^{68}Ga-DOTATATE uptake was positive in 45/49 patients (92%), with SUV_{mean} in positive adenomas ranging from 2.1 to 14.4 (median 5.5). A T2-hypointense, -isointense, and -hyperintense adenoma was observed in 2 (4%), 13 (37%), and 33 (69%) patients, respectively. In one patient T2-signal intensity was not assessed due to a predominant cystic adenoma. SUV_{mean} was not associated with maximum NFMA size or with T2-hypointensity.
Conclusions
This first series of ^{68}Ga-DOTATATE PET performed in NFMA patients demonstrates *in vivo* SSTR expression in the vast majority of cases. The high positive uptake rate when compared to earlier results obtained using Octreoscan (92% vs ~66%) most probably reflects the superior sensitivity and higher spatial resolution of PET imaging. Only 2 patients had a T2-hypointense adenoma, which did not coincide with high tracer uptake. It thus remains uncertain whether T2-hypointensity reflects $SSTR_2$ expression. The clinical use of ^{68}Ga-DOTATATE PET in selecting NFMA patients for somatostatin analogue treatment should be evaluated in well-designed intervention trials.

Introduction
Results of the first European real-world evidence from retrospective cohort of ACRONIS study previously confirmed the efficacy and tolerability of LA-PAS in heavily pre-treated, uncontrolled acromegaly patients. Here, we report results of the second interim analysis reflecting the prospective cohort.
Methods
Patients who were treated with LA-PAS for ≥6 months were included in this analysis. The primary objective was to document treatment efficacy, defined by the proportion of patients who achieved IGF-1 level normalization <1 upper limit of normal (ULN) and GH <1 µg/l at 6 months of LA-PAS treatment. Key secondary objectives were changes from baseline in standardized IGF-1 and GH levels, proportion of patients with IGF-1 normalization and GH normalization over time, overall safety and tolerability of LA-PAS.
Results
On 13 Sep 2019, 112 of 200 enrolled patients completed 6 months LA-PAS treatment. Among these, 94 and 109 were included in efficacy and safety analysis, respectively. The mean age of the patients was 50.1 years; 51.1% were male. Median time since diagnosis was 66.5 months; 73.4% had previous surgery and 19.1% had radiotherapy; 98.9% had taken prior medication, mainly first-generation SSAs (58.5% octreotide, 61.7% lanreotide), growth hormone receptor antagonists (38.3%) or dopamine agonists (37.2%) as mono- or combination therapy. In the safety analysis set, 22.0% and 37.6% of patients were diabetic or pre-diabetic prior to LA-PAS prescription, respectively. IGF-1 normalization <1 ULN and random GH <1 µg/l was achieved in 31.9% (95% CI, 21.4–43.9) of patients and IGF-1 normalization <1 ULN and random GH <2.5 µg/l in 44.4% (95% CI, 32.7–56.6) at 6 months. Median (95% CI) percentage reductions from baseline in IGF-1 and GH were 34.3% (43.0–27.6) and 66.8% (73.4–52.9) at 6 months, respectively. IGF-1 normalization (<1 µg/l and <1.3 µg/l) was achieved in 51.8% (40.6–62.9) and 72.3% (61.4–81.6) at 6 months. After median exposure of 22.1 months (range 5.9–29.8), 68.8% remained on starting dose, 22% were up-titrated once, 4.6% were down-titrated once and 4.6% required multiple dose changes. The most common adverse events (AEs in >10%) reported were hyperglycemia (21.1%), diagnosed diabetes mellitus (12.8%) and diarrhea (10.1%). One patient reported permanent discontinuation of LA-PAS due to Grade 2 hyperglycemia.
Conclusion
Findings from this prospective ACRONIS dataset confirm the efficacy of LA-PAS in previously uncontrolled acromegaly patients and are in agreement with those reported in a previous randomized trial (Gadelha, *et al.* Lancet Diabetes Endocrinol. 2014). The safety of LA-PAS was consistent with its known profile.

Background
Neuropsychiatric symptoms and cognitive dysfunction are common in Cushing´s disease (CD), and seem only partly reversible after biochemical remission has been achieved.
Aim
To investigate prescription of drugs associated with neuropsychiatric morbidity in a large national cohort of CD patients.
Methods
Patients in the Swedish Pituitary Registry, diagnosed with CD between July 2006 and January 2018 were included, $n=179$ (139 women), median age at diagnosis 45 years (range 11–81). Each CD patient was matched with four controls from the background population, by sex, age and living area. Data on dispensed antidepressants, sleeping pills/tranquilizers, opioids, anti-hypertensive and anti-diabetic drugs including insulin was collected from the Swedish Prescribed Drug Registry. Dispense of each drug was investigated from 5 years before diagnosis, during active disease, and at 5- and 10-year follow-up. Chi-square and logistic regression analyses were employed.
Results
In active disease 30% of CD patients vs 16% of controls were on antidepressants, OR 2.29, (95% CI 1.57–3.35); sleeping pills/tranquilizers 32% vs 10%, OR 4.16 (2.80–6.17); opioids 49% vs 12%, OR 6.75 (4.67–9.75). 130 CD patients (remission $n=110$, not remission $n=16$, remission status unknown $n=4$) were available for a 5-year follow-up. Use of antidepressants remained high, 27% in all CD patients regardless of disease control (in remission 26%), sleeping pills/tranquilizers, 24% (in remission 23%) and opioids, 35% (in remission 35%), whereas use of anti-diabetic drugs decreased from 28% at diagnosis to 13% (in remission 13%), RAS-blockade from 56% to 28% (in remission 25%), Ca-antagonists from 38% to 12% (in remission 8%). At 10-year follow-up of CD in remission ($n=52$), use of antidepressants and sleeping pills/tranquilizers still remained high, 25% and 21% respectively. In subjects eligible for analysis *before* diagnosis (CD $n=103$, controls $n=412$), 32% of CD vs 17% of controls, OR 2.39 (1.46–3.89) had been prescribed an antidepressant on at least one occasion; sleeping pills/tranquilizers 24% vs 17%, OR 1.62 (0.96–2.73); opioids 49% vs 25%, OR 2.91 (1.86–4.54). Notably, the CD vs control difference in use of antidepressants was apparent already 5 years before CD diagnosis.
Conclusions
This prospective registry study shows that a high rate of patients with CD were on drugs for neuropsychiatric morbidity and pain from at least 5 years before diagnosis. Regardless of remission status the rate remained high, suggesting non reversible effects on mental health and a need for long-term follow-up.

Purpose
To evaluate the relationship between basal dehydroepiandrosterone-sulfate (DHEA-S) levels and other tests used in the diagnosis and differential diagnosis of Cushing's Syndrome (CS) among the patients with pathologically confirmed CS.
Methods
In this multicenter study, the data of 623 patients with CS were evaluated retrospectively. The patients were classified as Group 1 ($n=353$ Cushing's disease;CD), Group 2 ($n=242$ adrenal CS) and Group 3 ($n=28$ ectopic ACTH syndrome; EAS). The groups were compared in terms of demographic data, estimated duration to diagnosis of CS, pre-operative ACTH, basal cortisol, DHEA-S, 24-hour urinary free cortisol (24 h-UFC) levels and dexamethasone suppression test (DST) results. Correlations between DHEA-S levels and all parameters were evaluated. A ROC curve was produced to calculate the optimal DHEA-S cut-off value in the differential diagnosis of CS. The effectiveness of the calculated DHEA-S cut-off level in demonstrating the accurate etiology of patients with gray zone in terms of ACTH levels (10–20 pg/ml) was assessed.
Results
The Group 1 patients were younger than the Group 2 patients ($P<0.001$), while Group 3 had more male patients than the others ($P<0.001$). Basal cortisol, ACTH, 24 h-UFC levels were significantly different between the three groups (Group 3>Group 1>Group 2), ($P<0.001$, for all comparisons). The DHEA-S level was significantly lower in Group 2 compared to the other two groups ($P<0.001$), while Group 1 and Group 3 had similar DHEA-S levels. There was a negative correlation between DHEA-S levels and age at diagnosis ($r=–0.184$, $P<0.0001$) and high-dose DST ($r=–0.133$, $P<0.0001$); and a positive correlation between basal cortisol ($r=0.247$, $P<0.0001$), ACTH ($r=0.550$, $P<0.0001$) and 24 h-UFC levels ($r=0.172$, $P<0.0001$).No significant correlation was found between DHEA-S levels and other parameters. The optimal cut-off DHEA-S value that providing differential diagnosis of CS was calculated to be 43.2 µg/dl [sensitivity of 88%(79–93%) and specificity of 76% (70–82%)] between Group 1 and Group 2. This DHEA-S cut-off level demonstrated the accurate etiology in 93% of 14 CD and 100% of 44 adrenal CS in patients with gray zone in terms of ACTH levels. The optimal DHEA-S cut-off value that providing differential diagnosis of CS was calculated to be 136.5 µg/dl [sensitivity of 91% (87–98%) and specificity of 73% (69–81%)] between Group 2 and Group 3. No significant cut-off level was found between Group 1 and Group 3.
Conclusion
This study showed that the DHEA-S cut-off value could be used for differential diagnosis of CD and adrenal CS with high sensitivity and specificity, at the initial evaluation.

Midparental height is an important predictive parameter in a late diagnosis of acromegaly and gigantism in adults. Single centre, pilot study

Anna Bogusławska[1], Aleksandra Gilis-Januszewska[2,3], Magdalena Godlewska[2], Marta Olszewska[4], Alicja Hubalewska-Dydejczyk[2,3] & Jerzy Starzyk[1]
[1]Chair of Paediatrics, Paediatric Institute, Jagiellonian University Medical College, Department of Paediatric and Adolescent Endocrinology, Cracow, Poland; [2]University Hospital in Cracow, Endocrinology Department, Cracow, Poland; [3]Jagiellonian University, Collegium Medicum, Chair and Department of Endocrinology, Cracow, Poland; [4]Jagiellonian University Collegium Medicum, Department of Paediatrics, Cracow, Poland

Introduction
Acromegaly is a rare disorder caused by excessive growth hormone production. Common clinical manifestations are visual changes as well as serious systemic complications. In childhood and adolescence, excessive growth hormone production leads to abnormal tall stature. To date, only a few studies have been published focusing on analysing the growth of patients with acromegaly, in particular regarding the growth of their parents and siblings. A single report (Perheentupa *et al.* 1986) suggested, that acromegalic patients came from high-growth families. The aim of this study is to test the relationship between the tall stature related to midparental height (MPH) and clinical features, the onset of diagnosis and comorbidities.
Methods
This is a pilot, one centre cohort study conducted in 2019 among adult acromegalic patients with no family history of pituitary adenoma. Patients were analysed in 2 subgroups depending on body height: normal stature and tall stature defined as body height above 97 percentile for sex, age, and ethnicity or >1.5 standard deviation (s.d.) from MPH. The structural anamnesis including e.g. data on parents/siblings/patient's body height was collected during a routine outpatient clinic visit.
Results
Among 100 consecutivepatients interviewed in the outpatient clinic, full data were available from 26 males (43%) and 34 females (57%) with a mean age at the diagnosis 46 years (19–75). Retrospectively 14 patients (23%) presented features of acrogigantism: 15% met criteria of gigantism, whereas 8% presented tall stature. Acrogigantism patients were significantly younger (33.64±10.74 vs 50.24±14.15 years) with concomitant hypogonadism (64.29 vs 26.83%), greater tumour size (21 vs 12 mm) and higher growth hormone concentration (62.5 vs 21.8 uIU/ml) in comparison to normal stature patients (<0.05). In acromegalic patients with normal stature father's height (–0.37±0.97 s.d.) and mother's height (–0.82±0.96 s.d.) were smaller in comparison to the polish population mean ($P<0.05$). Only female siblings' height in both groups and mother's height in tall stature group were above the polish population mean but not statistically significant.
Conclusion
According to our results, the higher stature of patients with sporadic somatotropinoma might be due to pre-existing unrecognized gigantism in adolescence and it is not associated with primary genetic tallness. Midparental hight is an important predictive parameter in a late diagnosis of acrogigantism.

Phenotypic differences between patients with familial pituitary neuroendocrine tumours due to MEN1 or AIP mutations

Pedro Marques[1], Daniela Magalhães[2], Francisca Caimari[1], Laura Hernández Ramírez[1,3], David Collier[1], Chung Lim[1], Karen Stals[4], Sian Ellard[4], Maralyn Druce[5], Scott Akker[5], Mona Waterhouse[5], William Drake[5], Ashley B. Grossman[1] & Marta Korbonits[1]
[1]William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, UK, Centre for Endocrinology, London, United Kingdom; [2]Centro Hospitalar e Universitário de São João, Porto, Portugal, Department of Endocrinology, Porto, Portugal; [3]Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH). Bethesda MD, USA, Section on Endocrinology & Genetics, Bethesda, United States; [4]Royal Devon and Exeter NHS Foundation Trust, Exeter, UK, Department of Molecular Genetics, Exeter, United Kingdom; [5]St. Bartholomew´s Hospital, West Smithfield, London, UK, Department of Endocrinology, London, United Kingdom

Introduction
Germline *AIP* and *MEN1* mutations are the main known aetiologies of familial pituitary neuroendocrine tumours (PitNETs), which represent 5% of all PitNETs. We compared the clinical and tumour characteristics of *AIP* (*AIP* mut) and *MEN1* mutation-positive (*MEN1* mut) PitNET patients.
Methods
We retrospectively analysed 70 *MEN1* mut and 167 *AIP* mut patients with PitNETs. *MEN1* genetic testing was performed according to currentguidelines, while *AIP* genetic analysis was offered to FIPA patients, as well as

sporadic pituitary macroadenomas with onset <30 yr or micro/macroadenomas with onset <18 yr.
Results
In our *MEN1* mut PitNET cohort, 52.9% were females, age at PitNET diagnosis was 29.6±16.6 yr (mean± s.d.) and 58.6% had a prolactinoma, whereas in the *AIP* mut PitNET cohort, 61.1% were males, mean age at PitNET diagnosis was 24.3±11.9 yr and somatotropinomas predominated (81.4%). *MEN1* mut PitNET patients had lower rates of hypopituitarism at diagnosis (21.4 vs 42.7%; $P=0.011$), fewer macroadenomas (42.4 vs 83.2%; $P<0.001$), extrasellar and suprasellar extensions (28.6 vs 66.7%; $P<0.001$, and 28.6 vs 54.3%; p=0.004, respectively), fewer pituitary deficits at diagnosis (0.3±0.7 vs 0.8±1.1; $P=0.006$) and smaller tumour diameter (14.6±15.0 vs 20.1±13.0 mm; p=0.005), and none had pituitary apoplexy (vs 8.2%; p=0.026) in comparison to *AIP* mut PitNETs. *MEN1* mut PitNET patients required fewer treatments (1.0±1.0 vs 2.1±1.7; $P<0.001$) and fewer operations (0.2±0.5 vs 0.9±0.8; $P<0.001$), less radiotherapy (13.4 vs 32.9%; p=0.003) and fewer multimodal treatments (30.4 vs 67.2%; $P<0.001$), and had a 5.5-fold less active disease at last follow-up (4.7 vs 25.0%; p=0.004) than *AIP* mut PitNETs.
When comparing individual tumour types, *AIP* mut somatotropinomas had higher rates of macroadenomas (90.0 vs 51.7%; $P=0.009$), extrasellar extension (75.7 vs 25.0%; $P=0.026$) and required more operations (1.1±0.8 vs 0.4±0.5; $P=0.009$) than *MEN1* mut somatotropinomas, and showed a trend for more cavernous sinus invasion (41.9 vs 0%; $P=0.096$). *MEN1* mut prolactinomas had lower pituitary apoplexy rate (0 vs 16.7%; $P=0.016$) and a trend for lower rates hypopituitarism at diagnosis (30.3 vs 62.5%; $P=0.090$) with fewer pituitary deficiencies (0.5±0.9 vs 1.4±1.5; $P=0.066$), and fewer operations (0.2±0.4 vs 0.4±0.5; $P=0.072$) than *AIP* mut prolactinomas. NF-PitNET did not differ between *MEN1* mut and *AIP* mut patients, except regarding age at first symptoms (higher in MEN1 subgroup, 53.5±5.0 vs 22.6±7.7 yr; $P=0.040$).
Conclusions
*AIP*mut PitNETs are in general more aggressive than *MEN1*mut PitNETs. This is dominated by more aggressive disease in *AIP*mut prolactinomas and somatotropinomas compared to *MEN1*mut prolactinomas and somatotropinomas, while *AIP*mut and *MEN1*mut NF-PitNETs (some of those possibly representing incidentalomas) may show an indolent course of disease and often require no treatment.

AEP601

A case of wolfram syndrome with primary hypogonadism

Murat Calapkulu, Muhammed Erkam Sencar, İlknur Ozturk Unsal, Hakan Duger, Muhammed Kizilgul, Hayri Bostan, Erman Cakal & Mustafa Ozbek
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Turkey

Introduction
Wolfram syndrome, is a rare autosomal recessive genetic disorder that is characterized by diabetes mellitus (DM), diabetes insipidus (DI), optic atrophy, and sensorineural deafness as well as various other possible disorders. DM is the first manifestation, and optic atrophy also onsets in the first decade of life. The onsets of DI and sensorineural deafness are in the second decade, urinary tract abnormalities are in the third decade, and neurologic abnormalities are in the fourth decade, respectively. Hypogonadotropic hypogonadism is a usual manifestation of the syndrome; however, as in the present case, primary hypogonadism can be rarely seen. Herein, we aimed to present a case of Wolfram syndrome with primary hypogonadism.
Case report
A 25- year old male patient admitted to our clinic with complaints of polydipsia, polyuria, and mouth dryness. The onset of DI and optic atrophy was at the age of thirteen and started desmopressin therapy. He was diagnosed with DM at the age of fourteen, and intensive insulin therapy was instituted subsequently. His polyuria and polydipsia complaints continued even at times with oral desmopressin treatment when his blood glucose levels were at normal values. The patient's laboratory tests revealed sodium:148 mEq/l (136–146) urine density:1005.In the hormonal panel; FSH: 33.4 IU/l (1.5–12.4), LH: 30.9 IU/l (1.7–8.6), total testosterone: 335 ng/dl (280–800). Serum IGF-1, ACTH, cortisol, TSH, free T4 levels were normal. Desmopressin (melt) dose was eventually titrated up to a 360 mg bid. Even with this dose, he was putting out 4 liters of urine daily. Therefore oral desmopressin therapy stopped, and desmopressin was started ten mg intranasally at three times a day. After intranasal desmopressin, his urine output decreased, and serum sodium gradually improved to 140 mmol/l. In the hypophysis MRI, gland dimensions were normal, and there were neither adenoma nor cystic lesions. In the scrotal ultrasonography, bilateral testicles were in the scrotum, and the sizes were slightly smaller than normal. Spermiogram analysis was revealed compatible with azoospermia. There were no trauma, surgery, infection, or cytogenetic defect history that could be related with primary hypogonadism. So primary hypogonadism was accepted as a component of Wolfram syndrome.
Discussion
As in the present case, the patients diagnosed with Wolfram syndrome requires long-term follow-up because of the various clinical disorders that can occur over the years. Primary hypogonadism should be kept in mind in case of symptoms and signs of hypogonadism at Wolfram syndrome.

Effect of silibinin on acth synthesis and secretion in human adenomatous corticotropes *in vitro*

Maria Francesca Cassarino[1], Antonella Sesta[1], Laura Libera[1], Donatella Bardelli[1], Marco Losa[2], Giovanni Lasio[3] & Francesca Pecori Giraldi[1,4]
[1]Istituto Auxologico Italiano IRCCS, Neuroendocrine Research Laboratory, Milan, Italy; [2]Ospedale San Raffaele, Department Neurosurgery, Milan, Italy; [3]Istituto Clinico Humanitas, Department Neurosurgery, Milan, Italy; [4]University of Milan, Department of Clinical Sciences & Community Health, Milan, Italy

Silibinin, a milk thistle extract with known hepatoprotective effects, has recently been shown to act upon tumoral corticotropes and revert the Cushingoid phenotype in an allograft mouse model (Riebold *et al.* 2015). Silbinin is known to inhibit HSP90 -a chaperone to the glucocorticoid receptor-thereby restoring sensitivity to glucocorticoid negative feedback in tumoral corticotropes. Aim of the present study was to assess the effect of silibinin on ACTH synthesis and secretion by human corticotrope adenomas *in vitro*.
Methods
Eight human ACTH-secreting pituitary adenomas were collected during surgery and established in culture as per our protocol (Pecori Giraldi *et al.* 2011). Specimens were treated with 10–50 µM silibinin for up to 72 hours. ACTH medium levels were measured by Elisa; *POMC* expression was assessed by RT-PCR (Cassarino *et al.* 2017).
Results
Silibinin reduced spontaneous ACTH secretion to a variable extent in individual adenomas: from 32 to 79% of baseline at 4 h, and 54–85% of baseline at 48 and 72 h. Silibinin was also effective in reinstating or enhancing sensitivity to steroid negative feedback: ACTH decreases during 10–50 µM silibinin incubation ranged from 10 to 63% of dexamethasone-treated wells at 4 hours, 70–80% at 48 hours and 36 to 80% at 72 hours, indicating long-lasting effect on glucocorticoid sensitivity. Silibinin induced a variable decrease in *POMC* expression, both as regards expression in control and dexamethasone-treated wells; some specimens exhibited a marked sensitivity to the inhibitory effect, with *POMC* expression decreasing to less than 50% of control.
Conclusions
This data suggests that silibinin can inhibit ACTH secretion and *POMC* synthesis and restore sensitivity to negative glucocorticoid feedback.

TGF-β increases caspase 3 activation and migration in bronchial carcinoids

Patricia Borges de Souza, Valentina Tagliatti, Simonaco Capobianco, Maria Rosaria Ambrosio & Maria Chiara Zatelli
University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Italy

Introduction
Typical and atypical bronchial carcinoids (TBC and ABC) are well-differentiated neuroendocrine neoplasms (NEN). First-line treatment is radical removal of the primary tumour; however, management of metastatic BC is still challenging. Bronchial carcinoids (BC) may benefit from treatment with mTOR inhibitors, although response rates are moderate. TBC have shown reduced sensibility to mTOR inhibitors respect to ABC, notwithstanding its less aggressive behaviour. PI3K/AKT/mTOR crosstalk with TGF-β has been reported and could explain the differential sensitivity of BC to treatment. Previous studies have reported TGF-β's ability to activate mTOR pathway and induce epithelial to mesenchymal transition (EMT), affecting cell survival, proliferation, migration and invasiveness.
Aims
The present study focused on understanding the possible crosstalk between TGF-β signalling and PI3K/AKT/mTOR in BC.
Materials and methods
Basal levels of TGF-β downstream proteins were analysed by Western blot in BC (4 TBC and 3 ABC). Functional assays (cells viability, migration and caspase 3/7 activation) were performed using TBC *in vitro* cell model (NCI-H727 cell line) after treatment with the mTOR inhibitor everolimus (Eve) at 100 nM concentration and/or 1 pM TGF-β.
Results
TGF-β/SMAD protein levels were higher in TBC vs ABC tissues. Mean differences (% TBC vs ABC) were as follows: TGF-βRI (17.85±5.298; $P=0.007$), TGF-βRII (50.07±23.52; $P=0.04$), Smad 2/3 (536.6±159.9; $P=0.008$). In addition, caspase 3 levels were higher in TBC vs ABC tissues (257.0±131.8, $P=0.03$). In NCI-H727 cells, TGF-β or Eve treatment alone had no effect on cell viability, whereas their combination slightly reduced it by >10% vs control ($P=0.009$) and this effect was not accompanied by apoptosis induction. TGF-β, however, increased caspase activation by 14% vs control ($P=0.04$). Combined treatment with Eve abrogated this effect. TGF-β induced migration in TBC cell model by 40% vs control, whereas combined treatment with Eve abrogated cell migration, reducing this phenomenon by 27% vs control ($P<0.0001$).
Conclusion
TGF-β/SMAD and PI3K/AKT have major roles in cells pathophysiology and have been reported to be activated simultaneously in advanced states of tumorigenesis. We report an increased expression of TGF-β/SMAD proteins as well as enhanced caspase activation in TBC cells. The interplay between these pathways could explain TBC increased resistance to medical therapy by inducing EMT. Combined treatment with the mTOR inhibitor Eve abrogated TGF-β induced EMT and, therefore, inhibition of TGF-β/SMAD and PI3K/AKT/mTOR pathways could potentially reduce tumour malignancy in these cells.

Salivary cortisol and cortisone – Effects of liquorice and blood contamination

Nils Bäcklund[1], Marcus Imamovic[1], Göran Brattsand[2], Staffan Lundstedt[2], Elisabeth Aardal[3], Tommy Olsson[1] & Per Dahlqvist[1]
[1]Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden; [2]Umeå University, Department of Medical Biosciences, Umeå, Sweden; [3]Linköping University, Department of Clinical and Experimental Medicine, Linköping, Sweden

Context
Late-night salivary cortisol is a recommended screening method for Cushing's syndrome. Liquorice intake may lead to falsely elevated salivary cortisol as glycyrrhizic acid inhibits the 11β-hydroxysteroid dehydrogenase type 2 induced conversion of cortisol to cortisone in the salivary glands. Furthermore, sample contamination by blood from the oral mucosa may also cause falsely elevated salivary cortisol levels. Salivary cortisone has been suggested to more closely reflect free plasma cortisol and is less likely to be affected by these preanalytical errors.
Objective
To determine if (i) liquorice consumption significantly increases late-night salivary cortisol levels, and if so, what dose is required for this to happen and how long wash-out period is required for salivary cortisol levels to normalize; (ii) what level of blood contamination lead to significantly increased salivary cortisol levels.
Design
Thirty healthy volunteers abstained from liquorice for four weeks prior to the study. Participants were randomized to a low, medium or high dose of liquorice, corresponding to a daily glycyrrhizic acid dose of 1.5, 3.0 or 6.0 mg/kg body weight. Saliva samples were collected during five days of baseline sampling, one week of daily liquorice consumption and four weeks of wash-out. Another sixteen healthy volunteers collected both saliva and blood samples, which were mixed to achieve a graded blood contamination of the saliva. Salivary cortisol and cortisone were analyzed with LC-MS/MS. Blood contamination was quantified using Cobas Hemolysis index (Roche Diagnostics) and by visual examination on a 7-point scale.
Results
Significant increases of salivary cortisol levels were observed during the seven days of liquorice intake in the medium and high dose groups (median increase 66% and 137%, respectively). The salivary cortisol levels returned to baseline four days after liquorice withdrawal in both groups. Salivary cortisol increased significantly by a 0.5% blood contamination. Visual grading corresponded very well to hemolysis index. Salivary cortisone levels were not affected by liquorice consumption or blood contamination.
Conclusion
Liquorice intake equivalent to a glycyrrhizic acid dose of 3–6 mg/kg body weight, corresponding to a daily intake of 100 g liquorice candy for a 70 kg person, causes a significant increase in late-night salivary cortisol levels. This effect weans off after four days. Saliva samples with a blood contamination of 0.5% leads to significantly increased salivary cortisol levels. Visual screening is sufficient to exclude significantly blood contaminated samples. Salivary cortisone levels are independent of both these preanalytical errors.

An education programme for patients with pituitary tumours and their relatives; preliminary results

Jenny Tiberg Persson[1], Sofie Jakobsson[2], Kristina Cid Käll[1], Lena Kullin[1], Ann-Charlotte Olofsson[1], Ia Wittboldt[1], Thomas Skoglund[3], Penelope Trimpou[1], Eva Jakobsson Ung[2] & Gudmundur Johannsson[1]
[1]Sahlgrenska University Hospital, Endocrinology, Göteborg, Sweden; [2]Sahlgrenska Academy Institute of Health and Care Sciences, Sweden; [3]Sahlgrenska University Hospital, Neurosurgery, Gothenburg, Sweden

Background
Patients with pituitary tumour live with life-long consequences of their disease. The first year after pituitary surgery represents a time period of symptoms, fear of tumour recurrence, existential concerns as well as extensive medical evaluations and decisions about hormone replacement. To increase wellbeing, a person-centred care practice up to 1 year after pituitary surgery covering self-management support, accessibility and continuity has been implemented and are under current evaluation. One part of this practice an education programme for patients and their relatives has been implemented.
Aim
To evaluate an education programme within a person-centred practice for patients with pituitary tumours and their relatives.
Method
After pituitary surgery all patients at a specialist endocrine clinic are offered a one-time education programme six-nine months after surgery. The content was developed in collaboration with patients and an interdisciplinary pituitary team. Specific content comprise surgery, tumour recurrence, medical evaluation and treatment, symptom and signs, health and quality of life with information from neurosurgeons, endocrinologists and specialist endocrine nurses. The education includes discussions on common experiences and skills needed to manage different symptoms in daily life. After participation patients are asked to complete a questionnaire with structured and open response alternatives on the benefit of participation and what could be added to the programme.
Findings
During one year 39 patients were invited and 33 attended. Participants were 26 to 81 years and 1/3 brought a relative. Totally, 27 patients completed the evaluation (82% response rate). All responders reported that the education

was meaningful. The peer-support and the medical information were rated equally important. Respondersreported that they felt comfortable in the group, but some thought should be more discussion among patients supported by physician and nurses. Some wanted more individual information from the other participants such as tumour type. The majority stated that they have gained new or more in-depth knowledge. Most participants thought the timing of the information after surgery and treatment was good. A few participants expressed a need to havethis type of information before surgery.
Conclusions
A pituitary tumour school can be a way to provide patients with more knowledge about their illness as well as an opportunity to exchange experiences. The time 6–9 months after the surgery was considered appropriate based on the participators evaluation.

Clinical picture and MRI findings in patients with hypophysitis – a single-centre experience

Izabella Czajka-Oraniec[1], Maria Stelmachowska-Banas[1], Karolina Cylke[2] & Wojciech Zgliczynski[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Bielanski Hospital, First Internal Ward, Warsaw, Poland

Hypophysitis is a rare clinical condition manifesting as pituitary dysfunction: hypopituitarism or diabetes insipidus (DI) and pituitary enlargement causing mass effect (headaches, visual disturbances) due to the inflammation of the pituitary gland. We conducted a retrospective analysis of medical records of patients diagnosed with hypophysitis in the Department of Endocrinology of the Bielanski Hospital from 2014 to 2019. Twenty-five patients were identified, which represents 0.3% of all patients hospitalized at the Department during that period. Women predominance was noted (80% females and 20% males) and a mean age of patients was 40.6 ± 16.2 years. No association with pregnancy and labour was present except for one patient. Primary hypophysitis was suspected in most cases. Secondary hypophysitis was recognized in 3 patients – one with Langerhans cell histiocytosis and two immunotherapy induced. Diagnosis was based on clinical picture, hormonal and imaging results. No histopathologic confirmations were available in 23 cases. The most common symptoms at presentation were headaches and DI (52% of cases each). Anterior pituitary dysfunction was frequently present – at least one tropic hormone deficiency was found in 60% of patients. Gonadotroph deficiency was the most frequent (48%), followed by TSH and ACTH deficiencies (in 44% and 40%, respectively). Panhypopituitarism was present in 7 cases (28%) and in 5 of those accompanied by DI. Hyperprolactinemia occurred less frequently, in 20% of cases. Visual disturbances caused by optic chiasm compression/infiltration or cranial nerves palsies were present in 9 cases (36%). The most frequent finding on MRI scans was the lack of posterior lobe bright spot ($n = 14$, 56%). Pituitary stalk thickening, pituitary enlargement alone or together with stalk thickening were present in 9 (36%), 7 (28%) and 7 (28%) cases, respectively. In one patient a unilateral internal carotid artery occlusion was found and in another patient the inflammation extend to hypothalamus. Nine patients with visual disturbances and severe headache were treated with high-doses of glucocorticosteroids with partial or complete resolution of symptoms, but in 4 patients relapses were observed.
Conclusion
Hypophysitis typically occurs in middle-aged woman without relationship to recent pregnancy. The most frequent symptoms at presentation are headaches and DI. The most common anterior pituitary deficiency is a gonadotroph deficiency, not isolated corticotroph deficiency as previously stated. High-dose glucocorticosteroids treatment exerts a positive effect in the form of at least partial relief of symptoms, especially headaches.

Since the first somatostatin receptor ligand (SRL) was used to treat acromegaly, predicting which patients could benefit from their use has become crucial to avoid months of ineffective treatment for non-responding patients. Although many biomarkers linked to SRL response have been identified, there is no consensus criterion on how to prescribe according to biomarker levels. In this study, we evaluate previously reported biomarkers using more exhaustive and accurate methods than those used in previous analyses to provide better predictive tools from the data. Using advanced mathematical modelling and artificial intelligence, a more accurate acromegaly patient stratification was obtained regarding their ability to respond to SRL. Our results show an association between extrasellar growth and high BMI for SRL non-responding patients. Furthermore, we provide different models of patient stratification. The mathematical algorithms generated achieved a much higher cross•validatedaccuracy when the population is fragmented according to relevant clinical characteristics. Considering all the models, we proposed a patient stratification based on the extrasellar growth of the tumor and the expression of E-cadherin, *GHRL*, *IN1-GHRL*, *SSTR5* and *RKIP* with accuracies that stand between 71 to 95%. This new strategy of data mining is necessary if we want to implement personalized medicine in acromegaly and requires an interdisciplinary effort between computer science, mathematics, biology and medicine. This new methodology opens a door to more precise personalized medicine for acromegaly patients.

Metabolism of glucose in patients with acromegaly treated with Pegvisomant and/or Pasireotide LAR after resistance to first generation somatostatin receptor ligands

Sabrina Chiloiro[1], Antonella Giampietro[1], Antonio Bianchi[1], Anna Maria Formenti[2], Cara Maya Fleseriu[3], Alfredo Pontecorvi[1], Andrea Giustina[2] & Laura De Marinis[1]
[1]Fondazione Policlinico Gemelli, IRCCS, Università Cattolica del Sacro Cuore, Rome, Pituitary Unit, Department of Endocrinology, Italy; [2]Vita Salute San Raffaele, Endocrinology, Milan, Italy; [3]University of Pittsburgh and Oregon Health and Science University, Pittsburgh, United States

Introduction
Acromegaly (Acro) is characterized by insulin sensitivityreduction, glucose intolerance (IGT) and diabetes mellitus (DM2 in 15%–38% of patients). Studies that investigated action of medical therapies for acro on glucose metabolism, didn't provide conclusive data. Association between blood glucose (BG) levels and serum IGF-I levels in patients with DM2 and acro has been suggested, however,IGF-I levels and hemoglobin A1c (HbA1c) correlation is still controversial due tomultifactorial influence.

Study aim
Investigate in a large retrospective cross-sectional multicenter study glucose metabolism in patients with acro resistant to 1st gen somatostatin receptor ligands (SRLs) treated with Pegvisomant (Peg) or Pasireotide LAR (Pasi).
Patients and methods
Consecutive patients enrolled per following inclusion criteria: (1) resistance to 1st gen SRLs (2) treated with Pasi or Peg both for at least 6 consecutive months. Exclusion:patients with treatments influencing glucose, exception being glucocorticoid replacement. Biochemical control of acro was defined as normal IGF-I.
Results
72 patients with active Acro: mean age 37 yrs (S.D.:15). 47 females (65.3%); 28 (38.9%) treated with Pasi and 44 with Peg (61.1%). Peg was monotherapy in 18 patients (40.9%) and combo with 1st generation SRLs 26 patients (59.1%). The number of patients with IGT and DM2 was superimposable between the 2 groups (Pasi and Peg-V). In Pasi group, 19 patients had acro control (67.9%); glucose metabolism worsened in 16 (57.1%). Worsening of glucose metabolism occurred most frequently in patients with persistently active acro (62.5%) and with higher BG and HbA1c at study start. Likewise, HbA1c was higher in patients with active acro, although HbA1c worsened during Pasi treatment both in euglycemic and IGT at study entry, regardless of normal IGF-I. In Peg group, 31 patients reached normal IGF-I (73%); glucose worsened in 12 (27.3%) but improved in 5 patients (11.4%). All patients who experienced glucose improvement had controlled acro, regardless of the combo use. Among 13 patients with active acro, BG worsened in 5 (38.4%). Patients with worsening BG control had higher HbA1c ($P=0.03$) and required higher Peg doses (mean 25 mg/day S.D.: 10; $P=0.04$). Patients with higher HbA1c had higher IGF-I, both at entry and study endand were treated with higher Peg dose (mean 25 mg/day).
Conclusion
We suggest that glucose abnormalities in patients treated with Peg (either mono or combo with 1st generation SRLs) or Pasi are dependent on both pre-treatment BG and persistence of active acromegalyand require close monitoring.

Biliary stone disease in acromegaly under somatostatinanalogues: A longterm safety study

Nunzia Prencipe[1], Daniela Cuboni[1], Chiara Bona[1], Alessandro Maria Berton[1], Mirko Parasiliti Caprino[1], Luigi Fenoglio[2], Valentina Gasco[1], Ezio Ghigo[1] & Silvia Grottoli[1]
[1]University of Turin, Medical Science Department, Turin, Italy; [2]Santa Croce and Carle Hospital of Cuneo, Medicine Department, Cuneo, Italy

Introduction
Somatostatin analogues (SSA) are one of the main effective drug used in acromegaly. Sludge and/or cholelithiasis development represents oneof the more common side effect. The aim of the study was to analyze the frequency of biliary adverse events (BAE) and possible predictive factors, to propose a work-up strategy for their management.
Method
This is a single centre, longitudinalretrospective study; we enrolled 91 acromegaly patients during SSA for at least one year. We evaluated biochemical markers of acromegaly (GH, IGF-1 e IGF-1/ULN) at diagnosis, at BAE onset or at last follow up. We also collected type, dose andduration of SSA, glucose and metabolic profile at diagnosis and follow up. For the detection of sludge/gallstone disease, an ultrasound was performed yearly. In patients developing BAE we evaluated ursodeoxycholic acid (UDCA)effectiveness.
Results
We divided patients into 4 groups: no BAE(G–); positive history for BAE (G+), cholelithiasis ($G+_{ch}$) and only sludge ($G+_{sl}$). 61,5% of patients developed at least one BAE (58.9% cholelithiasis and 41.1% only sludge). No differences between lanreotide, octreotide and pasireotide were found. Only five patients underwent cholecystectomy for symptomatic cholelithiasis. None of metabolic markers proved to be associated with BAE. All GH, IGF-I and IGF-1/ULN proved to be lower in $G+_{ch}$, compared to $G+_{sl}$, ($P=0.001$).Kaplan-Meier curve showed that 50% of subjects developed BAE within 5 years from the SSA start. In 71% of subjects with BAE,UDCA treatment was started; 60% had a complete resolutionwithout recurrence, while 40% did not benefit from therapy. The UDCA clinical efficacy was statistically greater in $G+_{sl}$ than in $G+_{ch}$ (regression in 88% of cases versus 30%; $p=0.0009$). The regression of BAE occurred after 12 months of therapy. Analyzing the Kaplan-Meier curve of the UDCA efficacy, it can be observed that in 50% of the subjects the BAE resolved after 5 years of therapy.
Conclusion
biliary stone disease is a frequent SSA adverse event, although it is often symptomless. Ultrasound follow-up and early UDCA therapy, represent a valid strategy in their management.

Importance of sexual function assessment in multidimensional evaluation of AGHD patients: Baseline results from the management of adult growth hormone deficiency (MAGHD) study

Maria Laura Monzani[1], Simone Pederzoli[1], Laura Volpi[1], Elisa Magnani[2], Chiara Diazzi[1] & Vincenzo Rochira[1]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Unit of Endocrinology, AUSL-IRCCS of Reggio Emilia, Reggio Emilia, Italy

Background
Patients with adult growth hormone deficiency (AGHD) have impaired health-related quality of life (QoL). While the effects of reduced muscle mass and vitality-loss on QoL have been well characterized in AGHD, the impact of AGHD on sexual function, a recognized factor influencing well-being, has never been deepened.
Aim
To investigate the prevalence of sexual dysfunction in AGHD patients referring to a single endocrinological center and grouped according to their history of r-hGH therapy.
Methods
The MAGHD Study aims to improve management of AGHD patients through a smartphone app (MAGHD-App) and a fit-watch. The 83 enrolled patients (31 Females, 52 Males, mean age 56.27 ± 14.68 years) were divided in 3 groups (G) according to r-hGH therapy: on long-term treatment (G1, $n=32$), previously treated (G2, $n=20$), never treated (G3, $n=31$). At the baseline visit, besidesclinical and biochemical data, a psychological assessment was performed. IIEF-15 (for males) and FSFI (for females) were employed to evaluate sexual function in addition to QLS-H and QoL-AGHDA routinely used to assess QoL. The nonparametric Kruskal-Wallis test was used for comparison among 3 groups.
Results
According to IIEF-15 results, the prevalence of erectile dysfunction (ED) in AGHD males was 60%. Erectile function (EF) score was significantly higher in G1 compared to G2 and G3 ($P<0.05$) with an ED prevalence of 37.5% in G1, 75% in G2 and 75% in G3. Even excluding interfering factors (serum testosterone <2 ng/ml and age ≥65 years), ED prevalence did not change significantly. Moreover, EF domain was inversely and directlycorrelated to age (R^2 0.130, β–0.360) and IGF1 levels (R^2 0.156, β 0.395), respectively. The prevalence of female sexual dysfunction according to FSFI was 89%. Even though desire, arousal, lubrication and overall scores were significantly higher (better results) in G1 compared to G2 and G3 ($P<0.05$), no correlation resulted between FSFI domains and IGF1 levels. Only an inverse correlation resulted between desire domain and age.
Conclusions
This real-life study documents a high prevalence of sexual dysfunction in AGHD patients, especially in untreated ones, and that r-hGH treatment seems to be associated to better sexual outcomes. These results suggest that the evaluation of sexual function should be integrated into global assessment of AGHD patients since sexual activity is able to influence both well-being and QoL.

Effects of different therapeutic approaches on cardiovascular risk in patients with acromegaly: Results of a multicentric study

Giuseppe Reimondo[1], Federica Spagnolo[2], Soraya Puglisi[1], Benedetta Lombardi Stocchetti[1], Marta Ragonese[2], Filippo Ceccato[3], Francesco Ferraù[2], Paola Berchialla[4], Scaroni Carla[3], Salvatore Cannavò[2] & Massimo Terzolo[1]
[1]Internal Medicine, San Luigi Gonzaga Hospital, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy;

[2]Endocrinology Unit, Policlinic Hospital G. Martino, Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy; [3]Endocrinology Unit, University-Hospital of Padua, Department of Medicine DIMED, Padova, Italy; [4]Statistic Unit, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy

The association between acromegaly and increased cardiovascular morbidity and mortality is widely recognised. The aim of this retrospective multicentric study is to evaluate the impact of different therapeutic approaches on the progression of cardiovascular risk (CVR) in acromegalic patients. At diagnosis and last follow up (follow up time of 13±8 years),we assessed BMI, blood pressure, glycaemic and lipid profile, GH and IGF1 levels in 199 patients with acromegaly (116 females), which received at least a medical treatment during follow up. To assess CVR, we used the Italian Heart Project Score (IHPS-CVR) and Framingham Score (FS-CVR), which were calculated both at baseline and last follow up. During follow up, major adverse cardiac events (MACEs) were recorded in 16 subjects. We divided patients in two groups according to received treatment: 60 patients treated only with medical therapy (MT) and 139 with a combination of medical therapy, neurosurgery and, in some cases, radiotherapy (MT+NS±RT). At baseline, MT patients were older ($P<0.001$), with higher prevalence of diabetes and hypertension ($P<0.001$), and had greater IHPS-CVR (P 0.002) and FS-CVR values ($P=0.004$), whereas the MT+NS±RTgroup showed higher GH levels ($P=0.023$) and largest pituitary adenomas ($P<0.001$). To adjust for these differences in the comparison of the 2 groups, we computed a propensity score using the clinical characteristics that differed at baseline as covariates for a logistic regression model. With an inverse probability weighting (IPW) we created a focused sample that allows for unbiased estimates of treatment effects. In our cohort, the estimated time-related profiles of CVR remain approximately constant over time in both groups. In addition, MT and MT+NS±RT groups appeared comparable regard to both IHPS-CVR and FS-CVR without any statistically significant differences at baseline (IHPS-CVR IC 95% : –4.38+2.68; FS-CVR IC 95% : –7.35+9.42) and at 10 years of follow up (IHPS-CVR IC 95%: –5.36+2.95; FS-CVR IC 95% : –9.92+8.12). Furthermore, MT and MT+NS±RT groups did not significantly differ for MACEs incidence rate (P 0.11). Finally, univariate analysis adjusted for gender, age and IPW showed that diastolic hypertension (P 0.008) and disease control (P 0.011) were the most significant risk factors for MACEs. In conclusion, this study suggests that treatment of acromegaly is able to slow the CVR progression although increasing age during follow-up, regardless the type of the therapeutic approach. The disease control significantly impacts on the cardiovascular risk, but also diastolic hypertension control could be an important therapeutic target to reduce the MACEs incidence.

IGF-I variability and its association with demographic and clinical characteristics in patients with acromegaly treated with injectable somatostatin receptor ligands (SRLs); results from OPTIMAL, an international prospective phase 3 study

Susan Samson[1], Lisa Nachtigall[2], Maria Fleseriu[3], Ehud Ur[4], Mark E Molitch[5], William Ludlam[6], Gary Patou[7], Asi Haviv[7], Yossi Gilgun-Sherki[7], Nienke Biermasz[8], Christian J Strasburger[9], Laurence Kennedy[10] & Shlomo Melmed[11]

[1]Baylor College of Medicine, Houston, United States; [2]MGH Neuroendocrine Clinical Center, Chestnut Hill, United States; [3]Oregon Health & Science University, Portland, United States; [4]UBC, Vancouver, Canada; [5]Northwestern University, Evanston, United States; [6]Chiasma, Mountain Lakes, United States; [7]Chiasma, Waltham, United States; [8]Leiden University Medical Center (LUMC), Leiden, Netherlands; [9]Charité – Campus Mitte (Berlin), Berlin, Germany; [10]Cleveland Clinic Foundation, Cleveland, United States; [11]Cedars-Sinai Medical Center, Los Angeles, United States

Background

Most patients responding to injectable somatostatin receptor ligands exhibit IGF-I variability around the upper limit of normal (ULN) during long-term follow up. These fluctuations are thought to result from assay variability, nutrition, comorbid conditions, concomitant medications and other unknown factors. The magnitude and factors affecting this variability arenot well understood in patients with acromegaly treated with injectable SRLs.

Methods

IGF-I levels of patients responding to and stably treated with injectable SRLs were measured over time in the CHIASMA OPTIMAL phase 3 study. Two time periods were assessed – Period 1, three assessments during screening before randomization to octreotide capsules ($n=56$); and Period 2, multiple assessments up to week 36, in patients rescued with SRL injections for ≥12 weeks ($n=21$).Time from last injection to each assessment in period 1 [Screening visits 1 and 2 (SV1 & SV2) and Baseline] was on average 6.8±10.7 (S.D.), 15.8 ±2.7, and 29.0±1.8 days, respectively. Correlation with demographics and Baseline characteristics including age, gender, weight, BMI, and residual tumor size to IGF-I variability was assessed. Percent change for each individual patient from Minimal to Maximal IGF-I values within each period was computed. The overall population mean was calculated (lowest value as the denominator and all other values as a percentage above this value).

Results

Overallmean within-patient percent change of IGF-I levelsduring Period 1 was 20.48±15.56 (range: 0.6–81). Mean IGF-I levels for SV1, SV2 and Baseline were 0.78±0.18,0.79±0.18, and 0.85±0.22 × ULN respectively. Overall increase in mean IGF-I levels from SV1 to Baseline (longest time interval) was statistically significant ($P=0.0002$; paired T-test). Overall mean within-patient percent change of IGF-I levels during Period 2 was 15.27±12.20 (range: 0–41.5). Mean duration of follow up during this period, after patients were already treated for 12 weeks with oral SRL, was 4.38 months (range: 2.67–7.47). The variability in Period 2 was similar to that observed in the entire sample evaluated in Period 1. No significant correlation was found between individual IGF-I percent change and any demographic and Baseline characteristics examined.

Conclusion

IGF-I levels fluctuate in patients with acromegaly responsive to injectable SRLs. These fluctuations can be up to 81% higher than the lowest (most controlled) value, with an average increase of approximately 20%. Significant IGF-I increases were observed at the end of the injection interval of long acting SRLs.

Analysis of adverse events in adult patients with acromegaly receiving oral octreotide capsules: Results from the phase 3, randomized, double-blind, placebo-controlled optimal study

Artak Labadzhyan[1], Susan Samson[2], Lisa Nachtigall[3], Maria Fleseriu[4], Mark E Molitch[5], William Ludlam[6], Gary Patou[6], Asi Haviv[6], Agata Baldys Waligorska[7], Nienke Biermasz[8], Peter Trainer[9], Laurence Kennedy[10], Shlomo Melmed[1] & Christian J Strasburger[11]

[1]Cedars Sinai Medical Center; [2]Baylor College of Medicine; [3]MGH Neuroendocrine and Pituitary Center; [4]Oregon Health & Science University, Portland, United States; [5]Northwestern University, Evanston, United States; [6]Chiasma; [7]Andrzej Frycz Modrzewski Krakow University; [8]LUMC – Endocrinology and metabolisme; [9]The Christie NHS Foundation Trust; [10]Cleveland Clinic Foundation; [11]Charité Campus Mitte

Background

Distinguishing non-specific signs/symptoms of acromegaly from treatment-emergent adverse events (TEAEs) in patients treated with somatostatin receptor ligands has proven difficult given limited data from placebo-controlled studies. The CHIASMA OPTIMALstudy provides a novel data set to evaluate the incidence of adverse events (AEs) in patients randomized to oral octreotide capsules (OOC) or placebo.

Methods

A multinational, randomized, placebo-controlled study was conducted in 56 adult patients with active acromegaly. Eligible patients had active disease (IGF-1 ≥ 1.3 ×ULN after last pituitary surgery) and an average IGF-1 ≤ 1.0 ×ULN in response to a stable dose of somatostatin analog injection. Patients were randomized (28/group) to OOC or placebofor 36 weeks, followed by an optional open-label extension for up to 1 year. Safety and tolerability were evaluated based on incidence of AEs, including incidence of new or worsening adverse events of special interest (AESIs).

Results

In this study, the safety profile of OOC was consistent with the known safety profile of injectable octreotide. No new safety signals were detected. Nearly all patients (55/56) experienced a TEAE (28 patients [100.0%] in the OOC group and 27 patients [96.4%] in the placebo group). Thirty-three patients (58.9%) experienced a TEAE considered to be related to study drug by the

blinded PI (64.3% of OOC group [18 patients, 40 events] and 53.8% of placebo group [15 patients, 41 events]). TEAEs with an incidence ≥5% that were more common in the OOC group vs placebo group included GI disorders, increased blood glucose, sinusitis, osteoarthritis, and cholelithiasis. TEAEs with an incidence ≥5% that were more common in the placebo group vs OOC group included arthralgia, headache, fatigue, hyperhidrosis, and peripheral swelling. GI disorders were the most common TEAE, reported in 64% of all patients (36/56) and at similar rates between the OOC (68%) and placebo (61%) groups. AESIs (defined as new or worsening signs of acromegaly) were observed in 15 patients (53.6%, 34 events total) in OOC group and in 26 patients (92.9%, 82 events total) in placebo group.
Conclusion
In this study, the safety profile of octreotide capsules was consistent with the known safety profile of injectable octreotide. Most patients receiving octreotide capsules or placebo demonstrated TEAEs, although the profile of most common TEAEs varied between groups. TEAEs observed in the placebo group may be indicative of underlying disease activity. Further analysis may elucidate the difference between treatment related AEs and signs/symptoms of active disease in acromegaly.

The effects of silent pituitary adenomas on pregnancy

Özge Baş Aksu[1], Özgür Demir[2], Asena Gökçay Canpolat[2] & Demet Çorapçıoğlu[2]
[1]Ankara University, Department of Internal Medicine, Ankara, Turkey; [2]Ankara University, Department of Endocrinology, and Metabolism, Ankara, Turkey

Silent pituitary adenomas are defined as a group of adenomas that are hormonally inactive and do not show clinical signs and symptoms of excess hormones. Data in the literature indicate that fertility is usually affected in women with silent pituitary adenomas.
Aim
To investigate the possible effects of silent pituitary adenomas on pregnancy.
Patients and Method
Thirty patients followed by silent pituitary adenoma, without hormone deficiency or excess, not receiving medical treatment were included in the study. Anterior pituitary hormone levels, follow-up periods, pituitary magnetic resonance imaging findings, number of gravidity, parity, abortus, ectopic pregnancy, stillbirths, presence of symptoms associated with adenoma size increase during pregnancy, adverse pregnancy outcomes, induction of labor history, delivery procedures, pregnancy week at delivery, birth weight, lactation duration were evaluated.
Results
The mean age of the patients was 41.26±9.06 years and the mean duration after the diagnosis was 92,8 months. Of the 30 patients with silent pituitary adenoma, 7 were followed by macroadenoma and 23 with microadenoma. Among all 92 pregnancies, 66 resulted in live births. No statistically significant difference was found between pregnancy week at delivery, birth weight, lactation duration in live births in macroadenoma and microadenoma groups. However, there was a statistically significant difference between the two groups with respect to adenoma size, the incidence of nausea-vomiting and visual impairment during pregnancy were more prominent in macroadenoma with respect to microadenoma ($P=0.016$ and $P=0.042$, respectively).
Discussion
Elective abortion, missed abortion, stillbirth, live birth rates and lactation duration are thought to be similar to the general population. In our study, spontaneous pregnancy rates were found to be high and no negative effects of silent pituitary adenomas on fertility were observed. Although rarely reported in the literature, there is an increase in the size of silent pituitary adenomas during pregnancy, however, no adenoma growth confirmed by MRI was observed in our study. In terms of pregnancy-related complications, silent pituitary adenoma was not associated with increased risk compared to the general population and there was no obvious negative effect on fetal development. Despite the high cesarean section rates in our country, silent pituitary adenomas were not associated with an increased cesarean section rate in our study. In conclusion, when the present findings are evaluated together, it is not possible to mention that the patients followed up with silent pituitary adenoma have negative effects on pregnancy outcomes, fetal development, and lactation.

Cushing's syndrome negatively affects socio-economic variables many years before the diagnosis: A nationwide registry-based cohort study

Andreas Ebbehoj[1], Esben Søndergaard[1], Peter Jepsen[2,3], Helene Matilde Lundsgaard Svane[2], Morten Madsen[2], Per Løgstrup Poulsen[1] & Jens Otto Jorgensen[1]
[1]Aarhus University, Department of Clinical Medicine – Department of Endocrinology and Diabetes, Aarhus, Denmark; [2]Aarhus University, Department of Clinical Medicine – Department of Clinical Epidemiology, Aarhus, Denmark; [3]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark

Introduction
Cushing's syndrome (CS) results from prolonged glucocorticoid excess. Both iatrogenic and endogenous CS cause somatic and neuropsychiatric morbidity that do not fully reverse after biochemical disease control. However, the real-world socio-economic consequences for patients and their families are largely unknown.
Aim
To determine the impact of CS on work status, income, education, marital status, parenthood, and depression before and after treatment.
Design
A nationwide registry-based cohort study.
Methods
Using the Danish health registries, we identified 411 patients diagnosed and operated for benign pituitary or adrenal CS between 1986–2017. Pituitary/adrenal ratio was 1.16. We matched each patient with ten persons from the background population of same sex and age (the reference population). We obtained registry data on socio-economic factors and anti-depressive medication, and followed them from up to ten years before diagnosis to ten years after surgery. We calculated crude and adjusted relative-risk (RR) of patients in working age returning to fulltime work two years after surgery using a modified Poisson regression.
Results
During a median follow-up of 13.4 years (5516 person-years), 20% ($n=84$) of CS patients and 11% ($n=454$) of reference population had died ($P<0.001$). Compared to the reference population, we found that fewer patients were in a fulltime job from seven years before diagnosis [68.2% vs 74.6%, $P=0.03$] to ten years after surgery [50.0% vs 70.3%, $P<0.001$] with the biggest difference observed the year after surgery [33.1% vs 72.2%, $P<0.001$]. Mean annual income was decreased by 6300 EUR (CI 95% 3400–9200) in the years after surgery. More patients were prescribed antidepressant drugs from six years before diagnosis [10% vs 5%, $P=0.004$] and up to ten years after surgery [16% vs 9%, $P=0.003$]. We found no differences between CS and reference population in educational achievement, marital status, and parenthood. Among CS patients, female sex, high age, low education, comorbidity, and a history of depression predicted lower likelihood of returning to work. When adjusted for the other factors, adrenal CS patients had better chance of returning to work than pituitary CS.
Conclusion
1) CS negatively affects essential socioeconomic variables even many years before the diagnosis, 2) Risk predictors included female sex, high age, history of depression, and pituitary CS, 3) The data underpin the importance of an early diagnosis and may also have implications for the management of patients receiving pharmacological glucocorticoid treatment.

