disorderaccompanied by a diagnosis of hypoparathyroidism or a recognised complication of hypoparathyroidism in the following 6–24 months. Patients' baseline characteristics were assessed during a 1-year preindex period and were followed for up to 5 years after their index date, which was the date of the first diagnosis. Each patient was matched with 4 nonhypoparathyroidism controls based on age, sex, the Charlson Comorbidity Index, and hospitalisation (within ± 30 days of index date), and HCRU was compared using the Fisher exact test. The analysis included 427 patients with chronic hypoparathyroidism (mean age, 61 years; 75% female). Over the 5-year follow-up period, HCRU was significantly higher in patients with chronic hypoparathyroidism compared with the control cohort (Table). HCRU included visits to family physician/specialist, emergency department visits, same-day surgery, and hospitalisations. Patients with hypoparathyroidism had approximately 3-times-longer hospital stays during the first year of follow-up and overall longer hospital stays during all 5 years than the control group. Given the lack of a specific diagnostic code for hypocalcaemia, a code for both hypo- and hypercalcaemic diagnoses was used with selection criteria aimed at identifying those with hypoparathyroidism. Also, there was a time lag between data collection and data analyses. This study confirms the demographic features of patients with chronic hypoparathyroidism in Canada are consistent with other countries. Chronic hypoparathyroidism is associated with a substantial healthcare burden in patients and also on the healthcare system.
Funding: Shire, a Takeda company.

Table HCRU of Patients With Hypoparathyroidism vs Matched Controls

	Hypoparathyroidism, %	Control, %	*P* Value
Visits to family physician	100	97	<0.05
Visits to specialist	100	93	<0.05
Emergency department visits	59	81	<0.05
Same day surgery	62	50	<0.05
Hospitalisations	72	54	<0.05

Cinacalcet use in pregnancy for a case of multiple endocrine neoplasia (MEN) 1 - associated primary hyperparathyroidism

Chiedza Mashamba[1], Papa Essilfie[2] & Mohit Kumar[1]
[1]Royal Albert Edward Infirmary, WWL Foundation Trust, Department of Diabetes and Endocrinology, Wigan, Greater Manchester, United Kingdom; [2]Royal Albert Edward Infirmary, WWL Foundation Trust, Department of Obstetrics and Gynaecology, Wigan, Greater Manchester, United Kingdom

Hypercalcaemia in pregnancy is associated with foetal (IUGR, miscarriage and preterm delivery), maternal (hypercalcaemic crisis, pre-eclampsia, and hyperemesis) and neonatal complications, with severity of hypercalcaemia correlating with the risk of complications. The true incidence of primary hyperparathyroidism in pregnancy is unknown.
A 32 year old lady (G6 P5) with known MEN 1 and associated primary hyperparathyroidism (peak calcium 3.30 mmol/l) presented to the antenatal endocrine clinic at 12 weeks gestation. Her adjusted calcium was 3.24 mmol/l. She was referred for parathyroidectomy at the local tertiary endocrine/ma-

ternity hospital as she was in her second trimester, but because of pre-existing psychological problems she failed to attend on multiple occasions and was lost to follow-up. She re-attended at 29 weeks gestation having been unable to tolerate an OGTT for GDM due to nausea. Having declined transfer, and with ongoing issues with nausea, hypercalcaemia and osmotic symptoms, and considering the high levels of calcium recorded in pregnancy, she was counselled about the use of Cinacalcet and commenced on 30 mg OD with a calcium of 2.90.The dose was titrated up to 30mg TDS slowly with a gradual decline in calcium to 2.77. At 37+1 labour was induced due to IUGR and SGA. The following day a baby (2400 g) was delivered by NVD, with Apgar 10 and 10. Discharge was 24 hours later with no complications, and there have been no issues with the baby to date. Mother was discharged home with Cinacalcet as she was not breastfeeding.
Second trimester parathyroidectomy for primary hyperparathyroidism in experienced hands is the consensus recommendation for pregnancy. Cinacalcet is a calcimimetic drug, lowering PTH levels via the CaSR receptor, that is licensed in Europe for the treatment of primary hyperparathyroidism where surgery is not an option. Studies have efficacy in calcium lowering has been shown in primary hyperparathyroidism and also specifically MEN 1 related. A lack of clinical data means that it is not licensed for use in pregnancy, with current evidence limited to case reports. Animal studies have shown no concerns to date.
MEN 1 associated hyperparathyroidism in pregnancy brings its own challenges including genetic counselling and the question of extent of surgical intervention. To our knowledge this is only the second reported case of the use of cinacalcet for MEN 1 – related primary hyperparathyroidism in pregnancy and adds to the evidence base, though in this case efficacy was only mild.

An enlarged parathyroid gland emerging in the bed of the thyroid may mimic local recurrence in patients after total thyroidectomy for the papillary thyroid cancer: How does recovery from postsurgical hypoparathyroidism work?

Paulina Godlewska[1], Joanna Długosińska[1], Elwira Bakuła-Zalewska[2], Marek Chojnowski[1] & Marek Dedecjus[1]
[1]The Maria Skłodowska-Curie National Institute of Oncology – National Research Institute, Department of Endocrinological Oncology and Nuclear Medicine, Warsaw, Poland; [2]The Maria Skłodowska-Curie National Institute of Oncology – National Research Institute, Department of Pathology, Warsaw, Poland

Anatomical proximity, common blood supply and variability of location of the parathyroid glands make them prone to damage in the course of thyroid gland surgery. Total thyroidectomy (TT) poses a greater risk of postsurgical hypoparathyroidism (hypoPT) than a unilateral lobectomy, and neck lymph nodes dissection is an established risk factor of HypoPT. HypoPT lasting longer than 6–12 months postoperatively is considered permanent. The mechanism responsible for the recovery of parathyroid gland function has been a subject of debate.
We present two patients in whom a neck sonography showed a hypoechogenic, vascularized structure in the bed of the thyroid gland which had been removed for papillary thyroid cancer (PTC).
A hypoechogenic lesion was visualized in the bed of the right thyroid lobe two years after TT for PTC of the ipsilateral thyroid lobe in a 70 yr man. Epithelial cells with signs of atypia, scattered lymphocytes as well as microcalcifications, suspicious for cancer recurrence, were found on fine needle biopsy. Excision of the lesion was performed. On the pathologic examination parathyroid adenoma, composed of main, oxyphyllic and clear cells was found. The patient was normocalcemic before as well as after the operation. Hypophosphatemia had been the only biochemical feature of hyperparathyroidism.
A 51-yr woman underwent TT for bifocal PTC. Parathyroid glands were not found in the pathological material, however she required treatment for postsurgical hypoPT. In the eighth year of the follow-up a raise in serum calcium concentration made further treatment for HypoPT unnecessary. Meanwhile a hypoechogenic vascularized 10 mm structure in the bed of the left thyroid lobe was shown on the sonography. Serum concentration of PTH, total calcium and phosphate were: 56 pg/ml (n 12–65 pg/ml), 2.4 mmol/l (n 2.2–2.65 mmol/l), 0.96 mmol/l (n 0.81–1.45 mmol/l), respectively. Scintigraphy with 99mTc-MIBI using planar and SPECT/CT technique was performed to elucidate a character of the lesion. A hot spot situated on the left and 15 mm beneath the thyroid cartilage, corresponding to the enlarged parathyroid gland was visualized.
According to the Guidelines for Treatment of Chronic hypoPT in Adults released recently by ESE, serum calcium concentration should be maintained in the low or slightly below normal range in order to avoid hypercalciuria.
In cases of postsurgical hypoPT, keeping low serum calcium concentration may favor hypertrophy or hyperplasia of the remaining functioning parathyroid parenchyma, which especially in patients with neck cancer anamnesis needs to be differentiated form a malignancy.

Fahr's disease in primary hypoparathyroidism – a case report

Adela Haxhiraj, Violeta Hoxha, Gerond Husi, Marjeta Kermaj & Agron Ylli
"Mother Teresa" University Hospital Centre, Endocrinology, Tirana, Albania

Introduction
Basal ganglia calcification or Fahr's Syndrome is a rare form of neurological disorder. Its prevalence goes from 2 to 12.5 %. It can be primary (idiopathic) or secondary (from metabolic disorders especially from hypoparathyroidism).We present the case of a female patient with hypoparathyroidism and secondary Fahr's Disease.
Case description
The patient L.J. 61 years old, from Pogradec, Albania, who came to the emergency room with complaints of body weakness, severe fatigue, left side numbness and headache. The patient mentioned several similar episodes during the years. A month ago, she got a head injury, with an open bleeding wound because of disorientation and extreme fatigue. The patient was being treated only for Arterial Hypertension withIrbesartan/ Amlodipin (150/5), one tablet a day.
At the emergency room, a CT of the head was performed in order to exclude acute cerebral damages. During the examination, diffuse cerebral and cerebellar calcifications were seen, identified as FAHR Disease. The patient was first hospitalised in the Neurology Department where she was treated for her immediate symptoms. During her hospital stay her blood test came as shown below: Biochemical parameters within normal range. Thyroid stimulating hormone (TSH) 3.241 U/ml (0.4 – 4). Total calcium 3.3 mg / dl (8.6 – 10.2 mg/dl). Phosphatemia 7.6 mg / dl (2.5 – 4.5 mg/dl). Blood Magnesium level 1.7. mg / dl (1.8 – 2.2 mg/dl). Calcium in 24-hour Urine 8.7 mg / day (100 – 300 mg/day). Phosphorous in 24-hour urine 14.2 mg/dl (400 – 1300). Parathyroid hormone (PTH) 1.2 ng / L (15 – 65 ng/ L). 25 – OH – Vitamin D 15.24 ng/ml (> 30 ng/ml).
During the thyroid ultrasound, it was evident a heterogeneous bilateral structure favouring Hashimoto's thyroiditis.
Normal electroencephalogram was obtained. The patient was later transferred in our Department because of the new found diagnosis: Primary Hypoparathyroidism, FAHR Disease and Hypovitaminosis D.
Patient began treatment with intravenous Calcium and in just a few days her symptoms became less evident. She was discharged from hospital with oral Calcium (2000 mg/day) and Vitamin D3 (2000 UI/day) and was advised to check in with her endocrinologist for future follow up.
Conclusions
Fahr's Disease is a well-known but rare complication of hypoparathyroidism. In order to early diagnose,a thorough clinical-radiological and biochemical evaluation should be made.

Varied clinical presentation of pseudohypoparathyroidism- series of three distinctive cases

Hemant Phatale & Priti Phatale
Samrat Endocrine Institute, Consultant Diabetologist and Endocrinologist, Aurangabad, India

Introduction
Pseudohypoparathyroidism (PHP) is a state of parathyroid hormone resistance and is characterised by low serum calciumand elevated serum phosphate and parathyroid hormone level

Case descriptions
We describe three cases diagnosed with PHP. *Case 1*: 14 year old male, known case of hypothyroidism, presented with carpopedal spasm and on treatment with 75 mg oflevothyroxine, with short height of 143 cm (less than 3rd percentile), BMI 23.23 kg/m^2 which was deemed to be overweight as per Indian Academy of Pediatrics (IAP) standard. The patient had signs of Albright Hereditary Osteodystrophy (AHO). Investigations revealed hypocalcemia (serum calcium 6.2 mg/dl), hyperphosphatemia (serum phosphorus level of 6.5 mg/dl) and high levels of Parathyroid Hormone (PTH) (889 pg/ml), normal vitamin D levels (25 OHD – 63.2 ng/ml). Alkaline Phosphatase (AP) levels were normal. TSH, FSH and calcitonin levels were elevated, with Sexual Maturity Rating (SMR) Tanner III and low testicular volume of 5 ml. *Case 2*: 13 years female presented with carpopedal spasm with signs of AHO, with short height of 128 cm (less than 3rd percentile), BMI 22.89 kg/m^2 (overweight). Investigations revealed hypocalcemia (serum calcium 5.8 mg/dl), hyperphosphatemia (serum phosphorus level of 4.8 mg/dl) and high levels of PTH (221 pg/ml), normal vitamin D levels (25 OHD –70.1 ng/ml), with elevated AP levels. TSH levels were normal. Patient had primary amenorrhea, hence had not attained menarche. FSH levels were 2.1 mIU/ml, LH 0.97 IU/l E 22 pg/ml. *Case 3*: 11 year old male presented with carpopedal spasm and convulsions. Investigations revealed hypocalcemia (serum calcium 7.3 mg/dl), hyperphosphatemia (serum phosphorus level of 7.56 mg/dl) and very high levels of PTH (1879 pg/ml), with normal AP. No signs of AHO, normal height, SMR was prepubertal with normal TSH levels.
Discussion
We diagnosed these as PHP based on the current global consensus statement with PTH resistance for the association of hypocalcaemia, hyperphosphataemia and elevated PTH in absence of vitamin D deficiency with normal magnesium levels and renal function. The case 1 with possible G(s) protein resistance, as FSH, TSH and calcitonin were high was diagnosed as PHP 1a. The second case was categorized PHP 1b but PHP 1a cannot be ruled out. Further, molecular analysis would have assisted with a precise diagnosis. The third case was diagnosed as PHP type 2. The management plan was based on true hypoparathyroidism including Vitamin D supplementation, with varied prognosis

Testosterone, estradiol and 25-hydroxyvitamin D effects at the proximal femur in 3D analysis from a standard 2D DXA scans of adult men

Mário Rui Mascarenhas[1], Ana Paula Barbosa[2] & Renaud Winzenrieth[3]
[1]Environmental Health Institute, Lisbon´s Faculty of Medicine, CEDML – Lisbon's Endocrinology, Diabetes and Metabolism Clinic (Osteoporosis Unit), lisboa, Portugal; [2]Environmental Health Institute, Lisbon´s Faculty of Medicine, CEDML – Lisbon's Endocrinology, Diabetes and Metabolism Clinic (Osteoporosis Unit), Endocrinology, Diabetes and Metabolism Service, Santa Maria University Hospital, CHLN-EPE, lisboa, Portugal; [3]Galgo Medical, Osteoporosis, barcelona, Spain

Sex steroid hormones play a pleomorphic role in preservation of BMD. The BMD, the blood circulating 25-hydroxyvitamin D [25(OH)D], testosterone and estradiol levels may decline with age and to contribute to bone fragility. Low vitamin D is associated with increased falls number and fractures.
Recently, a new software solution, 3D-SHAPER - allows measurements of both trabecular and cortical bone as well as 3D images -, it incorporates a model-based algorithm to analyse the bone in 3D from a standard DXA scan, with no additional radiation to the patients.
However, the role of the blood steroid hormones on the 3D analysis of the proximal femur is not yet recognized.
Objectives
To correlate the 3D parameters analysis, as assessed by 3D-SHAPER, with blood steroid hormone levels of adult men.
Material and methods
All participants (adult men=97) had a DXA exploration (QDR4500 Acclaim and Discovery W, Hologic Inc, USA) at spine and at non-dominant femur (g/cm^2). 3D DXA modeling was performed using a software algorithm (3D-SHAPER v2.9, Galgo Medical, Spain) in order to derive QCT-like subject-specific 3D models from the hip DXA scans of the study subjects. The following 3D measurements were extracted: the trabecular and cortical volumetric BMD (Trabecular/cortical vBMD), the cortical thickness (Cth) and the cortical surface BMD (Cortical sBMD) as well as neck cross-sectional moment of inertia (CSMI) and Z modulus. In addition, appendicular fat and lean mass were assessed using dedicated DXA acquisition.
Blood was collected for 25(OH)D (ng/ml), total testosterone (T, ng/ml), 17β-estradiol(E_2, pg/dl) and sex hormone binding globulin (SHBG, nmol/ml) measurements.
Adequate statistical tests were used.
Results
In 97 adult men [mean (± SD) age 60.1(±13.5) years, mean BMI 25.3 (2.7)kg/m^2] the mean BMD at the lumbar spine BMD=1.030 (± 0.2) and at the total femur=0.978 (±0.1), total body fat mass=20.7 (±15.7) kg and total body lean mass=52.8 (±15.5)kg. The mean E_2=28.3 (±19.6), T=4.9 (±11.8), SHBG=43.2 (±19.2) and 25(OH)D=24.1 (±11.0). The some of correlation coefficients are in Table below. No correlations were detected for the 3D parameters and 25(OH)D and the E_2 levels.

3D Analysis vs	vBMD Integral Total mg/cm^3	*P*	Volume Integral Total cm^3	*P*
T	–0.3035	0.0056	0.2499	0.0296
SHBG	0.2491	0.0223	0.2175	0.0469

Conclusions
It seems that androgens play a very important role on bone strength; normal men with low blood testosterone levels may have low 3D parameters and thus worse bone strength; it is possible that testosterone acts positively in bone strength. Further studies are needed on a larger cohort and it might be worth to investigate men with hypogonadism.

Trabecular bone score assessment in heart transplant recipients stratified by time after transplantation

Matej Rakusa, Andrej Janez & Mojca Jensterle
Department of Endocrinology, Diabetes and Metabolic Disease, University Medical Centre Ljubljana, Ljubljana, Slovenia, Ljubljana, Slovenia

Objective
Bone strength post heart transplant (HT) is affected by many factors including glucocorticoids, calcineurin inhibitors, hypogonadism, vitamin D deficiency, secondary hyperparathyroidism and cachexia. Trabecular bone score (TBS), novel texture index derived from lumbar spinal DXA improves fracture risk assessment in several different high-risk populations, whereas it remains largely understudied in HT recipients. We aimed to evaluate factors that affect TBS after HT.
Materials and Methods
We conducted cross sectional cohort study including 87 HT patients (69 males and 18 females),of median age 59.3 years (IQR 53–66.5) that were stratified according to post-transplantation time into Group 1 (less than 1 year after HT;22 patients), Group 2(1 to 3 years post HT; 15 patients) Group 3 (3 to 5 years post HT; 31 patients) andGroup 4(more than 5 years post HT; 19 patients). We compared TBS and BMD among those groups. In addition, we assessed impact of methylprednisolone, bisphosphonate, male hypogonadism and presence of vertebral fractures on TBS.
Results
Compared with Group 1, patients in the 2nd and 3rd Group had lower TBS (1.35 (IQR 1.26–1.41) vs 1.30 (IQR 1.26–1.36) vs 1.25 (IQR 1.17–1.29) respectively; (pairwise comparison between Group 1 and 3 P=0.020)), whereas in Group 4 TBS was higher than in Group 3 and comparable to Group 2 (1.31 (IQR 1.23–1.38). By contrast, BMD and T values did not differ among the 4 groups. Body mass index (BMI) was significantly higher in each group along observed time period (Group 1 (22.6 kg/m^2 (IQR 21.1–24.4)) vs Group 2 (24.7 kg/m^2 (IQR 24.2–28.0) vs Group 3 (28 kg/m^2 (IQR 25.5–30.4)) vs Group 4 (27.6 kg/m^2 (IQR26.2–30.0); <0.001 pairwise comparison: Group 3 vs Group 1 P <0.001 and Group 4 vs Group 1 P <0.001). Methylprednisolone, bisphosphonates, presence of male hypogonadism and vertebral fractures had no impact on TBS.

Conclusions
TBS in HT patients significantly differed among groups stratified by time after transplantation, independently of treatment with methylprednisolone, bisphosphonates or presence of male hypogonadism and vertebral fractures. By contrast, BMD was comparable among all Groups over time, being considered as less sensitive indicator of bone strength over post-transplantation time. Spontaneous reversal of declining trend in TBS observed more than 5 years after transplantation along with gradual significant improvement in BMI, imply cardiac cachexia and its reversal as one of the potential impacts on bone microstructure. The role of TBSin this population needs further investigation in longitudinal studies.

Efficacy of teriparatid therapy in resistant hypocalcemia depending postoperative hypoparathyroidism

Buğra Durmuş, Gülsüm Karaahmetli, Müge Keskin, Belma Tural Balsak, Hüsniye Başer & Dilek Berker
Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective
While postoperative hypoparathyroidism can usually be controlled with elemental calcium (Ca) and calcitriol therapy, rarely this treatment may be inadequate and teriparatid therapy may be used as an alternative. In the literature, it is reported that teriparatid therapy is effective and reliable in the treatment of patients with postoperative hypoparathyroidism, as well as improving quality of life and reducing the frequency of hospitalization. In this report, we present a case of postoperative hypoparathyroid disease that was followed up due to treatment resistant hypocalcemia and responded to teriparatid therapy.
Case
41 - year-old female patient, 3 years ago due to papillary thyroid carcinoma after total thyroidectomy developed in the hands-feet with numbness and tingling complaints were admitted to the outpatient clinic. Serum total calcium: 4.9 mg/dl, phosphate:5.5 mg/dl, intact PTH:0.7 ng/l were determined and oral Ca and calcitriol treatment was started after the diagnosis of postoperative hypoparathyroidism. Although calcitriol was given 6 mg/day, elemental Ca 15 gr/day dose, Ca values remained at 6.5–7 mg/dl (Table 1) level after the patient received replacement therapy for approximately 2 months. The patient's complaints continued clinically and the patient was hospitalized several times due to the need for intravenous Ca. Subcutaneous teriparatide acetate (recombinant human parathyroid hormone 1–34) was administered once a day at a dose of 20 µg/80 µl in addition to the existing treatment of the patient who did not respond to the treatment. Calcitriol requirement decreased to 2 mg/day and elemental Ca requirement decreased to 6 g/day according to Ca follow-up after Teriparatid treatment. After treatment, the patient's total serum Ca value increased to 8.2 mg/dl and the patient's hypocalcemia symptoms improved.

Table 1 Laboratory values before and after teriparatid treatment of the patient.

Laboratory parameters / Normal value range	Postoperative basal values	After initial dose of Ca and Calcitriol	After maximum dose of Ca and Calcitriol	After teriqaratid therapy
Serum total calcium (8.7 – 10.4 mg/dl)	4.99	6.84	7	8.2
Serum phosphate (2.4 – 5.1 m g/d l)	5.56	5.78	4.48	4.5
Serum intact PTH (18.4 – 80.1 ng/l)	0.7	4,9	4.6	5.8
25-0H Vitamin D (25 – 80 ng/m l)	45.6	31.8	31.6	205
Serum alkaline phosp hate (53 – 128 U/l)	56	52	37	52
Serum albmin (32 – 48 g/l)	42.7	38.8	37.7	38
Serum magnesium (1.3 – 2.7 mg/d l)	1.64	1.89	1.73	1.68
24 hr urine calcium (100–300 mg/day)	211.9	–	202	–
24 hr urine phosphate (0.4–1.3 mg/day)	0.542	–	0.297	–

Conclusion
It should be noted that recombinant human teriparatid therapy may be effective in patients with postoperative hypoparathyroid disease, which requires intravenous calcium infusion and hospitalization despite high doses of calcium and calcitriol therapy, and treatment change should not be delayed.

Trabecular bone score in postmenopausal women with primary hyperparathyroidism

Anna Bohdanowicz-Pawlak, Jadwiga Szymczak & Diana Jędrzejuk
Wroclaw Medical University, Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw, Poland

Introduction
Primary hyperparathyroidism (PHPT) is generally associated with increased fracture risk at all skeletal sites although greater bone loss is observed at the cortical than the trabecular bone sites. AsBMD alone does not adequately predict fracture risk, trabecular bone score (TBS) is proposed as a new method supporting risk assessment.
The aim of this study was to investigate correlation between TBS andthe severity of primary hyperparathyroidism.
Methods
The study group consisted of 29 postmenopausal women (age 64.6±8.2 years) with PHPT. Seven patients were diagnosed with kidney stones, two had bone fracturesand 1 had recurrent pancreatitis. In all patients BMD was measured by DXA at the lumbar spine (LS), the femur neck (FN), the distal third of the radius(R1/3) and the distal tenth of the radius (RUD). TBS was measured in LS –BMD. The correlation between TBS, BMD, laboratory results and clinical symptoms of PHPT were evaluated.
Results
BMD mean values (T-score) for LS, FN, R1/3 and RUD were –2.5±1.4, –1,7±0.6, –3.1±1.4, –2.4±1.07, respectively. TBS mean value was 1.1±0.12 (T-score – (–) 3.2±1.4) which means high risk of fractures. Serum parathormone concentration was 206±191 ng/l, serum calcium concentration 11.3±1.2 mg/dl and serum phosphate concentration was 2.5±0.2 mg/dl. There was no correlation between TBS and biochemical parameters such as: PTH, calcium, phosphate and 25-OH-Vitamin D, alkaline phosphatase, serum creatinine concentration andurine calcium excretion. The only correlation found was positive correlation between TBS and BMD at the ultradistal radius region (Spearman's $R=0.48$, $P<0.05$). We did not observe any correlation between TBS andtime since menopause or time since diagnosis of hyperparathyroidism. Body weight and BMI exerted a negative effect on TBS ($R=-0.54$ and $R=-0.38$ respectively, $P<0.05$).
Conclusions
Our observations suggest that TBS is not strongly associated withthe severity of PHPT. However, TBS value in patients with PHPT is significantly decreased, hence to determine its role as a predictor of bone fractureit is necessary to conduct long-term studiesin larger groups, especially in patients with fractures.

AEP226

The incidence of nephrolithiasis and osteoporosis in patients with asymptomatic hyperparathyroidism

Antonis Polymeris[1], Nikolaos Kalogeris[2], Apostolos Lafkas[2], Nektaria Papanikola[2], Eleni Herolidi[2], Christina Kogia[1] & Andromahi Vryonidou[2]
[1]Sismanoglio-Amalia Fleming General Hospital, Department of Endocrinology, Metabolism and Diabetes Mellitus, Athens, Greece; [2]Korgialenio-Benakio General Hospital, Department of Endocrinology, Metabolism and Diabetes Mellitus, Athens, Greece

Introduction
The clinical profile of patients with primary hyperparathyroidism has changed significantly in the last decades considering the fact that most cases are asymptomatic. This could be attributed to early diagnosis due to routinely serum calcium measurement. Only 5–27% of patients present with symptoms or signs related to osteoporosis, nephrolithiasis and hypercalcaemia. However, in patients with asymptomatic primary hyperparathyroidism (APHP) data concerning the incidence of these disorders are sparse.
The aim of our study was to record the incidence of nephrolithiasis and osteoporosis in patients with APHP.
Patients and Methods
57 women, aged 62.8±13.3 years, with APHP and normal renal function (GFR >60 ml/min/1.73 m^2) were studied retrospectively. None of the patients was on treatment with bisphosphonates, denosumab, thiazide diuretics or calcium and vitamin D supplements. All were assessed with serum calcium (corrected for albumin), phosphorus, iPTH, 250HD3 and creatinine levels, twenty-four-hour urinary calcium and creatinine levels, while GFR was calculated. Kidney ultrasound and bone density measurement (BMD) with DEXA were performed. Osteoporosis was considered when T-score was less than –2.5 at any site (L2-L4, femur neck and distal radius).
Results
Twenty out of the 57 patients with APHP (35.0%) had nephrolithiasis and 25 (43.8%) had osteoporosis. Patients with nephrolithiasis vs those without, had higher 250HD3 (24.6±8.0 vs 17.1±7.7 ng/ml, $P<0.003$), while there was no difference in age, BMI, serum calcium and PTH levels, and twenty-four-hour urinary calcium excretion ($P>0.05$). Patients with osteoporosis were older (69.3 ±10.0 vs 57.4± 13.1 years, $P<0.001$) and had higher serum PTH levels (160.6±93.9 vs 101.3±21.5 pg/ml, $P=0.002$), but did not differ in other parameters from women without osteoporosis.
Conclusions
Nephrolithiasis and osteoporosis are common in patients with asymptomatic primary hyperparathyroidism and therefore, bone mass density evaluation and kidney ultrasound should be included in the initial work up for early diagnosis and management.

Osteogenesis imperfecta type V due to a rare mutation c.119C> T in the IFITM5: A case report

Tatiana Grebennikova, Alina Gavrilova, Anatoly Tiulpakov, Natalia Tarbaeva, Galina Melnichenko & Zhanna Belaya
Endocrinology Research Centre, Moscow, Russian Federation

Osteogenesis imperfecta (OI) is a heritable skeletal disorder caused by defective bone formation. OI type V (MIM#:614757) develops due to mutation in the *IFITM*. Mutation c.-14C >T in the *IFITM5* is more common whereas only five reported patientshave a c.119C >T mutation. Patients with *IFITM5*:c.119C >T mutation usually have low-traumatic fractures in the prenatal period of development, severe limb and chest deformities, short height, vertebral fractures and inability to move independently in a childhood.
We present acase of an adult patient with OI type V due to a rare mutation p.119C>T:p.S40L in the *IFITM5*. A 32-year-old female (height, 95 cm; weight, 30 kg) was hospitalized with back pain, pain in joints and limited ability to move in a wheelchair. She had severe chest and long bonesdeformities, and joints contracture. CT scan showed the presence of ossifications of the interosseous membrane between the ulna and radius; multiple vertebral fractures. The patient denied relatives with similar clinical features, she did not have hearing loss, blue sclerae ordentinogenesis imperfecta. The patient sufferedher first fractureat the prenatal period of development. During childhood she had numerous fractures: long lower and upper limb bones, ribs, clavicle. At the age of 7 she had osteosynthesis on both femurs and tibiae. She became immobile at the age of 13.The patient followed treatment with zoledronic acid, calcium and vitamin D supplements from 26 to 28 years of age and then teriparatide 20 mg/day. The last fracture was diagnosed at the age of 29. Serum calcium, phosphate, creatinine, vitamin D, C-terminal telopeptide of type I collagen, PTH were within the reference ranges, but osteocalcin was slightly elevated 47.42 ng/ml (11–43).
Conclusion
This is a case of sever OI type V surviving into adulthood. OI is a clinically and genetically heterogeneous disease, so testing of pathogenic variants of the *IFITM5* may be useful.

DOI: 10.1530/endoabs.70.AEP227

AEP228

A case of severe asymptomatic hypercalcaemia in IgG kappa multiple myeloma, focal bone disease and inappropriately normal PTH as a differential diagnostic dilemma

Yuliya Manova[1], Neil Rabin[2] & Stephanie Baldeweg[1]
[1]University College London Hospital, Diabetes and Endocrinology, London, United Kingdom; [2]University College London Hospital, Department of Haematology, London, United Kingdom

We present the case of 63 years old female patient who was diagnosed with IG G kappa multiple myeloma in 2007. Cytogenetics investigations revealed high risk for progression of the disease (cytogenetics: 17 p deletion and t (4/14). The patient decided against active treatment. Over 10 years she was kept under observation with no symptoms. Her basal paraprotein levels slowly progressed from 14 g/l up to 18 g/l. In 2017 she developed mild hypercalcaemia (corrected calcium 2.72 mmol/l) and imaging investigations revealed focal myeloma bone deposits with no activity on FDG PET scan. During the following two years the patient remained asymptomatic. Calcium levels continued to rise (peak corrected calcium up to 3.2 mmol/l) despite treatment with bisphosphonate infusion (4 mg Zoledronic acid). Paraprotein levels increased up to 43 g/l. Inappropriately normal PTH levels, prompted further investigations in order to exclude concomitant hyperparathyroidism. Bone density scan revealed normal bone mass, bone markers showed normal metabolic bone activity (CTX 0.37, PNP1 58). Imaging investigations showed no topical parathyroid disease. We considered the differential diagnosis of pseudo-hypercalcaemia related to high levels of abnormal paraproteins. A simple venous blood gas test revealed normal ionised calcium of 1.20 (NR <1.3) which supported the hypothesis. Subsequent drop in PTH levels down to 2.8 pmol/l (NR >1.6) is likely to represent a response to variation in serum calcium levels within the reference range. Multiple myeloma bone disease in 90% of patients presents with symptomatic osteolytic bone disease. Treatment with bisphosphonates is essential to suppress cytokine induced activation of RANKL/OPG system and to correct hypercalcaemia. Disease control remains the major element in treatment of myeloma bone disease. Simple biochemical markers could support clinicians in their differential diagnostic reasonings and guide further therapeutic management. Pseudo-hypercalcaemia due to high paraprotein levels should be considered in the differential diagnosis of hypercalcaemia in multiple myeloma in asymptomatic patients to avoid unnecessary investigations and interventions.

Trabecular bone score in subjects after simultaneous pancreas kidney transplantation

Simona Kratochvílová, Jana Brunová & František Saudek
Institute for Clinical and Experimental Medicine, Diabetes Centre, Prague, Czech Republic

Introduction
Osteoporosis is a well known long-term complication after simultaneous pancreas kidney transplantation (SPK). Alterations of bone microstructure contribute to the risk of fracture and trabecular bone score (TBS) measurement offers and additional tool to quantify bone microarchitecture impairment.

Methods
There were 33 subjects with type 1 diabetes mellitus (23 men, 10 women, mean age 43.4±9.8 years) participating in a prospective observational study with areal bone mineral density (aBMD) of lumbar spine (LS) and femoral neck (FN) and lumbar TBS evaluation in years 0, 1 and 3 after the successful SPK. Apparatus Lunar Prodigy Primo with TBS insight software version 3.0.3.0 was used for the data retrievement.
Results
Mean creatinine, HbA1c (IFCC) andPTH concentrations 3 years after SPK were as follows: 136.7±68.9 umol/l; 38.8±6.9 mmol/mol and 11.7±8.1 pmol/l. LSaBMD wasinitially in osteopenic range but increased significantlyduring the whole follow-up (Z-score: –1.12±1.31 vs –0.14±1.25; $P<0.001$), FN aBMD remained diminished with only insignificant increase (Z score: –1.42±0.92 vs –1.19±0.83; NS). Mean TBS was low (1.201±0.118) and high-risk value (<1.23) was initially registered in 18 subjects (54%). Maximal TBS increment was documented during the first post-transplant year (1.201±0.118 vs 1.292±0,108; $P<0.01$) with later stabilization (1.292±0.108 vs 1.272±0.115; NS).
Conclusions
Subjects after SPK are at risk of low aBMD especially at cortical sites. Bone microstructure is significantly affected as documented by low TBS and diminished valuespersist despite its improvement during the first post-transplant year. Further investigation to identify risk factors connected with low TBS values and its role in fracture prediction in post-transplant period is needed.

Radium-223 was associated with high incidence of non-vertebral fractures in patients with castration-resistant prostate cancer (CRPC). The determinants of this effect are unknown and it is still unclear whether Radium-223 may induce skeletal fragility regardless of other therapies of CRPC. We aimed at evaluating the incidence and determinants of vertebral fractures (VFs), i.e. the hallmark of skeletal fragility, in CRCP patients undergoing Radium-223 therapy in the real-life clinical practice. We retrospectively reviewed 49 CRPC patients with symptomatic bone metastases treated with Radium-223 between July 2015 and May 2019. All patients underwent 11C-Choline PET/CT examination and VFs were assessed by the Genant's method using lateral images of spine CT and excluding from the analysis the vertebral bodies affected by bone metastases. Before starting Radium-223, 24 patients (49%) had VFs significantly associated with duration of androgen-deprivation therapy (ADT) (odds ratio: 1.29, C.I. 95% 1.01–1.64; $P=0.04$) and abiraterone acetate plus prednisone therapy (odds ratio 3.80, C.I. 95% 1.07–13.57; $P=0.04$). Patients received median number of 4 radium-223 doses (range 2-6) and were followed-up for a median period of 11 months (range 2–44). Radium-223 therapy achieved bone pain relief in 81.3% of patients, average PSA values reduction of 248±45%, progression free-survival and overall survival improvement, respectively in 41.7 % and 24.5% of patients. Forty-four patients were evaluated for incident VFs. During Radium-223 therapy, newVFs developedin 11 patients (25%) in relationship with pre-existing VFs (Hazard Ratio 6.89, C.I. 95% 1.17–40.59; $P=0.03$) and change in serum alkaline phosphatase values (Hazard Ratio 0.97, C.I. 95% 0.95–0.99; $P=0.02$), whereas the correlations with abiraterone plus prednisone therapy and duration of ADT were lost. Noteworthy, incident VFs did not correlate with the therapeutic outcomes of Radium-223. This observational study confirms that ADT may cause skeletal fragility especially when abiraterone is combined with prednisone. Interestingly, this study provides also aconvincing evidence that in real-life clinical practice, Radium-223 therapy may directly induce skeletal fragility with high risk of VFs independent of ADT and abiraterone plus prednisonetherapy. Therefore, skeletal health should be pro-actively evaluated in all patients with prostate cancer undergoing ADT and mainly in those candidate to Radium-223 therapy, in order to plan a therapeutic strategy for preventing fragility fractures in this clinical setting.

A follow-up of a patient with osteopetrosis successfully treated with bone marrow transplant at the age of 28

Viktor Zhilyaev, Zhanna Belaya, Svetlana Arapova, Elizaveta Mamedova & Tarbaeva Natalia
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Osteopetrosis is a rare hereditary disease caused by defective osteoclast differentiation or function. Hematopoietic stem cell transplantation (HSCT) is a potentially curative treatment for some forms of osteopetrosis. HSCT is usually performed in infancy. Currently there is also experience of HSCT for osteopetrosis in adults[1]. In this clinical case we describe the follow-up of a patient treated with HSCT[1] at the age of 28.
Clinical case
This male patient was diagnosed with osteopetrosis at the age of 5. He has one affected and one healthy sibling. His weight at birth was 4000 g and height 51 cm. He had a developmental delay (he learned to walk at the age of 3). A *CA2* mutation (Chr8:86389420 C>G p.Y193X) was revealed. Due to severe anemia and thrombocytopenia the patient required multiple blood transfusions. He also suffered from multiple low-traumatic fractures (clavicle, shoulder, multiple hip, tibia and fibula fractures). Secondary adrenal insufficiency was diagnosed due to extensive bone growth including sella turcica and the patient required hydrocortisone 10-15 mg per day. At the age of 26 his BMD was aboveaverage +6.0 SD Z-score lumber spine and+5.1 SD Z-score Total Hip. At the age of 28 the patient underwent HSCT[1]. He was re-examined in our clinic at the age of 30 with height 147.5 cm; weight – 54 kg with significant improvement in his clinical presentation: Hb – 123 g/l, thrombocytes – 134×10^9 cells/l ($152–372 \times 10^9$ cells/l), without any low-traumatic fractures, he did not require treatment for secondary adrenal insufficiency anymore: urinary free cortisol – 126,9 nmol/24 h; morning cortisol – 352 nmol/l. CT of the head revealed basal ganglia calcifications and thickening of the bones of the facial skeleton, temporal and sphenoid bones.
Conclusion
HSCT was beneficial, leading to the reversal of most dangerous osteopetrosis complications in an adult patient with moderate severity osteopetrosis.

Complex physical rehabilitation effect on postural control in patients with osteoporotic vertebral fractures

Ekaterina Makarova[1], Larisa Marchenkova[1] & Mikhail Eryomushkin[2]
[1]FSBI "National Medical Research Center of Rehabilitation and Balneology" of Ministry of Health of Russian Federation, Somatic Rehabilitation, Anti-Aging and Reproductive Health Department, Moscow, Russian Federation; [2]FSBI "National Medical Research Center of Rehabilitation and Balneology" Ministry of Health of Russian Federation, Orthopedics, biomechanics, kinesiotherapy and manual therapy department, Moscow, Russian Federation

Aim
To evaluate effect of complex physical rehabilitation on postural function in patients with osteoporotic vertebral fractures (VFs).
Materials and methods
Study comprised of 90 osteoporotic patients aged 50–80 (65.4±9.1 years) with VFs who were randomized as 2:1 into intervention group (group 1, $n=60$) and control group (group2, $n=30$). Patients in group1 received an intensive rehabilitation course including back muscle training with mechanical loads #10; sensorimotor training on double unstable platform #10; kinesohydrotherapy in a pool #15; physical exercises in a gym #10. Group 2 was prescribed only physical exercises in a gym #15. All patients were tested with Stabilometry, one leg standing test and Fukuda test at baseline,

at the end of rehabilitation course and in a month after the rehabilitation as follow-up.
Results
Baseline examination showed no any significant differences between groups in stabilometric parameters and coordination tests ($P>0.05$). There were significant changes in group1 after the rehabilitation course vs baseline in balance function coefficient (BFC) with opened eyes from 77.0±7.6 to 84.1±8.6% ($P=0.008$) and with closed eyes from 67.1±9.7 to 73.8±9.6% ($P=0.007$), at the area of statokinesiogram (ASKG) from 176.8±170.2 to 131.9±210,4 mm^2 ($P=0.04$), pressure center velocity (PCV) from 9.5±4.4 to 12.2±10.1 mm/s, ($P=0.0004$), displacement in Fukuda test from 41.4±21.3 to 32.8±14.5, ($P=0.03$) and in One leg standing test on both legs with open eyes from 9.7±21.7 to 17.8±31.8 sec and from 9.5±15.3 to 17.1±30.1 respectively ($P=0.001$). In group2 there was improvement in PCV from 9.2±4.7 to 10.1±3.9 mm/s ($P=0.05$). Positive dynamics in balance tests (BFC with open and closed eyes, PCV, ASKG, displacement in the Fukuda test, time for both legs in One leg standing test) were maintained in group1 in month of follow-up after the rehabilitation treatment. All the postural control parameters were significantly better in group 1 vs group 2 after 1 month of follow-up ($P<0.01$).
Conclusions
The complex physical rehabilitation aimed for trunk muscles and coordination trainings improve the postural function in patients with osteoporotic VFs.

Brown tumor with multiple localizations in primary hyperparathyroidism: About a case

Ajili Rihab, Arfa Sondos, Boubaker Fedia, Berrich Olfa, Wafa Alaya, Zantour Baha & Sfar Mohamed H
Taher Sfar, endocrinologie, mahdia, Tunisia

Introduction
A brown tumor is a rare osteolytic non-neoplastic lesion, due to an anomaly of bone metabolism, occuring in primary, secondary or tertiary hyperparathyroidism.
This is a case about a brown tumor with multiple localizations seen in primary hyperparathyroidism.
Observation
A 42 year old patient,with a history of Behçet disease diagnosed at the age of 38, is hospitalized in our department for the management of a fortuitously diagnosed hypercalcemia at 3.11 mmom/l. The treatment consisted in a rehydration, resulting in the progressive decrease of hypercalcemia.
A primary hyperparathyroidism was diagnosed based on a hypercalcemia reaching 3.21 mmol/l, hypophosphatemia at 0.6 mmol/l, an elevated level of PTH at 2278 pg/ml (N : 15–72), a hypercalciuria at 11.8 mmol/24 h. A vitamin D deficiency at 8.1 mg/l was also diagnosed. A cervical ultrasound and a Sestamibi parathyroid scintigraphy were done concluding to a parathyroid adenoma localized in the right inferior pole. A study of the repercussions of the hyperparathyroidism has shown an osteoporosis, a medullary nephrocalcinosis and a right renal lithiasis.
A surgical indication was established, after a preoperative preparation by vitamine D and bisphosphonates. After the surgey, the patient developed a hungrybone syndrome, treated by a calcium and vitamin D supplementation. A month after that, the patient developed pain in both legs, leading to the discovery of multiple osteolytic images in the both tibias, on the radiography. A bones scintigraphy showed multiple pathological fixations in the skull, right clavicle, the sternum, rib cage, lower extremity of the left femur and the two tibias, all in favor of brown tumors. The patient refused to do a bone biopsy and was treated by bisphosphonates.
Discussion and conclusion
Brown tumors complicate 4.5 % of cases of primary hyperparathyroidism. They are the result of an important osteoclastic activity. The most common localizations are the ribs,clavicles, pelvicgirdle and the mandible. The localization in the long bones is rare. In the case of this patient, there are multiple localizations. These benign bone tumors pose a problem of differential diagnosis with osteolytic metastases. Biopsy, if realised, show multinucleated giant cells, but these latters are not specific

The transition range and acceleration from normocalcemia to hypercalcemia in patients with primary hyperparathyroidism: Does it provide a new perspective?

Leyla Akdoğan, Cevdet Aydin, Hüsniye Başer, Neslihan Çuhacı Seyrek, Reyhan Ersoy & Bekir Cakir
Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective
Primary hyperparathyroidism (PHPT) is a clinical condition characterized by hypercalcemia-specific symptoms and signs caused by excessive secretion of parathormone. After the evaluation of blood calcium measurements within routine tests, the frequency of hyperparathyroidism increased and there is a marked decrease in the frequency of classical symptoms and signs. Recently, most PHPT cases are detected in the asymptomatic period, and which of these asymptomatic patients will go to surgery,is individually evaluated. In this study, it was investigated whether there is any feature that can be taken into account in the diagnosis and follow-up by considering the calcium course in the period until the development of hypercalcemia.
Methods
The biochemical records of patients who were operated with the diagnosis of PHPT and whose histopathological diagnosis was parathyroid adenoma were reviewed from our database. We evaluated patients who had at least 2 consequtive albumin corrected calcium levels before the time of first hypercalcemia were detected, during the preoperative period. The date when the first hypercalcemia detected, first hypercalcemic value, normocalcemic values and dates, and the intervals between them were recorded. We determined delta change and percentage changes within the patients who had at least 1 year of periyod between normocalcemia values.
Results
In this study,18(94.7%) female and 1(5.3%) male,19 patients with PHPT were included and the mean age was 52.21±10.9. The median time to develop hypercalcemia after the last normocalcemia time was 5 months (0.5–36 months). Median hypercalcemia level was 10.3 mg/dl (10.1–10.9),median for last normocalcemia was 9.8 mg/dl (9.3–10.0). It was found that the development time of hypercalcemia was decreasedas the normal calcium level increased ($P=0.044$). A higher hypercalcemic value was found as the time between normocalcemia and hypercalcemia increased ($P=0.049$). The course of increase in calcium levels over time was statistically significant ($P=0.0$). For the course of changes in normocalcemic values determined in these 19 patients until hypercalcemia was detected, delta change and percentage changes of 12 patients with 2 normocalcemic values at least 1 year intervals before the development of hypercalcemia were calculated.
Conclusion
Recently, some patients with primary hyperparathyroidism who are asymptomatic at the time of admission are treated surgically and some of them are followed up. Individualized treatment is applied in this regard, according to the guidelines some of the patients recommended surgery are followed, some of those recommended for follow-up are also operated. More information about the natural course of untreated primary hyperparathyroidism can help resolve this imprecise situation.

Role of preoperative calcium and vitamin d therapy to prevent postsurgical hypoparathyroidism

Sunghwan SUH[1], Mi Kyoung Park[1], Duk Kyu Kim[1] & Kyoungjune Pak[2]
[1]Dong-A University College of Medicine, Department of Internal Medicine, Busan, Korea, Republic of South; [2]Pusan National University Hospital, Busan, Department of Nuclear Medicine and Biomedical Research Institute, Busan, Korea, Republic of South

Background
Postsurgical hypocalcemia is the most common and most troubling long-term consequence of thyroidectomy. In this study, we investigated the potential role of routine calcium or vitamin D supplementation in preventing postsurgical hypoparathyroidism.
Methods
We carried out a systematic search of MEDLINE and EMBASE for English-language publications using the keywords "calcium", "vitamin D", and "thyroid cancer". The primary outcome was any postoperative hypocalcemia, and the secondary outcome was symptomatic hypocalcemia. We analyzed data from the studies using Review Manager (RevMan, Version 5.2, Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2012).
Results
Four studies that included 381 patients were eligible for this meta-analysis. The random-effects model showed no significant difference in the occurrence of hypocalcemia between calcium/vitamin D treatment and placebo/no treatment (OR 0.82, 95% CI 0.36–1.86, $P=0.63$). The occurrence of symptomatic hypocalcemia was lower in patients with calcium/vitamin D treatment than in those with placebo/no treatment (OR 0.44, 95% CI 0.22–0.88, $P=0.02$). In combined results, we found that preoperative calcium and calcitriol supplementation, in addition to routine postsurgical supplementation, was associated with a reduced incidence of symptomatic hypocalcemia after total thyroidectomy.
Conclusion
This study supports the use of preoperative calcium and vitamin D supplementation in conjunction with routine postsurgical supplementation for patients undergoing total thyroidectomy.

Is BMD still useful when we have FRAX?

Theodor-Eugen Oprea[1], Irina Nistor[2], Amalia Ioana Arhire[1,2], Elena Alexandru[2], Albu Alice[1,2], Carmen Sorina Martin[1,2], Anca Sirbu[1,2], Carmen Gabriela Barbu[1,2] & Fica Simona[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology, București, Romania; [2]Spitalul Universitar de Urgență Elias, Endocrinology, București, Romania

Introduction
The FRAX fracture risk assessment algorithm is able to integrate clinical risk factors independent of bone mineral density (BMD), evaluating the 10-years probability of fracture, therefore identifying patients in need for antiosteoporotic treatment, in which case bypassing the WHO (World Health Organization) criteria for densitometric diagnosis of osteoporosis.
Material and methods
We retrospectively analysed a total of 91 scans of women aged between 65–75 years old, from authors' DXA (dual X-ray absorptiometry) database, with no other medical records. We divided the patients in 3 groups according to Romanian FRAX intervention threshold and fracture risk prediction: low-risk, intermediate risk and high risk of fracture. Using DXA scan with Lunar IDXA, we extracted bone composition parameters like spine and hip BMD expressed as T-score. We analysed the obtained data using IBM SPSS Statistics 20.
Results
A total of 91 scans of postmenopausal women (mean age 69.9±3.01) with no previous diagnosis of osteoporosis, nor previous antiosteoporotic treatment, were included in our study, from which 18 of them (19.8%) had spine or hip T-score consistent with osteoporosis diagnosis (T score≤–2.5 DS), 47 (51.64%) with osteopenia and 29 (31.86%) had normal osteodensitometric parameters. Based on the interpretation of the Romanian FRAX without BMD results, 15 patients, (16.48%) were considered to be in the high-risk group, therefore, eligible for treatment, 44 (48.35%), 1 in the intermediate risk group, needing hip BMD addition and 32 (35.16%) in the low-risk group, for witch non further inquiry wold be necessary. Regarding the fracture risk probability estimated by Romanian FRAX without BMD, In the low-risk group, 2 out of 32 women had densitometric osteoporosis, 19 had osteopenia and 11 had normal BMD; on the other hand, in the the FRAX high-risk group, 5 women had osteoporosis, 7 had osteopenia and 3 out of 15 had normal BMD.
Conclusions
Although FRAX nowadays is widely used, accessible and proved to be efficient screening tool, measuring the BMD still plays an important role for fracture risk prediction, in which case it's value can be increased by combining it with more clinical factors. Considering the limited number of patients, the need of a more precise personal medical history, we cannot cast doubt on the utility of FRAX for screening patients at high or low-risk of osteoporosis, but because here is no 100% overlap between FRAX and densitometric results, BMD remains the core concept in the osteoporosis diagnosis and treatment.

Osteoporotic bone fracture hiding a rare sex chromosome disorder: Case report

Delfina Indira Fortes[1], Mario Rui Mascarenhas[2,3] & Ana Paula Barbosa[3]
[1]Endocrinology, Diabetes and Metabolism Department, Santa Maria University Hospital, CHULN-EPE, Lisbon, Portugal; [2]Environmental Health Institute, Lisbon's Faculty of Medicine, Lisbon, Portugal; [3]CEDML – Lisbon's Endocrinology, Diabetes and Metabolism Clinic (Osteoporosis Unit), Lisbon, Potugal

Introduction
The XXYY Syndromeis an extremely rare sex chromosomal disorder characterized by the presence of extra X and Y chromosomes, and clinically by tall stature, dysfunctional testes associated with infertility and hypogonadism, cognitive, affective and social functioning impairments, global developmental delay, and an increased risk of congenital malformations.
Case Report
A 46-year-old man was referred to theFracture Osteoporosis OutpatientClinic after a osteoporoticleft hip fracture.
He had a previous osteoporotic right hip fractureat 43 years-old and epilepsy, hypothyroidism, esophagitis, dyslipidemia and cognitive deficit.
Central obesity, reduced facial and body hair, poor muscle development, gynecomastia and testicular atrophy were observed.
The analytical evaluation showed normal thyroid function, P1NP 70.8 ng/ml, 25(OH)D 18.1 ng/ml, FSH18.7 U/l, LH 14.8 U/l,total testosterone 46.6 ng/dl. A karyotype study revealed a 48, XXYY syndrome.
He was started on intravenous zoledronic acid, intramuscular testosterone and oral calcium and vitamin D supplementation.
Conclusion
The 48 XXYY Syndrome,previously considered as a variant of Klinefelter syndrome, is nowadays described as a distinct clinical and genetic entity, as the medical problems and more complex psychological and neurodevelopmental involvement are usually present. The hypogonadism may also predispose these patients to osteoporosis and fragility fractures.

DOI: 10.1530/endoabs.70.AEP238

AEP239

The assessment of risk factors for osteoporosis and probability of osteoporotic fractures in patients undergoing medical rehabilitation

Larisa Marchenkova & Ekaterina Makarova
National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Somatic rehabilitation, anti-aging and reproductive health department, Moscow, Russian Federation

The aim of the study was to evaluate the risk of osteoporosis and related fractures in the patients treating in in-patient rehabilitation department.
Methods
The survey was conducted by means of questionnaire of 600 patients aged >50 y.o. ordinary treated in in-patient department of rehabilitation center. Risk factors for osteoporosis were assessed using IOF "One-minute osteoporosis risk test". 10-year probability of major osteoporotic fracture was calculated using Russian scale of FRAX on-line calculator.
Results
Assessment of osteoporosis risk factors revealed that 58.2% of responders had no risk factors, 6.8% had one risk factor, 3.8% - two, 0.6% - three, 9.1% - four, 21.5% - five or more risk factors. 45.8% of responders had experienced non-traumatic fractures in past, and a fractures occurred during rehabilitation procedures in 4.6% of ones. High probability of major osteoporotic fracture was revealed in 38% of all respondents, in particular in 45.7% of women and in 16.6% of men. The average 10-years risk for major osteoporotic fractures was 13.7% [1.6; 48.0] and for the hip fracture - 3.2% [0;16]. 8.6% of patients had 10-year absolute risk for major osteoporotic fractures more than 30%. 42.5% of respondents performed bone densitometry in the past. Osteoporosis was already diagnosed in 34.1% of respondents but only in 56.6% ($n=127$) of high fracture risk group. Among those who

never undergo densitometry there were 43.1% of patients with a high fracture risk. Anti-osteoporoitic treatment received just 31.0% among osteoporotic patients and 12.4% among subjects with high fracture risk.
Conclusions
45.7% of women and in 16.6% of men aged >50 y.o. ordinary treated in in-patient rehabilitation department have high risk of osteoporotic fracture, 41.2% patients had osteoporosis risk factors and 45.8% experienced non-traumatic fractures in past. Data indicate a high probability of non-traumatic fractures in those patients due to concomitant insufficient prescription of anti-osteoporotic medication.

AEP240

Hypothyroidism effect on bone tissue

Taras Krytskyy
Ternopil State Medical University, internal medicine №1, Ternopil, Ukraine

Background
The issue of hypothyroidism effect on bone tissue is underinvestigated, due to the small number of studies. In addition, it's not easy to determine the effect of reduced thyroid function on bone strength due to the fact that these patients are usually elderly and have many additional factors for the development of osteoporosis. The purpose of the study is to assess the status of bone mineral density (BMD) in men with hypothyroidism.
Materials and methods
We have examined 35 men with primary hypothyroidism aged 28–69 years. Duration of disease (from the time of diagnosis and initiation of thyroid hormone replacement therapy) was 3 to 26 years. The average daily dose of levothyroxine was 125.5±16.5 μg. Patients were in a state of compensation (no complaints and a normal level of thyroid-stimulating hormone on the background of hormone therapy). The control group consisted of 25 healthy, clinically euthyroid men aged 25–49 years.
Results
Osteopenia of varying severity was detected in 11 (31.4 %), osteoporosis — in 8 (22.9 %) patients, and in the remaining 16 (45.7 %) persons, BMD was within normal limits. When comparing bone density graphs in patients of different age groups, it was found that with age, the frequency and severity of bone loss increases. Duration of disease has the most significant negative effect on the BMD in patients with hypothyroidism. Although the incidence of osteopenia in the group of patients with disease duration from 5 to 15 years is greater (55.0 %) than in persons with disease duration of more than 15 years (41.7 %), but osteoporosis is 2.5 times more likely in patients with longer duration of disease than in people with disease duration of 5–15 years.
Conclusions
Violations of bone mineral density, which are manifested in the development of osteopenia and osteoporosis, are observed in 54.3 % of men with primary hypothyroidism. Severity of changes in bone mineral density is directly proportional to the age, duration of thyroid hormone replacement therapy and inversely proportional to the body mass index.

Bone turnover markers and bone quality between patients with hyperthyroidism and primary hyperparathyroidism

Madalina Sorohan[1,2], Roxana Dusceac[1,2], Dan Niculescu[1,2], Ionela Baciu[1,2], Simona Galoiu[1,2], Ramona Dobre[1], Bogdan Sorohan[2] & Catalina Poiana[1,2]
[1]CI Parhon National Institute of Endocrinology, Neuroendocrinology and Pituitary Pathology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Hyperthyroidism is widely known to be an important cause of secondary osteoporosis through the accelerated rate of bone turnover, while primary hyperparathyroidism is typically associated with loss of cortical bone and less so of trabecular bone, as seen on dual-energy x-ray absorptiometry (DXA). The evaluation of bone quality in these categories is not fully understood and needs further research. The aim of this study was to compare the bone quantity and quality, using bone turnover biomarkers, bone mineral density (BMD) and trabecular bone score (TBS) between patients with hyperthyroidism and primary hyperparathyroidism.
Methods
We performed a cross-sectional study on 52 patients evaluated in our clinic, between October 2018 and December 2019, 31 patients with hyperthyroidism (HT) and 21 patients with primary hyperparathyroidism (PHPT). The exclusion criteria were age <18 years, other secondary endocrine causes of osteoporosis. We analyzed demographic data, fragility fracture history, bone turnover markers, BMD and TBS.
Results
Among the 52 patients, the mean age was 58.1±11.8 years, female was the dominant gender (94.2%) and the mean body mass index was 28.2±5.8 kg/m^2. Patients from the PHPT group were significantly older (62.7 ±10.2 years vs 55±11.9 years, $P=0.01$), had a significantly higher serum calcium (10.9±0.5 mg/dl vs 9.6±0.3 mg/dl, $P<0.001$), parathormone level [103.5 (89.9–147.1) pg/ml vs 44.9 (32.8–46.9) pg/ml, $P<0.001$] and had more often prevalent fragility fractures (14.3% vs 6.5%, $P=0.35$). Additionally, a significantly higher percentage of patients with PHPT had a value of TBS <1.350 (85.7% vs 58.1%, $P=0.03$). Meanwhile, patients from the HT group had a significantly higher serum phosphorus (3.4±0.3 mg/dl vs 2.7±0.4 mg/dl, $P<0.001$) and bone turnover markers, like alkaline phosphatase (107.6± 41.2 U/l vs 78.1±23.4 U/l, $P=0.005$) and P1NP (122.3 (55.1–156) ng/ml vs 70.2 (50.4–82.5) ng/ml, $P=0.007$). We found that a TBS <1.350 had a sensitivity and specificity of 85.71% (95% CI, 63.66% to 96.95%) and 41.94% (95% CI, 24.55% to 60.92%), respectively, to predict bone fragility in patients with PHPT, with an accuracy of 59.62% (95% CI, 45.1% to 72.99%). However, there were no differences in BMD values on lumbar spine or hip between the two groups.
Conclusions
In conclusion, we found that patients with HT had higher bone turnover markers and patients with PHPT presented more often a TBS below 1.350. Thus, TBS could be a potential predictive marker for bone fragility in patients with PHPT.

Severe hypocalcemia and psuedotumor cerebri: Old, still not so well known relationship!

Madhuri Patil[1], Valerie Butler[2], Nadia Jamil[1], Benjamin Cameron[2] & Tiffany Egbe[2]
[1]University of Texas Health Science Center at Tyler / CHRISTUS Good Shepherd Health System, Longview, United States; [2]Christus Good Shepherd Medical Center, Longview, United States

Introduction
Clinical features of severe headache, vision loss, and papilledema; normal neuroimaging and elevated opening pressure on lumbar puncture are diagnostic of idiopathic intracranial hypertensions (IIH) or pseudotumor cerebri. Etiology is often attributed to obesity in young female patients. We present a rare case of Pseudotumor cerebri in a non-obese female patient with severe hypocalcemia.
Case
A 26 year old Hispanic female patient with past medical history of hypocalcemia, but off her medications, presented to ER for worsening headache for over a month. Without any specific triggers, she began having headaches in her bitemporal region. The pain was continuous, pressure-type, and 9/10 intensity at its worst. It was associated with nausea and blurring of vision and was refractory to ibuprofen. Patient endorsed severe muscle cramps on review of systems. Physical examination demonstrated mild distress due to the headache, positive Trousseau's sign, and bilateral papilledema. Laboratory studies revealed serum total calcium level of 4.8 mg/dl, albumin 3.5 g/dl, ionized calcium 0.71 mmol/l, serum phosphate 5.3 mg/dl, intact PTH 300.1 pg/ml, 25-OH Vitamin D 14.3 ng/ml and 1, 25-Dihydoxy Vitamin D 14.1 pg/ml, alkaline phosphatase 131 IU/l, 24-hour urinary calcium 48 mg/d and 24 hour urinary calcium/creatinine ratio 50 mg/g. Her MRI brain and MR venogram were unremarkable. Lumbar puncture had elevated opening pressure of 46 cm of H2O. The patient was started on Acetazolamide, oral calcium, and calcitriol without resolution of headaches and hypocalcemia. Acetazolamide was discontinued when she developed severe hypokalemia. With diagnosis of pseudohypoparathyroidism, the dose of elemental calcium was doubled and calcitriol dose increased to 1 mg BID with improvement of serum calcium, symptoms, and papilledema.
Discussion
While IIH could be associated with certain medications and systemic conditions, obesity or recent weight gain are the most commonly cited causes. Severe hypocalcemia is a rare and less known etiology of IIH. Cases of adult patients are reported with a variety of etiologies of severe hypocalcemia. Severe hypocalcemia leading to hypersecretion of cerebrospinal fluid is

postulated as a possible mechanism but evidence is lacking in literature. Chronic, rather than acute, severe hypocalcemia is likely to precipitate IIH. Visual symptoms, headache and papilledema are difficult to resolve with conventional medical therapy without correction of underlying severe hypocalcemia. We conclude that before considering surgical interventions for cases which are refractory to medical therapy, rare underlying conditions like severe hypocalcemia must be investigated and treated optimally.

Heterogeneity and diagnostic features of diabetes mellitus types in young patients

Zilya Kalmykova[1], Irina Kononenko[1], Alexander Mayorov[1], Anatoliy Tiulpakov[2], Ekaterina Koksharova[1], Olga Schmidt[1] & Marina Shestakova[1]
[1]Endocrinology Research Centre, Diabetes Institute, Moscow, Russian Federation; [2]Endocrinology Research Centre, Institute of Personalized Medicine, Moscow, Russian Federation

Heterogeneity of diabetes mellitus (DM) determines difficulties in the diabetes type verification and further treatment. With this regard, in 2019 WHO published a new classification of DM with categories: "hybrid types of diabetes" and "unclassified diabetes" intended for use in clinical practice.
Aim
To investigate the heterogeneity and clinical features of DM in young adult patients with an unspecified type of diabetes.
Materials and methods
50 young adult people±33.2 years (18–45 years) with an unspecified type of DM were included. All patients underwent a genetic testing for *GCK, HNF1α and HNF4α* genes mutations for MODY diagnosis. In all included patients we analyzed levels of GADA, IA-2A, ICA, IIA, ZnT8 antibodies and C-peptide levels during oral glucose tolerance test. Type 2 DM (T2DM) was established in patients no mutations and absence of β-cell antibodies.
Results
MODY2 was diagnosed in 46.94% of patients, MODY3 – 12.24%, MODY1 – 2.04%, T2DM – 28.57%, LADA – 2.04%, T1DM - 10.2%. MODY1 and LADA were established for only 2 patients and were not included in the statistical analysis. Debut of carbohydrate metabolism disorders in MODY2 and T1DM were diagnosed earlier than in other types of DM: 23 years [9; 41] and 25.4 years [18; 25] vs 30.5 years [10; 42] in MODY3 and 31.5 years [18; 45] in T2DM, (P <0.05). Median of HbA1c level did not differ between groups: in MODY2 6.4% [5.0; 10.3], MODY3 – 6.65% [5.6; 11.8], T2DM – 6.55% [5.2; 12.6], T1DM – 7.2% [6.4; 7.5], (P>0.05). BMI did not differ between groups: MODY2 – 20.6 kg/m² [15.6; 35.1], MODY3 -24.1 kg/m² [20.2; 29.3], T2DM – 23.1 kg/m² [18.5; 36.1], T1DM – 22.25 kg/m² [20.4; 23.0], (P>0.05). Significant differences were observed in C-peptide secretion levels: the lowest levels were observed in patients with T2DM (0 min – 1.29 ng/ml [0.64; 3.91], 60 min – 6.7 ng/ml [5.6; 12.2], 120 min – 4.45 ng/ml [3.1; 10.21]) compared with patients with other groups (MODY2, MODY3), (P <0.05).
Conclusion
The study demonstrates the significant clinical heterogeneity of DM in the young age group. Genetic and immunological tests are necessary to verify monogenic and autoimmune forms of DM and also important for determining further management. Young patients with T2DM require further studies, in order to identify underlying mechanisms of impaired insulin secretion.

Hemoglobin glycation index is associated with incident chronic kidney disease in subjects with impaired glucose metabolism: A 10-year longitudinal cohort study

Wonjin Kim[1] & JiHye Huh[2]
[1]CHA Gangnam Medical Center, CHA University, Department of Internal Medicine, Seoul, Korea, Republic of South; [2]Hallym University Sacred Heart Hospital, Department of Internal Medicine, Anyang, Korea, Republic of South

Objectives
We investigated associations between hemoglobin glycation index (HGI) and incident chronic kidney disease (CKD) in treatment naïve subjects with prediabetes or diabetes.
Methods
A prospective cohort study was conducted in 2,187 subjects with prediabetes or diabetes. The HGI was calculated as the measured HbA1c minuspredicted HbA1c, which was calculated from the linear relationship between HbA1c and fastingplasma glucose levels. Incident CKD was defined as occurring if eGFR decreased toless than 60 ml/min per 1.73 m^2 and decreased by more than 25% from baseline during follow up. The hazard ratio (HR) for incident CKD was calculated using Cox models.
Results
The overall prevalence of CKD was 335 (15.3%) during the 10-year follow-up period. The prevalence of CKD significantly increased from the first to third tertile of HGI. In multivariate analysis, the highest HGI tertile group showed the highest adjusted HR for incident CKD (HR, 1.57; 95% CI, 1.06–2.34) and this was significant even after adjustment for HbA1c.
Conclusion
High HGI was associated with increased risk for incident CKD in treatment naïve subjects with prediabetes or diabetes. These finding suggest that HGI might provide for predicting CKD in these patients regardless of HbA1c levels.

AEP245

Assessment of arrhythmia risk due to hypoglycemia with continuous glucose monitoring device and 24-hour holter monitoring

Mustafa Sahin, Caglar Keskin, Murat Cinel, Begum Bahceci & Demet Corapcioglu
Ankara University, Endocrinology and Metabolsim Department, Ankara, Turkey

Previous studies have shown increased hypoglycemia-associated cardiac arrhythmia and mortality in patients with type 2 diabetes and cardiovascular disease.
In this study, we aimed to evaluate the response of gastrointestinal hormones and glucoregulatory hormones to the oral glucose tolerance test in patients who were diagnosed with reactive hypoglycemia and to evaluate the risk of arrhythmia with long-holter ECG measurements in patients with a diagnosis of reactive hypoglycemia. In this prospective observation study, 64 patients (F / M: 42/22) who admitted to our clinic with reactive hypoglycemia-like complaints were subjected to oral glucose tolerance test with mixed meal. Patients with hypoglycemia symptoms who had plasma glucose values below 55 mg/dl in the first 4 hours of postprandial period were considered as reactive hypoglycemia.
Continuous glucose monitoring and 72-hour holter ECG examinations were performed synchronously in these patients. At the same time, prolonged OGTT test was performed in these patients. Glucose, insulin, leptin, glucagon, GLP-1, cortisol levels were evaluated in 0,15,30,60,90,120,180,240,300 minutes. Postprandial median glucose values were at hypoglycemic levels at 180 and 240 minutes.
During the test protocol a decrease of 26 mg/dl glucose in the hypoglycemic period, an increase of 21.4 pg/ml in GLP-1 levels, a decrease of 20.4 U/ml in insulin levels, an increase in glucagon level of 18.9 pg/ml, and an increase in cortisol level of 2.9 µg/dl were detected. Continuous glucose monitoring revealed symptomatic hypoglycemia in 2 of 7 patients (glucose <55 mg/dl). At least one hypoglycemic value was detected in 6 of 7 patients. No biochemical or clinical hypoglycemia was detected in one patient. 11 ectopic ventricular beats were detected in 2 patients with severe hypoglycemia.
Although the symptoms of postprandial hypoglycemia are seen in many individuals in the community, the frequency of reactive hypoglycemia was lower than expected when standard diagnostic tests were applied to these patients. Atrial and ventricular ectopic pulses may be seen in patients with reactive hypoglycemia, although severe cardiac arrhythmia is not observed. The mechanisms involved in the etiology of reactive hypoglycemia have still not been elucidated. We can speculate that the increase in GLP-1 and leptin hormone levels may be responsible for postprandial hypoglycemia.

Insights from whole exome sequencing in a Maltese cohort with gestational diabetes

Nikolai Paul Pace[1,2], Barbara Vella[1], Johann Craus[1], Samir Abou-Hussein[1], Ruth Caruana[1], Alex Felice[2], Charles Savona-Ventura[1] & Josanne Vassallo[1,2]

[1]University of Malta, Faculty of Medicine and Surgery, Msida, Malta; [2]Centre for Molecular Medicine and Biobanking, University of Malta, Malta

Background
Gestational diabetes (GDM) can be driven by mutations or rare variants in various genes associated with monogenic or atypical forms of diabetes. The reported frequency of monogenic defects of beta cell function in GDM varies extensively, in part due to differences in ethnicity, patient ascertainment criteria and techniques used for genetic analysis. The objective was to evaluate the frequency and molecular spectrum of mutations in a curated list of genes associated with monogenic/atypical diabetes in non-obese women of Maltese ethnicity with GDM.
Method
30 non-obese Maltese women who met the International Association of the Diabetes and Pregnancy Study Group (IADPSG) criteria for diagnosis of GDM and with a first-degree relative with non-autoimmune diabetes were included in this study. Whole exome capture and high throughput sequencing was carried out. Rare sequence variants were filtered, annotated and prioritized according to the American College for Medical Genetics guidelines. For selected missense variants we explored effects on protein stability and structure through homology predictions or PDB structures using in-silico tools.
Results
In total, we identified three pathogenic mutations and twelve variants of uncertain significance (VUS). The disease-causing mutations comprise a nonsense mutation in *GCK*, an insertion-frameshift at a mutational hotspot in *HNF1A* and a missense substitution in *ABCC8*. Critically, the *ABCC8* mutation leads to significant changes in interatomic interactions and to expansion of protein cavity volume, with resulting destabilising effects. Damaging VUS in *PDX1, KLF11, DYRK1B, TRMT10A, AKT2, BLK, GLIS3* and *NKX6-1* were detected, having either conflicting pathogenicity interpretationsor insufficient evidence for pathogenicity from in-vitro studies. Novel *NEUROG3* and *CEL* VUS were also detected. Stereochemical analysis reveals that the missense variants described in *NEUROG3, DYRK1B, TRMT10A*and*AKT2* have destabilising effects. Genotype-phenotype correlations for all detected variants are described, including associations with anthropometric traits, OGTT, HOMA-IR, treatment and post-pregnancy follow-up data where available. We show that GDM cases who were carriers of either pathogenic mutations or damaging VUS had a younger age of GDM diagnosis than females where no variant of interest was identified. (29 vs 32 years, $P=0.039$).
Conclusion
This study provides the first insightinto an underlying monogenic aetiology in non-obese women with GDM from a high-prevalence island population. It suggests that monogenic variants constitute an underestimated cause of diabetes detected in pregnancy, and that careful evaluation of GDM probands to identify monogenic disease subtypes is indicated.

Features of sarcopenia and body composition measured with bioimpedance in patients with diabetes mellitus type 2

Yulia Onuchina[1] & Irina Gurieva[2]
[1]Pirogov Russian National Medical University, The Russian Clinical and Research Center for Gerontology, endocrinology, moscow, Russian Federation; [2]Federal State Budgetary Institution «The Federal Bureau for Medical-social Expertise» of Ministry of Labor and Social Protection of the Russian Federation, Endocrinology, Moscow, Russian Federation

Aim
To investigate the association between presence of sarcopenia and type 2 diabetes mellitus (T2DM).
Methods
The study included 76 women over 60 years old (Me72[67;77] years). Patients were examined with evaluation of muscle mass, muscle strength and muscle function. Skeletal muscle mass index (SMMI) was evaluated with bioimpedance testing. Sarcopenia was defined as a SMMI ≤6,75 kg/m^2. Peripheral neuropathy was studied with calculation of NIS-LL scale (max points=96). Patients were divided into 2 groups: with sarcopenia (S+, $n=29$) and without sarcopenia (S–, $n=47$). We did not find any significant difference between age and diabetes duration in S+ and S- groups. Multivariable logistic regression model were adjusted for age. We plotted a ROC curve to compare the diagnostic accuracy of the anthropometric indicators and to find the optimal cut-off values of each indicators.
Results
The frequency of HbA1c level more then 8% were 72% in S+group and 49% in group S– ($P=0.041$). S+ group less frequently received metformin ($P=0.011$) and insulin ($P=0.044$). Patients with sarcopenia demonstrated more often chronic kidney disease (70%) than S– (27%, $P=0.024$). Diabetic neuropathy was more severein S+group than in S-group (NIS-LL: 12[7;17] vs 6 [4,8], $P<0.001$). Frequency of falls and fractures was noted more often in S+ group in comparison with S-group (66% vs 36%, $P=0.013$, 36% vs 13%, $P=0.003$). Patients S+had smaller BMI vs S- (25.2 [20,72;29,24] vs 31.6[28,9;35,9] kg/m^2, $P<0.001$), waist (89,5[83,75;100,5] vs 104[100;112] cm, $P<0.001$) and neck circumferences (37[22,5;38] vs 40[35;40] cm, $P<0.001$). According bioimpedance measurement S+patients was differed with more pronounced decrease of skeletal muscle massvs S-patients (16.5[14,8;17,3] vs 19,2[18,3;21,6] kg, $P<0.001$), fat mass (22.35[18,65;29,175] vs 31.8[27,4;40] kg, $P=0.006$) and mineralmass of bones (1.83[1,73;2,04] vs 2,18[2,09;2,45] kg, $P<0.001$). The multivariable logistic regression analysis revealed the associations of presence of sarcopenia in T2DM patients with NISLL more then 11 points (OR-22,14;95% CI[3,68-133,30], $P=0.001$). BMI cut-off points to identify sarcopeniasubjects was ≤29 kg/m^2 (sensitivity-87.2%; specificity-72.4%) for women with T2DM. Waist circumference cut-off pointsto identify sarcopenia subjects was ≤102,5 cm (sensitivity-85.1%; specificity-65.5%) for women with T2DM. Shoulder andlower leg circumferences were ≤30,5 cm (sensitivity-85.1%; specificity-65.5%) and ≤36 cm (sensitivity-91.5%; specificity 69%) for women with T2DM.
Conclusion
Sarcopenia was more often detected in patients with more severe peripheral neuropathy, poor glycemic control and history of falls. S+ patients characterized with more severe changes in the body composition not only in the skeletal muss, but also in the amount of fat mass and bone mineral density.

Evaluation of the endocrine cells ratio in the pancreas of rats with type 2 diabetes mellitus following long-term therapy with incretin mimetics and their combination with sulfonylureas drugs

Taisiia Tuchina[1], Ksenia Skotnikova[1], Anna Vtorushina[2], Olga Rogoza[1], Alina Babenko[1] & Mikhail Galagudza[1]
[1]Almazov national medical research center, St.Peterburg, Russian Federation; [2]First Pavlov State Medical University, St.Peterburg, Russian Federation

Introduction
New medicinal products that have been introduced into first-line therapy for type 2 diabetes mellitus (T2DM) include glucagon-like peptide-1 receptor agonists (GLP-1ra) and dipeptidyl peptidase-4 inhibitors (DPP-4i). These products have been shown to increase beta-cell proliferation. Some studies also demonstrated an increase in pancreatic alpha-cell proliferation. Various sulfonylureas drugs (SU) have been shown to produce different effects on apoptosis pancreatic cells. Therefore, we are interested in evaluating the effects of treatment with combinations of incretin mimetics with SU on pancreatic cells.
Goal of the study
The goal of this study was to evaluate the effects of long-term therapy with combinations of incretin mimetics and SU on the ratio of alpha- and beta-cells in a model of type 2 diabetes in 12-month-old rats.
Materials and methods
Streptozotocin-nicotinamide-induced model of type 2 diabetes was used. The animals received treatment according to the assigned groups over a period of 24 months. Treatment groups (5 animals per group): 1) control group (healthy animals); 2) animals with T2DM without any treatment; 3) animals with T2DM treated with Exenatide; 4) Vildagliptin; 5) Exanatide+ Gliclazide; 6) Vildagliptin+ Gliclazide; 7) Exenatide + Glibenclamide; 8) Vildagliptin + Glibenclamide. After the end of treatment, immunohistochemistry using anti-glucagon and anti-insulin antibodies was carried out.
Results
A volume ratio of alpha- and beta-cells of the pancreas was determined relative to the area of the pancreatic islets. The volumes of beta cells in the healthy control group was comparable to those in the groups receiving monotherapy with Exenatide,Vildagliptin, their combination with SU. There were statistically significant differences in the volumes of alpha-cells in the groups receiving Glibenclamide monotherapy andin combination with GLP1ra or DPP4iin comparison with the healthy control.

Conclusions
24-week treatment with GLP1ra and DPP4i resulted in normalization of both beta and alpha cell contents. The normalization of the content of alpha-cells in animals treated with Gliclazide-containing combinations was comparable to that observed in the groups receiving monotherapy with GLP1ra, DPP4i, and the healthy control group while the number of alpha-cells in the groups receiving incretin mimetics in combination with Glibenclamide was similar to the content of these cells observed in the group with untreated T2DM.

A multi-center, randomized, double-blind, parallel, active-controlled phase III clinical trial to evaluate the efficacy and safety of controlled-release pregabalin and immediate-release pregabalin in diabetic peripheral neuropathic pain

Jae Hyuk lee[1], Min-Kyung Lee[2] & Yang Im Hur[3]
[1]Hanyang University, Myongji Hospital, Division of Endocrinology, Department of Internal Medicine, Goyang-Si, Korea, Republic of South; [2]Hanyang University, Myongji Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Goyang-Si, Korea, Republic of South; [3]Seoul Paik Hospital, Inje University College of Medicine, department of Family Medicine, Seoul, Korea, Republic of South

Pregabalin is a highly used drug for the effective treatment of diabetic neuropathic pain. This study compared the efficacy and safety of a controlled-release (CR) Pregabalin tablet (GLA5PR GLARS-NF1) with an immediate-release (IR) Pregabalin capsuleafter 12 week administration in patients with diabetic peripheral neuropathy. In multicenter, randomized, double- blind, active- controlled, parallel- group, phase III study, the primary outcome was to confirm that CR pregabalin with once daily (after meal in the evening) is clinically non-inferior to IR pregabalin with twice daily regimen in improving the meanDaily Pain Rating Scale (DPRS) for the treatment of peripheral neuropathic pain. The efficacy endpoints in patients with diabetic peripheral neuropathic pain which were the target diseases, and patients who received and did not receive restricted concomitant medications during the clinical study were analyzed. 59 subjects in the study group and 58 subjects in the control group was allogated. Themean DPRS adjusted by using the baseline mean DPRS as a covariate was 3.26±0.23 in the study group and 3.41±0.32 in the control group (LS mean difference, –0.16; 95% CI, –0.79 to 0.48), indicating that the study group was not-inferior to the control group. In addition, no consistent trend was seen in comparison of sleep indicator between the groups for each subgroup, but at Week 12 after administration of the investigational product, a tendency of decrease was observed, similar to the result of the primary analysis. The overall adverse event profile of the study groupand control group was similar, and no serious ADR was observed. CR pregabalin treatment for 12 weeks was non-inferior compared to IR pregabalin in improvement of pain in patients with diabetic peripheralneuropathy. CR pregabalin can be used effectively and safely in diabetic peripheral neuropathic pain, and it is expected thattreatment effects can be maximized by improving patients' treatment compliance since the drug isadministered once daily.

Gestational diabetes in korea: Temporal trends in prevalence, treatment, and short-term consequences from a national health insurance claims database 2012 – 2016

Chan-Hee Jung[1], Ji-Oh Mok[1] & Sang-Hee Jung[2]
[1]Soonchunhyang University Bucheon Hospital, Bucheon, Korea, Republic of South; [2]Cha University Bundang Hospital, Seongnam, Korea, Republic of South

Aims
This population-based cross-sectional study aimed to investigate the recent trends in the prevalence and treatment of gestational diabetes mellitus (GDM) in a nationally representative sample of Korean patients. We also investigated trends of annual prevalence rate of pregnancy-induced hypertension (PIH) and cesarean section (C-section) in patients with GDM.
Methods
We used data from the Health Insurance Review and Assessment-National Patient Sample (HIRA-NPS) database, 2012–2016. GDM, PIH, and C-section weredefined according to ICD-10 codes. Non-GDM (n=54, 346) and GDM (n=8,137) patients between 2012 and 2016 were analyzed for each year.
Results
The annual increase of the prevalence of GDM was 11.2% in 2012–2016, with a significant continuous increasing trend (P<0.0001). Age group-stratified analysis showed that theannual prevalence of GDM significantly increased in below 40 years group, but statistically insignificant increasing trends in above 40 years group. Regarding treatment pattern during pregnancy in patients with GDM, there was no statistically significant increasing or decreasing trend. Diet only treatment showed increasing trend and insulin treatment showed decreasing trend, but both were statistically insignificant. PIH prevalence rate was shown significantly increasing trend by year, but statistically insignificant in both unadjusted and adjusted. Annual increase of C-section rate above 5% in GDM was statistically significant in both unadjusted and adjusted for age and PIH.
Conclusion
The prevalence of GDM in Korean women and C-section rates in women with GDM showed significantly increasing trendfrom 2012 to 2016. The present study is the first study to investigate the prevalence and treatment of gestational diabetes mellitus (GDM) and rates of pregnancy-induced hypertension (PIH) and cesarean section between women with and those without GDM in Korea using a large national database. There is a need for further efforts to monitor this trend and to identify associated risk factors for GDM.

Twin pregnancy with gestational diabetes mellitus: Maternal and fetal outcomes

Liliana Fonseca[1], Tiago Santos[1], Joana Vilaverde[1], Miguel Saraiva[1], Teresa Pereira[1], Inês Nunes[2], Clara Pinto[2], Rosa Rodrigues[2], Fernando Pichel[3] & Jorge Dores[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology department, Portugal; [2]Centro Materno Infantil do Norte – Centro Hospitalar e Universitário do Porto, Gynecology and Obstetrics Department, Portugal; [3]Centro Hospitalar e Universitário do Porto, Nutrition department, Portugal

Introduction
In singleton pregnancies, gestational diabetes mellitus (GDM) results in an increased risk for maternal and neonatal complications. In twin pregnancies, however, the effect of GDM on maternal and neonatal complications appears to be different in comparison to singletons. The few studies that investigated the consequences of GDM in twin pregnancies are small and present conflicting evidence, with some finding no difference in perinatal outcomes between GDM and non-GDM twins and others even demonstrating better outcomes.
Objetive
To Compare maternal and fetal outcomes in pregnant women with and without GDM in a twin pregnancy.
Methods
Observational and retrospective study comparing maternal and fetal outcomes in 42 women having a twin pregnancy complicated with GDM followed in a Portuguese tertiary hospital whose deliveries occurred between 2011 and 2018, with 83 pregnant women with twin pregnancies without GDM whose delivery occurred in 2018.
Results
There was no difference in maternal mean age (32.7±4.8 vs 32.8±4.8 years-old, P=0.936) and in fertility treatment rate (45.2% vs 34.9%, P=0.114), in both groups. The pre-pregnancy IMC and percentage of excessive weight gain was higher in the GDM group, with 24.9 (IQR: 22.4–28.5) vs 23.8 (IQR: 21.2–25.5) kg/m², P=0.007 and 10.7% vs 0%, P=0.005, respectively. No difference between the groups was found for: abortion rates, hydramnios, fetal death, chorionicity, induced and chronic hypertension. The GDM group it seems to had a higher risk of having preeclampsia, but without statistical significance (14.3% vs 7.2%, P=0.074). Regarding fetal outcomes, no difference was found between the two groups for hypoglycemia, hyperbilirubinemia, respiratory distress syndrome (RDS), NICU admission, birth trauma or neonatal death rates. Both groups presented a high prematurity rate (73.8% vs 72.3%, P=0.799, with and without GDM, respectively). There was a higher prevalence ofsmall for gestational age (SGA) babies in the group without GDM (40% vs 27.4%, P=0.049). None of groups had newborns with macrosomia or large for gestacional age (LGA).
Conclusion
There was no difference between maternal outcomes in twin pregnancy with or without GDM. Nevertheless, and although the results were not sig-

nificant, the group with GDM had a higher prevalence of preeclampsia, as described in other studies. Twin pregnancy complicated with GDM is not associated with neonatal morbidity occurrence, characteristic of the newborn from a diabetic mother observed in singleton pregnancy and this diagnosis seems to be protective for SGA occurrence.

Immunomodulatory and anti-diabetic actions of a structurally-modified analogue of esculentin-2CHa isolated from the skin secretion of the frog, lithobates chiricahuensis (ranidae)

Opeolu Ojo[1], Wendy Ofosu[2], Ayodele Abiodun Falobi[1], Ayokunle Benjamin Falana[1], Monica Sen[2] & Lesley Smyth[2]
[1]Research Institute in Healthcare Sciences, Faculty of Science and Engineering, University of Wolverhampton, Wolverhampton, United Kingdom; [2]University of East London, School of Health, Sport and Bioscience, London, United Kingdom

Aim
Our previousstudies have shown evidence for insulin-releasing actions of some amphibian skin peptides; including esculentin-2CHa. However, there is a need to further improve the potency of some of this peptides and to characterize their other beneficial effects. This study investigates the effect of a Leu[31]→Lys substitution on the insulin-releasing and immunomodulatory effects of esculentin-2CHa.
Methods
BRIN-BD11 cells were incubated for 20 min in a buffer containing esculentin-2CHa or [L31K] esculentin-2CHa at 5.6 mM or 16.7 mM glucose. Effects of [L31K]esculentin-2CHa in the presence of established modulatorsof insulin secretion were also examined. Acute *in vivo* effects of [L31K] esculentin-2CHa on glucose tolerance and insulin secretion were investigated in high fat fed mice. Expression of MHC I, II and cytokine release from [L31K] esculentin-2CHa –treated bone marrow dendritic cells (BM-DCs) were investigated by Flow Cytometry and ELISA.
Results
Leu[31]→Lys substitution significantly enhanced the insulinotropic effects of [L31K] esculentin-2CHa (0.01 nM–1 μM; 1.1–1.7-fold; $P<0.05$–0.001) compared with the native peptide. At 16.7 mM glucose, insulin-release in [L31K] esculentin-2CHa-treated cells increased by 1.3-fold ($P<0.001$). These actions were not associated with significant LDH release. Diazoxide (200 μM, 40%, $P<0.01$), verapamil (50 μM, 58%, $P<0.001$) and removal of extracellular calcium (56%, $P<0.001$) significantly inhibited insulin-releasing effects of [L31K] esculentin-2CHa. Increased insulin-release was observed in incubations involving [L31K]esculentin-2CHa and KCl (30 mM, 1.9-fold, $P<.001$), IBMX (200 μM, 3.1-fold, $P<0.001$) or tolbutamide (200 μM, 3.8-fold, $P<0.001$). [L31K] esculentin-2CHa improved glucose tolerance by 42% ($P<0.05$) and insulin secretion by 57% ($P<0.01$) in high-fat fed mice. The expression of MHC I and II, or the release of IL-10, IL-12 and IL-23 from BM-DCs were unaffected.
Conclusions
This study indicated that the Leu[31]→Lys-substitution improved the anti-diabetic actions of esculentin-2CHa without generating pro-inflammatory immune responses.

Congenital hyperinsulinemic hypoglycemia: A case report

Andrea Widmer[1], Urs Zumsteg[2], Gabor Szinnai[2], Isabel Filges[3], Stephanie Meier[3], Julie Marie Carmen De Geyter[3], Kwadwo Antwi[4], Jean-Marc Nuoffer[5], Damian Wild[4] & Emanuel Christ[1,4]
[1]University Hospital Basel, Division of Endocrinology, Diabetes, and Metabolism, Basel, Switzerland; [2]University Children's Hospital Basel, Division of Endocrinology, Diabetes, and Metabolism, Basel, Switzerland; [3]University Hospital Basel, Medical Genetics, Institute of Medical Genetics and Pathology, Basel, Switzerland; [4]University Hospital Basel, Division of Radiology and Nuclear Medicine, Basel, Switzerland; [5]University Hospital Berne, Inselspital, Division of Laboratory Medicine, Bern, Switzerland

Introduction
Persistent endogenous hyperinsulinemic hypoglycemia in neonates (congenital hyperinsulinism; CHI) is usually due to monogenetic gene variants affecting the insulin secretion. The genetic cause is known in about 50% of patients. We present a new variant within the *short-chain L-3-hydroxyacyl-CoA dehydrogenase (HADH)* gene causing CHI in two cousins.
Methods
The cases of two patients with CHI are presented with a follow-up of >30 years.
Results/Case Reports
A 32-year-old man (patient 1) and his 30-year-old cousin (patient 2) with CHI were referred to the outpatient clinic for treatment. According to the pediatric notes, the first hospitalization was at day 17 after birth in patient 1 (apnea with cyanosis during breastfeeding) and at day 10 in patient 2 (muscular hypotonia and sucking weakness). The diagnosis of CHI was established in both patients during the first hospitalization. A therapy with Diazoxide was initiated. The growth charts of both patients documented a disproportionate increase in weight in relation to height in childhood and adolescence, mainly due to recurrent hypoglycemic events with snacking of carbohydrates. In adulthood, the frequencies of hypoglycemic episodes increased leading to the referral. The patients belong to consanguineous family.
Investigation
1) A genetic analysis was performed in the *ABCC8*, *KCNJ11* and *HADH* genes resulting in a novel homozygous pathogenic variant in the *HADH* gene (*HADH*-variant c.796G>T). The disease is autosomal recessive. 2) Based on the finding an acylcarnitine-profile was performed showing an increased plasma 3-OHButyryl-carnitine, consistent with a dysfunction of the HADH enzyme. 3) Histologically, CHI is associated with pancreatic nesidioblastosis, which can be focal, atypical or diffuse. We have previously shown that nesidioblastosis can be morphologically characterized by targeting GLP-1 receptors, which are overexpressed. Therefore, a GLP-1-receptor-PET/CT with ^{68}Gallium-DOTA-exendinwas performed showing significantly increased uptake in the whole pancreas in both patients compatible with a diffuse form of nesidioblastosis. A surgical procedure was, therefore, not a therapeutic option.
Therapy
Intermittent monitoring with continuous glucose monitoring system and a somatostatin analogue was administered in addition to Diazoxide resulting in a significant decrease in hypoglycemic events. Patient 1 lost 24 kg within 9 months due to a decrease in snacking.
Conclusion
- A genetic work-up is mandatory in patients with CHI.
- The increased uptake of the GLP-1-receptor-PET/CT indicates an overexpression of GLP-1 receptor in this condition. The pathophysiological role of this finding is unclear.
- Therapy with Diazoxide and Octreotide has to be evaluated in adults with CHI and recurrent hypoglycaemias.

Chronic activation of adaptive immunity in type 2 diabetes

Malgorzata Garstka[1], Shan Liu[2], Xu Ren[2], Ying Kong[3], Xiaoqiang Xu[4], Xiaozhen Li[5], Yang Jiao[3], Na Huang[2], Xiaoyun Min[2], Ning Ma[2], Baohua Li[2], Ke Li[2] & Jing Xu[3]
[1]The Second Affiliated Hospital of Xi'an Jiaotong University, Core Research Laboratory, Department of Endocrinology, National & Local Joint Engineering Research Center of Biodiagnosis and Biotherapy, Xi'an, China; [2]The Second Affiliated Hospital of Xi'an Jiaotong University, Core Research Laboratory, Xi'an, China; [3]The Second Affiliated Hospital of Xi'an Jiaotong University, Department of Endocrinology, Xi'an, China; [4]Amigene Institute, Shenzhen, China; [5]The Second Affiliated Hospital of Xi'an Jiaotong University, Department of Health Management, Xi'an, China

Context
Type 2 diabetes (T2D) is associated with an increased incidence of infections and several cancers. Although low-grade inflammation and certain immune defects have been found in diabetic patients, the role of adaptive immune response remains to be fully elucidated.
Objective
We aimed to explore whether patients with T2D show defects in the activation of T cells.
Design
Immune cell phenotypes, T cell functional reactivity, surface receptors involved in T cell activation, and serum cytokines were compared between 24 T2D patients and 24-age, gender and BMI-matched healthy controls.

Results
Higher frequencies of CD4 T lymphocytes were observed in T2D patients than in healthy controls. Moreover, CD4 T showed augmented expression of co-stimulatory receptor CD28. After PMA/ionomycin stimulation, the percentages of IFNγ, IL-10 and p35-producing CD4 and CD8 T cells were significantly increased in T2D patients. CD4 and CD8 T cells showed augmented production of IFNγ, IL-10, IL-13, IL-17 and p35 cytokines. The percentages of regulatory T cells, B cells, monocytes and dendritic cells were comparable between T2D patients and healthy controls, however, B cells and CD16-positive monocytes expressed more surface MHC class I molecules. The serum levels of IL-10 were increased, while MIG were reduced in T2D patients. The frequencies of certain subtypes of T cells and production of cytokines by T cells were positively correlated to fasting blood glucose, HbA1c and IL-10, while negatively correlated to MIG.
Conclusions
These data indicate that hyperglycemia and chronic inflammation in T2D may lead to sustained activation of T cells, which may result in T cell dysfunction and unresponsiveness.

Thrombocyting haemostasis in children with diabetes mellitus type I

Nataliia Nikolaeva, Nina Bolotova, Andrei Averyanov, Vadim Poliakov, Elena Dronova & Nadezhda Nikolaeva
Saratov State Medical University, Russian Federation

Thrombocytes play important role in pathogenesis of diabetic vascular complications.
Aim
To study peculiarities of thrombocyting haemostasisin children with diabetes mellitus type 1 (T1DM).
Patients and methods
120 children (66 boys, 54 girls) 3–17 y.o. with T1DM were examined. The duration of the disease was: less than 1 year in 29 patients (HbAc1 7.5±0.4%) – group 1, from 1 to 5 years in 41 patients (HbAc1 8.7±1.4%) – group 2, more then 5 years in 50 children (HbAc1 11.4±2.2%) – group 3. Control group: 60 healthy children 3–17 y.o. The indexes of trombocyte aggregation (degree, speed and time of aggregation) measured by laser method with different inductors (ADP, adrenalin, kollagen) and intravascular aggregation were evaluated.
Results
Level of adrenalin-stimulating aggregation, speed of kollagen-stimulating aggregation and intravascular aggregation of thrombocytes were increased in group 1 in comparance of control group ($P<0,05$). Levels of ADP- and kollagen-stimulating aggregation ($P<0,05$) and intravascular aggregation ($P<0,001$) were also increased in group 2. Decrease of aggregation time was revealed in this group ($P<0,05$). Increase of all indexes of functional activity of thrombocytes ($P<0,05$) and increase of intravascular aggregation ($P<0,001$) were found in patients of group 3 in comparance of control group.
Conclusions
The changes of thrombocyting haemostasisin children with T1DM were reveald. Functional activity of thrombocytes in this children appeared to increase in correlation with duration of the disease and it may demand treatment.

Fatty liver, irrespective of ethnicity, is associated with reduced insulin clearance and insulin resistance in obese youths

Domenico Trico[1,2], Alfonso Galderisi[3], Brittany Galuppo[4], Bridget Pierpont[4], Stephanie Samuels[4], Nicola Santoro[4] & Sonia Caprio[4]
[1]University of Pisa, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy; [2]Scuola Superiore Sant'Anna, Institute of Life Sciences, Pisa, Italy; [3]University of Padova; [4]Yale University, New Haven, United States

Background
Non-Alcoholic Fatty Liver Disease (NAFLD) is the most common chronic liver disease in Western countries and identifies people at high risk to develop metabolic and cardiovascular disease. Fatty liver has been associated with reduced endogenous insulin clearance (EIC) and hepatic insulin resistance (HIRI), which are early features of type 2 diabetes. These relationships however might be differentially affected by the ethnic background, as populations of African ancestry typically have reduced intrahepatic fat content (HFF%) associated with impaired insulin clearance and sensitivity. Therefore, the aim of this study was to evaluatethe impact of the ethnicity on the relationships between HFF%, EIC and HIRI.
Methods
We analyzed cross-sectional and longitudinal data from the Yale Pediatric NAFLD cohort, a large ($n=620$) and well characterized cohort of overweight and obese adolescents from the three most prevalent racial and ethnic groups in the United States. The HFF% was quantified by a validated magnetic resonance imaging (MRI) method at baseline and after a median follow up of 2 years. Insulin secretion rate (ISR), EIC and HIRI were assessed during 3-hour, 9-point oral glucose tolerance tests (OGTTs) by modeling glucose, insulin, and C-peptide data.
Results
African Americans ($n=172$) exhibited the lowest HFF% and a prevalence of NAFLD less than half of Caucasians ($n=229$) and one third of Hispanics ($n=231$). Furthermore, African Americans had lower EIC and glucose-stimulated ISR, but similar HIRI and plasma insulin levels, compared with other ethnic groups. The HFF% correlated with EIC (std. $\beta=-0.13$, $P=0.0003$) and HIRI (std. $\beta=0.17$, $P<0.0001$), irrespective of the ethnic background, after adjustment for age, sex, ethnicity, BMI z-score, pubertal status, and plasma glucose levels. African Americans showed a lower susceptibility to intrahepatic fat accumulation at follow up, with a two-fold higher (52%) prevalence of adolescents whose HFF% remained stable (change $<\pm$ 1%) compared with Caucasians (28%) and Hispanics (20%) ($P=0.036$). Nevertheless, changes in HFF% over timewere associated with changes in EIC ($r=-0.25$, $P=0.02$) and HIRI ($r=0.22$, $P=0.04$) across all groups, without ethnic differences.
Conclusions
This study demonstrates that intrahepatic fat accumulation is associated with reduced EIC and HIRI in obese youths, irrespective of their ethnic background. Our data dissect the metabolic characteristics of populations of African ancestry and provide novel evidence about the pathogenetic role of liver steatosis in the development of hepatic metabolic abnormalities associated with type 2 diabetes progression.

Are we being too demanding with obese pregnant women with gestational diabetes?

Joana Lima Ferreira[1], Rosa Maria Príncipe[2], Adelina Sá Couto[2] & Grupo de Estudos de Diabetes e Gravidez Portuguese Society of Diabetology[3]
[1]Hospital Pedro Hispano, Endocrinology, Matosinhos, Portugal; [2]Hospital Pedro Hispano, Senhora da Hora, Portugal; [3]Sociedade Portuguesa De Diabetologia, Lisboa, Portugal

Introduction
Nutritional therapy is essential in the treatment of gestational diabetes mellitus (GDM). International recommendations suggest a target of 5–9 kg weight gain in obese women during pregnancy. However, some studies advocate a reduced weight gain (<5 kg) due to better obstetric and neonatal outcomes, compared to an adequate or excessive weight gain.
Aim
To compare obstetric and neonatal outcomes of obese women with GDM with insufficient, adequate and excessive weight gain during pregnancy.
Methods
A cohort of 4563 women with GDM, single fetus pregnancy and pre-pregnancy BMI ≥ 30 kg/m^2 from the Portuguese Registry of GDM was analysed.

T-test and Mann-Whitney U test were used to compare two groups for parametric and non-parametric variables, respectively. Chi square test was used to study differences between categorical variables. A level of significance $\alpha=0.05$ was noted.
Results
Women presented a mean age of 33.29±5.26 years old and a median pre-pregnancy BMI of 34.86 (IQR 5.36) kg/m^2. GDM were diagnosed in median at 23 (IQR 16) weeks of pregnancy. From all, 34.5%, 30.4% and 35.2% had insufficient, adequate and excessive gestational weight gain. The newborn's growth was evaluated according to Fenton curves in 98% of cases. Women with insufficient gain weight had a higher prevalence of small for gestational age (SGA), compared with the other two groups (13.1% vs 8.3% vs 7.5%, $P<0.0001$). By multiple logistic regression, insufficient weight gain during pregnancy was found to increase the possibility of SGA by 76% (OR=1.755, 95% CI=1.436–2.145, $P<0.0001$). A lower value of HbA1c in 3rd trimester was presented in pregnancies with insufficient weight gain (5.29±0.60 vs 5.34±0.45 vs 5.45±0.52, OR=0.612, 95% CI=0.518–0.724, $P<0.001$). Post-partum reclassification of diabetes was performed in 3123 women. Those with insufficient gestational weight gain had a higher prevalence of normal results), compared with the other two groups (91.4% vs 88.7% vs 88.5%, $P=0.004$ and $P=0.002$). No significant differences were found regarding week of diagnosis, treatment with insulin, gestational age, prematurity, global neonatal morbidity, neonatal hypoglycaemia or neonatal intensive care hospitalization between women with insufficient gain weight and the other two groups.
Conclusion
In clinical practice, we are very strict regarding weight gain in obese pregnant women, even those with insufficient weight gain. However, our data seems to validate the international recommendations because reduced weight gain could be harmful to the newborn growth.

Randomized controlled trial of different intensities of glycemic control in women with gestational diabetes

Polina Popova[1,2], Aleksandra Tkachuk[1], Elena Vasukova[1], Aleksandra Dronova[1], Yana Bolotko[1], Evgenii Pustozerov[3], Elena Vasilieva[1], Maria Kokina[1], Olga Li[1], Irina Zazerskaya[1], Tatiana Pervunina[1] & Elena Grineva[1,2]
[1]Almazov National Medical Research Centre, Institute of Endocrinology, Saint Petersburg, Russian Federation; [2]Saint Petersburg Pavlov State Medical University, Department of internal deseases, Saint Petersburg, Russian Federation; [3]Saint Petersburg State Electrotechnical University, Department of Biomedical Engineering, Saint Petersburg, Russian Federation

Background and aims
Current glycaemic treatment targets for women with gestational diabetes (GDM) are controversial. The aim of the study was to compare the effect of different intensities of glycaemic control in pregnant women with GDM on perinatal outcomes.
Materials and methods
Pregnant women in the 8th to 31st week of gestation were randomly assigned to 2 groups per target glycaemic levels: GDM1 (very tight glycaemic targets, fasting blood glucose (FBG) <5.1 mmol/l and <7.0 mmol/l postprandial) and GDM2 (less tight glycaemic targets, <5.3 mmol/l and <7.8 mmol/l, respectively). GDM was diagnosed according to World Health Organization (WHO 2013) criteria. Women were instructed on lifestyle changes and blood glucose monitoring. Insulin therapy was started if target blood glucose levels were exceeded in 2 or more measurements per week in GDM1 and in more than 1/3 of measurements per week in GDM2 group. The primary outcome was the incidence of large for gestational age (LGA) infants.
Results
A total of 616 women were randomly assigned to the study groups: GDM1 ($N=310$) and GDM2 ($N=306$). The rates of LGA infants were similar between the groups (13.7% and 15.6%, for GDM1 and GDM2, respectively, $P=0.550$). There were no significant differences in secondary outcomes including composite of stillbirth or perinatal death and severe neonatal morbidity (nerve palsy, bone fracture and shoulder dystocia) (2.5% and 2.1%, $P=1.0$), gestational age at birth (39.0±1.3 vs 38.9±1.5 weeks, $P=0.224$), birthweight (3423±492 vs 3429±539 g, $P=0.884$), macrosomia (birth weight >4000 g) (12.6% vs 13.3%, $P=0.900$), small-for-gestational age infant (9.8% vs 8.5%, $P=0.660$), neonatal hypoglycaemia (5.9% vs 6.3%, $P=1.0$), admission to the neonatal nursery (4.0% vs 5.3%, $P=0.598$), pre-eclampsia (15.0% vs 15.8%, $P=0.813$), cesarean delivery rate (24.3% vs 29.4%, $P=0.260$), gestational weight gain (9.8±6.7 vs 10.9±6.3 kg, $P=0.081$), any perineal trauma (27.2 vs 27.0%, $P=0.9$) and induction of labor (34.2% vs 30%, $P=0,313$) for GDM1 and GDM2, respectively. GDM1 group achieved lower mean FBG (4.8±0.4 mmol/l vs 4.9±0.5 mmol/l, $P=0.047$) and mean postprandial glucose values (6.1±0.5 mmol/l vs 6.3±0.6 mmol/l, $P<0.001$). The proportion of women prescribed with insulin was higher in GDM1 compared to GDM2 group (45.5% and 26.5%, $P<0.001$).
Conclusion
There were no clear differences in perinatal outcomes between the groups of women receiving very tight and less tight glycaemic targets. The frequency of insulin prescription was substantially higher in the very tight glycemic control arm.

AEP260

Weight loss through lifestyle modification or liraglutide is associated with improvement of NAFLD severity and changes in amino acid concentrations

Joan Khoo[1], Seok-Hwee Koo[1], Jianhong Ching[2], Gaik-Hong Soon[1] & Jean-Paul Kovalik[2]
[1]Changi General Hospital, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore

Introduction
Non-alcoholic fatty liver disease (NAFLD), defined as excess fat accumulation in the liver, is increasingly prevalent due to obesity. NAFLD may lead to steatohepatitis and eventually cirrhosis. Weight loss, either through diet and exercise or medications such as the glucagon-like peptide-1 agonist liraglutide, improves transaminitis, a marker of NAFLD severity. Visceral obesity is associated with increased plasma levels of the amino acids alanine, phenylalanine, tryptophan and tyrosine[1]. The glutamate-serine-glycine (GSG) index (= glutamate/[serine+glycine]), derived from the amino acids glutamate, serine and glycine which are involved in glutathione synthesis, is positively associated with hepatic insulin resistance and with hepatic inflammation on liver biopsy[2]. In this study we compared effects of weight loss from either lifestyle modification or liraglutide therapy on serum transaminases and amino acid profiles.
Methods
Thirty obese (mean age 40.7±9.1 years, BMI 33.2±3.6 kg/m^2, weight 96.4±15.8 kg) adults with NAFLD and transaminitis (mean ALT 87±34 U/L, AST 48±21 U/L) were randomized to either dieting (decrease by 400 kilocalories/day) plus moderate-intensity exercise (200 minutes/week) to induce ≥5% weight loss (DE group, $n=15$), or to liraglutide 3 mg daily therapy (LI group, $n=15$) with standard weight loss advice for 12 weeks. We measured serum alanine (ALT) and aspartate (AST) aminotransferases, amino acid profile, and insulin resistance calculated using homeostasis model assessment (HOMA).
Results
At baseline, plasma ALT and AST were positively associated with the GSG index, alanine and tyrosine levels. Both DE and LI groups had significant ($P<0.01$) and similar ($P>0.05$ between groups) reductions in weight (–3.3±2.9 vs –3.1±1.8 kg respectively), HOMA (–2.96±2.25 vs 2.03±2.11), ALT (–42±34 vs –34±27 U/l) and AST (–23±24 vs –10±15 U/l). GSG decreased in both groups, while alanine, phenylalanine, tyrosine and tryptophan decreased only with liraglutide.
Conclusion
Weight loss by either caloric restriction or liraglutide therapy is linked to reduction in severity of NAFLD, as indicated by decreases in transaminases and the GSG index. Liraglutide is additionally associated with reductions in alanine, phenylalanine, tyrosine and tryptophan, which are indicators of visceral obesity.

Lack of mitochondrial medium chain acyl-coenzyme A synthetase Acsm3 in an inbred rat strain with diet-induced hypertriglyceridemia and insulin resistance

Kristýna Junková[1,2], Ondřej Šeda[2], František Liška[2], Michal Pravenec[3], Josef Vcelak[1] & Lukáš Mirchi[2]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic; [3]Institute of Physiology of the Czech Academy of Sciences, Prague 4, Czech Republic

Introduction
Metabolic syndrome (MetS), the combination of obesity, glucose metabolism impairment, dyslipidemia and high blood pressure, is becoming a worldwide burden of morbidity and mortality. Both genetic and enviromental factors are involved in its pathogenesis, with heritability of each component of MetS 25–80%.
Aim
We aim to contribute to dissection of the genetic architecture of MetS using PD (polydactylous) rats, which present a unique mix of diet-sensitive MetS with severe hypertriglyceridemia, obesity and insulin resistance but normal blood pressure. In comparison, SHR (spontaneously hypertensive rat) has milder dyslipidemia and insulin resistance combined with hypertension. BN (Brown Norway) represents a strain resistant to MetS development.
Materials and methods
6 months old male rats of inbred strains PD, SHR and BN were fed high-fat diet (HFD, short to long-chain fatty acids (FAs)) for 4 weeks. Morphometric and metabolic parameters were measured and liver transcriptome was determined.
Results
The development of MetS was most striking in PD. Weight gain and adiposity increase was significantly higher in PD compared to both BN and SHR. PD animals also showed hyperinsulinemia and hypertriglyceridemia and impaired glucose tolerance after HFD. Analysis of liver transcriptome showed 941, 875 and 348 deregulated genes comparing PD vs BN, BN vs SHR and PD vs SHR, respectively. In PD, we found lack of *Acsm3* transcript and protein product – mitochondrial enzyme involved in activation of medium chain FAs for beta oxidation. Mitochondrial respiration rate for octanoate in liver homogenates revealed significantly lower oxygen consumption in PD compared to SHR rats. In addition, Acsm3 absence in PD rats was associated with about 100 times increase in hepatic stearoyl-CoA desaturase 1 (Scd1) gene expression.
Conclusion
Most striking finding in liver transcriptome was absence of *Acsm3* expression in PD rats. Since the gene is coding for an enzyme activating medium chain FAs, we suppose it could play a role in development of MetS in PD. This hypothesis is supported by the observed reduced mitochondrial octanoate respiration in liver homogenates and increased Scd1 expression. We found no causal mutation in *Acsm3*coding sequence, introns and core promoter, which could explain the absence of mRNA. To elucidate role of A*csm3*in MetS pathogenesis, a transgenic rescue of *Acsm3* in PD is underway.

Evaluation of serum and salivary subfatin and asprosin hormone levels in patients with nonalcoholic steatohepatisis

Ugurcan Cosar[1], Kader Ugur[2], Ramazan Fazıl Akkoç[3], Meltem Yardım[4] & Süleyman Aydın[4]
[1]Department of İnternal Medicine, Medical School, Firat University, Elazig, Turkey, İnternal Medicine, Turkey; [2]Department of Internal Medicine (Endocrinology and Metabolism Diseases), School of Medicine, Firat University, Elazig, Turkey, Endocrinology and Metabolism, Turkey; [3]Department of Anatomy, Medical School, Firat University, Elazig, Turkey., Elazığ, Turkey; [4]Department of Medical Biochemistry and Clinical Biochemistry (Firat Hormones Research Group), Medical School, Firat University, Elazig, Turkey., Elazıg, Turkey

Objective
Nonalcoholic steatohepatitis (NASH) is a metabolic disease characterized by liver steatosis. There is a correlation between liver steatosis and metabolic hormone dysregulation. Subfatin and asprosin are two important metabolic components of adipose tissue and play a role in carbohydrate metabolism, insulin resistance, and glucose regulation. Therefore, the primary aims of this study were to determine how serum and salivary subfatin and asprosin levels change simultaneously in samples obtained from patients with NASH; to compare these levels with those in control cases; and to determine whether there is any correlation of these levels with other metabolic parameters, such as high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL).
Materials and methods
Ninety-seven patients with NASH with a previous histopathological diagnosis and 30 healthy volunteers with no known disease (control group) were included in the study. The patients were classified under four stages: stage 1 ($n=30$), stage 2 ($n=30$), stage 3 ($n=22$), and stage 4 ($n=15$); 5 cc blood and 1 cc saliva were collected from the patients. Subfatin and asprosin levels in biological samples were studied using ELISA method. Other biochemical parameters (FBS, Hba1C, LDL, HDL, total cholesterol, triglyceride, AST, ALT, insulin, urea, creatinine, and uric acid) were studied using autoanalyzers.
Results
The median age and BMI of obese patients were significantly higher in the patient group than in the control group ($P<0.05$). Hba1C and glucose, insulin, LDL, total cholesterol, triglyceride, AST, ALT, urea, and uric acid levels were significantly higher and HDL levels were significantly lower in the patient group than in the control group ($P<0.05$). Serum and salivary asprosin levels of the patient group were significantly lower than those of the control group ($P<0.05$). Serum and salivary subfatin levels were lower in the patient group than in the control group; however, the difference was not significant ($P>0.05$).
Conclusion
On the basis of the study results, we concluded that subfatin and asprosin levels are lower in patients with NASH than in healthy subjects. In addition to serum, subfatin and asprosin are present in saliva. Both blood and saliva are thought to be the sources of subfatin and asprosin in saliva. Therefore, subfatin and asprosin are indicators of metabolic events (including NASH), and their presence in the saliva constitutes an important alternative to blood as the collection of saliva is noninvasive.

Keywords: nonalcoholic steatohepatitis, subfatin, asprosin.

Capabilities of ultrasonography in diagnosis of latent post-injection lipodystrophies

Irina Savasteeva[1], Tamara Evdochkova[2], Veronika Selkina[2] & Mariya Rusalenko[1]
[1]Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus; [2]Republican Research Center for Radiation Medicine and Human Ecology, ultrasonography, Gomel, Belarus

Introduction
Condition of injected skin and subcutaneous tissue is assessed by visual inspection and palpation and it has only 10–15% diagnostic value. The standard ultrasonography comparison of symmetrical skin areas is not valuable as they are usually used for injections.
Objective
We examined 143 patients, aged 43.3±3.9 years, with DM duration of 6.5±2.8 years, receiving basal-bolus insulin therapy.
Methods
Ultrasonography was performed for 78 volunteers with uninjected skin and subcutaneous tissue of the lumbar and epigastric regions. We determined correction factors that predict skin thickness at the injection site if insulin weren't administered.
Results
Ratio indices at the injection regions were calculated – the ratio of the dermis thickness of the studied to lumbar region. In the anterolateral shoulder region, normal indices were defined: for epidermis in the range of 0.9–1.0; for dermis – 0.5–0.7. In the anterolateral thigh region: for epidermis – 0.8–1.0; for dermis – 0.5–0.8. In the umbilical region: for epidermis – 0.8–1.0; for dermis – 0.6–0.8. In the upper outer quadrant of the buttock: for epidermis – 0.8–1.0; for dermis – 0.7–0.9. With values decrease, hypotrophic lipoatrophy development is expected. When performing ultrasonography and analyzing the ratios of the epidermis and dermis of the lumbar region to injection sites, changes were detected in every 4 (37 patients), which is 25%. Post-injection hypotrophic lipoatrophy was diagnosed in the umbilical region (49%), in the anterolateral shoulder (24%) and thigh (17%) regions, in the gluteal region (10%).

Conclusion
Using ratio indices during ultrasonography, it is possible to diagnose and treat post-injection lipodystrophies in the earliest time in order to achieve the highest insulin injection bioavailability.

Evaluation of glycemia course in patients with diabetes mellitus type

Elena Makhlina, Yana Navmenova & Irina Savasteeva
SI «The Republican Research Center for Radiation Medicine and Human Ecology», Endocrinology, Gomel, Belarus

Objectives
To analyze the indicators of carbohydrate metabolism depending on the characteristics of the manifestation of hypoglycemic reactions.
Materials and methods
The study daily glucose dynamics was carried out with Medtronik MINIMED Continious Glucose Monitoring System (CGMS), USA.
The standard glycose profile (4–5 per day) was measured in capillary blood with the Precision PCχTM glucose meter, MediSense. To analyze the continuous glycemic curve, the risk indices (RIn) of hypoglycemia and hyperglycemia were calculated over the study period.
We have examined 162 patients with diabetes mellitus type 1.
There was group 1 with the presence of hypoglycemic reactions ($n=99$), and group 2 with the absence of hypoglycemic reactions ($n=63$).
The groups are comparable in terms of mean age (28.59±7.10 years), duration of DM type 1 (10.46±7.28 years), and BMI (24.12±3.62 kg/m^2).
Results
in the total number of examined, the median RIn of hyperglycemia was 13.15 [9.00; 20.00], RIn of hypoglycemia was 5.25 [2.00; 9.60], HbA1C level was (9.00% [7.70; 10.60]).
When taking into account the presence of hypoglycemic reactions in the group 1, RIn of hyperglycemia was 11.80 [9.00; 18.30], RIn of hypoglycemia was 8.15 [4.50; 12.90], in group 2, RIn of hyperglycemia was 18 30 [10.20; 24.80], RIn of hypoglycemia was 1.20 [0.25; 3.25].
Assessing RIn of hypo- and hyperglycemia in groups taking into account the severity, in group 1, the high RIn of hypo- and hyperglycemia (76%) prevailed over the low one (RIn of hypoglycemia 10% and RIn of hyperglycemia (8%) $P<0.001$, in group 2 low RIn of hypoglycemia (69%) and high RIn of hyperglycemia (78%) accounted for the majority ($P<0.001$).
Conclusions
In the examined patients with DM type 1, the median RIn of hyperglycemia and RIn of hypoglycemia corresponds to a high risk of developing hyper- and hypoglycemic conditions and indicates decompensation of DM 1.
Decompensation of DM type 1 in patients with hypoglycemic episodes is caused by posthypoglycemic hyperglycemia.

Hand grip strength is correlated with peripheral neuropathy and metabolic control in patients with diabetes

Aura Diana Reghina[1,2], Ana Maria Balea[2], Mirela Iancu[2], Laura Ilinca[2], Anca Diana Niculica[1] & Simona Fica[1,2]
[1]University of Medicine and Pharmacy Carol Davila, Endocrinology and Diabetes, Bucharest, Romania; [2]Elias University Hospital, Endocrinology and Diabetes, Bucharest, Romania

Background
Peripheral neuropathy is the most prevalent chronic complication in diabetes and increases the risk of sarcopenia in these patients. Hand grip strength (HGS) measurement is a good predictor for the presence of sarcopenia.
The aim of the study was toevaluate HGS in diabetes patients with and without neuropathy and the clinical and paraclinical parameters that are correlated with HGS.
Methods
We evaluated 102 diabetes patients by clinical examination, Michigan Neuropathy Screening Instrument Questionnaire (MNSI-Q) and laboratory measurements. HGS was measured by grip strength dynamometer.
Results
Mean age was 62.8±8.6 years, 64% were women and mean duration of diabetes was 13.7±8.1 years and 43% of patients were diagnosed with peripheral neuropathy. Patients with peripheral neuropathy had higher duration of diabetes 16.8±8.4 vs 11.4±7.3 years ($P=0.001$) and a lower HGS 24.5±9.7 kg vs 30.3± 13.8 kg ($P=0.06$). Prevalence of peripheral neuropathy was similar in women and men. HGS was similar in women with or without neuropathy but HGS was significantly lower in men with neuropathy 33.3±6.8 kg vs 43±8.3 kg ($P=0.004$). HGS was corelated with glycated hemoglobin in the whole group ($r=–0.283$, $P=0.03$) and was negatively correlated with age ($\beta=–0.601$, $P=0.005$) and MNSI-Q score ($\beta=–0.36$, $P=0.05$) in men but not in women.
Conclusion
HGS is significantly correlated with the presence of peripheral neuropathy in men but not in women. HGS measurementisa very useful and easy to use tool in clinical practice to estimate the risk of sarcopenia in men with neuropathy.