Prevalence, predictors and outcomes of acute, life-threatening and perioperative complications in cushing's syndrome

Marie Helene Schernthaner-Reiter[1], Christina Siess[1], Alexander Micko[2], Stefan Wolfsberger[2], Christian Scheuba[3], Philipp Riss[3], Engelbert Knosp[2], Alexandra Kautzky-Willer[1], Anton Luger[1] & Greisa Vila[1]
[1]Medical University of Vienna, Clinical Division of Endocrinology and Metabolism, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Department of Neurosurgery, Vienna, Austria; [3]Medical University of Vienna, Department of Surgery, Vienna, Austria

Introduction
Cushing's syndrome is associated with significant chronic and acute complications including acute thromboembolic and cardiovascular events. We aimed to study the prevalence and predictors of acute and perioperative complications in patients with active Cushing's syndrome.

Methods
The prevalence, predictors and outcomes of acute, life-threatening and perioperative complications were evaluated in a cohort of patients with active biochemically verified Cushing's syndrome attending our endocrine department between 1978 and 2016. Any medical complications necessitating hospitalization, including admission to intensive care units (ICUs), from appearance of first symptoms of hypercortisolism until one year after biochemical remission by surgery (or, where surgical remission was not achieved, during continuing follow-up) were recorded and classified. Baseline factors relating to and predicting acute complications were tested using uni- and multivariate analysis.
Results
242 patients (m/f $n=54/188$) with Cushing's syndrome (pituitary $n=99$, adrenal $n=116$, ectopic $n=27$) were included in this study, 14% of which had malignant disease.
55% of patients experienced at least one acute complication including electrolyte disturbances (24%), infections (28%), thromboembolic events (19%: including 4% with cerebrovascular events, 9% with pulmonary embolisms and 6% with other thromboembolic events), cardiac arrhythmias necessitating medical intervention (5%), hypertensive crises (9%) and acute coronary events (3%).
The number of complications per patient significantly correlated with age, duration of hypercortisolism, severity of hypercortisolism (measured by biochemical parameters such as 24-hours urinary free cortisol – UFC), as well as markers of glucose and lipid metabolism. Multiple regression analysis revealed age at diagnosis, fasting glucose and UFC as independent predictors of the number of acute complications per patient. When patients with malignant disease were excluded from analysis, fasting glucose and UFC remained significant predictors. At least one ICU admission (excluding post-surgical observance) was required in 13% of patients. In the whole cohort as well as when malignant cases were excluded, the number of ICU days per patient was significantly related to age at diagnosis, parameters of glucose metabolism, and UFC, with UFC being an independent predictor of the number of ICU days per patient.
Conclusion
This cohort analysis highlights the high prevalence of acute and perioperative complications in Cushing's syndrome, with one in eight patients suffering a life-threatening situation necessitating ICU admission. These acute complications are positively predicted by the duration and degree of hypercortisolism, age and metabolic parameters, emphasizing the necessity for acute interventions aiming to reduce cortisol excess even before definitive disease cure is achieved.

SST5 expression and USP8 mutation in functioning and silent corticotroph pituitary tumors

Solene Castellnou[1,2], Alexandre Vasiljevic[2,3,4], Veronique Lapras[5], Véronique Raverot[6], Eudeline Alix[7], Francoise Borson-Chazot[1,2], Emmanuel Jouanneau[2,4,8], Gerald Raverot[1,2,4] & Lasolle Hélène[1,2,4]
[1]Groupement Hospitalier Est, Hospices Civils de Lyon, Service d'Endocrinologie, Bron, France; [2]Université Claude Bernard Lyon 1, Villeurbanne, France; [3]Groupement Hospitalier Est, Hospices Civils de Lyon, Centre de Pathologie Est, Bron, France; [4]Cancer Research Center of Lyon, INSERM U1052, CNRS, UMR5286, Lyon, France; [5]Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Service de Radiologie, Pierre-Bénite, France; [6]Groupement Hospitalier Est, Hospices Civils de Lyon, Centre de Biologie Est, Bron, France; [7]Groupement Hospitalier Est, Hospices Civils de Lyon, Département de cytogénétique, Bron, France; [8]Groupement Hospitalier Est, Hospices Civils de Lyon, Service de Neurochirurgie, Bron, France

Context
Somatostatin receptor type 5 (SST5) is inconsistently expressed by corticotroph tumors, with higher expression found in corticotropinomas having ubiquitin-specific protease 8 (USP8) mutations.
Aims
To study the correlation between characteristics of corticotropinomasand SST5 expression/USP8 mutation status; to describe the response to pasireotide in 5 patients.
Design
Retrospective cohort study.
Methods
Clinico-biochemical, radiological and pathological data of 62 patients, operated for a functioning orsilent corticotropinoma between 2013 and 2017, were collected. SST5 expression was measured by immunohistochemistry (clone UMB-4, Abcam, IRS>1 being considered positive) and Sanger sequencing was performed on 50 tumors to screen for USP8 mutations.
Results
SST5 expression was positive in 26 (41.9%) pituitary tumors. A moderate or strong IRS was found in 25.9% of the cohort and in 37.1% of the functioning corticotropinomas. Among functioning tumors, those expressing SST5 were more frequent in women (91.7% vs 60%; $P=0.004$) and had a lower grade ($P=0.04$) compared to others. USP8 mutations were identified in 26% of the cohort and were more frequent in functioning ($n=11/30$, 36.7%) compared to silent tumors ($n=2/20$, 10%; $P=0.05$). SST5 expression was more frequent in USP8 mut vs USP8wt tumors (90.9% vs 36.8%; $P=0.007$). Among treated patients, normal urinary free cortisol levels were obtained in 3 patients (IRS 0, 2, 6) while a 4.5-fold decrease was observed in one patient (IRS 4).
Conclusion
SST5 expression appears to be associated with functioning, USP8 mutand lower grade corticotropinomas. A correlation between SST5 expression or USP8 mut and response to pasireotide remains to be confirmed.

Efficacy, safety and pitfalls of glucocorticoid therapy for patients with autoimmune hypophysitis

Keita Tatsushima, Akira Takeshita, Noriaki Fukuhara, Mitsuo Yamaguchi-Okada, Hirokazu Fukuhara, Hiroshi Nishioka & Yasuhiro Takeuchi
Toranomon Hospital, Endocrine Centre, Tokyo, Japan

Background and aim
Autoimmune hypophysitis (AH) is a rare immune-mediated inflammatory disease. Glucocorticoid therapy represents a therapeutic choice for AH patients with symptoms from mass effect, such as headache and optic nerve compression. However, effective methods and adverse events of glucocorticoid therapy are unclear. We aimed to evaluate the efficacy and safety of glucocorticoid therapy in AH patients.
Patients and methods
The subjects were all patients who had been diagnosed as AH and who underwent glucocorticoid therapy at our hospital from January 1, 2013 to December 31, 2018. We performed a retrospective analysis based on the clinical records of these subjects. We investigated the symptoms, endocrine function and treatment complications.
Results
Sixteen patients (median age at diagnosis: 42 years; range, 29–75 years) were included. The initial treatments were; prednisolone ($n=7$) methylprednisolone pulse therapy ($n=8$) and hydrocortisone ($n=1$). The median duration of glucocorticoid treatment was 22 months. The median follow-up was 47.5 months. Headache and visual impairment improved in all patients within 3 months after the initiation of glucocorticoid therapy. Glucocorticoid therapy was effective for achieving mass reduction on MRI in 14 cases (88%). However, four patients relapsed during treatment with physiologic dose of hydrocortisone. Two of these patients underwent biopsy of the enlarged lesion again. In these cases, the diagnosis changed to germinoma and malignant lymphoma, respectively. As for the endocrine function, the change in the number of cases of hypopituitarism after the initiation of glucocorticoid therapy was changed as follows: GH, 12 to 7 cases; PRL, 8 to 2; gonadotropin, 10 to 7; TSH, 10 to 11; ACTH, 9 to 12; ADH, 12 to 11. As for adverse events, the mean BMI significantly increased from 24.6 to 27.0 kg/m^2. Two patients newly developed diabetes mellitus and one patient developed femoral head necrosis. These adverse events appeared in patients who underwent pulse therapy followed by prednisolone.
Discussion
Our study revealed that glucocorticoid therapy contributed to the improvement of symptoms due to mass effect in AH patients but did not improve their endocrine functions. It must be noted that two of recurrent cases were insidious malignant diseases. It is important to carefully reassess the diagnosis and clinical course without blindly believing pathological data. In addition, the combination of steroid pulse therapy and prednisolone caused some complications but also ameliorated diabetes insipidus in one case. Further studies are required to establish the efficacy and safety of glucocorticoid therapy in AH patients.

Observational study of aetiology, efficacy of treatment and outcomes of hyponatraemia following pituitary surgery in a major neurosurgical centre

Ziad Hussein[1,2], Plutarchos Tzoulis[3], Hani J Marcus[4], Joan Grieve[4], Neil Dorward[4], Stephanie Baldeweg[1,2] & Pierre-Marc Bouloux[2,5]
[1]University College Hospital, United Kingdom; [2]University College London, United Kingdom; [3]The Whittington Hospital, United Kingdom; [4]National Hospital for Neurology and Neurosurgery, United Kingdom; [5]Royal Free Hospital, United Kingdom

Introduction
Hyponatraemia is a relatively common complication following pituitary surgery. However, there is sparse data about its optimal management and impact on clinical outcomes.
Aims
To review the treatment and patient outcomes of hyponatraemia following pituitary surgery.
Methods
A retrospective single-centre study included all inpatients who developed serum sodium (sNa) ≤ 132 mmol/l following pituitary surgery from January 2016 to December 2019.
Results
Amongst 765 patients who underwent pituitary surgery over a 4-year period, 80 (10.4%) developed sNa ≤ 132 mmol/l including 42% males with a median age of 58 years. The commonest type of pituitary lesion was non-functioning pituitary adenoma (53%), followed by Cushing's disease (11%), acromegaly (10%), craniopharyngioma (9%), and prolactinoma (5%). The mean baseline preoperative sNa level was 139 mmol/l. Postoperatively, the mean sNa was 137, 134 and 132 mmol/l on day 3, 5 and 7 respectively. The mean nadir sNa was 126 mmol/l and occurred on average 6.7 days after surgery, with 31 patients (38%) having nadir Na ≤ 125 mmol/l. The proportion of hyponatraemic patients who developed postoperative CSF leak and required lumber drainage was 16.2%, much higher than 5% amongst normonatraemic patients.
The commonest cause of hyponatraemia was SIADH (77.5%), followed by hypocortisolism (6.2%) and overzealous DDAVP administration for diabetes insipidus (6.2%), while no cases of cerebral salt wasting were documented. Treatment was fluid restriction in the majority of patients (80%), ranging from 500–1500 ml/day, while 6 patients (7.5%) were administered hypertonic saline and one patient (1.3%) received tolvaptan.
Post therapy initiation, mean sNa was 128, 129, 129, and 134 mmol/l on day 1, 2, 3 and 5 respectively. The mean time to achieve Na > 5 mmol/l in SIADH group was 4.2 days. The mean Na on discharge was 137 mmol/l, while the readmission rate was 10% and the mean length of hospital stay was 11.5 days.
Conclusion
Hyponatraemia can occur 5–7 days following pituitary surgery, primarily caused by SIADH. Postoperative CSF leak is an independent risk factor for development of hyponatraemia after pituitary surgery.
The effectiveness of fluid restriction was limited, as evidenced by slow Na correction with mean time of 4.2 days to achieve Na > 5 mmol/l, contributing to increased length of hospital stay. This study highlights the need to study the efficacy and safety of agents, such as vaptans and urea, for the management of hyponatraemia after pituitary surgery.

Growth hormone deficiency in childhood acute lymphoblastic leukemia survivors – should systematic stimulation test be performed in all irradiated children?

Ines Damasio, Daniela Cavaco, Joana Maciel, Daniela Dias, Sara Donato, Sara Pinheiro, Ana Figueiredo, Joana Simões-Pereira & Conceiçao Pereira Portuguese Institute of Oncology Lisbon FG

Introduction
The combination of chemotherapy with prophylatic cranial radiotherapy (C-RT) allowed the improvement of survival rates of pediatric acute lymphoblastic leukemia (ALL) survivors while putting them at risk of develeping long-term endocrine deficiencies, like growth hormone deficiency (GHD).
Current evidence suggests that the prevalence of GHD in children treated with radiation doses ≥ 30–50 Gy for non-pituitary brain tumors is >50% and 100% in those exposed to the same dose for pituitary brain tumors. However, the prevalence of GHD in the setting of lower doses used for hematological malignancies (18–24 Gy) is not so well characterized.
Our aim was to evaluate our cohort of childhood ALL survivors that developed GHD.
Methods
Retrospective analysis of childhood AAL survivors followed the Late-Effects Clinics of our center between 1980–2019.
Results
We found 324 eligible patients with a mean follow-up of 7.9 ± 6.1 years. The mean age of ALL diagnosis was 6.1 ± 4.1 years. They were all treated with chemotherapy, 235 (72,5%) patients were exposed to C-RT with a median dose of 18 Gy (12–37). Sixty-one (18.8%) patients had hematopoietic cell transplantation, from whom 31 (50%) had total body irradion. We identified 120 cases (37%) of GHD with a mean age at diagnosis of 11,5 ± 4,3 years. Within the 235 irradiated patients of the cohort, we found 113 (49,8%) cases of GHD and this percentage raised to 73.9% when we analysed those who were submitted to insulin-tolerance test (ITT). The mean SDS of IGF-1, stature, growth velocity and bone age at diagnosis were –0.93 ± 1.09, –1.3 ± 1.2, –1.4 ± 1.1 and –0.76 ± 1.5, respectively. Sixty-six of the 120 (55%) patients with GHD were treated with somatropin. From the 50 treated patients in whom was possible to evaluate the final stature, 46 (92%) reached the family target heigh (FTH). This was not true for the non-treated patients with GHD (P = 0,017).
Conclusion
GHD was a common finding in our cohort and C-RT played a major role in its development. Our data show that GHD cases might be underestimated if ITT is not performed since the majority of patients didn´t have a severe IGF-1 deficit nor auxology ≤ 2SDS at diagnosis. We thereby highlight the importance of performing systematic GH stimulation test in irradiated children, given that a timely somatropin reposition allows the achievement of FTH.

9-CIS retinoic acid decreases pomc expression and cell viability in experimental model of ectopic cushing syndrome

Daniela Regazzo[1], Mattia Barbot[1], Filippo Ceccato[1], Albiger Nora[2], lizzul laura[1], Calabrese Fiorella[3], Rea Federico[3], Zuin Andrea[3], Marco Boscaro[1], Gianluca Occhi[4] & Scaroni Carla[1]
[1]University of Padova, Department of Medicine, Endocrinology Unit, Italy; [2]ULSS 6 Euganea, Italy; [3]University of Padova, Department of Cardiac, Thoracic and Vascular Sciences, Italy; [4]University of Padova, Department of Biology, Italy

Ectopic Cushing syndrome (EAS) is a rare condition characterized by ACTH-dependent hypercortisolism resistant to normal physiologic suppression by glucocorticoids. EAS is due to an extra-pituitary tumor producing bioactive molecules generated by post-translational cleavage of the proopiomelanocortin gene (POMC). EAS is associated with significant morbidity and mortality and although surgical resection of the primary ACTH-producing tumor remains the mainstay of therapy, not all tumors are easily and rapidly localized or are amenable to complete resection often exacerbating clinical symptoms. In this view pharmacological approach can play a crucial role but a safe and effective therapy is still lacking. Beside inhibitors of adrenal cortisol secretion, somatostatin analogs and dopamine agonists, alone or in combination, have been tried, with acceptable results only in a limited number of patients. 9 cis retinoic acid (RA) is derived from vitamin A showing encouraging effect in regulating ACTH secretion and cortisol levels in patients affected by Cushing's disease. We demonstrated that RA effect in reducing POMC transcription and ACTH production could be potentiated by the co-treatment with Bromocriptine (Br) as a consequence of the permissive role that RA exert on the dopamine receptor type-2 (DRD2). Aim of the present study was to evaluate whether RA alone or in combination with Br is effective in regulating POMC expression and cell viability in cellular model of EAS – i.e. the SCLC-derived cell line DMS79, and primary cultures from 4 bronchopulmonary carcinoids. In DMS79 RA induced a significant dose-dependent decrease in both POMC promotorial activity (67% of control cells at 1 uM, P = 0.0326) and mRNA steady state level (47% at 100 nM, P = 0.0023). After a prolonged incubation (6 days) 1uM RA induce a 39% reduction in cell viability without changes in cell cycle distribution. Concerning DRD2 expression, RA stimulated DRD2 promotorial activity and RNA expression in a dose dependent manner with maximal effect at 1 uM in both assays (130% P = 0.00035, and 424% of control cells, P = 0.00011, respectively). Interestingly, in 3 out 4 tumor cultures, ACTH

secretion was reduced of nearly 30% respect to control cells in presence of the combination of RA (5 nM) and Br (500 nM), while single drugs were less effective. Concluding, the effects of RA on POMC synthesis and cell viability in DMS79, and of the combination RA/Br on ACTH secretion in pulmonary carcinoids may represent a suitable starting point for assessing the potential of this treatment regimen in EAS. and has potentially important implications for novel therapeutic approaches.

Sporadic neuroendocrine neoplasms in young-adult patients: Differences in natural history, prognosis and treatment compared to adult-elderly patients

Barbara Altieri[1,2], Roberta Modica[1], Filomena Bottiglieri[1], Federica de Cicco[1], Antongiulio Faggiano[3] & Annamaria Colao[1]
[1]Federico II University, Department of Clinical Medicine and Surgery, Endocrinology Unit, Naples, Italy; [2]University Hospital of Würzburg, Department of Internal Medicine I, Division of Endocrinology, Würzburg, Germany; [3]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy

Introduction
Sporadic neuroendocrine neoplasms (NEN) occur rarely in young-adult (YA) patients, with an estimated incidence is about 2.8 cases per million, and data specific to their epidemiology are limited. The aim of our study was to better characterize the natural history, prognosis and management of NEN in YA patients (≤35 years old) compared to adult-elderly (AE; >35 years old).
Methods
A retrospective observational study including 204 patients, of which 24 (11.8%) YA and 180 (88.2%) AE, with confirmed diagnosis of sporadic NEN and referred to ENETS Centre of Excellence of Naples – Federico II University between 2010 and 2019 was conducted. Clinical and pathological data, type of treatment, disease-specific survival (DSS) and recurrence-free survival (RFS) were evaluated.
Results
Median age at diagnosis was 25 (16–35) years in YA and 59 (36–84) years in AE patients ($P<0.001$). Female gender was slightly more frequent in YA [M:F=9:15; odds ratio (OR) 1.3, 95% CI 0.9–1.8]. Primary tumor site significantly differed between YA and AE patients ($\chi^2=68.5$, $P<0.001$), being appendix the most common site of origin (41.7% vs 1.1%, respectively), followed by pancreas (33.3% vs 26.7%), lung (16.7% vs 20%) and midgut 4.2% vs 12.2%). Other tumor sites were more frequent in AE compared to YA patients (40.0% vs 4.2%). YA had a significantly higher frequency of low-grade well differentiate (G1) tumors in comparison to AE (78.3% vs 41.3%, OR 1.9, 95% CI 1.4–2.5, $P=0.001$). Functioning tumors were also more frequent in YA patients compared to AE (OR 2.2, 95% CI 0.8-5.4, $P=0.09$), and this was statistically significant considering only the pancreatic NEN (62.5% vs 20.8% in YA and AE, respectively; OR 3.0, 95% CI 1.4-6.5, $P=0.01$). Treatment strategy also differed, being YA treated with fewer regimes (OR 0.4, 95% CI 0.2-0.9, $P=0.007$), including surgery (91.7% vs 70.6%, $\chi^2=4.8$, $P=0.03$) and SSA (25% vs 53.9%, $\chi^2=7.1$, $P=0.008$). Targeted- and chemotherapy were equally used. No differences in DSS and RFS were observed, although YA patients had a trend to a better RFS (median 180 vs 93 months, HR 0.45, $P=0.07$). Among the YA group, age <19 years and G1 tumors were associated with better RFS ($P=0.04$ and $P=0.03$, respectively), although they were not confirmed as prognostic factors at multivariate analysis.
Conclusion
Clinical presentation of NEN significantly differed between YA and AE patients. Due to the lack of prognostic markers, awareness of these rare neoplasms results crucial for a better management.

Temporal trends in incidence, evaluation and management of neuroendocrine neoplasms of the appendix-15 years' experience

Orit Twito[1,2], Paran Haim[2,3], Avital Shmuel[2,4], Kravtsov Vladimir[2,5], Rotman-Pikielny Pnina[1,2] & Klein Noa[1]
[1]Meir Medical Center, Endocrinology, Kfar-Sava, Israel; [2]Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel; [3]Meir Medical Center, Surgery A, Kfar-Sava, Israel; [4]Meir Medical Center, Surgery B, Kfar-Sava, Israel; [5]Meir Medical Center, Pathology, Israel

Introduction
Appendiceal neuroendocrine neoplasms (ANEN) account for approximately 50% of all primary tumors of the appendix and are between the first and third-most frequent gastrointestinal neuroendocrine neoplasms. Data regarding trends in incidence, management and prognosis of ANEN is limited.
Aims
To evaluate temporal trends in ANEN incidence, evaluation and management over a 13-year period.
Materials and Methods
Appendectomy pathology reports from a single tertiary center were reviewed. Epidemiological, clinical and pathological data of ANEN patients were collected from electronic patient files.
Results
Between January 2005 and December 2018, 8,327 appendectomies were performed. A total of 57 ANENs were diagnosed. Theirmean age was 31.7±49 years; 70.2% were females; 17.5% were of Arab ethnicity; and 22.8% werediagnosed under 18 years of age.
The cohort was subdivided according to year of diagnosis into Period A (2005–2011) and Period B (2012–2018). No differences were found in ANEN incidence (Period A 0.68% and Period B 0.62%, respectively, $P=0.104$) or epidemiologic characteristics between periods. Pathologic features were similar in the two subgroups, although pathology reports were more comprehensive and applicable to international guidelines in Period B. More patients in Period B were followed in dedicated clinics. Somatostatin receptor imaging and biochemical studies such as serum Chromogranin A and urinary 5-Hidroxy-indol-acetic -acid (5-HIAA) was also more frequently used in Period B. Fifteen patients underwent right hemicolectomy (8/31 in period A, 7/26 in period B, $P=0.925$). Pathologic features of ANEN were similar between the two subgroups. Residual disease in hemicolectomy specimen was observed in 2/7 patients in Period A and 3/6 patients in Period B. For the duration of follow up (10.8±1.7 years in Period A and 3.5±1.9 years in Period B, $P<0.001$) all patients remained alive, and all patients except one remained disease free.
Conclusions
Over a 13-year period, no distinct temporal changes in epidemiological, clinical or pathological features of ANENs were noted. Although after 2011 the clinico-pathological evaluation was more detailed and elaborated, there was no change in hemicolectomy rate or disease prognosis. Large scale studies are needed, in order to consider revision of current international guidelines for ANEN evaluation and treatment, in particular the necessity of right hemicolectomy.

Contribution of NGS in the genetic analysis of neuroendocrine tumors associated with Multiple Endocrine neoplasia type 1 (MEN 1)

Illias Hamny, Borson-Chazot Françoise & Giraud Sophie
Hospices Civils de Lyon, Lyon, France

Objective
Next Generation Sequencing technique (NGS) allows the analysis of a whole set of genes in the same time. It is, now, used, in our laboratory for the genetic screening of neuroendocrine tumors associated with Multiple Endocrine neoplasia type 1(MEN1)The objective of the present study was to assess the efficiency of this approach and the relevance of the results regarding the current genetic screening recommendations.
Methods
The data of all patients tested by NGS during the last 3 years forneuroendocrine tumors associated with MEN1 were collected. NGS technique allowed the analysis of the coding sequence and the intronic bounds of 13 genes in a total of 583 patients.
Results
Genetic variants were identified in 53 patients: 30 of them were located in the MEN 1 gene, 5 in CDKN1B et 6 in a gene involved in familial hypocalciuric hypercalcema 38 were classified as pathogenic or probably pathogenic variants and 15 were classified as variant of undetermined signification. Most of patients with more than one neuroendocrine tumor did not carry any mutation. Statistical analysis identified three main predictors of positive genetic testing: male gender, age less than 50 years old at diagnosis, and having more than one type of endocrine tumor.
Conclusion
In this study, a genetic variant has been identified by NGS in 10% of cases with predictive factors of positive genetic testing in accordance with current guidelines. This suggests that NGS approach is a reliable technique for the

genetic screening of patients with neuroendocrine tumors. However, other approaches remain necessary to identify more mutations. Variants interpretation remains a major problem which needs a close collaboration between laboratories and clinicians and the improvement of new effective tools.

Malignant insulinoma treated with ^{177}Lu-DOTATATE: Results in the first year post-therapy

María Concepción Terroba-Larumbe[1], Jose Maria Palacio-Mures[1], Cristina Crespo-Soto[1], Baltasar Perez-Saborido[2], Guillermo Crespo-Herrero[3], Marta Ventosa-Viña[1], Manuel Acuña-Garcia[4], Mirian Alejo-Ramos[1], Itziar Anacabe-Goyogana[5] & Luis Cuellar-Olmedo[1]

[1]Hospital Rio Hortega, Endocrinologia y Nutricion, Valladolid, Spain; [2]Hospital Rio Hortega, Cirugia, Valladolid, Spain; [3]Hospital Universitario Burgos, Oncologia, Burgos, Spain; [4]Hospital Rio Hortega, Otorrinolaringologia, Valladolid, Spain; [5]Hospital Rio Hortega, Radiologia, Valladolid, Spain

Introduction

Neuroendocrine tumors (NETs) are rare and their clinical behavior and prognosis correlates with mitotic rate and Ki-67 index. Most patients with advanced NET have liver metastases unresectable and somatostatin analogues are the initial therapy of choice but when disease progresses despite treatment and there are positive somatostatin receptors, peptide receptor radioligand therapy (PRRT), using lutetium-177, is a therapeutic option.

Clinical case

A 42-year-old male with episodes of fasting hypoglycemia was diagnosed with a well-differentiated low-grade NET G1 Insulin secretor, located in the pancreas body, with multiple liver metastases, after performing a 72-hour fasting test, abdominal magnetic resonance (MR) and fine needle aspiration by echoendoscopy. Biochemical data to highlight: chromogranin 592 ng/ml (≤ 100), gastrin 409 pg/ml (13–115), GOT 77 IU/l, GPT 87 IU/l, GGT 170 IU/l. Abdominal MR revealed multiple focal lesions distributed throughout the hepatic parenchyma, 5–30 mm in size and 2.5 × 1.7 cm pancreatic mass located in the distal body. 111-In-pentetreotide SPECT-CT showed multiple deposits of intense uptake and variable size in hepatic parenchyma with high expression of somatostatin receptors (SSTRs) and small deposit of discrete uptake in the pancreas body. Hypoglycemia, not controlled with diazoxide, disappeared with sandostatin LAR. Distal spleno-pancreatectomy was performed in June 2017 and the histological report confirmed a pancreatic NET G1 with numerous perineural infiltrations and vascular embolisms, free circumferential borders, and metastases in 4 of 21 isolated nodes. Post-surgery markers: chromogranin 737.4 ng/ml, gastrin >1,000 pg/ml. In SPECT-CT there were no significant changes in liver metastases, so PRRT with 177Lu-DOTATATE combined with Sandostatin LAR 30 mg IM/month was scheduled. Temozolomide-capecitabine chemotherapy was administered prior to 4 lutetium cycles initiated in June 2018 and completed in January 2019. After 2 cycles, chromogranin was 108.9 ng/ml and gastrin 32 pg/ml. The markers are negative since February 2019 and liver function progressively improved. Since October 2018, successive CT scans report a decrease in the size and uptake of hepatic focal lesions with an increase in central necrosis compatible with a partial response to treatment, and pentetreotide scintigraphy in March 2019 demonstrates a significant improvement in liver involvement.

Discussion

Pancreatic NETs are more aggressive but respond better to systemic agents. The benefit of conventional chemotherapy in malignant insulinoma is limited and PRRT with lutetium-177 have proven its efficacy and low toxicity so could be a suitable systemic therapy in selected patients.

Introduction

Pancreatic neuroendocrine neoplasm (pNEN) patients often present with locally advanced or metastatic disease. The objective response rate of peptide receptor radionuclide therapy (PRRT) in pNENs is 55%. Therefore, PRRT may be a possibility for patients who are not eligible for upfront curative surgery.

Aims

To assess the potency of PRRT to render locally advanced or oligometastatic pNENs resectable and to evaluate the effect of surgery after early PRRT on survival.

Material and methods

A single-center retrospective analysis was performed on 50 pNEN patients, treated between 2000 and 2019 with ^{177}Lu-DOTATATE with a neoadjuvant or downstaging intent. Patients had resectable, borderline resectable or unresectable locoregional disease and/or metastatic disease.

Results

After PRRT, 26 patients underwent surgery with curative intent. Surgical and non-surgical patients had equal tumor diameters and metastatic sites at baseline. Patients in the surgical group had more grade 1 tumors than those in the non-surgical group ($P=0.001$) and more often completed the intended PRRT dose of 29.6 GBq ($P=0.007$). In 54% and 46% of the surgical and in 21% and 63% of the non-surgical patients, best responses were partial response and stable disease, respectively ($P=0.02$). One patient died due to surgical complications. Median progression free survival was 28 months for the non-surgical group and 68 months for the surgical group ($P=0.009$). Median overall survival was 66 months for the non-surgical group compared to 177 months for the surgical group ($P=0.002$).

Conclusions

This study shows the favorable long-term outcomes of pNEN patients that underwent surgery after neoadjuvant PRRT. Early PRRT followed by surgical evaluation is an option for patients with unresectable or oligometastatic pNEN.

Absolute oral bioavailability and absorption, metabolism, excretion of [14C]-Labeled paltusotine (CRN00808), an orally bioavailable, nonpeptide, selective, somatostatin receptor 2 (sst2) biased agonist for the treatment of acromegaly

Ajay Madan[1], Rosa Luo[1], Chris Ferrara-Cook[1], R. Scott Struthers[1], Sjoerd van Marle[2] & Alan Krasner[1]

[1]Crinetics Pharmaceuticals Inc, San Diego, United States; [2]PRA Health Sciences Research Martini, Groningen, Netherlands

Injected depot formulations of somatostatin peptide analogs are routinely used to treat acromegaly and neuroendocrine tumors (NETs). Paltusotine (CRN00808), a small molecule nonpeptide selective somatostatin receptor 2 (sst2) agonist, is being evaluated for efficacy and safety in patients with acromegaly. The current Phase 1 study (NCT04246749) was conducted in two Parts: In Part A, the absorption, metabolism, excretion, and mass balance of a single oral dose of 20 mg [14C]-paltusotine (3.0 MBq) oral solution was characterized in six healthy male subjects. Plasma, blood, urine, and feces were collected for up to 432 hours, and were analyzed for total radioactivity and paltusotine concentrations (plasma only). Metabolite profiling was conducted on the plasma, urine, and feces samples. In Part B, the absolute bioavailability of paltusotine was determined by administering a single oral dose of 20 mg paltusotine compared with a single micro-tracer intravenous (IV) bolus injection of 0.050 mg [14C]-paltusotine (0.0185 MBq) in five healthy male subjects. The IV dose was administered approximately 90 minutes after the oral dose. Plasma samples were collected for up to 144 hours and were analyzed for paltusotine and [14C]-paltusotine concentrations.

Part A of the study show that >90% of radioactivity was recovered within 7 days of dosing. The primary route of excretion was the feces (89.9% of dose) with minimal excretion in the urine (3.9% of dose). Absorption of total [14C]-paltusotine-derived radioactivity in plasma was rapid (median Tmax = 1 hour), and the geometric mean of Cmax, AUC0-inf, and t1/2 were determined to be 189 ng-equivalents/ml, 3180 ng-equivalents.hr/ml, and 31 hours, respectively. The pharmacokinetic parameters of unchanged paltusotine in plasma were similar, suggesting that majority of the circulating drug-derived radioactivity is accounted for by unchanged paltusotine and there are no abundant circulating metabolites. Data from Part B of the study show that the mean oral bioavailability of paltusotine was 70% and the mean clearance and volume of distribution after IV administration were 5.3 l/h and 240 l, respectively. Treatment emergent adverse events associated with paltusotine were generally mild and transient, and consistent with those reported with other somatostatin agonists. In conclusion, results from this clinical trial in healthy volunteers confirm that paltusotine has excellent drug-like properties for chronic once-daily oral treatment of patients with acromegaly and NETs.

Safety and IGF-1 levels with once daily oral sst2 agonist paltusotine (CRN00808) in acromegaly patients previously treated with peptide long-acting somatostatin receptor ligands: Initial data from the open label ACROBAT Edge phase 2 study

Miklos Toth[1], Murray Gordon[2], Mirjana Doknic[3], Emese Mezosi[4], Harpal Randeva[5], Tonya Marmon[6], Kim Fowler[6], Rosa Luo[6], Michael Monahan[6], Ajay Madan[6], Chris Ferrara-Cook[6], R. Scott Struthers[6] & Alan Krasner[6]
[1]Semmelweis University, Budapest, Hungary; [2]Allegheny General Hospital, Pittsburgh, United States; [3]Clinical Centre of Serbia, Belgrade, Serbia; [4]University of Pécs Medical School, Pécs, Hungary; [5]University Hospital Coventry & Warwickshire, Coventry, United Kingdom; [6]Crinetics Pharmaceuticals Inc, San Diego, United States

Peptide long-acting somatostatin receptor ligands (SRLs) are a first line medical treatment for acromegaly but are not efficiently absorbed when delivered orally. Years of injections with SRLs are associated with variable dose delivery, injection site reactions, and excessive life burden. Paltusotine (CRN00808) is a nonpeptide small molecule somatostatin type 2 (sst2) receptor agonist with high oral bioavailability (70%) and a 42–50 hour terminal elimination half-life in healthy volunteers, suitable for once daily dosing. We hypothesized that patients partially controlled on stable long-acting SRLs could successfully switch to once daily oral paltusotine while maintaining baseline IGF-1 levels. ACROBAT Edge (NCT03789656) is an ongoing open label, single-arm exploratory study to evaluate the safety and efficacy of paltusotine in patients with acromegaly who have not achieved normal IGF-1 levels with SRL monotherapy (group 1) or with a SRL in combination with a dopamine agonist (group 2). Additional exploratory subgroups, also eligible for enrollment in this trial, all have normal IGF-1 at baseline and include subjects treated with a SRL in combination with a dopamine agonist (group 3), pasireotide LAR monotherapy (group 4), or a SRL in combination with pegvisomant (group 5). The study schedule requires a final SRL injection to be administered 4 weeks prior to switching to paltusotine monotherapy for 13 weeks of dose titration, followed by a 4-week drug washout period. Change from baseline in IGF-1 to the completion of the 13-week dose titration period is the primary endpoint to be evaluated in a target sample size of 30 subjects in groups 1 and 2. The rise in IGF-1 during the wash out period is used to provide supportive evidence of efficacy. The IDS-iSYS assay calibrated to WHO recombinant reference standard 02/254 is used to measure IGF-1. Initial data available from the ACROBAT Edge study will be reported. This will include summary statistics for IGF-1 at baseline, completion of treatment period, and after washout. Safety data will also be summarized. To date, there have been no reported serious adverse events or treatment discontinuations due to adverse events. This data snapshot of open label data from ACROBAT Edge will provide important information in guiding clinical development of paltusotine for the treatment of acromegaly.

The time, mode and markers of pituitary function deterioration in patients with PROP1 mutation. Single centre, longitudinal observation

Aleksandra Gilis-Januszewska[1,2], Damian Rogoziński[2], Łukasz Kluczyński[1,2], Magdalena Godlewska[2], Anna Bogusławska[3], Beata Piwońska-Solska[2], Agata Zygmunt-Górska[3], Małgorzata Wójcik[3], Jerzy Starzyk[3] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Jagiellonian University, Collegium Medicum, Chair and Department of Endocrinology, Cracow, Poland; [2]University Hospital in Cracow, Endocrinology Department, Cracow, Poland; [3]Chair of Paediatrics, Paediatric Institute, Jagiellonian University, Medical College, Department of Paediatric and Adolescent Endocrinology, Cracow, Poland

Introduction
The mode of pituitary function deterioration in patients with PROP1 mutation is not fully known and understood. The function of adrenal axis requires special attention.
Aim
To investigate the time/mode/markers of pituitary function deterioration in families/sporadic patients with PROP1 mutation during longitudinal observation.
Methods
We performed retrospective longitudinal (36.4 years, s.d. = 13.6) analysis of 28 patients (23 with complete data, 11 M/12 W) with PROP1 mutation, including 7 families (16/23 70% of investigated population; 20/28 overall), with 2–4 affected siblings who were under medical supervision of the paediatric/adult endocrinology departments of our university. Follow up investigation of adrenal axis insufficiency (AI) with repeated ACTH analogue (Synacthen) and CRH tests were performed in 21 and 7 patients, respectively.
Results
All patients initially presented with growth failure at mean age (MA) 7.0 years (s.d. = 3.7). 14/23 patients were first diagnosed with GH/TSH deficiency occurred simultaneously, MA 6.6 years (s.d. = 3.0). 13/28 (older patients) received no/delayed/intermittent GH treatment in childhood. Gonadal deficiency was diagnosed in all patients MA 16.0 years (s.d. = 4.85). 19/23 (82,6%) of patients developed adrenal deficiency MA 25 years (s.d. = 16.0), the oldest newly diagnosed at the age of 57. The actual average dose of HC supplementation is 17.8 mg/day (0.25 mg/kg). There were no specific mode/order of pituitary deterioration among siblings. Mean morning cortisol and ACTH in patients with AI were 5.7 (s.d. = 4.0) and 20.7 (s.d. = 7.7) vs without AI 11.8 (s.d. = 5.5) and 21.8 (s.d. = 8.1), respectively. The peak cortisol increase during Synacthen test was in 60' by 3.2 (s.d. = 0,83) and by 1.9 times (s.d. = 0,26) in patients with/without AI, respectively. In CRH test the peak values of cortisol (in 60–120') and ACTH (in 15–30') were observed accordingly in patients with AI by 3.3 (s.d. = 1.0) and by 3.4 times (s.d. = 0.4) vs patient without AI by 2.5 and by 4.3 times).
Conclusions
In patients with PROP1 mutation there is no specific order of pituitary function deterioration even among affected siblings. Careful monitoring for possible adrenal insufficiency regardless of the time of observation and previous stimulation test results should be carried on. Morning (low) cortisol and ACTH (normal range) cannot serve as a marker of adrenal axis function. The increase of ACTH during CRH test in patients with adrenal insufficiency suggests that corticotropes are responsive. Further studies are needed to better understand the process, to improve the standards of care/diagnostic timing/procedures.

Clinical presentations of patients with MEN 1 syndrome and its phenocopies

Diana Dimitrova[1], Elizaveta Mamedova[1], Zhanna Belaya[1] & Galina Melnichenko[2]
[1]Endocrinology Research Centre, Neuroendocrinology and Osteopathies, Moscow, Russian Federation; [2]Endocrinology Research Centre, Head of Endocrinology Institute, Moscow, Russian Federation

Introduction
Multiple endocrine neoplasia type 1 (MEN 1) is a rare, autosomal dominant disease caused by mutations in the *MEN1* gene. The syndrome predisposes an individual to the development of primary hyperparathyroidism (PHPT), gastroenteropancreatic neuroendocrine tumors (GEP-NETs), pituitary adenomas (PA), as well as other endocrine and non-endocrine tumors

that usually manifest at a young age. If a patient with the MEN 1 phenotype does not carry mutations in the *MEN1* gene, the condition is considered a phenocopy of this syndrome. Comparison of clinical characteristics of mutation-positive and mutation-negative patients may help to identify factors predictive of a positive or negative genetic test.
Materials and methods
The clinical presentations of 85 patients with multiple endocrine neoplasia were analyzed over 5 years. Screening for *MEN1* gene mutations was done by Sanger sequencing or by next-generation sequencing using a panel of genes including *MEN1*.
Results
42 patients carried *MEN1* mutations and 43 patients were mutation-negative. The median age in the phenocopy group was 61 years [48; 65]; in MEN 1 group — 38 years [32; 50] with a predominance of females over males in both groups (82% in non-carriers vs 71% in carriers). The most common combination in the phenocopy group was PA/PHPT (91%) and acromegaly among these patients appeared in 72% cases (versus 11% in *MEN1* carriers). In *MEN1* mutation carriers the most frequent combination was PHPT/GEP-NETs/PA (57%) and mostly PA secreted prolactin (38%). GEP-NETs developed more frequently in *MEN1*carriers compared to non-carriers (72% and 16%, respectively, $P<0{,}01$). The prevalence of PHPT in both groups was almost 100% and multiple lesions of parathyroid glands were more common in carriers. Adrenal tumors were equally common in both groups (23% in non-carriers and 26% in carriers).
Conclusion
GEP-NETs in patients with MEN1 phenotypes could possibly predict the presence of a *MEN1* mutation. Phenocopies of MEN 1 are quite common and usually occur in older patients, with a female predominance; the most common combination of tumors in this group is PHPT/PA (GH secreting). The etiology of the combination of several endocrine MEN 1-associated tumors in such patients remains unknown. As possible causes, mutations in other, not yet established, genes, epigenetic changes, as well as a random combination of several tumors in one patient can be considered.

Functional panhypopituitarism of anorexia

Catarina Roque, Francisco Sousa Santos & João Sequeira Duarte
Egas Moniz Hospital C.H.L.O., Endocrinology, Lisboa, Portugal

A 30-year-old male was admitted to the neurotraumatology ward after head trauma with cerebral concussion, subdural & subarachnoidal haemorrhage. The Endocrinologist was called to evaluate high urinary debits. The patient was healthy until 4 years before admission. He enrolled on variate patterns of alimentary restriction that resulted in the loss of 28 kg. Since then he had visited multiple doctors (Cardiology, Haemathology, Psychiatry, Gastroenterology, Urology, Endocrinology) and performed extensive exams. In conclusion, he had history of sinus bradycardia, normocytic normochromic anemia, bile stones, suspected obstructive incontinence, diabetes insipidus, central hypothyroidism and hypogonadism of unspecified aetiology (normal anterior and posterior pituitary on RMI). From all prescribed drugs he adhered only to levothyroxine 112 mg and testosterone. He complained of weakness, fatigue, nocturia and lack of drive. After a thorough investigation during hospitalization a pathological cause for the syncopal head trauma could not be identified and the history of skipping meals became consistent. Blood tests revealed slight pancytopenia, low testosterone, low IGF-1, normal prolactin, cortisol 12 mg/dl (21 mg/dl after Synacthen), normal FT4 and low FT3, 24 h urinary debits of 2.8–3.6 l of urine with 621 mOsm, normal natremia and blood osmolality. He was discharged weighting 68 kg (192 cm, BMI 18 kg/m^2). Levothyroxine and testosterone were maintained. Control RMI showed a normal pituitary with adequate neural hyperintense sign, anti-hypophyseal Ab were negative. By exclusion and given specially the persistent low IGF-1 and FT3, it was postulated that he had hypopituitarism and possibly mild diabetes insipidus in the context of the alimentary disorder and that the syncope was due to low caloric intake. He was followed up by Nutrition, Psychology, Psychiatry, Physiotherapy and Neurology. Testosterone was weaned off progressively based on symptoms and blood tests and levothyroxine was reduced according to FT3 recovery. After 8 months, CBC was normal, FT3 improved slightly and TT was withing RR. After 12 months, there was increased frequency of shaving and body hair density, he recovered spontaneous erections and testosterone was stopped. Levothyroxine has been reduced to 88 mg.
Conclusions
Severe caloric restriction results in typical hypopituitarism with preserved ACTH-cortisol axis and less commonly accompanying mild DI. Pharmacological resistance to hormonal substitution is well known, caloric intake is the mainstay of treatment for adequate functional recovery.

DOI: 10.1530/endoabs.70.AEP631

A case of primary hypophysitis with cavernous sinus infiltration causing an unilateral internal carotid artery occlusion

Izabella Czajka-Oraniec[1], Maria Stelmachowska-Banas[1], Agnieszka Majos[1], Karolina Cylke[2] & Wojciech Zgliczynski[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Bielanski Hospital, First Internal Ward, Warsaw, Poland

Primary hypophysitis (PH) is a rare clinical entity usually presenting with headaches, pituitary deficiency, visual field defects and exceptionally with symptoms of cavernous sinus infiltration such as cranial nerve palsies. An internal carotid artery (ICA) occlusion is unusual complication of PH infiltrating the cavernous sinus. A 32-year old woman presented with a 4-year history of recurring headaches, right retro-orbital pain, periodic diplopia and secondary adrenal insufficiency. She was admitted to the Department of Endocrinology due to deteriorating headaches, right retro-orbital pain, symptoms of the rightsixthcranial nerve palsy and secondary amenorrhea. Hormonal test results revealed panhypopituitarism. MRI scan showeda sellar and suprasellar mass infiltrating the right cavernous sinus. Additionally, a complete occlusion of right ICA was visible which was confirmed by CT-angiography. No other neurological symptoms were present. Based on clinical presentation, results of hormonal tests and MRI the diagnosis of PH was established. High-dose glucocorticosteroids (GCs) treatment was initiated, which resulted in the headaches and retro-orbital pain remission, abducens nerve palsy subsiding and return of regular menses. The patient has been treated for 10 months with a gradual reduction of GCs dose. A partial regression of parasellar infiltration was revealed on MRI scans but ICA occlusion seems to be permanent. Experience in treatment of PH with ICA occlusion is sparse. Similarly, to a few cases published in the literature, in our patient GCs therapy was not successful in restoring blood flow inthe affected ICA, although it improved pituitary function and reduced cranial nerve palsy and headaches.

ACTH-secreting pituitary tumor with delayed aggressive clinical recurrence – management challenges

Isabela Gaita[1], Alexandru Cristescu[2], Augustina Enculescu[3], Catalina Poiana[1] & Serban Radian[1]
[1]C.I. Parhon National Institute of Endocrinology, C. Davila University of Medicine and Pharmacy, Pituitary and Neuroendocrine Diseases, Bucharest, Romania; [2]Colentina Clinical Hospital, Neurosurgery, Bucharest, Romania; [3]Personal Genetics, Pathology, Bucharest, Romania

Background
Pituitary adenomas (PA) are slow-growing, benign intracranial tumors. Rarely, they can be histologically and clinically aggressive.
Aim
To present a case of corticotroph PA with aggressive behavior following a long indolent interval after the initial surgery.
Case presentation
A 47 years old female presented in Nov 2007 with right temporal hemianopsia and left eye blindness, associating type 2 DM and severe mixed dyslipidemia. MRI demonstrated a 22×20×25 mm sellar tumor with suprasellar extension. Vision improved significantly following transsphenoidal resection. The patient was lost to follow-up for 12 years, during which she was symptom-free, despite persistence of a significant tumor remnant (21×19×16 mm, MRI in 2011). In Mar 2019, the 59 years old patient returned to our unit, with bitemporal hemianopsia and decreased visual acuity, insulin-requiring DM and dyslipidemia, central obesity, without other signs of Cushing's syndrome. 0800 h cortisolemia (21.13 mg/dl) was unsuppressed by 1 mg o/n DEX (5.85 mg/dl) and LDDST (3.39 mg/dl) and 0800 h ACTH was 26 pg/ml. The patient had thyrotroph, gonadotrop and likely somatotroph insufficiency. A partial transsphenoidal resection of a fibrous, difficult-to-resect tumour, led to biochemical remission of Cushing's disease (CD) (0800 h cortisolemia=5.2 mg/dl and 0.66 mg/dl after 1 mg o/n DEX) but no visual improvement. Post-operative MRI revealed

a 25×18×30 mm tumor with bilateral cavernous sinus invasion and chiasmal compression. A third transsphenoidal resection improved visual fields and acuity significantly and the patient developed corticotroph insufficiency (8AM cortisolemia = 1.46 mg/dl, ACTH = 6.6 pg/ml). Histopathological examination revealed a PA with frequent mitoses, IHC positivity for ACTH only, Ki-67 index 15% and p53 nuclear labeling in 30% of cells. SSTR2 and SSTR5 tumor immunoreactivity was positive, but pasireotide could not be administered for regulatory reasons. Visual fields and acuity declined progressively over 3 months and MRI in Jan 2020 revealed rapid tumor growth (27/30/33 mm). MDT recommendations were for repeat surgery (pending) followed by radiotherapy +/– temozolomide and close follow-up.
Conclusion
We report a case of aggressive functioning corticotroph adenoma occurring after a twelve years indolent interval. Immunohistochemical markers of proliferation predict an unfavourable clinic course and need of multimodal aggressive management. Combined temozolomide and radiotherapy (Stupp protocol) is a possibility.

DOI: 10.1530/endoabs.70.AEP633

Unusual case of women suffering from aggressive silent thyrotropinoma treated with somatostatin analogues during pregnancy

Magdalena Zgliczynska[1], Agnieszka Majos[2], Maria Stelmachowska-Banas[2] & Wojciech Zgliczynski[2]
[1]Centre of Postgraduate Medical Education, Second Department of Obstetrics and Gynecology, Bielański Hospital, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Department of Endocrinology, Bielański Hospital, Warsaw, Poland

Background
Thyroid-stimulating hormone (TSH) expressing tumors are one of the rarest pituitary adenomas and comprises 0.5–2% of all cases. To our knowledge, only four cases of thyrotropinoma in a pregnant women have been reported up to date.
Case presentation
We present a case of 24-year old women who reported to gynecologist due to secondary amenorrhea and severe headaches. Commissioned laboratory test showed, among others, prolactin 31.0 ng/ml and TSH 3.5 mIU/l. She was referred for magnetic resonance imaging (MRI) of the pituitary gland, where macroadenoma infiltrating the cavernous sinus was found. The octreoscan showed high expression of somatostatin receptors. The patient underwent incomplete transsphenoidal surgery without complications, what resulted in relief of headaches. Immunohistochemical examination revealed expression of TSH and growth hormone (GH), however, the patient did not had any signs of either secondary hyperthyroidism or GH excess. Therefore, the patient was administered somatostatin analogues, thereby obtaining restoration of regular menstruations. Shortly afterwards the patient became pregnant and the pharmacological treatment was discontinued. In the 11th week of pregnancy a severe headache, impaired vision and drooping of eyelid appeared. Urgent MRI proved large progression of the tumor and she was given short-acting octreotide 100 µg three times daily subcutaneously. As a consequence, rapid improvement and withdrawal of symptoms was observed. In the following weeks of pregnancy the treatment was maintained. Patient was regularly monitored, however, remained asymptomatic. At 30th week of pregnancy she was diagnosed with intrahepatic cholestasis and, therefore, the dose of octreotide was reduced to 100 µg per day and the ursodeoxycholic acid was added. Despite this, in the following weeks of pregnancy no clinical signs of tumor were observed. In 38th week of pregnancy the patient gave birth to a healthy daughter weighting 3800 g. After the pregnancy, she returned to long-acting somatostatin analogues and was qualified for the transsphenoidal surgery with subsequent radiotherapy.
Conclusions
Management of pregnant women with pituitary tumors is complex and requires an individual, patient-centered approach. This should include careful monitoring and calculation of both, maternal and fetal risk-benefit ratio. In the described patient, treatment with somatostatin analogues contributed to the reduction of the tumor size, restoration of the normal function of pituitary gland and, above all, successful conception. Moreover, it allowed the avoidance of surgery during pregnancy and achievement of satisfactory disease control so the patient could gave birth full-term.

Secondary amenorrhea, acute hydrocephalus and syndrome of inappropriate secretion of antidiuretic hormone as first manifestations of neurosarcoidosis

Asma Zargni[1], Ibtissem Oueslati[1], Aymen Ben Mehrez[1], Elyes Kamoun[1], Zohra Ben Amor[1], Sonia Nagi[2], Karim Zouaghi[3] & Melika Chihaoui[1]
[1]La Rabta hospital, Department of endocrinology, Tunis, Tunisia; [2]National institute of neurology, Department of radiology, Tunisia; [3]La Rabta hospital, Department of nephrology, Tunis, Tunisia

Introduction
Sarcoidosis affects both the central and peripheral nervous system in 5–16% of patients. In most cases, such involvement occurs within a multi-systemic disease. Endocrine manifestations of neurosarcoidosis can be expressed by hypothalamic dysfunction, diabetes insipidus, hypopituitarism, hyperprolactinemia, in isolated fashion or variedly combined.
Herein, we report a case of neurosarcoidosis revealed by an obstructive hydrocephalus, a syndrome of inappropriate secretion of antidiuretic hormone (SIADH) and a secondary amenorrhea in a 34-year-old woman.
Observation
A 34-year-old woman was referred to our department of endocrinology for secondary amenorrheafor the last two years. Her past medical history included an acute obstructive hydrocephalus treated with ventricular drainage and a severe hyponatremia secondary to a SIADH. She reported a weight gain, walking disorders and memory troubles. On physical examination, she had a body weight of 130 kg, a body mass index of 42 kg/m^2 and a blood pressure of 120/70 mmHg. On biological investigations she had a fasting blood glucose of 0.84 g/l, a natremia of 128 mmol/l, a kaliemia of 4.4 mmol/l, a serum osmotic pressure of 254 mOsm/l, a calcemia of 93 mg/l, an urine osmolality of 565 mOsm/kg and an urinary sodium level of 206 mmol/l. On hormonal investigations, she had a TSH of 1.7 mUl/l, a FT4 of 0.97 ng/dl, a morning cortisol of 16.6 µg/dl, a prolactin of 7 µg/l, a FSH of 1.3 IU/l, a LH of 0.45 IU/l and an estradiol of 13 ng/l. The diagnosis of hypogonadotropic hypogonadism was made. The bone densitometry revealed osteoporosis. The cerebro-medullary magnetic resonance imaging showed a micronodular enhancement of the acqueduct, the fornix columns with extension to the 3rd ventricle, the infundibulum, the pituitary stalk and the optic chiasm, as well as the right temporal and right cerebral peduncle associated with micronodular enhancement of the meninges, the base cisterns and perimedullary. The diagnosis of neurosarcoidosis was established. The patient was put on normal sodium diet, water restriction, bisphosphonates and estroprogestative replacement therapy. Then, she was referred to the department of internal medicine.
Discussion and conclusion
Hypothalamo-pituitary involvement by sarcoidosis is a rare condition. Its most frequent disorders are diabetes insipidus and hyperprolactinemia. Recent studies have demonstrated that gonadotropin deficiency was the most frequent manifestation of the disease as in our case. However, the SIADH is not common in neurosarcoidosis. It could be induced by the hydrocephalus. As hyponatremia persisted after ventricular drainage, SIADH might be caused by neurosarcoidosis.