Association between gestational glycemic profile and delivery with a large for gestational age baby in pregnant women with type 1 diabetes

Ekaterine Inashvili[1], Natalia Asatiani[2], Ramaz Kurashvili[2], Elena Shelestova[2], Mzia Dundua[2] & Ana Kopaleishvili[2]
[1]National Center for Diabetes Research, Endocrinology, Tbilisi, Georgia; [2]National Center for Diabetes Research, Tblisi, Georgia

Bacground
Hyperglycemia is believed to be the underlying cause for many of the adverse fetal, neonatal, and maternal outcomes in pregnancies complicated by type 1diabetes (T1DM). In particular, the rates of a large for gestational age (LGA) neonates and macrosomia remain high and suggest that hyperglycemia may not be the only driver of fetal overgrowth for women with T1DM.
Aim
Our aim was to assess the association between gestational glycemic profiles [HbA1c, postprandial (PG), fasting (FG), mean (MG) blood glucose]and delivery with a LGA baby in women with T1DM.
Methods
Totally, 321 pregnant women with T1DM were enrolled in the study. Data obtained for home-blood glucose monitoring (seven-point profiles), PG, FG, MG and HbA1c in the late 2nd and 3rd trimesters of pregnancy were analyzed. Gestational age at delivery was 37.2±1.3 weeks and birth weight (BW) was 3 383±358.3 g; in total, 86 (26%) neonates were born LGA. The patients were divided into 2 groups (Gr.): LGA-Gr. – 86 patients and non-LGA-Gr. – 235 patients.
Results
In the late 2nd and 3rd trimesters of pregnancy HbA1c, PG, FG and MG levels were statistically higher in LGA-Gr., than in non-LGA-Gr.: HbA1c (%) – 7.3±1.29 vs 6.2±1.63 ($P<0.001$); PG (mg/dl) – ($P=0.000$); FG (mg/dl) – ($P=0.000$); MG (mg/dl)- ($P=0.000$). Pre-pregnancy body mass index (BMI) was higher in LGA-Gr, than in non-LGA-Gr. (kg/m^2) – 27.5± 0.57 vs 22.9± 0.41 ($P<0.001$). In non-LGA-Gr. correlation between body weight (BW) and PG (r –0.794; $P=0.000$) and BW and pre-pregnancy BMI (r –0.580; $P=0.0076$) was observed, thoughno significant interaction betweeninfants BW and HbA1c, FG and MG was found.
In LGA-Gr. strong correlation between BW and PG (r –0.876; $P=0.000$), BW and HbA1c (r –0.603; $P=0.003$), BW and MG (r –0.611; $P=0.002$), BW and pre-pregnancy BMI (r –0.866; $P=0.001$), and no correlation between BW and FG were observed.
Conclusion
HbA_{1c} is less likely to be able to detect shorter-term glucose variability and does not always predict fetal macrosomia. Maternal postprandial glucose excursions in the late 2nd and 3rd trimesters and pre-pregnancy BMI might be relevant in the development of aLGA baby.

Peculitaries of markers of renal function in patients with Diabetic Kidney Disease depending on C/T polymorphism in the DIO 1 gene

Nataliia Abramova[1,2], Nataliia Pashkovska[1], Yulia Marchuk[1], Ivan Pankiv[1], Antonina Piddubna[1], Galina Koval[1] & Iryna Tsaryk[1]
[1]HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Чернівці, Ukraine; [2]Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Decrease in thyroid hormones (TH) levels is associated with reduced blood flow to kidneys and decreased glomerular filtration rate (GFR) along with alteration of tubular reabsorption.
Deiodinase type 1 is an enzyme that is active in liver and kidneys and plays an important role in TH metabolism.
The aim of the research was to study the dependence of markers of renal function on C/T polymorphism in the DIO 1 gene in patients with DKD.
Material and methods
The C/T polymorphism in the DIO1 gene was studied in 102 patients with diabetes type 2 (T2DM) complicated by CKD in stage ofmicroalbuminuria and 97 healthy subjects – control group.
To assess the dependence of biochemical markers of renal function on the C/T polymorphism in the DIO 1 gene, the following groups has been formed: 19 patients with CC genotype, 69 – with CT and 14 – with TT genotypes.
Blood sample was analysed for blood urea, serum creatinine, urine test for evaluation of microalbumin, creatinine levels. Albumin/creatinine ratio in urine and GFR by CKD-EPI formula were calculated. To access TH levels free triiodothyronine T_3(fT_3), free thyroxine T_4(fT_4), thyroid stimulating hormone (TSH) were determined.
Results
Disorders of distribution of genotype frequencies contributed by the reduction of CC genotype frequency was revealed in the group of enrolled patients comparing to the control group ($\chi^2=6.8$, $P<0.05$), while there was no significant difference between the frequencies of CT and TT genotypes ($\chi^2=2.4$, $P>0.05$ and $\chi^2=1.2$, $P>0.05$).
Blood urea ($P=0.032$), blood cleatinine ($P=0.035$) levels as well as microalbumin ($P=0.041$) and creatinine content ($P=0.039$) in urine were higher in group with TT genotype than in group with CC genotype.
Creatinine in blood serum ($r=-0.362$, $P<0.05$), microalbumin in urine ($r=-0.416$, $P<0.05$) correlated negatively with the level of fT_3. GFR correlated positively with fT_3 level ($r=0.374$, $P<0.05$) and negatively with fT_4 level ($r=-0.326$, $P<0.05$).
Conclusions
1. C allelehas protective properties against violation of TH metabolism in patients with T2DM.
2. Carriers of Tallele with DKD had significantly worse biochemical indices of renal function, that indicates the dependence of these markers on DIO1 polymorphism.
3. Results of correlation analyses showed the dependence between the levels of TH and biochemical indices of renal function.

Association of the APOEgene polymorphism with diabetic nephropathy

Taner Hasan[1], Slavica Josifovska[2], Ivana Trajkovska[1], Daniela Doneva[1], Natasha Nedeska[1] & Cvetanka Volkanovska Ilijevska[1]
[1]8th September City General Hospital, Endocrinology, Diabetes and Metabolism, Skopje, Macedonia; [2]Institute of Biology, Faculty of Natural Sciences Ss. Cyril and Methodius University, Molecular Biology, Skopje, Macedonia

The protein isoformes that are products of the Apolipoprotein E (*APOB*) gene polymorphism have partially altered biological activity and that may lead to greater susceptibility of the patientsto microvascular complications including Diabetic nephropathy (DN)in patients with the Type 2 diabetes mellitus (T2DM). The aim of this study was to evaluate the association between the allele ε2, ε3, and ε4 of the *APOE* gene, as well as their combination, with the development of DN in patients with T2DM from the North Macedonia. The genotypic and allele frequency of the polymorphisms rs429358 and rs7412 in the *APOE* gene was determined in a group of patients with T2DM (with and without DN), and in the control group healthy subjects. The study is designed as a case-control genetic association study. The samples from 88 patients with T2DM were analyzed, including 57 patients with DN and 31 without DN and 26 healthy controls. The demographic, clinical and laboratory data were analyzed in addition to the genetic profiling of the patients. Genotyping of the *APOE* gene polymorphism resulted in determination of the patient's genotype: ε2/ε2, ε3/ε3, ε4/ε4, ε2/ε3, ε2/ε4 or ε3/ε4, as well as of the alleles: ε2, ε3 or ε4. The results revealed a statistically significant association of the genotype ε2/ε3 ($P=0.016$) and the allele ε2 ($P=0.020$) with the occurrence of DN compared to the other genotypes and alleles. The presence of this genotype increases the chances of DN by 4,24 folds and the relative risk by 1,50 folds. In conclusion, the correlation of the *APOE*gene polymorphism and the development of the DN in patients with T2DM was confirmed indicating that there is a potential applicable value in the prognosis and treatment selection.

Characterizing familial partial lipodystrophy: Baseline data of the BROADEN study

Louis O'Dea[1], Joseph Tami[2], Veronica Alexander[2], Lynnetta Watts[2], Eunju Hurh[1], Brant Hubbard[1], Hartmut Schmidt[3], Anatoly Tiulpakov[4], Ann Mertens[5], Abhimanyu Garg[6] & Elif Oral[7]
[1]Akcea Therapeutics, Boston, United States; [2]Ionis Pharmaceuticals, Carlsbad, United States; [3]University Hospital Muenster, Gastroenterology, Hepatology, Endocrinology, Diabetology, and Infectology, Münster, Germany; [4]Endocrinology Research Centre, Moscow, Russian Federation; [5]KU Leuven, Clinical and Experimental Endocrinology – Department Chronic Diseases, Metabolism and Ageing, Leuven, Belgium; [6]University of Texas Southwestern Medical Center, Internal Medicine, Dallas, United States; [7]University of Michigan, Metabolism, Endocrinology and Diabetes Division and Brehm Center for Diabetes, Ann Arbor, United States

Introduction
Familial Partial Lipodystrophy (FPLD) is a rare genetic disorder characterized by marked loss of subcutaneous adipose tissue from the extremities and is associated with a variety of metabolic abnormalities. While phenotypic elements of the disorder can vary across genotypes, symptomatic presentation, disease severity, and onset can also vary among individuals with the same disease-causing variant, or even among family members. Due to this variability, and the rarity of the disease, an encompassing patient profile has been challenging to determine. Therefore, we present a detailed phenotypic/genotypic description of the FPLD patients who participated in a Phase 2/3 clinical trial.
Methods
Baseline data from patients with FPLD ($n=40$) participating in a phase 2/3 study of volanesorsen (apo C-III antisense oligonucleotide) were analyzed to provide greater insight into the clinical, genotypic and phenotypic profile of patients with FPLD. Patients were required to have FPLD by genetic, familial or phenotypic criteria, fasting triglycerides ≥ 2.3 mg/dl and confirmed diabetes mellitus by an elevated HgbA1c.
Results
Participants had a median age of 49 years (range 28–68 y), were predominately female ($n=29$, 72.5%), with a 78.4 kg (range 57.8–126.1 kg) median body weight and BMI of 29.8 kg/m^2 (range 21.0–44.2). Sixteen patients had genetically confirmed FPLD, with 12 harboring pathogenic missense variants in *LMNA* and 4 in *PPARG*. Additionally, three patients had variants of uncertain significance in FPLD related genes. No patient had a pathogenic variant in *PLIN1, AKT2* or *CIDEC*. Median fasting triglycerides were 8.6 mmol/l (range 2.4–60.4). Seven patients reported using triglyceride lowering medications (statins, fibrates, omega 3/fish oil). All patients had clinical diabetes mellitus with mean HgbA1C of 8.0% (s.d. 1.4%). Twenty-six patients reported use of insulin or other hypoglycemic medications. Medical history of fatty liver disease was reported by 26 patients and mean baseline hepatic fat fraction was 17.6% (s.d. 7.9%).
Conclusion
We conclude that the majority of the eligible participants for this trial lacked variants in the known FPLD genes. FPLD, type 2, due to *LMNA* variants was the most prevalent subtype of FPLD in our cohort followed by FPLD, type 3 due to *PPARG* variants. Both variant positive and negative patient groups had the hallmark traits of abnormal fat distribution, severely elevated triglycerides, diabetes and elevated HgbA1C, and significant hepatic steatosis. The complex characteristics of this disorder support the need for careful clinical phenotyping of the cases and investigation of the variability in the presentations.

A comparison of the level of appetite, food intake, metabolic hormones, basal metabolic rate and adiposity in normal and short stature children

Nighat Kausar[1], Maleeha Akram[1], Gulbin Shahid[2], Afzaal Ahmed Naseem[3], Mazhar Qayyum[1], Fahim Tahir[4], Sarwat Jahan[5], Kiran Afshan[5], Muhammad Rafi[6] & Syed Shakeel Raza Rizvi[1,7]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology, Rawalpindi, Pakistan; [2]The Children's Hospital, Pakistan Institute of Medical Sciences (PIMS), Department of Endocrinology, Islamabad, Pakistan; [3]University of Lahore, Sihala Campus, Islamabad, Pakistan; [4]National Institute of Health, Reproductive Physiology, Public Health Laboratories Division, Islamabad, Pakistan; [5]Quaid-i-Azam University, Department of Animal Sciences, Islamabad, Pakistan; [6]Pakistan Institute of Engineering and Applied Sciences (PIEAS), Islamabad, Pakistan; [7]University of Central Punjab, Quaid Campus, Rawalpindi, Department of Zoology, Rawalpindi, Pakistan

The acceleration in linear growth at puberty is attributed to the combined physiological effects of both somatotropic and gonadal axes. In synergy, growth hormone (GH) and gonadal steroids (testosterone (T) and estradiol (E2)) stimulate longitudinal bone growth through direct stimulation of chondrocytes and osteoblast. Nutrition such as sufficient amount of nutrients including calcium, phosphate, sodium, potassium and iron and vitamins like vitamin D, vitamin A and vitamin C play an important role in linear bone growth velocity at puberty in both sexes. Amongst others, the secretion of GH is stimulated by ghrelin through GH secretagogue receptor (GHSR). Ghrelin, secreted by enteroendocrine cells of gastrointestinal tract, stimulates the hunger center in the hypothalamus, increases appetite and plays a role in positive energy balance. The present study was designed to determine the level of appetite and food intake, plasma concentrations of metabolic hormones, ghrelin, leptin, obestatin, GH, prolactin (PRL) and triiodothyronine (T3) and basal metabolic rate (BMR) in normal and short stature boys and girls. The amount of food intake over a period of one week was determined through Child Eating Behavior Questionnaire (CEBQ) in 50 normal and 35 short stature children and the amount of calories, nutrients and vitamins were calculated from the food intake by using available literature for each food item. ELISA was used for analysis of plasma ghrelin, leptin, obestatin and PRL while RIA was used for analysis of plasma GH and T3. BMR was calculated by using the Harris and Benedict Equation (1918) for both boys and girls. Data were analyzed using Student's t test, ANOVA and Pearson correlation r. The results revealed that normal children exhibited increased appetite and food intake as compared to short stature children. Moreover, the concentrations of metabolic hormones T3, GH, PRL, obestatin and BMR were significantly higher in normal children as compared to short stature children indicating lower level of energy balance in short stature children. In contrast, the concentrations of ghrelin were significantly higher in short stature children as compared to normal children suggesting a lack of negative feedback effect on ghrelin secretion. Similarly, the concentrations of leptin were also higher in short stature children indicating greater deposition of fats and higher BMI of short stature children. In conclusion, normal children exhibited increased appetite, food intake and higher concentrations of T3, GH, PRL, obestatin and BMR, whereas short stature children had increased concentrations of ghrelin and leptin and higher adiposity.

MODY5 with a whole deletion of HNF1B based on 17q12 microdeletion in a patient with primary amenorrhoea due to severe genitalabnormalities

Aleksandra Kruszyńska[1,2], Agata Skórka[3,4] & Marzena Dębska[5]
[1]Centre of Postgraduate Medical Education (CMKP), Department of Endocrinology, Poland; [2]Bielanski Hospital, Department of Endocrinology, Warsaw, Poland; [3]The Medical University of Warsaw, Department of Paediatrics, Warsaw, Poland; [4]The Children's Memorial Health Institute, Department of Medical Genetics, Warsaw, Poland; [5]Centre of Postgraduate Medical Education (CMKP), 2nd Department of Obstetrics and Gynecology, Warsaw, Poland

Introduction
Maturity-onset diabetes of the young (MODY) 5 is caused by mutations in the *TCF2 (HNF1B)* gene encoding the transcription factor hepatocyte nuclear factor-1. However, in 60% ofthe patients with a phenotype suggesting MODY5, no pointmutation is detected in *TCF2* gene. In some of those patients genomic rearrangements may be responsible for the phenotype.
MODY5 or renal and diabetes syndrome (OMIM #137920) encompasses a wide clinical spectrum comprising diabetes, pancreas atrophywith subclinical exocrine deficiency, progressive nondiabetic nephropathy, kidney and genital malformations and liver abnormalities.
Case report
We present a case of a 22-year-old woman with primary amenorrhoea and hirsutism. In adolescence due to abnormal liver test she was diagnosed with Gilbert syndrome. During the current diagnostic process imaging findings including ultrasonography and MRI of the abdomen revealed normal vagina and ovaries but rudimentary uterus, bilateral kidney cysts, laboratory test revealed elevation of the serum levels of the liver transaminases, adrenal androgenization (NCCAH was excluded), impaired fasting glucose and impaired glucose tolerance with moderate hyperinsulinemia and hyperuricemia. She was consulted by a geneticist and renal cysts and diabetes syndrome was suspected. The sequencing of *HNF1B* gene was ordered but revealed no mutation, whereas multiplex ligation-dependent probe amplification (MLPA) P297-C1 revealed 17q12 deletion including genes: *LHX1, AATF* and *HNF1B* genes.
Conclusions
In conclusion we hope that our detailed description of the patient with the phenotype of MODY 5/renal cyst and diabetes syndrome due to 17q12 deletion will contribute to the further genotype-phenotype delineation of that syndrome. We would also like tostress that in patients with a phenotype suggesting MODY5 and no pointmutation detected in *HNF1B* gene, genomic rearrangements including deletions should be searched for.

Difficulties in diagnosing of artificial hypoglycemia: Insulin analogues

Marina Yukina, Nurana Nuralieva, Ekaterina Troshina, Natalia Malysheva & Larisa Nikankina
Endocrinology Research Centre, Clinical Endocrinology, Moscow, Russian Federation

Introduction
One of the manifestations of Munchausen syndrome is the deliberate injection of insulin to achieve hypoglycemia or artificial hypoglycemia. If human insulin is injected, we will always determine high level of insulin and low level of Cpeptideatthemomentofhypoglycemia. Incasesof insulin analogues injection the diagnos is maybe difficult when we use analyzers specific only to human insulin: the low level of IRI and C peptide will be determined.
Objectives
Tocomparethediagnosticaccuracyof analyzers AbbottArchitect (AA) andRoche (R) in determining the IRI levelafterinjectionthe insulin analogues.
Methods
120 patients with suspected NDH aged 18–80 wereincludedin a cross-sectional study. According to the results, we selected the patients ($n=14$) with hypoinsulinemic hypoglycemia (glucose less than 2.8 mmol/l, C peptide less than 0,6 ng/ml, IRI less than 3 μU/ml), diagnosed by the R kit. Then we determined the IRI level in the same blood sample using AA kit.
Results
IRIlevelsaccordingtothedataofdifferentanalyzers were different, but in 93% of cases ($n=13$) the differences were not clinically significant; the diagnosis did not changed (hypoinsulinemic hypoglycemia). Onlyinone patient we revealed significant change of IRI level (more than 2000%): 1.91 μU/ml by theR kit and 42 μU/ml by the AA kit. Taking into account the level of Cpeptide lessthan 0.6 ng/mlwe diagnosed the artificial hypoglycemia. In addition, we found the injection marks on the patient body. The patient was referred to a psychiatrist's consultation. The causes of hypoinsulinemic hypoglycemia in the other patients in our study are: non-β-cell tumors, adrenal and hepatic insufficiency.
Conclusion
inthecasesofusingkits, that determine only human IRI, if the deliberate injection of insulin analogues is suspected (hypoinsulinemic hypoglycemia), for the confirmation the diagnosis it is advisable to investigate the same blood samplewith hypoglycemia using kits, that also determine insulin analogues, forexample, the analyzer AA. Duringtheanalyze of the IRI levels it is required to take into account the C peptide value, which will be always low in cases ofdeliberate injection of any insulin.

Effects of different metabolic states and surgical models on glucose metabolism and secretion of ileal L-Cell peptides: Results from the HIPER-1 study

Eylem Cagiltay[1], Sjaak Pouwels[2] & Alper Celik[3]
[1]Sağlık Bilimleri Üniversitesi Gülhane Sağlık Bilimleri Enstitüsü, Turkey; [2]Street Elisabeth Hospital, Tilburg, Netherlands; [3]Metabolic Surgery Clinic, Istanbul, Turkey

Objective
To compare the impact of 4 surgical procedures (mini gastric bypass [MGB], sleeve gastrectomy [SG], ileal transposition [IT], and transit bipartition [TB]) versus medical management on gut peptide secretion, beta cell function, and resolution of hyperglycaemia in type 2 diabetes (T2DM).
Research design and methods
A mixed-meal tolerance test (MMTT) was administered 6–24 months after each surgical procedure (mini gastric bypass [MGB], sleeve gastrectomy [SG], ileal transposition [IT], and transit bipartition [TB], $n=30$ in each group) and the result was compared to matched lean ($n=30$) and obese ($n=30$) T2DM participants undergoing medical management
Results
MGB and IT participants had a greater increase in plasma glucose concentration following MMTT than SG and TB participants. MGB participants exhibited the greatest increase in the incremental area under the curve of plasma glucose concentration above baseline (ΔG_{0-120}) ($P<0.0001$). Insulin sensitivity was comparable across surgical groups, and statistically greater in surgical participants than in obese nonsurgical participants ($P<0.0001$). Beta cell responsiveness to glucose was greater in SG and TB than in MGB and IT participants ($P<0.001$) despite a smaller increase in $\Delta GLP\text{-}1_{0-120}$ relative to IT. Postoperative beta cell function was the strongest predictor of hyperglycaemia resolution.
Conclusions
The present study demonstrated that the level of beta cell function after bariatric surgery is the strongest predictor of hyperglycaemia resolution. The study also demonstrates a disconnection between postprandial GLP-1 levels and beta cell function among the studied surgical procedures.

The influence of simultaneous pancreas-kidney transplantation on the evolution of diabetic foot lesions and peripheral arterial disease

Sílvia Monteiro[1], Catarina Pereira[1], Diana Duarte[1], Tiago Santos[1], Filipa Silva[2], La Salete Martins[2], Cláudia Amaral[1], Cláudia Freitas[1], André Carvalho[1], Joana Martins[3], Luís Loureiro[3], Rui Carvalho[1] & Jorge Dores[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar e Universitário do Porto, Nephrology and Transplant, Porto, Portugal; [3]Centro Hospitalar e Universitário do Porto, Vascular Surgery, Porto, Portugal

Introduction
Simultaneous pancreas-kidney transplantation remains the best treatment option in type 1 diabetic patients with chronic kidney failure, providing a euglycemic state associated with an improvement on diabetic chronic complications. However, there are only a few studies addressing the potential ischemic deterioration of peripheral arterial disease, due to blood diverting from the iliac artery to the kidney graft.
Aim
Evaluate diabetic foot lesions and peripheral arterial disease evolution in simultaneous pancreas-kidney transplantation recipients and investigate if they are more frequent in ipsilateral lower limb of kidney graft.
Methodology
A retrospective cohort, including patients submitted to simultaneous pancreas-kidney transplantation inour tertiary center, between 2000 and 2017. Diabetic foot lesions and peripheral arterial disease frequencies were evaluated and then compared in the period before and after transplantation.
Results
Two-hundred and eleven patients were included, being 50.2% ($n=106$) female, with a median age at transplantationof 35 years. The median time since diabetes diagnosis was 23 years. The median time under dialysis was 22 months, 68.2% ($n=144$) undergoing hemodialysis. The mean HbA1c before the transplantation was $8.6\pm1.6\%$ and the most recent median was 5.5%. In 2019, the patient, kidney and pancreatic graft survival was 90.5% ($n=191$), 83.4% ($n=176$) and 74.9% ($n=158$), respectively. In the pre-transplant period, 12.3% ($n=26$) had peripheral neuropathy, 2.8% ($n=6$) had peripheral arterial disease and 5.3 ($n=11$) suffered some foot injury. In post-transplant period, 39.3% ($n=83$) had peripheral neuropathy, 17.1% ($n=36$) peripheral arterial disease and 25.6% ($n=54$) developed ulcers, 14 of which in the ipsilateral lower limb of kidney graft, 19 in the contralateral and 21 bilateral (25.9% vs 35.2% vs 38.9%, $P=0.49$). Nine patient (4.3%) underwent major amputation, 2 of the ipsilateral limb, 6 of the contralateral and 1 bilateral (22.2% vs 66.7% vs 11.1%, $P=0.09$).
Conclusion
Despitesimultaneous pancreas-kidney transplantation positive effects on diabetic chronic complications, we verified a high prevalence of peripheral neuropathy and diabetic foot ulcers in our sample. Diabetic foot lesions were not more frequent in the ipsilateral lower limb of kidney graft, reducing the 'steal syndrome' role in these patients.

Female AKR1D1 knockout mice have impaired intestinal health with evidence of gut dybiosis, increased gut permeability and an increased incidence of colon cancer

Anastasia Arvaniti[1,2], Shelley Harris[2], Nikolaos Nikolaou[2], Tom Potter[1], Roger Cox[3], Alex Odermatt[4], Jeremy Tomlinson[2] & Laura Gathercole[1,2]
[1]Oxford Brookes University, Department of Biological and Medical Sciences, Oxford, United Kingdom; [2]University of Oxford, Oxford Centre for Diabetes, Endocrinology & Metabolism, Oxford, United Kingdom; [3]MRC Harwell Institute, Oxford, United Kingdom; [4]University of Basel, Department of Pharmaceutical Sciences, Basel, Switzerland

Metabolic syndrome (MS) is an important etiologic risk factor for the development and progression of certain cancers, including colorectal. Bile acids (BA) are potent antimicrobials that support gastrointestinal health and the dysregulation of BA homeostasis is thought to contribute to gut dysbiosis and drive endotoxemia. Furthermore, an increase in the cytotoxicity ofintestinal BA species can directly damage enterocytes and promote carcinogenesis. We have previously shown that expression of bile acid synthesis enzyme, 5β-reductase (AKR1D1), is decreased in patients with non-alcoholic fatty liver disease (NAFLD), the hepatic manifestation of MS and here we demonstrate the impact of AKR1D1 deletion on gastrointestinal health in C57BL/6 mice. Female and male wildtype (WT) and AKR1D1 knockout (KO) mice were maintained on a control diet until 52-weeks of age. In both sexes, AKR1D1 deletion decreased BA levels and altered composition, as determined by LC-MS/MS analysis, leading to a more cytotoxic BA profile. Although 16s rRNA analysis ofcecal chyme showed no change in total bacterial counts there were family level changes in bacterial composition. Consistent with ileal damage, female AKR1D1KO mice had decreased villi lengthand increased crypt depth. Suggesting increased intestinal permeability and endotoxemia the expression of the tight junction genes *Claudin 1*, *ZO-1* and *Occludin* were reduced and the presence of bacterial DNA in the liver increased, as was hepatic mRNA and protein levels of TLR4 along with expression of TLR4 mediated genes, *Nfkb1* and *Tnfa*. In the colon female AKR1D1 KO mice had decreased crypt depth and greater numbers of cells stained for the proliferation marker Ki-67. Furthermore, there was increased incidence of abnormal growths (tumours and polyps) in the proximal colon; 20% of female AKR1D1 KO mice compared to 0% of WT. Interestingly, male AKR1D1 KO mice had a much milder intestinal phenotype with decreasedexpression of *Claudin 1*, *ZO-1* and *Occludin* but without signs of damage in the ileum or colon or of endotoxemia in the liver. No abnormal growths were found in either WT or AKR1D1 KO male mice. Collectively, our results suggest that reduced AKR1D1 activity, as that seen in patients with NAFLD, has a sex specific impact on intestinal health, driving intestinal damage and gut permeability and potentially contributing to the risk of colon cancer in females.

Metabolic and cardiovascular consequences of Ramadan fasting in type 2 diabetic patients

Fatma Boukhayatia[1], Ibtissem Oueslati[1], Meriem Cheikh[1], Bassem Hammami[2], Asma Kardi[1], Meriem Yazidi[1], Moncef Feki[2], Neila Ben Romdhane[3] & Melika Chihaoui[1]
[1]La Rabta hospital, Department of endocrinology, Tunis, Tunisia; [2]La Rabta hospital, Laboratory of biochemistry, Tunis, Tunisia; [3]La Rabta hospital, Laboratory of hematology, Tunis, Tunisia

Introduction
Ramadan fasting stands for abstaining from eating, drinking, smoking and oral medication use from predawn to sunset during one month. The duration of the fast from 10 to 19 hours, lifestyle changes and sleep disturbances can affect the glycemic control in diabetic patients with a high risk of hypoglycemia and hyperglycemia. However, fasting has been shown to improve insulin sensitivity and reduce oxidative stress, inflammation and the risk of atherosclerosis.
The objective of our study was to assess the impact of fasting on metabolic and cardiovascular profile in type 2 diabetic patients.
Methods
We conducted a prospective case-crossover observational study including 47 type 2 diabetic patients treated with metformin and / or sulphonylurea, with an HbA1c < 10% and who intended to fast the month of Ramadan 2019, in the absence of a major contraindications. Clinical and biological parameters were evaluated before (T0) and after the month of Ramadan (T1). Cardiovascular risk was estimated using the Framingham score.
Results
Study population included 26 women and 21 men with a mean age of 54.5 ± 10.3 years. The mean level of HbA1c before the month of Ramadan was 6.9 ± 0.9%. The number of days of fasting was 29.25 ± 2.31 days. The prevalence of hypoglycemia symptoms was 15%. No severe complications were recorded. During Ramadan fasting, dietary intake decreased by 19%. At T1, a weight loss was observed in 70% of cases with a significant reduction in weight ($P=0.004$), body mass index ($P=0.005$) and waist circumference ($P=0.02$). However, changes in blood pressure, fasting blood glucose, fructosamine level, total-cholesterol, triglycerides, HDLc, LDLc, uric acid and HOMA-IR index were not significant. There were a decrease in high-sensitivity CRP level ($P=0.05$) and in fibrinogen level ($P=0.005$). A decrease in Framingham score occurred in 35% of participants with a decline of 5.9 ± 3.6%.
Conclusion
Ramadan fasting reduced the cardiovascular risk in type 2 diabetics, essentially through an improvement in the inflammatory and anthropometric status. Moreover, favorable changes in lipid profile and blood pressure were not significant in our study.

Association and predictive ability of maternal body composition parameters in early pregnancy to identify gestational diabetes mellitus

Alexandra Cremona[1,2,3,4], Clodagh O'Gorman[1,4,5], Khadijah Ismail[4], Kevin Hayes[6], Alan Donnelly[1,7], Jill Hamilton[8] & Amanda Cotter[4,9]
[1]Health Research Institute (HRI), University of Limerick, Ireland; [2]University of Limerick, School of Allied Health (SAH), Ireland; [3]Irish Nutrition & Dietetics Insititute (INDI), Ireland; [4]University of Limerick, Graduate Entry Medical School (GEMS), Ireland; [5]University Hospital Limerick, Department of Paediatrics, Ireland; [6]University College Cork (UCC), Department of Statistics, Ireland; [7]University of Limerick, Physical Education and Sport Sciences (PESS), Ireland; [8]The Hospital for Sick Children, The Division of Endocrinology, Department of Paediatrics, Canada; [9]University Maternity Hospital Limerick (UMHL), Obstetrics & Gynaecology, Ireland

Background
Accurate early risk prediction for gestational diabetes mellitus (GDM) would target intervention and prevention in women at the highest risk. We evaluated maternal risk factors and parameters of body composition to develop a prediction model for GDM in early gestation.
Methods
A prospective observational study was undertaken. Pregnant women aged between 18–50 y of age with gestational age between 10–16 weeks were included in the study. Women aged ≤18 y, twin-pregnancies, known foetal anomaly or pre-existing condition affecting oedema status were excluded. 8-point skinfold thickness, MUAC, waist, hip, weight and ultrasound measurements of subcutaneous (SAT) and visceral abdominal adipose (VAT) were measured. Oral glucose tolerance test (OGTT) for GDM diagnosis was undertaken at 30w gestation. Binomial logistic regression models were used to predict GDM. ROC analysis determined discrimination and concordance of model and individual variables.
Results
188 women underwent OGTT at 30 w gestation. 20 women developed GDM. BMI (24.7 kg.m^2 (±6.1), 29.9 kg.m^{-2} (±7.8), $P=.022$), abdominal SAT (1.32 cm (CI 1.31–1.53),1.99 cm (CI 1.64–2.31), $P=.027$), abdominal VAT (.78 cm (CI .8–.96), 1.41 cm (CI 1.11–1.65), $P=.002$), truncal SFT (84.8 mm (CI 88.2–101.6), 130.4 mm (CI 105.1–140.1), $P=.010$), waist (79.8 cm (CI 80.3–84.1), 90.3 cm (CI 85.9–96.2), $P=.006$) and gluteal hip (94.3 cm (93.9-98.0), 108.6 cm (99.9–111.6), $P=.023$) were higher in GDM vs non-GDM. After screening variables for inclusion into the multivariate model, family history of diabetes, previous perinatal death, overall insulin resistant condition, abdominal SAT and VAT, 8-point SFT, MUAC and weight were included. The combined multivariate prediction model achieved an excellent level of discrimination, with an AUC of 0.860 (CI 0.774–0.945) for GDM.
Conclusions
An early gestation risk prediction model, which incorporates known risk factors, and parameters of body composition accurately identify pregnant women in their first trimester who developed GDM later on in gestation. This methodology could be used clinically to identify at risk pregnancies, and target specific treatment through referred services to those mothers who would most benefit.

Glucose metabolism and lipid profile in centenarians: What can they predict?

Lubov Matchekhina[1], Ksenia Eruslanova[2], Ekaterina Dudinskaya[1] & Olga Tkacheva[3]

[1]Russian Gerontology Research and Clinical Centre, laboratory of age-related endocrine and metabolic disorders, Moscow, Russian Federation; [2]Russian Gerontology Research and Clinical Centre, laboratory of cardiovascular ageing, Moscow, Russian Federation; [3]Russian Gerontology Research and Clinical Centre, Moscow, Russian Federation

Aim of the study
To assess the most important metabolic factors in centenarians and their impact on mortality and prognosis
Materials and Methods
Itwasalongitudinalstudy, including 82 centenarians (95 years and older), who live in Moscow. Complex geriatric assessment and blood tests were performed. Complex geriatric assessment included past medical history, FRAIL, IADL-C, MNA, GDS-15 and MOCA scores. We also analyzed levels of HbA1c, cholesterol, LDL, HDL. QoL questionnaires were used as well. In one year after the investigations we contacted patients' relatives or social workers to find out about patients' status. The statistical analysis was performed usingIBM SPSS Statistics package Version 26. Statistically significant were differences with $P<0.05$.
Results
Mean age of the patients was 98,3 [±1.9] years, while 87.8% of the cohort were women. Analyzing functional status we found out that 34,4% of the patients were frail, and the number of prefrail patients was 56,2%. Cognitive impairments of different severity were presented in 84,4% of the patients. The median lipids valueswere as follows: total cholesterol – 4,8 [4.2;5.8], triglycerides – 0.97 [0.8; 1.2], HDL – 1.3 [4.2; 5.8), LDL – 3,1 [2.6; 3.7], HbA1c –5.8 [5.6; 6.1]. In 59% of the patients HbA1c was below 6%; 33% had concentrations between 6% and 6.4%, and only in 8% we found HbA1c higher than 6.5%. None of the patients received any sugar-lowering therapy and only 2 (3.2%) were previouslydiagnosed with diabetes. No correlation was also found between HbA1c values and lipids profile. After dividing patients into subgroups depending on stage of carbohydrate metabolism disorders we did not notice any statistically significant differences in lipid profile in them ($P=0.005$). Comparing survivors and non-survivors groups we did not find any significant differences in total cholesterol, LDL, HDL and HbA1c ($P<0.005$). While comparing functional status and QoL with metabolic profile we discovered positive correlation ($r=.834$) between total cholesterol and index of instrumental activity, and between LDL and IADL as well as MNA score ($r=.732$ and .634 respectively).
Conclusion
In centenarians usual prognostic factors such as HbA1c and lipids do not have any impact on survivalbut they influence functional status and QoL. Further investigations of metabolic status in super old personsare needed to personalize their lifestyle and treatment goals.

Association of FT3 levels and FT3/FT4 ratio in the first trimester with the risk of developing gestational diabetes

María Isabel Álvarez Schettini[1], David Ruiz Ochoa[1], Luis Alberto Vázquez Salvi[1], Carlos Higinio Ortega Sánchez[1], Bernardo Alio Lavín Gómez[2] & Coral Montalbán Carrasco[1]
[1]Marqués de Valdecilla University Hospital, Endocrinology and Nutrition, Santander, Spain; [2]Marqués de Valdecilla University Hospital, Clinical Analysis, Santander, Spain

Introduction
Gestational diabetes (GD) is one of the most common complications of pregnancy. Thyroid hormones play an important role in carbohydrate homeostasis, however, their influence on the risk of developing gestational diabetes has shown contradictory results.
Objective
To explore whether variations in thyroid function parameters, within the thresholds of normality, can be associated with the risk of developing GD.
Material and Methods
In a case-control study, 107 pregnant women (37 cases and 70 controls) matched according to age, BMI and previous pregnancies, from a sufficient iodine population and with normal thyroid function were included. TSH, fT4 and fT3 and the fT3/fT4 ratio were assessed in the first (week 10–12) and second (week 24–28) trimester of pregnancy. Biomarker levels were categorized into tertiles and the odds ratio (OR) for gestational diabetes was calculated as a measure of association with their 95% CI.
Results
Mean age was 33.24±5.1 years in cases and 32.97±4.5 years in controls ($P=0.779$). There were also no significant differences between the groups in their BMI, smoking habits, presence of antithyroid antibodies, use of iodized salt or iodized supplements. Of the parameters analyzed, only the fT3: 3.10±0.27 vs 2.86±0.25 ($P<0.05$) and the fT3/fT4 ratio: 2.94±0.35 vs 2.67±0.29 ($P<0.05$) in the first trimester showed significantly different values between cases and controls. Patients with fT3 and fT3/fT4 levels in the higher tertile presented a higher risk of GD than pregnant women in the lower tertile. The association was: OR 7.50 (2.47–22.69) and OR 4.38 (1.51–12.64) for fT3 and fT3/fT4 ratio respectively. No significant associations were identified in any of the other parameters analyzed.
Conclusions
Our results suggest that pregnant women with the highest levels of fT3 and fT3/fT4 in the first trimester of pregnancy are at increased risk of developing gestational diabetes regardless of traditional risk factors.

Protein Kinase Cα attenuates neuronal insulin signalling and worsen neuronal insulin-resistance

Devanshi Mishra & Chinmoy Sankar Dey
Indian Institute of Technology Delhi, Kusuma School of Biological Sciences, New Delhi, India

PKCα has been implicated in different neuronal functions like, apoptosis, synaptic plasticity, and memory formation. PKCα has been linked to control insulin signalling in peripheral tissues as a feedback regulator. However, the exact mechanism how this kinase regulates insulin signalling in neuron is not yet understood completely. Therefore the objective of the present study was to understand the mechanism of action of PKCα on neuronal insulin signalling cascade. Recently we have shown in differentiated Neuro-2a (N2a) cells *in vitro,* that acute phorbol 12-myrisate 13-acetate (PMA), a well-known activator of PKC, (400 nM for 2.5 min) decreased Akt activity because of the activation of PKCα. In order to understand how the Akt activity was decreased, in our present study we have used differentiated N2a cells, treated them with or without chronic PMA (1 μM, 24 hours) (chronic PMA decreases endogenous PKC levels) or acute (400 nM for 2.5 min) PMA, with or without insulin (100 nM, 30 min). The inhibition in Akt activity was reversed and increased by 25% when neuronal cells were treated with chronic PMA, which decreased PKCα levels. This showed that PKCα inhibits insulin signalling pathway through Akt. To test PKCα contribution in insulin-resistance, N2a cells were differentiated in insulin-sensitive (MF) and insulin-resistance (MFI) condition, as reported earlier from our laboratory. Results have demonstrated that PKCα translocated 2.5 fold more in plasma membrane in MFI condition as compared to MF condition. However, when PKCα was inhibited using Go6983 (which blocked PKCα membrane translocation), Akt activity increased by 30% in the plasma membrane of neurons in MF (insulin- sensitive) condition. However, as the translocation of PKCα was more in plasma membrane in MFI (insulin resistant) condition, Akt activity was reduced in the plasma membrane in MFI condition. These data together demonstrated that PKCα negatively regulates insulin signalling in insulin-sensitive neurons and even worsen the signalling in insulin resistant N2a cells. Further studies are required to elucidate the role of PKCα in neuronal insulin signalling and insulin-resistance.

The MAFA gene mutation responsible for familial insulinomatosis and diabetes impairs insulin secretion and results in downregulation of critical cell cycle regulators

Donato Iacovazzo[1], Chung Thong Lim[1], Rosana Quezado[2], Juliana Drummond[3], Fernando Antonio de Sousa Barros[2], Joyceline Cuenco[4], Michael Brändle[5], Emily Walker[6], Min Guo[6], David Collier[1], Faraz Khan[7], Jun Wang[7], Tricia Tan[4], Sian Ellard[8], Roland Stein[6] & Marta Korbonits[1]

of Molecular Physiology and Biophysics, Nashville, United States; [7]Queen Mary University of London, Centre for Molecular Oncology, London, United Kingdom; [8]University of Exeter Medical School, Institute of Biomedical and Clinical Science, Exeter, United Kingdom

The islet-enriched transcription factor MAFA regulates the expression of genes critical to beta cell function and insulin secretion. We previously described anovel *MAFA* mutation (c.191C>T, p.S64F) causing familial insulinomatosis and diabetes mellitus, with male carriers more often developing diabetes and females more prone to insulinomatosis. The exact molecular mechanisms underlying these phenotypes are unclear. In this study, we assessed glucose metabolism and beta cell function in *MAFA*mutationcarriers and studied the effects of the S64F mutation in a beta cell line. Six seemingly unaffected carriers (3M, 3F) underwent oral glucose tolerance (oGTT) and mixed meal tolerance (MMTT) tests. Glucose, insulin, C-peptide, active GLP-1, GIP and glucagon were measured and results were compared to age-, BMI- and gender-matched healthy controls. Insulin secretion, cell viability, apoptosis and the transcriptome profile were investigated in INS-1 cells stably transduced with wild-type (WT) and S64F human MAFA.
The oGTT results were in keeping with diabetes or impaired glucose tolerance in five of the six carriers. During the oGTT and MMTT, glucose levels were increased in both male and female carriers compared to healthy controls, although males were more markedly hyperglycaemic. Insulin and C-peptide levels were reduced in male carriers while females showed higher insulin and C-peptide compared to controls. The insulinogenic index was reduced only in males, while females had higher HOMA-IR and lower Matsuda index suggesting insulin resistance. Active GLP-1 levels were significantly increased, while glucagon levels failed to suppress during the oGTT in *MAFA* mutation carriers.
In vitro, insulin secretion in response to glucose was significantly reduced in S64F-MAFA INS-1 compared to WT cells. S64F-MAFA cells were also more susceptible to apoptosis compared to WT. RNA-sequencing showed significant negative enrichment of genes involved with cell cycle regulation, cell division, DNA synthesis and repair in S64F cells. These include the transcription factor *Foxm1*, the centromere protein A-encoding *Cenpa* gene and several cyclins (*Ccnd1*, *Ccnd2*, *Ccne1* and *Ccna2)* and cyclin-dependent kinases (*Cdk1*, *Cdk14* and *Cdk18*). Among previously identified MAFA-regulated genes, *Ins2*, *Glp1r* and *Kcnj11* were also downregulated in S64F-MAFA cells.
The S64F *MAFA* mutation leads to impaired insulin secretion and increased susceptibility of beta cells to apoptosis secondary to downregulation of genes involved in glucose-stimulated insulin secretion and cell cycle regulation. These findings likely underlie the hyperglycaemic phenotype and reduced insulin secretion observed in males. However, the mechanisms causing hyperinsulinism in female carriers remain to be elucidated.

AEP282

Residual fasting C-peptide secretion and its association with glycemic control in type 1 diabetes

Sara Lopes, Mariana Barbosa, Inês Barros, Juliana Sá, Maria Joana Santos, Ana Margarida Monteiro, Vera Fernandes, Catarina Matos, Maria Lopes Pereira, Olinda Marques & Marta Alves
Hospital de Braga, Department of Endocrinology, Braga, Portugal

Background
Residual C-peptide (CP) secretion has been associated with better glycemic control in patients with type 1 diabetes (T1D).
Aim
To evaluate how residual fasting CP (fCP) secretion impacts glycemic control in T1D and to identify possible confounding factors.
Methods
A retrospective analysis of adult patients with T1D followed in our department that had their fCP and glucose levels obtained on the same blood sample during the year 2019. Patients with glucose <70 mg/dl were excluded. fCP <0.2 ng/ml was considered as an indicator of absolute insulin deficiency.
Results
98 patients were included:69 (70.4%) with fCP <0.2 ng/ml and 29 (29.6%) with fCP ≥0.2 ng/ml. Patients with fCP ≥0.2 ng/ml had higher age at diagnosis (35.6±10.0 vs 21.8±12.0 year-old; $P<.001$); all of them were diagnosed after 18 years of age (vs 53.6% in the group with fCP <0.2 ng/ml). This group also had fewer patients on functional insulin therapy (FIT) (20.7% vs 42%; $P<.001$), lower daily doses of insulin (0.5±0.2 vs 0.6±0.2 UI/kg/day; $P=.040$) and higher HbA1c variation in the last 2 years(1.7±1.3% vs 1.0±0.6%; $P=.001$). No differences were observed when comparing this groupwith fCP <0,2 ng/ml group in terms of disease's duration, current HbA1c, median HbA1c in the last 2 years and current BMI. In the subgroup of patients using FIT, the ones with fCP ≥0,2 ng/ml had lower current HbA1c (7.0±0.5% vs 7.9±0.9%; $P=.005$); no differences were observed when comparing with fCP <0.2 ng/ml patients in terms of disease's duration, daily insulin dose (UI/Kg/day) and HbA1c variation in the last 2 years. In the subgroup of patients not on FIT, the ones with fCP ≥0,2 ng/ml had higher medianHbA1c (8.7±2,2 vs 7.8±0.8%; $P=.033$) and HbA1c variation in the last 2 years (1.9±1.4 vs 1.9±0.7%; $P=.002$); no differences were observed when comparing with fCP <0.2 ng/ml patients in terms of disease's duration and daily insulin dose. In adjusted multivariate analysis, higher age at diagnosis was an independent predictor of fCP ≥0.2 ng/ml (ORa 1.091; $P=.012$).
Conclusions
Our findings suggest that patients with fCP ≥0.2 ng/ml doing FIT have better glycemic control than the ones with FIT and fCP <0.2 ng/ml. Nevertheless, that association was not found in patients with fCP ≥0.2 ng/ml without FIT. Thus, the potential benefit of persistent CP secretion seems to be dependent on the therapeutic scheme instituted. Additionally, it has been shown that higher age at diagnosis was a predictor for long-term fCP secretion. Therefore, we should try to implement FIT in all patients, although higher age at diagnosis might have the most potential advantage.

Identification of a diagnostic and prognostic miRNA signature in women with gestational diabetes mellitus

Begoña Sanchez-Lechuga[1], Shonna Pfeiffer[2], Luise Halang[2], Jochen HM Prehn[2], Antonio Campos-Caro[1], Maria M Byrne[3] & Cristina López-Tinoco[1]
[1] Hospital Universitario Puerta del Mar, Endocrinología y Nutrición, Cadiz, Spain; [2]Royal College of Surgeons in Ireland, Centre for Systems Medicine, Department of Physiology and Medical Physics, Dublin, Ireland; [3]Mater Misericordiae University Hospital, Endocrinology, Dublin, Ireland

Gestational Diabetes Mellitus (GDM) is characterized by insulin resistance accompanied byreduced beta-cell compensation to increased insulin demand, typically observed in the secondand third trimester and associated with adverse pregnancy outcomes. There is a need for abiomarker that can accurately diagnose GDM, predict onset and accurately monitor status, reducing foetal-maternal morbidity and mortality risks. To this end, circulating microRNAs(miRNAs) present themselves as promising candidates, stably expressed in serum and knownto play crucial roles in regulation of glucose metabolism. We analyzed circulating miRNAprofiles in a cohort of GDM patients ($n=31$) and nondiabetic controls ($n=29$) during the thirdtrimester for miRNA associated with insulin-secretory defects and glucose homeostasis. Weidentified miR-330-3p as being significantly upregulated in GDM compared to nondiabeticcontrols. Furthermore, increased levels of miR-330-3p were associated with better responseto treatment (diet vs insulin), with lower levels associated with exogenous insulin requirement. We observed miR-330-3p to be significantly related to the percentage of caesarean deliveries, with miR-330-3p expression significantly higher in spontaneously delivered GDM patients. These results suggest miR-330-3p may help direct personalized therapy in GDM, predictdiabetic outcome and/or severity and progression, and further discriminate the diagnosticcriteria employed in GDM diagnosis during pregnancy.

Inflammasome components and food addiction behaviors in morbid obesity and bariatric surgery: Novel promising targets for a chronic disease

Vicente Herrero-Aguayo[1,2,3,4], Prudencio Sáez-Martínez[1,2,3,4], Juan Luis López-Cánovas[1,2,3,4], Antonio Jesús Montero-Hidalgo[1,2,3,4], Antonio Membrives[1,3,5], Manuel David Gahete[1,2,3,4], María José Molina-Puerta[1,3,5], Justo Pastor Castaño[1,2,3,4], María Ángeles Gálvez-Moreno[1,3,6], Raúl Miguel Luque[1,2,3,4] & Aura Dulcinea Herrera-Martínez[1,3,6]
[1]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Spain; [2]University of Córdoba, Department of Cell Biology, Physiology and Immunology, Spain; [3]Reina Sofía University Hospital (HURS), Spain; [4]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Spain; [5]General Surgery Service, HURS, Spain; [6]Endocrinology and Nutrition Service, HURS, Spain

Obesity is a chronic metabolic disease associated with important metabolic and inflammatory comorbidities, which can be reversed or improved after bariatric-surgery (BS). However, some underlying mechanisms, independent of weight-loss, are still unknown. In this context, dysregulations in the inflammasome, a multiproteic complex that promotes cytokine maturation and induces cellular pyroptosis, has been associated to the development/stage of some cancer-types and obesity. However, whether the dysregulation in the expression ofinflammasomecomponents is associated to morbid-obesity, BS, the modification of patient´ personal/environmental-behaviors, as well as to comorbidities reversal has not been yet explored. Therefore, the aim of this study was to determine the presence of addictive food behaviors (AFB) in obese patients undergoing BS, evaluate the changes in inflammasome components after BS, and analyze their causal relationships with the reversal of metabolic comorbidities. To that end, we took advantage of the emerging evidenceshowing that gene expression pattern of peripheral blood mononuclearcells (PBMCs) commonly reflects and accompany disease-characteristic expression patterns, and may thus serve as ageneral sentinel, biosensor and early indicator of the instaurationof metabolic disease to analyze the inflammasome components and associated inflammatory factors (n=45; using a qPCR array based on Fluidigm technology) in the PBMCs of 22 patients before and 6-months after BS. Epidemiological/clinical/biochemical variables of the patients were recorded. AFB symptoms (evaluated using the Yale test) were observed in 18100% of patients. An overall dysregulation in inflammasome components, especially NOD-like receptors and cell-cycle and DNA-damage regulators, was observed in patients after BS. Interestingly, the molecular fingerprint of some inflammasome components (i.e. CXCL3/CCL8/TLR4/NLRC4/NLRP12) was able to perfectly discriminate between pre- and post-operative patients. Moreover, some alterations in the inflammasome were associated to certain basal metabolic comorbidities, including type-2 diabetes (CCL2/CXCR1/SIRT1), high blood pressure (AIM2/ASC/P2RX7) and dyslipidemia (CXCL3/NLRP7), as well as to the reversal of metabolic comorbidities after BS (IL18/NLRP12). Remarkably, the alteration in the inflammasome molecular profile after BS (especially cytokine/inflammation/apoptosis-related components) was also associated to some AFB. All these changes were independent of the surgical technique used. Altogether, BS induces a drastic alteration in the expression profile of inflammasome components of PBMCs, which is also modulated by personal/environmental behaviors. Moreover, the inflammasome molecular profile is associated to the presence and reversal of relevant metabolic comorbidities, suggesting that some inflammasome components might be used as novel diagnostic and therapeutic targets in morbid-obesity.

Secretion of bile acids in different techniques of bariatric surgery

Inés Jiménez[1], Isabel Ortega[1], Angelica Larrad[1], Ana Barabash[1], Elena Bordiu[1], Andrés Sánchez-Pernaute[2], Natalia Pérez-Ferre[1], Clara Marcuello[1], Pilar Matía[1], Antonio J Torres[2], Maria Angeles Cuadrado[1], Alfonso L Calle-Pascual[1] & Miguel A Rubio[1]

[1]Hospital Clinico Universitario San Carlos, Endocrinology, Madrid, Spain; [2]Hospital Clinico Universitario San Carlos, General Surgery, Madrid, Spain

Background

Bariatric surgery (BS) has proven to be an effective and sustainable long-term treatment in the remission of metabolic disorders. Bile acids (BAs) are involved in the improvement of metabolic comorbidities by acting on the distal ileum (releasing GLP1, PYY and FGF19) and on the microbiota. Our aim is to verify whether the formation of ABs depends on the type of bariatric surgery.

Subjects and Methods

21 patients (81% women) underwent bariatric surgery (BS); 9 patients were selected to Roux-en-Y gastric bypass (YRGB) and 12 to Biliopancreatic-diversion (BPD, type SADIS). The patients (with informed consent) were given a mixed meal test before (T1) and after 1 year post BS (T2), collecting samples at times 0-30-60-90-120 min for 15 fractions of ABs, conjugated and unconjugated forms (determined using a UPLC-tandem MS]. Statistics: descriptive mean±s.d. or median (IQR), area under curve (AUC) with non-parametric comparisons. Registry ISCRT81954082.

Results

Mean age: 50.2 (IQR: 43,354,5) y/o; BMI: 43.09±5.80 kg/m^2 in YRGB group vs 48.4±5.27 kg/m^2 SADI-S group. Type-2 diabetes mellitus was present in 56% and 58%, respectively. Total weight loss at one-year was 38.5% (IQR:27.9–44.9) for YRGB and 39.5% (31.4–42.4) in SADIS subjects. Both total and conjugate baseline ABs increased significantly at one year of follow-up (T2). Although BAs increased twice as much after BPD as with YRGB, there were no significant differences between the two surgical techniques. Glycine conjugated BAs (glycocolic, Glycodeoxycholic, and Glycoqueneoxycholic) were the most prominent. (see table). The increase of total postprandial BAs measured by AUC was also significantly increased at one year in both techniques (YRGB: 174.95 T1 vs 416.28 T2; SADI-S 226.08 T1 vs 386.60 T2; P<0.05)

Table 1 Bile acids values according type of bariatric surgery and time point.

	YRGB			SADIS		
	T1	T2	P	T1	T2	P
TOTAL BAs (mg/l)	0.873	1.666	P=0.038	1.049	3.467	P=0.003
CONJUGATED BAs (mg/l)	0.236	1.004	P=0.028	0.431	2.581	P=0.005
UNCONJUGATED BAs (mg/l)	0.651	0.543	P=0.3	0.624	0.744	P=0.158

Conclusions

BAs are increased after one year of bariatric surgery, regardless of the bariatric technique, in particular glycine conjugated forms that are dependent on intestinal microbiota and may play a prominent role in the remission of metabolic comorbidities.

Liraglutide and PYY$_{3–36}$ combination therapy partially achieves the metabolic benefits of Roux-en-Y gastric bypass surgery in diet-induced obese rats

Ulrich Dischinger[1], Julia Hasinger[1], Malina Königsrainer[2], Carolin Corteville[2], Cristoph Otto[2], Martin Fassnacht[1], Mohamed Hankir[2] & Florian Seyfried[2]

[1]Universitätsklinik Würzburg, Medizinische Klinik I – Endokrinologie/Diabetologie, Würzburg, Germany; [2]Universitätsklinik Würzburg, Chirurgie I, Würzburg, Germany

Background

Circulating levels of the appetite-suppressing and glucoregulatory gut hormones glucagon-like peptide 1 (GLP-1) and peptide tyrosine tyrosine 3–36 (PYY$_{3–36}$) are markedly increased after Roux-en-Y gastric bypass surgery (RYGB), which may contribute to some of its profound metabolic benefits in morbidly obese individuals.

Objectives

To directly compare the metabolic effects of chronic systemic administration of the clinically approved GLP-1 analogue liraglutide in combination with PYY$_{3–36}$ to RYGB in a standardized and controlled setting.

Methods

High-fat diet-induced obese male Wistar rats (n=58) were randomized into 6 treatment groups: RYGB (n=15), sham-operation (n=13), liraglutide subcutaneous (s.c.; 0.4 mg/kg/day)+saline mini-pump (n=5), PYY$_{3–36}$ mini-pump (1 mg/kg/day)+saline s.c. (n=5), liraglutide+PYY$_{3–36}$ (n=11), saline s.c.+mini-pump (n=9). At the start of interventions, animals were given simultaneous free access to high-fat and low-fat diets ad libitum, high-fat food preference and body weight were measured at regular intervals. Open field (OF) and elevated plus maze (EPM) tests were performed about 4 weeks after intervention. Terminal blood samples were collected for biochemical analysis.

Results

Post intervention, the RYGB group lost maximally 8.6±2.9% body weight, while the sham treated animals gained weight continuously. Compared to sham, the bodyweight of RYGB treated animals was about 20% less in the end of the observation period. The PYY+liraglutide and liraglutide only group lost maximally 7.7±3.2% and 5.5±2.4%, whereas the saline and PYY only group gained weight continuously. PYY+liraglutide treated animals were maximally about 17%, liraglutide only treated animals about 13.5% lighter than saline treated animals. Food intake largely followed the same pattern with the RYGB group consuming the least food followed by the liraglutide+PYY$_{3–36}$ group and then by the liraglutide group. Only RYGB treated animals showed a significantly reduced preference for 60% fat diet

compared to sham treated animals in the observation period. PYY+liraglutide or RYGB led to no clear differences regarding the behavior in OF or EPM compared to saline or sham.
Conclusions
Liraglutide and PYY_{3-36} combination therapy partially achieves the metabolic benefits of RYGB. Other double or triple gut hormone combination therapies may therefore be required to achieve the full metabolic benefits of RYGB.

AEP287

The day-to-day variability of insulin sensitivity measured during ogtt in young adult males

Adriana Kauffmann[1,2] & Davide Carvalho[3]
[1]Queensland University of Technology, Brisbane, Australia; [2]Institute of Health and Biomedical Innovation, Health, Brisbane City, Australia; [3]Faculty of Medicine Universidade do Porto, Porto, Portugal

There are a wide range of tests to measure insulin sensitivity. Alternative techniques for estimating insulin sensitivity include measurements made during the oral glucose tolerance test (OGTT). We aimed to describe the weekly intraindividual daily variability of measures of insulin sensitivity indexes (HOMA-IR, QUICKI, Matsuda's insulin sensitivity index (ISIM), Insulinogenic Index, Early C Peptide, Stumvoll's Insulin Sensitivity Index (ISIS), $OGIS_{120}$) and the impact of body composition, physical activity behaviour, and dietary intake, when using OGTT. Twenty-six healthy, weight stable, young males that visited QUT on 3 occasions over a 3-week period, completed the study. At 1-wk participants had a DXA scan to assess body composition, and received an accelerometer (ActiGraph- GT3X) which they wore during 14 days. Over the next 2-wks, participants undertaken repeated OGTTs, scheduled 7 days apart. Glucose, insulin and C-peptide were measured to assess each participant insulin sensitivity using OGTT at 0, 30, 60, 90 and 120 minutes. Dietary interviews were conducted by phone during a 3-week period, using a multiple-day, multiple-pass, 24-h recall and dietary intakes were assessed using FoodWorks 7 software. Despite of being one of the simplest and largely used surrogate measures of insulin sensitivity, the dailyvariability for HOMA (CV32%) was markedly higher compared with QUICKI (CV5%). The lowest variability was demonstrated by the ISIS (CV2%) and the highest reproducibility (ICC.927). The OGIS 120 also showed a low variability (CV4%). The fat trunk % was negative correlated with fasting insulin ($r=-.433$, $P<.05$), confirming relationship between abdominal fat, hyperinsulinemia and the clinical risk of diabetes. Significant correlation was found between OGIS120 and the length of vigorous physical activity spent a day ($r=573$, $P=.001$). These findings reinforce that reduction of daily physical activity resulted in negative impact on insulin sensitivity in young healthy men. The $Fiber_{intake}$ had a significant negative correlation between $OGIS_{120\ Day\ 2}$ ($P=0.013$; $r=.478$). However, the $Fiber_{iptake}$ explained only 0.03% of the variance of OGTT by $OGIS_{120\ Day\ 2}$. A significant negative correlation ($P=.013$;$r=-.481$) was observed between percentage of body fat and $Fiber_{intake}$, suggesting higher $Fiber_{intake}$ predicted lower body fatness. In conclusion, the insulin sensitivity evaluation obtained from OGTT in apparently healthy individuals is quite consistent and produced reliable results using ISIS. We suggest the use of QUICKI when only fasting measures are available to measure insulin sensitivity.

Association between the circadian rhythm and the inhibitory effect of glucocorticoids on browning of adipocytes

Noemi Congiusta[1], Iacopo Gesmundo[1], Mariarosaria Negri[2], Pasquale Pagliaro[3], Rosario Pivonello[2], Claudia Penna[3], Ezio Ghigo[1] & Riccarda Granata[1]
[1]Division of Endocrinology, Diabetes and Metabolism, University of Torino, Medical science, Turin, Italy; [2]Federico II university, Clinical Medicine and Surgery, Napoli, Italy; [3]University of Turin, Clinical and Biological Sciences, Torino, Italy

White adipose tissue (WAT) stores excess energy as triglycerides, while brown adipose tissue (BAT) dissipates energy through heat, acting as a defense against cold and obesity and as a positive regulator of metabolic functions. The thermogenic function of BAT is mainly regulated by the mitochondrial uncoupling protein 1 (UCP1) in brown adipocytes. Moreover, it has been shown that chronic exposure to glucocorticoids (GC) or synthetic GC receptor (GR) agonists inhibits the activity of brown adipocytes and browning of WAT. Despite the broad literature on the regulation of BAT function and body temperature, little is known on the mechanisms controlling circadian thermogenic rhythms and, more importantly, how this pattern is affected by GC. Thus, aim of this study was to assess the impact of GC on browning of 3T3-L1 adipocytes and on the association with expression of clock genes. 3T3-L1 adipocytes were transdifferentiated into brown adipocytes, then synchronized by serum shock before mRNA analysis of UCP-1 and clock genes. The increase in UCP-1 mRNA substantiated the transdifferentiation into brown adipocytes. Moreover, clock gene expression analysis confirmed the rhythmic regulation of 3T3-L1 adipocytes after serum shock synchronization, with a peak of mRNA expression at 4 h (indicated as Zeitgeber time 4, ZT4) for *Clock* and *Bmal1* (light phase genes), and a peak at ZT16 for *Rev-erbα* and *Rev-erbβ* (dark phase genes). Administration of the GR-agonist dexamethasone (Dexa) to transdifferentiating adipocytes increased the mRNA expression of brown genes (*UCP-1, Tmem26, CD137 and Cidea*) at ZT16, whereas their levels were reduced at ZT4 and ZT10. These preliminary findings suggest that, depending on the time of the day, treatment with GC may have a different impact on metabolism, such as browning of adipocytes and the metabolic functions of both white and brown adipocytes.

Association of nutritional support with in-hospital mortality in malnourished medical inpatients – a population-based cohort study

Alexander Kutz, Kaegi-Braun Nina, Mueller Marlena, Mueller Beat & Schuetz Philipp
Kantonsspital Aarau, Endocrinology, Diabetes, Metabolism, Aarau, Switzerland

Background
Malnutrition has been associated with increased adverse clinical outcomes and affects a considerable proportion of hospitalized medical patients. While recent evidence from clinical trials revealed a survival benefit from nutritional support, data from a large real-world population is still missing.
Methods
In this population-based cohort study, using a Swiss administrative claims database from January 2012 to December 2017, we created a medical inpatient cohort of malnourished patients and matched patients on nutritional support 1:1 on propensity score. The primary outcome was all-cause in-hospital mortality. Secondary outcomes were length of hospital stay, 30-day all-cause hospital readmission, and discharge to a post-acute care facility. We performed sensitivity analyses by stratification for degree of malnutrition.
Results
After propensity score matching, we identified 56'822 cases in the cohort. Patients receiving nutritional support compared with matched controls had a significantly lower in-hospital mortality (2'178 of 28'411 [7.7%] vs 2'490 of 28'411 [8.8%]; OR 0.86 [95% CI, 0.81 to 0.92], $P<0.001$). Malnourished patients on nutritional support faced a 2.5-day longer hospitalization (95% CI 2.3 to 2.7, $P<0.001$). All-cause 30-day readmission rate was significantly lower in the intervention group (17.2% vs 18.4%; OR 0.92 [95% CI, 0.88 to 0.97], $P<0.001$) but there was no difference in the frequency of discharge to post-acute care facility (45.4% vs 44.9%; OR 1.02 [95% CI, 0.98 to 1.06], $P=0.286$). Sensitivity analyses showed an even more pronounced reduction in risk of in-hospital mortality among patients with severe malnutrition (OR 0.71 [95% CI, 0.61 to 0.83], $P_{\text{for interaction}}=0.009$).
Conclusions
In this large cohort study, nutritional support was associated with a lower risk of in-hospital mortality in direct comparison with malnourished medical patients without nutritional support as treated in routine care. These findings are in line with previous controlled data and will help to inform patients, practitioners and authorities regarding the effectiveness of nutritional support in clinical practice.

Magnesium supplementation and higher magnesium levels in T2DM patients are associated with better glycemic control and higher rates of total and partial remission post-bariatric surgery

Maria Silva[1,2], Fernando Mendonça[1,2], Maria João Fonseca[3], Maria João Ferreira[1,2], Daniela Salazar[1,2], Jorge Pedro[1,2], Vanessa Guerreiro[1,2], João Sergio Neves[1,2,4], Eva Lau[1,2,4], Sandra Belo[1,2,4], Ana Varela[1,2,4], Paula Freitas[1,2,4] & Davide Carvalho[1,2,4]
[1]Centro Hospitalar Universitário São João, Porto, Portugal, Department of Endocrinology, Diabetes and Metabolism, Portugal; [2]Universidade do Porto, Faculdade de Medicina, Portugal; [3]Institute of Public Health of the University of Porto (ISPUP), Portugal; [4]Instituto De Investigação e Inovação em Saúde, Universidade do Porto (I3S), Portugal

Introduction
Magnesium (Mg) is an essential mineral for human health. Chronic Mg2+ deficiency and low Mg2+ dietary intake have been associated with increased risk of T2DM. Despite the increased risk of T2DM associated with Mg2+ deficiency; T2DM is often accompanied by hypomagnesemia, especially in patients with poorly controlled glycemic profiles.
Bariatric surgery remains the most effective long-term therapy for the management of patients with severe obesity. After surgery, micronutrient deficiencies are one of the most common and compelling problems.
Objective
To analyse the effect of Mg supplementation and serum levels in T2DM metabolic parameters and remission after bariatric surgery.
Methods
We performed a cross-sectional study of obese patients who underwent bariatric surgery. Data was assessed preoperatively and one-year after surgery. T2DM was defined as fasting plasma glucose (FPG) ≥126 mg/dl, glycated haemoglobin (HbA1c) ≥6.5%, 2-h plasma glucose after a 75-g oral glucose tolerance test ≥200 mg/dl or the use of anti-diabetic medication (ADM). Complete T2DM remission was defined as HbA1C < 6.0% and no ADM use and partial T2DM remission was defined as HbA1C < 6.5% and no ADM use.
Results
Of a total of 2241 patients submitted to bariatric surgery, we included 644 patients with T2DM. At baseline, 39% of the patients ($n=251$) had Mg deficiency and only 4% of them were on Mg supplementation. Patients with Mg deficiency had poorer metabolic control (HbA1c, FPG, insulin, C peptide, HOMA-IR and number of ADM) compared with patients without Mg deficiency with statystical significance for HbA1c (HbA1c = 6.55 ± 1.34 vs HbA1c = 7.17 ± 1.55, $P<0.0001$), FPG (FPG = 112.45 ± 28.28 vs FPG = 122 ± 42.58, $P<0.006$), and number of ADM (ADM = 1.063 ± 0.89 vs ADM = 1.39 ± 1.07, $P<0.0001$). At the first year, 16.1% of patients had complete T2DM remission. It was more common among patients without Mg deficiency ($P<0.001$). Similar to baseline, patients withoug Mg deficiency had better metabolic control with statystical significance.
Conclusion
Mg supplementation and higher serum Mg levels in patients with T2DM-were associated with better metabolic control and higher rates of complete and partial remission at the first year post-surgery.

DOI: 10.1530/endoabs.70.AEP290

Nesfatin-1, an appetite-suppressing and anti-obesogenic neuropeptide, is decreased in the human brainstem of obese subjects.

Aristea Psilopanagioti, Maria Makrygianni, Sofia Nikou, Souzana Logotheti, Dionysios Chartoumpekis & Helen Papadaki
University of Patras, School of Medicine, Patras, Greece

Background/Aims
Food intake is orchestrated by complex neuronal networksresiding in the forebrain, hypothalamus, and brainstem, via orexigenic and anorexigenic neuropeptides. Nesfatin-1, the amino-terminal fragment of nucleobindin 2, is a potent anorexigenic and anti-obesogenic neuropeptide, with widespread central distribution in rodents. In obese humans, our research group has recently reported reduced nesfatin-1 protein expression in the lateral hypothalamic area, a brain structure involved in appetite and body weight regulation and connected with brainstem feeding centres. In spite of the wealth of data in animals, no information is available about nesfatin-1 localization in the human brainstem. The aim of the present study was to explore nesfatin-1 distribution pattern in human brainstem nuclei as well as the association between nesfatin-1 protein expression and body mass index.
Methods
For this purpose, human brainstemsections from 20 autopsy cases (13 males, seven females; 8 normal weight, 6 overweight, 6 obese) were examined using immunohistochemistry and double immunofluorescence labeling
Results
Intense nesfatin-1 immunoexpression was observed in various brainstem areas, including nuclei involved in energy homeostasis and in autonomic and behavioral functions, such as the nucleus of the solitary tract, dorsal motor nucleus of vagus, area postrema, inferior olive, reticular formation, raphe nuclei, locus coeruleus, parabrachial nuclei, and pontine nuclei, and in Purkinje cellsof the cerebellum. In addition, nesfatin-1 was extensively colocalized with neuropeptide Y and cocaine- and amphetamine-regulated transcript (peptides playing pivotal role in food intake and energy metabolism)in nucleus of the solitary tract, inferior olive, locus coeruleus, and dorsal raphe nucleus. Interestingly, nesfatin-1protein expression was significantly lower in obese than normal weight subjects in nucleus of the solitary tract ($P<0.05$).
Conclusions
These findings provide for the first time neuroanatomical support for the potential role of nesfatin-1 in the human brainstem neuronal network controlling food intake and energy balance. In the nucleus of the solitary tract, an important hub of energy statusintegration and a neural substrate of food reward, altered neurochemistry such as nesfatin-1 deficiency may contribute to dysregulation of homeostatic and/or hedonic feeding behavior and thus to obesity.

Digital evaluation of ketosis and other diabetes emergencies (DEKODE) algorithm: Automated auditing system for diabetic ketoacidosis (DKA) management

Agnes Johnson[1], Lucretia Thomas[1,2], Eka Melson[2], Joht Singh Chandan[3], Sandip Ghosh[4], Parth Narendran[4,5] & Punith Kempegowda[2,4]
[1]University of Birmingham, Medical School, United Kingdom; [2]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [3]University of Birmingham, Institute of Applied Health Research, United Kingdom; [4]University Hospitals Birmingham NHS Foundation Trust, Diabetes and Endocrinology, Birmingham, United Kingdom; [5]University of Birmingham, Institute of Immunology and Immunotherapy, United Kingdom

Background
Effective management of diabetic ketoacidosis (DKA) improves clinical outcomes. Regular auditing and performance feedback are key to achieving sustained and significant improvement in the management of DKA. One of the major limitations for maximal impact of an audit is the delay from initiation to results as the latter may not be applicable to the then current practice. In order to overcome this, we created an automated auditing system called Digital Evaluation of Ketosis and Other Diabetes Emergencies (DEKODE). This system identifies DKA episodes based on prescriptions for fixed rate intravenous insulin infusion (FRIII). Here, we retrospectively validated DEKODE system for monitoring DKA management.
Methods
To retrospectively validate DEKODE model, all episodes identified by DEKODE from September 2018 to August 2019 was manually verified for confirmation of diagnosis. DKA duration was defined as the difference in time between FRIII prescription time and end time for DEKODE. For manually collected data, the difference in the time from diagnosisto resolution as per standard criteria was considered as DKA duration. Further, appropriateness of glucose and ketone measurements during entire DKA duration and fluids prescribed in the first 12 hours of diagnosis were compared between the two datasets. The difference between manual and automated data for DKA duration, FRIII appropriateness, hourly glucose and ketone measurements were analysed using Prism v6.0 (Graphpad Inc) and results are presented as mean and standard error of mean (S.E.M.). Difference in frequencies of hypokalemia and hyperkalemia between manual and automated data was analysed by chi-square test.
Results
150 episodes were identified by DEKODE during the study period. Of these, 147 had manually confirmed DKA. There was no significant difference in DKA duration between DEKODE and manual data (mean ± S.E.M., 16.0 ± 1.0 hours; 17.5 ± 0.9 hours; P = ns) respectively. Similarly, there was no difference in FRIII appropriateness (98.3% ± 1.2%; 97.9% ± 1.1%; P = ns), hourly glucose (98.5% ± 2.6%; 105.6% ± 2.5%; P = ns) and ketone measurements (43.3% ± 2.1%; 47.1% ± 2.2%; P = ns) between the two systems. DEKODE

also accurately predicted the frequency of kalaemic complications with no significant difference in the number of patients recorded with hyperkaelema (7/147; 6/150; P=ns) and hypokalaemia (9/147; 9/147; P=ns). However, DEKODE over-predicted proportion of fluids prescribed (96.9%±3.2%; 84.4%±3.1%; P=0.0047).
Conclusion
DEKODE system could reliably predict DKA duration and management. This can help in monitoring DKA management cutting time from collecting data to analysis, thus providing real-time performance results. Further prospective validation is currently underway.

Type 2 diabetes did not show significant risk effect on cerebral aneurysm in Koreans: A single center, cross-sectional study

Hoon Sung Choi[1], Jin Taek Kim[2] & Ji Won Yoon[3]
[1]Kangwon National University School of Medicine, Department of Internal Medicine, Chuncheon-si, Korea, Republic of South; [2]Nowon Eulji General Hospital, Eulji University College of Medicine, Department of Internal Medicine, Seoul, Korea, Republic of South; [3]Seoul National University Healthcare System Gangnam Center, Seoul, Korea, Republic of South

Backgrounds
Cerebral aneurysms are a common disease that affects 1–5% of general populations, with an annual rupture risk of 0–1%. Smoking, high blood pressure, diabetes and aging have been considered as risk factors for cerebral aneurysms, but there were few epidemic studies. In this study, we evaluated the risk effect of diabetes on cerebral aneurysm in Korean population.
Methods
We used data from participants who underwent brain MRA and laboratory test for the screening purpose at the Healthcare System Gangnam Center of Seoul National University Hospital between January 2010 and December 2013. Among a total of 18,477 participants, we analyzed 9,235 whose clinical and laboratory data were eligible. Participants with diabetes were 1,350 (14.6%). Cerebral aneurysm was defined as an abnormal focal dilatation of a cerebral arteries with a maximum diameter greater than 3 mm.
Results
Compared the participants without diabetes, those with diabetes have older age, higher proportion of male and smoking, heavier weight, higher blood pressure, and higher levels of fasting glucose, serum cholesterol and CRP. The proportion of participants with cerebral aneurysm were 4.1% in the diabetic group and 3.7% in the non-diabetic group without statistical significance (P=0.523). In logistic regression, old age and lower LDL-cholesterol showed significant risk effects on cerebral aneurysm, but male gender, diabetes, obesity and smoking did not. Multivariate analyses showed corresponding results.
Conclusion
In this study, diabetes was not significant risk factor of risk of cerebral aneurysms. Neither smoking, obesity, nor hypertension were significant risk factors. Of note, we found that the prevalence of cerebral aneurysms decreased as LDL cholesterol levels increased. The lack of association between the traditional risk factors of atherosclerosis and cerebral aneurysm requires further studies.

Fibroblast growth factor 21 (FGF21) in hyper- and hypothyroidism, association with metabolic disturbances

Ewa Szczepańska, Małgorzata Gietka-Czernel, Piotr Glinicki, Helena Jastrzębska, Jadwiga Słowińska-Srzednicka, Renata Kapuścińska, Stefan Zgliczyński & Wojciech Zgliczyński
Medical Centre of Postgraduate Education, Endocrinology Department, Bielański Hospital, Warsaw, Poland

Background
FGF21 is a critical metabolic regulator with beneficial effects on lipid and glucose metabolism. FGF21 is produced primarily by the liver and stimulates fatty acids oxidation, which prevents hepatic triglycerides accumulation and nonalcoholic fatty liver disease (NALFD). FGF21also increases insulin sensitivity and glucose uptake in adipose tissue. Paradoxically FGF21 is elevated in insulin resistance states e.g. NALFD, obesity and type 2 diabetes. It is not determined if it results from FGF21 resistance or compensatory increased secretion. In animals and *in vitro* studies thyroid hormones increase FGF21 secretion.
Aim
Investigate the association between circulating FGF21 and thyroid hormones, glucose and lipid metabolism in patients with hyper- and hypothyroidism
Methods
57 hyperthyroid patients with Graves disease, 29 hypothyroid patients with autoimmune thyroid disease and 21 healthy controls were included. Additionally, a subset of 13 hyperthyroid patients was analyzed before, and after radioiodine treatment, in three different thyroid statuses typically occurring in this group – hyperthyroidism, hypothyroidism, and euthyroidism after l-thyroxin treatment. Serum FGF21 was measured with immunoassay.
Rresults
Serum FGF21 levels did not differ significantly in hyperthyroid and hypothyroid patients as compared with healthy subjects [median 100.30 (interquartile range, 59.61–191.93) and 141.50 (66.80–247.40) vs 78.50 (54.00–11.90) pg/ml P=0.196 and 0.058 respectively]. In hyperthyroid patients treated with radioiodine, serum FGF21 level did not change in hyperthyroidism as compared with euthyroidism and hypothyroidism, however it has increased dramatically in hypothyroid phase compared with euthyroidism stage [102.30 (51.4–153.70) vs 199.30 (131.70–266) vs 70.80 (21.80–187.90) pg/ml, P=0.999, P=0.080 and P=0.018 respectively]. In hyperthyroidism, there was no significant correlation between FGF21 serum levels and thyroid hormones, lipids, and glucose metabolism. In rapid onset hypothyroidism after radioiodine treatment, increased FGF21 serum levels correlated positively with triglycerides and cholesterol (Spearman coefficient rs=0.46 and rs=0.36 respectively) and correlated inversely with fT4 and SHBG (rs=–0.34 and rs=–0.41 respectively). In euthyroidism FGF21 serum levels correlated positively with insulin and HOMA index (rs=0,49 and rs=0.47) and correlated inversely with QUICKI index and SHBG (rs=–0.46 and rs=–0.51).
Conclusions
There was no stimulatory effect of thyroid hormones on FGF21 secretion. Circulating FGF21 rose markedly in rapidly developing hypothyroidism after radioiodine treatment and associated with the increase in triglycerides and cholesterol serum levels. In the critical metabolic state of lipid overload, FGF21 secretion may have a compensatory effect promoting lipid oxidation.

Excess risk of thyroid cancer in individuals with type 1 diabetes compared to those without diabetes in Finland; nationwide study

Sari Mäkimattila[1], Valma Harjutsalo[2,3,4], Carol Forsblom[2,3,4] & Per-Henrik Groop[2,3,4,5]
[1]University of Helsinki and Helsinki University Hospital, Abdominal Center, Endocrinology and Diabetes, HUS, Finland; [2]Folkhälsan Research Center, Helsinki, Finland; [3]Abdominal Center, Nephrology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [4]Research Program for Clinical and Molecular Metabolism, Faculty of Medicine, Helsinki, Finland; [5]Department of Diabetes, Central Clinical School, Monash University, Melbourne, Australia

The prevalence and possible excess risk of thyroid cancer in T1D compared to individuals without T1D is poorly known. Therefore, the aim of this study was to assess excess risk of thyroid cancer in adults with long-term T1D compared to sex- and age-matched control individuals.
Study included 4758 individuals with T1D from the Finnish Diabetic Nephropathy (FinnDiane) Study. For each individual, three nondiabetic control individuals who were matched for sex, age, and place of residence in the year of diagnosis of diabetes in the FinnDiane patient, were selected from the Finnish Public Registry, altogether 12710. The thyroid cancers were identified by linking the data with the Finnish Care Register for Health Care (data available for the years 1970–2015). The types of cancers as well as the presence of metastaseswere assessed by reviewing the medical records. Cochran–Mantel–Haenszel test was used to compare risks and produce odds ratios (ORs)with 95% confidence intervals (CI) between individuals with T1D and controls.
The median age of the FinnDiane individuals at the end of follow-up in 2015 or death was 51.4 (IQR 42.6–60.1) years. As many as 27 (0.57%) had thyroid cancer, compared to 27 (0.21%) in the control individuals giving rise to an OR of 2.67 (95% CI 1.57–4.56, P=0.0002). The median age at diagnosis of thyroid cancer was 38.5 years (IQR 33.6–46.6) in T1D and 42.8 years

(29.4–49.9) in controls ($P=0.83$). Women had higher risk in the controls (OR=3.07 (1.30–7.26) while the risk in T1D was no different between the sexes, OR=1.61 (0.74–3.47). Median HbA1c was 8.8% (8.2–9.5) in those with T1D and thyroid cancer while it was 8.3% (7.4–9.2) in the rest of the FinnDiane individuals ($P<0.0001$). 16.7% of thyroid cancers were associated with thyroid autoimmunity.
The distribution of different types of thyroid cancers was similar in those with T1D and the controls. Most of the cancers were papillary; 81.5% in T1D and 88.9% in the controls, while 14.8% were follicular in T1D and 11.1% in the controls. There was only one medullary cancer in T1D. Signs of metastases were observed in 2 out of 27 individuals with T1D and in 7 out of 27 in the controls ($P=0.12$).
The prevalence of thyroid cancer is 2.7 fold in individuals with T1D and equal between the sexes. The data suggest that poor glycemic control is associated with risk of thyroid cancer in T1D.

Pulse wave velocity and circulating Retinol binding protein 4: A cross sectional association in early postmenopausal women

Eleni Armeni[1], Meletios P Nigdelis[2], Asimina Chondrou[1], Panagiotis Anagnostis[2], Areti Augoulea[1], Dimitrios Rizos[3], George Kaparos[3], Andreas Alexandrou[1], Dimitrios G Goulis[2], Raphael Patras[4], Evmorfia Aivalioti[4], Kimon Stamatelopoulos[4] & Irene Lambrinoudaki[1]
[1]National and Kapodistrian University of Athens, Aretaieio Hospital, 2nd Department of Obstetrics and Gynecology, Athens, Greece; [2]Medical School, Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Thessaloniki, Greece; [3]National and Kapodistrian University of Athens, Aretaieio Hospital, Hormonal and Biochemical Laboratory, Athens, Greece; [4]National and Kapodistrian University of Athens, Alexandra Hospital, Department of Therapeutics and vascular pathophysiology, Athens, Greece

Introduction
Recent evidence recognized the value of Retinol-Binding Protein (RBP4), as potential biomarker of cardiovascular and cerebrovascular pathology. The possible association between RBP4 and functional vascular disease remains unexplored, while recent data in postmenopausal populations suggested lack of association between RBP4 and subclinical atherosclerosis. We evaluated the possible link between RBP4 and menopause-specific cardiovascular risk factors, in a sample of apparently healthy postmenopausal women.
Methods
We recruited 123 healthy postmenopausal women, retrieved from a University Menopause Clinic. Inclusion criteria were menopausal age of equal or less than 10 years. Exclusion criteria were: 1) no intake of hormone therapy, antihypertensive, Participating women were not on treatment with hormone therapy, antihypertensives or hypolipidemic treatment. Women were instructed to fast for at least 8 hours and not to smoke, aiming for a blood tests for biochemical/hormonal assessment. Sonographical evaluation was performed immediately thereafter and included carotid-femoral pulse wave velocity (PWV) and calculation of the carotid artery stiffness index (S.I.)
Results
Univariate correlations were observed between RBP4 values and age, LDL-cholesterol and marginally significant with S.I., PWV, homocysteine, circulating estrogen, triglycerides. Women with RBP4 values higher than the median vs lower RBP4 values presented with higher levels of homocysteine (homocysteine: RBP4<10.5 ng/ml vs≥10.5 ng/ml: 11.2±2.81 μmol/l vs 12.52±3.44 μmol/l, P-value=0.049 ANCOVA adjusted for age, BMI, HOMA-IR). PWV was independently associated with RBP4 (b-coefficient=0.440, P-value=0.007), in multivariate models adjusted for age, menopausal age, LDL-cholesterol, circulating estrogen, smoking, pulse pressure, homocysteine, Similarly, S.I. was associated with RBP4 levels (b-coefficient=0.324, P-value=0.039) and insulin resistance, in models adjusted forage, menopausal age, LDL-cholesterol, circulating estrogen, smoking.
Conclusions
The results of this study show that higher RBP4 serumlevels are associatedwith greater aortic and carotid stiffness, in a sample of healthy postmenopausal women. Larger studies are required to further elucidate the significance of our findings.

Metabolic syndrome severity score for predicting cardiovascular events: A nationwide population-based study from Korea

Ji Hye Huh, Wonjin Kim, Jun Goo Kang, Seong Jin Lee & Sung-Hee Ihm
Hallym University Sacred Heart Hospital, Department of Internal Medicine, Anyang, Korea, Republic of South

Background and aims
Recently, a metabolic syndrome severity score (MS score) using a dataset of the Korea National Health and Nutrition Examination Surveys has been developed. We aimed to determine whether the newly developed score is a significant predictor of cardiovascular (CV) events among the Korean population.
Methods
From the Korean National Health Insurance System, 2,541,364 (aged 40–59 years) subjects with no history of CV events (ischemic stroke or myocardial infarction [MI]), who underwent health examinations from 2009–2011 and were followed up until 2014–2017, were identified. Cox proportional hazard model was employed to investigate the association between MS score and CV events. Model performance of MS score for predicting CV events was compared to that of conventional metabolic syndrome diagnostic criteria (ATP-III) using the Akaike information criterion and the area under the receiver operating characteristic curve.
Results
Over a median follow-up of 6 years, 15,762 cases of CV events were reported. MS score at baseline showed a linear association with incident CV events. In themultivariable-adjusted model, the hazard ratios (95% confidence intervals) comparing the highest vs lowest quartiles of MS score were 1.48 (1.36–1.60) for MI and 1.89 (1.74–2.05) forstroke. Model fitness and performance of the MS score in predicting CV events were superior to those of ATP-III (Table 1).

Table 1 Model fit analysis and model performance of metabolic syndrome indicators.

Event	Model	MS indicator	AIC	AUC (95% CI)	*P*-value*
CV events					
	1	ATP-III	181,473.2	0.718 (0.714–0.722)	<0.001
		MS score	181,292.2	0.720 (0.716–0.724)	
	2	ATP-III	183,029.2	0.704 (0.700–0.708)	<0.001
		MS score	182,600.6	0.708 (0.704–0.712)	
Stroke					
	1	ATP-III	100,892.9	0.705 (0.699–0.711)	0.003
		MS score	100,828.8	0.707 (0.701–0.712)	
	3	ATP-III	101,508.2	0.693 (0.688–0.699)	0.003
		MS score	101,406.9	0.696 (0.690–0.702)	
MI					
	1	ATP-III	103,820.7	0.741 (0.735–0.746)	<0.001
		MS score	103,696.9	0.743 (0.738–0.748)	
	3	ATP-III	105,174.2	0.720 (0.714–0.725)	<0.001
		MS score	104,813.0	0.726 (0.721–0.731)	

Model 1: adjusted for age, body mass index, current smoking, heavy alcohol consumption, regular exercise, and family income
Model 2: Model 1+ further adjusted presence of hypertension, diabetes, medication for dyslipidemia, and total cholesterol.
**P*-value: DeLong's test for ROC curves of two metabolic syndrome indicators.

Conclusions
The newly developed age- and sex-specific continuous MS score for the Korean population is an independent predictor of ischemic stroke and MI in Korean middle-aged adults even after adjusting for confounding factors.

High prevalence of cognitive dysfunction and vitamin B12 deficiency in patients with type 2 diabetes over 50 years

Letícia Weinert[1,2], Fabiana Romani[3] & Eduardo Coelho Machado[3]
[1]Hospital Escola UFPEL, Endocrinology, Pelotas, Brazil; [2]Catholic University of Pelotas, Campus I, Pelotas, Brazil; [3]Universidade Federal Pelotas Faculdade de Medicina, Pelotas, Brazil

Introduction
Hyperglycemia is a common disorder in elderly patients. Diabetes management in this population requires evaluation of medical, pharmacological and functional domains. Screening for diabetes chronic complications should include, in addition to traditional micro- and macrovascular disease, search for cognitive impairment and vitamin B12 deficiency.
Objective
To evaluate the prevalence of cognitive impairment, depression, and associated clinical variables in a population of adult patients with type 2 diabetes.
Methods
Individuals over 50 years and with type 2 diabetes, assisted at the Federal University of Pelotas, South of Brazil, were included in the study. We performed a cross-sectional study with application of a face-to-face questionnaire and evaluation of outpatient clinical records for clinical and demographic variables analysis. We use Mini-Mental State Examination (MMSE) to assess cognitive impairment, and Patient Health Questionnaire-2 (PHQ) and PHQ-9 to evaluate depression.
Results
We included 116 patients, with a median age of 62 years, 68.1% were women, 76.7% have white skin color, and 81% have 8 years of study or less. The mean A1c was 9.6%. Over 70% of the patients have at least one microvascular complication, and 52.6% have clinical macrovascular disease. The prevalence of cognitive dysfunction was 35.3% and that of depression was 33.6%. The group of patients with cognitive dysfunction has higher rates of B12 deficiency (60% vs 36.6% in controls; $P=0.01$) and of benzodiazepine use (51.3% vs 30.6% in controls; $P=0.03$). The presence of microvascular complications was also higher in the group of patients with cognitive dysfunction (85.4% vs 66.7% in controls, $P=0.003$). Other clinical variables were not different between groups. B12 deficiency was associated with cognitive impairment even after adjustments [1.78 (1.07–2.98)]; while the association with benzodiazepine use was not significant after statistical adjustments [1.58 (0.95–2.64)].
Discussion
Patients over 50 years and with type 2 diabetes have a high prevalence of cognitive dysfunction and depression, and B12 deficiency was associated with cognitive impairment. Therefore, we strongly suggest that clinical doctors actively search for these comorbidities.

Prevalance of undiagnosed dementia in young diabetic population in central india

Bharat Saboo
Prayas Diabetes Center, Diabetology, Indore, India

Dementia is increasing day by day as longevity is increasing. There is a underlying need to evaluate Dementiaamongst Diabetics as they are more prone for dementia, By identifying early and preventing the incidence or advance of microangiopathy we can play an important role in maintaining quality of life and reducing mortality in patients with diabetes mellitus. Type 2 diabetes is a robust cause of cognitive impairment and decline in even in younger adults.
Multiple population-based studies have reported an association between Type 2 diabetes and cognitive impairment and older adults with Type 2 diabetes experience global cognitive decline at a rate that is double those without Type 2 diabetes over a 5-year period. General cognitive slowing, thought to be a marker for accelerated brain aging and dementia risk, is related to Type 2 diabetes in middle-aged and older adults.
Patient were selected from central india and inclusion criteria were: diagnosis of Type 2 diabetes; age between 20–60 years; no peripheral or central vestibulopathy or any other neurological disease, no history ofcerebrovascular accident and myocardial infarction. 324 diabetics and 306 non diabeticwere randomly selected, screened by using mini mental status examination questionnaire in local language, results were analysed
A prevalance of 6.7 percent was seen in young diabetics, more in females, non smart phone users, and having low academic qualification, As compared to Non- Diabetics who had a prevalance of 0.7 percent.
There is no data regarding prevalance of dementiain young diabetics in india.
The current understanding about dementia is inadequate for development of appropriate feasible tools for screening the population in early phase of dementia as there is a dearth of manpower and financial resources and huge gaps in research, especially in areas of pathophysiology and disease-modifying pharmacological agents. Therefore, the only viable option as of now is primary prevention of dementia by addressing risk factors and promotion of protective factors. However, for effective handling of epidemic, we need to empower the health-care workers and professionals in screening and management of dementia. An effective systemic health-care model should be developed for delivery of services to the families and patients with dementia keeping our sociocultural beliefs in mind. Every step should be taken to improve awareness regarding dementia and its preventive measures, to halt the epidemic, thereby contributing to a healthy and prosperous nation.

Features of phenotypes of diabetic kidney disease depending on the type of underlying disease

Iryna Tsaryk[1], Nataliia Pashkovska[2], Galina Koval[1], Nataliia Abramova[1], Yulia Marchuk[1], Antonina Piddubna[1] & Ivan Pankiv[1]
[1]HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Чернівці, Ukraine

Introduction
Chronic kidney disease (CKD) is one of the leading causes ofdisability and mortality in patients with diabetes mellitus. Existence of specific phenotypes of diabetic kidney disease (DKD) is established nowadays. The prevalence of the classic albuminuric phenotype has decreased by 24% over the past decade (NHANES).
The purpose of our work was to investigate the phenotypic features of DKD depending on the type of diabetes.
Materials and methods
A comprehensive survey of 1576 patients with diabetes was analyzed, 447 of which were of type 1 diabetes mellitus (T1DM), 1041 were of type 2 diabetes mellitus (T2DM) and 88 patients were with latent autoimmune diabetes in adult (LADA). We studied the frequency and features of the course of CKD, as well as the prevalence of phenotypic forms of DKD: classical albuminuria, nonalbuminuric renal dysfunction and progressive decrease in renal function. Glomerular filtration rate (GFR) was evaluated using the CKD-ERI formula, albuminuria, albumin-creatinine ratio (AKR), and kidney ultrasound were analyzed.
Results
The incidence of CKD in T1DM was 38% (203 patients), 23% (242 patients) in T2DM and 30% (34 patients) in LADA. In T1DM, CKD stage was recorded with the following frequency: G1 – 24%, G2 – 58%, G3a – 16%, G3b – 1%; by albuminuria category: A1 – 21%, A2 – 79%. In T2DM, stage G1 occurred in 8% of patients, G2 in 48%, G3a in 26%, Gb in 14%, G4 in 4% of patients; albuminuria in stage A1 was reported in 29% of patients, and A2 in 71%. In turn, with LADA G1 stage CKD occurred in 17% of patients, G2 – in 63%, G3a – in 16%, G3b – in 3%, G 4 – in 1%; albuminuria in stage A1 was reported in 37% of patients, and A2 in 63%. Classical albuminuric phenotype was reported in 21% of patients with T1DM, 29% of patients with T2DM, and 25% of patients with LADA. The proportion of patients with nonalbuminuric renal dysfunction was 60% for T1DM, 43% for T2DM, and 53% for LADA. In turn, progressive kidney damage was detected in 19% of T1DM, 28% of T2DM, and 22% of LADA cases.
Conclusion
Nonalbuminuric DKD was observed in 60% of cases of T1DM, in T2DM – 43%, while LADA was diagnosed in 53% of cases. The incidence of classic albuminuric phenotype is higher in T2DM, and progressive kidney damage is 1.5 times higher than in patients with T1DM and LADA.

Maturity- onset diabetes of the young type 6 (MODY6): A case report of two relatives (mother and daughter) with undescribed heterozygous variant of mutation in NeuroD1 gene

Valentina Kalugina
Novgorod Regional Diabetes Centre, Veliky Novgorod, Russian Federation

A 37-year-old Caucasian female, pharmacist, referred to Diabetological center in February 2017. The main complaint was frequent urination.
Medical history
She was diagnosed with T2DM at the age of 32 year. She was taking Metformin 850 mg twice daily. Her plasma glucose was 7.8 mmol/l at fasting; 10.8 mmol/l postprandial.
Family history
Her father has elevated glucose levels also (up to 8 mmol/l before meal). Her mother has passed away soon after the delivery of her second child at the age of 31 year (baby died also on the second day after birth).
Patient has a 12- year- old daughter.
Physical examination
BMI is 23 kg/m^2 (height 157 cm, weight 56 kg)
No other NeuroD1-associated clinical phenotypes, including cerebellum hypoplasia, psychic development retardation, sensorineural bradyacuasia or visual impairment were revealed.
Laboratory findings
Her HbA1c was 5.77%, C-peptide level was 1.52 ng/ml (1.07–11.8 ng/ml); glutamate decarboxylase and pancreatic islet antibodies were negative.
The probability of patient having MODY was 58% (using Diabetes Diagnostics calculator by Exeter University).
Patient`s daughter glycemia was 9.8 mmol/l at random site. She had not been diagnosed with diabetes mellitus previously. Her HbA1c was 6.3%, C-peptide level was 1.96 ng\ml (1.07–11.8 ng/ml); glutamate decarboxylase, zinc transporter 8 and IA-8 antibodies were negative. The results of the oral glucose tolerance test were 6.4 mmol/l at fasting, 12.3 mmol/l after 30 minutes, 15.3 mmol/l after 60 minutes, 13.6 mmol/l after 120 minutes.
In July 2017 the mutation in the neurogenic differentiation factor 1 gene (NeuroD1) was revealed in both patients (a heterozygous undescribed previously mutation variant c. 1022A>T: p. H341L. The analysis was performed at The National Endocrinology Research Centre. Moscow) The diagnosis of MODY6 was established.
To the date both patients take no medication. Their blood glucose levels are 6–7 mmol/l at fasting, 6–8 mmol/l after the meal.

Challengesrelated to prevention and management of diabetes mellitus inprimary healthcare settings

Rusudan Kvanchakhadze[1], Nana Mebonia[1], Elena Shelestova[2], Tamar Maghradze[2] & Ramaz Kurashvili[2]
[1]National Center for Disease Prevention and Public Health, Tbilisi, Georgia; [2]National Centre for Dabetes Research, endocrinology, Tbilisi, Georgia

Introduction
Over 94% of total mortality in Georgia is attributable to non-communicable diseases (NCDs). Alhought various NCDs guidelines and protocols have been developed and approved in Georgia, their implementation at the primary healthcare (PHC) level has not been successful. The AIM of the study was to assess PHCs approaches to prevention and management of diabetes.
Methods
General practitioners (GPs), family and village doctors were involved in a cross-sectional survey with two-stage random sampling design, that was conducted in two regions of Georgia: Stage 1 – sampling frame consisted of all PHCs/village ambulances of the selected regions; Stage 2 – randomly selected family and village doctors from each of the selected facility. Study tool: Self-Completed Questionnairebased on the Package of Essential NCDs (PEN) interventions for PHC. Mean score for knowledge for diabetes (DM) management and control was calculated and compared among professional groups (family vs village doctors) and regions (Tbilisi vs Kakheti) using one-way Analysis of Variance.
Results
In total, 293 doctors (mean age 54.3±12.0 years) participated in the study. Participants were more experienced in management and control of DM than other NCDs. About two thirds of respondents had good knowledge on management and control of DM, they managed to response correctly to 80% of questions. Mean score for knowledge of DM management and control was almost similar among family and village doctors (*P=0.31)*, as well asbetween the regions (*P=0.01*). Although over 80% of physicians have positive attitudes towards prevention and management of DM, smoking was the only status of patients' that was 'always' determined bydoctors (80% of doctors; 95%CI=72.6%–82.4%); less than 50% (95%CI=40.2%–51.7%) of doctors collected information about body mass index (BMI); approximately 50% (95%CI=41.6%–53.3%) of them spent no more than 20 min in a typical visit of a patient with high glucose and⁄or high cholesterol levels.
Conclusions
Family/village doctors': 1. knowledge on DM and its risk factors is moderate, 2. management practices are relevant but not standardized, 3. attitudes towards DM screening andprevention are positive. These findings highlight the needs of effective interventions among family/village doctors to ensure that they are actively involved in prevention and management of DM.

AEP303

An assessment into the insulin secretion during visceral leishmaniasis

Sukrat Sinha
Nehru Gram Bharati University, Department of Zoology, Hanuman Ganj, India

Objective
Visceral Leishmaniasis is a macrophage associated disorder. About 5 percent of the patients may develop insulin dependent diabetes mellitus. It appears to have a direct action on pancreatic beta cells, resulting in initial insulin release followed by impaired insulin secretion. Within this context we looked into alternate therapies of treatment.
Methods
In this study, we investigated whether alteration in the CD2 mediated coordination of an immune response was associated with down regulation of CD4 associated Th1 cell response during Visceral Leishmaniasis (VL) and insulin secretion.
Results
Leishmania donovani (Ld) infection in VL patients markedly reduced expression of CD2 cell surface antigen on CD4+ cells. T-cells of VL patients were mostly in G0/G1 stage of the cell cycle (98.20%) with little or no activity of protein kinase C-alpha (PKC-alpha) isoform. However, pre-incubation with activating anti-CD2 monoclonal antibody (MAb) resulted in a corresponding increase up to 2.52-fold in T-cells of G2/M population supported by both activity and expression of PKC-alpha isoform.
Conclusion
These findings imply that infection with L. donovani induces less CD2 on the surface of CD4+ T-cells, which once activated orchestrate the protective IFN-gamma dominant host defense mechanism via PKC-mediated signal transduction and cell cycle but sugar control strategies must also be undertaken simultaneously to circumvent infection.

Diagnostic accuracy of fatty liver index in type 1 diabetes mellitus patients

Jonathan Mertens[1,2,3], Dirinck Eveline[1], Weyler Jonas[2], Vonghia Luisa[2], Francque Sven[2] & De Block Christophe[1]
[1]University Hospital Antwerp, Endocrinology, Edegem, Belgium; [2]University Hospital Antwerp, Hepatology, Edegem, Belgium; [3]University of Antwerp, Laboratory of Experimental Medicine and Pediatrics, Antwerpen, Belgium

Introduction
Nonalcoholic fatty liver disease (NAFLD) affects ±55% of subjects with type 2 diabetes and contributes to cardiovascular mortality. NAFLD data in type 1 diabetes (T1DM) are scarce. Biopsy is the diagnostic reference but is not suited for routine screening. Ultrasound (US) is validated to diagnose steatosis as first-line imaging but is restricted to trained operators. The Fatty Liver Index (FLI) is a score to predict fatty liver based on triglycerides, Body Mass Index (BMI), gamma-glutamyl-transpeptidase (GGT) and waist circumference (WC), and stratifies risk groups in primary work-up. FLI <30 is considered to rule out steatosis, FLI ≥60 to rule in steatosis and trigger

referral. We investigated the reliability of FLI to predict steatosis using ultrasound as the reference method in T1DM.
Methods
We consecutively recruited 331 T1DM patients who underwent anthropometry, US and lab-tests. We used the area under the receiver operating characteristic curve (AUROC) and Youden's Index to determine diagnostic accuracy.
Results
Prevalence of steatosis was 22% (74/331) based on US. WC (89±13 vs 103±14 cm, $P \leq 0.001$), BMI (25. 3±4.1 vs 30.0±4.9 kg/m^2, $P \leq 0.001$), GGT (33±2 vs 47±5 mU/l, $P=0.007$), HDL (64±16 vs 58±18 mg/dl, $P=0.005$) and triglycerides (80±40 vs 113±84 mg/dl, $P \leq 0.001$) differed significantly between the steatosis and non-steatosis group. Age, gender and ALT did not differ. The AUROC of the FLI for diagnosis of steatosis was 0.78 (95% CI: 0.71–0.84). Optimal cut-off according to Youden's Index was ≥30 (sensitivity 0.84, specificity 0.63, PPV 0.82, NPV 0.92). Thirteen subjects with steatosis on US had a FLI <30 (13/175:7.4%). We further assessed the predefined threshold of ≥60 (sensitivity 0.55, specificity 0.84, PPV 0.50 and NPV 0.87). Thirty-three out of 74 patients with steatosis had a FLI <60, so 45% of cases would not be diagnosed. Comparison of groups with FLI <30 and FLI 30–59 showed significant differences in systolic blood pressure (133±17 vs 140±20 mmHg, $P=0.004$), creatinine (0.8±0.2 vs 0.9±0.6 mg/dl, $P=0.007$) and HDL (67±17 vs 57±16 mg/dl, $P<0.001$), indicating a higher metabolic risk profile in the latter.
Conclusion
Diagnostic accuracy of FLI for diagnosis of steatosis is moderate in T1DM patients with optimal cutoff ≥30. The FLI cutoff ≥60 would miss the diagnosis of steatosis in 45% of cases, whereas the cutoff ≥30 would miss only 7.4%. The subjects with a FLI score 30–59 had a more severe risk profile compared to subjects with FLI <30. Therefore, we propose the cutoff ≥30 in primary decision making based on FLI to diagnose NAFLD in T1DM patients.

CTRP-1 levels are related to insulin resistance in gestational diabetes mellitus

Carola Deischinger, Alexandra Kautzky-Willer, Karoline Leitner, Sabina Baumgartner-Parzer & Juergen Harreiter
Vienna, Endocrinology and Metabolism, Vienna, Austria

Introduction
CTRP-1 belongs to the adipose tissue-derived C1qTNF superfamily of proteins involved in e.g. glucose metabolism regulation. Recent studies have shown significant differences in CTRP-1 levels between type 2 diabetics and controls. We aim at investigating a possible link between gestational diabetes mellitus (GDM) and CTRP-1 as there is little data on CTRP-1 and its possible functions in pregnancy.
Patients and Methods
In 167 women (93 with normal glucose tolerance (NGT), 74 GDM) of a high-risk population for GDM at a tertiary treatment center, CTRP-1 levels were investigated in respect to GDM. Glucose tolerance, insulin resistance and secretion were assessed with indices (Matsuda index, Stumvoll first phase index, ISSI- 2, AUC insulin, AUC glucose) derived from an oral glucose tolerance test (oGTT) performed at <21 weeks of gestation (GW) and GW 24 to 28. GDM (44.3% of whole cohort) was further divided into GDM subtypes depending on a predominant insulin sensitivity (GDM-IR) or secretion deficit (GDM-IS).
Results
There was no significant difference in CTRP-1 levels between GDM (mea $n=76.86$ ng/ml; S.D.=37.81) compared to NGT ($P=0.104$). However, GDM-IR women (44.00±43.00 ng/ml) had significantly lower CTRP-1 levels compared to the GDM-IS group (83.79±23.08 ng/ml; $P<0.001$) and women with NGT (82.2±35.34 ng/ml; $P<0.001$) Throughout pregnancy, CTRP-1 levels did not change significantly, except for the GDM-IR group. Here, CTRP-1displayed a downwards trend when correlated with gestation week. In the whole population, CTRP-1 levels correlated negatively with BMI, diastolic blood pressure, AUC insulin, adiponectin levels, fetal birth weight and positively with HbA1c, Matsuda Index and ISSI-2.
Conclusion
The results of the present study further point towards CTRP-1 being a metabolic biomarker for insulin resistance in GDM. To establish its exact function, further investigations on CTRP-1 in relation to hyperglycemia and insulin resistance are imperative.

New-onset diabetes mellitus after liver transplantation in the patients with acute liver failure: Is there any effect of pretransplant hypoglycemia?

Ömercan Topaloğlu[1,2], Muhammet Cengiz[1], Ayşe Cengiz[3], Bahri Evren[1], Saim Yoloğlu[4], Sezai Yılmaz[5] & İbrahim Şahin[1]
[1]Inonu University Medical Faculty, Endocrinology, Malatya, Turkey; [2]Kocaeli Derince Training and Research Hospital, Endocrinology, Derince/Kocaeli, Turkey; [3]Inonu University Medical Faculty, Internal Medicine, Malatya, Turkey; [4]Inonu University Medical Faculty, Biostatistics, Malatya, Turkey; [5]Inonu University Medical Faculty, General Surgery, Malatya, Turkey

Introduction
The frequency of new-onset diabetes after transplant (NODAT) is 5–30% in liver transplant recipients. We aimed to analyze the frequency and predictors of NODAT in the patients undergoing liver transplantation (LTx) due to acute liver failure(ALF), and to investigate whether pretransplant hypoglycemia had any effect on NODAT.
Materials and methods
Adult patients undergoing LTx due to ALF were analyzed retrospectively. The patients with chronic liver failure or diabetes were excluded. We measured pretransplant random blood glucose(RBG) and posttransplant fasting blood glucose(FBG). NODAT was diagnosed according to principally 1st month FBG (group 1:<100, group 2:100–125, group 3:>125 mg/dl). The participants were subgrouped according to age, gender, BM, etiology, antiviral medication, thyroid function, pretransplant RBG, donor type, immunosuppressive drug, common infection, and surgical complication.
Results
A total of 91 patients were analyzed; mean age was 33.48 (±13.35), and 52.7% ($n=48$) of them was female. The etiology was Budd-Chiari syndrome in 3 (3.29%), acute viral hepatitis in 38 (41.75%), drug or toxin-related in 21 (23.07%), and other/unknown causes in 29 (31.86%) patients. The ratio of NODAT was 26.98% on the 1st month. NODAT group had a higher pretransplant RBG than the others. Pretransplant hypoglycemia did not have any effect on NODAT; however, pretransplant hyperglycemia increased the risk of NODAT by 4.065 times ($P=0.018$).
Conclusions
We showed that pretransplant hyperglycemia increased the risk of NODAT by 4 times, but hypoglycemia did not affect. The frequency of NODAT decreased progressively during follow-up. We recommend perioperative glycemic control should be maintained as early as possible to manage NODAT; however, it might be complicated in such a clinical condition.

Perception regarding marriage of diabetics in central indian population

Bharat Saboo[1,2]
[1]Prayas for Care of Diabetes Society, Diabetology, Indore, India; [2]Prayas Diabetes Center, Diabetology, Indore, India

Background
Marriage is an integral part of Indian society. In spite of the large number of people with diabetes mellitus (DM) in India, India is not a diabetes-friendly society. The society suffers from lots of myths regarding diabetes and insulin use. This survey highlights perceptions of general population with regards to marriage, associated diabetes distress, and suggests potential solutions. If no one is ready to accept diabetics as a bride or groom for their children and they can't have a family, it's a serious issue. There is no survey till date on this topic with surveyed population.
Methods
1365 Randomly selected people, males and females, from rural and urban areas of central India were asked to fill a survey questionnaire online as well as in paper. The inclusion criteria were age 30–60, having at least one children and no history of mental disorder. The results were analyzed, inclusion criteria were age 30–60, no history of mental disorder.
Results
Responses were analyzed and plotted. Most of the respondents (78%) were not willing to accept a diabetic groom or bride for their children, the acceptability was more in males, persons coming from urban areas, having higher academic qualification, and in those with children with diabetes, the acceptability in even the known diabetics is only 15%. Most of the responders were worried about the complication of the disease. Majority of responders (74%) think diabetes affect future progeny.

Conclusion
Misconception regarding social, occupational, marital abilities, fertility, genetics, quality of life in young people living with DM raises major barriers to marriage, People with DM are wrongly assumed to be sick, disabled, dependent persons, unsuitable for marriages, and likely to have complicated pregnancies with the possibility of having children with diabetes. Diabetes distress and psychological issues are major problems related to marriage in young people with DM. Counseling of patients, family, relatives, prospective spouse, and increasing social awareness regarding diabetes through mass communication will serve as the keys to their resolution.

Effect of maternal obesity and degree of glucose intolerance on neonatal hypoglycaemia and birth weight: A retrospective observational cohort study in women with gestational diabetes mellitus

Alexandra Cremona[1,2,3,3,4], Jean Saunders[5], Amanda Cotter[3,6], Jill Hamilton[7], Alan Donnelly[1,8] & Clodagh O'Gorman[1,3,9]
[1]University of Limerick, Health Research Institute (HRI), Ireland; [2]Irish Nutrition & Dietetic Institute (INDI), Ireland; [3]University of Limerick, Graduate Entry Medical School (GEMS), Ireland; [4]University of Limerick, School of Allied Health (SAH), Ireland; [5]University of Limerick, Statistics Consulting Unit (SCU/CSTAR @ UL), Ireland; [6]University Maternity Hospital Limerick (UMHL), Obstetrics & Gynaecology, Ireland; [7]University of Toronto, The Division of Endocrinology, Department of Paediatrics, Canada; [8]University of Limerick, Physical Education & Sports Science (PESS), Ireland; [9]University Hospital Limerick, Department of Paediatrics, Ireland

Introduction
Gestational diabetes mellitus (GDM) is an increasing problem worldwide. Post-natal-hypoglycaemia and excess-foetal-growth are known important metabolic complications of neonates born to women with diabetes. This retrospective-cohort-study aims to determine the influence of obesity and glucose-intolerance on neonatal-hypoglycaemia and birth-weight over the 90th percentile (LGA).
Methods
Data were abstracted from 303 patient medical records from singleton pregnancies diagnosed with GDM. Data were recorded during routine hospital visits. Demographic data were acquired by facilitated questionnaires and anthropometrics measured at the first antenatal appointment. Blood-biochemical-indices were recorded. Plasma glucose area under the curve (PG-AUC) was calculated from 75 g oral glucose tolerance (OGTT) results as an index of glucose intolerance.
Results
OGTT results of 303 pregnant women aged between 33.6 y (29.8–37.7), diagnosed with GDM were described. Neonates of mothers with a BMI of over 30 $kg.m^{-2}$ were more likely to experience neonatal hypoglycaemia (24 (9.2%) vs 23 (8.8%), $P=0.016$) with odds-ratio for neonatal-hypoglycaemia significantly higher at 2.105, 95% CI (1.108,4.00), $P=0.023$. ROC analysis showed poor strength of association (AUC 0.587 (95% CI, .487 to .687). Neonatal LGA was neither associated with nor predicted PG-AUC or obesity; however, multiparous women were 2.8 (95% CI (1.14, 6.78), $P=0.024$) times more likely to have a baby born LGA.

Table 1 Maternal and neonatal characteristics stratified according to maternal BMI at 12 weeks gestation.

	BMI < 30 $kg.m^{-2}$	BMI ≥ 30 $kg.m^{-2}$	*P*-value
n	188	107	–
Maternal age (y)	33.1 (29.6–36.8)	34.8 (26.1–38.3)	0.141
Previous GDM	32 (10.9%)	34 (11.6%)	0.003**
Fasting plasma glucose (mmol/l)	4.6 (4.3–5.2)	5.1 (4.5-5.3)	<0.001***
1 h post 75 g glucose challenge (mmol/l)	10.2 (9.1–10.7)	(8.9–10.9)	0.885
2 h post 75 g glucose challenge (mmol/l)	7.0 (6.2–8.4)	6.6 (5.9–8.3)	0.315
PGAUC	25 (23.0–26.0)	24 (22.0–27.0)	0.745
Required insulin treatment	16 (5.4%)	19 (6.4%)	0.018*
Macrosomia	18 (6.1%)	17(5.8%)	0.107
LGA	23 (7.9%)	16 (5.5%)	0.542
NNU admission	33 (11.2%)	27 (9.2%)	0.116
Age adjusted birth centile	53.9 (31.1–77.1)	39.9 (16.4–79.6)	0.052
Neonatal hypoglycaemia	23 (8.8%)	24 (9.2%)	0.016*

Conclusion
Maternal BMI during the first trimester of pregnancy exhibits a strong influence on neonatal hypoglycaemia but not neonatal birthweight in a cohort of pregnancies affected by GDM. Multiparous women are more likely to have an infant born LGA. Future studies should examine the relationship between maternal adiposity, together with accurate markers of insulin sensitivityon the outcome of neonatal hypoglycaemia.
Data presented as median (IQR) or where frequency Count (percentage).

Untargeted plasma metabolomics identifies broad metabolic perturbations in glycogen storage disease type I

Mathis Tamara[1], Poms Martin[2], Gautschi Matthias[3], Plecko Barbara[4], Baumgartner Matthias[2] & Michel Hochuli[5]
[1]University Hospital Zurich, Department of Endocrinology, Diabetes, and Clinical Nutrition, Zurich, Switzerland; [2]University Children's Hospital, Division of Metabolism and Children's Research Center (CRC), Zurich, Switzerland; [3]University Hospital Bern, Inselspital, Division of Pediatrics, Institute of Clinical Chemistry, Bern, Switzerland; [4]University Children's Hospital, Medical University, Graz, Austria; [5]University Hospital Bern, Inselspital, Diabetes, Endocrinology, Nutritional Medicine and Metabolism, Bern, Switzerland

Background/Introduction
The primary metabolic defect in glycogen storage disease type I (GSDI) results in fasting hypoglycemia and typical secondary metabolic abnormalities (e.g. hypertriglyceridemia, hyperlactatemia, hyperuricemia). The aim of this study was to broadly assess further perturbations of the metabolic network in GSDI by using untargeted plasma metabolomics.
Methods
Plasma samples of 14 adult GSDI patients (11 GSDIa, 3 GSDIb. Mean age 26.4 y, range 16–46 y) on standard treatment were compared to a cohort of 31 healthy controls utilizing ultra-high performance liquid chromatography (UHPLC) in combination with high resolution tandem mass spectrometry (HR-MS/MS) and subsequent statistical multivariate analysis. Significantly altered features were identified by mining against an internal library as well as online databases Metlin and mzCloud.
Results
The metabolic profile showed numerous alterations of metabolites in different areas of the metabolic network, e.g. in central pathways of energy generation such as the tricarboxylic acid cycle, in the metabolism of creatine, in the urea cycle, in the amino acid and purine/pyrimidine metabolism, but also changes of enzyme cofactors such as biotin. These metabolic alterations were consistently seen in patients of both GSD subtypes (Ia and Ib).
Conclusion
The metabolic defect of GSDI has profound effects on a variety of metabolic pathways in both GSDI subtypes, in addition to the known typical metabolic abnormalities (e.g. in lipid metabolism). The effect of glycemic control on these metabolic alterations, as well as the mechanisms behind these observations remain to be further elucidated.

Characterization of muscle function, lifestyle and motivational indices in obese women

Chiara Marocco, Vittoria Cella, Lorenzo Innocenti, Viviana Bimonte, Gian Pietro Emerenziani, Edoardo Mocini, Elisabetta Ferretti, Andrea Lenzi, Vincenzo Bonavolontà, Rachele Fornari, Lorenzo Maria Donini, Carlo Baldari, Maurizio Bertollo, Laura Guidetti & Silvia Migliaccio
Department of Movement, Human and Health Sciences University of Rome 'Foro Italico', Rome, Italy

Introduction
Obesity is a chronic metabolic condition characterized by an excess of adipose tissue leading to an increased risk of developingdiseases such as diabetes mellitus and cardiovascular pathologies. Unbalanced nutrition and sedentary lifestyle are among the main influencing factors leading to a reduction in muscle mass, strength and functionality, predisposing obese subjects to sarcopenia and functional disability. Moreover, recent studies suggest the possible presence, in these patients, of alterations in their volition in performing lifestyle actions. Thus, the aim of our study was to evaluate the possible correlations among indices of muscular function (MF), lifestyle and volition.
Methods
Twenty-one obese women (age: 41.8±11.8 years; BMI: 38.2±3.2 kg/m^2) were recruited at the High Specialization Center for Obesity Care, Policlinico Umberto I, Sapienza University of Rome. After clinical assessment, all subjects were evaluated for: Body composition (BC) by DXA, and for upper and lower limbs indices of MF by Handgrip test (HGT) and Sit to Stand 30s (STS). Furthermore GPAQ, Predimed questionnaire to determine the Mediterranean diet (MeDi)adherence, Volition Exercise Questionnaire (VEQ), Exercise Motivations Inventory (EMI-2), Psychobiosocial States in Physical Education (PBS-SPE), Decisional Balance Inventory (DBI) and physical activity level (PAL) motivational indices were administered, in order to evaluate individual lifestyle. Potential relationships among all variables were analyzed by Pearson correlation.
Results
BCshowed high percentage Fat Mass (40.9±3.4%) and low level of Lean Mass (59,1±4,5%). The results of the T-tests with independent samples showed no significant differences between sedentary and active groups, for questionnaire and motor test variables. Furthermore, correlations indicate a significant relationship between the HGT strength indices and the GPAQ, but not with STS. Finally, the facilitatory volition correlates positively with the STS, while the inhibitory one correlates negatively (R=0.52; R=–0.39; P<0.05).
Conclusions
In conclusion, our results indicate that high PAL and good adherence to MeDi do not correlate with the STS, which show indices below normal level. However, it is interesting how STS positively correlates with VEQ. Literature data suggestHGT as the most suitable tool for assessing general muscle strength, but results suggest greater relevance of STS as an indicator of poor MF while also detecting a discrepancy between upper and lower limb MF. Therefore, an interdisciplinary holistic evaluation is essential in obese subjects to define and validate the parameters indicative of health status and muscle functionality.

Study of the effect of sibutramine on central mechanisms of regulation of eating behavior in patients with obesity by means of fMRI. Preliminary results

Oksana Logvinova[1], Polina Kuznetsova[2], Evdokiia Tsvetkova[3], Elena Kremneva[2], Ekaterina Troshina[1], Tatiana Romantsova[3], Marine Tanashyan[2], Anastasia Kornilova[2] & Evgenia Kolpakova[1]
[1]Endocrinology Research Centre, Department of Clinical endocrinology, Moscow, Russian Federation; [2]Research Center of Neurology, Moscow, Russian Federation; [3]I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Endocrinology № 1, Moscow, Russian Federation

Introduction
Patient's nutrition is generally considered to be the main cause of the accumulation of excess body weight. However, this accumulation can be mitigated by treatment involving drugs with a central mechanism of action. By using functional Magnetic Resonance Imaging (fMRI) we can meliorate our understanding of the organization of neuronal networks responsible for eating behavior, and see how they respond to the mechanisms of action of sibutramine in the treatment of the obesity.
Purpose
To assess changes in eating behavior by fMRI in obesity patients, who took sibutramine for 3 months.
Methods
The study included 30 patients (87% women) with obesity having BMI of ≥30 kg/m^2 with mean age of 32.6 years, mean body weight (BW) – 110.0 kg, mean waist circumference – 109.8 cm. All patients were right-handed. The control group included 23 people with normal BMI of comparable gender and age. All participants underwent initial fMRI-mapping focused on the dominant hemisphere of the brain. The obesity cohort was treated with sibutramine (Reduxine) at a dose of 10 or 15 mg per day for 3 months. After treatment patients with obesity underwent a second fMRI mapping to assess changes against the initial mapping.
Results
According to fMRI in the group with obesity (before treatment), there was a lower activation of the upper and lower parietal lobes in both hemispheres as well as a lower activation the lateral right frontal cortex compared to the healthy control group. Furthermore, in the obese group there was also a pronounced activation in regions 45, 46, and 9 in the DorsoLateral PreFrontal Cortex (DLPFC) of Broadman fields on the left. Activation of the Supplemental Motor Area (SMA) and DLPFC on the right in patients with obesity was absent, compared to the control group. After 3 months of treatment with sibutramine 80% of patients lose ≥5% of BW. After treatment in obese individuals there was a decrease in activation of the visual cortex, DLPFC and the appearance of activation in area 8 of the Broadman field on the left.
Conclusion
DLPFC and SMA are essential parts of the control neural network related to eating behavior. According to fMRI observations in this study, obese patients treated with sibutramine for 3 months, had a decrease in activation in the projection of the left DLPFC what was regarded as a change in disordered patterns of eating and may indicate increased appetite control due to the treatment.

Combination of baseline body weight with active plasma ghrelin level could predict early response with liraglutide 3.0 mg in patients with obesity

Oksana Logvinova & Ekaterina Troshina
Endocrinology Research Centre, Clinical Endocrinology, Moscow, Russian Federation

Introduction
Liraglutide 3.0 mg could be effective option for obesity management. It is known that patients who have ≥5% weight loss in 16 weeks ('early responders' (ERs)) will have ≥10% weight loss in 56 weeks [1]. Predictors of this early response (ER) in 16 weeks are unknown.
Methods
22 obese patients (30% men; median age 40.0 [33.0; 48.5]) were recruited. The exclusion criteria were diabetes, psychotic disorders, obesity due to secondary causes, deconditioning of concomitant diseases and current or 3-month prior usage of anti-obesity medications. Contraindications for liraglutide were excluded in all participants. Baseline body weight (BBW), BMI, waist circumference (WC) and eating behavior regulator levels in fasting state such as leptin, ghrelin, obestatin and GLP-1 (ELISA) were evaluated. Patients were prescribed liraglutide with standard dose escalation from 0.6 to 3.0 mg per day. In 16 weeks re-examination was performed. Statistical analysis include Wilcoxon and Mann-Whitney tests and linear regression analysis.
Results
Baseline plasma level for active ghrelin was 6.07 [3.41; 9.22] fmol/ml, for obestatin 1.85 [1.73; 2.26] ng/ml, for GLP-1 3.98 [2.91; 4.89] ng/ml and for leptin 66.49 [29.83; 108.12] ng/ml. The median (Me) of BBWchange was –7.30 [–11.50; –4.50] kg, Me BMI change –2.51 [–4.05; –1.39], Me WC change –6.00 [–9.50; –4.00]. All changes were statistically significant (P<0.007, Wilcoxon test). 14 patients (64%) lose ≥5% and 8 patients did not have ER. To identify predictor(s) of ER, baseline characteristics of ERs and non-ERs were compared. There was statistical tendency for smaller BBW in ERs (P=0.019, Mann-Whitney test). Since the study had limited number of observations, multivariate analysis was not used. With the method of linear regression analysis AUC for combinations of BBW with base-

line plasma eating behavior regulating-peptides were evaluated. The best AUC was for combination of BBW with active ghrelin level (0.893, 95% CI [0.708–0.989]). The mathematical model for result prediction was created. The quality of model due to the Hosmer-Lemeshov criteria was good (3.987; $P=0.858$). The sensitivity of model was 86%, 95% CI [65%; 97%], specificity 63%, 95% CI [41%;83%], predictive value of positive result 80%, 95% CI [60%; 95%], predictive value of negative result 71%, 95% CI [49%; 89%].
Conclusion
In our study, mathematical model including BBWin combination with plasma fasting active ghrelin level was a good tool for predicting probability of the effectiveness of liraglutide 3.0 mg therapy in patients with obesity with the sensitivity 86%. However, further studies with a larger sample of patients are required.

Omega-3 PUFA and probiotics as a single formulation for insulin resistance and obesity: Evidence from animals to randomized clinical studies

Nazarii Kobyliak[1], Tetyana Falalyeyeva[2], Galyna Mykhalchyshyn[1], Olexiy Savchuk[2], Dmytro Kyriienko[1,3], Lyudmyla Ostapchenko[1] & Iuliia Komisarenko[1]
[1]Bogomolets National Medical University, Endocrinology, Kyiv, Ukraine; [2]Taras Shevchenko National University of Kyiv; [3]Kyiv City Clinical Endocrinology Center, Kyiv, Ukraine

Background
Probiotics and omega-3 polyunsaturated fatty acids supplementation (PUFA) have beneficial effect on obesity related disorders in animal models. We have previously shown, on rats with monosodium glutamate-induced obesity, that in take of the combination based on live probiotics and omega-3 PUFA is accompanied by the preventive effect concerning experimental obesity development, lead toinsulin resistance (IR) improvement and more obvious decrease of he paticsteatosis as well as lipid accumulation as compared to probiotic alone. Despite of animal data, randomized placebo-controlled trials (RCT) are still lacking or inconsistent.
In respect to our experimental data, we aimed to carry out place bo-controlled RCT for the efficiency of acombination of multi probiotics with omega-3 PUFA as anadjunction to the standardanti-diabetictherapy on the main metabolic parameters in T2D patients.
Methods
A total of 54 patients met the criteria and were included in double-blind single center RCT, to receive 'Symbiter-Omega' (biomass of 14 probiotic bacteria genera *Bifidobacterium, Lactobacillus, Lactococcus, Propionibacterium* withomega-3 PUFA as single formulation) or placebo for 8-weeks administered as a sachet formulation. The primary main outcome was the change HOMA2-IR (homeostasis model assessment-estimated insulin resistance). This model canbe calculated using the software available at http://www.dtu.ox.ac.uk/homacalculator/index.php. Secondary outcomes were the changes in glycemic control-related parameters, β-cells functionalactivity, anthropomorphic variables and markers of a chronic systemic inflammatory response.
Results
Combineduse of the probiotic mixture with omega-3 PUFA leadstoa significant reduction of HOMA2-IR ($P=0.018$) and improvement of insulin sensitivity (% S) ($P=0.010$) after 8 weeks of treatment period. Simultaneously were detected lowering of HbA1c from 8.26±0.82 to 7.80±0.86% ($P=0.006$). In patients that received placebo insignificant difference for both primary outcomes was found. Additionally, assecondaryoutcomesthefunctionalactivityofβ-cells (% B) was assessed. The intragroup analysis showed a trend to reduce the % B, which was more expressed in the placebo group. In secondary outcome analysis slight significant decrease of bodyweight and BMI as compared to placebo were found. Treatment with omega-3-enrichedprobiotics was accompanied by significant reduction of pro-inflammatorycytokines within intragroupcomparis on during the treatment, namely IL-1β ($P=0.015$), TNF-α ($P=0.002$), IL-6 ($P=0.001$) and IL-8 ($P=0.033$) correspondingly.
Conclusion
Probiotic combination with omega-3 PUFA modestly improved insulin resistance and obesity related parameters in patients with type 2 diabetes.

Antibodies to insulin receptor in the diagnosis of non-diabetic hypoglycemia

Marina Yukina, Nurana Nuralieva, Ekaterina Troshina, Natalia Malysheva & Larisa Nikankina
Endocrinology Research Centre, Clinical Endocrinology, Moscow, Russian Federation

Introduction
One of the autoimmunenon-diabetic hypoglycemia (NDH) causes isthe antibodies to insulinreceptor (AB-rIRI) formation and/orinsulin resistance type B (TBIR).
Objectives
To determine the prevalence of increased AB-rIRI level in patients with suspected NDH of different genesis and in healthy individuals; to determine significance of AB-rIRI investigation in NDH diagnosis.
Methods
In a prospective study we determined AB-rIRI (reference 0–3,65 ng/ml) and IRI at the beginning of fasting test in 104 patients aged 18–80 with suspected NDH. According to results, patients were divided into 4 groups: with insulinoma (group 1; $n=49$), hyperinsulinemic hypoglycemia of other genesis(group 2; $n=12$), hypoinsulinemic hypoglycemia (group 3; $n=13$), withouthypoglycemia (group 4). 10 healthyindividualswereincludedingroup 4 ($n=40$). Each group was divided into subgroups with (A) and without (B) high level of AB-rIRI. In subgroup A we selected subgroup C, in which AB-rIRI level in dynamics (in3,5 months)was determined.
Results
TBIRwasnotrevealed.
High AB-rIRI was revealed in 15.8% ($n=18$) of participants. In group 1 high level of AB-rIRI (Me 4.78 ng/ml [min 3.92; max 10.59]) was confirmed in 39% of cases ($n=7$), in group 2 in 17% ($n=3$; Me 4.16 ng/ml [min 3.77; max 12.3]), in group 3 in 11% ($n=2$; Me 14.84 ng/ml [min 6.46; max 23.21]), in group 4 in 33% ($n=6$; Me 7.97 ng/ml [min 3.68; max 17.26]). Frequency of AB-rIRI carriage in patients with NDH consisted 16% ($n=12$), in group 4–15% ($n=6$). When comparing AB-rIRI levels in subgroups A there were no significant differences ($P=0.52$). AB-rIRI level in all patients of subgroup 1C ($n=4$) was normal after surgery. Insubgroups 2C ($n=1$) and 3C ($n=1$) AB-rIRI levels were high, in subgroup 4C ($n=2$) AB-rIRI levels were significantly higher ($P=0.028$): Me 16.84 ng/ml [min 15.018; max 18.661]. Wecontinuethepatients' observation.
Comparative analysis ingroups 2–4 revealed that in subgroups Aclinical and laboratory signs of insulinresistance occurred significantly more often ($P=0.02$).
Conclusion
The AB-rIRI carriage is not so rare and probably has multi factorial etiology. It is not excluded that patients-carriers are in latent phase of TBIR, so they need careful observation, AB-rIRI'smechanism of action and pathogenesis of formationrequires data accumulation and further study. Given the equivalent increase of AB-rIRI in patients as in healthy individuals, analysis of this parameter in NDH primary diagnosisis inexpedient.

Time to glycemic control – an observational study of 3 different operations

Alper Celik[1], Sjaak Pouwels[2], Fatih Can Karaca[1], Eylem Cagiltay[3], Surendra Ugale[4], Ilker Etikan[1], Deniz Büyükbozkırlı[1] & Yunus Emre Kilic[1]
[1]Metabolic Surgery Clinic; [2]Elisabeth Tweesteden Hospital, Intensive Care; [3]Department. of Endocrinology, GATA Haydarpaşa Training & Research Hospital; [4]Department of Bariatric and Metabolic Surgery, Virinchi Hospitals

Background
Medical treatment fails to provide adequate control for many obese patients with type 2 diabetes mellitus (T2DM). A comparative observational study of bariatric procedures was performed to investigate the time at which patients achieve glycemic control within the first 30 postoperative days following sleeve gastrectomy (SG), mini-gastric bypass (MGB), and diverted sleeve gastrectomy with ileal transposition (DSIT).
Methods
Included patients had a body mass index (BMI) ≥30 kg/m^2; T2DM for ≥3 years, HbA_{1C}>7% for ≥3 months, and no significant weight change (>3%)

within the prior 3 months. Surgical procedures performed were SG ($n=49$), MGB ($n=93$), and DSIT ($n=109$). The primary endpoint was the day within the first postoperative month on which mean fasting capillary glucose levels reached <126 mg/dl. Multivariate logistic regression analysis was used to identify predictors of glycemic control.
Results
The cohort included 251 patients with a mean BMI of 36.04±5.76 kg/m^2; age, 52.84±8.52 years; T2DM duration, 13.09±7.54 years; HbA_{1C}, 8.82±1.58%. On the morning of surgery, mean fasting plasma glucose was 177.63±51.3 mg/dl; on day 30, 131.35±28.7 mg/dl ($P<0.05$). Mean fasting plasma glucose of <126 mg/dl was reached in the DSIT group (124.36±20.21 mg/dl) on day 29, and in the MGB group (123.61±22.51 mg/dl), on day 30. The SG group did not achieve the target mean capillary glucose level within postoperative 30 days.
Conclusion
During the first postoperative month, glycemic control (<126 mg/dl) was achieved following DSIT and MGB, but not SG. Preoperative BMI and postprandial C-peptide levels were independent predictors of early glycemic control following DSIT.

Appropriateness of the 6 mm insulin needle length comparing the glycemic control in overweight-obese and normal weight patients with type 2 diabetes – four years observational study

Bensley Gonsalves
Bliss Total Diabetes Care, Diabetes, Mumbai, India

Introduction
The length of the insulin needle in last three decades has reduced from 16 mm to 4 mm. The BMI of 10 kg/m^2 difference accounts for a 4 mm difference in subcutaneous tissue thickness. We compared the glycemic control in patients switched from 4 mm needle to 6 mm needle in the Normal Weight (NW) patients (BMI<25 kg/m^2) with the Obese and Overweight (OOW) patients (BMI≥25 kg/m^2)
Methods
We observed 93 T2DM patients (51 females) for the change in HbA1c over a period of four years from Bliss Total Diabetes Care (BTDC) registry from 2016 to 2019. Comparisons were made using ANOVA, Fisher's exact and unpaired *t* test.
Results
The mean HbA1c in the total population at baseline was 9.1% (s.d.±1.9, minimum 5.3, maximum 14, range 8.3, 95% CI 8.7 to 9.5) which significantly reduced to 8.5% (s.d.±2.1, minimum 5, maximum 14, range 8.7, 95% CI 8.1 to 8.9), ($P=0.039$). The mean reduction in HbA1c in the NW ($n=33$) and OOW ($n=60$) was 0.4% (s.d.±1.6, minimum –3, maximum 4.6, range 7.6, 95% CI –0.17 to 0.98) and 0.7% (s.d.±1.8, minimum –3.7, maximum 6, range 9.7, 95% CI 0.27 to 1.2), ($P=0.39$ NS), respectively. We compared the proportions for patients achieving the good glycemic control (HbA1c<7%) in NW ($n=7$) and OOW (19) with inadequate glycemic control in NW ($n=26$) and OOW (41). The association between the glycemic control (target HbA1c<7%), and BMI was not statistically significant ($P=0.33$ NS)
Discussion
The overweight and obese patients achieved a favourable, numerically superior glycemic reduction with 6 mm needle, which would be accounted by the better penetration of the thicker subcutaneous tissue and effectiveness to inject insulin. However, the difference was statistically insignificant which may be attributed due to the chronic progressive nature of diabetes with multiple, unadjusted confounding variables.
Conclusion
We found that longer insulin pen needles may be a better option for their appropriateness and effectiveness in patients with higher BMIs. In order to contribute immensely to the evidence-based decisions of appropriate needle length, the results of our study need corroboration with larger multi-centric studies.

Pancreas-kidney transplantation improves quality of life in type 1 diabetes patients

María Dolores Alcántara-Laguna[1], Manuel Durán-Martínez[2], Rafael Calleja-Lozano[2], Juan Manuel Sánchez-Hidalgo[2] & María Ángeles Gálvez-Moreno[1]
[1]Hospital Universitario Reina Sofia, Endocrinology and Nutrition, Córdoba, Spain; [2]Hospital Universitario Reina Sofia, General and Digestive Surgery, Córdoba, Spain

Introduction
Diabetes is increasing its prevalence as an enhancement of treatment options arises and mortality declines. Pancreas transplantation has been postulated as one of them, specifically indicated for cases with end-stage renal failure where kidney transplantation is required besides. It has been analysed whether there is a clinical benefit in terms of quality of life (QoL) in patients undergoing pancreas-kidney transplantation (PKT) compared to dyalisis population or other solid-organ transplantation.
Objective
To determine if PKT has a medium-short term impact in QoL in patients with type 1 diabetes mellitus (T1DM) and end-stage renal disease (group PKT) compared to patients with T1DM without end-stage renal disease and indication for PKT (group no-PKT).
Methods and patients
We analysed data from 40 patients admitted in Hospital Universitario Reina Sofía from 2013 to 2018 for simultaneous PKT. We compared them to a random sample of 40 patients suffering from T1DM under insulin treatment for at least 5 years before the study (group no-PKT). Quality of life was assesed using the 36-Item Short Form Health Survey questionnaire (SF-36). Quality of life data were analysed with Mann-Whitney U Test. Continuous cuantitative variables were compared using Student's T Test. Data was analysed using SPSS v. 24.
Results
Patients in both groups showed a similar distribution regarding sex and BMI. No-PKT patients were older than PKT receptors (42.9 vs 38.32 years old, statistically significant). T1DM patients not undergoing PKT had an average duration of the disease of 26.37 years and a HbA1c of 7.92% (63.1 mmol/mol). SF-36 showed a favorable statistically significant ($P<0.05$) impact of PKT when compared to no-PKT group in general health, bodily pain, social functioning, vitality, mental health and health change scales. There were no differences in physical functioning and emotional role SF-36 scales. We observed worse statistically significant ($P<0.05$) results regarding physical role scale in PKT recipients.
Conclusions
1. In our sample, baseline characteristics of patients undergoing PKT are similar to those described in the literature.
2. PKT has a beneficial overall impact in quality of life in patients suffering from T1DM and end-stage renal failure from our sample. However, there are some aspects were we did not find a beneficial result.
3. More studies with a larger sample and follow-up period, prospective data and comparable control groups should be performed in order to confirm these results.

Glycemic control in patients with acute myocardial infarction in an intensive care unit

Volha Isachkina[1] & Larissa I Danilova[2]
[1]10th Minsk City Hospital, endocrinological department, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, endocrinological department, Minsk, Belarus

Background
Dysglycemia is independently associated with increased risk of death in critically ill adults. The aim of this study was to analyze the differences in glycemic control between the diabetic and non- diabetic patients underwent acute myocardial infarction (AMI).
Materials and methods
Retrospective descriptive study of patients with acute myocardial infarction (AMI) admitted to the intensive care unit (ICU) from January to June 2016, including blood parameters, glycemic treatment, mortality and length of intra hospital stay.
Results
267 individuals with AMI were admitted to the ICUduring the study period. 27.3% of them had a previously diagnosed type 2 diabetes (T2DM) and 10.8% had newly diagnosed diabetes. 50.94% were women and the mean age was 72.36 (s.d. 10.49)/ 69.35 (s.d. 11.9) in diabetics/ non-diabetics. Blood glucose on admission was measured in 79.45% T2DM patients/48.45% patients without T2DM in anamnesis. HbA1c was determined only in 28.8% T2DM patients (mean HbA1c was 6.9%, s.d. 0.93). In diabetic patients

the mean glucose level at admission/during ICU stay – 12.41 mmol/l (s.d. 7.33 mmol/l) /9.94 mmol/l (s.d. 4.57 mmol/l). In 23.3% of diabetic patients more than 80% of blood glucose values fell in the target range from 3.9 to 10 mmol/l. The most common treatment used was sliding-scale insulin 36.9%, sliding-scale+IV insulin 12.3% and IV insulin only in 5.6%.
In non-diabetic patients the mean glucose level at admission/ during ICU stay was 6.72 mmol/l (s.d. 2.27 mmol/l)/6.5 mmol/l (s.d. 1.99 mmol/l). About 30 percent of patients without diabetes develop stress hyperglycemia (SH), 19% of them were treated with insulin (sliding-scale). In only 6.45% of patients with SH achieved 80% of blood glucose values in target range from 3.9 to 7.8 mmol/l. Studies showed that time in targeted blood glucose range from 3.9 to 7.8 mmol/l >80% is associated with survival in critically ill patients without diabetes.
Regarding outcomes, 11.7% of diabetics died versus 9.1% in non-diabetics ($P<0.05$). As to non-diabetic patients in normoglycemic ones intrahospital mortality consists 5.5% vs 35.5% in patients with SH ($P<0.005$).
Conclusion
hyperglycemic patients (both with T2DM and SH) have poorer outcomes after acute myocardial infarction. Our study reviled the insufficient quality of glycemic control in hyperglycemic patients with AMIin ICU. The reason for the poor glycemic control may be the widespread use of sliding scale insulin therapy instead of IV insulin, which is recommended in most international protocols.

AEP319

Vitamin D supplementation and glucose metabolism parameters in pre-diabetic women

Alena Andreeva[1] & Tatiana Karonova[1,2]
[1]VA Almazov National Medical Research Centre, Endocrinology, Street Petersburg, Russian Federation; [2]IP Pavlov First State Medical University, Endocrinology, Street Petersburg, Russian Federation

Objective
To assess glucose metabolism (GM) parameters before and after vitamin D treatment in pre-diabetic women.
Material and Methods
In the study were included fifty eight women with prediabetes (impaired fasting glucose (IFG) or impaired glucose tolerance (IGT)) aged from 40 to 55 with signed informed consent. The study didn't include women with diseases affecting the vitamin D metabolism, as well as women receiving regular vitamin D supplementation. All included women were randomized to two groups: to receive 4,000 IU (group 1, $n=30$) and 500 IU (group 2, $n=28$) cholecalciferol daily for 3 months. At the beginning of the study groups were comparable at age, BMI, HbA1c level. At the baseline and at the end of the study were determined the levels of 25(OH)D and GM parameters including HbA1c, glucose, insulin during OGTT (0, 60, 120 min).
Results
Baseline serum 25(OH)D level was 19.9±8.8 ng/ml, 87.9% of women were insufficient 21 (36.2%) or deficient 30 (51.7%): 28 (93.3%) ingroup 1 and 23 (82.2%) in thegroup 2. After 3 months serum 25(OH)D level increased in all patients (mean 34.3±14.5 ng/ml), however, normalization was detected only in group 1–40.4±14.8 ng/ml. An analysis of GM parameters revealed a decrease in plasma glucose levels at 60' ($P=0.04$) and 120' ($P=0.04$), and reduction in HbA1c level of 6.8% (5,9±0.2% → 5.5±0.2) ($P=0.001$) in women who received 4,000 IU/day. Also, cholecalciferol treatment did not lead to a significant change in fasting insulin level, but was accompanied by an increase in insulin level at 120' by 28.8% (66.7±63.7 → 85.9±3.5) ($P=0.03$) after three months only in group 1. Type 2 diabetes was diagnosed in three (10.7%) women in group 2, while 50% of women had normal glucose level and HbA1c in the group 1 ($P=0.001$).
Conclusion
A dose of 4,000 IU cholecalciferol over three months is associated with a normalization of 25(OH) D level and improved glucose metabolism parameters in pre-diabetic vitamin D insufficient women.

Euglycemic DKA after initiating an SGLT-2 Inhibitor and the P90X diet

John Berquist, Jason Kaplan & Tessa Young
Michigan State University McLaren Oakland, Internal Medicine, Pontiac, United States

Introduction
We present a case of a patient with type two diabetes mellitus (T2DM) who started empagliflozin, a sodium-glucose cotransporter-2 (SGLT2) inhibitor and the P90X diet and presented with euglycemic DKA seven days later.
Case Presentation
A male in his 5th decade of life with a history of T2DM presented for a routine office appointment and had a measured hemoglobin A1C of 9.3. His home diabetes regimen consisted of metformin and sitagliptan. Due to his uncontrolled diabetes, he started empaglifozin 10 mg daily and the P90X diet. One week later, he developed abdominal pain, nausea, and vomiting and presented to the emergency department with an associated 10 pound weight loss. Upon presentation, his serum glucose was 192 mg/dl. Further workup revealed a venous blood pH of 7.09, serum bicarbonate 11 mmol/l (21–32 mmol/l), beta-hydroxybutyrate 10.78 mmol/l (0.02–0.27 mmol/l), anion gap 30 and potassium 4.9 mmol/l (3.5–5.1 mmol/l). He was diagnosed with euglycemic DKA.
Discussion
Euglycemic ketoacidosis, DKA without marked hyperglycemia, is a rare presentation of DKA for type two diabetics. There are multiple reports in the literature of a higher predisposition to euglycemic DKA when taking empagliflozin [1] [2] [3]. It is recommended that any diabetic patient who presents with symptoms of DKA and euglycemia should be evaluated for DKA. Our patient started two treatments for T2DM simultaneously after already taking metformin and sitagliptan. The patient started the P90X diet, a moderate-low calorie (1200–1500 per day), low carbohydrate (approximately 55–90 grams per day) diet and empagliflozin; both of which could leave him prone to ketosis. This case illustrates the need to judiciously treat uncontrolled diabetic patients. Although the patient received standard care, initiating two treatments simultaneously, the P90X diet and empagliflozin, potentially led to euglycemic DKA

Severe insulin resistance with cirrhosis: A case report

Himmet Durmaz[1], Berna Evranos Ogmen[1], Konul Ahmadova[1], Aynur Kucukcongar Yavas[2], Caglar Keskin[3], Ahmet Dirikoc[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Clinic of Pediatric Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey

Background
Alstrom syndrome is a rare autosomal recessive genetic disorder characterised by vision loss, hearing loss, childhood obesity, insulin resistance and hyperinsulinemia, type 2 diabetes, hypertriglyceridemia, cardiomyopathy, and progressive pulmonary, hepatic, and renal dysfunction. Hyperinsulinemia develops early, and pancreatic islets show beta-cell proliferation, thus suggesting that both insulin resistance and increased insulin secretion might contribute to glucose intolerance. Increased triglyceride levels, steatosis in the liver and pancreas can also amplify the insulin resistance.
Case presentation
A 20-year-old male patient was diagnosed with congenital amaurosis at the age of 6, diabetes mellitus and hypothyroidism at the age of 8, and hearing loss at the age of 9. Then mutations in ALMS1 detected and Alstrom syndrome was diagnosed. No pathology was detected in bone marrow biopsy for pancytopenia in 2015, and follow-up planned. Chronic liver disease and esophageal varices were detected in 2017. He was admitted to our Endocrinology outpatient clinic with high blood sugar. The serum level of FPG, HbA1c, insulin (fasting), and c-peptide were 148 mg/dl, 10.5%, 63.1 mU/l (3–25) and 5.31 mg/l (0.81–3.85), respectively. Anti-GAD, anti-islet antibody and anti-insulin antibody were negative. He was hospitalised for blood glucose regulation. His height was 155 cm and body weight was 55 kg. On admission, he received 15 units/day insulin glargine and 25 units/day insulin aspart. The total daily insulin requirement increased to 216 units and blood glucose was in the range of 150–300 mg/dl. Due to cirrhosis, the recommendation of pediatric metabolic disease doctors was taken, and then metformin and pioglitazone treatment were started while sodium benzoate treatment was continuing. Liver decompensation did not develop at follow-up and insulin requirement gradually decreased to 160 units/day and blood glucose decreased to 90–190 mg/dl.
Conclusion
In diabetes mellitus types with insulin resistance such as Alstrom syndrome, drugs that increase insulin sensitivity such as metformin and glitazone come into prominence. Due to cirrhosis of our case, metformin and pioglitazone treatment was started cautiously. There was a significant decrease in insulin

requirement and improvement in the brittle blood glucose profile without any side effects.

Switching from liraglutide to dulaglutide, is it worth it?: Outcomes at 24 weeks follow-up

Manuel Cayón-Blanco[1] & Carolina García-Figueras-Mateos[2]
[1]Universitary Hospital Jerez de la Frontera, Endocrinology and Nutrition, Jerez de la Frontera, Spain; [2]Universitary Hospital Jerez de la Frontera, Internal Medicine, Jerez de la Frontera, Spain

Introduction
Once-daily liraglutide and once-weekly dulaglutide, both glucagón-like peptide-1 receptor agonists, improve glycemic control and reduce weight in patients with type 2 diabetes mellitus (T2DM) with a similar efficacy according to head-to-head trial AWARD-6. Nevertheless, there is a lack of evidence in a real-world setting. The focus of our study is to assess changes in glycemic control and weight resulting from switching from liraglutide to dulaglutide in patients with T2DM from baseline to week 24 in a real-world cohort of patients.
Methods/Design
Observational and retrospective study carried out in T2DM poorly controlled patients in routine clinical practice. Variables used to assess efficacy were changes in HbA1c, fasting plasma glucose (FPG) and weight from switching to week 24. Changes in antidiabetic drugs for maintaining adequate glycemic control were also recorded. Continuous variables are presented as mean and standard deviation or as a median and interquartile range based on data distribution. Categorical variables are presented as frequencies.
Results
Data from 26 patients (55.5% women; age: 57.4±11.6 years; HbA1c: 7.1 [6.2–8.4]%; duration of T2DM: 12.6±8.7 years) were collected. Failure to achieve metabolic and/or weight targets with liraglutide was the main cause for switching. At week 24, a non-significant reduction of HbA1c (–0.33%; $P=0.09$) and a non-significant increase in weight (+2.53 Kg; $P=0.25$) were observed. FPG was significantly reduced in the whole cohort (–22.3 mg/dl; $P=0.022$) but the difference was non-significant when only patients on insulin, were analyzed. Patients on insulin also, required more insulin units for their glycemic control at week 24 (0.16 IU/kg [0.13–0.17] vs 0.53 IU/kg [0.29–0.93]; $P<0.0001$). Treatment intensification was required in 26.9% of subjects at week 24.
Conclusions
In patients with long-duration T2DM and obesity, switching from once-daily liraglutide to once-weekly dulaglutide doesn't result in beneficial effects in improvement of glycemic control or weight reduction at week 24. Our results, in a real-world setting, are consistent with a previous clinical trial, showing non-inferiority between both treatments. In our experience, there is no efficacy data to recommend switching.

The impact of new technologies on metabolic control in children with type 1 diabetes mellitus during early and middle childhood

Irina Bojoga[1,2], Simona Gabriela Duta[1], Ioana Ruxandra Calapod[1], Luminita Cima[1,2], Sorin Ioacara[1,2] & Simona Fica[1,2]
[1]'Elias' University Emergency Hospital, Bucharest, Romania, Endocrinology, Diabetes Mellitus, Nutrition and Metabolic Diseases, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania, Endocrinology and Diabetes, Bucharest, Romania

Background
Using new technologies, such as glucose sensors and insulin pumps, may help patients with type 1 diabetes mellitus achieve better glycemic control and quality of life. With the occasion of implementing the National Program for free distribution of continuous glucose monitoring systems (CGMS) starting with January 2019, children aged under 13 years were investigated in order to assess the association between previous use of CGMS and insulin pumps and the metabolic control, evaluated by glycated haemoglobin (HbA1c).

Materials and methods
In this unicentric, cross-sectional study, we evaluated the patients aged less than 13 years, who were admitted to our Department for their first distribution of a fully reimbursed CGMS between January 1st and December 21st, 2019. Patients were divided in 4 groups, according to previous use of a CGMS (CGMS+/CGMS-) or an insulin pump (PUMP+/PUMP-). The group using an insulin pump without using a glucose sensor (CGMS-/PUMP+) was not included in the further analysis because it had only 7 subjects.
Results
The study included 167 patients, 68 girls (40.7%), mean age 9.0±3.0 (range: 2.3–12.9) years, mean diabetes duration 3.8±2.6 years. The CGMS-PUMP- group had 40 subjects, mean age 8.9±2.6 years, mean diabetes duration 3.4±2.6 years, HbA1c 7.9±1.3% (63 mmol/mol). The CGMS+PUMP- had 62 subjects, mean age 9.3±3.2 years ($P=0.55$ vs CGMS-PUMP-), mean diabetes duration 3.4±2.7 years ($P=0.95$ vs CGMS-PUMP-), HbA1c 7.6±1.0% (60 mmol/mol, $P=0.18$ vs CGMS-PUMP-). The CGMS+PUMP+ group had 58 subjects, mean age 8.6±3.1 years ($P=0.6$ vs SENS-PUMP-), mean diabetes duration 4.5±2.4 years ($P=0.028$ vs CGMS-PUMP-), HbA1c 7.3±0.8% (56 mmol/mol, $P<0.01$ vs CGMS-PUMP-). The number of patients using either a CGMS or insulin pump was 127 (76% of the total number of patients)
Conclusions
Children on multiple daily insulin injections using glucose sensors had a similar metabolic control with thosewithout access to a CGMS. However, children using both insulin pump and CGMS had a significantly lower HbA1c as compared with those using none of them. We notice the remarkable high percentage of children using at least one of the technologies that we investigated. In order to achieve the best results, we recommend using the glucose sensors and insulin pumps simultaneously in children aged less than 13 years.

Long-term efficacy and safety of flash glucose monitoring system: 30-month real-life experience

Cosimo Rodia[1], Pierpaolo Falcetta[1], Alessandra Bertolotto[2], Cristina Bianchi[2], Stefano Del Prato[1] & Michele Aragona[2]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]Azienda Ospedaliero-Universitario Pisana, Diabetes and Metabolic Disease Unit, Pisa, Italy

The use of FreeStyle Libre (FSL) or Flash Glucose Monitoring (FGM) system becomes increasingly popular among people with diabetes, especially type 1 diabetes (T1DM) and several randomized and controlled study have shown how its use is associated with less and shorter hypoglycemic events without deterioration of HbA1c. Nevertheless, there are not yet consistent and lasting data reporting the impact of FGM in people with diabetes in real-life conditions. In this study we evaluated the safety, the acceptance and the efficacy of the FGM system in routine medical practice. In this 30-month prospective observational study we analyzed the glucometabolic data of 656 patients with DMT1 (85%) or insulin-treated DMT2 (15%) (M/F ratio: 1/1; average age 47±15 years; diabetes duration 20.5±13.0 years; MDI 83%; CSII 17%; BMI 26.1±5.1 kg/m^2; total daily insulin dose (TDD) 46±22 IU/day) evaluated every 6 months in our clinic from January 2017 to July 2019. There was a wide diffusion of this type of monitoring and a high percentage of satisfaction (re-prescription rate>97%). Only 3.6% of patients stopped the system and only a quarter of these because they did not consider the system reliable. There was also a rapid and significant improvement in the glycemic control (HbA1c from 7.9±1.3% to 7.6±1.0% with an average reduction of 0.3±1.1% in the first 6 months of follow-up; $P<0.0001$) and this improvement last more than 24 months). This led to a significant increase in the percentage of patients with HbA1c in target (≤7%). This increase was steadily growing throughout the follow-up period from 27.3% at baseline to 41.8% at 24 months ($P=0.005$). We also experienced a lower incidence of severe hypoglycemia and ketoacidosisthroughout the follow up period. However, we did not find any differences in BMI or TDD. The analysis of the Ambulatory Glucose Profile after 6 month showed an inverse relationship between the number of scans and HbA1c ($R=0.243$; $P=0.0032$); estimated HbA1c ($R=0.166$; $P=0.03$), average glucose ($R=0.161$; $P=0.04$) and average duration of hypoglycemia ($R=0.190$; $P=0.01$). There was

instead a direct correlation between daily scans and time in range(TIR) ($R=0.181$; $P=0.02$). Our study shows that the use of FGM is safe (does not increase the risk of severe hypoglycemia or ketoacidosis), effective (early and long-lasting reduction of HbA1c) and represents a valid alternative to self-monitoring of blood glucose.

Evaluation of the effects of phone support programme for patients with type 2 diabetes in treatment with insulin glargine 300 u/ml (T-coah)

Almudena Lara-Barea, Isabel Mateo-Gavira, Esteban Sánchez-Toscano, Daniel Medina-Rivero & Manuel Aguilar-Diosdado
Puerta del Mar University Hospital, Endocrinology and Nutrition, Cádiz, Spain

Introduction
T-Coach program is a phone support platform for patients with type 2 diabetes (T2D) treated with insulin glargine 300 U/ml in order to adjust basal insulin dose, reinforce diabetes education and encourage patients to get their goals through regular phone calls. The aim of the study was to evaluate T-Coach program effectiveness in metabolic control and level of satisfaction in patients with T2D.
Methods
We conducted a retrospective, descriptive and observational study that includes patients with T2D enrolled in T-Coach program from October 2016 to October 2019, attending the Endocrinology Unit of Puerta del Mar University Hospital (Cádiz). We analyzed demographic and clinical characteristics, biochemical parameters (fasting glycemia, HbA1c), insulin dose and number of concomitant drugs before, at 3 months and at 6 months after program inclusion. Patient's satisfaction with use of the platform was evaluated.
Results
105 patients were included in T-Coach program. The mean age was 66.96±11.27 years old, with a mean time of evolution of T2D about 13.99±8.17 years. We verified that 56.9% of patients ($n=61$) had microangiopathic complications and 18.6% ($n=22$) had macrovascular complications. Basal insulin dose was 31.01±18.02 U/day and 35.06±20.75 U/day at 6 months. Mean fasting blood glucose levels dropped from 205.19±75.24 mg/dl to 117.1±53.50 mg/dl at 6 months ($P<0.001$). Mean baseline HbA1c was 9.27±1.75% and at 6 months 7.26±1.39% ($P<0.001$). The degree of patient satisfaction was high, with scores above 9/10 on most items evaluated.
Conclusions
In our region, T-Coach program is an effective way to help patients with T2D to reach their optimal insulin glargine U300 dose and improves glycemic control. Majority of patients expressed high satisfaction with the support programme.

Inappropriately elevated serum C-peptide after dosing may interfere with PK and/or PD measurements of study insulin in a euglycemic clamp

Hui Liu, Hongling Yu, Lisi Sun, Jingtao Qiao, Jiaqi Li, Huiwen Tan & Yerong Yu
West China Hospital of Sichuan University, Endocrinology & metabolism, Chengdu, China

Objective
To examine the relationship between C-peptide levels and endogenous insulin secretion and to understand the effects of elevated C-peptide after dosing on evaluating study insulin and its analogs' PK/PD values in euglycemic clamps.
Method
The study included 33 healthy male volunteers who underwent an 8-h euglycemic clamp with a subcutaneous injection of insulin aspart (0.2 U/kg). Blood glucose (BG), C-peptide, human insulin, and insulin aspart (IAsp) levels were tested at pre-defined time. They were divided into two groups according to C-peptide levels postdosing. Group A: at least one of C-peptide concentrations postdosing was higher than the baseline; group B: C-peptide concentrations postdosing were all below the baseline. The baseline of serum C-peptide was defined as the mean value of –30 min and 0 min predosing. The time profiles of BG, human insulin and C-peptide were recorded, the relationship between human insulin and C-peptide was examined and the factors affect C-peptide were analyzed. IAsp's PK/PD values were collected.
Results
There were 22 in group A and 11 in group B. Baseline BG and CVBG were comparable. The 'clamped' BG was 99.7%±7.1% (group A) and 94.9%±5.1% (group B) of baseline respectively. IAsp's PK values were consistent in two groups while $AUC_{GIR,0-8h}$ was higher in group A than B (1815±551 mg/kg vs 1327±306 mg/kg, $P=0.01$). The C-peptide (308 pmol/l vs 299 pmol/l, $P=0.75$) and human insulin (24.0±7.4 pmol/l vs 29.5±10.2 pmol/l, $P=0.09$) were of no significant difference at baseline but group B had a much lower C-peptide (168 pmol/l vs 309 pmol/l, $P<0.01$) and human insulin (17.3 pmol/l vs 26.0 pmol/l, $P<0.01$) postdosing. The method using C-peptide to predict endogenous insulin secretion had a sensitivity of 85.19% (138/162) and a specificity of 79.20% (316/399). CVBG and the extent of postdosing C-peptide higher than baseline were positively correlated ($r=0.51$, $P=0.01$). The AUC of human insulin higher than baseline decreased with AUC of clamped BG higher than target declining.
Conclusion
Inappropriate elevated serum C-peptide concentrations after exogenous insulin administration indicate insufficient inhibition of endogenous insulin secretion. The BG levels during euglycemic clamp are preferably controlled below the baseline level to sufficiently inhibit endogenous insulin secretion of the subject. The estimated insulin PK values obtained from C-peptide correction method may not be very accurate if postdosing C-peptide level is higher than the baseline.

Metabolic effects of semaglutide after the first months of treatment: A new GLP-1-RA revolution?

Sara Jiménez, Begoña Pla, Ana M Ramos-Leví, Raffaele Carraro, Marcos Lahera, Iñigo Hernando, J Alfonso Arranz & Mónica Marazuela
Hospital Universitario de La Princesa, Division of Endocrinology and Nutrition, Madrid, Spain

Background
Semaglutide is a glucagon-like peptide-1 receptor agonist (GLP-1-RA) whose role as a second-line treatment for patients with type 2 diabetes (T2D) has significantly increased. It has demonstrated cardiovascular safety and superiority in terms of glycaemic control and weight loss, compared to other GLP-1-RAs. The most common side effects are mild gastrointestinal, but it may also cause renal failure secondary to dehydration and an increased risk of diabetic retinopathy (DR) complications may be observed in patients with pre-existing DR.
Objectives
To evaluate the effects of short-term treatment with semaglutide, including changes in weight, blood pressure, fasting glucose, HbA1c, LDL-cholesterol, triglycerides and renal function; its safety regarding side effects; and the potential role of semaglutide in the overall improvement of patients with T2D.
Methods
A follow-up study of 38 patients with T2D and obesity (body mass index-BMI>30 Kg/m^2) who started treatment with once-weekly injectable semaglutide in our centre. Data were obtained from the medical records and analysed with SPSS v25.
Results
The mean age of patients was 59.89±9.96 years; 50% were women. Mean T2D disease duration was 14.23±12.39 years, mean HbA1c was 8.27±1.61%, mean BMI was 38±5.7 kg/m^2 and 36.8% of patients had been on a previous GLP-1-RA. Significant improvement were observed at the first follow-up visit after starting semaglutide (79.74±41.3 days) in weight (104.77 vs 108.38 kg; $P<0.001$), BMI (36.7 vs 38.03 kg/m^2; $P<0.001$), fasting glucose (139.13 vs 171.76 mg/dl; $P=0.023$) and HbA1c (7.54 vs 8.27%; $P=0.002$). The potential benefit was higher with optimal/increased doses of semaglutide. A non-significant improvement in LDL-cholesterol and triglycerides was noted. Patients previously treated with another GLP-1-RA experienced no significant changes. However, in patients previously treated with oral antidiabetic drugs (OAD) there were significant improvements in weight (–4.2 kg, $P<0.001$) and HbA1c (–2.95%, $P=0.003$). Regarding therapeutic optimization, we observed a reduction in the required dose of basal insulin (42 vs 46 units; $P=0.05$) in prior insulin users. Adverse events were mild in severity, occurred mainly during the first days/weeks (88.89%), and only two cases required treatment discontinuation.

Conclusions
Semaglutide resulted in significant reductions in HbA1c, fasting blood glucose and body weight during short-term treatment. In addition, adverse events were uncommon. Long-term treatment studies in larger sample populations are required for a better evaluation of this new GLP-1-RA.

The icone study': Multicenter evaluation of the impact of contour next one and contour diabetes app on self-management and adherence in insulin-treated patients with diabetes type 1 or 2

Diego Fernandez-Garcia[1], Eva Aguilera Hurtado[2], Alfonso Arranz Martin[3], Beatriz Gonzalez Aguilera[4], Blanca Gonzalez Jauregui[5], Edelmiro Luis Menendez Torre[6], Rebeca Reyes Garcia[7], Alfonso Soto Gonzalez[8], Cristina Tejera Perez[9], Beatriz Fernandez-Tresguerres[10] & Thorsten Petruschke[10]
[1]Xanit Hospital, Benalmádena, Spain; [2]Hospital Germans Trias i Pujol, Badalona, Spain; [3]Hospital de La Princesa, Madrid, Spain; [4]hospital universitario virgen macarena, Sevilla, Spain; [5]Hospital Universitario Cruces, Barakaldo, Spain; [6]Central University Hospital of Asturias, Oviedo, Spain; [7]Torrecárdenas Hospital, Almería, Spain; [8]Hospital Universitario A Coruña, A Coruña, Spain; [9]Hospital Arquitecto Marcide, Ferrol, Spain; [10]Ascensia Diabetes Care Deutschland GmbH, Leverkusen, Germany

Objectives
The primary objective was to determine if the use of Contour Next One (CNO) with Contour Diabetes app (APP) was associated with improved self-management using the Summary of Diabetes Self-Care Activities questionnaire (SDSCA). A secondary objective was to establish if CNO and APP together had impact on adherence to self-monitoring blood glucose (BG), indicated by frequency of BG readings and hypoglycemic events. Other secondary objectives were to observe a possible change in HbA1c, patient empowerment and quality of life. Besides satisfaction with the CNO and APP was assessed.
Material and methods
prospective, observational-study in nine clinical practices in Spain. 87 Multiple dose Insulin-treated patients with either type 1 or 2 diabetes mellitus were enrolled. Patients used already the CNO but had not included the APP yet. Patients had a recent HbA1c test and previous 3 month glucose data. Each patient had two on site visits at 0 days (visit 1) and 90 days (visit 2).
Results
84 patients were eligible for the analysis (88.1% type 1; 11.9% type 2). Statistical significant differences were observed in the SDSCA scores for General diet and Specific diet questions with an increase of 1 day of median between visits. Besides a significant increase was observed in the total number of BG readingsbetween visits [median 259.1 vs 276.1] and in the number of readings per day [median 2.9 vs 3.1]. Furthermore, the % of BG values in range was significantly increased in visit 2 [median 51.0% vs 54.0%] and the average of BG values decreased [median 169.0 vs 161.5 mg/dl]. Consequently a significant decrease in the HbA1c value was observed between visits [mean 7.6% vs 7.38%]. On the other hand, there were no significant differences in the % of hypo/hyperglycemic episodes although a trend was observed in visit 2 toward a decrease in episodes >250 mg/dl. No significant differences were found in the questionnaires related to Quality of life and empowerment. The overall satisfaction of patients and Health Care Practitioners with CNO and the APP scored high.
Conclusion
The effects of the joint use of CNO and the APP are already observed after a relative short period in multiple dose insulin-treated patients with diabetes type 1 or 2. The CNO with the APP helped the patients to have a better glycemic control by means of improving their adherence to self-monitoring and diet self-management, all without reducing their quality of life or empowerment.

Experience of using insulin therapy with the closed loop method among patients with type 1 diabetes mellitus in Russia

Anna R Volkova, Maria Chernaya & Ksenia A Vlasova
Pavlov University, Endocrinology, Saint-Petersburg, Russian Federation

The aim
To evaluate the efficiency and safety of using closed loop systems in patients with type 1 DM living in Russia.
Results
88 respondents (or those legal representatives) with type 1 DM in insulin therapy by closed loop systems, members of Russian-speaking community, were included to the study. 90% of respondents living in Russia. All respondents using do-it-yourself artificial pancreas systems (DIYAPS): Loop (19.3%), Open APS (30.7%) and Android APS (50%). Hlycated haemoglobin was normal in 90% of cases of using DIYAPS. 89% of respondents notice improvement of glycemic control. Among the advantages of closed loop therapy, respondents noted an increase time-in-range (78% of respondents), a decrease in the frequency of mild hypoglycemia (61% of respondents), a decrease in the frequency of severe hypoglycemia (59% of respondents), and improved glycemic control at night (86% of respondents) .
Conclusions
The use of pump insulin therapy using closed loop systems leads to a decrease in the level of glycated hemoglobin by 0.5% ($P=0.01$) compared with the use of standard pump insulin therapy. The majority (78%) of type 1 DM respondents receiving closed-loop pump insulin therapy noted an increase in the time-in-range compared to standard pump insulin therapy. The use of closed-loop systems is associated with a decrease in the frequency ofmild (in 61% of respondents) and severe hypoglycemic conditions (in 59% of respondents) compared to standard pump insulin therapy in respondents with type 1 DM.

Use of statins and cognitive performance in elderly type 2 diabetic patients

Valentina Fagotto, GianLuca Colussi, Andrea Da Porto, Alessandro Cavarape & Leonardo Alberto Sechi
Clinica Medica, Department of Medicine, University of Udine, Udine, Italy

Background
Type 2 diabetes (T2D) is known as risk factor for mild cognitive impairment (MCI), which can lead to confirmed dementia. T2D patients often take statins for cardiovascular prevention but, nowadays, it is not clear if these drugs could also prevent cognitive impairment.
Objective
We aimed to evaluate the association between statins in primary or secondary cardiovascular prevention and cognitive performance in old T2D patients referring to our Internal Medicine offices.
Material and method
We enrolled 40 consecutive, over 60 years, T2D patients (average of 75±6 years), nine females and 31 males, all affected by essential hypertension.
Patients affected by major adverse cardiovascular events or confirmed dementia were excluded. We registered anthropometric data (BMI 27.1 kg/m^2) and evaluated major cardiovascular risk factors as pulse blood pressure (PBP) and all patients underwent *Montreal Cognitive Assessment* (MoCA), a MCI screening test and *Frontal Assessment Battery* (FAB) for the screening of executive functions impairment. Both tests were corrected for school grade and FAB also for age.
Results and conclusion
21 patients taking statins got higher MoCA and FAB scores (respectively +17%, $P=0.015$ and +15%, $P=0.048$), higher pulse PBP (73±17 vs 64±11 mmHg, $P=0.046$), and lower LDL levels (59±29 vs 85±34 mg/dl, $P=0.036$) if compared with patients not taking these drugs. MoCA score was directly correlated to age ($r=0.329$, $P=0.038$), while considering FAB no other significative correlation was found. Even considering potential confounders as age, sex, BMI, DBP and HbA1c, taking statins still remains associated to MoCA scores ($\beta=0.466$, $P=0.002$). To sum up, elderly T2D patients taking statins have a better cognitive performance compared with patients with same age and disease profile not taking this pharmacological class. Future treatment trials could explore the role of preventive therapy with statins in cognitive impairment development.

Clinical and metabolic benefits of sodium-glucose cotransporter 2 inhibitors (SGLT2i) therapy in diabetic patients with psychiatric comorbidities

María Concepción Terroba-Larumbe[1], Cristina Crespo-Soto[1], Jose Maria Palacio-Mures[1], Manuel Gonzalez-Sagrado[2], Rosa Conde-Vicente[2], Marta Ventosa-Viña[1], Silvia Peña-Lozano[1], Ainara Portela-Martin[1], Marta Fernandez-Nuñez[3], Mar Calleja-Barnada[1] & Luis Cuellar-Olmedo[1]
[1]Hospital Rio Hortega, Endocrinologia y Nutricion, Valladolid, Spain; [2]Hospital Rio Hortega, Unidad de apoyo a investigacion, Valladolid, Spain; [3]Hospital Rio Hortega, Oftalmologia, Valladolid, Spain

Introduction
Sodium-glucose cotransporter 2 inhibitors (SGLT2i) therapyhas proven effective in type 2 diabetes but there is little data on its effect in patients with psychiatric comorbidity, who usually present worse metabolic and clinical control. The aim of this study was to evaluate if there are differences in the effect of this therapy in relation to the presence of these pathologies.
Methods
225 patients included in a therapy protocol with SGLT2i, 54.9% men, mean age 63.7±10.0, time of evolution of diabetes 11.1±9.0 years, were evaluated analyzing the changes in clinical and biochemical parameters at baseline and after one year of therapy with SGLT2i. The analysis was performed in the global and separating in two groups according to the presence of psychiatric comorbidity. Quantitative variables are expressed by mean (standard deviations). Qualitative variables are expressed by frequencies and percentages. Paired samples T-test are used in the statistical analysis. We consider significant $P<0.05$.
Results
24.4% of patients presented psychiatric comorbidities, and the most frequent diagnoses were anxiety (34.5%), depression (32.7%) and anxiety-depressive syndrome (16.4%). Baseline data and after follow-up expressed as means (s.d.) and means difference (s.d.) (95% CI): weight (kg) 91.2±19.7 vs 87.9±19.1; 3.4±5.1 (2.6 to 4.2) ($P<0.001$), body mass index (kg/m^2) 34.5±6.2 vs 33.3±6.1; 1.2±2.1 (0.9 to 1.6) ($P<0.001$), glycated hemoglobin (%) 8.2±1.2 vs 7.4±1.1; 0.7±1.2 (0.5 to 0.9) ($P<0.001$), glucose (mg/dl) 169.6±69.3 vs 143.5±46.3; 26.2±73.5 (14.7 to 37.6) ($P<0.001$), systolic blood pressure (mmHg) 149.9±17.8 vs 144.0±18.8; 5.9±20.2 (2.5 to 9.3) ($P=0.001$), diastolic blood pressure (mmHg) 84.0±11.3 vs 82.0±10.7; 2.0±10.2 (0.3 to 3.7) ($P=0.024$), high-density-lipoprotein cholesterol (mg/dl) 45.3±11.9 vs 48.8±13.7; 3.5±11.4 (5.3 to 1.6) ($P<0.001$), triglycerides (mg/dl) 189.0±102.5 vs 160.7±77.8; 28.4±94.0 (13.6 to 43.1) ($P<0.001$), glomerular filtration rate (ml/min/1.73 m^2) 82.6±34.0 vs 88.2±24.5; 5.6±26.8 (9.9 to 1.3) ($P=0.01$). There were no significant changes in total cholesterol, low-density-lipoprotein cholesterol and albuminuria. In the separate analysis we found no significant differences regarding the benefit in patients who had psychiatric comorbidity.
Conclusions
Psychiatric comorbidity in diabetic patients is associated with worse results of some pharmacological treatments, probably due to a loweradherence to changes in lifestyle. In our study, SGLT2i therapyoffers the same advantages in terms of metabolic and clinical control in this group of patients

Immune checkpoint inhibitors (ICIs) and 'Fulminant Diabetes': Two emblematic cases

Daniele Sgro'[1], Rosa Giannarelli[2], Michele Aragona[2], Nicola Viola[1], Giada Cosentino[1], Alessandro Brancatella[1], Francesco Latrofa[1], Stefano Del Prato[2], Ferruccio Santini[1], Claudio Marcocci[1] & Isabella Lupi[1]
[1]Department of Clinical and Experimental Medicine, Endocrinology Units, University of Pisa and University Hospital of Pisa, Pisa, Italy; [2]Department of Clinical & Experimental Medicine, Section of Diabetes, University of Pisa, Nuovo Ospedale Santa Chiara, Via Paradisa, 2, 56124, Pisa, Italy

Context
Programmed cell death protein 1/programmed cell death protein ligand 1 (PD-1/PD-L1) are key regulators in T-cell activation and tolerance. Nivolumab (PD-1 inhibitor) and Atezolizumab (PD-L1 inhibitor) are monoclonal antibodies approved for the treatment of several types of advanced cancers. Immune checkpoint inhibition caused by these drugs can result in immune-related adverse events (irAEs) New-onset diabetes mellitus has been reported in fewer than 1% of patients and is a rare but life-threatening irAE, which is often characterized by rapid-onset hyperglycemia and ketoacidosis, with low levels of endogenous insulin secretion. Here we report two cases of new-onset diabetes associated with anti-PD-1 and anti-PD-L1 therapy that showed a rapid fall into insulin-dependence.
Case 1
A 60-year-old man received Atezolizumab for metastatic lung adenocarcinoma. After two doses, he developed hyperglycemia, requiring basal-bolus insulin therapy. After the fourth dose, the patient was admitted to our Departement because of severe weakness, nausea, abdominal pain, and dizziness. Laboratory tests revealed severe hyperglycemia with ketoacidosis, low levels of c-peptide, hyperkalemia, and hyponatremia. Islettyrosine phosphatase 2(IA2) antibodies and anti-glutamic acid decarboxylase (GAD) antibodies were undetectable. Further investigations revealed the DRB1*04 and DQB1*03 haplotypes, which are usually associated with increased susceptibility to T1DM. After resolution of ketoacidosis, due to persistence of mild hyponatremia and hyperkalemia, an adrenal dysfunction was suspected. The evaluation of HPA-axis revealed the presence of a Primary adrenal insufficiency with 21OH –hydroxylase antibodies positivity
Case 2
A 43-year-old woman, affected by a malignant skin melanoma, was treated with nivolumab. After the second cycle, she was diagnosed with transient thyrotoxicosis followed by autoimmune hypothyroidism, requiring replacement therapy with levothyroxine. After the sixth cycle, severe ketoacidosis arose, which required insulin therapy. Antibodies against pancreatic beta cells antibodies were negative. HLA typing revealed DQB1*02; DQB1 *0602; DQA1 *0102 haplotypes that are not usually associated with increased susceptibility to T1DM.
Conclusion
ICIs related 'fulminant diabetes' is a rare but potentially life-threatening irAE that manifests with severe ketoacidosis and needs to be diagnosed timely and managed properly. After the first manifestation of ICIs-related diabetes, the beta-cell function is usually permanently impaired, resulting in a long-term need for insulin injection.
Moreover, fulminant diabetes can manifest in the context of an autoimmune polyglandular syndrome, as described in our 2 cases. The coexistence of ketoacidosis and adrenal crisis, although rare, represents an extremely severe combination of iRAEs.

Vitamin B12 levels and its association with glycaemic control and pregnancy outcomes in women with gestational diabetes

Dimitra Pappa[1], Parthena Navrozidou[2], Eleftheria Barmpa[1], Irontianta Gkorezi Ntabela[2], Alexander Daponte[2] & Alexandra Bargiota[1]
[1]University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece; [2]University Hospital of Larissa, Department of Obstetrics and Gynaecology, Larissa, Greece

Introduction
Data on Vitamin B12 deficiency and its relationship with Gestational Diabetes Mellitus (GDM) andpregnancy outcomes are limited. The aim of the present study is to determine, in pregnant women with GDM, the association between Vitamin B12 levels and glycemic control, as well as with pregnancy outcomes.
Methods
We studied 44 women with GDM, mean age 31.9±5.8 years old, at the second trimester and at labor and measured weight, height, body mass index (BMI), HbA1c, Vitamin B12 (B12) and folic acid (FA) levels, as well asthe gestational age at delivery (GAd), childbirth type and offspring birthweight (of BW).
Results
Baseline mean gestational age was 26.3±7.3 weeks, mean mother weigh, BMI and HbA1c were 80.17±17.07 kg, 29.89±6.11 kg/m^2 and 5.1±0.3% respectively. Mean B12 and FAlevels were 241.80±122.04 pg/ml and 13.67±6.58 ng/ml respectively. 28 out of 44 women had normal B12 (63.63%, NB12), 16 out of 44 had B12 deficiency (LB12) (36.36%, B12<150 pg/ml) and 13 of the LB12 had adequate FA levels. There was no relationship between B12 levels and HbA1c ($r=-0.025$, $P=0.874$), and B12 levels and BMI ($r=-0.128$, $P=0.419$). NB12 women gave birth to 15 females and 13 males, 16 (57.14%) by caesarean section, mean GAd was 38.18±0.94 weeks and mean of BW was 3220±380 gr. LB12 women gave birth to 11 females and six males (one twin pregnancy), 7 (43.75%) by caesarean section, mean GAd was 37.93±2.43 weeks and mean of BW was 3059.38±658.35 gr. In both LB12 and NB12 there was no relationship between B12 and GAd ($r=0.185$, $P=0.493$ and r=–0.141, $P=0.473$

respectively), between B12 and of BW (r=0.232, P=0.387 and r=–0.112, P=0.569 respectively) and B12 and child birth type.
Conclusion
A significant percentage of pregnant women with GDM had B12 deficiency. B12 deficiency, does not seem to have any associationwith either the glycemic control and the body mass index of the pregnant women, or with gestational outcomes. More studies with a larger number of participants are needed to confirm these findings.

Study on lipid compositions of the skeletal and liver tissues in animals with the induced alimentary obesity and insulin resistance

Sanobarkhon Irgasheva, Tokhir Ishanhodjaev, Elvira Ibragimova & Talat Saatov
Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Biochemistry, Tashkent, Uzbekistan

Obesity is thought to be a main risk factor of insulin resistance and diabetes mellitus. Study on concentrations of lipids in the tissues of animals with experimental model of obesity resulting in insulin resistance remains currently central. The work was initiated to study the spectrum of lipids and their concentrations in the tissues of experimental animals with the induced alimentary obesity.
Alimentary obesity with concurrent insulin resistance was induced in the outbred rats by means of a 6-month high-calorie carbohydrate diet. The thin-layer chromatography was used to determine the spectrum of lipids (Kates, 1975); neutral lipids were measured spectrophotometrically (Prokhorova, 1982), while phospholipids were measured by phosphorus (Vaskovsky *et al.*, 1975).
The model of obesity and insulin resistance induced, body mass and body fat mass of rats was found to increase by 62% and 6.2%, respectively. The blood glucose and cholesterol were found to increase, but insulin sensitivity of some tissues declined. As to lipid composition in the skeletal muscle of animals with alimentary obesity, lysophosphatidylcholine (LPC), phosphatidylethanolamine (PE) and cardiolipin were found toincrease by 18%, 17% and 10%, respectively, whilesphingomyelin (SPH), phosphatidylcholine (PC), phosphatidylinositol (PI) and phosphatidylserine (PS) reduced by 41%, 24%, 17% and 39%, respectively; total phospholipids were found to decrease by 16%. In the liver tissues of rats with alimentary obesity, lysophosphatidylcholine (LPC), cardiolipin and phosphatidic acid (PA) were observed to reduce by 280%, 7% and 29%, respectively, while LPC, PC, PI and PS were found to decrease by 31%, 24, 3% and 5%, respectively. The increase in LPC and PA in the tissues under study could be the evidence for activation of phospholipases taking place in alimentary obesity. The neutral lipids, such as cholesterol, non-esterified fatty acids and total lipids were established to increase by 33%, 60% and 22%, respectively, in the skeletal muscle, and by 23%, 49% and 17% in the liver tissues, respectively
Our findings demonstrated that in the alimentary obesity model with the increased blood glucose and cholesterol there are changes in lipid composition of the insulin sensitive tissues. The changes are likely to produce an effect on the receptor sites of insulin in the tissues under study and cause the onset of insulin resistance.

Centre-Université de Paris, Hôpital Universitaire Necker enfants malades, Service d'Endocrinologie, gynécologie et diabétologie pédiatrique, Paris, France

Context
The transition period between pediatric and adult medicine is associated with poor patient outcomes and an important number of patients lost to follow up. Intervention exist but the few published randomized trials do not allow to study long-term patient outcomes nor intervention sustainability in time. Objective. Describe the cohort of patients in adult care who benefit from a new transition program based on case management approach, its activity and follow-up outcomes.
Methods
A longitudinal study was led since September 2016 in adult services of endocrinology, nutrition and diabetology of a French University Hospital. Patients with any endocrine disease diagnosed during childhood and transferred to adult care were included. The care pathway for these patients was built in three steps. Step 1 is dedicated in liaising with pediatric services and patient to facilitate its first visit in adult care. Step 2 defines the care pathway in adult service based on the needs assessment realized by the coordinator upon the patient's arrival in adult service. Step 3 focuses in liaising with structures outside hospital (GP, educational and social sector). Thorough the follow-up, the coordinator is identified as the key contact by the patients. Attendance to medical appointments, clinical, and social data are collected throughout patient follow-up.
Results
Since 3 years, 500 patients benefited from the case management mainly for their obesity (n=91, 18%), type 1 diabetes (n=54, 11%), malignant brain tumor (n=68, 14%) or congenital hypopituitarism (n=42, 8%). They were aged 19 in median at transfer in adult care, sex ratio : 0,5. A large majority live in the parental home (409, 82%), 169 (34%) are university students, 130 (26%) are in high school, 90 (18%) are in medico-social institution. Patients who required most of support from the coordinator usually combine one (or more) somatic disease and either a neuro-cognitive disorder or a psychiatric disorder, they all have social difficulties. In patients with more than 3 months of follow-up (median : 18 months), 22/418 (5%) are out of follow-up. Concerning the patients for whom the follow-up is 36 months or more, the percentage of out of follow-up is the same: 5%.
Conclusions
The case manager addresses the complex needs of diverse patients. With time, the cohort will provide unprecedented long-term results of patients with various conditions who went through transition.

The complexity of associations between type 2 diabetes mellitus and comorbidities in multimorbid population in Lithuania

Kristina Švaikevičienė[1,2], Roma Puronaitė[1,2], Žydrūnė Visockienė[1,2] & Vytautas Kasiulevičius[1,2]
[1]Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania; [2]Vilnius University Faculty of Medicine, Vilnius, Lithuania

Introduction
Diabetes is one of the most common chronic diseases in multimorbid population and one of the most frequently detected conditions in multimorbid disease clusters. Approximately 40% of diabetic patients have three or more coexisting chronic conditions.
Aim
To assess the frequency (percentage) of chronic conditions co-occurring with diabetes in multimorbid Lithuanian population.
Methods
Database fromthe Lithuanian National Health Insurance Fund under the Ministry of Health covering the period from 2012 till 2014was used. We exploited a reduced chronic diseases list with the diagnostic codes of ICD-10-AM (I11; I20; I25; I50; I48; E11; E06.3; E89; J44; J45; M05; M15-M19; M80; M81; M54; G54; G55). A series of heat maps for co-occurrence of 17 (diabetes included) chronic conditions were developed. Heat maps were stratified by age and gender to displaythe frequencies of chronic conditions

dyads. Chronic conditions were included into the heat maps if the frequency of co-occurrence with type 2 diabetes mellitus (E11) was 10% and more.
Results
Data of 103367 patients with diabetes (63.0% female) were analyzed. Hypertensive heart disease (I11) and angina pectoris (I20) were the most common chronic conditions associated with E11 for both genders in all age groups. I11 varied from 61.4% to 77.3% and from 84.5% to 91.1% with the highest frequency of 77.3% in the 60–69 years age group and 91.1% in the same age group in female and male respectively. Meanwhile I20 varied from 13.4% to 38.1% and from 21.7% to 50% with the highest frequency of 38.1% in the 70–75 years age group and 50% in the same age group in female and male respectively. Atrial fibrillation and flutter (I48) co-occurred with E11 earlier in male (50–59 years age group) than in female (70–75 years age group). Chronic obstructive pulmonary disease co-occurred with E11 only in male group and ranged 13.1% in the 70–75 years age group.9 chronic conditions were associated with E11 only in male, age groups of 50–59 and 70–75 years.
Conclusions
The most commonly associated conditions with diabetes were hypertensive heart disease and angina pectoris. There were differences in gender: chronic obstructive pulmonary disease was associated with diabetes only in male and atrial fibrillation and flutter co-occurred with diabetes earlier in male than in female. The number and frequencies of associations increased with age in both gender groups.

Lipoprotein (a) in patient with type 2 diabetes mellitus and healthy subjects

Chaicharn Deerochanawong[1,2,2], Rungtip Dansirikul[1] & Pattraporn Konthong[1]
[1]Rajavithi hospital, Rangsit medical school, Department of Medicine, Bangkok, Thailand; [2]Rajavithi Hospital, College of Medicine, Rangsit University, Department of Medicine

Backgroud
Increased lipoprotein (a) {Lp(a)} concentrations are associated with cardiovascular disease. Whether type 2 diabetes increase the level of Lp(a) still controversial. We studied the level of Lp(a) in health and type 2 diabetes Thai subjects and studied the relationship between Lp(a) and metabolic factors in both groups
Methods
The study included 180 normal glucose tolerance healthy subjects that have age and sex matched with 180 type 2 diabetes patients. All participants were fasting for 10–12 hours at night and have blood samples for Lp(a), total cholesterol, triglyceride, HDL-C, LDL-C, BUN, Cr, FBS, HbA1c. Lp(a) was measured by rate nephelometry methods with the immunochemistry systems. The coefficient of variance of Lp(a) were 3.4 and 6.4% for intra and interassay variability, respectively.
Results
The mean age of diabetic subjects was 60.8±11.5 years and 55% was male that were not statistically different from the healthy control. All subjects had blood creatinine level less than 2 mg/dl. Mean HbA1c of diabetes subjects was 7.5±0.9%. The mean Lp(a) level was 23.6 mg/dl in control and 22.8 mg/dl in diabetes subjects that is no statistically different (NS). The median Lp(a) was 16.3 and 14.0 in control and diabetes subjects respectively (NS). The percentage of subjects who had Lp(a) more than 30 mg/dl was 26.1% and 25.0% in control and diabetes subjects respectively (NS). The total cholesterol and LDL-C level are no statistically different between control and type 2 diabetes subjects. The diabetes subjects had higher triglyceride level than control (156.6±69.1 vs 126.8±39.7 mg/dl) and lower HDL-C level than control (42.8±12.4 vs 52±12.8 mg/dl). The correlation between log Lp(a) and other factors include age, sex, lipid profile, fasting plasma glucose, HbA1c and creatinine was studied by spearman rank in both diabetic and control subjects. There was significant negative correlation with serum triglyceride in both diabetes and normal subjects and there was only significant positive correlation with HDL-C cholesterol in healthy subjects. The other factors were not significant correlated with log Lp(a).
Conclusions
Lp(a) level in type 2 diabetes were not different from healthy subjects. Lp(a) in both type 2 diabetes and healthy subjects had negative correlation with serum triglyceride level.

Correlation between BMI and cognitive performance in type 2 diabetic patients

Valentina Fagotto, GianLuca Colussi, Andrea Da Porto, Alessandro Cavarape & Leonardo Alberto Sechi
Clinica Medica, Department of Medicine, University of Udine, Udine, Italy

Background
The association between diabetes (DM) and cognitive impairment is already well established. DM affects multiple superior domains, *in primis* working memory and executive functions and damages nervous system in both morphological and functional ways. The *Montreal Cognitive Assessment*(MoCA) is a neuropsychological test defined as the best tool evaluating mild cognitive impairment (MCI) in DM.
Objective
Our study aimed to investigate a correlation between anthropometric variables and *MoCA*scores in an adult cohort of type 2 diabetic patients referring to our Internal Medicine offices between November 2018 and April 2019.
Material and methods
We excluded subjects affected by diagnosed dementia, brain trauma or injuries, major adverse cardiovascular events during the previous 6 months or portal-systemic encephalopathy. We recruited 40 *over* 60 (75±6.06 years) patients and collected their anthropometric, clinical and laboratory data and then they underwent *MoCA* testing, which score was corrected by school grade. In order to exclude *MCI*, minimum score was of 26.
Results
Participants had a *MoCA* average score of 21.6 (±4.7) over 30. Recall memory resulted the most affected cognitive domain (average 32%), while space-time orientation the least (average 96.7%). Although our cohort was limited by number, a significative statistic correlation between BMI and *MoCA* score emerged (r 0.329). We registered a progressive neuropsychological score increase with increasing BMI considering our population divided in tertiles by MoCA results, which was biologically significative according to the well-known *obesity paradox*. This correlation was confirmed even after correction for sex, age and years of diabetic disease.

AEP340

Prevalence and prognosis impact of diabetes in cirrhotic patients

Bradai Samir, Imen Akkari, Mrabet Soumaya & Ben Jazia Elhem
CHU Farhat Hached, gastroenterology, Sousse, Tunisia

Introduction
The prevalence of diabetes increases during cirrhosis resulting from a significant alteration in carbohydrate metabolism modifying the management of diabetes and worsening the liver prognosis. The aim of this work is to determine the prevalence of diabetes during cirrhosis, and to assess its prognostic impact on the disease.
Material and method
this is a study collecting all cirrhotics followed in the gastroenterology department over a period of 4 years. We divided the patients into 2 groups: G1: diabetic patients and G2: non-diabetic patients.
Results
A total of 71 patients with a mean age of 62 years (25–83 years), were collected. Viral origin was the most common cause (40.8%). The prevalence of diabetes was estimated at 45.07% (n=32). The factors associated with diabetes were: advanced age (age> 60, P=0.04), presence of another criterion of metabolic syndrome (P=0.001), viral etiology C (P=0.045) and a disease classified Child–Pugh B (P=0.04). Stage C was more frequent in group 1 patients with no significant difference (31.25% vs 28.2%, P=0.4). There was no significant difference between the 2 groups regarding gender. In addition, there was no difference between the 2 groups concerning the risk of occurrence of complications of cirrhosis (oedemato-ascitic decompensation, refractory ascites, digestive hemorrhage due to varicose vein rupture, ascites fluid infection and hepatic encephalopathy) apart from hepatocellular carcinoma which was more frequent in group 1 without significant difference (29.03% vs 15.38%, P=0.1).
Conclusion
The prevalence of diabetes during cirrhosis is quite high. This requires special attention for therapeutic management and constitutes a negative prognostic factor aggravating the state of the liver.

Anti-Lipogenic effects of cabergoline: A molecular study on white adipocytes

Mariarosaria Negri, Claudia Pivonello, Feliciana Amatrudo, Annalisa Gentile, Tatiana Montò, Roberta Patalano, Chiara Simeoli, Rosario Ferrigno, Renata Simona Auriemma, Annamaria Colao & Rosario Pivonello
Federico II University, Clinical Medicine and Surgery, Naples, Italy

Obesity is caused by an imbalance between dietary energy intake and expenditure. The expression of dopamine receptors (DRs) in human adipocytes has been already demonstrated. Moreover, the effects of cabergoline, a dopamine agonist, on body weight and glucose homeostasis in obese subjects without hyperprolactinemia has already been reported. The current study investigates the effects of cabergoline on lipid accumulation and on adipogenic factors expression to better define the pivotal role of dopaminergic system in obesity etiology. To this purpose, 3T3-L1 cells, the most-well established mouse model for adipogenesis in *in vitro* studies, were used. Proliferating 3T3L1 cells were suitably differentiated in mature adipocytes and mRNA levels of DRs were monitored during the differentiation process by RT-qPCR. Moreover, effect of escalating doses of cabergoline (10^{-8} M and 10^{-6} M) alone or combined with 2×10^{-8} M insulin, on lipid accumulation were investigated through Oil Red O staining after 3 days of treatment. To confirm the anti-lipogenic action of cabergoline, mRNA and protein levels of adipogenic factors were measured by RT-qPCR and WB analysis respectively. Intracellular analysis of pAMPK Thr172 and pAKT Ser473 was performed to confirm anti-lipogenic action of cabergoline by inducing fat β-oxidation process.
3T3-L1 showed increased DRs mRNA levels during differentiation, concomitantly to insulin receptor, with maximum expression levels at day 12 of differentiation. Quantitative measurement of the intracellular oil droplet revealed that after cabergoline 10^{-8} M and 10^{-6} M, alone and with 2×10^{-8} M insulin, the lipid content decreases by about 60% compared to control ($P<0.0001$). Besides, cabergoline 10^{-8} M and 10^{-6} M alone and with 2×10^{-8} M insulin significantly down-regulates leptin gene expression compared to control ($P<0.001$). While gene expression of adiponectin and PPARγ remains unchanged after treatment, protein levels of bothare inhibited after 3 days of exposure with cabergoline 10^{-6} M alone and with a stronger inhibition when cabergoline was combined with 2×10^{-8} M insulin. Inhibition of fatty acid synthase and pAKT Ser473 protein expression and activation of pAMPK Thr172 after cabergoline 10^{-6} M alone or combined with 2×10^{-8} M insulin confirm that cabergoline can reduce *de novo* synthesis and accumulation of lipids by stimulating fat β-oxidation.
In conclusion, these data demonstrated a novel role of cabergoline in the suppression of lipid accumulation by reducing adipogenic- and fatty acid synthesis-related factors expression in mature 3T3-L1 cells. The combination with insulin can increase this effect providing the basis for a novel research addressed to anti-obesity use of cabergoline.

Modification of standard thresholds improves performance of noninvasive scores of liver fibrosis in patients undergoing bariatric surgery

Diego Meneses[1], Ana Cos Blanco[2], Ramón Corripio[3], Carmen Méndez[4], Antonio Olveira Martín[5], Míriam Romero[5], David Vicent[6] & Lucrecia Herranz[7]
[1]Hospital Universitario Fundación Jiménez Díaz, Endocrinology Department, Madrid, Spain; [2]Hospital Universitario La Paz, Obesity Unit, Madrid, Spain; [3]Hospital Universitario La Paz, Metabolic Surgery Unit, Spain; [4]Hospital Universitario La Paz, Patology Departament, Madrid, Spain; [5]Hospital Universitario La Paz, Liver Unit, Madrid, Spain; [6]Hospital Universitario La Paz, Instituto de Investigación Sanitaria del Hospital Universitario La Paz, Madrid, Spain; [7]Hospital Universitario La Paz, Endocrinology Department, Madrid, Spain

Background
In bariatric surgery (BS) patients, nonalcoholic fatty liver disease and fibrosis are present in up to 90% and 24%, respectively. Several fibrosis risk scores have been developed and have been validated in cohorts different from morbid obesity (MO). We aimed to determine whether established liver fibrosis scores were accurate in predicting fibrosis in MO subjects.
Material and methods
Cross-sectional analysis in a cohort of MO patients undergoing BS in a Hospital in Spain over a 2 – year period. Demographics, anthropometric, clinical and laboratory features were assessed. The APRI, FIB-4, Forns, NAFLD-fs, BARD, BAAT and Hepamet fibrosis scores were calculated.
Liver biopsies were performed during BS. The NAS score and Kleiner scale were used to assess steatohepatitis (NASH) and fibrosis, respectively.
Student *t*-test, Fisher-Pitman, Pearson's chi-squared or Fisher's exact tests were used. A $P<0.05$ was considered significant. The AUROC was calculated, as well as measures of diagnostic accuracy based on established thresholds. Modified cutoff values for differentiating F2–4 (SF: significant fibrosis) disease were calculated. Logistic regression analysis was performed to find predictors of significant fibrosis.
Results
50 patients were included. Nine participants (18%) had SF. Sixteen (32%) had NASH. Proportion of patients with NASH was higher in the SF group (88.9 vs 19.5%, $P<0.05$). BMI, HbA1c, ALT, AST an GGT levels were significantly different in patients with SF. Basal glucose, HbA1c, AST and GGT were identified as independent predictor of SF.
APRI, FIB-4, Forns and Hepamet fibrosis scores were significantly higher in the SF group ($P<0.05$). When thresholds were modified to optimize detection of significant fibrosis, they were considerably lower than those described in the literature, this allowed to identify a greater proportion of fibrosis, improving sensitivity and consequently increasing negative predictive value (NPV).
BARD (AUC 0.76) and Forns (AUC 0.67) scores had the best performance considering the cutoff suggested by the ROC analysis, both with sensitivity of 88.9%, specificity of 51.2%, NPV of 95.5% and efficiency of 58%, which makes them appropriate to exclude fibrosis.
Conclusions
Basal glycemia, HbA1c, AST and GGT are independent predictors of SF in our population. Existing scoring systems are unable to stratify fibrosis risk in MO patients using established threshold. It is necessary to modify these cutoffs to improve accuracy. By doing so, the BARD and the Forns scores had a good global performance with NPP of 95.5% and permits to predict the absence of SF.

Effects of bariatric surgery on heart rhythm disorders: A systematic review and meta-analysis

Elijah Sanches[1] & Sjaak Pouwels[2]
[1]HMC Westeinde, Den Haag, Netherlands; [2]Street Elisabeth Hospital, Tilburg, Netherlands

Background
Obesity is associated with cardiac structural changes, repolarization abnormalities and rhythm disorders. The aim of this systematic review is to provide an overview of the literature on obesity, cardiac arrhythmias, obesity associated ECG abnormalities and the effects of bariatric and metabolic surgery.
Methods
A systematic search on the effects of obesity and bariatric surgery on cardiac arrhythmias and associated ECG abnormalities was conducted. The methodological quality of the included studies was rated using the Newcastle-Ottawa scale (NOS) for non-randomized trials. The agreement between the reviewers was assessed with Cohen's kappa.
Results
Fourteen studies were included with a methodological quality ranging from poor to good. The agreement between the reviewers, assessed with the Cohen's kappa, was 0.75. Majority of the studies showed a significant decrease of QT interval and related measures after bariatric surgery. Regarding atrial fibrillation the results were conflicting. Seven studies were included in the meta-analysis on effects of bariatric surgery on QTc interval and a significant decrease in QTc interval of –33.62 ms (95% CI: –49.767 to –17.446) was seen. Similar effects were seen after bariatric surgery regarding P-wave dispersion and showed a significant decrease after bariatric surgery (–12.87 ms (95% CI: –17.739 to –8.004)).
Conclusion
Obesity is associated with prolongation of QTc interval, lengthening of P-wave and QTc dispersion and also with rhythm disorders like atrial fibrillation. Significant weight loss by bariatric and metabolic surgery results in a significant decrease in QTc interval and P-wave dispersion. The effects on atrial fibrillation are conflicting and not yet fully understood.

Physical activity is associated with lower arterial stiffness after the menopause: The effect of BMI

Eleni Armeni[1], Stavroula Paschou[1], Iliana Karagkouni[1], Areti Augoulea[1], George Georgiopoulos[2], Dimitrios Rizos[3], George Kaparos[3], Konstantinos Panoulis[1], Michael Apostolakis[1], Nikolaos Tsoltos[1], Kimon Stamatelopoulos[2] & Irene Lambrinoudaki[1]
[1]National and Kapodistrian University of Athens, Aretaieio Hospital, 2nd Department of Obstetrics and Gynecology, Athens, Greece; [2]National and Kapodistrian University of Athens, Alexandra Hospital, Department of Therapeutics and Vascular pathophysiology, Athens, Greece; [3]National and Kapodistrian University of Athens, Aretaieio Hospital, Hormonal and Biochemical Laboratory, Athen

Introduction
Metabolic syndrome and cardiovascular disease (CVD) are well-known long-term implications of the menopausal transition. Lifestyle practices like exercise could potentially act protective with regards to future cardiovascular risk at midlife. We aimed to assess the impact of physical activity on the development of subclinical CVD in postmenopausal women, adjusting for the effect of underlying obesity.
Methods
This cross-sectional study from a University Menopause Clinic evaluated a total of 623 apparently healthy postmenopausal women. Anthropometric parameters were evaluated, and women were classified into normal weight [body mass index (BMI) ≤25 kg/m^2 $n=194$] and overweight-obese (BMI >25 kg/m^2, $n=431$). Fasting blood samples were obtained to assess biochemical and hormonal profile. Sonographical assessment was performed immediately thereafter including functional [pulse wave velocity, (PWV)] and structural markers [intima media thickness (IMT) and atherosclerotic plaques presence] of subclinical vascular disease. Main outcome measures consisted of the extent of subclinical CVD according to severity of physical activity and the potential confounding effect of obesity.
Results
In the total sample, mean values of PWV differed according to the intensity of physical activity (sedentary vs walking vs moderate vs vigorous: 9.07±1.22 m/s vs 9.12±1.72 m/s vs 8.47±1.31 m/s vs 7.94±0.40 m/s, ANOVA *P*-value for linear trend 0.003). Physical activity of moderate intensity is associated with lower levels of PWV (b-coefficient=–0.126, *P*-value=0.001), adjusting for age, menopausal age, BMI, lipids, insulin resistance, smoking, blood pressure. This was not the case for walking or activity of severe intensity. Overweight-obese vs normal weight women had higher levels of common carotid artery (CCA) IMT (13.8±1.0 mm vs 13.3±1.5 mm, *P*-value=0.005), greater PWV (9.1±1.5 m/s vs 8.4±1.5 m/s, *P*-value<0.001) and higher frequency of plaques in CCA (54.9% vs 30.6%, *P*-value <0.001). In the subgroup analysis, the association between physical activity and PWV remained significant only for women with normal weight but not for overweight-obese participants.
Conclusion
Physical activity seems to be related with a protective effect on the extent of subclinical CVD in postmenopausal women. Exercise of moderate intensity is linked with lower levels of PWV after the menopause, an effect mainly pronounced in normal weight women.

Role of an automated screening tool in familial hypercholesterolemia

Antti Jokiniitty[1], Saara Metso[1], Tanja Saarela[2] & Markku Eskola[3]
[1]Tampere University Hospital, Endocrinology, Tampere, Finland; [2]Tampere University Hospital, Clinical Genetics, Tampere, Finland; [3]Tampere University Hospital, Tampere Heart Hospital, Tampere, Finland

Familial hypercholesterolemia (FH) remains underdiagnosed in general population. Screening programs in unselected individuals have shown modest results in identifying patients with FH. Incidence of FH is higher in young patients with coronary artery disease (CAD), especially when associated with high LDL-cholesterol levels. Targeted screening in this population could add value to FH-index patient identification. We have established an IT-based automated screening tool to enhance diagnostics, treatment and cascade screening of FH.
Objectives
To assess if an automated screening tool would provide additional support in recognition of potential FH-patients.
Methods
The study is based on the data collected from consecutive patients undergone coronary angiography in the Heart Hospital at Tampere University Hospital between 2007 and 2017 and fullfilling the criteria of the automated screening tool, i.e. premature CAD verified in angiography (men<55 years and women<60 years) and history of high total (>8 mmol/l) or LDL-cholesterol (>5 mmol/l) level. Health records were analyzed to determine if patient had diagnosis of FH prior to CAD diagnosis, if they were diagnosed for FH based on clinical criteria after CAD, if genetic testing had been conducted and if cascade screening had been initiated.
Results
The automated screening tool identified 211 patients from 28.295 angiographies that fullfilled the criteria. After excluding patients with apparent secondary hypercholesterolemia 162/211 (77%) patients were included in further assesment regarding FH. A total of 107 (66%) patients had probable/definite FH and 55 (34%) had possible FH based on the DLCN (Dutch Lipid Clinic Network) – criteria. Only one patient was a known FH-gene carrier before diagnosis of CAD. Only 20 patients from the cohort (13 probable/definite and 7 possible for FH) were analyzed using genetic testing. Five of them (25%) had pathogenic FH-variant and two of them were admitted to Department of Clinical Genetics for cascade screening. 142 (88%) of patients (94 with DLCNC score ≥6 and 48 with DLCNC score 5) had not been tested for genetic mutations of FH. None of the patients were diagnosed with FH based on clinical criteria before or after CAD.
Conclusions
FH is an underdiagnosed and undertreated condition. Automated screening tool in cardiac care could provide additional support for clinicians and reduce the inter-clinician variability in diagnostics, treatment and cascade screening of patients and family members potentially having FH. Further studies are needed to optimize the threshold values and exclusion criteria in the automated screening tool.

Sodium taurocholate cotransporting polypeptide (NTCP) is a new and promising target for treatment of hypercholesterolemia: A proof of concept from a randomized double-blind placebo-controlled phase I trial

Zhenzhen Zhu[1], Cuili Fan[2], Shanwei Zhu[1], Lizhen Wang[1], Fei Cai[2], Xian Gao[2], Li Zhang[1], Xiaolu Tang[2], Hongli Liu[2] & Zhenman Wei[1]
[1]No. 5 Medical Center, Chinese PLA General Hospital, Phase I unite, Peking, China; [2]HEP Pharma, R&D Department, Shanghai, China

Bile acids (BAs) are synthesized by converting cholesterol in hepatocytes and recycling it via enterohepatic circulation. Most BAs are reabsorbed into hepatocytes, where they inhibit their own synthesis by activating FXR pathway. NTCP is a major transporter of BAs via absorption from portal blood into hepatocytes. Hepalatide is a 47aa synthetic peptide that specifically binds NTCP resulting in BA spillover of hepatocytes into the systemic circulation. In this way, BA synthesis is uncoupled from negative feedback and more cholesterol can be broken down, which presents a new strategy for lowering cholesterol. The current phase I trials included a single-dose escalating stage (NCT02612506) and a multiple-dose escalating stage (NCT03023787). In the single-dose trial, 45 healthy subjects were recruited into six cohorts with escalating doses of 0.525, 2.10, 4.20, 6.30, 8.40, and 10.50 mg. In each cohort, subjects were blindly randomized into the active and placebo groups at a 4:1 ratio. No SAE took place and there was no significant difference between the adverse events (AEs) in the hepalatide treatment and placebo cohorts. The concentration of BAs in plasma increased in a linear relationship with dosage. In the multiple-dose trial, 35 healthy subjects were recruited into three cohorts with escalating daily doses of 4.20, 6.30, and 8.40 mg for 7 days. In each cohort, subjects were blindly randomized into the active and placebo groups at a 4:1 ratio. No SAE were observed and no AE was more serious than grade I as defined using NCI CTCAE (Version 4.03). Increased concentration of plasma BAs was observed, which was normalized after drug withdrawal in all hepalatide treatment cohorts. The administration of hepalatide for 7 days reduced serum total cholesterol (TC) in a dose-dependent manner, resulting in a significantly lower TC in the 8.4 mg cohort at the end of the 7-day treatment than in the placebo cohort ($P=0.0029$). The LDL-c was decreased by an average of 20% in the 6.3 mg and 8.4 mg cohorts with a maximum decrease of 39% in one healthy subject. The reduction in LDL-c showed a significant difference between both the 6.3 mg and 8.4 mg cohorts and the placebo cohort.

In conclusion, administration of hepalatide increased peripheral BAs in a linear manner. Seven-day treatment with hepalatide reduced blood TC and LDL-c significantly. This is the first clinical trial to assess the concept of NTCP as a promising target for treatment of hypercholesterolemia.

Prevalence andassociated factors with sensitive neuropathy in a population of patients with diabetes

Chaima Jemai[1] & Sinène El Frigui[2]
[1]National institute of nutrition of Tunis, C, Tunisia; [2]Hôpital Universitaire Sahloul (CHU Sahloul), Sousse, Tunisia

Introduction
Sensitive neuropathy is a degenerative complication of diabetes, precipitated by chronic glycemic imbalance. It is estimated that it is present in 50% of diabetics, and that it requires treatment in 10 to 20% of cases.
This study aimedto assess the prevalence of sensitive neuropathy and to identify the factors associated with it in a population of patients with diabetes.
Patients and methods
This is a descriptive and analytical, prospective cross-sectional study, involving 100 diabetic patients. Screening for sensitive neuropathy (SN) was done by the Semmes-Weinstein monofilament test (10g). We studied the association of SN with: Smoking, diabetes duration, body mass index (BMI), glycemic control and the presence of diabetic retinopathy.
Results
The mean age was 54±12.9 years, The sex ratio was 0.78. Diabetes was type 2 in the majority of cases (78%). The average duration of diabetes was 13.62±6.29 years. 78% of the population has been unbalanced. The prevalence of sensitive neuropathy was 41%. In univariate analysis, the factors associated with NS were smoking ($P=10^{-3}$, OR [95% CI]=5.67 [2.2; 14.1], daration of diabetes >15 years ($P=10^{-3}$, OR [95% CI]=7.76 [3.1; 19.1]), diabetic retinopathy ($P=0.001$, OR [95% CI]=4, 6 [1.8; 11.6]) and glycemic imbalance ($P=0.015$, OR [95% CI]=4 [1.2 ; 13]. BMI was not an associated factor ($P=0.509$). In multivariate analysis, the factors associated with NS were the presence of diabetic retinopathy ($P=10$-3, OR [95% CI]=7.25 [2.5; 21]), smoking ($P=0.007$, OR [95% CI]=4.9 [1.5; 15.4]) and the duration of diabetes ($P=0.032$, OR [95% CI]=3.3 [0.8; 13.3]. The glycemic balance was not associated with NS ($P=0.09$, OR [95% CI]=3.3 [0.8; 13.3]).
Conclusion
Our results match those of the literature for most of the factors studied.

DOI: 10.1530/endoabs.70.AEP347

AEP348

Assessment of renal insufficiency in the absence of albuminuria in patients with type 2 diabetes mellitus

Ezgi Demirtaş[1], Fatma Belgin Efe[2], Ahmet Toygar Kalkan[2], Medine Nur Kebapçı[2], Göknur Yorulmaz[2] & Aysen Akalın[2]
[1]Eskişehir Osmangazi University Medical Faculty, Internal Medicine, Eskişehir, Turkey; [2]Eskişehir Osmangazi University Medical Faculty, Endocrinology and Metabolism, Eskişehir, Turkey

Introduction
Diabetic nephropathy is a clinical syndrome characterized by overt proteinuria and decreased renal function in the course of diabetes mellitus. The earliest symptom is the presence of albuminuria, but a decrease in glomerular filtration rate(GFR) has been observed in patients without albuminuria. In our study, it was aimed to investigate the presence and prevalence of nonalbuminuric diabetic kidney disease observed in patients with type 2 diabetes, and to determine the characteristics and prevalence of patient groups with this feature.
Material and methods
Normoalbuminuric ($n=138$), and albuminuric ($n=40$) patients records with T2DM over 40 years of age, followed by 2014–2018 in our clinic, with GFR < 60 ml/min/1.73 m^2 were examined retrospectively. Various demographic and diabetes-related clinical and laboratory features and risk factors of patients in the study group were recorded. These variables in the group of patients with normoalbuminuric were compared with albuminuric patients. During the comparison, nonparametric methods were used because the patient distribution wasn't normal. We want to share the data of the first 138 patients as a preliminary evaluation, since the study was not completed.
Results
In the study, 93 female and 45 male patients were found to be normoalbuminuric, 11 female and nine male patients were microalbuminuric, 12 female and eight male patients were macroalbuminuric. In the comparison between the groups, it was observed that normoalbuminuric patients were older than albuminuric patients, shorter diabetes duration, lower LDL and triglyceride levels, and HbA1C mean and arterial blood pressures were higher in albuminuric patients. Diabetes duration ($P=0.047$), HbA1C overall average ($P=0.048$), retinopathy ($P=0.017$) and macrovascular complications ($P=0.004$) compared to Mann-Whitney-U test were significantly different between the groups (Table 1). Microalbuminuric and macroalbuminuric patients were compared due to the difference between the albuminuric and non-albuminuric groups and no significant difference was found in the parameters ($P>0.05$).
Conclusion
These results emphasize the role of different variables in the development of diabetic nephropathy. Progress of renal dysfunction and albuminuria can be delayed if effective blood pressure control is achieved and blood lipids and HbA1C levels are kept within the treatment targets in normoalbuminuric patients.

Table 1 Statistics of normoalbuminuric and albuminuric patients.

	Normoalbüminuric($n=138$)	Albuminuric($n=40$)	*P*-value
Age(median)	68	67	0.176

Rhinosinusal mucormycosis: A devastating infection in diabetes Mellitus

Mohamed Masmoudi, Mehdi Hasnaoui, Malika El Omri, Rihab Lahmar, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital Mahdia, Ent Department, Mahdia, Tunisia

Introduction
Mucormycosis is an unusual but serious fungal infection that most commonly affects people with diabetes mellitus. Treatment shoud be initiated urgently and associates antifungal treatment, surgical resection and control of risk factors. This infection is associated with high morbidity and mortality rates.
Case reports
We report three cases of rhinosinusal mucormycosis occuring occurring in one female and two males. The medium age of the patients was 57 years ranging from 52 to 65 years. Uncontroled diabetes was noted in the three cases. The first case was presented with a 4-day history of left facial oedema, exophtalmos and nasal obtsruction. The second and the third cases were presented with septic shock and an extensive acute nasal skin necrosis.

There was no history of fever, purulent discharge, paresthesia and foul odor. On examination, edema of the left hemiface as well as oculomotor paralysis and exophthalmos were noted for the first case, highly inflammatory nasal mucosa, purulent secretions, periortbital edema and black necrotic spot over the hemiface for the other cases. Facial CT scan examination showed signs of mucormycosis : maxillary, sphenoidal and ethmoidal sinusitis, with extension towards the soft tissues, bone erosion and orbit involvement in all the cases. Histological findings were consistent with mucormycosis.
Amphotericin B in combination with surgical debridement was used in the treatment of all the cases. A fatal outcome was noted in 2 cases.
Conclusion
Uncontrolled diabetes mellitus is considered to be the main predisposing factor for rhinosinusal mucormycosis. To prevent and reduce mortality rate of this acute disease, early diagnosis based on clinical findings and biopsy is recommended.

PHIGNA-DM2 study: Fatty liver and nonalcoholic steatohepatitis prevalence in type 2 diabetes in an andalusian cohort

Antonio Jesús Martínez Ortega[1,2], Pablo Remon[1,2], Alejandro Deniz Garcia[1], Javier Ampuero[3,4], Manuel Romero-Gomez[3,4,5], Pedro Pablo Garcia-Luna[1,2,5] & Alfonso Soto-Moreno[1,2]
[1]Virgen del Rocio University Hospital, Endocrinology and Clinical Nutrition, Seville, Spain; [2]Institute of Biomedicine of Seville (IBiS), Endocrinology and metabolic diseases, Seville, Spain; [3]Virgen del Rocio University Hospital, Gastroenterology and Hepatology, Seville, Spain; [4]Institute of Biomedicine of Seville (IBiS), Hepatic diseases, Seville, Spain; [5]Seville University, Medicine, Seville, Spain

Introduction
Non-alcoholic fatty liver disease (NAFLD) is an underdiagnosed complication in Type 2 Diabetes (T2D). This condition can evolve into steatohepatitis (NASH) and more severe entities such as liver cirrhosis and hepatic failure, being currently the first cause for liver transplantation in our environment. In Andalusian T2D patients, the exact prevalence is still unknown. Our aim is to assess the prevalence of NAFLD/NASH in a cohort of these patients.
Material and methods
Descriptive prospective study, conducted at the Endocrinology Department of the Virgen del Rocio University Hospital between 10th May 2018 and 31st December 2019. After favourable evaluation from the local ethics committee, all T2D patients admitted to this department were offered enrolment, excluding those with pre-existing liver disease or alcohol abuse, as well as those below 18 years old. We used as screening tools the Hepatic Steatosis Index (HSI), Fibrosis-4 (FIB-4) and NAFLD Fibrosis Score (NFS), whose results were afterwards compared with transient elastography (FibroScan) obtained from the same patient. Quantitative variables were expressed as median [Interquartile range] while qualitative ones were recorded as n patients (percentage). This study was possible thanks to a supporting grant from Menarini Spain.
Results
Total sample $n=105$, 45 females (F) and 60 males (M), aged 60.0 years [53.5–68.5] (M 59 [54–68], F 63 [53–69]). BMI 34.21 Kg/m^2 [31.22–43.26] (M 33.76 [31.24–42.99], F 34.67 [30.54–43.26]). T2D duration: 9 years [4–16] (M 10.00 [5.25–19.00], F 9 [2.5–12.5]); HbA1c 7.30% [6.45–8.35] (M 7.40 [6.60–8.93], F 7.10 [6.20–7.80]). HSI: positive (>36) in $n=96$ (94.12%), median 46.55 [42.51–57.17]; FIB-4 risk of fibrosis: low risk (<1.3) $n=79$ (76.7%), moderate (2.66–1.30) $n=22$ (21.36%), very high (>2.67) $n=2$ (1.94%). NFS risk of fibrosis: low (<–1.455) $n=6$ (9.37%), moderate (–1.455 to 0.676) $n=42$ (65.63%), High/Very High (>0.676) $n=16$ (25.00%). Liver Elastography: No fibrosis/mild fibrosis F0-F1 (<7.5 kPa) $n=52$ (73.24%), Fibrosis F2 (7.5–9.5 kPa, moderate) $n=12$ (16.90%), Fibrosis F3 (9.5–14 kPa, severe) $n=4$ (5.63%), Cirrhosis F4 (> 14 kPa) $n=3$ (4.23%).
Conclusions
In our series, up to 26.76% of asymptomatic patients show moderate to severe hepatic fibrosis and are at risk of developing cirrhosis. FIB-4 seems to be more precise than NFS in estimating liver fibrosis degree. Our results, if confirmed in other populations, should made physicians aware of the importance of NASH in T2D and prompt the early screening and follow-up of this condition.

Evaluation of clinical factors predictive of diabetes remission after bariatric surgery

Almudena Lara-Barea, Isabel Mateo-Gavira, Esteban Sánchez-Toscano, Daniel Medina Rivero & Manuel Aguilar Diosdado
Puerta del Mar University Hospital, Endocrinology and Nutrition, Cádiz, Spain

Introduction
Bariatric surgery is an effective treatment in order to achieve an important weight loss and improvement of metabolic comorbidities. This study aimed to assess the clinical factors that can influenced on evolution of type 2 diabetes (T2D) and obesity patients after bariatric surgery.
Methods
We conducted a cohort study with a sample of patients with type 2 diabetes and class II obesity or above who underwent bariatric surgery at Hospital Universitario Puerta del Mar (Cadiz) from January 2005 to December 2016. We evaluated demographic variables, clinical and analytical parameters, anthropometric measurements and surgery complication rates. We analized the variables before and two years after surgery. The multivariate analysis includes the possible clinical factors that predict T2D remission two years after bariatric surgery.
Results
83 patients were included with a mean age of 44.13±10.38 years. Two years after surgery, the percentage of overweight lost was 63.43±18.59% and T2D was resolved in 79.5%. The body mass index range (RR: 1.886; $P=0.022$), T2D duration more than five years (RR: 0.022; $P=0.040$), baseline insulin treatment (RR: 0.001; $P=0.009$) and absence of macrovascular complications (RR: 34.667; $P=0.002$) were related with T2D remission. 15.6% of patients presented early complications and 20.5% developed late complications.
Conclusions
In our setting, bariatric surgery is an effective and safe technique for sustained weight loss in the mid-term, with a high rate of T2D's resolution. An absence of insulin treatment, higher baseline BMI, shorter T2DM duration and absence of macrovascular complications are factors predictive of diabetes remission after bariatric surgery.

The relationship between cardiovascular autonomic neuropathy and markers of oxidative stress in patients with type 2 diabetes mellitus

Olena Stepura[1,2], Olga Gonchar[3] & Borys Mankovsky[1,2]
[1]State Scientific Institution 'Center for Innovative Medical Technologies of the National Academy of Sciences of Ukraine', Department of diagnosis and treatment of metabolic diseases, Kyiv, Ukraine; [2]PL Shupyk National Medical Academy of Postgraduate Education, Department of Diabetology, Kyiv, Ukraine; [3]Bogomoletz Institute of Physiology NAS of Ukraine, Department of hypoxic states investigation, Kyiv, Ukraine

Introduction
Cardiovascular autonomic neuropathy (CAN) is a significant risk factor for cardiovascular morbidity, mortality in patients with diabetes mellitus (DM). On the other hand, oxidative stress is one of the important factor of pathogenesis of diabetic complications. However, an association between CAN, cardiovascular autonomic reflex tests (CARTs), heart rate variability (HRV) and markers of oxidative stress in patients with DM was not fully investigated.
Objectives
The aim of this study was to investigate the relationship of CAN, CARTs, HRV and oxidative stress markers in patients with type 2 DM.
Materials and methods
We examined 15 patients with type 2 DM, six males and nine females (aged 60,1±1,61 years, duration of diabetes – 10,3 ±1,26 years, HbA1c – 9,1±0,69%) (data are presented everywhere as mean±s.e.m.). All patients were performed CARTs by Ewingand the followingmarkers of oxidative stress were measured in the plasma – superoxide dismutase, catalase, glutathione peroxidase, malondialdehyde. The diagnosis of CAN was confirmed in patients with 2 positive tests. The statistical analysis was performed using SPSS statistical package version 23.0 for Windows.
Results
CAN by 2 abnormal tests was diagnosed in 33,3% patients, and by 3 abnormal tests – in 66,7% patients. We found positive correlation between

levels of glutathione peroxidase and the 30:15 ratio, ($r=86.3$, $P<0.05$), and level ofcatalase and LF:HF ratio ($r=2.56$, $P<0.01$). Negative correlation was found between level of catalase and Valsalva ratio, ($r=-5.4$, $P<0.05$).
Conclusion
We found somerelationship between the presence of CANand markers of oxidative stress which could suggest the possible role of oxidative stress in the development of CAN in patients with type 2 DM.

Relationship between pregnancy induced hypertension in women with gestational diabetes mellitus and proinflamatory cytokines

Almudena Lara-Barea[1], Begoña Sánchez-Lechuga[1], Alvaro Vidal-Suárez[1], Antonio Campos-Caro[2], Manuel Aguilar-Diosdado[1] & Cristina López-Tinoco[1]
[1]Puerta del Mar University Hospital, Endocrinology and Nutrition, Cádiz, Spain; [2]Puerta del Mar University Hospital, Immunology, Cádiz, Spain

Justification and objectives
Gestational Diabetes Mellitus (GDM) is associated with an increased risk of Pregnancy-Induced Hypertension (PIH). Previous studies suggest a relationship between inflammatory markers and the development of PIH and obstetric and perinatal complications. The aim of the study was to establish the relationship between pro and anti-inflammatory cytokines and the development of PIH and the impact on obstetric and perinatal outcomes.
Material and methods
From an established prospective cohort of pregnant women with GDM, we studied 11 who developed PIH and 143 who remained normotensive; for reference values, we included 90 healthy non-diabetic normotensive pregnant women. Plasma levels of pro-inflammatory cytokineswere measured at 28–32 weeks of pregnancy, before the clinical onset of PIH. Baseline characteristics, metabolicparameters and obstetric and perinatal outcomes were analyzed.
Results
Higher levels of sFlt-1/PIGF ratio [4.92±2.72 vs 2.27±1.38, $P=0.009$] and lower levels of adiponectin [10.09±1.03 vs 12.88±2.74, $P=0.001$] were observed in pregnant women with GDM who developed PIH compared to normotensive women with GDM. Higher levels of resistin [7.20±3.02 vs 5.81±3.03, $P=0.001$] were observed in pregnant women with GDM compared to control group. We observed lower birth weight [2652.2±638.2 vs 3255±513.4 g, $P=0.011$], and higher prevalence of Small for Gestational Age (SGA) newborns [45.5 vs 8.4%, $P=0.003$] and Intrauterine Growth Retardation (IGR) [27.3 vs 4.2%, $P=0.018$] in pregnant women who developed PIH. Higher rate of hypoglycemia in newborn [27.3 vs 3.5%, $P=0.013$] were found in women with PIH compared to normotensive pregnant women.
Conclusions
We concluded that pregnant women with DMG who develop HIE have a characteristic proinflammatory profile, with significantly lower levels of adiponectin and a higher sFlt1/PlGF ratio. This group have a higher rate of adverse pregnancy and neonatal outcome compared to normotensive pregnant women: lower birth weight, a higher incidence of SGA and IGR, and higher prevalence of hypoglycemia in newborn.

DOI: 10.1530/endoabs.70.AEP353

AEP354

The pattern of nerve involvement in type 1 diabetic patients with subclinical peripheral neuropathy

Maryia Mashkova[1], Alena Shishko[1], Irina Bylodid[1], Alena Semushina[2] & Natalia Korshova[3]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Republican Scientific and Practical Center of Hygiene, Minsk, Belarus; [3]Endocrinology Medical Center, Minsk, Belarus

The concept of a subclinical form of diabetic peripheral neuropathy (DPN) is well established. Although there has been considerable research of peripheral neuropathy in type 1 diabetes, still there is controversy regarding the pattern of nerve involvement in diabetic neuropathy. Detection of the pattern of nerve involvement can help to establish a protocol for screening of DPN in its subclinical stage.
Aim
The aim of this study was to describe the pattern of nerve involvement in type 1 diabetic patients with subclinical neuropathy using nerve conduction studies (NCS).
Materials and methods
65 patients with type 1 diabetes (DM1) and 34 controls without diabetes matched to the patient group were included. All patients and controls underwent a standard neurological examination (NSS and NDS (the variant used in Belarus) score) and bilateral NCS of the sensory and motor lower limb nerves using NeuroSoft machine. Interpretation of the results was based on the following normal reference ranges:n. Peroneus superficialis A>10 μV, v>45 m/s; n Suralis A>5 μV, v>45 m/s; n Peroneus profundus A>3 mV, v>40 m/s; n Tibialis A>3.5 mV, v>40 m/s.
Results
Clinically evident DPN was detected in 14 diabetic patients from 65 examined. The use of NCS allowed to identify the subclinical stage of polyneuropathy (abnormalities in at least two of the electrophysiological parameters) additionally in 35 patients who had no symptoms and clinical signs of DPN. Regarding abnormal NCS parameters in patients with subclinical diabetic neuropathy, amplitudes reduction for the *n*. Peroneus superficialis and n. Peroneus profundus predominated. Median of the amplitude for n. Peroneus superficialis in patients with subclinical DPN was 7.22 [5.25; 8.54] μV vs 12.4 [10.57; 16.2] μV in the controls, $P<0.001$; for n. Peroneus profundus 2.21 [1.68; 2.68] mV vs 3.15 [3.04; 3.42] mV, $P<0.001$. Significant differences in the amplitudes for *n*. Suralis and *n*. Tibialis has not been identified. Nerve conduction velocity (NCV) in patients with the subclinical DPN and the control groups was within the reference range. However, the medians of NCV for *n*. Suralis and *n*. Tibialis were significantly lower in the group of patients with neuropathy compared with the controls – 47.08 [44.35; 50.13] m/s vs 51.3 [47.6; 59.05] m/s, $P=0.025$ and 44.8 [42.15; 48.2] m/s vs 49.35 [48.30; 53.45] m/s, $P=0.004$, respectively.
Conclusion
In patients with type 1 diabetes with a subclinical stage of diabetic polyneuropathy the most frequent neurophysiological abnormality was reduced amplitudes (the axonal damage) for sensory and motor fibers of n. Peroneus.

Nursing networking for insulin pump therapy

Sanja Minic[1], Sanja Medenica[1,2], Emir Muzurovic[1,2], Sreten Kavaric[1,2], Aleksandar Djogo[1], Djordjije Krnjevic[1], Olivera Boskovic[1] & Snezana Vujosevic[1,2]
[1]Clinical Center of Montenegro, Department of Endocrinology, Internal Medicine Clinic, Podgorica, Montenegro; [2]School of Medicine, University of Montenegro, Podgorica, Montenegro

Objective
Diabetes mellitus is among the most common of chronic disorders with increasing prevalence worldwide, affecting 50000 citizens in Montenegro. The insulin pump is a medical device that works on the principle of continuous insulin injection, and is used in the control of diabetes in insulin dependent patients. The objective of this study was to highlight the role of nurse in education of the patients, implantation of insulin pump and nursing networking for insulin pump therapy in Montenegro.
Methods
The study enrolled all patients between 2016 and 2020 starting insulin pump therapy, 23 females and seven males. The indications were unsatisfactory glycoregulation, incipient nephropathy and pregnancy planning. Three patients discontinued insulin pump therapy during the further treatment.
Results
Patients were from different parts of Montenegro, central part 14 patients, southern 6 patients, and northern part 8 patients. The diabetes was diagnosed in patients between 2nd and 28th year. At the moment of the insulin pump therapy initiation the youngest patient was 16 year-old and the oldest patient was 56 year-old. Glycated hemoglobin before the insulin pump therapy initiation ranged between 5.2 and 12.4%, and after starting insulin pump therapy between 5.2 and 9.8%. Three female patients achieved pregnancyand healthy offspring, and also one male patient had healthy offspring. Seven female patients are in the process of planning pregnancy. The most common diabetes complications was diabetic nephropathy and neuropathy, and the most common comorbidity was primary hypothyroidism in chronic autoimmune thyroiditis. Finally, the study results showed that glycoregulation was significantly better in patients with continuous nurses support than those with standard care.

Conclusions
The nurse has a very important role in the insulin pump implantation team in education of the patients for using insulin pump and better understanding its technical characteristics, as well as knowing how to calculate carbohydrate units for the each meal. Improving awareness of insulin pump therapy as a mode of insulindelivery and creating confidence in caring for patients with insulin pump is essential in improving their glycoregulation.

Effect of lipid metabolism of mothers with type 1 diabetes and obesity on clinical and laboratory parameters of their newborns

Veranika Prylutskaya[1], Anzhalika Solntsava[1], Antonina Goncharik[1], Marya Pavlovets[1] & Ivan Kurlovich[2]
[1]Belarus State Medical University, 1st Childhood Disease, Minsk, Belarus; [2]Republic Research and Practical Center «Mother and child», Administration, Minsk, Belarus

Background and objective
According to recent studies, adipose tissue produces important biological factors (adipokines include leptin, adiponectin, etc.) for hormonal, lipid and glucose metabolism, insulin resistance, endothelial dysfunction and atherosclerosis development. The study of this factors and it's correlation with maternal lipid metabolism and neonatal anthropometric characteristics would be of great interest.
This study aims to analyze lipid metabolism features in women with type 1 diabetes T1D and/or obesity and it's correlation with newborns' hormonal and anthropometric parameters.
Methods
A prospective observational study was performed in RSPC «Mother and child» in 2018–2019. 89 full-term neonates from mothers with DT 1 and excess body weight/obesity were divided into 4 groups: Gr1 – from mothers with T1D and BMI<25.0 kg/m^2 (n=25); Gr2 – from mothers with T1D and BMI≥25.0 kg/m^2 (n=21); Gr3 – from mothers with BMI≥25.0 kg/m^2 (n=18); control group (GrC) – from mothers without diabetes and healthy BMI (n=25). Neonates' BMI was 13.86 [13.14; 14.98], 14.36 [13.42; 14.77], 13.05 [12.57; 13.27], 12.00 [11.70; 12.04] kg/m^2 ($P_{1\text{-}C}$=0.002, $P_{2\text{-}C}$=0.002, $P_{3\text{-}C}$=0.007, $P_{1\text{–}3}$=0.016, $P_{2\text{–}3}$=0.004), Z-scoreBody weigh – 0.90 [0.45; 3.10], 2.15 [1.18; 2.24], 0.60 [0.11; 1.10], –0.47 [–0.57; –0.16] ($P_{1\text{-}C}$=0.002; $P_{2\text{-}C}$=0.002; $P_{3\text{-}C}$=0.012; $P_{2\text{–}3}$=0.001). Physical development indicators for newborns were assessed using Intergrowth-21st. Statistica 10.0 was used for statistical analysis.
Results
Mothers' serum cholesterol level during first stage of labor was 9.1 [7.9; 10.9], 9.8 [7.6; 10.4], 7.5 [6.1; 7.8], 9.4 [9.2; 10.0] mmol/l ($P_{1\text{–}3}$=0.006, $P_{2\text{–}3}$=0.018); TGc – 3.8 [2.6; 4.9], 3.8 [2.2; 5.1], 2.7[2.0; 3.3], 2.7 [2.5; 4.1] mmol/l ($P_{2\text{–}3}$=0.018); LDL-P – 4.4 [4.1; 5.9], 4.8 [3.9; 5.4], 3.7 [3.2; 4.2], 4.9 [4.4; 5.2] mmol/l ($P_{1\text{–}3}$=0.007, $P_{2\text{–}3}$=0.018). Leptin levels in the 1st day of life in Gr1, Gr2, Gr3– 5.10 [3.18; 28.06], 35.78 [6.43; 47.47], 5.46 [2.13; 9.16] ng/ml ($P_{2\text{–}3}$=0.043). Gr1, Gr2, Gr3, GrC cord blood leptin levels – 5.3 [4.0; 23.3], 7.9 [4.2; 49.5], 17.4 [7.3; 20.4] ng/ml. We found out a positive correlation between mothers' TGc, HDLP and neonates' cord blood leptin levels (r=0.512, r=0.658); TGc, LDL-P and leptin levels in the 1st day of life (r=0.525, r=0.523). We revealed a positive correlation (P<0.05) between newborns' hormonal and anthropometric parameters: leptin levels in the 1st day of life and body weight (r=0.594), body weight z-score (r=0.634).
Conclusions
Maternal lipid metabolism has great impact on their newborns' hormonal and anthropometric parameters. Further study of metabolic disorders in babies from mothers with T1D and obesity can help to improve medical care quality in the neonatal period.

Different steroidogenesis in patients with alzheimer's disease and Type 2 diabetes mellitus

Marketa Vankova, Martin Hill, Josef Vcelak, Daniela Vejrazkova & Bela Bendlova
Institute of Endocrinology, Molecular Endocrinology, Praha, Czech Republic

Alzheimer's disease (AD) is a neurodegenerative diseasethat is manifested by a progressive loss of cognitive and behavioral function. In previous studies, we have constructed a predictive model for the classification of AD patients based on levels of circulating steroids and their polar conjugates.
Both AD and Type 2 diabetes mellitus(T2DM) are well known to affect the levels of some steroid hormones, however, in the opposite direction, and in a gender-dependent manner. The aim of this study was to determine whether AD patients can be identified in the group of T2DM patients based on circulating steroids and their polar conjugates.
Methods
We evaluated the spectrum of steroid hormones in 86 patients with T2DM. The group consisted of 54 women (median age 71.2 years) and 32 men (median age 69.6 years), seven women and seven men had both AD and T2DM, the remaining 47 women and 25 men had only T2DM. To evaluate the balance between the steroids in reversible metabolic steps or activities of steroidogenic enzymes, we used product to precursor ratios. The data were processed by GLM ANOVA and multidimensional regression using O2PLS method (Statgraphics 18 × 64, SIMCA v 12.0).
Results
T2DM patients with AD generally exhibited lower adrenal steroidogenesis compared to T2DM patients without AD. Furthermore, there was decreased steroid sulfotransferase (SULT2A1) and 5α-Reductases (SRD5A) activities in the combined group of T2DM and AD but increased aldoketoreductases of subfamily 1C (AKR1C1) activity in both genders.
Conclusion
By using our O2PLS model, it is possible to distinguish between the group of patients with T2DM + AD and the group of only T2DM. The predictivity of the OPLS model for men is high: sensitivity = 0.875 (0.529, 0.978) and specificity = 1 (0.857, 1)as well as for women: sensitivity = 1 (0.646, 1) and specificity = 1 (0.917, 1).
Supported by the grants NV 18-01-00399, MH CZ-DRO (EU 00023761).