Complicated endocrinopathy after liver transplantation for unusual diagnosis

Tereza Havrdova[1], Halima Gottfriedova[2] & Jana Brunová[1]
[1]Institute for Clinical and Experimental Medicine, Diabetes Centre, Prague, Czech Republic; [2]Institute for Clinical and Experimental Medicine, Transplantation Centre, Prague, Czech Republic

Introduction
Langerhans cell histiocytosis (LCH) is a very rare haematological disease, with difficult diagnosis for its very variable clinical picture. It is caused by monoclonal proliferation of cutaneous Langerhans cells. It affects most commonly the skin and bones, less often bone marrow, liver, pituitary and CNS.
Case report
A 74-year-old female patient with progressive sclerosing cholangitis was referred to a transplant centre to consider liver transplant treatment options.

Langerhans cell histiocytosis (LCH) was diagnosed by a liver biopsy. Other examinations, including trepanobiopsy and PET/CT, revealed no other lesions of LCH. The finding was evaluated by the hematologist as unifocal histiocytosis with isolated liver involvement at MGUS level. After the examination, the patient underwent liver transplantation. Immunosuppressive therapy (tacrolimus, mycophenolate mofetil and corticoids) was initiated. Postoperative course was significantly complicated by bleeding and biliary leak, requiring repeated surgical revisions, protracted abdominal infection and repeated need for percutaneous biloma drainage. Chronic sepsis, malnutrition, sarcopenia, decreased mobility and depressive syndrome dominated in the clinical picture. Two months after transplantation, polyuria (of about 7 – 10 litres/24 hours) appeared. The fluid withdrawal test confirmed suspected diabetes insipidus. Etiopathogenetically, there was a possible association with the administration of linezolid in antibiotic therapy, but also with the underlying histiocytosis. After the application of desmopressin (in doses of 60 – 300 µg/day) the polyuria gradually decreased to diuresis about 3 litres/24 h. CT examination described a small pituitary bearing, possible granuloma in histiocytosis or adenoma. Later, the MR region of the Turkish saddle was performed showing a very small pituitary volume with an empty-sella and slight infundibulum enlargement indicating possible discrete LCH in this region. Pituitary profile revealed hyperprolactinaemia (1912 mIU/l), low levels of LH, FSH and TSH, and normal levels of ACTH as well as cortisol. Cabergoline was added to the therapy. Its administration in a small dose (0.5 mg/week) led to a rapid decrease of prolactinemia. The gradual withdrawal of desmopressin did not cause polyuria to return. Currently, the patient is in a satisfactory clinical condition and except cabergoline treated only with a small dose of corticoids as a part of her maintenance immunosuppressive regiment.
Conclusion
We point to a rare hematological disease complicated with probably related endocrinopathy.

A rare association of hypogonadotropic hypogonadism and GH deficiency in a patient with Addison's disease

Hiba-Allah Chatti, Ibtissem Oueslati, Meriem Yazidi, Nadia Khessairi, Wafa Grira, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Primary adrenal insufficiency is a classically rare but potentially serious disease due to the risk of acute adrenal crisis. Although autoimmune origin is the first etiology in adults, genetic causes are most common in children. Herein, we reporta case of coexisting hypogonadotropic hypogonadism and growth hormone (GH) deficiency in a patient with Addison's disease.
Observation
A 15-year-old boy was referred to our department for short stature. He had no family history of autoimmune diseases. His past medical history included a primary adrenal insufficiency. This diagnosis was established on the basis of a very low morning cortisol level of 5 nmol/l with a very high ACTH level of 419 ng/l (nr: <48 ng/l). Thus, the patient was put on replacement therapy with hydrocortisone and fludrocortisone.
On physical examination, he had a body height of 146 cm (between –2 S.D. and –3 S.D.) and an impuberism with a Tanner classification of G1A1P1. His bone age was less than 10 years. The peak of GH under insulin induced hypoglycemia test was 1 mU/l and under glucagon test 3.6 mU/l. A complete deficit in GH has been established. The evaluation of the other pituitary axes revealed hypogonadotropichypogonadism with absence of response to the GnRH test. Thyroid function (TSH and FT4) and prolactinemia were normal. The hypothalamic-pituitary MRI revealed a partial empty sella. The patient received treatment with growth hormone (at a dose of 0.02 mg/kg/day) for 2 years. The final height was 160 cm. He was also put on androgens with a normal development of secondary sexual characteristics.
Conclusion
We report an unusual coexisting of hypogonadotropic hypogonadism, GH deficiency and Addison's disease. The autoimmune involvement of adrenal gland and pituitary is unlikely in our patient since his thyrotropic and corticotropic axes were not affected. A genetic mutation affecting both the adrenal gland and the pituitary gland should be evoked, in particular the DAX1 mutation. This mutation results in adrenal hypoplasia and hypogonadotropichypogonadism. Its role in the development of GH deficiency is not known but it has been described in the literature in particular with a novel missense NROB1 mutation.

46XY DSD as initial clinical presentation in a patient with syndromic combined pituitary hormones deficiency

Vera Lozovanu[1], Carmen Emanuela Georgescu[2], Ramona Oana Irimia[3] & Cristina Alina Silaghi[2]
[1]County Clinical Emergency Hospital Cluj, Endocrinology, Cluj-Napoca, Romania; [2]'Iuliu Haţieganu' University of Medicine and Pharmacy, Endocrinology, Cluj-Napoca, Romania; [3]Sanovil Clinic, Bistrita, Romania

Background
Combined pituitary hormone deficiency (CPHD) is characterized by multiple pituitary hormone deficiencies, due to mutations of pituitary transcription factors involved in pituitary ontogenesis. The genetic basis for CPHD is complex, involving a variety of syndromic and non-syndromic presentations with variable degrees of phenotype-genotype correlations. In male infants with CPHD, gonadotropin deficiency is suggested by the presence of a microphallus and undescended testes, as the growth of the penis and normal testicular descent are dependent upon the normal secretion of fetal LH in the second and the third trimesters. However, more severe genital abnormalities, such as hypospadias or ambiguous genitalia, indicate a defect of hCG-driven androgen secretion and/or action in early fetal life, before the initiation of endogenous hypothalamic-pituitary-gonadal axis activity. Herein, we describe a clinical case of a 15-year-old and 5 months male with a history of premature delivery, ambiguous genitalia at birth (Prader stage 3), who was admitted to the Department of Endocrinology due to underdeveloped genitalia and delayed puberty. Postnatally, it was suspected apartial 46XYDSD after chromosome analysis. Physical examination revealed an overweight patient of normal height, Taner stage 1, micropenis, bifid scrotum, penoscrotal hypospadias, palpable prepubertal gonads in the scrotum (after orchidopexy). Hormonal assayse stablished the combined deficiencies of pituitary hormones: GH, TSH, ACTH, and gonadotropins. The provocative tests revealed no response to GnRH but a significant increase in testosterone level after hCG. Ultrasound imaging didn't find either Mullerian structures or adrenal hyperplasia; the testicular structure was normal, but with a hypoplasic aspect. Brain MRI showed a normal adenohypophysis, a hypoplasic and ectopic neurohypophysis, and a thin pituitary stalk with interruptions. The hand radiogram revealed a bone age of 12. The genetic testing results are at work.
Conclusion
This case illustrates an atypical presentation of CPDH with normal growth despite GH deficiency and genital anomalies indicating an androgen deficiency in early fetal life. It also highlights the need to evaluate the hypothalamic-pituitary axis in selected cases of intersex, and questions the prevailing assumptionsabout the mechanisms underlying the control of testosterone secretion during embryogenesis.

Clinical and hormonal features of congenital hypopituitarism

Elyes Kamoun, Ibtissem Oueslati, Anaam Ben Chehida, Nadia Khessairi, Meriem Yazidi, Wafa Grira, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, Department of endocrinology, Tunis, Tunisia

Introduction
Congenital hypopituitarism is a rare disease induced by mutations in transcription factors involved in the pituitary development or ubiquitous transcription factors. It can be associated with a malformative syndrome. We herein describe clinical and hormonal features of congenital hypopituitarism in two Tunisian families.
Observation 1
We report the case of three sisters, born at term to healthy consanguineous parents. The index case was referred at the age of 20 years for delayed

growth. Physical examination showed a short stature with a height of 125 cm (< −4 s.d.), an immature appearance, a high-arched palate, low blood pressure and female external genital organs with Tanner stage 1. Her bone age was seven years. On hormonal investigations, she had a combined pituitary hormone deficiency. The pituitary magnetic resonance imaging (MRI) found a pituitary hypoplasia. Her two sisters had the same clinical presentation. Molecular analysis of PROP1 concluded to a homozygous mutation in three sisters.
Observation 2
We report the case of two sisters, born at term to healthy consanguineous parents. The index case was referred at the age of 14 years for delayed growth. Physical examination showed a short stature with a height of 131 cm (between −3 and −4 s.d.), a microcephaly, a saddle nose, a high-arched palate and female external genital organs with Tanner stage 1. Her bone age was eleven years. Hormonal investigations revealed a partial growth hormone deficiency, a corticotropin and gonadotropin deficiency. The pituitary MRI was normal. Her 8-year-old sister had an intellectual disability, and a delayed growth. She was 131 cm (< −4 s.d.) and had a digital agenesis. Hormonal investigations only showed a corticotropin deficiency. The pituitary MRI was normal. Molecular analysis is still ongoing.
Conclusion
These two cases highlight the disparities of the phenotype presentation, sharing only the consanguinity and short stature in the siblings, motivating the investigations and leading to the diagnosis of congenital hypopituitarism. Molecular analysis is recommended for the genotypic diagnosis and guides the familial investigations and genetic counseling.

AEP640

Looking for cyclic cushing's syndrome

Maria Elena Lopez Alaminos, Mikel Gonzalez Fernandez, Karol Almendra Alvarado Rosas, Leticia Serrano Urzaiz, María Martínez García, Pablo Trincado & Patricia de Diego Garcia
Hospital Universitario Miguel Servet, Zaragoza, Spain

Introduction
Cyclic Cushing´s syndrome (CCS) is a rare disorder with a wide clinical variability, characterized by repeated episodes of cortisol excess and periods of normal or even low cortisol secretion. Different periodical diagnostic tests are required to confirm hypercortisolism and thereafter imaging techniques and laboratory studies can be performed to localize the cause.
Case report
A 17-year-old female patient with a personal history of advanced puberty and non-treated obesity is admitted to Internal Medicine reporting myalgias, headache and a rapid weight gain of 15 kgs. Physical examination reveals facial plethora, violaceous striae, hirsutism and menstrual disorders. In conjunction with Endocrinology, initial laboratory testing is guided towards diagnosis of Cushing syndrome, but all results result normal. However, due to a great clinical suspicion, the study is prolonged and during the follow-up, alternating normal and abnormal tests are obtained. Petrosal sinus sampling is indicated concurring with abnormal 1 mg- dexamethasone suppression and pituitary magnetic resonance showed a 4 mm adenoma.

	08/02/19	01/03/19	20/03/19	08/04/19
24 h free cortisol µg/24 hours	43.86	36.46	**279.55**	44.53
Nugent µg/dl	0.84	**2.43**	**11.67**	
Cortisol 00:00 h µg/dl	0.88	**7.04**	**8.17**	5.95
Cortisol 8:00 h µg/dl	2.94		9.80	
Cortisol 20:00 h µg/dl	1.31		3.93	
ACTH pg/ml	23.1	37	28.8	21.5

	Petrosal sinus sampling		
	Peripheral	**RPS**	**LPS**
ACTH pg/ml	34.6	478.8	92.13
ACTH 5 minafter CRH pg/ml	73.9	80.3	53.4

A successful hemi-hypophysectomy is performed with great clinical improvement and an ACTH-producing pituitary adenoma is reported in the pathology sample.
Discussion
Cycles of hypercortisolism in CSS can occur regularly or irregularly with intercyclic phases ranging from days to years showing normal cortisol or even hypocortisolemia. The fluctuating clinical picture and discrepant biochemical findings make cyclic CCS sometimes extremely hard to diagnose.
Ethical aspects
The case has the informed consent of the patient.

Medical treatment leading to remission of ectopic cushing's syndrome

Desiree Seguna[1], Marianna Shiafkou[1], Anju Sahdev[2], Ma'en Al-Mrayat[3] & Scott Akker[1]
[1]Street Bartholomew's Hospital, Department of Endocrinology, London, United Kingdom; [2]Street Bartholomew's Hospital, Department of Radiology, London, United Kingdom; [3]University Hospital Southampton NHS Foundation Trust, Department of Endocrinology, Southampton, United Kingdom

A 35 year-old lady presented to her local hospital with a 3 year history of fatigue, weight gain, recurrent tonsillitis and oligomenorrhoea. Examination revealed facial plethora, round facies and thin skin on the dorsum of the hand. She appeared tanned, with evidence of spontaneous bruising and difficulty standing up from a chair unaided. No striae were present. Blood pressure was 152/91 mmHg. Investigations revealed a 0900 h cortisol of 632 nmol/l (ACTH 59 ng/l) and an elevated UFC of 727 mmol/day. An ONDST failed to suppress at 520 nmol/l (0900 h ACTH 72 ng/l). A cortisol day curve showed loss of normal circadian rhythm, with cortisols ranging from 617–776 nmol/l. IGF-1 was elevated on numerous occasions, peaking at 380 microgram/l (81.2–278.1), with detectable GH of 4.43 mg/l, but without clinic features of acromegaly. MR pituitary was unremarkable. An IPSS did not show a peripheral-to-central gradient, suggesting ectopic ACTH production. The patient failed to respond both clinically and biochemically to high doses of metyrapone and was referred to our centre for further investigations. A cortisol day curve performed on a test dose of octreotide, showed an excellent biochemical response, with cortisol levels of less than 50 nmol/l. A block-and-replace regime, with octreotide and hydrocortisone, was hence commenced. No causative ectopic ACTH source was found on full scanning, including Ga-Dotatate PET-CT. However, a 12 mm enhancing lesion was seen within the left kidney, raising concerns for a possible renal cell carcinoma. The patient proceeded to left adrenalectomy and left partial nephrectomy. Histology confirmed a renal oncocytoma, with no post-operative change in cortisol levels. Long-term management options were discussed, including removal of the remaining adrenal gland. However, given that the patient was clinically well, a block-and-replace regime was opted for. Over the next few months, the pre-octreotide 0900 h cortisol rose from less than 50 nmol/l (ACTH 10 ng/ml) to133 nmol/l (ACTH 28 ng/ml). Detectable cortisol and ACTH levels could signify recovery of the HPA axis or tumour escape. A pre-octreotide ONDST showed complete cortisol suppression to 10 nmol/l, suggesting recovery of the HPA axis. The dose of hydrocortisone was tailed down until it was altogether stopped and the patient remains in clinical remission on monthly injections of octreotide. We are unaware of other cases in the literature of ectopic Cushing's managed with octreotide, where there has been full recovery of the HPA axis. We herein discuss the implications of this treatment in the medium to long-term.

An uncommon cause of atrial fibrillation

Mary Llaro[1], Ana Martinez[2], Ivan Quiroga[2], Paola Parra Ramírez[3], Elisa Moya[4] & Benito Blanco[2]
[1]Hospital Nuestra Señora del Prado, Department of Endocrinology, Talavera de la Reina, Spain; [2]Hospital Nuestra Señora del Prado,

Department of Endocrinology, Talavera de la reina, Spain; [3]Hospital Universitario La Paz, Department of Endocrinology, Madrid, Spain; [4]Hospital Universitario Infanta Cristina, Department of Endocrinology, Madrid, Spain

Thyrotropin-secreting pituitary adenomas (TSHomas) are rare functioning pituitary adenomas, accounting for less than 1%. They commonly present as macroadenomas with symptoms of hyperthyroidism. Though surgery is the first line therapy, cure is achieved in only 30–40%, with high rate of post-surgical hypopituitarism. We propose somatostatin analogs having a new role in the management. We report a case of 73 years-old man with a 6-month history of palpitations and progressive dysnea due to an atrial fibrillation. Personal history of hypertension and colon cancer in remission. No family history of thyroid disease. He denied weight lost, visual symptoms, headache, iodine contrast or amiodarone intake. In hospital his heart rate was 130 beats/minute, blood pressure 140/60 mmHg. He had signs of heart failure and goiter. No visual defects were found nor dysthyroid eye disease. Initial thyroid biochemistry revealed a free thyroxine (FT4) concentration 3.95 ng/dl (0.93–1.70 ng/dl), TSH 5.49 µIU/ml (0.27–4.2 µIU/ml) and free triiodothyronine (FT3) 6.3 pg/ml (1.8–4.3 pg/ml), thyroid receptor antibody (TRAb): <0.6 IU/l (negative; <1 IU/l). Alpha subunit 8.1 IU/l (reference range <0.7 IU/l), alpha subunit/TSH molar ratio: 20, sex hormone binding globulin (SHBG) 186 nmol/l (10–57 nmol/), prolactin 17 ng/ml (4–15.2 ng/ml); other pituitary hormones were within the normal reference range. Thyroid ultrasound revealed a goiter with millimetric cystic nodules. The TRH test after 200 mg of TRH iv showed a blunted response: TSH 4.30 at 0 minutes; 4.20 at 20 minutes; 4.10 at 40 minutes; 4.10 at 60 minutes. The pituitary MRI revealed a sellar lesion of 13 mm, with suprasellar extension but without cavernous sinus invasion. Thus, a thyrotropin-secreting pituitary adenoma was suspected but the patient refused surgery and radiotherapy. We started octeotride LAR 20 mg i.m. treatment every 28 days. After six months FT4 decreased to 1.49 ng/dl, TSH to 0.55 µIU/ml and FT3 to 2.42 pg/ml all of them within the normal range. The MRI showed a 7 mm sellar lesion. After 2 years, the patient is in good clinical condition, with no hospital admissions, thyroid hormones are within the normal range and the sellar lesion is stable.

Conclusion

This case supports the increasing evidence of somatostatin analogs as primary therapy in the management of some thyrotropin-secreting pituitary adenomas achieving excellent biochemical and radiologic response.

Osmotic demyelination syndrome in a patient with noonan syndrome and anterior hypopituitarism

Tzy Harn Chua & Wann Jia Loh
Changi General Hospital, Endocrinology, Singapore

Introduction

Management of severe hyponatremia is challenging because of the need to balance the risk of overcorrection leading to osmotic demyelination syndrome (ODS) as well as under-correction causing complications, particularly in a patient with hypocortisolism and hypothyroidism. Case reports of patients with Noonan syndrome with hypopituitarism are rarely reported in literature. We report a case of a patient with Noonan syndrome and untreated anterior hypopituitarism who presented with symptomatic hyponatremia and developed transient episode of ODS.

Case Presentation

A 50-year-old male presented with a two-day history of insomnia, severe nausea and dizziness. He was found to have hyponatremia (109 mmol/l). A thorough history taking revealed that he was found to have chronic anterior hypopituitarism with hypocortisolism, hypothyroidism and hypogonadism with 2 previous hospital admissions of severe hyponatremia in the last 15 years. However, each time, he would stop his hormonal treatment after a year and currently has stopped allmedications for 8 years. On examination, he had typical features of Noonan syndrome. He also had clinical features of hypogonadism which were bilateral gynecomastia, very small testes, and absent facial, pubic, and axillary hair. Initially, the sodium level risen from 109 mmol/l to 113 mmol/l over 22 hours. Despite careful administration of small volume of fluid (only 150 mls normal saline), hydrocortisone and levothyroxine replacement, his sodium level risen to 123 mmol/l over the next 15 hours. He developed a transient acute episode of hypertonia and aphasia due to ODS. Intravenous dextrose 5% fluid and desmopressin were used to lower his sodium level and his symptoms resolved. He made full recovery on discharge. Compared to his magnetic resonance imaging (MRI) pituitary fossa scanperformed 8 years ago which showed a non-enhancing 2 mm lesion in the left pituitary gland likely a non-functioning micro-adenoma, his repeat MRI pituitary scan was normal currently.

Conclusion

Patients with hyponatremia from chronic anterior hypocortisolism and hypothyroidism are a high risk of ODS. Careshould be taken to avoid a rise of >4–6 mmol/l per 24 hours. Early recognition, rescue desmopressin and dextrose 5% fluid to reduce serum sodium concentration were helpful to treat acute ODS.

A case of developmental delay by 18q23 deletion syndrome

Catarina Chaves[1], Mariana Martinho[1], Carla Brandão[2], Catarina Rodrigues[1], Filipe Cunha[1], Susana Garrido[1], Margarida Vieira[1] & Margarida Almeida[1]
[1]Centro Hospital Tâmega e Sousa, Serviço de Endocrinologia, Penafiel, Portugal; [2]Centro Hospital Tâmega e Sousa, Serviço de Pediatria, Penafiel, Portugal

Introduction

Monosomy 18q represents a partial deletion of the long arm of chromosome 18, with an estimated prevalence of 1:100 000. This syndrome is characterized by a highly variable phenotype. The symptoms and their severity depend on which part of the chromosome is missing. Most common manifestations are hypotonia, developmental delay, short stature, growth hormone deficiency, hearing loss and external ear anomalies, intellectual disability, palatal defects, dysmorphic facial features, skeletal anomalies, and mood disorders.

Case presentation

The patient, a 14 year old male, was first evaluated at the Pediatrics Department due to mild cognitive delay, postnatal proportional short stature, and absence of pubarche. He was born at 39 weeks old, with abnormal weight (46 cm, < 5th centile, –2.1 SDS). He had dysmorphic features, hypotonia, his heigh was 141 cm (< 5th percentile, – 2.7 SDS) and his body mass index (BMI) was 14.8 (–2.58 SDS) and Tanner stage 1. The lab tests showed hemoglobin 15.4 g/dl (13.9 – 16.3), IGFBP-3 3.22 (3.3 – 10), IGF1 91 (173 – 414), LH 1.2 mIU/ml (1.2 – 8.6), FSH 1.6 mIU/ml (1.3 – 19.3), total testosterone 0.4 ng/ml (1.6 – 7.5), free testosterone 0.36 pg/ml (0.3 – 1.7), TSH 3.23 mUI/ml (0.38 – 5.33), with negative celiac disease screening, normal phospho-calcium metabolism, hemoglobin, renal, glucose and lipid profile. The bone maturation was 3 years delayed concerning his chronological age. The clonidine test suggested GH insufficiency. Cerebral MRI was unremarkable. Genetic study: 18q23 deletion in an array and confirmed in FISH. Karyotype 46, XY, del (18) (q23). He started supplementation with testosterone 50 mg every 4 weeks. He transitioned to adult Endocrinology department at 18 years old and maintained testosterone supplementation. He had a normal testes. Testicular ultrasound: normal testicular. Echocardiogram and renal ultrasound, performed to screen for comorbidities associated with this syndrome, found no changes. In the last evaluation: Weight: 41.5 kg (< 5th percentile, – 4.1 SDS), height: 161.5 cm (< 5th percentile, –2.1 SDS). Tanner 5. Hormonal evaluation showed normal gonadotropins and testosterone, prompting testosterone deficiency reassessment.

Discussion

This case shows an uncommon cause of GH insufficiency. In patients with 18q23 deletion syndrome, GH deficiency is common, and there are case reports of concomitant hypothyroidism. In this case, the patient had, in addition to GH deficiency, an initial hypogonadotropic hypogonadism which has not been previously described.

Sodium copeptin ratio differentiates patients with and without acute diabetes insipidus post neurosurgery

Cherie chiang[1], Emma Boehm[2], Julie Sherfan[3], Nimalie Perera[3], John Wentworth[2] & James King[4]
[1]The Royal Melbourne Hospital, Pathology, Diabetes and Endocrinology, Parkville, Australia; [2]The Royal Melbourne Hospital, Diabetes and Endocrinology, Parkville, Australia; [3]Royal Prince Alfred Hospital, Chemical Pathology, Camperdown, Australia; [4]The Royal Melbourne Hospital, Neurosurgery, Parkville, Australia

Background
The diagnosis of central diabetes insipidus (DI) relies on indirect measurement of serum/urine sodium and osmolality. Since the diagnosis can only be made when an inappropriately dilute urine is paired with a significantly concentrated serum, the process is tedious for the clinician and uncomfortable for the patient. Copeptin is the C-terminal portion of the anti-diuretic hormone (ADH) prohormone which correlates with the less stable ADH, therefore providing a direct measurement of posterior pituitary response to hyperosmolar stress[1,2].
Aim
This study aims to assess the diagnostic accuracy of copeptin in patients with central DI compared with subjects who underwent pituitary surgery without DI.
Methods
Serum samples from subjects with central DI, control subjects post pituitary surgery with no DI (NDI) and control subjects with SIADH were collected and analysed on the BRAHMS KRYPTOR copeptin assay. Groups were compared using unpaired T-test and Levene's test for equal variance.
Results
56 samples from 22 subjects (13 females, nine males, mean age 53.9±15.5 y.o.) were analysed. Two subjects had resolved DI (RDI) after copeptin analysis and were successfully weaned off DDAVP and reclassified as NDI. Of the DI subjects, 1 had acute and 5 had chronic DI. Copeptin was lower in DI compared to NDI group ($P=0.013$), while serum sodium, osmolality, urine osmolality were similar. Copeptin did not differentiate between the SIADH and NDI groups. After exclusion of NDI samples with serum sodium ≤140 mmol/l, the area under the curve was 0.97 (95% CI 0.9 to 1.0), a copeptin cut-off of 2.9 pmol/l predicts DI with a sensitivity of 92% and a specificity of 90%.

Table Biochemical parameter between groups.

	DI	NDI	SIADH
No.	6	12	4
Age (years)	42±16 #	56±13	67±14
Serum Na (mmol/l)	142±9 #	139±2	122±4 *
Serum Osmol	289±15 #	290±5	253±0.7 *
Urine Osmol	371±203	635±219	445±216
Copeptin (pmol/l)	1.89±0.59 *	12.98±13	22.68±34.45

* $P<0.05$ vs NDI, # $P<0.05$ vs SIADH.

Conclusion
Copeptin concentration of <3.0 pmol/l concurrently with serum sodium concentration of >140 mmol/l predicted central DI when using post pituitary surgery subjects without DI as controls.

Differences in acquired and idiopathic adult-onset growth hormone deficiency

Boey Yee Cheng, Lizy Gill, Sarah Brown, Isabel Palau & Nicole Allie
Ipsos

Introduction
Growth hormone deficiency (GHD) is a medical condition affecting adults and children who lack sufficient growth hormone. The objective of this study was to compare diagnoses in acquired and idiopathic adult-onset GHD patients.
Methodology
Results are from Ipsos' EU5 GHD Therapy Monitor Study 2018, which is an online study conducted among physicians treating both paediatric and adult GHD patients. 156 sampled physicians provided data on the last 5 consecutive GHD patients (reporting on 779 patients) seen between November 2018 and January 2019. Data included demographics, comorbidities, diagnostic tests, disease history, and treatment patterns. Descriptive analysis was conducted using appropriate statistical tests.
Results
Two thirds (66%) of adult-onset GHD patients ($n=220$) treated by endocrinologists in the study have acquired GHD, whilst the remaining have idiopathic GHD. Specific tests used to confirm diagnosis in the two types of patient groups varies slightly. Adult-onset patients with acquired GHD are significantly more likely to have their diagnosis confirmed using an IGF-1 blood test than those with idiopathic GHD (89% vs 70%, $P<0.01$). Idiopathic patients are significantly more likely than acquired patients to have had a hand X-ray (27% vs 6%, $P<0.01$) and/or karyotyping (26% vs 3%, $P<0.01$) tests to confirm diagnoses of GHD. Unsurprisingly, when looking at types of tests idiopathic GHD patients are significantly more likely to have genetic testing than those with acquired GHD to confirm diagnosis, likely due to the nature of the condition. While fatigue is the most common first symptom observed among the adult-onset GHD patients, data suggest it is more likely to impact acquired GHD patients than idiopathic patients (79% vs 47%, $P<0.01$). Significantly more adult-onset patients with idiopathic GHD present with truncal obesity (45% vs 27%, $P<0.01$) and dry skin (38% vs 21%, $P<0.01$) than patients with acquire GHD.
Conclusion
There is a lack of standard diagnostic criteria for both acquired and idiopathic GHD leading to potential delays in diagnoses for the patient population. This study highlights the differences in first symptoms and diagnostic tests between idiopathic and acquired adult-onset GHD patients. Further research is needed to understand which diagnostic tests are being used in each type of GHD in order to identify a more standardised approach to diagnosis.

Evaluation of the of alpha2-adrenergic receptors stimulation effect on copeptin secretion, based on the result of the test with clonidine used in the diagnosis of children with short stature

Renata Stawerska[1,2], Marzena Kolasa-Kicińska[2], Adrian Krygier[3], Maciej Hilczer[2] & Andrzej Lewinski[2,4]
[1]Medical University of Lodz, Department of Pediatric Endocrinology, Lodz, Poland; [2]Polish Mother's Memorial Hospital – Research Institute of Lodz, Department of Endocrinology and Metabolic Diseases, Poland; [3]Polish Mother's Memorial Hospital – Research Institute of Lodz, Protein and Lipid Oxidative Stress Laboratory, Lodz, Poland; [4]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Poland

Introduction
Copeptin can be used as a tool to directly assess serum antidiuretic hormone (ADH) level. A certain pool of ADH are synthesized in hypothalamus, together with corticoliberin (CRH). Then they are released into the pituitary portal circulation, where through the V1bR receptor ADH stimulates adrenocorticotropic cells and ACTH secretion, followed by cortisol and catecholamines production. The stimulus for ADH secretion is, among others, stress. In turn, presynaptic stimulation of the α 2 receptor inhibits the secretion of noradrenaline. On the other hand, stimulation of the alpha2-receptor is widely used in the diagnosis of growth hormone deficiency (GHD) in children. Clonidine, by stimulation of the presynaptic alpha2-adrenergic receptor, in addition to inhibiting the release of noradrenaline, stimulates the secretion of somatoliberin (GHRH) from the hypothalamus, which in turn stimulates the synthesis of GH. Because other possible ADH effects on the pituitary have not been recognized so far, we decided to evaluate the effect of stimulating alpha2-adrenergic receptors after clonidine administration

on copeptin, as well as to assess the differences in response to the above mentioned stimulation in groups of children with normal and decreased GH secretion (ISS and GHD groups).
Material and methods
The serum concentrations of copeptin, GH, cortisol and ACTH at individual time points (0', 30', 60', 90' and 120') during the 2-h stimulation test for GH secretion after oral clonidine administration at a dose of 0.15 mg/m^2 were assessed. The test was carried out for diagnostic purposes in 49 children (mean age± S.D.: 9.55 ± 3.48 yrs) with short stature (height < − 2.0 S.D.). In 29 children ISS and in 20 GHD were diagnosed.
Results
We did not find any differences between copeptin concentration in groups of GHD and ISS children. In both groups (GHD and ISS children), a significant reduction in copeptin secretion after clonidine administration was observed: mean pg/ml ± S.E.M.: 0'–460.5 ± 103.7; 30'–369.0 ± 74.4; 60'–353.1 ± 75.7; 90'–339.0 ± 63.1; 120'–376.1 ± 73.0. ACTH and cortisol levels also decreased with consecutive withdrawals during the stimulation test for GH secretion.
Conclusions
Short-term adrenergic stimulation of alpha2-receptors (after oral clonidine administration) seems to influence (reduce) copeptin secretion in children with short stature in both the ISS and GHD groups.

Typical carcinoid of the nose: The role of somatostatin agonist following surgery

Fernando Pazos[1] & Sergio Obeso[2]
[1]Valdecilla Hospital, Endocrinology, Santander, Spain; [2]Valdecilla Hospital, Otorhinolaryngology department, Santander, Spain

Carcinoid tumors (CT) seldom develop in the head and neck area. Several authors doubt the existence of authentic neuroendocrine tumors in the nose. Most of the CT arise in the larynx.
Clinical case
A 54 years old woman, who had a right-sided nasal obstruction, rhinorrhea, and sometimes purulent discharge in 2016. In 2002 she had hyperthyroidism by Graves disease and treated for two years with remission after that. The examination of the nose revealed a dark red bleeding mass filling the area from the right nasal cavity to the nasopharynx. The biochemical and serum hormonal values were in a normal range. Urine 5 -HIIAA was 2,5 mg/24 h. MRI T1 and T2-weighted images revealed a mass fo 4.1 × 4.2 cm, slightly higher signal in T2 and isointense in T1, that extended into the right nasal cavity and ethmoidal sinus. A biopsy was performed, which revealed CT. Octreoscan with SPECT showed an intense nasal uptake. Right internal maxillary artery embolization was performed. In the next two days, the tumor was resected through a right lateral rhinotomy. Histopathological examination revealed neuroendocrine tumor low grade, ki67 < 2%. Positive immunohistochemical staining to CD56, synaptophysin and chromogranin A, and a negative one to CK. The resection was almost total, with no octreoscan uptake. The post MRI revealed a minimal residual lesion. Lanreotide treatment was introduced after surgery; the dose was 120 mg every four weeks the first year and every 8 weeks after that. No secondary effects or biochemical alterations were observed.
Discussion
A limited number of cases have been reported for CT arising in the nose. As in our case, the majority of typical carcinoids are non-functional. The patients mainly complain of local symptoms such as nasal congestion. Surgery is considered to be the first-line treatment for localized disease. In the case of a close margin of the lesion or a residual tumor, the recommendation was radiotherapy or chemotherapy for more advanced disease. We confirm that the tumor expresses somatostatin receptors. We treated the residual tumor with lanreotide with no progression of the disease after three years of follow-up. The somatostatin analogs may be a useful adjuvant therapy for stable residual disease. We have done a review of the published cases

Multi-hormonal secretion in a young male with a large cystic pancreatic neuroendocrine neoplasm

Georgios Boutzios[1], Eleni Koukoulioti[1], Nikolaos Garmpis[2], Ilias Giovannopoulos[1], Konstantinos Bourgalis-Michalopoulos[1] & Dimitrios Mantas[2]
[1]National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]National and Kapodistrian University of Athens, Second Department of Propedeutic Surgery, Athens, Greece

Introduction
The molecular pathogenesis of pancreatic neuroendocrineneoplasms (PNEN) is increasingly yet incompletely understood. PNEN typically occur sporadically or may occur within the context of hereditary tumor predisposition syndromes. PNEN can also be associated with endocrinopathy of hormonal hypersecretion. We present a young male with a multi-hormonal neuroendocrine neoplasm of pancreas.
Case presentation
A 24-year-old male, non-smoker, with a history of epileptic seizures, hypophyseal Rathke cyst and tonsillectomy presented with hypoglycemias. Family history was unremarkable. Prolonged fasting test was indicative for insulinoma. Abdomen CT was performed and showed a 4 cm cystic lesion of the pancreatic tail. EUS with FNAB was performed and the cytological result was compatible with PNEN. The patient underwent distal pancreatectomy. Histology revealed a well differentiated PNEN, Grade 2 (Ki67 6%), CgA (+), Syn (+), SSTR2a (+), insulin (+), Glucagon (–) with insulin production. Moreover, another small lesion of well differentiated PNEN (1.3 mm) Grade 1 (Ki67 1%), CgA (+), Syn (+), SSTR2a (+), Glucagon (+), insulin (–) with glucagon production was histologically found. Due to the young age of the patient and multi-hormonal appearance of the neoplasm, a gene analysis for MEN1 and VHL was performed and was negative.
Conclusion
This is a rare case of functional PNEN with two different pancreatic lesions producing competitive hormones. The clinical symptoms are compatible with the larger producing neoplasm.

Differentiation of Insulinoma from accessory spleen by 99mTc-labelled heat-denaturated red blood cell scintigraphy

Emre Gezer[1], Berrin Çetinarslan[1], Dilek Karakaya[2], Zeynep Cantürk[1], Alev Selek[1], Mehmet Sözen[1] & Serkan İşgören[3]
[1]Kocaeli University, Faculty of Medicine, Endocrinology and Metabolism, Kocaeli, Turkey; [2]Medical Park Gebze Hospital, Endocrinology and Metabolism, Kocaeli, Turkey; [3]Kocaeli University, Faculty of Medicine, Nuclear Medicine, Kocaeli, Turkey

Introduction
Neuroendocrine tumors (NETs) are rare tumors harboring overexpression of somatostatin receptors (SSTRs) on their cell membrane. Gallium 68-tetraazacyclododecane tetraacetic acid-octreotate (68Ga-DOTATATE) positron emission tomography/computed tomography (PET/CT) is an important imaging modality in diagnosis and staging of NETs. Because some organs such as spleen, adrenal glands and liver physiologically express SSTR, it might be challenging to distinguish some pancreatic NETs located in the pancreatic tail from accessory spleen next to the splenic hilum. In this manuscript, we report a case with hypoglycemia attack and 2 different masses displayed by 68Ga-DOTATATE PET/CT.
Case Report
A 63-year-old woman presented to the emergency with profuse sweating and light-headedness. Her blood glucose level was 45 mg/dl (2.5 mmol/l) and dextrose 5% infusion was started immediately. In the first hour after cessation of infusion, symptomatic hypoglycemia was developed with high insulin and C-peptide levels, 41 µIU/ml (1.9 – 23) and 12.7 ng/ml (0.9 – 7.1), respectively. The levels of antibodies to endogenous insulin were normal. Insulinoma was suspected and endoscopic ultrasonography (EUS) was planned, but it could not be performed. As a result, 68Ga-DOTATATE PET/CT was applied. It revealed two masses with increased tracer uptake located adjacent to the splenic hilum and inferior pole of the spleen which were reported as accessory spleens. 99mTc-labelled heat-denaturated red blood cell (99mTc-HDRBC) scintigraphy was applied to distinguish a NET in the

pancreatic tail from accessory spleen at the splenic hilum. Enhanced tracer uptake remained in the inferior pole of spleen, but not in the splenic hilum. The lesions were suggestive of insulinoma in the pancreatic tail and an accessory spleen adjacent to the inferior pole of spleen. Hemipancreatectomy and splenectomy were performed. The histopathological findings revealed a grade 1 pancreatic neuroendocrine tumor.
Discussion
99 mTc-HDRBC scintigraphy is a beneficial imaging method to display the functional splenic tissue. Therefore, it may be a reasonable imaging option to distinguish splenic tissue from NETs or their metastases. The basic mechanism of this imaging technique is based on denaturated red blood cell uptake by functioning spleen for the removal of abnormal erythrocytes. As described in our case report, 99 mTc-HDRBC scintigraphy is a useful nuclear medicine method to differentiate a NET in the pancreatic tail from accessory spleen at the splenic hilum. In conclusion, 99 mTc-HDRBC scintigraphy is a practicable specific diagnostic technique which may avoid unnecessary surgeries in the presence of enhanced tracer uptake or vice versa.

Predictors of Cushing's disease remission after transsphenoidal endoscopic surgery

Natalia Kuritsyna, Uliana Tsoy, Vladislav Cherebillo, Artem Paltsev, Alexandr Tsiberkin, Elena Vasilieva & Elena Grineva
National Medical Research Center, VA Almazov, Sankt-Peterburg, Russian Federation

Purpose
The postoperative levels of cortisol and ACTH are the most commonly used markers for the prediction of Cushing's disease (CD) remission after transsphenoidal surgery (TSS). However, there is still no consensus on the collection time and threshold values of basal cortisol and ACTH levels after surgery to predict remission of CD.
Aim
To study the significance of early postoperative serum cortisol and plasma ACTH testing in the prognosis of CD remission after TSS.
Materials and methods
101 patients with Cushing's disease (12 men, 89 women, mean age 41 years (15–72) confirmed after TSS were included. In all patients basal morning serum cortisol and plasma ACTH at 2 days and at 14 days postoperatively were measured. The results of TSS were evaluated one year after surgery Remission criteria were: secondary adrenal insufficiency or combination of normal midnight ACTH and serum cortisol levels, normal 24-hour urine free cortisol (UFC) excretion and serum cortisol suppression less than 50 nmol/l in 1-mg dexamethasone test. The optimal threshold value of hormone levels for prediction of CD remission after TSS was calculated by ROC-analysis.
Results
One year after surgery CD remission was confirmed in 63 patients, whereas in 38 patients hypercortisolism persisted. The optimal value of basal serum cortisol at 2 days after TSS for prediction of CD remission was ≤388 nmol/l, with sensitivity 94,9% and specificity 75,9% ($P<0.001$), and for 14 days it was ≤417,7 nmol/l, with sensitivity 96,4% and specificity 87% ($P<0.001$). The optimal value of plasma ACTH at 2 days was ≤20 pg/ml with sensitivity and specificity 83.3% and 95.8% respectively ($P<0.001$), and at 14 days it was ≤41.71 pg/ml, with sensitivity and specificity 94.4% and 88.9%, respectively ($P<0.001$).
Conclusion
Serum cortisol and plasma ACTH levels had a comparable high predictive accuracy when measured at 2 days and 14 days after surgery in the prediction of CD remission after TSS. High threshold values of serum cortisol and plasma ACTH in our study could be explained that not only specificity, but sensitivity were calculated for both markers.

Acrodat – a useful tool to manage acromegaly patients

Helena Alves, Marta Almeida Ferreira, Patrícia Tavares, Diogo Ramalho, Catarina Machado, Lucia Almeida, Sara Correia & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, Department of Endocrinology, Vila Nova de Gaia, Portugal

Introduction
Acromegaly is a rare condition associated with metabolic abnormalities, risk of cardiovascular complications and increased mortality. Even when biochemical control is achieved, following surgery or medical treatment, patients still complain about disease-related symptoms.
Material and methods
Retrospective study of acromegaly patients, followed in an Endocrine outpatient clinic. Clinical and biochemical data was recorded. ACRODAT was used to easily understand if patients were controlled, if they were symptomatic or if they had comorbidities [diabetes; cardiovascular disease (CD); sleep apnea] before and after treatment. Symptoms were evaluated by *Signs and Symptoms Score* (SSS). Surgical cure and biochemical control were considered to be an insulin growth factor-1 (IGF-1) value less than once the upper limit of normal (ULN) for sex and age. Descriptive and inferential statistics were used, with significance level $\alpha=0.05$.
Results
Twenty-nine patients were evaluated – mean age=48 years-old (11–80); mean follow-up time=63 months (11 – 106). Ten patients achieved disease control following surgery. First evaluation, before surgery: mean IGF-1=2.63 above ULN; 7 patients were symptomatic [median SSS score=9 (6–18)]; 5 had comorbidities. Last evaluation after surgery: mean IGF-1=0.77 above ULN; 2 patients were still symptomatic [median SSS score=2 (1 – 3) – $P=0.018$]; 7 had comorbidities – among these, there was one patient who resolved sleep apnea. Ten patients were controlled with medical therapy, after non-curative surgery. First evaluation, before surgery: mean IGF-1=2.88 above ULN; 7 patients were symptomatic [median SSS score=6 (4 – 25)]; 4 patients had comorbidities. Last evaluation after surgery: mean IGF-1=0.78 above ULN; 4 complained about symptoms [median SSS score=6 (2 – 10) – $P=0.046$]; 5 patients had comorbidities – among these, there was a patient with new-onset diabetes, another developed CD and another with complains about sleep apnea. Four patients are waiting for surgery; three are still uncontrolled despitesurgery and medical treatment; two patients have died (one because convulsive crisis and another because of pneumoniae and end-stage renal failure). Because this is a retrospective study, it wasn't possible to collect data about quality of life.
Conclusions
ACRODAT is a useful tool in the follow-up of acromegaly patients. It allows us to evaluate symptoms in a measurable manner, and to understand better how the disease impairs patients' lives. It may help making treatment decisions. Another advantage relates to comorbidities: allowing to report the ones that improve and the new-onset diabetes, CD and sleep apnea. With this registry it's possible to manage better each particular patient.

Characterization of pituitary adenomas by immunohistochemistry of pituitary-specific transcription factors and their correlation with hormonal subtypes

Araceli García-Martínez[1], Sandra Silva-Ortega[2], Beatriz López-Muñoz[3], Óscar Moreno-Pérez[3], Irene Monjas[4], Javier Abarca[5], Antonio Picó[3] & Ignacio Aranda[2]
[1]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Research Laboratory, Alicante, Spain; [2]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Pathology Department, Alicante, Spain; [3]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Endocrinology Department, Alicante, Spain; [4]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Otorhinolaryngology Department, Alicante, Spain; [5]Alicante University General Hospital, Alicante Institute for Health and Biomedical Research, Neurosurgery Department, Alicante, Spain

Introduction
The immunohistochemical characterization of Pit-1, Tpit and SF-1 transcription factors allows the identification of the three adenohypophyseal cell lines and has been incorporated into the latest WHO classification of pituitary adenomas (PA). The aim of the present study was to quantify the protein expression of pituitary-specific transcription factors (TF) by immunohistochemistry (IHC) and to correlate these results with the identification based on hormonal protein expression. Moreover, to validate these results by qRT-PCR in a subset of samples.
Material and methods
We selected 144 PA with complete information. These adenomas had been previously classified according to the IHC of the pituitary hormones: 18

densely granulated somatotroph adenomas (DGSA), 17 sparsely granulated somatotroph adenomas (SGSA), 9 lactotroph adenomas, 49 gonadotroph adenomas, 18 corticotroph adenomas and 29 null cell adenomas. We quantified the immunohistochemical expression of Pit-1 (PA5–59662), Tpit (ab243028) and SF-1 (ab217317) (cutoff 5%) on Tissue Microarrays. We quantified the relative gene expression of TPIT, PIT-1, SF-1, GATA2 and ESR1 by qRT-PCR.
Results
The mean age of the patients was 54 years, 65 were women and 79 men. Three cases were eliminated due to their double tumor nature. 49 PA were Pit-1 IHC positive of which 18 expressed GH, 14 GH and PRL, 8 PRL, 2 TSH, 1 LH and TSH and 6 were null. 19 were Tpit IHC positive of which 10 were Cushing (expressed ACTH) and 9 were silent (8 expressed ACTH and 1 was only Tpit). 67 expressed SF-1 by IHC of which 49 expressed FSH/lH and 18 only SF-1, without hormonal expression. 6 tumors were confirmed as null. Moreover, gene expression of TF agreed with the IHC identification.
Conclusion
The IHC study of the expression of pituitary-specific TF proteins allows a better identification of PitNETs, significantly reducing the percentage of null cell tumors.

Our experience with lu-dotatate in patients with neuroendocrine tumors in a tertiary hospital

Diego Munoz, Juan Carlos Percovich Hualpa, Bettina Weber, José Atencia Goñi, Laura González Fernández, María Miguélez González, Noemí Brox Torrecilla, Roberto José Añez Ramos, Alejandra Maricel Rivas Montenegro, Aurelio López Guerra, Yoko Lucía Olmedilla Isishi, María Ángeles Vélez Romero, Javier Ágreda García, María Picallo Pérez, Susana Monereo Megías & Rogelio García Centeno
Hospital General Universitario Gregorio Marañón, Madrid, Spain

Introduction
Lutetium-177-DOTATATE (Lu177) is approved in patients with well-differentiated (G1 and G2) neuroendocrine tumors (NETs) positive to somatostatin receptors, progressive and unresectable or metastatic. Lu177 has been shown to increase progression-free survival and the quality of life of these patients.
Material and methods
Retrospective descriptive study of a series of 15 cases with NETs treated with Lu177. Demographic data, tumor characteristics, previous and concomitant treatments, response to Lu177 treatment and possible adverse reactions have been collected.
Results
We describe 15 patients, 9 men and 6 women with 62±11 years old of average age. The location of the primary tumor was ileum in 7 patients, pancreas in another 7 and lung in 1. Regarding the degree of differentiation, 5 were G1 (33%), 8 G2 (53%) and 2 G3 (13%). All of them presented liver metastases, 7 lymphatic, 2 bone, 4 peritoneal implants and 1 ovarian metastases. 11 of them were functional, the remaining 4 were not. As a concomitant treatment, everyone was receiving somatostatin analogues (13 lanreotide and 2 octreotide). As previous treatments, 6 had received everolimus, 4 chemotherapy with cisplatin+etoposide and 5 intrahepatic treatment (embolization with yttrium spheres). In all of them uptake was visible in scintigraphy with analogues prior to treatment with lutetium. 11 patients completed the 4 doses of 200 mC1, 1 received 3 cycles, another 2 cycles and 2 patients 1 cycle. The follow-up time was 6 to 42 months. The radiological response of the lesions (according to RECIST 1.1 criteria) was partial response in 3 patients (27%), stabilization in 2 (18%) and tumor progression in 6 (54%) of them (2 exitus for this reason). In the 5 patients with partial response or tumor stabilization there was also a metabolic response mesured by Octreoscan and a biochemical response with decreased levels of Chromogranin A. 4 are waiting to complete the cycles. Adverse reactions have all been self-limited, the most frequent were gastrointestinal (nausea 26% and vomiting 20%), mild thrombocytopenia(26%), mild anemia (6.6%) and mild neutropenia (6.6%). No anaphylaxis or nephrotoxicity reactions have been observed.
Conclusions
In our experience, treatment with Lu177 in patients with metastasic NETs has been able to control the disease in 45% of the patients that completed the 4 cycles with mild gastrointestinal and hematological adverse effects. Lu177 treatment is an excellent therapeutic option, as long as it is decided within the consensus of a multidisciplinary team.

Characteristics of severe forms of Cushing's disease compared to milder cases

Panagiotis Mourelatos, Vasiliki – Ioanna Mitravela, Maria Balomenaki, Dimitris Margaritopoulos, Aristeidis Diamantopoulos, Sofia Kanellopoulou, Dimitra Vassiliadi & Stylianos Tsagarakis
Evangelismos Hospital, Department of Endocrinology, Diabetes and Metabolism, National Expertise Center for Rare Endocrine Disorders, Athens, Greece

Introduction
Cushing's disease (CD) is associated with significant morbidity and mortality due to cerebro-cardiovascular, thrombotic or infectious complications. However, there is significant variation in the clinical presentation and consequences of hypercortisolism, resulting in a wide clinical spectrum, ranging from mild to severe or even life-threatening disease requiring immediate treatment.
Aim
The description of patients with severe CD in comparison with milder forms, with regards to their clinical characteristics and outcome.
Patients and methods
171 patients with CD (144 females), mean age 45±14 years who were admitted in our Department. We defined biochemically severe CD (BCD, $n=19$) by serum cortisol more than 36 μg/dl at any time or a 24-h urinary free cortisol > 4 × ULN and/or severe hypokalaemia (<3.0 mmol/l), and as clinically severe CD (CCD, $n=15$) the presence of one or more of the following: sepsis, opportunistic infection, uncontrolled hypertension, heart failure, acute psychosis, progressive debilitating myopathy, thromboembolism or uncontrolled hyperglycaemia. Patients fulfilling both criteria were defined as severe CD (SCD, $n=21$). The remaining patients were defined as non-severe CD (NSCD, $n=116$).
Results
There were no differences in age and mean adenoma size among groups; the prevalence of macroadenomas was 27% in NSCD patients, 16% in BCD, 27% in CCD and 14% in SCD. Baseline ACTH levels were higher in BCD and SCD groups compared to CCD and NSCD groups and the ACTH-to-cortisol ratio was similar among groups. Early, 90-days-mortality from sepsis/opportunistic infections was observed in 3 (20%) patients with CCD and 2 (9.5%) patients with SCD, despite medical aggressive management with ketoconazole and metyrapone. When only patients with long-term follow-up (>2 years, mean follow- up time 4.7±2.8 years) were considered ($n=120$), bilateral adrenalectomy to control hypercortisolism was performed in 27% of BCD, 38% of CCD and 31% of SCD, compared to only 8.6% of NSCD patients. Long-term mortality (mean time to death after diagnosis 10.9±5.8 years) was higher in SCD (19%) and BCD (13%) vs 2.5% in NSCD.
Conclusions
Cushing's disease remains a detrimental disease with significant early and late mortality, especially in patients presenting with severe biochemical and/or clinical hypercortisolism.

The impact of variations in laboratory measurements of IGF-1 and random growth hormone on the classification of acromegaly disease activity status: Lessons from the UK Acromegaly Register Reference Laboratory

Bilal Bashir[1,2], Safwaan Adam[1,2], Philip Monaghan[2,3], Zoe Plummer[4], Natasha Archer[4], John Ayuk[5,6] & Peter Trainer[1,2]
[1]The Christie NHS Foundation Trust, Manchester, United Kingdom; [2]Manchester Academic Health Sciences Centre, Manchester, United Kingdom; [3]The Christie Pathology Partnership, Manchester, United Kingdom; [4]Society for Endocrinology, Bristol, United Kingdom; [5]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [6]University of Birmingham, Birmingham, United Kingdom

Background
The UK Acromegaly Register contains data for 2700 patients. IGF-1 and random growth hormone (GH) measurements are used for disease monitoring. The registry reference laboratory (RRL) uses the Immunodiagnostic systems (IDS)-iSYS immunoassay platform for GH and IGF-1. The RRL uses age- and sex-specific reference ranges for IGF-1. We compared IGF-1 and GH results fromlocal laboratories to those of the RRL (pre-defined as

the Gold standard) to determine the extent of differences and the implications for classification of disease activity status.
Methods
Blood samples were separated for local (IGF-1 *5 centres*, GH *4 centres*; Table 1) and paired RRL analysis. Controlled disease was defined for IGF-1 as below the upper-limit of the laboratory reference range and for GH as <1 mg/l. We calculated the RRL vs local assay correlation co-efficient and percentage bias and also compared respective disease activity status classifications between individual centres and the RRL.
Results
The total number of IGF-1 and GH measured were 277 and 121 respectively. Key results are summarised in Table 1.

Table 1

Centre	Analyser	No. of paired samples	Correlation with RRL	% bias	Number of discordantly *elevated* readings§ (%)	Number of discordantly *normal* readings§ (%)
			IGF-1			
1	Mediagnos-RIA-CTI	39	0.97***	+ 11.2	1(3)	9(23)
2	Siemens-Immulite-Xpi-2000†	45	0.91***	+6.5	3(7)	0
3	Siemens-Immulite-Xpi-2000†	128	0.96***	+ 10.8	12(9)	6(5)
4	IDS-iSYS†	19	0.80***	+ 7.3	0	0
5	IDS-iSYS†	46	0.88***	– 1.53	2(4)	3(7)
			GH			
1	Siemens-Immulite -Xpi-2000	43	0.97***	+ 12.1	4(9)	1(2)
2	Siemens-Immulite -Xpi-2000	40	0.83***	+ 8.31	1(3)	3(8)
3	Beckmen-Unicell	16	0.92***	– 15.2	0	0
4	Siemens-Immulite -Xpi-2000	22	0.99***	– 1.26	1(5)	0

***P*-value <0.001.
†Inter-laboratory differences in IGF-1 reference range despite same analytical platform.
§RRL definition of disease activity status was considered as the Gold standard; an elevated result in the local laboratory was classified as normal in the RRL (discordantly *elevated*) or local result was deemed normal but regarded as elevated at the RRL (discordantly *normal*).

Discussion
Our results show a relatively modest bias and strong correlation between local and RRL IGF-1 values. Consequently, differences in disease activity classification may predominantly represent inter-laboratory IGF-1 reference range variances. There were differences in the bias and accuracy of GH measurements (compared to RRL) of local laboratories even when utilising the same analytical platform. Further standardisation, traceability and commutability of assays and harmonisation of reference ranges might improve biochemical monitoring thereby potentially enhancing clinical decisions.

Prevalence of non-alcoholic fatty liver disease in patients with Cushing disease (CD)

Pablo Remon[1], Eva Venegas-Moreno[1], Alejandro Deniz-Garcia[1], Raquel Millan[2], Elena Dios-Fuentes[1], Natalia Martin[2], Maria C Rico[2], Ainara Madrazo[3], Manuel Romero-Gómez[4] & Alfonso Soto-Moreno[1]
[1]Virgen del Rocio Hospital, UGC Endocrinology and Nutrition, Sevilla, Spain; [2]FISEVI, Sevilla, Spain; [3]FISEVI, UGC Endocrinology and Nutrition, Sevilla, Spain; [4]Virgen del Rocio Hospital, UGC Digestive and Gastroenterology, Sevilla, Spain

Introduction
The prevalence and comorbidities of NAFLD in CD are unknown. There is only one study wich set the prevalence of NAFLD by CT images in 20%[1].
Objectives
Describe the prevalence of NAFLD and fibrosis in CD and analize predictive biomarkers of NAFLD
Methods
Transversal descriptive study. 31 patients with CD; 11 active, 20 cured. Women 24 (77%), men 7 (23%). 54 years mean age. NAFLD was valorated by Hepatic Steatosis Index (HSI) and Controlled Attenuated Parameter (CAP dB/m). Fibrosis stage by FIB4 and transition elastography (kPa). Date of control of hypercortisolism was determinated by normalization of free urinary cortisol 24 hours.
Results
31 patients. 20 (65%) cured (11 with hydrocortisone treatment) and 11 (35%) with active disease, 3 (10%) non controlled. HTA 14 (45%), dyslipemia 16 (52%), type 2 Diabetes 7 (23%). Obesity (BMI > 30 kg/m^2) 15 (48%) and 10 (32%) overweight. 3 patients with previous mayor vascular event. Pathologic HSI (> 36) in 24 (77%). NAFLD clasiffication by CAP: S1 (248–268 dB/m): 3 (10%); S2 (268 –280 dB/m): 3 (10%); S3 (> 280 dB/m): 9 (29%); S0 en 16 (51%). All patients with HIS > 36 were classified as S2-3 with a correlation between HSI and CAP (coef 0,416). Besides, an association between NAFLD and active CD was observed (80% Vs 20%, *P* 0.07) NAFLD was also associated with obesity (83% vs 26%, *P* = 0,03), presence of DM, HTA and/or DLP (92% vs 53% *P* = 0,046) and longer time to get hormonal control (117 vs 29 months, *P* = 0,001). 3 (9.7%) patients with ET values >8.9 Kpa (F3-F4). All ET > 89 K Pa patients presented HSI > 36, but no one pathologic FIB4 value. ET > 8,9 kPa was associated with longer time to get hormonal control.
Conclusions
– A high prevalence of NAFLD has been observed in our series, with higer prevalence in non cured patients.
– HSI formula classified correctly NAFLD patients.
– FIB4 seems not to be a godo predictor of fibrosis.

Tumour progression in clinically non-functioning pituitary adenomas-does somatostatin analogue therapy decrease the risk?

Natalia Zawada
Medical University of Lodz, Diabetology and Metabolic Diseases Department, Lodz, Poland

Introduction
The management of clinically non-functioning pituitary adenomas (NFPA) remains a debated issue. Surgery, which is indisputably indicated in invasive NFPA, is rarely curative. Moreover, it is not always feasible due to potential complications or contraindications. Expression of somatostatin receptors (SSTR) form the rationale for the use of somatostatin analogues (SSA) in NFPA.
Aim
To compare the risk of NFPA progression in patients treated with SSA vs those without pharmacotherapy.
Material and methods
57 patients with NFPA (subgroup A-40 after incomplete surgery + subgroup B-17 not operated) were enrolled into the study. SSTR scintigraphy and additionally immunohistochemistry (subgroup A) were performed. The presence of SSTR was confirmed in 25 patients (17 from subgroup A + 8 from subgroup B) in whom SSA therapy was started (every 4 weeks: octretide LAR 20 mg intramuscular or lanreotide autogel 120 mg deep subcutaneous injection). The duration of the therapy varied from 16 months to 18 years. Adenoma size was estimated in pituitary magnetic resonance imaging.
Results
Tumour progression rate was twice higher in patients who were not treated with SSA (71.9% vs 36%). In subgroup A tumour volume increased in 35.3% patients treated with SSA compared to 74% those without pharmacotherapy. Moreover, in subgroup B tumour progression was noticed in 37.5% SSA treated patients vs 66.7% not SSA treated patients.
Conclusions
SSA significantly decrease the probability of tumour progression in NFPA, however, further studies should be carried out.

Predictors for remission after transsphenoidal surgery in acromegaly: A dutch multicenter study

Eva Coopmans[1], Mark Postma[2], Thalijn Wolters[3], Sebastiaan van Meyel[1], Romana Teodora Netea-Maier[3], Sebastian Neggers[1] & Andre van Beek[2]
[1]Erasmus University Medical Center Rotterdam, Department of Medicine, Endocrinology section, Pituitary Center Rotterdam, Rotterdam, Netherlands; [2]University Medical Center Groningen, Department of Endocrinology, Groningen, Netherlands; [3]Radboud University Medical Center, Division of Endocrinology, Department of Internal Medicine, Nijmegen, Netherlands

Context
Transsphenoidal surgery (TSS) is the primary treatment of choice in acromegaly. It is important to identify patients in whom surgical cure is not attainable at an early stage, both to inform patients on expected treatment outcome and to select those who are more likely to need additional therapy.
Objective
To identify predictors for remission and relapse after TSS in acromegaly.
Design
Retrospective study in three large tertiary neurosurgical referral centers in the Netherlands.
Methods
We analyzed clinical data since 2000 from three cohorts (Rotterdam, Groningen and Nijmegen, total $n=282$). Multivariate regression models were used to identify predictors of early biochemical remission (12 weeks-1 year postoperatively) according to the 2010 consensus criteria, long-term clinical remission (no additional treatment applied at last follow-up) and relative GH and IGF-1 reduction.
Results
The presence of a macroadenoma (vs. microadenoma, OR = 0.17, [0.09 – 0.34], $P \leq 0.0001$) was associated with a lower chance of early biochemical remission. A lower random GH concentration at diagnosis (OR = 0.98, [0.97 – 0.99], $P = 0.0058$) was associated with a higher chance of long-term clinical remission, while cavernous sinus invasion (OR = 0.35, [0.16 – 0.77], $P = 0.0097$) and the presence of a macroadenoma (OR = 0.43, [0.20 – 0.93], $P = 0.0321$) were associated with a lower chance of long-term clinical remission. Higher GH and IGF-1 concentration at diagnosis were associated with more relative IGF-1 reduction (ß = 8.90, SE = 1.59, $P \leq 0.0001$; ß = –0.22, SE = 0.05, $P \leq 0.0001$, respectively).
Conclusion
Tumor size, GH concentration at diagnosis and cavernous sinus invasion are the best predictors for remission after transsphenoidal surgery in acromegaly.

Metyrapone treatment in endogenous Cushing's syndrome. Results from a prospective multicenter, open-label, phase III/IV study: PROMPT
Background
Metyrapone is a steroidogenesis inhibitor approved in Europe for the treatment of endogenous Cushing's syndrome (CS) based on observational retrospective studies published over more than 50 years. We present data from the first prospective study designed to confirm metyrapone efficacy and good tolerance in patients with CS.
Methods
This single arm, open-label, multicenter, international trial enrolled 50 patients with CS who had three baseline 24 hours urine free cortisol (UFC) values at least 50% above the upper limit of normal (ULN = 165 nmol/24 h). Metyrapone was titrated over 12 weeks (W12) to achieve normal urine (mean of 3 values, mUFC) and serum cortisol levels. Patients whose mUFC did not exceed 2.5-fold the ULN could enter a 6-month extension period. The primary efficacy endpoint was the proportion of patients with mUFC ≤ ULN at W12 assessed in a central laboratory using LC-MS/MS. The most important secondary endpoint was a mUFC decrease of ≥ 50% at W12.
Results
At baseline, mean age was 47 years, mean mUFC (s.d.) was 1042 (1337) nmol/24 h and median mUFC (range) was 570 (291–8476) nmol/24 h (3.5 × ULN). Diabetes mellitus (65%) and hypertension (51%) were the most common comorbidities at baseline. At W12: 48% (23 of 48 patients) met the primary endpoint. Another 40% (19 of 48 patients) had mUFC ≤ 2 × ULN at W12. Median percentage decrease in mUFC from baseline to W12 was –74%. Secondary endpoint was met by 81% of patients who had a mUFC decrease of 50%. Final median metyrapone dose was 1500 (250; 5500) mg/day at W12. At W12, circulating cholesterol, HbA1C and fasting glucose improved with mean decrease of 12%, 3% and 6% respectively and median systolic and diastolic blood pressure also decreased by 3.4 and 3.5 mmHg respectively. At W12, ACTH increased 20% (+ 9 ng/l) from baseline. Twenty six (52%) patients experienced mild to moderate related adverse events (AEs). One patient discontinued before W12 because of an unrelated SAE on day 2 (pneumonia with septic shock). The most common AEs were nausea (24%), decreased appetite (18%), fatigue (14%), headache (10%), peripheral edema (6.0%), hypokalemia (6.0%) and hypertension (6.0%). Reversible adrenal insufficiency occurred in 6 (12%) patients.
Conclusions
This prospective study in patients with CS confirms that metyrapone effectively lowers UFC levels with a tolerability profile similar to the previously reported safety profile.

Background
Pegvisomant(PegV) and Pasireotide LAR(Pasi) are commonly used in acromegaly patients resistant to first-generation SRLs. Predictors of response to therapy with PegV and Pasi in this subset of patients are still unclear. These findings may be useful in choosing the most appropriate therapeutic option for the personalized treatment of patients affected by more aggressive disease. We aimed to identify individual predictors of responses.
Methods
We conducted a longitudinal retrospective cross-sectional study in a multicenter study on 64 acromegaly patients resistant to first-generation SRLs. We enrolled in the study patients (1) who underwent surgical resection as first-line therapeutic option, (2) defined resistant to adjuvant treatment first-generation SRL at high dose, after at least 6 consecutive months of therapy, (3) treated with Pasi or PegV for at least 6 months. Patients treated with radiotherapy in the previous 10 years were excluded. Biochemical control was defined as normal IGF-I.
Results
51 patients were treated with PegV and 31 with Pasi. 57 patients were female. Mean age was 37.5 months (SDS: 13.4). Mean IGF-I×ULN at study entry was 3.4 (SDS: 1,1). The clinical, biochemical and morphological features was similar between the two groups. In the Pasi-treatment group, 18 patients were switched from PegV (15 as not-controlled and 3 for intolerance).Of the 51 patients treated with PegV, biochemical control was obtained in 36 (70.6%) and among the 31 patients treated with Pasi, biochemical control was obtained in 20 (64.5%). In the PegV-treatment group, patients resistant totherapy showed significantly higher Ki67 compared to the responding patients ($P=0.04$), a more frequent invasion of the ventricular system ($P=0.006$), and higher values of IGF-I×ULN before treatment ($P=0.01$). In the Pasi-treatment group, patients resistant to therapy showed significantly higher Ki67 compared to responders ($P=0.001$), higher IGF-I×ULN before treatment ($P=0.04$), a higher prevalence of d3-isoform of the GH receptor ($P=0.04$) and a low/absent expression of subtype 5 of somatostatin receptors ($P=0.04$). The SSTR2A expression was similar between the two groups of treatment ($P=0.06$).
Conclusions
Our data confirm in real life scenario the efficacy of Pegvisomant and Pasireotide LAR in obtainingbiochemical control of acromegaly in patients affected by more aggressive disease and suggest that molecular markers may be useful for optimizing an individualized treatment outcome.

AEP663

Efficacy of monotherapy versus combined GH receptor antagonist therapy in patients with somatostatin receptor analogues resistant acromegaly

Găloiu Simona Andreea[1,2], Emma Margarit[2], Maria Lavinia Popa[2], Ionela Baciu[1,2], Dan Niculescu[1,2], Raluca Trifanescu[1,2], Radian Serban[1,2], Anda Dumitrașcu[3], Andra Caragheorgheopol[4] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]C.I.Parhon National Institute of Endocrinology, Pituitary and neuroendocrine disorders, Bucharest, Romania; [3]C.I.Parhon National Institute of Endocrinology, Radiology, București, Romania; [4]C.I. Parhon National Institute of Endocrinology, Research laboratory, București, Romania

Background and Aims
GH receptor antagonist (Pegvisomant –PEG) has been shown to obtain IGF1 normalization in 60–90% of patients with acromegaly in clinical trials. The aim of the study is to evaluate real life response and side effects of PEG treatment in monotherapy versus combined with somatostatin analogues and/or cabergoline in patients with somatostatin analogues resistant acromegaly.
Methods
We included 40 patients (22F/18 M) consecutively evaluated between Jan2001-Dec2019. Baseline and at 6 months, and then yearly till 10 years serum IGF1, glucose, hepatic enzymes and tumor diameters were recorded.
Results
All patients were previously operated and 26 were irradiated. There were 9 patients treated with PEGmonotherapy (highest dose 136.11±61.93 mg/week) and 31 patients received combination therapy (highest PEG dose 81.93±42.30 mg/week). IGF1 levels were lowered after 6 months and 1year of treatment and then remained stable till 10 years of treatment with PEG (from 2.27±0.18 ×ULN to 1.86±0.16 and 1.35±0.13 xULN at baseline, 6 months and 1 year, respectively, $P=0.012$ baseline versus 6 months and <0.001 baseline versus 1 year; 0.001 1 year vs 6 months). We obtained control of acromegaly in 20% of patients at 6 months, and in 42% and 58.3% after 1 and 3 years. There were no hepatic adverse reactions and tumor diameters nonsignificantly raised from 15.76±2.18 mm at baseline to 20.36±2.99 mm at 6 months, 18.43±3.62 mm at 1 year and 24.96±67 mm at 4 years ($n=6$). In patients treated by monotherapy, glucose level were lower at 6 months versus baseline (88.61±19.68 and 101.96±16.49 mg/dl, respectively, $P=0.01$). Patients treated by monotherapy were more frequently controlled (8/9; 88.88%) than patients treated with combination (12/31; 38.70%), $P=0.01$.
Conclusion
After 3 years of treatment with pevisomant, more than 50% of patients with somatostatin analogues resistant acromegaly were controlled. Patients treated with monotherapy were more frequently controlled and had better glucose control.

The role of repeated prolactin samples in patients with hyperprolactinaemia

Catarina Rodrigues[1], Filipe Cunha[1], Catarina Chaves[1], Margarida Silva Vieira[1], André Silva[2], Susana Garrido[1], Mariana Martinho[1] & Margarida Almeida[1]
[1]Centro Hospitalar Tâmega e Sousa, Endocrinology, Penafiel, Portugal; [2]Centro Hospitalar Tâmega e Sousa, Clinical Pathology, Penafiel, Portugal

Introduction
Current guidelines recommend a single prolactin sampling for the diagnosis of hyperprolactinaemia. Nonetheless, in some patients, prolactin levels may normalize in a subsequent sampling or if prolactin is collected through a venous catheter some time after puncture. We aimed to assess the percentage of patients in which prolactin remained elevated in repeated sampling and to determine the best prolactin cutoff associated with persistent hyperprolactinaemia.
Methods
We retrospectively studied patients referred to the endocrinology clinic of the Centro Hospitalar do Tâmega e Sousa from 2006 to 2019 due to hyperprolactinaemia (referral prolactin – rPRL). We included those that underwent repeated prolactin samples by a peripheral venous catheter. The first sample (PRL0') was collected immediately after catheter insertion, the second sample 20 – 30 min after catheter insertion and the third sample 40 – 60 min after. The lowest value of these last two samples was defined as the nadir prolactin (nPRL). Prolactin was considered normal if within the reference range for sex and menopausal status. We excluded patients treated with dopamine receptor agonists. The endpoint under analysis was persistently elevated PRL0' and nPRL. Receiver-operating characteristic (ROC) curves were used to determine the best rPRL cutoffs to predict elevated PRL0' and nPRL. A logistic regression analysis was used to test the association between the rPRL cutoffs and persistent hyperprolactinaemia.
Results
We studied 53 patients (three males), mean age 34±3 years, and 51.0% treated with possible hyperprolactinemic drugs. Median rPRL: 48.0 ng/ml (39.5 – 72.5), PRL0': 34.3 ng/ml (18.0 – 50.8) and nPRL: 29.5 ng/ml (11.4 – 44.4). PRL0' was elevated in 35 (66.0%) patients and in 7 of them a normal nPRL was reached; therefore 28 (52.8%) patients presented persistent hyperprolactinaemia. The areas under de ROC curves for the association between rPRL and elevated PRL0' and nPRL was 0.70 (95% CI : 0.56–0.85) and 0.70 (95% CI : 0.56 – 0.84), respectively. The best cutoff for elevated PRL0' was 53.4 ng/ml: 51.4% sensitivity, 88.9% specificity, 83.8% positive predictive value (PPV) and 62.0% negative predictive value (NPV). The best cutoff was the same for elevated nPRL prediction: sensitivity=53.6%, specificity=80.0%, PPV=75.0% and NPV=60.6%. Patients with rPRL>53.4 ng/ml had an OR of elevated PRL0' and nPRL of 5.29 (95% IC: 1.30–21.59, $P=0.02$) and 3.65 (95% CI : 1.12 –11.90, $P=0.03$), respectively.
Conclusions
Approximately half of the patients referred due to hyperprolactinaemia reach normal levels in repeated sampling. Patients with prolactin>53.4 ng/ml (2 times the upper reference level) have 80% probability of having real hyperprolactinaemia.

Assessment of disease control in patients with acromegaly treated with long-acting somatostatin analogs (SMSa) varies according to the time when IGF-I levels are measured during the month following the injection

Albrici Cristina[1], Anne-Lise Lecoq[1], Magaly Vialon[2], Grunenwald Solange[2], Aldo Cocco[3], Safouane Hamdi[4], Cimino Vincenzo[1], Luigi Maione[1], Philippe Caron[2] & Philippe Chanson[1]
[1]Assistance Publique-Hôpitaux de Paris, Hôpital Bicêtre, Endocrinology and Reproductive Diseases, Le Kremlin-Bicêtre, France; [2]CHU de Toulouse, Endocrinology, Toulouse, France; [3]Politecnico di Milano, Mathematics, Milan, Italy; [4]CHU de Toulouse, Institut Fédératif de Biologie-Service de Biochimie, Toulouse, France

Introduction
Acromegaly is associated with multiple comorbidities and excess mortality. However, disease burden is reduced by maintaining IGF-1 (and/or GH) levels under safe levels. First generation long-acting SMSa, administered at monthly intervals, represent the first line medical treatment. According to guidelines, its efficacy is evaluated through IGF-I measurements. However, there are no data indicating the optimal time for measuring IGF-I levels after the SMSa injection, and if the interval between the injections and the blood sampling might have importance for assessing the disease control.
Aim
To determine in real life if the time when IGF-I is measured after SMSa injection provides a consistent and correct evaluation of disease control in order to improve understanding of patients' response to chronic treatment and to set up a more pertinent follow-up program.
Methods
Retrospective analysis of four (to five) weekly blood sampling performed for IGF-I measurement in 35 patients (males, 49%; mean age, 60±14 years) with acromegaly treated with long-acting SMSa (octreotide LAR, $n=9$; lanreotide Autogel, $n=26$) for a mean duration of 9.4±8.9 years. Blood was sampled according to the following schedule: just before the SMSa injection and then one, two, three, and eventually four weeks after the injection (the fourth sampling being made just before the next injection). IGF-I was also measured weekly in six healthy controls (mean age, 40±11 years) for four weeks. Data were analyzed through charts, t-test and repeated measures ANOVA test.
Results
According to IGF-I levels, acromegaly was considered as controlled in 58.8%, 73.5%, 71.9% and 64.7% of patients before injection, at the first, second and third week following the injection, respectively. Only 58.8% of patients had normal IGF-I during the entire follow-up. Repeated measures ANOVA test showed statistically significant difference between the four measures ($P=0.005$). Reproducibility between IGF-I levels measured just before the injection (first sampling) and four weeks later, just before the next injection, was good (two-sided t-test, $P=0.29$). IGF-I variability in uncontrolled patients was higher than that of healthy controls.
Conclusion
Our study highlights that evaluation of disease control in patients on long-acting SMSa may vary according to the time when IGF-I is measured after the injection. According to our study, a single random IGF-I measurement does not properly reflect monthly hormone profile in 41.2% of our patients. If IGF-I is measured one week after the injection more patients are considered as controlled than when IGF-I is measured later between monthly injections.

Surgical and clinical outcome in elderly patients affected by non-functional pituitary adenoma treated by endoscopic transnasal transsphenoidal surgery: A monocentric study

Emilia Biamonte[1], Davide Milani[2], Elisabetta Lavezzi[1], Nazarena Betella[1], Miriam Cellini[1], Giovanni Battista Lasio[2], Gherardo Mazziotti[3] & Andrea Lania[3]
[1]Endocrinology, Diabetology and Andrology Unit, Humanitas Clinical and Research Center, IRCCS, Rozzano (MI), Italy; [2]Division of Neurosurgery, Humanitas Clinical and Research Center, Rozzano (MI), Italy; [3]Endocrinology, Diabetology and Andrology Unit, Humanitas Clinical and Research Center, IRCCS; Department of Biomedical Sciences, Humanitas University, Rozzano (MI), Italy

The rate of diagnosis of pituitary adenomas in the elderly is increasing, as a consequence of the improved life expectancy. The management of elderly patients affected by pituitary adenomas are still a subject of debate in literature. In particular, data on the safety of endoscopic transnasal transsphenoidal surgery (TNS) are still controversial. The primary endpoint of the present study is to assess the surgical outcome of a cohort of patients who underwent TNS for non-functional pituitary adenoma (NFPA). The secondary endpoint is to evaluate their endocrinological post-TNS outcome and to compare the results with those of a younger control group. Between 2012 and 2019, 353 patients with NFPA underwent TNS-surgery atour Pituitary Centre;among them, only the 188 patients with a complete clinical, hormonal and radiological baseline evaluation and at least one complete post-TNS evaluation were selected. The average follow-up period was 52 months (range 6 – 210). Patients were divided in two groups, depending on their age at surgery (group 1: patients ≥70 years-old; group 2: patients <70 years-old). Data about endocrinological and surgical outcome from the two groups were compared by Pearson's chi-square test. Forty-three percent of the 188 patients enclosed in the study were ≥70 years-old [group 1; mean age 74.3, range 70 – 84], while 57% ($n=107$) were <70 years-old [group 2; mean age 50.9, range 21 – 68]. At the first evaluation, visual defects were more common in group 1 (61.7% vs 44.3%; $P=0.03$), while headache was predominant in group 2 (36.8% vs 16%; $P=0.002$). No significant differences in either pre-TNS surgery pituitary deficits presence or the specific type of hormonal deficits were found between the two groups. Similarly, group 1 and group 2 did not differ in surgical complications rate, the onset of novel post-TNS pituitary deficits, visual field normalization rate, and remission rate. After surgery, a higher recovery rate of pre-existing pituitary deficits was observed in group 2 patients (32.4% vs 6.3%, $P=0.000$). In particular, we observed a higher frequency of both gonadal function and GH secretion in group 2 patients (15.8% vs 1.3%, $P=0.001$ and 6.34% vs 0%, $P=0.03$ respectively). In conclusion, age should not be considered as a predictive factor of surgical complications or worse endocrinological outcome, even if it seems to be associated with a poorer recovery of pre-TNS pituitary deficits.

Gender differences in airway obstruction in men and women with acromegaly: A longitudinal study

Sylvère Störmann, Katharina Schilbach, Felix Amereller, Matthias W Angstwurm & Jochen Schopohl
Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany

Introduction
Acromegaly is a slowly progressing systemic disease that leads to numerous changes in metabolism and organ function. A large cross-sectional study showed signs of subclinical airway obstruction in female patients. We performed a longitudinal study of lung function testing to compare parameters of airway obstruction in male and female patients with acromegaly over time.
Methods
40 patients with acromegaly (24 male, 16 female) underwent repeat lung function testing with a mean interval of 10.1±4.3 years. Lung function parameters were converted to percentages of predicted values obtained from normative data to correct differences of absolute values for age, sex, height and weight. We investigated the impact of disease activity on changes of airway obstruction by categorizing patients as biochemically controlled if at the date of repeat testing random growth hormone levels were below ng/ml and IGF-I levels within the age and sex reference range of the assay used. We calculated group comparisons using an independent samples t-test with a significance threshold of 0.05 and interpreting p values below 0.1 as trend.
Results
While FEV_1, FEF_{75}, FEF_{50}, and FEF_{25} did not differ significantly between male and female patients over time, we found a significant increase of total specific resistance in women (sR_{tot}: $P=0.014$; men – 5.0%, women +30.2%). Furthermore, in women there is a trend for increased total airway resistance (R_{tot}: $P=0.078$; men –3.6%, women +17.2%) as well as decreased peak expiratory flow (PEF; $P=0.096$; men+5.5%, women –10.4%). Changes in airway obstruction were unrelated to biochemical control of acromegaly.
Conclusion
Female patients with acromegaly seem to develop airway obstruction over time, regardless of disease activity. The mechanism of this change remains to be elucidated.

Background
Data on the impact of withdrawal from long-acting somatostatin receptor ligand (SRL) injections on disease activity in patients with acromegaly are limited. The CHIASMA OPTIMAL study assessed the efficacy and safety of oral octreotide capsules (OOC) in adult patients with acromegaly responding to SRL injections. The placebo arm of this study allowed for assessment of acromegaly activity in patients after withdrawal from SRL treatment.
Methods
A multinational, randomized, placebo-controlled study was conducted in 56 adult patients with active acromegaly. Patients had evidence of active disease (IGF-I≥1.3 × ULN after last pituitary surgery) and an average IGF-I≤1.0 × ULN on a stable dose of SRL injection (≥3 months). Patients were randomized 1 month after last injection to OOC or placebo for 36 weeks, with an optional open-label extension (OLE). The primary aim was to determine the proportion of patients maintaining biochemical response (IGF-I≤1.0 × ULN; average, week 34 and 36).
Results
The trial met the primary endpoint, with 58% (16/28) of patients receiving OOC maintaining IGF-I response vs 19% (5/28) receiving placebo ($P=0.008$). The median time to loss of response (2 criteria evaluated: IGF-I>1.0 and ≥1.3 × ULN) was 16 weeks in the placebo group; while not reached in the OOC group. Of the 5 patients in the placebo group who maintained their biochemical response at 36 weeks, only 2 did not meet loss of response criteria. When IGF-I values for any 2 consecutive visits were analyzed for patients receiving placebo, 93% (26/28) lost response based on IGF-I>1 × ULN and 79% (22/28) lost response based on IGF-I≥1.3 × ULN. Irrespective of biochemical control of acromegaly, 26/28 patients receiving placebo experienced active disease-related symptoms reported as AEs of special interest (AESIs). Most common AESIs (≥5%) included arthralgia/arthritis (60.7%), soft tissue swelling (35.7%), headache (32.1%), hyperhidrosis (25%), carpal tunnel (14.3%), musculoskeletal pain (14.3%), weight increased (7.1%) and tongue disorders (7.1%). The 5 patients receiving placebo with controlled IGF-I at 36 weeks received active treatment in the OLE by decision of study PIs, as they were deemed to have either lost their response during the study or had active acromegaly symptoms.
Conclusion
93% of patients receiving placebo lost response following withdrawal of injectable SRLs, with a median duration of 16 weeks. All 5 patients receiving placebo who met the primary endpoint criteria at the end of the study were assessed clinically to have active disease and received OOC treatment in the OLE.

Impact of imputation method on efficacy results from the phase 3 optimal study of oral octreotide capsules in adult patients with acromegaly

Susan Samson[1], Lisa Nachtigall[2], Maria Fleseriu[3], Murray Gordon[4], Mojca Jensterle[5], Atanaska Elenkova[6], Mark E Molitch[7], William Ludlam[8], Gary Patou[8], Asi Haviv[8], Nienke Biermasz[9], Peter Trainer[10], Christian J Strasburger[11], Laurence Kennedy[12] & Shlomo Melmed[13]
[1]Baylor College of Medicine, Houston, United States; [2]MGH Neuroendocrine and Pituitary Center, Chestnut Hill, United States; [3]Oregon Health and Science University, Portland, United States; [4]Allegheny General Hospital, Pittsburg, United States; [5]University Medical Center Ljubljana, Ljubljana, Slovenia; [6]Medical University Sofia, USHATE, Sofia, Bulgaria; [7]Northwestern University, Evanston, United States; [8]Chiasma, Waltham, United States; [9]Leiden University Medical Center, Oegstgeest, Netherlands; [10]The Christie NHS Foundation Trust, Manchester, United Kingdom; [11]Charite Campus Mitte, Berlin, Germany; [12]Cleveland Clinic Foundation, Cleveland, United States; [13]Cedars Sinai Medical Center, Los Angeles, United States

Objective
The phase 3 CHIASMA OPTIMAL study assessed efficacy and safety of oral octreotide capsules (OOC) in patients with acromegaly controlled on injectable somatostatin receptor ligands (SRLs). Sensitivity analyses were conducted for efficacy endpoints using two methods of imputation (i.e., the process of replacing clinical data with substitution values) to address missing data points due to some subjects reverting back to their prior injectable SRL treatment.
Methods
Patients were ≥18 years of age and had evidence of active acromegaly with an average IGF-I≤1.0 × ULN (utilizing the IDS iSYS assay calibrated to WHO recombinant reference standard 02/254). At baseline, patients were randomized to receive OOC or placebo for 36 weeks. The primary endpoint waspproportion of patients maintaining biochemical response, defined as IGF-I≤1.0 × ULN (2-value average at weeks 34 and 36) (Samson *et al.* ENDO 2020). Per study protocol, patient study discontinuations were considered non-responders regardless of clinical response at the time of discontinuation (non-response imputation). Additional exploratory analyses were performed utilizing the last observation carried forward (LOCF) analysis, as well as a completers analysis of response among the subgroup that completed the entire 36 weeks on study drug. The response rates reported for the primary end point are slightly adjusted for stratification differences as prespecified in the statistical analysis plan.
Results
Twenty-eight patients received OOC and 12 failed to maintain biochemical response based on the primary endpoint. Seven of these 12 patients discontinued treatment early – 5 due to treatment failure and 2 due to AEs. The remaining 5 patients completed the 36-week protocol on study drug. Of these 5 patients, 4 had IGF-I values between >1.0 and ≤1.3 × ULN and 1 completed the study with an IGF-I of 1.7 × ULN with no clinical symptoms. 58.2% of patients in the OOC group met the primary endpoint of maintenance of biochemical response at the end of study using the non-response imputation. Using LOCF imputation, 64.3% (18/28) of patients met this endpoint. Of those completing the study ($n=21$), 76.2% maintained response.
Conclusion
CHIASMA OPTIMAL primary endpoint was assessed using the non-response imputation for patients who discontinued treatment early, with a 58.2% response rate. However, when assessing the response rate based on LOCF imputation, or in study completers, similar to other phase 3 studies for acromegaly, the rate was imputed at 64.3% and 76.2%, respectively.

Eucaloric very low-carbohydrate ketogenic diet as a new supportive treatment modality for acromegaly?

Eva Coopmans[1], Kirsten AC Berk[2], Nour El-Sayed[1], Sebastian Neggers[1] & Aart Jan Van der Lely[1]
[1]Erasmus University Medical Center, Department of Internal Medicine, Endocrinology section, Pituitary Center Rotterdam, Rotterdam, Netherlands; [2]Erasmus University Medical Center, Department of Internal Medicine, Division of Dietetics, Rotterdam, Netherlands

Objective
Acromegaly is caused by a growth hormone (GH)-secreting pituitary tumor and its signs are linked to increasedGH-dependent hepatic insulin-like growth factor I (IGF-I) synthesis. A eucaloric very low-carbohydrate ketogenic diet (euVLCK;<50 g/day) induces ketosis and reduces portal insulin concentrations, which down-regulate hepatic GH receptors and reduce IGF-I synthesis. Somatostatin receptor ligands (SRLs) reduce GH secretion by the pituitary tumor,resulting in IGF-I normalization in about 50% of patients. Remaining patients should switch to (or add) the expensive drug pegvisomant (PEGV). Our concept is that in acromegaly a euVLCK diet exerts insulin-induced IGF-I normalization without the unwanted increase in GH, as the GH-inhibiting SRL therapy is continued.
Method
We performed a proof-of-concept study ($n=11$, six females) to determine whether a 2-week euVLCK diet (35 g carbohydrate, 155 g fat and 115 g protein/day) as adjuvant to first-generation SRLs reduces IGF-I concentrations in uncontrolled acromegaly patients.

Results
During the euVLCK diet, mean carbohydrate intake decreased from 194.4 [s.d. 143.1] gramsto 32.6 [14.7]. IGF-I concentrations decreasedsignificantly (median 0.83 [IQR 0.62 – 0.91] ULN vs 1.10 [1.02 –1.25], $P=0.014$) and normalized in all but one patient, without the concomitant increase in GH (median 1.9 [IQR 0.4–3.7] µg/l vs 2.0 [0.7 – 3.6], $P=1.00$). This patientstill showed substantial decrease in GH after the euVLCK diet and presented with the highest degree of insulin resistance. Overall, HbA1c decreased slightly(mean 38.6 [s.d. 4.4] mmol/mol vs 39.8 [5.2], $P=0.028$). Insulin resistance, lipids and body composition did not change significantly. Although the diet was eucaloric, mean body weight decreased by about 1 kg. Of note, weight loss was not associated with changes in IGF-I concentrations ($r_s=-0.24$, $P=0.47$).Overall, the diet was well tolerated and all patients completed the study. Interestingly, SRL dose reduction was warranted in three out of six patients continuing a low-carbohydrate ketogenic diet (80 g/day; median 0.83 [IQR 0.75 – 1.01] ULN after median 3.0 months) as adjuvant to their initial SRL therapy.
Conclusion
This proof-of-concept study illustrates the ability of an adjuvant euVLCK diet to achieve control of IGF-I without affecting GH concentrations in acromegaly patients uncontrolled with first-generation SRLs. Our results could affect the clinical management of acromegaly as a euVLCK diet might deploy as an effective adjuvant treatment in some patientsbefore initiating PEGV treatment. Additional studies are needed to evaluate long-term safety and efficacy of and compliance with an euVLCK diet.

To score or not to score? Is Ki-67 analysis worthwhile in pituitary neuroendocrine tumours?

Paul Benjamin Loughrey[1,2], Stephanie Craig[2], Brian Herron[3], Fatima Abdullahi Sidi[2], Stephen McQuaid[2], Paul Kelly[3], Matt Humphries[2], Eileen Parkes[4], Darragh McArt[2], Steven Hunter[1], Marta Korbonits[5] & Jacqueline James[2]
[1]Royal Victoria Hospital, Regional Centre for Endocrinology and Diabetes, Belfast, United Kingdom; [2]Queen's University, Patrick G Johnston Centre for Cancer Research, Belfast, United Kingdom; [3]Royal Victoria Hospital, Cellular Pathology, Belfast, United Kingdom; [4]University of Oxford, Medical Oncology, Oxford, United Kingdom; [5]William Harvey Research Institute, Centre for Endocrinology, London, United Kingdom

Pituitary neuroendocrine tumours (PitNETs) are heterogeneous and have limited biomarkers to predict their behaviour, thus making their prognostication difficult. Ki-67 is a protein expressed in active phases of the cell cycle and is one of the biomarkers utilized in routine assessment of PitNET tissue. Current European Society of Endocrinology recommendations advise that histopathological analysis of PitNETs should as a minimum include Ki-67 proliferation index and anterior pituitary hormones. In addition, when Ki-67 index is≥3%, p53 immunodetection and mitotic count should be undertaken. In order to obtain accurate Ki-67 assessment, manual counts of 1000 cells should be completed, which demands significant time and may be open to subjectivity. In addition, Ki-67 thresholds vary across studies and there has been debate about the proposed cut-off value of 3%. There are no internationally agreed guidelines for modern image analysis approaches in PitNETs. A retrospective assessment of Ki-67 index was piloted in 30 PitNETs of varying cell types using QuPath digital image analysis software. Digital cell counts of Ki67 index were undertaken in 1000 cells and 10,000 cells for comparative purposes. Average Ki-67 index per 10,000 cell count was 1.12% and per 1000 cell count it was 1.17%. Diagnostic reports of the 30 tumour samples identified three tumours with increased Ki-67 index. Digital image analysis of these three samples identified one of these as having a Ki-56 index≥3%, while the other two had Ki-67 index<3% on both 10,000 and 1000 cell counts. In addition, digital image analysis also identified a further sample with Ki-67 index≥3% which was not originally reported as elevated. When appropriate detection thresholds are defined, QuPath digital analysis software identifies PitNET cells and Ki-67 positive cells. QuPath also facilitates assessment of Ki-67 in larger numbers of tumour cells which may provide a better representation of whole tumour Ki-67 expression. A further 200 tumour slides will be analyzed and presented alongside the 30 samples in this pilot study. In conclusion, this pilot study demonstrates QuPath is a reliable method to score Ki-67 index in PitNETs.

Giant prolactinomas: Is it possible to stop treatment?

Susana Mallea-Gil[1], Sabrina Diez[2], Gloria Tubert[3], Mariela Cuccia[3], Noelia Rodriguez[2], Graciela Stalldecker[2], Maria de los Angeles Sosa[1], Bruno Peressotti[1], Adriana Palazzo[1] & Carolina Ballarino[1]
[1]Hospital Militar Central, Endocrinology, Buenos Aires, Argentina; [2]Hospital Pirovano, Endocrinology, Buenos Aires, Argentina; [3]Hospital Fernandez, Endocrinology, Buenos Aires, Argentina

Giant prolactinomas are tumors with a large size >4 cm and/or prolactin levels higher than 3000 ng/ml and/or highly invasive growth. Today dopamine agonists (DA), mainly cabergoline (CAB), are the first-line choice in the treatment of these tumors
To assess the efficacy, safety and long-term follow-up of patients with giant prolactinomas treated with DA. We retrospectively reviewed the clinical records of 33 patients with giant prolactinomas. Mean age at diagnosis was 39.5±18.5 years, 73% men. The median follow-up time was 6.6 years (2.5 – 9.6). At diagnosis, median prolactin (PRL) level was 4.700 ng/ml (3.131 – 10.900), mean maximum diameter of the tumors was 4.77±1.15 cm; headaches were present in 58%, hypogonadism in 79%; 85% had invasive tumors, 82% had visual field (VF) impairment. Since diagnosis, almost all patients were treated with CAB except 2, who were started on bromocriptine, both were switched to CAB afterwards. Results: 64% of patients normalized PRL levels (median time of 6 months) with a mean dose of 1.66±1.49 mg/week of CAB. Fifty-three percent of patients reached this prolactin nadir in 2–4 months with a maximum dose <2 mg/week. Median PRL level in the last visit: 34.78 ng/ml. Ninety-four percent of patients decreased PRL level during follow-up: 48% normalized PRL, 13% remained with mild hyperprolactinemia, 39% with significant hyperprolactinemia. Eighty-five percent of tumors reduced volume, 36% evolved to empty sella, the remaining tumors achieved a mean decrease 1.48 cm compared to initial size (69% average reduction compared to the initial diameter). VF remained normal in patients in whom it was not affected, in the patients who presented VF involvement: 42% improved, 49% remained unchanged, 9% worsened. Complications during follow-up: Cerebrospinal fluid leak 3 patients, chiasmatic ptosis 1, intra-tumoral hemorrhage 1. In follow-up, 5 patients required surgery; 5 patients died, 3 because of the tumor. In 4 patients CAB was stopped between 48–264 months after initiating treatment, but in all of them CAB was reinitiated due to symptomatic hyperprolactinemia, in 28 patients treatment was never discontinued.
Conclusions
With low-moderate does of CAB and very few complications, CAB was effective in treatment of giant prolactinomas reducing tumor size (some of them evolved to empty sella) and normalizing PRL levels in almost half of our patients. In our experience of 25 years of follow-up we have not had any patients without treatment.

Development of a local reference range for hypertonic saline-stimulated copeptin

Emily Brooks[1,1], Caroline Bachmeier[2], Juanita Vorster[3], Jane Sorbello[1], Faseeha Peer[1], Viral Chikani[1], Goce Dimeski[4], Jacobus Ungerer[2], Carel Pretorius[2] & Warrick J Inder[1]
[1]Princess Alexandra Hospital, Endocrinology, Woolloongabba, Australia; [2]Royal Brisbane and Women's Hospital, Chemical Pathology, Herston, Australia; [3]Princess Alexandra Hospital, Woolloongabba, Australia; [4]Princess Alexandra Hospital, Chemical Pathology, Woolloongabba, Australia

Hypertonic saline stimulated copeptin measurements have recently been described for the diagnosis of central DI. A copeptin cut-off of >4.9 pmol/l has a diagnostic accuracy of 96.5% for distinguishing primary polydipsia from central DI[1]. A copeptin assay has recently been established in our laboratory. Validation of hypertonic saline-stimulated copeptin concentrations in our local population is needed before this test can be used with confidence in patients presenting to our institution with polyuria-polydipsia syndrome. The aim of this study was to develop a local reference range for hypertonic saline-stimulated copeptin in healthy volunteers. Twenty healthy volunteers (10 male and 10 female) were recruited. Subjects underwent a hypertonic saline test, as previously described (3). Hypertonic saline (3%) was administered as an initial 250 ml bolus followed by 0.15 ml/kg/minute until a target serum sodium of ≥150 mmol/l was reached. At this time, blood was drawn for copeptin measurement.

Median age was 28.5 years (range 25 – 50); median body weight was 75.05 kg (range 50.4 – 106); median baseline plasma sodium was 138 mmol/l (range 135 – 143) and median serum osmolality was 291.5 (range 281 – 297). Median peak sodium was 152 mmol/l (range 150-154) with osmolality 314.5 mmol/kg (range 306 – 320). Median volume of hypertonic saline infused was 1536 ml (1230 – 2220 ml) and median hypertonic saline stimulated copeptin was 33.8 pmol/l (9.6 – 167.4). Overall symptom burden was 6/10 (range 3/10 – 9/10). 10 patients' experienced nausea and 3 patients experienced vomiting. Copeptin was significantly higher in those who experienced nausea (35.4 pmol/l; range 30.2 – 82.3 pmol/l) and those who experienced vomiting (91.6 pmol/l; range 58.9 – 95.5 pmol/l) compared to those patients who did not experience either (19.7 pmol/l; 13.0 – 30.9 pmol/l) ($P=0.0465$ and $P=0.0085$ respectively). There were no serious adverse events.
Nausea and/or vomiting were associated with significantly higher copeptin levels. Development of a local reference range for hypertonic saline stimulated copeptin measurements will assist in interpretation of the test in our local population of patients presenting with polyuria-polydipsia syndrome.

A key role for conservative treatment in the management of pituitary apoplexy

Claire Marx[1,2], Muriel Rabilloud[2,3], Francoise Borson-Chazot[1,2], Caroline Tilikete[2,4,5], Emmanuel Jouanneau[2,6,7] & Gerald Raverot[1,2,7]
[1]Hospices Civils de Lyon, endocrinology, Bron, France; [2]Lyon I University, Lyon, France; [3]Hospices Civils de Lyon, I.f.c.s Hospices Civils de Lyon, Lyon, France; [4]Hospices Civils de Lyon, Neuro-ophthalmology and neurocognitive unit, Bron, France; [5]CRNL INSERM U1028 CNRS UMR5292, Bron, France; [6]Hospices Civils de Lyon, Neurosurgery Department, Bron, France; [7]INSERM U1052, CNRS, UMR5286, Lyon, France

Objective
The management of pituitary apoplexy, a rare emergency neuroendocrine condition, is controversial. The aim of the present study was to compare the outcome of patients with pituitary apoplexy managed either by a conservative or surgical approach.
Methods
A retrospective cohort study including patients diagnosed between 2007 and 2018 in a tertiary French university hospital. Pituitary apoplexy score was retrospectively applied in a perspective of therapeutic decision support.
Results
Forty-six patients were treated for a pituitary apoplexy either with conservative management ($n=27$) or surgery ($n=19$). At initial evaluation, visual field defects and visual acuity impairments were more frequent in patients from the surgery group. At one year there were no statistical differences in the rates of complete/near-complete resolution of visual field defects (100% vs 91.7%), visual acuity impairment (100% vs 87.5%) and cranial nerve palsies (83.3% vs 100%), between conservative and surgical treatment groups. Endocrine function prognosis was poor regardless of the treatment. Pituitary apoplexy score ($n=42$) was at 3.4 on average in the early surgery group and 1.4 in the conservative treatment/delayed surgery group. Among patients with a score <4, 31.3% were operated at first line and did not present better outcomes than patients managed conservatively. 80% of patients with a score ≥4 underwent surgery.
Conclusions
Pituitary apoplexy score may be a reliable parameter for defining therapeutic strategy. Patients with non-severe and non-progressive neuro-ophthalmological deficits can be managed conservatively without negative impact on outcomes, thus surgery should be reserved foronly those patients with a Pituitary apoplexy score ≥4.

Gender dimorphism of intramuscular fatty infiltration and related muscle dysfunction in patients with long-term control of acromegaly

Luciana Martel-Duguech[1], Jorge Alonso-Pérez[2], Helena Bascuñana[3], Jordi Diaz-Manera[2], Alicia Alonso-Jimenez[2], Jaume Llauger[4], Claudia Nuñez-Peralta[4], Paula Montesinos[5], Susan M. Webb[1] & Elena Valassi[1]
[1]IIB-Sant Pau and Department of Endocrinology/Medicine, Hospital Sant Pau, UAB, and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unidad 747), ISCIII; Barcelona (Spain); [2]Neuromuscular Disorders Unit, Neurology Department, Hospital Sant Pau, Barcelona (Spain); [3]Rehabilitation Unit, Hospital Sant Pau, Barcelona (Spain); [4]Radiology Department, Hospital Sant Pau; [5]Philips Spain

Background
Muscle weakness persists in patients with acromegaly (ACRO) even long-term after disease control. Mechanisms determining this sustained impairment are not known. We hypothesized that alteration of muscle architecture, due to intramuscular fatty infiltration, is associated with muscle dysfunction in these patients.
Patients and methods
Thirty-seven acromegalic patients [21 females and 16 males, mean (± S.D.) age, 53±9 years, BMI, 27±4 kg/m^2 and duration of control, 92±58 months], and 37 age, gender and BMI-matched controls were studied. The degree of fatty infiltration (FF, fat fraction) in the thigh muscles was measured using magnetic resonance imaging (MRI), 2-point Dixon sequence in the anterior, posterior, and combined anterior and posterior compartments, rectus femoris and vastus intermedius. The following muscle function tests were also performed: Gait Speed Velocity (GS), Timed Up and Go (TUG), 30-Second Chair Stand and Hand Grip Strength.
Results
Mean FF (%) in all the compartments analysed was increased in patients as compared with controls ($P<0.01$ for all the comparisons). ACRO female patients had greatermean FF in the anterior (29.2±6.8% vs 20.5%±3.9%, $P<0.01$), posterior (38%±8.4% vs 27%±5%, $P<0.01$), combined anterior and posterior compartments (33.7%±7% vs 23.7%±4%, $P<0.01$),rectus femoris (28.9%±8% vs 16.9%±4.9, $P<0.01$) and vastus intermedius (21.3%±5.6 vs 14.9%±2%, $P<0.01$), as compared with males. Gait speed was slower in ACRO patients as compared with controls (1.18±0.2 vs 1.33±0.2 $P<0.05$). Performance on TUG was worse in ACRO women as compared with ACRO men (6.5±1.1 vs 5.5±1 for TUG; $P<0.05$). Greater mean intramuscular FF in all the compartments analysed was associated with worse performance on TUG ($P<0.01$), in patients only. Muscle mass and intramuscular FF in both posterior and combined anterior and posterior compartments were associated with IGF-I SDS in ACRO men only ($r=0.49$ and $r=0.54$, $P<0.05$ for both correlations). Thirty-second chair stand was negatively associated with GH in ACRO men only ($P<0.05$). In a multiple linear regression model, female gender and older age predicted intramuscular FF in the combined anterior and posterior compartment ($\beta=0.49$; $P<0.05$), in ACRO patients. Intramuscular FF of the combined anterior and posterior compartments predicted the performance on TUG after adjusting for gender and age ($\beta=0.75$, $P<0.01$) in ACRO. Conclusions: Intramuscular fatty infiltration is increased in ACRO patients with long-term control of the disease, especially in females. ACRO females also present with poorer muscle function than males. Intramuscular fat accumulation may be one of the mechanisms underlying sustained muscle weakness in acromegaly.

and Department of Endocrinology/Medicine, Hospital Sant Pau, UAB, and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unidad 747), ISCIII; Barcelona Spain

Background
Current guidelines recommend that susceptible patients should be tested and treated for AGHD. Still, it is not universally recognised as a distinct entity and reimbursement of GH replacement therapy is not available in some countries.
Aim
1) to record current practice of AGHD management throughout Europe and benchmark it against existing guidelines, 2) to evaluate educational status of health care professionals.
Patients and methods
Practicing endocrinologists were encouraged by ESE to complete an electronic questionnaire with aggregated data of AGHD patients diagnosed and/or treated in 2017–2018.
Results
Twenty-nine centres from 17 European countries and one from Australia participated with 2148 AGHD patients including 30% of childhood onset. The aetiology included non-functioning pituitary adenoma (26%), craniopharyngioma (14%) and genetic/congenital mid-line malformations (14%). Centres reported a maximum of 254 and a minimum of 9 patients, of which 71% were treated with GH. The percentage of treated patients ranged from 100% to 0 in countries, where GH treatment was not publically reimbursed at study entry; however, variability was observed between centres within the same country. Eighty-four percent of GH treatments were still on-going at the end of the study period. The main reasons for interruption were adverse events (22%, in 37% due to new cancer or tumour recurrence), administrative reasons (13%), lack of compliance (12%) and lack of positive effect (11%). Low adherence to guidelines was observed in many countries regarding diagnostic tests, cut-off values for GH, treatment initiation and/or transitioning. In 64%, no quality-of-life (QoL) questionnaire was reported. Requirements for treatment initiation beyond a biochemical test included, in some centres, patient compliance (72%), impaired QoL (45%),severe fatigability (35%), central obesity (10%), and age <65 years (10%). A common major cause of dissatisfaction was low AGHD awareness by non-endocrine health care professionals, and extent and quality of post-graduate AGHD curriculum training.
Conclusion
Despite available guidelines on AGHD since 2007 recommending GH replacement in adult hypopituitary patients, there are still countries in Europe where AGHD substitution therapy is not reimbursed. Knowledge among professionals and health administrators of adult GHD should be improved in order to optimize care of adults with hypopituitarism and GHD.

Carpal tunnel syndrome is common in patients with undiagnosed acromegaly – a swedish nationwide study

Konstantina Vouzouneraki[1], Daniela Esposito[2,3], Sebastian Mukka[4], Daniel Granfeldt[5], Oskar Ragnarsson[2,3], Per Dahlqvist[4] & Daniel S Olsson[2,3]
[1]Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden; [2] Sahlgrenska University Hospital, Department of Endocrinology, Gothenburg, Sweden; [3]Sahlgrenska Academy, Institute of Medicine, Department of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden; [4]Umeå University, Department of Surgical and Perioperative Sciences, Umeå, Sweden; [5]PharmaLex, Gothenburg, Sweden

Background
Carpal tunnel syndrome (CTS) is common in patients with acromegaly, with a reported prevalence of 19–64%. We have studied CTS in a large national cohort of patients with acromegaly, and the temporal relationship between the diagnosis of the two diseases.
Methods
Retrospective nationwide cohort study including patients diagnosed with acromegaly in Sweden between 2005 and 2017. Patients with acromegaly were identified in the Swedish National Patient Registry. Diagnosis of CTS and its potential risk factors, such as diabetes mellitus and acromegaly treatments were collected from the Swedish National Health Registries from 8.5 years before the diagnosis of acromegaly until death or end of the study. Standardized incidence ratio (SIRs) with 95% confidence intervals (CIs) were calculated with the Swedish population as reference. Cox regression models were used to identify potential risk factors for CTS in patients with acromegaly.
Results
The analysis included 556 patients with acromegaly (278 women, 50%), diagnosed at a mean age of 50±15 years. CTS was diagnosed in 48 (8.6%) patients, and 41 (7.4%) had been operated for CTS during the study period. SIR (95% CI) for CTS was 3.8 (2.8 – 5.0). The risk for CTS was similar for acromegaly patients with and without diabetes mellitus (SIR 3.5, 95% CI 1.6 – 6.7 vs SIR 3.9, 95% CI 2.7 – 5.3). Women with acromegaly had a higher risk (HR 2.5, 95% CI 1.3 – 4.7, $P=0.0038$) for CTS than men. CTS was diagnosed prior to acromegaly diagnosis in 42 out of 48 (88%) of the patients (median 3.1 years earlier, range 0.3 – 8.5 years). Thirty-five of 41 (85%) patients operated for CTS had undergone surgery before the diagnosis of acromegaly (median time 2.2 years, range 0.3 – 8.5 years).
Conclusion
Patients with acromegaly have a four times higher incidence of CTS compared to the general population. The vast majority of patients are diagnosed with CTS prior to acromegaly. The increased risk of CTS and the temporal relationship indicate a potential time-window for shortening the diagnostic delay in acromegaly by increasing the awareness of acromegaly in patients with CTS.

Levoketoconazole in the treatment of endogenous Cushing's syndrome: Extended evaluation phase results of the SONICS study

Maria Fleseriu[1], Richard J Auchus[2], Yona Greenman[3], Sabina Zacharieva[4], Eliza B Geer[5], Roberto Salvatori[6], Rosario Pivonello[7], Ulla Feldt-Rasmussen[8], Laurence Kennedy[9], Michael Buchfelder[10], Beverly M K Biller[11], Fredric Cohen[12] & Anthony P Heaney[13]
[1]Oregon Health and Science University, Portland, United States; [2]University of Michigan Medical School, Ann Arbor, United States; [3]Tel Aviv University, Tel Aviv, Israel; [4]Medical University-Sofia, Sofia, Bulgaria; [5]Memorial Sloan Kettering Cancer Center, New York, United States; [6]Johns Hopkins University, Baltimore, United States; [7]Università Federico II di Napoli, Naples, Italy; [8]Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [9]Cleveland Clinic, Cleveland, United States; [10]University Hospital Erlangen, Erlangen, Germany; [11]Massachusetts General Hospital, Boston, United States; [12]Strongbridge Biopharma, Trevose, United States; [13]University of California Los Angeles School of Medicine, Los Angeles, United States

Background
The phase 3, open-label SONICS study of levoketoconazole demonstrated sustained reduction in mean urinary free cortisol (mUFC) in adults with endogenous Cushing's syndrome (CS). The extended evaluation phase (Ext) of SONICS reported here further assessed long-term safety, tolerability, and benefit/risk of this treatment.
Methods
SONICS consisted of dose-titration (150 – 600 mg BID to attain maximally tolerated dose for mUFC normalization), 6-month maintenance, and 6-month Ext phases. Safety and efficacy evaluations occurred at Month 9 (M9) and Month 12 (M12) in Ext. Potential liver toxicity, QTc prolongation, and adrenal insufficiency were prespecified AEs of special interest. Exploratory efficacy assessments included mUFC response, changes in CS clinical signs and symptoms, quality-of-life (Cushing QoL score), and symptoms of depression (BDI-II score) from baseline to M9 and M12. Serum ACTH levels were assessed in those with Cushing's disease. The concentration-response relationship of levoketoconazole and mUFC levels was assessed. Treatment adherence was defined as ≥80–120% intake of the study drug.
Results
94 patients were enrolled and treated with ≥1 levoketoconazole dose; 77 patients entered and 61 completed the maintenance phase. 60 patients entered and 46 completed Ext. The most common incident AEs in Ext ($n=60$) were arthralgia (6.7%), headache (6.7%), hypokalemia (6.7%), QTc prolongation (6.7%), and nasopharyngitis (5.0%). AEs led to study discontinuation in Ext in 4 (6.7%) patients. No patients experienced increased ALT or AST>3 × ULN, had suspected adrenal insufficiency, or had QTcF interval of >460 msec in Ext. Serious AEs were reported in 4 patients during Ext, but none were considered levoketoconazole-related. 27 of 49 (55.1%) and 18 of 44 (40.9%) patients had normalized mUFC at M9 and M12, respectively. Concentration-response modeling indicated no evidence for tolerance to (ie, 'escape' from) mUFC reduction. Furthermore, mean ACTH levels at M9 and M12 were similar in those with ($n=15$) and without ($n=21$) mUFC normalization at M12. Treatment adherence was reduced at M12 (82.0%) relative to M9 (91.4%), likely accounting for the decreased mUFC normalization rate at M12. Mean improvements from baseline in CS clinical signs and

symptoms (acne, hirsutism, and peripheral oedema scores), and Cushing's QoL and BDI-II scores observed following 6 months of maintenance phase were generally maintained at M9 and M12.
Conclusions
In the SONICS study Ext, levoketoconazole was well tolerated with no new drug-related safety signals observed. Sustained mUFC response and improvements in CS clinical signs and symptoms, quality-of-life, and symptoms of depression were demonstrated in those completing Ext.