The trio of severe hypertriglyceridemia, acute pancreatitis and diabetic ketoacidosisin a young subject not known before with diabetes. A case report

Marjeta Kermaj[1], Thanas Fureraj[1], Violeta Hoxha[1], Klodiana Poshi[1], Dorina Ylli[1], Adela Haxhiraj[1], Edlira Elezi[1], Ermira Muco[2], Mariola Kapia[3], Mirjeta Guni[3] & Agron Ylli[1]
[1]UHC 'Mother Tereza', Endocrinology, Tirana, Albania; [2]UHC 'Mother Tereza', Infectious Diseases, Tirana, Albania; [3]American Hospital, Endocrinology, Tirana, Albania

Introduction
The trio of severe hypertriglyceridemia, acute pancreatitis and diabetic ketoacidosis (DKA) is a rare occurrence. Previous cases have presented DKA as the initial factor, contributing to subsequent hypertriglyceridemia and pancreatitis. Moderate hypertriglyceridemia is commonly observed in DKA but severe hypertriglyceridemia is very rarely reported.
Case report
We report a case, male 29 years old, diagnosed with hypertriglyceridemia 3 years ago. There was no family history for diabetes mellitus (DM) but his father was being treated for hypertriglyceridemia. Our patient referred that the last 3 years of his life were very stressful and with an unhealthy lifestyle. He did not use alcohol and was not a smoker. He was treated with fibrates during first year but he has stopped them himself. He was presented at emergency unit with 24-hour history of upper abdominal pain, nausea, vomitus, polyuria, fatigue and high temperature. Conscious, tachycardic, normotensive, febrile, overweight. On abdominal palpation, he felt epigastrium pain. Laboratory examinations: Severe hypertriglyceridemia (>5000 mg/dl), hyperglycemia, elevated amylase and lipase. Leukocytosis with high neutrophils. Elevated C-reactive protein. Electrolytes normal level. Urine analyses: ketonuria, glucosuria and infection. Arterial blood gases: mild metabolic acidosis. HbA1c11.9%, C-peptide normal, all autoimmune markers for DMT1 resulted negative. Abdominal ultrasound showed hepatosteatosis grade 2 and was suggestive of acute pancreatitis. Firstly, he was hospitalized in intensive unit care where he was treated with insulin, liquids I/v, antibiotics and fibrates without oral food. After 48 hours he got out of diabetic ketoacidosis but upper abdominal pain kept going. An abdominal CT scan showed images of acute pancreatitis. In consultation with gastrohepatologist, he was treated with non-steroid anti-inflammatory drugs associated with inhibitors of proton-pump without oral food. After 2 days he was without upper abdominal pain. He transferred to Endocrinology Department where he started

oral food associated with pancreatic enzymes. After ten days he discharged in good condition under treatment with fibrates, omega oils and statin, insulin for hyperglycemia and pancreatic enzymes. 2 weeks later, he stopped insulin because of normoglycemia and after 1 month, he had normal lipid level in blood under treatment. He is following a healthy life style.
Conclusion
Untreated a pre-existing lipid disorder especially in subject with an unhealthy life-style and a stressful life can lead to the rare trio of severe hypertriglyceridemia, acute pancreatitis and diabetic ketoacidosis, a life-threatening situation. Every medical physician must be aware of this situation to do the early correct intervention to prevent it.

Case of type 1 diabetes development after programmed cell death-1 inhibitor immunotherapy

Mi Kyung Kim[1], Jae Seok Park[1] & Nan Hee Cho[2]
[1]Keimyung University School of Medicine, Internal Medicine, Daegu, Korea, Republic of South; [2]Keimyung University Dongsan Hospital, Internal Medicine, Daegu, Korea, Republic of South

Programmed cell death-1 (PD-1) receptor inhibitor is an immune check point blockade for anticancer treatment and is currently used for various malignancies such as melanoma, non-small cell lung cancer, and so on. However, an immune check point blockade is associated with a risk for immune related adverse events. Among these events, Type 1 diabetes is rare. We present a case of a 52-year-old man, with no previously diabetic history, who developed diabetic ketoacidosis (DKA) after 10 doses of nivolumab for non-small cell lung cancer. One week after the 10th nivolumab therapy, he visited the emergency room because he had severe nausea and vomiting and was diagnosed DKA. He had a glycemia of 616 mg/dl, and arterial blood gas values showed a pH of 6.982 and very low bicarbonate. After continuous IV insulin and hydration, glucose level and acidosis was normalized. Further testing showed C peptide level was 0.26 ng/ml, insulin antibody was 7.18% (normal range ≤7%) and glutamic acid decarboxylase antibody was 0.13 U/ml (normal range 0–1.00 U/ml). Basal bolus multiple daily injections were started for glycaemic control. In addition, thyroid function was changed from thyrotoxicosis to overt hypothyroidism suggesting he had thyroiditis. One month later, he restarted nivolumab treatment with multiple insulin injections without any additional adverse events.
Physicians are becoming more aware of immune adverse event because the treatment using immune check point is increasing. Therefore, blood glucose monitoring during PD-1 inhibitor is necessary to avoid diabetic ketoacidosis

Arare case of caucasian patient with insulin autoimmune syndrome induced by a-lipoic acid

Spyridoula Glikofridi[1], Labrini Papanastasiou[1], Athina Markou[1], Vasileios Andrianesis[2], Christos Gravvanis[1] & Theodora Kounadi[1]
[1]General Hospital of Athens G. Gennimatas, Unit of Endocrinology and Diabetes Centre, Athens, Greece; [2]General Hospital of Athens Laiko, First Department of Propaedeutic Medicine, Athens, Greece

Introduction
Insulin autoimmune syndrome (IAS) is characterized by spontaneous hypoglycemia caused by insulin autoantibodies (IA) in the absence of exogenous insulin administration. The occurrence of IAS may be influenced by a genetic predisposition determined by HLA class II. IAS is frequently reported in Japanese and Koreans due to their genetic predisposition (HLA-DRB1*0406) rather than in the Caucasians. Some drugs containing sulfhydryl compounds are known to initiate the onset of IAS. A-lipoic acid (ALA) contains two sulfur atoms and can promote insulin S-S bounding dissociation and expose insulin to the antigen presenting cells. T cells of predisposed patients are stimulated, resulting in IA formation.
Case description
A 52-year-old female with medical history of oral medical supplements consumption, containing ALA, was admitted at the emergency Department with severe hypoglycemia accompanied by neuroglycopenic and adrenergic symptoms. Intravenous dextrose solutions along with many short mixed meals were administrated. After the exclusion of adrenal insufficiency and hypothyroidism, a 72-hour fasting test was attempted, but was ended 3 hours later because the patient experienced palpitation and sweating with low blood glucose level (39 mg/dl). Serum insulin and c-peptide levels were high (27.7 μI U/ml and 2.7 ng/ml respectively). Pancreatic Magnetic tomography and endoscopic ultrasonography did not prove the existence of an insulinoma while IA levels were very high (101 U/ml). The excessive consumption of medical supplements, containing ALA [which improve glucose metabolism], the absence of other clinical signs and the high IA levels established the diagnosis of IAS. ALA supplementations were discontinued and diazoxide was initiated. Glucose levels were increased and after three months of treatment, the patient was recovered completely. IA were decreased, but they have not been normalized yet. Diazoxide treatment was gradually decreased and discontinued. Her HLA genotype analysis has not been completed yet.
Conclusion
IAS should be considered in patients with sudden episodes of hypoglycemia, when the imaging investigation was unremarkable and medications containing sulfhydryl compounds, such as ALA were consumed.

Autoimmune causes of hypoglycemia

Marta Baraia-Etxaburu[1], Pilar Álvarez[1], Amaia Vela[2], Jorge Monroy[1], Ruth Sáez de la Maleta[1], Ana María Delgado[1], Gema Grau[2], Amaia Rodríguez[2], Enrique Ruiz[1] & Itxaso Rica[2]
[1]Burgos University Hospital, Spain; [2]Cruces University Hospital, Barakaldo, Spain

Background
Identifying the etiology of hypoglycemia in a non-diabetic patient is a significant challenge. Hyperinsulinemic hypoglycemia can lead to pancreatectomy in patients with no evident organic disease. Insulin autoimmune syndrome (IAS) or Hirata diseaseand Type B insulin resistance syndrome are the two typesof autoimmune hypoglycemia, with a low worldwide prevalence.
Objective
We report two real-lifecases that illustrate each of them.
Results
The first case depicts a 69-year-old woman who had frequent episodes of symptomatic hypoglycemia, which happened to occur three hours after the intake of food. Amonth earlier, she had received a 7-day treatment with amoxicillin. Besides, she had a daughter with type 1 diabetes, celiac disease and autoimmune subclinical hypothyroidism. She underwent a prolonged fast test in which no clinical or analytical hypoglycemia were found. Nevertheless, severe hyperinsulinemia was detected, even though it wasnot correlated with the levels of serum glucose, C peptide and proinsulin, which showed normal values. Insulin autoantibodies (IAA) were positive with a 76.8% fixation (RV<8.2%). Moreover, there was no pathological finding within HbA1, nor the adrenal, thyroid and somatotroph axis. In addition, sulfonylureas were not detected in urine. Afterwards, the oral glucose tolerance test showed initial hyperglycemia (insulin bound by IAA becomes ineffective), followed by hypoglycemia due to the release of the insulin-IAA complexes. A diet low in simple carbohydrates and frequent intake of small meals encouraged a successful clinical evolution of the IAS. On the other hand, the second patient was a three-year-old girl, with neonatal diagnosis of DiGeorge syndrome, who had suffered various episodes of symptomatic hypoglycemia with no obvious cause. In this case, the patient showed a remarkable acanthosis nigricans and high glucose variability. Severe hyperinsulinemia and very low serum glucose levels were simultaneously found, with normal C peptide. Nonetheless, anti-insulin antibodies and the exhaustive study for hyperinsulinism were negative. Frequent hospitalizations in relation to severe respiratory infections ended-up with a combined therapy of high-dose corticotherapy and gammaglobulins. From that moment on, serum insulin levels progressively decreased until normalisation and hypoglycemia eventually disappeared. Pending the results of the anti-insulin receptor antibodies (sent to an international laboratory) to confirm the diagnosis, the clinical picturecould be considered asthe type B insulin resistance syndrome.

Conclusions
Autoimmunity related to insulin or to insulin receptor should be ruled out in order to reach the aforementioned uncommon diagnoses, ensuring a correct clinical management and avoiding an unnecessary and non-effective pancreatic surgery.

Cardiovascular manifestation of alkaptonuria

Preet Shah[1] & Ankita Hingolikar[2]
[1]Dewsbury and District Hospital, Endocrinology and Diabetes, Dewsbury, United Kingdom; [2]Jaslok Hospital and Research Centre, General Medicine, Mumbai, India

Case History
A 64-year-old gentleman presented with progressive exertional breathlessness since 1 year. He had started noticing pigmentation in the eyes 2 years back, and gave a history of passing black coloured urine since childhood. He had never consulted a medical professional for the same. Examination revealed hyperpigmentation of both ears and conjunctivae, and an ejection systolic murmur (Grade V) at the aortic area, which radiated to both his carotids. A sample of his urine revealed the colour of his urine to be cola-coloured. Echocardiography confirmed valvular aortic stenosis with the pressure gradient across the aortic valve being 72 mm Hg, and the valve area being 0.8 cm^2. The gas chromatography-mass spectrometry analysis of his urine revealed that urinary levels of homogentisic acid were elevated, thus confirming the diagnosis of alkaptonuria. He refused surgery, hence, after a discussion between the patient, the treating cardiologist, and the cardiothoracic surgeon, a transcatheter aortic valve replacement (TAVR) was done by his cardiologist. Alkaptonuria, one of the first disorders in humans found to conform with the principles of Mendelian recessive inheritance[1], is a rare hereditary disorder in which deficiency of homogentisate 1,2 dioxygenase (HGD) (the enzyme predominantly produced by hepatocytes in the liver and within the kidney, and is responsible for the breakdown of HGA; an intermediate in the tyrosine degradation pathway) leads to urinary excretion of homogentisic acid in large amounts, which darkens on standing[2]. Accumulation of oxidized homogentisic acid pigment in connective tissue (ochronosis) also occurs, namely in the sclerae of the eye, as well as the concha of the ear[3]. The disease may be picked in the patients when they are young owing to the peculiar colour of their urine, but may often be ignored until their latter years. Patients usually present with degenerative arthritis in the middle age. Degenerative cardiac disease, especially aortic stenosis as in this case, may also occur and is an important clinical problem in older patients[4].

The quantitative relationship between Autonomous cortisol secretion, Dysglycemia and the Metabolic syndrome

Jonathan Bleier[1,2], Gadi Shlomai[1,2,3], Boris Fishman[1,2], Zohar Dotan[2,4], Barak Rosenzweig[2,4] & Amir Tirosh[2,3]
[1]Sheba Medical Center, Internal Medicine D, Ramat gan, Israel; [2]Tel Aviv University, Sackler faculty of medicine, Tel Aviv, Israel; [3]Sheba Medical Center, The Institute of Endocrinology, Diabetes and Metabolism, Ramat Gan, Israel; [4]Sheba Medical Center, Department of Urology, Ramat Gan, Israel

Objective
Autonomous cortisol secretion (ACS) is the most common endocrine abnormality in the evaluation of adrenal incidentalomas. The categorization of ACS is derived from a 1 mg dexamethasone suppression test (DST). Impaired DST is associated with several metabolic derangements. In this study we assess the correlation between post-DST cortisol level, analyzed as a continuous parameter, and indices of glycemic metabolism.
Study design
We prospectively collected data of 1976 patients evaluated for adrenal incidentalomas in a large tertiary medical center between December 1st, 2017 and August 31st, 2019. 73 patients completed the evaluation process. Post-DST cortisol levels were analyzed for correlation with various metabolic parameters, including fasting plasma glucose (FPG) and hemoglobin A1c (HbA1c) among the general cohort and for subgroups stratified by the number of metabolic syndrome (MS) criteria.
Results
Post-DST cortisol demonstrated a linear correlation with FPG and HbA1c across its entire cortisol range ($R=0.51$ and 0.41, respectively, $P\leq0.01$). The correlation between post-DST cortisol and FPG was strengthened with increased number of metabolic syndrome criteria. Patients with 4 MS criteria show a stronger correlation ($R=0.92$) compared to patients with only a single criterion ($R=0.509$). Furthermore, mean post-DST cortisol levels increased as the number of MS criteria accumulated.
Conclusion
Post-DST cortisol should be viewed as a continuous parameter in risk stratification algorithms for development of the MS and particularly dysglycemia.

***In vitro* and *in vivo* insulinotropic actions of magainin-AM1 on pancreatic beta cells and high fat fed mice**

Ayodele Abiodun Falobi[1], Ayokunle Benjamin Falana[1], Yasser HA Abdel-Wahab[2], Peter R Flatt[2] & Opeolu Ojo[1]
[1]University of Wolverhampton, School of Sciences, Wolverhampton, United Kingdom; [2]Ulster University, School of Biomedical Sciences, Coleraine, United Kingdom

Aim
Insulin-releasing effects and potential anti-diabetic actions of peptides isolated from the skin secretion of the African clawed frog, *Xenopus amieti* has been reported. However, peptides such as magainin-AM1 has not been previously studied for its ability to stimulate insulin secretion or promote glucose uptake. This study investigated insulin releasing effects as well as possible underlying mechanisms.
Methods
Acute and chronic actions of magainin-AM1 were investigated using clonal pancreatic beta cells, BRIN-BD11, in buffers containing increasing glucose concentrations, magainin-AM1 alone (0–3 µM) or magainin-AM1 (1 µM) with modulators of insulin secretion. Insulin concentrations were measured by ELISA. Cytotoxicity and cell viability were examined in peptide-treated cells. Membrane potential and intracellular calcium concentrations were measured using Flexstation scanning fluorimeter. Glucose tolerance and insulin secretion were monitored in peptide-treated diabetic mice.
Results
Magainin-AM1 acutely stimulated insulin release from BRIN-BD11 cells in a concentration-dependent manner (1.4–1.6-fold, 100 nM–3 µM, $P<0.001$–0.05). The stimulatory effects of magainin-AM1 reduced in the presence of diazoxide (28%, $P<0.01$), verapamil 31%, $P<0.01$), calcium-free buffer (31%, $P<0.001$) and increased in incubations containing KCl (1.1-fold, $P<0.05$). Pre-treatment of cells with magainin-AM1 increased secretory responses to KCl (1.3-fold, $P<0.05$) but had no effect on responses to other secretagogues. These actions are not associated with reduced cell viability and cytotoxicity. Membrane potential and intracellular calcium concentration were increased by 1.9-fold ($P<0.01$) and 1.5-fold ($P<0.001$) in peptide-treated cells. Reduced blood glucose 24%, $P<0.05$) and enhanced insulin secretion (1.6-fold, $P<0.05$) were observed in peptide-treated mice.
Conclusions
These results suggest that the anti-diabetic properties of magainin-AM1 may involve the K_{ATP}-dependent pathway.

The acute effects of short-term insulin therapy on the secretory ability of beta cells in patients with diabetes mellitus type 2, after the secondary failure of the oral therapy

Aleksandra Grbic, Gabrijela Malesevic, Valentina Soldat-Stankovic, Bojana Caric & Snjezana Popovic-Pejcic
University Clinical Center of the Republic of Srpska, Faculty of Medicine, University of Banja Luka, Department of Center for Diabetes with Endocrinology, Banja Luka, Bosnia and Herzegovina

Introduction
Secondary failure (SF) to treatment with oral therapy is defined as the absence of a favorable reaction to the oral therapy which was effective in the previous course of the treatment. The aim of the work was to investigate the acute effects of the short-term insulin therapy on the secretory ability of endocrine pancreatic beta cells and the insulin resistance. Materials and Methods: 98 patients with diabetes mellitus type 2 (DM T2) and confirmed the SF to the oral therapy were selected for the study. These patients were divided into two different groups based on their body weight, and each group received a different insulin treatment regimens. The patients with a normal body mass (group A) were treated with a mono-insulin intensive conventional therapy (so called Basal-bolus regimen), while the group B patients (the group with an increased body mass) were treated with a combined insulin therapy (basal insulin plus metformin) in the duration of three months. All involved patients were tested prior to the insulin therapy and then three months after its startfor the factors of glycoregulation (glycated hemoglobin A1c (HbA1c), fasting plasma glucose (FPG), 2h postprandial glucose (2h-PPG) and selfmonitoring of blood glucose (SMBG), and the homeostatic models for the estimation of values forthe insulin secretion and resistance (HOMA-β% and HOMA-IR) were calculated from the pairs of fasting glycemia and insulinemia. Main results: Results of the study show the improvement in glycoregulation, a decrease in insulin resistance (IR) and improvement in the endogenous pancreatic capacity for the both tested groups, when compared to the period prior to the insulin therapy started. Group A: FPG (9.5 vs 6.1, $P<0.001$), 2h-PPG (11.6 vs 6.9, $P<0.001$), HbA1c (9.0 vs 6.7, $P<0.001$), HOMA-β% (39.03 vs 83.42, $P<0.001$), HOMA-IR (4.87 vs 2.45, $P<0.001$). Group B: FPG (9.4 vs 6.3, $P<0.001$), 2h-PPG (11.6 vs 6.9, $P<0.001$), HbA1c (9.0 vs 6.7, $P<0.001$), HOMA-β% (54.8 vs 96.92, $P<0.001$), HOMA-IR (7.27 vs 3.38, $P<0.001$). Conclusion: The short-term insulin therapy, including normal-weight and overweight patients with DM T2 results in an improvement of glycoregulation, decrease in insulin resistance and recovery of secretory ability of beta cells of endocrine pancreas. Key words: secondary failure, diabetes mellitus type 2, HOMA-β%, HOMA-IR.

Clinical pharmacology of insulin aspart: Hyperinsulinemic euglycemic clamp study of the biosimilar product

Artem Dorotenko[1], Igor Makarenko[1], Anna Mosikyan[2], Maksim Magruk[2] & Roman Drai[3]
[1]GEROPHARM, Pharmacology and early phase of clinical trials department, Street Petersburg, Russian Federation; [2]GEROPHARM, Medical department, Street Petersburg, Russian Federation; [3]GEROPHARM, RnD, Street Petersburg, Russian Federation

Introduction
Rapid-acting insulins is widely used in the treatment of either type 1 diabetes mellitus, or type 2 diabetes mellitus. A mealtime injection of rapid-acting insulin, such as insulin aspart, allow the diabetic patients to control the levels of post-prandial glucose. The clinical development plan of the insulin biosimilarsusually contains pharmacology studies to evaluate pharmacokinetics (PK), pharmacodynamics (PD) and clinical safety of the investigational products.
To demonstrate Insulin Aspart, solution for intravenous and subcutaneous administration, 100 U/ml (GEROPHARM, Russia) and NovoRapid Penfill, solution for intravenous and subcutaneous administration, 100 U/ml (Novo Nordisk, Denmark) have comparable PK/PD profiles hyperinsulinemic euglycemic clamp (HEC) in healthy volunteers has been performed.
Methods
26 healthy male Caucasian volunteers aged between 18 to 50 years were subjected in a randomized, double-blind, crossover study of the comparative pharmacokinetics of the two different formulations of insulin aspart: Insulin Aspart, GEROPHARM (test drug, T) and NovoRapid Penfill, Novo Nordisk (reference drug, R). Subjects who met the inclusion/non-inclusion criteria underwent the procedure of HECfollowing the subcutaneous injections either T (0.3 IU/kg) or R (0.3 IU/kg) in the abdomen region. After the performed injections of insulin aspart, the levels of plasma glucose were monitored every 5 minutes for 8 hours. The adjustment of the glucose infusion rates was based on the blood glucose measurements. This data was used to evaluate the PD profiles of investigational drugs. Regular blood samplingwas performed during the study. The insulin concentrations in the blood samples of the subjects were determined using avalidated ELISA method. The results of the analytic procedures were used to calculate the PK parameters of insulin aspart and fit the concentration-time curves. The clinical study was approved by The Ministry of Health of the Russian Federation, as well as by the independent local ethical committees (NCT04184466).
Results
The confidence intervals for the ratio of the geometric mean of Insulin Aspart (GEROPHARM) for C_{ins} and AUC_{ins-t} were 110.51–124.02% and 102.12–110.24% respectively; for GIR_{max} and AUC_{GIR0-t} – 94.35–117.53% and 91.09–113.84%. Both PK and PD parameters were well within 80–125% limits for establishing comparability between two formulations of insulin aspart.
Conclusions
Our data demonstrated, thatInsulin Aspart (GEROPHARM) and NovoRapid Penfill (NovoNordisk) have comparable PK and PD profiles in healthy subjects in HEC paradigm. Thus, in this clinical trial the high level of similarity of R and T formulations of insulin aspart was experimentally confirmed.

AEP367

Does short term intensive insulin therapy in newly diagnosed type 2 diabetes mellitus delay eventual insulin dependence?

Madhuri Patil[1] & Uma Gunasekaran[2]
[1]University of Texas Health Science Center at Tyler / CHRISTUS Good Shepherd Health System, Longview, United States; [2]University of Texas Southwestern Medical Center, Endocrinology, Dallas, United States

In patients with type 2 diabetes mellitus (T2DM), dysfunction of β-cellsstarts years before the diagnosis of T2DM and rapidly worsens after overt hyperglycemia. Use of short-term intensive insulin therapy (STIIT) at the time of diagnosis of overt hyperglycemia has shown clinical recovery of β-cells for up to 2 years. A systematic literature review of studies looking for the effect of STIIT, used within two years of diagnosis of T2DM, on the duration from relapse of hyperglycemiato eventual insulin dependence is presented in this abstract. The key phrases ‘type 2 diabetes mellitus’, ‘short-term insulin therapy’, ‘β-cellfailure’, and ‘permanent insulin dependence’ were used to search English literature. For simplicity the duration of diabetes in these studies was divided into three periods: Period 1. Diagnosis of T2DM to end of STIIT which includes total weeks of STIIT, Period 2. End of STIIT until relapse of hyperglycemia i.e. total glycemic remission period, and Period 3. Relapse of hyperglycemia to permanent dependence on insulin therapy. Studies were excluded if all of their participants had diagnosis of T2DM for more than 2 years at the time of inclusion, i.e., if period 1 was more than 2 years. Six clinical trials involving STIIT were identified (Period 2). No studies that examined the clinical course of T2DM in their patients beyond the relapse of hyperglycemia (Period 3) were identified. This literature review identified a lack of data about this important clinical question- do ‘recovered’ β-cells from STIIT exhibit a better response to non-insulin therapies after the end of period 2 and, hence, delay the secondary β-cell failure in period 3?There is a need to conduct studies with longer follow up to characterize the differences in the disease course between patients treated with STIIT and patients treated with non-insulin therapies. This can help us understand the scope of STIIT beyond the initial functional remission of β-cells.

Nurse education in diabetes and endocrinology – important part of the improvement of care provided to people with diabetes and other endocrine disorders

Marina Saxvadze[1], Ramaz Kurashvili[2], Liana Tsutskiridze[3] & Elena Shelestova[4]
[1]Tbilisi Cancer Center, Surgical Department, Tbilisi, Georgia; [2]National Center for Diabeted Research, Tbilisi, Georgia; [3]National Center for Diabeted Research, Clinical Department, Tbilisi, Georgia; [4]National Center for Diabeted Research, Diabetes Education and Nutrition Department, Tbilisi, Georgia

Background and aims
Diabetes (DM) is a huge global health emergency of the 21st century. Around 463 million adults haveDM. Every 2-nd adult with DM is undiagnosed. Over 374 million people have impaired glucose tolerance, their risk of developing DM is very high. According to Diabetes Atlas-2019 DM national prevalence for Georgia is 7.1%. Increasing prevalence of DM/other endocrine disorders, specific health needs ofthese populations, increasing load on healthcare require more active nurse involvement inprovision of DM/endocrine care. Though globally nurses role in DM prevention/care is important, there are no trained diabetes or endocrine nurses in Georgia, who receive properknowledge on DM/other endocrine problemswhile studying at the collage.
Methods
Under the initiative of the Association of Professional Development of Georgian Nurses and Nurse Assistants Post Diploma Training of nurses was initiated in 2015. A Memorandum of Understanding and Support was signed with Georgian Union of Diabetes and Endocrine Associations, and DM was included as one of the 10 Modules of the Training Program. Diabetes Module for nurses started in 2016; it is a 2-day, 10 hour training; screening, diagnosis, management and prevention of DM/ its complication are discussed. Contracts were signed with several in-hospital and out-hospital medical facilities. Besides, together with Georgian Association of Medical Education and Evidence-Based Medicine a Summer School on Diabetes/Endocrinology for Nurses is functioning since 2016.
Results
Trainings were carried out in 5 cities; over 300 cardiology, surgery, endocrinology, obstetrics/gynecology, laboratory nurses were trained. During initial testing 3–4 out of 5 replies were wrong. Final testing showed significant improvement in knowledge. Manual for Nurses was prepared/printed. Medical facilities requested continuation of trainings continue; Course in Endocrinology for nurses will start in 2020.
Conclusion
Diabetes as one of non-communicable diseases (NCDs) has allocated a large proportion of cost, time and human resources of health systems. If other endocrinopathies are added the burden may ruin almost any health system. Nurses are health care providers who should be actively involved in prevention and early detection of DM/its complications and other endocrine disorders. After adoption of UNO Political Declaration and WHO Resolutions on NCDs, Governments are paying more attention to these conditions. The role of nurseshas started to change. We need not only totrain nurse-podiatrists, educators, diabetes/endocrine nurses, but to train all nurses in DM/endocrinology. There is an increased need for establishing new nurse specialties, such as nurse-practitioners/nurse-specialists to provide high-quality diabetes/endocrine care.

Insulin regulated aminopeptidase (IRAP) inhibition affects glucose metabolism in obese pre-diabetic Zucker rats

Katarina Krskova[1], Lucia Balazova[1], Viktoria Dobrocsyova[1], Erika Balogova[1], Maciej Suski[2], Rafal Olszanecki[2] & Stefan Zorad[1]
[1]Institute of Experimental Endocrinology, Biomedical Center, Slovak Academy of Sciences, Bratislava, Slovakia; [2]Chair of Pharmacology, Jagiellonian University Medical College, Kraków, Poland

Skeletal muscle and adipose tissue has been identified as an endocrine organ and their metabolism exerts an impact on whole-body metabolism. Endocrine functions attributed to adipokines and myokines are involved in body weight regulation and insulin sensitivity. Obesity is associated with dys-regulation of adipose tissue and skeletal muscle metabolism and is accompanied with insulin resistance. Our study investigates the effect of insulin regulated aminopeptidase (IRAP) inhibition on the regulatory mechanisms of metabolism of subcutaneous and visceral adipose tissue and skeletal muscle in the fully developed stage of obesity and insulin resistance in Zucker rats. The obese Zucker rats, the genetic model of obesity, pre-diabetes and metabolic syndrome, were administered with an IRAP inhibitor – HFI-419 (MerckMillipore, Germany) at a dose of 29 µg/100 g/day by osmotic minipumps. Glucose utilization was monitored by the intraperitoneal glucose tolerance test (ipGTT) and measured in the blood of the rat tail. In the tissues of interest, gene expression was determined by real-time quantitative PCR and protein expression was measured by Western blot. IRAP inhibition improved glucose utilization and significantly decreased the area under the curve for the glucose level during ipGTT. In visceral adipose tissue, we observed significantly up-regulated protein expression of Akt protein and AS160 (Akt substrate 160 kDa) protein phosphorylation in obese rats treated with HFI-419 in comparison with obese controls, indicating stimulation of the insulin receptorsignalling pathway. In subcutaneous fat depot, administration of HFI-419 significantly reduced expression of glucose transporter GLUT1. In skeletal muscle, significantly increased expression of sirtuin 1 (SIRT1) and superoxide dismutase1 and 2 (SOD1, SOD2), was found. Our results showed an improvement in glucose utilization during theglucose tolerance testafter administration of an IRAP inhibitor in insulin resistant obese Zucker rats. In the tissues studied, we revealed different molecular mechanisms leading to improvement of insulinsensitivity of these tissues. We conclude that thepositive metabolic effect of the IRAP inhibitor observed in obese rats is the improvement of glucose transport into adipocytes and theregulation of redox balance inskeletal muscle. The study was supported by grants VEGA 2/0174/17 and APVV-15-0229 grants.

Relationship of blood dopamine and leptin with anthropometric data in childhood obesity

Liudmila Viazava[1], Anzhalika Solntsva[2] & Elena Zaytseva[3]
[1]Republican Center of Medical Rehabilitation and Balneotherapy, Endocrinological department, Minsk, Belarus; [2]Belarusian State Medical University, The 1st department of children disease, Minsk, Belarus; [3]National Institute for Higher Education, Mins, Belarus

Background
Some of neurohormonal peptides, such as dopamine and leptin, get involved in modulationof food ingestion, eating behaviorand obesity.
Study aim was to detect associations blood dopamine, leptin and anthropometric indexes to predict the probability of obesity in children.
Material and methods
223 children (11–17.9 y.; II – V Tanner stages) with BMI ≥2 SDS and BMI=±1 SDS (normal weight (NW) were included into retrospective cross-sectional study. We use anthropometric data (weight, height, BMI, SDS BMI); blood dopamine (DA) and leptin (L) concentrations results (enzyme-linked immunosorbent assay method). Children were split up into three groups: NW (n=30); alimentary obesity (AO, SDS BMI ≥2 &≤4; n=86), extreme obesity (EO, SDS BMI>4; n=107) andalso into gender (girls/boys; n=111/112) and pubertal subgroups (early (EP)/late puberty (LP); n=71/152). Statistical analysis was performed using non-parametrical indexes, Spearman's correlations and binary logistic regression (P<0.05).
Results
DA levels were increased in EO children (30.00 (7.60–97.50) pg/ml) relatively NW (6,28 (4,57–26,54) pg/ml; P=0,003) and AO peers (10,44 (4,80–46,88) pg/ml; P=0,01). Only boys had similar pattern of blood DA differences: 31.88 (9,69–93,75) pg/ml in EO group, compared to NW – 6,46 (3,73–26,54) pg/ml; P=0,008) and AOpeers (7,83 (4,47–13,04) pg/ml; P=0,001). Girls did not have DA differences (P>0.05). DA levels had weak positive correlations with BMI (r=0.4; P<0,001) and BMI SDS (r=0.4; P=0.002)in the both gender LP patients. L concentrations gradual raised from NW group (4.77 (2.43–11.06); P_{NW-AO}<0.001); through AO (22.65 (12.60–35.86); P_{AO-EO}=0.02) to EO peers (31.29 (18.67–50.70) ng/ml; P_{EO-NW}<0.001). Girls had the same

pattern of raised Lconcentrations ($P \leq 0.001$). L levels had mild correlation with BMI ($r=0.6$; $P<0.001$) and BMI SDS ($r=0.7$; $P<0.001$) in EP childrenrelatively to LP peers ($r=0.3$; $P=0,01$ and $r=0.4$; $P=0,001$ properly). We developed math models to predict the probability of obesity depends on the DA and L concentrations. These models had high percentage of correct predicted values (86.7 – 90.4%), applied to prognosis the probability of a progressive childhood obesity and its variants (AO and EO).
Conclusion
DA concentrations were associated to BMI and SDS BMI in children with obesity particularly in boys and LP subgroups ($P<0.05$). L levels had positive relationships with anthropometric indexes mostly in girls and EP participants ($P \leq 0.001$). Math models, based on the DA and L concentrations, allowed to predictthe probability of obesity (AO and EO) in children.

The influence of obesity on changes in adipokines during the menstrual cycle

Monika Šrámková[1,2], Lucie Kolátorová[1], Josef Včelák[1], Olga Lischkova[1], Luboslav Stárka[1] & Michaela Dušková[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Department of Medical Chemistry and Clinical Biochemistry, Prague, Czech Republic

The purpose of the menstrual cycle is to prepare the egg for fertilization and implantation. The changes and functions of the basic steroid hormones during the menstrual cycle are well known. However, changes to other hormones occur during the menstrual cycle as well, including those influencing the intake of food. These changes have been described inconsistently in the literature, especially considering differences in overweight and obese women. The aim of this study was to describe the relationships between hormones associated with food intake and steroid during the menstrual cycle, along with differences between normal-weight and overweight women. The study included 27 healthy women (average age 28.0±3.4 years) with regular menstrual cycles (cycle length 28±days) who did not use any pharmaceuticals. These women were followed for one menstrual cycle, with regular measurements of body composition parameters, blood samples taken (fasting between 0700 and 0800 h), and daily food intake noted. We analyzed the following steroid hormones: cortisol, cortisone, DHEA, 7α-OH-DHEA, 7β-OH-DHEA, 7-oxo-DHEA, pregnenolone, 17-OH-pregnenolone, testosterone, aldosterone, corticosterone, androstenedione, estrone, estradiol, estriol (LC-MS/MS), and progesterone (RIA); complex of hormones associated with food intake: c-peptide, ghrelin, GIP, GLP-1, glucagon, insulin, leptin, PAI-1, resistin and visfatin (immunoassay), and LH, FSH, SHBG (radioimmunoassay), glycemia, osteocalcin, and the lipid spectrum (immunoassay). According to BMI the women were divided into two groups: those with BMI up to 25 ($n=15$), and those with BMI 25–30 ($n=12$). The study was approved by the local Ethical Committee. The steroid hormones showed similar physiological changes during the cycles of both groups. 7β-OH-DHEA was higher during all cycle in normal weight women.17-OH pregnenolone and androstenedione were higher in the overweight women. As expected, hormones associated with food intake, osteocalcin and SHBG were significantly different between the two groups. Leptin levels were significantly different in overweight women, and their profile lacked the typical consistent changes during the menstrual cycle. In contrast, while the adiponectin profile was similar in both groups, the levels of adiponectin were significantly higher in the overweight women.
Our study confirmed differences in the levels of certain hormones in overweight women during the menstrual cycle. These results should help improve our understanding of menstrual cycle problems that can occur in women after their weight increases.

The effect of SNP (rs174537) in FADS1 gene on fatty acid composition in serum lipids

Tereza Metelcová[1,2], Markéta Vaňková[2], Hana Zamrazilová[2], Milena Hovhannisyan[2], Eva Tvrzická[3], Barbora Staňková[3], Martin Hill[2], Josef Včelák[2] & Marie Kunešová[2,3]
[1]1st Medical Faculty, Charles University, Prague, the Czech Republic; [2]Institute of Endocrinology, Prague, Czech Republic; [3]4th Department of Internal Medicine, 1st Medical Faculty, Charles University, Prague, Czech Republic

Background
Fatty acid desaturase 1 (*FADS1*) gene controls the fatty acid metabolism pathway in the human body (Sergeant *et al*., 2012). Single nucleotide polymorphism (SNP) in *FADS1* gene and percentage of polyunsaturated fatty acids inserum lipids was associated (Klingel *et al*., 2018). Genetically predisposition to higher plasma arachidonic and stearic acid levels were associated with incidence oflarge-artery stroke and venous thromboembolism (Yuan *et al*., 2019).
Methods
Samples obtained in the COPAT project (Childhood Obesity Prevalence And Treatment) were used. Genomic DNA was extracted from peripheral blood leucocytes in whole blood samples. For genotype analysis TaqPath (LC480, Roche) was used. Sample of 754 adolescents (376 girls and 378 boys) from the Czech Republic was examinated in this project. Association of SNPs with fatty acid composition was conducted using the SIMCA-P12 (Umetrics, Umea, Sweden).
Results
The relationship of the risk allele (rs174537) with 12 fatty acids was significant. In SNP (rs 174537) has been relationship between risk allele and two fatty acids (20:4 n-6; 18:3 n-6) in all three lipid classes.
Conclusion
Single nucleotide polymorphisms (rs174537) in *FADS1* gene had a significant negative relationship with two fatty acids, (20:4 n-6 and 18:3 n-6), in all three lipid classes.
Conflict of Interest
None Disclosed.

The educational training to the Mediterranean diet-like pattern is followed by improvement in cardiometabolic parameters and ecology of the microbiome in children with obesity: Preliminary results of the GOOD DAY trial

Roberta Ricotti[1], Francesca Archero[1], Valentina Landoni[1], Valentina Mancioppi[1], Marina Caputo[2], Simonetta Bellone[1], Arianna Solito[1], Giorgia Novello[3], Elisa Gamalero[3], Flavio Mignone[3], Maria Cavaletto[3], Emanuela Agosti[4], Elisa Bona[3] & Flavia Prodam[2,4]
[1]SCDU Pediatrics, University of Piemonte Orientale, Department of Health Sciences, Novara, Italy; [2]SCDU Endocrinology, University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]University of Piemonte Orientale, Department of Sciences and Technological Innovation, Alessandria, Italy; [4]University of Piemonte Orientale, Department of Health Sciences, Novara, Italy

Introduction
In the pediatric population the progression of obesity-related diseases can be delayed or prevented through changes in lifestyle, including the promotion of a Mediterranean-like dietary (MD) pattern.
Objective
We aimed to assess the efficacy of an educational training to MD based on gamification with respect to a conventional weight-loss treatment in obese

pediatric subjects on weight decreased and cardiometabolic risk factors (GOOD-DAY Trial; NCT03154255). We also aimed to evaluate the modulation of gut microbiome ecology with respect to dietary changes and clinical parameters.
Methods
A total of 67out of planned 80 subjects (6 and 18 years) with obesity, diet naïve or with failure to a previous weight loss program have been already recruited. We collected auxological, metabolic and nutritional parameters (KIDMED score; IDEFICS food frequency questionnaire) every 3 months for 24 months. Stools were collected three times: at T0, after six months (T2), and 12 months (T4) of interventions (gamification on MD, GAME, or conventional diet loss program, NO GAME). DNA was extracted directly from 0.25 g of stool using the Power SoilRKit. DNA was amplified with primers for the V3 and V6 regions of 16S rDNA tagged with Multiplex Identifier sequences using Microbiota Solution B Kit optimized for Illumina Miseq sequencing. Raw FastQ sequences were analyzed using MicrobAT Software. Statistical analyses were performed using R software. Metabolomic analyses are ongoing.
Results
We present clinical data of the first 35 subjects who ended the study. The microbiome data were analyzed for all the subjects at baselines and 14 out of 35 who concluded the study at T2 and T4. At baseline, clinical, metabolic characteristics and microbial communities were homogeneous among children; unclassified *Prevotella sp*. were more present in prepubertal subjects. All the children decreased their weight, waist circumference ad glucose levels at fasting at T4. Total and LDL cholesterol decreased, and HOMA-beta increased only in GAME children at T4, irrespective of weight loss. At T4, *Firmicutes*sp. increased and *Bacteroides sp*. decreased in the GAME group, diversely by NO GAME. The heatmap of the cluster revealed that, whether *Bifidobacterium adolescentis* increased in all the subjects over time, *Actinobacteria* and *Bifidobacterium longum subsp. null* also increased in the GAME group at T4.
Discussion
These preliminary results highlight the importance of adherence to the MD in weight loss, by improving some metabolic parameters. Gut microbiome seems could have a role on metabolic changes following lifestyle changes inspired to MD.

Liraglutide downregulates the expression of miRNA-424 in patients with obesity

Georgios K Dimitriadis[1], Federica Dimitri[2], Danielle Bate[3], Bianca Leca[3], Allan Davasgaium[3], Gyanendra Tripathi[4], Alexander D Miras[5], Francesco Rubino[6], Mark Christian[7] & Harpal S Randeva[3]
[1]King's College Hospital, Endocrinology and Metabolism, United Kingdom; [2]University of Warwick, Life Sciences, Coventry, United Kingdom; [3]University Hospital Coventry & Warwickshire, United Kingdom; [4]University of Derby, United Kingdom; [5]Imperial College London, Hammersmith Campus, United Kingdom; [6]King's College London, United Kingdom; [7]Nottingham Trent University, United Kingdom

Aims
Liraglutide 3 mg once daily is an approved, prescription injectable Glucagon Like Peptide-1 receptor agonist that, when used with a low-calorie diet and increased physical activity, can reduce excess weight in patients with obesity. MiRNAs are small non-coding single stranded RNAs that regulate gene expression post-transcriptionally by inhibiting their mRNA target translation into proteins. MiRNAs can be secreted in the blood stream and affect the molecular pathways of distal cells. Several studies have demonstrated that obese patients express a differential pattern of circulating miRNAs compared to lean subjects. The effects of liraglutide in circulating miRNAs remain largely unknown.
Methods
To investigate whether treatment with 3 mg liraglutide can affect the level of circulating miRNAs, we tested the expression of several miRNAs in the plasma of 16 obese patients enrolled in a clinical trial at baseline and after 8 weeks of treatment with qPCR analysis using the Locked Nucleic Acid technology. RNA was extracted using miRNeasy Serum/Plasma Advanced Kit (Qiagen) and reverse transcribed into cDNA using miRCURY Universal RT Kit (Qiagen). MiRNA expression was analysed using SYBR green (Sigma) and LNA primer assays (Qiagen). Cel-miR-39-3p and Unisp6 spike-ins were used as controls of RNA extraction and reverse-transcribed respectively to normalise the expression of the miRNAs of interest.
Results
At baseline, participants had a mean weight of 120.5 kg (±19.64) and BMI of 42.18 kg/m^2. At week 8, participants had lost a mean of –6.1 kg (S.D.± 2.39) of body weight ($P<0.01$). Among the tested miRNAs, expression of miR-424 was significantly ($P=0.008$) decreased after 8 weeks of treatment. Statistical analysis was performed using paired, two-tailed student t-test with level of significance set at $P<0.05$.
Conclusions
Although there has been growing interest in the roles of obesity induced miRNAs in insulin resistance and T2DM, their molecular targets and regulation mechanism are not completely understood. According to evidence, upregulated expression of miR-424 impairs insulin-signaling and insulin-induced glycogen synthesis in hepatocytes of patients with obesity. Herein we demonstrate that miR-424 induced by obesity is reduced after treatment with liraglutide and this could be a potential weight-loss independent mechanism of action by which liraglutide exerts its beneficial effects on insulin resistance.

Predictors of metabolic disease in normal weight postmenopausal women: A cross-sectional study

Eleni Armeni[1], Stavroula A Paschou[1], Areti Augoulea[1], Dimitrios Rizos[2], George Kaparos[2], Anastasia Palaiologou[2], Anastasia Soureti[1], Iliana Karagouni[1], Michael Apostolakis[1] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Hormonal and Biochemical Laboratory, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Introduction
The aim of this study was to evaluate predictors of metabolic disease in normal weight postmenopausal women.
Patients and methods
This cross-sectional study included 457 non-obese postmenopausal women, recruited from the Menopause Clinic of Aretaieio Hospital, National and Kapodistrian University of Athens. The diagnostic criteria of the International Diabetes Federation for the definition of Metabolic Syndrome were used, in order to classify women into metabolically healthy (<3 criteria, MHNW) and metabolically obese (≥3 criteria, MONW).
Results
Compared to the MHNW phenotype, MONW was positively associated with chronological age (58.9±7.9 years vs 54.3±6.6 years, $P<0.001$), years since menopause (YSM, 12.4±8.5 years vs 7.1±6.2 years, $P<0.001$), waist circumference (WC, 92.1±6.6 cm vs 82.3±8.4 cm, $P<0.001$) and waist to hip ratio (WHR, 0.87±0.06 vs 0.81±0.08, $P<0.001$). ROC curve analysis showed that WC represents a superior predictor of MONW compared with WHR (WC, AUC 0.815, 95% CI 0.773–0.858). Accordingly, WC of at least 86.5 cm predicted the MONW phenotype with sensitivity 72.7% and specificity 69.4%. Multivariate regression analysis showed that WC of at least 86.5 cm predicted the MONW phenotype in a model adjusted for age and YSM (OR 4.689, 95% CI 2.626–8.373, $P<0.001$).
Conclusions
This study provided evidence that MONW women have increased chronological age and YSM compared with MHNW women. Metabolic disease can be predicted by a WC greater than 86.5 cm, irrespectively of age and YSM.

Phase angle (PA) and body composition changes in obese patients with associated comorbidities (by AACE criteria) through a very low calorie diet (VLCD) program

Isabel Maria Cornejo Pareja, Isabel M[a] Vegas-Aguilar, Beatriz Fernández-Medina, Francisco J Tinahones & Jose Manuel García-Almeida
Endocrinology and Nutrition Department, Virgen de la Victoria Universitary Hospital, Malaga, Spain

Introduction
Obesity is defined as a chronic disease by AACE/ACE. Includes presence/severity of complications. VLCD diets induce relevant weight loss by improving these complications. PA is a bioelectric measure of the cell mass and it is marker a global prognostic factor of cellular functionalism.
Methods
Case-control retrospective study of severe obesity in a weight loss program comparing intensive intervention (41 cases, VLCD 800 kcal/d, 1g protein/kg) vs conventional (22 controls, cardiac rehabilitation program with Mediterranean diet and exercise). Clinical variables (AACE), anthropometric (impedance measurement), analytical and pharmacological changes are measured.
Objective
To evaluate anthropometric changes, body composition and bioelectrical measures such as PA, resistance (Rz) and reactance (Xc), analytical changes and effects on obesity complications and therapeutic changes in both groups.
Results
Average age in cases 58.0±13.5 years, (59% women) with a BMI of 46.3±10.0 kg/m^2. 79.3% arterial hypertension, 93% carbohydrate alterations (82.7% T2DM, 10.3% Prediabetes), 82.8% dyslipidaemia, 44.5% steatosis, 10.3% polycystic ovary, 55.1% SAHS, 55.2% osteoarthritis, 27.5% gastroesophageal reflux, 34.5% urinary incontinence, 20.7% immobility, 86.2% psychological disorder. 55% used ≥3 antihypertensive drugs, 48% insulin, 59% statins and 18% fibrates. 6 months after intervention: We observed a weight loss of 16.9±12.8 kg with a BMI reduction of 6.24±4.69 kg/m^2 in cases compared to –2.7±0.9 kg and –0.92±0.3 kg/m^2 in controls. In cases, there was a decrease in Fat-Mass (FM) of – 14.7±10.2 kg with a slight decrease in Fat-Free-mass (FFM) –2.3±7.0 kg and a rise in Body-Cell-Mass (BCM)+3.0±6.4 kg. In VLCD group, there was a significant increment in PA+1.18±0.98 associated with an increase in Rz +35.0±59.9 and Xc +11, 8±10.2 (P<0.05), related with hydration –3.8±4.6% and nutrition changes+93.0±195.2 Ucr/m, without changes in control group. An important improvement in glycaemia, cholesterol, triglycerides, transaminases and microalbuminuria was evident in both groups, being more relevant with intensive intervention. Reduction HbA1c 2.1±0.4% (P<0.001) vs 0.4±0.4% (P=0.36).
Conclusions
VLCD produces an improvement in body composition (PA and BCM) with reduction in obesity complications (2 stage of AACE), associated a reduction in treatments needs (insulin therapy suspension in 84% of cases, reduction in others drugs) and metabolic changes (HbA1c): fundamental objectives in the intervention.

The additive effect of obesity in the incidence of neurocognitive disorders in offspring of women with gestational diabetes

Andreu Simó, Veronica Perea, Maite Valverde, Carmen Quirós, Aida Orois, Luis García-Pascual & MªJosé Barahona
Hospital Universitari Mútua de Terrassa, Endocrinology, Terrassa, Spain

Aim
Gestational diabetes (GDM) has been associated with an increased risk ofneurocognitive outcomes in offspring such as attention deficit/hyperactive disorders (ADHD) and autism spectrum disorders (ASD). However GDM-related comorbidities (obesity or excessive weight gain –EWG-) in this setting have been scarcely studied. So, the aim of our study was to estimate the risk of ADHD and ASD in this population.
Material and methods
Cohort study. Singleton pregnancies complicated by GDM between 1991–2008 were selected. Maternal data was prospectively collected during pregnancy. ADHD and ASD diagnostic was obtained from medical records. Cox proportional hazards modeling adjusting for potential confounders were applied to estimate the effect of maternal obesity and EWG during pregnancy.
Results
A total of 1118 pregnancies were selected. The median follow-up was 17.5 years [14.5–21.4] with 12% (n=142) and 0.01% (n=14) of subjects diagnosed of ADHD and ASD, respectively. As table 1 shows, maternal obesity increased the risk of ADHD. EWG was only associated with increased risk of ADHD in the early-GDM subgroup. Neither maternal obesity nor EWG were associated with ASD. Insulin use during pregnancy did not modify the results.

Table 1

		Total cohort (n=1118)	Early GDM (n=202)	Late GDM (n=916)
ADHD	**Maternal weight (kg/m²)**			
	18.5–24	Ref.	Ref.	Ref.
	<18.5	0.61[c] (0.09–4.40) 0.63[a] (0.09–4.53)	7.19[c] (0.83–62.15) **11.80[a] (1.26–110.0)**	–

ASD	**Maternal weight (kg/m²)**			
	18.5–24	Ref.	Ref.	Ref.
	<18.5	n/a	n/a	n/a
	25–29	1.90[c] (0.55–6.59) 2.36[a] (0.66–8.42)	n/a	1.61 (0.43–5.98) 2.42 (0.61–9.58)
	≥ 30	2.37[c] (0.63–8.82) 2.76[a] (0.72–10.6)	n/a	0.80 (0.09–6.91) 0.66 (0.074–6.11)
	EWG	0.44[c] (0.57–3.42) 0.64[a] (0.08–5.20)	2.09[c] (0.18–23.08) 3.14[a] (0.26–38.60)	n/a

Data was expressed as Hazard Ratio and 95% Confidential Interval. [c]: crude model. [a]: adjusted model including maternal age at pregnancy, weeks of gestation, C-section, Apgar <3 at min 1 or 5, small for gestational age (percentile <10) and current smoking during pregnancy.
ADHD: attention deficit/hyperactive disorder. ASD: autism spectrum disorder. EWG: excessive weight gain during pregnancy according to OMS criteria. Early/Late gestational diabetes mellitus (GDM): diagnosed </≥ 26 weeks of gestation, respectively.

Conclusions
Beyond deleterious effect of hyperglycaemia, maternal weight itself plays a role increasing the risk of ADHD in offspring. Regarding ASD, the low number of subjects did not allow reliable conclusions.

Bariatric surgery impact on cardiovascular risk factors: Is age a factor to consider?

Fernando Mendonça[1], Maria Silva[1], Maria João Ferreira[1], Daniela Salazar[1], Vanessa Guerreiro[1], Jorge Pedro[1], Joao Sergio Neves[1], Sara Viana[1], Sandra Belo[1], Ana Varela[1], Paula Freitas[1], Davide Carvalho[1] & CRIO group .[2]
[1]Centro Hospitalar e Universitário de S. João, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar e Universitário de S. João, Centro de Responsabilidade Integrado de Obesidade, Porto, Portugal

Introduction
Despite the abundance of data addressing the influence of patient's age on surgery-related complications, its impact on several cardiovascular risk factors following bariatric surgery has been overlooked.
Methods
Retrospective unicentric study of 1728 obese patients who underwent bariatric surgery between January/2010 and June/2015. Patients were divided in three groups, according to their age at surgery: <40 (n=751), 40 to 59 (n=879), and ≥60 years old (n=98). Parameters with cardiometabolic impact, such as body anthropometric measures, lipid profile, and glycemic status, before and 24 months after surgery, were compared between these groups. A multiple linear regression was performed, adjusting differences between groups for sex, surgery type, and body mass index (BMI) variation.
Results
The group <40 years old presented more weight loss (–35.4±9.0 kg, P<0.001), greater BMI reduction (–15.8±6.1 kg/m^2, P <0.001), and larger changes in waist (–34±13.8 cm, P<0.001) and hip circumferences (–28.7±11.9 cm, P<0.05).The group of ≥60 years old presented the heaviest reduction in fasting glucose (–23.3±11.0 mg/dl, P<0.001) and A1c

(–0.7±1.0%, $P<0.001$), and also had a tendency to have the biggest changes in systolic blood pressure (–14.7±18.7 mmHg; $P=0.071$).
Conclusion
Patients with ≥60 years old benefit the most from bariatric surgery regarding parameters with cardiometabolic impact, presenting heavier reductions in fasting glucose as well as A1c, and a tendency towards a higher decrease in systolic blood pressure. No clinically-significant differences in lipid profile were observed between groups.

TGFβ1 downregulates hepatic SHBG production by decreasing HNF-4α levels via SMAD and STAT3 pathways

Laura Brianso-LLort, Lidia Fuertes-Rioja, Cristina Hernandez, Rafael Simo & David Martinez
Vall d'Hebron Research Institue, Diabetes and Metabolism, Barcelona, Spain

Low plasmasex hormone-binding globulin (SHBG) levels are present in fatty liver disease, which represents a spectrum of diseases ranging from hepatocellular steatosis through steatohepatitis to fibrosis and irreversible cirrhosis. We are interested in studying the molecular mechanisms by which plasma SHBG levels are reduced in fatty liver disease. In this regard, we have previously shown that fat accumulation in the liver reduces SHBG production by reducing hepatic nuclear factor 4 alpha (HNF-4α), a main regulator of SHBG expression. Transforming growth factor β1 (TGFβ1) plays an important role in the pathogenesis of liver fibrosis, being involved in activation of hepatic stellate cells, stimulation of collagen gene transcription, and modulation of matrix metalloproteinase expression. The aim of the present studywas to evaluate the role of TGFβ1 in regulating hepatic SHBG production. For this purpose, *in vitro* and *in vivo* studies were performed using human HepG2 cells and human *SHBG*transgenic mice. Our results showed that TGFβ1 treatment reduces SHBG production (mRNA and protein) in HepG2 cells. In addition, human *SHBG* transgenic mice treated withTGFβ1 showed a significant reduction SHBG expression as well as in plasma SHBG levels. Mechanistically TGFβ1 downregulates HNF-4α levels via SMAD and STAT3 pathways through TGFβ1 receptor I. Taking together, we found for the first time that TGFβ1 regulates hepatic SHBG production. These results may explain why patients with fibrotic livers show low plasma SHBG levels.

Cryptogenic cirrhosis and metabolic syndrome: What relationship?

Samir bradai, Imen Akkari, Mrabet Soumaya & Ben Jazia Elhem
CHU Farhat Hached, Sousse, Tunisia

Introduction
Cryptogenic cirrhosis is cirrhosis that remains of unknown etiology after an exhaustive investigation. The relationship of cryptogenic cirrhosis with metabolic syndrome is strongly suggested. The aim of this work was to study the clinical-progressive profile of cryptogenetic cirrhosis and to determine the frequency of the metabolic syndrome.
Patients and methods
This is a study collecting all cirrhotic patients over a period of 4 years in our gastroenterology department. The patients were divided into 2 groups (group 1 (G1): cryptogenic cirrhosis and group 2 (G2): cirrhosis of known etiology).
Results
A total of 71 patients were collected with an average age of 62 years. Viral origin was the most common cause (40.2%). Cirrhosis was classified as cryptogenic in 26.7% of cases ($n=19$). Metabolic syndrome was more common in group 1 with a significant difference (68.4% vs 30.4%, $P=0.006$). In group 1 patients, at least one criterion of the metabolic syndrome was found: diabetes (68.4%), hypertension (21.05%), dyslipidemia (10.5%) and overweight (73.6%)). Biologically, more than half of the patients in group 1 (57.8%) had disturbances in the liver balance: cytolysis in 21.05%, cholestasis in 15.8% and an isolated increase in GGT in 21, 05% of cases. By comparing the 2 groups, no significant difference was found in terms of sex, age and complications of cirrhosis except hepatocellular carcinoma which was more frequent in patients in group 2 with a significant difference ($P=0.05$).
Conclusion
Cryptogenetic cirrhosis and metabolic syndrome are strongly associated. This association argues in favor of the role of non-alcoholic steatohepatitis as the main cause of cryptogenetic cirrhosis. This association also does not expose to a greater risk of complications.

Association of osteoprotegerin and metabolic status in children with obesity

Hanna Mikhno[1], Anzhalika Solntsava[2] & Helena Dashkevich[3]
[1]2nd city children`s hospital, Belarus; [2]Belarusian State Medical University; [3]10th city clinical hospital

Objective
Determination of changes in metabolic status and osteoprotegerin concentrations in obese children.
Methods
We examined 221 children in the University Hospital (Minsk) from 2017 to 2019 yrs. Their anthropometric parameters (height, weight, body mass index (BMI)) were determined. Blood levels of osteoprotegerin (OPG), insulin were determined. In the biochemical blood test, the parameters of uric acid, insulin were evaluated. All children were divided into 2 groups: group 1 children with morbid obesity – 159 patients (98 boys(B)/61 girls(G)) (BMI more than 99th percentile for sex and age) (BMI 32,95±4,61 kg/m^2, age 14,16±2,28 years); group 2 – 62 patients (B/G=31/31) with alimentary obesity (BMI-95-99th percentile for sex and age) (BMI 27.86±2.04 kg/m^2, age 14.77±2.05 years). The control group consisted of 84 patients (B/G=45/39) with normal body weight (BMI 19.86±2.24 kg/m^2, age 14.32±2.11 years).
Results
In the subgroups of boys with obesity, there were significant differences in the concentration of uric acid in comparison with the control (alimentary obesity 426.55±62.25 mmol/l vs 242.58±49.90 mmol/l ($P=0.01$)), morbid obesity 324.10±59.33 mmol/l vs 242.58±49.90 mmol/l ($P=0.01$)). Girls with obesity have a significant increase in uric acid level in comparison with the control group (alimentary obesity 328.10±51.43 mmol/l vs 213.0±39.64 mmol/l ($P=0.0001$), morbid obesity 409.04±84.23 mmol/l vs 213.0±39.64 mmol/l ($P=0.0001$)). In boys with obesity higher concentrations of OPG were detected relative to the control group (alimentary obesity 259.98±108.07 ng/ml vs 225.12±55.88 ng/ml ($P=0.09$), morbid 322,22±82,14 ng/ml vs 225.12±55.88 ng/ml ($P=0.001$)). In girls with obesity higher concentrations of OPG were detected relative to the control group (alimentary obesity 326.84±104.02 ng/ml vs 254,39±78,29 ng/ml ($P=0.046$), morbid 347.33±93,50 ng/ml vs 254.39±78.29 ng/ml ($P=0.03$)). In boys with obesity higher concentrations of insulin were detected relative to the control group (alimentary obesity 18.9±12.7 μU/ml vs 9.1±4.2 μU/ml ($P=0.0001$), morbid 28.71±7.36 μU/ml vs 9.1±4.2 μU/ml ($P=0.001$)). In girls with obesity, the concentration of insulin relative to the control group was (alimentary obesity 20.28±6.25 μU/ml vs 14.10±6.80 μU/ml ($P=0.001$)) morbid obesity 23.32±9.65 μE/ml vs 14.10±6.80 μU/ml ($P=0.001$)).
Conclusion
Children with obesity have an increase in insulin and OPG rates.

Different effects of 5α-dihydrotestosterone treatment on hepatic and visceral adipose tissue inflammation in animal model of polycystic ovary syndrome

Danijela Vojnovic Milutinovic[1], Natasa Velickovic[1], Marina Nikolic[1], Ana Djordjevic[1], Jelena Brkljacic[1], Ana Teofilovic[1], Biljana Bursac[1], Sanja Jelaca[2] & Djuro Macut[3]
[1]Institute for Biological Research 'Sinisa Stankovic', University of Belgrade, Department of Biochemistry, Belgrade, Serbia; [2]Institute for Biological Research 'Sinisa Stankovic', University of Belgrade, Department of Immunology, Belgrade, Serbia; [3]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia and Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Polycystic ovary syndrome (PCOS) is a complex reproductive disorder that is usually associated with metabolic disturbances such as obesity, dyslipidemia and insulin resistance. In this study, female rats treated with nonaromatizable 5α dihydrotestosterone (DHT) were used as an animal model of PCOS. The aim of this study was to assess the presence of inflammation

in liver and visceral adipose tissue (VAT), which accompanies metabolic disturbances in animal model of PCOS. Female (21 days old) Wistar rats were treated subcutaneously with DHT pellets, while control animals received placebo pellets. Glucose, triglycerides, free fatty acids (FFA) were determined in blood plasma, while corticosterone was analyzed both in plasma and liver. Expression of genes and proteinsinvolved in lipid metabolism, such as sterol regulatory element binding protein1 (SREBP-1), fatty acid synthase (FAS) and acetyl-CoA carboxylase (ACC), lipin-1, adipose tissue triglyceride lipase (ATGL) and hormone-sensitive lipase (HSL), were analyzed in the VAT of treated rats. Tissue inflammationevaluated by nuclear factor kappa B (NFκB)protein level and intracellular distribution, as well as by TNFα, IL6 and IL1β mRNA levels. Glucocorticoid signaling was examined at the level of 11 beta hydroxysteroid dehydrogenase type 1 (11βHSD1) and 5α-reductase, as well asby glucocorticoid receptor (GR) leveland its subcellular distribution. The results showed that DHT treatment induced increase of lipogenic factors (SREBP-1, lipin-1, FAS and PEPCK), while the level of lipolytic enzyme HSL was decreasedin VAT. These molecular alterations were accompanied by adipocyte hypertrophy, visceral obesity and elevated plasma FFA and triglyceride concentrations. Those changes in lipid metabolism were possible trigger for low-grade inflammation observed in the VAT and characterized by NFκB activation and increasedIL6 and IL1β mRNA levels. In spite of increased VAT proinflammatory mediators, the level of proinflammatory cytokines, IL6 and IL1β, was decreased in the liver of DHT-treated rats, while the activation of NFκB remained unchanged. The state of suppressed inflammation in the liver could be an outcome of stimulated glucocorticoid signaling, as judged byincreased hepatic corticosterone level and GR activation. The augmentation of hepatic glucocorticoids could be a net result of increased expression of 11βHSD1 and decreased expression of 5β-reductase mRNA. In conclusion, the results showed that abdominal obesity and dyslipidemia in the animal model of PCOS were accompanied with hypertrophic adipocytes, lipid accumulation and low-grade inflammation in the VAT. However, these metabolic disturbances did not resultin hepatic inflammation due to increased tissue levels of glucocorticoids.

AEP383

Association of AdipoQ gene & its expression in adipose tissue with post prandial hypertriglyceridemia and glucose intolerance

Madhu SV[1], Brijesh Mishra[1], Basudev Banerjee[2], Aslam Mohd[1] & Vivek Agrawal[3]
[1]University College Of Medical Sciences, Endocrinology, New Delhi, India; [2]University College Of Medical Sciences, Biochemistry, New Delhi, India; [3]University College Of Medical Sciences, Surgery, New Delhi, India

Background
AdipoQ gene is located at the 3rd chromosome and encodes foradiponectin which is involved in fat metabolism and insulin sensitivity and plays a protective role in diabetes and atherogenesis. AdipoQgene variants have been reported to be associated with hypertriglyceridemia and risk of diabetes in different studies. We aimed to study whether polymorphism of rs2241766 polymorphic form of AdipoQ gene & its expression in adipose tissue is associated with post prandial hypertriglyceridemia and glucose intolerance.
Methodology
Polymorphism study of AdipoQ gene rs2241766 was carried out by using PCR-RFLP method in 200 age and sex matched subjects who were recruited in three groups {NGT ($n=67$), Prediabetes($n=66$) and T2DM($n=67$} with varying glucose tolerance following 75 gm OGTT. Gene expression studies using Real Time PCR were also done in subcutaneous and omental adipose tissue in 10 subjects from each group who were scheduled to undergo abdominal surgery. A Standardized oral fat challenge test was performed in all the study subjects to determine their post prandial Tg responses besides measurement of anthropometric (BMI, Waist) and Glycaemic (Fasting, Postprandial plasma glucose and HbA1c) indices and fasting serum insulin.
Results
The mean age of study subjects were 40.25±8.27 years and their mean BMI was 28.12±4.89 kg/m^2. There were 93 males and 107 females. TT geno types of rs2241766 polymorphic form of AdipoQ gene showed significantly lower 2 hr PPTg (190±84 vs 244±98 mg/dl $P=0.008$), Triglyceride area under curve (2445±1139 vs 2993±1436 mg dl^{-1} 2 hr^{-1} $P=0.05$), fasting-plasma glucose (99±13 vs 111±35 mg/dl $P<0.001$) and postprandial plasma glucose (140±46 vs 173±79 mg/dl $P=0.002$) as compared to GG+GT genotypes. Distribution of TT genotype of rs 2241766 polymorphic form of AdipoQ gene was found to be significantly lower inthe T2DM subjects (71% vs 79% $P=0.01$) as compared to NGT subjects. AdipoQ gene expression was 3.1 fold lower in prediabetes group ($P<0.01$) and 2.6 fold lower in T2DM group ($P=0.003$) as compared to NGT group in subcutaneous adipose tissue which correlated significantly with postprandial plasma glucose levels ($r=-0.48$ $P<0.04$)
Conclusion
The findings of the present study indicate that TT allele of rs2241766 polymorphic form of AdipoQ gene is associated with lower postprandial triglyceride levels and a lesser degree of glucose intolerance in Asian Indian subjects. Glucose intolerant subjects also display lower AdipoQ gene expression in adipose tissue.

Evaluation of macrovascular complications with Ankle-Brachial index in Type 2 diabetes

Gamze Gülçiçek[1], Meral Mert[2] & Berk Akyol[3]
[1]Bakırköy Dr. Sadi Konuk Training and Research Hospital, Internal Medicine, İstanbul, Turkey; [2]Bakırköy Dr. Sadi Konuk Training and Research Hospital, Endocrinology, İstanbul, Turkey; [3]Kreiskrankenhaus Greiz, Internal Medicine, Greiz, Germany

Aim
In our study; we aimed to evaluate the relationship between Ankle-brachial index (ABI) values and diabetes duration, and macrovascular complications in patients with DM with demographic data, anthropometric measurements, as well as clinical and laboratory data.
Materials and methods
Our study is a cross-sectional study of 226 randomly selected DM patients who were admitted to the diabetes outpatient clinic of our hospital between April 2019 and October 2019. All patients' data, such as age, sex, height, weight, waist and hip circumference, wrist and ankle circumference, family history, DM duration, chronic disease history, claudication, neuropathy, diabetic foot ulcer history, as well as routine blood and urine examinations at control were recorded. In addition, ABI was also measured in patients. Patients with ABI values of ≤0.90 were classified as PAD-positive, and those with >0.90 were classified as PAD-negative. The data, measurements and metabolic parameters we obtained, were evaluated to determine whether they are risk factors for ABI value, their association with ABI value, and differences according to ABI value.
Results
A total of 226 patients (138 female, 88 male) with a mean age of 52.8±10.3 years were included in the study. ABI was positive in 29.2% of the patients. There was no significant difference in ABI value between age, sex, family history, body mass index (BMI), waist circumference and duration of diabetes. A significant correlation was found between ABI and coronary artery disease ($P=0.004$), diabetic foot ulcer ($P=0.000$), smoking ($P=0.000$) and wrist circumference ($P=0.026$). No significant correlation was found between ABI value and glycylated hemoglobin A1c (HbA1c), low density lipopretein (LDL) cholesterol, triglyceride, non-high density lipoprotein (non-HDL) cholesterol levels and atherogenic index. Logistic regression analysis revealed that diabetic foot, coronary artery disease, BMI, duration of diabetes and HbA1c had a negative impact on ABI.
Conclusion
In our study, we obtained positive ABI values consistent with PAD in 29.2% of patients, suggesting that each patient with DM should be evaluated for PAD. Among patients with diabetes, those with a history of diabetic foot ulcers and/or cardiovascular disease, obesity, long duration of diabetes and patients with increased HbA1c levels under treatment, are considered as priority groups for peripheral arterial disease.
Keywords: peripheral artery disease, diabetes mellitus, ankle-brachial index.

AEP385

Maternally inherited diabetes and deafness presenting as diabetic ketoacidosis

Sheeba Shaikh & Edward Jude
Tameside and Glossop Integrated Care NHS Foundation Trust, Diabetes and Endocrinology, Ashton under lyne, United Kingdom

Background
A 29 year old female presented to the Emergency department with headache, vomiting and loose stools for 24 hours. She was not known to have diabetes. She had a background of bilateral sensorineural deafness for 6 years and

resolved Gillian Barre syndrome 8 years prior. She has a family history of deafness and diabetes mellitus in her maternal grandmother and mother; and diabetes in her maternal aunty and two maternal uncles diagnosed with pre-diabetes. She has a partner and two children aged two and nine years with no history of diabetes or deafness.
Investigations and management
On admission her blood glucose was 22.3 mmol/l, blood ketones were raised (4.9 mmol/l), low blood low PH (6.836) and low bicarbonate (5.7 mmol/l). Other investigations were as follows: WCC 19.2, serum sodium 130 mmol/l, creatinine 68 umol/l; calcium 2.15 mmol/l, magnesium 0.50 mmol/l, HbA1c 26 mmol/mol, vitamin B12 114 ng/l, folate 7.0 mg/l, ferritin 40 mg/l and negative pregnancy test. Examination revealed low BMI (18.3) with no signs of infection on systemic examination. Patient was managed as Diabetic Ketoacidosis with fixed rate insulin infusion followed by variable rate insulin infusion. She was then assessed by the diabetic team and started on basal-bolus insulin regime; diabetes education provided on discharge. Further investigations revealed negative Anti-GAD antibodies, negative Anti-islet cell antibodies, negative TTG IGA, normal Thyroid function test. Patient is managed by Diabetes Community team and awaiting results from genetic testing for MIDD.
Discussion
Type 1 and Type 2 diabetes constitute the most common types of DM. With increasing insight into genetic medicine, monogenic diabetes has gained interest as rare aetiology of adult onset diabetes. Maternally Inherited Diabetes and Deafness is caused by mitochondrial DNA defect accounting for 1% of diabetes mellitus. A to G (adenine to guanine) substitution at 3243 is the most common associated DNA mutation which then results in defective oxidative production of energy. Salient features comprise of Diabetes, Deafness, Maculopathy and Positive family History of Deafness and Diabetes. Other features consist of left ventricular failure, focal segmental glomerular sclerosis. Approximately 20% present as type 1 DM and 8% as DKA. Diagnosis involves genetic testing of 3243 A>G mutation in blood or urine sample. Management includes early recognition and prevention of systemic complications by commencing patient on appropriate treatment and regular follow up.
Conclusion
Clinicians should have low threshold for suspecting MIDD in a patient with low BMI, Anti Gad negative and a family history of Diabetes and Deafness.

DOI: 10.1530/endoabs.70.AEP385

AEP386

Association of depressive symptoms and diabetes-related distress with glycemic control, self-care activities and quality of life in diabetic patients

Mladen Grgurevic[1], Kristina Kljajic[1], Tonko Gulin[2,3] & Dario Rahelic[1,3]
[1]Merkur University Hospital, Vuk Vrhovac Universitv Clinic for Diabetes, Endocrinology and Metabolic Diseases, Zagreb, Croatia; [2]Sestre Milosrdnice University Hospital Center, Department of Nephrology and Dialysis, Zagreb, Croatia; [3]University of Zagreb, School of Medicine, Zagreb, Croatia

Background
Depressive symptoms (DS) and diabetes-related distress (DD) are common comorbidities in diabetic patients adversely affecting diabetes self-management and patients' well-being.
Aim
To examine associations between DS and DD with glycaemic control, quality of life and diabetes self-management.
Materials and methods
Depressive symptoms, DD, quality of life, diabetes self-management and metabolic indicators were assessed in 148 participants included in a Day Hospital educational programme (aged 42±15 years, 57% female, 78% T1 diabetes) at baseline and after a one-year follow-up. Associations between these variables were analysed in patients with: 1. depressive symptoms (n=26), 2. diabetes-related distress (n=14), 3. both symptoms (n=19), and 4. without symptoms (n=89) by using Kruskal-Wallis test. Prognostic value of the included variables for one-year metabolic outcomes was determined by regression analysis.
Results
The groups differed with respect to health-related quality of life and diabetes self-management: examinees without symptoms reported better quality of life (Kruskal-Wallis H=10,4 P=0,02; H=52,9 P<0.01) and better adherence to diet (H=8,9 P=0,03), self-monitoring blood glucose (H=7,9 P=0,05) and exercise (H=12,3 P<0,01). Metabolic indicators did not differ between the groups. Examinees without emotional symptoms improved their HbA1c (7.6%±1.2 vs 7.3%±1.1 P=0,04) during a follow-up period while other groups did not. Diabetes-related distress was shown to be a long-term predictor of metabolic control (stand. ß=.228 P=.025), while quality of life could be predicted by DS (stand.ß=–.422 P<.0001) and DD (stand.ß=–.329P<.0001; stand.ß=–.459 P<.0001).
Conclusion
Depressive symptoms and DD are longitudinally associated with patients' quality of life, diabetes self-management and diabetes control. Both symptoms should be recognized in order to establish an appropriate clinical approach.

Keywords: diabetes, depressive symptoms, diabetic-related distress, glycemic control, self-management of diabetes, quality of life.

Albuminuria and carotid intima-media thickness as surrogate markers of atherosclerosis in asymptomatic patients with type 2 diabetes

Gabrijela Malesevic, Snjezana Popovic Pejicic, Aleksandra Grbic, Bojana Caric, Ivona Risovic & Valentina Soldat Stankovic
University Clinical Center of the Republic of Srpska, Banja Luka, The Republic of Srpska, Bosnia and Herzegovina, Department of Center for Diabetes with Endocrinology, Banja Luka, Bosnia and Herzegovina

Introduction
Clinical assessment of atherosclerotic complications in type 2 diabetes mellitus (DM) was diverted to the detection of subclinical form of atherosclerosis using the non-invasive diagnostic methods. Surrogate markers of subclinical atherosclerosis are carotid intima-media thickness (IMT) and albuminuria. The aim of this study was to analyze a relationship between the presence of albuminuria and carotid IMT in patients with type 2 DM and silent ischemia.
Methods
Our study included 62 patients, aged 40–70, with type 2 diabetes, without previous history of cardiovascular disease. The patients performed exercise stress test and based on the results, were divided into two groups. The first group consisted of 25 patients with ischemic heart disease (IHD), whereas the second group consisted of 37 patients without IHD. In all patients, we measured IMT with ultrasound and albumin in 24-hour urine. The obtained values were compared between the groups.
Results
Patients with IHD were older, with a longer duration of diabetes, dyslipidemia and higher level of HbA1c compared to the control group without IHD (P<0.05). There was a statistically significant higher value of carotid IMT in the group of patients with IHD (1.08±0.17 mm) compared to those without IHD (0.78±0.17 mm) (P<0.001). The presence of albuminuria was significantly higher in the study group with IHD (22 patients) compared to the control group (9 patients), which has a statistical significance (P<0.001). In patients with IHD albuminuria was present in 22 and in patients without IHD in 9 patients, which was statistically significantly higher in the group of patients with IHD compared to the control group (P<0.001).
Conclusion
Patients with increased carotid intima-media thickness and albuminuria have a greater risk of IHD.

Keywords: diabetes mellitus, intima-media thickness, albuminuria.

Exacerbations of psoriasis in patients with type 2 diabetes

Elena Brutskaya-Stempkovskaya[1], Vadzim Sushynski[1], Elena Shishko[1], Tatsiana Sikorskaya[1] & Anastasia Plotnikova[1,2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk central city polyclinic N21, Minsk, Belarus

Psoriasis patients have an increased risk of cardiovascular disease, stroke, hypertension, and type 2 diabetes (T2D). External factors (infections, stress, trauma, endocrine diseases) can trigger psoriasis. Skin diseases in patients with T2D are increased, hyperglycemia leads to damage to vascular intima. Itching of the skin leads to disruption of the repair and regeneration.
Objective
To study the influence of T2D on the exacerbations of psoriasis.

Materials and methods
We studied hospitalized patients with T2D and psoriasis in dermatological clinic during 5 years ($n=47$)-the main group. Comparison group 1-patients with psoriasis without T2D ($n=40$), comparison group 2-patients with T2D without psoriasis ($n=37$). Patients were excluded: with the psoriatic arthritis, GFR ≤ 45 ml/min/1.73 m^2.
Results
Patients of the main group (women-53.2%, men-46.8%, mean age 61.0±7.7 years), comparison group 1 (women-55%, men-45%, mean age 60.5 ±7.5 years), comparison group 2 (women-54%, men-46%, mean age 62.0±7.8 years) were same in clinical, anthropometric, anamnestic and laboratory data (AST, ALT, total cholesterol, creatinine, $P>0.05$). Patients of the main group and comparison group 1 differed in serum glycemia ($P=0.005$). Patients of the main group had an increase HLA1c level (11.8 (7.9–12.3)) compared with the comparison group 2 (6.8 (6.1–7.3), $P=0.006$) in the exacerbation of psoriasis period.
The number of hospitalization in 5-year period was in 2.6 times higher in patients of the main group – 55 cases (1.17 exacerbations / person for a 5-years period), in the comparison group 1–18 cases (0.45 exacerbations/ person for a 5-years period).
Conclusions
Psoriasis exacerbations in patients with psoriasis and type 2 diabetes were in 2.6 times often in 5-year period compared with psoriasis without type 2 diabetes. There is probably a correlation between psoriasis exacerbation and type 2 diabetes decompensation.

Disordered eating behaviour in type 2 diabetic patients receiving oral hypoglycemic drugs

Veranika Lobashova[1], Alla Shepelkevich[2] & Yulia Dydyshko[2]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, Endocrinologic, Minsk, Belarus; [2]Belarusian State Medical University, Endocrinologic, Minsk, Belarus

Objective
Patients with type 2 diabetes mellitus (DM) are expected to follow numerous dietary recommendations which can be difficult to adhere and that can cause changes in their eating behavior. Few studies have examined prevalence rates eating disorders in adults with type 2 DM despite the fact that DM is highly correlated with overweight and obesity. The aim of the study was to assess the prevalence of disordered eating behavior in type 2 diabetes mellitus patients received oral hypoglycemic agentsusing EAT-26 questionnaire
Method
342 patients with type 2 diabetes mellitus receiveing oral hypoglycemic agentswere examined. The mean age 64 (58–69) years, mean body mass index (BMI)- 31.6(28.4–35.1) kg/m^2, duration of diabetes mellitus was 6(2–10) years. The group of women consisted of 223 patients (the mean age 64 (58–50) years, the mean BMI 31.6 (28.6–35.7) kg/m^2, the mean duration of DM 6 (5–10) years, the group of men include 108 patients, mean age 63 (56.5–68) years, BMI 31.3(28.3–33.9) kg/m^2, duration of DM 6 (2–10) years. There were no statistic differences in age (U=11088, 5 $P=0.077$), BMI (U=11659.0 $P=0.276$), duration of DM (U=8461.5 $P=0.800$) in the subgroups. The EAT-26 questionnaire was used in order to identify the high-risk subjects for eating disorders. The cut off 20 was used as a criteria for diagnosis.
Results
The prevalence of disordered eating behavior according to the results of cut off EAT-26 questionnaire in type 2 DM patients was 18.1% (62 of 342 patients had the score 20 and higher). The mean score of EAT-26 was 11(6–16). Statistical differences were revealed in the EAT –26 score depending on gender (U=10026.0 $P=0.002$). The mean EAT score in subgroup of men was lower 9 (5–14) than in the subgroup of women 12 (7–17). The prevalence of disordered eating in the subgroup of men was 14.8% (16 of 108 patients). In the subgroup of women 20.6% (48 of 233 patients).
Conclusion
The prevalence of disordered eating behavior in type 2 DM patients tested by EAT-26 questionnaire was 18.1% (in the subgroup of men 14.8%, in the subgroup of women 20.6%).

Insulin need and determinants of insulin usage in diabetes mellitus during pregnancy

Bengur Taskiran & Guven Baris Cansu
Kutahya University of Health Sciences, Endocrinology, Kutahya, Turkey

Aim
We aimed determinants of insulin usage in pregnant women with impaired carbohydrate metabolism (ICM).
Methods
We collected 164 pregnant women in any trimester who were referred to endocrinology unit due to suspicion of ICM by obstetricians. Diagnostic laboratory criteria were as follows: fasting glucose ≥126 mg/dl in first trimester; 1 hour 50 g challenge test glucose ≥180 mg/dl; any value exceeding threshold during OGTT (fasting glucose ≥92 mg/dl, 1 hour glucose ≥180 mg/dl, 2 hour glucose ≥153 mg/dl). Those with previous diagnosis of DM were also included. Insulin therapy was initiated in case of measurements exceeding target values (at least 2 fasting glucose ≥95 mg/dl and either 1 hour or 2 hour postprandial glucose ≥140 mg/dl ≥120 mg/dl, respectively) despite medical nutrition therapy.
Results
Mean and S.D. values were: age 31.4±4.7 years, gestational age (GA) at initial visit to endocrinology unit 25.9±5.2 weeks, GA at initiation of insulin 26.7±7.8 weeks, number of pregnancies 2.3±1.4, TSH 1.76±1.21 mIU/l, and hemoglobin A1c 5.82±1.06%. Insulin users ($n=90$) had higher fasting glucose ($P=0.001$), 2 hour OGTT-glucose level ($P=0.004$), and hemoglobin A1c ($P=0.001$) at diagnosis in comparison to non-insulin users ($n=74$). Insulin users who gave birth before 36 weeks had higher hemoglobin A1c than those after 36 weeks (6.32±1.68% vs 5.62±1.68%, $P=0.014$). GA at diagnosis was positively correlated with GA at insulin initiation ($r=0.634$, $P=0.001$). GA at diagnosis was significantly lower in subjects who gave birth before 36 weeks in comparison to those after 36 weeks (22.0±7.8 weeks vs 26.2±5.6, $P=0.01$). There was a positive correlation in-between ($r=0.466$, $P=0.002$). GA at insulin initiation was positively correlated delivery date (before vs after 36 weeks) ($r=0.510$, $P=0.006$). Insulin dosage was negatively correlated with delivery date (final total dosage: $r=-0.453$, $P=0.016$). GA at insulin initiation was negatively correlated with initial basal insulin dose ($r=-0.283$, $P=0.007$). Insulin dosage increased significantly from baseline to final visit (basal: 2.53±2.38 vs 3.73±3.97 U, bolus: 2.27±3.45 vs 5.20±6.12 U, total 4.80±3.88 vs 11.98±12.09 U). A positive correlation was detected between initial and final total insulin dosage ($r=0.643$; $P=0.001$).
Conclusion
Pregnant women need basal insulin more frequently than bolus insulin. Insulin userswith higher hemoglobin A1c level and those who need higher insulin dosage are at higher risk for delivery before 36 weeks. Early insulin initiation avoids delivery before 36 weeks. Basal insulin demand is higher in women who were initiated insulin at an earlier GA.

Arginine metabolism and gut microbiota changes in pediatric patients with type 1 diabetes

Elena Aghajanova[1,1], Arthur Melkonyan[1], Nina Alchujyan[2], Bayburdyan Gayane[1], Margarita Hovhannisyan[3], Lusine Navasardyan[1], Renata Markosyan[1], Lusine Kalantaryan[1], Vrej Issa[1], Lusine Arakelyan[1] & Zara Gevorgyan[4]
[1]Yerevan State Medical University, Endocrinology, Yerevan, Armenia; [2]H. Bunyatyan Institute of Biochemistry NAS RA, Department of pathological biochemistry and radioisotope methods, Yerevan, Armenia; [3]H. Bunyatyan Institute of Biochemistry NAS RA, Yerevan, Armenia, Department of pathological biochemistry and radioisotope methods, Yerevan, Armenia; [4]Yerevan State Medical University, Laboratory diagnostics, Yerevan, Armenia

Introduction
Incidence of type 1 diabetes mellitus (T1DM) is rising steadily around the globe, including Armenia. It is one of the most common autoimmune and metabolic disorders in pediatric population, resulting from autoimmune destruction of pancreatic β-cells leading to insulin deficiency. Gut microbiota

(GM) is reportedly involved in the pathogenesis of T1DM likely by influencing the immune response with the help of arginine-metabolizing enzymes. Arginase is known to contribute to decreased availability of L-Arginine, particularly to nitric oxide synthase, which may cause a subsequent reduction of Nitric oxide synthases/nitric oxide (NOS/NO) production attributed to the pathological processes associated with diabetes. Here, we aimed to investigate the correlation between GM and cytoplasmic and mitochondrial arginase isoforms in peripheral leukocytes of patients with T1DM.
Materials and methods
All T1DM patients ($n=108$) and healthy controls ($n=108$) were recruited at the Muratsan University Hospital, Department of Endocrinology, Yerevan, Armenia. GM was evaluated in the feces of all participants. Qualitative and quantitative examination of the intestinal microflora was performed by sowing fecal samples in appropriate nutritional environments. Fasting peripheral blood was draw into 3.8% sodium citrate anticoagulant, mixed with 6% dextran, and peripheral leukocytes were isolated by conventional procedures. Leukocyte cytoplasmic and mitochondrial fractions were prepared by differential centrifugation. Arginase assay was based on the accumulation of L-ornithine produced by arginase in the reaction mixture during 1 hour incubation and determined by means of ninhydrin. Measurement of the nitric oxide stable metabolites in protein-free samples was performed using Griess-Ilosvay reagent.
Results
In T1DM patients, colony numbersof E. coli ($P<0,001$), Bifidobacterium spp. ($P<0.002$), Lactobacillus spp. ($P<0,0002$) were drastically decreased with a concomitant increase of Candida albicans ($P<0.003$), and a manifestation of Staphilococcus ($P<0.0001$) aureus was also observed. Changes in GM were associated with 1.3 and 1.5 fold increase intheactivity of cytoplasmic and mitochondrial arginase isoforms respectivelyin newly diagnosed T1DM patients, and 1.6 and 1.7 fold increase in patients with duration of T1DM more than 1 year.
Conclusion
Quantitative and qualitative changes in the content of GMin T1DM patients were observed. These were associated with changes in arginine metabolism in peripheral leucocytes. Increase in the activity of arginase isoforms in cytoplasmand mitochondrias of leucocytes in T1DM patients was revealed, associated with a decrease in nitrates level, suggesting the involvement of these processes in pathogenesis of T1DM.

Freestyle libre flash glucose monitoring system in pregnant woman affected by type 1 diabetes: Our experience

Carmen Bautista Recio, Ana Gomez Perea, Marta Domínguez López, Stella González Romero, Natalia Colomo Rodriguez, Rosario Vallejo Mora, Maria Soledad Ruiz de Adana Navas & Gabriel Olveira Fuster
Regional Hospital of Malaga, Endocrinology and Nutrition, Malaga, Spain

Objective
Prospective observational study in a group of pregnant patients affected by type 1 diabetes (T1DM), that are monitored by the Endocrinology and Pregnancy Unit.
Material and methods
Weevaluated 12 pregnant patients with T1DM in which a FreeStyle Libre Flash Glucose Monitoring Systemwas installed, in addition to their capillary glucose self-control (SMBG), over the past year 2019. Time above range (TAR), time in range (TIR) and time below range (TBR) were measured, and all data captured by the sensor, like daily readings, as well as capillary glycosylated hemoglobin, fetal biometrics and birth data, among others.
Results
The mean age of the patients was 31.58±s.d. 5.48 years. The mean time of evolution of his T1DM was 10.7 years±s.d. 10.31. 75% had not planned their gestation. The treatment in 83% of the patients was basal-bolus therapy and 17% ISCI (Medtronic 640 G). The mean pregestational glycosylated hemoglobin was 7.69%±s.d. 1.73. The mean pre-installation glycosylated hemoglobin was 6.9%±s.d. 0.9. The mean post-installation was 6.2%±s.d. 0.86. Visits were scheduled every 4 weeks. The data covering the 14 days prior to the first medical review since the installation of the sensor were the following: average glucose 128.75±s.d. 27.32 mg. The time above the target (blood glucose >140 mg) was 21.92%±s.d. 22.11, the time on target (70–130 mg) was 57.17%±s.d. 28.29, the time below The target (<70 mg) was 15.08%±s.d. 10.63. The mean low glucose events was 12.14±s.d. 7.64, with an average duration of 125±s.d. 26.65 minutes. The average of data collected by the sensor of the patients was 90.80%±s.d. 9.63, as well as readings of 8.56±s.d. 5.17. Fetal ultrasound was consistent with gestational age in 100% of pregnant women during their follow-up. Childbirth occurred in 50% of patients during the year 2019. The average weight of the newborn was 3191.50±s.d. 136.02 grs.
Conclusions
FreeStyle Libre Flash Glucose Monitoring Systemcan improve the outcome and quality of life in pregnant patients affected byT1DM, however, the evidence to support its use in pregnant women is limited. Studies with more patients are needed to determine if sensor measurements can completely replace theblood glucose self-controls (SMBG).

2-hr vs 1-hr glucose tolerance testing for pre-DM diagnosis, among HIV-infected patients

Vanessa Guerreiro[1], Ana Cristina Santos[2], Rosário Serrão[3], António Sarmento[3], Davide Carvalho[1] & Paula Freitas[1]
[1]Centro Hospitalar Universitário de São João, Serviço de Endocrinologia, Diabetes e Metabolismo, Porto, Portugal; [2]Instituto de Investigação e Inovação em saúde da Universidade do Porto, Porto, Portugal; [3]Centro Hospitalar Universitário de São João, Serviços de Doenças Infeciosas, Porto, Portugal

Introduction
Plasma glucose concentration at 1h(1hPG) during an oral glucose tolerance test(OGTT) may be a better predictor of future diabetes mellitus(DM) than 2-h post load glucose concentration(2hPG). HIV-infected individuals may have differential risk of DM compared to the general population, and the optimal diagnosis algorithm for DM in HIV-infected persons remain unclear. We evaluated the agreement of the methods 1 hPG vs 2 hPG) for the diagnosis of pre-DM, as well as the CV risk, insulin resistance and β-cell function in patients with 1 hPG<155 vs≥155 mg/dl.
Methods
As part of a cross-sectional study, 225 Caucasian, non-institutionalized, HIV-1 infected adults under combined antiretroviral therapy (cART) were evaluated. Patients with DM diagnosis were excluded. To define pre-DM with 2 hPG we used 2019 ADA guidelines criteria; to define pre-DM in 1 hPG we used glucose≥155 mg/dl. Differences between groups were tested by unpaired *t*-test. We used HOMA-IR, QUICKIand HOMA-β. Kappa coefficient was used to evaluate the concordance of two methods in pre-DM diagnosis.
Results
We included 225 patients (63.6% males; mean age: 45.3±11.1 years) with baseline BMI: 24.7 (IQR 6.18) kg/m^2, waist circumference 91.0 (IQR 17.9) cm and hip circumference 94.0 (IQR 11.3) cm. The mean fasting plasma glucose (FPG) was: 91.4±11.6 mg/dl, 1 hPG : 158.2±43.4 mg/dl, 2 hPG : 123.1±35.4 mg/dl and A1c:5.2±0.4%. Patients with 1 hPG≥155 mg/dl had higher FPG (95.2 mg/dl vs 87.3 mg/dl; $P<0.001$), 2 hPG(138.9±35.4 vs 105.9±26.3; $P<0.001$), A1c (5.3% vs 5.1%; $P=0.020$) and C-Peptide levels (3.3 ng/ml vs 2.8 ng/ml; $P=0.039$) than those with 1 hPG<155 mg/dl but the difference in HOMA-IR, HOMA-β and QUICKI index between two groups was not significant. Patients with 2 hPG≥140 mg/dl had not only higher FPG levels and at 1hPG, but also higher HOMA-IR (2.9 vs 2.1; $P=0.03$) and C-Peptide levels (3.4 ng/ml vs 2.9 ng/ml; $P=0.027$) than those with 2 hPG<140 mg/dl. 52% of patients had pre-DM diagnosis accordingly 1 hPG criteria and only 27.6% had the same diagnosis with 2 hPG criteria. There was no statistically significant correlation between 1h-OGTTand lipid profile or blood pressure. The concordance correlation coefficient between the methods for diagnosis of pre-DM was 0.363, $P<0.001$.
Conclusion
We observed that, in HIV-infected patients, 1 hPG criteria identified more patients with pre-DM than 2 hPG criteria. Although previous studies, performed in general population, have identified 1 hPG as a method associated not only with decreased insulin sensitivity but also with early signs of cardio-metabolic dysfunction, in our study these differences were not significant between two groups. Further investigation is needed to determine whether 1hPG should be considered as an adjunctive tool to predict dysglycemia and cardiometabolic dysfunction in setting of HIV infection.

Thiamine-responsive megaloblastic anemia syndrome with dysrhythmia

Ibrahim El Ebrashy, Hemmat El Haddad, Heba Moustafa, Mai Galal, Randa Salam & Mohamed Magdi
Cairo University, Endocrinology department, Cairo, Egypt

Introduction
Thiamine responsive megaloblastic anemia syndrome(TRMA), is an autosomal recessive disorder due to mutation of gene (SLC19A2) encoding thiamine transporter protein TRMA ischaracterized by a triad of anemia, diabetes mellitus, and sensorineural deafness.
Case report
A 15 year old girl admitted to the ERwith diabetic ketoacidosis. She was diagnosed as neonatal diabetesat the age of 16 months and wasput on insulin therapy. Her parents arehealthyfirst cousins. Heryounger sister was deaf, diabetic, died at age of 18 month. At the age to 2 monthsHer mother noticed her child dyspneic with rapidheart beats. Upon medical consultation she was diagnosed as having severe anemia (Hemoglobin: 3 g/dl). Where shereceived blood transfusion. The attacks were recurrent & bone marrow examination was done by the age of 2 revealing; megaloblastic anemia with ringed sideroblasts. She was kept on frequent blood transfusion every 2 weeks. At the age of 9 months, her mother noticed poor response to voices. Audiometry was done showingsensory neural hearing loss and hearing aids were offered . At the age of 2 years, upongradual diminution of vision, electroretinography showed bilateral retinal dystrophy and retinitis pigmentosa. At the age of 9 years, She startedVitamin B1, B6 and B12 Supplementation which markedly reduced the frequency of blood transfusion (1 packed RBCs every 3–4 months). Menarche occurred at the age of 14 years with (Oligomenorrhea)
Physical examination
No dysmorphic features.pulse: 115/minute, pallor. Grade III/VI systolic ejection murmur, over the base.
Laboratory findings
Hemoglobin 7.5 g/dl, MCV 115 fl hematocrit 18%, and white blood cell count 10 000/mm^3 (60% neutrophil, 36% lymphocytes, 4% monocyte). The reticulocyte count; 1% platelet count; 106000/mm^3. The peripheral smear showed anisopoikilocytosis with a predominance of macrocytic cells and no hemolytic findings. Bone marrow aspirate showed normal cellularity but abnormal erythropoiesis with megaloblastic and dyserythropoietic. ECG showed premature atrial extrasystoles with partial RBBB verapamil 40 mg/day was recommended. The patient was put on high dose of oral thiamine (75 mg daily). Hemoglobin showed a steady rise (to Hb=12.8 g/dl) with mild anisocytosis, decreased frequency of transfusion. She was given a hearing aidplanned for cochlear implant.
Conclusion
Children presenting with the triad of anemia, diabetes and deafness should be evaluated for TRMA syndrome, especially in areas with high background consanguinity Stressing the need toward early diagnosis and treatment with thiamine.

Betamethasone administration in pregnant women with pre-existing diabetes mellitus

Ioannis Kakoulidis, Ioannis Ilias, Anastasia Linardi, Aikaterini Michou, Charalampos Milionis, Evangelia Venaki & Eftychia Koukkou
El Venizelou Hospital, Department of Endocrinology, Diabetes & Metabolism, Athens, Greece

Introduction
Betamethasone (BM) is widely used in pregnancy. Its diabetogenic potential is known, and in combination with placental insulin resistance in pregnancy, leads to a transient increase in glycemia. Our aim was to study the changes in glycemia in women with singleton pregnancies and pre-existing diabetes mellitus, under insulin therapy, after administration of BM for obstetric causes.
Materials and methods
We closely monitored and assessed the glycemic profile of 11 women with singleton pregnancies (mean age± s.d.: 35.5±5.0 years; mean gestational age± s.d.: 33.6±3.7 weeks; mean weight gain± s.d. : 9.8±5.6 kg) who were given BM during their hospitalization for obstetric causes. Three women had DM type 1, five women DM type 2, one woman MODY-1, and one woman had cystic fibrosis-related diabetes. Nine women received 24 mg of BM and 2 women 12 mgof BM, respectively. Five women had concurrent thyroid disease. The evaluation of glycemia was based on ten capillary plasma blood glucose measurements/day with point-of-caredevices. The intervention for correction of hyperglycemia was in accordance with ADA and EASD guidelines. We used analysis of covariance to assess the total daily insulin dose after BM, with age, gestational age, weight change in pregnancy, BM dosage, insulin dosage before BM, duration of hyperglycemia as variables and the presence of thyroid disease as a factor.
Results
Asignificant change in the glycemic profile in most patients was noted during the first 24 hours of BM administration, lasting on average approximately 2.1±1.0 days. The mean increase in total daily dose of insulin was of 14.4% (in two women their insulin needs decreased whereas in nine women their insulin needs increased by 25.7%). The noted increase in insulin needs tended to be associated with insulin dosage before BM ($P=0.062$) and the duration of hyperglycemia ($P=0.077$); it was unrelated to diabetes type ($P=0.151$).
Conclusions
The alteration in glycemia, after BM administration was as expected. However, the increase in insulin needs was lower than the reported in the literature increase of 30–40%. This could be attributed to greater attention and compliance of women with previous known diabetes entering pregnancy, compared to women with newly diagnosed diabetes during gestation. Further studies are needed to draw more reliable conclusions.

AEP396

Falling insulin requirements in women with pregestational diabetes

Adi Carmi[1], Yifat Wiener[2,3], Shapiro Hovav Tali[3], Shlomit Koren[2,4] & Ronit Koren[1,2,3]
[1]Shamir medical center, Department of Internal Medicine A, Zerifin, Israel; [2] Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel; [3]Shamir medical center, Division of Maternal-Fetal Medicine, Department of Obstetrics and Gynecology, Zerifin,; [4]Shamir medical center, Diabetes unit, Zerifin, Israel

Background
Previous studies evaluating the association between falling insulin requirements (FIR) during late pregnancy and adverse maternal and neonatal outcomes yielded controversial results.
Methods
We conducted a retrospective cohort analysis of data collected from women delivering at Shamir Medical Center (a referral university-affiliated facility in central Israel), between 2008–2018. The percent of FIR was calculated by dividing the remainder between the peak total insulin dose during the third trimester and the trough total insulin dose following that peak dose by the highest insulin dose. We compared women with FIR <15% to those with FIR >15% in regard with a composite outcome of any of the following maternal or neonatal complications: Cesarean-section due to fetal distress, pre-eclampsia, induction of labor due to intra-uterine-growth-retardation, small-for-gestational-age or fetal acidemia (cord blood PH <7.2).
Results
In the final analysis, we included 87 pregnancies in 80 women. Sixteen (18.4%) women had a more than 15% FIR during the 3rd trimester. There were 27 women (31%) who had T1DM and the rest T2DM. Women with FIR >15% had lower pre-gestational body mass index (BMI) at baseline (24.9±4.43 vs 28.16±5.79 kg/m^2 $P=0.049$). Women having >15% FIR also had significantly more hypoglycemic episodes during pregnancy though there were no differences in severe hypoglycemia. Composite outcome occurred in 5 (31.3%) deliveries in women with FIR >15% and in 29 (40%) of deliveries in women with FIR <15% $P=0.47$. There were no significant differences in all other maternal or neonatal outcomes in women with FIR ≥15% compared with FIR <15%.
Conclusions
FIR during the 3rd trimester occurs in a considerable number of diabetic women. In our cohort of women with pregestational diabetes (T1DM and T2DM), 3rd trimester FIR was associated with increased risk for maternal hypoglycemia during pregnancy but not with other adverse maternal or neonatal outcomes.

Exposure to phenolic compounds (Bisphenol A and Methyl Paraben) in pregnancy and its relationship with gestational diabetes mellitus, insulin homeostasis and pancreatic beta cell function

Joaquin Serrano[1], Antonio Picó-Alfonso[1], Mariana F Fernández[2], Juan Pedro Arrebola[3], Rocio Alfayate-Guerra[4], Maria Teresa López[5] & Oscar Moreno-Perez[1]

[1]Endocrinology and Nutrition Department, Hospital General Universitario de Alicante – ISABIAL. Miguel Hernandez University., Alicante, Spain; [2]Universidad de Granada, Centro de Investigación Biomédica, Instituto de Investigación Biosanitaria (ibs. GRANADA), Granada, Spain; [3]CIBER de Epidemiología y Salud Pública (CIBERESP), Granada, Spain; [4]Laboratorio de Hormonas, Hospital General Universitario de Alicante. ISABIAL., Alicante, Spain; [5]Laboratorio de Hormonas, Hospital Universitario de San Juan. FISABIO., San Juan de Alicante, Spain

Objectives
The effect of exposure to endocrine disruptors (exogenous chemical compounds that interfere with hormonal homeostasis), such as Bisphenol A (BPA) and Methyl Paraben (MPB), on gestational diabetes mellitus (GDM) has only been investigated in a small number of studies, with inconclusive results. Our objective was to investigate the association between concentrations of BPA and MPB in urine and the presence of DMG, insulin sensitivity and function of beta cells in a cohort of pregnant women in the Mediterranean area.
Material and methods
Multicenter case-control study, nested in a gestational cohort. Sequential sampling of women with pathological O'Sullivan (week 24–27 gestation), and indication of GDM confirmation test (OGTT 100 g, 3 h) was performed. We analyzed the presence of GDM (Carpenter and Coustan), insulin sensitivity through Matsuda-SOG Index (WBSII), and beta cell function by a trapezoidal model with calculation of the incremental area of insulin and glucose under the curve (AUCins and AUGglu, respectively), and by disposition index (DI) [(AUCins / AUGglu) * WBSII]. Concomitantly, urine concentrations of BPA and MPB were quantified by liquid chromatography coupled to mass spectrometry (HPLC-MS). The relationship between the urinary levels of BPA and MPB with the dependent variables was studied using Spearman correlation tests and multivariate logistic and linear regression models.
Results
Of the 110 women included 34.5 [29–38] years old, 26 [24.7–28] weeks of gestation, BMI 27.9 [24–32] kg/m^2, 40.4% of them met the GDM criteria. The study population had a urinary concentrations of BPA 2.95 [1.17–4] µg/l, and MPB 12.1 [4.4–35.4] µg/l. BPA levels of the 3rd vs 1st tertile were not associated with an increased risk of GDM [OR 0.84 (0.3–2.3)], neither with differences in WBSII or DI. These variables were also not correlated by Spearman. 3rd vs MPB levels 1st tertile were not associated with an increased risk of GDM [0.76 (0.3–1.9)], but with a higher WBSII ($P<0.01$). A negative correlation was also found between MPB and HbA1c, HOMA-IR, AUCins / AUGglu and positive with WBSII ($P<0.05$). This relationship disappears when a multivariate linear regression analysis is performed, in which it is found that BMI (B = –0.1, $P=0.002$) would be the only independent factor associated with WBSII.
Conclusions
In pregnant women with pathological O'Sullivan, higher concentrations of BPA or MPB in urine were not associated with an increased risk of GDM, lower insulin sensitivity, or lower beta cell function.

The prophylactic effects of metoprolol, diltiazem and pilocarpine on hypoglycemia-induced prolongation of QT interval

Eylem Cagiltay[1] & Sjaak Pouwels[2]

[1]İstanbul Bilim Üniversitesi Tıp Fakültesi, Turkey; [2]Street Elisabeth Hospital, Tilburg, Netherlands

Background
Insulin-induced hypoglycemia has been demonstrated to prolong the corrected QT (QTc) interval. Prolongation of QTc interval, especially in diabetic patients using insulin, can cause fatal ventricular arrhythmias. The aim of this study was to evaluate the effects of metoprolol, diltiazem and pilocarpine on hypoglycemia-induced QTc prolongation.
Methods
Thirty rats were randomly distributed into the following five groups: Group 1 (1 ml/kg saline, $n=6$), Group 2 (40 U/kg crystalline insulin + saline, $n=6$), Group 3 (40 U/kg crystalline insulin + 1 mg/kg metoprolol, $n=6$), Group 4 (40 U/kg crystalline insulin + 0.8 mg/kg pilocarpine, $n=6$), Group 5 (40 U/kg crystalline insulin + 2 mg/kg diltiazem, $n=6$). Three hours after insulin injection, blood glucose level was measured in all groups. Blood glucose <40 mg/dl was defined as hypoglycemia. Electrocardiograms (ECG) were taken in lead I (DI) and QTc was calculated by using Bazett' s formula.
Results
Group 2 (insulin + saline) showed that they had significantly prolonged QTc interval compared to control group ($P<0.0001$). However, treatments of the rats with metoprolol, pilocarpine and diltiazem significantly prevented the prolongation of QTc interval compared to insulin + saline group ($P<0.005$, $P<0.005$ and $P<0.01$, respectively).
Conclusion
The findings of the present study demonstrated the efficacy of metoprolol, pilocarpine and diltiazem in the prevention of hypoglycemia-induced QTc prolongation. These agents may be considered in the prophylactic therapy of high-risk patients who are using insulin.

AEP399

Serum vaspin level in patients with diabetes mellitus type 2 as a predictive index of atherosclerosis

Daniel Pylov[1], Ivan Smirnov[2] & Larysa Zhuravlyova[1]

[1]Kharkiv National Medical University, Internal Medicine #3 and Endocrinology, Kharkiv, Ukraine; [2]Kharkiv Regional Hospital, Head of Endocrinology Department, Kharkiv, Ukraine

Background
It has been proved that the adipose tissue is an active endocrine organ. It secretes a large number of adipokineswhich are involved in and affect regulation of metabolic process and can influence pathogenesis of atherosclerosis. Vaspin-new representative of adipokineswhich is secreted by adipose tissue and have an insulin-sensitizing properties. Vaspin engagement into atherosclerotic process poorly investigated.
Aim
To establish the value of plasma vaspin level in patients with diabetes mellitus type 2 (DM2) for prediction cardiovascular disease.
Methods
Thirty-one patient (55.1 ± 1.9 years) with DM2 (9.1 ± 2.8 years of duration) who do not have major adverse cardiovascular events were included to the study. The BMI (28.18 ± 0.8 kg/m^2), fasting plasma glucose level (FPG), HbA_1c, total cholesterol (TC), low-density lipoproteins (LDL), triglycerides (TG), C reactive protein (CRP) serum vaspin level and intima media thickness of carotid arteries (IMT CA) by ultrasound were measured. Control group healthy volunteers (54.8 ± 1.1 years) matched for age, gender and BMI.
Results
The study results showed that all patients had an adequate control of DM2 by oral hypoglycemic agents FPG 8.18 ± 0.92 mmol/l; HbA_1c 7.49 ± 0.21%. Dyslipidemia was present TC 6.40 ± 0.63 mmol/l; LDL 3.39 ± 0.52 mmol/l, TG 2.35 ± 0.15 mmol/l and there is no active process of inflammation CRP 1.33 ± 0.12. Serum vaspin level was significantly higher in patients with DM2 than in control group 3.47 ± 0.42 pg/ml vs 2.42 ± 0.19 pg/ml, $P<0.05$). In multivariate analysis after adjusting for atherosclerotic risk factors vaspin had positive correlation with IMT CA 1.02 ± 0.23 mm vs 0.71 ± 0.11 mm ($r=0,37$, $P<0,02$); immunoreactive insulin (0.6 $P<0,001$) FPG (0.62 $P<0,001$), HbA_1c (0.56, $P<0,001$), TG ($r=0,31$, $P<0,04$). No significant correlation was found between vaspin and BMI, TC, LDL, and plaque existence in carotid arteries.
Conclusions
Serum vaspin level was found significantly higher in patients with DM2 and thicker intima media than age-matched healthy subjects with normal IMT. The vaspin level had significant correlation with all known parameters which are involved in and promoted atherogenesis. Therefore, vaspin may have a pleiotropic effects and can be engaged in atherosclerosis development.

Systematic screening reveals large number of undiagnosed and untreated cardiovascular risk factors in adults with prader-willi syndrome

Karlijn Pellikaan[1], Anna Rosenberg[1], Kirsten Davidse[1], Aart Jan Van der Lely[1] & Laura De Graaff[1,2,3]
[1]Erasmus University Medical Center, Internal Medicine, division of Endocrinology, Rotterdam, Netherlands; [2]Erasmus University Medical Center, Academic Center for Growth Disorders, Rotterdam, Netherlands; [3]Dutch Center of Reference for Prader Willi Syndrome, Netherlands

Introduction
Prader-Willi syndrome (PWS) is a complex hypothalamic disorder, combining hypotonia, intellectual disability (ID), pituitary hormone deficiencies and hyperphagia. In PWS, up to 3% of patients die every year. In half of the patients, the cause of death is obesity related and / or of cardiovascular origin. Obesity is caused by hyperphagia combined with a low energy expenditure. Untreated hormone deficiencies like hypogonadism and hypothyroidism can cause low muscle mass and low basal rest metabolism (BRM) leading to this low energy expenditure. Patients with PWS should exercise one hour daily to compensate for their low BRM. However, hormone deficiencies usually cause fatigue, leading to exercise intolerance. Musculoskeletal and / or behavioral problems can also cause reduced physical activity. The subsequent sedentary lifestyle can induce cardiovascular risk factors like hypertension, hypercholesterolemia and diabetes mellitus (DM). Another risk factor often present in PWS is sleep apnea (SA). SA can lead to pulmonary hypertension and further increase in obesity. These health problems often remain unnoticed and untreated, which is partly due to the behavioral phenotype of PWS. However, if left untreated, these risk factors can cause cardiovascular complications leading to hospital admission or even death. To reveal yet undiagnosed health problems, we performed a systematic health screening among adults with PWS.
Methods
We systematically screened 115 adults with PWS (mean age 31.4±12.1 y, mean BMI 31.8±9,5 kg/m^2) for the presence of undiagnosed health problems and cardiovascular risk factors. Based on a medical questionnaire, medical file search, extensive interview, thorough physical examination and biochemical measurements we made an overview of the undiagnosed health problems in adults with PWS. If possible, we performed polygraphy to test for SA.
Results
Undiagnosed health problems (hypertension, DM, hypercholesterolemia, SA, hypothyroidism and hypogonadism) were present in 50% of the patients. 10% had multiple undiagnosed health problems simultaneously. All males and 94% of females had hypogonadism and 15% had hypothyroidism. Hypertension and / or hypercholesterolemia were present in 20% and DM was present in 16%. One-third of patients was not on a diet and 22% exercised less than 30 minutes a day. SA was present in 17 of 26 patients tested.
Conclusion
We detected a striking number of undiagnosed health problems among adults with PWS which, if left untreated, can pose a serious health threat. Systematic screening is needed to detect these problems at an early stage. This will prevent complications and might even reduce mortality in this vulnerable patient population.

The severity of insulin resistance in hypertensive patients depending on triglyceride-glucose index

Andriy Nesen[1], Vira Zlatkina[2], Volodymir Chernyshov[1], Volodymir Shkapo[1] & Tatyana Starchenko[3]
[1]LT Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Clinical epidemiology of non-infectional diseases, Ukraine; [2]Kharkiv National Medical University, Clinical pharmacology and internal medicine, Kharkiv, Ukraine; [3]LT Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Arterial hypertension, Kharkiv, Ukraine

Objective
To establish the association of triglyceride-glucose index (TyG) index with metabolic parameters of cardiovascular risk (CVR) in patients with arterial hypertension (AH). We examined 255 patients – 123 women and 132 men aged 45–55 years with AH stage II grade 2which were divided on TyG index into two groups: gr.1 –TyG index<4.81 units (n=134) and TyG index>4.82 units (n=121) – gr.2.
Methods
HOMA-insulin resistance (IR), biochemical blood analysis (lipid metabolism parameters, uric acid (UA)).
Results
Analysis of metabolic differences in patients with AH depending on IR presence for TyG index shows that in the case of decreased tissue sensitivity to insulin, the state of lipid metabolism is deteriorated mainly due to disturbances in the system oflipolisis and lipids containing TG, lipid transport system as evidenced by an increase in TG levels of 2.26 times (P<0.0001) and magnitude of the lipid ratio of TG/HDL 2.88 times (P<0.0001). The retention of TC in peripheral tissues in IR (TyG index>4.82 units) is accompanied by HDL lowering by 16.7% (P<0.0001) and an increase in the lipid ratio of TC/HDL by 33, 7% (P<0.0001). Poor efficiency of the reverse transport of TC system functioning in IR condition is also confirmed by the lipid ratio increase of LDL/HDL by 26.3% (P<0.0008), which indicates the advantage of the TC flow to the peripheral tissues over his withdrawal. The lipid profile in IR differs by an additional 24.8% (P<0.0001) increase of non-HDL-C compared to individuals without IR. In relation to TC (non-HDL/TC), this increase is 18.2% (P=0.02). The average of UA did not exceed normal ranges (0.360 mmol/l) in groups compared to TyG index, but was 10.7% (P=0.005) higher at TyG index>4.82 units.
Conclusions
Association of TyG index in patients with AH with atherogenic dyslipidemia as a CVR factor, is realized due to the lipoprotein lipolysis of TG-containing lipoproteins system and inverse TC transport system disorders. The association of TyG index with hyperglycemia and UA levels disoders is realized through metabolic factors as glucose tolerance disturbance and hyperuricemia.

Fish oil and metformin combination to target dyslipidemia in women with polycystic ovarian syndrome

Olivia Weaver[1], Mahua Ghosh[2], Katerina Maximova[3], Spencer Proctor[1] & Donna Vine[1]
[1]University of Alberta, Metabolic and Cardiovascular Disease Laboratory, Division Human Nutrition, Edmonton; [2]University of Alberta, Department of Medicine, Edmonton; [3]University of Alberta, School of Public Health, University of Alberta, Edmonton, Canada

Background
Woman with Polycystic Ovarian Syndrome (PCOS) are at risk of developingmetabolic syndrome (MetS), insulin resistance, dyslipidemia, Type 2 Diabetes and Cardiovascular Disease. Atherogenic dyslipidemia occurs in>70% of women with PCOS which includes high fasting plasma TG, LDL-C, non-HDL-C or ApoB, and low HDL-C. In addition to diet and lifestyle as the first-line intervention, metformin is commonly prescribed for impaired glucose sensitivity. However, metformin has limited effects on blood lipids in women with PCOS. Furthermore, treatments for dyslipidemia are limited due to safety in young women of reproductive age. Fish oil (FO) and icosapentyl ethyl supplementation, rich in eicosapentanoic acid (EPA) and docosahexanoic acid (DHA), has been shown to reduce fasting TG, but the effectiveness of FO in combination with metformin is unknown in conditions of the MetS and PCOS. The aim of this pilot study was to determine the effect of FO in combination with Metformin on fasting blood lipids in high-risk women with PCOS.
Methods
Participantswere female, age 18–30 years, diagnosed with PCOS who were recruited from the community and endocrine clinics in Edmonton, as part of a randomized clinical trial (n=30). Participants were randomized into intervention groups including: 1) dietary supplementation with fish oil (FO; containing 2520 mg EPA+1680 mg DHA/d, n=13), 2) fish oil+metformin (FO+Metformin 1500 mg/d, n=7) or 3) metformin alone (n=7) for 12 weeks. Inclusion criteria consisted of PCOS diagnosis using NIH-AEPCOSS criteria, BMI>25 kg/m^2, elevated fasting plasma triglycerides (>150 mg/dl), impaired insulin sensitivity (glucose 100–125 mg/dl) and/or diagnosed with T2D (glucose>126 mg/dl). Statistical analysis was completed via 2-way RM-ANOVA (GraphPad 8.0).
Results
FO+Metformin treatment significantly reduced fasting plasma TG from baseline compared to other treatment groups (Combination 2.45±0.43 vs

1.64±0.25*, Metformin alone 1.7±0.2 vs 1.5±0.22, FO 2.3±0.19 vs 2.2±0.19 mmol/l). Combination treatments had no significant effects on fasting insulin-glucose indices or androgen hormones. However, these treatments tended to reduce LDL-C and non-HDL-C (~10%), as well as blood glucose, fasting insulin (~5%) and HOMA-IR (~7–10%).
Conclusion
These pilot analyses demonstrate that the FO+Metformin combination treatment significantly reduces fasting plasma TG levels compared to metformin or fish oil alone in high-risk women with MetS and PCOS. A longer-term trial with larger cohort is warranted to determine the efficacy of this treatment to improve plasma TG, apoB-lipoprotein remnants and early subclinical atherosclerotic CVD risk in women with PCOS.

Epicardial fat accumulation and coronary artery calcification in non-alcoholic fatty liver disease

Carolina M. Perdomo[1], Ana Ezponda Casajús[2], Marta García Goñi[1], Juana K. Zapata Cardenas[1], Óscar Beloqui Ruiz[3], Gema Fruhbeck[1], Gorka Bastarrika Alemañ[2] & Javier Escalada[1]
[1]Clínica Universidad de Navarra, Endocrinology and Nutrition, Spain; [2]Clínica Universidad de Navarra, Radiology, Spain; [3]Clínica Universidad de Navarra, Internal Medicine, Spain

Patients with non-alcoholic fatty liver disease (NAFLD) have a higher prevalence of cardiovascular disease, particularly patients with liver fibrosis. Studies have shown a relationship between epicardial fat/coronary calcium and myocardial ischemia.
Aim
Quantify epicardial fat and coronary calcium assessed by computed tomography (CT) in patients with NAFLD. Additionally, determine whether patients with hepatic fibrosis quantitatively assessed by liver elastography (LE), Fibrosis-4 (FIB-4) Score and NAFLD Fibrosis Score correlate with an increased risk of cardiovascular disease by assessing epicardial fat and coronary calcium volume quantified by CT.
Methods
A retrospective and cross-sectional study was conducted in 81 patients with NAFLD. Patients with other causes of liver disease were excluded. Clinical data, serum markers and imaging studies (CT and LE) were obtained. In LE, the presence of increased liver stiffness was determined if ≥8.2 kPa. On CT, epicardial fat and visceral fat were quantified between –45 to –190 voxels and coronary calcium according to the Agatston method.
Results
The average age was 58.98±10.63 years. 82.72% (67/81) were men, with an average BMI of 30.22±4.83 kg/m^2 and body fat (CUN-BAE) of 33.96±7.56%. A 43.21% (35/81) had hypertension, 53.08% (43/81) dyslipidemia, 17.28% (14/81) OSAS, 17.28% (14/81) hyperuricemia, 35.80% (29/81) had type 2 diabetes, 30.86% (25/81) had prediabetes and 64.19% (52/81) were current or former smokers. A moderate-severe insulin resistance (HOMA-IR of 6.43±2.74) was found. Patients with diabetes had 7.44±7.07 years of evolution with a mean HbA1c of 7.19±0.91%. A 13.58% (11/81) presented increased liver stiffness assessed by LE. On average, the patients presented a liver stiffness (LE) of 6.24±2.94 kPa, coronary calcium of 291.97±484.98 and epicardial fat of 201.98±107.85 cm^3. There was a significant positive correlation between liver stiffness (LE) and epicardial fat (r=0.274; P=0.027), as well as with coronary calcium (r=0.66; P=0.005). Additionally, a positive correlation was found between epicardial and visceral fat (r=0.731; $P\leq$ 0.001). Patients with liver stiffness (LE) had a significantly higher epicardial fat volume (283.74±130.11 vs 166.14±81.26 cm^3; P=0.014) and a non-significant higher coronary calcium score (325.13±417.96 vs 124.78±179.93; P=0.188). No significant correlation was found between FIB-4 Score or NAFLD Fibrosis Score and epicardial fat volume or coronary calcium.
Conclusions
Hepatic fibrosis assessed by LE and visceral fat assessed by CT is positively correlated with epicardial fat and coronary calcium. The early identification of these situations may alert clinicians to establish preventive measures in order to reduce the cardiovascular risk of these patients.