Role of NGS in the diagnostic work-up of pituitary tumors and 'incidental findings'

Giulia Del Sindaco[1,2], Elisa Sala[1], Giulia Carosi[1,3], Arianna Cremaschi[1,2], Roberta Mungari[1], Andreea Liliana Serban[1,3], Beatrice Mantovani[1,2], Rita Indirli[1,2], Emanuele Ferrante[1], Luca Persani[2,4], Maura Arosio[1,2] & Giovanna Mantovani[1,2]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [4]Auxologico San Luca, Endocrinology Unit and Metabolic Diseases, Milan, Italy

Background
Pituitary tumors are mostly sporadic, but in less than 5% of cases they can be associated to genetic syndromes, so harbouring germline mutations. Familial pituitary tumors are often more aggressive, so it's important to detect them, for both a better early diagnosis and genetic counselling. Before the development of Next-Generation Sequencing (NGS), Sanger sequencing was the most widely used method of DNA sequencing. Therefore, DNA samples were analysed following a phenotype-drivenstrategy, using direct sequencing of the coding regions of one single candidate gene at a time. Since 2000, the introduction of NGS, a massively parallel sequencing of millions of fragments of DNA, improved the accuracy of genetic testing with an overall reduction in time and costs. Consequently, genetic testing is more and more integrating into the clinical practice. In addition, some rare phenotypes are common to different clinical conditions caused by different genetic mutations. In this case NGS is useful to identify genotype-phenotype associations not recognized with single genes sequencing method, the so-called *'incidental findings'*.
Materials and methods
We carried out genetic testing in 25 patients (mean age 46.9), between November 2014 and September 2019. All patients received a diagnosis of pituitary tumor and were suspected to have a genetic syndrome according to the indications given by the literature. 14 patients were investigated for MEN-1 and 11 patients for FIPA. Gene analysis was performed with targeted NGS panel testing for the following genes: AIP, CDKN1b, CDC73, MEN-1, RET, PRKAR1A.
Results
2 patients had a mutation in AIP, thus confirming the suspected FIPA (2/11, 18%). 21 patients were negative for mutations in all the analysed genes. In one patient with suspected MEN-1, we unexpectedly found a heterozygosis mutation in exon 7 of *PRKAR1A* (well known as responsible for Carney Complex). The last patient, with a suspected MEN-1 too, had a heterozygosis mutation in the exon-intron junction of exon 2 of *CDKN1b* (responsible for MEN-4).
Conclusions
Our experience shows that the use of NGS should be now considered as an important step in the diagnostic work-up of pituitary tumors with suspected germline mutations. Moreover, massively parallel sequencing may lead to 'incidental findings', with clear implications not only inclinical practice but also for its consequent ethical issues.

fMRI for cognitive evaluation of adult survivors of childhood craniopharyngioma

Daniel Svärd[1], Eva Marie Erfurth[2], Sigridur Fjalldal[2], Robin Hellerstedt[3], Peter Mannfolk[4], Johan Mårtensson[5] & Cecilia Follin[6]
[1]Lund University, Department of Diagnostic Radiology; [2]Skåne University Hospital, Department of Endocrinology, Lund, Sweden; [3]Lund University, Department of Psychology, Lund, Sweden; [4]Skåne University Hospital, Department of Medical Imaging and Physiology, Lund, Sweden; [5]Lund University, Department of Logopedics, Phoniatrics and Audiology, Lund, Sweden; [6]Skåne University Hospital, Department of Oncology, Lund, Sweden

Introduction
The morbidity of craniopharyngioma (CP) includes cognitive dysfunction with attention deficits, impaired episodic memory and processing speed (Fjalldal *et al.*, 2013) and CP patients with hypothalamic damage are more affected. fMRI is a technique used to investigate cortical activity by detecting alterations in blood flow in response to stimuli or actions. Previously pre- and post-meal fMRI responses to visual food cues were investigated showing higher activation in patients with CP compared to controls (Christian *et al.*, 2012). Further, fMRI was used in an emotional face recognition task where neural activity revealed differential recruitment of fronto-limbic brain regions during recognition in patients with CP (Ozyurt *et al.*, 2014). The multi-source interference task is an fMRI paradigm that reliably activates the cingulo-fronto-parietal cognitive/attention network (Bush *et al.*, 2006). Our aim was to study activation in the cingulo-fronto-parietal cognitive/attention network using fMRI. We hypothesized that the patient group would demonstrate different cortical activation patterns compared to controls.
Methods
Included were 29 adult childhood craniopharyngioma patients (median age 36 [18–49] years) surgically treated, 13 with hypothalamic damage, and 15 without. Twenty-nine controls were matched for age, sex, and smoking habits. A gradient echo EPI sequence (TR/TE 1500/30 ms/ms) with a number of 25 slices, a number of 64 dynamics, and a voxel size of $3\times3\times4\,mm^3$ was used for the fMRI task. An additional MP-RAGE sequence (TR/TE 1900/2.54 ms/ms, $1\,mm^3$ isotropic resolution) was acquired to be able to perform the data analysis. The multi-source interference task was performed (Bush *et al.*, 2006). fMRI data processing was carried out using FEAT (FMRI Expert Analysis Tool) Version 6.00, part of FSL (FMRIB's Software Library, www.fmrib.ox.ac.uk/fsl). Z (Gaussianised T/F) statistic images were thresholded non-parametrically using clusters determined by $Z>3.1$ and a (corrected) cluster significance threshold of $P=0.05$ (Woolrich *et al.*, 2001). Higher-level analysis was carried out using FLAME (FMRIB's Local Analysis of Mixed Effects) stage 1 (Beckmann *et al.*, 2003).
Results
Activation maps demonstrate activation in expected areas (i.e. cingulo-fronto-parietal activation). No significant differences in activation was found between the patients gorup and controls.
Conclusion
In spite of well-known cognitive impairment in patients with CP we found no functional alterations in the cingulo-frontoparietal cognitive/attention network using fMRI.

DOI: 10.1530/endoabs.70.AEP680

Effects of long-term growth hormone replacemente therapy on body composition in adult patients with growth hormone deficiency

Rosa María García Moreno[1], Paola Parra Ramírez[1], Gonzalo Baonza Saiz[2], Patricia Martin Rojas-Marcos[1], Beatriz Lecumberri[1] & Cristina Álvarez Escolá[1]
[1]La Paz University Hospital, Endocrinologý and Nutrition Department; [2]Ramón y Cajal University Hospital, Endocrinologý and Nutrition Department

Introduction
Growth hormone deficiency (GHD) is associated with worsening body composition and growth hormone replacement therapy (GHRT) has shown to improve it in several studies. The objectives of this study were to evaluate the effects of long-term GHRT on body composition in adult patients with GHD andassess, in this population, the agreement between two different methods to measure fat mass that are total body fat mass (FM) and relative fat mass (RFM).
Material and methods
We conducted a retrospective, longitudinal study in a cohort of patients with GHD under GHRT, followed in the Endocrinology and Nutrition Department of La Paz University Hospital. A total of 79 adult patients (46 women, 33 men), with mean age of 39.1 year-old at starting GHRT, were evaluated

for a mean time of 5 years (range 1 to 15 years). RFM, FM, body mass index (BMI) and waist-to-hip (W/H) ratio were measured at baseline and during follow-up, FM was measured by bioelectrical impedance analysis (BIA), RFM was calculated using a linear equation based on height-to-waist ratio proposed by Woolcott *et al.*, [Equation for women: 76–(20×(height/waist)); equation for men: 64–(20×(height/waist))]. The evolution of these parameters was assesed using ajusted generalized estimating equation models. The agreement between RFM and FM was estimated using the intraclass correlation coefficient (ICC).
Results
FM measured by BIA did not changesignificantly during the follow-up ($P=0.087$). RMF did not change the firsts years, but from the 3rd year of follow-up, it gradually increasedcompared to baseline (3rd year: OR=2.86; 95% CI=1.05–7.80; $P=0.04$. 4th year: OR=3.62; 95% CI=1.25–10.5; $P=0.02$. 5th year: OR=3.41 95%; 95% CI=1.32–8.8; $P=0.01$. 10th year: OR=5.56; 95% CI=2.19–14.5; $P=0.003$). After the 2nd year of therapy, BMI progressively increased (2nd year: OR=2.10; 95% CI=1.22–3.63; $P=0.008$. 3rd year: OR=2.19; CI 95%=1.18–4.07; $P=0.01$. 4th year: OR=2.30; 95% CI=1.02–5.17; $P=0.04$. 5th year: OR=2.84; 95% CI = 1.31–6.17; $P=0.008$. 10th year: OR=7.46; 95% CI=2.52–22.2; $P=0.0003$). W/H ratio did not change significantly ($P=0.06$). RFM showed good degree of agreement with FM measured by BIA (ICC 0.78, 95% CI=0.75–0.81).
Conclusions
1) In our population, we did not observe improvement in the anthropometric measures during GHRT. 2) RFM showed good agreement with FM measured by BIA, so it could be used to replace this technique when it is not avaliable.

Perception of stature and quality of life in young adult men referred for tall stature during adolescence. Perception of stature and quality of life in young adult men referred for tall stature during adolescence.

Jean De Schepper[1,2], Justine Wynand[3], Kathleen De Waele[1], Saskia Van der Straaten[1], Martine Cools[1], Marieke Den Brinker[4,5], Hilde Dotrement[6], Jesse Vanbesien[2] & Inge Gies[2]
[1]UZ Gent, Pediatrics, Gent, Belgium; [2]UZ Brussel, Pediatrics, Brussel, Belgium; [3]Faculty of Medicine and Health Sciences, Pediatrics, Gent, Belgium; [4]University of Antwerp, Faculty of Medicine and Health Science, WILRIJK (Antwerpen), Belgium; [5]University Hospital Antwerp, Department of Paediatrics, Division of Paediatric Endocrinology and Diabetology, Edegem (Antwerp), Belgium; [6]UZ Antwerpen, Pediatrics, Edegem, Belgium

Background and aims
Little is known about the long-term psychosocial effect of tallness and its treatment in male adolescents.[1] Therefore, psychosocial outcome, including adult coping with tall stature were investigated in young adult men, who had consulted for tall stature during adolescence.
Methods
All adult men (age >18 years) who had been referred for tall stature or rapid growth during adolescence (ages 11 to 16 years) between 2010 and 2013 in 3 Flemish University Hospitals and had bone age assessment, were invited to complete the SF36 instrument and a custom-made questionnaire. Relevant data were retrieved from their medical files.
Results
Of the 65 eligible subjects (having no underlying growth disorder and a normal mental development), 24 completed the psychosocial evaluation. Eight of them had been treated with high dose testosterone. Median (range) age was 20.5 (18 and 25) years and median self-reported height was 197 (185–207) cm. Current age and height were similar in the treated and untreated men, but predicted height was significantly higher in treated men (202.6 vs 198.9 cm, $P<0.05$). The ideal adult stature mentioned by participants was 190 cm. At adolescence respectively 88 and 75% and at adulthood respectively 63 and 88% of treated and untreated men reported to be satisfied with their stature. In total 75% of treated and untreated men were satisfied with the received recommendation to treat or not. Median scores on the eight SF36 subscales were similar between treated and untreated men, with the exception of a lower median score on general health perceptions in treated men. Median SF36 subscale scores were not significantly different from an age matched British control group, with the exception of higher scores on role limitations due to emotional problems in tall men. Positive perception of stature during adolescence was correlated with better scores on social functioning and bodily pain.
Conclusion
The majority of young men,being between 5–17 cm taller than the population mean, who participated in a psychosocial assessment, were satisfied with their current stature and previous decision to receive growth suppressive hormonal treatment or not. Previously treated men however, had a lower score on general health perceptions.

Pituitary neuroendocrine tumors (PitNETs) are mostly benign lesions originating from the anterior pituitary and represent 10–15% of all the intracranial neoplasms. PitNETscan be classified in non-secretory, clinically non-functioning pituitary adenomas (NFPAs), and secretory, comprising prolactin (PRL), growth hormone (GH) and adrenocoticotropic hormone (ACTH) PitNETs. Surgical resectionis the first line treatment for PitNETs, whereas chemotherapy and radiotherapy are preferred for resistant or metastatic tumors. Growth hormone-releasing hormone (GHRH), apart from promotingpituitary GH secretion, exerts many extrapituitary functions, including stimulation of cell proliferation and survival. GHRH, GHRH receptor (GHRH-R) and splice variant 1 (SV1) of GHRH-R, are expressed in different cancer cell types, where they promote cell proliferation and tumor progression. Conversely, GHRH antagonists inhibit the growth of different tumors *in vitro* and *in vivo*; moreover, it has been demonstrated that first generation GHRH antagonists reduce GH secretion in tumoral rat GH-secreting (GH3) cells. However, to date the role of GHRH antagonists in PitNETs remains largely unknown. Thus, we aimed to clarify the role of last generation GHRH antagonists, MIA-602 and MIA-690, on survival, apoptosis and hormone secretion using murine ACTH-secreting PitNETs cells (AtT-20/D16v-F2)and rat PRL- and GH-secreting PitNET cells, transfected with human GHRH-R(GH3-hGHRHR). Our results show that MIA-602 and MIA-690 dose-dependently reduced cell survival and promoted apoptosis in tumoral ACTH-secreting cells and GH3-hGHRHR; in addition, we observed an increase in expression of the proapoptotic protein BAX and the tumor-suppressor protein P53,paralleled by a reduction of the antiapoptotic protein Bcl-2. MIA-602 and MIA-690 also reduced colony formation and expression of c-Myc oncoprotein, indicating inhibitory activity on migration and proliferation. Furthermore, the combination of MIA-602 or MIA-690 with Temozolomide (TMZ), the main chemotherapy agent for PitNETs, produced a synergistic effect on inhibition of cell survival in AtT-20 cells. Finally, both antagonists were able to modulate the secretion of ACTH and GH in AtT20/D16v-F2 and GH3-hGHRHR, respectively. Overall, these results indicate that GHRH antagonists display antitumor activities in ACTH and GH cell lines and suggest their potential use for the treatment of PitNETs, alone or in combination with standard therapies.

Instituto Maimonides de Investigacion Biomedica de Cordoba (IMIBIC).

Introduction
Non-functioningpituitary adenomas (NFPAs) are of benign nature but a sizeable number of NFPAs show aggressive features. Surgery is not always effective in treating NFPAs and thus other therapeutic options are needed. Previous studies have reported that NFPAs express somastostatin receptors (SSTRs) and dopamine receptors (DRDs).
Aim
To systematically analyze the expression of SSTRs and DRDs in a large cohort of clinically well-characterized patients with NFPAs and analyze their potential association with relevant clinical and molecular aggressive features.
Methods
Retrospective study with 113 patients that underwent transsphenoidal surgery in our center. Relevant clinical variables including invasion, surgical cure, recurrence and histological subtype were obtained to analyze potential associations between these variables and DRD and SSTR expression. Real-time quantitative PCR (qPCR) was used to evaluate SSTT and DRD expression. SSTRs was also by immunohistochemistry (IHQ) in. Histological markers E-cadherin, Ki-67 and p53 were also analyzed by IHQ.
Results
As assessed by qPCR, SSTR3 was the predominant SSTR subtype detected, followed by SSTR2, SSTR5, and SSTR1. A similar expression pattern was observed by IHQ. 84% of NFPAs showed elevated SSTR3 levels and 27% of NFPAs showed elevated SSTR2 expression levels. However, only 11% of NFPAs showed high SSTR5 levels. Regarding DRD expression, DRD2 was the predominant DRD subtype, followed by DRD4, DRD5, and DRD1. Only a minor portion of NFPAs displayed substantial Ki67 and p53 levels. No significant associations between SSTR and DRD expression and tumor size, invasion, cure after surgery, E-cadherin, Ki67 and p53 levels.
Conclusions
No associations between SSTR and DRD expression and clinical and molecular aggressive features were found in NFPAs. A notable number of NFPAs displayed substantial SSTR2 and SSTR5 levels providing a rationale for the potential use of SSTR2 and SSTR5 agonists in these groups of NFPAs.

High prevalence of pituitary deficiency after cranial radiation therapy for skull base meningioma: The importance of an annual screening.

Perrine Raymond[1], Thomas Cuny[2], Marc Klein[3] & Valerie Bernier-Chastagner[1]
[1]Institute Cancer De Lorraine – Alexis Vautrin, Vandœuvre-lès-Nancy, France; [2]Ap-Hm, Marseille, France; [3]CHRU de Nancy – Hôpitaux de Brabois, Vandœuvre-lès-Nancy, France

Purpose
To determine the risk of developing hypopituitarism after cranial irradiation for skull base meningiomas. Cranial irradiation is often chosen as first treatment in skull base meningiomas to avoid risk to proximally-located critical structures. While cranial irradiation has been associated with high risk of inducing hypopituitarism, few studies concern meningiomas.
Methods and materials
Fifty-two adult patients receiving photon-beam therapyfor skull base meningiomas between 1978 and 2014 were included. All five anterior pituitary axes were screenedusing baseline blood measurementsbefore radiotherapy, then each year until March 2019. The pituitary gland (PG) was delineated on CT and the mean dose to it was estimated.
Results
Mean age at diagnosis was 56 years ±14 and 80% were women. Median follow-up was 7 years. Sixty percent of patients developed hypopituitarism (all 5 axes involved) 10 years after the radiotherapy. The frequency of gonadotropic, TSH, ACTH and GH deficiencies as well as hyperprolactinemia10 years after the radiotherapy was 37%, 28%, 18%, 15% and 13% respectively. Twenty-one percent developed deficiencies of two axes only, however noone-axis deficiency was observed. In the multivariate analysis, an estimated dose to the PG ≥ 50 Gy or a meningioma ≥40 mm significantly increased the risk of developing hypopituitarism.
Conclusion
Cranial radiation therapy in the treatment of skull base meningioma is correlated with a high risk of developing hypopituitarism (60% prevalence after 10 years), particularly when associated with tumor size of ≥ 40 mm and an estimated radiation dose to the PG ≥ 50 Gy. The gonadotropic axis was the most frequently affected.
Annual follow-up appears therefore necessary to identify patients requiring treatment for such deficiencies.

Role of 68ga-dotatoc pet/ct in the management of neuroendocrine tumors

Laura Hernández-Montoliu[1], Inmaculada Peiró[2], Jose Luis Vercher[3], Judith Suils[3], Alexandre Teulé[4], Cristina Sánchez[4], N Vilarrasa[1], Jordi Puig de la Bellacasa[1], Fernando Guerrero[1] & Carles Villabona[1]
[1]Bellvitge University Hospital, Endocrinology, L'Hospitalet de Llobregat, Spain; [2]Institut Català d'Oncologia – L'Hospitalet de Llobregat, Clinical Nutrition Unit, L'Hospitalet de Llobregat, Spain; [3]Bellvitge University Hospital, Nuclear Medicine-PET, L'Hospitalet de Llobregat, Spain; [4]Institut Català d'Oncologia – L'Hospitalet de Llobregat, Medical Oncology, L'Hospitalet de Llobregat, Spain

Introduction
Primary tumours in some patients with metastatic neuroendocrine tumors (NET) cannot be found by conventional imaging as CT, MRI and scintigraphy. ^{68}Ga-DOTATOC PET/CT (^{68}Ga-PET) appears to have superior sensitivity, specifity, and better resolution than ^{99m}TC-octreotide SPECT/TC (SSTR scintigraphy) and can improve decision-making process, however its cost is higher, and its availability is limited.
Aims
Evaluate the role of ^{68}Ga-PET in diagnosis, staging, re-evaluation and change of treatment in a group of NET patients with controversial diagnosis.
Material and methods
In the last 8 months we performed a ^{68}Ga-PET in 19 controversial NET. We collected demographic data, tumor grade, location, NET therapy, 6 months-previous CT and/or MRI and SSTR scintigraphy as well as indication and results of ^{68}Ga-PET.
Results
19 patients were evaluated, Ten males and nine females, mean age of 56±14.2 years. Location of NET: 5 unknown primary tumor (3 metastatic disease and 2 ectopic ACTH secretion), 7 pancreatic NET (6 out of them with metastatic disease), 4 midgut NET, 2 paragangliomas and 1 gastric NET. Grade of NET: G1: 3; G2: 8; G3 1; NEC: 1. Function: 2 producing ACTH (all with unknown primary tumor). Metastasic disease: 5 with hepatic metastasis, 6 with hepatic and extrahepatic disease and 1 with bone and lung dissemination. Indication of ^{68}Ga-PET: 5 for unknown primary NET, 6 for re-staging, 3 for staging after diagnosis, 4 for evaluatingresponse to treatment and 1 for diagnosis. In 2 patients with metastatic unknown NET, ^{68}Ga-PET found primary midgut NET, but none of unknown ectopic ACTH secretion tumors were found. In 11 patients (57.9%), more lesions in ^{68}Ga-PET than in SSTR scintigraphy were detected. In 9 patients (47.4%) ^{68}Ga-PET allowed changes in decision-making process.
Conclusions
^{68}Ga-PET can be useful for diagnosis, re-staging and re-evaluation for recurrence and can lead to changes in management in controversial NET patients.

Endoscopic transsphenoidal pituitary surgery (ETPS) for pituitary tumors: Outcomes and complications

Eva Venegas-Moreno[1], Pablo Remon[1], Elena Dios-Fuentes[1], Alejandro Deniz-Garcia[1], Eugenio Cardenas[2], Ariel Kaen[2], Ignacio Martin-Schrader[2], Natividad Gonzalez-Rivera[3], Florinda Roldan[4], David Cano-Gonzalez[5] & Alfonso Soto-Moreno[1]
[1]Virgen del Rocio, UGC Endocrinology and Nutrition, Seville, Spain; [2]Virgen del Rocio, UGC Neurosurgery, Seville, Spain; [3]Virgen Macarena, UGC Endocrinology and Nutrition, Seville, Spain; [4]Virgen del Rocio Hospital, UGC Radiology, Sevilla, Spain; [5]IBIS, Seville, Spain

Methods
Restrospective descriptive study of patients who underwent ETPS for pituitary adenoma removal performed by the same surgical team in Virgen del Rocio Hospital of Seville from January 2014 to January 2019.
Results
174 patients had a pituitary adenoma (44 GH, 36 ACTH, 94 Non functioning). 54.02% were female. In acromegaly, 39 (88.63%) patients were operated by ETPS as initial approach. 20 (51.28%) patients had cavernous sinus invation. At outcome analysis, 28 (71.19%) achieved biochemical and morphological remission; Cure rate was 100% for microadenomas, 67.66% for macroadenomas, 89.47% for non-invasive adenomas and 55% for invasive adenomas. Additionally, 5 patient with persistant disease after microscopic transsphenoidal surgery (MTS) were operated by ETPS, 3 (60%) were cured. 75 nonfunctioning adenomas were operated by ETPS as initial approach. After surgery, 46 (61.33%) were cured, with similar rates for invasive (59.57%), non-invasive (59.57%) adenomas and tumors larger than 25 mm (54.72%). 47 (62.67%) patients had visual impairment before surgery, 27 (57.44%) patients developed a full recovery after the surgery. 19 patients were operated by ETPS after unsuccessful MTS. Regrowth of pituitary remmant was observed in all reinterventions, 11 (57.89%) presented new campimetric deficits; after the intervention 6 (31.58%) reached cure criteria, with a cure rate for invasive adenomas of 33.33%; 10 (90.9%) presented full o partial recovery of visual impairment. 27 ACTH secreting adenomas were operated by ETPS by first time. After the surgery, 22 (81.48%) patients were cured. 9 patients were reoperated after an unsuccessful MPS, 6 (33.33%) were macroadenomas. 6 (66.67%) patients with a second operation were cured. Regarding complications, 2 patient had LCR fistula, 4 suspiction meningitis and 2 epistaxis.
Conclusions
The cure rates observed in our series were higher tan in the most MPS published series. Reintervention is an adequate treatment approach in cases of recurrence and resistant Cushing disease and Acromegaly.

Do cardiovascular risk factors predispose to pituitary apoplexy?

Imen Gargouri, Hadjkacem Faten, Ben Othman Wafa, Mnif Mouna & Abid Mohamed
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Pituitary apoplexy (PA) is a rare incident defined by the occurrence of necrosis and/or haemorrhage of the pituitary gland. The low incidence of PA makes it difficult to bring out from the studies its precipitating factors and especially its relationship with cardiovascular risk factors (CVR). The objectives of this studies were to characterize a number of patients with PA and to establish the link between PA and their CVRs.
Methods
It is a retrospective study including a group of patients in the Endocrinology department of Hedi Chaker Hospital in Sfax over an 18-year period (2000 – 2017). The data collected was analysed by the SPSS version 20 software.
Results
This study included 44 patients (20 women versus 24 men) with a mean age of 50.04±12.58 years. Fourteen patients (31.8%) had a pituitary adenoma known before the onset of apoplexy, secreting in 9 cases. Precipitating factor have been found in 14 cases (31.8%). A high blood pressure was found in two cases. CVR were dominated by the presence of overweight in 27 patients (61.4%) and android obesity in 17 patients (38.6%), followed by smoking in 15 patients (34%) and type 2 diabetes in 11 patients (25%). Four patients had treated dyslipidaemia at diagnosis (9.1%): two patients had mixed dyslipidemia treated with atorvastatin andtwo patients had isolated hypertriglyceridemia treated with fibrates. Two patients had a cardiac history: unstable angina in one case andcoronary disease in the second. We analysed these features and we found no correlation between these factors and the occurrence of PA.
Conclusion
We conclude through these data that having weather a metabolic syndrome or a documented cardiovascular disease do not precipitate the occurrence of PA in patient with pituitary adenoma. We explain these results with the low number of this cohort and of the pathology itself.

Trabecular bone score as a useful tool for assessment of fracture risk in acromegaly

Aleksandra Jawiarczyk-Przybyłowska, Jowita Halupczok-Żyła, Joanna Syrycka, Małgorzata Rolla, Agnieszka Zembska, Eliza Kubicka & Marek Bolanowski
Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw, Poland

Acromegaly is a rare disease, caused by an excessive secretion of growth hormone (GH), and consequently the insulin like growth factor 1 (IGF-1). Patients with acromegaly have an increased risk of fractures, which might be correlated with insufficient quality of bone. It is known that use of FRAX in acromegaly is not validated, however we do not have other useful tools to assess real risk for fractures. The new valuable tool in the assessment of bone structure is the trabecular bone score (TBS) measurement, which provides some information on bone microarchitecture from a routine DXA. The high TBS score reflects better bone structure, whereas a low TBS score indicates impaired bone structure associated with higher fracture risk.
Purpose
The aim of this study was to assess the usefulness of TBS in prediction of fractures in patients with acromegaly.
Materials and methods
We studied 63 patients with acromegaly and 42 healthy controls (CG). Acromegaly patients were divided into three subgroups on the basis of disease activity (AA – active acromegaly, CTA – controlled treatment acromegaly (during somatostatin analogues therapy) and CA – cured acromegaly). In all patients blood samples were obtained to assess the hormonal and metabolic status. The bone mineral density (BMD) of the lumbar spine (LS) (L1-L4), femoral neck (FN) was measured using the dual-energy X-ray absorptiometry (DXA) method by densitometer. All TBS values were analyzed using the TBS iNsight software, (Med-Imaps, Pessac, France) using spine DXA files from the database.
Results
Lumbar spine TBS was significantly lower in the whole acromegaly group (AA+CTA+CA) vs CG (1.22±0.13 vs 1.29±0.10, $P=0.019$). In contrast, BMD at all sites did not differ between these groups. Additionally, TBS was significantly higher in CG compared to CTA (1.29±0.10 vs 1.18±0.12, $P=0.00$) as well as to CTA+CA (1.29±0.10 vs 1.21±0.14, $P=0.00$). Similarly, BMD also did not differ among these groups. The risk of major fractures and hip fractures was significantly higher in the whole acromegaly group as well as in CTA+CA and in CTA compared to CG ($P=0.00$ for all).
Conclusions
The present results confirmed the higher risk of fractures in acromegaly patients despite of BMD results. Low TBS score reflects worse bone structure in acromegaly. TBS may be a useful tool for predicting risk of fractures in acromegaly patients.

Metabolic abnormalities in patients with childhood onset of hypopituitarism – single center,long term observation

Łukasz Kluczyński[1,2], Aleksandra Gilis-Januszewska[1,2], Damian Rogoziński[1], Magdalena Godlewska[1], Jacek Pantofliński[1], Agata Zygmunt-Górska[3], Małgorzata Wójcik[3], Jerzy Starzyk[3] & Alicja Hubalewska-Dydejczyk[1,2]
[1]University Hospital, Endocrinology Department, Krakow, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland; [3]Jagiellonian University, Medical College, Department of Pediatric and Adolescent Endocrinology, Krakow, Poland

Background
Hypopituitarism is a condition caused by deficiency in one or multiple pituitary hormones. The disease is associated with various metabolic disorders and decreased quality of life that are particularly marked in patients with childhood onset of the disorder. There are manyfactors influencing the metabolic status of patients such as different treatment modalities (surgery, radiotherapy, chemotherapy) and current supplementation (e.g. steroid or testosterone/estradiol substitution)which should be taken into consideration. This specific group of patients requires an extensive care because of increased risk of metabolic abnormalities.
Aim
To present the metabolic characteristic of patients with childhood onset of hypopituitarism on the basis of long term observation in the pediatric/adult endocrinology departments of our university.
Methods
We analyzed retrospectively current complete data of 35/75 patients with childhood onset of pituitary dysfunctions (13 W/22 M). 28/75 patients with PROP-1 mutation were excluded from this study due to the separate analysis. Etiologically, congenital malformations were found in 13/35 of patients; 10/31 were treated for craniopharyngioma, 3/35 for histiocytosis, 2/35 for germinoma. The mean age of diagnosis was 9.18 years (s.d. 4.8).
Results
29/35 of patients presented with somatotropic axis deficiency. Deficits in gonadal, thyroid and adrenal hormones were detected in 26/35, 25/35 and 18/35 of patients, respectively. Body weight abnormalities were found in 24/35 of patients (obesity in 9/35 of patients, overweight in 10/35 of cases and underweight in 5/35 of them). Extreme values were observed in patients operated for craniopharyngioma (cachectic patient with BMI 16,9 and obese one with BMI 46,5). Systolic and diastolic blood pressure were higher in 6/35 and 8/35 cases, respectively. 18/35 of patients were diagnosed with various lipid disturbances (among them 15/25 of patients with central hypothyroidism and 15/29 with somatotropic pituitary dysfunction). Kidney function was preserved in all patients. 8/35 of patients had at least one liver enzyme elevated. Vitamin D deficit was found in 12/35 of cases. Oral glucose tolerance test (performed in 26/35 of patients) revealed diabetes in 1 case, impaired glucose tolerance in 3 patients (all of them had secondary hypoadrenalism and were treated with hydrocortisone) and confirmed insulin resistance (IR) in 14/26. The highest incidence of IR were observed in patients with history of craniopharyngioma (6/7) and histiocytosis (2/2).
Conclusions
Majority of patients with childhood onset of hypopituitarism characterizes with at least one metabolic dysfunction. Proper management of hormonal abnormalities and early administration of treatment might preserve these patients from serious consequences.

Early basal growth hormone level and nadir growth hormone level in oral glucose tolerance test as predictors for surgical cure in acromegaly

Alexandr Tsiberkin, Uliana Tsoy, Vladislav Cherebillo, Natalya Kuritsyna, Anna Dalmatova, Andrej Polezhaev, Lidia Belousova & Elena Grineva
Almazov National Medical Research Centre, Institute of Endocrinology, Akkuratova str 2, Russian Federation

Introduction
Growth hormone (GH) level is a direct marker of active residual adenoma tissue after acromegaly surgery. However, the value of early postoperative GH for prediction of surgical cure in acromegaly has not been established and therefore is not used in everyday clinical practice.
Aim
The aim of our work was to study the 24-hour basal postoperative GH level and the nadir of GH level after the oral glucose tolerance test (OGTT) two weeks after surgery as predictors of surgical cure in acromegaly.
Materials and methods
A prospective cohort study included patients with newly diagnosed acromegaly. All patients underwent transsphenoidal surgery (TSS) performed by one neurosurgeon. The basal GH level 24 hours after surgery and the nadir GH in OGTT carried out two-weeks postoperatively were measured in all cases. The results of TSS were estimated twelve months after operation. The biochemical remission of acromegaly was defined as nadir GH level in on an OGTT < 0.4 µg/l along with age and gender normalized values of insulin-like growth factor 1 (IGF-1).
Results
Thirty-nine patients (32 women and 7 men) with mean age 53.0 ± 7.9 years (35–63 years) were enrolled into the study. 31 patients harbored macroadenomas (79.4%). Remission rate was 46.1% (18/39) on follow-up after 12 months (in microadenomas it was 75% (6/8), in macroadenomas – 38.7% (12/31)). Preoperative basal GH and IGF-1 levels did not differ in remission and persistence groups. Basal 24-hour postop GH level decreased in all patients when compared with baseline and was significantly lower among patients in remission group: 1.8 ± 0.9 vs 5.3 ± 2.8 µg/l, $P = 0.0002$. The GH level <1.30 µg/l showed the highest prognostic value for acromegaly remission with sensitivity of 93.7% (95% CI, 81.1–98.3) and specificity of 83.5% (95% CI, 60.1–93.8). The nadir GH level <1.0 µg/l in two-week postop OGTT had a sensitivity of 85.7% (95% CI, 60.1–97.5) and specificity of 80.0% (95% CI, 54.8–92.9) in prediction of acromegaly remission 12 monthsafter surgery.
Conclusion
Early postoperative GH level can predict the outcome of surgical treatment in acromegaly. Our data suggests that the basal 24-hours postoperative GH < 1.3 µg/is a stronger predictor of acromegaly remission after TSS than the nadir GH < 1.0 µg/l in two-week postop. These findings require further research.

Quantitative bone assessment by radiofrequency echographic multi-spectrometry (REMS) in patients with acromegaly – a preliminary study

Jowita Halupczok-Żyła, Małgorzata Rolla, Aleksandra Jawiarczyk-Przybyłowska, Katarzyna Kolackov & Marek Bolanowski
Wroclaw Medical University, Department and Clinic of Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland

Introduction
Acromegaly is a rare diseaseresulting most commonly from pituitary adenoma. A chronic increase of growth hormone (GH) and insulin-like factor 1 (IGF-1) leads to many systemic complications including osteoporosis and fractures. Radiofrequency echographic multi-spectrometry (REMS) is a new non-ionizing technique to diagnose osteoporosis.
Purpose
The objective of the study was to evaluate bone mineral density (BMD) by REMS in patients with well-controlled and cured acromegaly. The associations between BMD measured by REMS and GH, IGF-1 concentrations and BMD measured by dual energy X-ray absorptiometry (DXA) were investigated in acromegaly patients.
Material and methods
The study group comprised 33 patients with acromegaly and 24 controls (CG). Based on clinical picture and hormonal evaluation (GH and IGF-1 concentrations) the acromegaly group was divided into two subgroups: well-controlled acromegaly (WCA) – (normal IGF-1 during somatostatin analogues therapy) and cured acromegaly (CA) – (normal IGF-1, patients after successful surgery). Blood samples were obtained from patients with acromegaly to measure concentrations of GH and IGF-1. REMS was performed in all participants, whereas DXA in the acromegaly group only.
Results
There were no significant differences in T-score, Z-score and BMD measured by REMS at lumbar spine (LS) and femoral neck (FN) among the subgroups of patients with acromegaly and controls (WCA, CA and CG). Similarly, we did not observe significant differences in T-score, Z- score and BMD measured by DXA at LS and FN between WCA and CA groups. IGF-1 concentration correlated positively with T-score, Z-score and BMD measured by REMS and DXA at LS and FN in the WCA + CA and WCA groups ($P < 0.05$). No significant correlations were observed between GH levels and T-score, Z-score and BMD measured by REMS and DXA. Positive correlations between BMD LS assessed by DXA and BMD LS evaluated by REMS were found in WCA + CA and CA groups. There were no significant correlations between BMD FN measured by REMS and DXA.
Conclusion
The present study shows potential utility of REMS assessment of trabecular bone deterioration in acromegaly, as shown by results obtained in lumbar spine. There are no differences in BMD measured by REMS in patients with well-controlled and cured acromegaly. The association between IGF-1 concentration and BMD may suggest an anabolic action of IGF-1 in well-controlled acromegaly.

Analysis of the value of bilateral inferior petrosal sinus sampling in the diagnosis and treatment of Cushing's disease in patients with a negative or inconclusive result of magnetic resonance imaging

Andrzej Styk[1], Piotr Zięcina[2], Piotr Piasecki[2], Krzysztof Brzozowski[2], Przemysław Witek[3], Jerzy Narloch[2], Marek Wierzbicki[2] & Grzegorz Zieliński[1]
[1]Military Institute of Medicine, Department of Neurosurgery, Warsaw, Poland; [2]Military Institute of Medicine, Department of Interventional Radiology, Warsaw, Poland; [3]Military Institute of Medicine, Department of Endocrinology, Warsaw, Poland

Diagnosis and treatment of Cushing's disease is one of the greatest challenges of modern endocrinology. This is related to the fact that pituitary corticotropinomas are small tumours that are difficult to visualize in magnetic resonance imaging (MR). In about 40% of patients with Cushing's disease, MR scans of the pituitary gland do not reveal any changes. The method that allows to localize the source of adrenocorticotropin (ACTH) secretion is bilateral inferior petrosal sinus sampling (BIPSS), which has so far been performed rarely in our country. The treatment of choice of this disease is transphenoidal resection of corticotropinoma allowing remission of hypercortisolemia in 64–98% of operated patients. The results of surgical treatment depend to a large extent on locating the source responsible for excessive ACTH secretion. The aim of this study was the assessment of usefulness of bilateral inferior petrosal sinus sampling in diagnosis and treatment of Cushing's disease in 74 patients with negative or inconclusive MR imaging of pituitary adenoma. All patients had BIPSS performed and ACTH values were used to assess the ratio of the concentration in central vs peripheral blood and between right and left inferior petrosal sinus before and after administration of CRH. Confirmation of the pituitary secretion of ACTH-dependent hypercortisolemia was obtained in 68 patients, in 6 patients the result indicated ectopic ACTH secretion. All patients with pituitary ACTH secretion underwent a transsphenoidal operation, which in three cases (4.4%) did not lead to a cure. A statistically significant correlation was also shown between BIPSS result and localization of adenoma confirmed intraoperatively. The results of bilateral inferior petrosal sinus sampling in patients with Cushing's disease and negative or inconclusive result of pituitary imaging presented in the study allow for differentiation of the pituitary and non- pituitary source of ACTH secretion and are highly helpful in localization of corticotropinomas, as well as affect the effectiveness of surgical treatment. It has been demonstrated that the greatest diagnostic significance during bilateral inferior petrosal sinus sampling have results obtained in the 3rd minute after CRH administration and that BIPSS is a safe and well-tolerated procedure. In the group of ACTH-secreting pituitary adenomas examined, the diameter of the tumor was the only significant factor influencing the effectiveness of surgical treatment.

Micromegaly or acromegaly? A retrospective longitudinal study on clinical aspects and comorbidities in a large cohort of patients referred to a single tertiary center

Giulia Carosi[1,2], Elisa Sala[1], Alessandra Mangone[1], Giulia Del Sindaco[1,3], Roberta Mungari[1], Arianna Cremaschi[1,3], Emanuele Ferrante[1], Maura Arosio[1,3] & Giovanna Mantovani[1,3]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Introduction
The diagnosis of acromegaly is confirmed in the presence of high IGF-1 levels and inadequate suppression of growth hormone (GH) after glucose load. According to guidelines, a GH nadir (GHn)>0.4 ng/ml is considered diagnostic with ultrasensitive assays. However, some acromegalic patients with lower GHn, also called 'micromegalic', are reported, but a systematic collection of their clinical features is unavailable.
Aim of the study
The main aim was to characterize a group of patients with high IGF1-levels but GHn < 0.4 ng/ml, focusing on acromegalic clinical features and comorbidities. The second one was to evaluate the clinical and hormonal progression over time.
Materials and methods
We performed a longitudinal retrospective study, including 49 patients referred to the Endocrinology Unit of the Ospedale Maggiore Policlinico, from 2009 to 2019, who presented high IGF-1 levels and GHn <0.4 ng/ml. GH was measured with an ultrasensitive assay. Data on typical acromegalic clinical features, comorbidities, pituitary imaging, IGF-1, GHn and GH random were collected, both at the time of the first finding of high IGF1 (diagnosis) and at the last follow up (FU).
Results
At diagnosis, mean age was 53.9 ± 16 S.D. years and 30/49 were females. Diagnostic evaluations started because of acromegalic facies in 45%, pituitary disease in 43% and various endocrinopathies in other ones. Patients with acromegalic facies showed a high prevalence of comorbidities, overlapping with those of classic acromegaly: glucose metabolism alterations in 82 vs 44% in patients with facies and without facies respectively, hypertension in 59 vs 28%, goiter in 50 vs 28%, carpal tunnel in 41 vs 4%, neoplasms in 41 vs 12%, cardiopathy in 36 vs 20%, colonic polyposis in 23 vs 16% (note that only 14 colonoscopies were performed). The ANOVA analysis showed that patients with a higher number of comorbidities had higher GHn levels (P 0.036) and GHn > 0.1 ng/ml was strongly associated with the presence of specific comorbidities (carpal tunnel OR 5.4, goiter OR 4.8 etc.). Pituitary imaging was available in 41/49 showing an adenoma in 16/41 (4 macro, 16 microadenomas) with other 4 new microadenomas at the last FU. Mean FU was 4.4 ± 3.2 years and we observed an increase of some comorbidities (hypertension + 20%, neoplasms + 20% and goiter + 16%), while IGF1 and GH levels did not significantly change.
Conclusions
Patients with acromegalic features, high IGF1 levels but a GH nadi r < 0.4 ng/ml, also called 'micromegalic', seem to clinically overlap with classic acromegaly. In our group, acromegalic facies and GHn > 0.1 ng/ml are strongly associated with comorbidities that, unlike IGF1 and GH, seem to worsen over time.

Markers of recurrence in cushing's disease: The role of post-operative serum cortisol and desmopressin test

Mattia Barbot, Filippo Ceccato, Laura Lizzul, Alessandro Mondin, Daniela Regazzo, Marialuisa ZIlio & Carla Scaroni
University of Padova, Department of Medicine-DIMED, Endocrinology Unit, Padova, Italy

Introduction
Transsphenoidal surgery (TSS) is the first-choice treatment in Cushing's disease (CD). When performed by experienced neurosurgeon, post-operative remission can be achieved in 70–80% of cases; however, recurrences during follow-up are quite frequent, involving around 20–30% of patients initially in remission. Early detection of relapses is crucial to avoid cortisol-related comorbidities. The aim of the study was to find reliable predictors of recurrence after neurosurgery in patients with CD.
Materials and methods
Forty CD patients (32 F/8 M, median age at diagnosis 39 years, range 13–67) in remission after TSS and with postoperative follow-up of at least 24 months (median 121.5, range 27–212 months) were included in the study. Remission was defined in the presence of at least two of the following criteria: i) post-surgical hyposurrenalism; ii) normal urinary free cortisol (UFC) and late-night salivary cortisol (LNSC) for at least 12 months; iii) serum cortisol < 50 nmol/l after 1 mg dexamethasone suppression test. All patients were submitted to at least one desmopressin (DDAVP) test during follow-up (6–12 months after surgery) and in 37/40 cases even in the diagnostic phase.
Results
Nine patients (22.5%, 8 F/1 M) experienced disease recurrence after a mean time of 32.2 months (range 18–62). Patients with macroadenomas were more prone to recur postoperatively P = 0.003). Early post-operative serum cortisol was lower in patients in prolonged remission compared to that of relapsed patients (55.5, IQR 33.3–54 nmol/l vs 191.5, IQR 57.5–417.5 nmol/l, P = 0.025), even though there was some degree of overlap between groups. A threshold of 76 nmol/l for serum cortisol was able to identify patient

at high risk of relapse with sensitivity (SE) and specificity (SP) of 75%. Patients with recurrence displayed a greater ACTH and cortisol response ($P=0.0001$) to DDAVP test compared to those in prolonged remission. An absolute increase in ACTH>7.6 ng/l was identified through the ROC curve analysis (AUC=0.8796; 95% CI :75–100) as the best predictor of recurrence, with SE of 88.9% and SP of 83.3%. After TSS, no differences in UFC and LNSC values were observed between groups.
Conclusions
The presence of corticotroph macroadenoma is a risk factor for CD relapse. DDAVP test is more accurate than the evaluation of serum cortisol in the immediate post-surgical period in predicting late recurrence. The re-appearance of a positive response to this test is an early marker of future relapse, that precedes the increase in LNSC and UFC by several months thus patients displaying such alteration should be closely monitored.

Long-term response to cabergoline treatment in men with macroprolactinoma is independent of tumor size

Yaron Rudman[1,2], Hadar Duskin-Bitan[1], Barak Pertzov[3], Yossi Manisterski[4], Hiba Masri-Iraqi[1] & Ilan Shimon[1]
[1]Rabin Medical Center, Beilinson Hospital, Institute of Endocrinology and Metabolism, Petah Tikva, Israel; [2]Rabin Medical Center, Beilinson Hospital, Internal medicine E, Petah Tikva, Israel; [3]Rabin Medical Center, Beilinson Hospital, Pulmonary institute, Petah Tikva, Israel; [4]Maccabi Health Care Services, Endocrinology and Metabolism clinic, Tel Aviv, Israel

Objective
To study the outcomeof menwith macroprolactinoma followingcabergoline treatment based on tumor size.
Design
A retrospective cohort study using a single tertiary referral center registry.
Methods
The study included 96 men with macroprolctinoma, aged 16–84 years (mean 47.3 years) treated from 1993 to 2019,for a mean follow-up of 7.5 years. The cohort was subdivided into 3 groups according to baseline adenoma diameter: group A, adenomas of 10–19 mm ($n=36$), group B,20–39 mm ($n=43$), and group C,giant prolactinomas ≥40 mm ($n=17$). Cabergoline was started at a weekly dose of 0.5 mg and progressively increased as necessary (weekly cabergoline dose, 0.5–10 mg). Nineteen men required pituitary surgery, 3 (8%), 10 (23%), and 6 (35%) in group A, B and C, respectively.
Results
Mean prolactinoma maximal diameter at presentation was 15.0, 28.1 and 49.8 mm in group A, B and C, respectively, decreasing following treatment to 7.6, 13.6 and 16.6 mm ($P<0.01$). Mean baseline prolactin levels were 685, 2,134 and 24,316 ng/ml ($P<0.01$) in group A, B and C,decreasing following treatment to 15, 68 and 31 ng/ml ($P=0.48$). Prolactin suppression to <3 ×ULN was achieved in 34 (94%; mean weekly cabergoline dose, 1.2 mg), 35 (81%; cabergoline dose, 2.0 mg) and 14 (82%; cabergoline dose, 2.8 mg) men ($P=0.21$) in the different groups. Treatment duration until complete prolactin normalization was 10.8, 17.9 and 21.9 months, occurring in 33 (92%), 31 (72%) and 14 (82%) men in group A, B and C, respectively. Visual defect was depicted in 4 (11%), 14 (33%) and 9 (56%) patients ($P=0.03$) in group A, B and C, respectively. Improvement was achieved in 4/4, 13/14 and 9/9 men. Residual visual field impairment at the end of follow-up was noticed in 0 (0%), 7 (16%), and 6 (40%) patients ($P=0.01$)in group A, B and C, respectively. Low baseline testosterone was discovered in 26 (72%), 40 (93%) and 17 (100%) patients ($P<0.01$) in group A, B and C. Hypogonadism following treatment persisted in 2 (6%), 5 (11%) and 2 (12%) men, respectively ($P=0.61$). Sexual dysfunction at presentation was reported by 23 (68%), 33 (79%) and 14 (82%) patients in group A, B and C, respectively, but improved in 21/23 (91%), 25/29 (86%) and 10/13 (77%) patients in the different groups.
Conclusion
Cabergoline is very effective in most men with macroprolactinoma, regardless of initial tumor size.

Inferior petrosal sinus sampling – 16 years of experience from a single tertiary center in Israel

Matan Fischer[1], Avivit Cahn[1], Benjamin Glaser[1], Gil Leibowitz[1], Joshua Stokar[1], Rivka Dresner-Pollak[1], José E. Cohen[2] & J. Moshe Gomori[3]
[1]Hadassah-Hebrew University Medical Center, Endocrinology and Metabolism Service, Department of Medicine, Jerusalem, Israel; [2]Hadassah-Hebrew University Medical Center, Department of Neurosurgery, Jerusalem, Israel; [3]Hadassah-Hebrew University Medical Center, Department of Endovascular Neurosurgery and Interventional Neuroradiology, Jerusalem, Israel

Introduction
IPSS (Inferior petrosal sinus sampling) is a reliable test for differentiating Cushing's disease from ectopic ACTH secretion. In the past 30 years, Hadassah Hebrew University Hospital has been the sole national referral center for IPSS in Israel, carrying out the test for all patients country-wide.
Methods
In this retrospective study we reviewed the records of all patients who underwent IPSS in our institution, for whom electronic data were available. Medical records were reviewed, and additional information was collected from the referring endocrinologists.
Results
Between 2003 and 2019 IPSS was performed in 63 patients. Male/female ratio was 19/44 and the average ± s.d. age was 45.1±14.9. Indications for referral included: absence of a visible pituitary adenoma on MRI (43patients, 68.3%); inconclusive biochemical testing (16 patients, 25.4%); and persistent hypercortisolemia following prior pituitary surgery (12 patients, 19.0%). Over one indication per patient may have been listed. IPSS results compatible with pituitary ACTH secretion were found in 52/63 patients (82.5%), of whom 48/52 (92.3%) underwent subsequent pituitary surgery. Biochemical cure was reported for 31/52 patients (59.6%) and 6/52 (11.5%) had residual or recurrent disease, although pathological results indicated pituitary adenoma. Thus, in 37/52 (71.2%) patients with IPSS results compatible with pituitary ACTH secretion, Cushing's disease was confirmed. The final outcome was unknown in 15/52 (28.8%) patients, of whom 4 did not undergo surgery and in 11 hypercortisolemia did not resolve following surgery and confirmatory pathology results were unavailable. IPSS test results were consistent with ectopic ACTH secretion in 11/63 patients (17.5%). A documented ACTH secreting ectopic tumor was discovered in 4 patients (1 medullary thyroid carcinoma and 3 carcinoid), 3 were found to harbor an adrenal adenoma and in 2 the source of ACTH hypersecretion was not found. Pituitary surgery was performed in two patients in spite of IPSS results indicating an ectopic source of ACTH, and their hypercortisolemia had subsequently resolved. Overall, IPSS correctly established the diagnosis in 44 (69.8%) patients – accurately revealing a pituitary source in 37 patients and a non-pituitary source in 7 patients. A false negative result was noted in 2 patients (3.2%). The high rate of inconclusive outcomes (17/63, 27.0%) precludes reliable estimation of sensitivity and specificity of the test. No major complications of the IPSS procedure were documented.
Conclusions
In this select population of diagnostically challenging patients with Cushing syndrome, IPSS was safe and feasible, and led to definitive diagnosis in 69.8% of the patients.

Determinants of epicardial fat in patients with acromegaly

Betina Biagetti, Raúl Herance, Anna Casteràs, Roser Ferrer, Jordi Mesa & Rafael Simo Canonge
Vall d'Hebron University Hospital, Barcelona, Spain

Background
Epicardial adipose tissue (EAT), the visceral fat of de myocardium, has been positively related to insulin resistance (IR), cardiovascular risk and the left ventricular myocardial mass. Whether EAT thickness in acromegaly is mediated by GH/IGF-1, IR or other factors remains to be elucidated.
Objective
The aims of this study were: 1) To investigate whether EAT in patients with ACRO is linked to IR and pro-inflammatory and anti-inflammatory related cytokines, 2) To examine whether EAT is related to circulating GH/IGF-1 and its metabolic signature: low serum levels of branched amino acid (BCAAs). 3) To assess whether EAT is related to myocardial hypertrophy.
Methods
Thirty patients with acromegaly were included in the study. EAT andventricular myocardial masswere assessed by echocardiography. Circulating levels of pro-inflammatory and anti-inflammatory cytokines, glucose and insulin were measured using commercial kits. Serum BCAAs were assessed by 1-H-MR.
Results
We analysed 30 patients: 5 were active despite medical treatment, 14 controlled and 11 in remission. EAT was positively associated with HOMA-IR (rho: 0.40, p:0.03)). Conversely adiponectin, was negatively correlated (rho: –0.43 p: 0.02). We did not find any relationship between EAT and GH/, IGF-1 or BCAAs. In addition, EAT was unrelated to myocardial mass.
Conclusion
EAT positively correlated with HOMA-IR and negatively with adiponectin. This relationship seems not to be mediated by GH/IGF-1 or BCAAs. Our results suggest that other factors unrelated to GH/IGF-1 but directly related to IR are the main responsible of the excess of EAT observed in patients with acromegaly.

Disconnection hyperprolactinaemia and its correlation with tumour size: A study of 210 patients with histologically proven non-functioning pituitary macroadenomas

Arpan Das[1], Omar Elalfy[2], Caroline Hayhurst[3], Pablo Goetz[3], Amr Mohamed[3], J Steve Davies[1], D Aled Rees[1] & Andrew Lansdown[1]
[1]University Hospital of Wales, Department of Endocrinology, Cardiff, United Kingdom; [2]School of Medicine, Cardiff University, Cardiff, United Kingdom; [3]University Hospital of Wales, Department of Neurosurgery, Cardiff, United Kingdom

Background
Serum prolactin levels at presentation can be useful in distinguishing between non-functioning pituitary macroadenomas and prolactinomas in order to guide appropriate therapy. Although thresholds have been suggested to distinguish between the two tumour-types, there remains some debate regarding discriminatory levels.
Objective
To assess the baseline serum prolactin levels in a series of patients with histologically-proven non-functioning pituitary tumours and to correlate prolactin levels with size of tumour, which may reflect degree of stalk compression.
Methods
Patients presenting to the University Hospital of Wales, Cardiff, with non-functioning pituitary adenomas (histologically proven) between 2011–2019 were studied by examining biochemical, histological and radiological data.
Results
A total number of 210 patients with histologically-proven non-functioning pitutiary macroadenomas were identified (130 male, 80 female). The median age at surgery was 57 yrs (range 24–86 yrs). Median prolactin inthe total group was 408 mU/l (range 3–3390), males 321 mU/l (range 35–1581), females 656 mU/l (range 3–3390). 96/210 (45.7%) patients had a high prolactin. 24/96 (25%) of these patients were on medications that could cause a high prolactin. Median prolactin for patients on medications was 792 mU/l (range 443–3390). Median male prolactin on medications was 766 mU/l (range 443–1450) and in females 792 mU/l (range 618–1880). In the total group, 88.1% had serum prolactin <1000 mU/l and 99.0% <2000 mU/l. Of the 2 patients with prolactin >2000 mU/l, one was taking an oestrogen preparation for initial presumed polycyctic ovary syndrome. There was a negative correlation between tumour size and prolactin levels with Pearson's correlation of –0.09 ($P=0.24$). Those with tumour size <10 cm^3 had mean prolactin 561 mU/l compared to 486 mU/l in those with tumours >10 cm^3 ($P=0.3$).
Conclusions
Our large data series supports previous evidence that serum prolactin is rarely >2000 mU/l in non-functioning pituitary adenomas. In these cases a trial of dopamine agonist therapy is warranted to see if there is any reduction in tumour size. Although a negative correlation between tumour size and serum prolactin was seen, this was not found to be statistically significant.

Role of 1 mg ACTH Stimulation Test to predict adrenocortical reserve and need of glucocorticoid therapy in non-functioning pituitary adenomas undergoing surgery

Arpit Garg[1], Sunil Mishra[1], Ambrish Mithal[1], Sudhir Dubey[2] & VP Singh[2]
[1]Medanta – The Medicity, Department of Endocrinology and Diabetes, Gurugram, India; [2]Medanta – The Medicity, Department of Neurosurgery, Gurugram, India

Background
Peri-operative glucocorticoids are routinely administered to patients undergoing trans-sphenoidal surgery for non-functional pituitary adenomas (NFPA) irrespective of the integrity of hypothalamic-pituitary-adrenal (HPA) axis.
Aim
To evaluate HPA axis before and three months after endoscopic trans-sphenoidal adenomectomy (E-TSA) in patients with clinically NFPA utilizing 1 mg ACTH stimulation test and determine the need for glucocorticoid administration.
Design
Open prospective study.
Setting
Tertiary care referral hospital.
Patients
From July 1st, 2017 to December 31st, 2018, 63 consecutive patients (48 ± 12.5 years, M:F = 2.3:1) with intra/suprasellar non-functioning pituitary adenoma requiring surgical excision were enrolled in this study.
Interventions
Glucocorticoids were administered to patients with demonstrable hypocortisolism. Perioperative glucocorticoids were administered to patients with peak cortisol <16 µg/dl during 1 mg ACTH test preoperatively. Postoperatively, glucocorticoids were given to patients with 0800 cortisol <8 mg/dl on the third postoperative day. At three months follow up, glucocorticoids were given to patients with peak cortisol <16 µg/dl on LDACTH test. Main outcome measurements: Stimulated cortisol using low dose (1 mg) ACTH test (LDACTH) was determined preoperatively. After E-TSA, 0800 cortisol was determined on the third post-operative day and LDACTH test was repeated at three months after surgery.
Results
Hypocortisolism was present in 43 patients (68.2%) pre-operatively and persisted in 33 patients (52.4%) on the third post-operative day. Thirty-three patients (52.4%) had hypocortisolism at three months after surgery. Fourteen patients (22.2%) didn't require glucocorticoids during the entire study period and thirty patients (47.6%) didn't require glucocorticoids after three months. None of the patients developed adrenal crisis during the study. There was a significant correlation between postoperative day third 0800 cortisol ≥ 8 mg/dl and stimulated cortisol (LDACTH) ≥ 16 mg/dl at three months ($r=0.62$, $P<0.0001$). Postoperative day third 0800 cortisol <8 mg/dl had 75% sensitivity and 58.1% specificity in predicting adrenal insufficiency at three months after surgery (AUC 0.66, $P=0.026$).
Conclusions
HPA function is preserved in significant proportion NFPA patients undergoing E-TSA. Perioperative glucocorticoids should be given only in patients with demonstrable preoperative hypocortisolism on 1 mg ACTH test. Postoperative day third 0800 cortisol <8 mg/dl is a reasonable predictor of adrenal insufficiency at three months after surgery.

Gigantism associated with hyperprolactinemia due to a pituitary macroadenoma in an adolescent girl

Spyridon Nikitas Skarakis[1], Georgios Chroussos[2], Christina Kanaka-Gantenbein[2], Evangelia Charmandari[2] & Feneli Karachaliou[1]

[1]Attikon University Hospital, Third Department of Pediatrics, Attikon University Hospital, National and Kapodistrian University of Athens, Chaidari, Greece; [2]'Aghia Sofia' General Children's Hospital, Division of Endocrinology, Metabolism and Diabetes, Athina, Greece

Aim
To describe the clinical course of an adolescent girl with gigantism.
Background and methods
In young persons with open epiphyses, overproduction of GH results in gigantism, with consequent longitudinal growth acceleration[1]. Pituitary gigantism is extremely rare, and its cause in the majority of patients is a pituitary adenoma[1]. Here, we present a 12, 5 years-old girl investigated for tall stature [183.5 cm (+4.24 SDS)].
Results
In the case reported here, the girl exhibited significant growth acceleration since she was 7 years-old, with coarsening of her facial features, and scoliosis of her thoracic spine. Her initial workup revealed a high insulin-like growth factor 1 (IGF-1), GH, and prolactin level, with no suppression of GH at the oral glucose tolerance test (OGTT); ACTH and cortisol values as well as thyroid function were within normal ranges. Magnetic resonance imaging (MRI) of the pituitary revealed a homogenous and diffusely enlarged pituitary gland, attributed to a pituitary macroadenoma (7.7×16 mm), which extended outside the pituitary gland. Whole exome sequencing analysis did not show any pathological findings. Thyroid ultrasound revealed cystic and solid nodules, with benign FNA. Firstly, she was treated with octreotide and cabergoline, followed by transsphenoidal surgical removal of the tumor. Postoperative levels of IGF-1 and prolactin decreased significantly; however GH levels at the OGTT test were partially suppressed, consistent with residual disease. Therefore, she underwent adjunctive radiation therapy. At 3-year follow-up, pituitary MRI findings represent an empty sella without significant functioning pituitary tissue, with remaining pituitary tumor mainly at the lateral sides of the sella. Her OGTT shows sufficient suppression of the GH level and her IGF-1 is in the lower side of the normal limit for her age, with stable clinical remission. At present, she is under octreotide treatment with no complaints, while cabergoline was stopped by the time prolactin levels were decreased.
Conclusion
This case demonstrated the difficulty of treating gigantism due to a GH/prolactin secreting pitutitary macroadenoma. At the same time, GH oversecretion is related to nodular thyroid disease, which requires careful evaluation with thyroid ultrasound. Genetic basis of the disease remains unclear in our patient.

Cabergoline resistance in a patient with prolactinoma with debut before puberty

Natalia Fedorova, Larisa Dzeranova, Ekaterina Pigarova, Svetlana Vorotnikova
Endocrinology Research Center, Moskva & Russian Federation

Prolactinomas are the most common hormone-active pituitary tumors, most common in young women, whose main reason for going to the doctor is menstrual irregularity. At the onset of the disease before puberty in children, there is a delay in sexual development, in girls primary amenorrhea.
A 27-year old woman has been observed since 15 years, when hyperprolactinemia was first detected, level of PRL was 10 900 IU/l, and according to MRI pituitary endosellar microadenoma. Cabergoline therapy was prescribed, which the patient received irregularly. The dose of cabergoline is gradually increased to 3.5 mg per week. However, no decrease in prolactin levels was observed. Adenoma growth was noted. After 7 years of observation, an increase in the size of adenomas with supra-parasellar growth (16×18×26 mm), prolactin levels ranged from 11 230 –16 800 IU/l. In connection with the patient's refusal from surgery, the dose of cabergoline was increased to 4.5 mg per week. However, against this background, no positive dynamics were observed. During the entire observation period, the patient has primary amenorrhea, decreased libido, and obesity (BMI 35). On examination: the mammary glands are not sufficiently developed. At the age of 32, the patient began to notice headaches. When examining PRL was 16800 mU/l, the negative dynamics of the size of the adenoma: dimensions 21×22×18 mm with parainfrasurpasellar growth, the distance to the chiasm 2.5 mm. The patient is again offered an operation, to which she agreed. The patient underwent transnasal transphenoid adenomectomy. The histological examination and immunohistochemistry of surgical sample confirmed PRL-secreting pituitary adenoma, Ki-67–7.4%, positive p53. In hormonal blood tests in the postoperative period, the prolactin level is 498–742 IU/l. There were no signs of diabetes insipidus, adrenal insufficiency, or secondary hypothyroidism. 2 months after surgery, menstruation first came. In terms of monitoring and, if necessary, the appointment of hormone replacement therapy with sex hormones This clinical case demonstrates the delay in sexual development in a girl of 15 years with hyperprolactinemia, as well as the success of transnasal adenomectomy with resistance to cabergoline.

A rare etiology of hyperprolactinemia: Factitious hypoglycemia

Mehdi Kalthoum[1], Radhouan Gharbi[2], Hajer Kandara[2], Meriem Adel[2], Manel Jemel[2] & Ines Kammoun[2]
[1]Hospital Charles Nicolle, Endocrinology-diabetology, Tunis, Tunisia; [2]Institut De Nutrition, Endocrinology-diabetology, Tunis, Tunisia

Introduction
While prolactin is most well known for its role in lactation and suppression of reproduction, its physiological functions are quite diverse. There are many etiologies of hyperprolactinemia, including physiologic as well as pathologic causes. Factitious hypoglycemia a rare case of induced hyperprolactinemia
Case report
We report a case of 17-years-old girl presented to with sever hypoglycemia mesured at 30 mg/dl. The patient had no significant medical personal history, and she had a younger sister with type 1 diabetes mellitus. Physical examination of the patient showed: weight of 44 kg, BMI = 20 kg/m^2 and bilateral induced galactorrhea with no other abnormalities. Laboratory analysis revealed normal renal and hepatic function and confirmed the exogenous injection of insulin with hyperinsulinism at 191uUI/ml and low C-peptid level 0.71 ng/ml concomitant to hypoglycemia at 37 mg/dl. Endocrine studies were notable for high levels of prolactin 3063 mUI/ml (102–496 mUI/ml), normal adrenal gland function (cortisol = 512 nmol/l after Synacthen test) and normal thyroid hormones level (TSH = 0.67 uUI/ml and FT4 = 17.95 pmol/l). Magnetic resonance imaging of the pituitary gland was done and showed no abnormalities. The patient was referred to psychiatric evaluation and management. On follow up she had no recurrent episodes of hypoglycemia, she had no more galactorrehea and prolactin level returned to normal in 3 weeks (prolactin = 370 mUI/ml).
Conclusion
It is known that are many physiologic and pathologic causes of hyperprolactinemia. Stress is an important physiologic cause of hyperprolactinemia, and its clinical significance is still being explored. We report a rare case of factitious hypoglycemia as cause of stress-induced hyperprolactinemia.

Pituitary gland metastasis of endometrial cancer: A case report

Aydan Farzaliyeva[1], Özlem Turhan İyidir[2], Feride Pınar Altay[2] & Neslihan Başçıl Tütüncü[2]
[1]Başkent University, Internal Medicine, Turkey; [2]Başkent University, Endocrinology and Metabolism

Introduction
Tumour metastasis to pituitary gland is very rare and constitutes only 1% of all pituitary lesions. Breast and lung cancer are the most common neoplasms reported to metastasize to pituitary gland. Most of the pituitary metastasis are asymptomatic, and thus can be easily overlooked in imaging studies.

Polyuria and polydipsia due to diabetes insipidus are the most common sypmtoms in these patients. Patients may also present with visual impairment and symptoms of panhypopituitarism. Here, we present a case of endometrial carcinoma with pituitary metastasis.
Case
71-year-old female presented with a one-week history of loss of apetite and nausea. When questioned, she also reported headache and mild polyuria. One week before admission, she developed gradual right palpebral ptosis, diplopia, and progressive deterioration of vision. Her initial cranial MRI revealed 17×17 mm contrast-enhanced sellar tumor and brain edema. The main differential diagnosis of the sellar mass was pituitary metastasis of malignancy. The patient admitted initially to Neurology Department. On admission, her physical examination was normal except for the low blood pressure and right palpebral ptosis. Her ophtalmologic examination confirmed third nerve palsy. She had a history of endometrial serous carcinoma diagnosed in 2017, and she had undergone total histerectomy,bilateralsalpingo-oophorectomy, bilateral pelvicand para-aorticlymph nodedissection and omentectomy. After six cycles of paclitaxel-carboplatin, 18F-fluorodeoxyglucose (FDG) positron emission tomographic/computed tomographic (PET/CT)revealed liver and bone metastasis. She received six cycles of bevacizumab and doxorubicin, and she was on remission until her follow-up visit in June 2019. Routine laboratory evaluation showed a mild hypernatremia (Na=151 mEq/l) and low urine density (1005). Initial pituitary hormonal assessment demonstrated panhypopituitarism. Hypernatremia, low urine density and osmolality were compatible with diabetes insipidus. She was immediately treated with steroids, levothyroxine and desmopressin after the diagnosis. In subsequent days, her sodium levels were back to normal and urine output decreased. An 18F-FDG-PET-CT confirmed pituitary metastasis. Unfortunately, the patient was lost a week later due to extensive tumor burden. An autopsy was not performed.
Discussion
In conclusion, we present a case with sellar mass,ophthalmoplegia, headaches, hypopituitarism, mild diabetes insipidus, and known history of malignancy; imaging studies revealed pituitary metastasis. To the best of our knowledge, this is the second case of pituitary metastasis of endometrial carcinoma. Sudden onset of diabetes insipidus and ophtalmoplegia in a patient with known history of malignancy should raise the suspicion of pituitary metastasis.

Microprolactinoma, PCOS Or stress induced hyperprolactinemia? – case report

Luciana Oprea[1], andreea banica[1], Iuliana Ilie[2], Carmen Iordachescu[1] & Madalina Musat[1,3]
[1],C.I. Parhon'' National Institute of Endocrinology, Bucharest, Romania; [2]Gral Medical Clinic, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Hyperprolactinemia is one of the most common problems in clinical endocrinology. It relates with various etiologies (physiological, pharmacological, pathological), the clarification of which requires careful history taking and clinical assessment.
We present the case of a 15-year-old girl, with history of secondary amenorrhea and headache in the presence of mildly elevated prolactin level, diagnosed as a microprolactinoma on MRI scan (4–5 mm) and treated with cabergoline (1 mg/week) for 2 years. At presentation she had resumed menses with low prolactin. Cabergolinewas stopped for 5 months,while she remained asymptomatic, with monthly menstrual cycles induced by progesterone. Biochemistry revealed: normal thyroid function tests, hyperprolactinemia: 4 × ULN (1229 uUI/ml) with equivocal reduction after PEG-47%), normal estradiol, low gonadotropes, normal IGF-1, normal urinary free cortisol, normal 17-(OH) progesterone and normal testosterone level. Pelvic ultrasound showed normal aspect of the ovaries. Sequential Pituitary MRI (2017): incidentaloma 4–5 mm; 2018: microadenoma (5–6 mm), (2019) stationary lesion of 7 mm after 2 yrs of cabergoline. The etiology of the elevated prolactin and of the secondary amenorrhea is challenging in this case, also the need of cabergoline treatment. Most guidelines propose in case of normal prolactin levels and no visible tumor remnant on MRI, after 2 years of low dose cabergoline, to try to stop medication. In this case, the presence of stationary, but visible pituitary microadenoma on MRI and resumed hyperprolactinemia after cabergoline cessation, could be indicative of either stress induced or tumor-secreting PRL, but there is no clear cut-off value of serum PRL level that could be usedto distinguish between them. Dimitriadis G *et al.* proposed the cutoff of PRL level exceeding 85.2 ng/ml in women with PCOS that is suggestive of a PRL -producing adenoma. In addition, pituitary MRI could be justifiable in young PCOS patients with milder PRL elevation, low LH levels and concomitant symptoms suspicious of a pituitary adenoma (Dimitriadis G, Angelousi A, Mehta H, Shad A, Mytilinaiou M, Kaltsas G, et al. The value of PRL in predicting prolactinoma in hyperprolactinemic PCOS. European Journal of Clinical Investigation. 2018;48:e12 961). In our case,the absence of PCOS criteria is limiting our possibilities to use this threshold. We will discuss the differential diagnosis and management of this unusual case.

A prolactinoma of rare localization as part of familial isolated pituitary adenomas

Hind Asbar, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Mohammed VI University Hospital, Marrakech, Marrakesh, Morocco

Introduction
The syndrome of familial isolated pituitary adenomas (FIPA) or predisposition to pituitary adenomas (PAP) is characterized by the presence within the same family of at least 2 isolated pituitary adenomas without any other type of associated endocrine tumor. We report the case of a prolactinoma attached to the pituitary stalk as part of FIPA, revealed by erectile dysfunction.
Case report
A 40 year old man presented with eretile dysfunction since the age of 19. The investigations revealed a hyperpr *et al.* olactinemia at 289 ng/ml, a normal IGF1 for the age, hepatic, renal function, calcium levels, and the rest of the pituitary showed no abnormality. Pituitary MRI revealed the presence of a 27 × 21 × 14 mm mass suspended from the pituitary stalk. In the presence of a family history of 2 paternel cousins treated for isolated prolactinomas the diagnosis of familial isolated pituitary adenoma was established.
Discussion
More than 200 families with FIPA have been described in the medical literature. These pituitary tumors may present as homogenous with the same tumor phenotype or heterogeneous with different patterns of pituitary tumor phenotypes (GH, Prolactine, ACTH secretion or non functioning pituitary adenomas) within the same kindred. Patients with FIPA are significantly younger at diagnosis and have significantly larger pituitary adenomas than matched sporadic pituitary adenoma counterparts. About 20% of FIPA have mutations in the aryl hydrocarbon receptor interacting protein gene (AIP) usually associated with a worse outcome. Genetic study was not feasible at our level.
Conclusion
Familial isolated pituitary adenomas (FIPA) must be searched from anamnesis in front of any pituitary tumor and search by PCR (mutations of the AIP gene) given its prognostic interest. Our case is interesting not only by localization of the pituitary adenoma but also by the familial background.

AEP708

A rare coexistence of acromegaly, myasthenia gravis, sicca syndrome, and elevated serum IgG4 levels: A single case report

Wan-Chen Wu[1] & Abel Po-Hao Huang[2]
[1]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan; [2]National Taiwan University Hospital, Surgery, Taipei, Taiwan

62-year-old woman was an employee of catering service. She had progressive limb weakness, easpecially proximal part since May, 2015, with diurnal change. She had difficulties in lifting arms, holding plates steady, and knee buckling while walking, which made her quit the job. Generalized myasthenia gravis (MG) was confirmed by positive acetylcholine receptor antibody (12.8 nmol/l) and marked decremental changes in repetitive stimulation test in November, 2015. Her limb weakness was much improved under pyridostigmine treatment. Chest CT scan revealed no thymoma, but thyroid nodules were incidentally found. Thyroid function test was normal. Thyroid ultrasound showed bilateral multinodular goiter, and fine needle aspiration

cytology showed negative for malignant cells. Otherwise, persistent elevation of serum IgG4 (214–249 mg/dl) was incidentally noted since May, 2016. She had dry mouth and dry eyes, but denied pancreatitis or mass lesions. Laboratory evaluation showed elevated ESR (27 mm/1-hr), positive of anti-ENA antibody (Ab) and anti-SS-A (8.028 U/mL), but negative of other auto-antibodies (anti-TPO, TA, ANA, anti-SS-B/dsDNA/SM/RNP/SCL-70/CENP/Jo-1/Ribosomal-P). She started hydroxychloroquine and pilocarpine treatment for Sicca syndrome. In November, 2019, thickened lips and widened teeth space were noted, but she denied enlarged fingers or feet, enlarged tongue, snoring, or arthralgia. Blood test showed high serum IGF-1 (588 ng/ml) and hGH (8.19 ng/ml). 75g OGTT showed paradoxical response and non-suppressible of GH (nadir 9.47 ng/ml) after glucose loading, and acromegaly was confirmed. Sella MRI revealed a 1.0 cm well-defined, non-enhancing nodule at left aspect of pituitary gland. She received endoscopic transnasal transsphenoidal adenomectomy on 2020/12/30. Serum GH level on post-operative day 1 decreased to 2.2 ng/ml. She reported subjectively better feeling with less limb weakness after surgery. Follow-up laboratory test in January, 2020 showed normal thyroid and adrenal function, and slightly decreased serum IgG4 levels (200 mg/dl). MG is a chronic autoimmune neuromuscular disease. Patients with MG usually have a higher incidence of other autoimmune disorders. The association between acromegaly and MG is extremely rare. There were only two cases of GH-secreting adenoma in MG patients reported. There was no report of association between acromegaly and other autoimmune disorders, such as sicca syndrome or IgG4-related disease, except one study reported higher thyroid autoimmunity in acromegaly patients than normal population. However, the identification of anti-pituitary antibodies in patients with acromegaly and other types of pituitary adenomas in some studies may suggest a possible involvement of autoimmunity in pituitary tumorigenesis.

A case of cyclic cushing's disease – cortisol surfing; catching the cortisol wave!

Mark Sutton-Smith[1], Zeeshan Yasin[1], Hessa Boharoon[1], Oluwagbemiga Idowu[1], Javier Alegre-Abarrategui[2], Ramesh Nair[3], Karim Meeran[1] & Jeannie F. Todd[1]
[1]Imperial Centre for Endocrinology, Imperial College Healthcare NHS Trust, Hammersmith and Charing Cross Hospitals, London, United Kingdom; [2]Department Histopathology, Imperial College Healthcare NHS Trust, Charing Cross Hospital; [3]Department Neurosurgery, Imperial College Healthcare NHS Trust, Charing Cross Hospital

A 28-year-old woman presents with a one-year history of marked weight gain of 18 kg, increasing hirsutism and night sweats. Clinically, hyperandrogenism and Cushing's syndrome were suspected. A diagnosis of Polycystic ovarian syndrome was made based on Rotterdam criteria and Metformin was initiated. Initial testing for Cushing's syndrome demonstrated a high 24 h urinary free cortisol (306 nmol/l) with incomplete cortisol suppression on an overnight dexamethasone suppression test (cortisol 60 nmol/l).However, a follow up low dose dexamethasone suppression test (48 h cortisol <28 nmol/l) and repeat overnight dexamethasone suppression test (Cortisol 44 nmol/l) were normal, casting doubt on the diagnosis of Cushing's syndrome. Clinical suspicion for Cushing's syndrome remained high as she continued to gain weight and experienced cyclic symptoms of rapid weight gain, easy bruising and emotional lability, and for this reason, further investigations were carried out. Serial midnight salivary cortisol and cortisone measurements were elevated ranging 3.5–7.4 nmol/l (normal <2.6 nmol/l) and ranging 12.8–31.3 (normal <18 nmol/l) respectively. Later a follow-up overnight dexamethasone suppression test showed no suppressibility of cortisol (84 nmol/l). Cyclic Cushing's syndrome was now suspected. A pituitary MRI showed a 3 mm right sided microadenoma and inferior petrosal sinus sampling clearly excluded ectopicACTHsecretion. Endoscopic transsphenoidal pituitary tumour resection was scheduled and performed using Brainlab image guidance. A day 4 cortisol (<28 nmol/l) was consistent with surgical remission and hydrocortisone was started. Histology of the pituitary lesion showed clear features of a Corticotroph adenoma. A follow up six-week insulin tolerance test confirmed secondary hypoadrenalism (peak cortisol 112 nmol/l).Post-operatively patient symptomology has now resolved with a reduction of Cushingoid features over time. She is having periods every 28 days (previously 26 days) and has plans for pregnancy in the coming year. Cyclic Cushing's syndrome is a rare, difficult to diagnose, form of Cushing's syndrome. It is often overlooked and is characterised by a cyclic pattern of normal cortisol interspersed with episodes of hypercortisolaemia. Intercycles periods can range from days to months. With the advent of the obesity epidemic it is becoming increasingly important for clinicians to remain vigilant when clinical suspicion of Cushing's syndrome is high despite conflicting Cushing syndrome screening results. We recommend the use of various cortisol screening tests in a temporal fashion and make use of a symptom diary whenever Cyclic Cushing's syndrome is suspected as the Cortisol Wave can be easily missed!

Successful pregnancy in a woman with acromegaly treated with lanreotide

Renata Orłowska-Florek, Joanna Sztembis, Agnieszka Gala-Błądzińska
Street Queen Jadwiga Clinical District Hospital No. 2 in Rzeszów, Clinic of Internal Medicine, Rzeszów, Poland

Introduction
Pregnancy in an acromegalic woman is rare and generally safe, but tumor expansion may occur. As this is a rare occurrence, little is known about the optimum management of such patients during pregnancy. We present the case of a woman with acromegaly treated with Lanreotide during pregnancy
Case report
A 29-year-old woman with acromegaly underwent transsphenoidal resection of invasive pituitary macroadenoma in August 2014, without cure. In November 2014, the IGF-1 level was 889 ng/ml (n:117 –239) and Lanreotide 120 mg was administered (s.c) every 6 weeks. In August 2015, a pregnancy in the woman was confirmed for the first time in week 14 due to irregular, rare periods. Lanreotide therapy was discontinued. In September 2015, MRI was repeated because of headache, sweating and hot flashes. The enlargement of the tumor, especially in cavernoussinus, was revealed. Lanreotide was reintroduced. The symptoms were reduced. The rest of the pregnancy was uneventful. On 29 January 2016, the patient gave birth to a healthy 2650 g son who has developed normally to date. The birth weight of her older children, born before her diagnosis, was 3200 g and 3100 g.
Conclusions
1. Lanreotide therapy during pregnancy is safe.
2. Exposure of the fetus to Lanreotide throughout pregnancy does not induce any malformations but it can induce slight fetal growth retardation.

Isolated adrenocorticotropic hormone deficiency in a female with ectopic posterior hypophysis

Georgios Boutzios[1], Eleni Koukoulioti[1], Konstantinos Bourgalis-Michalopoulos[1], Ilias Giovannopoulos[1], Myrto Miliou[1], Eleni Papaoiconomou[1] & Gerasimos Tsourouflis[2]
[1]National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]National and Kapodistrian University of Athens, Second Department of Propedeutic Surgery, Athens, Greece

Introduction
Some endocrine disorders, including hypophysitis and isolated adrenocorticotropic hormone (ACTH) deficiency, are caused by an autoimmune response to endocrine organs. Previous data have also shown that isolated ACTH deficiency may be associated at least in part with a paraneoplastic syndrome. We present a rare case with isolated ACTH deficiency along with ectopic posterior hypophysis.
Case presentation
A 53-year-old woman (menopause 45 yo), non-smoker, with a history of Hashimoto thyroiditis with normal thyroid function, osteopenia and cholelithiasis presented with fatigue and weakness gradually increasing in the last two months. Laboratory tests showed low morning ACTH: 9.8 pg/ml (n.v. 7–64), cortisol: 3.1 μg/dl (n.v. 6.2–19.4), DHEAS: 11 μg/dl (35.4–256) and Testosterone: <2.5 nmol/l (20–130), increased FSH and LH levels due to menopause and normal TSH, PRL and IGF-1 levels. Plasma renin activity and aldosterone levels were also normal. A pituitary MRI was performed and showed an ectopic posterior hypophysiswithout other abnormalities. An abdominal CT revealed atrophy in both adrenals. Due to the history of autoimmune thyroid disease, IgG4and CBG levels were also estimated and found to be within normal range. The patient was treated with hydrocortisone per os and showed rapid improvement of her symptoms.

Conclusion
Although the pathogenesis of some autoimmune endocrine diseases has been elucidated, it remains obscure for most. Further evaluation for the pathogenesis of isolated ACTH deficiency is needed.

Thickening of the pituitary stalk: About 4 cases

Aicha Bouzid[1] & Djamila Meskine[2]
[1]Medical University of Algiers, Endocrinology & Metabolism Laboratory Algiers 1, EPH Bologhine, Algiers, Algeria; [2]Medical University of Algiers. EPH Bologhine, Medecine, Algiers, Algeria

Introduction
Pathologies of the pituitary stem are very often revealed during diabetes insipidus. The introduction of MRI constituted, in this context, a major diagnostic contribution. We report 4 cases of thickening of the pituitary stem observations. These are 4 patients (3 women and one man) whose age varies from 30 to 47 years, the circumstances of discovery are represented by amenorrhea in women and polyuropolydipsic syndrome in men. Clinically, diabetes insipidus was found in 3 patients, a gonadotropic deficit in 2 patients, a thyrotropic deficit in one case and panhypopituitarism in one case. The etiological investigation made it possible to retain the diagnosis of sarcoidosis in 2 cases and the diagnosis of Langerhansian histiocytosis in a patient, it was negative in one case.
Discussion
The pituitary stem connects the hypothalamus and the pituitary gland. It consists of two parts: at the top, the infundibulum, in direct contact with the tuber cinerum, at the hypothalamic level, at the bottom, the pituitary stem itself, which is extended by the posterior lobe of the pituitary gland. In case of pathology of the pituitary stem, the clinical picture is dominated by the occurrence of diabetes insipidus. It's the most common mode of revelation. The thickening of the pituitary stem associated with diabetes insipidus can be observed in the event of tumor, granulomatous or inflammatory pathology. The etiological diagnosis of 'large pituitary stems' is sometimes very difficult. Tumor lesions should be considered first, especially in children or adolescents, as they condition the prognosis and treatment. In adults, inflammatory or granulomatous causes are more common. In the case of a large pituitary stem, completely isolated, simple monitoring, without histological evidence, can be offered (by renewing the MRI at 3–6 months). A very prolonged monitoring of the remote MRI is essential (annual monitoring), in the hypothesis of a histiocytosis with prolonged evolution or of a germinoma, in particular in the child and the adolescent.
Conclusion
The stem can be the target of various infiltrative, infectious and tumor pathologies. An exhaustive etiological investigation is essential to guide therapeutic managemen

Pregnancy and pituitary adenomas: A case series

Roxana Dumitriu[1], Roxana Dusceac[1,2], Iulia Florentina Burcea[1,2], Ionela Baciu[1,2], Cristina Capatina[1,2], Anda Dumitrascu[1] & Catalina Poiana[1,2]
[1]National Institute of Endocrinology C. I. Parhon, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Department of Endocrinology, Bucharest, Romania

Introduction
Pituitary tumours may interfere with fertility and pregnancy may be uncommon in these cases, but some patients can conceive spontaneous. Also in pregnancy, due to the physiologic changes of the pituitary gland, gradual volume increase and cellular hyperplasia that target hormonal secretion, the evaluation of the pituitary function is very complex.
Clinical cases
We present 5 cases of female patients (24 – 35 years old) that were diagnosed with different pituitary tumours and conceived. 2 patients were with acromegaly, 1 of them with macroprolactinoma, 1 with with microprolactinoma and the last one with non-functional pituitary adenoma. All women conceived naturally. We report 6 pregnancies with a positive outcome out of a total of 9. The patients with acromegaly had macroadenomas, one of them had conceived before the biochemical diagnosis of acromegaly. The other patient had gonadotroph deficiency after transsphenoidal surgery and gamma-knife radiosurgery and substitutive therapy. She had a spontaneous pregnancy during the estroprogestative treatment. She had a decrease in IGF-1 during pregnancy which after pregnancy returned to pathological elevated values. The patient diagnosed with microprolactinoma had an early pregnancy failure before her diagnostic was established. The patient conceived (twin pregnancy) under treatment with dopamine agonist her disease was controlled, and it was stopped immediately after the confirmation of the pregnancy. Unfortunately due to major cardiac malformations of the foetuses pregnancy interruption was indicated. The patient with macroprolactinoma had conceived many years prior the diagnostic. After thediagnostic of macroprolactinoma she conceived under treatment with bromocriptine. The gynaecologist indicated pregnancy interruption. Due to the resistance under high doses of dopamine agonists the patient underwent 5 cycles of temolozolomide with good outcomes. She conceived again and the pregnancy outcome was good. The last patient from our series had a non-functional pituitary microadenoma and successfully conceived after several years of attempts. During pregnancy the hormonal profile showed elevated IGF-1 (2×upper normal limit), and GH slightly elevated, most likely due to the physiological changes in pregnancy. The pregnancy outcome was positive. During pregnancy hormonal follow-up was made using IGF-1, GH (assay with no distinction of pituitary GH versus placental GH, PRL (prolactin), visual field and pituitary imaging was performed after delivery.
Conclusions
Managing pituitary dysfunctions in pregnancy can be challenging. The indications are to stop any medications that control prolactin or GH hypersecretion during pregnancy. Patients with different pituitary disorders can have successful pregnancies, even in patients with uncontrolled hypersecretion.

Short stature in turner syndrome: Should we assess growth hormone secretion?

Elyes Kamoun, Ibtissem Oueslati, Marwa Chiboub, Meriem Yazidi, Wafa Grira, Fatma Chaker, Melika Chihaoui
La Rabta hospital, Department of endocrinology, Tunis, Tunisia

Introduction
Short stature is a common feature in Turner syndrome. It is caused by haplo-insufficiency of the SHOX gene. Growth hormone deficiency does not occur in this disorder as confirmed by the normal GH response to stimulation tests. However, few cases of coexisting GH deficiency and Turner syndrome have been reported. We herein describe two cases of GH deficiency in patient with Turner syndrome.
Observation 1
A 20-year-old patient was referred for delayed puberty. Physical examination showed a short stature with a height of 1 m38 (< −4 s.d.), dysmorphic features and female external genital organs, with Tanner stage 3. Her bone age was inferior to 17 years. On hormonal investigations, she had a primary hypogonadism (elevated FSH and LH levels and a low estradiol level), a severe GH deficiency and a corticotropin deficiency. Genetic testing confirmed the diagnosis of Turner syndrome. The pituitary magnetic resonance imaging (MRI) was normal. The patient was put on hormone replacement therapy.
Observation 2
A 16-year-old patient was referred for delayed puberty. On physical examination, she had a body height of 1 m 37(< −4 s.d.), multiples nevi and female external genital organs with Tanner stage 1. Her bone age was 9 years. She had a primary hypothyroidism, a primary hypogonadism, a severe GH deficiency and a corticotropin deficiency. Genetic testing confirmed the diagnosis of a classical Turner syndrome: 45 × 0. The pituitary MRI was normal. The patient was put on hormone replacement therapy.
Conclusion
These two cases highlight the necessity of GH investigations in patients with Turner syndrome and a severe short stature (body height < −4 s.d.). In addition, GH deficiency testing should be performed in the presence of at least one deficiency in the hypothalamic-pituitary axis. GH treatment is recommended in Turner syndrome. However, there are no recognized treatment recommandations in case of coexisting GH deficiency.

Case of differential diagnosis in a patient presenting with paroxysmal arterial hypertension

Irina Vaychulis
Federal State Budgetary Educational Institution of Higher Education 'South-Ural State Medical University' of the Ministry of Healthcare of the Russian Federation, Internal Medicine Department, Chelyabinsk, Russian Federation

Arterial hypertension (AH) may be the initial clinical presentation of various endocrine disorders. An accurate diagnosis provides an opportunity to achieve a cure of AH in some cases. Female patient, born in 1971, was referred to endocrinologist in 2018, at the age of 47 y, presented with AH and adrenal adenoma. Since the age of 35 y (2006), after the third delivery she had been suffering from AH with paroxysmal BP surges up to 180/120 mmHg, accompanied by panic, anxiety, sweating, tremor, palpitations, urge to urinate or defecate. Repeated urine catecholamines and metanephrines tests as well as adrenal US images were unremarkable. She had been followed by cardiologists with diagnose of hypertensive disease (paroxysmal hypertension). Despite regular taking 2–3 antihypertensive medications the paroxysmal attacks repeated occasionally. In 2017 the left-sided 17×14 mm adrenal mass (adenoma?) was found on CT and in 2018 she was referred to endocrinologist. Careful examination revealed moderate central body fat redistribution, normal BMI, rounded face and facial redness (though patient denied any significant changes in her appearance). No striae, easy bruising, hirsutism or thinning of the skin were found. Laboratory tests demonstrated normal 24-h urine metanephrines, 24-h urine free cortisol, plasma electrolytes, glucose, TSH, prolactin, renin and aldosterone, but increased ACTH level of 68-71-99 (normal<46) pg/ml, increased late-night salivary cortisol- 17,1 (normal<9.4) nmol/l and no suppression of plasma cortisolafter 1 mg overnight dexamethasone test. At the same time 4×4×2 mm microadenoma on pituitary MRI and osteopenia had been detected. The diagnosis of ACTH-dependent endogenous hypercortisolism (Cushing's disease) was established. Retrospective analysis of patient's medical history had revealed that in 2008 ACTH elevation up to 81.8 (normal≤63.3) pg/ml was detected, but the subsequent retesting had shown ACTH at the upper level of normal range. In 2012 and 2014 no microadenoma was clearly identified at the pituitary MRI. In 2019 the transsphenoidal resection of microadenoma was performed and Cushing's disease was histologically confirmed. After surgery BP and ACTH levels had returned to normal, and the paroxysmal attacks have not been recurred up to date. The non-typical features of this case comprise long duration of undiagnosed endogenous hypercortisolism with only manifestation of paroxysmal AH, inconsistent laboratory results, slow progression of rather modest signs of Cushingoid appearance, formation of unilateral adrenal mass. All these characteristics, more closely resembling the clinical picture of pheochromocytoma, could be misleading for cardiologists and resulted in the delayed correct diagnosis.

AEP716

A rare case of panhypopituitarism caused by TNF-α inhibitors

Vaios Koutroukas, Ioannis Dimitropoulos
University Hospitals Plymouth Trust, Diabetes and Endocrinology Department, Plymouth, United Kingdom

Aim
To present an unusual case of hypophysitis caused by TNF-α inhibitors and demonstrate the importance of astuteness with regards to endocrine axes testing when clinical circumstances indicate.
Case
A 78-year-old gentleman with known fistulating Crohn's disease (treated with adalimumab and infliximab in the past) presented with vomiting, dizziness, hyponatraemia and hypotension in early December 2018. SST showed he was cortisol-deficient, initially attributed to a right-sided adrenal haemorrhage (abdominal CT), as a result of previous ileal resection surgery.
In mid-December 2018, he was readmitted with diurnal and nocturnal polydipsia and polyuria and was subsequently diagnosed with diabetes insipidus. Further endocrinological testing revealed secondary hypogonadism and secondary hypothyroidism; low ACTH levels in combination with low cortisol levels confirmed secondary hypoadrenalism. Sequential MRIs raised the possibility of hypophysitis, which was further supported by the subsequent resolution of the inflammatory changes. He is currently receiving appropriate replacement therapy. Due to lack of precipitating factors or relevant past medical history, hypophysitis was attributed to a late effect of either adalimumab or infliximab.
Conclusions
This case highlights the importance of checking the integrity of different endocrine axes in light of an unexpected hormonal deficiency. Moreover, whilst it is well-known that immune checkpoint inhibitors, such as ipilimumab or nivolumab, can cause hypophysitis, it appears that TNF-α inhibitors can have a similar effect; the exact mechanism, though, remains to be elucidated.

Natural course of incidentally found nonfunctioning pituitary macroadenoma

Tina Dusek[1], Ana-Marija Kasnar[2], Ivana Kraljevic[3], Tanja Skoric Polovina[3], Mirsala Solak[4], Annemarie Balasko[4], Karin Zibar Tomšić[4], Hrvoje Popovac[4], David Ozretic[5], Ivan Jovanovic[5] & Darko Kastelan[4]
[1]University Hospital Center Zagreb; [2]Zagreb University School of Medicine; [3]University Hospital Center Zagreb; [4]University Hospital Center Zagreb, Endocrinology; [5]University Hospital Center Zagreb, Radiology

Introduction
The widespread use of neuroimaging leads to the increased detection of asymptomatic pituitary adenomasnot causing significant mass effect. Their optimal management remains unclear.
Aim of the study
To explore the natural course of incidentally found nonfunctioning pituitary macroadenomas.
Patients and methods
This was a longitudinal study that enrolled patients with clinically nonfunctioning pituitary macroadenomas who weren'tinitially referred to surgery either because of the relatively small tumor size or due to the increased surgical risk. Pituitary tumor size was regularly monitored with MRI. Significant increase/decrease in tumor size was defined as the increase/decrease of at least>3 mm in tumor diameter.
Results
The study included 41 patient (15 males, median age 59 years). Median tumor size was 15 mm (11–45 mm) in the largest diameter. Median follow-up was 36 months (range from 6 to 78 months). During follow-up, three patients were referred to surgery of whom only one had significant tumor growth. In 9 patients tumor size decreased, in 5 tumor size increased (only one of them needed surgical treatment) and in the remaining 27 patients no significant change in tumor volume was detected during follow-up.
Conclusion
The results suggest that it is quite unlikely for the initially asymptomatic nonfunctioning pituitary adenoma to undergo clinically significant increase in its size. It speaks in favor of the conservative approach in the management of that group of patients.

Evaluation of early predictors of metabolic syndrome in patients with gastroenteropancreatic neuroendocrine tumors (GEP-NET)

Filomena Bottiglieri[1], Roberta Modica[1], Luigi Barrea[1], Federica de Cicco[1], Roberto Minotta[1], Giovanna Muscogiuri[1], Silvia Savastano[1], Antongiulio Faggiano[2] & Annamaria Colao[1]
[1]Endocrinology Unit, Department of Clinical Medicine and Surgery, 'Federico II' University, Naples, Italy; [2]Endocrinology Unit, Department of Experimental Medicine, Sapienza University, Rome, Italy

Metabolic syndrome and obesity (MetS) are supposed to have a role in cancer but data analysing their association with GEP-NET are lacking. Aim of this study was to explore the association of early predictors of MetS with GEP-NET, usingas tools Fatty Liver Index (FLI), a predictor of non-alcoholic fatty liver disease (NAFLD)and Visceral Adiposity Index (VAI), a gender-specific indicator of adipose dysfunction. A cross-sectional case-control observational study was conducted. VAI and FLI were calculatedin GEP-NET patientsreferred to the ENETS Center of Excellence of Naples, Endocrinology Unity of Federico II University between January 2015 and November 2019, as well as control healthy subjects, age, sex and BMI-matched. VAI isbased on waist circumference (WC), body mass index (BMI), triglycerides, and HDL cholesterol levels. FLI isbased on BMI, WC, triglycerides and GGT. We enrolled 103 patients with histologically confirmed G1/G2 GEP-NET (53 M, 50 F; 57.06 ± 15.95 years). GEP-NET were G1 (60%), G2 (40%) and metastatic in 26%. Differences in VAI and FLI were observed in GEP-NET patients compared with 103 controls. GEP-NET had a higher value of VAI and FLI compared with controls($P < 0.001$). These differences were associated to GEP-NET aggressiveness. Both VAI and FLI were higher in G2 than in G1 ($P < 0.007$, $P < 0.002$ respectively), and in metastatic vs non metastatic ($P < 0.001$, $P < 0.005$ respectively). In addition, higher value of VAI and FLI were significantly correlated with progressive disease ($P < 0.001$). This is the first study reporting an association between early predictors of MetS, VAI and FLI, and GEP-NET. VAI and FLI may represent a tool of evaluation in all conditions in which overt MetS is not present in GEP-NET.

Experience in complex therapy of selective and non-selective dopamine agonists in women with resistant prolactinomas for recovering of ovulation function

Svetlana Vorotnikova, Larisa Dzeranova, Ekaterina Pigarova & Natalia Fedorova
Endocrinology Research Center, Moskva, Russian Federation

Experience in complex therapy of selective and non-selective dopamine agonists in women with resistant prolactinomas for recovering of ovulation function.

Introduction

Prolactinomas are the most common pituitary adenomas and dopamine agonists (DA) still remain the first choice of treatment. Nevertheless, it does not always exert an adequate effect and endocrinologists face the challenge of resistant prolactinomas more frequently. This problem is very important for women who desire to become pregnant. In view of this fact, the search for a new ways for overcoming medical resistance becomes one of pressing issues in endocrinology. We present two clinical cases of women with DA-resistant prolactinomas, which successfully conceived after addition of bromocriptine to stable long-term high-dose cabergoline treatment.

Clinical case #1

A 26-year old woman presented with menstrual disturbances since 15 years old, secondary amenorrhea, galactorrhea for 3 past years. Clinical examination revealed hyperprolactinemia (PRL 10 000 IU/l, no macroprolactinemia), endosellar macroprolactinoma (10 × 11 × 12 mm) without visual disturbances, hypoplastic uterus. Administration of carbegoline with maximum dose 3,0 mg per week didn't result in significant clinical or laboratory improvement. The further increment of cabergoline dose was not possible due to patient's socioeconomic problems. However, the recovery of menstrual function and decrease in prolactin level to 1800 IU/l was observed after complex therapy of selective and nonselective DA (cabergoline 3.0 mg/week and bromocriptine 8 mg/day). And after 3 months of the therapy the patient naturally conceived. No pregnancy, delivery or fetus-associated complications were noted. She had a term delivery of a girl, weight – 3000 g, length – 50 cm.

Clinical case #2

A 27-year old woman presented amenorrhea, prolactin level was 13 146 IU/l, by MRI microprolactinoma 8*8 mm was detected. The therapy with cabergoline was started in dose 0.5 mg per week with escalation to maximum dose 4.5 mg per week. Despite treatment menstrual disturbance were persisting and prolactin level decreased to 2010 IU/l. Ultrasound examination revealed normal follicular count without signs of ovulation. The patient was recommended to add to the therapy bromocriptine in dose 2.5 mg per day. In two months, the patient got pregnant without recovering of menstrual function. Nowadays clinical examination on 26 gestational week did not present any fetal problems.

Conclusion

These clinical observationsdemonstrate an overcoming medical resistance to DA and achievement of natural pregnancy in patients with resistant prolactinoma using combination of selective and non-selective DA.

An analysis of craniopharyngioma patients in malta: Epidemiology, patient characterisation and long-term sequelae

Sarah Craus[1] & Mark Gruppetta[1,2]
[1]Mater Dei Hospital, Malta; [2]University of Malta, Malta

Background

Despite being benign, craniopharyngiomas are challenging tumours to manage and can cause significant morbidity and mortality in both the paediatric and adult population.

Method

Our aim was to analyse epidemiology, patient characteristics and long-term sequalae through a population-based study in Malta. A thorough research was carried out to identify patients who were diagnosed with craniopharyngioma in our local population. Subjects were identified from various hospital databases. Presenting features, patient and tumour characteristics, treatment modalities, long-term sequelae and epidemiology were analysed.

Results

From a cohort of 29 patients, 62.1% were male. The mean age at presentation was 32.4 years (s.d. ± 19.0). 11 patients (37.9%) were diagnosed with childhood onset craniopharyngioma (age at presentation < 20 years) whilst 18 patients (62.1%) had adult-onset craniopharyngioma. Median follow up period since time of diagnosis was 13.0 years (IQR 5–25). For incidence estimates, 13 patients who were diagnosed between June 2008 and June 2019 were included. The background population formed 4.8 million patient-years at risk. The overall SIR was 3.0/1,000,000/year, with the highest SIR in the 10–19 year age group. The estimated prevalence rate was 52.7/1,000,000 people, with lower prevalence rates for childhood- compared to adult-onset (20.3/1,000,000 vs 32.4/1,000,000 people). Visual disturbances and symptoms secondary to raised intracranial pressure were the commonest presenting complaints. Most tumours were multi-cystic (42.9%) and were commonly located in the intrasellar region with suprasellar extension. The median longest tumour diameter was 31.0 mm (IQR 21–41), with statistically significant difference between childhood- and adult-onset disease; 43.0 mm (IQR 42.5–47.25) vs 27.0 mm (IQR 20.55–31.55) ($P = 0.011$). All 24 patients who underwent neurosurgical intervention (82.8%) had adamantinomatous craniopharyngioma. 58.6% of patients required radiotherapy. The commonest long-term sequalae were hormone deficiencies (93.1%), followed by obesity (20.7%). Most patients required hormonal supplementation of more than one pituitary axis. 7 patients (30.4%) had evidence of tumour regrowth or recurrence during follow-up. 3 patients passed away throughout their follow up.

Conclusion

This study enabled us to obtain important data on the epidemiology of craniopharyngiomas, which was previously lacking. It also enabled us to better characterise these tumours and their long-term sequelae, broadening our knowledge with an aim to improve the patients' quality of life.

Septo-optic dysplasia with late-onset diagnosis: An uncommon presentation of a rare disease

Vitória Duarte[1], Catarina Ivo[1], David Veríssimo[1], Sara Franco[2], Filipa Bastos[2], Mafalda Marcelino[1], Henrique Vara Luiz[2] & Jorge Portugal[2]
[1]Hospital das Forças Armadas, Portugal; [2]Hospital Garcia de Orta, Portugal

Background

Septo-optic dysplasia (SOD), also known as de-Morsier syndrome, is a rare congenital disorder characterized by any combination of optic nerve hypoplasia, pituitary dysfunction and midline abnormalities of the brain. Clinical diagnosis requires the presence of at least two of the features. This disorder is equally prevalent in males and females, with a reported incidence of 1/10,000 live births. There is wide variation in the severity of the clinical features found. The most common endocrine anomaly is GH deficiency followed by ACTH and hypothyroidism.

Case report
A 37-year-old man with complaints of chronic back pain performed a CT scan of the spine which revealed diffuse bone demineralization. Later, a DEXA scan confirmed the diagnosis of osteoporosis. Subsequently, laboratory studies were requested and a low testosterone level was identified. No relevant medical or family history. He did not have children. He denied asthenia or decreased libido. The patient presented normal body hair distribution, no gynecomastia, normal testicular volume, 79 kg and 173 cm. An evaluation of the pituitary axis confirmed a low testosterone level (155 ng/dl), with gonadotropins in the low normal range (FSH 2.7 UI/l, LH 2.2 UI/l), suggestive of central hypogonadism. TSH, Prolactin, ACTH, Cortisol, GH and IGF-1 levels were within the reference range. A brain MRI was requested and reported an absent septum pellucidum, thinning of the corpus callosum and underdevelopment of optic nerves, features compatible with septo-optic dysplasia. He was referred to an ophthalmologist yet no macula or optic disc defects were found. The patient started testosterone replacement therapy with good biochemical response. After the diagnosis, he fathered a child with a diagnosis of Costello syndrome. Both parents were then referred to the Genetic Department.
Discussion
Patients with SOD are often diagnosed during infancy with visual, neurologic or endocrine defects. The few adult patients reported in the literature were diagnosed due to drug-resistant epilepsy. Our patient was asymptomatic, thus the diagnosis was made during a clinical investigation for secondary causes of osteoporosis. The sole endocrine anomaly found was gonadotropin deficiency, the least common reported. Nonetheless, the diagnosis of SOD was based on the classic features presented on MRI.
It is curious that father and child were diagnosed with rare congenital diseases. Costello syndrome is characterized by short stature, developmental delay and a characteristic facial appearance. Only about 350 affected individuals have been reported worldwide. As far as we know, no relation between the two diseases have been described.

Doses of tolvaptan needed in chronic therapy of SIADH-induced euvolemic hyponatremia vary according to the etiology of SIADH

Xavier Pérez Candel[1], Celia Lopez Nevado[1], Martin Cuesta[1], Miguel Angel Rodriguez Cabezas[2], Virginina Puebla[2], Paz de Miguel[1], Emilia Gomez Hoyos[3], Teresa Ruiz[1], Alfonso Calle Pascual[1] & Isabel Runkle[1]
[1]Hospital Clínico San Carlos, Servicio de Endocrinología y Nutrición, Madrid, Spain; [2]Hospital Clínico San Carlos, Servicio de Farmacia Hospitalaria, Madrid, Spain; [3]Hospital Clinico de Valladolid, Servicio de Endocrinología y Nutrición, Valladolid, Spain

Introduction
Clinical trials indicate that Tolvaptan is safe and effective in the treatment of patients with sustained mild/moderate SIADH-induced euvolemic hyponatremia. Tolvaptan doses are often modified during chronic use. We present the weekly doses of a series of patients on chronic therapy, followed up in outpatient clinic.
Methods
Retrospective, cross-sectional. 114 patients receiving tolvaptan for chronic SIADH were followed up in a Hyponatremia outpatient clinic in a tertiary hospital, initiating therapy between 2011 and 2019. Therapeutic goal: euvolemia, and serum sodium (SNa) 138–140, inmmol/l. Patients were instructed to drink freely when thirsty, and during meals. Salt was freely added to diet. Tolvaptan doses were modified as follows: increased 7.5 – 15 mg/day if patients were euvolemic with SNa ≤ 136, without polydipsia. Doses were lowered 50% when SNa > 140 mmol/l, patients presented thirst, polyuria, or low central venous pressure (maximum height of the internal jugular vein pulse below the sternal angle).Classification according to etiology of SIADH/additional diagnosis, for comparison of weekly doses: medication-induced (interruption of medication not viable) (MED), idiopathic SIADH of the elderly (IDIO), non-oncological pulmonary disease (PULM),neurological/neurosurgical disease (NEURO), oncological ectopic SIADH (ONCO), patients with chronic SIADH of diverse etiologies and prior episodes of heart failure (HF), and OTHERS. Weekly doses, mg, compared among groups. [Interquartile range].
Results
66 (57.9%) women. Median age: 76 [65–83.3]. Mean Pre-tolvaptan Nadir SNa: 121.1 (s.d.:5.86). MED: 22/114 (19.3%) patients, IDIO: 25/114 (22%), PULM: 17/114 (14.9%), NEURO: 9/114 (7.9%),ONCO: 13/114 (11.4%), HF: 6/114 (5.3%), others: 22/114 (19.3%). Median months therapy: 11[5.3–33.5], 45[20–61], 27[12.5–61] months, 7 [4.5–20.5], 10 [7–26.5], 46 [20.8–69.8], 21.5 [10.5–38] respectively.
Final median doses were significantly lower than at start in MED: 26.25 [22.5–52.5] vs 105 [52.5–105] ($P<0.001$), IDIO 26.25[22.5–52.5] vs 105 [52.5–105] ($P<0.001$), PULM 26.25 [26.3–105] vs 105 [78.8–131.3] ($P=0.019$), NEURO 26.25 [0–65.62] vs 105 [52.5–105] ($P=0.002$), OTHERS 52.5[26.25–105] vs 105 [52.5–210] ($P=0.006$).
Final median doses were significantly higher in ONCO: 105 [52.5–262.5] than in MED: ($P=0.001$), IDIO ($P<0.001$), PULM ($P=0.043$), NEURO ($P=0.012$), OTHERS ($P=0.017$).
There was no correlation between pre-tolvaptan nadir SNa and final doses.
Mean nadir SNa during tolvaptan therapy: 135.35 (s.d.:2.85). Mean maximum tolvaptan SNa: 141.04 (s.d.:1.8).
Side effects
No patient presented hypernatremia, nor liver-enzyme elevation. Thirst and/or polyuria were indications for lowering dose.
Conclusion
Chronic ambulatory tolvaptan therapy in SIADH is safe and effective. Doses can often be reduced, with the exception of oncology patients and SIADH patients with a history of heart failure. Eunatremia seems to be easier to maintain than to attain.