Effects of azilsartan vs telmisartan on insulin resistance and metabolic biomarkers in patients of essential hypertension associated with type 2 diabetes mellitus: An open-label, randomized clinical trial

Bikash Meher[1,2]
[1]All India Institute of Medical Sciences, Pharmacology, Bhubaneswar, India; [2]Bhubaneswar, Pharmacology, Bhubaneswar, India

Background
Based on various preclinical studies, it is anticipated that azilsartan, an angiotensin II receptor blocker, will increase insulin sensitivity in addition to its antihypertensive effect. The present study was undertaken to evaluate the effect of azilsartan compared to telmisartan on insulin sensitivity in patients of hypertension coexisted with type 2 diabetes mellitus.
Methods
This study was a prospective, randomized, active controlled, open-label, parallel-group trial conducted in a single tertiary care center. Participants with grade I or II essential hypertension associated with type 2 diabetes were randomized into two groups. One group received oral telmisartan 40 mg/day and other group receive oral azilsartan 40 mg/day for 12 weeks. The primary endpoint of our study was the change in the homeostasis model assessment-insulin resistance (HOMA-IR) and secondary end points were change in the metabolic biomarkers like leptin and adiponectin values from the baseline at the end of the treatment period. We also evaluated its safety and efficacy on blood pressure.
Result
The mean changes in HOMA-IR from the baseline at the end of treatment were 0.32 (–0.61.1.26) in the telmisartan group and 0.15 (–0.64.0.94.52) in the azilsartan group. The mean difference in the changes from the baseline in HOMA-R between the azilsartan and telmisartan groups was 0.3 (–0.87.1.48) which was not statistically significant. There were also no statistically significant changes observed between two groups in metabolic biomarkers like leptin and adiponectin. Reduction in clinic systolic and diastolic blood pressure were observed at the end of 12 weeks treatment in both groups. No serious treatment-emergent adverse events (TEAEs) were observed.
Conclusion
Both telmisartan (40 mg) and azilsartan (40 mg) didn't show any significant effects on insulin resistance parameters and metabolic markers after 12 weeks administration to patients with grade I or II essential hypertension associated with type 2 diabetes mellitus.

Aldo-keto reductase (AKR) 1C1 – a potential driver of cell cycle progression in hepatocellular carcinoma

Ismael da Conceição, Nikolaos Nikolaou, Anastasia Arvaniti, Laura Gathercole, Leanne Hodson & Jeremy Tomlinson
Oxford Centre for Diabetes, Endocrinology and Metabolism, Radcliffe Department of Medicine, University of Oxford, Headington, United Kingdom

The health burden associated with non-alcoholic fatty liver disease (NAFLD), the hepatic manifestation of the metabolic syndrome, continues to escalate. Not only is NAFLD associated with significant liver-specific and cardiovascular morbidity and mortality, but patients are at risk of the development of hepatocellular carcinoma (HCC); a malignancy where the incidence continues to rise and there are very limited therapeutic strategies. Aldo-keto reductase 1C1 (AKR1C1) has a fundamental role in steroid hormone and drug metabolism. It has a variety of enzyme activities including converting progesterone to 20α-hydroxyprogesterone. AKR1C1 has been strongly associated with progression of cancers including breast and lung, as well as the development of chemotherapeutic drug resistance. AKR1C1 is most highly expressed in the liver, and yet its role to regulate metabolic and proliferative phenotype in human hepatocytes or hepatoma cell lines has not been explored. We have hypothesised that AKR1C1 activity contributes to enhanced hepatocellular proliferation through dysregulation of cell cycle regulators including the cyclin-dependent kinase (CDK) family that are crucial in driving G1/S transition. CDKs are also a target of the tumour suppressor, p53. We propose that AKR1C1 inhibition might represent a novel approach to the treatment of HCC. AKR1C1 was highly expressed in human liver, hepatocytes and hepatoma cell lines (HepG2 and Huh7). Functional activity in hepatoma cell lines was confirmed through

the conversion of progesterone to pregnanediol-3-glucuronide, as measured by a commercially available ELISA. Cells were treated with the AKR1C1 inhibitor, 3-Bromo-5-phenylsalicylic acid (5-PBSA) (24 h, 100 μM), which successfully decreased enzyme activity (vehicle: 3.51 ± 1.08 vs 5-PBSA: 0.01 ± 0.01 ng/ml). In HepG2 and Huh7, AKR1C1 inhibition with 5-PBSA down-regulated the mRNA expression of multiple CDKs including CDK1, CDK2, CDK4and CDK6, as measured by real-time PCR. In addition, the cell division cycle 6 gene (CDC6), which encodes a protein crucial for DNA replication, was decreased following AKR1C1 inhibition. We have demonstrated the expression and functional activity of AKR1C1 in human hepatoma cell models. Inhibition with 5-PBSA had a profound impact to alter the expression of crucial cell cycle regulating genes, raising the possibility that AKR1C1 inhibition may represent an emerging strategy to treat HCC.

Connection of glucose control with the 25-OH vitamin D status in type 1 diabetic young patients

Lusine Navasardyan, Anna Ghubatyan, Renata Markosyan & Yelena Aghajanova
Yerevan State Medical University, Endocrinology, Yerevan, Armenia

Background and aims
A growing number of studies show the impact of vitamin D deficiency on chronic diseases, such as obesity, type 2 diabetes, cardiovascular disorders etc. Recently the lower limit of vitamin D sufficiency, appeared to be safe and sufficient for skeletal health in the healthy general population, was documented as 20 ng/ml (50 nmol/l). The aim of current work is to evaluate whether the 25-OH vitamin D status is associated with the glucose control in type 1 diabetic young patients.
Materials and methods
We have randomly investigated 64 type 1 diabetic patients of 20–35 years of age, with the duration of diabetes > 5 years. This is the age of bone plateau, when the maximal bone mineral density is already achieved, and is relatively stable period for bone metabolism. The male/female ratio of all investigated patients was 1/1.13, mean age was 24.06 ± 1.08. Fasting serum 25-OH vitamin D and HbA1c levels were measured. Anthropometric and anamnestic data was collected. The patients were divided into three groups depending on their 25-OH vitamin D status: < 20 ng/ml, 20–30 ng/ml, and > 30 ng/ml. All analyses were performed using statistical software (IBM SPSS Statistics for Windows, Version 21.0). In all cases values of $P < 0.05$ were considered statistically significant.
Results
39.1% ($n = 25$) of investigated patients found to have vitamin D insufficiency (< 20 ng/ml); 35.9% ($n = 23$) – vitamin D low sufficiency (20–30 ng/ml); and 25% ($n = 16$) – vitamin D sufficiency (> 30 ng/ml). The groups were comparable based on mean age, sex and diabetes duration. No correlation was found between vitamin D and HbA1c absolute levels. But the mean HbA1c in the groups were as follows: 9.96 ± 0.83; 8.26 ± 0.64 and 7.82 ± 0.79, respectively, showing that in the groups with higher 25-OH vitamin D the glucose control was better ($P < 0.05$). No any connection between sex, age, duration of diabetes, weight and vitamin D status in the groups was revealed.
Conclusion
Lower 25-OH vitamin D is associated with the poorer glucose control in type 1 diabetic young patients. The vitamin D threshold levels should be further revised and investigated, particularly considering the presence of chronic diseases, such as type 1 diabetes, which we suppose should be different from the general population threshold.

Microangiopathy and cardiovascular risk in type 2 diabetic population

Mehdi Kalthoum, Ibtissem Ben Nacef, Imen Rojbi, Meriem Adel, Nadia Mechirgui & Karima Khiari
Hospital Charles Nicolle, Tunis, Tunisia

Introduction
Type 2 diabetes is a springboard to metabolic and cardiovascular complications. The objective of our work was to investigate the different cardiovascular risk factors in diabetic type 2 population, and study relation between the level of cardiovascular risk and the occurrence of degenerative complications.
Patients and methods
Retrospective study including 149 patients with type 2 diabetes consultant at the Department of Endocrinology at the Charles Nicolle hospital.
Results
Our population showed a mean age of 59.3 ± 10.6 years, sex ratio of 58.3% and an average of 9.61 years of diabetes. The age was a risk factor in 67.79% of the population and family history of cardiovascular disease were present in 6.04%. Smoking was present in 53%, alcoholism in 8.7% and inactivity in 38.2% of the population. 30.87% of patients were on overweight and 33.56% were obese with android obesity in 69.3% and an average waist size of 99.4 cm ± 11.62. We found a low HDL cholesterol, hypertriglyceridemia and high LDL cholesterol in respectively 65.6%, 34.6% and 34.9% of the population. Hypertension was present in 64.4% of the population. For diabetic macrovascular complications (23.9% of the population) we found coronary artery disease (21.4%), a cerebrovascular accident (6.4%), arteritis of the lower limbs (26.8%) and limb amputation (11.4%). Micoangiopathic complications of diabetes were found in 70.4% of the population with retinopathy in 66.6% neuropathy in 43.3% and autonomic neuropathy in 15.4% of the population. Renal failure was present in 34% of the population with a mean creatinine 105.2 umol/l. The overall cardiovascular risk in patients was calculated according to the SCORE tool with a high risk (5% ≤ SCORE < 10%) in 4.7% and a very high risk (score ≥10%) in 95.3% of the population. Among the latter group microangiopathy complications were more frequent with 69.3% against only 28% for the first group.
Conclusion
The presence of cardiovascular risk factors increases the risk of occurrence of degenerative complications of diabetes. This justifies the need for a comprehensive care, targeting both diabetes and other cardiovascular risk factors in order to improve the profile of our diabetic patients.

Prolonged QT interval during diabetic ketoacidosis: A case series

Ghariani Rania[1], Chrif Yosra[1], Samar Derbal[1], Rihab Laamouri[2], Ben Dahmene Fatma[1] & Abdallah Maya[1]
[1]Regional Hospital of Ben Arous, Internal Medecine, Tunis, Tunisia;
[2]University of Tunis Manar- Faculty of medecine of Tunis, Tunis, Tunisia

Introduction
Prolonged QT syndrome is defined as exceeding of the QT interval on the elecrocardiography (ECG) (> 450 ms in men and > 460 ms in women). It is either congenital or secondary to medication, electrolyte disturbances, heart disease. However, prolonged QT due to diabetic ketoacidosis (DKA) was rarely described. In this study, we tested the hypothesis that QTc prolongation occurs during DKA and returns to normal with resolution of ketosis.
Patients and methods
A retrospective study to evaluate the effect of DKA on the QT interval corrected for heart rate. Our patients were followed in the Internal Medicine department of the regional hospital of Ben Arous within 4 years (2016–2019). We performed electrocardiography during DKA and after recovery. We measured QTc as the QT interval divided by the square root of the R-R interval.
Results
Among 112 patients with a prolonged QT interval on the ECG, 22 patients (19.64%) had DKA, including 12 women and 10 men. The mean age was 54 years (20–87 years). Eighteen patients were followed for type 2 diabetes and 4 patients were diagnosed with type 1 diabetes. There was no medical history of cardiac disease. At the ECG, the QT interval was prolonged with a mean duration of 481 ms (451–543 ms). Three patients were treated with furosemide in one patient, Chlorothiazide in one patient and Indapamide in another leading to a prolongation of the QT interval. Associated electrolyte disturbances were found in 3 patients: 2 cases with hypokalemia and another with hypocalcemia. After correction of DKA with insulin and rehydration, ECG control was normal.
Conclusion
The consistent association between various ketotic conditions and prolonged QTc and/or sudden death raises the question of whether ketosis may directly affect cardiac repolarization. Accurate QT measurement is imperative in DKA patients. Identifying associated electrolyte disturbances, drugs that prolong the QT interval can help reduce the risk of torscardiac arrythemia and sudden death in DKA.

Factors associated with good knowledge of foot health in a population of patients with diabetes

Chaima Jemai[1] & Sinène El Frigui[2]
[1]Natioanal institute of nutrition of Tunis, C, Tunisia; [2]Hôpital Universitaire Sahloul (CHU Sahloul), Physical medicine and rehabilitation, Sousse, Tunisia

Aims
To assess the knowledge of diabetic patients on the health of their feetand to identify the associated factors with good knowledge, while providing podiatric advice.
Methodology
It was a descriptive and analytical transversal prospective studyabout 100 diabetic patients (44 men, 56 women; age range 29–87 years). They had an evaluation of their knowledge on the diabetic foot, using a pre-established questionnaire as well as a metabolic evaluation.
Results
The mean age was 54±12.9 years, The sex ratio was 0.78. 56% had a secondary or higher education level. Active smoking was 35% common. Diabetes was type 2 in the majority of cases (78%). The average duration of progression of diabetes was 13.62±6.29 years. 78% of the population has been unbalanced. 34% of the population had good knowledge of preventive measures for diabetic foot. Having good knowledge of preventive measures was significantly associated with secondary or higher education ($P=0.005$), female gender ($P=0.026$) and glycemic control ($P=0.043$).
Conclusion
The prevalence of patients with good knowledge of preventive measures for diabetic foot was low in our study and did not exceed one third of the population. Larger studies are essential in order to identify the factors associated with poor podiatric knowledge and podiatric practices, as well as the factors which slow down adherence to preventive measures recommended.

Foot self-care practices of Diabetic patients in Tunisia

Mouna Sghir[1], Soumaya Elarem[1], Aymen Haj Salah[1], Ikram Haddada[1], Wafa Allaya[2] & Wassia Kessomtini[1]
[1]Tahar Sfar Hospital, Physical Medicine And Rehabilitation, Mahdia, Tunisia; [2]Tahar Sfar Hospital, Endocrinology, Mahdia, Tunisia

Introduction
Diabetic foot is a major health problem for people with diabetes mellitus. It can cause serious complications leading to lower extremity amputations. Furthermore, foot self-care practice is one of the most important self-management behaviors to prevent the ocurrence of diabetic foot ulcers.
The aim of this study was to identify foot self-care practices among diabetic patients in a Tunisian population.
Methods
A cross-sectional study was conducted over a period of 3 months. A self-prepared questionnaire was used to collect data from a sample size of 150 diabetic patients at Tahar Sfar hospital and Ezzahra primary care center in Mahdia
Results
The mean age of patients was 56.91±12.6 years with a range of 20 to 86 years. A low level of education was found in 76% of cases. In addition to diabetes, 41.4% of patients had a history of hypertension and 46% of them had hypercholesterolemia. Smoking was found in 13.3% of cases. Half of patients were using oral medications, 28% were using insulin therapy and 21.3% were using both oral and insulin therapies. Regarding patients' knowledge of the diabetic foot, 74.7% had no idea about the impact of diabetes on the foot. Many errors in daily care practices were revealed.
Conclusion
Our patients have a low level of knowledge and a lack of education on diabetic foot. It is therefore important to educate them to prevent serious complications of the diabetic foot.

Particularities of the evolution of type 1 diabetes in 102 Tunisian adolescents

Sellami Sonda[1], Berriche Olfa[1], Hechaichi Aicha[2] & Maha Belhadj[1]
[1]National Institute of Nutrition, Tunis, Tunisia; [2]National Observatory of New and Emerging Diseases, Tunis, Tunisia

Introduction
One of the most common chronic diseases in adolescents is type 1 diabetes (T1D).
This period of growth is characterized by hormonal fluctuations and psychological changes which are risk factors for diabetes imbalance.
Aims
Describe the clinical, paraclinical and therapeutic profile in adolescents with type 1 diabetes in Tunisia
Methods
Cross-sectional study conducted atthe Institute of Nutrition in Tunis over a one-year period between January 2017 and January 2018. We have included 102 adolescents with type 1 diabetes (T1D) hospitalized ($n=68$) or followed at the consultation of diabetology ($n=34$).
Results
The population studied consisted of 102 adolescents with type 1 diabetes, 51% of whom were female with an average age of 16.8±1.7 years.
Participants classified underweight (UW) were 3(2.9%), those of normal weight (NW) were 82 (80.4%), overweight (OW) 10 (9.8%) and obese (O)7 (6.9%). Abdominal obesity was present in 21.6% of patients with a significant female predominance (34.6% of girls vs 8% of boys, $P<10–3$). The mean duration of diabetes was 7.1±4.3 years. The mean age of diabetes discovery was 9.7±4.4 years. More than half (53.9%) used human insulin and 46.1% used insulin analog. The daily average of insulin dose was 1±0.4 u/kg/day. Low adherence to treatment was observed in 29.4% of patients. Insulin omission was found in 7.8%. The average fasting glucose was 13±6.1 mmol/l. The average rate of HbA1c was 10.6±2.2% with extremes ranging from 5.8 to 16.8%. The majority (78.9%) of our patients had an HbA1c level>9%. Diabetic retinopathy was noted in 3.9% of patients, peripheral neuropathy in 5.9%, and diabetic nephropathy in 5.9%. Dyslipidemia was diagnosed in 30.4% of diabetics with a significantly higher frequency in girls (girls: 38.5% vs boys: 22%; $P=0.05$).
Conclusion
Diabetes in adolescence is characterized by poor and unstable blood sugar. Improving the quality of care for young diabetics insisting on therapeutic and nutritional education is necessary in order to avoid chronic complications of diabetes and provide them with a better quality of life.

Relationship between chronic pancreatitis and non-alcoholic fatty liver disease in patients with type 2 DM

Gulzor Rakhmonova[1], Aziza Abdullaeva[1], Nigora Maksutova[2], Mokhira Aykhodjaeva[3] & Zulaykho Shamansurova[1,4]
[1]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan; [2]Republican Specialised Scientific Practical Medical Center of Endocrinology, Diabetic nephropathy, Tashkent, Uzbekistan; [3]Republican Specialised Scientific Practical Medical Center of Endocrinology, Diabetic cardiology, Tashkent, Uzbekistan; [4]Institute of Biophysics and Biochemistry at NUU, Metabolomics, Tashkent, Uzbekistan

Background
People with type 2 Diabetes Mellitus (DM2) more predisposed to Non-Alcoholic Fatty Liver Disease (NAFLD). Accompanied chronic pancreatitis impaired glycemic control by affecting gastrointestinal absorption, also by affecting of pancreatic insulin secretion. We study the frequency of NAFLD in DM2 patients with accompanied chronic pancreatitis.
Material and methods
In 44 people with DM2 blood glucose, HbA1c, Cholesterol, triglycerides, LDLP, HDLP, fibrinogen, ALAT, ACAT, bilirubin levels, prothrombin index, serum alpha amylase activity were measured. In addition pancreas, liver structure assessed by ultrasound. Results showed that 37% observed people with DM2 have NAFLD. Blood glycemia, HbA1c, fibrinogen, ALAT, ASAT, bilirubin levels were comparable in both with NAFLD and without. Blood Cholesterol, Triglycerides, VLDLP levels were significantly higher in patients with NAFLD which confirmed by ultrasound. Interestingly, that 26 (59%) patients with DM2 have accompanied chronic pancreatitis, which determined in 15 patients (94%) in the group with NAFLD and in 11 patients

(39%) without NAFLD, which suggested about involvement of chronic pancreatitis into pathogenesis of NAFLD.
Conclusion
NAFLD is a frequent among people with DM2 and determined in 37%. Interestingly, NAFLD showed the relationship with presence of chronic pancreatitis in people with DM2. Chronic pancreatitis in patients with DM2 involved into pathogenesis of NAFLD.

Fungal necrotizing external otitis in diabetic patients

Mohamed Masmoudi, Mehdi Hasnaoui, Malika El Omri, Wadii Thabet, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital mahdia, ENT department, Mahdia, Tunisia

Introduction
Fungal necrotizing otitis externa is a serious and potentially life-threatening condition that is challenging to manage. Diabetic patients are susceptible to develop this severe infection. The diagnosis is often delayed and its frequency has increased over the last few years.
Material and methods
we reported 8 cases of fungal necrotizing external otitis in diabetic patients treated in the ENT department of Tahar Sfar Hospital in Tunisia from 1992 to 2018.
Results
Our study investigated three men and five women. They were all diabetics. The mean age was 61 years ranging from 69 to 74 years. All four patients were first treated for bacterial necrotizing otitis externa. Diagnosis was reviewed after a lack of response to antibiotic therapy. Aspergillus flavus was isolated in one case, Candida albicans was isolated in 6 cases an association of candida and aspegillus flavus was found in one case. Computed tomography scan showed signs of invasive necrotizing external otitis in all cases. It showed lysis of the facial canal in one case, sigmoid sinus thrombosis in one case, jugular vein thrombosis in one case and lysis of the carotid canal in one case. One patient developed facial palsy during disease progression. The equilibration of diabetes was obtained in all the cases. Treatment was based on amphotericin B and oral voriconazole during 6 months. Heparin was not used for the cases of septic thrombosis. The side effets of the antifungal treatment are carefully monitoring. After an average follow-up of one year, a regression of the infection was observed in 5 cases, one patient was not followed up, one patient developped a recurrence and one patient died with heart stroke.
Conclusion
Fungal necrotizing otitis externa should be suspected in cases where there is no response to antipseudomonal antibiotic therapy. Deep biopsies from the external auditory canal or the mastoid are usually needed to confirm the diagnosis.

Non-alcoholic fatty liver disease and type 2 diabetes mellitus: Diagnostic methods

Feruza Haydarova & Dildora Sadikova
Centr Endocrinology, Endocrinology, Tashkent, Uzbekistan

Actuality
Type 2 diabetes mellitus patients have a higher risk of developing severe liver disease compared with non-diabetes patients. According to the data, among patients with type 2 diabetes, the incidence of cardiovascular, cerebrovascular and peripheral vascular diseases, as well as nephropathy and retinopathy, is significantly higher in the case of concomitant NAFLD. The fact of liver damage in T2DM is beyond doubt. The liver plays a key role in all metabolic processes and at the same time is a target in the formation and progression of metabolic disorders, in particular, insulin resistance.
Purpose
To study the feature of the instrumental method for the diagnosis of FibroScan in patients with type 2 diabetes with NAFLD.
Materials and methods
40 patients were examined. 20 patients with type 2 diabetes and NAS and 20 patients type 2 diabetes and NASH. All patients underwent measurements of liver stiffness using a FibroScan. Average age: 56±4.6; Hb1c-9.5%; BMI-30.2 kg/m^2; Diabetes experience 7±2.3 years.
Results
In patients with type 2 diabetes and NAS, F0 was more often detected 42%, and in patients with type 2 diabetes and NASH, F1 was detected 29%. According to the results of FibroScan, the degree of F4 fibrosis was more common in patients with type 2 diabetes and NASH 11%, respectively 4%. The average value of steatosis in 40 patients was: S0-1-2 (5%), S2 – 33 (82.5%), S3-5 (13.5%).

The stage of fibrosis (kPa)	T2DM + NAS *n* = 20	T2DM + NASH *n* = 20
F0	42%	21%
F1	29%	29%
F2	17%	16%
F3	8%	23%
F4	4%	11%

Conclusion
According to our study, fibrotic changes were more common in patients with type 2 diabetes and NASH. Liver FibroScan is an effective approach for the diagnosis of liver fibrosis in patients with type 2 diabetes and NAFLD

Association between diabetic peripheral neuropathy (DPN) and hypertiglyceridemia in patients with type 2 diabetes in georgia

Tamar Maghradze, Elena Shelestova, Maka Moistsrapishvili & Ramaz Kurashvili
Tbilisi, National Center for Diabetes Research, Tbilisi, Georgia

Background
Diabetic neuropathy is a widespread chronic diabetes complication. This heterogeneous group of conditions affects different parts of nervous system and presents with diverse clinical manifestations. Diabetic peripheral neuropathy (DPN) is a common complication of type 2 diabetes (T2DM), it may cause foot ulcer, gangrene or amputation. The risk of developing DPNincreases with age, diabetes duration and poor glycemia control. About 60% to 70% of all T2DM people will eventually develop DPN. Hypertiglyceridemia is a typical lipid disorder in patients with poorly controlled T2DM.
The Aim of this study was to assesseffect of hypertiglyceridemia on DPN in patient with T2DM.
Methods
In total, 62 T2DM patients with DPN(33 men and 29 women) were enrolled in the Study Group (SG). Their mean age was 56±7 yrs and diabetes durationvaried from 5 to 10 yrs. In all SG patients hypertiglyceridemia was diagnosed. Anotherage, sex and diabetes duration matched 50 patients with normal triglycerides (TG) who had no DPN were used as controls (CG). HbA1c in SG was 8.1±1.2% and inCG – 7.7±1.1%. According to current Guidelines, to assess DPN following neuropathy tests were performed in all the patients: 10-g monofilament test, tip-term/temperature test, vibration test with 128-Hz tuning fork, prick test and neurological examination with Sudoscan, a non–invasive method forassessment of small fiber function (Impeto Medical, France). Results of all neurological tests in SG patients (monofilament, tip-term/temperature, prick, vibration tests) were positive, Sudoscan examination revealed presence of small fiber neuropathy. In CG patients all tests, except Sudoscan, were negative, while Sudoscan revealed small fiber damage. Association between hypertiglyceridemia and DPN was assessed. Serum triglyceride levels in SG patients were elevated (mean TG level 299±45 mg/dl, while in CG patients they were100±20 mg/dl).
Results
According to neurological examinations prevalence of DPN in SG comprised 64, 5% (40 cases). TG concentration was significantly higherin T2DM patients with DPN when compared to patients without DPN and normal TG levels ($P = 0.005$). Elevated serum triglyceride levels were associated with DPN ($P < 0.044$).

Conclusion
This study shows that increased serum triglyceride levelsmay play important clinical role in DPN development in patients with T2DM. The problem needs further investigation with the inclusion of other important parameters.

AEP416

Hypoglycaemia during ramadan in patients with diabetes from Tunisia

Olfa Lajili, Kamilia Ounaissa, Rim Rachdi, Nessrine Souissi, Zeineb Zemni & Chiraz Amrouche
National Nutrition Institute, Outpatient Departement and functional exlorations, Tunis, Tunisia

Introduction
Fasting during Ramadan is an obligatory practice for adultMuslims. Although exemptions exist in certain conditions, including diabetes, the majority ofdiabetic patients fast despite this concession with the risk of complications mainly hypoglycemic accidents.
The aim of this study is to establish the relationship between hypoglycemic accidents and drug treatment, therapeutic education, clinical and biological characteristics oftunisian diabetic patientsduring Ramadan 2019.
Methods
A prospective descriptive observational study including 85 diabetic patients followed at the National Nutrition Institute of Tunis. Clinical and biological data are noted before four to eight weeks and after the month of Ramadan 2019.
Results
The mean age was 55.8 ± 12.7 years. Most of the patients had type 2 diabetes (97.7%). A slight female predominance was noted (52.3%). The average duration of diabetes was 10.6 ± 6.6 years. Two thirds of the patients are classified as high or very high risk for fasting. Only 30% of the patients were allowed to fast. Treatment with oral antidiabetics, insulin, or a combination of the two was prescribed in 50%, 12.8% and 37.2% of cases. The average of HB1AC before and after Ramadan was 8 ± 1.2%, and 8.6 ± 1.35% respectively. Severe hyperglycaemia (>3 g/l) was reported in 5.8% of cases. Hypoglycemic accidents were noted in 18.6% of patients, 14.9% of whom were on insulin ($P = 0.026$), either alone or in combination with oral antidiabetics, 16.27% were at high or very high risk ($P = 0.128$), 87.5% with type 2 diabetics ($P = 0.03$) and 13.95% uneducated for fasting ($P = 0.82$). Most of patients fasted all month (72.1%). Hypoglycemic accidents were the main cause of breaking fasting (62% of cases, $P < 0.01$). Half of the patients did not glycemic monitoring during the fasting but without significant impact on the incidence of hypoglycaemia. In addition, there were no hospitalized patients during this month.
Conclusions
The consequences of fasting in diabetic patients were mainly hypoglycaemia. Insulin therapy wasa predictor of hypoglycemia during Ramadan. Identification of individuals who required Ramadan specific education is essentielto prevent these complications.

Clinical and metabolic impact of ramadan fasting in tunisian patients with diabetes

Olfa Lajili, Kamilia Ounaissa, Rim Rachdi, Ben Ali Khaoula & Chiraz Amrouche
National Nutrition Institute of Tunis, Outpatient Departement and functional explorations, Tunis, Tunisia

Introduction
Ramadan fasting is one of the sacred rites in Islam. Diabetes patients are spared this obligation. However, mostof them insists on fasting.
The aim of this study is to assess the clinical and metabolic impact of Ramadan fasting in Tunisia patients with diabetes during Ramadan 2019.
Materials and methods
Prospective descriptivestudy carried out during Ramadan 2019 including 86 diabetic patients followed at the National Institute of nutrition of Tunis. Clinical and metabolic data were recordedfrom patients' files, as well as by conducting individual interviews and physical exam. The period of our study covered one to three months before Ramadan and one month after it.
Results
The mean age was 55.8 ± 12.7 (23–80 years). The sex ratio was 1,08 (F/M). The average BMI was 28.22 ± 4.22 kg/m^2. Most of patients had type 2 diabetes (97.7%). The average duration of diabetes was 10.6 ± 6.6 years. Patients were treated with oral anti-diabetics alone, insulin or the association between the two, in 50%, 13% and 37% of cases respectively. Two thirds of patients were classified as high to very high risk for fasting and 32.3% had a low or intermediate risk. Only 30% were educated, 24% before one month, 4% before two months and 2% before three months. Half ofof participants (55%) experienced a weight loss after Ramadan, 28% a weight gain, and 18% no change in weight. Furthermore, we did not objectify a relationship between the change in BMI and initial BMI. Regarding the metabolic impact, we noted a significant increase in mean HbA1c (8 ± 1.2 vs 8.7 ± 1.35; $P < 0.01$), but not significant in Triglycerides and glomerular filtration rate while we noticed a non-significant decrease in total cholesterol, LDL cholesterol, HDL cholesterol and uric acid. We did not notice a significant difference inthe parameters studied between educated and uneducated patients. The main complications were hypoglycaemia (18,65%) and hyperglycaemia (5.8%). Otherwise, No acute metabolic accident or hospitalization were reported.
Conclusions
Ramadan fasting had a negative impact on glycemic balance, and a variable effect on the lipid profile and weight status. This underlines the importance ofimprovingthe education of patients with diabetes to avoid acute complications during this month.

Cognitive impairment in patients with type 2 diabetes is associated with increased level of circulating Granzyme B

Nataliia Pashkovska[1], Galina Koval[1], Olga Pashkovska[2], Nataliia Abramova[1], Yulia Marchuk[1], Ivan Pankiv[1] & Antonina Piddubna[1]
[1]HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Chernivtsy, Ukraine; [2]Charles University, Third Faculty of Medicine, Prague, Ukraine

Introduction
Diabetes mellitus is known as a factor of cognitive impairment. The risk of dementia in patients with type 2 diabetes mellitus (T2DM) increases almost twice. The results of epidemiological, visualization and autopsy studies showed the presence of both cerebrovascular and neurodegenerative mechanisms of brain lesions. Cell death of key substrates – neurons and endothelial cells lays in the basis of the formation of cerebral disorders. Granzyme B (GrB) is a serine protease, which exerts both intracellular apoptotic and extracellular functions, leading to tissue injury, inflammation and repair.
The aim of the study was to find out role of the granzyme-induced mechanisms of programmed cell death in the development of cognitive impairment in patients with type 2 diabetes.
Material and methods
70 patients with cognitive impairmentin T2DM and 26 healthy individuals who formedthe control group were examined. Patients were classified using neuropsychological assessment tests. The Mini-mental State Examination test (MMSE), Montreal Cognitive Assessment (MoCA) test and the determination of cognitive-induced potentials were used to evaluate cognitive functions. Serum Granzyme B (GrB) was measured by Human Granzyme B Elisa kit (Bender MedSystems).
Results
Mild cognitive impairment was diagnosed in 47 patients with T2DM, dementia in 23 subjects. T2DM patients had 56% higher serum level of GrB than the control group ($P = 0.03$). The changes were statistically insignificant in the group of patients with mild cognitive impairment, while in subjects with dementia the level of GrB was almost twice higher compared to the control group ($P = 0.04$). Positive correlations were established between the MMSE and MoCA tests results of patients with T2DM and levels of GrB, direct correlation – the latent period P300 and levels of GrB ($P < 0.05$). Thus, serine protease GrB can play a role in the mechanisms of brain damage in T2DM by converting procaspase 3 to active caspase 3. Activation of cytotoxic T- cells leads to the release of perforine and granzymes from their granules. Perforine forms in the plasma membrane of target cells the pores through which granzymes penetrate. Also, recent studies have shown that GrB plays an significant role in the processes of destabilization of atherosclerotic plaques, that important in the aspect of vascular dementia in DM.
Conclusion
Cognitive impairment in patients with type 2 diabetes is accompanied by an increase in granzyme-induced apoptotic processes.

AEP419

Clinical evidence of the cost effectiveness of bariatric surgery in management of type 2 diabetes mellitus and obesity to prevent associated co-morbidity

Mahamud Bashir[1], Shrini Patel[1], Davina JUGNARAIN[2] & Gideon Mlawa[1]
[1]Queen`s Hospital, London, United Kingdom; [2]Barts and the London Medical School, London, United Kingdom

Introduction
Diabetes is a chronic condition which has become a major public health concern approaching epidemic proportions globally. Effective diabetes management often presents many challenges. Clinicians and patients often become overwhelmed by the need to address co-morbid chronic conditions in addition to patients' diabetes-specific treatment goals. It is widely accepted that bariatric surgery can help improve health in a range of metabolic diseases, including T2DM and obesity. Bariatric surgeries promote weight loss, which can lead to improvements in hyperglycemia and dyslipidemia.
Case review
A 68year oldwas referred to the to theendocrine team with poor diabetic control, ongoing chronic kidney disease and previous history of non- alcoholic fatty liver and prostate hyperplasia, for which he was taking Metformin- (1 g BD), Forxiga- (10 mg OD), Finasteride- (5 mg OD) and Alfuzosin- (10 mg o.d.). On physical examination the patients Weightwas 131 kg, hisheart rate was – 99 bpm, and hisBlood pressure was 154/8 mmHg. There was no evidence of peripheral neuropathy or ulceration. Laboratory findings showed, *Urea*-8.8, *Creatinine*-114, *eGFR>60* and *HBA1C*-77 mmol/ mol
The patient was referred to a dietician to help with his weight loss and diebetic control. The patient was again seen by the endocrine team 6 months later and his weight remained alarmingly high (126 kg) despite consulting a dietician and his diabetes remained uncontrolled. Following successful gastric bypass surgery in December 2018 the patient lost 20 kg and he showed good diabetic control with glucose level of 4.5–6.0 mmol/l. his most recent HbA1c was 33 which is within normal range.
Discussion
Following, successful gastric bypass the patient glucose level returned to normal physiological level and there was gradually decline in HbA1c. Therefore, all previously prescribed anti diabetic drugs were stopped and the patient also demonstrated substantial weight loss. The use of surgical intervention for obese Type 2 diabetes patients at risk of disease progression should be considered because diabetes is the leading cause of non-traumatic lower extremity amputation and blindness in the United Kingdom. Majority of diabetes-related amputations in England are preventable if patients get the right early preventative care upon recognition of uncontrolled diabetes.
Conclusion
Bariatric surgery is robust means for treating diabetes and obesity. The use of this would limit both the over prescription of anti-diabetic therapy and lower their cost, which at the moment is estimated to cost the NHS over billion pounds.

Pecularities of bile homeostasis in patients with chronic cholecystitis combinedwith diabetes mellitus type 2

Yulia Marchuk, Nataliia Pashkovska, Nataliia Abramova, Galina Koval, Antonina Piddubna, Ivan Pankiv & Iryna Tsaryk
HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Черновцы, Ukraine

Introduction
In order to improve the early diagnostics of cholelithiasis in patients with chronic acalculous cholecystitis combined with diabetes mellitus type 2 (DM), individual parameters are usually not sufficient. Therefore, we decided to establish and analyze the correlation between the serum and biochemical parameters of bile to evaluate biochemical connections in a system of lipid homeostasis by comorbid pathology. The aim of our study was to determine the peculiarities of disorders of bile homeostasis by patients with chronic acalculous cholecystitis combined with diabetes mellitus type 2.
Methods
A detailed clinical examination was carried out in 50 patients with chronic acalculous cholecystitis combined with diabetes mellitus type 2 (group 1 in the main group), 40 patients with diabetes mellitus type 2 (2 group), 40 patients with chronic acalculous cholecystitis (3 group) and 20 practically healthy individuals.
Results and discussion
In patients of the 1st group, the ratio of bile acids/cholesterol (BA/CH) was significantly lower compared with patients with group 2 ($P<0.05$). It was found that in the patients of the 1st group there was an inverse average strength correlation connection between the serum cholesterol level and the ratio of phospholipids/CH in bile ($r=–0.64$, $P<0.05$). This indicates that the lithogenicity of bile in this category of patients depends on an elevated level of cholesterol in the blood, which can be used as a marker of lithogenesis. Patients in the 2nd group revealed a reliable direct correlation between the level of phospholipids (PL) in serum and the ratio of PL/CH in bile ($r=0.71$, $P<0.05$) and the inverse correlation between the concentration of β-lipoproteins and the ratio of BA/CH in bile ($r=–0.74$, $P<0.05$). In patients of the 3rd group, we found a direct correlation between the level of high density lipoprotein (HDL) in serum and the ratio of PL/CH in the bile ($r=0.76$, $P<0.05$), the level of serum phospholipids andratio of PL/CH in bile ($r=0.66$, $P<0.05$), serum HDL and ratio BA/CH ($r=0.67$, $P<0.05$), and the level ofHDL and the Isaacson index ($r=0.77$, $P<0.05$).
Conclusion
Thus, patients with chronic acalculous cholecystitis and diabetes mellitus type 2 have established a reliable correlations between the serum cholesterol level and the ratio of phospholipids/cholesterol in the bladder portion of the bile in the absence of reliable correlations between the lipids of serum and the bile.

Pecularities of antithyroid autoimmunity indicators in patients with diabetes mellitus type 2 depending on leptin level and impact of selenium-containing medicines intake on their titers

Nataliia Abramova & Nataliia Pashkovska
HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Черновцы, Ukraine

During the last three decades the number of patients with diabetes mellitus (DM) type 2 have increased, which is associated with an increase in the prevalence of obesity among the world's population. DM type 2 and obesity are closely linked with the production of leptin by adipose tissue. Diseases of the thyroid gland (TG) as well as type 2 DM are the most common endocrine pathologies. Many studies have found an increase of antithyroid antibodies titers against the background of DM type 2. According to the literature data, a chronic autoimmune thyroiditis (AIT) affects 10% of women and 20% of male population.
The aim of the study
To determine the characteristics of antithyroid autoimmunity in patients with type 2 diabetes mellitus, depending on the leptin level in blood serum and develop a method of the identified changes correction.
Materials and methods
Depending on the leptin level in blood serum patients were divided into groups as follows: Group I – level of leptin – less than 10 ng/ml (12 patients), group II – level of leptin within 10–25 ng/ml (19 patients), group III – level of leptin more than 25 ng/ml (15 patients).
Thyroid autoimmunity was diagnosed by antibodies to thyroid peroxidase (AT-TPO) and thyroglobulin (AT-TG) determination in the blood serum.
In order to evaluate the effectiveness of treatment, patients were randomly divided into two groups: 20 people with DM type 2 received standard treatment. The main group included 30 people who receivedsodium selenite, which is equivalent to 100 micrograms of selenium, by 1 tablet per day for 30 days against the background of basic therapy.
Results of the study
According to obtained data AT-TG level in group III was 2.1 times higher than in group I ($P<0.05$). AT-TPO titers in groups II and III was 44.3% and 92.2%, respectively higher than in group I ($P<0.05$).
A significant improvement of indicators that reflect the autoimmune processes against thyroid tissue have been found only in the group of persons who took sodium selenite with standard therapy: the level of AT-TG became 22.3% lower ($P<0.05$) and AT-TPO – 30.6% than before sodium selenite treatment ($P<0.05$)
Conclusions
1. In patients with diabetes mellitus type 2 an antithyroid antibodies titers increase.

2. Significant decrease in antibodies to thyroglobulin and thyroid peroxidase titers in patients with type 2 diabetes mellitus against the background of sodium selenite intake have been observed.

The associations between adipocytokines and future vascular complications in type 2 diabetes

Ji-Oh Mok, Chan-Hee Jung & Sung-Koo Kang
Soonchunhyang University Bucheon Hospital, Internal Medicine, Bucheon-si, Korea, Republic of South

Aims/Introduction
It is thought that adipocytokines contribute to the increased riskof vascular complications in type 2 diabetes (T2DM). However, some data indicate that adipocytokines may protect against cardiovascular disease. The net effects of adipocytokines on vascular pathology are complex and not completely understood. Although previous our cross-sectional studies showed that adipocytokines such as adiponectin, leptin, and TNF-alfa were associated with vascular complications in patients with T2DM, there is still limited information on the relationship between future development of microangiopathies and adipocytokines in T2DM. The aim of this study was to investigate the relationship between baseline serum levels of adiponectin, leptin, and TNF-alfa and future presence of vascular complications in Korean T2DM.
Methods
Ninety nine patients among 140 patients who were measured baseline serum adiponectin, leptin, and TNF-a levels were recruited. They were evaluated for diabetic nephropathy, retinopathy, neuropathy, and carotid atherosclerosis during follow up.
Results
The mean age and duration of diabetes, and duration of follow up were 53 years, 6.7 years, and 7.8 years, respectively. Baseline mean serum leptin levels were significantly lower in patients with carotid atherosclerosis than in those without it during follow up ($P=0.017$). Multivariate logistic regression analysis showed that the odds ratio for the presence of carotid atherosclerosis in the lowest tertile of leptin was 4.6 (95% confidence interval 1.3–15.7), as compared with the patients in the highest tertile of leptin level. Baseline mean levels of adiponectin and TNF-alfa were not significantly associated with any of the three microangiopathies and carotid atherosclerosis during follow up. Baseline serum leptin levels were not associated with any of the three microangiopathies.
Conclusions
These results suggest that decreased serum leptin levels in T2DM may be associated with future development of carotid atherosclerosis. Future prospective studies with larger numbers of patients are required to establish a direct relationship between plasma adipocytokine concentrations and the development or severity of vascular complications.

Serum osteoprotegerin level in relation to ankle brachial index among type 2 diabetic patients with subclinical hypothyroidism

Ghada Shoaeeb[1], marwa atef[2], Yasser Hafez[1], Sherif Ezzat[1] & Loai Elahwal[1]
[1]Internal medicine department, Faculty of medicine, Tanta University, Egypt; [2]Medical Biochemistry department, Faculty of medicine, Tanta University, Egypt

Background
Osteoprotegerin (OPG) acts as an important regulatory molecule in vascular disease. The presence of diabetes mellitus greatly increases the risk of peripheral artery disease, Also both subclinical and overt hypothyroidism have been clearly linked with dyslipidemia, which is a known risk factor for peripheral arterial disease.
Aim
We aimed to evaluate the relation between serum osteoprotegerin and peripheral artery disease among type 2 diabetic patients with subclinical hypothyroidism (SCH).
Patients and methods
60 participants were enrolled in the study, (Group1) 20 type 2 diabetic patients with normal thyroid function, (Group 2) 20 type 2 diabetic patients with subclinical hypothyroidism and (Group 3) 20 healthy subjects, they were subjected to complete history taking, complete clinical examination, routine laboratory investigations, serum OPG level, neck ultra sound and Doppler study for ankle brachial index (ABI).
Results
We found that OPG levels were statistically elevated in type 2 diabetic patients with SCH group over type 2 diabetic patients with euthyroidism (*P* value 0.040). Additionally, lower ABI in type 2 diabetic patients with SCH than those with euthyroidism proving increase incidence of PAD in group 2 than group 1 than the nondiabetic patients with statistically significant results in between groups.
Conclusions
Our results found that diabetic patients with SCH revealed an independent association between TSH and serum level of OPG. Likewise we found a statistically significant difference between OPG level and ABI among type 2 diabetic patients. That's why OPG can act as a marker of peripheral artery disease among diabetic patients with SCH.
Keywords: Type 2 DM, sub-clinical hypothyroidism, ankle brachial index, osteoprotegerin.

The role of peripheral serotonin in obese wistar rats studied by using of LP533401

Ivaylo Bogomilov[1], Vesela Mihneva[2], Nadka Boyadjieva[3], Rumen Nikolov[3] & Ivona Daskalova[2]
[1]Military Medical Academy-Sofia/Medical University- Sofia, Endocrinology/ Pharmacology, Sofia, Bulgaria; [2]Military Medical Academy-Sofia, Endocrinology, Sofia, Bulgaria; [3]Medical University-Sofia, Pharmacology, Sofia, Bulgaria

Background and aims
Although 95% of serotonin is produced in the periphery, its functions have been ignored until now. Recently it became clear that theserotonin system in the periphery regulates multiple physiological aspects independently of the brain-derived serotonin. In particular, peripheral serotonin playsa pivotal function in the regulation of glucose and lipid homeostasis by acting on different organs and cell types. Serotonin produced in pancreatic b- cellspromotes insulin secretion and during pregnancy also b-cell proliferation. Serotonin produced in intestine acts on the liver to promote gluconeogenesis and tosuppress hepatic glucose uptake, and on white adipocytes to promote lipolysis and to suppress glucose uptake, adiponectin production and insulin action. Serotonin produced directly in the adipocytes suppresses thermogenesis and glucose uptake in another functional type of fat – brown adipose tissue. Moreover, serotonin might act directly on muscle to promote glycolysis, and it promotes cytokine production in macrophages. With our study, we want to see how peripheral serotonin affects peripheral insulin resistance and obesity in rats.
Materials and methods
Serotonin is a crucial factor supporting pancreatic b-cell function, using the Tph1 inhibitor – LP533401 (peripheral serotonin inhibitor), in our experiments, aiming suppressing serotonin synthesis in intestinal enterochromaffin cells and in pancreatic b-cells of experimental animals. We used 30 Wistar rats separate in 2 groups- rats with obesityand healthy rats (control group). Each of this groups was separated in other 2 – one with daily intraperitoneal injection of LP533401 (0.2 mg/kg) and one without. In 4 weeks period we were tracking blood glucose level, insulin secretion and rats weight. Thedifferences in the mean values among the groups are greater than would be expected by chance; there is a statistically significant difference ($P\leq0.001$) using SPSS program.
Results
It was shown that after application of LP533401 the weight of the rats in obese groupdecreased by 35.4% ($P<0.05$), and by 15.4% ($P<0.05$) in the control group using LP544401 and no significant dynamic in the groups without daily intraperitoneal injection of LP533401. Theresearch also shows decreasing of insulin resistance by 35.8% ($P<0.05$) in obese rats group using LP533401 compering with the results in the beginning of the study.
Conclusion
Using LP533401 inhibitor for treatment of obesity in male Wistar rats, LP533401 significantly reduces peripheral insulin resistance and further reducing body weight not only in the obese and diabetic rats group, but also in the control group.

Determining the nutrition, sleep quality and body composition conditions of working shift workers in furniture production

Ferhan mantar & Hande Dilan Kanmış
Bahcesehir University, Nutrition And Dietetic, Istanbul, Turkey

Approximately 20 percent of the world's working population is working shifts. The shift working system that affects such a large population often causes circadian rhythm disturbances. These disorders adversely affect nutritional habits and quality, sleep patterns and quality, and body composition. The risk of chronic diseases, especially obesity and diabetes, increases due to the direct and indirect effects of disruption in the circadian rhythm. The aim of this study is to compare the data on nutrition habits, sleep quality and body composition of workers working in day and night shifts in furniture production. The study was carried out on a total of 290 male workers working in 6 different furniture manufacturing factories in the 24–60 age range of 215 shifts during the day shift and 75 shifts during the night shift. Demographic characteristics and nutritional habits were questioned by demographic questionnaire. Pittsburgh Sleep Quality Questionnaire was used to determine the sleep quality; In order to determine the dietary quality, a frequency of food consumption questionnaire was used and was evaluated by Mediterranean Diet Compatibilty Score. Body weight, height, waist and hip circumference, body fat percentage and lean tissue mass were measured in order to evaluate the body composition. Results obtained from the study; Significant differences were found between age, body weight, BMI, hip circumference, waist circumference and body fat percentage between shift working status and groups ($P<0.05$). Waist hip ratio and fat free weight did not differ between the groups($P>0.05$). However, it was concluded that all body composition data evaluated were higher in night shift workers. Demographic characteristics revealed that marital status, number of people living in households, education level, alcohol and cigarette smoking, chronic disease, water consumption and occupational accident status were related to shift working status ($P<0.05$). It was found that the mean Mediterranean diet compatibility score ($11,15 \pm 1,93$) of the day shift workers was statistically significant and higher than the mean Mediterranean diet compliance score ($9.35 \pm 1,79$) of the night shift workers ($P<0,05$). When the nutritional habits were examined, it was concluded that shift working status had a significant relationship with the number of meals and skipped meals, but there was no significant relationship between meal preferences. When the sleep quality was examined, it was concluded that other Pittsburgh sleep quality components (subjective sleep quality, sleep latency, habitual sleep activity, sleep disorder, sleep medication use, daytime dysfunction) and total score were significantly higher and higher in the night shift workers ($P<0.05$).

Effects of bariatric surgery in patients with craniopharyngioma

Ulrich Dischinger[1], Laura Kötzner[1], Ann-Cathrin Koschker[1], Christina Haas[1], Martin Herrmann[2], Martin Fassnacht[1] & Florian Seyfried[3]
[1]Universitätsklinik Würzburg, Medizinische Klinik I – Endokrinologie/Diabetologie, Würzburg, Germany; [2]Universitätsklinik Würzburg, Klinik und Poliklinik für Psychiatrie, Psychosomatik und Psychotherapie, Würzburg, Germany; [3]Universitätsklinik Würzburg, Chirurgie I, Würzburg, Germany

Effects of Bariatric Surgery in Patients with Craniopharyngioma
Objectives
The prime objective of this study is the identification of the limiting factors of metabolic surgeries on weight reduction in patients with craniopharyngioma (CP) and consecutive hypothalamic obesity (HO).
Patients
As of now, 37 patients were included, of which5 patients presented with HO and earlier bariatric surgery (mean BMI 50.44 kg/m^2), 5 patients presented with HO without bariatric intervention (mean BMI 43.95 kg/m^2), 9 underwent bariatric surgery as a treatment of alimentary obesity in the past (mean BMI 40.09 kg/m^2), 7 patients were alimentary obese with a mean BMI of 47.33 kg/m^2 and no previous bariatric surgery and 6 participants were healthy controls (mean BMI 24.02 kg/m^2).
Methods
For evaluation of eating behavior and quality of life standardized questionnaires and nutrition reports and for the subjective preference for sweet foods a taste-reward-test were used. A modified oral glucose tolerance test was performed to analyze the gastrointestinal hormone status after a defined test meal. Blood was taken right before and 15, 30, 45, 60, 120 min after meal ingestion.
Results
The BMI of patients with HO and bariatric surgery was significantly higher than that of patients with alimentary obesity and bariatric surgery ($P<=0.05$). Surprisingly, patients with HO that underwent bariatric surgery had still significantly ($P<=0.05$ bzw. 0.01) higher GLP-1 levels than patients of all other groups (at 15 and 30 min after meal ingestion), especially than patients with alimentary obesity and bariatric surgery. There was no statistically significant difference found for PYY.
Conclusion
Patients with HO after bariatric surgery have significantly higher levels of GLP-1 at certain time points after a defined meal, although this doesn't account for PYY. We conclude, that firstly the effects of bariatric surgery are annihilated through the hypothalamic damage and secondly GLP-1 agonists are no valid treatment for most of these patients. Measuring GLP-1 might at least be useful before starting such a treatment.

Relationship between blastocystis sp. parasitization and metabolic syndrome in an obese spanish population

Jana Caudet-Esteban[1,2], Susana Cifre Martinez[2], María Trelis Villanueva[3], Rosa Camara-Gómez[1], Rosana Palasí[4] & Juan Francisco Merino Torres[1]
[1]University and Polytechnic Hospital La Fe, Endocrinology and Nutrition Service, Valencia, Spain; [2]Health Research Institute La Fe, Department of Endocrinology, Nutrition and Clinical Dietetics, Valencia, Spain; [3]Valencia University, Department of Pharmacy and Pharmaceutical Technology and Parasitology, Valencia, Spain; [4]University and Polytechnic Hospital La Fe, Department of General and Digestive Surgery, Valencia, Spain

Introduction
Blastocystissp. (*BS*) is the most common intestinal parasite that is isolated in human fecal samples. Its pathogenic role is still questioned. While some consider it a beneficial component of the human intestinal microbiota, some evidence relates it with dysbiosis and development of metabolic syndrome (MS). Its presence has been inversely correlated with BMI.
Objective
The objective of this study is two-fold: determining the prevalence of *BS* through molecular analysis fecal samples of Spanish obese subjects and relating it with the presence or absence of MS according to the NCEP ATP III definition.
Methods
Clinical, anthropometric and biochemical data were gathered from type II and type III obese subjects attended in an Obesity Unit in our hospital. Fecal samples were obtained in order to perform PCR amplification and rRNA small subunit sequencing of the *BS* gene. Anthropometric measurements and biochemical analysis were undertaken after an overnight fast. Waist circumference was recorded with a standard flexible non-elastic metric tape.
Results
Fecal samples were obtained from 65 obese subjects of 48.0 (±10.2) years old, 41 women and 24 men. Mean BMI was 45.5 kg/m^2 and every subject showed an abdominal circumference of high risk (130.1±13.6 cm). We obtained PCR positive results for *BS* in 28 samples (43.1%). 46.4% of *BS* positive patients were diagnosed with MS whereas 59.4% of *BS* negative subjects met the same criteria. Attending to individual comorbidities: 51.1% were hypertensive (56.7% in *BS* negative, 42.8% in *BS* positive), 68.0% dyslipidemic (no differences between groups), and 58.2% presented some kind of dysglicemic state (60.1% and 56.7%, respectively) with an incidence of type II DM of 28.5% in *BS* positive patients and 37.8% in *BS* negative patients. No differences were found between groups attending to plasmatic leptin levels (52.3 ng/ml in *BS* positive and 52.4 ng/ml in *BS* negative) or HOMA-R index (6.0 and 6.1, respectively), but higher insulin plasmatic levels (34.7 vs 21.2 mg/ml) were detected in the *BS* negative group.
Conclusions
Yet preliminary, these clinical results suggest a protective effect of *BS* in the development of MS in our population of obese subjects. However, no differences were found in analytical parameters of insulin-resistance, which has been described as the cornerstone of metabolic syndrome.

Adiponectin and omentin-1 concentrations in patients with systemic sclerosis

Wojciech Bik[1], Klaudia Dopytalska[2], Małgorzata Kalisz[1], Anna Litwinuk[1], Agnieszka Baranowska-Bik[3] & Irena Walecka-Herniczek[2]
[1]Centre of Postgraduate Medical Education, Department of Neuroendocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Department of Dermatology, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Adipokines belong to a group of proteins involved in the pathogenesis and progression of immune/inflammatory diseases. It is an open question whether and how adipokines contribute to these diseases. Adiponectin might be a key regulator of the immune system, playing a role in the progression of inflammatory disorders. Omentin has been recognized as an anti-inflammatory adipokine with influence on immune response regulation and inflammation, Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by vasculopathy and fibrosis of the skin and internal organs. The studies showed a possible role of adipokines in the development of fibrosis and modulation of the immune response in the course of SSc. We aimed to evaluate plasma levels of adiponectin and omentin-1 in SSc patients in basal conditions as well as in prospective observations.
Material and methods
59 patients with SSc and 27 healthy controls, matched with age, BMI and HOMA-IR, were enrolled in the study. The severity of the skin fibrosis in SSc individuals was evaluated using the Rodnan scale. In all participants, fasting plasma adiponectin and omentin-1 concentrations were assessed using the ELISA.
Results
Omentin-1 levels were significantly higher in patients with SSc compared with the controls. These differences remained marked after adjustment to BMI. No changes were seen between omentin-1 concentrations in prospective analyses in SSc patients (0, 6 months, 9 months). Although adiponectin had a trend to lower values in SSc individuals in comparison to the controls, the differences were not significant. However, after adjustment to BMI, these differences became significant. Similar to omentin-1, there were no adiponectin fluctuations in the follow-up. Amongst two selected adipokines, only adiponectin levels correlated with the Rodnan scale ($R=-0.21$, $P<0.05$). To conclude, adiponectin and omentin-1 cannot be regarded as potential metabolic markers of a course of systemic sclerosis. However, higher omentin-1 and lower adiponectin concentrations after adjustment to BMI, as seen in SSc patients, may indicate an influence of these adipokines on pathomechanisms involved in systemic sclerosis.

Table 1 Basal adiponectin and omentin concentrations in SSc individuals and the controls.

	SSc	Control	P	P (after adjustment to BMI)
Adiponectin (ug/ml)	8.47 ± 4.06	10.6 ± 5.4	ns	< 0.05
Omentin-1 (ng/ml)	604 ± 93	506 ± 138	< 0.05	< 0.05

Table 2 Follow-up assessment of adiponectin and omentin-1 in SSc individuals.

	0	6 months	9 months	p
Adiponectin (mg/ml)	8.47 ± 4.06	8.72 ± 3.85	8.04 ± 3.81	ns
Omentin-1 (ng/ml)	604 ± 193	619 ± 257	601 ± 238	ns

The management of nonalcoholic fatty liver disease with a choline containing antioxidant compound

Panagiotis Athanassiou[1], Lambros Athanassiou[2], Anastasios Kotrotsios[3], Marina Gatsiou[1], Pavlos Tsakiridis[1], Eirini Devetzi[1], Maria Mavroudi[1], Georgia Kaiafa[4], Christos Savopoulos[4] & Ifigenia Kostoglou-Athanassiou[5]
[1]Street Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; [2]Medical School, University of Athens, Department of Physiology, Athens, Greece; [3]Private Practice, Karditsa, Greece; [4]AHEPA Hospital, Aristotle University of Thessaloniki, First Propedeutic Department of Medicine, Thessaloniki, Greece; [5]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece

Nonalcoholic fatty liver disease has an increased worldwide prevalence due to obesity and the use of various drugs affecting the liver. The pathogenesis of nonalcoholic fatty liver disease is presently not completely defined. In addition, there is a paucity of agents for its treatment. Choline deficiency has been shown to induce nonalcoholic liver disease. Systemic autoimmune rheumatic diseases require chronic systemic treatment with various agents, which may affect liver function. Therefore, the management of nonalcoholic fatty liver disease attains importance. Prunus mume, the Asian plum of the rosaceae family, has been studied for its antioxidant, anti-inflammatory, and liver protecting properties. The aim was to describe the use of a Prunus mume extract in patients with nonalcoholic fatty liver disease and autoimmune musculoskeletal rheumatic diseases. In a group of 50 patients, 25 male and 25 female, with nonalcoholic fatty liver disease in the context of autoimmune musculoskeletal rheumatic diseases, an extract of Prunus mume 300 mg (Prunus mume extract 150 mg, choline bitartrate 82.5 mg, oleanolic acid 1.3%, ursolic acid 1.7%) was administered once daily. In this group the levels of alanine aminotransferase, aspartate aminotransferase, gamma-glutamyl transferase, cholesterol, HDL, LDL and triglycerides were measured before, 1, and 3 months later. Observations were also performed in a control group of 50 patients. A liver ultrasound was performed. In this group of patients with nonalcoholic fatty liver disease in the context of autoimmune musculoskeletal rheumatic diseases after 3 months of treatment with the Prunus mume extract 300 mg daily the levels of alanine aminotransferase decreased significantly by 35.1% ($P<0.01$), those of aspartate aminotransferase decreased by 8.2% ($P<0.01$) and those of gamma-glutamyl transferase decreased by 12.4% ($P<0.01$). The LDL/HDL ratio decreased by 10.9% ($P<0.05$), HDL levels increased by 11.5% ($P<0.05$) and triglycerides decreased significantly by 7.2% ($P<0.05$). The diagnosis of nonalcoholic fatty liver disease in the context of autoimmune musculoskeletal diseases presents a problem andthe systemic treatment of the disorder is presently in the focus of scientific research. The management of nonalcoholic fatty liver disease with a Prunus mume extract has beneficial effects on various metabolic parameters as it has antioxidant, anti-inflammatory and liver protecting properties and may contribute to a good quality of life.

Muscle endocrinology and its relation with liver disease

Carlos Miguel Peteiro Miranda, José Jorge Ortez Toro, Borja Sanz Martín, Sergio Román Gimeno, Rosana Urdaniz Borque, José Antonio Gimeno Orna & María Julia Ocón Bretón
HCU Lozano Blesa, Endocrinology and nutrition, Zaragoza, Spain

Background
Evidence suggests that muscle mass depletion is associated with poor clinical outcomes in clinical population. However, the significance of sarcopenia in the liver transplantation (LT) population remains unclear. The purpose of this study is to investigate the prevalence and the impact of sarcopenia and sarcopenic obesity in cirrhosis patients awaiting LT.
Methods
We retrospectively analyzed patients who underwent LT at our center between January 2013 to January 2019. Data analysis was performed from October 2019 to December 2019. Body composition parameters including skeletal muscle mass index (SMI) and visceral fat area (VFA) were evaluated by preoperative plain computed tomography imaging at the level of the third lumbar vertebra (L3) and also clinical and biochemical parameters were taken. Sarcopenia was defined using FLEXIT cut-points (SMI: male <50 cm^2/m^2; female <39 cm^2/m^2) and obesity a VFA >130 cm^2. Cox regressions and Kaplan-Meier analysis was performed.

Results
The study included 137 patients (108 men) with a mean age of 57,4 (s.d. 9,05),83 (60,6%) had sarcopenia and 29 (21.2%) had sarcopenic obesity. Multivariate analysis identified low SMI as independent risk factor for death after LT [OR 8,293 (3,284–20,040) $P<0.0001$].
Conclusions
Preoperative sarcopenia is an important independent predictor of post-liver transplantation mortality in cirrhosis patients. A high SMI is an excellent predictor for survival in this group of patients.

Differential miRNA expression profile in adipose and muscle tissue of obese individuals with T2DM

Paula Morales Sánchez[1,2,3,4], Sandra Rodríguez Rodero[1,2,3,4], Lourdes Sanz[5], Estrella Turienzo[5], José Luis Rodicio Miravalles[5], Sonia Amoza País[5], Maria Moreno Gijón[5], Sandra Sanz Navarro[5], Jessica Ares Blanco[4], Edelmiro Menéndez Torre[2,4,6,7] & Elias Delgado Álvarez[2,4,6,7]
[1]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Cancer Epigenetics and Nanomedicine, Oviedo, Spain; [2]CIBER – Center for Biomedical Research Network, Rare Diseases, Madrid, Spain; [3]Centro de Investigación en Nanomateriales y Nanotecnología (CINN), Cancer Epigenetics and Nanomedicine, El Entrego, Spain; [4]Central University Hospital of Asturias, Endocrinogy and Nutrition, Oviedo, Spain; [5]Central University Hospital of Asturias, Surgery Department, Oviedo, Spain; [6]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Endocrinology, Nutrition, Diabetes and Obesity, Oviedo, Spain; [7]University of Oviedo, Medicine, Oviedo, Spain

Aim
Obesity represents a risk factor for the development of type 2 diabetes mellitus (T2DM). Although, this seems to reflect common environmental and genetic factors underlying both pathologies, the link between these conditions is not so clear. A diverse group of elements, including miRNAs, has been implicated in the development of these two metabolic diseases. miRNAs are involved in complex regulatory networks of gene expression. This suggests that alterations in their expression levels, their cellular location, and their action may have far-reaching effects on cellular physiology and even invoke sustained alterations. Thus, the main objective of this pilot study is to establish if the differential miRNA expression profile in patients diagnosed with obesity are associated with the presence of T2DM.
Materials and methods
miRNA-seq technology (NGS) was applied to sequence the miRNA profile of visceral adipose tissue (VAT) ($n=6$) and paired skeletal muscle tissue (SMT) ($n=6$) of obese women which underwent bariatric surgery, with and without T2DM. To establish the miRNA expression pattern in the different tissues analyzed, miRDeep2 software was used. Differentially expressed miRNAs analyses were performed with edgeR. Prediction of target genes of the miRNAs was established using the TargetScan program. Statistical computing was performed in R environment.
Results
After sequencing was performed, patients with T2DM were compared to those without it. Expression analysis revealed 95 (61 up and 34 downregulated) differentially expressed miRNA out of 807 (11.77%) in VAT and 40 (16 up and 24 downregulated)out of 663 miRNAs (6.03%) in SMT. Besides Principal Analysis Component didn't showed a clear separation between groups. Despite this, GOrilla tool was used to identify the biological processes that could be altered. Biological processes upregulated in the SMT of obese patients with T2DM were involved in cell migration, signal transduction or regulation of metabolic processes. Downregulated pathways were mainly related to negative regulation of transcription mechanisms and macromolecule biosynthesis. Otherwise, biological processes implicated in covalent chromatin modification were upregulated in VAT of T2DM obese individuals. Interestingly, in VAT, downregulated miRNAs identified were significantly enriched in pathways related to glucose response. Some genes that appeared in this last category were: PPARGC1A, PDK3, LIN28A, ACVR1C.
Conclusions
Patients with obesity and T2DM have a differential miRNA profile in those tissues associated with insulin resistance compared to those that are not. Further studies will be necessary to analyse the genes and routes actually involved in the development of T2DM.

Do early gestation maternal body composition parameters identify neonates born large for gestational age?

Alexandra Cremona[1,2,3,4], Amanda Cotter[4,5], Khadijah Ismail[4,5], Kevin Hayes[6], Alan Donnelly[1,7], Jill Hamilton[8] & Clodagh O'Gorman[1,4,9]
[1]Health Research Institute (HRI), Ireland; [2]University of Limerick, School of Allied Health (SAH), Ireland; [3]Irish Nutrition & Dietetic Institute (INDI), Ireland; [4]University of Limerick, Graduate Entry Medical School (GEMS), Ireland; [5]University Maternity Hospital Limerick (UMHL), Obstetrics & Gynaecology, Ireland; [6]University of Cork, Department of Statistics, Ireland; [7]University of Limerick, Physical Education and Sport Sciences (PESS), Ireland; [8]The Hospital for Sick Children, The Division of Endocrinology, Department of Paediatrics, Toronto, Canada; [9]University Hospital Limerick, Department of Paediatrics, Limerick, Ireland

Background
Globally, birth-weights are increasing progressively. Birth-weights large for gestational age (LGA) defined as ≥90th centile are linked to increased delivery complications, and adiposity in the neonate. This has been linked to glucose intolerance and CVD later in life. Oversupply of nutrients *in utero* contribute to excess foetal growth, and maternal obesity may contribute to this rise. The aim of this study is to examine the relationship between parameters of maternal body composition to neonatal birth weight.
Methods
A prospective observational study was undertaken. Pregnant women aged between 18–50 y of age with gestational age between 10–16 weeks were included in the study. Women aged ≤18 y, twin-pregnancies, known foetal anomaly or pre-existing condition affecting oedema status were excluded. 8-point skinfold thickness, MUAC, waist, hip, weight and ultrasound measurements of subcutaneous (SAT) and visceral abdominal adipose (VAT) were measured. Birth outcomes were abstracted from medical notes post-partum. Birth centiles were adjusted for maternal ethnicity, weight, height and gestational age at birth. Shapiro Wilk's test and visual inspection of Q-Q plots were used to assess distribution of data. Spearman rho correlation analysis was used to assess the relationship between all test variables and outcome measures as continuous variables. Non-parametric independent sample test was used to assess differences between group medians using LGA as a binary-classification.
Results
224 women were recruited in their first trimester of pregnancy. Twenty five neonates were born LGA. Very few significant, but weak (rho~.1) correlations were found with unadjusted birth weight and all test variables. No correlations were found for all test variables when correlated with birth weight centile. Medians and 95% confidence intervals.(CI), as well U statistic asymptotic *p*-values are reported for both groups in Table 1 below. No test variables were found to be statistically different ($P<0.05$) between neonates born LGA and non-LGA.

Associations between FSH levels and indices of total and regional obesity in women after menopause

Eleni Armeni[1], Stavroula A. Paschou[1], Areti Augoulea[1], Stefanos Stergiotis[1], Panagiota Chatzivasiliou[1], Dimitrios Rizos[2], George Kaparos[2], Konstantinos Panoulis[1], Anastasia Palaiologou[1] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Hormonal and Biochemical Laboratory, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Introduction
Recent evidence reports a controversial extra-gonadal role of follicle stimulating hormone (FSH). Conflicting data support that the association between FSH and obesity might be maintained by a direct or even indirect effect to the adipose tissue. The aim of this study was to evaluate the associations between FSH concentrations and various obesity indices in women after menopause.
Patients and methods
This cross-sectional study included 420 postmenopausal women (age 55.6±6.5 years, 8.01±6.7 years since menopause) with low insulin resistance (inclusion criteria: years since menopause>1, FSH>25 IU/ml, HOMA-IR<5). We recorded anthropometric parameters. Indices of regional adiposity were sonographically assessed, including subcutaneous fat and preperitoneal fat. Blood samples were obtained for biochemical and hormonal evaluation.
Results
Mean values of BMI were 25.8±4.0 kg/m^2. Waist circumference and BMI presented a stepwise decrease with increasing quartiles of FSH (Waist, FSH Q1 vs Q2 vs Q3 vs Q4: 93.2±2.4 vs 87.6±4.4 vs 85.4±1.8 vs 80.89±2.8; BMI, FSH Q1 vs Q2 vs Q3 vs Q4: 27.6±5.2 vs 26±4.8 vs 25.8±7.1 vs 23.9±2.9; ANOVA p-value for linear trend<0.001, both cases). Similarly, subcutaneous and preperitoneal fat measures decreased linearly with increasing quartiles of FSH (ANOVA *P*-value for linear trend<0.001). Stepwise linear regression analysis showed that preperitoneal fat is inversely associated with FSH, independently of circulating estrogen (*b* coefficient=–0.130, *P*-value=0.029) and traditional cardiovascular risk factors. The association between FSH and subcutaneous fat was not evident following adjustment for circulating estrogens, implying a possible mediation effect of the latter on this association.
Conclusions
FSH is inversely associated with indices of total and regional adiposity in women after menopause. The exact mechanism of this interaction remains to be elucidated in future studies.

Thyroid stimulating hormone, insulin resistance and leptin in patients with obesity after bariatric surgery

Anna R. Volkova, Galina Semikova & Michael Fishman
Pavlov First State Medical University of Street Petersburg, Saint Petersburg, Russian Federation

Background
The function of the thyroid gland effects on obesity and comorbidities. It has been proven for bariatric surgery to be the most effective in obesity treatment.
Aim
To evaluate the dynamics of body weight, thyroid status, leptin and insulin resistance in obese patients after bariatric surgery.
Materials and methods
78 obese patients were observed after bariatric surgery (sleeve gastrectomy – 46, gastric bypass – 32). Body mass index (BMI), thyroid stimulating hormone (TSH), free T4, fasting plasma leptin, insulin and glucose were estimated; the insulin resistance index HOMA-IR was calculated. The dynamics of body weight was estimated by BMI and the excess BMI loss (% EBMIL). After 3 years of follow-up, 50 patients were examined.
Results
Subclinical hypothyroidism (SH) was detected in 37.2% of patients with high degrees of obesity. A correlation was found between BMI and TSH level (R=0.5; P=0.01). HOMA-IR was increased in most patients with obesity of the II and III degree (5.2±2.3 ng/ml). In the SH group, the leptin level was significantly higher than in the group with a normal TSH level: 44.1±7.4 ng/ml and 33.0±4.7 ng/ml (P=0.004). Among patients with initial SH, spontaneous reduction of TSH levels occurred in 42.7% patients 3 years after surgery.
Conclusions
Postoperatively, the decrease of BMI was associated with the decrease of TSH, leptin and HOMA-IR. The data obtained may reflect the effect of adipose tissue on the functional state of the thyroid gland in patients with high degrees of obesity after bariatric surgery. This seems to be extremely important for maintaining body weight.
Keywords: obesity, thyroid stimulating hormone, leptin, insulin resistance, bariatric surgery.

Fructose-induced alterations of hepatic lipid metabolism are modulated by chronic stress in male rats

Natasa Velickovic[1], Danijela Vojnovic Milutinovic[1], Jelena Brkljacic[1], Ana Teofilovic[1], Biljana Bursac[1], Marina Nikolic[1], Ljupka Gligororovska[1], Sanja Kovacevic[1], Ana Djordjevic[1], Frédéric Preitner[2], Luc Tappy[3] & Gordana Matic[1]
[1]Institute for Biological Research 'Siniša Stankovi•, Department of Biochemistry, Belgrade, Serbia; [2]Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland; [3]University of Lausanne, Department of Physiology, Lausanne, Switzerland

Overconsumption of fructoseenriched beverages and everyday stress are both involved in the pathogenesis of metabolic disorders through their effects on hepatic lipid metabolism. The aim of this study was to investigate whether highfructose diet and chronic stress synergistically perturbs lipid metabolism in rat liver. Therefore, we analyzed the effects of 9-week 20% liquid fructose diet and 4-week chronic unpredictable stress, separately and in combination, on dyslipidemia, VLDL-TG kinetics, intrahepatic triglycerides (IHTG), liver *de novo* palmitate (DNPalm) content and fatty acid (FA) composition. In parallel, hepatic fractional *de novo* lipogenesis (fDNL) by stable isotope tracer protocol, as well as expression of lipid metabolism regulators were also analyzed. Results showed that highfructose diet led to hypertriglyceridemia, increased plasma VLDL-TGs and free FA (FFA), and increased visceral adiposity. Fructose diet also augmented the

level of palmitate, palmitoleate and oleate in the liver, the latter being result of increased desaturase activity. In addition, newly synthesized palmitate (DNPalm content) was increased in the liver of fructose-fed animals, most likely as a result of stimulated fDNL. Chronic stress alone did not exert such effects, but when combined with fructose, stress decreased FFA level, ameliorated fructose-induced TG accumulation, and augmented the release of VLDL-TGs. Stress also enhanced the effects of high-fructose diet on fDNL, which was accompanied with increased expression of key regulators of lipid metabolism, that resulting in stimulated export of newly synthesized palmitate in the form of VLDL-TGs. These results imply that high-fructose diet affects hepatic lipid metabolism by stimulating fDNL and increasing *de novo* synthesized palmitate, which is partially accumulated in the liver and in part released into circulation in the form of VLDL-TGs. On the other hand, stress in combination with high-fructose diet potentiated hepatic fDNL, but it decreased temporary TG storage and redirected newly synthesized palmitate into VLDL-TGs. Thus, the combination of high-fructose diet and chronic stress, as hallmarks of modern lifestyle, exerts more detrimental influence on lipid homeostasis than the individual factors, judged by stimulated fDNL and increased export of VLDL-TGs to non-hepatic tissues.

Autoimmune polyglandular syndrome type ii presenting as an endocrine emergency

Malika Ichiche, Iconaru Laura & Karmali Rafik
CHU Brugmann, Endocrinology, Laeken, Belgium

Introduction
Autoimmune polyglandular syndrome (APS) is a group of polyendocrinopathies characterizedby multiple glands insufficiencies associated with other autoimmune diseases resulting from immune mediated destruction. We describe a patient with type 2 APS presenting first with diabetes type 1 followed later by adrenal insufficiency and Hashimoto disease.
Case report
A 23-year-old male, known with diabetes type 1, presented with a very low blood pressure. He complained of nausea, vomiting, general weakness, easy fatigability, postural dizziness and gradual darkening of the skin since 3 months.
Physical examination revealed both general hyperpigmentation and vitiligo. Laboratory studies showed significant hyponatremia, hyperkaliemia. Morning cortisol was very low 28 nmol/l (22.1–353) and elevated ACTH 1557 ng/ml (7.2–63.3), with a high level of adrenal autoantibodies, which confirm the diagnosis of autoimmune primary adrenal insufficiency. He was started on replacement therapy with physiological doses of prednisolone and fludrocortisone resulting in marked improvement in his symptoms. Further evaluation revealed also an auto-immune hypothyroidism which required Levothyroxine supplementation.
The analysis for mutations in the AIRE gene was negative, without excluding genetics polymorphisms. Screening for other auto-immune diseases associated with APS 2 was negative.
Discussion
Both APS 1 and 2 are associated with type 1 diabetes. The type 2 syndrome is much more prevalent than the type I syndrome and primary adrenal insufficiency is its principal manifestation. Adrenal insufficiency is the initial manifestation in about 50 percent of patients, occurs simultaneously with autoimmune thyroid disease or diabetes mellitus in about 20 percent, and follows them in about 30 percent.
Our patient had type 1 diabetes and presented with adrenal insufficiency with an adrenal crisis. He was diagnosed as a case of APS type 2 consistent ofAddison's disease, type 1 diabetes, autoimmune thyroid disease and vitiligo. We could not detect mutations in the AIRE gene. However it is possible that certain mutations are not detectable with the used technique.
Conclusion
In type 1 diabetes patients and their relatives a search for APS is crucial given predilection to other concomitant autoimmune diseases. Furthermore regular surveillance in these patients is crucial to screen for these other autoimmune disorders even decades after the initial diagnosis.

DOI: 10.1530/endoabs.70.AEP436

Hepatic steatosis indices as a predictors of vitamin D3 deficiency in patients with non-alcoholic fatty liver disease and type 2 diabetes

Udwan Mahmoud[1], Nazarii Kobyliak[1], Dmytro Kyriienko[2] & Iuliia Komisarenko[1]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Kyiv City Clinical Endocrinology Center, General Endicrine Pathology, Kyiv, Ukraine

Background
Recently, vitamin D3 deficiency is considered one of the factors associated with the development of non-alcoholic fatty liver disease (NAFLD). The aim was to evaluate steatosis indices and metabolic parameters in NAFLD depending on D3 status.
Materials and methods
According to the recommendations of the European Society of Endocrinology, all patients were divided into 3 groups: group 1 – with an optimal level of vitamin D3 (30 ng/ml); group 2 – D3 insufficiency (21–29 ng/ml) and group 3 – D3 deficiency (<20 ng/ml).
Results
The study included 126 T2D patients with NAFLD diagnosed with US. The highest hepatic steatosis (HSI) and fatty liver (FLI) index values were diagnosed in D_3 deficiency as compared to optimal group (HSI – 43.34±6.59 vs 39.67±4.37; $P=0.032$ and FLI – 79.21±19.61 vs 64.96±17.72; $P=0.007$). Triglyceride and glucose index (TyG) also insignificantly growth parallel to D3 status worsened ($P=0.175$). In multivariate logistic regression analysis according to the results obtained, regardless of the transaminases activity HSI (Nagelkerke $R^2=0.215$) and FLI (Nagelkerke $R^2=0.163$) were associated with vitamin D_3 deficiency. According to other logistic models, HSI and TyG indices (Nagelkerke $R^2=0.358$) as well as body mass index (BMI) and T2D duration (Nagelkerke $R^2=0.328$) were independent predictors associated with D3 deficiency in this cohort of patients.
Conclusions
hepatic steatosis indices (HSI, FLI and TyG) independently from anthropometric parameters and transaminase activity associated with D3 deficiency in NAFLD patients.

Clinical differences between patients with new-onset diabetes and those without it in a cohort of individuals with pancreatic cancer

Carlos Silva Vaca, David Males, ALBA MARTIN GONZALEZ, Elena García, Guillermo Martínez & Miguel León
Hospital 12 De Octubre, Endocrinology and Nutrition, Madrid, Spain

Background
Pancreatic Cancer (PC) is uncommon; however, it is one of the most deadly cancer types of all. New-onset diabetes (NOD) is associated with a higher risk of pancreatic cancer than general population, particularly if late-onset. An association between new-onset diabetes and increased mortality in patients with pancreatic cancer has been suggested but clinical relevant differences between those individuals with new-onset diabetes and those without are not well established in this population.
Aims
We aim to identify if any clinical differences between individuals with new-onset diabetes and those without exist within a cohort of patients with pancreatic cancer.
Materials and methods
The data was obtained from an institutional registry of 236 patients with pancreatic cancer at '12 de Octubre' University Hospital in Madrid, Spain during the period of time from 2013 to 2017. The patients' imaging studies and hospital records were reviewed. Diabetes Mellitus (DM) was defined by known medical history, or abnormal fasting blood glucose and HbA1c levels according to the American Diabetes Association 2019 criteria within four years of the cancer diagnosis. New-onset diabetes was defined by an arbitrary duration cutoff of ≤3 years since diagnosis. SPSS25.0 software package was used to perform the statistical analysis.
Results
A total of 222 patients fulfilled the inclusion criteria and were included in the final analysis. Patients were predominantly white (215, 96.8%) males (55%) with a median (Interquartile range, IQR) age of 69 (15) years. The median age of the patients was 69 years; 62 (27.9%) patients were 76 years of age or older and had pathologically confirmed pancreatic cancer. Almost one third of patients (27.3%) presented NOD criteria before PC diagnosis,

it accounted for 31.6% of those with a previous history of diabetes. Before PC diagnosis, Patients with NOD had presented impaired fasting glucose more frequently than those without NOD, they also presented with higher fasting plasma glucose value at diagnosis of PC ($P<0.05$). There were no statistical differences in terms of previous history of alcohol consumption, smoking, body-mass index, hepatitis B or C virus immune status, family history of pancreatic cancer or diabetes, A1c, Ca19.9, Amylase, GOT, Alkaline Phosphatase, or GGTvalues at diagnosis of PC ($P>0.05$). Tumor location, size or stage, presence of metastatic disease, metastatic location or bile duct obstruction did not differ between individuals with NOD and those without NOD ($P>0.05$).

HbA1c in the diagnosis of dysglycemia

Samira Belkacem[1] & Semrouni Mourad[2]
[1]Faculté de médecine alger, Medical, Alger, Algeria; [2]Faculté de médecine alger, Service d 'endocrinologie CHU beni messous, Alger, Algeria

Introduction
Type 2 diabetes is a painless and silent pathology, often overlooked, 30% to 50% underdiagnosed. Its prevalence is constantly increasing. It affects 3 new cases every 10 seconds and more than 6 million per year.
Aim of the work
Compare the HbA1c test to the carbohydrate status established by the HGPO on a sample of an unknown Algerian population with diabetes but at high risk. And try to establish HbA1c thresholds by appreciating the validity of this test for the diagnosis of diabetes mellitus, pre-diabetic states and normal subjects. This test has not yet been validated by Algerian national studies.
Material and method
500 patients over the age of 40, consultants at the level of primary care structures, volunteers, but at high risk of diabetes, are subjected to a questionnaire, then to screening by the realization of oral hyperglycemia (HGPO), an HbA1c (HPLC method), an FNS, and an ophthalmological examination (fundus). The sensitivity and specificity of HbA1c at different thresholds for the diagnosis of diabetes and pre-diabetes were studied by ROC curve.
Results
53.2% of patients have dysglycemia: 23.8% have diabetes mellitus, 29.4% have pre-diabetes: 6.8% moderate fasting hyperglycemia (HMJ). 22.6% ITG glucose intolerance. The optimal HbA1c threshold for the diagnosis of diabetes mellitus is 6.27% with a sensitivity of 78% and a specificity of 88%, VPP: 67.88%, VPN: 92.83%, AUC is 0.919. For the diagnosis of pre-diabetes, the optimal HbA1c threshold is 5.83%, with a sensitivity of 71% and a specificity of 81%, VPP: 80.6%, VPN: 72%. The AUC is 0.8157.
Conclusion
The prevalence of diabetes and pre-diabetes in this work is high (23.8% and 29.4%). The use of HbA1c by a standardized method can be a means of screening in subjects at high risk subjects. This HbA1C screening strategy should be verified at the level of the general Algerian population and involve a periodic assessment.

Diabetic ketoacidosis with hypertriglyceridemia-induced acute pancreatitis as first presentation of diabetes mellitus associated with risperidone treatment, a case report

Yasir Elamin & Fatima Al-Rubaish
Imam Abdulrahman Bin Faisal University, King Fahd University hospital, Internal Medicine and Endocrinology, Khobar, Saudi Arabia

The triad of hypertriglyceridemia-induced acute pancreatitis with concurrent diabetic ketoacidosis (DKA) is rare in previously undiagnosed diabetic patients. Drug-induced diabetesis one of the main adverse effects of Risperidone, a second generation (atypical) class of antipsychotic used in the treatment of schizophrenia and bipolar disorder, however, Risperidone-induced diabetic ketoacidosis is rare. We are reporting a case of diabetic ketoacidosis associated with hypertriglyceridemia- induced acute pancreatitis as the first presentation of Risperidone-induced diabetes
Case
A 29 years old Pakistani male with a background diagnosis of schizoaffective disorder presented to the Emergency Department with nausea, vomiting and abdominal pain three weeks after starting Risperidone treatment. He reported a history of polyurea and polydipsia few days after initiation of Risperidone treatment. Examination showed obese male with evidence of dehydration and abdominal tenderness. Laboratory investigations revealed marked hyperglycemia with blood glucose level of 583 mg /dl and high anion gap metabolic acidosis. It also showed evidence of acute pancreatitis with serum lipase more than 15 000 U/l (Normal range 73–393) associated with severe hypertriglyceridemia with triglyceride level more than 2000 mg/dl (Normal range less than 150). He was managed with intravenous insulin infusion and hydration as per diabetic ketoacidosis protocol. He responded slowly and required high doses of insulin to correct his hyperglycemia, metabolic acidosis and hyperglyceridemia. Acute pancreatitis responded well to conservative measures. The patient was discharged on subcutaneous insulin therapy along with oral fenofibrates.
Conclusion
Risperidone induced diabetic ketoacidosis with concurrent hypertriglyceridemia-induced acute pancreatitis is rare. Prompt recognition of the coexistence of these three entities is crucial for adequate management.

Does the association between patterns of fruit and vegetables and metabolic syndrome incidence vary according to lifestyle factors and socioeconomic status?

Parvin mirmiran[1], Bahar Bakhshi[1], Somayeh Hossainpour[1] & Fereidoun Azizi[2]
[1]Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Nutrition and Endocrine Research Center, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Endocrine and metabolism, Tehran, Iran

Background
The aim of this study was to investigate the association between the identified patterns of fruits and vegetables and metabolic syndrome incidence, and to investigate whether lifestyle factors (weight change and smoking) and socioeconomic status (education and occupation status) modify the effect of the patterns on metabolic syndrome risk.
Methods
We prospectively studied 1915 participants of the Tehran Lipid and Glucose study aged 19–74 years who were follow-up for dietary assessment using a validated, semi-quantitative food frequency questionnaire. Linear regression was used to compute energy-adjusted intakes of fruit and vegetables using residual methods. Patterns of fruit and vegetables, based on 17 food groups, were obtained by factor analysis (principal component analysis). To simplify the interpretation, an orthogonal rotation procedure (varimax rotation) was used. Four interpretable factors were retained based on the Cattel test graph (screen plot). Dietary patterns were describe according to foods with loadings>0.3. Four extracted dietary pattern scores were categorized into tertiles. Additionally, we evaluated the effect modification of lifestyle factors and socioeconomic status on the association between different dietary fruit and vegetable patterns and risk of MetS using Cox regression. A significant interaction was defined as $P<0.20$.
Results
We identified four major patterns of fruits and vegetables by factor analysis: 'fresh fruit pattern', 'vegetable pattern', 'dried Fruit and cruciferous vegetable pattern', 'potatoes and fruit juice pattern'. After control for potential confounders, the highest tertile of 'vegetable pattern' was negatively associated with MetS risk (HR: 0.74, 95% CI : 0.60–0.91) and the highest tertile 'potatoes and fruit juice pattern' increased risk of MetS (HR: 1.49, 95% CI : 1.23–1.82). Among participants with weight gain<7% during follow-up, all four identified patterns reduced Mets risk, compared to the reference. When stratified by smoking, 'vegetable pattern' and 'dried Fruit and cruciferous vegetable pattern' lowered MetS risk among non-smokers. Stratification based on education, resulted in MetS risk reduction across tertiles of 'fresh fruit pattern', 'vegetable pattern' and 'dried Fruit and cruciferous vegetable pattern' in educated participants.
Conclusions
The reduction in metabolic syndrome risk caused by fruits and vegetables intake depends on the modifying effect of lifestyle and socioeconomic factors.
Keywords: metabolic syndrome, fruits, vegetables, lifestyle, socioeconomic status.

Diabetes mellitus and glucose-6-phosphate dehydrogenase deficiency: About a case report

Zohra Hadj Ali, Yosra Htira, Rahma Khalaf, Rihab Yamoun, Salma Abadlia, Zeineb Zemni & Faika Ben Mami
National Nutrition Institute, C, Tunis, Tunisia

Introduction
The glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common enzyme deficiency in humans. In red blood cells, the pentose phosphate pathway is the only source of nicotinamide adenine dinucleotide (NADPH), and defense mechanisms against oxidative damage are highly dependent on G6PD activity. The occurrence of acute haemolysis in patient with G6PD deficiency and diabetes has been reported and ascribed to various mechanisms. Her we report a case of patient with G6PD deficiency that his diabetes was revealed by haemolysis crisis.
Case report
A 58-year-old man, who had a G6PD deficiency in its hemizygous form, treated with folic acid, was admitted for acute haemolysis following consumption of beans. He complained of fatigue, polyuria, blurred vision of one month. He had lost a weight and his body mass index was 30 kg/m^2. Physical examination was unremarkable. Plasma glucose concentration was 18 mmol/l and ketonuria was 2+. G6PD activity was decreased to 7% of the lowest normal value. The patient was treated with fluids and potassium replacement, and intravenous insulin. He rapidly recovered and good glycaemic control was obtained with subcutaneous insulin injection. After a 4-year follow-up, diabetes was controlled (mea capillary blood glucose 6 mmol/l, HbA1C 5.9%) with diet and insulin, and no relapses of haemolysis has occurred (blood haemoglobin 14.6 g/dL, total bilirubin 8 µmol/l). Also, He was treated for arterial hypertension with converting enzyme inhibitor, hydrochlorothiazide and bisoprolol, and for ischemic stroke with salicylic acid and statin.
Conclusion
Experimentally, hyperglycemia decreases the expression of the G6PD gene and the activity of his enzyme. Conversely, G6PD deficiency promotes oxidative stress and disrupts the secretion of insulin by beta cells. In subjects at risk of G6PD deficiency, hemolysis should be sought following diabetes decompensation. These two pathologies can worsen reciprocally. An etiological link between them is plausible.

Results of survey of patients trained in the outpatient diabetes school

Ina Taukin[1], Volha Shyshko[1], Alena Yurenya[1], Volha Lazovtseva[1], Tatjana Mokhort[2] & Iryna Bilodid[2]
[1]City Endocrinology Dispensary, Endocrinology, Minsk, Belarus; [2]Belarusian State Medical University, Endocrinology, Minsk, Belarus

Background
Constant feedback is required for optimal performance, allowing for flexible planning of outpatient diabetes schools.
Aim
To study patient satisfaction with the results of education in the outpatient school for type 1 diabetes (s.d.).
Materials and methods
96 patients with type 1 diabetes (T1D) were included. The survey contained 5 questions: Have patients previously been trained at the s.d.? Which sources do they use to receive information? Does the patient suppose that he has enough knowledge about diabetes? Does the patient fully implement the doctor's recommendations? What is a convenient time for attending classes? Does the patient is involved in social networks?
Results
74.5% of the patients surveyed had previously received training at the s.d. 32.26% had been trained more than 3 years ago. 54,84% had undergone training in hospital. 3,22% have been trained in s.d. 67.74% regularly receive information from their attending endocrinologist. 29.03% – from books on the T1D. 58.06% – from the Internet. 22.58% – from other patients with the T1D. 61.3% consider they have enough knowledge about T1D. There's not enough knowledge: 12.9% do not know why they have hypoglycemia; 16.3% are not sure about the correctness of BU calculation and selection of insulin doses; 20,0% are not sure that they can help themselves with hypoglycemia; 12.9% are in need of an individual diet and food selection; 3.22% do not know enough about foot care. 70.91% of patients believe that they are implementing all the doctor's recommendations; not following the recommendations: 9.68% do not follow the nutrition recommendation; 16.1% do not follow the recommendations for physical activity; 12.9% do not keep a self-control diary; 3.2% break the date of appointment for a second medical examination; 3.2% do not perform frequent self-control due to lack of test strips. 3.22% of patients are ready to attend classes daily. 6.45% of patients are ready to attend classes every day. 51.61% of patients are more comfortable attending classes once a week (on Saturdays).
Conclusion
Patients with T1D type have insufficient knowledge on the prevention of acute complications, calculating CE and insulin doses, ready to visit classes on diabetes and most of them suppose they have enough knowledge about diabetes.

Factors associated with being underweight among diabetic outpatient in Cotonou

P. Lionel Medenou[1], Bihan Hélene[2], Alassani Adebayo[3], Tatulashvilli Sopio[2] & Camille Baudry[4]
[1]Diabetes screening, treatment and follow up center of Cotonou, Diabetology, Cotonou, Benin; [2]Hospital Avicennes, Endocrinology, Paris, France; [3]Departemental hospital center of Parakou, Internal medicine department, Parakou, Benin; [4]Hospital Avicennes, Endocrinology, Parakou, France

Introduction
Under-nutrition is a greater risk factor for low productivity andpoor health as diabetes[1]. In Benin 11.9% of males and 9.5% of females were underweight[2] and 5.3% of the population have diabetes[3]. There is no data available on underweight among diabetic in Benin.
The aim of this study is to determine the prevalence of underweight among diabetic and the associated factors.
Method
It was a cross sectional study including 408 diabetics followed up at Cotonou. They have benefited from food survey including a 24 hour dietary recall, the rating of a consumption score then anthropometric measurements. The energy intake was evaluated by the software 'Alimenthèque' and compared to the energy requirements determined by Harris and Benedict's formula. The under weight was defined by BMI < 18 kg/m^2.
Result
The average age of patients was 54.95 ± 0.61 years with a female male sex ratio of 2.11. The prevalence of underweight was 4.67%. The average age of diabetics with weight deficit was significantly higher: 57.26 vs 48.23 years. Factors associated with underweight in multivariate analysis are single diabetics, those with low energy intake, and those with moderate and low food diversification.
Discussion and conclusion
This study suggests a lower prevalence of underweight among diabetic patients compared to the general population. This is partly explained by the urban site of this study, because the current nutritional transition in the sub-Saharan region is mostly urban[4]. These results also highlight the importance of nutritional assessment and survey for diabetic patients in particular those belonging to a vulnerable group: elderly patients, single patients.
Key words: Underweight, diabetes, Cotonou.

Prevalence of dyslipidemia in elderly diabetics

Ramla Mizouri, Hajer Zahra, Khadija Ben Naceur, Aroua Temessek & Faika Ben Mami
Institut National de Nutrition de Tunis, Service C

Introduction
Diabetes in the elderly is often accompanied by other comorbidities, particularly dyslipidemia, which considerably increases the cardiovascular risk in these patients.
The aim of our work was to determine the lipid profile in elderly diabetic subjects.
Methods
This was a descriptive and analytical study carried out on 100 elderly type 2 diabetics hospitalized in our department for unbalanced diabetes. Each patient underwent a complete clinical examination, a biological assessment including the lipid assessment with a complete assessment of the impact of diabetes.
Results
The average age of our population was 69.36 years with a predominance of the age group ranging from 65 to 70 years (56%). There is a clear female predominance (74%). The average BMI was 26.7 kg/m^2. Only 14% of this population had a low socio-economic level. The majority had retained their autonomy (90%). The average duration of progression of diabetes was 15 years with an average HBA1c of 10.2%, of which 54% were on insulin therapy. The mean cholesterolemia was 4.89±1.02 mmol/l, the mean triglyceridemia was 2.27±1.22 mmol/l and the mean LDLemia was 2.24±0.4 mmol/l. Our patients had isolated hypercholesterolemia in 11.2% of cases, hyper LD Lemia in 6.2% of cases and hypoHDLemia in 42.8% of cases. Isolated hypertriglyceridemia was noted in 14.8% of cases. Only 12% of our population had a correct lipid balance under treatment. The analytical study had not shown any positive association between the existence of dyslipidemia and the following factors: the level of HbA1c and the duration of diabetes.
Conclusion
Dyslipidemia is common in elderly diabetics, especially hypo-HDLemia and hypertriglyceridemia. Screening should be systematic and adequate management will prevent cardiovascular accidents.

Real-time continuous glucose monitoring impact on the metabolic control over the summer in children with type 1 diabetes

Simona Gabriela Duta[1], Irina Bojoga[1,2], Calapod Ioana Ruxandra[1], Alexandra Marin[3], Elisabeta Malinici[2,4], Sorin Ioacara[2,4] & Simona Fica[1,2]
[1]Spitalul Universitar de Urgență Elias, Endocrinology, București, Romania; [2]Carol Davila University of Medicine and Pharmacy, București, Romania; [3]C.I. Parhon National Institute of Endocrinology, Endocrinology, București, Romania; [4]Spitalul Universitar de Urgență Elias, Diabetes, Bucharest, Romania

Background
Type 1 diabetes is a chronic disease requiring constant management and a disciplined lifestyle, especially in children. Real-time continuous glucose monitoring system (RT-CGMS) can be a useful tool in maintaining good glycemic control. In our medical centre, beginning with January 2019, a National Program for free distribution of RT-CGMS has been set in motion. The results from one of our previous studies indicated a significant increase in glycosylated haemoglobin (HbA1c) levels after 6 months from RT-CGMS initiation in children already on RT-CGMS at baseline, presumptuously due to a poor metabolic control during the summer months. The present study analyses this hypothesis.
Methods and materials
The analysis included 73 patients, aged under 18 upon entering the national program, who were divided into two groups, depending on the existence of a RT-CGMS at baseline: with previous RT-CGMS at baseline (RT-CGMS+) and without a RT-CGMS at baseline (RT-CGMS-). The baseline medical visit for these patients was done in June and July 2019 when they received free glucose monitoring sensors. The 3 months visit was considered at 90±30 days from baseline. This is a unicentric, prospective cohort study.
Results
We evaluated 73 patients, 36 women (49.3%), mean age 11.2±3.8 years (range: 2.3–17.8 years), mean diabetes duration 4.7±3.1 years. The RT-CGMS+group has 26 subjects, mean age 11.1±4.1 years, mean diabetes duration 5.4±3.1 years, with a mean HbA1c 7.0±0.5% (53 mmol/mol) at baseline. The RT-CGMS- group has 47 subjects, mean age 11.3±3.6 years (P=0.90 vs RT-CGMS+), diabetes duration 4.3±3.1 years, and HbA1c 7.6±1.1% (60 mmol/mol, P=0,016 vs RT-CGMS+) at baseline. There was a significant increase in HbA1c after 90.2±8.1 days in the RT-CGMS+ group reaching 7.5±0.6% (58 mmol/mol, P<0.01 vs baseline). The HbA1c variation did not change significantly in the RT-CGMS- group, with a value at 3 months of 7.8±1.1% (62 mmol/mol, P=0.075 vs baseline).
Conclusions
The results of the three months follow-up over the summer for the two patient groups indicated that RT-CGMS initiation in patients previously not exposed to RT-CGMS cancels the increase of HbA1c levels registered in patients previously exposed to RT-CGMS, who continue to use it for the same study period. This finding is consistent with the poor glycemic control observed during the summer in most patients, and especially in teenagers.

The impact of real-time continuous glucose monitoring on metabolic control in children with type 1 diabetes

Calapod Ioana Ruxandra[1], Irina Bojoga[1,2], Simona Gabriela Duta[1], Ana-Maria Stancu[3,4], Amalia Arhire[1,2], Sorin Ioacara[1,2] & Simona Fica[1,2]
[1]Spitalul Universitar de Urgență Elias, Endocrinology, București, Romania; [2]Carol Davila University of Medicine and Pharmacy, București, Romania; [3]Parhon Hospital Bucharest, București, Romania; [4]'Carol Davila' University of Medicine and Pharmacy, General Medicine, Bucharest, Romania

Background
Real-Time Continuous Glucose Monitoring Systems (RT-CGMS) represent a minimally invasive method for frequent glucose monitoring, allowing a better glycemic control for patients with type 1 diabetes. With the occasion of implementing the National Program for free access to RT-CGMS, we assessed the 6 months impact of RT-CGMS on the metabolic control, evaluated by glycated haemoglobin (HbA1c).
Methods
In this unicentric, prospective cohort study, we assigned patients with type 1 diabetes, aged less than 18 years, receiving the free RT-CGMS from a pediatric diabetes centre and returning for the 6 months resupply visit by January 9th, 2020. The allowed 6 months visit window was ±30 days. Patients were divided into two groups according to whether they already had a RT-CGMS at baseline or not: RT-CGMS+ (with RT-CGMS already used at baseline) and RT-CGMS- (without RT-CGMS at baseline).
Results
The study was completed by 63 patients, 28 women (44.4%), mean age 10.1±3.8 (range: 3.1–17.9) years, mean diabetes duration at baseline 5.1±3.4 years, who were evaluated at baseline and at 180.8±11.5 days. The RT-CGMS+ group had 31 patients, mean age 9.9±3.7 years, mean diabetes duration 5.2±3.0 years, mean HbA1c at baseline 7.3±0.7% (56 mmol/mol). The RT-CGMS- group had 32 patients, mean age 10.3±3.9 years (P=0.67 vs RT-CGMS+), mean diabetes duration 4.9±3.8 years (P=0.73 vs RT-CGMS+), and baseline HbA1c 7.9±1.1% (63 mmol/mol, P<0.01 vs RT-CGMS+). The HbA1c significantly rose at 6 months in RTCGMS+ group to 7.5±0.7% (58 mmol/mol, P<0.01 vs baseline). However, in the RT-CGMS- group, the HbA1c didn't have a significant change at 6 months, reaching 8.0±1.0% (64 mmol/mol, P=0.71 vs baseline).
Conclusions
The introduction of a RT-CGMS to patients without previous access to this technology was associated with a complete resolution of the natural tendency towards an increase in HbA1c at 6 months, which was seen in patients already using a RT-CGMS and continued to use it for another 6 months. A possible explanation for the HbA1c increase registered in children already on RT-CGMS at baseline might be the effect of summer months when diabetes management was possible less stringent. Further work is needed to verify this hypothesis.

AEP448

Phospholipid metabolism in patients with type I and 2 diabetes mellitus

Gulnora Artykbaeva & Talat Saatov
Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Biochemistry, Tashkent, Uzbekistan

The onset of diabetes mellitus caused by insulin deficiency and insulin resistance is simultaneous with the onset of disorders in lipid and carbohydrate metabolism. Phospholipids are subjected to major alterations in the lipid structures. The data on composition of phospholipids in diabetes mellitus are discordant. The work was initiated to study concentrations of phospholipids in blood of patients with type 1 and type 2 diabetes mellitus. 24 patients with type 1 DM (T1DM) and 34 patients with type 2 DM (T2DM) were recruited for the study. Blood glucose, lipid profiles and blood serum phospholipids were measured. The chloroform-methanol mixture was used to extract the phospholipids. Thin-layer chromatography was used to fractionate them. In patients with T2DM the total phospholipid fractions were found to decrease as compared to the controls (103.63±4.744 μg of phosphorus/mg of protein vs 207.6±4.4 μg of phosphorus/mg of protein). In T1DM patients the total phospholipid fractions were reduced as compared to the controls. As to individual phospholipid fractions in T1DM and T2DM, the alterations were found oppositely directed. Thus, acidic phospholipids, such as phosphatidylinositol (PI) and sphingomyelin (SPH) increased, while the neutral ones, to name phosphatidylethanolamine (PE) and phosphatidylcholine (PC) decreased as compared to the controls. Intensity of acyl residuals of all phospholipid fractions is subject to alterations in insulin deficiency. Transacylation as a chain-termination in fatty acid synthesis in phospholipids is impaired due to inhibition of the acylase reaction with activation of phospholipases to result in suppression of acyl group synthesis. The reduction in synthesis of choline-containing phospholipids can be explained by the disorders in methylation of phosphatidylethanolamine which is a precursor in the process. Failure of the metabolic pathways to reuse exogenous choline due to the deficiency of ATP, A coenzyme, pyridoxal phosphate and other co-factors of lipid metabolism in insulin deficiency could be another cause for the disorder of phospholipid synthesis in diabetes. The increase in lysophosphatidylcholine in diabetes can be associated with the peroxidation of phosphatidylcholine and the disorders in diacyl phospholipid forms. Disorders in major and minor components of phospholipids take place in type 1 DM and type 2 DM. As the result, concentrations of total phospholipids change to result in the lipid metabolism dysregulation.

High prevalence of psychiatric disorders and its association with worse glycemic control in patients with type 1 diabetes

Thiago M Fritzen[1], Ticiana C Rodrigues[1], Saskia C de Boer[2], Isabele B Denk[2], João Alberto Succolotti Deuschle[2], Isabel Conte[1], Maurício Picolo Menegolla[1] & Letícia Weinert[2]
[1]Universidade Federal do Rio Grande do Sul, Endocrinology, Porto Alegre, Brazil; [2]Hospital Escola UFPEL, Endocrinology, Pelotas, Brazil

Introduction
Chronic diseases such as type 1 diabetes can be associated with psychiatric disorders. Previous data suggest a high prevalence of depression, anxiety, disordered eating and diabetes distress among patients with diabetes. Mental health problems could interfere with treatment adherence, glucose control and chronic complications.
Objective
We aim to evaluate the prevalence of psychiatric disorders, drug abuse, and treatment adherence in patients with type 1 diabetes. We also aim to study the association of mental health problems with glycemic control and chronic complications.
Methods
A cross-sectional study was designed to apply face-to-face standardized questionnaires and to evaluate patients' clinical data from medical records. We included patients with type 1 diabetes over the age of 10 who are assisted at two public hospitals linked to federal universities in Southern Brazil. Patients signed a consent form and the study was approved by Ethics Committee. We used Patient Health Questionnaire-2 (PHQ) and PHQ-9 to evaluate depression, Self Care Inventory-Revised to evaluate treatment adherence, and Eating Attitudes Test to study eating disorders. We also apply a questionnaire to investigate licit and illicit drugs use and anxiety symptoms.
Results
We included 166 patients with a median of 33 years (22–45 years), 53.6% were women, with a median of 14 years (6–25 years) since diabetes diagnosis, and a median of A1c of 8.5% (7.8–9.4%). 91 patients (54.8%) was diagnosed with one mental health disorders (20.5% of patients have depression and 40.4% have anxiety), and 79 (47.6%) patients had positive screening for eating disorder. About drug use, 16 (9.6%) patients are active smokers, 30 (18.1%) patients drink alcohol regularly, and 2 (1.2%) patients use illicit drugs. The comparison between patients with and without psychiatric illness showed a worse glycemic control in the group with mental disorder (A1c 9.0% vs 8.5% in controls); there was no other clinical or laboratorial difference between groups. Patients with suicidal ideation or attempt are almost entirely depressed (34 patients [94.4%]). 91 patients (54.8%) were considered to have good adeherence to treatment; this group of patients has a better A1c than non-adherent patients (8.4% vs 8.8%; $P=0.023$).
Discussion
The prevalences of psychiatric illness, drug use and eating disorders are high among patients with type 1 diabetes and it is associated with a worse glycemic control. Clinical doctors should be aware of this scenario and, therefore, do screening for mental disorders in this population.

Congenital anomaly of the kidney and urinary tract and mody 5 due to 17Q12 deletion syndrome; a case report

Athanasios Siolos[1], Maria Merkoviti[1], Ioannis Georgiou[2], Ekaterini Siomou[3] & Stelios Tigas[1]
[1]Ioannina University Medical School, Department of Endocrinology, Ioannina, Greece; [2]Ioannina University Medical School, Laboratory of Medical Genetics and Human Reproduction, Ioannina, Greece; [3]Ioannina University Medical School, Department of Pediatrics, Ioannina, Greece

Hepatocyte nuclear factor 1B (*HNF1B*) defects (mutations or deletion) are associated with amultisystem disorder, including urinary tract abnormalities and diabetes (MODY 5, maturity-onset diabetes of the young type 5). We present the case of a patient with congenital anomalies of the kidney and urinary tract in the context of 17q12 deletion syndrome who several years later, presented with MODY 5. A 20-year-old male presented at the outpatient Endocrine Clinic with new-onset diabetes mellitus. Laboratory findings revealed a HbA1c of 7.9%, with no evidence of ketoacidosis, detectable C- peptide levels (2.3 ng/ml) and negative antibodies to glutamic acid decarboxylase (GAD), tyrosine phospahtase (IA2) and insulin (IAA). He had a history of right ureterovesical junction obstruction repaired at the age of 2 and persistent hypomagnesemia, hypermagnesuria and hypocalciuria were found at the age of 15. A deletion of 1.4 Mb at chromosomal band 17q12 was then detected by array-comparative genomic hybridization, encompassing two OMIM genes, the Acetyl-CoaCarboxylase-Alpha (ACACA, OMIM#200350) and Hepatocyte Nuclear Factor-1-B (HNF-1B, OMIM#1890907). Elevated liver enzymes had been noted since the age of 17, and hypoplasia of the pancreas had been detected on an MRI scan. In addition, the patient exhibited learning difficulties, and mild mental retardation had been documented at the age of 16 (Wechsler Intelligence Scale III-R Full scale IQ score: 58). Based on the phenotypic features and results of the genetic analysis, a diagnosis of 17q12 deletion syndrome was made. The 17q12 deletion syndrome is caused by deletion of a 1.4 Mb region of 17q12 which encompasses genes like *HNF-1B, ACACA* and *LHX1*. Clinical features include diabetes mellitus of the MODY 5 type, functional and structural kidney and urinary tract disorders, cholestatic hepatopathy, structural pancreas malformations, intellectual/learning disabilities, neuropsychiatric disorders and facial dysmorphia. Recent evidence suggests that MODY 5 is a common feature in patients with 17q12 deletion syndrome whilston the other hand, whole gene *HNF1B* deletions are observed in up to 50% of MODY 5 cases. Notably, as recently reported by Laffargue *et al.*, complete deletion of the *HNF1B* gene and 17q12 microdeletion syndrome may be considered as the same genetic disorder (5). Clinical features suggestive of the 17q12 deletion syndrome should prompt clinicians to request chromosomal microarray analysis in patients with suspected MODY 5.

Sleep quality of diabetic patients with metabolic syndrome, is therea difference?

Savaş Karataş[1] & Aysun Isiklar[2]
[1]T C Saglik Bakanligi Istanbul Egitim ve Arastima Hastanesi, istanbul, Turkey; [2]Acıbadem Altunizade Hastanesi, Istanbul, Turkey

Objective
Poor sleep quality is a prevalent health problem among patients with diabetes. Metabolic syndrome (MetS) is common in type 2 diabetic patients, and associated with morbidity and mortality. We aimed to investigate sleep quality among type 2 diabetes patients according to their metabolic syndrome status.
Participants
This was an analysis of data collected from 189 adult type 2 diabetic patients.
Methods
The patients were divided into two groups (metabolic and non-metabolic) based on the presence of MetS. Anthropometric measurements, blood pressure and serum glucose, lipid levels were collected. The Pittsburgh Sleep Quality Index (PSQI) was calculated for all patients .
Results
There was no significant difference in subjective sleep quality scores between the two groups ($P>0.05$). However, there was a significant difference in sleep latency scores between the two groups; the scores of patients with MetS were lower than those of patients without MetS ($P=0.010$, $P<0.05$). Sleep quality was low in 57.1% ($n=108$) of the patients with diabetes.
Conclusions
Poor sleep is common among diabetic patients, but in this study metabolic syndrome existence was not associated with sleep quality in type 2 diabetic patients.

Retinol-binding protein in the diagnosis nafld and type 2 diabetes

Zvenigorodskaya Larissa, Shinkin Mikhail, Nilova Tamara, Petrakov Alexander & Varvanina Galina
Moscow Clinical research and practice center named after Loginov, Moscow, Russian Federation

Retinol binding protein (RBP) is an adipokine, related to insulin resistance (IR). Excess free fat acid reduces the binding of insulin by hepatocyte receptors and leads to hyperinsulinemia. RBP transport protein synthesized in hepatocytes and adipocytes. The level of RBP increases in patients with obesity, diabetes and non-alcoholic fatty liver disease (NAFLD). It is positively correlated with the degree of severity of the inflammatory process and fibrosis. The RBP regulates the activity of insulin in tissues, skeletal muscles, and the liver.
Purpose of research
Determine RBP in patients with NAFLD and type 2 diabetes. Compare the results of RBP with markers of lipoprotein-associated inflammation phospholipase (FLA2) and nitrogen oxide (NO), which inhibits the proliferation of collagen and regulates hepatic blood flow.
Material and methods
208 patients with NAFLD and type 2 diabetes were examined. The average age is 57.3±5.2. There were 76 patients with type 2 diabetes and 132 with impaired glucose tolerance (NTG). BMI more than 30 kg/m^2 (34.85±1.79). Clinical, biochemical, and instrumental research methods were performed. RBP was determined in 89 patients with type 2 diabetes using the immunoassay method in blood serum. The control group consisted of 15 practically healthy person. FLA was determined by immunoenzyme method. NO metabolites were determined by Express method.
Research result
The RBP content in the control group was 26.15±1.31 mg/l. The RBP content in patients with type 2 diabetes without NAFLD (group 1) was reduced by 12.8% and amounted to 20.34±3.8 mg/l. The RBP content in 49 patients with NAFLD and2 diabetes (group 2) was significantly increased by 48.9% and amounted to 38.96±11.47 mg/l. The FLA2 content was increased by 4.78 times in relation to the control in group 2. The content level stable nitric oxide metabolites was increased in parallel with liver activity enzymes. There is a direct positive correlation between FLA2 and NO. The correlation coefficient was $r=0.625$ $P=0.001$.
Conclusion
The level of RBP was significantly increased in patients with type 2 diabetes and NAFLD compared with control and group 1. Increase in the content of inflammatory markers accompanied by an inflammatory process in the liver with increased activity liver enzymes and the severity of morphological changes.

AEP453

Prevalence of disordered eating behaviour in type 2 diabetic patients receiving insulin

Veranika Lobashova[1] & Alla Shepelkevich[2]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, Endocrinologic, Minsk, Belarus; [2]Belarusian State Medical University, Endocrinologic, Minsk, Belarus

Objective
Diabetes mellitus represent a demanding set of biopsychosocial challenges(-depression, anxiety disorders, eating disorders) for patients and their families regardless of the age of disease onset. Disordered eating behaviors and eating disorders(ED) represent a spectrum of symptoms that may include restricted caloric intake, distorted body image, binge eating and/or purging behaviors such as excessive exercise, vomiting, and the use of laxatives to lose weight. The prevalence of eating disturbances varies and depends on studied population (age, BMI) and used methods of diagnosis. The aim of the study was to assess the prevalence of disordered eating behavior in type 2 diabetes mellitus(DM) patients received insulin using EAT-26 questionnaire.
Method
263 patients with type 2 DM receiving insulin were examined. The mean age was 62 (57–67) years, mean weight 91 (78–105) kg, duration of diabetes mellitus 12 (8–17) years. The group of women consisted of 186 patients (the mean age 62 (57–58) years, the mean duration of DM 12 (7–18) years), the group of men include 77 patients (mean age 60 (56–66) years, duration of DM 12 (8–16) years). There were no statistic differences in age ($U=11088$, 5 $P=0.077$), BMI ($U=11659$, 0 $P=0$, 276), duration of DM ($U=8461$, 5 $P=0.800$) in the subgroups. Our study assess the prevalence of ED by using EAT-26 questionnaire as a screening instrument. The cut off 20 was used as a criteria for diagnosis.
Results
The prevalence of disordered eating behavior according to the results of cut off EAT-26 questionnaire was 35.3% (93 of 263 patients had the score 20 and higher). The mean score of EAT-26 was 15 (9–21). Statistical differences were revealed in the EAT –26 score depending on gender ($U=5453.0$ $P=0.002$). The mean EAT score in subgroup of men was lower 12 (7–20) than in the subgroup of women 16 (10–22). The prevalence of disordered eating in the subgroup of men was 25, 9% (20 of 77 patients). In the subgroup of women 39, 2% (73 of 186 patients).
Conclusion
The prevalence of disordered eating behavior in type 2 DM receiving insulin patients tested by EAT-26 questionnaire was 35.3%.

DOI: 10.1530/endoabs.70.AEP453

AEP454

Constructing a model for the differential diagnosis MODY diabetes and type 2 diabetes

Alla Ovsyannikova[1,2], Oksana Rymar[2], Elena Shakhtshneider[2] & Mikhail Voevoda[1,2]
[1]Novosibirsk State University, Novosibirsk, Novosibirsk, Russian Federation; [2]Research Institute of Internal and Preventive Medicine – Branch of the Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Novosibirsk, Russian Federation

Most young patients with hyperglycemia are diagnosed with type 1 diabetes mellitus and type 2 diabetes mellitus (T2DM) but up to 10% of all cases of the disease occur in MODY diabetes. Diagnosis of the correct type of diabetes mellitus (DM) leads to the appointment of pathogenetic effective therapy, adequate management of pregnancy and the prevention of specific complications. The aim of the study was to create a model for the differential diagnosis of T2DM and MODY.

Materials and methods
We examined 108 people in Novosibirsk city who had debut of DM up to 35 years: 92 patients has been confirmed by molecular – genetic testing MODY, 91 – type 2. All patients had a clinical examination, blood sampling for biochemical and hormone (TSH, C-peptide) analyzes. A model was constructed to study the most significant factors during the diagnosis of type of diabetes using binary logistic regression.
Results
Both groups of patients were comparable in gender, age, and duration of diabetes. Median of age of the patients at moment of examination was with T2DM – 29.5 [17.7;37.0] years, with MODY – 24.0 [0.0;35.0] years ($P=0.280$). After creating various regression models the most significant factors associated with diabetes were identified: 'the presence of relatives with diagnosed diabetes for them under 35 years of age', 'the presence of relatives with impaired carbohydrate metabolism and obesity', 'overweight and obesity'. A final regression model is constructed to determine the significance of these factors. Among the analyzed factors associated with the type of diabetes all three were statistically significant ($P<0.001$).
Thus when studying the influence of a hereditary history, clinical and laboratory factors in MODY and T2DM during the construction of binary regression models it was determined that the presence of relatives with verification of hyperglycemia up to 35 years was associated with MODY diabetes and the presence of excess weight and obesity in patients with T2DM as well as relatives with diabetes and obesity. These results should be taken into account when conducting differential diagnosis of the type of diabetes mellitus in individuals with diagnosed hyperglycemia up to 35 years.