Soluble alpha klotho measurement: Comparison of measurements by different commercially available assays in healthy subjects and active acromegaly

Junia Ribeiro de Oliveira Longo Schweizer[1], Katharina Schilbach[1], Michael Haenelt[1], Sylvère Störmann[2], Jochen Schopohl[2] & Martin Bidlingmaier[1]
[1]Ludwig Maximilians Universität, Endokrinologisches Labor – Medizinische Klinik und Poliklinik IV, München, Germany; [2]Ludwig Maximilians Universität, Medizinische Klinik und Poliklinik IV, München, Germany

Background
Recent studies reported high soluble α-klotho concentrations (α-klotho) in active acromegaly, with normalization after successful therapy. We showed that α-klotho correlates to GH and even better to IGF-I. So far, most studies employed an immunoassay from Immuno-Biological Laboratories (IBL) for measurement of α-klotho, but other assays are available. Agreement between assays remains questionable since α-klotho exists in several isoforms: KL1-KL2 (shed by α-cut), KL1 (shed by β-cut) and truncated KL1 (synthesized by alternative splicing). In vitro studies suggest that IGF-I stimulatesα-klotho shedding.
Objective
Our aim was to compare measurements by assays that presumably differ in specificity for α-klotho isoforms in healthy controls and patients with acromegaly.
Methods
Circulating concentrations of solubleα-klotho were measured in 32 healthy controls and 22 patients with acromegaly by immunoassays from IBL and Immundiagnostik (IDK).
Results
α-klotho concentrations (pg/ml, median, interquartile) measured by IDK were ~8 times higher compared to IBL in healthy controls (6000 (4648–8681) vs 731 (558–899.7); $P<0.0001$), but only ~2 times higher in patients with acromegaly (11310 (6659–18172) vs 4809 (3048–10267); $P=0.0017$). Both Passing-Bablok and Bland-Altman showed greater disagreement between assays in all samples (Kendall's $\tau=0.04$ and 0.55, respectively). While the assays did not correlate in healthy controls (r Spearman=0.04, $P=0.83$), there was intermediate correlation in acromegaly (r Spearman=0.7, $P=0.0003$).
Conclusion
Results from both assays disagree dramatically. Lack of correlation suggests this is mainly caused by different recognition of isoforms rather than different standards. Since the KL1-KL2 isoform is equally detected by both assays, while the smaller shedding products are not, the better correlation in active acromegaly suggests that the proportion of the KL1-KL2 isoform increases in acromegaly. Furthermore, it is obvious that only results from studies using the same α-klotho assay can be compared.

Metformin and everolimus: A promising combination for neuroendocrine tumors treatment

Eleonora Vitali[1], Ilena Boemi[1], Sara Piccini[2], Giulia Tarantola[2], Alessandro Zerbi[3], Valeria Smiroldo[4], Elisabetta Lavezzi[2], Anna Spada[5], Giovanna Mantovani[5] & Andrea Lania[2]
[1]Humanitas Clinical and Research Center, Laboratory of Cellular and Molecular Endocrinology, Rozzano, Italy; [2]Humanitas Clinical and Research Center, Endocrinology and Diabetology Unit, Rozzano, Italy; [3]Humanitas Clinical and Research Center, Pancreas Surgery Unit, Rozzano, Italy; [4]Humanitas Clinical and Research Center, Oncology Unit, Rozzano, Italy; [5]IRCCS Ospedale Maggiore Policlinico, Milan, Italy

Treatment options for neuroendocrine tumors (NET), including everolimus, are rarely curative, as NETs frequently show resistance to medical therapy. In fact, the use of everolimus, an mTOR inhibitor, is limited by the development of resistance, probably due to the activation of Akt signalling. Metformin seems to have anticancer effects in neuroendocrine tumors (NETs). A recent retrospective study found longer progression-free-survival in diabetic pancreatic neuroendocrine tumor (P-NET) patients treated with everolimus and/or somatostatin analogs that were also taking metformin, irrespective of glycemic status, suggesting that metformin could have direct anticancer effects on NETs. Interestingly, metformin is able to inhibit mTOR and it also blocks the IGFR-1/IRS-1/PI3K/Akt cascade, providing the rationale for the use of metformin and everolimus in combination. We investigated the effects of metformin and everolimus alone and in combination on NET cell proliferation, apoptosis and colony formation, and the involvement of the Akt and mTOR pathways, also by developing everolimus resistant QGP1-R and H727-R cells. We demonstrated that metformin and everolimus in combination are more effective than monotherapy in inhibiting pancreatic-NETs cell proliferation, while no additive effects are observed on pulmonary-NETs cell proliferation. The combinatorial treatment is more effective than monotherapy in inhibiting colony formation and mTOR phosphorylation in both NET cell lines. We demonstrated that in QGP1 cells, metformin did not affect Akt phosphorylation; conversely, it significantly decreased Akt phosphorylation in H727 cells. Using everolimus resistant NET cells, we confirmed that metformin maintained is anticancer effects, acting by two different pathways: Akt dependent or independent, depending on cell type, both leading to mTOR suppression. Considering the promising anticancer effects of the everolimus and metformin combination in NET cells, our results provide the rationale for its use in NET patients.

One year of growth hormone therapy in spanish adults with prader-willi syndrome (PWS) improves body composition without changes in bone mineral density

Laia Casamitjana, Olga Giménez-Palop, Rocío Pareja, Raquel Corripio, Josep León, Assumpta Caixàs
Parc Taulí Hospital Universitari

Introduction
PWS is the most common cause of genetic obesity. These patients have an abnormal body composition with increased amounts of fat mass (FM), reduced lean body mass (LBM) and diminished bone mineral density (BMD), all similar to patients with growth hormone deficiency (GHD).The abnormal body composition has been described due to impairment of the activity of GH-IGF system and to hypogonadism. Studies ongrowth hormone (GH) treatment in PWS adults from other European countries show improvement in body composition without changes in BMD.
Objectives
Our objective was to investigate the effect of GH on body composition in GHD genotype-positive PWS adults who had been under GH therapy for one year.
Design and patients
Twenty-seven PWS patients were diagnosed from GHD through two different stimulation tests: glucagon test and GHR+Harginine test[1]. At the time of the study, eighteen of them were undergoing sex steroid replacement therapy. Body composition was examined with DXA (Lunar Prodigy) before and after one year GH therapy. GH was initiated at 0.2 mg/day and adjusted depending on IGF-I values (values had to be at the upper part of the range). Total body water was estimated by bioelectrical impedance.
Results
Baseline body composition was: LBM 45.0±1.35%, 38.6±1.6 kg, total FM 54.4±1.34%, 48.9±3.0 kg. After one year of GH therapy, LBM increased significantly in 2.1% (*P* 25–75: 0.7–3, *P*=0.03), 3.1 kg (*P* 25–75: 0.04–6.2 kg, *P*=0.05), and total FM decreased also significantly in –1.6% (*P* 25–75: –0.5–2.7, *P*=0.005), –1.9 kg (*P* 25–75: –0.5–3.3 kg, *P*=0.01). Total body water increased in 0.5 kg, 0.7% (*P*=0.06). In relation to BMD, pre-treatment Z scores were lower than expected for age (lumbar spine *Z*–1.3±0.3 SD., total femur *Z*–1.2±0.24 SD.; femur neck *Z*–1.1±0.25 SD.). No significant changes were seen after one year of GH therapy. There was no correlation between the increase in IGF-I and changes in LBM and FM. No severe side effects were reported.
Conclusion
Our results are consistent with previous data and show that one-year treatment with GH in adult patients with PWS is safe, effectively improves body composition and does not change low bone mineral density.

Efficacy and safety of urea in syndrome of inappropriate secretion of antidiuretic hormone on a secondary hospital

Antonio Moreno Tirado, Paloma González Lázaro, Cristina Contreras Pascual, Cristina Montalban Mendez, Alvaro Garcia Manzanares Vazquez De Agredos, Florentino Del Val Zaballos, Julia Silva Fernandez, Francisco Javier Gomez Alfonso, Ines Rosa Gomez Garcia, Amparo Lomas Meneses
Hospital La Mancha Centro, Alcazar De San Juan (Ciudad Real), Spain

Introduction
The most common cause of hyponatraemia is the syndrome of inappropriate antidiuretic hormone (SIADH). The diagnosis typically requires hyponatraemia in the setting of reduced serum osmolality, inappropriately concentrated urine with normal sodium excretion levels, and the absence of interfering medications, hypothyroidism and adrenal insufficiency. Unless hypertonic saline is indicated for acute onset profound hyponatraemia and/or with severe symptoms, the mainstay of management has traditionally been fluid restriction, a treatment often difficult to implement practically and effective in less than 50% of patients. Recent European and American guidelines differ in their approach to second-line management. Urea has been used for the treatment of SIADH since the 1980s but only few case reports/series have demonstrated it is an effective adjunct where fluid restriction is impractical or ineffective.
Objective
The objective of the study was to demonstrate that treatment with urea in patients with SIADH is a safe and effective alternative when fluid restriction has failed.
Methods
Treatment with urea (15 g/day) was started in all patients with biochimical diagnosis of SIADH (serum and urine natremia, plasmatic and urine osmolarity was determined) between 2016 and 2019. In all patients hypothyroidism and adrenal insufficiency was excluded. Results were analysed with SPSS v. 21.
Results
20 Subjects (55% men) were analysed with an average age of 77.05±15.4 years old, with biochemical diagnosis of SIADH. In our serie, the main cause of SIADH was drugs (50%), other causes were 25% paraneoplasia, 10% brain hemorrhage, 10% lung patology and 5% idiopathic. Initial natrium level was 124±3.8 mEq/l before treatment was started, with an average plasm osmolality 269±15.4 mOsm/l, urinary sodium 114±98,8 mEq/l, and urinary osmolality 484.6±235.56 mOsm/kg. Treatment with 15 g/day with urea was started with a median duration of 35 days, the natrium level was corrected in all patients, and it could be discontinued in 85% of them. The final average natrium level was 136.7±4 mEq/l, plasm osmolality 295.25±28.85 mOsm/l, urinary sodium 88.6±28.7 mEq/l and urinary osmolality 528.6±186.5 mOsm/kg. A rate mortality of 55% was observed, none of them due to SIADH.
Conclusions
Urea is safe and effective in fluid restriction-refractory hyponatraemia. We recommend urea with a starting dose of 15 g/day in patients with SIADH and moderate to profound hyponatraemia, as in our serie 100%, sodium levels were normalized and in 85% treatment with urea could be discontinued.

Multiple metastatic NET of unknown primary site in a young patient with carcinoid syndrome: Can we treat it as a gastrointestinal NET?

Diana Lambrinoc[1], Alexandru Morea[1], Roxana Duşceac[1,2] & Cătălina Poiană[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disease, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Introduction
Neuroendocrine tumours (NETs) of unknown primary site are relatively uncommon, representing about 10% of all NETs. Of these, particularly the well-differentiated NETs often present initially with liver metastases, and most of these represent gastroenteropancreatic NETs. The presence of carcinoid syndrome is also common.
Case presentation
We describe the case of a 40 years-old patient presented in 2013 with flushing, diarrhea, and back pain. The chest-abdomen-pelvis CT showed several small lung nodules, multiple vertebral sclerotic bone metastasis, along with an osteolytic lesion on sacrum. It also revealed metastatic lesions in both hepatic lobes along with several enlarged abdominal lymph nodes. The upper and lower gastrointestinal endoscopy didn't show any lesion. A hepatic biopsy was performed, histopathological examination and immunochemistry showing well differentiated G1 NET, with Ki-67 < 3%, positive for chromogranin A, somatostatin receptor type 2 and 5 and also for CDX2, indicating a midgut origin. The serum serotonin, chromogranin A and urinary 5-hydroxyindoleacetic acid (5-HIAA) levels were elevated, thereby treatment with somatostatin analogues (SSA) was initiated, improving the carcinoid syndrome. The tumour markers had, however, an oscillating evolution (Table 1). For bone metastasis he received zoledronic acid and radiation therapy for pain control. A 99 mTc-Tektrotyd scintigraphy and SPECT/CT were also performed, still unable to showcase the primary site. Furthermore in December 2019, the patient has undergone the first therapy cycle of ^{177}Lu-DOTATOC peptide receptor radionuclide therapy (PRRT) and tolerated it well. The second cycle will be administered in February 2020.

Table 1 Serum Chromogranin A, Serotonin and urinary 5-HIAA/24 h levels during SSA therapy.

Date	5-HIAA mg/24 h (N: 2–9)	Serotonin mg/l (N: 80–400)	Chromogranin A mg/l (N: 27–94)	SSA	Dose of SSA/28 days

Discussion
We showcase the importance of comprehensively investigating NETs of unknown origins as they are characterized by variable, yet frequently indolent evolution. Patients with abdominal masses on imaging scans and no evidence of the tumour on upper or lower endoscopy can be considered to have small intestinal primary tumours and should be treated according to guidelines.

A relationship between motilin and ghrelin in human motilin receptor transgenic mice

Bunzo Matsuura[1], Tomoe Kawamura[2], Hironobu Nakaguchi[2], Sayaka Kanzaki[2], Hidenori Senba[1], Teruki Miyake[2], Shinya Furukawa[2] & Yoichi Hiasa[2]
[1]Ehime University Graduate School of Medicine, Lifestyle-related Medicine & Endocrinology, Toon, Japan; [2]Ehime University Graduate School of Medicine, Gastroenterology & Metabology, Toon, Japan

Motilin (M), erythromycin (EM) and ghrelin (G) are recognized as important regulators of gastrointestinal motor function in humans that are mediated by class I guanine nucleotide-binding protein (G protein)-coupled motilin receptor (MR) and growth hormone secretagogue receptor (GHSR). These receptors have also been demonstrated as clinically useful pharmacological targets. However, a molecular relationship between MR and GHSR activation has been unclear. We generated human MR transgenic (hMR-Tg) mice because rodents do not endogenously express M and MR. In the current study, we examined gastric prokinetic effects, and relationship between M and G after administration of M, EM and G in hMR-Tg mice. M and EM affected concentration-dependent contraction of gastric smooth muscle in hMR-Tg mice but not in WT mice. Intraperitoneal (ip) and intracerebroventricular (icv) administration of EM significantly promoted gastric emptying in hMR-Tg mice but not in WT mice. The changes in gastric empty responses to EM icv administration were altered by atropin, but those to EM ip administration was not. G ip and icv administration significantly promoted gastric emptying in both hMR-Tg mice and WT mice. EM ip and icv administration reduced serum ghrelin concentration. According to our data, the hMR-Tg mice are useful for the evaluation of gastric prokinetic drugs in humans.

Characterization of epithelial-mesenchymal transition in growth hormone-secreting adenomas

Joan Gil[1], Montserrat Marques-Pamies[2], Araceli García-Martínez[3], Guillermo Serra[4], Susan Webb[5], Miguel Antonio Sampedro-Nunez[6], Antonio Pico[3], Monica Marazuela[6], Mireia Jorda[1], Manel Puig-Domingo[1,2]
[1]Germans Trias i Pujol Research Institute, Endocrinology and Nutrition, Badalona, Spain; [2]Germans Trias i Pujol University Hospital, Endocrinology and Nutrition, Badalona, Spain; [3]Hospital General Universitario de Alicante-Institute for Health and Biomedical Research (ISABIAL), Alicante (Alacant), Spain; [4]Son Espases University Hospital, Departament of Endocrinology, Palma, Spain; [5]CIBERER U747, ISCIII, Research Center for Pituitary Diseases, Hospital Sant Pau, IIB-SPau, Universitat Autònoma de Barcelona, Department of Endocrinology/ Medicine, Barcelona, Spain; [6]Hospital de La Princesa, Departament of Endocrinology, Madrid, Spain

First generation somatostatin receptor ligands (SRL) are the first-line drugs in primary acromegaly treatment or after surgical failure in patients with active acromegaly. In previous studies we confirmed the association of the expression of *SSTR2*, Ki67 and E-cadherin (*CDH1*) in responsive GH-secreting adenomas response to SRL. Moreover, E-cadherin showed a greater predictive capacity than most of the markers described. Loss of E-cadherin is a typical mark of epithelial-mesenchymal transition (EMT) in solid tumors. Then, the objective of the subsequent work was to study the association of the EMT with the somatotropinomas response to SRL. We analyzed the expression of 8 genes related to EMT (*CDH1*, *CDH2*, *SNAI1*, *SNAI2*, *ESRP1*, *RORC*, *VIM* and *TWIST*) and other SRL response genes such as *SSTR2* and Ki-67 in 57 somatotropinomas (80% treated with SRL before surgery), using RT-qPCR. The results showed an expression pattern compatible with a EMT in 14% of tumors. When a cluster analysis was performed, epithelial markers (*CDH1*, *RORC*, *ESRP1*) clustered with *SSTR2* on one hand, and mesenchymal markers (*CDH2*, *SNAI1*, *SNAI2*, *VIM*, *TWIST*) with Ki-67. However, no clusterization of the tumors depending SRL response was found. The values of *CDH2* and *RORC* were higher in patients treated with SRL before surgery (F.C. = 3.14, $P = 0.02$, and F.C. = 2.39, $P < 0.01$, respectively). *SNAI1* and *RORC* showed differences, the latter only in SRL pretreated patients, between responding patients and resistant to SRL (HR = 2.03, $P = 0.05$ and HR = 0.59, $P = 0.01$, respectively). In addition, RORC levels correlated with the percentage decrease in IGF-1 after therapy with SRL (Pearson $r = 0.40$, $P = 0.03$).

Therefore, we conclude thatEMT occurs in some somatotropinomas, but it does not seem to explain their response to SRL in this subset of tumors. However, in the rest of somatotropinoma *SNAI1* and *RORC* may predict the response to SRL treatment.

Global methylation-demethylation status in pituitary neuroendocrine tumors as potential therapeutic target

Borbála Szabó[1], Kinga Németh[2], Katalin Mészáros[2,3], Nikolette Szücs[1], Sándor Czirják[4], Lilla Reiniger[5], AttilaPatócs[2,3,6] & Henriett Butz[2,3,6]
[1]Semmelweis University, 2nd Department of Internal Medicine, Faculty of Medicine, Budapest, Hungary; [2]Semmelweis University, Momentum Hereditary Endocrine Tumors Research Group, Budapest, Hungary; [3]Semmelweis University, National Bionics Program, Budapest, Hungary; [4]National Institute of Clinical Neurosciences, Budapest, Hungary; [5]Semmelweis University, 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary; [6]Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary

Background
The altered DNA methylation of certain genes in Pituitary Neuroendocrine Tumors (PitNETs) are well known. However little information is available regarding global methylation changes and the process of demethylation in these tumors. In addition, influencing global methylation-demethylation could be a potential new therapeutic option especially in clinically non-functional PitNETs.
Material and methods
Overall, 44 fresh frozen pituitary adenoma tissues (29 gonadotroph, 12 somatotroph, 3 corticotroph) were collected and characterized according to the 2017 WHO classification. Decitabine was used to alter global methylation-demethylation status on *in vitro* GH3 and RC-4B/B cell lines. In tissue samples 5-hydroxymethylcytisone (5 hmC), UHRF1-2 protein and Ki-67 were assessed by immunohistochemistry; gene expression of DNA Methyl-transferase (DNMT1), methyl-cytosine dioxygenases (TET1-3) and ubiquitin-like with PHD and ring finger domain (UHRF1-2) were investigated by RT-qPCR. 5-methylcytosine (5 mC) and 5 hmC level were determined by HPLC-MS/MS method.
Results
Decitabine decreased 5-methylcytosine (5 mC) and increased 5 hmC levels *in vitro* in both pituitary cell lines. Parallel, cell proliferation and viability were decreased significantly. UHRF1-2 were also altered upon decitabine treatment *in vitro*. Interestingly, in PitNET tissue samples 5 hmC was gradually decreased in samples with higher Ki-67 index. In samples with different histology UHRF2 showed different expression, while UHRF1 showed gradual increase in adenoma samples with higher Ki-67 index. Additionally, UHRF2 positively correlated with 5 hmC level in pitNET tissues and both UHRF1 and UHRF2 showed significant positive correlation with DNMT1 and TET1-3 expression.
Conclusion
Our results showed that methylation-demethylation process (5 hmC, DNMT1, TET1-3 and UHRF1-2) is closely linked to proliferative behaviour of PitNETs. Altering global 5 mC and 5 hmC level can be a potential, new therapeutic target in therapy resistant pituitary tumors.

The expression of oxytocin receptor (OXTR) in metastatic pancreatic neuroendocrine tumors (PNETs)

Darko Katalinic[1], Stephan Bildat[2], Elke Kattner[2], Lilly Soerensen[3], Ivan Aleric[1] & Aleksandar Vcev[1]
[1]Faculty of Dental Medicine and Health and Faculty of Medicine, Josip Juraj Strossmayer University of Osijek; [2]Herford Teaching Hospital; [3]Department of Cancer Medicine

Introduction
Pancreatic neuroendocrine tumors (PNETs) are rare malignant neoplasms which incidence is continually increasing. They are characterized by diverse biological behaviour and impact on the patients' prognosis, ranging from clinicaly indolent to very aggressive. Oxytocin receptor (OXTR) is a member of the family of G-protein receptors and is present on the cell-surface of the gastrointestinal organs. Unfortunately, theimpact of OXTR signaling on the development of PNETs and its underlying molecular mechanisms involved in gastrointestinal oncogenesis remains unsufficiently researched. Theaim of our study was to assess the expression of OXTR in a group of patients diagnosed with metastatic PNETs.
Material and methods
Metatatic PNETs (liver metastases) specimens ($n=24$) matched control (normal) tissue were surgically collected and mRNA expression was determined by Real-time polymerase chain reaction (Real-time-PCR). OXTR expression for tumor and control tissue was additionally analysed by immunohistochemistry.
Results
Compared to normal tissue, the OTXR showed significant overexpression in metastatic PNETs. Moreover, significant overexpression of OXTR in tumor tissue was confirmed by immunohistochemistry.
Conclusion
Our findings highlight the possibility of making OXTR a promising novel molecular target for imaging and different therapeutic approach in patients diagnosed with metastatic PNETs.

Metastatic insulinoma managed with lutetium (177LU) and somatostatin analog

Mehmet Sözen, Zeynep Canturk, Berrin Cetinarslan, Alev Selek, Emre Gezer
Kocaeli University, Endocrinology and Metabolism, kocaeli, Turkey

Background
Insulinoma is a rare tumour representing 1–2% of all pancreatic neoplasms and it is malignant in only 10% of cases. Locoregional invasion or metastases define malignancy, whereas dimension (> 2 cm), CK19 status, tumor staging and grading (Ki67 > 2%), and age of onset (> 50 years) can be considered elements of suspect.
Case presentation
We report a case of malignant insulinoma in a 80 year old woman presenting symptoms compatible with hypoglycemia. Low blood glucose levels (< 40 mg/dl) were documented during of these episodes. Symptoms regressed with food intake and intravenous glucose administration. No abnormality was detected in the biochemical evaluation. Prolong fasting test was performed, and the patient underwent symptomatic hypoglycemia at the 5th hour. Plasma glucose level was 39 mg/dl, insulin level 36.4 uIU/mL and C-peptide 9.28 ng/ml. Glucagon responce was measured 10 min. intervals, 85 mg/dl, 95 mg/dl and 113 mg/dl respectively. These results were suggestive of endogenous hyperinsulinemia. Magnetic resonance imaging revealed a invasive mass in the pancreatic tail location ~ 63×40 mm in size and multiple metastatic nodules in the the liver. Ga–68 DOTATATE PET-CT, which showed a lesion located in the pancreatic tail location and multıpl metastatic lesion in the liver, with a high somatostatin receptor density. Tru-cut biopsy made from liver lesions revealed the insulinoma tumour metastasis. Synaptophysin, pancytoceratine and chromogranin were positive. The histopathological diagnosis was suggestive of a neuroendocrine, grade-2 tumour (mitotic rate 1/10 HPF, KI-67 proliferative index 15%). Lanreotide 120 mg IM was started an every 28 days basis. The patient received 2 infusions of radiolabeled somatostatin analog lutetium (177LU) 8 weeks apart and denied any hypoglycemia. After the second administration of the lutetium, Ga–68 DOTATATE PET-CT had shown objective metabolic and radiologic response to treatment. Lutetium treatment was given as 8 cycles. Treatment of the patient with metabolic and radiological responses continues with lanreotide 90 mg/every 28 days.
Conclusions
We report a case of metastatic insulinoma treatment with somatostatin analog and Lutetium. Due to previous glycemic control reports and objective responses in unresectable cases, we decided to use Lutetium together with lanreotide. The patient's hypoglycaemia improved immediately after treatment. Unresectable metastatic insulinomas may present as a major therapeutic challenge for the physician. Treatment with landreotide and Lutetium

(177LU) seems to be effective in the management of severe, life-threatening, and refractory hypoglycemia associated with malignant insulinoma, as shown in the case presented here.

Tobacco smoke induces aberrant pulmonary neuroendocrine differentiation via different MAPK pathways

Zhaofeng Liang, Wei Xie, Rui Wu, Chunfeng Xie, Xiaoting Li & Caiyun Zhong
Nanjing Medical University, Department of Toxicology and Nutrition, Nanjing, China

Tobacco smoke (TS) is the major cause of lung cancer, including pulmonary neuroendocrine tumors such as small cell lung cancer and large cell neuroendocrine carcinoma. Unlike squamous cell carcinomas and adenocarcinomas, the precursor lesions for subtypes of pulmonary neuroendocrine tumors have not been historically defined, and theexpression of neuroendocrine markers has been served as critical indices for the identification of these tumors. Mitogen-activated protein kinases (MAPKs) pathways play central roles in the development of cancer. To date, the role and regulation of MAPK pathways in TS-induced abnormal pulmonary neuroendocrine differentiation has not been elucidated yet. By employing long-term TS exposure of normal human bronchial epithelial cells and 12-weeks mouse smoking model approaches, in the present study we demonstrated that long-term TS exposure induced abnormal differentiation of human bronchial epithelial cells towards a neuroendocrine-like phenotype, as shown by increased cell proliferation, colony formation ability, invasive capacity, morphological change (from epithelial round-shaped to a neuroendocrine-like phenotype manifested by cell elongation and the emission of filopodia), and upregulated expression of pulmonary neuroendocrine differentiation markers including CgA, NCAM, SYN, and NSE. TS-induced aberrant pulmonary neuroendocrine differentiation was associated with MAPKs/AP-1 activation. Inhibition of EKR1/2 and p38 pathwaysdiminished TS-induced neuroendocrine differentiation in human bronchial epithelial cells. Furthermore, *in vivo* studies also revealed TS-induced neuroendocrinedifferentiation and MAPKs/AP-1 activation in mice. These effects were attenuatedby inhibition of p38 activation, but rather EKR1/2 and JNK pathwaysinhibition. Collectively, we illustrated the distinct roles of MAPK pathways in TS-induced abnormal neuroendocrine differentiation, among which p38 pathway serves as the pivotal player in this process. Findings from our study could provideimportant information for TS-induced aberrant pulmonary neuroendocrine differentiation, shedding new light on the carcinogenic process of TS-associated neuroendocrine lung cancers and its target intervention.

Use of tolvaptan in acute post-surgical hyponatremia in patients with pituitary diseases

Emanuele Ferrante[1], Rita Indirli[1], Beatrice Mantovani[1], Arianna Cremaschi[1], Andreea Liliana Serban[1,2], Elisa Sala[1], Marco Locatelli[3], Giulio Bertani[3], Maura Arosio[1] & Giovanna Mantovani[1]
[1]Endocrinology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, Milan, Italy; [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [3]Neurosurgery Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, Milan, Italy

Introduction
Hypotonic hyponatremia is frequently observed after pituitary surgery. In this context, use of vasopressin V2-receptor antagonists is not standardized. The aim of this retrospective study is to explore the role of Tolvaptan in the management of acute hyponatraemia after pituitary surgery.
Methods
We collected clinical, safety and efficacy data of patients treated with Tolvaptan after pituitary surgeryin our Centre between April 2011 and February 2019.
Results
In 12 patients (8 women, median age 57.5 years) treated with Tolvaptan, hyponatraemia occurred in the 4th–7th post-operative day and was preceded by diabetes insipidusin 9 cases. In 5 patients the first line of treatment was 24 hours fluid restriction (range 6–36 hours), however the procedure was ineffective (median variation in sodium levels: –3, range: –8 to –1 mEq/l). Tolvaptan was administered in a single dose in 8 patients and in 2 doses in 4 [initial dosage: 7.5 mg ($n=5$), 15 mg ($n=6$), 30 mg ($n=1$)]. Median pre-Tolvaptan sodium was 125 mEq/l (range 112–129). One patient was mildly symptomatic, two patients had moderate symptoms and one severe. All patients were euvolemics. Twenty-four hours after the last administration of Tolvaptan, sodium was normalized in 9 out of 12 patients. Overcorrection (151 mEq/l) was observed in one patient, whereas mild hyponatremia persisted in 2. In two patients treated with a single dose of Tolvaptan, initial normalization of natremia was followed by further reduction in sodium levels (after 48 and 72 hours, respectively). No patient developed any side effects during Tolvaptan treatment. Correction rate was 12.5 (5 – 26) mEq/l/24 h after the first dose of Tolvaptan, and 11.5 (8 – 16) mEq/l/24 h after the second dose, with an absolute variation of natremia of +15.5 (7 – 26) mEq/l. No correlation between different doses provided and rate of correction was observed. Instead, overall variation of natremia was inversely proportional to the pre-treatment sodium levels ($P=0.02$). Overall, median length of hyponatraemia was 2 days (1.5 – 6).
Conclusions
Even at low doses, Tolvaptan is an effective and safe treatment for transient acute hyponatraemia in patients who underwent pituitary surgery, when fluid restriction is unable to determine an increase in sodium levels. In some patients, a single administration of Tolvaptan may not be sufficient and repeated administrations should be considered until hyponatraemia is resolved.

Metabolic status of patients with combined pituitary hormone deficiency due to PROP1 mutation

Damian Rogoziński[1], Aleksandra Gilis-Januszewska[1,2], Łukasz Kluczyński[1,2], Magdalena Godlewska[1] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Univeristy Hospital in Cracow, Departament of Endocrinology, Cracow, Poland; [2]Department of Endocrinology, Jagiellonian University, Collegium Medicum, Cracow, Endocrinology Department, Cracow, Poland

Introduction
Combined pituitary hormone deficiency (CPHD) due to PROP1 mutation is a rare cause of childhood-onset pituitary disfunction. Treatment with growth hormone is crucial for the proper development during childhood and adolescence, and to maintain adequate metabolic processes in the adulthood. There are other factors influencing patients metabolism e.g. steroid and estradiol/testosterone treatment.
Aim
To assess metabolic status of patients with CPHD due to PROP1 mutation.
Methods
20/28 patients with PROP1 CPHD who are under medical supervision of the Department of Endocrinology (12 F/8 M; mean age [MA] 43.2±14.2) completed routine laboratory tests during 2019.
Results
In all patients GH, TSH and gonadal axes deficiencies were diagnosed. In 17/20 adrenal and 1/20 ADH deficiency was diagnosed. 9/20 (older patients) received (due to no compliance/other reasons): no/delayed/intermittent GH treatment in childhood. In adulthood 7/21 patients were intermittently treated with GH. 8/12 F and 8/9 M have received sex hormones supplementation. The sub-group of patients properly treated with HGH (t-HGH) in childhood consisted of 6 W/6 M, MA 33, 3±7.3 y, mean final height (MFH) 170.4±6.0 cm. In subgroup of patients not treatedwith HGH (nt-HGH) in childhood there were 6 W/2 M, MA 58.0±8.1 y, MFH 139.6±7.4 cm.
Combined analysis of all patients revealed that the most frequent disorders were hyperlipidaemia (65%), low bones mineralization (57%), vitamin D deficiency (50%), overweight (45%), visceral obesity (45%), hypertension (35%) and insulin resistance (35%).
The most common metabolic problems in nt-HGH were bone demineralization (100%), hyperlipidaemia (100%) and visceral obesity (75%) whereas in t-HGH low vitamin D concentration (50%), hyperlipidaemia (42%) and visceral obesity (42%).
In both group we have observed elevated markers of insulin resistance, however none of the patient met diabetes criteria.
Conclusions
Metabolic abnormalities are very common among patients with CPHD related to PROP1 mutation.
Metabolic changesand osteoporosis observed in young adults prove that even correct replacement therapy cannot prevent the health deterioration. Further investigation on understanding of metabolic disorders and setting

standards of care (e.g. treatment of osteoporosis in young adults) are needed. This specific group of patients needs an extensive care of multidisciplinary team of experienced endocrinologist, cardiologist, rheumatologist and dietician.

AEP736

Kisspeptin levels in children and adolescents

Olga Gumeniuk
Saratov State Medical University, Russian Federation

Kisspeptin (metastin, HH13, KiSS-1, KiSS-1 metastasis-suppressor, KiSS-1 metastasis suppressor) is a neuropeptid that is encoded by the KISS1 gene (Messager *et al.*, 2005). Kisspeptin-GPR54 signaling has an significant role in initiating secretion of gonadotropin-releasing hormone at puberty (K. Skorupskaite *et al.*, 2014). Is known that kisspeptin to play a role in tumor suppression (especially in breast tissue), (E.J. Mead *et al.*, 2007).

Objectives

To determine kisspeptin levels in healthy children and adolescents, in children and adolescents with endocrine and mammalogic diseases.

Patients and methods

Serum kisspeptin levels was determined in 123 children and adolescents (aged 0.7–18 yrs), in the 8 groups, including control groups. The healthy children was 12, healthy adolescents – 30, children with central precocious puberty (precocious puberty CPP and premature isolated the larche PT) – 11, girls with amenorrhea – 23, adolescent girls with dyshormonal mammary dysplasia – 12, patients with polycystic ovary syndrome (POS) – 9, pregnant adolescent girls – 15 and adolescents with gynecomastia was 11 boys. The concentration of kisspeptin was measured kisspeptin (total) using competitive enzyme immunoassay. Results were analyzed using Pearson's chi-squared test. Data are expressed as median, P value of <0.05 was considered statistically significant. This study was carried out in accordance with the Helsinki Declaration.

Results

The investigation shows that healthy and pregnant adolescent girls, boys with gynecomastia had kisspeptin median level was 30 pg/ml. Among the girls with amenorrhea kisspeptin level was lower 10 pg/ml ($P=0.01$). Girls with mastopathy (dyshormonal dysplasia) had kisspeptin level 50 pg/ml ($P=0.03$). Serum kisspeptin levels were significantly higher in children with CPP and PIT and adolescent girls with polycystic ovary syndrome than in control group (80 and 300 vs 30 pg/ml, $P=0.01$ and $P<0.01$).

Conclusions

Kisspeptin level was various in healthy children, girls with amenorrhe, mastopathy, polycystic ovary syndrome, premature isolated thelarche, children with central precocious puberty, pregnant adolescent girls and boys with with gynecomastia. In this study data received that serum kisspeptin level was significantly lower in girls with amenorrhea and higher in children with CPP and PT, girls with mastopathy and POS. Kisspeptin levels in girls with mammological diseases are statistically significantly higher, which can be explained by compensatory reactions in response to proliferation in mammary glandular tissue. The serum kisspeptin level may be used as a biomarker of sexual disorders, polycystic ovary syndrome and mammary diseases and in girls.

Body composition and bone mineral density in 107 patients with childhood onset growth hormone deficiency (CO-GHD) at the time of transition from pediatric to adulthood endocrine care

Mirjana Doknic[1,2], Marko Stojanovic[1,2], Tatjana Milenkovic[3], Vera Zdravkovic[2,4], Jesic Maja[2,4], Sladjana Todorovic[3], Mitrovic Katarina[3], Rade Vukovic[2,3], Dragana Miljic[1,2], Sandra Pekic Djurdjevic[1,2], Ivan Soldatovic[2,5] & MilanPetakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Department of Neuroendocrinology, Belgrade, Serbia; [2]University of Belgrade, Medical Faculty, Belgrade, Serbia; [3]Mother and Child Health Care Institute of Serbia'Dr Vukan Cupic', Department of Endocrinology, Belgrade, Serbia; [4]University Children's Clinic Tirsova, Department of Endocrinology, Belgrade, Serbia; [5]Institute of Medical Statistics and Informatics, Belgrade, Serbia

Transition from childhood to adulthood is a vulnerable period in all adolescents and particularly inCO-GHD patients. Low bone mineral density (BMD) and body composition alterations are frequently reported in young adults with CO-GHD, but relevant large monocentric studies are lacking.

Patients and Methods

In a monocentric, observational, retrospective cross-sectional study conducted from 2005–2019, 107 CO-GHD patients were analyzed (17–26 years old, 80 males) at the time of transfer from pediatric to adult endocrine care. Median age at transfer was 19.6±2.2 years. Subjects withcongenital and idiopathic GHD (CON) were compared with age-, sex- and BMI-matched patients with hypothalamic/pituitary tumor history (TUM). Body composition (% fat, fat mass – FM and lean body mass – LBM) and BMD in lumbar spine (LS) and femoral neck (FN) – (BMD g/cm^2, Z score) were analyzed by DXA.

Results

Congenital and idiopathic causes of GHD were more frequent than hypothalamic/pituitary tumoral causes (74.8% vs 25.2%).All patients received GH replacement during childhood for average duration of 5.4±1.4 yrs. GH replacement was discontinued prior to transfer for 2.7±0.9 yrs. Recovery of GH/IGF-I axis was confirmed by retesting in 15.5%. Percentage of fat was significantly higher in TUM vs CON (30.1 vs 34.0 kg; $P<0.05$) and LBM was significantly higher in CON (46.2 vs 40.1 kg; $P<0.05$). BMD (g/cm^2) and Zsc in LS and FN were lower in TUM (> P 0.05) while FM was higher in TUM ($P>0.05$).

Conclusion

Patients with CO-GHD caused by hypothalamic/pituitary tumors demonstrated worse body composition and lower BMD at the time of childhood to adulthood transition compared to matched transition patients with congenital CO-GHD

Management of pregnant women with prolactinomas and analysis of their pregnancy outcomes

Khurshida Nasirova, Sitorakhon Muminova
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

The purpose of the study was to study the characteristics of the course of pregnancy and childbirth in women with prolactinomas, as well as the effect of pregnancy on the size and functional activity of prolactin-secreting pituitary adenomas.

Materials and methods

70 women with prolactinomas during pregnancy were examined. The age of the examined patients from 20 to 38 years (28.9±0.5 years). The duration of the disease ranged from 3 months to 20 years and averaged 2.8±0.2 years. The menarche age ranged from 11 to 18 years and averaged 13.2±0.2 years. A regular menstrual cycle before pregnancy was present in 6 (8.5%) patients with prolactinoma. Opsomenorrhea was present in 30 (42.8%) and amenorrhea 15 (21.4%). Before pregnancy, lactorrhea of I-II degree was present in 40 (57.1%) women, III degree – in 7 (10%) women. Pregnancy occurred during therapy with dopamine agonists. 6 (8.5%) patients underwent stimulation of ovulation with clomiphencitrate. Three (4.2%) women with macroprolactinoma had asymmetric bitemporal hemianopsia. 10 (14.2%) patients in the past underwent surgery on the pituitary gland. In 2 (2.8%) patients with pituitary macroadenoma, surgical treatment was combined with radiation therapy. Microadenomas were present in 51 (72.8%) patients, macroadenomas – in 19 (27.1%) women. The sizes of prolactin before pregnancy ranged from 3 mm to 42 mm (9.2±1.0 mm). The average tumor size in patients with pituitary microadenoma was 5.0±0.3 mm, with macroadenoma – 18.0±1.8 mm. The level of prolactin in the blood of patients ranged from 900 mIU/l to 10,000 mIU/l and averaged 3361.8±307.2 mIU/l.

Results

With microadenomas due to the low risk of tumor growth, observation without treatment is possible based on clinical symptoms. With macroadenomas, pregnancy must be planned to achieve control of tumor growth. Careful observation or treatment with dopamine agonists throughout pregnancy is preferred, depending on the particular patient. To minimize risks to the fetus, treatment with dopamine agonists should be started after the first trimester. Breastfeeding may be allowed, as there is insufficient evidence against this. Patients requiring dopamine agonists to prevent tumor growth should continue treatment, although lactation may be impaired.

Conclusion

Preference is given to careful observation or treatment with dopamine agonists throughout pregnancy, depending on the particular patient.

Interleukin-6 response to insulin-induced hypoglycemia is associated with hypothalamic-pituitary-adrenal axis activation

Juliana Drummond[1], Erica Vieira[1], Beatriz Rocha[1], William Pedrosa[2], Antonio Ribeiro-Oliveira Jr[1] & Antonio Teixeira[3]
[1]Federal University of Minas Gerais, Brazil; [2]Hermes Pardini – Aimorés, Brazil; [3]McGovern Medical School, Houston, United States

Introduction
Increased plasma levels of interleukin-6 (IL-6) in response to acute hypoglycemia have been well documented. Counter-regulatory hormones are likely to play a role in this inflammatory response.
Objective
To study the interaction between IL-6 and counter-regulatory hormones during hypoglycemic stress.
Methods
We conducted an exploratory single center study involving 23 patients (mean age = 34.15 ± 8.87 years, $n = 12$ women) undergoing insulin tolerance test (ITT) for suspected pituitary dysfunction. Procedure-related symptoms of anxiety and hypoglycemia were measured using a standardized questionnaire. Blood levels of IL-6, adrenocorticotrophic (ACTH), adrenaline, noradrenaline, growth hormone (GH), prolactin and serum and salivary cortisol were determined throughout the ITT.
Results
Insulin-induced hypoglycemia was safely achieved in all subjects and elicited a significant dynamic response of ACTH, adrenaline, noradrenaline, GH, prolactin and serum and salivary cortisol ($P < 0.001$ for all variables). IL-6 plasma levels significantly increased after hypoglycemia ($P < 0.001$). The increase of plasma IL-6 levels during hypoglycemia correlated with the increase of serum cortisol ($rs = 0.46$; $P = 0.022$), salivary cortisol ($rs = 0.52$; $P = 0.021$), plasma ACTH ($rs = 0.47$; $P = 0.023$) and anxiety symptoms ($rs = 0.441$; $P = 0.004$).
Conclusion
Hypoglycemic stress-induced IL-6 increase is associated with the activation of the hypothalamic-pituitary-adrenal axis, reinforcing the concept that inflammatory response to stress may be regarded as a component of a broader counter-regulatory response.

The effect of dual-release versus conventional hydrocortisone on fatigue, measured by ecological momentary assessments

Victor Boesen[1], Stine Borresen[1], Thea Christoffersen[1], Marianne Klose[1], Torquil Watt[1,2] & Ulla Feldt-Rasmussen[1]
[1]Copenhagen University Hospital Rigshospitalet, Department of Endocrinology and Metabolism, Denmark; [2]Copenhagen University Hospital Herlev Gentofte, Department of Internal Medicine, Gentofte, Denmark

Background
Replicating the physiological cortisol secretion is key in treatment of glucocorticoid insufficient individuals. A sub-optimal replication may explain the impaired quality of life experienced by these individuals. The study investigates fatigue measured by ecological momentary assessments in patients treated with conventional hydrocortisone compared with a once-daily dual-release formula of hydrocortisone (Plenadren) that follows the cortisol physiology more closely.
Methods
The 21-week open-label switch pilot trial included patients with adrenal insufficiency due to hypopituitarism ($n = 27$). While treated with their usual hydrocortisone regimen, fatigue was assessed four times daily for 20 days using a momentary item version of the Multidimensional Fatigue Inventory. Participants switched treatment to an identical daily dose of Plenadren. The intervention period was 16 weeks and was concluded with repeating the fatigue assessments for 20 days.
Results
On four out of five fatigue subscales, we found statistically significant yet modest treatment effects. Fatigue was reduced 0.7–1.1 points, on a scale ranging from 4–20, when treated with Plenadren compared with conventional hydrocortisone. Changes corresponded to small effect sizes but were below scale-specific minimal important changes. We found larger between-person variances and smaller within-person variances when treated with Plenadren. On an individual level, nine participants (one third) experienced improvements above the minimal important change whereas four participants deteriorated. The method of ecological momentary assessment could furthermore detect a significant diurnal curve of fatigue, and a visual change of the pattern between conventional hydrocortisone and Plenadren.
Conclusion
The Plenadren-related reduction in fatigue was significant but not necessarily of clinical importance when looking at group level. However, there was a large inter-individual treatment effect, why patients with great benefit in quality of life should be identified. Furthermore, the method of ecological momentary assessments was highly suitable for studying fatigue in this patient population.

Cushing's syndrome in the 21st century, not what it used to be: A single institution experience

Arza Rosset, Yona Greenman, Gabi Shefer, Etty Osher, Naftali Stern, Karen Tordjman
Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel

Background
True Cushing's syndrome (CS) is an exceedingly rare condition, thus to avoid unnecessary and costly testing, a diagnostic investigation should only start based on solid clinical suspicion. The current obesity epidemic has become a hurdle in discriminating subjects at real risk for CS from those with the metabolic syndrome. Moreover, many CS patientsrecently diagnosed do not fit the typical clinical profile of 'at risk subjects'.
Aim and Design
To characterize the clinical presentation of patients with confirmed CSat Tel Aviv Sourasky Medical Center between 2000–2018. Relevantclinical, laboratory, imaging and pathological datawere retrospectively retrieved and analyzed fromCS patients' charts.
Results
We identified 76 patients with CS (79%women) with a clear increased incidence over the years. The subtypes comprised: 49 Cushing's disease (CD) 64.5%, 16 benign adrenal process (BA) 21.1%, 7 ACC 9.2%, and 4 cases of ectopic ACTH secretion (ECT) 5.3%. Mean age was 47.9 ± 15.3 y (range: 18–79), by ANOVA ($P = 0.003$), CD subjects being significantly younger than subjects with ECT. Clinical suspicion of CS initiated a diagnostic work-up in only 15 subjects (19.7%). In 48 (63%), an investigation started either for incidental imaging or laboratory findings, or for nonspecificreasons(i.e obesity). Once the diagnosis was known, in 50% of the cases an endocrinologist noted the patient did not appear to suffer from CS. The most common co-morbidities were hypertension (62.7%), hyperlipidemia (48.6%), obesity (48.6%), osteoporosis, and diabetes (36.8%).The most common symptoms were muscle weakness in both genders (29.6%), and menstrual disturbances in women of reproductive age (46.8%). Acute weight gain was reported by only 17.1% of subjects. Finally, the most common signs were abdominal obesity (70%), buffalo hump (38%), and a round/moon face (37.5%). Typical striae were noted in only 20.8% of subjects. All these features were less frequent than usually quoted in the literature. We generated a disease severity score which was positively correlated with serum cortisol after an overnignt dexamethasone suppression test ($r = 0.42$, $P = 0.003$), but not with urinary free cortisol excretion.
Conclusions
Our tertiary institution's experience suggests the incidence of diagnosed CS is rising. Nonetheless, clinicians should be aware that the majority of modern era CS patients might escape diagnosis due their non-classical presentation. Our findings add further uncertainty as to which patients should be screened for CS.

Visual impairment in patients with pituitary apoplexy

Imen Gargouri, Hadjkacem Faten, Belabed Wafa, Ben Salah Dhouha, Mnif Mouna, Charfi Nadia, Rekik Nabila & Abid Mohamed
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Pituitary apoplexy (PA) is a rare incident defined by the occurrence of necrosis and/or haemorrhage of the pituitary gland. PA is a clinical syndrome

characterized by the sudden onset of headache, vomiting, visual impairment and decreased consciousness in some cases. The objectives of our study are to describe its clinical features and characterize the visual impairments in a cohort of PA in the region of Sfax.
Methods
It is a retrospective study including a group of patients in the Endocrinology department of Hedi Chaker Hospital in Sfax over an 18-year period (2000–2017). The data collected was analysed by the SPSS version 20 software.
Results
This study included 44 patients (20 women vs 24 men) with a mean age of 50.04±12.58 years. Fourteen patients (31.8%) had a pituitary adenoma known before the onset of apoplexy, secreting in 9 cases. Precipitating factor have been found in 14 cases (31.8%). At the time of apoplexy, an ophthalmological examination was performed in 34 patients only (77.3%). Visual loss was diagnosed in 10 patients (22.7%) who presented macroadeomas in all cases. A decrease in visual acuity was variable, ranging fromloss of some diopters (2 to 8) in 7 patients to a simple unilateral light perception in two cases and total blindness of one eye in one case. Bitemporal hemianopsiawas observed in 13 patients, and impairment of the visual field in 4 case. Papillary oedema was observed in 5 cases and a simple papillary pallor in 2 cases. Complete optic atrophy was observed in one case with a 2.5 cm macroadenoma and with compression of optic chiasm. The diagnosis of oculomotorpalsy was made in 9 cases (20.5%).Involvement of the common oculomotor nerve (III) was present in 7 cases (15.9%). Palsy of the pathetic nerve (IV) was noted in 4 cases. Palsy of theexternal oculomotor nerve (VI) was noted in both cases with total oculomotorpalsy.
Conclusion
The clinical picture of pituitary apoplexy is characterized by the sudden onset of oculomotor palsy or blindness with acute headaches and even consciousness impairment which need a fast intervention to prevent visual and life-threatening complications.

Central hypothyroidism as an adverse effect of bexarotene treatment for cutaneous T-cell lymphoma

Susan Felder[1], Stefan Zechmann[1], Katharina Baur[2], Eleonora Seelig[1], Emanuel Christ[1], Andreas Holbro[2] & Eliska Potlukova[1]
[1]University Hospital Basel, Endocrinology, Basel, Switzerland; [2]University Hospital Basel, Haematology, Basel, Switzerland

Introduction
Central hypothyroidism is rare, estimated to occur in 1:20,000 to 1:80,000 in the general population. Pituitary mass lesions and adverse effects of their treatment are the most common causes of central hypothyroidism. In recent years, the incidence of pituitary hormonal deficiencies as adverse effects of novel molecular targeting anticancer drugs has risen sharply. Especially checkpoint inhibitors are associated with partial or complete hypopituitarism. In this report, we describe a case of isolated central hypothyroidism as a side effect of the retinoid X-receptor-selective ligand (RXR) bexarotene, used for treatment of cutaneous T-cell lymphoma.
Case report
A 74-year-oldmale patient presented with skin changes accompanied by severe pruritus. A skin biopsy revealed a cutaneous T-cell lymphoma (Sézary syndrome). Due to progressive disease under the initial therapeutic approaches, a third-line therapy with bexarotene was initiated. Only six days after initiation of bexarotene, the levels of free thyroxine (fT4) decreased to 7.7 pmol/l (with a nadir of 6.5 pmol/l in the follow-up) and the level of thyroid-stimulating hormone fell to 0.104 mIU/l (with a nadir of 0.005 mIU/l in the follow-up). Upon initiation of levothyroxine substitution (initially 50 mg/d, later 75 mg/d), the levels of fT4 increased, but remained in the hypothyroid range. After increasing the dose to 100 mg levothyroxine/day, the fT4 normalized (12.3 pmol/l). The patient did not develop symptoms of hypothyroidism and there were no deficiencies of other pituitary hormones.
Discussion
Bexarotene is a ligand of the retinoid X-receptor, and central hypothyroidism belongs to its described adverse effects. Link between thyroid function and vitamin A metabolism has been first described in the early 1970s when central hyperthyroidism was found in rats with vitamin A deficiency. Supplementation with levothyroxine reversed this by suppressing TSH secretion. Bexaroten seems to exert its effect by forming a heterodimer with thyroid hormone receptor in peripheral tissue. In addition,it inhibits the transcription of TSH-β subunit independently of triiodothyronine and promotes the clearance of thyroid hormones, resulting in accelerated hypothyroidism. Therefore, an increased thyroid replacement dose may be warranted in patients with bexarotene-induced hypothyroidism

Pasireotide-induced hyperglycemia and efficacy of antidiabetic treatments in patients with acromegaly: Evaluation of two referral centers

Ludovica F.S. Grasso[1], Sabrina Chiloiro[2], Rosa Pirchio[1], Antonella Giampietro[2], Renata S. Auriemma[1], Antonio Bianchi[2], Maria Cristina De Martino[1], Mariarosaria Negri[1], Annamaria Colao[1], Alfredo Pontecorvi[2], Laura De Marinis[2] & Rosario Pivonello[1]
[1]University Federico II of Naples, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Fondazione Universitaria A. Gemelli, IRCCS, Unità Operativa di Patologia Ipofisaria, Dipartimento di Endocrinologia e Diabetologia, Area Endocrino-Metabolica e Dermo-reumatologica, Rome, Italy

Pasireotide (PAS) has a safety profile similar to first-generationsomatostatin analogues (SSA), except for a higher frequency of hyperglycaemia-related adverse events (AEs). However, consensus on the best management of PAS-induced hyperglycaemia in acromegalic patients has still to be defined. The current study aims at investigating the effects of long-term PAS treatment on glucose metabolism, by evaluating the clinical management of hyperglycemia-relatedAEs in acromegalic patients followed in two Italian referral centers, participating to the PAOLA study. The role of metabolic parameters (weight, BMI, fasting glucose and HbA1c levels) and markers of disease activity (GH, IGF-I, duration of PAS treatment) were investigated as potential predictors of hyperglycemia development. A total of 31 patients (16 F/15 M, mean age 47.6 years) entered the study. Patients were treated with PAS for a mean time of 34 months (6–67). Glycemic control was established with HbA1c at 7%. During PAS treatment, mean FPG and HbA1c concentrations significantly increased ($P=0.005$) after 6 months of treatment, remaining persistently elevated until the last follow-up ($P=0.005$). At baseline, pre-existing diabetes mellitus (DM) was found in 6 (19%), and glucose intolerance (GI) in 4 (13%) patients. Hyperglycemia-related AEs, generally mild to moderate, were reported in 24 patients (77.4%, 5 worsening DM, 9 DM, 9 GI), occurring after a mean time of 6 months (1–17 months). One patient discontinued because of DM. At regression analysis, baseline glucose levels resulted aspotential predictors of hyperglycemia during PAS therapy ($P=0.04$, $r=0.25$). At study entry, 4 patients (13%) were already treated with antidiabetic drugs. Eight patients (33.3%) were treated only with hypocaloric diet for the study duration. Starting of new antidiabetic treatment was required in 12 patients (50%) throughout the study, and metformin (MET) was as first-line therapyfor all patients. Seven (58.3%) patients did not control glucose and HbA1c levels despite MET monotherapy, needing further therapies. MET was associated with DPP-4 inhibitor in 2 patients (16.6%), GLP-1 agonist in 3 patients (25%), GLP-1 agonist and glargine insulin in 2 patients (16.6%) patient to control hyperglycemia. Five patients (20.8%), 1 patient treated with MET (20%), 1 with hypocaloric diet (20%), 1 with MET and glargine insulin (20%) and 2 with insulin (40%) were uncontrolled at last follow-up. In conclusion, the results of the current study show a long-term effect of PAS therapy on glucose metabolism, but treatment with MET or its association with incretin resulted in good glycemic control in most patients.