Acidosis is not a sine qua non for DKA

Göktuğ Sarıbeyliler[1], Caner Kapar[2], Ayşenur Yılmaz[2], Alpay Alibeyoğlu[2], Cemile İdiz[1], Ümmü Mutlu[1], Vefa Nasifova[1], Ozge Telci Caklili[1], Ayşe Merve Çelik[1], Ramazan Çakmak[1], Nurdan Gül[1], Kubilay Karşıdağ[1] & Nevin Dinççağ[1]
[1]Istanbul Faculty of Medicine, Endocrinology and Metabolic Disorders, İstanbul, Turkey; [2]Istanbul University Istanbul Faculty of Medicine, Internal Medicine, İstanbul, Turkey

Although Diabetic ketoalkalosis (DKAlk) has beendescribed as a mixed acid-base disorder over half a century ago, there is unawareness among physicians. Here, we present two cases to emphasize DKAlk which is more common than it's thought.
Case-1
A thirty-year-old female patient with type-1 diabetes and ten weeks of pregnancy presented with several weeks of vomiting. She also reported that she had hyperthyroidism for 2 weeks and that she used propylthiouracil 50 mg/day in addition to insulin. Physical examination revealed volume depletion findings such as dehydration andtachycardia. Laboratory findings are shown in the table. These findings suggested metabolic acidosis masked by alkalosis. Fluid replacement and insulin infusion therapy was applied rapidly. Propylthiouracil was increased to 150 mg/day, in addition to iodine restriction. After 3 days, ketonuria disappeared and pH and delta gap were found as 7,44 and 13,5, respectively. In this case, the acid-base disorders were DKA, metabolic alkalosis due to hyperemesis gravidarum and respiratory alkalosis due to pregnancy and gestational thyrotoxicosis.
Case-2
A thirty-two-year-old female patient with type-1 diabetes and sixteen weeks of pregnancy was admitted to emergency department with vomiting, dysuria and sore throat. She had hypotension andtachycardia as results of severe dehydration. Laboratory findings are shown in the table. She also had pyuria and high levels of CRP (42.99 mg/l) and ESR (85 mm/h). These results were compatible with combined alkalosis and acidosis. After 24-hour fluid replacement, insulin infusion and ceftriaxone therapy, hypovolemia improved, ketonuria disappeared, glucose levels returned to normal range. While clinical situation improved within days, all other laboratory results ameliorated. Thyroid disorder was interpreted as subacute thyroiditis and followed without treatment; fT4 and fT3 levels decreased spontaneously at the end of the second week (fT4:11.29 pmol/l, fT3:3.88 pmol/l). In this case DKA, metabolic alkalosis due to vomiting caused by acute pyelonephritis and respiratory alkalosis due to pregnancy and thyroiditis were observed. As conclusion, acidosis is not a sine qua non for DKA. Awareness should be raised about DKAlk. It should always be kept in mind that mixed acid-base disorders can mask DKA and DKAlk may be in the foreground of the picture.

Effect of dietary intake of branched chain amino acids on type 2 diabetic patients

Nehal Hamdy[1], Randa Salam[1], El sayed Hammad[2] & Samah Abd el shafy[3,3]
[1]Cairo University, Endocrinology department, Egypt; [2]National nutrition institute, clinical nutrition department, Cairo, Egypt; [3]Al Kasr Al Aini Hospital, Therapeutic nutrition, Cairo, Egypt

Background
BCAAs up regulate glucose transporters and activate insulin secretion has been widely demonstrated. However, several researchers have suggested that excessive intake of amino acids could lead to inhibition ofinsulin signalling. BCAAs may induce insulin resistance throughm TOR activation insulin resistance may be linked with high intake of BCAAs, Controversiesremain on whether an increase in plasma BCAA levels is a cause or consequence of insulin resistance.
Aim
The aim of the study is to measure the effect of consumption ofBCCAs on lipid profile and glucose level in type 2 obesediabetic patients.
Subject and methods
Participants enrolled in the study 280 patients (139 male,141 female) with type 2 diabetes formore than 5 years. Attending Endocrinology out patient clinic. Written consent was obtained from all participants. Anthropometric measurement (height, weight, waist circumference, body mass index. Dietaryassessmentparticipants had to complete food frequency questionnaire (24 hour recall) for 5 days and analysis for branched chain amino acid intake wasperformed using food composition table, life style, socio-demographic level, laboratory investigations including, fasting glucose, HbA1c, cholesterol, triglyceride, LDL, HDL.
Results
Mean Age 38.24±4.28, male 49.6%, female 50.4%, diabetes duration 8.86±2.26 years, BMI; 29.89±3.02, protein intake 77.75±14.76 g, Leucine 4.75±1.01g, valine 4.04±0.89 g, Isoleucine 4.09±0.92 g, fasting glucose 206.60±51.01 mg. A1C 9.33±1.18, cholesterol 238.79±40.37 mg/dl, triglycerides 103.47±14.01 mg/dl. LDL178.20±43.32 mg/dl/HDL 44.03±9.55 mg/dl. All of our patients took higher load for age and ideal weight of (leucine, valine, and isoleucine is likely to be 0.04, 0.017–0.02, and 0.019 g/kg respective) mainly from plant source protein. Regarding correlation with A1C (Valine $P=0.01$, $r=0.02$/isoliosine $P=0.08$ $r=0.156$). Regarding correlation with LDL (liosine $P=0.07$ $r=0.156$).
Conclusion
High BCCAs intake mainly from plant source is associated with dyslipidaemia and poor glycaemic control proper dietary counselling is important in diabetic.

Real-life clinical experience with GLP1 analogs and SGLT2 inhibitors in the treatment of diabetes type 2 and obesity

José Pérez-Rodríguez, Dulce Calderón-Vicente, Javier González-López, David Martín-Iglesias & Mubarak Alramadan
Virgen de La Luz Hospital, Endocrinology and Nutrition, Cuenca, Spain

Objectives
SGLT2 inhibitors and GLP1 analogs are the treatment of choice after metformin in patients with type 2 diabetes (DM2) and overweight-obesity (OB).

The aim of this study is to analyze the effectiveness and safety of these treatments alone or in combination.
Methodology
This is a retrospective observational study in the usual clinical practice. We analyzed the effects of SGLT2 inhibitors and GLP1 analogs treatments in patients with DM2 and OB who have poor metabolic control after metformin. We measured: HbA1c, weight, insulin dose, systolic blood pressure and LDL cholesterol levels at 0, 3, 9 and 15 months. Likewise the proportion of adverse effects were registered.
Results
A total of 90 patients, 48 men and 42 women, with a average age of 62.7±9.7 years were analyzed. At the beginning they had an average BMI of 35.6±7.0 kg/m^2 andHbA1c of 7.9±1.1%. The average evolution time of DM2 was 12.2±9.4 years and 68.9% patients were insulin dependent with an average initial insulin dose of 37.3±2.6 IU. 23.3% of patients were treated with GLP1 analogs (liraglutide, lisixenatide, weekly exenatide, or dulaglutide), 55.6% were treated with SGLT2 inhibitors (dapaglifozin, canaglifozine, or empaglifozine) and 21.1% with a sequential combination of both. Regarding metabolic control, we observed a significant reduction in HbA1c at 3 months: –0.61±1.20% (P<0.001), at 9 months: –0.70±1.12% (P<0.001) and at 15 months: –0.73±1.31% (P=0.004). Regarding weight, we also found a significant improvement at 3 months: –2.13±2.63 kg (P<0.001), at 9 months: –3.63±3, 07 kg (P<0.001) and at 15 months: –3.83±4.14 kg (P<0.001). Insulinized patients required significantly lower doses of insulin at 3 months: –3.62±7.95 IU (P=0.001) and at 9 months: –6.45±12.16 UI (P=0.002), without reaching statistical significance at 15 months: –6.50±17.81 UI (P=0.12). We didn´t observe significant changes in systolic blood pressure and LDL levels. Finally, we registered adverse effects in iSGLT-2 patients: genital mycosis in 7.8% and urinary tract infections in 4.4%; andina GLP-1 patients: vomiting in 1.1%.
Conclusions
The results of this study corroborate the benefits obtainedin clinical trials with the GLP1 analogs and SGLT2 inhibitors in metabolic and weight control, with a low rate of adverse effects.

Glucose scan behaviour in people with type 1 diabetes using flash glucose monitoring in a real-world setting

Daniel Hochfellner, Haris Ziko, Hesham Elsayed, Monika Cigler, Lisa Knoll, Tina Pöttler, Felix Aberer & Julia Mader
Medical University Graz, Endocrinology and Diabetology, Graz, Austria

Introduction
Flash glucose monitoring (FGM) enables people with diabetes to regularly track their glucose levels without performing capillary finger-stick measurements (SMBG). Clinical studies have shown improvement in glycemic control, reduction of hypoglycemia, improvement in comfort and quality of life in people with type 1 diabetes (T1D) using this technology. In contrast to continuous glucose monitoring, FGM requires the performance of a scan to obtain the current glucose level. The analysis aimed to investigate whether patients' scanning behaviour alters closer to an outpatient clinic visit.
Methods
We analysed registry data collected by at tertiary diabetes centre in Austria. People with T1D routinely using FGM to manage their diabetes were included in the analysis. FGM data of the last 90 days before a routine outpatient clinic visit were analysed. We assessed the effect of scan frequency on parameters of glycemic control such as eA1c (estimated A1c) and time in range (TIR) two weeks and three months prior to consultation. We tested for normal distribution using Shapiro-Wilk test and compared scan frequency, changes in eA1c and TIR using paired two-sample t-test.
Results
Data from 89 individuals (49% female, age 42.3±13.9 years, BMI 25.1±4.0 kg/m^2, diabetes duration 20.1±12.5 years, CSII vs MDI 18 vs 71) were analysed. Data are two weeks vs three months before a regular outpatient clinic visit, respectively. The mean scan frequency was 13.2±8.3 scans/day vs 10.5±4.4 scans/day (P<0.01). EA1c 58.9±11.8 mmol/mol vs 59.2±10.7 mmol/mol (P=0.664) and TIR (70–180 mg/dl) 53.9±16.3% vs 53.11±14.8% (P=0.346) were not significantly different between the two time periods.
Discussion
We observed a significant increase in daily scan frequency two weeks prior to a scheduled outpatient clinic visit as compared to the three months before the visit This is analogous to earlier findings in SMBG, showing an increase in performance and documentation of glucose values before an outpatient clinic visit. Despite this increase in glucose checks, there was no significant improvement in glycemic control assessed by FGM such as eA1c and TIR. The recommended treatment goal of >70% TIR 70–180 mg/dl was not achieved in our population. Thus, we can assume that only an increase in scan frequency might not necessarily result in relevant improvement in glycemic control. Therefore, effort must be made to motivate and educate FGM users better to make use of the full potential of FGM.

Mediterranean diet as a novel adjuvant treatment for type 1 diabetes

Alexis Kyriacou[1,2], Angelos Kyriacou[2,3] & Josie MM Evans[1]
[1]Stirling University, Stirling, United Kingdom; [2]CEDM Centre of Endocrinology Diabetes & Metabolism, Limassol, Cyprus; [3]Salford Royal NHS Foundation Trust, Endocrinology, Salford, United Kingdom

Introduction
The importance of good glycaemic control in Type 1 diabetes (T1D), including its association with reduced cardiovascular disease, is well established. Current education programs focus on carbohydrate counting and its matching to the insulin dose. We set out to investigate the association between Mediterranean diet (MD) and the glycaemic control in patients with T1D.
Study design
This was a cross-sectional study that was a collaboration between Cyprus and the UK, which recruited patients with T1D from Limassol, Cyprus. The sample was randomly selected from the database of the Cyprus Diabetes Patients' Association.
Statistics
The MD was examined for its association with glycaemic control through a predefined multivariate linear (OLS) regression model. The MD was measured through a priori Mediterranean diet score, namely MedDietScore and the glycaemic control through HbA1c and fasting glucose. The covariates were gender, age, BMI, C-peptide, household income, injection method, smoking status and insulin adjustment to carbohydrate intake. Statistics were analysed using STATA 16.0.
Ethics
Ethics approval was received from the Cyprus National Bioethics Committee (EEBK/EII2016/09) and from the University of Stirling, UK (NICR 16/17 – Paper No.44).
Results
The study recruited 103 participants (median age 33 yrs (IQR 26,43); 51 males). Themean MD score was 31.7 (s.d.±5.7) points with a median HbA1c at 60 mmol/mol (51,74) and fasting glucose at 168 mg/dl (102,247). The adherence to the MD was significantly associated with HbA1c [b=–0.015, (–0.026, –0.0045), P=0.006] but not with fasting glucose. The OLS model predicted a reduction in HbA1c (mmol/mol) by 1.5% for every additional point in the MedDietScore scoring system. A post-hoc analysis indicated that the fasting glucose did not mediate the effect of the MD on the HbA1c: the indirect effect (simple mediation analysis) was not statistically significant (b=–0.0027, P=0.180) and when fasting glucose was added to the OLS model, the prediction power of MD on HbA1c remained largely unchanged (b=–0.014, P=0.005).
Conclusion
Patients with T1D in Cyprus appear to have a modest adherence to the MD, with a concerning low uptake in the younger subpopulation. Adherence to the MD was significantly associated with HbA1c and the predicted change was clinically significant. This improvement in HbA1c is more likely mediated via the non-fasting glucose excursions. The adoption of the MD should be encouraged in the structured education programs for T1D.

Impact of interval walking training on albuminuria and leptin/adiponectin ratio in patients with type 2 diabetes mellitus

Jelizaveta Sokolovska[1], Ksenija Krilatiha[2], Karina Ostrovska[3], Leonora Pahirko[4], Gunita Varblane[1], Austris Cirulnieks[2], Aija Klavina[3] & Leo Selavo[2]
[1]University of Latvia, Faculty of Medicine, Riga, Latvia; [2]University of Latvia, Faculty of Computing, Riga, Latvia; [3]Latvian Academy of Sport Education, Riga, Latvia; [4]University of Latvia, Faculty of Physics, Mathematics and Optometry, Riga, Latvia

Background
Physical activity is the first-line treatment in type 2 diabetes. Interval walking training has demonstrated good tolerability and more pronounced positive effects on physical fitness and metabolism in type 2 diabetes, compared to continuous walking. However, the effects of interval walking on vascular health markers, such as albuminuria, has not been extensively studied. Type 2 diabetes is associated with derangements in leptin/adiponectin axis, which might predispose affected individuals to vascular inflammation. The aim of this randomized controlled study was to investigate the effects of interval walking training delivered through smart mobile devices upon albuminuria and leptin/adiponectin ratio in patients with type 2 diabetes.
Methods
The study randomized patients with type 2 diabetes aged 35–75 into control ($n=26$) and interval training (IT, $n=14$) groups. Patients in IT group had to perform three 60-min interval walking sessions (3 min intervals of slow and fast walking with the intensity of 40% and 70% of the peak energy expenditure) *per* week delivered by smartphone application for four months. The adherence to training protocol was monitored remotely. Variables measured were albuminuria, leptin/adiponectin ratio, glycaemic control, lipid profile, anthropometric measures. Leptin and adiponectin concentration was measured in serum samples was measured by Luminex technology.
Results
In the IT group compared to control group, we observed a statistically significant decrease in albuminuria ($P=0.002$, interaction effect) and leptin/adiponectin ratio ($P=0.01$, interaction effect). As albuminuria and leptin/adiponectin ratio have been associated with progression of vascular complications of diabetes, our results indicate that interval walking training is effective for improvement of vascular health in diabetes.

The effect of empagliflozin treatment on biomarkers of fibrosis in patients with type 2 diabetes and a very high risk of cardiovascular events

Denis Lebedev & Alina Babenko
National Medical Research Center. VA Almazov, Insitute of endocrinology, Sankt-Peterburg, Russian Federation

Objective
To evaluate the alterations of fibrosis biomarkers during empagliflozin treatment in patients with type 2 diabetes mellitus (T2DM) and a very high risk of cardiovascular events.
Materials and methods
Twenty-six patients with type 2 diabetes mellitus received 10 mg of empagliflozin within 24 weeks. Inclusion criteria: women and men aged 18 to 70 years with T2DM, glycated hemoglobin (HbA1c) 7.0–11.0%, stable hypoglycemic therapy at least 12 weeks before inclusion in the study, the presence of cardiovascular risk factors. Exclusion criteria: the presence of coronary heart disease, chronic heart failure or other clinically significant cardiovascular diseases, estimated glomerular filtration rate (GFR), according to CKD-EPI (GFR < 60 ml/min/1.73 m^2.). HbA1c, creatinine, galectin-3, tissue inhibitor of metalloproteinase-1 (TIMP-1), carboxyterminal propeptide of collagen type I (P1CP), matrix metalloproteinase-9 (MMP-9), ST-2, NT-proBNP, total cholesterol, LDL, HDL, triglycerides (TG) were evaluated.
Results
The age of the patients was 52 years (45–61), the HbA1c level at the time of the study inclusion was 8.6% (7.7–9.5), BMI 32.1 kg/m^2 (29.9–34.9). After 24 weeks of treatment, there was a significant decrease of HbA1c – 7.8% (7.2–8.1), $P=0.0001$ and BMI – 31.0 kg/m^2 (29.3–33.6), $P=0.002$. There were no significant differences between the concentrations of galectin-3 before treatment and after 24 weeks of treatment – 8.6 ng/ml (7.2–10.9) and 10.4 ng/ml (6.6–13.2), $P=0.571$. Significant differences were observed between the initial P1CP concentration and P1CP concentration after 24 weeks of treatment – 120.4 ng/ml (114.2–168.8) and 104.4 ng/ml (89.0–168.8) ($P=0.019$). However, after applying the Holm-Bonferroni, the differences were not significant. The concentrations of TIMP-1 after 6 months did not significantly differ compared with the initial values, 210 ng/ml (177–226) and 208 ng/ml (172–240), respectively, $P=0.861$. A significant negative correlation was obtained between the LDL concentration after 6 months of treatment and the ST-2 concentration after 6 months of treatment (LDL and ST ($r=-0.883$, $P=0.002$). A positive correlation was found between the initial concentration of galectin-3 and the initial concentration of SST ($r=0.501$, $P=0.02$).
Conclusions
Empagliflozin therapy for 24 weeks does not lead to a significant changes in fibrosis biomarkers, such as galectin-3, TIMP-1, P1CP, MMP-9, ST-2 in patients with type 2 diabetes and a very high risk of cardiovascular events.

Effects of semaglutide on glycemic control and body composition in patients with type 2 diabetes mellitus and obesity in a real life setting in spain

Bogdana luiza luca[1], Roberto Miguel Sierra Poyatos[1], Jersy Cardenas[1], Nancy Sanchez Gomez[1], Maria Jesus Silva Rodriguez[1], Naiara Modroño Mostoles[1], Teresa Montoya Alvarez[1], raquel sanchez lopez[1], Eva Cruces Vega[2], Alicia Estrella[1], Pilar Barrio[1], Begoña Sanchez Lechuga[1], Irene Gonzalo Montesinos[1], maria Jose De la Cruz Fernandez[1], Enrique Perez Alvarez[1] & Clotilde Vazquez Martinez[1]
[1]Hospital Universitario Fundacion Jimenez Diaz, Endocrinology, Madrid, Spain; [2]Hospital Universitario Infanta Elena, Valdemoro, Spain

Introduction
Semaglutide is a GLP1 receptor agonist (GLP1RA) recently approved in Spain for the treatment of Type 2 Diabetes (T2D) and the National Health Service finances it for patients with T2D and body mass index (BMI) > 30 with a poor metabolic control with metformin.
Objectives
Evaluate the effects of Semaglutide on glycemic control and body composition in patients with T2D (PwT2D) and obesity after 6 months of use in a real life setting.
Material and methods
This is a retrospective observational study. We included PwT2D and obesity without prior treatment with GLP1RA, who started semaglutide treatment (added to other antidiabetic drugs) between May 2019 and July 2019 in our clinic and maintained it for at least 6 months. Anthropometric measurements (including body composition when available – estimated with bioimpedance Inbody270), fasting glucose (FG) and glycated hemoglobin (HbA1c) were collected at baseline and at 6 months. Statistical analysis was performed with STATA 14. Paired T-student test for comparison between baseline and 6 months and logistic regression to evaluate Semaglutide dose (≤0.5 and 1.0 mg), age, sex, duration of T2DM, BMI and HbA1c at baseline as possible predictors of Semaglutide efficacy to achieve HbA1c < 7%.
Results
We included 75 patients (62% men), with a mean age of 62.3 ± 9.2 years and a mean duration of T2D of 11.3 ± 7.4 years. The maximum weekly dose of semaglutide used were: 0.25 mg (2.7%), 0.5 mg (85.3%), 1 mg (12%). After 6 months of treatment, there was significant improvement of glycemic control: HbA1c decreased from 8.08 ± 1.52% to 6.68 ± –1.07 (mean difference –1.39%; $P=0.000$) and FG from 169.4 ± 55.9 to 131.5 ± 38,2 mg/dl (mean difference –37.9; $P=0.000$). 28% of patients had a HbA1c < 7% in the beginning and 63% after 6 months of treatment with semaglutide. Baseline HbA1C was an independent predictor to achieve HbA1c < 7% 6 months after starting Semaglutide (OR 0,5; CI95% 0.31 to 0.81).
Table 1 shows the changes in anthropometric measurements.

Table1 Anthropometric measurements.

	Baseline	6 months after (mean difference)	P
Body weight (kg)	99.46 ± 18.87	94.11 ± 18.09 (–5.34)	0.000
BMI (kg/m^2)	36.14 ± 5.96	34.19 ± 5.5 (–1.95)	0.000
Waist circumference (cm)	118.2 ± 12.95	111.98 ± 14.36 (–6.22)	0.000
Fat mass (%)	42.46 ± 7.65	40.8 ± 8.5 (–1.58)	0.162
Muscle mass (kg)	30.65 ± 7.36	29.74 ± 6.12 (–0.91)	0.385

Conclusions
PwT2D in our clinic treated with Semaglutide (mostly 0.5 mg/week) for 6 months had a significant decrease in HbA1c, FG, body weight and waist circumference. The percentage of patients with HbA1c < 7% almost doubled.

Study on hypoglycemic effect of polyphenolic compounds isolated from the Euphorbia L. plants growing in uzbekistan

Talat Saatov, Mukhammadjon Mustafakulov, Tokhir Ishanhodjaev & Elvira Ibragimova
Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Biochemistry, Tashkent, Uzbekistan

Members of the *Euphorbia L.* genus have been used both in both traditional and alternative medicine for treatment of a wide range of disorders since time immemorial. Due to a wide spectrum of compounds of phoyphenolic nature, they are known to show anti-oxidant, anti-inflammatory, antimicrobial, fungicidal and antileukemic effects. The work was initiated to study a hypoglycemic effect of polyphenolic compounds isolated from two types of the Euphorbia L. genus. Polyphenolic compounds isolated from various organs of *Euphorbia ferganensis* (euphobin-1) and *Euphorbia franchetii* (euphorbin-2) growing in Uzbekistan were the objects for the study. Experimental diabetes mellitus was induced in rats by means of multiple administration of a diabetogenic dose of alloxan. Blood glucose reaching 11–12 mmol/l in 10–12 days, optimal dose of euphorbin was administered intragastrically every day for 10 days. Effect of euphorbin on the carbohydrate and lipid metabolism in blood and tissues of animals with experimental diabetes was compared to the one produced by quercetin, a polyphenol, and gliclazide, an antihyperglycemic agent. Optimal dose of euphorbin administered to animals with the induced alloxan diabetes was found to cause blood glucose decline from 12.0 to 8.1 mmol/l; the glycated hemoglobin reduced by 28%, while glycogen in the liver tissue increased by 14%. In rats with alloxan diabetes, the hexogenase activity in the muscles of the animals and the glucokinase activity in the liver could be seen. Euphorbin compounds, those of euphorbin 2, in particular, were found to decrease bloodcholesterol, triglycerides and low density lipoproteins by 29, 35 and 18%, respectively, alongside with the increase in high density lipoproteins and lipase activity to the control values. Thus, the hypoglycemic effect produced by euphorbin formulations and quercetin is believed to be determined not only by their influence on the β-cells of pancreas when viable β-cells undertake functions of the damaged ones (Sedigheh Asgary *et al.*, 2012), but also by partial restoration of carbohydrate and lipid metabolism in the tissues of rats with alloxan diabetes.

The effectiveness of glucagon-like peptide 1 receptor agonist and prebiotic on short-chain fatty acids and carbohydrate metabolism in patients with carbohydrate metabolism violation

Lilit Egshatyan[1,2,3], Nane Khachaturian[1,2], Svetlana Silvestrova[1] & Ashot Mkrtumyan[1,2]
[1]The A.S. Loginov Moscow Clinical Scientific Center, Moscow, Moscow, Russian Federation; [2]A.I. Evdokimov Moscow State University of Medicine and Dentistry, Moscow, Moscow, Russian Federation; [3]Endocrinology Research Centre, Ministry of Health of Russian Federation, Moscow, Russian Federation

Background
Short-chain fatty acids (SCFAs) are organic fatty acids produced in the distal gut by bacterial fermentation of macrofibrous material. SCFAs play an important role in health and disease. They may reduce the risk of inflammatory diseases, type 2 diabetes, obesity, heart disease and other conditions.
Aims
to examine the effectivenessof glucagon-like peptide (GLP)-1 receptor agonist and prebiotic treatment on SCFAs, carbohydrate metabolism in patients with carbohydrate metabolism violation.
Materials and methods
In study were enrolled 19 patients with carbohydrate metabolism violation. The mean age of patients was 47 (30–60) years old. The levels of SCFAs, serum fasting glucose, glycated hemoglobin (HbA1c), and body mass index (BMI) were examined at baseline and at 12 weeks on therapy.
Results
At baseline the average glucose levels were 7,31 [5,6; 15,2] mmol/l, HbA1c – 7,2 [4,9; 9,9]%; and BMI – 39,8 [32,1; 51,0] kg/m^2. Significant positive relationship between acetate and HbA1c ($r(s)=0.34$; $P=0.022$), propionate and glucose ($r(s)=0.2$, $P=0.034$), and negative relationship between butyrate and BMI ($r(s)=–0.36$, $P=0.017$) were revealed at baseline. Patients in the GLP-1 and prebiotic therapy groups had a significant decrease in BMI, HbA1c and acetate after 12 weeks, with the mean decrease being 5.1 [1.4; 9.7] kg/m^2, 2.7 [1.0; 3.1]%; 2.34 [1.4; 2.9] mg/g ($P<0.01$), respectively. After therapy significant increase the level of butyrate: +0.6 [0.3; 0.6] mg/g ($P<0.01$).
Conclusions
The preliminary results are indicating a positive effect of GLP-1 and prebiotic therapy on weight, carbohydrate metabolism and short-chain fatty acids in patients with carbohydrate metabolism violation.

Adherence with lipid treatment guidelines in Swiss patients with diabetes mellitus – results from the SwissDiab study

Hélène Singeisen[1], Frida Renstroem[1], Michael Braendle[1,2] & Stefan Bilz[1]
[1]Cantonal Hospital Street Gallen, Divison of Endocrinology and Diabetes, Street Gallen, Switzerland; [2]Cantonal Hospital Street Gallen, Divison of General Internal Medicine, Street Gallen, Switzerland

Introduction
The major cause of death and disability in patients with diabetes mellitus is atherosclerotic cardiovascular disease (ASCVD). Therefore, treatment guidelines specify strict target lipid levels for these patients. The aim of this study is to evaluate the adherence of diabetes mellitus type 1 and 2 patients (DM1 and DM2, respectively) with respect to the European and Swiss lipid treatment guidelines (ESC/EAS and AGLA, respectively).
Methods
The Swiss Diabetes Registry (SwissDiab) is a multicenter prospective observational cohort study of patients with diabetes treated at Swiss tertiary centers. Participants with DM1 and DM2 and a visit between 01.01.2018 and 30.09.2019 were included. Achievement of the LDL-cholesterol targets defined by the 2016 ESC/EAS and 2018 AGLA guidelines was assessed. Baseline characteristics as well as lipid-lowering medication were assessed stratified by diabetes type and in secondary analysis also by adherence to the respective guidelines.
Results
Overall, 187 participants with DM1 and 260 with DM2 were included. The ESC/EAS and AGLA LDL-cholesterol targets were met in 38% of DM1 participants and in 36% of DM2 participants. Among participants that did not reach the LDL-cholesterol targets based on the ESC and AGLA guidelines, 69% with DM1 and 26% with DM2 were not prescribed lipid-lowering medication. No difference in baseline characteristics, diabetes duration and HbA1c was observed between participants that reached and did not reached the LDL-cholesterol targets, regardless of diabetes type.
Conclusion
The proportion of SwissDiab participants with DM1 and DM2 that reach the LDL-cholesterol treatment targets is poor (<40%), consistent with previous studies showing that 20–40% of patients at high risk of ASCVD, such as DM patients, fail to reach established lipid treatment targets. The majority of DM1 patients that do not reach the LDL-cholesterol targets are not prescribed any lipid-lowering medication, suggesting that initiation of any lipid-lowering treatment would improve adherence to the lipid guidelines. The majority of DM2 patients do not reach the LDL-cholesterol targets despite being prescribed lipid-lowering medication, suggesting that combination lipid-lowering therapy should be reinforced to improve adherence to the lipid guidelines. In summary, our data strongly support that lipid-lowering strategies including high-dose statins and combination lipid-lowering treatments must be reinforced in Swiss patients with diabetes. The need is even more pressing in light of the more stringent 2019 ESC/EAS lipid guidelines in order to follow current recommendations and provide patients with the full benefits of these therapies.

Effectiveness of PCSK9 inhibitors in familial hypercholesterolemia in asturias, spain

Silvia González Martínez[1], Raul Rodriguez Escobedo[2], Juan Luis Fernández Morera[2], Alfonso José López Alba[1], José Antonio Álvarez Tamargo[3], Carlos José Lamela Piteira[4] & Francisco Villazón González[2]
[1]Hospital Vital Álvarez-Buylla, Endocrinology, Santullano, Spain; [2]Central University Hospital of Asturias, Endocrinology, Oviedo, Spain; [3]Hospital Vital Álvarez-Buylla, Cardiology, Santullano, Spain; [4]Hospital Vital Álvarez-Buylla, Hospital Pharmacy, Santullano, Spain

Introduction
Familial hypercholesterolemia (FH) is a genetic disorder characterized by high levels of LDL cholesterol (LDL-C) from birth. Treatment with statins and ezetimibe achieves in most cases large reductions in LDL-C. In those patients in whom the reduction in LDL-C is insufficient or who have intolerance to such treatments, the appearance of PCSK9 inhibitors has been an effective and safe alternative to achieve the LDL-C objectives.
Materials and methods
The results of the lipid profile of patients with FH treated with PCSK9 inhibitors in healthcare areas IV and VII of Asturias (Spain) were retrospectively analyzed. The indications for its use are those included in the consensus document of the Spanish Society of Atherosclerosis (2016).
Results
Data were obtained from 46 patients with FH treated with PCSK9 inhibitors, with a mean follow-up of 20.6 months. The average age was 59.13 years, with a similar distribution by sex (52.2% male).

Table 1 Evolution of medians of total cholesterol (TC), LDL cholesterol (LDL-C), HDL cholesterol (HDL-C) and triglycerides (TG) at the beginning of treatment, 2, 6, 12 and 24 months.

	TC (mg/dl)	LDL-C (mg/dl)	HDL-C (mg/dl)	TG (mg/dl)
Initial	264,5	189	45	124
2 months	139	67	47	115
6 months	160	75	46	111
12 months	159	75	50	102,5
24 months	165	80	51	103

Table 2 Evolution of TC, LDL-C, HDL-C and TG at the beginning of treatment, 2, 6, 12 and 24 months expressed as a percentage.

	TC	LDL-C	HDL-C	TG
2 months	– 47,45%	– 64,55%	+ 4,44%	– 7,26%
6 months	– 39,5%	– 60,32%	+ 2,22%	– 10,48%
12 months	– 39,89%	– 60,32%	+ 11,11%	– 17,34%
24 months	– 37,62%	– 57,67%	+ 13,33%	– 16,94%

Conclusions
PCSK9 inhibitors are an effective treatment alternative for patients with FH. Although its maximum effect is achieved 2 months after the start of treatment, its effect is maintained at 2 years, with LDL- C reductions of more than 55%. Likewise, there is a slight increase in HDL-C and a moderate decrease in TG.

Outcomes of long pouch roux-en Y gastric bypass (LPRYGB): 4-years experience in primary and revision cases

Rui Ribeiro[1], Sjaak Pouwels[2] & Chetan Parmar[3]
[1]Clínica de St[o] António, Lusíadas, Amadora, Portugal; [2]Street Elisabeth Hospital, Tilburg, Netherlands; [3]The Whittington Hospital, United Kingdom

Background
One of the most important complications of the One Anastomosis Gastric Bypass (OAGB) is enterobilioacid reflux (EBAR). We report the concept of the Long Pouch Roux-en Y Gastric Bypass (LPRYGB) meaning a Roux-en-Y with a long pouch and a 100 cm alimentary limb to avoid EBAR, with a long biliopancreatic limb to increase metabolic effects.
Methods
A total of 300 LPRYGB cases in a four-year period, with a 90% follow up rate, were analyzed. Anthropometric, technical feasibility, morbidity, weight loss and comorbidity outcomes were analyzed.
Results
The percentage total weight loss (%TWL) was 30.5% at 4 years of follow up (32.3% in primary and 28.3% in revisions). Six intra-operative (2%) and 28 post-operative complications (9.3%) were seen. Out of this 28 complications 11 (3.6%) were late complications. Reoperations were performed in 15 patients (5.0%). Clinically relevant EBAR was present in 3 cases only (1%) 4 years after the operation.
Conclusions
The LPRYGB combines the main advantages of the OAGB (light restriction and moderate malabsorption) with the anti-reflux effect from the Roux-en-Y diversion.

The relationship between estradiol and obesity in men

Hana Pospisilova, Luboslav Stárka, Martin Hill & Michaela Dušková
Institute of Endocrinology, Prague, Czech Republic

Introduction
Obesity increases the incidence of hypogonadism in men, and hypogonadism in turn plays a role in obesity. One of the first mechanisms proposed to explain this was a hypothesis based on the principle that obese men have higher estrogen levels, and that increased estrogens provide feedback to the hypothalamic-pituitary-testicular axis, reducing the secretion of gonadotropins and leading to a decrease of overall testosterone levels. This concept has since been questioned, though never completely disproven.
Methods
A total of 224 healthy men (except for their obesity) aged 20 to 78 with a broad range of body mass index (BMI) from 18 to 39 were enrolled in the study. All patients signed informed consent forms before taking part in the study. Blood withdrawal and anthropomorphic data were obtained from fasting subjects in the morning between 7:30 and 8:30 am. Serum total testosterone and estradiol were determined by radioimmunoassay. SHBG, lutropin and follitropin were measured using immunoradiometric assay. Moreover, we have calculated free testosterone. The men were then divided into three subgroups according to BMI. The first subgroup consisted of 109 men with BMI between 18 and 25 (normal weight men), the second group included 78 men with BMI between 25 and 30 (considered overweight), and the third subgroup had 37 men with BMI 30 to 39 (considered obese). We compared hormone levels betwen groups.
Results
The differences in estradiol levels between the groups were not significant. Though there was a relative increase of 10% in the levels of estradiol in obese men compared to normal weight men. In the overweight group there was even a decrease compared to normal weight men. In comparison with normal weight men, obese and overweight patients had significantly lower levels of total testosterone and higher SHBG, and in consequence the free androgen index. Total testosterone differed significantly between overweight and obese men, whereas SHBG differed significantly between normal weight men and overweight men, but not between overweight and obese men. Levels of FSH and LH showed no significant differences among the groups, though there was a slight tendency toward higher levels in obese men.
Conclusion
Our findings are in line with the idea that estrogen production in overweight and obese men with BMI up to 39 kg/m^2 does not significantly influence endocrine testicular function.
Acknowledgments
The study was supported by the project MHCZ-DRO (Institute of Endocrinology-EÚ, 00023761).

Role of biochemical indices in the pathogenesis of metabolic syndrome

Olga Smirnova[1], Eduard Kasparov[2] & Olga Moskalenko[1]
[1]Scientific Research Institute of Medical Problems of the North FRC KSC SB RAS, clinical pathophysiology laboratory, Krasnoyarsk, Russian Federation; [2]Scientific Research Institute of Medical Problems of the North FRC KSC SB RAS, Institute Director, Krasnoyarsk, Russian Federation

The defeat of the metabolic syndrome (MS) of young people with the development of severe vascular and diabetic complications determines the relevance of its study for the purpose of early diagnosis. Changes in blood at the preclinical stage of MS are reversible, while the main pathogenetic factors of MS are insulin resistance and dyslipidemia. The aim of the study was to assess the role of biochemical parameters in the pathogenesis of MS.
Materials and methods
50 MS patients and 35 healthy volunteers were examined. The glucose level was determined by the glucose oxidant method, the lipid profile was evaluated using standard test systems. Insulin levels were determined by enzyme-linked immunosorbent assay using a DRG test system. The method of chemiluminescence (CL) of neutrophils (NG) determined the time to reach the maximum (Tmax), maximum intensity (Imax) and the area (Smax) under the curve in the spontaneous and induced state. Statistical data processing was carried out using Statistica for Windows 8.0 application software packages with determination of median (Me) and interquartile range (C25-C75). The statistical significance of the differences was determined using the Mann – Whitney rank test $P<0.05$.
Results
In patients with MS, an increase in insulin and glucose levels was detected in the blood compared with the control group ($P<0.05$). Insulin resistance was evaluated by HOMA, in patients with MS revealed a two-fold increase ($P<0.05$). In most patients with MS, the level of triglycerides was within normal limits, only 40% of patients showed an increase in total cholesterol ($P<0.05$), in 100% of patients increased unesterified fatty acids (NEFA) ($P<0.05$). NG CL values were increased: Tmax, Imax, Smax, which indicates the activation of free radical oxidation of blood cells in MS ($P<0.05$).
Conclusion
In patients with MS, a violation of tissue resistance to insulin was detected, which requires constant monitoring of glucose in the blood. Of the lipid profile, the most significant indicator is an increase in NEFA, which leads to a decrease in hepatocyte binding of insulin and the development of peripheral insulin resistance. An increase in free radical oxidation enhances oxidative stress in MS.

Sleeve gastrectomy with loop duodenal switch (Fixed common channel) – Modification of single anastomosis duodenoileal bypass with sleeve for diabesity: An Institutional experience

Amar Vennapusa[1,2] & Ramakanth Bhargav Panchangam[3]
[1]Amar Bariatric and Metabolic Centre, Bariatric and Metabolic Surgery, Hyderabad, India; [2]Dr. Amar Bariatric & Metabolic Center, Bariatric & Metabolic Surgery, Hyderabad, India; [3]Endocare Hospital, Endocrine Surgery, Vijayawada, India

Introduction
Biliopancreatic diversion with duodenal switch (BPD DS) is the most effective metabolic surgery, but accounts for<1% of metabolic surgeries performed Worldwide due to its technical complexity and severe malabsorption. Its loop modification, single anastomosis duodenoileal bypass with sleeve (SADI S) with 200–250 cm common channel, reduces malabsorption to some extent. But a 250 cm common channel appears to be shorter for Indian patients. 'Sleeve gastrectomy with loop duodenal switch (Fixed common channel) – SG LDS (FCC)' is a further modification of SADI S, with a common channel length of 300 or 350 cm to reduce malabsorption further, without compromising on metabolic efficacy.
Material and methods
Between November 2014 and December 2019, 146 patients underwent SG LDS (FCC). Outcomes of these patients were retrospectively analyzed from prospectively entered database.
Results
Out of 157 patients, 22, 13, 101 and 10 had common channel of 250, 300, 350 and varied lengths. Mean BMI was 45.29±7.58 kg/m^2. 50.96% patients were suffering from type 2 diabetes. Mean excess weight losswith 25 BMI cut off point was 74.04%, 99.75% and diabetes remission with HbA1C<6 cut off, was 80.6%, 90.9% at 6 months and 1 year intervals respectively, Protein malnutrition with albumin levels<3 g/dl, was 44.4% and 8.6% with 250 and 350 cm common channel length respectively. 30 day mortality was zero.
Conclusions
SG LDS (FCC) appears to be a very effective and safe surgery. Maintained long term weight loss and Diabetes remission were positively significant. Malabsorption risk is greatly reduced when common channel length is increased to 300–350 cm or more.
Key words
Single anastomosis duodenoileal bypass, loop duodenal switch, fixed common channel, SADI S).

Circulating steroid hormones and BMI in men

Natalya Mazurina, Ekaterina Ershova, Ksenya Komshilova, Marina Galieva, Evgeniya Seniushkina, Vitaly Ioutsi & Ekaterina Troshina
Endocrinology Research Centre, terapeutic endocrinology, Moscow, Russian Federation

Introduction
Previous studies reported significant associations of steroid hormones with anthropometric parameters including body-mass-index (BMI) and waist circumference, as well as with some metabolic parameters such as triglycerides.
Methods
48 reproductive age males (age 18–49) were included in the study (27 obese individuals, 12 persons with excess body weight, 9 normal weight controls). We have examined the association between circulating steroid hormones and BMI. Plasma levels of aldosterone, progesterone, DHEA-S, 17-OH, 11-desoxicortisol, 21-desoxicortisol, androstenedione, corticosterone, testosterone and cortisol were quantified by liquid chromatography-mass spectrometry (LCMS), which provides high precision and specificity in the low concentration range.
Results
We compared three groups and confirmed statistically significant difference in plasma 17-OH levels ($P=0.005$), androstenedione levels ($P=0.048$) and testosterone levels ($P=0.0003$). Negative correlations were observed between plasma 17-OH concentration and BMI ($r=-0.49$, $P<0.001$), plasma androstenedione and BMI ($r=-0.29$, $P=0.044$), plasma testosterone and BMI ($r=-0.66$, $P<0.001$)
Conclusion
17-OH, androstenedione and testosterone plasma concentrations were negatively associated with BMI in men of reproductive age. Testosterone deficiency in obesity is well known and is due to aromatization in adipose tissue. Low 17-OH and androstenedione in obesity may reflect the influence of adipose tissue on steroid metabolism as well as on adrenal steroid production.

AKR1D1 regulates androgen availability *in vitro* by generating metabolites that are unable to activate the androgen receptor

Elena Gangitano[1,2], Karl Storbeck[3], Nikolaos Nikolaou[1] & Jeremy Tomlinson[1]
[1]University of Oxford, Oxford Centre for Diabetes, Endocrinology & Metabolism, Oxford, United Kingdom; [2]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [3]Stellenbosch University, Department of Biochemistry, Stellenbosch, South Africa

Introduction
AKR1D1 is a 5β-reductase that sits at the interface of steroid hormone metabolism and primary bile acid biosynthesis. 5β-reduced androgens are widely believed to be inactive, but to our knowledge there are currently no data that have directly tested their ability to activate the androgen receptor (AR). We therefore wanted to test the ability of AKR1D1 to regulate androgen availability *in vitro* and to determine if 5β-reduced androgens are able to activate the AR.
Methods
Human embryonic kidney cells (HEK293), that do not express AKR1D1, were transfected with either empty vector (EV) or AKR1D1. Cells were

treated with testosterone (T), 5α-dihydrotestosterone (5α-DHT), androstenedione (A4) or 11-ketotestosterone (11-KT) (all 200 nM) for 24 h. Media was collected for further analysis. Testosterone clearance was determined using a commercially available ELISA assay. The ability of androgens, their 5β-reduced metabolites, and the collected media from the AKR1D1 overexpression experiments, to activate the AR was determined using HEK293 cells co-transfected with AR and an ARE-luciferase construct.
Results
Successful AKR1D1 overexpression was confirmed using qPCR and Western Blot analysis. AKR1D1 over-expression increased T clearance ($P<0.001$). Using the AR/ARE co-transfection system, T and 5α-DHT were able to activate the AR. In contrast, 5β-DHT was inactive. In experiments using the conditioned media, AKR1D1 overexpression significantly reduced the ability of T, A4 and 11KT to activate the androgen receptor ($P<0.003$, $P<0.02$ and $P<0.007$, respectively).
Discussion and conclusion
We have demonstrated that 5β-reduced androgens are unable to activate the AR. In addition, we have shown that AKR1D1 clears androgens, including T, A4 and 11KT, and therefore has a potent role to regulate androgen availability and action. AKR1D1 is highly expressed in the liver, and it is dysregulated in diabetes and NAFLD. Alterations in androgen availability as a consequence of changes in AKR1D1 activity and expression, may be crucial in the pathogenesis of NAFLD.

Refeeding syndrome – an unexpected clinical case

Francisca Puga[1], Patrícia Baptista[2], Margarida França[2] & João Araújo Correia[2]
[1]Centro Hospitalar Universitário do Porto, Serviço de Endocrinologia, Porto, Portugal; [2]Centro Hospitalar Universitário do Porto, Serviço de Medicina Interna, Porto, Portugal

Refeeding syndrome can be defined as the potentially fatal shift in fluids and electrolytes that may occur after the reintroduction of feeding after a period of starvation or fasting in malnourished patients. The hallmark characteristic of refeeding syndrome is hypophosphatemia. However, the syndrome is complex and may also feature abnormal sodium and fluid balance, changes in glucose, protein and fat metabolism, hypokalemia, hypomagnesemia and thiamine deficiency. The underlying mechanism of this condition rests on the rise of insulin levels caused by refeeding, promoting cellular glucose and phosphorus uptake, leading to a sharp decline in serum phosphorus concentrations. Chronic alcoholics, elderly people, oncologic and anorectic patients are at higher risk of developing this condition. The authors report the case of a 54-year-old woman with history of *anorexia nervosa* and chronic alcoholism admitted with acute alcoholic hepatitis. On admission her body mass index (BMI) was 14,5 kg/m^2, and she started nutrition based on hospital culinary diet with enteric supplementation, adding up to a total intake of 2520 to 2720 kilocalories (Kcal) per day. On day 5 at the ward, the patient developed neurologic symptoms and signs consistent with Wernicke encephalopathy. Soon she developed shock with hypotension, and respiratory failureleading to inotropic support and mechanic ventilation. While in the intensive care unit, blood tests revealed severe hypophosphatemia, hypomagnesaemia, hypokalemia and thiamine deficiency. Other causes of shock, such as infection, pulmonary thromboembolism, acute coronary syndrome or structural heart disease, were excluded. Parenteral phosphate, thiamine, magnesium and potassium were administered and feeding was restarted at a slower rate. Her electrolytes normalized and she gradually improved and was discharged after 30 days with a caloric intake of 1000–1200 Kcal, motivated to maintain a progressive weight increase. This case illustrates the vulnerability of malnourished patientsto refeeding syndrome. Although it is necessary to combat malnutrition, the process of refeeding should be cautious. Measures should be taken to identify the risk of refeeding syndrome and prevent this potentially fatal condition.

Clinical analysis of three families caused by mitochondrial DNA mutation A3243G

Luyang Yang[1,2], Jing Yang[1], Yunfeng Liu[1] & Jinhua Yin[1]
[1]First Hospital of Shanxi Medical University, Endocrinology, Taiyuan, China; [2]Shanxi Medical University, First Clinical Medical College, Taiyuan, China

Maternally inherited diabetes and deafness (MIDD) is a rare form of diabetes caused by a mitochondrial DNA mutation. The condition is maternally inherited as mitochondrial DNA is practically only derived from oocytes. Patients typically have progressive insulinopenia, sensorineural hearing loss and maculardystrophy. We reported here 3 mitochondrial diabetes (two females and one male) and their families. Both of the 3 patients had diabetes, progressive loss of motor skills and sensorineural hearing loss. The average age of onset for diabetes was 34 years oldand the mean disease course was 16 years. At the beginning, they were all diagnosed as type 2 diabetes. After an average of 16 years, they were finally diagnosed as MIDD. The genetic testsshowed they all had A3243G mitochondrial DNA mutationwith different variation frequencies (12.80%, 25.00% and 13.95%, respectively). Besides, the third patient also had T16189C mitochondrial DNA mutation. Diabetes were non-insulin dependent at onset, but on average of 3 years later they started insulin therapy. In addition, patient 1 had suffered from headache for 1 month. A brain magnetic resonance imaging revealed cerebral infarction in left occipital lobe (subacute stage). So she also combined with MELAS (mitochondrialmyopathy, encephalopathy, lactic acidosis and stroke) syndrome. She has two daughters. The younger daughter was 20 years old and she had suffered from hearing loss for 1 year. She had the same mutation with her mother. But the genetic test of the asymptomatic older daughter was normal. The second patient's daughter and sister carried the same mutation with differentvariation frequencies (77.15%, and 5.12%, respectively). But her parents and brother were normal. The third patient's sister also suffered from diabetes and hearing loss when she was 23 years old. But she died of stroke at 30 years old. So we guessed that shesuffered from MIDD and MELAS syndrome. Even though this disease is maternal inheritance, but not all the people in this case follow the rule. It's partly due to the diverse levels of mutated mtDNA in different tissues. The identification of monogenic forms of diabetes is difficult. However, this condition should be considered when a history of diabetes associated with both hearing loss and relevant family history.

Descriptive analysis of body composition and phase angle (PA) in achondroplastic patients: Case-control study

Isabel Mª Vegas-Aguilar[1], Isabel Maria Cornejo Pareja[1], Antonio Leiva Gea[2], Francisco J Tinahones[1] & Jose Manuel García-Almeida[1]
[1]Endocrinology and Nutrition Department, Virgen de la Victoria Universitary Hospital, Malaga, Spain; [2]Traumatology Department, Virgen de la Victoria Universitary Hospital, Malaga, Spain

Introduction
Data on body composition in patients with achondroplasia are scarce. The Phase Angle (PA) is a bioelectric measurement of our body cells. The PA is considered to be a global prognostic factor that gives information about cellular function in relation to body composition.
Objectives
To describe body composition parameters PA, standardized PA (sPA), resistance (Rz), reactance (Xc), body cell mass (BCM), total body water (TBW), fat mass (FM), fat free mass (FFM) in a group of patients diagnosed with achondroplasia compared with controls paired by age and sex.
Material and methods
Observational study of 33 subjects (24 patients with achondroplasia and 9 controls). Bioimpedanciometry (by using AKERN 101 equipment) as well as anthropometric, nutritional and analytical data were collected.
Results
Body composition parameters were significantly different between achondroplastic patients and the control group. PA values were significantly lower in achondroplastic patients than in controls (5.3±0.1 deg vs 6.5±0.7 deg, respectively; $P=0.001$) as well as sPA (+0.9±0.8 vs –1.1±1.5 deg; $P=0.001$). Other body composition measurements are detailed in table 1. In addition, the sPA significantly correlated with PA ($r=0.930$), Xc ($r=0.873$), BCM ($r=0.646$) and height ($r=0.515$).

Table 1

Achondroplastic Patients ($n=24$) Mean (Standard deviation)		Controls ($n=9$) Mean (standard deviation)	P
Age (years)	14.3 (1.6)	14.0 (1.9)	0.655
Weight (Kg)	36.1 (8.5)	57.7 (12.4)	0.000
Height (cm)	123.3 (9.3)	164.7 (7.5)	0.000
FFM (Kg)	30.5 (5.2)	45.7 (7.1)	0.000
TBW (L)	25.6 (3.6)	32.7 (5.5)	0.000
BCM (Kg)	15.0 (3.1)	26.2 (4.7)	0.000
FM (Kg)	5.6 (5.4)	12.0 (7.8)	0.012
PA (deg)	5.3 (1.0)	6.5 (0.7)	0.001
sPA (deg)	−1.1 (1.5)	+0.9 (0.8)	0.001

Conclusions
There are relevant differences in the crude and standardized phase angle between the achondroplastic and healthy populations, adjusted for age and sex. These differences are related to a lower cell mass (BCM, FFM) and less clearly with water (TBW) and fat depots (FM).

AEP476

A comparative analysis of the impact of the filipino plate method 'Pinggang Pinoy' vs standard nutrition education on food group proportions and 2-hour postprandial blood sugar levels of filipino diabetes patients

Richultz Montevirgen[1], Lizette Kristine Lopez[1] & Kristine Bea Mendoza[2]
[1]The Medical City – Ortigas, Internal Medicine, Section of Endocrinology, Pasig, Philippines; [2]The Medical City – Ortigas, Nutrition Management Services, Pasig, Philippines

Objectives
To assess whether nutrition education via the Filipino Plate Method 'Pinggang Pinoy' will be effective in developing better meal planning skills and 2-Hour Post Prandial Blood Sugar levels (2h-PPBS), comparable to standard nutrition education as recommended by the ADA.
Research design and method
The Filipino Plate Method 'Pinggang Pinoy' is a simple tool for nutrition advise and would only take approximately 15 minutes to teach as compared to the Standard Nutrition Advise which is more complicated and take as long as 90 minutes to teach. We enrolled a total of 148 Type 2 Diabetic subjects, with 113 participants (76%) completing up to the 2-Hour Post Prandial Blood Sugar levels (2 h-PPBS) determination. The participants were divided into two groups, wherein baseline knowledge were gathered. After which they received two sets of lectures one being The Filipino Plate Method and the other group receiving the Standard Nutrition Advise. Post teaching assessment for both groups were done after 3–6 days, in which they have undergone the same process of data collection. The Post Teaching scores from the Pre Teaching scores were compared based on 3 parameters: Meal Planning Drawing scores, Actual Meal Scores and 2-Hour Post Prandial Blood Sugar levels (2 h-PPBS) results.
Results
Interms of the actual plate scores, wherein overall score significantly increased from pre-teaching to post-teaching, and within both groups ($P<0.001$). Across groups, the Filipino Plate method group had a higher median score of 8/9 compared to 9/9 for the general education group ($P=0.018$). In terms of meal planning scores, the overall score significantly increased from pre-teaching to post-teaching, and within both groups ($P<0.005$). Across groups, the post-teaching scores were similar with a median of 5/10 ($P=0.274$). On baseline and on post-teaching, the 2 h-PPBS absolute values were significantly higher for the general education group compared to Plate method group. Scores remarkably decreased from baseline to post-teaching. However, the relative change, had insufficient evidence to demonstrate a statistically significant difference in 2 h-PPBS values between the two groups.
Conlusion
The Filipino Plate method 'Pinggang Pinoy' may improve meal planning skills, actual meal choices and proportions and may improve 2-Hour Post Prandial Blood Sugar, and maybe comparable to the Standard Nutrition Advise in patients with Type 2 Diabetes.

Comparison of basal metabolism rate assessment in athletes using indirect calorimetry, bioimpedance, and wearable monitors

Antonio Fernandes Oliveira-Filho[1], Adriana Nunes[2], Wesley Cavalcanti Cruz[1], Erika Carla Silva Lima[1], Lucas Cosmo Rocha[1], Edmar Candeia Gurjao[3] & Paulo Eduardo Silva Barbosa[1]
[1]State University of Paraiba, Center for Strategic Health Technologies, Brazil; [2]Federal University Rio Grande Norte, Brazil; [3]Federal University Campina Grande, Brazil

Wearable physical activity monitors are growing in popularity as they provide the opportunity for self-monitoring, real time data collection and data sharing for cardiovascular and sports medicine. However, there are discussions about the accuracy of their energy expenditure estimate. This study examined and compared basal metabolic rate through indirect calorimetry and through wrist-worn devices and bioimpedance. The group consisted of 30 healthy male individuals, professional football athletes, the age ranged from 20 to 38 years (26.81±4.78 years). Basal Metabolic Rate (BMR) data from the FitbitIonic collected during the protocol were compared with RJL System Bioimpedance and Indirect Calorimetry Cosmed. Anthropometric measures, body composition, and laboratory data were also observed. Spearman correlation and Mann-Whitney tests were used to calculate differences and correlations to examine associations between kcals measured from the Fitbit and bioimpedance from indirect calorimetry. Basal metabolic rate was 1824 kcal to 3504 kcal (2620.75±424.79). Results indicate significant ($P<0.001$) underestimations of kcals for Fitbit Ionic (1771±111,64). Moderate correlations were observed for the Fitbit and bioimpedance data. Body composition seems to influence Fitbit results, but hormonal status or anthropometric and physical findings were not associated to them. These findings support that caution is necessary when incorporating wearable devices BMR data, especially with weight reducing goals

Effectiveness of the low-calorie diet and exercise as an adjunct to the orlistat for the sustained change in metabolic parameters in young patients with type 2 diabetes with obesity

Sachin Chittawar & Laxmi Mohnani
Gandhi Medical College, Medicine, Bhopal, India

Introduction
Obesity is a multifactorial disease which poses a serious public health problem, with an alarming epidemic character. The increase in bodyweight is associated with an increased risk of excessive fatrelated metabolic diseases including diabetes

Methods
We conducted an observational study to evaluate the clinical effects of orlistat in obese patients (BMI≥30 kg/m^2), adhering to low calorific diet limited to 1000–1100 kcal per day, moderate aerobic exercise of at least 150 minutes per week. We evaluated 100 consecutive patients during four visits (4, 6 and 12 months) over one year (June 2018–May 2019) in age group 21–40 years, adherent to orlistat 120 mg thrice daily. Educational interventions for the importance of the healthy lifestyle were provided periodically. The study was approved by the institutional ethics committee. ANOVA and unpaired t-test was used for the statistical analysis
Results
The mean age was 27.8 years (S.D.±8.51), with 46% less than 30 years. The mean baseline weight (kg) and HbA1c (%) was 88.7 (S.D.±14.06) and 8.2 (S.D.±2.11), respectively, which reduced to 68.02 (S.D.±10.29) and 6.3 (S.D.±1.15); $P<0.001$. The patients ($n=34$) with the lowest calorie intake (1000–1100 kcal/day) and with highest duration of exercise (>75 minutes per day) ($n=14$) achieved the maximum weight loss of 28.92 and 28.71 kg, respectively ($P=0.006$ and 0.001). The mean reductions at 4, 6 and 12 months in the body weight and HbA1c compared to baseline were 6.3, 14.5, 20.68 kg and 1.05, 2.17, 1.95% respectively ($P<0.001$)

Discussion
We observed a direct relationship for the benefits for the weight loss associated with the daily duration of exercise and the inverse relationship for the weight loss and calorie intake. Sustained lifestyle management as an adjuct to the orlistat therapy in young patients with T2DM, provides favorable benefits for the glycemic and metabolic parameters which may be attributed to improved adipocyte function and may go beyond the efficacy in weight reduction. The results of our study need to be corroborated with a large multi-centric trial

The effect of demographic factors on obesity in children (COSI project 2019), preliminary results

Radka Taxová Braunerová[1], Pavla Kalousková[1], Tereza Metelcová[1,2], Bohuslav Procházka[3], Anežka Malechová[1], Jana Vignerová[1], Jana Pařízková[1], Martin Hill[1], Hana Zamrazilová[1] & Marie Kunešová[1]
[1]Institute of Endocrinology, Obesity Management Centre, Prague, Czech Republic; [2]Charles University, First Faculty of Medicine, Prague, Czech Republic; [3]Paediatric Clinic, Kolín, Czech Republic

Introduction
Demographic factors such as place of residence, urbanization grade and family background are considered to be associated with overweight and obesity in children. Our study investigates differences in obesity prevalence and related characteristics in children from urban, semi-urban, and rural areas, and in children from complete and incomplete families. The study is part of the fifth round of World Health Organization Europe's Childhood Obesity Surveillance Initiative (COSI)*.
Methods
We measured weight, height, waist and hip circumference in a representative sample of 2409 7-year-old Czech children in 2019. BMI was calculated from the data and the sample was classified using the WHO reference. Further health-related, behavioural and socio-economic information was gathered using family and school questionnaires. For the purpose of this analysis we evaluated a subsample of 1607 children. The association between dependent variables (place and urbanization grade of residence, family completeness) and a set of mutually correlated overweight/obesity predictors was evaluated using multivariate regression with a reduction of dimensionality, known as bidirectional orthogonal projections to latent structures (O2PLS).
Results
The urbanization grade of residential location appears to play a significant role in child obesity-related factors. In rural areas, more school playgrounds are available after school, children need to travel to school a longer distance but are less likely to walk to school. Children are also more likely to live with both parents, while in urban areas more families are single-parent. Neither BMI nor weight category was affected by the place of residence. The analysis revealed that children from complete families had significantly higher weight and height. This, however, did not translate into differences in BMI or weight category of the children, either.
Conclusion
Children from urban, semi-urban, and rural areas are exposed to different sets of obesity-related factors, as are children from complete and incomplete families. Family completeness also correlates with the children's weight and height. Yet no significant correlation was found between the urbanization grade, place of residence, or family background and BMI and the weight category in 7-year-old Czech children.

Investigating the role of olfactory receptors in endometrial cancer cells

Rand Shibel
Tel Aviv University, human molecular genetics and biochemistry, Tel Aviv-Yafo, Israel

Laron syndrome (LS) is a rare autosomal recessive genetic disorder caused by growth hormone receptor (GH-R) gene mutations, leading to congenital insulin-like growth factor-1 (IGF1) deficiency and dwarfism. Epidemiological studies have shown that there are no LS patients that suffer from cancer, which means they are protected from cancer development. While the mechanisms associated with cancer protection in LS are unknown, cancer protection might involve the insulin (INS) and IGF1 signaling pathways. These hormones have been implicated in the etiology of several epithelial neoplasms and have a crucial role in endometrial cancer development.
To investigate the potential cancer protective pathways in LS patients, our laboratory has previously conducted genome wide transcriptome analyses (microarray analysis) using lymphoblastoid cell lines derived from LS patients and healthy controls. The olfactory receptor (OR5H2) gene was among a group of genes shown to be differentially expressed in LS patients. The involvement of the OR5H2 gene in endometrial cancer biology is unknown. Furthermore, most of the differentially expressed genes, including the OR5H2, were not previously linked to IGF1 signaling.
The aim of the project is to evaluate the expression and regulation of the OR5H2 gene in endometrial cancer cells. In addition, we are interested in assessing the potential regulation of OR5H2 expression by IGF1 and insulin. The overall aim of my project is to elucidate the potential role of OR2H5 in endometrial cancer. Two endometrial cancer cell lines will be used in this project as Type II: Uterine serous papillary endometrial carcinoma type 1-derived and uterine serous papillary endometrial carcinoma type 2-derived (USPC-1 and USPC-2). Utilizing these two types of cells will let us examine also the P-53 effect on the regulation of the target gene, for the USPC2 cell line is P-53 mutant, whereas P-53 is wild type in USPC1 cell line.
Evaluation of OR5H5 basal expression levels in preliminary studies using RT-PCR showed differences in basal expression levels between the two endometrial cancer cell lines.

Nesidioblastosis a rare cause of hipoglycemia in adults

Maria Elena Lopez Alaminos, Mikel Gonzalez Fernandez, Karol Almendra Alvarado Rosas, Leticia Serrano Urzaiz, Patricia de Diego Garcia, Pablo Trincado & Javier Acha Perez
Hospital Universitario Miguel Servet, Zaragoza, Spain

Introduction
Noninsulinoma pancreatogenous hypoglycemia syndrome (NIPHS) is an entity with low prevalence (4%), more frequent in neonates and infants and with a male preponderance, characterized by endogenous hyper insulinemic hypoglycemia, not caused by an insulinoma. Pancreatic histology usually reveals diffuse nesidioblastosis.
Case report
A 21-years-old man without a remarkable personal or family history was referred describing a 15 kg weight gain and late-afternoon asthenia and drowsines for the last two years that improved eating carbohydrates. He also described several episodes of loss of consciousness and neuroglycopenic symptoms cooccurring with glycemia of 32 mg/dl despite nutritional modifications and diazoxide. Results of a fasting test showed: glycemia 42 mg/dl, plasma insulin 11.5 mcrUI/ml, C-peptide 2.35 ng/ml, proinsulin 1.5 pmol/l, low beta-hydroxybutyrate, a negative sulfonylurea/meglitinide screen and negative insulin antibodies and insulin-receptor antibodies. As an insulinoma was suspected, transabdominal ultrasonography, abdominal computed tomography (CT), magnetic resonance imaging (MRI), and a 99 m Tc somatostatin receptor scintigraphywere performed, with negative results. A selective arterial calcium stimulation test (SACST) with hepatic venous sampling after calcium gluconate infusion did not show any gradient.

	Superior mesenteric artery	Gastroduodenal artery	Splenic artery
Basal Insulin mcr UI/ml	19.50	21.30	19.10
Insulin 30 s mcrUI/ml	22.20	24.40	33.20
Insulin 60 s mcrUI/ml	35.90	35.30	48.30
Insulin 120 s mcrUI/ml	71.60	71.60	67.10

Due to persistent symptoms refractory to medical management and localization results a partial pancreatectomy was performed in which histopathology descriptions showed patchy nesidioblastosis changes, islet cell hypertrophy and redifferentiation of islet of Langerhans cells from pancreatic duct epithelium. After surgery patient´s symptoms greatly improved.

Discussion
The predominant clinical feature of noninsulinoma pancreatogenous hypoglycemia syndrome (NIPHS) is usually postprandial hypoglycemia but also fasting hypoglycemia can occur, with biochemical findings similar to insulinoma. For patients with NIPHS and refractory postprandial hypoglycemia, surgery remains the mainstay of therapy.

Adherence to treatment in 102 tunisian adolescents with type 1 diabetes

Sellami Sonda, Berriche Olfa, Bendag Nadra, Amal SMIDA & Jamoussi Henda
National Institute of Nutrition, Tunis, Tunisia

Background
Type 1 diabetes mellitus is the most common chronic illness in childhood. His treatment involves a multifaceted regimen that includes daily blood glucose monitoring, insulin injections, a dietary plan, and regular exercise. Patients, especially during adolescence, do not fully adhere to the diabetes treatment and, as a result, they appear to be at risk for serious medical complications, including hyperglycemic episodes, Ketoacidosis and microvascular complications such as retinopathy, nephropathy and neuropathy.
Aims
To assess adherence to treatment in a group of Tunisian adolescents with type 1 diabetes and study the consequences on the balance of diabetes
Methods
Cross sectional study concerning 102 adolescents with type 1 diabetes hospitalized or followed at the consultation of diabetology of the Institute of Nutrition in Tunis over a one-year period between January 2017 and January 2018. To assess adherence to treatment, we used the validated version in Arabic of the self-questionnaire derived from the Medication Adherence Questionnaire (MAQR) from Morisky-Green. This questionnaire contains 6 yes/no items. It targets memory and attention, as well as knowledge and opinion. It allows you to define three grip profiles:
– Good adherence if the answer is 'no' for the 6 items
– Moderate adherence if 1 or 2 'yes' answers
– Poor adherence if 3 or more 'yes' answers
Results
The study population consisted of 102 adolescents with type1 diabetes and 51% were female. The mean duration of diabetes was 7.1±4.3 years. The daily average of insulin dose was 1±0.4 u/kg/ day. The average number of injections per day was 3.4±1 with extremes ranging from 2 to 5 injections per day. Adherence to treatment was good in 12.8% of patients, moderate in 57,8% and poor in 29,4%. Insulin omission was present in 7.8%. The average rate of HbA1c was 10.6±2.2% with extremes ranging from 5.8 to 16.8%. Diabetic retinopathy, nephropathy, and neuropathy were found respectively in 3.9%, 5.9%, and 5.9%. The average number of ketosis or Ketoacidosis in the last year was 3,6±6,3 per year. severe hypoglycemia rate in the past 3 months was 1.8±7,9 per month.
Conclusion
Child routines and the complexity of diabetes treatment may influence behaviorally problematic youths 'risk for poor adherence to T1DM treatment. Clinicians and parents are encouraged to cultivate child routines early in development because it may reduce the risk for parent – child conflicts in adolescence, which can compromise the adherence to treatment.

AEP483

Evolution of lipidic parameters in a population of patients with type 2 diabetes after switching on insulin analogs

Chaima Jemai, Cyrine Chaari & Feika Ben Mami
National institute of nutrition of Tunis, C, Tunisia

Introduction
The advent of insulin analogs has significantly reduced the undesirable effects of human insulin, particularly hypoglycemia. Beneficial effects on the lipid balance have also been described. The aimof our study was to describe the evolution of the lipidic parameters after the switch on insulin analogs.
Patients and methods
This is a longitudinal retrospective study about 61 patients with type 2 diabetes, switched to insulin analogs since at least 3 months. Clinical and biological data were taken from medical records. During the study, no modification or introduction of lipid-lowering therapy was made.
Results
The mean age was 60.7±10.2 years. The sex ratio was 0.96. Diabetes had evolved for an average of 18.1±8.9 years. Retinopathy and diabetic nephropathy were frequent by 49% and 41.7% respectively. The mean duration of insulin analog therapy was 17.33±10.13 months. Determir was the most prescribed slow insulin analog (59%). Insulin Aspart was the most widely prescribed rapid insulin analog (76.8%). 82% of the patients were hypertensive. 85.2% were dyslipidemic. The mean CT and LDL levels decreased significantly during the 3 periods studied (CT (T0)=4.9 mmol/l, CT at 3 months=4.63 (P=0.035), CT at 6 months=4, 45 (P=0.02), CT at one year=4.25 (P=0.017), (LDL (T0)=3.2 mmol/l, LDL at 3 months=2.98 (P=0.012), LDL at 6 months=2.75 (P=0.003), LDL at 1 year=2.5 (P=0.001) The HDL level remained stable The TG level increased without reaching the significance level. The percentage of patients achieving the LDL objective was maximum at 1 year (T0: 18.2%, at 3 months: 31.4%, at 6 months: 37.1%, at 12 months: 55.6%). The percentage of patients achieving the HDL target remained stable (T0: 33.3%, at 3 months: 31.4%, at 6 months: 33.3%, at 12 months: 33.3%). The percentage of patients achieving the TG target was maximal at 1 year (T0: 68.5%, at 3 months: 71.4%, at 6 months: 69%, at 12 months: 73%).
Conclusion
The modification of the lipidic parameters after switching to insulin analogs had been reported in the literature. It was linked, among others, to the weight change. Studies on a larger scale are essential in order to better characterize the variation in the lipidic balance after switching to analogs and to identify the associated factors.

Flash glucose monitoring system: Impact on glycaemic control and body mass index in type 1 diabetes mellitus

Juliana Sá, Sara Lopes, Mariana Barbosa, Inês Ferreira Barros, Ana Margarida Monteiro, Vera Fernandes, Catarina Matos, Marta Alves, Maria Lopes Pereira, Olinda Marques & Maria Joana Santos
Hospital de Braga, Endocrinology, Braga, Portugal

Background
The use of Flash Glucose Monitoring (FGM) for the management of type 1 diabetes mellitus (T1D) is rapidly increasing.
Aims
To assess the longitudinal evolution of glycated haemoglobin (HbA1c) and body mass index (BMI) with the use of FGM in patients with T1D; to determine predictive factors of benefit with the use of this technology.
Materials and methods
Retrospective study of T1D patients, using FGM ≥6 months and treated with multiple daily doses of insulin. Patients whochanged the type of basal insulin, began/suspended oral hypoglycaemic drugs or were/became pregnancy during the analysed period were excluded.
Results
179 patients included, 52.5% males. The median age (Md) was 43.0 (P25 31.0; P75 52.0) years old, median duration of disease was 18.0 (P25 10.0; P75 28.0) years and 33.5% were treated with functional insulin therapy. The initial HbA1c was Md 7.9% (P25 7.2; P75 8.8); 49.1% with initial HbA1c≥8%. The initial BMI was 24.0 Kg/m^2 (P25 21.9; P75 26.2); 39% were overweight/obese. FGM usage time was 6 months in 25.7%, 12 months in 34.6% and ≥18 months in 39.7% patients. FGM was associated with a significant improvement in HbA1c during the first year, with Md HbA1c 7.6% (P25 7.0; P75 8.3) at 6 months and 7.7% (P25 6.95; P75 8.5) at 12 months (P<0.05). At 6 months, there was a significant increase in the number of patients with HbA1c<7% (16.1% vs 25.0%) and a significant reduction in the number of patients with HbA1c≥8% (49.1 vs 37.1%) (P<0.05). In multivariate longitudinal regression analysis, initial HbA1c 8.0–8.9% (HR 1.886; CI 1.321; 2.450) and ≥9.0% (HR 3.108, CI 2.454; 3.761) and initial BMI 25.0–29.9 kg/m^2 (HR –0.397; CI –0.793; –0.001) were predictors of greaterHbA1c reduction. BMI increased significantly during the 12 months follow-up, especially during the second 6 months, with BMI Md 23.8 (P25 21,9; P75 26,2) kg/m^2 and 24.0 (P25 22.0; P75 26.2) kg/m^2 at 6 and 12 months, respectively (P<0.05). In multivariate longitudinal regression analysis, initial BMI 25.0–29.9 kg/m^2 (HR 4.319, CI 3.185; 5.453) and ≥30 kg/m^2 (HR 8.112, CI 3.919; 12.306) were predictors of greater weight gain.
Conclusion
In the first year of FGM use, there was a significant improvement in HbA1c, mainly in patients with a previous worst glycemic control. When starting

FGM, weight control strategies should be considered, especially in overweight/obese patients.

AEP485

Effect of ramadan's fastingon the glycemic balance of a diabetic population with an HbA1C before the fast greater than 10%

Chaima Jemai & Feika Ben Mami
National institute of nutrition of Tunis, C, Tunisia

Introduction
International recommendations prohibit fasting of the month of Ramadan in patients with diabetes, particularly unbalanced ones.
The aim of our study was to describe the evolution of the glycemic balance in unbalanced diabetics with an HbA1C before the fasting greater than 10%.
Patients and methods
This is a descriptive evaluative study carried out on 25 patients with type 2 and with an HbA1C before fasting greater than 10%. These patients were advised not to fast and the risks involved were explained to them. Then they had an education and a therapeutic adjustment by referring to the recommendations of the Amercian Diabetes Association (ADA)of 2016.
Results
The average age was 56.5 8.8 years with extremes of 35 and 70 years. The sex ratio was 0.62. The average duration of the progression of diabetes was 9±6.4 years. The average body mass index (BMI) was 28.8±6.1 kg/m^2 with extremes of 20.5 and 45.1 kg /m^2. 72% were overweight or obese. The days fasted were successive with an average of 20.3±9.6 days. (48% (n=12) had fasted for the entire month. After the fasting, HbA1C had increased from 10.26±1.58% to 10.78±0.92% after fasting (+0,52±1.7%, P=0.137). 19.2% (n=5) had hypoglycaemia motivating the cessation of fasting in 15.3% (n=4). 11.5% (n=3) had hyperglycemia justifying the end of the fast in all cases.
Conclusion
Fasting for the month of Ramadan should be strongly discouraged in very unbalanced diabetic patients given the risks involved, including hypoglycemia and glycemic imbalance.

AEP486

Glycemic variability in type 1 diabetes

Tiago Santos[1], Isabel Inácio[2], Bruno Soares[3], Joana Vilaverde[1], Sofia Teixeira[1] & Helena Cardoso[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar do Baixo Vouga, Endocrinology, Aveiro, Portugal; [3]Instituto Ciencias Biomédicas Abel Salazar, Porto, Portugal

Introduction
Glycemic variability (GV) is emerging as a measure of glycemic control in type 1 diabetic patients (T1DM) given that it provides an integrated picture of postprandial hyperglycemia and hypoglycemic episodes and is associated with diabetic complications and mortality. However, little is known about the best way to address this problem in clinical practice.
Aim
To characterize GV in T1DM patients followed in our center and to identify clinical predictors for higher GV.
Methodology
Retrospective cohort study, including adults with T1D diagnosed clinically for ≥12 monthsthat were using flash glucose monitoring (FGM) systems ≥70% of the time. Raw data fromFGMwas downloaded in each visit from July 1st 2018 to December 31st 2019, and two periods of 28 consecutive days were selected, for each patient, and analyzed the following parameters: % of time in range (TIR [70–180 mg/dl]), % of time below range (TBR [<70 mg/dl]), % of time below 55 mg/dl (TBR55),% of time above range (TAR [>180 mg/dl]), % of time above 250 mg/dl (TAR250) and coefficient of variation (CV). A cutoff threshold value of 36% for CV was assumed to separate stable from labile glycemic control.
Results
Inclusion of seventy-five T1DM patients (62.7% female), with mean age 46.7±13.5 years and mean duration of T1DM 25.4±13.3 years. Fifty (66,7%) patients were using CSII. Carb counting was used by 59 (78.7%) patients. Adjuvant therapy was used in 22 (29.3%) patients (21,3% metformin, 5.3% GLP-1 agonists, 4.0% DPP4- inhibitors and 4.0% SGLT2 inhibitors). Mean A1c was 7.6±0.9% and 18 (25.7%) patients had HbA1c≤7%. Microvascular complications were present in 38 (48.7%) patients (diabetic retinopathy in 45.3%, nephropathy in 24.2% and peripheral neuropathy in 17.3%) andmacrovascular complications in one (1.3%) patient. Median TIR/TBR/TAR were 49 (38–70)%; 5.0 (3–7.5)% and 44.5 (30.5–57.5)%, respectively. Nine (12%) patients with TIR>70% and 29 (38.7%) with TBR<4%. Mean CV was 41.2±7.3 reflecting labile control in 80% (n=60) patients. Vascular complications were more frequent in this group (58.3% vs 20%, P=0.01). Disease duration was associated with higher CV [OR: 1,28 (CI 95%: 1.03–1.60)] but neither age, sex, body mass index, carbs counting, CSII or adjuvant therapy showed to be predictors of GV in our sample.
Conclusions
GV was high in this sample and associated with longer disease duration, translating the difficulties that both patients and health care professionals face every day and reinforcing the need for strategies to reduce GV effectively.

Efficacy and safety of switching from a dipeptidyl peptidase-4 inhibitor to a glucagon-like peptide-1 receptor agonist: A real-world experience

Carolina García-Figueras-Mateos[1] & Manuel Cayón-Blanco[2]
[1]Universitary Hospital Jerez de la Frontera, Internal Medicine, Jerez de la Frontera, Spain; [2]Universitary Hospital Jerez de la Frontera, Endocrinology and Nutrition, Jerez de la Frontera, Spain

Introduction
Glucagon-like peptide-1 agonists (GLP1a) and dipeptidyl peptidase-4 inhibitors (DPP4i) are both incretin-based therapies for type 2 diabetes (T2DM) but with distinct efficacy according to glycemic and weight control and side effect profiles. There is scarce information about changes observed after switching from a DPP4i to a GLP1a in patients with T2DM on a complex treatment regimen and routine clinical practice conditions. To assess these changes, we carried out this study to analyze if there were any beneficial effects of switching from DPP4i to once-weekly dulaglutide (a GLP1a) in poorly controlled patients with T2DM. Safety of that switch was also evaluated.
Methods/Design
An observational and retrospective study was carried out in T2DM poorly controlled patients in routine clinical practice. Variables used to assess efficacy were changes in HbA1c, fasting plasma glucose (FPG) and weight from switching to week 12 to 20 (period 1) and week 21–36 (period 2). Additionally, changes in antidiabetic drugs to maintain adequate glycemic control were evaluated. Safety variables were: hypoglycemic events and side effects related to GLP1a.
Results
Data from 60 patients (age: 61.3±9.4 years; HbA1c: 8.6±1.3%; duration of T2DM: 13.4±8.4 years) were collected. 63.3% of the cohort was on insulin. A significant reduction (P<0.001) in HbA1c, FPG and weight was observed in both periods of follow-up: HbA1c: –1.39% (CI 95%: –1.7 to –1.1) and –1.37% (CI 95%: –1.6 to –0.9); FPG: –33.2 mg/dl (CI 95%: –61.4 to –16.7) and –34.6 mg/dl (CI 95%: –57.3 to –18.2); weight: 2.14 kg (CI 95%: –3.99 to –2.36) and –3.36 (CI 95%: –3.35 to –1.45). In patients on insulin, a significant reduction in insulin doses was observed only in the first period (–0.13 IU/kg; P=0.031). Any intensification of antidiabetic treatment was required in 7.8% and 30.9% of the cohort in period 1 and 2, respectively. At least, one hypoglycemic event (no severe) was described in 12.7% of the patients. No patients required withdrawal from dulaglutide during follow-up.
Conclusions
Switching from DPP4i to GLP1a (dulaglutide) in patients with T2DM, and routine clinical practice, of our cohort, resulted in sustained HbA1c, FPG and weight reductions without compromising safety.

Evaluation of the results obtained with flash continuous glucose monitoring in patients with type 1 diabetes after a structured training program

Begoña Pla Peris, Ana M Ramos Leví, Marcos Lahera Vargas, Raffaele Carraro Casieri, Nerea Aguirre Moreno, Carolina Knott Torcal, Mónica Marazuela & Alfonso Arranz Martín
Hospital Universitario La Princesa, Division of Endocrinology and Nutrition, Madrid, Spain

Introduction
Funding of continuous glucose monitoring (CGM) has been established by Madrid Health Service for adults with type1 Diabetes Mellitus (DM) who meet specific criteria. This has brought to lightthe need foran increasedinvestment in care time. In our Division, a structured training program has been established, consisting of 2 training sessions (TS); the first one based on basic contents to initiateFlash-CGM, and the second one, more intensive and targeted, focused on the correct interpretation of the resulting data.
Aims
To evaluateglucose control of patients with type 1DM after undergoing a structured training program on theuse of Flash-CGM and toevaluatethe degree of patient satisfaction withtrainingitself, and regarding their management of DM.
Methods
Analysis of downloaded LibreView data of 50 patients using Flash-CGM. Description of demographic and analytical variables, and those related to glycaemic control provided by Flash-CGM system, after undergoing two TS separated in time. Descriptive and inferential statistics: SPSSv.25
Results
50 patients with type1 DM, 27 women, aged 39 [18–86], mean DM duration 20.76±12.27 years. Initial/previous/prior Hba1c: 7.3% [5.5–9.3%]. 5 used insulin pump and 21 were previous users of Flash-CGM. Number of scans/day:17 in pump-patients, 12 in patients on multiple daily injections. A decrease in mean HbA1c was noted with use of Flash-CGM (7.224 to 7.092%, $P=0.117$). No significant differences in glycaemic control adjusted for DM duration, gender, BMI, time using Flash-CGM or being on a pump were found between the two TS. We observeda decrease in the number of scans in non-previous users after the second TS (12.25±4.84 to 11.11±4.37, $P=0.021$). Younger users (≤39 years) reduced their number of scans after the second TS (13.16±5.71 to 11.04±4.12 ($P=0.001$). No significant correlation between the number of scans and time in range was found after the first TS. There was a significant correlation between the number of scans and time in range after the second TS (beta regression coefficient 0.371, $P=0.009$). Hypoglycaemic events and time in hypoglycaemia improved (15.75±16.30 (1st TS) to 13.57±6.8 (2nd TS) and 106.78±34.5 min (1st TS) to 104.59±37.98 min (2nd TS), (non-significant decrease). Patients showed a high degree of satisfaction (93% in DTSQ-c scale), better understanding of DM (95.4% DTSQ-c) and of glycaemic behaviour (93.3% EVA scale), and an overall high satisfaction (88.8%) with the training program received.
Conclusion
Flash-CGM increases time in range, HbA1c and quality of life. After the training program, satisfaction and understanding of glycaemic behaviour improve, denoting the importance of a continuous training process.

The association of vitamin B12 deficiency with metformin uses

Entela Puca[1], Sonila Bitri[1], Blertina Dyrmishi[2], Ema Lumi[3], Albana Daka[1] & Edmond Puca[4]
[1]American Hospital 2, Tirana, Albania; [2]Hygeia Hospital, Endocrinology, Tiranë, Albania; [3]Korce, Endocrinology, korca, Albania; [4]Mother Teresa Hospital, Tiranë, Albania

Introduction
Metformin is the first line treatment of type 2 diabetes, but now has been reported to cause a decrease in level of Vitamin B12.
The aim of the study is to describe the prevalence of vitamin B12 deficiency in adults with type 2 Diabetes Mellitus who were in treatment with metformin compared in those without diabetes.
Material and methods
Total number of patients were 130 between 16–84 years old. Mean age 54.2±16.4 years. Female were 56.9% (74 patients) and males 43.1% (56 patients). Serum B12 concentrations were quantified by chemiluminescent enzyme immunoassay. Patients were considered vitamin B12 deficiency if the level was less than 200 pg/ml and borderline-low B12 (≤300 pg/mL) they were in treatment with metformin over one year.
Results
The mean vitamin B12 level in all patients was 337.1±155.5 pg/ml. A total of 16.1% (21 patients) showed vitamin B12 deficiency with mean vitamin B12 level of 145.3±30.4 pg/m; and 48.4% (63 patients) showed borderline-low B12 with mean vitamin B12 level of 214±56.9 pg/ml. The mean concentration of B12 was significantly lower in the metformin treated group (264 pg/ml) compared to those without diabetes (409 pg/ml) ($P=0.06$). About 21.5% of persons with diabetes receiving metformin were vitamin B12 deficient (<200 pg/ml) compared to 4% of persons without diabetes.
Conclusions
Uses of metformin was associated with Vitamin B12 deficiency. Routine testing of vitamin B12 levels in metformin-treated patients should be considered and the clinician must be aware of the possibility of metformin-related B12 deficiency.

Keywords: Vitamin B12, metformin.

Clinical and safety profile of empagliflozin in nepalese type 2 diabetes patients

Ansumali Joshi, Priyadarshini Yonzon, Luna Thapa & Ritika Karki
Kathmandu Diabetes and Thyroid Center, Kathmandu, Nepal

Background
The only available SGLT2 inhibitor in Nepal till date is empagliflozin. Empaglilozin has shown to be cardioprotective and renoprotective in randomized trials. It has shown to reduce some weight. There is a lack of data of SGLT2 inhibitors in Nepalese Type 2 diabetes patients.
Aim
The aim of our study is to determine the effects of empagliflozin in glycemic control in terms of HbA1C reduction, weight, improvement in eGFR and side effect profile in Nepalese Type 2 diabetes patients.
Method
This is a retrospective study conducted in our OPD patients from February to September 2019 who were initiated on empagliflozin 10 mg per day who were already on other OHAs and/or insulin therapy. A total of 440 patients were prescribed empagliflozin out of which 230 patients came for the follow up at 3 months and 111 patients in 6 months. Hence, only the data from 111 patients who completed 6 months follow up were analyzed. 55.9% ($n=62$) patients were on insulin treatment.
Result
The findings of the study revealed that, out of 111 patients, 53.15% ($n=59$) were female and 46.8% ($n=52$) were male. Mean HbA1C at the time of initiation of empagliflozin was 7.9 (±1) % while it reduced to 7 (±1) % in 6 months. There was improvement in eGFR from 85 to 92 ml/min/1.73 m^2. There was weight loss from 71 (±13) kg to 68 (±11) kg at the end of 6 months. There were few incidence of genital infection. Notably, vulvovaginitis was observed in 15.25% of female patients ($n=9$), urinary tract infection in 5.4% of all patients ($n=6$), balanoposthitis in 3.84% of male patients ($n=2$).
Conclusion
There was improvement in glycemic control, weight loss and improvement in eGFR after initiation of empagliflozin in Nepalese Type 2 diabetes patients at the end of 6 months follow up.

AEP491

The efficacy of dulaglutide in the treatment of patients with type 2 diabetes and NAFLD in real clinical practice

Olga Nechaeva[1], Alexander Dreval[1], Pavel Bogomolov[2], Alexey Bueverov[2] & Ekaterina Liusina[2]
[1]Moscow Regional Research Clinical Institute named by MF Vladimirsky, Endocrinology, Moscow, Russian Federation; [2]Moscow Regional Research Clinical Institute named by MF Vladimirsky, Hepatology, Moscow, Russian Federation

Background
Dulaglutide has been approved as a hypoglycemic agent for the treatment of patients with T2DM. A positive effect on carbohydrate metabolism and body weight was shown in RCT.
It was found that GLP-1 agonists may prevent the progression of NAFLD directly affecting lipid metabolism and inflammation.
Aim
To assess the effect of dulaglutide on carbohydrate and hepatic metabolism in patients with T2DM and NAFLD in real clinical practice in Moscow Region.
Design
Open observational prospective cohort study of real clinical practice. After approval by LEC 45 pts with T2DM and NAFLD, BMI ≥ 27 kg/m^2, receiving basic therapy at the time of inclusion with daily dose of metformin ≥ 1,500 mg as monotherapy or as part of a combination therapy were condacted to the study with treatment of dulaglutide subcutaneus injections 1,5 mg weekly for 26 weeks. Mean age 55.6 ± 10.6 лет, 16(36%) men. All patients undergo physical examination withheight, weekly weight, waist and hip circumference measurement, monthly blood sampling tests (HbA1c, FPG, ALT, AST, GGT, lipids, hematology), ultrasound, elastometry using Fibroscan before and after 26 weeks of treatment. Also FIB4, FLI were calculated before and after 26 weeks of treatment. Statistical analysis was done using by MedCalc Version 19.1 using Wilcoxon test for nonparametric and Fisher test for parametric data. Results presented in median with interquartile range (IQR).
Results
In real clinical practice with weekly visits it was found statistically significant difference of weight loss. 5% weight loss was found in 56.0% pts, 10% weight loss – in 7.0% of patient, median weight loss was –5 kg in 26 weeks. A statistically significant decrease in weight, BMI, waist circumference, HbA1c, ALT levels was detected in the whole group, despite the fact that the goal of more than 5% of the initial weight loss have reached only 56,0% of patients. There was no statistical difference in hip circumference, FPG, AST, GGT, lipids levels. Median of HbA1c decreased from 7.4% (6.1–8.4) to 6,3 (5.6–6.8), ALT median decreased from 67.2 (IQR 35.5–96.9) to 38.2 (IQR 22.6–62.9). A downward trend in FLI and TE was also noted, although absolute values corresponded to a high risk of steatosis.
Conclusion
In real clinical practice Dulaglutide may have a positive effect on weight loss, metabolic and hepatic parameters in patients with NAFLD and T2DM.

AEP492

Association of B12 levels with metformin use in type 2 diabetes patients

Ivan Pankiv
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background
Metformin is the most widely used oral antihyperglycaemic drug, but it may lower B_{12} status, which could have important clinical implications.
Aim
To study serum Vitamin B_{12} levels in patients with type 2 diabetes mellitus who were receiving metformin and compared them to those never treated with metformin.
Materials and Methods
A total of 60 patients with type 2 DM (group 1, $n=35$, receiving metformin and group 2, $n=25$, never treated with metformin) from the endocrinology clinic in Chernivtsi were studied. Serum vitamin B_{12} levels were measured in all patients.
Results
The serum vitamin B_{12} levels were 239.6 ± 37.4 pg/ml in metformin group and 293.6 ± 42.3 pg/ml in the no metformin group ($P=0.37$). When adjusted for duration of DM, metformin use was associated with a 57.2 ± 7.3 pg/ml ($P=0.03$) lower serum vitamin B_{12} levels. Serum vitamin B_{12} levels were higher by 41.4 pg/ml in patients with DM of 1–5 years compared to those with recently diagnosed diabetes ($P=0.41$). Serum vitamin B_{12} levels were higher by 119.4 pg/ml in patients with duration of DM > 5 years compared to those with recently diagnosed diabetes ($P<0.02$). Similarly, serum vitamin B_{12} levels were 77.1 pg/ml higher in > 5 years DM duration group compared to 1–5 year duration of DM group ($P=0.03$). Serum vitamin B_{12} levels for the entire cohort were higher by 11.8 ± 1.7 pg/ml ($P<0.01$) for every 1 year increase in the DM duration.
Conclusions
Metformin use was associated with a lower serum vitamin B_{12} levels when adjusted for duration of DM. Increasing duration of DM was associated with higher serum vitamin B_{12} levels.

DOI: 10.1530/endoabs.70.AEP492

AEP493

Insulin usage and injection practices in a largeIndian cohort: An audit

Manash Baruah
Excelcare Hospitals, Endocrinology, Guwahati, India

Objective
Despite an increase ininsulin utilization in India over the past 10 years, wide variation exists in injection practices and usage across the Indian geography. This cross-sectional study was designed to audit various aspects of insulin usage, tolerability and efficacy of insulin regimens, degree of variability in injection techniques and its causes, interactions, and associations with glucose control and other outcomes.
Methods
Data for this cross-sectional retrospectivestudy was collected from the prescription registry of an electronic database including consecutive patients attendinga private urban referral clinic from North Eastern India between January 2006 until December 2016. T2DM patients using insulin for more than 3 months and having aninitial HbA1c level at registration were included. Information on patient demography, HbA_{1c}, insulin injection practices (including injection site, rotation, needle reuse, and lipohypertrophy), self-monitored blood glucose, and hypoglycemic events in the past 6 months were collected.
Results
Data of 1454 patients with T2DM (60.38% male, mean age 54.63 ± 10.79 years, range 18–85 years) on median duration of insulin therapy for 2.00 (0.0: 37) years were collected. Mean dose of insulin was 33.1 ± 17.8 units/day. Majority were taking human insulin (61.21%) andt he rest (34.59%) were on insulin analogues. Premix insulin (67.88%) was the most common type of insulin used followed by basal insulin (10.90%), basal bolus (6.50%), bolus only insulin (6.33%) and combination of premix with bolus (5.7%). 62.53% used pen device. OAD failure (33.15%), glucotoxicity (30.26%), and diabetic complications (20.36%) were prominentindications for starting insulin. Mean HbA1c(%) was 9.2 ± 2.2. Less than 16% of patients had HbA1c < 7%. Faulty injection practices were underscored by improper rotation of injection sites (67.61%) and needle reuse (73.11%). Majority followed right practices w.r t. storage (65.13%), hygiene (82.1%), correct site and angle for injection (78.4% and 81.84% respectively). Visible or palpable Liohypertrohy (LH) was found in 12.38% of subjects which was significantly associated with wrong rotation and needle reuse. Hypoglycemic events were insignificantly associated with type of insulin, or various attributes of insulin injection practices.
Discussion
This study, in spite of inherent limitations, convincingly shows that metabolic control remains poor amongst patients using insulin. Wrong injection practices, resultant LH and inadequate dose may be contributory.
Conclusion
There are identifiable faulty injection practices amongst T2DM patients on insulin, and therapeutic inertia amongst prescribing physicians which can be rectified by proper interventions targeting patients and HCPs.

AEP494

Vitamin D, osteoprotegerin and metabolic status in children with obesity

Hanna Mikhno[1], Anzhalika Solntsava[2] & Helena Dashkevich[3]
[1]2nd city children`s hospital; [2]Belarusian State Medical University.; [3]10th city clinical hospital

Objective
Determination of changes in metabolic status and vitamin D, osteoprotegerin concentrations in obese children.

Methods
We examined 221 children in the University Hospital (Minsk) from 2017 to 2019 yrs. Their anthropometric parameters (height, weight, body mass index (BMI)) were determined. Blood levels of vitamin D, osteoprotegerin (OPG), insulin were determined. In the biochemical blood test, the parameters of uric acid, glucose were evaluated. All children were divided into 2 groups: group 1 children with morbid obesity – 159 patients (98 boys(B)/61 girls(G)) (BMI more than 99th percentile for sex and age) (BMI 32.95±4.61 kg/m^2, age 14.16±2.28 years); group 2 – 62 patients (B/G=31/31) with alimentary obesity (BMI-95-99th percentile for sex and age) (BMI 27.86±2.04 kg/m^2, age 14.77±2.05 years). The control group consisted of 84 patients (B/G=45/39) with normal body weight (BMI 19.86±2.24 kg/m^2, age 14.32±2.11 years).
Results
In the subgroups of boys with obesity, there were significant differences in the concentration of uric acid in comparison with the control (alimentary obesity 424.10±65.25 mmol/l vs 242.58±49.90 mmol/l (P=0.01)), morbid obesity 324.10±59.33 mmol/l vs 242.58±49.90 mmol/l (P=0.01)). Girls with obesity have a significant increase in uric acid level in comparison with the control group (alimentary obesity 324.10±59.33 mmol/l vs 213.0±39.64 mmol/l (P=0.0001), morbid obesity 409.04±84.23 mmol/l vs 213.0±39.64 mmol/l (P=0.0001)). In boys with obesity higher concentrations of OPG were detected relative to the control group (alimentary obesity 259.98±108.07 ng/ml vs 225.12±55.88 ng/ml (P=0.09), morbid 322.22±82.14 ng/ml vs 225.12±55.88 ng/ml (P=0.001)). In girls with obesity higher concentrations of OPG were detected relative to the control group (alimentary obesity 326.84±104.02 ng/ml vs 254.39±78.29 ng/ml (P=0.046), morbid 347.33±93.50 ng/ml vs 254.39±78.29 ng/ml (P=0.03)). In the obese boys, the level of vitamin D is significantly lower than in the control group (alimentary obesity 29.56±6.01 ng/ml vs 33.02±4.10 ng/ml (P=0.05), morbid obesity 27.56±5.75 ng/ml vs 33.02±4.10 ng/ml (P=0.05)). Obese girls showed a significant decrease in vitamin D relative to the control group (alimentary obesity 24.21±10.75 ng/ml vs 31.34±7.35 ng/ml (P=0.05), morbid obesity 23.52±4,18 ng/ml vs 31.34±7.35 ng/ml (P=0.04)). In boys with obesity higher concentrations of insulin were detected relative to the control group (alimentary obesity 18.9±12.7 µU/ml vs 9.1±4.2 µU/ml (P=0.0001), morbid 28.71±7.36 µU/ml vs 9.1±4.2 µU/ml (P=0.001)). In girls with obesity (alimentary obesity 20.28±6.25 µU/ml vs 14.10±6.80 µU/ml (P=0.001)) morbid obesity 23.32±9.65 µE/ml vs 14.10±6.80 µU/ml (P=0.001)).
Conclusion
Children with obesity have a significant decrease in the concentration of vitamin D. There is an increase in insulin and OPG rates.

AEP495

Is body mass indexbefore the fast of the month of ramadan associated with the evolution of lipid parameters in diabetic women?

Chaima Jemai & Feika Ben Mami
National institute of nutrition of Tunis, C, Tunisia

Aim
The objective of our study is to describe the evolution of the parameters of the lipid balance after fasting in a population of diabetic women, and to determine if the BMI before the fast is associated with the variation of these parameters.
Materials and methods
This is a prospective evaluative study conducted on 44 female patients with type 2 diabetes who have received prior education and therapeutic adjustment adapted according to the recommendations of the ADA 2016.
Results
The mean age was 53.31±11.93 years. The average BMI was 30.33±5.26 kg/m^2. 73.3% (n=33) were at high and very high risk related to fasting (ADA 2016). The days fasted were successive with an average of 24.75±8.7 days. The majority (73.3%, n=33) had fasted for the entire month. 77.6% (n=35) were obese with an average BMI of 31.78±4.4 kg/m^2. There was no significant difference between patients with normal BMI and those who were obese in terms of average age and average number of fast days. HbA1C decreased from 8.49±1.73% to 8.16±1.89% after fasting (P=0.079). The CT, TG, HDL and LDL were respectively 4.67±0.88, 1.2±0.44, 1.15±0.24 mmol/l and 1.15±0, 31 g/l before fasting, respectively. They increased respectively after fasting to 4.62±0.88 (P=0.613), 1.27±0.4 (P=0.197), 1.16±0.24 mmol/l (P=0.873) and at 1.11±0.3 g/l (P=0.326). Either an average decrease of –0.04±0.62 mmol/l of CT, an average increase of +0.07±0.35 mmol/l of TG, an average increase of +0.005±0.21 mmol/l in HDL and an average decrease of –0.039±0.26 g/l in LDL. In obese, the mean change in CT was –0.15±0.57, mmol (+036±0.68 mmol/l in the case of normal BMI, P=0.025). The TG was +0.04±0.37 mmol/l (+0.17±0.29 mmol/l (normal BMI), P=0.349). The HDL values were –0.004±0.2 mmol/l (+0.04±0.25 mmol/l (normal BMI), P=0.57). And that of LDL was –0.07±0.25 g/l (+0.07±0.27 g/l (normal BMI), P=0.139). Thus, BMI was associated only with the variation in CT in our population.
Conclusion
The literature reports disparate results in terms of variation in lipid parameters after the fast of the month of Ramadan. They remain highly sensitive to several factors including diet. Studies on a larger scale are essential to better characterize these variations.

AEP496

Interrelationship between fasting evaluation of insulin sensitivity, body composition, physical activity and total energy expenditure in obese males

Adriana Kauffmann[1,2] & Davide Carvalho[3]
[1]Queensland University of Technology, Brisbane, Australia; [2]Institute of Health and Biomedical Innovation, Health, Brisbane City, Australia; [3]University of Porto, Porto, Portugal

The prevalence of obesity markedly increased in the last 2 decades. This have asserted researchers' attention to the role of adipose tissue throughout the pathophysiology process of a number of diseases. Fatness, namely abdominal fat, is a risk for insulin resistance, type 2 diabetes mellitus (T2DM), and cardiovascular disease. Physical activity is recommended as one of treatment options for individuals with T2DM. This study aimed to determine the relationship between insulin sensitivity measured by HOMA-IR/QUICKI and: total body fat [measured by dual energy X-ray absorptiometry (DXA)], waist circumference, daily physical activity behavior [measured by the ActiGraph accelerometer]; daily total energy expenditure (TEE) and activity energy expenditure (AEE) [measured by doubly labelled water (DLW)]. Following the collection of fasting baseline blood samples and anthropometric evaluation, 43 obese men (39.38±8.44 years of age) were advised to remain sedentary and not initiating any exercise programme during a period of four weeks of weight-stable diet (an energy balance diet were prescribed for all participants). The participants of this study were part of weight stabilization period from a big weight loss intervention study [Queensland University of Technology (QUT) in Brisbane, Australia]. During this 4-week period measurements of AEE, resting metabolic rate (RMR) and physical activity levels (PALs) were recorded at week-4 and baseline. Participants were instructed to wear the accelerometer GT1 Min the first visit (week-4) and TEE was tracked over a period of time of 14 days. This study showed that obesity (BMIs ranging from 30 to 45 kg/m² and body fat with mean of 39.2±5.3%) is a good predictor of insulin resistance (HOMA-IR=4.69±2.63 and QUICKI=0.31±0.02). The participants had markedly increased cardiovascular risk, with a mean waist circumference of 110.1±8.3 cm. Physical activity was positive correlated at moderate intensity (min/day) with fasting plasma glucose (r=.397, P<.006). The linear regression showed that moderate-intensity physical activity behaviour explained 15% of variation of fasting plasma glucose. The limitations of this study are the capability of GT1M to only capture activities on a flat surface. Another limitation of this study is the inability of energy expenditure measurements from the DLW method to capture aspects of activity such as mode or intensity, which may be more important for stimulating the physiological training adaptations. In conclusion, daily physical activity seems to be a bigger determinant of insulin sensitivity than total daily expenditure.

DOI: 10.1530/endoabs.70.AEP496

AEP497

The effectiveness of complex treatment of obesity on theknee osteoarthritisand the dynamics of cytokines, depending on the degree of weight loss

Ekaterina Strebkova & Ludmila Alekseeva
Nasonova Research Institute of Rheumatology

Objective
Assess the effectiveness of complex treatment of obesity with the use of orlistat (intestinal lipase inhibitor) on the knee OA (KOA) and the dynamics of cytokines (CRP, IL-6, TNF-α) depending on the degree of weight loss.
Methods
50 female patients (45–65 y.o.) with Kellgren-Lawrence stage II-III KOA and obesity (BMI > 30 kg/m²). Patients in Group 1 ($n=25$) took 120 mg of orlistat 3 times a day in combination with a low-calorie diet and exercise for 6 months. Patients in Group 2 ($n=25$) were recommended non-drug therapy for obesity for 6 months. At baseline and after 6 months, the clinical parameters of the KOA (WOMAC) were evaluated, the quality of life was assessed (EQ-5D). A laboratory study of peripheral blood was conducted at baseline and after 6 months: CRP, IL-6, TNF-α.
Results
After 6 months of complex treatment of obesity with the use of orlistat, patients in Group 1 achieved a significant weight loss of 10.07% ($P<0.05$). Depending on the degree of weight loss in Group 1, 15 patients lost > 10% and 10 patients lost 5–9.9% of the initial body weight. In the 2nd group, an insignificant weight loss of 0.84% ($P>0.05$) was achieved, all patients in Group 2 lost less than 5%. Depending on the degree of weight loss, it is noted that in patients with weight loss more than 5% better than WOMAC (pain, stiffness, functional state) ($P<0.05$), EQ-5D ($P<0.05$) compared with less weight loss. In patients with weight loss > 10%, a significant decrease in CRP level was observed ($P=0.03$) compared with baseline and patients with a 5–9.9% weight loss ($P=0.03$) and < 5% ($P=0.02$). Data for statistically significant changes from TNF-α and IL-6, depending on the degree of weight loss was not detected.
Conclusion
The results of the study demonstrated a significant effectiveness of the complex treatment of obesity in patients with KOA. A decrease in body mass of more than 5% helps to improve the clinical manifestations of KOA. A decrease in body weight of more than 10% demonstrates a decrease in the level of CRP, which suggests an effect on meta-inflammation in OA.

AEP498

Evolution of comorbidities associated with obesity one year after bariatric surgery, our hospital experience

Joaquin de Carlos, Emma Anda, Ana Zugasti, Estrella Petrina, Amelia Marí, Henry Rendón & Sonsoles Botella
Complejo Hospitalario de Navarra, Endocrinology, Pamplona, Spain

Bariatric surgery (BS) improves quality of life and health due to the beneficial effect on the metabolism at multiple levels. Specifically, its effectiveness in weight loss and the attenuation or resolution of comorbidities associated with obesity, means lower morbidity and mortality compared to other types of interventions. The objective is to analyze the evolution of obesity-related diseases after twelve months of follow-up.
Methods
Retrospective study with 31 patients who underwent gastric bypass surgery between May 2017 and January 2019 at the Complejo Hospitalario de Navarra. The statistical analysis was carried out by performing Wilcoxon test and linear regression with SPSS.
Results
Average age of patient is 54 years (s.d. 7.9), 45% (14) of them were men and 55% (17) women. The most frequent comorbidities before BS were: arterial hypertension (68%), obstructive sleep apnea (39%), hypercholesterolemia (32%), diabetes (29%), pre-diabetes (29%), microangiopathy (13%), nonalcoholic fatty liver disease (10%), coronary heart disease (2.5%). Pre-surgical BMI was 43.4 kg/m² (s.d. 4.8), dropping to 30 kg/m² (s.d. 2.8) one year after surgery ($P<0,05$). Percentage of fat-free mass at the begining, measured by TANITA was 54% (s.d. 6.7), increasing by 21,7% to 66,1% (s.d. 8.6) at 12 months ($P<0,05$). The Percentage of Excess BMI Loss (PEBMIL) was 73.65% (s.d. 14.2). Weight loss and decrease in the percentage of fat mass is the basis of the improvement of cardiovascular risk factors. The reduction in prescription of the number of lipid lowering treatments was not significant. However, the lipid profile was significantly improved ($P<0.05$). LDL decreased from 112 mg/dl (s.d. 35) to 96 mg/dl (s.d. 31), HDL from 43 mg/dl (s.d. 10) to 52 mg/dl (s.d. 12), and triglycerides from 154 mg/dl (s.d. 61) to 86 mg/dl (s.d. 39). The percentage of hypertensive patients was reduced by 19%, and the average number of drugs prescribed was also reduced from 2 to 1.8 ($P>0,05$). Complete remission rate of diabetes was 77% (7), with an average Hb1Ac of 6% and a mean basal glucose of 97 mg/dl. As side effects, 79% had some nutritional deficit, with vitamin D being the most frequently supplemented.
Conclusions
In the study population, BS reaches the quality indicators and objectives of recommendations. Weight and fat reduction was the basis for improving metabolic comorbidities and cardiovascular risk factors associated with obesity.

DOI: 10.1530/endoabs.70.AEP498

AEP499

Obesogens and obesity pandemic

Hassan Heshmati
Endocrinology Metabolism Consulting, LLC, Anthem, United States

Introduction
Obesity is a worldwide pandemic associated with increased morbidity/mortality and high cost for the society. The prevalence of obesity has doubled in more than 70 countries (including developing countries) since 1980. The number of adult subjects with obesity is around 700 million worldwide. The current pandemic in obesity cannot be explained solely by alterations in food intake and/or decrease in exercise. Obesity pandemic coincides with the marked increase of the industrial chemicals in the environment over the past 60 years.
Obesogens
Humans are constantly exposed to a variety of endocrine disrupting chemicals through air, water, and food. Several categories of chemicals are involved (industrial, agricultural, residential, and pharmaceutical). Some endocrine disrupting chemicals have short half-lives (minutes or hours) while others, highly lipophilic (accumulating in the adipose tissue), have long half-lives (years). Several endocrine disruptors can alter regulation of energy balance and weight control to favor weight gain and obesity. The exposed subjects are predisposed to weight gain despite normal diet and exercise. These endocrine disruptors are called obesogens. The list of obesogenic chemicals is continuously growing. Obesogens promote obesity by inducing an increase in the number of adipocytes and storage of fat. The metabolic programming of obesity risk may be linked to *in utero* or lifetime exposure to obesogens. Exposure to obesogens during development can play a role in the development of obesity later in life (developmental origins of adult disease). The developing fetus and neonate are very sensitive to perturbation by obesogens. In many cases, the damage is irreversible due to lack of protective mechanisms such as DNA repair, competent immune system, or mature blood/brain barrier.
Conclusion
The prevalence of obesity is increasing continuously. Diet and physical activity are not the only contributing factors. The developmental exposures to obesogens play a role in the obesity pandemic. Obesogens alter metabolic processes and predispose some subjects to weight gain and obesity. Urgent interventions, particularly among children, are needed. Exposure to obesogens should be reduced or avoided especially in fetus and neonate.

Comparative effectiveness of three methods for body composition assessment in the verification of manifestations of sarcopenia in obese patients

Valeriia Vasileva, Larisa Marchenkova & Valeriy Sergeev
National Medical Research Center of Rehabilitation and Balneology, Moscow, Russian Federation

Aim of the study was to compare the effectiveness of three methods of body composition assessment such as bioimpedans analysis (BIA), air-replacement bodyplatismography (BodPod) and Dual X-ray absorptiometry Total body program (DXA Total Body) in the verification of reducing of skeletal muscle mass as sign of sarcopenic obesity in obese patients.
Material and methods
The study group included 95 patients aged 21–69 y.o. (average age 53.9 ± 11.05 years) with BMI ≥ 30.0 kg/m². The control group included 37 patients aged 37–69 y.o (average age 50.73 ± 10.6 years) of the same age without obesity with BMI 20.0–29.9 kg/m². Body composition was tested using BIA, BodPod and DXA with calculating fat, lean and skeletal muscles mass (kg) and % in all the patients.

Results
According to BIA the groups differ only in fat mass (FM) 42.75 (4.8;6.3) vs 33.15 (28.4;35.5) kg; $P=0.036$ and did not differ ($P>0.05$) in lean (LM), skeletal muscle mass (SMM) and in % of FM and SMM. According to BodPod analyses groups differed in the FM 3.4 [36.81; 69.94] vs 31.02 [23.22; 38] kg, $P=0.007$, % FM 45.4 [42.1; 53.8] vs 37.7 [28.6; 41.1], $P=0.003$ and % LM – 54.6 [46.2; 57.9] vs 62.3 [58.9; 71.4], $P=0.003$, but had statistically equivalent values of LM 55 [49.48; 67.77] vs 40.36 [33.12; 49.06] kg, $P=0.19$. According to DXA Total Body analyses statistically significant differences ($P<0.05$) have been identified between the groups in FM and % FM of the hands, feet, trunk, total body ($P>0.05$), but not in LM and % LM ($P>0.05$).
Conclusions
From methods of body composition assessment, air-replacement bodyplatismography (BodPod) is the most sensitive in the verification of skeletal muscle mass reduction in obese patients. This method shows that patients with obesity have a significantly reduced muscle mass compared with normal weight or overweight subjects.

Combination of topiramate and empagliflozin is considered a good option for treatment of obesity

Mahmoud Younis
Egypt Ministry Of Health, Endocrinology, Kafr Elsheikh, Egypt

Objectives
The aim was to show if the combination of topiramate and empagliflozin have the greatest weight decreasing effect in comparison to each drug alone and to control.
Design
Observational cohort prospective study 6-month trial.
Materials and methods
Observational cohort prospective study with the following of 200 obese patients who were in 4 parallel groups. Had been monitored in a private clinic, each group 50 patient's number, with 35 females and 15 males with 50 patients as a control.
The results show that both topiramate and empagliflozin have weight loss effect if used alone with significant *P*-value which is 0.0480 with topiramate and 0.0048 with empagliflozin and the greatest weight loss effect if used in combination with a *P*-value less than 0.0001.
Conclusion
Combination of topiramate and empagliflozin show a considerable reduction of body weight and so is considered as an option for treatment of obesity.
Keywords: obesity, empagliflozine, topiramate, combination therapy.

Different short-term responses of image dissatisfaction and distortion to sleeve gastrectomy

Erika Naliato
Teresopolis Medical Association, Ricardo A T Castilho Center of Studies, Teresopolis, Brazil

Introduction
Bariatric surgery is one of the most important treatment modalities for obesity. Studies suggested that obese subjects have distorted body image perception. Dissatisfaction with body shape is one of the leading reasons for treatment referral.
Aim
To prospectively study body image perception and its relationship with body composition in patients treated with bariatric surgery.
Methods
Nineteen patients were evaluated before and after sleeve gastrectomy using the Stunkard Figure Rating Scale (SFRS) and bioimpedance. Image dissatisfaction and distortion, body mass index (BMI), body fat percentage, muscle mass, and visceral fat were studied.
Results
Fifteen women and four men (mean age = 41.63 ± 10.17 years) were investigated. After surgery (3.7 ± 1.4 months), BMI decreased from 42.53 ± 6.53 to 33.88 ± 5.55 kg/m^2 ($P=0.0001$), body fat from 49.21 ± 4.33 to 43.21 ± 4.76% ($P=0.003$), visceral fat index from 23.3 ± 2.6 to 17.6 ± 4.9 ($P<0.0001$), and muscle mass from 32.13 ± 6.29 to 28.75 ± 6.67 kg ($P=0.0002$). According to the SFRS, all subjects presented image dissatisfaction both at baseline and after surgery. However, dissatisfaction scores were higher at baseline (4.2 ± 1.4) than postoperatively (2.9 ± 1.3, $P=0.0008$). Dissatisfaction was correlated with BMI ($r=0.4632$, $P=0.0034$), body fat percentage ($r=0.5284$, $P=0.0006$), and visceral fat index ($r=0.4457$, $P=0.0050$). In the multiple regression model, after the adjustment for the influence of other variables, body fat percentage was identified as the main influence on the dissatisfaction scores. When self-image distortion was present (pre- and postoperative prevalence of 45.8 and 54.2%, respectively), it consisted of underestimation of body shape and scores did not change significantly after surgery (0.68 ± 0.67 vs 0.89 ± 0.74, $P\pm0.2590$). Women had a higher relative risk of image distortion than men ($RR=1.522$, $P=0.0391$).
Conclusion
All patients presented image dissatisfaction both preoperatively and after a short postoperative period. Dissatisfaction improved significantly after sleeve gastrectomy as a result of a decrease in body fat percentage. Nevertheless, there was no significant change in image distortion, a common feature in this cohort and reportedly involved in the very pathogenesis of obesity.

Impact of isoflavone intervention on microbiota, predicted metagenome and metabolic profile in polycystic ovary syndrome

Christoph Haudum[1,2], Lisa Lindheim[1], Angelo Ascani[1], Christian Trummer[1], Julia Münzker[3], Angela Horvath[2,4] & Barbara Obermayer-Pietsch[1,2]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria; [2]CBmed – Center for Biomarker Research in Medicine, Graz, Austria; [3]Leipzig University, Department of Medicine, Integrated Research and Treatment Centre for Adiposity Diseases, Leipzig, Germany; [4]Medical University of Graz, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Graz, Austria

Objective
Polycystic ovary syndrome (PCOS) affects 5–20% of women of reproductive age worldwide and is associated with disorders of glucose metabolism. Hormone and metabolic signalling may be influenced by phytoestrogens, such as isoflavones. Their endocrine effects may modify symptom penetrance in PCOS.
We investigated, whether women with PCOS and healthy controls differ in their capacity to metabolize dietary isoflavones and whether this capacity is associated with PCOS-typical metabolic, microbiome and predicted metagenomic markers.
Objectives
After clinical and biochemical characterisation, urine isoflavone levels were measured in PCOS and control women before and 3 days after a defined isoflavone intervention via soy milk. In parallel, bacterial equol production was evaluated using the log (equol:daidzein ratio) and microbiome, metabolic and predicted metagenome analyses were performed. Urine isoflavone and equol levels were measured by mass spectrometry in women with PCOS ($n=24$) and non-PCOS controls ($n=20$) before and after 3 days ofsoy challenge. Bacterial equol production was evaluated using the log(equol:daidzein ratio). Group size was calculated according to the effects of equol. Metagenome analyses were performed using PiCRUST (Phylogenetic Investigation of Communities by Reconstruction of Unobserved States), LEfSe (Linear discriminant analysis effect size) and QIIME1.9 (Quantitative Insights Into Microbial Ecology).
Results
We found metabolic changes, decreased glucose ($P=0.01$) and fasting insulin ($P<0.01$) as well as a decreasedrespective HOMA2-IR ($P<0.02$) in PCOS patients, but not in control women ($P=0.48$, $P=0.70$, $P=0.72$) after isoflavone intervention. Investigating the effect of an equol rise on androgenic as well as fertility markers, these two categories correlated negatively with the rise of equol (-0.364, $P=0.021$, -0.396, $P=0.021$ resp.). In addition, we found PCOS-associated predicted metagenomic pathways improved after soy intervention with specific strains linked to carbohydrate metabolism as well as inflammation being increased in PCOS women but not in controls.
Summary and conclusions
There is increasing evidence on specific interactions between energy metabolism, hormone systems and bacterial pathways e.g. via active intestinal

compounds. The importance of the equol producing gut microbiota and metagenomic pathway changes in PCOS women may therefore be considered from a new perspective. However, dietetic and microbiota-associated aspects in PCOS should be investigated in more detail in the near future.

AEP504

Genetic variability in antioxodative and inflammatory pathways modifies the risk for PCOS and influences metabolic profile of the syndrome

Rok Herman[1], Mojca Jensterle[1], Andrej Janez[1], Katja Goricar[2] & Vita Dolzan[2]
[1]University Medical Center Ljubljana, Ljubljana, Slovenia, Department of Endocrinology, Diabetes and Metabolic Disease, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, Pharmacogenetics Laboratory, Institute of Biochemistry, Slovenia

Background
Polycystic ovary syndrome (PCOS) is a complex endocrine and metabolic disorder of multifactorial etiopathology likely to involve the interactions between genetics and lifestyle. Chronic inflammation and oxidative stress (OS) may participate in the pathophysiology of the syndrome. The question of the extent to which OS and inflammation are causally related to the development of the syndrome and metabolic complications remains unanswered. Furthermore, the role of NLRP3 inflammasome as an important trigger of inflammatory pathways and *NLRP3* and *CARD8* polymorphisms have never been addressed in PCOS yet.
Purpose
The aim of our study was to investigate genetic variability in the pathways associated with OS and inflammation and to assess their relationship with the risk of PCOS development as well as with metabolic characteristics in PCOS patients.
Methods
We conducted a case-control study conducting of total 169 Slovenian PCOS patients and 83 healthy blood donors. They were genotyped for polymorphisms in antioxidative (SOD2 rs4880, CAT rs10 01179, PON1 rs85 4560, and rs662) and inflammatory pathways genes (NLRP3 rs35 829419, CARD8 rs20 43211, *TNF*α rs18 00629, *IL1*β rs11 43623, and rs16 944, IL6 rs18 00795) using competitive allele-specific polymerase chain reaction (PCR). Logistic regression and Mann-Whitney test were used in the statistical analysis.
Results
SOD2 rs4880, CARD8 rs20 43211 and *IL1* rs16944 were associated with the risk of developing PCOS. Furthermore, the interactions between CARD8 rs20 43211 and *IL6* rs18 00795 and between *IL1*b rs11 43623 and IL6 rs18 00795 also significantly affected the risk for PCOS. With regards to glucose homeostasis, *CAT* rs10 01179, SOD2 rs4880, PON1 rs85 4560, *NLRP3* rs35 829419, and *TNF*α rs18 00629 were significantly associated with response to the glycaemic load.
Conclusions
Our data indicates that genetic variability in antioxidative and inflammatory pathways influences the development of PCOS and glucose homeostasis in PCOS patients.

Challenging hypoglycaemia management in a patient with metastatic insulinoma

Angeliki Giannopoulou, Ashutosh Surya, Ravi Nidumolu, Justyna Witczak, Nagappan Kumar & Aled Rees
University Hospital of Wales, Endocrinology, Cardiff, United Kingdom

Background
Metastatic insulinomas are very rare (fewer than 1:100000) and therefore may pose a therapeutic challenge as there are no case controlled studies comparing the efficacy of various therapeutic approaches avialable. The Ki 67 index from the histology of the primary tumour is an established prognostic marker for metastatic disease with tumours showing low Ki 67(<3%) being defined as low risk of early recurrence.
Case Presentation
A 60 year old female presented with severe episodes of fasting hypoglycaemia with glucose levels as low as1 mmol/l requiring prolonged dextrose 10% infusion. This was accompanied by raised insulin and C-peptide values when confirmed severe hypoglycaemia occured (>100 mU/l and 2953 pmol/l, respectively). Her past medical history included a distal pancreatectomy and splenectomy fourteen years ago when she had an incidental finding of a cystic lesion in the pancreas. The histology at the time revealedit was a low grade pancreatic neuroendocrine tumour (NET). For the next 5 years she was having regular follow ups with repeat imaging of her abdomen and repeat chromogranin A and B levels and as there was no evidence of tumour recurrence hence she was discharged from the surgical follow up. Repeat CT imaging revealed multiple large volume liver metastases (largest measuring 11.3 cm), an 8.2 cm left para-aortic metastatic tumour deposit anda smaller metastatic deposit anterior to the left renal vein. CT guided biopsy showed a grade 2 well differentiated NET with Ki 67 4.5%. Despite commencementand uptitration of diazoxide (100 mg TDS) and octreotide (200 mg TDS), patient continued to have symptomatic severe hypoglycaemic episodes requiring continous 10% dextrose infusion at 125 mls/hour. She also developed drug-induced rash. Following a multidisciplinary team discussion, decision wasmade to perform hepatic artery embolisation but despite that the hypoglycaemic episodes recurred the next day. Eventually, patient under went laparatomy for right hemihepatectomy and resection of the left retroperitoneal mass. She was euglycaemic after the procedure and had a good postoperative recovery. Subsequent histology showed well differentiated grade 2 NETconsistent with metastatic spread of previous pancreatic neuroendocrine tumour (insulinoma). She remains euglycaemic and well.
Discussion
This case illustrated that metastases from a neuroendocrine tumour may occur many years since initial presentation. Metastatic insulinoma may be quite challenging to manage. The initial approach is to manage symptoms pharmacologically whilst decision is made regarding definite management with options including surgery, embolization, radiotherapy, chemotherapy or liver transplant depending on individual circumstances.

Does the pilgrimage increase the podiatry risk in diabetic patients?

Salah Ameni[1], Yosra Hasni[1], Safa Amara[2], Zomorda Kamoun[3], Saoussen Mrad[3], Asma Ben Abdelkarim[3], Molka Chadli[3], Ghada Saad[3], Maha Kacem[3], Amel Maaroufi[3] & Koussay Ach[3]
[1]University Hospital Farhat Hached Sousse, Endocrinology Department, Sousse, Tunisia; [2]Higher School of Health Technicians, Sousse, Tunisia; [3]University Hospital Farhat Hached Sousse, Sousse, Tunisia

Background
The number of diabetic pilgrims could exceed 220000/year. Among the complications that can be observed in these patients, foot lesions are very common. We are therefore interested in this study in the assessment of podiatric risk among diabetic pilgrims.
Material and methods
A Cross-sectional study covered 43 diabetic patients from the city of Sousse, intending to perform the pilgrimage during 2019. The evaluation was made before and after pilgrimage and included clinical examination, evaluation of neuropathy and peripheral arterial disease.
Results
The average age of patients was 62.5±5.4 years. Diabetes was in chronic imbalance in 39.5% of cases with an average glycated hemoglobin of 7.9±1.3%. The clinical exam after the return of pilgrimage showed that the most frequent pological lesions were hyperkertosis (96.8%) as well as superficial fungal infections. Three patients had food ulcers which were mainly due to walking injuries and unsuitable shoes. The study of the risk of developing a foot ulcer showed that it was significantly associated with a lower total cholesterol, HDL cholesterol or LDL cholesterol and a higher triglyceride level (*P* respectively 0.02; 0.02; 0.01 and 0.04). The study of the other risk factors had not shown any significant correlation. However, there was a significant increase in the systolic pressure index in the left as well as the right foot after the pilgrimage (1.03±0.19 vs 1.11±0.19 and 1.03±0.28 vs 1.11±0.18, $P<0.05$)
Conclusion
The Pilgrimage increases the risk of developing foot injuries among diabetic patients. Therefore, an assessment and an adapted care to the grade of risk are essential before, during and after the pilgrimage.

Diabetic foot: An important, yet underestimated complication in albanian healthcare

Eni Celo[1], Sokol Hasho[2] & Florian Toti[3]
[1]Trauma University Hospital, Tirana, Albania; [2]Spitali Universitar 'Shefqet Ndroqi', Tiranë, Albania; [3]Mother Theresa University Hospital

Diabetic foot is a main complication of Diabetes Mellitus that affects 15–25% of diabetes patients at least once in their lifetime. This complication has severe consequences at patient's life quality and a high cost not only for the patient but also for the society. However, this complication is still underestimated in Albania.
Aim of study
Our main objective is to summarize the causes and pathogenic mechanisms leading to diabetic foot, and to focus on the management of this important health issue.
Materials and method
This is a prospective study with homogenous cohort. All DF patients presented at our clinic from April 2016 to December 2018.The patients were evaluated for the risk factors like neuropathy, peripheral arterial disease and also the different elements of diabetic foot management. There were studied 131 patients. The data was analysed according to IBM SPSS Statistics 23.
Results
Out of 131 patients enrolled (124 of them had Diabetes mellitus tip II, 7 had Diabetes mellitus tip I), aged from 41 to 91 with a mean age of 63.5. Mean diabetes duration was 12.3 years. 85% of the wounds were infected. We isolated a total of 32 strains. Among them 10 were the most alert pathogens identified (*Staphylococcus aureus, Pseudomonas aeruginosa, Escherichia coli, Enterococcus faecalis, Staphylococcus spp, Proteus vulgaris, Proteus mirabilis*, *Streptococcus b-haemoliticus, Klebsiella pneumoniae, Acinobacter baumanii*). The most sensitive antibiotic was Ceftriaxone and the most resistant was Ciprofloxacin. According the local surgical treatment minor amputations were present in 69 patients, debridement in 47 patients. Negative pressure wound therapy was used in 23 patients.
Conclusion
A multidisciplinary approach should be employed because of the multifaceted nature of foot ulcers and the numerous comorbidities that can occur in these patients.

Diabet foot unit of the marqués de valdecilla university hospital: A data-analytic look of a multidisciplinary team

Carlos Higinio Ortega Sánchez[1], María Isabel Álvarez Schettini[1], Nathalia Margarita Castillo Ledesma[2], Joan Manuel Mora Barrios[3], Enrique Pérez Álvarez[4] & Coral Montalbán Carrasco[1]
[1]Marqués de Valdecilla University Hospital, Endocrinology and Nutrition Department, Santander, Spain; [2]Marqués de Valdecilla University Hospital, ENT Department, Santander, Spain; [3]Marqués de Valdecilla University Hospital, Hematology Department, Santander, Spain; [4]Infanta Leonor University Hospital, Endocrinology and Nutrition Department, Madrid, Spain

Objective
We will analyze various characteristics of the patients who attend the HUMV Diabetic Foot Unit for a week. The variables studied are sex, age, type of diabetes, years of evolution, type of current treatment, last glycosylated hemoglobin, presence of other cardiovascular risk factors and existence of previous ulcerations and amputations
Material and methods
We worked with Microsoft Excel to coollect the data and perform the statistical study.
Results
We analyze 64 patients, with a mean age of 69.78±3.13 years with the following distribution by sex: 57.81% of men and 42,19% of women. Regarding the type of diabetes, we found 89.06% of type 2 diabetes and 10.94% of type 1 diabetes. We observed an average of 16.45±1.73 years of diabetes evolution with a last HbA1c mean of 7.73±0.36%. The treatment followed included insulin therapy in 70.31% of patients compared to an exclusively oral treatment in 29.69%. About the existence of other cardiovascular risk factors: arterial hypertension was present in 87.50%, dyslipidemia in 76.56% and patientes who had the three cardiovascular risk factors reached 70.31%. Regarding smoking, 14,06% of the patients declared active consumption, 34.38% reported being former smokers and 51.56% denied their use. There are other predisposing factors of diabetic foot, 35% of patients were diagnosed with peripheral arterial disease and 21.67% with diabetic neuropathy; both pathologies were in 10% of patients and only 33.33% had none of them. Focusing on the pathological history of history of his lower extremities, 62.50% had presented previous ulcerations, while for 37.50% of the patients it was their first diabetic ulcer. The incidence of amputations reached 34.38% representing 55% in patients with a previous history of ulcerations. Regarding the origin of the patients, 40.35% had been referred from Endocrinology and Nutrition Department, 21.05% from Primary Care, 8% from Cardiocascular Surgery Department and the remaining 14.04% came from other specialties.
Conclusions
We verify that patients treated in this unit have a very high cardiovascular risk, so it would be necessary to consolidate multidisciplinary teams of diabetic foot to work on the prevention of risk factors and treat concomitant pathologies that avoid the high number of amputations with important human, social, and economic consequences.

Lower urinary tract symptoms in patients with metabolic syndrome and life quality impact: Preliminary results

Mouna Sghir[1], Soumaya Elarem[1], Haj Salah Aymen[1], Ikram Haddada[1], Zantour Baha[2] & Kessomtini Wassia[1]
[1]Taher Sfar Hospital, Physical Medicine And Rehabilitation, Mahdia, Tunisia; [2]Taher Sfar Hospital, Endocrinology, Mahdia, Tunisia

Introduction
Recent epidemiological surveys have demonstrated a significant association between MS and lower urinary tract symptoms (LUTS). The aims of this study were to determine LUTS in patients with metabolic syndrome (MS) and to evaluate their impacts in patients' life quality.
Patients and methods
A cross-sectional study was conducted on patients with metabolic syndrome MS diagnosed according to the criteria of the US National Cholesterol Education Programme Adult Treatment PanelIII (NCEP ATP III). Clinical evaluation included body mass index (BMI) and waist circumference measurement. Biological data were also collected including fasting blood sugar, postprandial glycemia, glycosylated hemoglobin (HbA1c), cholesterol and triglyceride levels. Lower urinary tract symptoms were assessed using the urinary symptom profile (USP) questionnaire and the impact in life quality was evaluated using Ditrovie score.
Results
Forty patients were collected with a mean age of 60.2 years (±10.5) and a sex-ratio of 0.5. All patients were diabetic and 62.5% had hypertension. The mean BMI was 26.6±5.8 and waist circumference was 98.8±8.3 cm. Mean USP total score was 11.1±7.8. Overactive bladder symptoms were found in 60% of the patients, stress incontinence symptoms in 50% of the cases and dysuria in 22.5% of them. Mean Ditrovie score was 2.25. The USP total score wasn't correlated to age ($P=0.07$) nor to fasting blood sugar level ($P=0.89$) nor to HbA1C level ($P=0.29$). Ditrovie score was significantly correlated to the overactive bladder USP score ($P=0.014$).
Conclusion
LUTS are frequent in patients with MS including meanly Overactive bladder symptoms and stress incontinence symptoms. Their impact in life quality is correlated to overactive bladder symptoms.

Fungal necrotizing otitis externa in diabetic patients: Clinical features and diagnostic difficulties

Meherzi Abir[1,2], Amal Kdissa[1,1], Mouna Khalifa[1], Monia Ghamam[2], Mouna Bellakhdhar[1], Kermani Wassim[1] & Abdelkefi Mohamed[2]
[1]Sousse, ENT department Farhat Hached Hospital, Sousse, Tunisia; [2]Sousse, ENT, Sousse, Tunisia

Objectives
To describe and analysis theimpact of diabetes on clinical presentation andthe difficulties we could affront within the management of this entity.

Materials and methods
A retrospective study conducted between 2006 and 2019 based on 24 patients managed at our Otolaryngology Head and Neck Surgery Department.
Results
24 poorly controlled diabetic patients were enrolled in this study: 15 men and 9 women, with a mean age of 66 years. All patientspresented severe and persistent otalgia and otorrhea. External auditory canal narrowed:19 cases, granulation tissue 7 cases, polyp in 5 cases; facial nerve pulsy: 5 cases. Destruction of the bony meatus (79%), mastoid 25%; the obliteration of normal soft-tissue planes at the skull base 12,5%, the parapharyngeal extension 4% and the temporomandibular joint (4%) were documented by CT scans. Diagnosis was reviewed after a lack of response to antibiotic therapy it was established based on the Ear swabs for culture andhistopathologic. Aspergillus flavus (41%) and Candida (47%) were the fungal agents isolated. 2 patients were treated without identifying the causal fungus. Voriconazole was the first-line therapy, with a median length of treatment of 2 months. 2 patients underwent a mastoidectomy. The clinical outcome was favorable with 18 patients free of disease whose diabetes was controlled, otological sequelae were reported. 4 patients were not followed up.
Conclusion
It is a serious disease with high morbidity-mortality rate especially for poorly controlled diabetic patients. Underestimation of the entity may lead to a prolonged and ineffective treatment.

HNF1A MODY revealed by recurrent hypoglycemia

Rym Belaid, Ben Sebaa Rabah & Penfornis Alfred
Corbeil Essones Hospital, Diabetology, France

Introduction
Hepatocyte nuclear factor 1A MODY (HNF1A-MODY) is the most common form of Maturity-onset diabetes of the young (MODY) diagnosed in adults. It is caused by heterozygous mutations in the *HNF1A* gene and is associated with progressive β-cell failure and increasing hyperglycemia due to reduced insulin secretion. HNF1A-MODY is characterized by a large phenotypic variability. We herein report the case of a 40-year-old diabetic woman who was identified as having mutation of the HNF1A gene, after repeated hypoglycemia under insulin therapy.
Case report
A 40-year-old woman was admitted to our diabetology department for the management ofuncontrolled diabetes due to an abrupt withdrawal of insulin therapy. She had a family history of diabetes on oral antidiabetics in her mother and her two paternal aunts. Her diabetes was discovered at the age of 24 year old by an asymptomatic glycosuria. She was put at the age of 27 year-old, during her first pregnancy, under insulin therapy. After delivery, the patient reported recurrent hypoglycemia and an important weight gain despite lowering the dose of insulin. She had extremely poor glycemic control secondary to non-compliance with insulin and her glycated hemoglobin (HbA1c) ranged between 9% and 11.5%. Assays of antiglutamic acid decarboxylase (anti-GAD) and anti-islet antigen 2 (anti-IA2) antibodies were performed during hospitalization and were negative. A C-peptide testing, concomitant with normal glucose level, was normal (0.8 ng/ml). The molecular study identified a novel truncating mutation in the HNF1A gene (*P*.Gly292fs). The patient treated by a low dose of sulfonylureas (Gliclazide 30 mg) and an Inhibitors of dipeptidyl peptidase 4 (sitaglipitin 100 mg) with a good glycemic control and the absence of recurrent hypoglycemia.
Conclusion
Our case showed the interest of evoking the diagnosis of HNF1A diabetes in the presence of recurrent hypoglycemia under low dose of insulin in a diabetic person.

DOI: 10.1530/endoabs.70.AEP511

Development of diabetic complications in patients with type 2 diabetes mellitus and impaired circadian rhythms

Mayya Garieva & Anyuta Kosyan
Russian Medical Academy of Continuous Professional Education, Endocrinologies, Moscow, Russian Federation

The study involved 37 people with type 2 diabetes who received oral hypoglycemic medications, aged 35–65 years. The first group included 22 people with a daily work schedule, and the second group included 15 people with a night work schedule of more than 5 years as a model of patients with impaired circadian rhythm. Comparative analysis of descriptive data shows the predominance of creatinine levels ($P<0.05$) and, accordingly, a decrease in GFR (P 0.05) in the group of patients with night mode. Despite poor glycemic control, long duration of DM2, AH, and greater age in the group of patients working during the day ($P<0.05$), GFR values in both groups do not differ statistically, which indicates a decrease in the filtration capacity of the kidneys in both groups. The earlier decrease in the filtration capacity of the kidneys in group 2 can be explained by a higher level of glycemic variability, the value of which has a direct correlation with the level of creatinine ($r=0.656$; $P<0.05$) and the reverse – with GFR ($r=–0.657$; $P<0.05$). Despite the significant difference between patients 'age, diabetes experience, and carbohydrate metabolism, there was no statistically significant difference between TSS and NIS-LL in the groups. Correlation analysis showed that the severity of diabetic polyneuropathy in group 1 patients was negatively affected by weight gain, AH experience (TSS scores positively correlated with BMI ($r=0.564$; $P<0.05$) and AH experience ($r=0.472$; $P<0.05$)) and SD2 experience (NIS-LL has a positive correlation with SD2 experience ($r=0.459$; $P<0.05$) and AH experience ($r=0.312$; $P<0.05$)), and an increase in HDL leads to an improvement in the course of diabetic polyneuropathy. indicators of polyneuropathy (TSS and NIS-ll) are negatively correlated with the level of HDL ($R=–0.4$; $P<0.05$).Similar data were obtained in other studies. In group 2 patients, the severity of diabetic polyneuropathy, according to TSS scales, is negatively affected by an increase in LDL ($r=0.550$; $P<0.05$), cholesterol ($r=0.516$; $P<0.05$), and glycemic variability ($r=0.330$; $P<0.05$). The manifestation of diabetic polyneuropathy in group 2 of the same degree as in group 1 patients can be explained by the higher variability of glycemia in patients with night mode.

Anemia is associated risk factor of chronic kidney disease in diabetes type 2 patients

Volha Vasilkova[1], Tatsiana Mokhort[2], Ludmila Korotaeva[3], Oksana Shestovets[3], Yulia Yarets[3], Yana Borovets[1] & Irina Vasuhina[3]
[1]Gomel State Medical University, Endocrinology, Gomel, Belarus; [2]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [3]The Republican Research Centre for Radiation Medicine and Human Ecology, Laboratory, Gomel, Belarus

Introduction
Diabetes is the leading cause of chronic kidney disease (CKD) and is associated with excessive cardiovascular morbidity and mortality. On the other hand, anemia is common among those with diabetes and CKD and greatly contributes to patient outcomes.
Aim
The aim of this study was to investigate the prevalence and associated risk factors of CKD among the patients with diabetes type 2 (DT2).
Methods
We examined at baseline 300 patients with DT2 and CKD aged between 30 and 65 years. Control group included 100 patients without diabetes the same age. Blood samples for measurement of routine chemistry were taken after an overnight fast of at least 12 hours. The albumin and creatinine levels were measured for albuminuria and estimated glomerular filtration rate (eGFR) assessment. Anemia was defined as hemoglobin level <13 g/dl in men and <12 g/dl in women. Univariate and multivariate logistic regression analyses were conducted to identify factors associated with CKD.
Results
The total prevalence of anemia was higher in patients with DT2 in comparison to control (57.3% vs 28.6%, $P=0.003$). Prevalence was higher in diabetics with decreasing eGFR (P for trend 0.001). In multivariate analyses, anemia (OR = 8.167, 95% CI : 3.785–35.145), hyperuricemia (OR = 0.956, 95% CI : 0.918–0.975) and hyperhomocysteinemia ($R=1.856$, 95% CI : 1.718–1.975) were independently associated with the presence of CKD.
Conclusion
Prevalence of anemia progressively increases with advancing stages of CKD and is higher in patients with DT2 than matched non-diabetic patients. Thus, common chronic non-communicable diseases, including diabetes, anemia, hyperhomocysteinemia, hyperuricemia were associated with greater prevalence of CKD.

AEP514

Lipid metabolism in patients with diabetic nephropathy

Sitorakhon Muminova & Said Ismailov
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Introduction
Diabetes is the most common endocrine disease in the world. Persistent hyperlipidemia in type 2 diabetes is accompanied by damage to various organs, on the basis of which generalized changes in the microvasculature lie. In patients with diabetes mellitus with chronic kidney disease, dyslipidemia can be aggravated with hyperglycemia and insulin resistance. Control of dyslipidemia is an important therapeutic goal, since normalization of lipid metabolism and glycemic status reduces the risk of renal complications in type 2 diabetes. Aim of the work to study lipid metabolism in patients with type 2 diabetes mellitus with diabetic nephropathy.
Materials and methods
The study included 50 patients with type 2 diabetes. Group 1 of 25 patients with type 2 diabetes mellitus did not have a history of diabetic nephropathy; Group 2 of 25 patients had chronic kidney disease (CKD-C2, A2) with type 2 diabetes. The median age was 52.7±3.78 years: type 2 diabetes was 8 years: BMI-27.6: Hb1C-10.5%: Fasting glycemia – 8.8 mmol/l.
Results
Dyslipidemia was observed in 37% of type 2 diabetes without CKD and 78% of type 2 diabetes with CKD. Patients with atherogenic VLDL dyslipidemia, a high level of TG+VLDL was 25% among patients with type 2 diabetes and 71% among patients with type 2 diabetes with CKD. GFR in patients with type 2 diabetes was 89 ml/min, patients with type 2 diabetes with GFR 65 ml/min.
Conclusion
According to our results, we can conclude that lipid metabolism is significantly impaired among patients with diabetic nephropathy. Depending on the course of CKD, lipid metabolism is also exacerbated. Regular screening of diabetic nephropathy with dyslipidemia can be useful for controlling the risk of macrovascular complications.

Increased ultra sensitive CRP: Abiomarker of microvascular risk in men with type 2 diabetes

Olfa Lajili, Aroua Tmessk, Mariem Rayhane Soltane, Ben Ali Khaoula, Eya Safi, Mariem Madhbouh, Yosra Htira & Feika Ben Mami
National Nutrition Institute, Department C, Tunis, Tunisia

Introduction
RaisedCRP is observed in obesity, metabolic syndrome and type 2 diabetes in the absence of any inflammatory or infectious disease. Indeed, it may constitute a mark of cardiovascular risk and macro and micro-vascular complications. The objective of our study is to assess the association between raised ultra-sensitive CRP and macro-vascular and micro-vascular complications in a group ofpatients with type 2 diabetes (T2DM).
Materials and Methods
A comparative retrospective observational study including 176 patients with T2DM followed in department C of the NationalNutrition Institute of Tunis. Clinical and biological data were collected from medical records. Patients were classified into two groups according to the level of ultra-sensitive CRP (Group 1: low CRP < 3 mg/l and group 2: high CRP ≥ 3 mg/l).
Results
The mean age was 58.8±12 years. A female predominance was noted (62%). The mean duration of diabetes was 12±7.7 years. The average BMI was 28.9±5.4 kg/m^2. The average HBA1c was 10.5±2.3%. Half of the patients were on insulin (49.2%). The mean CRP was 5.1±4.3 mg/l with no significant difference between the two sexes. Two-thirds of women (71.6%) and 38% of men had high CRP (P=0.02). Patients with elevated CRP were on insulin and had higher BMI and uric acid levels (P=0.008, P=0.037 and P=0.04 respectively). Macro and micro-vascular complications were noted in 23.3% and 52.2%, 38.8% and 57.7%, 13.8% and 53.2%, in the whole population, in male patients and female patients respectively. Depending on gender, there was not a significant difference regarding macrovascular complications (coronary artery disease, stroke and peripheral artery disease) between patients with normal or elevated CRP. In contrast, in men the prevalence of micro-angiopathy, represented by diabetic nephropathy (27%) and diabetic retinopathy (47.5%), was higher in patients with elevated CRP (P=0.02).
Conclusion
Our study found that women with type 2 diabetes had higher CRP levels. In contrast, raised CRP was associated with a higher risk of microvascular complications, mainly diabetic retinopathy and nephropathy, in men with type 2 diabetes.

Evaluation of anxiety frequency in school-aged children with diabetes mellitus type 1 depending on carbohydrate metabolism compensation

Yana Navmenova, Elena Makhlina & Maria Rusalenko
SI «The Republican Research Center for Radiation Medicine and Human Ecology», Endocrinology, Gomel, Belarus

To study anxiety frequency in school-aged children with diabetes mellitus type 1 (DM type 1) depending on carbohydrate metabolism compensation.
Materials and methods
96 patients with DM type 1 aged 13.9±1.97 years. Diabetes duration is 1.72±22.33 Year. We determined glycated hemoglobin (HbA1). The level of HbA1 of 7.5% or more indicated the decompensation of carbohydrate metabolism. Evaluation of the anxiety level was carried out using the Spilberger-Hanin scale of self-assessment of anxiety with the determination of reactive (RA) and personal anxiety (PA). The patients were divided into 2 subgroups: group 1 with HbAl level of 7.5% and higher (n=35) and group 2 with HbAl level under 7.5% (n=61).
Results
In group 1, high PA was detected in 10 people (28.6%), and high RA in 13 people (37.14%). In group 2, high PA was detected in 11 people (18.0%), and high RA in 9 people (14.7%). The incidence of high PA in group 1 was significantly higher than in group 2 (χ^2=5.75, P±0.01). The frequency of RA in group 1 was also higher than in group 2 (χ^2=8.81, P=0.03). The risk of developing high PA significantly increased the growth of HbAl level (b=0.16) (Exp (b)=1.18; 95% CI–1.03±1.34; P<0.02).
Conclusion
The frequency of high anxiety occurrence, both personal and reactive, is significantly higher in patients with decompensation of carbohydrate metabolism. The risk of developing high personal anxiety increases with the progression of decompensation of carbohydrate metabolism.

Prevalence of peripheral and cardiac autonomic neuropathy in hypertensive pre-diabetic georgian patients by Sudoscan

Ana Kopaleishvili, Ramaz Kurashvili, Tinatin Akhobadze, Natalia Asatiani & Elena Shelestova
National Center for Diabetes Research
დიაბეტისკვლევისეროვნულიცენტრი, Endocrinology, T'bilisi, Georgia

Background
Sudomotor function is used to assessperipheral autonomic system. Electrochemical Skin Conductancemeasurement using electrochemical reaction betweenchloride ions in sweat and stainless steel plate electrodes is a simple, non-invasive and quick method. Several factors, including age, sex, BMI, glycemic status influence sweat function.
Aim
Our aim was to determineprevalence of peripheral (DPN) and cardiac autonomic neuropathy (CAN) in hypertensive pre-diabetic patients by Sudoscan.
Methods
Based on their glycemia status participants (n=70) were divided into 2 groups (Gr.):Gr.1– n=38, 20 men/18 women (mean age 63.2±4.3 yrs)

had impaired fasting glucose (IFG) or impaired glucose tolerance (IGT) or IFG+IGT and hypertension; Gr. 2–$n=32$, 18 men/14 women (mean age 62.8±3.6 yrs) had hypertension, but no IFG/IGT or IFG+IGT. Following tests/analysis were performed in all thd patients: Sudoscan test, HbA1c, oral glucose tolerance test (OGTT), BMI, LDL-C, TG, systolic and diastolic blood pressure (SBP, DBP). According to Sudoscan results neuropathy is defined as: 1) no neuropathy: >70 (feet)/>60 (hands); 2) moderate neuropathy: 50–70 feet/40–60 hands; 3) severe neuropathy <50 (feet)/<40 (hands). CAN was defined according to CAN risk score: <30–no risk of CAN; ≥30 – at risk of CAN. There was no significant difference in sex, age, SBP/DBP between the groups.
Results
Among Gr.1 patients with pre-diabetes and hypertension prevalence of moderate or severe neuropathy, both DPN and CAN, was more prevalent (no neuropathy – 4 patients/10%; moderate neuropathy – 20 patients/52%; severe neuropathy – 14 patients/36%; CAN–<30–29 patients/76%; ≥30–9 patients/23%), than in Gr. 2 ones without IFG or IGT, or IFG+IGT (no neuropathy – 16 patients/50%, moderate – 12 patients/37.5%, severe-4 patients/12.5%; CAN <30–4 patients/12%; ≥30–28 patients/87%). HbA1c (%) and OGTT were higher in Gr.1, than in Gr.2 patients (5.9±0.3 vs 4.1±0.5, $P=0.005$). There was no statistically significant difference in LDL-C/mmol/l (2.32±0.9 vs2.14±0.4, $P=0.85$) and TG/mmol/l (2.02±1.2 vs 1.9±0.9, $P=0.93$) levels between the groups, while BMI(kg/m^2) was higher in Gr.1 compared to Gr.2 (33.7±2.3 vs 27.2±1.2, $P=0.01$).
Conclusion
The overall prevalence of DPN and CAN was higher in hypertensive patients with pre-diabetes than in those without pre-diabetes. Thus, Sudoscan is an easy, non-invasive and quick method to detect DPN or CAN in an early stage. Though further studies are necessary to approve Sudoscan advantage over other well-known diagnostic methods.

Hyperuricemia as independent cardiovascular risk factors in T2D

Ergita Nelaj, Margarita Gjata, Irida Kecaj, Ilir Gjermeni & Mihal Tase
UHC 'Mother Teresa', Internal Medicine, Tirane, Albania

Background
Uric acid is an inflammatory factor and may have a role in endothelial dysfunction and act as a mediator of diabetic nephropathy. Hyperuricemia is a risk factor for cardiovascular events and renal insufficiency in diabetic patients. The aim of this study was to evaluate the relationships between serum uric acid concentration and level of urinary albumin excretion as well as markers of subclinical atherosclerosis in patients with type 2 diabetes mellitus.
Materials and methods
A cross-sectional analytical study was conducted in 120 patients with T2D without a history of gout. Serum uric acid and urinary albumin-creatinine ratio were determined. The relationships between serum uric acid concentration and carotid intima-media thickness or plaque score were investigated additionally in these patients. Other metabolic parameters including lipid profile, hemoglobin A1c, glomerular filtration rate, body mass index, blood pressure, blood glucose.
Results
The mean age of the patients was 58.45±10.11 years old. Serum uric acid levels for normoalbuminuric, microalbuminuric, and macroalbuminuric patients were 4.44±1.17 mg/dl, 4.97±1.68 mg/dl, and 7.27±1.08 mg/dl, respectively. Serum uric acid level correlated positively with urinary albumin-creatinine ratio ($P=0.04$). Positive correlation was found between serum uric acid concentration and intima-media thickness ($r=0.233$, $P=.0087$).There was a significant relationship between hyperuricemia and serum triglyceride, fasting blood glucose, hemoglobin A1c, glomerular filtration rate, and serum creatinine levels ($P<0.001$).
Conclusions
Serum uric acid concentration is associated with microalbuminuria and subclinical atherosclerosis in patients with type 2 diabetes mellitus. So, we conclude that serum uric acid plays a role in diabetic nephropathy as well as in cardiovascular eventsin T2D.
Keywords: diabetes, uric acid, proteinuria, atherosclerosis.

Neurological disorder in a patient with decompensated T2DM

Paula Maria Fernandez-Trujillo-Comenge, Alba Hernández Lázaro, Agnieszka Kuzior, Manuel Esteban Nivelo-Rivadeneira, Ana Delia Santana-Suarez & Francisco Javier Martinez-Martin
University Hospital of Gran Canaria Dr. Negrin, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain

Introduction/aim
Neurological symptoms are rarely related to decompensated type 2 diabetes mellitus. However, thanks to complementary tests, we can identify this association more easily.
Material and method
Review of the patient's clinical record and the relevant literature.
Results
A 76-year old man complained in the last year of a progressive, involuntary and disabling movement disorder consisting in hemichorea of the left upper and lower limbs. He presented psychotic thoughts, cognitive impairment, as well as moderate weight loss. He had a clinical history for more than 10 years of a poorly controlled type 2 diabetes mellitus (haemoglobin A1c 14.4%) treated only with 20 units of glargine insulin daily, moreover with irregular adherence. No diabetic complications had been described. He also suffered from dyslipidaemia without pharmacological treatment, anxiety and depressive disorder, subclinical hypothyroidism, a lack of self-care, and a smoking habit. His medication included omeprazole 20 mg per day and atenolol 50 mg per day. In the lab test there was nothing remarkable, apart from high glucose levels (around 200–300 mg/dl), and low total plasmatic protein concentration (5.67 g/dl). Tests for HIV and drugs were negative. An MRI of the brain showed high signal intensity of right-basal ganglia on T1-weighted images, in particular on putamen, which could be associated with a case of non-ketotic hyperglycemia-induced hemichorea. Once the right treatment for his diabetes was established (20 UI glargine insulin, plus 12 units in total of insulin aspart daily) and his capillary glucose levels were in range, the choreiform movements gradually improved until they were completely absent.
Conclusions
When considering neurological disorders, we rarely associate those with diabetes mellitus; however, sometimes we must think out of the box to reach the correct diagnosis. Although there haven't been many confirmed cases until now, we should include non-ketotic hyperglycemia in the differential diagnosis of acute movement disorders such as chorea.

Short and long-term glycemic variability associated with severe hypoglycemia and retinopathy in type 1 diabetes mellitus

Borja Sanz Martín, Sergio Roman Gimeno, Carlos Miguel Peteiro Miranda, Jose Jorge Ortez Toro, Ana Agudo, Rosana Urdaniz & José Antonio Gimeno Orna
Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain

Introduction
Severe hypoglycemia and retinopathy are two of the main complications of diabetes mellitus (DM). Traditionally, glycosylated hemoglobin (or A1C) has been used as the gold standard measurement of glycemic control; however, there is a significant percentage of complications riskassociated with the evolution of diabetes that is not fully explained by this single marker. Short and long-term glycemic variability has been postulated as one of the main variables that contribute to increase that risk.
Objectives
To determine if there is an association between any parameter of measurement of short and/or long-term glycemic variability with the risk of developing severe hypoglycemia and retinopathy.
Material and methods
A case-control study was performed, with descriptive and analytical aspects on 103 type 1 DM patients controlled by self-monitoring of capillary blood glucoseusing glucometers with bolus calculator. Patients are being treated in the Hospital Clínico Lozano Blesa's Endocrinology and Nutrition Department. Glycemic variability data has been collected from the download of glucometers and from the A1C values obtained in successive blood tests. Statistical analysis was performed with Mann-Whitney U test, χ^2 test and

Fisher's exact test. The statistical significance has been accepted for values of $P<0.05$.
Results
A lower mean BMI (22.25 vs 25.90 kg/m^2, P 0.016) and a higher standard deviation of blood glucose mean (81.3 vs 68.6 mg/dl; P 0.003) were observed among patients with severe hypoglycemia, and there were more episodes of severe hypoglycemia in those patients with an unfavorable Clarke test (4 vs 0; P 0.035). On the other hand, the average patients' age (47.89 vs 37.43 years; P 0.001) and the time of evolution of diabetes (36.64 vs 15.42 years; $P<0.001$) were higher among those patients with retinopathy, but not the age of onset of DM (11.26 vs 22.19; P 0.001) nor the C-peptide value (0.052 vs 0.251 ng/ml; $P<0.001$).
Conclusions
Severe hypoglycemia is more frequent among patients with greater short-term glycemic variability (defined as the standard deviation of mean glycemia) while no association has been observed with any measure of long-term variability. In opposition, retinopathy has not shown an association with any parameter of glycemic variability.

Baseline characteristics of a cohort of type 1 diabetes patients on continuous subcutaneous insulin infusion therapy. Evaluation of glycemic variability parameters and complications.

Edurne Lecumberri Pascual, Nuria Bengoa Rojano, Maria Fernandez Argüeso & Maria Lia Nattero Chavez
Hospital Ramón y Cajal, Endocrinology, Diabetes and Nutrition, Madrid, Spain

Introduction
Glycemic variability (GV) has been associated, regardless to A1C levels, to chronic complications of diabetes mellitus (DM).
Objective
To describe baseline characteristics, GV parameters, and microvascular complications rates in a selected simple of type 1 diabetes patients (T1DM) on continuous subcutaneous insulin infusion (CSII).
Methods
We performed a retrospective observational study with 130 T1DM patientson (CSII). Time in range (TIR) was defined as the % of time of glucose levels between 70–180 mg/dl. Low glycemic variability was defined if the coefficient of variation (CV) was lower than 36%. Data of the three previous months from the insulin pump were downloaded and analyzed.
Results
The mean age was 37±13 years-old. 51.5% were female and 19.3% of smokers. Mean BMI was 24.8±4.0 kg/m^2. Duration of T1DM was 21±10 years. Mean duration of CSII therapy was 6.3±5.4 years. The mean HbA_{1c} was 7.1±0.8% and the mean HbA_{1c} before CSII was 7.4±1.0%. 33.8% of patients were on statins, with a mean LDL-c of 100±26 mg/dl. The prevalence of diabetic retinopathy (DR) was 20.8% (95% CI : 14.7–28.5), of whom 19.2% had non-proliferative retinopathy and 1.5% had proliferative retinopathy. The prevalence of diabetic nephropathy (DN) was 10% (95% CI : 5.9–16.36), of whom 77% had microalbuminuria and 23% macroalbuminuria. 24.6% (95% CI : 18.0–32.7) presented cardioautonomic dysfunction. Regarding GV: mean TIR was 60±14%, mean time in hyperglycemia-TIH (>180 mg/dl) was 32±14%, and mean time in hypoglycemia-TIh (<70 mg/dl) was 8±7%. After applying the stepwise logistic regression model ($P<0.001$, $R^2=0.561$), we observed that the association factors for developing DR were LDL-c, ExpB 0.973 (95% CI 0.948–0.999); duration of DM, ExpB 1.256 (95% CI 1.123–1.405); and HbA_{1c} before CSII, ExpB 2.243 (95% CI 1.168–4.309). The association factors for DN ($P<0,001$ y $R^2=0.234$) were LDL-c ExpB 0.96 (95% IC 0.94–0.99) y DBP ExpB 1.11 (95% IC 1.03–1.19), and finally, the only factor for CAN was age (ExpB 1.1 95% CI 1.04–1.15). 13.84% of patients got the combined objective of $HbA_{1c}\leq7\%$, TIR ≥70% and TIh ≤10%. 54% of patients had $HbA_{1C}\leq7\%$ and CV ≤36% altogether.
Conclusion
Around half of our patients were on quite good control according to GV parameters, and had less DR and DN comparing to the T1DM general population on multiple injections insulin therapy, despite the long duration of the disease.

The role of tau-protein in the diagnosis of cognitive impairment in diabetes

Mariia Matveeva[1], Julia Samoilova[1] & Natalie Zhukova[2]
[1]Siberian State Medical University, Endocrinology and diabetology, Tomsk, Russian Federation; [2]Siberian State Medical University, Neurology and neurosurgery, Tomsk, Russian Federation

Diabetes mellitus (DM) is a metabolic disease, which is accompanied by systemic damage to organs, including the central nervous system. Clinically, these changes are associated with cognitive impairment, the pathogenesis of which is also largely heterogeneous.
Objective
To evaluate the role of tau-protein in the diagnosis of cognitive impairment in patients with type 1 and type 2 diabetes.
Materials and methods
The study was tested in the ethics committee, all patients signed an informed consent. Research design – observational, transverse, one-stage. The study included 126 patients with type 1 diabetes, the average age of which was 29.1±8.5 years and a control group of 25 people were comparable by sex and age. In addition, 204 patients with type 2 diabetes at the age of 60.8=11.9 years were examined, the control group consisted of 20 people comparable by sex and age. Patients were evaluated for blood glucose, hemoglobin A1c (HbA1c), and the level of tau-protein. Cognitive function was tested using the Montreal Cognitive Impairment Scale (MoCA). To assess glucose variability, we continuously monitored glycemia with an estimate of the coefficients.
Results of the study
Patients with type 1 and type 2 diabetes had cognitive impairment of 22.3 (20–25) and 21.3 (19–24) points according to the MoCA test).The clinical spectrum of disorders varied depending on the type of diabetes. When assessing the level of tau-protein, a significant increase in its content was recorded among patients with type 1 and type 2 diabetes ($P=0.001$, $U=113.0$; 0.001; $U=11.0$). Correlation analysis showed a positive relationship between tau-protein and fasting glycemia, glycated hemoglobin and the MoCA test; in addition, in the type 2 diabetes group, a correlation of tau-protein level with the presence of cognitive impairment and the age of patients was found. Significant associations of the coefficients of variability and communication with tau protein were detected only in the group with type 1 diabetes.
Conclusion
Cognitive impairment in diabetic patients is associated with taupathy and chronic hyperglycemia.

Diabetic muscle infarction: A life changing diagnosis with poor long term prognosis

Pramod Manjunath[1], Rana Siddique[1], Vivek Rajagopal[1] & Rahat Tauni[2]
[1]West Suffolk Hospital, United Kingdom; [2]West Suffolk Hospital, Diabetes & Endocrinology, Bury Street Edmunds, United Kingdom

A 64 year old Caucasian man with long standing type 1 diabetes and complications of retinopathy, neuropathy and nephropathy was referred with suspected deep venous thrombosis (DVT) in the left lower limb. He had a week's history of worsening pain and swelling in the medial left thigh and struggled to weight bear on that leg. He felt unwell a day before admission and was found to have hyperosmolar hyperglycaemic state with ketosis on admission. Ultrasound Doppler was negative for deep venous thrombosis. T2-weighted magnetic resonance imaging (MRI) with gadolinium contrast demonstrated hyper-intense signal in the adductor compartment of the left thigh muscles. He was diagnosed to have diabetic muscle infarction and was managed with analgesia, bed rest, slow intravenous fluids, aspirin and statin. Rigorous glycaemic control was achieved with intravenous insulin. His pain and swelling improved in two weeks and he was discharged home.
Diabetic muscle infarction, also known as diabetic myonecrosis, is a serious but under-diagnosed complication of long standing diabetes. Although most patients recover from the acute episode with conservative management, the recurrence rate is high. Most patients have diabetes related microvascular complications and there is a high rate of mortality and morbidity due to microvascular and macrovascular disease. Timely diagnosis

and early involvement of the diabetes team can avoid unnecessary invasive investigations in many cases thereby improving outcomes and shortening hospital stay.

The connection between dopamine activated AVP release regulation and sugar substitutes

Krisztian Sepp[1], Péter Hausinger[2], Zsolt Molnár[3], Marianna Radács[3], Anna László[4], Andrea Serester[3], Márta László[3], Andrea Csikós[3], Zsuzsanna Valkusz[1] & Márta Gálfi[3]
[1]Endocrine Unit of First Department of Internal Medicine, Faculty of Medicine, University of Szeged, Hungary, Szeged, Hungary; [2]Invasive Cardiology Department, Second Department of Internal Medicine and Cardiology, Faculty of Medicine, University of Szeged, Szeged, Hungary, Szeged, Hungary; [3]Institute of Applied Natural Science, Juhász Gyula Faculty of Education, University of Szeged, Hungary, Szeged, Hungary; [4]Department of Biometrics and Agricultural Informatics, Faculty of Horticultural Science, Szent István University, Budapest, Hungary, Budapest, Hungary

The human homeostasis is determined by psycho-neuro-endocrine-immuno processes. This biological balance-system depends on their communication of direct environment (eg. nutrition, respiration, etc. as in the metabolism). The basic of human communication-way with environment are defined by nutrition. This contains various agents: eg. proteins, lipids, sugars, vitamins, ions, etc. When the elements of nutrition is substituted, the markers of homeostatic processes and regulations are needed to follow. In this work our aim was to investigate the AVP mediated neuroendocrine regulation, by sugar (erythritol, saccharin, xylitol, stevia) substitutes. In the experiment Wistar ♂ rats were treated with erythritol*in vivo*: 0.05 g/500 cm^3, saccharin: 2.5 g/500 cm^3, xylitol: 0.05 g/500 cm^3 and stevia: 0.05 g/500 cm^3 for 16 weeks (n=5/groups). After treating, neurohypophysis were prepared from the Wistar rats for *in vitro* primer, monolayer cell culture model (NH). The tissues were digested enzymatically (trypsin: 0.2%/Sigma, Germany/ for 30 min; collagenase/Sigma, Germany/: 30 µg/cm^3 for 40 min; dispase/ Sigma, Germany/: 50 µg/cm^3 for 40 min in phosphate-buffered saline; temperature: 37°C). Mechanical dissociation was achieved with nylon blutex sieves (∅: 83 and 48 µm). Cultures were controlled for viability (>95%) by trypan blue tests,after than for function for AVP release (in aspecific and specific regulation). In the research protocol investigation was in NH models: untreated as control, treated with 10^{-6} M of dopamine (DA) and/ or sulpiridine, and then exposed to erythritol, saccharin, xylitol and stevia, during 120 min. The AVP releases of NH model were measured by radioimmunoassay. The protein content was detected by modified Lowry method. The data were analysed by ANOVA statistical program (n=6). Our results showed mild modified AVP release activity by different treatments of sugar substitutes. However the AVP release showed expressed changes in the neuroendocrine regulation, when the *in vivo* sugar supplementation was combined by *in vitro* DA stimulation. The DA receptor (R_{DA}) functions were tested by sulpiridine. Our experiments showed that the mechanisms of DA regulated AVP release were supervised by $R2_{DA}$. These processes were modulated by erythritol, saccharin, xylitol, stevia. This works was supported by EFOP-3.6.1-16-2016-00008 and EFOP-3.4.3-16-2016-00014, TAMOP-4.2.4.A/2-11/1-2012-0001.

Hyponatraemia in hospital care

Oisín Ó Murchú[1] & Maeve Durkan[2]
[1]University College Cork, Medicine, Cork, Ireland; [2]Bons Secours Hospital Group, Endocrinology, Cork, Ireland

Introduction
Hyponatraemia (serum sodium <136 mmol/l) is associated with significant morbidity and mortality. International guidelines suggest a clear algorithm for investigation, inclusive of measurements of paired urine sodium and osmolality, thyroid function tests and a morning cortisol. The aim of this study was to prospectively investigate the assessment, management and clinical outcomes associated with hyponatraemia on hospital admission.
Methods
This prospective study was conducted from 03/09/2018-03/10/2018, and follow-up data was collected six months thereafter. Information was garnered on hyponatraemic admissions through a combined review of patient charts and the hospital's laboratory database.
Results
Of the 418 patients admitted, 75 (18%, 35 male, 40 female) had hyponatraemia, with a mean age of 74 years (S.D.=14). Eleven were excluded on the basis of a recent surgical or oncological admission. 63 (84%) had mild (130–135 mmol/l), 9 (12%) had moderate (125–129 mmol/l) and 3 (4%) had severe (<125 mmol/l) hyponatraemia. Only 4 (5%) patients had measurements of paired serum and urine osmolality and sodium, 19 (25%) of thyroid function, and 1 (1%) of morning cortisol. Only 9 (12%) were assessed by a consultant endocrinologist. 47 (63%) were taking a culprit medication (ACE inhibitor, ARB, diuretic, SSRI, SNRI, tricyclic antidepressant) on admission, 15 (32%) of which were ceased. The mean length of hospital stay was 7 days for mild, 9 days for moderate and 16 days for severe cases, and there were 2 in-hospital mortalities. Of the 73 surviving patients, 23 (31%) did not have a sodium measurement performed at discharge, and 27 (37%) were discharged with persistent hyponatraemia. Over a 6 month follow-up period, 26/73 (36%) of hyponatraemic cases were readmitted, compared with 100/332 (30%) of normonatraemic patients. Over the same period, hyponatraemic admissions had a mortality rate of 16% (12/73), while normonatraemic admissions had a rate of 4% (13/332). The difference in proportions is significant, $\chi^2(1, N=405)=16.2$, $P<0.001$.
Conclusions
Hyponatraemia was a highly prevalent condition on admission which was largely under investigated; laboratory tests recommended by current expert guidelines were underutilised, and specialist advice was rarely sought. Management was also suboptimal; significant proportions were discharged without measurement or correction of serum sodium concentrations. Hyponatraemia was ultimately associated with a 4.5-fold excess in mortality at six months post-discharge. These findings emphasise the need for the development of Irish guidelines and the introduction of electronic alert systems to improve hospital practice.

Triglyceride and glucose (TyG) index is an effective biomarker to identify severe acute pancreatitis

Kyongjoo Lee
Yonsei University Wonju College of Medicine, Department of Internal Medicine, Korea, Republic of South

Background
To predict severe acute pancreatitis (AP) at early stage is important to reduce morbidity and mortality. We aimed to investigate the association between the triglyceride and glucose index (TyG index) and the prognosis of acute pancreatitis.
Methods
The TyG index was calculated as the ln[fasting triglycerides (mg/dl) × fasting plasma glucose (mg/dl)]/2. Patients were then categorized into low TyG index group (<5) and high TyG index group (≥5). Multivariable logistic regression analysis was used to investigate the independent association between TyG index and the severity of AP.
Results
A total of 313 patients with AP were recruited in this study. The proportion of patients with severe AP and the percentage of intensive care unit admissions and mortality were higher in patients with high TyG index than in those with low TyG index. The hospital stay was longer in patients with high TyG index (7.9 vs 6.0 days, P=0.019) and the area under the curve of TyG index for predicting severe AP was 0.731 (95% CI 0.64–0.82, $P<0.001$). TyG index was the significant independent factor for severe AP (OR 2.59, 95% CI 1.27–5.30, P=0.009) and intensive care unit (OR 7.34, 95% CI 2.89–18.65, $P<0.001$). (Table 1)

Table 1 The association between TyG index and severe acute pancreatitis.

	OR	*P* value*	OR	95% CI	*P* value#
Gender (Male)	0.623	0.282	0.658	0.227–1.907	0.658
Age	0.995	0.664	1.007	0.976–1.039	0.667
Gallstone	0.408	0.072			
Alcohol	2.056	0.113	2.212	0.757–6.464	0.147
Smoking	1.375	0.463			
Hypertension	1.205	0.670			
Diabetes mellitus	0.926	0.877			
Body mass index	1.048	0.286			
C-reactive protein	1.036	0.154			
Procalcitonin	1.014	0.013	1.015	1.002–1.027	0.019
TyG index	2.436	0.002	2.593	1.268–5.304	0.009

* Univariate analysis was done.
# Multivariate analysis was done.
OR, odds ratio; CI, confidence interval; TyG index, triglyceride and glucose index.

Conclusion
Our findings suggest that the TyG index is an independent prognostic factor in patients with AP and may be suitable as a simple prognostic indicator for severe AP.

Hormonal function of muscles in acromegaly in relation to metabolic disorders

Łukasz Mizera[1], Jędrzej Grzegrzółka[2], Jowita Halupczok-Żyła[1], Diana Jędrzejuk[1], Katarzyna Kolackov[1], Marek Bolanowski[1] & Jacek Daroszewski[1]
[1]Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland; [2]Wroclaw Medical University, Division of Histology and Embryology, Department of Human Morphology and Embryology, Wroclaw, Poland

Skeletal muscle constitutes the largest endocrine organ in human body through capability of secreting myokines, which biological activity plays a key role in energy homeostasis. Among the myokines irisin (Ir) is of particular interest, considering it's broad spectrum of protective influence on obesity and metabolic diseases development, determining therapeutical potential of this molecule. Latest studies indicate close interrelations between Ir and myostatin (Mstn), myokine that plays a principal role in muscle mass regulation. Acromegaly is a rare disease characterised by uncontrolled GH overexpression, what makes it an attractive, naturally occurring, research model for the studies of GH action. In this work GH relations with Ir and Mstn circulating levels were evaluated. The studied population consisted of 43 acromegalic patients and 39 healthy controls. Ir, Mstn, GH and IGF-1 serum concentrations were measured. Body composition was determined using dual-energy X-ray absorptiometry (DXA). Following glucose and lipid homeostasis parameters were evaluated: fasting glucose and insulin, HOMA-IR, HOMA-β, total cholesterol, LDL cholesterol, HDL cholesterol, triglicerides, atherogenic factors (Castelli I, Castelli II, AC, AIP, TG/HDL). The study group was divided into subgroups based on disease activity as well as lipid and glucose metabolism abnormalities. The results revealed decrease in Ir serum concertation in acromegaly ($P=0.02$ vs controls) What's more, Ir levels were negatively correlated with HOMA-IR ($r=-0.51$, $P=0,01$), fasting insulin ($r=-0.43$, $P=0.01$), were relatively lower in acromegalic patients with insulin resistance (IR+) ($P=0.04$ vs IR^-) and negatively correlated with atherogenic factors. GH was negatively correlated with Mstn. Our findings indicate impaired endocrine function of skeletal muscle in the stetting of chronic GH overexpression, possible role of Ir alterations in the development of glucose abnormalities as well as relation with cardiovalcular risk in acromegaly. Additionally the role of GH in a regulation of Mstn was revealed.

Sarcopenia can predict response to therapy in NSCLC patients treated with PD-1 inhibitors: A longitudinal prospective study.

Marta Tenuta[1], Emilia Sbardella[1], Carla Pandozzi[1], Alain J. Gelibter[2], Grazia Sirgiovanni[2], Elisa Giannetta[1], Carlotta Pozza[1], Andrea Lenzi[1] & Andrea Isidori[1]
[1]Viale Regina Elena, 324, Experimental Medicine, Roma, Italy; [2]Viale Regina Elena, 324, Oncology B, Roma, Italy

Introduction
Immune checkpoint inhibitors (ICI) show promising efficacy in the treatment of a wide range of advanced cancers, butlong-term response is currently limited to a subset of patients. Sarcopenia is a condition characterized by loss of skeletal muscle mass and decreased muscle function which occurs in approximately 50% of advanced cancer patients,related to malnutrition, inflammation, and treatments.
Objective
The aim of this prospective observational study was to investigate the relationship between sarcopenia (evaluated using DXA scan) and PD-1 inhibitors outcomes, in terms of OS and PFS, in patients with advanced NSCLC.
Materials and methods
41 stage IV NSCLC patients about to start anti PD-1, were enrolled from the Policlinico Umberto I outpatient Oncology (May 2017-September 2019). Routine blood test, endocrine, inflammatory and body composition evaluation with dual-energy X-ray absorptiometry (DXA) were performed at baseline. aLM cut-offs to define sarcopenia were ≤7.23 kg/m^2 in men and ≤5.67 kg/m^2 in women. Patients were divided into two groups based on best responseusing RECIST criteria 1.1:clinical benefit(CB)group (including complete, partial response or stable disease), and progression disease (PD) group. The statistical analysis was carried out with non-parametric tests and results are reported as medianand interquartile range. Ethics Committee approval number 4946.
Results
Overall 17/41 patients (41.5%) resulted sarcopenic based on aLMscore. Specifically, a significant higher number of patients had sarcopenia in the PD group compared to CB. Nogender difference was found regarding prevalence of sarcopenia ($P=0.732$). aLM waslower in PD vs CBgroup: PD=6.11 kg/m^2 (3.8;6.4) vs CB=7.6 kg/m^2 (5.7;7.9), $P=0.046$. As a matter of fact, lean mass was lower in PD vs CB: PD=36.3 kg (13.05;40.92) vs CB=51.80 kg (39.45;52.93), $P=0.042$. Patients with sarcopenia showed significantly worse PFS (4.9 months, 95% CI : 0.0–14.1, $P=0.03$) and worse OS (10.9 months, 95% CI : 2.6–19.2, $P=0.024$) compared to subjects without sarcopenia. In addition, considering inflammatory biomarkers, patients with sarcopenia showed higher NLR ratio ($P=0.005$), higher LLR ratio ($P=0.005$), higher CRP ($P=0.021$) compared to sarcopenic patients.
Conclusions
Subjects with sarcopenia showed worse PFS and OS compared to subjects without sarcopenia. This supports the idea that sarcopenia can reflect the increased metabolic activity of more aggressive tumors, which involves systemic inflammation and muscle wasting. Furthermore, sarcopenic patients showed higher levels of inflammatory biomarkers compared to non-sarcopenic patients. Assessment ofsarcopenia may help identify patients more likely to achieve a better response to anti PD-1 in routine clinical practice.

Gliomas are a common tumor type that affects the glial cells with common features of malignant tumors such as aggressive invasiveness, malignant transformation and vascular proliferation through the central nervous system. Currently, standard therapeutic strategies to treat malignant gliomas are not efficient having alow-rate survival (~12 months). Hence, there is a clear necessity for the identification of novel diagnostic/prognostic tools and therapeutic strategies to manage and treat these devastatingtumor pathologies. In this sense, a relevant relationship between metabolic/endocrine factors and tumor development/progression has been widely reported since defects in endocrine and metabolic homeostasis underlie many common human diseases, including tumor progression. In this context, we carried out an interaction omics-based approach to identify potential endocrine/metabolic biomarkers with diagnostic, prognostic and/or therapeutic potential in low- and high-grade gliomas. For that purpose, we analyzed the correlation among radiological data, IDH1/2 mutations, gene expression profiling of multiple endocrine/metabolic elements in 25 tumor biopsies samples from patients (Age 48±10-years/72%-men) clinically diagnosed with glioma (WHO2016). Initially, we used high resolution ^{31}P and ^{1}H magnetic resonance spectroscopy (MRS) in order to obtainthe quantification of 19 metabolites with a LCModel, while gene expression profiling was performed using qPCR of 19 genes related to energy metabolism. Moreover, IDH1/2 common mutation (IDH1R132H/IDH2R172H) was verified by immunohistochemistry and Sanger sequencing. Sequentially, all data was integrated using the mixOmics (R-package) allowing to build correlation network plot graphs and correlation maps to identify the most significant interactions, that were analyzed thereafter. Our results shown that the most frequent clinical features were intracranial hypertension and focal deficit. Remarkably, we found no differences between the metabolic or gene expression profiles in grade III vs IV glioma samples. However, there was a statistical significance or near-threshold correlation between some endocrine/metabolic patterns and IDH-mutation, where Alanine (4.7±1.3% IDHw vs 2.5±0.7 IDHmut), Glycine (2.7±0.5% vs 1.6±0.4%), Glycerophosphorylcholine (3.9±0.4% vs 6.4±0.9%) and Myo-inositol (4.9±1.0% vs 11.9±2.1%) were the most important biomarkers. Over expression of Lactate Dehydrogenase subunit-B (LDHB, 19±3% vs 31±6%) and Aconitase-1 (ACO1, 0.5±0.1% vs 1.2±0.3%) had also a significant or near-threshold relationship with IDH-mutation. Altogether, these results indicate that the endocrine-metabolic interaction patterns analyzed by this novel interactomic approach could be a useful tool to improve our knowledge of glioma behavior as well as being a potential source to identify novel biomarkers and therapeutic targets in order to tackle this pathology.

Reversal effect of Vitamin D (VitD) on exosome-mediated everolimus resistance (EveR) in hepatocellular carcinoma (HCC) cell line: A molecular study

Annalisa Gentile, Mariarosaria Negri, Tatiana Montò, Roberta Patalano, Cristina de Angelis, Chiara Simeoli, Rosario Ferrigno, Maria Cristina De Martino, Renata Simona Auriemma, Annamaria Colao, Rosario Pivonello & Claudia Pivonello
Federico II University, Clinical Medicine and Surgery, Naples, Italy

Cancer exosomes emerged as important mediators of cancer drug resistance. Drug exposure-mediated EveR in HCC cell lines can be reversed by VitD pre- and co-treatment. The current study aimed to investigate whether cancer exosomes from EveR HCC cell line are able to induce EveR in parental cells and whether VitD may activate reversal effect on exosome-mediated EveR. To this purpose, parental JHH-6 and EveR JHH-6 cell line were used. The uptakeof exosomes, staining with membrane dye PKH67, has been evaluated using immunofluorescence (IF). Recipient parental JHH-6 cells were treated for 16 days with exosomes from EveR cells (Exo EveR parental JHH-6) and cell proliferation was evaluated by DNA assay in parental, EveR and Exo EveR parental JHH-6 cells after treatment with everolimus (EVE) at escalating doses (from 10^{-11}M to 10^{-7}M) for 6 days, with and without VitD 10^{-7}M at lowest EVE concentrations used to better visualized the drug effect. Intracellular c-MYC and YAP-1 protein regulation was investigated by western blot (WB) after 6 days of VitD treatment in parental JHH-6, EveR JHH-6 and Exo EveR Parental JHH-6. JHH-6 parental cells were able to uptake exosomes from EveR JHH-6 cells within 18 hrs as shown by IF. Exosome's uptake conferred EveR to parental JHH-6 cells. This effect was visible in particular at lowest EVE concentrations. Treatment with EVE 10^{-10}M induced 19.76% of inhibition ($P=0.05$ vs control) in parental JHH-6 but no significant inhibition in EveR JHH-6 and Exo EveR parental JHH-6; EVE 10^{-9}M induced 56.53% ($P=0.0001$ vs control) in parental JHH-6, 26.11% of inhibition ($P=0.05$ vs control; $p=0.05$ vs EVE 10^{-9}M in parental JHH-6) in Exo EveR parental JHH-6 but not in EveR JHH-6. VitD alone induced 50.19% of inhibition ($P=0.0001$ vs control) in parental JHH-6 but no significant inhibition in EveR JHH-6 and Exo EveR parental JHH-6, while co-treatment of VitD with EVE 10^{-11}M and 10^{-10}M induced 54.78%, 56.09% and 29.61% of inhibition ($P=0.0001$ and $P=0.01$ vs EVE 10^{-11}M alone) and 28.06%, 25.37% and 38.60% of inhibition ($P=0.01$, $P=0.05$ and $P=0.0001$ vs EVE 10^{-10}M alone)in parental, EveR and Exo EveR parental JHH-6, respectively. Moreover, EveR and Exo EveR parental JHH-6 showed c-Myc and YAP-1 protein upregulation compared to parental JHH-6 but 6 days VitD treatment downregulated their expression. In conclusion, these preliminary data demonstrated that VitD may regulate exosome-mediated drug-resistance mechanisms in JHH-6 cell line, although these mechanisms need to be confirmed in other HCC cell lines.

Diazoxide-induced diabetic ketoacidosis in a patient with insulinoma

Huilin Koh, Vanessa Au & Wann Jia Loh
Changi General Hospital, Singapore, Singapore

Introduction
Although the first-line treatment of insulinoma remains to be surgical resection, medical therapy is necessary for non-localizable or non-resectable tumors, poor surgical candidates, or when surgery is declined. We present an interesting case of a patient with well-controlled insulinoma on diazoxide for 5 years who presented acutely with diabetic ketoacidosis (DKA).
Case presentation
A 85-year-old female presented to the Emergency Department with 2 days of severe vomiting associated with poor oral intake, generalized weakness, polydipsia and polyuria. For the last 5 years, she was compliant with low dose diazoxide with generally good control of her insulinoma. There was no fever, diarrhea, or abdominal discomfort. She reported unintentional weight loss over 4–5 months as well as polyuria for about 2–3 weeks. On examination, she was hypotensive and tachypneic but afebrile. With a plasma glucose of 57.9 mmol/l, high anion gap metabolic acidosis (pH 7.17, bicarbonate 9 mmol/l), ketonuria and ketonemia, and a calculated effective serum osmolality of 304 mOsm/kg, she had diabetic ketoacidosis with hypovolemic shock and severe acute kidney impairment (Creatinine 399 umol/l). She was treated with fluids, intravenous insulin, and cessation of diazoxide, leading to resolution of DKA within 2 days, and normalisation of renal impairment after 5 days. There were no clinical evidence of any acute precipitating factors apart from diazoxide use. Further history revealed that she had a recent admission 3 weeks ago for a rare event of symptomatic hypoglycemia despite compliance to diazoxide. Her diazoxide dose was increased from 100 mg to 300 mg, which precipitated hyperglycemia and acute kidney injury. There were no clinical evidence to suggest a metachronus change in the insulinoma to glucagonoma. There was no necrolytic migratory rash, and serum glucagon concentration was appropriately suppressed during hyperglycemia. MRI of the pancreas also showed that the insulinoma was stable in size at 6 mm without new nodules in the pancreas or liver. Her diazoxide dose was reduced to her usual dose and she did not have further recurrence of hyperglycemia at 1 year of review. In view of her old age and comorbidities, she declined surgical intervention for insulinoma
Conclusion
Diazoxide is a non-diuretic renally-cleared benzothiadiazine derivative that binds to ATP-dependent potassium channel on the beta-cell, hence inhibiting calcium influx and exocytosis of insulin. Patients on diazoxide are at risk of DKA and care should be taken to avoid diazoxide toxicity, especially in the elderly.

Atypical multiple endocrine neoplasia: A case report

Ben salem Maram, Bchir Najla, Zouaoui Chadia, Chayma Besrour, Rihab Laamouri, Jaidane Amel & Ouertani Haroun
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Background
Multiple endocrine neoplasia (MEN) are rare and are characterized by the association of a neoplasia or hyperplasia of at least two endocrine glands. Rare cases of atypical MEN were reported in the literature. We describe a rare combination of acromegaly, papillairy thyroid carcinoma and primary hyperaldosteronism.
Case presentation
We report a case of a 48-year old woman operated for papillary thyroid carcinoma. Five years later, she was diagnosed with acromegaly on the basis of typical clinical and hormonal characteristics (IGF1 plasma level of 836.7 ng/l and GH plasma level >103.8 mUI/l). The pituitary MRI revealed a pituitary macroadenoma of 20 mm of diameter invading the cavernous sinus, the posterior pituitary gland and the pituitary stalk. During the hospitalization, she presented high blood pressure and hypokalemia. A primary hyperaldosteronism was confirmed by a high aldosterone level and a high aldosterone to plasma active renin ratio. The CT scan showed a 13 mm adrenal adenoma. The association of papillary carcinoma of thyroid, acromegaly and primary hyperaldosteronism allowed retaining the diagnosis of MEN. The investigations for other endocrine neoplasia were negative. The patient was operated for the pituitary macroadenoma and was treated by spironolactone for the Conn's adenoma pending the acromegaly's control.
Conclusion
We have described an uncommon case of three endocrine tumors: acromegaly, papillary thyroid carcinoma and Conn's adenoma. This combination could be part of the MEN1 syndrome or due to the mitogenic effect of the GH-IGF1 hyperactivation.

Follow-up case report of an endoscopic ultrasound-guided ethanol ablation: An alternative option for the treatment of pancreatic insulinoma

Anna Vágvölgyi[1], Rea Nagy[1], Renáta Bor[1], Anna Fábián[1], Krisztián Sepp[1], Sándor Hamar[2], László Tiszlavicz[2], Zoltán Szepes[1] & Zsuzsanna Valkusz[1]
[1]University of Szeged, Faculty of Medicine, First Department of Internal Medicine, Szeged, Hungary; [2]University of Szeged, Faculty of Medicine, Department of Pathology, Szeged, Hungary

Insulinomas are predominantly benign pancreatic neuroendocrine tumors presenting with hyperinsulinemic hypoglycemia. Patients with significant hypoglycemic episodes can pose a management challenge. Based on the extent and the aggressiveness of the disease patients may be offered different treatment regimens. Although surgical resection is currently the standard treatment for pancreatic insulinoma, alternative treatment options, such as endoscopic ultrasound-guided fine needle injection may be necessary for symptomatic patients who are not candidates for surgical resolution. We present the follow up history of a now 88-year-old woman who presented with a 10 year history of fasting hypoglycemia in 2013 and was diagnosed with an insulinoma. Considering her age and comorbidities, instead of surgical intervention she was started on diazoxide treatment. Later that year she underwent ultrasound-guided alcoholic ablation of her neuroendocrine tumor, the first such procedure reported in the Hungarian literature. After the intervention she did not require diazoxide therapy for a year. Because of the recurrence of asymptomatic fasting hypoglycemic episodes, diazoxide therapy was restarted at the end of 2014. She was hypoglycemia-free until the end of 2019, when she got admitted with repeated hypoglycemic episodes occurring during the night, despite diazoxide therapy. Endosonography revealed the progress of her pancreatic insulinoma and laboratory studies showed fasting hypoglycemia with hyperinsulinemia. Because of the continued high risk of surgical resection, the decision was made to proceed with another endoscopic ultrasound-guided alcohol injection. Following the intervention the patient was discharged without diazoxide therapy and did not show hypoglycemic tendency. This case history confirms that endoscopic ultrasound-guided alcoholic ablation can be a successful minimally invasive alternative treatment for patients with pancreatic neuroendocrine tumors in whom surgery is not feasible. Our case highlights that the major limitations of ultrasound-guided ethanol ablation are the possibility of late recurrence that would require retreatment, incomplete ablation and the risk of progression during the follow-up.

Diverse regulation of HIF-1 on VEGF in renal cell carcinoma

Bojana Beleslin Cokic[1], Svetozar Damjanovic[2], Sandra Bizic Radulovic[3], Tijana Suboticki[4], Vladan Cokic[4], Ivana Milicevic[1], Gordana Rodic[1], Jadranka Antic[1] & Djuro Macut[1]
[1]Clinics for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Genetic Laboratory, Belgrade, Serbia; [2]Clinics for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [3]Clinic of Hematology, Clinical Center of Serbia, Outpatient Clinic and Diagnostic Department, Belgrade, Serbia; [4]Institute for Medical Research, Laboratory of Experimental Hematology, Belgrade, Serbia

The clear cell renal cell carcinoma (ccRCC) can be sporadic or familiar, with the mutated von Hippel-Lindau (VHL) gene. The inactive VHL protein prevents degradation of hypoxia inducible factor (HIF) that promotes overexpression of angiogenic factors such as vascular endothelial growth factor (VEGF) and erythropoietin (EPO). Sequencing and multiplex ligation-dependent probe amplification (MLPA) of VHL gene in 43 samples of ccRCC in tumors vs surrounding healthy tissues revealed 27 somatic mutations. Further, testing the loss of heterozygosity (LOH) among 27 samples showed 23 biallelic and 4 monoallelic alterations in *VHL* gene. We detected an increase in VEGF mRNA and protein with a low HIF-1 gene expression in ccRCC compared to healthy tissue. To observe HIF-1 induction of VEGF mRNA, we examined tumors without or with VHL mutation (monoallelic and biallelic). In comparison to normal renal tissue, we observed a significant induction of VEGF mRNA expression in wild type tumor samples with a progressive increase in samples with monoallelic and biallelic inactivation of VHL. The human RCC 786-O cell line, a model with biallelic inactivation of *VHL*, demonstrated significant proliferation after 48 h at 21% and 3% oxygen. The human RCC Caki-1 cell line, a model with a wild type *VHL*, showed very slow proliferative effect at normal and low oxygen tension compared to 786-O cells, with significant changes after 48 h at normal oxygen tension and 10% FBS. HIF-1 protein expression was increased at low serum at 21% and 3% oxygen, both in 786-O and Caki1 cell lines. VEGF protein expression was generally low at 3% oxygen tension in 786-O cells, while it was induced at 3% and 21% oxygen after 24 h and 48 h, respectively at 10% FBS in Caki1 cells. Inactivation of *VHL* stimulated VEGF protein expression in RCC tumor tissues, but not in 786-O cell line. Hypoxia stimulated both VEGF and HIF-1 protein expression in Caki1 cell lines, regardless of *VHL* inactivation. Our data suggest diverse regulation of HIF-1 on VEGF, depending on VHL alternation, hypoxia and nutrition situation in tumor and RCC cell line.

Endocrine related immune adverse events associated with programmed death ligand-1 (PD-L1) therapy in hematologic malignancies: A retrospective analysis

Valentina Lo Preiato[1], Anna Buganè[1], Beatrice Casadei[2], Lisa Argnani[2], Pier Luigi Zinzani[2], Uberto Pagotto[1] & Carla Pelusi[1]
[1]Endocrinology Unit, Center for Applied Biomedical Research, Department of Medical & Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, S. Orsola-Malpighi Hospital, Bologna, Italy; [2]Institute of Hematology 'L. e A. Seràgnoli', University of Bologna, Bologna, Italy

Background
PD-L1 represents a novel class of drugs for treatment of a broad spectrum of malignancies including onco-hematologic diseases. This treatment is associated with several immuno-related adverse events (irAEs). Thyroid diseases and diabetes are among the most common PD-L1 endocrine-irAEs reported in solid cancers.

Aims
To describe the frequency, the onset and the characteristics of PD-L1 endocrine-irAEs in patients with hematologic malignancies.
Materials and methods
We retrospectively collected data of 62 patients with lymphoma, attending the Institute of Hematology Seràgnoli of Bologna between June 2014 and August 2018, treated with PD-L1 (Nivolumab or Pembrolizumab) according to the Authority-approved doses and administration. All patients underwent metabolic and hormonal exams before the initiation of PD-L1 and during follow-up.
Results
Of 62 patients (median age: 29 years, range: 16–68), 18 affected by Nodular Sclerosis Hodgkin Lymphoma (NSHL) were treated with Nivolumab, 26 and 18 affected by NSHL and Primary Mediastinal B-cell Lymphoma, (PMBCL) respectively were treated with Pembrolizumab. All patients were followed for a median of 112 weeks (range: 4–270). The total frequency of PD-L1 endocrine-irAEs was 8.1%, characterized by only thyroid diseases. Four (2 NSHL and 1 PMBCL on Pembrolizumab, and 1 NSHL on Nivolumab) developed sudden-onset hypothyroidism at different times (from 16 to 44 weeks after PD-L1 starting). One NSHL on Pembrolizumab had an initial thyrotoxicosis at 6 weeks turning to overt hypothyroidism after 9 weeks. All 5 subjects were asymptomatic. Two of them had positive anti-thyroid autoantibodies (anti-thyroid peroxidase and anti-thyroglobulin), whereas none had detectable anti-TSH receptors. All hypothyroid subjects started l-tyroxine therapy. None of the patients developed diabetes. At the last follow up, of the 5 patients with endocrine-irAE, 3 showed complete remission and 2 disease progression of the lymphoma. No correlations were found between the endocrine-irAEs and previous oncologic therapies ($P=0.081$), and tumour outcomes ($P=0.278$ for best response to Pembrolizumab; $P=0.921$ for the last response to Pembrolizumab; $P=0.278$ for deaths).
Conclusion
The frequency of PD-L1 endocrine-irAEs in this cohort of hematologic malignancies was lower than those reported for solid cancers, and only characterized by thyroid disease. Unexpectedly, no case of PD-L1 inducing diabetes mellitus was shown. As for solid tumours the onset of endocrine-irAES was extremely variable and no correlation with tumour outcome was found.

Real medical challenges in the diagnostic of gastrinomas

Oana Alexandra Ciobanu[1], Cristian Tieranu[2,3], Dana Terzea[4,5], Irina Nistor[1], Marius Mitrache[1] & Fica Simona[1,6]
[1]Elias Emergency University Hospital, Endocrinology and Diabetes Department, București, Romania; [2]Elias Emergency University Hospital, Gastroenterology Department, Bucuresti, Romania; [3]Carol Davila University of Medicine and Pharmacy, Department of Gastroenterology, Bucuresti, Romania; [4]Onco Team Diagnostic, Anatomical Pathology, Bucuresti, Romania; [5]Carol Davila University of Medicine and Pharmacy, Research, Bucuresti, Romania; [6]Carol Davila University of Medicine and Pharmacy, Department of Endocrinology, Bucuresti, Romania

Introduction
Chronic hypergastrinemia is no longer an uncommon phenomenon. Zollinger-Ellison syndrome [ZES], chronic atrophic gastritis [CAG] type A, proton pump inhibitors [PPI] therapy, or Helicobacter pylori-induced CAG type B are causes of hypergastrinemia. Serum gastrin levels >1000 pg/ml (> 0 times the upper limit of normal) and PH gastric below 2 is the diagnostic of ZES, but two -thirds of ZES patients have serum gastrin levels below 1000 pg/ml. We present the case of a 63 years old female with a history of abdominal pain, chronic diarrhea, heartburn, vomiting, duodenal peptic ulcer. Additional evaluation revealed: chromogranin A level 6.5-fold higher (465.7 ng/ml), but under PPI therapy taken for the digestive symptomatology, thus nonspecific, hyperparathyroidism (vitamin D deficiency, normocalcemia), chronic autoimmune thyroiditis with an euthyroid phase. At referral, the patient was in mild distress due to the chronic diarrhea with a clinical evaluation showing normal blood pressure, IMC–26 kg/m^2 with pale skin.
The patient was referred to gastroenterology department, where the digestive symptomatology was responsive to higher dose of PPI (pantoprazole 120 mg/day). Endoscopic features excluded the atrophy expressed in CAG-A, while multiple proeminent sessile lesions (PFL) and superficial ulcerations were found. The biopsy of multiple ulcers (<1 cm) in the duodenum II showed the absence of Helicobacter Pylori and a histologic appearance (HA) similar to well differentiated neuroendocrine tumors. The immunohistochemistry showed the presence of chromogranin A and KI-67 positive in epithelial cells, inconclusive. A second endoscopy with biopsy of PFL was made, while the echo-endoscopy revealed another tumor around 1 cm diameter in the duodenum I with a HA suggestive for malignancy. Due to the insufficient material another biopsy was recommended. Fasting serum gastrin values were 6.5-fold higher under PPI therapy, thus nonspecific. After vitamin D supplementation, we can not exclude the primary hyperparathyroidism: normal vitamin D, normocalcemia, still a high value of PTH at 135.6 pg/ml with densitometric diagnosis of osteoporosis at the forearm without fragility fractures. The screening for MEN1 showed normal prolactin and IGF 1 levels. The control of acid output was achieved with a dose reduction of pantoprazole at 80 mg/day. Because of the lack of disponibility of 68 Gallium-DOTATATE, it was recommended to perform an Octreoscan.
Conclusion
This case raises awareness that often medical practice shows lack of correlation between clinical and paraclinical evaluation making a disease diagnostic like ZESa real challenge.

Keywords: ZES, hypergastrinemia, hyperparathyroidism, duodenal ulcers.

Pheochromocytoma due to TMEM127 mutation – the importance of genetic test for clinical decision

Silvia Paredes[1], Sara Lopes[1], Isabel Torres[2] & Marta Alves[1]
[1]Hospital de Braga, Serviço de Endocrinologia, Portugal; [2]Instituto Português de Oncologia do Porto, Serviço de Endocrinologia

Background
Catecholamine-secreting tumors that arise from chromaffin cells of the adrenal medulla and the sympathetic ganglia are respectively referred to as pheochromocytomas and paragangliomas. The classic triad of symptoms in patients with pheochromocytoma (PHEO)consists of episodic headache, sweating, and tachycardia. Approximately one-half have paroxysmal hypertension; the rest have either primary hypertension or normal blood pressure. Clinicians should always consider PHEO when evaluating for secondary causes of hypertension, as missing this diagnosis can result in devastating complications, including death.
Clinical case
A previously healthy 53-year-old woman presented to her general practitioner with daily pulsatile bilateral frontal headaches persisting for 6 months, reporting different characteristics than her usual migraines. She complained of paroxysmal episodes of fatigue, palpitations, heat, sweating, and non-quantified weight gain in the previous months. Her past medical history was unremarkable, except for sporadic migraines since adolescence. She denied other relevant pathological medical history and had no previous hospital admissions or surgeries. She was not on regular medication or supplements. The physical examination was notable for a high diastolic blood pressure (BP) (137/106 mmHg) and a body mass index of 25.4 kg/m^2. Arterial hypertension was diagnosed, no treatment started, and she underwent investigation of secondary causes of arterial hypertension. During workup, high urinary metanephrines were detected and the abdominal MRI evidenced 2 nodular bilateral adrenal lesions. ^{18}F-FDG-PET/CT scanning revealed mild to moderateuptake in both lesions without extra-adrenal uptake, the ^{123}I-MIBG scintigraphy demarcated the right lesion as suspicious and a CT-scan confirmed the heterogeneous nodular lesion on the right adrenal gland as suspicious for PHEO. A right adrenalectomy was performed with posterior resolution of symptoms and normalization of urinary metanephrines and histology confirmed a PHEO. Genetic testing became available five months after surgery and revealed a TMEM127 gene mutation detected in heterozigoty (NM_017849.3:c.410-2A>C p.?).
Discussion
TMEM127 is a negative regulator of mammalian target of rapamycin effector proteins, which promote cell growth and protein translation. Due to the high prevalence of multicentric and bilateral tumors and also renal cell carcinoma in TMEM127-related PHEO, periodic surveillance of the surgical site and the contralateral adrenal gland is mandatory. Moreover, cortical-sparing procedures should be favored in order to preserve adrenocortical function. This case report evidences the benefit of genetic testing for an accurate clinical management and treatment of patients and mutation carriers in TMEM127-related PHEO.

Functional and morphologic response to somatostatin analogues of a pancreatic gastrinoma with unusual presentation

Mihai Constantin Marinescu[1], Ionela Baciu[1,2], Polina Pascu[1], Alexandra Rotarescu[1], Maria Cristina Baleanu[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania

Introduction
Gastrinoma is rare gastrin-secreting neuroendocrine tumor (NET), usually located in the pancreas or duodenum. The most common presentations of gastrin secreting tumor is Zollinger-Ellison Syndrome (ZES). Only about 10% of patients have non demonstrable ulcer.
Case presentation
A 67 years old female, with premature menopause, mild hypothyroidism with optimal replacement treatment, osteopenia and history of chronic gastritis, is admitted to our clinic accusing debilitating diarrhea (10 episodes/day), about 1 year before presentation. Clinical examination was normal, excepting abdominal tenderness. Carcinoid syndrome was suspected, and neuroendocrine tumor markers were measured, revealing high levels of gastrin (5× upper limit of normal) and Chromogranin A (CGA). Neuron Specific Enolaze, Serotonin and urinary 5 hydroxyindoleacetic acid were normal. Prolactin, PTH and calcium levels were normal. Also Thyroid function was normal. Upper endoscopy performed before admission did not reveal any gastric or duodenal ulcers. Classic imaging testing (CT and MRI) revealed no images suggesting a neuroendocrine tumor, but showed an adrenal incidentaloma. Lab test revealed normal values of ACTH, Cortisol, Dehydroepiandrosterone Sulfate, plasma Metanephrines and Normetanephrines, Rennin and Aldosterone. SPECT-CT somatostatin receptor scintigraphy (SRS) with 99 mTc-Tektrotyd was performed, and revealed high accumulation in the head and uncinate process of the pancreas. She was referred for surgical evaluation, but the tumor was considered inoperable. Somatostatin analogues (SSA) treatment was started in association with proton pump inhibitors (PPI) and sucralfate. At the 3 months follow up the patient presented with improvement of symptoms (3–4 normal stools/day). Also lab test revealed normalisation of gastrin and CGA. SRS with 99 mTc-Tektrotyd was repeated and revealed significant shrinkage of the tumor. Due to SSA treatment patient developed secondary diabetes mellitus, and was started on metformin.
Conclusion
Although ZES is the most common presentation of gastrinoma, 10% of patients do not present typical symptoms. Despite the fact that surgical treatment is the only curative treatment, SSA analogues is a viable treatment option in selected cases, especially when surgery is not possible, and may lead to improvement of symptoms and also induce morphologic and functional response.

Involvement of the splicing machinery in the antitumoral actions of metformin in prostate cancer

Antonio J. Montero-Hidalgo[1,2,3,4], Juan M. Jiménez-Vacas[1,2,3,4], Vicente Herrero-Aguayo[1,2,3,4], André Sarmento-Cabral[1,2,3,4], Miguel López[5,6], Justo P Castaño[1,2,3,4], Manuel D Gahete[1,2,3,4] & Raúl M Luque[1,2,3,4]
[1]University of Cordoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [2]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [3]Reina Sofía University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]University of Santiago de Compostela, Department of Physiology, CiMUS, Santiago de Compostela, Spain; [6]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Santiago de Compostela, Spain

Metformin has recently emerged as a potential therapeutic tool for different tumour pathologies, including prostate cancer (PCa)[1], one of the leading causes of cancer-deaths in men worldwide. However, the molecular mechanisms underlying the antitumor effects of metformin in PCa are not fully elucidated. In this context, previous reports have suggested a relationship between metformin and the process of alternative splicing in some cell-types. Nevertheless, the potential role that the splicing machinery [spliceosome components (SCs) and splicing factors (SFs)] might play in the antitumor effects of metformin in PCa remains unknown. Therefore, the aim of this study was to examine the effects and implications of metformin on the expression levels of key splicing machinery components and splicing variants in PCa. Specifically, expression levels of 14 SCs and 28 SFs were measured by a microfluidic-based qPCR array in androgen-dependent and -independent PCa-derived cell lines (LNCaP and PC-3, respectively) and in PC-3-induced xenograft tumours under low- and high-fat diets conditions in response to metformin (5 mM *in vitro*; 250 mg/kg/day *in vivo*). Moreover, different mechanistic (qPCR/Western-Blot) and functional (cell-proliferation) assays in response to metformin and/or in response to the silencing of certain SCs/SFs (using specific siRNAs) were implemented. Metformin reduced the expression level of 21% (3/14) of the SCs and 43% (12/28) of the SFs studied in LNCaP and PC-3 cells. Likewise, downregulation of certain SCs and SFs in response to metformin treatment was also observed *in vivo* in PC-3 induced xenografts. Interestingly, some of these changes were diet (low-fat vs high-fat) dependent, while others were diet-independent. Remarkably, three elements of the splicing machinery (*NOVA1, SF3B1* and *SRRM1*) were consistently reduced in response to metformin in both *in vitro* and *in vivo* models. In fact, silencing of these three elements completely blocked the anti-proliferative actions of metformin in PCa cells. Consistently, metformin reduced the expression levels of certain splicing variants related to PCa development or aggressiveness (e.g.: *KLF6-SV1*, *RAC1B*, *SST_5TMD4*) in PCa cells. Finally, we evaluated whether these changes exerted by metformin were AMPK-dependent or -independent using adenoviruses encoding either a dominant-negative or constitutively-active isoform of AMPKa. Altogether, our results suggest that the antitumor effect exerted by metformin in PCa might be mediated, at least in part, by the modulation of certain splicing machinery elements (*NOVA1/SF3B1/SRRM1*) and splicing variants(*KLF6-SV1/RAC1B/SST_5TMD4*).

Hyponatremia and dermatomyositis as the first manifestations of small cell lung cancer

Elzana čikić[1], Benida Šahmanović[1], Majda Delić[2], Amil Čikić[3] & Vasilije Bošković[4]
[1]Clinical Center of Montenegro, Department of Internal Medicine, Podgorica, Montenegro; [2]Health Center of Vareš BIH, Vareš, Bosnia and Herzegovina; [3]Health Center of Bijelo Polje Montenegro, Bijelo Polje, Montenegro; [4]Clinical Center of Montenegro, Montenegro

Introduction
Dermatomyositis is an inflammatory connective-tissue disease, characterized by inflammation of the muscles and the skin. It is more frequent among women and in 25% of cases it is related to malignancy, such as ovarian, breast, colon cancer, melanoma, non-Hodgkin's lymphomas, lung cancer, myelo-hyperplastic syndromes, and nasopharyngeal cancer. In 1/3 of cases dermatomyositis precedes malignancy, in 1/3 they present simultaneously, and in the remaining 1/3 of cases it occurs after the diagnosis of malignancy. A common paraneoplastic syndrome caused by ectopic hormone production is hyponatremia, which occurs in 15% of SCLC patients. Patients frequently but not always experience a decline in sodium level at relapse, making declining sodium a tumor marker for cancer progression, although this has not been prospectively studied. Small studies have suggested that hyponatremia is associated with shortened survival and it is poor prognostic factor for patients with SCLC.
Case report
A 67-year-old woman admitted to our hospital on August 23rd, 2019, due to severe hyponatremia. The patient was diagnosed with Dermatomyositis one month earlier, according to the results of the following physical, laboratory, EMNG examinations and biopsies. For the last 2 years, the patient was referred to the pulmologist due to productive cough, chest tightness and shortness of breath. A CT scan of the chest was performed in Mart 2019, which showed no significant changes.
Clinical findings on admission
Punctuate red rashes scattering on the face, chest and extremities, difficulty swallowing, proximal muscular weakness were noted. Pulse oxygen saturation (SPO_2) was 85%, BP 100/60 mmHg without orthostasis, pulse 86/min. She had no edema or ascites. Laboratory findings: TSH 1.45 mIU/l, cortisol 546 nmol/l, blood urea 4,0 mmol/l, creatinine 38 mcmol/l, CK 1194 IU/l, AST 123 IU/l, ALT 46 IU/l, LDH 389 IU/l, plasma sodium (P_{Na}) 116 mmol/l, potassium 3.9 mmol/l, serum osmolality 239 mOsm/kg/H2O,

uric acid 94 mcmol/l, urine osmolality 557 mOsm/kg H2O, urine sodium (U_{Na}) 106 mmol/l. MSCT examination of the chest revealed a large tumor mass in the upper mediastinum 118×56 mm with numerous macronodular focal changes in the lung. Biopsy from mediastinal lymph nodes was performed and histopatological findings showed: Small cell carcinoma. The immunohistochemistry assay of lymph node: CK ±, Synaptophysin +, CD56 +, LCA-, Ki67 positive in 90% of tumor cells.
Numerous secondary deposits have been identified in the brain by NMR examination.
She died on 12th of September, 2019, 20 days after being diagnosed with hyponatremia.

Correlation of chromogranin a and standard metabolic parameters in patients with gastroenteropancreatic neuroendocrine tumors (GEP-NETs)

Ivana Bozic-Antic[1], Sanja Ognjanovic[2], Bojana Popovic[2], Tatjana Isailovic[2], Tamara Bogavac[2], Dusan Ilic[2], Valentina Elezovic-Kovacevic[2] & Djuro Macut[2]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Department for Neuroendocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Department for Neuroendocrine Tumors and Hereditary Cancer Syndromes

Introduction
Chromogranin A (CgA) is a major representative of the protein family named granins stored predominately in secretory granules of the diffuse neuroendocrine system. Circulating CgA serves as a biomarker of neuroendocrine tumors (NETs), but its increased plasma concentration is present in various cardiovascular, gastrointestinal, renal and inflammatory diseases. Intra-granular and/or extracellular proteolysis of CgA generates a variety of biologically active fragments, which seem to beinvolved in the regulation of metabolism (pancreastatin and catestatin), cardiovascular system (vasostatin, catestatin), innate immunity (chromacin), angiogenesis and tissue repair (serpinin). It was shown that in rat models pancreastatin promotes insulin resistance by inhibiting insulin action on glucose and lipid metabolism while low catestatin promotes hypertension. The aim of this study is to analyze correlation between CgA levels and standard metabolic indices in patients with NETs.
Materials and methods
We analyzed 20 patients (mean age 47.5±14.8 yrs) with newly diagnosed well-differentiated gastroenteropancreatic NETs (GEP-NETs), 10 women and 7 men. In all subjects we measured waist circumference (WC), blood pressure (BP), fasting glucose (FG), HbA1c, total cholesterol (TC), HDL, LDL, triglycerides (TG), CgA, glucose and insulin during 2-hour oral glucose tolerance test (OGTT). We calculated body mass index (BMI), markers of insulin resistance (HOMA-IR and Matsuda index), area under the curve (AUC) for glucose and insulin during OGTT and lipid accumulation product (LAP) as a surrogate marker of metabolic syndrome (MetS).
Results
Impaired glucose tolerance was detected in one patient, impaired fasting glucose in two patients and others (17/20) had normal glucose tolerance. Our patients had (mean±s.d.) CgA 264.9±182.1 ng/ml, HOMA-IR 2.4±1.8, Mathsuda index 4.9±2.3, LAP 66.7±36.5, systolic BP 127±5 mmHg and diastolic BP 81±13 mmHg. CgA correlated with FG (r=0.572, p=0.021), Tg (r=0.532, P=0.034), systolic BP (r=0.536, P=0.039), diastolic BP (r=0.535, P=0.040).
Conclusion
This pilot study shows that CgA could serve as a marker of initial derangement of metabolic disturbances in newly diagnosed patients with NETs.

Bisphenols release from dental composite materials

Markéta Šimková[1,2], Antonín Tichý[3], Michaela Dušková[4], Jana Vítků[1], Lucie Kolatorova[1] & Pavel Bradna[3]
[1]Institute of Endocrinology, Department of steroid hormones and proteohormones, Prague, Czech Republic; [2]University of Chemistry and Technology, Prague, Department of Natural Compounds, Prague, Czech Republic; [3]Institute of Dental Medicine, First Faculty of Medicine of the Charles University, Prague, Czech Republic; [4]Institute of Endocrinology, Prague, Czech Republic

Resin-based composite materials have become most used in restorative dentistry as a result of continuous effort to reduce the use of dental amalgam. Since 2018, it has been banned in children under 15 years of age, pregnant and nursing women. As these materials often contain bisphenol A glycidyl methacrylate (Bis-GMA) or derived monomers, bisphenol A (BPA), known for its endocrine disrupting effects, may be released and represent a low-dose and long-term source of BPA for the human body. To evade the problem of BPA presence, its structural derivatives such as BPS, BPF, and BPAF are often used in industry. The aim of this work was to determine the maximal amounts of BPA released from Bis-GMA-containing and 'BPA-free' restorative composites, and to describe the kinetics of BPA release to methanol using liquid chromatography tandem mass spectrometry (LC-MS/MS). Bis-GMA-containing composites Charisma Classic (CC) and Filtek Ultimate (FU), and 'BPA-free' Charisma Diamond (CD) and Admira Fusion (AF) were used in this study. Specimens (diameter 6 mm, height 2 mm, n=5) were light-cured from one side (20 s, 1000 mW/cm^2), and stored at 37 °C in 2 ml of methanol which was exchanged after 1, 4, 9, 16, 35, 65, and 130 days. Bisphenol concentrations were measured using LC-MS/MS. In order to gain high sensitivity, dansyl chloride derivatization was carried out[1]. The total amounts of BPA released from 'BPA-free' materials CD (8.31±1.47 ng/g) and AF (5.18±1.30 ng/g) after 130 days were significantly lower compared with Bis-GMA-containing composites CC (146.17±6.99 ng/g) and FU (182.61±5.94 ng/g). The highest release of BPA was observed within the first day of incubation, followed by a gradual decrease. The release was still ongoing since the 35-days values at a similar daily rate until 130 days of incubation. Alternative bisphenols (BPS, BPF, BPAF) were not detected. As the total amounts of BPA released within 130 days were several orders of magnitude lower than the tolerable daily intake 4 µg/kg body weight/day, these materials should not pose a serious health risk according to the current criteria.

A monitoring project to study nationwide trends of endometriosis incidence for environmental purposes inFrance: First step results

Annabel Rigou[1], Julie Chesneau[1], Michel Canis[2], Emile Daraï[3], Arnaud Fauconnier[4], Anita Balestier[1], Marina Kvaskoff[5], Chrysoula Zacharopoulou[6], Alexia Peyronnet[1], Mélina Le Barbier[1] & Joëlle Le Moal[1]
[1]Santé publique France; [2]University Hospital of Clermont-Ferrand; [3]Tenon University Hospital; [4]Hospital of Poissy Saint Germain; [5]Inserm UMR 1018; [6]Bégin military Hospital

Introduction
Endometriosis is a complex reproductive disease without clear etiology, thought to be on the increase, and possibly related to endocrine disruptor (EDs) exposure such as PCBs, dioxins, phthalates, or pesticides. It is part of a national project on reproductive health indicators related to EDs in France. We aimed to build a nationwide indicator of endometriosis incidence based on routinely collected data, usable to study temporal and spatial trends for environmental purposes.
Methods
A multidisciplinary expertise gathering clinicians, epidemiologists, statisticians and experts in health data mining was composed to elaborate a strategy for tracking new cases of endometriosis from the French national health care data system. We built corresponding algorithms, using ICD-10 codes for diseases and/or medical acts and/or drugs. We performed a review of literature on the epidemiology of endometriosis and links with EDCs exposure. We analyzed the usefulness of the indicators regarding our environmental purposes.
Results
Monitoring endometriosis nationwide was only possible using hospital discharges. We built 3 indicators:
– The first one involved only diseases codes of endometriosis (N80);
– The second one involved also codes for the main surgical acts, thought to enable histological diagnosis, observed nationwide in hospital discharges (a posteriori approach);

– The third indicator was issued from an a priori approach: the experts deciding which diseases codes and acts were the most relevant to identify specific forms of endometriosis, i.e. endometriomas. For each indicator, incident cases were defined as the first stay recorded without occurrence at least in the 5 prior years. In the period 2006 to 2017, we identified nationwide 30 600, 23 600 and 7500 new annual operated cases, with indicators 1 to 3, respectively. For comparison, we estimated the annual crude incidence rate with the first indicator to 12.9/10 000, which is of the same order of magnitude as in European countries using similar methods.
Conclusion
All three indicators are usable to monitor hospital cases of endometriosis nationwide, and analyze temporal trends and spatial trends at the postcode scale for environmental purposes, to explore environmental issues that are geographically determined. The indicator one reflects the better the hospital incidence, the other ones could be used for sensibility studies. The main limits of this monitoring method are the undervaluation of the public health problem, because only hospital cases are included, and possible variations of treatment or coding. A close collaboration with clinicians is critical to overcome these limits.

Vasoinhibin dimerization and measurement in human sera with a new vasoinhibin elisa

Jakob Triebel[1], Nils Müller[1], Johannes Ebnet[1], Leon Neugebauer[1], David Harris[1], Christin Friedrich[1], Hülya Markl-Hahn[1], Juan Pablo Robles[2], Magdalena Zamora[2], Gonzalo Martínez de la Escalera[2], Carmen Clapp[2] & Thomas Bertsch[1]
[1]Institute for Clinical Chemistry, Laboratory Medicine and Transfusion Medicine, General Hospital Nuremberg & Paracelsus Medical University, Nürnberg, Germany; [2]Instituto de Neurobiología, Universidad Nacional Autónoma de México (UNAM), Mexico

Vasoinhibin, historically also known as 16K PRL, is a peptide hormone with antiangiogenic, antivasodilatatory, and antivasopermeability effects generated by proteolytic cleavage of prolactin (PRL). The discovery of its role in diabetic retinopathy and peripartum cardiomyopathy led to the development of new pharmacological treatments and their evaluation in clinical interventional trials (ClinicalTrials.gov Identifier: NCT03161652 and NCT00998556). Recent insights into the function and three-dimensional structure of vasoinhibin revealed a structure conformed by a three-helix bundle and some degree of dimerization. To study the level of vasoinhibin dimerization and the presence of vasoinhibin in human serum, recombinant human vasoinhibin and human sera were investigated by SDS-PAGE and Western blotting, preparative electrophoresis, mass spectrometry, immunoprecipitation, and ELISA. Commercial poly- and monoclonal anti-PRL antibodies were used, and monoclonal anti-vasoinhibin antibodies, designed to specifically bind vasoinhibin and not PRL, were generated by the hybridoma technique. A sandwich ELISA for vasoinhibin was developed, using anti-vasoinhibin monoclonal antibodies. Over 90% of recombinant vasoinhibin monomers aggregated to form a 28 kDa dimer which is resistant to standard denaturating and reducing conditions and dissociated only after prolonged exposure to heat and ß-mercaptoethanol or DTT. Western blotting analysis and immunoprecipitation demonstrated the presence of a highly abundant, 28 kDa endogenous protein in human sera, with immunochemical features of vasoinhibin. The ELISA, calibrated with a recombinant human vasoinhibin-standard, had a detection limit of 39 ng/ml, a quantitation limit of 207 ng/ml, and intra-assay- and inter-assay coefficients of variation of 12.5% and 14%, respectively. Serum samples from 9 individuals were tested, and showed variable concentrations ranging from 1 to 210 µg/ml. The contribution of endogenous vasoinhibin to these measurements is under investigation.

Context
Cytochrome P450 (CYP) 17A1 is located at major branch points of steroidogenesis exerting two distinct catalytic activities: 17α-hydroxylase generates glucocorticoid precursors and 17,20-lyase generates the principal sex steroid precursor dehydroepiandrosterone (DHEA). CYP17A1 deficiency (17OHD) is a rare form of congenital adrenal hyperplasia. In severe 17OHD, affected individuals typically present with both glucocorticoid and sex steroid deficiency and mineralocorticoid excess due to accumulation of steroid precursors. Partial enzyme defects have been rarely reported.
Aims and objectives
To analyse the genetic and phenotypicspectrum of seven patients with 17OHD.
Methods
Urinary steroid profiling (GC-MS), sequencing analysis of the *CYP17A1* gene, *in silico* analysis utilising the crystallized human CYP17A1 protein structure (PDB: 3RUK), *in vitro* analysis employing a HEK293 cell CYP17A1 overexpression assay with quantification of steroid conversion by LC-MS/MS.
Patients and results
The clinical spectrum ranged from neonatal adrenal insufficiency with failure to thrive and conjugated jaundice toisolated sex steroid deficiency with normal blood pressure and normal serum cortisol after ACTH stimulation. We found five novel (p.Pro409Leu, p.Gly111Val, p.Ala398Glu, p.Ile371Thr and p.Tyr60Ile*fs*Lys88X), and three previously described *CYP17A1* sequence variants (p.Arg347His, p.Gly436Arg, p.Phe53/54del). *In vitro* functional analysis showed correlation of 17α-hydroxylase activity with the severity of the phenotype: the missense variants p.Ile371Thr, p.Ala398Glu and p.Arg347His, carried by patients with normal cortisol response, retained up to 14% of residual 17α-hydroxylase activity. The known variant p.Phe53/54del, found in two siblings with a moderate phenotype, retained 5.8% of WT activity. The sequence variants p.Pro409Leu, p.Gly111Val, p.Gly436Arg and p.Tyr60Ile*fs*Lys88X, carried by severely affected patients, had <1% residual 17α-hydroxylase activity. In contrast, 17,20-lyase activity was nearly abolished in all variants studied, except for p.Ile371Thr, which retained 3.6% of WT activity. A diagnostic ratio of urinary mineralocorticoid to glucocorticoid metabolites, reflecting 17α-hydroxylase activity, correlated well with both the *in vitro*17α-hydroxylase activity and the severity of the clinical phenotype. *In silico*mutant protein analysis identified conformational changes rather than disruption of co-factor binding for all variants studied.
Conclusion
Our findings expand the genetic and clinical spectrum of 17OHD. We describe novel phenotypes at both extremes of the spectrum, with severe neonatal adrenal insufficiency on the one hand, and isolated sex steroid deficiency with normal cortisol response to stimulation on the other. Importantly, attenuation of 17α-hydroxylase activity is readily detected by urinary steroid profiling in all cases, thus providing a powerful tool for the biochemical diagnosis of 17OHD.

Mental disorders in adult patients with diencephalon lesions by craniopharyngiomas.

Yuliya Sidneva[1,2], Ludmila Astafyeva[1], Oleg Zaitsev[3], Sergey Urakov[4], Pavel Kalinin[1], Maxim Kutin[1], Boris Kadashev[1], Aleksey Shkarubo[1], Dmitry Fomichev[1], Dmitry Andreev[1], Oleg Sharipov[1], Irina Voronina[1], Shukur Abdulatipov[1] & Iliay Chernov[1]

[1]NN Burdenko National Medical Research Center of Neurosurgery, Pituitary, Moscow, Russian Federation; [2]Clinical and Research Institute of Emergency Pediatric Surgery and Trauma, Rehabilitation, Moscow, Russian Federation; [3]NN Burdenko National Medical Research Center of Neurosurgery, Neuropsychiatry, Moscow, Russian Federation; [4]NN Burdenko National Medical Research Center of Neurosurgery, Diagnostics, Moscow, Russian Federation

The tumors of the thalamic-hypothalamic-pituitary system (diencephalon region, DR) include a fairly large group. These are pituitary adenomas, craniopharyngiomas (CP), pineal tumors, gliomas, meningiomas, and others. Tumors differ in the location, histological structure, and manifestations of the clinical picture with the corresponding hormonal changes, approaches and methods in treatment. Psychopathological symptoms are revealed in the symptoms of lesion of the DR in addition to cerebral, neuroendocrine symptoms, neurological disorders. It is represented by emotional, motivational, personal, cognitive impairments, inversion of the sleep-wake cycle, seizures.
Objective
To study of mental disorders in patients with diencephalon lesions (on a model of benign tumor of craniopharyngiomas).
Materials and methods
120 adult patients (18–68 years old, median 39 ± 2; 59 women and 61 men) who were first admitted for treatment with a diagnosis of CP (2007–2015). The main method was psychopathological; data from endocrinological, neurological, neuroimaging. CP were classified according to initial growth and relation to the third ventricle: endosuprasellar (n = 26), suprasellar (with initial growth in the pituitary stalk, with no penetration into the third ventricle) (n = 45), extra-intraventricular (n = 35) and intraventricular (n = 14). Hypopituitarism/panhypopituitarism, diabetes insipidus was detected in 89%before surgery.
Results
Mental disorders in the clinical picture of CP were detected in 103 (85.8%) patients with syndromes: emotional and volitional disorders in 79 (65.8%), memory impairment in 71 (59.1%), personality changes in 71 (59.1%), paroxysmal conditions in 55 (45.8%), sleep disorders in 54 (45%), and consciousness disorders in 24 (20%). Mental disorders do not manifest themselves in isolation, but together with each other, and therefore are superior to each other in the clinical picture or to varying degrees with various topographic and anatomical variants of CP : in 65% of cases with endosuprasellar, in 86% – with stalk, in 100% – with extra-intra- and intra-ventricular CP. The most severe mental disorders: Korsakov's syndrome, aspontaneity, akinetic mutism, personality defect were noted in 21% of cases, more often in patients with extra-intra-ventricular CP.
Conclusion
Mental disorders in the clinical picture of CP were detected in 85.8% of patients before surgery, determined by the location of the damage – topographic and anatomical variants of CP, the spread and effect of the tumor on the structures of the DR, limbic system, and III ventricle, with corresponding neuroenodcrine disorders.

Late effects of allogeneic stem cell transplants on the endocrine and metabolic systems

Nicholas Ng, David Moloney & Marie-Louise Healy
Street James's Hospital, Endocrinology Department, Dublin, Ireland

Stem cell transplants are used to treat and cure many types of haematological malignancies as well as rare solid-organ tumours. The conditioning regimes, medications and potential graft vs host disease can have effects on many organ systems in the body. The Endocrinology Department has designed a follow-up service over the past 3 years for patients in remission due to increasing awareness of the potential endocrinological and metabolic effects of allogenic stem cell transplant. This study aims to identify the effects allogenic stem cell transplant has on those systems. We retrospectively analysed patients who received bone marrow transplants in St. James Hospital between 2002 to 2018. We have analysed patients above 18 years old who have undergone stem cell transplant, attended the late effects clinic and are clinically in remission and deemed long term survivors. Metabolic and endocrinological markers such as liver function tests, glycated haemoglobin, fasting lipids, thyroid function tests, and reproductive hormones levels were obtained and measured over time. There were 412 late effects patients who had stem cell transplants between 2002 to 2018. We have analysed year one data from 100 patients who had bone marrow transplant between January 2016 to December 2019. Average age of these patients at time of bone marrow transplant are 43.6 (± 14.4) years old.2 patients had biochemical evidence of hypothyroidism. 17 had biochemical evidence of subclinical hypothyroidism. Average time of onset was 10.7 (± 4.3) months from receiving bone marrow transplant. Average thyroid stimulating hormone (TSH) at time of onset was 6.65 (± 4.33) mU/l with free T4 of 13.12 (± 4.32) pmol/l. 1 patient developed subclinical hyperthyroidism with TSH 0.04 mU/l and T4 of 21 pmol/l prior to developing hypothyroidism. There were 45 females analysed so far. 4 of those patients under 40 years old developing hypoestrogenism, all within 3 months of transplantation. 55 males were analysed with none having biochemical evidence of hypogonadism within that one year. 53 patients had deranged liver function tests with average time of onset of 7.4 (± 2.1) months. The long-term effects of bone marrow transplant on metabolic and endocrinological systems are still largely unknown. This study emphasizes the need for ongoing endocrinological support for these patients as well as further research into the long-lasting impact bone marrow transplants can have on these patients.

Joining forces in endocrine cancer genetics

Karin van der Tuin
Leiden University Medical Center (LUMC), Clinical Genetics, Leiden, Netherlands

Patient- and family center edendocrine cancer care encourages active collaboration between the departments of endocrinology, oncology, surgery, pathology, chemistry, radiology, nuclear medicine and clinical genetics. The implementation of high-throughput DNA/RNA sequencing platforms has allowed novel molecular information to be used to optimize primary endocrine cancer care including tumor classification, prognostic forecasting, stratification for targeted treatment in recurrent disease and the identification of patients at high risk for tumor development. Multiple Endocrine Neoplasia (MEN) type 1–2 and von Hippel-Lindau syndrome were among the first hereditary tumor predisposition syndromes to be recognized and over time the number of endocrine tumor syndromes and associated genes has expanded significantly. Depending on the specific endocrine tumor type, 10–30% of cases are associated with genetic factors, in which up to 15 different genes per tumor type may be implicated. The proportion of inherited disease in the context of the totaldisease population in clinical practice might be an underestimate owing to still unidentified genetic causes orbecause heredity is not recognized due to an unavailable, incomplete or misdiagnosed family history and/or variable penetrance. Identification of a causative germline mutation may not onlyhave important clinical implications for the index patient (proband), it also facilitates cascadetesting and surveillance of relatives in order to prevent, or at least allow early identification of, (pre)malignant conditions. Current challenges in known tumor predisposition syndromes include accurate estimates of variant pathogenicity, disease penetrance, genotype-phenotype relationships and the variable phenotypes within families, and from there to tailored treatment and surveillance guidelines. While endocrine neoplasia syndromes show many features commonly seen in familialdisease (early onset, family history, multifocal neoplasia, multiorgan involvement), some of these syndromes are considered to be phenotypically complex and heterogeneous. The use of whole exome sequencing for diagnostic and research purposes may lead to identification of a syndrome that was not in the initial differential diagnosis. The drawback of testing many genes is the complex interpretation of the results. Pre-test genetic counseling to establish the preferred sequence modality and tiered informed consent is therefore of utmost importance. Improving endocrine cancer genetics requires not only local, national and international collaborations between the medical disciplines involved but also the interaction between basic and clinical research, taking research from bench to beside and back again.

Patient perception and views on quality of care for rare endocrine diseases. Results from an EndoERN survey

Susan Webb[1], Jette Kristensen[2], Diana Vitali[3], Sandra van Klink[4], Charlotte van Beuzekom[4] & Anna Nordenström[5]
[1]Hospital S Pau, IIB-Sant Pau, Research Center for Pituitary Diseases; Centro de Investigación Biomédica en Red de Enfermedades Raras

(CIBERER, Unidad 747), ISCIII; Universitat Autònoma de Barcelona (UAB), Department Medicine/Endocrinology, Barcelona, Spain; [2]Danish Addison Patient Association, Aarhus, Denmark; [3]ePAG & Chair of Associazione Displasia Ottica e Ipoplasia del Nervo Ottico, Rome, Italy; [4]Endo-ERN Coordinating Center, Leiden, Netherlands; [5]Pediatric Endocrinology, Astrid Lindgren Children´s Hospital, Karolinska University Hospital, Stockholm, Sweden

Introduction
An aim of the ERNs is empowering patients, by education & learning about their experiences after diagnosis of a rare endocrine disease (RED), to identify gaps and improve outcome. Thus, EndoERN Work Package 4 designed a survey, to learn about patients perceptions on quality of care and existing gaps in diagnosis/management.
Aim
Evaluate results of a 21 question survey answered on-line on a Likert scale by individual patients with RED or support groups.
Patients and method
questions were answered in their own language, related to delay and number of professionals contacted before correct diagnosis, time to find a specialist and specific treatment, satisfaction with current treatment, information received and health care follow-up, possibility of access to specific specialist support, and if not, whether they would have liked to have this access, availability of written information on their condition, contact with patient/support groups, and impact of their condition on everyday quality of life.
Results
There were 598 responses from 25 countries (58% individual patients, 34% patient groups and 8% both); 66% were females. Data from pituitary, adrenal, thyroid, parathyroid, gonadal, genetic and autoimmune endocrine diseases were collected. While in 36% a diagnosis was made in <1 year, in 28% it took more than 5 years. In 64% it took 2 to 7 professionals to reach correct diagnosis, after which in more than half a specialist/specific treatment was available within 1 month; 60% manifested being satisfied with current treatment. As far as access to other health professionals, the majority (59 to 67%) manifested not to have had access to specific psychological support, psychologist/social worker, dietician or physiotherapist/rehabilitation specialist, but would have liked to (42 to 49%), As far as information on their condition, treatment possibilities, and degree of satisfaction with health care follow-up, around half were either satisfied or very satisfied; 53% had received written information on their condition and 87% had contacted patient/support groups; 78% declared to completely or moderately agree with the sentence 'The personal limitations related to the disease, impact on my everyday quality of life'. Conclusions: Diagnostic delay is a problem in RED, although once diagnosed, access to specific specialists and treatment was mostly <1 month. Most are satisfied with treatment despite significant impact of their condition on their lives and difficulties to access all desired health professionals. Whether these results are extensible to all European patients with RED is unknown.

AEP549

True hyponatremia – An unusual side effect of IV Immunoglobulins

Elena Daniela Aflorei[1], Amanda Jane Bracken[2], Roxana Stanciu[3], Dan Tanase[3] & Ngai Kong[1]
[1]Stockport NHS Foundation Trust, Diabetes and Endocrinology Departament, Stockport, United Kingdom; [2]Stockport NHS Foundation Trust, Pharmacy Departament, Stockport, United Kingdom; [3]Stockport NHS Foundation Trust, Chest Medicine Department, Stockport, United Kingdom

Background
Guillain-Barré syndrome is a rare but very serious autoimmune disorder and it's caused by the immune led demyelination of the peripheral nervous system. The symptoms are mainly weakness and numbness, but can also consist in severe respiratory failure due to paralysis. The treatment consist in administration of intravenous immunoglobulins (IVIGs) which shorten the duration of disease.
Case presentation
A 67 year-old man was referred to our Endocrinology team due to hyponatremia. The patient was admitted in the hospital 6 days previously due to 1-day history of hand and legs numbness and weakness. He denied any recent history of trauma to the spine Two weeks prior to this current emergency visit, he complained of flu like symptoms and upper respiratory tract infection. On admission he was alert, and not in respiratory distress. His presenting vitals were stable. Neurological: reduced tone, muscle power of 4/5 bilateral upper and lower limbs, absent tendon reflexes at the patellas and ankles, bilateral downgoing plantar response and reduced sensation to soft touch and pin prick from knee below. The cranial nerves were intact. Examination of cardiovascular, respiratory systems, abdominal and skin were unremarkable. His full blood count, renal and liver function, cardiac enzymes, blood gas were within normal limits.
Patient received 5 days of IVIGs and then the Sodium dropped to 125 mmol/l. This was considered SiADH, started on fluid restriction and referred to Endocrinology. Seen by our team 48 h later (bank holiday) – patient was stable but worsening hyponatremia.
Initial impression
Pseudohyponatremia secondary to IVIGs (this medication is known can increase plasma Osm).
Final Diagnostic
True Hypotonic Hyponatremia as further investigations revealed low Plasma Osmolality 263 mmol/kg with significant increased Urine Osmolality (687 mmol/kg) and loss sodium in the urine. The fluid restriction was stopped and for next few days the hyponatremia actually initially worsen (lowest Na 117 mmol/l) due to a very complex mechanism. The patient received iv fluids and slow salt tablets for 3 days. The Sodium level had slowly improved and remained stable. We reviewed other cases which were previously treated with IVIG. Unfortunately the data was limited but other cases of hyponatremia post IVIGs were identified.
Conclusions
We would like to highlight our case for the need to be vigil about such complications and to avoid fluid restriction in cases of patients treated with IVIGs as this can worsen hyponatremia.

Publication outcome of abstracts presented at European Congress of Endocrinology via web scraping and automated searches

Emre Sedar Saygili[1] & Bulent Okan Yildiz[2]
[1]Endocrinology Clinic, Canakkale State Hospital, Turkey; [2]Department of Internal Medicine, Division of Endocrinology and Metabolism, Hacettepe University, Ankara, Turkey

Background
Conversion rates of the presentations into publications could be a measure of the scientific Impact of a conference. The aim of the current study was to determine the publication rates of abstracts presented at the 16th European Congress of Endocrinology (ECE 2014) and the factors affecting these rates by using computer algorithms specially coded for this analysis.
Methods
All presentations of the ECE 2014 were collected with the web scraping – Python coding from official website and converted into the desired formats. Parameters were transformed to Google Scholar and PubMed search links with coding. A special interface was coded to evaluate the results of the three searches on the same screen and to save the results into the database. Web Scraping was coded in Python version 3.4 with the open source code/module BeautifulSoup version 4.4.0. The time frame for publication search was between May 2013 and August 2019.
Results
A total of 1205 abstracts from 71 countries were featured. Among these, 1145 (%95) were poster presentations and 60 (%5) were oral presentations. Subsequently, 341 abstracts (28.3%) were published as a full paper. The conversion rates to publication for oral and poster presentations were 65% and 26.4% respectively (OR : 5.18, 95% CI : 3.0–8.96, $P<0.01$). The median time to publication was 12 months (IQR : 2–24 months). Impact Factors (IF) of publications from oral and poster presentations were median IF of 5.0 (IQR : 3.83–5.96), and 2.94 (IQR : 1.77–3.83), respectively ($P=0.01$). Median number of citations of publications from oral and poster presentations were 12 (IQR : 6–33) and 6 (IQR : 2–15), respectively ($P=0.01$). A total of 90 (7.5%) multi-country abstracts were identified. Multi-country collaborative studies were turned into more publications than single-country studies (OR: 3.91 95% CI : 2.52–6.06, $P<0.01$). As of August 2019, a total of 3835 citations to the papers generated from ECE 2014 were identified with a median of 6 (IQR: 2–17) at the Web of Science. The congress potential impact factor was calculated as 3.18.

Table 1 Publication conversion rates according to type of studies.

	Presented (n, %)	Full Publication (n, %)
Clinical studies	739 (61.3%)	222 (30%)
Case reports	301 (25%)	49 (16.3%)
Basic/translational studies	165 (13.7%)	70 (42.4%)
Total	1205	341

Conclusion
This first study evaluating the publication outcome of ECE shows that 28.3% of the abstracts presented at the congress are published with 12 months of median time to publication.

AEP551

TNF-α induces hyperpolarization in agrp neurons without affecting pomc neurons of the arcuate nucleus

Fernanda Chaves[1], Renata Frazao[2] & José Donato Junior[1]
[1]Institute of Biomedical Sciences, Department of Physiology and Biophysics, São Paulo, Brazil; [2]Institute of Biomedical Sciences, Department of Anatomy, São Paulo, Brazil

Neurons expressing the agouti-related protein (AgRP) and the pro-opiomelanocortin (POMC) are part of the central system responsible for regulating energy balance and food intake. The hypothalamus is sensitive to changes in the inflammatory state. Either high-grade inflammation (e.g., caused by sepsis) or low-grade inflammation (caused by obesity) disturbs the hypothalamic function via inflammatory cytokines. Understanding how these cytokines interact and regulate the circuits that control energy homeostasis is critical to understanding the pathophysiology of energy balance disorders. AgRP or POMC reporter mice were used to evaluate the acute electrical effects of interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) on these neurons through whole-cell patch-clamp. Our results showed that 73% of AgRP cells were active and 27% quiescent during the recordings ($n=33$ cells from 19 mice, 24 active and 9 quiescent). IL-6 (10 ng/ml) had no effect on theresting membrane potential (RPM) or membrane resistance(IR) of AgRP neurons. In contrast, TNF-α (20 ng/ml) induced a significant hyperpolarization in approximately 31.5% of registered cells (6 out of 21 neurons, change in RPM: -9.8 ± 0.9 mV; $P<0.0001$), although a non-significant reduction in the IR ($P=0.5$) was observed. Regarding POMC neurons, we found that 61% of POMC cells were active and 39% quiescent during the recordings ($n=38$ cells from 22 mice, 23 active and 15 quiescent cells). Both IL-6 and TNF-α had no significant effects on the electrical properties of POMC neurons. Therefore, these findings suggest that cytokines that are altered during sepsis or obesity may affect the activity of neuronal circuits that regulate energy balance. Additionally, the acute inhibitory effect of TNF-α on AgRP neuronal activity may explain the suppression in food intake observed during situations of high-grade inflammation.

AEP552

The extent of variation in the reporting of clinical activity by reference centres in the field of rare pituitary and thyroid disorders within Endo-ERN, a new reference network for rare endocrine conditions in Europe

Friso de Vries[1], Mees Bruin[1], Angelica Cersosimo[1], Faisal Ahmed[2], Robin Peeters[3], Nienke Biermasz[1], Olaf Hiort[4] & Alberto Pereira[1]
[1]Leiden University Medical Center (LUMC), Endocrinology, Leiden, Netherlands; [2]Queen Elizabeth University Hospital, Glasgow, United Kingdom; [3]Erasmus MC, Rotterdam, Netherlands; [4]Universitätsklinikum Schleswig-Holstein – Zentrale Lübeck, Lübeck, Germany

Objective
Self-reported volume of patients and specific interventions is a specific network criterion that needs to be fulfilled by reference centres that are eligible for inclusion within Endo-ERN. The aim of the present study is to evaluate how self-reported volume data in the original applications were obtained, which data are retrievable, and which set is best suitable to use for future centre evaluations. This overview is provided for two Main Thematic Groups (MTGs) of Endo-ERN: Pituitary and Thyroid.
Design and methods
Review of application forms and continuous monitoring data of Endo-ERN and a survey distributed to participating centres. A list of 'key procedures' for the assessment of the performance of RCs was composed with the help of the chairs of the concerned MTGs.
Results
In the application forms, the variation in number of procedures ranged from 20 to 5500/year for Pituitary and from 10 to 2700/year for Thyroid). The survey response rate was 63% for both MTGs. The number of performed key procedures also varied widely. However, ranges were significantly smaller than those of performed procedures in general. The median numbers of new patients reported for the ERN continuous monitoring program (2017 and 2018) were comparable with those reported in the application and survey, however, some centres reported large alterations in the number of new patients.
Conclusions
The number of new patients, patients under chronic care, and related procedures vary widely between RCs. In addition to the size of the practice, this is also due to non-uniform definitions of new patients and procedures used by the reporting RCs. Application of uniform definitions, in addition tothe development of MTG subtheme specific performance indicators, is urgently needed. This will allow a more reliable assessment and comparison of RC and overall Endo-ERN performance.

AEP553

'I would say this is a good clinic for friends & family to be looked after in if they need similar treatment or care' – Young Adult Endocrine (YAE) Service Evaluation

Chona Feliciano, Helena Gleeson & Andrew Toogood
University Hospital Birmingham, Department of Endocrinology, Queen Elizabeth Hospital, Birmingham, United Kingdom

Aim
To evaluate the current service provisions and provide action plan for improvement within the YAE service.
Methods
A friends and family questionnaire given to all patients attending the YAE service from October 2018 – January 2019. Survey questions included: whether they thought this was a good clinic for friends and family to be looked after in, what we did well and what we could do better. For YA patients transferring from children's service, additional questions included whether: they think their transfer went smoothly, if they met a member of the adult team before transfer and they know the name of someone to contact, as well aswhat we did well and what we could do better.
Results
There were a total of 111 young adults (YA), age 16–24 years old, who completed the friends and family questionnaire. 58 (52%) were aged between 16–19, 53 (48%) had transferred from children's services, 52 (47%) were attending for their first or second appointment. About 99 (88%) agreeda lot or a bit with the following statement 'I would say this is a good clinic for friends & family to be looked after in if they need similar treatment or care'. They found the staff friendly and helpful. 20 YA patients made suggestions including more wide range of leaflets, to be seen by the same consultant, exercise advice, free gym membership, more information on pregnancy issues and conduct-skype appointments. For YA patients that had transferred from children's service; 48 (90%) agree that the transfer had gone smoothly for them, 39 (74%) were aware of meeting a member of the adult team and 38 (72%) knew the name of someone to contact. 9 (17%) YA patients offered suggestions for improvements, including more support after the appointment, less confusing by speaking 'smaller' words and days where just young people come to clinic. YA patients highlighted issues with the appointment system.
Conclusions
This YAE service evaluation has demonstrated that the majority of YA patients are satisfied with the service and felt that transfer went smoothly. However, improvements are required to comply with national transition guidance and meet the needs of YA patients.

Neurofibromatosis type 1: About two cases

Aicha Bouzid[1], amina laloui[2], Djamila Meskine[3] & Said Azzoug[1]
[1]Medical University of Algiers, Endocrinology & Métabolism Laboratory Algiers 1,EPH Bologhine, Medecine, Algiers, Algeria; [2]EPH Bologhine, Medecine, Algiers, Algeria; [3]Medical university of algiers. EPH Bologhine, Medecine, Algiers, Algeria, Medecine, Algiers, Algeria

Neurofibromatosis type 1 is a genetic multisystemic disorder involving the skin, the central and peripheral nervous systems, bones, and the cardiovascular and endocrine systems. We report 2 cases of type 1 neurofibromatosis in 2 patients aged 27 and 23 years respectively. The dermatological lesions (neurofibroma and café au lait spots) were the revealing symptoms. Cerebral MRI revealed a glioma of the optic chiasm developing along the Optic nerves. NF1 has been known for 10 years in the 1st patient, the glioma is stable to differences in imaging controls, after the opinion of the neurosurgeon, radiotherapist and oncologist, simple monitoring is recommended, progress is currently favorable, the search for other lesions is negative. Concerning the youngest patient, the diagnosis of NF1 is recent, the dermatological lesions have been evolving for 3 years, in addition to the glioma, he has a cystic nodular lesion of 18 mm in the pineal region and a delay in stature and Lisch nodules, the search for pheochromocytoma is negative and the abdominopelvic CT scan is without abnormalities, the hormonal assessment is in progress.
Discussion
The gene responsible for NF1 is a tumor suppressor gene, has been located on chromosome 17 in region 17 Q 11, 2. It codes for the protein neurofibromin. Its penetrance is close to 100% at the age of 5 and de novo mutations represent around half of the cases. Neurological manifestations are frequent, exist in half of the cases. 15 to 20% of patients have tumors of the nervous system (gliomas, astrocytomas, neurofibromas). Glioma of benign histology, can sit at any level of the optic pathway, and is expressed by exophthalmos, reduced visual acuity, visual field impairment, precocious puberty by hypothalamic involvement and rarely hydrocephalus, but often asymptomatic and without progression, thus recommending a systematic ophthalmological evaluation (visual examinations, cerebral and orbital MRI) annually mainly in the population of children under 10 years of age and more widely spaced in adults. as well as a systematic search for precocious puberty. The treatment is based on chemotherapy allowing stabilization see tumor reduction. NFI is a genetic disorder responsible for disorders in the differentiation of ectodermal tissue. Despite the discovery of the gene responsible for this disease, the diagnosis remains clinical and is based on defined criteria. Progressive lesions are however very rare and their frequency is very different according to age. In the absence of clinical signs predicting these, clinical monitoring is advised.

Invivo endocrine internet: An unique model of endocrine system

Ramakanth Bhargav Panchangam[1], Ramesh Bangaraiahgari[2], Rafi Mohammad[2], Sabaretnam Mayilvaganan[3], Rajesh Bangaraiahgari[4] & Rajkiran Reddy Banala[5]
[1]Endocare Hospital, Endocrine Surgery, India; [2]Surabhi Medical College, Biochemistry, India; [3]SGPGIMS, Endocrine Surgery, India; [4]Surabhi Medical College, Anatomy, India; [5]Sri Rishika Life Sciences Pvt Ltd, Genetics, India

Background
Endocrine system (ES) is unique amongst all organ systems (OS) in human body. ES is a conglomeration of different endocrine organs. So far, the only models of proof o fintegrity within ES are APUD cell concept; HPA axis; HPG axis; biochemical pathways of hormones. But, the flaws in the above models are their presumptive and extrapolative nature. We wanted to test a model that every endocrine disease has collateral effect on other endocrine organs. We took nontoxic goiter (thyroid) and primary hyperparathyroidism as prototypes.
Material and methods
This prospective case-control study was conducted on 300 cases (270 thyroid and 30 parathyroid) and age matched 300 controls from healthy blood donors over a period of 12 months. Institutional ethical committee approval was obtained. All thyroid and parathyroid cases underwent uneventful curative thyroidectomy and parathyroidectomy respectively. Exclusion criteria were subjects with any febrile illness, candidates with stress, anxiety neurosis, allergies, chronic drug use, diabetes, systemic or chronic inflammatory disease or calcium/vitamin D supplements, any medication which interferes with the normal function of the hypothalamic-pituitary axis, menopausal age group. Serum samples were collected preoperatively, from all the subjects in both groups as per the standard collection times and procedures. Statistical analysis was performed by SPSS 20.0. *P* value of <0.05 was considered significant.
Results
Mean prolactin, Luteinising hormone (LH), follicular stimulating hormone (FSH), parathormone, cortisol and testesterone in thyroid cases and controls were 28.6±8.2 ng/ml (12–87), 24.3±1.9 IU/l (10–57), 16.6±3.4 IU/l (8.4–41), 23.5±4.7 pg/ml (15–65), 7.2±2.4 mg/dl (4–16.5),256±57 ng/dl (167–478) and 14.5±3.4 ng/ml (8–18), 11.4±2.5 IU/l (2.5–12.5), 6.2±2.9 IU/l (3.5–21), 21.1±5.3 pg/ml (9–46), 11.2±3.6 mg/dl (5.5–19), 212±45 ng/dl (115–368) respectively. There was statistically significant difference of prolactin, LH, FSH and cortisol values between thyroid cases and controls. But statistical difference was significant only for prolactin, FSH and LH between parathyroid cases and controls.
Conclusions
Our study highlights an unique model of endocrine homeostasis and integrity of ES. The results provides a distinct opportunity to screen and pre-emptively treat subclinicalendocrine diseases. But, the exactpathophysiological mechanism and significance ofhormonal interplay between varied endocrine organs needs active research.
Keywords: thyroid, parathyroid, prolactin, goiter, cortisol, insulin.

Autoimmune polyglandular syndrome (APS) type 2 associated with chronic kidney disease

Ibrahim El Ebrashy, Hemmat ElHaddad, Heba Moustafa, Hoda El Rawi, Samar Amin, Aya Taraby, Randa Salam & Mohamed Magdi
Cairo University, Endocrinology department, Cairo, Egypt

Introduction
Autoimmune polyglandular syndrome (APS) is a rare disease, that is defined by the presence of two or more glandular insufficiencies caused by autoimmune mechanisms and that may be associated with other pathologies and immunological phenomena. It is characterized by the Presence of circulating organ specific antibodies and lymphocytic infiltration of the affected gland.
Case report
A 38-year-old female known to have autoimmune polyglandular syndrome type 2. 14 years ago, she wasdiagnosed with hypothyroidism and primary adrenal insufficiency on Eltroxin 100 mg and hostacortine 5 mg. 4 years ago, she developed type 2 diabeteson insulin mixtard 34 U before breakfast and 12 U before dinner. She had secondary amenorrhea for 4 years ago. Referred from emergency department with hyperkalemia.
On examination
The patient is fully conscious, Pulse: 90 beats/minute/BP: 190/100/RR: 16–20/minute, BMI: 23.55 kg/m^2. Normal head and neck, cardic, chest, abdominal examination.
Investigation showed.
Leukocytosis (white blood cells: 14,100 cells/µl) with a neutrophil count of 84.9%), HB 13.1, normal coagulation profile, elevatedurea 79 mg/dl, elevated creatinine 1.15 mg/dl, low eGFR56 ml/mit, normal urine analysis, Albumin/Creatratio: 10 mg/mmol, normal sodium level. 135 mEq/l, hyperkaleamia (Potassium 9.7 mEq/l), normal calcium (9.2 mg/dl) normal phosphrous (4.9 mg/dl), hyperurceamia (8.3 mg/dl), arterial blood gases showing metabolic acidosis (pH: 7.31, PCo2: 33.2 mmHg, HCo3: 16.7 mmHg, Anion Gap: 12.6). Negative HCV, HBsAG. Renin >128 pg/ml(4–46)/Aldosterone 50.3 pg/ml (30–350). Thyroid profile normal (TSH: 2.82 mIU/l,FT4: 1.4 µg/dl, F T3: 91 ng/dl). Positive anti TPO. Post-menopausal FSH: 80.4 IU/l/post-menopausal LH: 84.3 IU/l. A 12-lead ECG revealed normal sinus rhythm with no hyperkalemic changes Abdominal sonar: Bilateral small sized kidneys. She sought medical advice and wasfound to have renal impairment (Creatinine 4 mg/dl then dropped to 1.4 mg/dl following hydration with IV fluids). Repeated admission with hyperkalemia resistant to anti hyperkalemic measures without any ECG changes and was placed on Kayexalate. Interstitial nephritis wassuspected however, our patient refused to do renal biopsy. Last creatinine done 1.5 mg/dl, eGFR 41 ml/mint. Here, we reported a case of APS-2 with an uncommon condition involved 3 endocrine organs (thyroid, adrenal, and ovarian) with interstitial nephritis.
Conclusion
Patient education, detailed evaluation, and long term follow up of patients and first-degree relatives for possible co-existence of diseases are the cornerstones for managing patients with APS.

Role of endocrine specialist nurse in early inpatient discharge

Anna Hawkins, Nancy Enriquez, Edel Casey, Stuart Jones, Frederick Nkonge, Eltayeb Marouf, & Khash Nikookam
Barking, Havering & Redbridge University Hospitals NHS Trust, Endocrine and Diabetes, Ilford, United Kingdom

Adult endocrine specialist nursing (ESN) is a highly specialised role and in recent years nurses have expanded their roles according to local need (Kieffer.V, *et al.* 2015). As an Endocrine team we review our practice, striving to provide the highest standard of research based, patient centred care. This involves ensuring the best use of resources and service provision in an ever more demanding environment. A new initiative lead by the ESN with consultant supervision was put in place to offer, where clinically feasible on selected inpatients the option of early discharge with next day review of pending results and/or medication adjustment. Our patients were selected from acute medical wards undera Diabetes and Endocrine speciality. During 2019 the consultants identified 45 different patients who would be eligible for early discharge. They were given an appointment to return to the early discharge clinicswhich were set according to demand, Monday to Friday by the lead ESN. Of these patients 27 had an endocrine condition/s and 18 were diabetes related. Patients generally required between 1 to 3 appointments. In total 68 clinic visits were needed, which equates to freeing up a minimum of 74 bed days. Of those who attended 100% were very satisfied with the care received and the reduced length of their hospital stay.
Conclusion
Following this trial we are putting forward a business case to increase the ESN capacity, with consultant supervision, to offer the early discharge clinic to other wards. This would ensure patients are seen by the right specialist, in a timely manner, in the most appropriate environment (endocrine investigation unit). Patients will receive the best possible care while ensuring better utilisation of bed capacity and junior doctor's time which can subsequently be redirected towards ever changing demands in the hospital/s.

Delay in diagnosis and clinical course of autoimmune polyglandular syndrome

Rada Sparavalo[1] & Sanja Borozan[2]
[1]General hospital Niksic, Endocrinology, Niksic, Montenegro; [2]Clinical Centre of Montenegro, Endocrinology, Podgorica, Montenegro

Autoimmune polyglandular syndromes (APS) are a rare group of autoimmune disorders that affect more than one endocrine gland, although non-endocrine organs can be involved. Concerning the variable evolution of this clinical entity over time, our case aims to emphasise the importance of regular follow-up and screening for polyglandular autoimmunity in selected patients in order to decrease a possibility of future complications consistent with APS. We report the case of a 20-year-old female presented with frequent episodes of hypoglycemia over the last 2 years, extreme fatigue, weight loss, nausea, vomiting, abdominal pain and secondary amenorrhea. She was diagnosed with type 1 diabetes mellitus (T1DM) at the age of 6 years and necrobiosis lipoidica at 9 years. Her mother has primary hypothyroidism and celiac disease while her second-degree maternal lineage was positive for type 2 diabetes mellitus, brain tumour, Wiskott-Aldrich syndrome and primary immune thrombocytopenia. On physical examination, she was unconscious, hypotensive, with diffuse cutaneous hyperpigmentation and BMI of 17.6 kg/m^2. Initial biochemical investigations showed blood glucose of 0.8 mmol/l, hyponatremia, hyperkalemia, low-normal calcium level (ionized calcium 1.12 mmol/l), hemoglobin A1c of 11.1%. Serum cortisol in daily profile was 19.2.13.3.16.4 nmol/l, ACTH 668.7 pg/ml (7.2–63.3 pg/ml), anti-adrenal antibodies positive at 1 in 160 dilutions. PTH 1,73 pmol/l (1.6–8.6 pmol/l), vitamin D 19.6 nmol/l. Anti-ovarian antibodies 14 U/ml (normal below 10 U/ml). Thyroid hormones and antibodies and were normal; screening for celiac disease negative. The diagnosis of autoimmune adrenal insufficiency was established and the treatment with Hydrocortison initiated, with good clinical response on 3-month follow-up visit. Menstrual cycles are resumed. PTH and calcium values are still low-normal, despite vitamin D supplementation, requiring additional periodical assessment. In a patient with T1DM and a positive family history, further recommendations are needed to alert psysicians about timely serological screening for coexistence of other autoimmune disorders in order to exclude APS.

Activity of pure, novel and non-steroidal molecules as inhibitors of AK1C enzyme

Marisa Cabeza[1], Jhoan H. Piermattey Johan[2], Ricardo Gaitán-Ibarra[2], Juan Soriano[3] & Yvonne Heuzr[4]
[1]Universidad Autónoma Metropolitana-Xochimilco, Sistemas Biológicos, Mexico DF, Mexico; [2]Universidad de Cartagena, Doctorado en Ciencias Biomédicas, Cartagena, Colombia; [3]Hospital General de México, Patología, Mexico DF, Mexico; [4]Universidad Autónoma Metropolitana-Xochimilco, Producción agrícola y animal, Mexico DF, Mexico

Prostate and seminal vesicles are male accessory sex glands secreting fluids that, together with sperm, form the semen. Clear evidence indicating these organs depend on androgens was found the men suffering hypogonadism because, in them, the function of these glands decreases markedly. Because prostate and seminal vesicles are androgen-dependent organs, they have been used as a model to test antiandrogenic drugs in different animal species.
The objective of this study was to demonstrate the antiandrogenic effect of two pure, novel, and non-steroidal molecules (JP01B and JP03) on the hamster's prostate and seminal vesicles.
The biological activity of both compounds was determined as *in vivo* as *in vitro* experiments. The *in vivo* experiments were performed in hamsters castrated and treated with testosterone (T), T, and finasteride/or each one of the new compounds. For the *in vitro* experiments to determine the metabolism of radiolabeled T en the presence or absence of JP01B and JP03, we followed the conversion of T into their radiolabeled metabolites using the human prostate homogenates as a source of steroidal enzymes. The results indicated that JP01B and JP03 significantly decreased the weight of the seminal vesicles but not that of the prostate. However, treatment with T and finasteride (an inhibitor of DHT formation) reduced the mass of both glands. *In vitro* experiments indicated that both new compounds inhibited the activity of the AK1C enzyme by decreasing the formation of labeled 5α-androstane-3β, 17β-diol compared to the control. However, an accumulation of 5α-dihydrotestosterone (DHT) was determined, which also indicates the presence of the enzyme 5α-reductase. It is a well-known fact that DHT increases the weight of the prostate and seminal vesicles. These data could explain that hamsters treated with T and JP01B or T and JP03 did not reduce prostate growth. However, this does not clarify why the seminal vesicles did significantly reduce their weight. One interpretation could be the presence of estrogen receptor β (ERβ) in this tissue, as has been previously demonstrated. The ERβ is capable of inducing mitosis of epithelial cells, cell morphogenesis, and secretory modulation of specific proteins in the seminal vesicles. Therefore, data suggest that JP01B and JP03 could also be ERβ antagonists in seminal vesicles.

Proliferation index (Ki67) is a powerful predictor of recurrence in pituitary adenoma

Hugh Logan Ellis, Evi Xekouki, Andy King, Nick Thomas, Sinan Barazi, Eleni Maratos, Peter Bullock, Benjamin Whitelaw, Jackie Gilbert & Simon Aylwin
King's College Hospital, United Kingdom

Introduction
In 2017 the term 'Atypical adenoma' was removed from the WHO classification, and 'High-risk adenomas' was introduced as a term to classify those with rapid growth, radiological invasion, and a high Ki-67 proliferation index. In this retrospective cohort study we have sought to identify the clinical and histological characteristics which are associated with worse outcomes.
Methods
Data
We created a dataset of 1793 patients who were discussed at the Pituitary MDT at King's College Hospital, a tertiary centre in central London from the electronic medical record. The nature and date of treatment was recorded as well as clinical characteristics which were hypothesised to be significant. Survival analyses were performed using cox regression, events were recorded as time of re-operation or radiotherapy, patients were censored at time of last follow-up within the electronic patient record. Incidences when radiotherapy or re-operation which occurred less than one year after the initial

treatment were not included within the analysis as these were treated as primary treatment failure rather than recurrence.
Results
Ki67 was strongly associated with recurrence in a multivariate model ($P<0.05$). Hazard ratio 1.08 (95% CE 1.04–1.14). We created risk groups of low (<3%), intermediate (3–9%) and high (<9%) which were also statistically significant ($P<0.05$, (when compared with <3%). Hazard ratios were1.7240 (95% CE 1.1597–2.563) and 2.8109 (1.6804–4.702) respectively. Male sex was also significantly associated with reccurance ($P=0.003$, HR = 1.5873 (1.1648–2.163). The above findings remained the case when only NFPAs were analysed. For non-functioning adenomas, initial presentation with a visual field deficit was a significant hazard for recurrence ($P<0.05$, HR = 1.6300 (1.0740–2.474)). There was no significant increase in hazard between silent corticotroph and other types of non-functioning adenoma.
Discussion
These results demonstrate that the previous 'atypical adenoma' category may be of clinical value. In this cohort Ki67 could be used to stratify patients by risk.

The expression level and binding affinity of glucocorticoid receptors in patients with Cushing's syndrome

Qi Zhang, Hui Liu, Zhen Xiao & Yerong Yu
Sichuan University West China Hospital, Department of Endocrinology and Metabolism, Chengdu, Sichuan, China

Summary
Objective
To evaluate the expression level and binding affinity of glucocorticoid receptors (GRs)in patients with endogenous Cushing's syndrome(CS) and to determine whether there is partial glucocorticoid resistance.
Methods
Fifty-eight patients with CS and forty-one age- and sex-matched healthy volunteers were studied. The expression level and binding affinity of GRs in peripheral blood mononuclear cells (PBMLs) were examined by flow cytometry (FCM). The differences between the two groups were compared, and the correlations of GR level and affinity with serum cortisol concentrations and 24-h urinary free cortisol (UFC) were also analyzed.
Results
The expression level and binding affinity of GRs in CS patients were 11.9±2.6 and 5.7±2.0, while the values of normal controls were 21.5±3.4 and 10.7±2.4, respectively. There was a significant decrease in GR expression and binding affinity in the patients with CS. No correlation was observed between serum cortisol concentrations or 24-hour UFC and GR expression or binding affinity in CS patients.
Conclusion
The expression level and binding affinity of GRs are obviously decreased in patients with CS. To overcome glucocorticoid resistance and avoid glucocorticoid withdrawal syndrome after surgical resection of the causal tumor, a higher than physiological dose of glucocorticoid replacement should be given to CS patients after surgery.

Osteopathy is an emerging complication of acromegaly, characterized by increased bone turnover, profound abnormalities in trabecular bone structure and high risk of vertebral fractures (VFs). The therapeutic management of skeletal fragility in acromegaly is a challenge, since the risk of fractures may remain high after the control of acromegaly and the effectiveness of bone-active drugs in this clinical setting is unknown. In this retrospective-multicenter study, we aimed at evaluating the effectiveness of bone-active drugs on risk of VFs in patients with active or controlled acromegaly. Two-hundred-forty-eight patients with acromegaly (114 females; median age 57 years, range 21–88; 137 patients with active acromegaly) were evaluated for prevalent and incident VFs by a quantitative morphometric approach. At the study entry, prevalent VFs were found in 78 patients (31.5%). Treatment with bone-active drugs was performed in 52 patients (21%): oral bisphosphonates in 39 cases, oral raloxifene in 2 cases, oral strontium ranelate in 1 case, i.v. zoledronate in 1 case, s.c. teriparatide in 3 cases, s.c. denosumab in 3 cases, multiple therapies in 3 cases. The median follow-up was 48 months (range: 12–132); for homogeneity, the follow-up was categorized in 1–2 years (48 cases), 2–4 years (84 cases), 4–6 years (93 cases) and >6 years (23 cases). During the follow-up, 65 patients (26.2%) experienced incident VFs in relationship with pre-existing VFs (HR 2.76; C.I. 95% 1.64–4.65; $P<0.001$) and duration of active acromegaly (HR 1.01; C.I. 95%, 1.002–1.02; $P=0.005$), independently of age ($P=0.39$), sex ($P=0.45$), hypogonadism (P-0.99) and diabetes ($P=0.94$). Treatment with bone-active drugs decreased the risk of incident VFs only in patients with active acromegaly at the study entry (HR 0.20, C.I. 95% 0.06–0.68; $P=0.01$), independently of prevalent VFs ($P=0.002$). The effect of bone-active drugs on risk of VFs was not statistically significant in patients with cured/controlled acromegaly (HR 0.61, C.I. 95% 0.26–1.40 $P=0.24$). In conclusion, this multicenter study showed for the first time that bone-active drugs (i.e., most of them with inhibitory effects on bone resorption) may prevent VFs in patients with active acromegaly. Future prospective studies are needed to assess whether anabolic and anti-resorptive bone-active drugs may have different effects in decreasing the risk of VFs in patients with active and controlled acromegaly.

Macrophages involvement in neuroendocrine tumor behaviour and progression

Ilena Boemi[1], Eleonora Vitali[2], Giampaolo Trivellin[3], Valeria Smiroldo[4], Elisabetta Lavezzi[4], Alessandro Zerbi[5], Constantine Stratakis[3] & Andrea Lania[4]
[1]Humanitas Clinical and Research Institute, Cellular and Molecular Endocrinology Laboratory, Rozzano, Italy; [2]Humanitas Clinical and Research Institute, Department of Medical Oncology and Hematology, Rozzano, Italy; [3]NIH Clinical Center, Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States; [4]Humanitas Clinical and Research Institute, Endocrinology and Diabetology Unit, Rozzano, Italy; [5]Humanitas Clinical and Research Institute, Pancreas Surgery Unit, Rozzano, Italy

Neuroendocrine neoplasms (NENs) are rare tumour showing a wide spectrum of clinical behaviours. Therapeutic options available for NET treatment are rarely curative and mostly palliative, as NETs frequently show resistance to pharmacological therapy. Cancers develop in complex tissue environments, which they depend on. Tumour-associated macrophages (TAMs) are a major cellular component of the tumour microenvironment. Two polarized state of macrophages are described in literature: M1 (anti-tumour promoting effects) and M2 (pro-tumour promoting effects). The role of macrophages

in pancreatic (Pan-) and pulmonary (Lung-) NENs is poorly understood. So, a better understand of the role of macrophages could provide new insights into the behaviour of pulmonary and pancreatic NETs, more effective therapeutics strategies that could overcome pharmacological resistance and provide new immune markers. In NEN TAMs are not well characterized. We aimed to characterized TAM within Pan- and Lung-NEN. Taking advantage of multiparametric flow cytometry analysis we found that the TAMs were, in large part, M2-like. Theyalso express HLADR, CD115, CCR2 and CX-3CR1.To assess the effects of M1, M2 macrophages on biological behaviour of NEN, primary cells and NEN cell lines QGP-1 (pancreatic-NEN) and H727 (pulmonary-NEN) were cultured with macrophages conditioned medium (CM). We found out that CM of M1 macrophages strongly decreased cell proliferation of both Pan- and Lung-NEN primary cells. Effect confirmed in cell lines (QGP-1, H727), where M1 CM significantly decreased tumorigenesis of cells. Interestingly, the CM of NEN cell lines promoted the differentiation of macrophages into an M2 phenotype. A key role in supporting tumours growth is played also by stimuli, such as cytokines. We discovered that QGP-1 and H727 cells secrete specific chemokines and this secretion was influenced by treatment with M1 CM. Sene Set Enrichment Analysis on RNAseq data from QGP-1 and H727 cells treated with M1 CM revealed an enrichment in the genset for inflammatory response, apoptosis and p53 pathway. Results confirmed by mass spectrometry analysis for M1 CM-specific proteins. The supernatant was enriched, compare to control, in complement factors, lysozymes, cathepsin, and hypoxia and stress induction stimuli. A better understanding of the immunological characteristics of the malignancy is necessary to explore and test immunotherapeutic strategies. Using multiparametric flow cytometry technique we decided to perform the immunophenotype of peripheral blood from NEN patients. The present study demonstrated differences of the amount and immunophenotype of circulating granulocytes, lymphocytes, monocytes and their subpopulations between NEN patients and healthy individuals.

Cushing's syndrome & disease: Why does it take so long to diagnose; is the interdisciplinary medical team aware of the signs and symptoms; what are the consequences?

Margaret McBride
Division of Health Research, Lancaster, United Kingdom

Background
CS and CD, a baffling portmanteau of symptoms, each often ascribed to other medical conditions, but together representing diagnostically, challenging medical conditions. Often coming, 'disguised', as other stand-alone medical conditions My diagnosis of CS and CD took me on a tortuous diagnostic journey taking almost 6 years to diagnose. My GP, during her 12 years of practice had never diagnosed CS. As part of my current PhD study of CS/CD, one of my objectives is to measure the levels of awareness of these medical conditions by Health Professionals; if they are knowledgeable of the CS/CD signs and symptoms and if they practice effective communication in order to improve their patients' health outcomes.
Work in progress results
A pilot survey was conducted during September 2019 with a study population of 11 Cushing's members of the Pituitary Foundation UK, median age of 47 years. Fifty-five percent of the participants were diagnosed with CS, median length of time for a diagnosis being 2.9 years. Seventy-three percent were diagnosed with CD, median time for diagnosis, 4.3 years, 27% of those were diagnosed with both CS and CD. Forty-five of the participants had to give up work due to their comorbidities created by the disease processes, 21% for psychological reasons and 89% for physical medical conditions. Eighty-two percent were in remission, but all participants were experiencing additional medical conditions which they had not experienced prior to the Cushing's diagnosis. One hundred per cent of the participants reported that they experienced a lack of advice and guidance from their endocrine team, particularly related to family involvement. Only 1 participant had been diagnosed by her GP, the median number of physicians consulted prior to their diagnosis was 4, the median length of time for referral to the endocrine team was 4.5 years. Only 1 participant received advice from their endocrine team about joining a support group. Twelve Health Professionals ranging from GPs, (*2*) Nurses (*3*), medical doctors (*3*), AHPs (*4*) when interviewed had very little or no experience of diagnosing or treating CS or CD.
Conclusion
The interim results suggest that there exists a lack of clinical support and Health Professional awareness of Cushing's which results in an unacceptable length of time for diagnosis. It is crucial therefore that Health Professionals from all disciplines should be made fully aware of the signs and symptoms of CS and CD and the endocrine disorders support organisations.

[1]Université de Paris, Institut Cochin, INSERM, CNRS, Paris, France; [2]Medical Oncology, Assistance Publique Hôpitaux de Paris, Hôpital Cochin, Paris, France; [3]Sorbonne Université, Inserm, UMS Pass, Plateforme Post-génomique de la Pitié-Salpêtrière, P3S, Paris, France; [4]Department for Endocrinology, Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-University, Munich, Germany; [5]Université de Paris, PARCC, INSERM, Paris, France; [6]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service de Génétique, Paris, France; [7]Department of Endocrinology, Center for Rare Adrenal Diseases, Assistance Publique-Hôpitaux de Paris, Hôpital Cochin, Paris, France; [8]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich, Zurich, Switzerland

The effective treatment and optimal prognosis of hypercortisolism (Cushing's syndrome – CS) depend on accurate and early diagnosis. However, hormonal assays can be complex, requiring multiple tests, and not predictive for any related complications, neither for their duration and severity. Identifying novel, specific and easily measurable biomarkers may improve CS diagnosis as well as the evaluation of complications. Since stress-associated epigenetic markers can be measured at blood level, we analyzed the whole blood methylome of patients, before and after hypercortisolism cure, in order to identify a specific methylation signature of cortisol excess. We collected paired blood samples of 47 patients with confirmed hypercortisolism, obtained before (Pre) and several months after (Post) treatment, and we extracted leucocyte DNA. Methylome data were generated by the Infinium MethylationEPICBeadChip (850K probes; Illumina), and pre-processed and pre-analyzed by adapting different packages (minfi, ChAMP) specifically developed for methylation array analysis for the R software. The entire set of probes was analyzed by both unsupervised and supervised approaches in a training sub-cohort of 48 paired samples (Pre/Post treatment) from 24 patients. The results were then tested on the rest of samples, used as validation cohort. Unsupervised clustering, based on the most variable features, showed a distribution of samples in pairs, each corresponding to an individual, thus expectedly accounting for the highest source of variability among samples. Interestingly, all sample pairs showed a common group of CpGs differentially methylated in the Pre compared to the Post condition, thus indicating the presence of a specific cortisol-related methylation signature. Consistently, the projection of the two most representative components of variability (PCA analysis) allowed to well discriminate Pre samples from Post samples. A supervised pairwise comparison of the samples, performed taking into account some meaningful covariates (particularly blood cell composition), allowed to identify 12 significant CpGs (adjusted P-value < 0.05) perfectly discriminating the Pre from the Post samples. Hierarchical clustering performed on the validation cohort using the same 12 selected CpGs allowed to classify samples according to their status of hypercortisolism with an accuracy of 0.81. The prediction power of the model raised to 0.97 (where 1 corresponds to perfect prediction) when we calculated the C statistic after having performed logistic regression on the validation cohort. Our results show that a specific hypercortisolism-related epigenetic signature exists and that it is measurable at the whole blood level. This approach promises to be powerful to identify specific biomarkers of cortisol excess and of its related complications.

Plasma microRNA levels in patients with active acromegaly

Alexander Lutsenko[1], Zhanna Belaya[1], Alexey Nikitin[2], Alexander Solodovnikov[3], Anastasia Lapshina[1], Elena Przhiyalkovskaya[1] & Galina Melnichenko[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Pulmonology Scientific Research Institute under FMBA of Russia, Moscow, Russian Federation; [3]Ural State Medical University, Ekaterinburg, Russian Federation

Background
Plasma microRNAs (miRs) (miR-4446-3p, miR-215-5p, miR-342-5p) were downregulated in patients with active acromegaly (AM) compared with healthy control subjects as assessed by next-generation sequencing.
Aim
The aim of this study wasto validate the previously observed finding in the newly enrolled patients with AM using qRT-PCR.
Materials and methods
Morning plasma samples were collected from fasting patients with AM and age- and sex-matched healthy controls and stored at –80°C. Total RNA isolation:QIAcube with miRNeasy Mini Kit. Reverse transcription was done by TaqMan Advanced miRNA cDNA Synthesis Kit. MicroRNA expression assessed by StepOnePlus Real-Time PCR system with TaqMan Advanced miRNA Assay. We measured plasma expression of five microRNAs: miR-4446-3p, miR-215-5p, miR-342-5p, miR-210-3p and miR-146a-5p. We performed IHC for SSTR2 and SSTR5 expression in tissue samples of patients who underwent neurosurgery. For correlation analysis, we used Kendall rank correlation coefficient.
Results
We enrolled 47 patients with AM – mean age 45.3 years (95% CI 41.5–49.1), body mass index (BMI) 29.9 kg/m^2 (28.3–31.6), gender ratio (m:f) 14:33, IGF-1–710.65 ng/ml (637.84–783.46) and 28 healthy controls matched by age and gender (mean age 44.3 years (39.1–49.5), body mass index (BMI) 27.7 kg/m^2 (25.09–29.45), gender ratio (m:f) 9:19). We found three microRNAs to be downregulated in AM compared with healthy controls. MiR-4446-3p: 0.471 (0.386–0.556) in AM vs 1.023 (0.866–1.180) in healthy controls ($P<0.001$, FDR<0.001). Similarly, miR-215-5p–0.360 (0.263–0.457) in AM vs 0.994 (0.761–1.228) in healthy controls ($P<0.001$, FDR<0.001). Differences in miR-146a-5p levels was 1.201 (1.015–1.387) in AM vs 1.585 (1.272–1.898) in healthy controls ($P=0.036$, FDR$=0.06$). Postoperative adenoma samples were obtained from 42 patients and stained for SSTR2 and SSTR5 expression. Correlation analysis showed positive correlations between GH levels and tumor volume as measured by MRI (0.65, $P<0.001$), SSTR5 expression and tumor volume (0.33, $P<0.05$), miR-210-3p and miR-146a-5p levels (0.28, $P<0.05$); negative correlation between miR-146a-5p and SSTR2 expression (-0.32, $P<0.05$).
Conclusions
In this validation study we confirmed a downregulation of plasma miR-4446-3p, miR-215-5p and miR-146a-5p in patients with AM vs healthy subjects, which makes them promising biomarkers for further research.

Multigene liquid biopsy (NETest) is diagnostic of pancreatic and small bowel neuroendocrine tumours and correlates with imaging

Anna Malczewska[1], Magdalena Witkowska[1], Karolina Makulik[1], Agnes Bocian[1], Agata Walter[1], Monika Wojcik-Giertuga[1], Joanna Pilch-Kowalczyk[2], Wojciech Zajecki[3], Lisa Bodei[4], Kjell Oberg[5] & Beata Kos-Kudla[1]
[1]Department of Endocrinology and Neuroendocrine Tumors, Medical University of Silesia, Katowice, Poland; [2]Department of Radiology and Nuclear Medicine, Medical University of Silesia, Katowice, Poland; [3]Department of Pathology in Zabrze, Medical University of Silesia, Katowice, Poland; [4]Molecular Imaging and Therapy Service, Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, United States; [5]Department of Endocrine Oncology, University Hospital, Uppsala, Sweden

Introduction
There is a substantial unmet clinical need for an accurate and effective blood biomarker for gastroenteropancreatic neuroendocrine tumours (GEP-NETs). Current monoanalyte biomarkers are ineffective. The NETest, a novel multianalyte signature, provides molecular information relevant to disease biology. We therefore evaluated, under real-world conditions, the clinical utility of the NETest as a liquid biopsy in GEP-NETs.
Aim(s)
Independently evaluate the NETest for diagnosis of GEP-NETs and identification of disease progress in a tertiary referral centre (an ENETS Centre of Excellence).
Materials and methods
Cohorts: pancreatic NETs (PNETs, $n=67$), small bowel NETs (SBNETs, $n=44$) and normal controls ($n=63$). Well-differentiated PNETs, $n=62$, SB-NETs, all ($n=44$). Disease extent assessment at blood draw: morphologic imaging ($n=110$)–CT ($n=106$), MRI ($n=7$) and/or functional 68Ga-DOTA-TATE PET/CT ($n=69$) or 18F-FDG PET/CT ($n=8$). Image-positive disease was defined as either CT/MRI or 68Ga-DOTA-TATE PET/CT/18F-FDG PET/CT-positive. Both CT/MRI and 68Ga-DOTA-TATE PET/CT negative diagnosis in well-differentiated NETs was considered image-negative disease. NETest (normal: 20). Assay: PCR (spotted plates). Data: mean ± S.D.
Results and diagnosis
NETest was significantly elevated in NETs ($n=111$; 26 ± 21) versus controls (8 ± 4, $P<0.0001$). Seventy-five GEP-NETs (42 PNET, 33 SBNET) were image-positive. Eleven (8 PNET, 3 SBNET; all well-differentiated) were image-negative. In image-positive, NETest was significantly higher (36 ± 22) vs image-negative (8 ± 7, $P<0.0001$). NETest accuracy (97%), sensitivity (99%) and specificity (95%). Concordance with imaging: 1) morphologic: NETest was 92% (101/110) concordant with morphologic imaging, 2) functional: 94% (65/69) with 68Ga-DOTA-TATE PET/CT and 3) dual modality (CT/MRI and 68Ga-DOTA-TATE PET/CT): 96% (65/68). In 70 CT/MRI positive, NETest was increased in all (37 ± 22). In 40 CT/MRI negative, NETest was normal (11 ± 10) in 31. In 56 68Ga-DOTA-TATE PET/CT positive, NETest was elevated (36 ± 22) in 55. In 13 68Ga-DOTA-TATE PET/CT negative, NETest was normal (9 ± 8) in ten. Radiological disease status assessment (RECIST 1.1): NETest was significantly higher in progressive (61 ± 26; $n=11$) compared to stable disease (29 ± 14; $n=64$; $P<0.0001$).
Conclusion
NETest is effective as a diagnostic for gastroenteropancreatic NETs. Elevated NETest accurately correlates with diagnosis and identification of disease progress in GEP-NETs.

Modelling neuroendocrine tumours using 3 dimensional cell culturing

Lilla Krokker[1], Borbála Szabó[2], Kinga Németh[3], Balázs Sarkadi[2], Katalin Mészáros[3], Attila Patócs[1,3,4] & Henriett Butz[1,3,4]
[1]Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary; [2]Semmelweis University, 2nd Department of Internal Medicine, Budapest, Hungary; [3]Semmelweis University, Hungarian Academy of Sciences, Hereditary Tumours Research Group, Budapest, Hungary; [4]National Institute of Oncology, Budapest, Hungary

Introduction
In vitro monolayer cell cultures are not able to faithfully model the biological features of the three dimensional (3D) structure of solid tumours. There are limited information about the applicability of 3D cell culturing methods for modeling of tumours of endocrine organs.
Aim
The aim of our work was the establishment and characterization of three-dimensional *in vitro* models of various endocrine tumour cells in order to test their applicability for evaluation of pathomechanisms of tumorigenesis.
Materials and methods
Induction of spheroid formation of tumor cell lines of pituitary (RC4-B/C, GH3), adrenal cortex (H295R) and adrenal medulla (PC12) cell lines were performed using serum-free defined medium (SFDM), ultra-low attachment plate (ULA), hanging drop culturing method and matrigel. AlamarBlue and Trypan Blue assays were used to examine cell proliferation and cell viability. Pharmacological treatment (mitotane, itaconate and glutaminase inhibitor) were applied for studying cell proliferation. Severe combined immundeficient mice (SCID) were used for xenograft formation of H295R cells. *In vitro* and *in vivo* hormone production was assessed by HLPC-MS/MS.3D culture models were compared both to 2D and xenografts models.
Results
While pituitary adenoma cells did not form 3D cultures, *in vitro* spheroid induction of H295R cells were successful by three different methods. PC12 cells (chromaffin cells) formed 3D spheroids using serum-free defined media (SFDM). 3D culturing resulted in changes in cell viability, proliferation compared to 2D monolayer cultures. Interestingly, hormone producing of H295R cells was higher in 3D cultures compared to monolayer cultured cells, similarly to the *in vivo* model.

Conclusion
Based on the phenotype features and biological characteristics (viability, proliferation and hormone production), *in vitro* 3D culture represents a better model of endocrine tumors compared to monolayer culturing. Therapeutic options of neuroendocrine tumours are limited, therefore establishing a new, cheap, easy handling *in vitro* model could help to better understand the pathogenesis and to identify novel therapeutical approaches for these tumors.
Grants and financial support
This work has been funded by Semmelweis Innovation Found (STIA_19) to Henriett Butz, National Program of Bionics (Program Medical Bionics lead by Attila Patócs) and grant received from National Research and Innovation Office (grant NKFIH K125231 to AP). Difference in plasma miRNA levels in inferior petrosal sinus samples from patients with ACTH-dependent Cushing's syndrome as assessed by next-generation sequencing (NGS).

Zhanna Belaya[1], Anastasia Malygina[1], Alexey Nikitin[2], Philipp Koshkin[2], Ivan Sitkin[1], Liudmila Rozhinskaya[1], Galina Melnichenko[1] & Ivan Dedov[1]
[1]The National Medical Research Center for Endocrinology, Moscow, Russia, Moscow, Russian Federation; [2]Pulmonology Research Institute, Federal Medical-Biological Agency of Russia, Moscow, Russia, Moscow, Russian Federation

Introduction
ACTH-secreting pituitary adenoma tissue differs from normal pituitary gland tissue in microRNA (miR) expression. MiRs are secreted into circulation and can be detected as potential biomarkers
Aim
To evaluate the difference in miR levels in plasma samples drained from inferior petrosal sinuses in patients with Cushing's disease (CD) and ectopic-ACTH syndrome (EAS).
Materials and methods
we enrolled 24 patients with ACTH-dependent Cushing's syndrome (CS) requiring bilateral inferior petrosal sinus sampling (BIPSS). BIPSS was performed through a percutaneous bilateral approach. Once catheters were properly placed, blood samples were withdrawn simultaneously from each petrosal sinus and a peripheral vein. In addition to ACTH, prolactin measurements were used as additional proof for correct catheter placement. Plasma samples from both sinuses were stored at –80°C. MiRNA isolation from plasma was carried out by an Rneasy Plasma/Serum Kit (Qiagen, Germany) on the automatic QIAcube station according to the manufacturer protocol. To prevent degradation, we added 1 unit of RiboLock Rnase Inhibitor (Thermo Fisher Scientific, USA) per 1 µl of RNA solution. The concentration of total RNA in the aqueous solution was evaluated on a NanoVue Plus spectrophotometer (GE Healthcare, USA).MiR expression was then analyzed by sequencing on Illumina NextSeq 500 (Illumina, USA). The libraries were prepared by the QIAseq miRNA Library Kit following the manufacturer standard protocols. Sequencing was performed on a total of 24 samples. Data analysis and interpretation was conducted on Qiagen GeneGlobe Data Analysis Center.
Results
Among 24 enrolled patients (mean age 48 years (minimum 23, maximum 69); M:6, F:18) 12 subjects were confirmed as CD and 12 as EAS. 108 miRNA were differently detected (P <0,05) in inferior petrosal sinus samples of patients with CD vs EAS. We divided these miRNAs into 3 groups based on the significance of the results. The first group consisted of samples with the highest levels of detected miR in both groups. Four miRNAs were included: hsa-miR-1203 was downregulated in CD vs EAS–36.74 (P=0,013), and three other were upregulated in CD vs EAS: hsa-miR-383-3p 46.36 (P=0,01), hsa-miR-4290 6.84 (P=0,036), hsa-miR-6717-5p 4.49 (P=0,031). The vast majority of differently expressed miRNAs are involved in oncogenesis signaling pathways.
Conclusion
Plasma miR levels differ in inferior petrosal samples taken from patients with CD vs EAS. These miRs need to be validated by different methods and in peripheral plasma samples in order to be used as potentially non-invasive biomarkers to differentiate ACTH-dependent CS.

Challenges in the management of pituitary involvement in granulomatosis with Polyangitis (GPA): 2 cases managed at Imperial college healthcare trust

Preeshila Behary[1], Nigel Mendoza[1], Karim Meeran[1], Anastasia Gontsarova[1], Niamh Martin[1], Spencer Ellis[2], James Tomlinson[1], Jeremy Levy[1], Stephen Mc Adoo[1] & Florian Wernig[1]
[1]Imperial College NHS trust, London, United Kingdom; [2]East and North Hertforshire NHS Trust, Stevenage, United Kingdom

Granulomatosis with Polyangitis (GPA) typically affects the lungs, kidneys and ENT system. Pituitary involvement is extremely rare, affecting less than 1% of all cases. The most common pituitary manifestations are secondary hypogonadism and Diabetes Insipidus (DI).Corticosteroids and immunosuppressive agents represent mainstay of medical management. Treatment needs to be initiated promptly and individualised according to clinical response.
Case 1
A 54-year-old woman presented in 2017 with sinusitis, haemoptysis and cavitating lung lesions on imaging. The clinical presentation and strongly positive c-ANCAs and Proteinase 3 (PR3) antibodies led to a diagnosis of GPA. Disease remission was achieved with Corticosteroids, Cyclophosphamide and Mycophenolate (MMF). She re-presented in August 2019 with blurring of vision and headache. Humphrey field testing revealed a bitemporal visual field defect. Secondary hypothyroidism, hypogonadism and DI were confirmed biochemically. A pituitary MRI showed a suprasellar mass with increased peripheral signal enhancement and chiasmal compression. The pituitary/vasculitis MDT felt that the pituitary lesion was likely inflammatory in nature. An increase of prednisolone to 60 mg led to a reduction in the size of the pituitary lesion. She subsequently received two doses of Rituximab together with Cyclophosphamide and the plan is the wean her steroids.
Case 2
A 50-year-old woman presented with haemoptysis and multiple cavitating lung lesions on imaging in 2016. She tested strongly positive for c-ANCA with high PR3 titres. A diagnosis of pulmonary GPA was made. She was started on Prednisolone 60 mg and both Cyclophosphamide and Rituximab. Unfortunately, she developed an allergic reaction to the latter. In 2018, she experienced intermittent headaches. A pituitary MRI revealed an enlarging suprasellar mass with peripheral enhancement, abutting the optic chiasm. Visual fields remained normal. She proceeded to a pituitary biopsy as per the recommendation of the pituitary/vasculitis MDT. This confirmed lymphocytic hypophysitis. She later developed sinusitis and pituitary insipidus confirmed on water deprivation testing. Her most recent pituitary MRI showed an increase in the volume of the pituitary lesion, with a change in its shape suggesting worsening pituitary GPA. PR3 antibody levels were rising. Prednisolone was increased to 60 mg and Azathioprine replaced by MMF. Management of pituitary GPA remains challenging. Both patients developed a pituitary flare whilst their disease had been in remission otherwise. Corticosteroids are important in remission induction, but cause significant morbidity. The response to conventional steroid-sparing agents remains variable and the role for Rituximab in pituitary GPA is to be determined in clinical studies.

Deletion of chromosome 1q24-1q32 and combined pituitary hormone deficiency type 4: Insight into the challenges of genotype-phenotype correlation

Claudia Giavoli[1], Graziamaria Ubertini[2], Federico Giacchetti[3], Giulia Rodari[1], Eriselda Profka[3], Stefano Cianfarani[4], Maura Arosio[1] & Marco Cappa[2]
[1]University of Milan, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Clinical Sciences and Community Health, Endocrine Unit; [2]Bambino Gesù Children's Hospital, IRCCS, Rome, Endocrinology Department; [3]University of Milan, Department of Clinical Sciences and Community Health; [4] Tor Vergata University, Dipartimento Pediatrico Universitario Ospedaliero, 'Bambino Gesù' Children's Hospital

Background
Interstitial deletions of the long arm of chromosome 1 are rare and classified as proximal or intermediate, the intermediate spanning bands 1q24–1q32. This region contains several genes, including LHX4, a LIM-homeodomain transcription factor essential in the early steps of pituitary ontogenesis. Indeed, mutations in the LHX4 gene are related to combined pituitary hormone deficiency type 4 (CPHD4, OMIM 602146).
Aim
outline the impact of a deletion involving the 1q24–1q32 region in two unrelated boys followed in different Italian hospitals (b1: Rome, b2: Milan), enlightening the complex phenotype, including pituitary hormone deficiency.
Case reports
Both boys (b) were born at term, small for gestational age (b1: 2600 gr, –3.6 SDS; b2: 1800 gr –3.3 SDS), from non-consanguineous parents. At birth, common mild dysmorphic features such as very small feet and hands were evident. In both children brain MRI showed a poorly developed sella turcica, pituitary hypoplasia, thin pituitarystalk, ectopicneurohypophysis, and corpus callosum hypoplasia. Nonetheless, hormonal picture was different, showing b1 neonatal hypoglycaemia that led to diagnosis of GH deficiency and central hypoadrenalism, with central hypothyroidism defining the condition of CPHD and having b2 an uneventful neonatal period. In the latter, decreased linear growth was first observed at the age of 6 months. At that time, endocrine evaluation showed normal thyroid function, low GH, IGF-I and cortisol levels, suggesting GH deficiency and central hypoadrenalism. In both patients adequate replacement therapy was started. Due to the complex phenotype, in which CPHD and severe growth retardation were accompanied by mild neurodevelopmental delay, CGH-array was performed. Boys shared a quite similar genotype, with alteration involving the intermediate region of chromosome 1 (b1: del1q25.1q31.3, b2: arr1q24.3q31.1). During follow-up tocurrent age of 5.5 years, auxological and hormonal data were collected. CPHD was confirmed in b1, while in b2 a short synachten test performed at the age of 2 years showed a normal cortisol peak, narrowing the hormonal picture to isolated growth hormone deficiency.
Conclusion
diagnosis of hypopituitarism in neonatal period is extremely challenging. On this context, neuroradiological abnormalities are strongly supportive. Besides, in the era of precision medicine, accurate genotype characterization seems quite essential. However, as these reports show, even though CGH-Array allowed defining a common genetic condition likely causative of the clinical picture, follow-up revealed a different phenotype evolution.

Baseline IGF-I values influence the effect of rhGH therapy on fat mass: Short, medium and long term study on adults with GH deficiency

Eriselda Profka[1], Giulia Rodari[2], Federico Giacchetti[1], Alessandro Draghi[1], Maura Arosio[2] & Claudia Giavoli[2]
[1]University of Milan, Department of Clinical Science and Community Health, Italy; [2]University of Milan, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico Milan, Department of Clinical Science and Community Health, Endocrine Unit, Italy

Background
One of the main effects of growth hormone therapy (rhGH) in the adult GH deficient patient (AGHD) is to positively modify body composition, with a reduction in fat mass (BF) and an increase in total lean mass (LM). However, the response to replacement therapy is highly variable and, contrary to what described in children, the potential predictive factors are not yet known.
Aim of the study
To assess the impact of basal IGF-I levels on variations of body composition induced by rhGH therapy (median dose 0.2 mg/day) in AGHD.
Study protocol
A monocentric longitudinal prospective study in 44 patients (age at diagnosis 46.1 ± 11 years) with GHD of different aetiology (17 NFPA, 7 craniopharyngiomas, 4 prolactinomas, 4 acromagaly, 2 Cushing diseases, 1 TSH pituitary adenoma, 3 empty sella, 1 Rathke's cleft cysts, 2 hypophysitis, 2 idiopathic, 1 post-traumatic). Patients have been divided into two groups based on theIGF-I basal levels: Group A with IGF-I > –2 SDS (n = 15, 8 M) and group B with IGF < –2 SDS (n = 29, 13 M). Body composition evaluated with dual-energy X-ray absorptiometry and IGF-I levels were assessed at 12 months (n = 44, 21 M), 3–5 years (n = 40, 19 M), and 7–10 years (n = 29, 11 M).
Results
At baseline, no differences were observed between the two groups except for BF %, higher in group B. In the short term, BF % decreased in both groups (from 33 ± 7% to 30 ± 7% group A and from 38 ± 7% to 36 ± 8% in group B, P < 0.05), however, this reduction remained significant in the medium and long term only in group B (35 ± 8% and 37 ± 9%, P = 0.002 and 0.04 vs baseline, respectively). Nevertheless, in both groups, BF% showed an increase at last follow up. Instead, LM showed a sustained increase in both groups and at all times of observation. The IGF-I SDS levels as well as the rhGH dose did not differ between the two groups in the short, medium and long term.
Conclusions
basal IGF-I levels can be predictive of the effect of rhGH therapy on BF %, suggesting greater efficacy in patients with more severe deficiency. The relative increase in BF % observed in the long term still leaves open the question on the parameters to be used in order to define the optimal timing of stopping rhGH therapy in AGHD.

The SAGIT instrument: Potential utility in treatment decision-making in acromegaly

Nadia Sawicka-Gutaj, Paulina Ziółkowska, Katarzyna Ziemnicka, Ewelina Szczepanek-Parulska, Agata Czarnywojtek & Marek Ruchała
Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland

Introduction
The SAGIT instrument was developed for clinicians to assess the status and evolution of the disease in patients with acromegaly. Currently, it is investigated in the validation phase. The aim of our study was to evaluate the potential utility of SAGIT instrument for distinguishing acromegaly clinical stages and its usefulness in treatment decision-making at a single Polish endocrine center.
Patients and methods
Medical charts of adults with confirmed acromegaly hospitalized at the Department of Endocrinology within the last 24 months were retrospectively reviewed. Clinical and biochemical data were collected. SAGIT instrument was completed using patients' medical records. Patients were divided into three categories: stable/controlled; active/uncontrolled; treatment-naïve. Also, treatment decisions were recorded as: continue current therapy with no change/no treatment initiation; intensify current therapy/initiate a treatment; reduce the current treatment.
Results
Among 108 patients, 58% were female, the average age was 55.5 years, and the median time of disease duration was 90 months. Median BMI was 28.5 kg/m^2. There were 14 treatment-naïve patients. Fifty % (n = 47) of treated patients did not achieve biochemical control. Current acromegaly treatment was continued in 38.3% (n = 18) of these patients. Median SAGIT score in treatment-naïve patients was higher than in treated patients (13 vs 6; P = 0.004). Also, patients who did not exhibit hormonal control had a higher SAGIT score than the controlled group (11 vs 4, P < 0.001). In ROC curve analysis, SAGIT score of 6 or less discriminated controlled patients from uncontrolled (P < 0.0001, sensitivity 85.1%, specificity 77.0%). Lack of signs and symptoms (S = 0) predicted controlled disease with a sensitivity of 83% and specificity of 39.3% (P = 0.0114). In uncontrolled treated patients, SAGIT score higher than seven indicated for treatment change (P = 0.0009, sensitivity 79.3%, specificity 66.7%)
Conclusions
The SAGIT instrument is easy to use even when completed in the retrospective medical-record review. Our study indicates for its potential utility for distinguishing clinical stages of acromegaly and in decision-making.

Cushing's disease: Assessment of MGMT expression in pituitary corticotroph tumors and its relationship to clinical, pathological and ultrastructural parameters

Przemyslaw Witek[1,2], Maria Maksymowicz[3], Katarzyna Szamotulska[4], Aleksandra Stasiewicz[2], Agnieszka Wojciechowska-Luzniak[2] & Grzegorz Zielinski[5]
[1]Military Institute of Medicine, Endocrinology Outpatient Clinic, Warszawa, Poland; [2]Warsaw Medical University, Department of Internal

Medicine, Endocrinology and Diabetes, Warszawa, Poland; [3]Maria Sklodowska-Curie Institute of Oncology, Department of Laboratory Diagnostics and Pathology, Warszawa, Poland; [4]Institute of th Mother and Child, Department of Epidemiology and Biostatistics, Warszawa, Poland; [5]Military Institute of Medicine, Department of Neurosurgery, Warszawa, Poland

Background
O-6-Methylguanine-DNA-methyltransferase (MGMT) is a DNA repair enzyme. It has been demonstrated that its higher expression counteracts cytotoxicity of alkylating agents used in the treatment of glioblastoma or invasive pituitary tumors. Little is known on the relationships between MGMT expression and invasiveness of corticotroph adenomas in Cushing disease (CD).
The Aim
To evaluate MGMT expression and its associations with clinical, neuropathological and ultrastructural features of surgically treated corticotroph tumors.
Study population and methods
This cohort study included 72 consecutive patients (60 females) aged 44.15±15.15 yr operated via transsphenoidal approach (TSS) according to the same surgical protocol. Clinical, pathological and ultrastructural parameters were evaluated in light of surgical outcomes. MGMT expression was graded in four categories (<25%, 25–50%, 50–75%, >75%), Ki-67 labeling index in 3 categories (<3%; 3–10%; and >10% positive nuclei), p53 expression in 3 categories (<5%; 5–50%and >50% possitive cells) and mitotic index (MI) in 2 categories (≤2 vs >2 mitoses per 10 high power fields). Early remission was recognised on the basis of hormonal assessement 6 months after TSS.
Results
The proportions of patients in each MGMT expression category (<25%, 25–50%, 50–75%, >75%) were as follows: 19.4, 15.3, 15.3, 50.0%, respectively. Tumors with lower MGMT expression had significantly larger maximal diameter (medians: 15 mm for <25% vs 6 mm for >75%, P_{trend}=0.001), higher plasma ACTH (medians: 119.45 pg/ml for <25% vs 59.45 pg/ml for >75% MGMT expression, P_{trend}=0.002), higher mitotic index (21.4% patients with MI>2 for <25% MGMT expression vs 2.8% patients with MI>2 mitoses for >75% MGMT expression, P_{trend}=0.026) and higher expression of *P* 53 protein (14.3% patients with *P* 53>50% for <25% MGMT expression vs 0.0% patients with *P* 53 >50% for >75% MGMT expression, P_{trend}=0.007). There was a borderline relationship between higher Ki-67 and lower MGMT expression (P=0.099). We confirmed an association between sparsely granulated ultrastructure of corticotroph adenomas (SGCA) and lower MGMT expression: 64.3% SGCA for <25% vs 22.2% SGCA for >75% MGMT expression category, P_{trend}=0.005). Moreover, men presented with lower MGMT expression (35.7% men in <25% MGMT category vs 2.8% with MGMT expression >75%, P=0.004). Six months after TSS lower MGMT expression predicted lower early remission rate in CD. Early biochemical remission rates in each MGMT categories (<25%, 25–50%, 50–75%, >75%) were: 35.7%, 54.5%, 72.7% and 77.8%, respectively (P=0.036).
Conclusion
The lower MGMT expression is characteristic for more invasive corticotroph tumors that may be associated with a lower effectiveness of surgical treatment of CD.

Temporal trends in craniopharyngioma management and long term endocrine outcomes

Ziad HUSSEIN[1,2], Nigel Glynn[3], Niamh Martin[4], Akram Alkrekshi[5], Nigel Mendoza[6], Nair Ramesh[6], Katherine Mccullough[7], Hani J Marcus[8], Neil Dorward[8], Joan Grieve[8], Peirre Bouloux[9], Maralyn Druce[3,10,11] & Stephanie Baldeweg[1,2]
[1]University College Hospital, United Kingdom; [2]University College London, United Kingdom; [3]Street Bartholomew's Hospital, United Kingdom; [4]Imperial College London, United Kingdom; [5]The MetroHealth System Campus of Case Western Reserve University, Cleveland, United States; [6]Imperial College Healthcare NHS Trust, United Kingdom; [7]Royal Surrey County Hospital, United Kingdom; [8]National Hospital for Neurology and Neurosurgery, United Kingdom; [9]University College London, Centre for Neuroendocrinology, Royal Free Campus, United Kingdom; [10]Barts and The London School of Medicine and Dentistry, United Kingdom; [11]1Queen Mary University of London, United Kingdom

Background
The management of craniopharyngiomas remains controversial.
Objective
This study sought to examine temporal trends in the management of craniopharyngioma and their impact on long-term patient outcomes, with focus on endocrine consequences.
Methods
This was a cross sectional, multicentre study. Patients treated between 1951 and 2015 were identified and divided into four quartiles based on the date of initial surgery. Patients' demographics, clinical presentation, treatment and outcomes were collected from retrospective medical record review. Temporal trends of the data were assessed during the period of the study.
Results
In total, 142 patients with both childhood onset craniopharyngioma (48/142; 33.8%) and adult onset disease (94/142; 66.1%) were recruited. Quartile one and four contained 36 patients each and quartile 2 and 3 contained 35 patients each. The median follow-up was 15.4 years (IQR 5.4–23.9 years). Variable data were available for the development of deficiency of individual pituitary hormones at latest clinical review. GH was impaired in 88% (119/135; 88%), 81% (99/1121; 81%) were gonadotrophin deficient, 86% (119/139; 86%) had secondary hypothyroidism, and 82% (116/141; 82%) were ACTH deficient. Permanent cranial diabetes insipidus occurred in 63% (87/139; 63%). The incidence of anterior panhypopituitarism reduced significantly across the quartiles during the time course of the study (P=0.004). Anterior panhypopituitarism was not affected by treatment modality (surgery vs both surgery and radiotherapy) (P=0.17). BMI data were available for 105 patients of which 88 (88/105; 84%) had raised BMI with a median BMI of 29.2 kg/m^2 (IQR 25.5–34.6 kg/m^2). There was no association between BMI and the age of diagnosis (P=0.14) and no significant trend of BMI rate over the study period (P=0.14). Across quartiles, there was a significant trend towards using transsphenoidal surgery and away from employing transcranial surgery (P<0.0001). 86 patients (86/138; 62%) received post-operative radiotherapy, the overall use of radiotherapy was not statistically different among the four quartiles (P=0.33). Craniopharyngioma recurred in 51 patients (51/142; 36%). There was no significant difference in the recurrence rate between the two age groups (P=0.4) as well as the rate of recurrence during the time course of the study (P=0.15).
Conclusion
The rate of hypopituitarism in craniopharyngioma has significantly improved reflecting the trend toward less aggressive neurosurgical techniques and high precision radiotherapy. Long term follow is required to provide appropriate care for the complex sequelae in patients with craniopharyngioma.

Background
Patients with acromegaly responding to injectable somatostatin receptor ligands (SRL) are often treated for decades without deterioration of biochemical response (except for routine fluctuations in IGF-I control), unless there are changing clinical circumstances such as persistent or recurrent tumor growth. Oral octreotide capsules (OOC) have been formulated as a potential therapy for acromegaly and the safety and efficacy was evaluated in the CHIASMA OPTIMAL pivotal study. In CHIASMA OPTIMAL, 58% of patients receiving OOC met the primary endpoint and maintained their baseline response levels (IGF–I ≤1 ×ULN) vs 19% of patients receiving placebo (P=0.008). At the end of treatment, mean IGF-I levels of the OOC treatment group were maintained within normal range in all patients and 75% of patients in this group maintained IGF-I levels ≤1.1 ×ULN. This analysis describes the durability of OOC treatment response (Samson *et al.* ENDO 2020).

Methods
Patients were ≥18 years of age, had evidence of active disease, and an average IGF-I≤1.0 × ULN receiving a stable dose of SRL injections (≥3 months). Patients were randomized to OOC (40 mg/day; $n=28$) or placebo ($n=28$) for 36 weeks. Dose was titrated to 60 or 80 mg OOC (or placebo) through week 24 at investigator discretion based on increased IGF-I levels and/or worsening acromegaly signs/symptoms. Patients not responding (OOC or placebo) could revert to prior injectable SRL therapy if they met the predefined withdrawal criteria (i.e., IGF–I≥1.3 × ULN for 2 consecutive visits on the highest dose and exacerbation of clinical signs/symptoms). The primary endpoint was proportion of patients maintaining biochemical response, defined as IGF–I≤1.0 × ULN (average: weeks 34 and 36). Patients who discontinued oral treatment (OOC or placebo) were considered non-responders regardless of clinical response at the time of discontinuation (non-response imputation or WOCF). For this analysis, the proportion of week 24 responders (IGF–I≤1.0 ×ULN) in the OOC group who maintained their response at the end of study is presented.
Results
Analyzing a subgroup of 12 patients who were responders (IGF-I≤1.0 × ULN) to OOC when assessed at week 24 (end of dose titration phase) in the OOC treatment arm, 11 of these 12 patients had a sustained or durable response to end of treatment at 9 months (91.7%).
Conclusion
Efficacy was durable in CHIASMA OPTIMAL. This suggests that patients who respond to OOC with maintained normal IGF-I may potentially be maintained on treatment without deterioration in IGF-I control. Longer-term extension studies are ongoing.

Biochemical control of most patients reverting to injectable long-acting somatostatin receptor ligands is achieved after one dose: Results from the phase 3, randomized, double blind, placebo-controlled optimal study

Maria Fleseriu[1], Susan Samson[2], Lisa Nachtigall[3], Artak Labadzhyan[4], Atanaska Elenkova[5], Mark E Molitch[6], William Ludlam[7], Gary Patou[7], Asi Haviv[7], Nienke Biermasz[8], Christian J Strasburger[9], Laurence Kennedy[10] & Shlomo Melmed[4]
[1]Oregon Health & Science University, United States; [2]Baylor College of Medicine, United States; [3]MGH Neuroendocrine and Pituitary Center, United States; [4]Cedars Sinai Medical Center, United States; [5]Medical University Sofia, Bulgaria; [6]Northwestern University, United States; [7]Chiasma, United States; [8]Leiden University Medical Center, Netherlands; [9]Charité Campus Mitte, Germany; [10]Cleveland Clinic Foundation, United States

Background
Injectable somatostatin receptor ligands (SRLs) are currently the most widely used therapy for acromegaly. Oral octreotide capsules (OOC) are a potential therapy for acromegaly; the safety and efficacy were evaluated in the CHIASMA OPTIMAL pivotal study (Samson *et al.* ENDO 2020). As reported, mean IGF-I levels of the OOC group were maintained within normal range at end of treatment in all patients. However, some patients may not respond to OOC treatment (25% of OOC and 68% of placebo required rescue, $P=0.003$). This analysis describes the degree and rapidity with which patients achieve biochemical control (IGF–I≤1.0 × ULN) when reverted to their prior injectable SRL.
Methods
Patients with confirmed acromegaly and receiving a stable dose of injectable SRL (≥3 months) were randomized to OOC (40 mg/day; $n=28$) or placebo ($n=28$) for 36 weeks. Patients were dose titrated to 60 or 80 mg of OOC (or placebo) through week 24 at investigator discretion based on increased IGF-I levels and/or worsening acromegaly signs/symptoms. Patients could be rescued via prior injectable SRL therapy if they met predefined withdrawal criteria (IGF–I≥1.3 × ULN; 2 consecutive visits on the highest doseand exacerbation of clinical signs/symptoms) or discontinued treatment for any reason. Seven patients in the OOC and 19 in the placebo group required rescue. The change in IGF-I from Baseline was compared to the end of the Double-blind Placebo Controlled period.
Results
In patients rescued up to week 32 (with ≥4 weeks of follow-up), baseline IGF-I levels(mean; Screening Visit 2 and Baseline) were 0.80 and 0.87 × ULN in OOC and placebo groups,respectively. In patients receiving rescue therapy, the end of study IGF-I levels (mean; week 34 and 36) were 0.80 and 0.89 × ULN in OOC and placebo groups, respectively. The median time to return to normal IGF-I values following loss of response was 4.0 weeks after discontinuing either OOC or placebo. Therefore, most patientswho required rescue following a short trial of OOC returned to their baseline values following a single SRL injection.
Conclusion
Most treatment failures in the CHIASMA OPTIMAL trial(either OOC or placebo) rescued with injectable SRL re-established their baseline response levels after a single injectable SRL administration (at pre-study dose). Based on these data, patients may potentially be treated with OOC and for those not responding, either not biochemically-controlled or who have adverse effects, they may be able to return to injectable SRLs with immediate IGF-I control after one SRL injection.

Association between sagittal spine imbalance and radiological vertebral fractures in acromegaly: Does it reflect a pathophysiological link?

Miriam Cellini[1], Emilia Biamonte[1], Nicoletta Trenti[2], Massimiliano Mazza[1], Davide Milani[3], Emanuele Ferrante[4], Elisabetta Lavezzi[1], Giovanna Mantovani[5], Maura Arosio[5], Maurizio Fornari[3], Luca Balzarini[2], Andrea Lania[6] & Gherardo Mazziotti[6]
[1]Endocrinology, Diabetology and Andrology Unit, Humanitas Clinical and Research Center, IRCCS, Rozzano (MI), Italy; [2]Department of Radiology, Humanitas Clinical and Research Center IRCCS, Rozzano (MI), Italy; [3]Department of Neurosurgery, Humanitas Clinical and Research Center IRCCS, Rozzano (MI), Italy; [4]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico – Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [6]Endocrinology, Diabetology and Andrology Unit, Humanitas Clinical and Research Center, IRCCS; Department of Clinical Sciences, Humanitas University, Rozzano (MI), Italy

Chronic exposure to GH hypersecretion may alter the physiological balance of the spine through inducing degeneration of intervertebral discs and impaired trophism of facet joints. Moreover, GH in excess may also cause profound deterioration in bone microstructure with consequent increase in risk of fragility vertebral fractures (VFs). In this cross-sectional study,we evaluated for the first time in acromegaly the association between spine imbalance and VFs. Thirty-eight patients with acromegaly (median age 55 years; 20 males; 12 with active disease) were consecutively evaluated for sagittal spine parameters and morphometric VFs (EOS imaging system, Paris, France), quality of life (SF-36 questionnaire), pain and disability (Womac questionnaire). Thirty-eight subjects without history of pituitary disease, matched for age and sex with acromegalic patients, acted as controls for evaluation of VFs. VFs were significantly more frequent in acromegaly patients as compared to control subjects (34.2% vs 5.3%; $P=0.003$). All fractured patients with acromegaly had VFs in the thoracic tract with spine deformity index (SDI) ranging from 1 to 9. In acromegaly, the prevalence of VFs was significantly higher in patients with kyphosis (i.e., thoracic Cobb angle >50%) as compared to those without kyphosis (55.6% vs 15.0; $P=0.02$). The thoracic Cobb angle in fractured patients was not associated with the SDI ($P=0.61$). In acromegalic patients without VFs, the thoracic Cobb angle was significantly associated with lumbar Cobb angle ($P=0.003$), which in turn was significantly associated with sacral slope ($P<0.001$) and pelvic incidence ($P<0.001$) reflecting compensatory adapation of the spine. These associations were not found in patients with VFs. Acromegaly patients with VFs showed also lower SF-36 Health score ($P=0.002$) and higher Womac-pain score ($P=0.03$) as compared to patients who did not fracture. The association between VFs and SF-36 Health score remained significant ($P=0.005$) after correction for the thoracic Cobb angle, whereas that with the Womac-pain score was lost ($P=0.16$). In conclusion, this study provided a first evidence that: 1) VFs may be associated with spinal kyphosis and sagittal imbalance in acromegaly, likely reflecting an effect ofabnormal spinal compressive loading on fracture risk, such as already demonstrated in post-menopausal osteoporosis; 2) VFs may impact on quality of life of patients with acromegaly, independent of kyphosis; 3) the low dose biplane X-ray imaging system may be proposed in the real-life clinical practice asa reliable diagnostic tool for a comprehensive evaluation of spine arthopathy and VFs in acromegaly.

Once-weekly somapacitan in japanese adults with growth hormone deficiency was well tolerated, with similar efficacy to daily growth hormone: A randomised trial

Fumio Otsuka[1], Yutaka Takahashi[2], Shigeyuki Tahara[3], Yoshihisa Ogawa[4], Michael Højby Rasmussen[5] & Koji Takano[6]
[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Department of General Medicine, Okayama, Japan; [2]Kobe University Graduate School of Medicine, Department of Internal Medicine, Kobe, Japan; [3]Nippon Medical School, Department of Neurosurgery, Tokyo, Japan; [4]Novo Nordisk Pharma Ltd., CMR Development Division, Tokyo, Japan; [5]Novo Nordisk A/S, Global Development, Søborg, Denmark; [6]Kitasato University, Department of Endocrinology, Diabetes and Metabolism, Sagamihara, Japan

Somapacitan is a long-acting, reversible albumin-binding growth hormone (GH) derivative. The objective of this trial was to evaluate the safety, efficacy and treatment satisfaction of onceweekly somapacitan versus daily GH (Norditropin) over 52 weeks in Japanese patients with adult GH deficiency (AGHD). This was a phase 3, multicentre, randomised, open-label, parallel-group, active-controlled trial (NCT03075644). Patients previously treated with GH were randomised 1:3 to daily GH or somapacitan, to undergo 20 weeks of dose titration and 32 weeks of fixed-dose treatment. The primary endpoint was the incidence of adverse events (AEs) from baseline to week 53. Secondary endpoints included change from baseline in visceral, subcutaneous and total adipose tissue (VAT, SAT and TAT, respectively) assessed with computerised tomography scans; change from baseline in treatment satisfaction, evaluated using Treatment Satisfaction Questionnaire for Medication (TSQM-9) scores; andoccurrence of anti-somapacitan antibodies. In total, 62 patients were randomised (daily GH $n=16$; somapacitan $n=46$); 60 patients completed the trial. Baseline characteristics for daily GH versus somapacitan groups, respectively, were: female, 43.8% vs 47.8%; adult-onset GHD, 87.5% vs 80.4%; mean (S.D.) age, 49.3 (11.5) vs 54.1 (12.1) years; weight 67.9 (12.0) vs 69.4 (22.7) kg; body mass index 24.8 (3.7) vs 26.4 (6.7) kg/m^2; and GH dose at screening 0.29 (0.14) vs 0.31 (0.17) mg. Rate of AEs per 100 patient-years was similar between treatment arms (daily GH, 309.8; once-weekly somapacitan, 312.7). Most AEs were mild (97.9% and 93.1%, respectively); none were severe. Four AEs in the somapacitan arm were serious; all were considered unlikely related to treatment. No anti-somapacitan antibodies were detected during treatment. Mean insulin-like growth factor-I standard deviation score (IGF-I SDS) at baseline was maintained with both treatments. Most patients had IGF-I SDS values <+2. No significant differences in VAT, SAT and TAT were seen in either treatment group after 52 weeks (estimated difference, somapacitan – daily GH [95% CI]): –1.74 [–18.13; 14.66], –11.53 [–35.54; 12.48], and –12.85 [–47.31; 21.62] cm^2, respectively. TSQM-9 scores were not significantly different between treatments, but showed a tendency in favour of somapacitan (estimated difference [95% CI]): 4.87 [–3.46; 13.20] for effectiveness, 6.79 [–1.04; 14.61] for convenience, and 6.88 [–1.08; 14.85] for overall satisfaction. No new safety concerns were identified. Improvements in body composition were similar in both cohorts. The safety and tolerability of somapacitan in Japanese patients with AGHD were consistent with results from the global phase 3 trial (REAL 1).

Real life efficiency of pegvisomant therapy in acromegaly

Sofia Maria Lider Burciulescu[1], Monica Livia Gheorghiu[1], Andra Caragheorgheopol[2], Mariana Purice[2] & Corin Badiu[3]
[1']CI Parhon' National Institute of Endocrinology, Tiroida 1, Bucharest, Romania; [2']CI Parhon' National Institute of Endocrinology, Laboratory, Bucharest, Romania; [3']CI Parhon' National Institute of Endocrinology, Tiroida 2, Bucharest, Romania

Introduction
Pegvisomant (PEG) is an efficient treatment for acromegaly but the recommendation for this treatment is less active due to its high cost. In Romania it is reimbursed in doses up to 30 mg s.c/day or as 40 or 80 mg/week in combination with a somatostatin analog (SSA).
Design
Retrospective analysis of 18 consecutive patients treated with PEG for acromegaly (either as monotherapy, or in combination with SSA and/or cabergoline (CAB), or both consecutively. All patients had a macroadenoma, underwent surgery, all had residual disease, 17 underwent radiotherapy. In the study were included 12 women, 6 men, mean age 44.5 years old (range: 19–70). Before commencing PEG, patients had an elevated IGF◀ level: mean 875.3±397.3 ng/ml. The mean duration of the PEG treatment was 3±1.6 years.
Results
14 patients had PEG in monotherapy, mean dose 16±5.2 mg/day (112 mg/week). From these, 8 normalised IGF1, 2 of them were disease free after RT and PEG therapy. In 4 patients optimal response was not achieved with 30 mg PEG/day. From 6 patients with combined therapy: SSA+PEG or SSA+PEG+CAB (mean PEG dose 58.6±24 mg/week), 2 patients normalised IGF1 (33%). Adding CAB decreased IGF1 levels but did not normalise them. In the whole group 4 patients (22%) had side effects: a tumor increase with 2.5–8 mm in 2 patients, after 8 and 24 months, respectively, and elevated transaminases in 2 patients (1 of these tolerated a lower PEG dose+SSA, the other one stopped PEG therapy).
Conclusions
Pegvisomant is an effective treatment for acromegaly (in 55% in our series), if the dose is well titrated and tolerated during treatment. Special attention is needed for the potential side effects (noted in 22% of our series).

AEP581

Sheehan like syndrome in males: A case series of three patients developing pituitary infarction following hypotension

Ambreen Qayum, Shamaila Zaman, Sanas Mohammad, Jeannie F Todd & Karim Meeran
Imperial College Healthcare NHS trust, Endocrinology and Diabetes, London, United Kingdom

Pituitary apoplexy caused by pure infarction is rare. Here we present three cases of pituitary macroadenoma infarction following hypotension.
1. An 84 year old gentleman had a 2×2 cm pituitary macroadenoma causing chiasmal compression and a bitemporal hemianopia. He had panhypopituitarism and was on prednisolone, thyroxine and testosterone replacement. Before surgical intervention of the macroadenoma, he fell and broke his humerus, which required internal fixation but was complicated by an infected prosthesis. He required further operative interventions. Following a four hours procedure, he reported worsening of vision, which resolved spontaneously. His prolactin which had been 1095 fell to 48 mU/l and a three months interval MRI showed a reduction in size of the pituitary macroadenoma. Pituitary MRI two years later shows only a slender amount of tissue in the sella.
2. A 68-year old man underwent elective coronary artery bypass grafting (CABG). Post operatively he complained ofheadache, blurred vision and had a left sided third nerve palsy. CT head and MRI pituitary confirmed a 3.5 cm pituitary macrodenoma stretching the optic chiasm. Pituitary profile one day following CABG showed TSH 0.89 (NR 0.3–4.2 mU/l), T3 2.7 (2.5–5.7 pmol/l), T4 8.1(NR 9.0–23.0 pmol/l), 3 pm cortisol 125, LH 1.3 (2.0–12.0 u/l), FSH 2.2 (1.7-8.0 u/l), GH 0.17 ng/l, prolactin <13 mU/l. He was started on prednisolone replacement. Because of his recent CABG, timing of neurological surgical intervention was considered carefully. On review in neurosurgery outpatients, a pituitary MRI showed a marked reduction in the size of pituitary adenoma with no compromise of optic chiasm.
3. A 70-year old man with known severe aortic stenosis developed symptoms of a TIA. CT head identified a 1.8 cm pituitary macroadenoma. MRI pituitary showed no chiasmal compromise. Baseline pituitary function showed no deficiency. His cardiac and neurological symptoms with aortic stenosis necessitated urgent valve replacement. He was on cardiopulmonary bypass with BP 60–80 mmHg systolic for one hour during the surgery. He developed secondary hypothyroidism few weeks later. His repeat MRI showed complete involution of the macroadenoma.
Conclusion
Sheehan syndrome is pituitary infarction due to systemic hypotension in physiologically enlarged pituitary. Our patients demonstrate that the same pathophysiology can cause hypopituitarism in males who have a pituitary adenoma rather than pituitary hyperplasia of pregnancy. The location of pituitary gland and its unusual blood supply makes it prone to ischemia in setting of systemic hypotension when physiologically or pathologically enlarged.

An asynchronous double growth hormone secreting pituitary adenoma ofa different proliferative potential – a case report

Malgorzata Trofimiuk-Muldner[1], Bartosz Domagała[2], Lukasz Kluczynski[1], Grzegorz Sokolowski[1], Grzegorz Zielinski[3], Maria Maksymowicz[4], Monika Pekul[4] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland; [2]University Hospital in Krakow, Department of Endocrinology, Kraków, Poland; [3]Military Institute of Medicine, Department of Neurosurgery, Warszawa, Poland; [4]M. Skłodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Pathology and Laboratory Diagnostics, Warszawa, Poland

Background
Double pituitary adenomas are a rare entity, which requires clinical attention and a careful follow-up.
Case report
A 37-year-old man presented with left-sided painful gynecomastia. He denied typical symptoms of excessive growth hormone (GH) secretion and did not show any acromegalic features. Due to low testosterone and LH levels with mild hyperprolactinaemia, the patient was referred to pituitary MR, which revealed an 11×13 mm right-sided sellar tumor. An increased IGF-1 was noted subsequently (1482 ng/ml; N 109–284 ng/ml), together with the lack of GH suppression in OGTT. Transphenoidal resection of pituitary tumor performed in 2012 led to biochemical (IGF-1 260 ng/ml, GH 0.08 ng/ml) and radiological remission of the disease. A histopathology report revealed a densely granulated somatotropic pituitary adenoma with mild nuclear atypia, expressing somatostatin receptors [sstr2A (+), sstr5 (±)]. Due to gradually increasing IGF-1 levels (with low, although rising, GH values ranging from 0.07 to 0.92 ng/ml) in subsequent years, OGTT was repeated in 2015, showing appropriate GH suppression. In 2016, however, acromegaly recurrence was confirmed both biochemically (increasingly high IGF-1–664 ng/ml – and unsuppressed post-OGTT growth hormone) and in MR imaging. The patient was reoperated in June 2017. The second histopathology reported an oncocytic somatotropic acidophil stem cell pituitary adenoma with Ki-67 > 3% and mitotic figures. Subsequent anterior pituitary lobe insufficiency (adrenal, thyroid and gonadal axis) was found and adequately treated. Complete tumor removal was confirmed by MR performed three months after repeated surgery, as well as a low GH level (0.97 ng/ml), although accompanied by borderline IGF-1 values (277 ng/ml). Eighteen months after surgery, the recurrence of acromegaly was again confirmed, with adenoma regrowth and increased GH (2.31 ng/ml) and IGF-1 (474 ng/ml). Octreotide LAR was started (despite retina wrinkling which was observed when lanreotide was administered before the first surgery), which led to a normalization of GH (0.96 ng/ml) and IGF-1 levels (152 ng/ml), as well as partial pituitary tumor regression after six months therapy.
Conclusion
In a case of GH-secreting pituitary adenoma recurrence after apparent successful surgery, a double pituitary adenoma with more aggressive histology should be considered.

AEP583

Not just another headache – a rare case of recurrent pituitary collection

Su Tee[1], Robert Andrew James[1], Claire Nicholson[2] & Yaasir Mamoojee[1]
[1]Royal Victoria Infirmary, Endocrinology, Newcastle Upon Tyne, United Kingdom; [2]Royal Victoria Infirmary, Neurosurgery, Newcastle Upon Tyne, United Kingdom

A 27 year old lady presented in 2016 with a 3 month history of intermittent headache and visual disturbance, 3.5 months post-partum. She had a past medical history of cluster headache; treated with verapamil and short courses of oral steroids (she had no recent steroid courses prior to presentation). She was found to have a partial right sixth nerve palsy but normal visual fields on Goldmann's testing. She had biochemical evidence of secondary adrenal insufficiency (sodium 120 mmol/l, random cortisol 31 nmol/l) and hypogonadotrophic hypogonadism (oestradiol <50 pmol/l, LH 3 iU/l, FSH < 1iU/l). She also had polyuria and polydipsia, blood and urine tests were consistent with mild diabetes insipidus. Urgent MRI showed a complex pituitary mass, with suprasellar extension and optic chiasm impingement, thought initially to be a craniopharyngioma. She was commenced on hydrocortisone replacement and desmopressin with good effect. Review of previous MRIs to investigate headaches showed the lesion was not previously present, hence it was unlikely to be a craniopharyngioma. She underwent trans-sphenoidal adenomectomy in November 2016 – unexpectedly, pus was aspirated which was positive for Strep pneumoniae, H. influenzae and Staph epidermidis. Histology showed granulomatous inflammation within a Rathke's cleft cyst. Her adrenal insufficiency and diabetes insipidus resolved post-operatively, but she still had evidence of hypogonadotrophic hypogonadism. Three years following initial presentation, she was re-referred urgently with recurrent polyuria and polydipsia. Reassessment showed central hypothyroidism (TSH 0.19 mU/l, fT4 10.3 pmol/l, ft3 2.7 pmol/l), persistence of hypogonadotrophic hypogonadism (oestradiol <60 pmol/l, LH 6.9 iU/l, FSH 2.5 iU/l) and diabetes insipidus (sodium 145 mmol/l, serum osmolality 294 mmol/kg; urine osmolality 142 mmol/kg). MRI confirmed a recurrence of a loculated pituitary lesion – she underwent further trans-sphenoidal drainage in Oct 2019, but cultures were negative for any pathogens this time.
In addition, she then developed diarrhoea and mouth ulcers, which prompted investigations under the gastroenterology team. Colonoscopy has shown active inflammation within the ileum and colon, and she is being treated for presumed Crohn's disease. Tests for syphilis, blood-borne viruses, sarcoidosis and vasculitis have been negative. Pituitary abscesses are extremely rare (0.2–1% of all pituitary disease) – it is even rarer to have recurrent episodes in the absence of any systemic immunosuppression or pituitary irradiation. Only 8 previous cases of recurrent pituitary abscess have been reported in the literature. Additionally, we discuss whether this patient could have an underlying multi-system condition driving multi-organ inflammation; or whether her pituitary issues could be an extra-intestinal manifestation of inflammatory bowel disease.

A novel mechanism regulating dopamine receptor type 2 (DRD2) signal transduction in PRL- and ACTH-secreting pituitary tumoral cells: The role of cAMP/PKA-induced filamin A (FLNA) phosphorylation in the control of responsiveness to DRD2 agonist

Federica Mangili[1], Donatella Treppiedi[1], Rosa Catalano[1], Elena Giardino[2], Maura Arosio[2], Anna Spada[1], Giovanna Mantovani[2] & Erika Peverelli[1]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

The actin binding protein filamin A (FLNA) is required for somatostatin receptor 2 (SST2) and dopamine receptor 2 (DRD2) expression, intracellular localization and signaling in GH- and PRL-secreting pituitary tumors, respectively, playing a role in tumor responsiveness to somatostatin analogs and dopaminergic drugs. FLNA functions are tightly regulated by several mechanisms, including FLNA phosphorylation. It has recently been shown that in GH-secreting pituitary tumors FLNA phosphorylation on Ser2152 switches FLNA function from a scaffold that allows SST2 signal transduction, to a signal termination protein that hampers all SST2 antitumoral effects. Aims of the present study were to evaluate in PRL- and ACTH-secreting pituitary tumor cell lines MMQ and AtT-20, endogenously expressing DRD2: 1) the effects of cAMP pathway activation and DRD2 agonist on FLNA phosphorylation; 2) the impact of FLNA phosphorylation on DRD2 intracellular signal transduction.
We found that forskolin increased (+2.87±onefold, $P<0.05$ in MMQ; +1.92±0.8 fold, $P<0.05$ in AtT-20), and DRD2 agonist BIM53097 reduced (–77.3±2%, $P<0.001$ in MMQ; –52.7±3%, $P<0.05$ in AtT-20), FLNA phosphorylation on Ser2152. The overexpression of a phosphomimetic (S2152D) FLNA mutant in both cell lines completely prevented DRD2 antiproliferative effects, that were comparable in cells transfected with empty vector, wild type FLNA as well as phosphodeficient FLNA mutant (S2152A) (–20.6±5%, $P<0.001$ in MMQ; –36.6±12%, $P<0.01$ in AtT-20). Accordingly, S2152D FLNA expression abolished the expected ability of BIM53097 to increase (in MMQ) or decrease (in AtT20) ERK phosphorylation, an effect that was maintained in S2152A FLNA expressing cells (+178±65%, $P<0.05$ in MMQ; –55±13%, $P<0.01$ in AtT-20).
In addition, the inhibitory effects of DRD2 on PRL secretion (–19±1%, $P<0.05$ in MMQ expressing S2152A FLNA) were completely lost in S2152D FLNA transfected cells. In conclusion, our data demonstrated that cAMP pathway and DRD2 agonist regulated FLNA activity by increasing or decreasing, respectively, FLNA phosphorylation on Ser2152. Moreover, we found that FLNA phosphorylation prevented DRD2 signaling in PRL- and ACTH-secreting tumoral pituitary cell lines, suggesting that this post-translational FLNA modification might represent a new GPCRs regulatory mechanism. In pituitary tumors expressing DRD2, modulation of P-FLNA

might suggest new pharmacological strategies to overcome drug resistance, and P-FLNA might represent a new biomarker for tumor responsiveness to dopaminergic drugs.

Kisspeptin-54 accurately identifies hypothalamic dysfunction in men with congenital hypogonadotropic hypogonadism

Ali Abbara[1], Pei Chia Eng[1], Maria Phylactou[1], Sophie Clarke[1], Edouard Mills[1], Germaine Chia[1], Lisa Yang[1], Chioma Izzi-Engbeaya[1], Channa Jayasena[1], Alexander Comninos[1], Richard Ivell[2], Ravinder Anand-Ivell[2], Jesse Rademaker[3], Xu Cheng[3], Richard Quinton[4], Nelly Pitteloud[3] & Waljit Dhillo[1]
[1]Imperial College London, United Kingdom; [2]University of Nottingham, United Kingdom; [3]University of Lausanne, Lausanne, Switzerland; [4]Newcastle University, United Kingdom

Background
Hypogonadotrophic hypogonadism is characterised by hypogonadism in the context of low/inappropriately normal gonadotrophin levels. Congenital Hypogonadotrophic Hypogonadism (CHH) occurs due to disrupted GnRH neuronal migration, or impaired hypothalamic GnRH secretion or action. However, no direct test of hypothalamic GnRH neuronal function currently exists. Kisspeptin-54 is a neuropeptide that stimulates endogenous hypothalamic GnRH release. Thus, we investigated whether kisspeptin-54 could be used to interrogate hypothalamic function in men with CHH.
Methods
Men with CHH (low testosterone, low/inappropriately normal gonadotrophin levels, incomplete pubertal development; $n=21$) and healthy eugonadal men ($n=21$) received an intravenous bolus of either GnRH (100 mg), or kisspeptin-54 (6.4 nmol/kg), on two study visits at least one week apart. Serum gonadotrophins were measured every 15 mins for 6 hrs following injection. Increases in serum gonadotrophins from baseline following GnRH/kisspeptin in eugonadal men and CHH were compared by Mann Whitney U test.
Results
The maximal rise in LH following KP54 was significantly greater in healthy men (12.5 iU/l) than in men with CHH (0.4 iU/l; $P<0.0001$). Following KP54, all men with CHH had an LH-rise <2 iU/l, whereas all healthy men had an LH-rise >4 iU/l. Thus, the LH-rise after KP54 more effectively discriminated men with CHH from healthy men (auROC 1.0) than GnRH (auROC 0.88). Anosmic men with CHH (ie Kallmann syndrome) had even lower LH-rises following KP54 than normosmic men with CHH ($P=0.017$).
Conclusion
In summary, akisspeptin-54 test of hypothalamic GnRH neuronal function more accurately discriminated men with CHH from healthy men thana GnRH test. Consequently, a kisspeptin-54 test can be used to better identify patients with CHH to direct genetic testing, and to rapidly assess for evidence of spontaneous reversal of hypothalamic dysfunction in patients with known CHH. Thus, KP54 demonstrates potential as a specific test of hypothalamic GnRH function when assessing patients presenting with disorders of puberty.

Growth hormone-releasing hormone (GHRH) promotes survival and proliferation of neural stem cells and reduces amyloid-β-induced toxicity

Dana Banfi[1], Iacopo Gesmundo[1], Ezio Ghigo[1], Andrew V Schally[2] & Riccarda Granata[1]
[1]University of Turin, Division of Endocrinology, Diabetes and Metabolism, Department of Medical Science, Italy; [2]University of Miami Miller School of Medicine, Division of Endocrinology, Department of Medicine, Miami, United States

Neurogenesis, a process by which new neurons are generated from precursors, still persists in discrete regions of the adult hippocampus. Impairment in neurogenesis is an important feature in the pathogenesis of neurodegenerative diseases, such asAlzheimer's disease (AD). The hippocampus is critical for learning and memory and is a main target of AD, which causes massive neuronal death, reduction in neurogenesis and impairment in cognitive functions. Therefore, preventing neuronal loss or increasing the production of new neurons may represent a potential therapeutic strategy to reduce AD-induced cognitive decline. Growth hormone-releasing hormone (GHRH), apart from promoting growth hormone (GH) secretion from the pituitary, exerts many extrapituitary functions, including stimulation of cell survival, cardioprotection and protection against diabetic retinopathy. Furthermore, expression of GHRH, as well as GHRH-receptor (GHRH-R) and its splice variants (SVs), has been demonstrated in different brain regions, including the cerebral cortex, cerebellum and brain stem cells. To date, however, the role of GHRH on neurogenesis and neuroprotection is still unknown. Thus, we sought to investigate the role of GHRH on survival, proliferation, apoptosis and differentiation of rat hippocampal neural stem cells (NSCs), in stress conditions such as growth factor deprivation and amyloid-β peptide 1–42 ($A\beta_{1-42}$)-induced toxicity, and to define the underlying mechanisms. We found expression of both mRNA and protein for pituitary GHRH-R in NSCs. Moreover, GHRH dose-dependently increased cell survival and proliferation and reduced apoptosis in NSCs culturedunder both growth factor deprivation and $A\beta_{1-42}$. In addition, GHRH counteracted the effect of $A\beta_{1-42}$on elevation of the proapoptotic protein BAX and inhibition of the antiapoptotic protein Bcl-2. Finally, the role of GHRH was examined on differentiation of NSCs into neuronal lineages, such as neurons, oligodendrocytes, and astrocytes. Interestingly, GHRH increased the mRNA levels of the neuronal marker *Tuj1*, while showing no significant effect on *GFAP* and *Ripk1*, specific for astrocytes and oligodendrocytes, respectively. Collectively, these results, suggest a role for GHRH in preventing neuronal loss and in promoting neurogenesis, with potential therapeutic application of its agonistic analogs in neurodegenerative diseases, such as AD.

Pancreatic neuroendocrine tumour with suspected extrarenal secretion of 1,25-dihydroxyvitamin D3

Alwyn Yung Zhuang Choo[1,2] & Kamrudeen Mohammed[2,3]
[1]Hull Royal Infirmary, Endocrinology and Diabetes, Hull, United Kingdom; [2]Hull University Teaching Hospitals NHS Trust, Endocrinology and Diabetes, Hull, United Kingdom; [3]Hull York Medical School, Honorary Senior Lecturer, Heslington, United Kingdom

Background
Hypercalcaemia can occur in 20–30% of malignancy. Neuroendocrine malignancy-related hypercalcaemia is relatively rare with few reported cases, mostly in pancreatic neuroendocrine tumours. It could be related to humoral hypercalcaemia of malignancy (PTHrP secretion), production of 1,25-dihydroxyvitamin D3 ($1,25(OH)_2D3$) by the tumour or production of PTH by the tumour[1,2]. Here we describe a case of metastatic neuroendocrine tumour with possible extrarenal secretion of $1,25(OH)_2D3$, which to our knowledge was previously described in one other case report[3].
Clinical case
A 44-year old gentleman had presented with symptoms of tiredness and vague abdominal discomfort for 3 months. Initial tests showed moderate hypercalcaemia with adjusted calcium of 3.28 mmol/l (2.20–2.60 mmol/l). There was mild hypophosphataemia of 0.58 mmol/l (0.80–1.50 mmol/l) suggestive of a PTH-related effect. However, serum PTH was suppressed at 0.2 pmol/l (1.3–9.3 pmol/l). Serum total 25-OH Vitamin D was within reference range at 31.9 nmol/l (25–50 nmol/l) but surprisingly $1,25(OH)_2D3$ level was elevated at 142 pmol/l (20–120 pmol/l). PTH-related peptide measurement was not performed due to resource limitations. Urinary calcium:creatinine ratio was 2.00 and urinary calcium excretion was high at 25.3 mmol/24 hours (2.5–7.5 mmol/24 hours) which excluded familial hypocalciuric hypercalcaemia. Serum and urine protein electrophoresis were negative for monoclonal band (paraprotein). CT abdomen demonstrated a large 14 cm retroperitoneal partly enhancing solid and partly cystic/non-enhancing mass in the upper abdomen suspected to be arising from the tail of the pancreas. There was a similar lesion in the right lobe of his liver which was hyperenhancing measuring 8.5 cm, and splenic vein obstruction with numerous collaterals. Ultrasound guided biopsy of his liver lesion showed features of neuroendocrine tumour with strongly positive immunohistochemistry stain for AE1/AE3 and Synaptophysin and weakly positive with Chromogranin and focal positivity with S100. The tumour was negative with PAX-8, Melan-A, SMA, Calretinin, CD31 and Desmin. Ki-67 index was 37.1% indicating a high-grade neuroendocrine tumour.
Hypercalcaemia was acutely managed by intravenous hydration and Zoledronic acid. As the tumour was high-grade with metastases, a decision was made for 3-weekly chemotherapy with Carboplatin and Etoposide, with serial CT monitoring.

Conclusion
Neuroendocrine malignancy should be considered as a potential cause of hypercalcaemia in malignancy. This case illustrates a pancreatic neuroendocrine tumour with possible extrarenal secretion of $1,25(OH)_2D3$ level resulting in hypercalcaemia.

New advances in the diagnosis of gonadotroph tumours

Araceli García-Martínez[1], Cristina Morote-Guillén[2], Sebastián Martínez-López[1], María Eugenia Torregrosa-Quesada[3], Sandra Silva-Ortega[4], Beatriz López-Muñoz[5], Óscar Moreno[5], Ignacio Aranda[4] & Antonio Picó[5]
[1]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Research Laboratory, Alicante, Spain; [2]Miguel Hernández University of Elche, School of Medicine, San Juan de Alicante, Spain; [3]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Biochemical Analysis Department, Alicante, Spain; [4]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Pathology Department, Alicante, Spain; [5]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Endocrinology Department, Alicante, Spain

Introduction
Gonadotroph tumours (GT) are the most common subtype of silent pituitary neuroendocrine tumours. The diagnosis of this subtype of tumours is established after surgery. There are no reliable markers of aggressiveness to predict their clinical course and, moreover, immunohistochemistry (IHC) usually classifies GT as null cell tumours. The aim of the present study was to correlate molecular, immunohistochemical and biochemical gonadotropin expression, to quantify the gene expression of transcription factors of gonadotroph lineage and to correlate molecular data with demographic, clinical and radiological variables.
Material and methods
34 molecularly identified GT were selected from PitNET collection of the Biobank of the Alicante Health and Biomedical Research Institute. Demographic variables (age, gender), clinical variables (neurophthalmological manifestations, pituitary hormone deficiency, invasiveness of the cavernous sinus, maximum tumour diameter, re-intervention), biochemical variables (pre-surgical concentrations of FSH and LH), IHC variables (protein expression of FSH and LH) and molecular variables (expression of FSH, LH, gonadotroph lineage transcription factors (ESR1, SF1 and GATA2)) were studied.
Results
13 patients (38.2%) were women and 21 (61.8%) men. The average age was 58.9±15.4 years. Among neurophthalmological manifestations the most prevalent was the oculomotor manifestation (58.8%) followed by headache (38.2%). 24 tumours (70.6%) were invasive. GT showed higher expression of GATA2 gene (mean: 10.590±9.309) compared with SF1 (mean: 0.619±0.284) and ESR1 (mean: 0.225±0.271). We observed a statistically significant correlation between gene and IHC expression of FSH ($r=0.380$, $P=0.024$). Protein expression of FSH correlated positively with pre-surgical concentrations of FSH ($r=0.45$, $P<0.01$). Tumour size correlated negatively with FSH gene expression ($r=-0.44$), $P<0.01$). None of the aforementioned variables had a significant association with growth and aggressiveness ($P>0.05$).
Conclusions
The positive correlation between pre-surgical levels of FSH and the IHC expression of FSH would allow anticipate the diagnosis of GT before surgery. The quantification of expression gonadotroph-lineage transcription factor genes could help diagnose these tumours.

The cushing's collaborative patient survey results

Elena Valassi[1], Antoine Tabarin[2], Iacopo Chiodini[3], Richard Feelders[4] & Cornelie Andela[5]
[1]Research Center for Pituitary Diseases, Hospital Sant Pau, Department of Endocrinology, Barcelona, Spain; [2] Diabetes and Nutrition, CHU ode Bordeaux, Department of Endocrinology, Pessac, France; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [4]Erasmus Medical Centre, Department of Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [5]Leiden University Medical Center, Department of Medicine, Division of Endocrinology, Leiden, Netherlands

Background
Early diagnosis of Cushing's syndrome and initiation of effective treatment are essential to limit long-term morbidity and early mortality. However, diagnosis is often delayed due to the non-specificity of symptoms, or because symptoms are not recognised by physicians, leading to more complex treatment needs and a worsening of patient quality of life. A survey was conducted to better understand the patient experience of Cushing's syndrome and the true burden of the disease. Here we report preliminary results from an interim analysis.
Method
An 11-question online patient survey, available in English and translated to eight languages, was distributed via the World Alliance of Pituitary Organisations and local patient organisations. All survey feedback received between 19 March 2019 and 19 January 2020 was analysed.
Results
In total, 250 participants from 26 countries participated; 58% of participants were aged 35–54 years and 92% were female. After diagnosis and subsequent treatment, 37% of participants surveyed reported that they were not satisfied with their treatment. The five symptoms reported most burdensome were obesity/weight gain (15.5%), fatigue (10.7%), depression/mood problems (9.5%), sleep disturbances (8.7%) and anxiety (8.2%). A delay in diagnosis of more than 2 years was reported in almost half of survey participants and a delay of more than 3 years was reported in 27% of participants. Endocrinologists (62.4%), followed by primary care physicians (16.0%), most commonly made the initial diagnosis or prescribed screening tests for Cushing's syndrome Endocrinologists (98%) and primary care physicians (53%) were also most commonly involved in disease management after diagnosis. After treatment, 83% of participants still experienced symptoms of Cushing's syndrome, including fatigue (72.0%), muscle weakness (47.0%), obesity/weight gain (43.1%), memory problems (41.4%) and lack of attention/concentration (38.8%). Despite the ongoing nature of these symptoms, many patients reported not receiving treatment for them. The symptoms most commonly treated were depression/mood problems and anxiety (40.5%), hypertension (36.0%), bone problems and fragility (23.9%), sleep disturbances (17.0%) and muscle weakness (12.1%). Most participants said that their work and social life had been most affected by their illness.
Conclusion
Results from this survey suggest that many patients experience a delayed diagnosis and that even after diagnosis and treatment, patients can continue to experience symptoms that affect their work and social life, and the disease burden post treatment remains high. Correct and timely diagnosis, as well as management strategies that address the wider symptoms of the disease, may improve the patient experience.

High-dose corticosteroid treatment of immunotherapy-induced hypophysitis: A multi-centric, restrospective analysis

Felix Amereller[1], Mamta Joshi[2], Timo DEUTSCHBEIN[3], Leo Duffy[2], Paul Carroll[2], Sophie Papa[4], Katharina Schilbach[1], Jochen Schopohl[1] & Sylvère Störmann[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München; [2]Department of Endocrinology, Guy's & Street Thomas' NHS Foundation Trust, London, UK; [3]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital Wuerzburg; [4]Guy's & Street Thomas' NHS Foundation Trust, London, UK

Introduction
Hypophysitis is a frequent side effect of oncologic immunotherapy. The recommended standard treatment is systemic high-dose corticosteroids (HDS), however, recent studies have questioned the benefits of this treatment. We sought to examine the effect of HDS on immunotherapy-induced hypophysitis (IH) in a multi-centric cohort.
Methods
Medical records of 41 patients with IH treated by specialist endocrinologists at three tertiary referral centres in Germany and the UK were retrospectively analysed. Only patients with a follow-up of ≥6 months were included (mean 25±14 months). While 29 patients did not receive specific treatment of IH, 12 were treated with HDS. Pituitary function, symptoms and MRI signs of IH during the course of disease were encoded into a database. We compared the groups using chi square test with a significance threshold of 0.05.

Results
The most frequently used drug for HDS was prednisolone ($n=10$, 40–80 mg/day), the other two patients received dexamethasone. Pituitary function improved (i.e. at least one hormone axis recovered) more often after HDS (5/12) than w/o treatment (6/29), however, the level of significance was not met ($P=0.16$). On the other hand, symptoms (mostly fatigue) resolved more often under hormonal substitution in untreated patients (15/29 vs 4/12; $P=0.28$). An improvement of MRI findings was observed in a similar portion of patients in both groups (25% HDS; 24% w/o treatment; $P=0.95$). Overall, none of the differences in outcomes reached the level of significance.
Conclusions
In our cohort, the course of IH did not differ significantly in patients with and w/o HDS. This finding aligns with other studies that could not find benefits of HDS. Instead, an appropriate replacement of hormone deficiencies seems sufficient.

Assessment of hypercoagulability in patients with cushing syndrome before and after surgical cure

Andreea Liliana Serban[1,2], Armando Tripodi[3], Rita Indirli[1,4], Beatrice Mantovani[1,4], Elisa Sala[1], Lidia Padovan[3], Maura Arosio[1,4], Giovanna Mantovani[1,4] & Emanuele Ferrante[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy, Milan, Italy; [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [3]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Milano, Italy, Italy; [4]Department of Clinical Sciences and Community Health, University of Milan, Italy

Background
Patients with Cushing's Syndrome (CS) have a high risk of venous thromboembolism (VTE) related to a hypercoagulable state. Previous studies showed increased levels of procoagulant factors but also an elevation of some of the anticoagulants factors and fibrinolytic enzymes. Once patients achieve disease remission, there is a significant decrease of some procoagulant factors but if these alterations are completely reversible is still unclear. Compared to traditional tests, thrombin generation assay (TGA) provides a global representation of haemostasis. Previous studies with TGA demonstrated that patients with endogenous hypercortisolism present a hypercoagulable profile compared to healthy controls.
Aim
To assess the short- and long-term modification of TGA in patients with CS after disease remission.
Patients and methods
19 patients with CS (16 pituitary adenomas, 2 adrenal adenomas, and 1 ectopic CS, female/male: 12/7, mean age 44.8±11,4 years) that achieved surgical remission and 19 controls matched for age and gender. Clinical characteristics, cortisol secretion profile and TGA parameters before surgical intervention, after 6 months and 5 years of persistent remission were assessed. Endogenous thrombin potential (ETP) ratio (ETP with/ETP without thrombomodulin) represents the resistance to the anticoagulant activity of the thrombomodulin and may be considered the best parameter through which in vivosubtle procoagulant imbalance can be detected.
Results
– Cortisol secretion profile: morning serum cortisol levels: 20.3 (median, IQR: 17–29) µg/dl, serum cortisol after 1 mg DXM: 12.7 (IQR: 4.2–17) µg/dl, urinary free cortisol: 1.65×ULN (IQR: 0.9–2.6)
– TGA: Patients with CS showed an ETP ratio significantly increased compared to controls (0.62±0.09 vs 0.56±0.09; $P=0.034$). No significant correlation between ETP ratio and cortisol secretion was found.
6 months after remission
– TGA: CS patients presented an ETP ratio significantly increased compared to controls (0.64±0.09 vs 0.56±0.09, $P=0.01$) and similar to baseline (0.64±0.09 vs 0.62±0.09, $P=0.87$).
5 years after remission
– TGA: ETP ratio of CS patients showed a significant decrease (0.55±0.14 vs 0.62±0.09, $P=0.02$) and was similar to the controls (0.55±0.14 vs 0.56±0.09, $P=0.7$).
Before surgery:
Conclusions
Plasma hypercoagulability detected in patients with active hypercortisolism persists at short-term and seems to be reversible after long-term remission of disease. Our observation is in line with other studies that demonstrated an increased VTE risk in post-operative period and suggests that in CS patients, especially in the presence of other risk factors for VTE, a long-term antithrombotic prophylaxis should be considered.

Morphometric vertebral fractures are highly prevalent in patients with non-functioning pituitary adenoma and related to older age and hypopituitarism

Stefano Frara[1], Luigi Di Filippo[1], Mauro Doga[1], Anna Maria Formenti[1], Marco Losa[2], Eugenia Resmini[1], Francesco Tecilazich[1], Pietro Mortini[2] & Andrea Giustina[1]
[1]Università Vita-Salute San Raffaele, Chair of Endocrinology, Milan, Italy; [2]Università Vita-Salute San Raffaele, Chair of Neurosurgery, Milan, Italy

Introduction
Recent studies showed that morphometric vertebral fractures (VF) are an early and frequent complication in patients (pts) withhyperfunctioning pituitary adenomas and hypopituitarism (independently from the etiology). GH excess or severe deficiency play a negative key role on bone health in this clinical setting. Disease control or adequate replacement therapies still remain a cornerstone for the clinician to reduce the burden of osteo-metabolic complications. To date, however, data on skeletal outcomes in pts with non-functioning pituitary adenomas (NFPA) are scanty.
Purpose of the study
To retrospectively evaluate the prevalence and determinants of VF in pts with NFPA.
Patients and methods
We consecutively enrolled 98 pts [51 males (M), 47 females (F); mean age 53±12 years old] with NFPA, attending the Pituitary Unit in IRCCS Ospedale San Raffaele for trans-sphenoidal surgery (TNS). We collected all biochemical data on pituitary function and histological exams. Pituitary hormonal deficiency was defined in case of low peripheral hormone levels and inappropriately normal or low pituitary hormones or in all those cases when replacement therapy was already prescribed. Consequently, hypopituitarism was defined by the presence of at least one pituitary deficiency. The vertebral fracture assessment (VFA) was based on Genant classification and completed on chest X-ray (MTRx), performed for anesthesiologic reasons.
Results
We observed a high prevalence of VF in pts with NFPA: 27 out of 98 pts (27.5%) were fractured and 10 (37.04%) had multiple VF, with no gender differences (M17/F10; *P=0.18*). Fractured pts were significantly older than non-fractured ones (mean age 57.93±12.52 vs 51.83±11.94; *P=0.03*). Moreover, pts with VF had significantly lower levels of fT3 (mean 2.26±0.71 vs 2.71±0.55 pg/ml; *P=0.005*) and GH (mean 0.39±0.53 vs 0.85±1.72 mg/ml; *P=0.05*). Based on biochemical parameters of pituitary axes, 56 pts (57.14%) had hypopituitarism. The prevalence of VF was significantly higher in pts with hypopituitarism: 20 out of 56 pts showed VF (35.7%) as compared to those without hypopituitarism (7/42, 16.67%) (*P=0.04*). Finally, the histological examination was positive for FSH in a significantly higher number of pts with VF than in non-fractured ones (15/27, 55.56% vs 23/71, 32.39%; *P=0.04*).
Conclusions
Our data demonstrated a high prevalence of VF in pts with NFPA. Based on these results, we suggest to perform a VFA in pts with NFPA at diagnosis, particularly those with hypopituitarism. Prospective post-surgical studies are needed to evaluate the incidence of VF and its relationship to biochemical and histological parametrs as well as surgical outcomes.

Course of serum potassium levels during the hypertonic saline infusion test for diagnosis of diabetes insipidus

Laura Potasso[1,2], Julie Refardt[1], Irina Chifu[3], Martin Fassnacht[3], Wiebke Kristin Fenske[4] & Mirjam Christ-Crain[1,2]
[1]University Hospital of Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital of Basel, Department of Clinical Research, Basel, Switzerland; [3]University Hospital of Würzburg, Department of Internal Medicine I, Divison of Endocrinology and Diabetes, Würzburg, Germany; [4]Leipzig University Medical Center, Integrated Research and Treatment Center for Adiposity Diseases IFB, Leipzig, Germany

Introduction
Onset of hyperkalemia has previously been reported during the administration of hypertonic resuscitation solutions. Since the hypertonic saline infusion test has recently been validated for the diagnosis of diabetes insipidus, we aimed to investigate the course of plasma potassium levels during the test.
Material and methods
Data of 144 patients undergoing osmotic stimulation with hypertonic saline infusion at 11 tertiary medical centres in Germany, Switzerland and Brazil from July 2013 to June 2017 were analyzed. Patients received a 250 ml bolus of 3% NaCl solution, followed by 0.15 ml/min/kg body weight continuously infused targeting a plasma sodium level of 150 mmol/l. Blood samples and clinical data were collected every 30 minutes. The primary outcome of this secondary analysis was percentage of patients developing hyperkalemia.
Results
Of the 144 patients, 9.7% (n =14) developed hyperkalemia of >5 mmol/l, 2% (n=3) >5.5 mmol/l and 0.7% (n=1)>6 mmol/l. The majority of the affected patients were diagnosed with primary polydipsia (86% >5 mmol/l and 100% in the other 2 groups). Hyperkalemia was transient and not clinical symptomatic in all patients. Onset of hyperkalemia was related with duration of the infusion test, showing a peak after 120 minutes. A plasma sodium <146 mmol/l at 30-minute test duration was associated with development of hyperkalemia >5 mmol/l (OR 5.5, 95% CI 1.6–25.4, P=0.01). No association was found with plasma chloride or pH levels.
Conclusion
Patients with primary polydipsia are at risk to develop hyperkalemia while undergoing hypertonic saline infusion test, although its incidence is low. Particular attention should be paid if test duration exceeds 90-minutes and in patients with a plasma sodium <146 mmol/l after 30 minutes.

Concordant testing results in differential diagnosis in ACTH-dependent cushing's syndrome: A retrospective study of high dose dexamethasone suppression test (HDDST) and DDAVP stimulation test

Jingtao Qiao, Weiwei Zhang & Yerong Yu
West China Hospital of Sichuan University, Endocrinology •metabolism, Chengdu, China

Background
Investigating the origin of ACTH determine disparate treatment and prognosis in ACTH-dependent Cushing's Syndrome. We want to detect the value of combination of HDDST and DDAVP stimulation test for identifying Cushing's disease (CD) and Ectopic ACTH-dependent Cushing's Syndrome (EAS).
Methods
We retrospectively recorded 102 ACTH-dependent Cushing's Syndrome (87 CD and 15 EAS) in West China Hospital from January 1, 2010 to December 31, 2019. Focus on HDDST and DDAVP test, evaluated sensitivity (SE), specificity (SP) and cut-off obtained with ROC analysis respectively, estimate diagnostic accuracy when experiencing concordant tests.
Results
EAS patients have higher ACTH, serum cortisol, 24 h UFC levels, inversely weaker response to 1 mg dexamethasone suppression test (1 mg-DST) than CD (P<0.01). As for HDDST, 24 hUFC suppression below 61.69% suggested a pituitary origin with a SE of 81% (95% CI : 70–90) and a SP of 79% (95% CI : 49–95). Suppressed series had lower baseline level compared with non-suppressed group (P<0.01). A threshold percentage ACTH increase after DDAVP stimulation of 44.63% was able to identify CD with a SE of 91% (95% CI 83–97) and a SP of 80% (95% CI 52–96). When two parallel test results consistent, the diagnostic accuracy matched to BIPSS or pathology verification could reach 95.52%, up to 100% attached MRI≥6 mm findings.
Conclusion
Combined with HDDST and DDAVP stimulation test can enhance accuracy rate searching origin of ACTH secretion, especially in cases with≥6 mm MRI uncovering, BIPSS could be avoid.

Background
Clinically non-functioning pituitary macroadenomas (NFMA) have been reported to express various somatostatin receptor (SSTR) subtypes, but results are inconsistent across different studies. This may be related to limited sensitivity and specificity of techniques used to date, i.e. immunohistochemistry in surgical specimens and ^{111}In-DTPA-octreotide scintigraphy (Octreoscan) *in vivo*. The aim of this study was to assess SSTR expression in NFMA *in vivo* using ^{68}Ga-DOTATATE PET, which provides superb $SSTR_2$affinity and offers superior sensitivity and spatial resolution as compared to Octreoscan. An additional interest was the proportion of patients with a T2-hypointense adenoma on MRI and the relation with tracer uptake, as T2-hypointensity has been associated with higher $SSTR_2$expression in GH-secreting adenomas.
Methods
Forty-nine patients diagnosed with NFMA underwent ^{68}Ga-DOTATATE PET/CT of the head in the framework of a randomised controlled trial assessing the effect of the somatostatin analogue lanreotide on NFMA size. ^{68}Ga-DOTATATE uptake was assessed after co-registration with T1-weighted pituitary MRI. A circular region of interest was placed within the adenoma and the mean standard uptake value (SUV_{mean}) was evaluated. An SUV_{mean} of >2 was considered positive. Signal intensity of the adenoma was assessed visually on a coronal T2-weighted sequence of the same MRI and was classified as hypointense, isointense or hyperintense as compared to normal pituitary tissue.