The characteristic of patients with pituitary stalk lesions – single center,long term observation

Łukasz Kluczyński[1,2], Aleksandra Gilis-Januszewska[1,2], Damian Rogoziński[1], Magdalena Godlewska[1], Jacek Pantofliński[1], Agata Zygmunt-Górska[3], Małgorzata Wójcik[3], Jerzy Starzyk[3] & Alicja Hubalewska-Dydejczyk[1,2]
[1]University Hospital, Endocrinology Department, Krakow, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland; [3]Jagiellonian University Medical College, Department of Pediatric and Adolescent Endocrinology, Krakow, Poland

Background
Pituitary stalk lesions (PSL) is a general term used to describe changes located in the pituitary infundibulum. Special anatomical locus makes the diagnosis difficult to establish. Most of the patients with PSL characterizes with hypopituitarism and multiple metabolic abnormalities.
Aim
To present the characteristic of patients with PSL.
Methods
We analyzed data of 35 patients (21 M/14 W) with pituitary stalk lesions on the basis of long term observation in the pediatric/adult endocrinology departments of our university. Current metabolic data were available for 19 patients. The etiologies were divided into three groups (congenital, inflammatory, neoplastic) and classified as exact, probable or unknown.
Results
The mean age of diagnosis was 28 years (s.d. 24.26). The most common causes of PSL were congenital malformations (16/35, 45.7%), an inflammatory etiology was found in 13/35 (37.1%), while neoplasms were diagnosed in 6/35 (17.1%) of patients. The exact etiology was established in 24/35 (68.6%) cases (16 congenital malformations, 5 histiocytosis, 1 Erdheim-Chester disease, 1 germinoma, 1 hypophysitis). The probable cause was suggested in 7/35 patients (20.0%) – six with the suspicion of lymphocytic hypophysitis and one with a metastasis from a disseminated neuroendocrine cancer. The origin of 4/35 PSL (11.4%) remains unknown. During hormonal assessment the most common insufficiency concerned the thyroid axis, found in 18/35 (51.4%) patients, followed by somatotropic (17/35, 48.6%), gonadal (15/35, 42.9%) and adrenal axis (11/35, 31.4% of cases) insufficiencies. 12/35 (25.7%) patients were diagnosed with diabetes insipidus. Some deficits were transient. Obesity/overweight were present in 10/19 and cachexia in 3/18 of cases. 3/18 of patients, all with lymphocytic hypophysitis, had significantly elevated systolic and diastolic blood pressure. Lipid disturbances were diagnosed in 12/19 of patients (among them in 7/11 of relatively young patients with congenital malformations, in 9/12 of patients with secondary hypothyroidism and in 10/15 of cases with somatotropic axis deficiency). 3/19 patients characterized with higher values of liver enzymes (ALT, AST, GGTP). Vitamin D deficit was found in 10/19 of cases. Hyperinsulinemia/insulin resistance were found in 6/19 of patients (only 2 of them were on hydrocortisone).
Conclusions
The diagnosis, management and treatment of the pituitary stalk lesions remain challenging. Difficulties in establishing the exact diagnosis mightbe related to the non-specific, transient characteristics of the symptoms and hormonal insufficiencies. Metabolic abnormalities in patients with hypopituitarism caused by PSL are very common. Long term observations might help better the understanding of the disease and result in improvement of management.

Preoperative pegvisomant as a potential therapeutic option to improve cardiac function in Acromegaly-induced cardiomyopathy: Two cases

Matthias E. Ernst, Gurpreet Anand & Felix Beuschlein
Clinic for Endocrinology, Diabetology and Clinical Nutrition, University Hospital, Zurich, Switzerland

Introduction
Acromegaly is a rare chronic disorder caused by growth hormone hypersecretion due to GH-producing pituitary adenoma. Surgery is the first-line treatment modality. However, patients with severe cardiac involvement are high-risk candidates for pituitary surgery. These patients may benefit from rapid preoperative biochemical control of acromegaly. There is emerging evidence of efficacy of pegvisomant, a GH-receptor antagonist, (either alone or in combination with somatostatin receptor ligands) in achieving rapid normalization of IGF-1. However clinical experience in using pegvisomant as monotherapy in preoperative setting in high-risk cardiac patients is lacking. We present two cases with acromegaly-induced dilated cardiomyopathy (DCM) who had preoperative treatment with pegvisomant.
Case reports
Case 1: A 53-year-old woman with biochemically confirmed acromegaly (random GH 10.5 mg/l (normal range 0.02–1.23), IGF1 1015 mg/l (normal range 71–224)) was referred to our clinic. Neuroimaging (MRI) of the head revealed a pituitary adenoma (15×14×6 mm). The patient was considered high-risk for surgery due to acromegaly-induced comorbidities especially the heart failure with reduced left ventricular ejection fracture (LVEF) of 29% and a severe mitral insufficiency. In addition, she had diabetes and obstructive sleep apnea. We started treatment with pegvisomant (daly 10 mg). Within two months of treatment, the IGF-1 decreased to 450 mg/l. LVEF improved to 37%. Not surprisingly, diabetes control also got better with reduced requirement for insulin. Tongue size and upper airway swelling decreased as well. Resection of pituitary adenoma was uneventful with complete biochemical and structural remission. *Case 2*: A 46-year-old man was admitted with congestive heart failure. Imaging (TTE, cardiac MRI) revealed a DCM with a LVEF of 20% and a severe aortic regurgitation. Careful clinical examination revealed typical clinical findings suggestive of acromegaly. The diagnosis was confirmed by elevated random GH; 38 mg/l and elevated IGF-1; 1080 mg/l. MRI scan of the brain showed a pituitary adenoma with infiltration of the cavernous sinus (32×22×20 mm). To optimize cardiac function, aortic valve replacement was scheduled before pituitary surgery. In addition, we started preoperative treatment with pegvisomant. After two months, the IGF-1 decreased to 700 mg/l. The aortic valve replacement was successful. LVEF in this case remained unchanged in short-term follow-up. However, NT-proBNP was regredient. The pituitary surgery is still pending.
Discussion
Severe cardiovascular disease in patients with acromegaly portends high mortality rate (almost 100% within 15 years). Preoperative treatment with pegvisomant may reduce perioperative risk by rapidly normalizing IGF-1 levels.

Background
Patients with acromegaly have substantially reduced quality of life (QoL). Delayed diagnosis is common and a long duration of untreated acromegaly leads to decreased QoL and increased morbidity and mortality.
Aim
This longitudinal study examined QoL in patients with acromegaly who received lanreotide autogel.
Material and methods
This was a 2-year prospective, observational, multicenter study conducted in Poland (NCT02396966). We included patients with acromegaly who received treatment with lanreotide autogel 120 mg for ≥3 months and <3 years. QoL was measured with the Acromegaly Quality of Life questionnaire (AcroQoL).
Results
Of 152 patients enrolled from November 2014 to May 2018 in 37 centers, 24 were excluded due to major protocol deviations; thus, results are reported for 128 patients in the study population. At baseline, the median (95% CI) time from diagnosis was 3.3 (2.8, 4.2) years, and the median (95% CI) time since lanreotide autogel initiation was 13.4 (10; 17) months. In 85.9% patients, acromegaly was symptomatic at baseline; headaches (57.0%), sweating (57.8%), and joint symptoms (64.1%) were most common. Hormonal and symptomatic control was stable from baseline to study completion. At baseline, treatment satisfaction was high (88.3% completely or rather satisfied). During the study, treatment satisfaction was unchanged for 88.2% of patients. Mean (95% CI) AcroQoL scores at baseline were as follows: total score, 50.3 (47.3, 53.3); physical dimension, 48.8 (45.2, 52.4); psychological dimension, 51.3 (48.2, 54.4); appearance subdimension, 40.7 (37.5, 43.8); and personal relations subdimension, 62.5 (58.8, 66.2). From baseline to month 24, the appearance subdimension improved 3.8 points (1.1, 6.4),

whereas the remaining AcroQoL scores did not change substantially. The total AcroQoL score remained unchanged over 2 years regardless of prior acromegaly treatment, prior surgery, prior radiotherapy, biochemical control, or lanreotide dosing interval. No new safety findings were identified.
Conclusions
Overall, global QoL and its physical and psychological aspects remained stable albeit compromised despite hormonal and symptomatic control throughout the study, whereas the AcroQoL psychological appearance subdimension improved. Most subjects remained satisfied with treatment during the study.

Soluble klotho: A possible predictor of quality of life in acromegaly patients

Eva Coopmans[1], Nour El-Sayed[1], Jan Frystyk[2,3,4], Nils Erik Magnusson[4], Jens Otto Jorgensen[5], Aart Jan Van der Lely[1], Joseph AM Janssen[1], Ammar Muhammad[1] & Sebastian Neggers[1]
[1]Erasmus MC, Rotterdam, Netherlands; [2]Odense University Hospital, Odense, Denmark; [3]University of Southern Denmark, Sønderborg, Denmark; [4]Aarhus University, Aarhus, Denmark; [5]Aarhus University Hospital, Aarhus, Denmark

Purpose
Although quality of life (QoL) is improved in patients with acromegaly after disease control, QoL correlates only weakly with traditional biomarkers. Our objective is to investigate a potential relation between the new serum biomarker soluble Klotho (sKlotho), GH and insulin-like growth factor 1 (IGF-1) levels and QoL.
Methods
In this prospective cohort study, we investigated 54 acromegaly patients biochemically well-controlled on combination treatment with first-generation somatostatin receptor ligands (SRLs) and pegvisomant (PEGV) at baseline and nine months after switching to pasireotide LAR (PAS-LAR; either as monotherapy, $n=28$; or in combination with PEGV, $n=26$). QoL was measured by the Patient-Assessed Acromegaly Symptom Questionnaire (PASQ) and Acromegaly Quality of Life (AcroQoL) questionnaire.
Results
Switching to PAS-LAR treatment significantly improved QoL without altering IGF-1 levels. QoL did not correlate with GH or IGF-1 levels, but sKlotho correlated with the observed improvements in QoL by the AcroQoL global ($r=-0.35$, $P=0.012$) and physical sub-dimension ($r=-0.34$, $P=0.017$), and with PASQ headache ($r=0.28$, $P=0.048$), osteoarthralgia ($r=0.46$, $P=0.00080$) and soft tissue swelling score ($r=0.29$, $P=0.041$). Parallel changes in serum sKlotho and IGF-1 ($r=0.31$, $P=0.023$) suggest sKlotho and IGF-1 to be similarly dependent on GH. Comparing the PAS-LAR combination therapy and the monotherapy group we did not observe a significant difference in improvement of QoL.
Conclusion
Patients experienced improved QoL during PAS-LAR, either as monotherapy or in combination with PEGV. Soluble Klotho concentrations appear to be a useful marker of QoL in acromegaly patients but the underlying mechanisms remain to be investigated.

Pregnancy outcomes in women receiving growth hormone therapy enrolled in NordiNet international outcome study (IOS) and American Norditropin Studies: Web Enabled Research (ANSWER Program)

Beverly Biller[1], Charlotte Höybye[2,3], Anna Camilla Birkegård[4], Alberto Pietropoli[5] & Matthias Weber[6]
[1]Massachusetts General Hospital, Harvard Medical School, Neuroendocrine & Pituitary Tumor Clinical Center, Boston, United States; [2]Karolinska University Hospital, Department of Endocrinology, Stockholm, Sweden; [3]Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [4]Novo Nordisk A/S, Søborg, Denmark; [5]Novo Nordisk Healthcare AG, Zürich, Switzerland; [6]University Hospital, University of Mainz, Unit of Endocrinology, Medical Department, Mainz, Germany

Recombinant human growth hormone (GH) is not indicated for use during pregnancy and in women of childbearing potential not using contraception. Nonetheless, in clinical practice, some women taking GH replacement conceive during treatment and many continue GH during their pregnancy. Here we report data on GH-treated women enrolled in two complementary, international, non-interventional registry studies, NordiNet IOS (NCT00960128; 2006–2016) and ANSWER (NCT01009905; 2002–2016), that assessed effectiveness and safety of real-life treatment with Norditropin (somatropin). Patient information was entered at routine clinic visits by participating physicians using a web-based system. Overall, 54 pregnancies were reported in 40 female patients with GH deficiency (GHD): 28 women had one pregnancy, 10 had two and two had three pregnancies. Median (range) age at estimated conception date was 31.9 (23.0–41.8) years. Pituitary disease aetiology included pituitary/hypothalamic tumours/adenomas in 27.5%, craniopharyngioma in 12.5%, idiopathic/congenital in 25.0% and other causes of acquired GHD in 30.0%. Seven patients had isolated GHD. Twenty-four (60.0%) patients had adult-onset GHD and 14 (35.0%) had childhood-onset GHD (missing, $n=2$). At baseline, 27.5% of patients reported one additional pituitary hormone deficiency, 10.0% had two, 17.5% had three, 20.0% had four, 2.5% had five and 5.0% had six. Deficiency of LH/FSH was present in 50.0%, TSH in 42.5%, ACTH in 35.0% and ADH in 12.5% of patients at conception. Seven (17.5%) patients had diabetes insipidus. GH dose (mg/day) at conception was >0.6 in 20 (37.0%) pregnancies, 0.4–0.6 in nine (16.7%) and ≤0.4 in six (11.1%). In seven (13.0%) pregnancies GH therapy was stopped by conception, permanently discontinued/stopped before study inclusion in two (3.7%), and patient was not treated in two (3.7%) (missing, $n=8$). During pregnancy, GH therapy was stopped (≤5 months/before conception) in 27 (50.0%) pregnancies, partially continued (> 5 –<7 months) in two (3.7%) and continued in 16 (29.6%) pregnancies (no treatment, $n=3$; missing, $n=9$). Among the 18 pregnancies with continued/partially-continued GH therapy, mean daily dose was >0.6 mg in 10, 0.4–0.6 mg in six and ≤0.4 in two. Forty-two (77.8%) pregnancies resulted in the birth of a healthy child; no birth defects were reported. There were five (9.3%) spontaneous abortions and two elective terminations (patient wish, $n=1$; medical indication, $n=1$). Outcome was unknown for five pregnancies.
In these women, most pregnancies resulted in the birth of healthy children. These data add to available knowledge on the outcome of pregnancy in GH-treated women with GHD.

Country-specific differences in adult growth hormone deficiency diagnosis and treatment rates

Navid Nedjatian[1], Bjørnar den Hollander[2] & Yacine Amirouche[1]
[1]Novo Nordisk, Zürich, Switzerland; [2]Meridian HealthComms, Manchester, United Kingdom

Background
Adult growth hormone deficiency (AGHD) is a rare disease associated with adverse metabolic abnormalities and possibly increased cardiovascular morbidity and mortality. Although basic prevalence data is available, little is known about the rates of diagnosed and treated patients.
Aim
To understand the rates of AGHD diagnosis/treatment and details about patients' growth hormone (GH) dose, age and treatment duration.
Methods
From 2015–2018, 435 endocrinologists across US, Germany, Switzerland, UK, France and Japan completed a survey providing details about the number of AGHD patients under their care, number of patients treated, GH dose, age and treatment duration. Percentages of undiagnosed patients were estimated based on respondents' projections of undiagnosed patients and published prevalence literature. Results were stratified by country and AGHD subtype (childhood onset [CO], pituitary adenoma [PA] and traumatic brain injury [TBI] and others [not shown]).
Results
The numbers of diagnosed and GH-treated adult patients across the six countries are shown in Table 1. In the US, Germany, Switzerland and UK, mean GH dose ranged from 0.43–0.78, 0.42–0.48 and 0.40–0.56 mg/day for AGHD-CO, -PA and -TBI, respectively. The opinion of the respondents regarding the gap in diagnosis is summarised in Table 2. Treatment duration, drop-out and resumption rates varied by country and AGHD subtype.

Table 1

	US	Germany	Switzerland	UK	France	Japan
AGHD-CO						
Patients diagnosed, N	3,325	1,252	142	2,052	560	1,346
Patients treated, N (%)*	2,333 (70.2)	964 (77.0)	101 (71.1)	1,549 (75.4)	438 (78.2)	1,070 (79.5)
AGHD-PA						
Patients diagnosed, N (%)	7,177	2,059	211	5,215	1,658	2,323
Patients treated, N (%)*	3,352 (46.7)	1,128 (54.8)	119 (56.3)	3,695 (70.8)	1,283 (77.4)	1,751 (75.4)
AGHD-TBI†						
Patients diagnosed, N (%)	6,324	1,651	123	1,735	553	1,093
Patients treated, N (%)*	2,229 (35.2)	768 (46.5)	61 (49.6)	1,255 (72.3)	428 (77.4)	824 (75.4)

*Of diagnosed patients. †AGHD-TBI with persistent hypopituitarism.

Table 2

	US	Germany	Switzerland	UK	France	Japan
Estimated undiagnosed patients,%						
AGHD-CO	17.4	16.1	15.1	34.0	18.6	4.7
AGHD-PA	56.4	53.2	53.7	31.0	21.3	36.0
AGHD-TBI*	64.3	54.7	55.7	42.0	21.3	35.8

*AGHD-TBI with persistent hypopituitarism.

Discussion
The analysis suggested substantial differences in diagnosis/treatment rates of AGHD-PA and AGHD-TBI, with lower rates in US, Germany and Switzerland compared with UK, France and Japan. The AGHD-CO diagnosis/treatment rates were relatively high everywhere as expected based on preceding childhood diagnosis. Determining the causative factors behind country-specific differences in GH treatment may help improve care for AGHD patients.

Evaluation of haemolitic complement activity (ch50) and igg subclasses in adult growth hormone deficiency: Preliminary data

Edoardo Vergani[1], Carmine Bruno[1], Umberto Basile[2], Cecilia Napodano[2], Gaia Piunno[1], Annunziata Stefanile[2], Francesca Gulli[3] & Antonio Mancini[1]
[1]Fondazione Policlinico Universitario A Gemelli IRCCS, Università Cattolica del Sacro Cuore, Dipartimento di Medicina e Chirurgia Traslazionale, Rome, Italy; [2]Fondazione Policlinico Universitario A Gemelli IRCCS, Rome, Dept. of Laboratory Medicine, Rome, Italy; [3]Ospedale "S. G. Vannini", Rome, Italy

Adult Growth Hormone Deficiency (GHD) is a condition characterized by low grade chronic inflammation; increased levels of free light chains of immunoglobulins have been described; moreover, it shares some features with metabolic syndrome (MetS), including insulin resistance and oxidative stress, but with a different pattern of antioxidant response. Finally, it is known that GH, directly or via IGF-1 activity, influences many aspects of immune response; both humoral and cellular branches are modulated, but no data are available about complement function.
CH50 is a screening assay for the activation of the classical complement pathway and it is sensitive to the reduction, absence and/or inactivity of any component of the pathway. The CH50 tests the functional capability of serum complement components of the classical pathway to lyse sheep red blood cells (SRBC) pre-coated with rabbit anti-sheep red blood cell antibody (haemolysin). The subclasses of IgG can also depict a scenario of immune response, knowing the different functions of specific subclasses. No data are reported on CH50 and IgG subclasses in GHD.
Therefore, we performed a case-control study in a group of adult GHD patients evaluating CH50 levels and IgG subclasses to further explore the pattern of inflammatory markers in this condition.
We includedpatients with total GHD (GH peak after stimulation with GHRH+arginine <9 ng/ml with BMI < 30 or <4 ng/ml with BMI ≥ 30 kg/m^2; $n=15$) or partial GHD (peak between 9 and 16 ng/ml with BMI < 30 kg/m^2 $n=12$) with mean ± SEM BMI 27.7 ± 2.6 kg/m^2 and mean ± SEM age 51.3 ± 2.5 ys. We also included a control group ($n=29$) of patients matched by age (mean ± SEM 49.4 ± 1.7 ys).
An opposite pattern of the parameters studied was observed, with a significant increase of CH50 in GHD vs controls (Mean ± SEM 51.2 ± 2.5 and 30.5 ± 1.7 U/l respectively, $P<0.05$), while a significant decrease of IgG4 was present in the same groups (0.23 ± 0.05 and 0.62 ± 0.11 g/l respectively, $P<0.05$).
These datasubstantiate the hypothesis of chronic low-grade inflammation in GHD even if a causal relationship cannot be established and a vicious circle could ensue, with increase in inflammatory molecules in turn influencing GH secretion. However, these data cannot be conclusive and further studies are needed to establish the role of such molecules as biological markers and their usefulness in prognostic and personalized treatment of such condition.

FDG PET contribution to ectopic prolactinoma diagnosis - case report

Michal Krcma[1] & Radka Fuchsova[2]
[1]University Hospital Plzen, 1st Clinic of Internal Medicine, Plzen, Czech Republic; [2]University Hospital Plzen, Department of Immunochemistry, Plzen Czech Republic

Pituitary adenomas are in the majority of cases diagnosed by magnetic resonance imaging (MRI). In some cases, especially in functional tumors, there are too small adenomas for MRI resolution and we need other diagnostic modality (including petrosal sinus catheterization for laterality). Usefulness of positron emission tomography (PET) with fluorodeoxyglucose was demonstrated in some case report. In this case, we present 36 y/o women with no other comorbidities, which came at first in 2012 for 10 months persistent amenorrhea with normal gynecologic finding. Diagnosis of hyperprolactinemia was determined (PRL 2820 mIU/l = 132.5 ng/ml; 7 × ULN) and treatment with cabergoline (0.5 mg/weekly) was started. MRI revealed 4 mm microadenoma in right half of pituitary gland. Other pituitary function were normal. Until 6 months, PRL was normalized and cycle was restored. Next follow-up was lost. After five years, the patient came with the same problem – persistent amenorrhea with minor PRL elevation (1398 mIU/l), we started the same treatment with cabergoline. In contrary to previous course, no effect was observed, PRL increased regardless of the cabergoline dose (max 2 mg daily). Other pituitary functions remained normal. Switch to bromocriptine and next to quinagolide was not successful, maximal tolerated doses were completely inefficient and PRL was continuously increased (to 7038 mIU/l). MRI repeatedly (altogether 3 examinations in 1.5 year) with no pituitary pathology, originally founded microadenoma in right half of pituitary gland was disappeared. Macroprolactinemia was excluded. Therefore PET/MRI with FDG was performed, even with thought of ectopic prolactinoma. Surprisingly, we found thin (3 mm) strip of tissue around left carotid artery with sphenoid propagation (length 10 mm), with increased FDG uptake (SUV max 15). No other pathology was found. Neurosurgery cannot be radical in this case and then this locus was irradiated by gamma knife (35Gy on 46% isodose, Dmax 76Gy) with decreased PRL level to 1041 mIU/l after 3 months and 890 mIU/l after 6 months. MRI after 6 months showed regression of this "ectopic" prolactinoma to 4.5 mm length.
Conclusion
Treatment resistant hyperprolactinemia represents less than 5% of prolactinomas. Irradiation or neurosurgery are possible therapeutic modalities.

Hybrid radiologic methods (PET FDG with MRI) can contribute to diagnosis in cases of ectopic or very small pituitary tumors.

SF-12 or SF-36 in pituitary disease? towards concise patient-reported outcomes measurements

Merel Van der Meulen[1], Nienke Biermasz[1], Amir Zamanipoor Najafabadi[1], Daniel Lobatto[1], Wouter van Furth[2], Cornelie Andela[1], Alberto M Pereira[1] & Thea P.M. Vliet-Vlieland[3]
[1]Leiden University Medical Center (LUMC), Endocrinology, Leiden, Netherlands; [2]Leiden University Medical Center (LUMC), Neurosurgery, Leiden, Netherlands; [3]Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands

Objective
Pituitary diseases cause a wide range of local and systemic symptoms and severely affect patients' health-related quality of life (HRQoL), which can be monitored using both disease-specific and generic questionnaires. The most frequently used generic HRQoL questionnaire is the Short Form-36 (SF-36), generating a mental (MCS) and physical component score (PCS). The shorter 12-item version (SF-12) can improve efficiency of patient monitoring and outcome measurement and reduce the burden for patients. This study therefore aimed to determine whether the SF-12 can be used instead of the SF-36 in pituitary care.
Study design and methods
Data of a longitudinal perioperative cohort study (August 2016 – December 2018) were used, comprising 103 adult patients endoscopically operated for a pituitary adenoma with 6 months follow-up. A chronic care cross-sectional cohort study in 431 adults with a pituitary tumor was analyzed in parallel. Both studies were conducted in a tertiary referral center in the Netherlands. The PCS and MCS of SF-36 and SF-12 were measured preoperatively, and 6 weeks and 6 months postoperatively. Agreement between questionnaires on each timepoint and over time was assessed with intraclass correlation coefficients (ICC) and Bland-Altman plots, presenting the limits of agreement (95% of the observed values). Linear regression analysis was used to determine the association of baseline factors with a large individual difference (>5 points) between SF-36 and SF-12.
Results
For PCS, ICCs were 0.590 preoperatively, 0.548 at 6 weeks and 0.622 at 6 months. ICCs for MCS were higher, respectively 0.952, 0.948, and 0.943. At the same time points, mean differences between SF-36 and SF-12 were 4.1, 4.7 and 5.9 points for PCS, and 1.3, 1.5, and 1.7 points for MCS. Limits of agreement for change (6 months vs preoperatively) were –14.0 to 16.9 for PCS and -7.8 to 8.7 for MCS. Similar results were found in the cross-sectional cohort. No baseline factors were consistently associated with a large individual difference between the SF-36 and SF-12.
Conclusions
The SF-12 can reliably reproduce the MCS in pituitary patients, but PCS of SF-36 and SF-12 is less well correlated. Moreover, wide limits of agreement show that individual differences between the SF-36 and SF-12 can be large. The SF-36, that also offers the advantage of generating HRQoL domain scores, is therefore recommended for use in pituitary care. Further strategies to reduce the number of questions in both validated generic and disease-specific HRQoL questionnaires must be evaluated for this patient population.

The role of surgery in the treatment of craniopharyngioma: A comparison of the transsphenoidal approach and the interbasal hemisphere approach based on surgical outcomes

Takayuki Matsuo & Kensaku Kamada
Nagasaki University, Neurosurgery, Nagasaki, Japan

The transsphenoidal approach has been utilized in intrasellar craniopharyngioma surgeries. However, the advent of endoscopic extended transsphenoidal approach (EETSA) has expanded its indication to suprasellar craniopharyngiomas. We compared the indication and limitations of EETSA to those of unilateral basal interhemispheric approach (UBIHA), which presents similar indications for surgery. We analyzed 60 patients with tumors located below the foramen of Monro and the lateral boundary extending slightly beyond the internal carotid artery (UBIHA: $n=36$; EETSA: $n=24$). Postoperative magnetic resonance imaging (MRI) revealed gross total resection in 20 patients in the EETSA group (83.3%) and 24 in the UBIHA group (66.7%). Postoperative MRI in the EETSA group revealed residual tumor at the cavernous sinus in two patient, at the prepontine in two; in the UBIHA group, residual tumors were located in the retrochiasmatic area in four patients, infundibulum-hypothalamus in two, on the stalk in two, and in the intrasellar region in two. No intergroup differences were observed in the preservation of pituitary function and postoperative improvement of visual function. The extent of resection was better with EETSA than with UBIHA. EETSA is considered the first-line therapy because the distance between the optic chiasm and the superior border of the pituitary is large; the lateral extension does not go beyond the internal carotid artery; and the tumor does not extend inferiorly beyond the posterior clinoid process. However, in patients showing poorly developed sphenoid sinuses or pituitary stalks anterior to the tumor, surgery is difficult regardless of the selection criteria.

An analysis of incidence and characteristics of cushing's syndrome in malta: A population based study

Miriam Giordano Imbroll[1,2], Alexia Giovanna Abela[1,2], Josanne Vassallo[1,2] & Mark Gruppetta[1,2]
[1]Department of Medicine, University of Malta Medical School, Mater Dei Hospital, Msida, Malta; [2]Neuroendocrine Clinic, Mater Dei Hospital, Msida, Malta

Aim
There are few reports discussing incidence and characteristics of the whole group of Cushing's syndrome patients in the literature. The aim was to establish the incidence of endogenous Cushing's syndrome with in-depth analysis of their various subtypes in a well-defined population.
Methods
Retrospective cross-sectional analysis of Cushing's syndrome patients diagnosed between 2008 and 2017. A thorough search for patients was carried out in the central hospital registries including outpatients departments, surgical registries, radiological department and specialty clinic databases.
Results
26 patients were identified as diagnosed with Cushing's syndrome over the 10-year period equating to a standardised incidence rate (SIR) of 4.7/1,000,000/yr with an almost equal SIR among males and females. Analysing the various subtypes of Cushing's syndrome, the majority ($n=13$) were due to an ACTH secreting pituitary adenoma (SIR 2.5/1,000,000/yr). In this subtype males had a SIR of 3.4/1,000,000/yr compared to 1.7/1,000,000/yr in females. ACTH independent Cushing's had a SIR of 1.8/1,000,000/yr with a strong female predominance (9:1) (SIR females: 3.0/1,000,000/yr; males: 0.5/1,000,000/yr). The SIR of ectopic ACTH secreting tumours was 0.4/1,000,000/yr. Interestingly hypokalaemia was present at diagnosis in those patients who harboured malignant causes for their Cushing's syndrome (ectopic ACTH secreting tumours or adrenocortical carcinomas) and had markedly elevated cortisol levels at baseline compared to the rest ($P<0.001$). Mean cortisol post overnight dexamethasone suppression test-was 1714 nmol/l (± 692 S.D.) in the malignant patients and 522 nmol/l (± 288 s.d.) in those patients with a benign tumour ($P=0.004$). Mean ACTH values for Cushing's disease patients was 110.4 (± 77.2 SD) pg/ml while in the ACTH independent group it was 5.5 (± 4.7 S.D.) pg/ml ($P<0.001$).
Conclusion
Cushing's syndrome is a rare disease. Although the numbers are small, we could still establish distinct characteristics in the different subtypes.

Patients receiving a range of doses of prior injectable somatostatin receptor ligands respond to oral octreotide in the treatment of acromegaly: Results from the phase 3 optimal study

Lisa Nachtigall[1], Susan Samson[2], Maria Fleseriu[3], Marek Bolanowski[4], Mark E Molitch[5], William Ludlam[6], Gary Patou[6], Asi Haviv[6], Patrick Manning[7], Nienke Biermasz[8], Andrea Giustina[9], Christian J Strasburger[10], Shlomo Melmed[11] & Laurence Kennedy[12]
[1]MGH Neuroendocrine and Pituitary Center, Portland, United States; [2]Baylor College of Medicine, Portland, United States; [3]Oregon Health & Science University, Portland, United States; [4]Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Evanston,

United States; [5]Northwestern University, Evanston, United States; [6]Chiasma, Italy; [7]Dunedin Hospital, Italy; [8]LUMC - Endocrinology and Metabolisme, Italy; [9]University of Brescia, Italy; [10]Charité Campus Mitte, Italy; [11]Cedars Sinai Medical Center, Italy; [12]Cleveland Clinic Foundation, Italy

Background
Injectable somatostatin receptor ligands (SRLs) are the most widely used therapy to control acromegaly. Oral octreotide capsules (OOC) have been formulated as a potential therapy for this disorder and the efficacy and safety was evaluated in the CHIASMA OPTIMAL prospective phase 3 study in patients with acromegaly who were controlled on injectable SRL treatment of varying doses (Samson *et al*. ENDO 2020).
Methods
Patients with confirmed acromegaly who had been receiving a stable dose of injectable SRL (≥3 months), were randomized to receive OOC (40 mg/day) or placebo for 36 weeks. Patients were dose titrated to 60 or 80 mg OOC or equivalent placebo through week 24 at the investigator's discretion based on increased IGF-I levels or worsening acromegaly signs/symptoms. The primary efficacy endpoint was the proportion of patients who maintained their biochemical response at the end of 36 weeks, defined as average IGF-I ≤1 xULN between Weeks 34 and 36. An analysis evaluated maintenance of response based on prior dose of injectable SRL. Prior doses of injectable SRL were categorized based on the following classifications: octreotide 10 mg every 4 weeks or lanreotide 60 mg every 4 weeks or 120 mg every 8 weeks were stratified as low; octreotide 20 mg every 4 weeks or lanreotide 90 mg every 4 weeks or 120 mg every 6 weeks were stratified as medium; octreotide 30 mg or 40 mg or lanreotide 120 mg every 4 weeks were stratified as high. Randomization was stratified based on low dose vs med/high dose and efficacy results compared for these strata. The response rates reported for the primary endpoint are adjusted for stratification differences as prespecified in the statistical analysis plan.
Results
Six patients (21.4%) in the OOC group had received prior treatment with low doses of injectable SRLs while 22 (78.6%) had received prior treatment with medium-high doses of injectable SRLs. Maintenance of response was observed in 16 patients receiving OOC. This included 66.7% of patients (n=4) previously receiving low doses of injected SRLs and 54.5% of patients (n=12) on medium-high injected doses. The treatment effect was consistent irrespective of prior dose of injectable SRL (odds ratio: 5.4 in low dose and 5.9 in medium-high dose).
Conclusion
The CHIASMA OPTIMAL study recruited a population receiving predominantly medium-high doses of injectable SRLs and demonstrated maintenance of response in 58% of patients. OOC treatment effect was consistent irrespective of prior dose of injectable SRL.

AIP gene germline mutations in non-selected patients with sporadic pituitary macrodenomas

Malgorzata Trofimiuk-Muldner[1], Bartosz Domagała[2], Grzegorz Sokolowski[1], Anna Skalniak[1], Dorota Pach[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland; [2]University Hospital in Krakow, Department of Endocrinology, Kraków, Poland

Up to 5% of all pituitary tumors are hereditary (e.g. due to menin or AIP genes mutations). AIP gene mutations are more common in subjects with acromegaly, less than 30 years old at the onset of disease, and with FIPA family history. The study was aimed at the assessment of the frequency and characteristics of AIP-mutation related tumors in non-selected patients with pituitary macroadenomas.
Material and methods
The study included subsequent 131 patients (57 males, 74 females; median age 42 years (IQR 25 years) diagnosed with pituitary macroadenomas, and with a negative family history of FIPA or MEN1 syndromes. The following tumors were identified: 11 ACTH-secreting, 49 GH-secreting (including 7 pluri-hormonal ones), 6 gonadotropinomas, 23 prolactinomas, 1 TSH-oma, and 43 non-secreting adenomas. Sanger sequencing was used for the assessment of AIP gene variants. The study was approved by the Ethics Board of JUMC.
Results
An AIP mutation was identified in five of 131 included subjects (3.8%): one diagnosed with Cushing's disease, two with acromegaly, and two with non-secreting adenomas. In two patients, the identified mutation usually predisposes to ACTH-secreting adenomas, in two patients – mutations of unknown clinical significance were found (usually connected with pituitary adenomas), and the mutation detected in one patient was described as benign. Patients harboring hereditary AIP gene variations did not differ from the rest of the study group in median age at diagnosis (41 vs 42.5 years, P=0.8), median largest tumor diameter (25 vs 24 mm, P=0.6), gender distribution (60% of females vs 56.3%, P=0.8), secreting tumor frequency (60% vs 67.5%, P=0.7), or acromegaly diagnosis frequency (40% vs 37.3%, P=0.9). 2 of the 5 patients with identified AIP gene mutations agreed for their families to be offered AIP genetic testing: (1) An AIP mutation was found in the asymptomatic mother of one acromegalic female patient. (2) The AIP mutation of unknown clinical significance was detected in the son of a male patient with acromegaly, clinically unscreened yet.
Conclusions
In our series of apparently sporadic pituitary macroadenomas, AIP gene mutation carriers did not differ substantially from patients with negative genetic testing. A risk factor-centered approach to AIP genetic screening may result in missing germline mutations, therefore, there is a need to establish if such a situation negatively impacts a patient's and his/her family outcomes.

Silent corticotroph adenoma: Experience with six cases

Guillermo Serra Soler[1], Carlos Antich Barceló[1], Javier Bodoque Cubas[1], Honorato García Fernández[1], Antonio Mas Bonet[2], Ester Antón Valentí[3], Elena Mena Ribas[1], Santiago Tofé Povedano[1], Iñaki Argüelles Jiménez[1] & Vicente Pereg Macazaga[1]
[1]Hospital Universitary Son Espases, Endocrinology, Palma de Mallorca, Spain Endocrinology, Palma, Spain; [2]Hospital Universitary Son Espases, Radiology, Palma, Spain; [3]Hospital Universitary Son Espases, Anatomical Pathology, Palma de Mallorca, Spain

Introduction
Silent corticotroph adenomas (SCA) represent a subtype of pituitary adenomas whose prevalence is 3% of pituitary adenomas. They are characterized by having a positive immunohistochemistry to corticotropin (ACTH) without clinical or biochemical data of hypercortisolism. The diagnosis is a challenge since they are considered as ANF, and it is with the pathology report after surgery when they are classified as SCA. They have more aggressive behavior and recur more than ANF
Case Report
Of the 129 pituitary adenomas operated on in our hospital in the last ten years (2009 – 2019), six SCA were found. The average age was 58.8 years (45 – 72) and 4/6 cases (67%) were women. All were macroadenomas, with an average size of 27 mm±8, with headaches in 5/6 (83%) and visual disturbances in 5/6 (83%). None of them showed signs and/or symptoms of hypercortisolism. Type 1 SCA was found in 3/6 (50%) and type 2 in the other 50%. The average preoperative ACTH value was 59 pg/ml±29, with an average cortisol of 13 µg/dl±2. Four out of six cases (67%) had high ACTH levels and all had normal plasma cortisol. Five of six cases (83%) had invasion of cavernous sinus and 2/6 (33%) suffered an apoplexy. Knosp's grade of cavernous sinus invasion was equal to or greater than 3 in 4/6 cases (67%). Multiple microcysts were found in the T2 sequence of pituitary MRI in 5/6 cases (83%), a liquid content of less than 50% in 4/6 (67%) and more than 50% in 2/6. Five of six cases (83%) presented with preoperative hypogonadotropic hypogonadism. Two of six cases (33%) presented "de novo" postoperative hypopituitarism. The average follow-up time was 37 months (3–78). Of six cases, two experienced a progression after surgery, one had a stable remnant, two did not have a remnant and one waiting for the pituitary MRI. The two cases that progressed had highervalues of ACTH, Knosp's grade and Ki-67, with less than 50% liquid content. Both required radiotherapy and one of them a second surgery
Conclusions
- SCA are a subtype of pituitary adenomas whose diagnosis regarding ANF is difficult. A high preoperative ACTH value and/or the presence of multiple microcysts in the T2 sequence of pituitary MRI could make us suspect the existence of SCA
- Because of the greater recurrence, SCA require closer clinical and radiological follow-up and an evaluation by a multidisciplinary team

MRI follow-up of patients with acromegaly treated with first-generation somatostatin analogues (SMSa): Is there a difference during primary or post-operative treatment?

Grandgeorge Naia[1], Barchetti Giovanni[2], Grunenwald Solange[1], Bonneville Fabrice[2] & Philippe Caron[1]
[1]CHU Larrey, Department of Endocrinology and Metabolic diseases, Toulouse, France; [2]CHU Purpan, Department of Neuroradiology, Toulouse, France

Objectives
First-generation SMSa are the medical treatment of choice in the management of acromegaly, mainly as adjuvant treatment of pituitary surgery when normal IGF-1 is not obtained or as primary treatment in selected patients. The main objective of this study is to evaluate regular pituitary MRI follow-up of acromegalic patients treated with SMSa as adjuvant treatment of pituitary surgery. The secondary objective is to compare the anti-tumoral effect of SMSa in post-operative period to the effect observed during primary treatment of acromegalic patients.
Patients and methods
In a monocentric, retrospective study we included all acromegalic patients treated with SMSa after a pituitary surgery or first-line therapy, and regularly followed by MRI scans for at least 3 years. The height of pituitary adenomas or post-operative remnants was measured along the coronal plane, perpendicularly to the optic chiasm, and all MRI scans are seen by the same neuro-radiologist.
Results
We included 27 patients (11 women, 16 men, mean age 39.5±12.2 years) treated with SMS a after surgery. The post-operative evaluation revealed persistent GH/IGF-1 hypersecretion (GH=4.2±9.9 ng/ml, IGF-1=175±74% ULN) and adenoma remnants (9.25±5.34 mm). After 6.1±4.5 years of SMSa treatment,the adenoma height did not decrease significantly in controlled (n=11, 8±5.0 vs 6.5±3.5mm, ns) or uncontrolled (n=16, 9.78±5.54 vs 9.35±4.71mm, ns) patients, with 20 adenoma remnants remaining stable. A significant increase (≥ 2 mm) of adenoma height was observed in a patient with acromegaly revealed by pituitary apoplexy and with histological aggressiveness criteria. Eighty three patients (32 men, 51 women, mean age 50±12 years) with mean GH=19.3±25.6 ng/ml, IGF-1=284±110 % ULN and pituitary adenoma height=12.9±4.7 mm were primary treated with SMSa : adenoma height decreased significantly in controlled patients (11.9±4.8 mm vs 9.6±3.3 mm, P<0.001) after 8.9±4.9 years, and in partially responders (13.6±4.5 mm vs 11.5±4.5 mm, P<0.001) after 2.0±1.6 years. Compared to the patients post-operative treated with SMSa, a greater anti-tumor effect was observed when SMSa was primary administered (2.20±3.03 mm vs 0.75±2.65 mm, P<0.02).
Conclusion
This clinical study shows that regular post-operative MRI monitoring of adenoma remnants does not seem necessary during SMSa treatment, but it remains indicated for rare patients with atypical adenoma and histological aggressiveness criteria, and confirms that first-generation SMS a have an anti-tumoral effect significantly lower in adjuvant treatment than in primary treatment.

Associations of endocrine and metabolic complications of childhood- and adult-onset craniopharingeoma with the histological subtype

Soncka Jazbinsek[1], Mojca Jensterle[2] & Primoz Kotnik[1]
[1]University Children's hospital, University medical center Ljubljana, Department of endocrinology, diabetes and metabolism, Ljubljana, Slovenia; [2]University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolism, Ljubljana, Slovenia

Objective
Studies comparing endocrine and metabolic outcomes of childhood- and adult-onset craniopharyngioma (CP) are generally based on the age-of-disease onset only. The aim of this study was to analyze the role of histological tumor subtype (adamantinomatous (aCP) or papillary (pCP)) on the development of long-term endocrine and metabolic CP comorbidities.
Methods
47 patients with CP treated from 1979 onwards (19 patients with childhood-onset disease) in a single center university institution were included. Median follow-up since presentation was 13 years (interquartile range: 0.2 – 38 years) and comparable between age-of-disease-onset and histological subtype groups. Data on tumor histology was extracted from patients' records, and re-evaluated by a single by an experienced pathologist when tissue samples were still available.
Results
At presentation 54% of childhood- and 41% of adult-onset CP patients had at least one pituitary axis affected. Individual hormonal axis were similarly affected when groups were compared by age-of-diagnosis or histology subtype. At follow-up 100% of childhood- and 93% of adult-onset patients had at least one pituitary hormone deficiency. Growth hormone (GH) deficiency, central diabetes insipidus and panhipopituitarism were more prevalent in childhood-onset aCP and least prevalent in adult-onset pCP. 20% of childhood-onset CP patients were already obese at diagnosis, whereas none of the adult-onset patients were obese. At follow-up only 11% of patients with childhood- and 4% of adult-onset CP were normal weight, with obesity rate increasing to 55% in the first and 46% in the latter group. Risk for obesity positively correlated with the presence of hydrocephalus at diagnosis, hypothalamic and third ventricular floor damage after surgery. Metabolic syndrome (MetS) was present in 80% of childhood- and 68% of adult-onset patients.
Conclusions
Long-term endocrine and metabolic complications are very frequent in CP patients. Patients with a CP, especially with childhood-onset, are generally more affected.

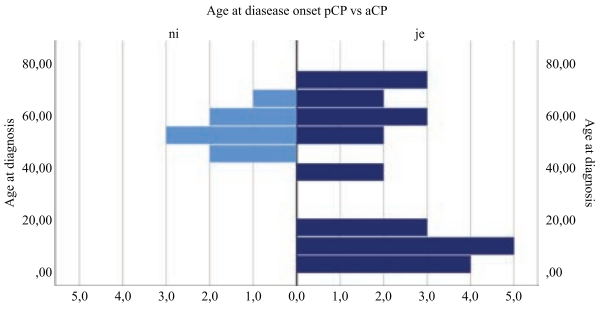

Figure 1 Frequency of CP diagnosis according to age-of-diagnosis and histological subtype.
Light blue – pCP
Dark blue – aCP
Data on histological type was missing in 6 childhood-onset CP and 7 adult-onset CP.

The united russian registry on patients with acromegaly

Zhanna Belaya[1], Olga Golounina[2], Liudmila Rozhinskaya[3], Mikhail Isakov[4], Alexander Lutsenko[3], Elena Przhiyalkovskaya[3], Ekaterina Pigarova[3], Galina Panyushkina[5], Alexander Dreval[6] & Galina Melnichenko[3]
[1]The National Medical Research Centre for Endocrinology, Neuroendocrinology and Bone Disease, Moscow, Russian Federation; [2]Sechenov First Moscow State Medical Univesity, Moskva, Russian Federation; [3]The National Medical Research Centre for Endocrinology, Moscow, Russian Federation; [4]Aston Consulting, Moscow, Russian Federation; [5]Voronezh Regional Clinical Hospital #1, Voronezh, Russian Federation; [6]Moscow Area regional research clinical institute n.a. M.F. Vladimirskiy, Russian Federation

Background
The registry is the main source of information about patients with acromegaly for assessing the quality of medical care, effectiveness of treatment, determining the compliance of real clinical practice with existing standards and patient management protocols.
Aims
To analyze the epidemiological, demographic and clinical characteristics of acromegaly in the Russian Federation and the effectiveness of various treatment methods.
Materials and methods
The object of the study was the database of the united Russian registry of patients with pituitary tumors with specific analysis of patients with acro-

megaly only. We analyzed 4114 patients with acromegaly included in the online system by February 2019.
Results
Based on the data collected by February 2019 32% of patients had complete clinical and laboratory remission of the disease; the percentage of patients with no remission was 68%, among them 22.5% had significant improvements in clinical presentations and decrease in GH and IGF1 without IGF1 normalization. The average age of patients at the onset of the disease was 42.7 years, at the stage of diagnosis – 45.8 years. The ratio of men to women was 1:2.6.Among patients with acromegaly and hypopituitarism complications such as hypothyroidism (66%) and hypogonadism (52%) were registered more often followed by secondary diabetes mellitus (15.7%) and acromegalic arthropathy (15%). The proportion of patients receiving neurosurgical treatment increased from 35.7% to 49.6% in 2012 – 2019; the percentage of patients undergoing radiation therapy decreased significantly from 17.7% in 2012 to 0.8% in 2019. Remission was achieved in 40.47% after neurosurgery and 28.95% after medical treatment as a first line therapy $P<0.01$. The number of patients receiving medical treatment at the time of the study was 1209. Among them 51% of patients being treated with long-acting lanreotide and 24% receiving long-acting octreotide achieved remission ($P<0.0001$)
Conclusions
Remission of acromegaly remains suboptimal despite increased surgical activity, which corresponds to global trends. Long-acting lanreotide was significantly superior versus long-acting octreotide in the rate of acromegaly remission, which does not correspond with clinical trials and can be explained by the generic forms, regional differences in medical supply and demand towards medical nurse qualification with regards to the injection of long-acting octreotide.

Immunohistochemical subtypes of growth hormone-secreted pituitary adenoma and relationship with the clinical course and seconder malignancy

Gamze Akkus[1], Ralp Cetinalp[2], Emine Bagir[3], Mehtap Evran[1], Sinem Sengoz[1], Suzan Zorludemir[3], Murat Sert[1] & Tamer Tetiker[1]
[1]Cukurova University, Endocrinology, Adana, Turkey; [2]Cukurova University, Neurosurgery, Adana, Turkey; [3]Cukurova University, Pathology, Adana, Turkey

Purpose
Most of the acromegaly cases are due to agrowth hormone-secreting pituitary adenomas of which immunohistochemical subtype seperated as sparsely granulated adenoma (SGA) and densely granulated adenoma (DGA). SGA's were reported to have more aggressive clinical course and therapy resistance. We investigated our patients for these aspects.
Method
Forty (F21, M19) patients with acromegaly who diagnosed and operated for pituitary adenoma at our University Hospital were included. Medical history, duration of the disease and comorbidities were assessed. Considering the current guidelines for acromegaly managements, serum growth hormone (with 75 g oral glucose tolerance test-OGTT), insulin like growth factor 1 (IGF-1) levels, computed tomography (CT) or magnetic resonance imagings (MRI) of the pituitary were performed. Immunohistochemical staining of postoperative tissue materials and subtypes of pituitary adenomas were evaluated by an experienced cytopathologist.
Results
Mean age of the patients was 48 years (range, 30 – 66). Of 40 patients, 30 had macroadenoma and 10 microadenoma. There were 25 (25/40) patients with SGA and 15 (15/40) with DGA. The remission rate after primary surgery of 40 patients was 9/40. Of 9 patients, 2 were SGA (2/25) and 7 DGA (7/15) ($P=0.001$, SGA vs DGA). Complete disease remission was seen in 15 of 40 (37.5%) patients. In those who achieved endocrine remission, 9 had only transsphenoidal surgery (TSS) and the remaining 6 patients were treated with somatostatin analogues and gamma-knife radiotherapy additional to TSS. As compared with the DGA, SGA showed more cavernous sinus infiltrasion (18 vs 10, $P=0.05$). Abnormal abdomen ultrasonography findings including hepatomegaly, hepatosteatosis, splenomegaly were found in all patients with SGA, but only in 6 patients with DGA. Furthermore, 4 neoplasia of the other site of body were found in the patients with SGA.
Conclusion
Immunohistochemical subtype of the pituitary adenoma seemed to have potential to affect the clinical course and therapy of acromegaly. SGA was revealed as more prone to cavernous sinus invasion, comorbidity and resistance to therapy. Carcinogenesis related with malignancy was more common in patients with SGA. Further studies are needed.

Prolactinoma In childhood and adolescence – a systematic review and meta-analysis

Ved Bhushan Arya, Simon Aylwin, Ritika R Kapoor & Charles R Buchanan
King's College Hospital, United Kingdom

Background and Objective
Data on the epidemiology, effects of dopamine agonists and long term outcome of prolactinoma in children and adolescents have been gradually accumulating but are still scarce. We conducted a systematic review and meta-analysis of published literature (1994 – 2019) to study the epidemiology of prolactinoma in patients<20 years old, and determine the management strategies adopted.
Methods
Relevant studies were identified through Medline search and from the reference list of retrieved studies. Pertinent data were extracted. Both "random" and "fixed" effects meta-analysis were used to pool outcomes across studies.
Results
Of 635 articles retrieved, 610 were discarded during the title and abstract analysis. Another seven articles were excluded after full-text analysis as they did not report on our research questions. A total of 18 articles, describing 487 patients, were then reviewed. A pronounced sex difference was noted with 75.7% (95% CI 69.6 to 81.3%) of patients being female. Patients were divided into those with macroprolactinoma ($n=288$), microprolactinoma ($n=151$) and size not specified ($n=48$). After excluding one large series which reported only macroprolactinomas, the proportion of patients with macroprolactinomas (57.6% [95% CI 51.2% to 64.0%]) was still higher than with microprolactinomas. Both macroprolactinomas (134 vs 67 F:M) and microprolactinomas (137 vs 6 F:M) were more common in females as compared to males. Even more striking was the difference in the distribution of size (micro/macro) between the two sexes. In males, only 6/73 (8.2%) of tumours were microprolactinoma as compared to 137/271 (50.5%) in females (risk difference 0.463; [95% CI 0.386 to 0.541]; $P<0.001$). Medical or surgical therapy was adopted as first-line therapy in 67.4% and 32.6% respectively. Surgery was, surprisingly, the initial treatment in 87/273 (31.9%) with macroprolactinoma, and 26/126 (20.6%) with microprolactinoma. In patients where the initial treatment was medical, 45/186 (24.2%) of macroprolactinoma patients and 20/100 (20%) of microprolactinoma patients subsequently proceeded to surgical intervention. Growth hormone, Adrenocorticotrophic hormone, Thyrotropin and Arginine Vasopressin deficiency were reported in 39 (8.7%), 43 (9.6%), 47 (10.5%) and 15 (3.3%) patients respectively (inadequate data to qualify whether pre- vs post-surgery.
Conclusions
Microprolactinoma occurs almost exclusively in females and is an uncommon diagnosis in males in this age group. Macroprolactinoma is also more common in girls compared to boys. A surprising number of patients proceeded to surgery before medical therapy, and surgery is part of overall management in a substantial proportion. Association with other pituitary hormone deficienciesis not uncommon.

Combined pitutitary hormone deficiency in a patient with charge syndrome

Spyridon Nikitas Skarakis[1,2], Feneli Karachaliou[2], Marina Mitrogiorgou[2], Aristofania Simatou[2], Evangelia Bountouvi[2] & Vassiliki Papaevangelou[2]
[1]General Hospital of Athens 'G. Gennimatas', Department of Endocrinology and Diabetes Center, Athens, Greece; [2]National and Kapodistrian University of Athens, School of Medicine, University General Hospital ATTIKON, Athens, Greece, Third Department of Pediatrics, Athens, Greece

Background
CHARGE is an autosomal-dominant syndrome which includes a variable combination of ocular coloboma, heart defects, atresia of the choanae, retar-

dation of growth and development, and genitourinary and ear abnormalities CHARGE syndrome has rarely been associated with anterior pituitary dysfunction and with structural abnormalities of the pituitary gland only twice. We report the case of a child with CHARGE association and congenital hypopituitarism due to structural abnormalities of the pituitary gland.
Case presentation
The patient was a boy born with IUGR (birth weight 2020 gr, 37 weeks' gestation). Clinical features included retinal coloboma and micropthalmia, choanal atresia, dysplastic auricles with small accessory auricle, multicystic dysplastic kidney and hypospadias with cryptorchidism. Endocrine testing revealed central hypothyroidism and secondary hypoadrenalism. There was inadequate response to low-dose intravenous Synacthen stimulation test, with serum cortisol peaking at 10.3 µg/dl at 1 hour. He was started on thyroxine and hydrocortisone replacement, with hydrocortisone replaced first and thyroxine after a couple of days. Because of severe growth impairment by the age of 3.4 years (HSDS:–4.71, HVSDS: –3.62), growth hormone secretion was evaluated. A severe GHD was detected (peak GH 1.56 ng/ml in both tests) and rhGH therapy was initiated. MRI revealed ectopic posterior pituitary, without clinical significance.
Conclusion
We describe the case of a boy fulfilling criteria of CHARGE association[1,2] presenting with multiple anterior pituitary hormone deficiencies and structural pituitary abnormality. To our knowledge this is the 3rd case in the literature where congenital hypopituitarim in CHARGE syndrome is associated with pituitary structural abnormalities and especially ectopic posterior pituitary.

Controversies in the spectrum of GH-IGF-I axis disorders requiring replacement therapy

Giulia Rodari[1], Ivan Cavenaghi[2], Eriselda Profka[2], Federico Giacchetti[2], Maura Arosio[1] & Claudia Giavoli[1]
[1]University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Department of Clinical Sciences and Community Health, Endocrinology Unit, Milano, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background
Growth hormone deficiency (GHD) is the most frequent endocrinological disorder inchildren with short stature, but there are significant controversies in the diagnosis due to lack of reliablediagnostic criteria. Moreover, at final height (FH) attainment, many subjects diagnosed withisolated GHD re-test normal. It is not clear whether this represents a form of transient GHD or a false positive diagnosis during childhood.
Aim
To evaluate differences in long-term outcomes (height gain □HT at FH) and retesting results in 57 GHD children (M=34, 59.6%) according to biochemical diagnosis: Group A (n=25) with max GH peak at stimulation test<8 µg/l, Group B (n=19) with max GH peak between 8 and 10 µg/l and Group C (n=13) with mean GH<3 µg/l (neurosecretory dysfunction, NSD). At FH all patients underwent to retesting after at least 1 month off therapy. Median GH dose at FH was 0.025 mg/kg/day.
Results
40/57 (70.2%) were pre-pubertal at diagnosis and showed a FH of –1.22±0.93 SDS not significantly different in the three groups (P=0.14) with a satisfactory □HT at FH of 1.37±1.00 SDS (P=0.08). Nonetheless, Group B showed the highest percentage of "poor responders" with 46% patients with □HT FH<1SDS (vs 13% and 12% in Group A and C, respectively) and with 25% children not reaching Mid-parental height (MPH) vs 6% and 0% in Group A and C, respectively. At linear regression, low HT SDS (P=0.0006), MPH difference (P=0.0039) and low IGF-I SDS at baseline (P=0.0035) were the most important predictive factors of □HT at FH. At FH attainment, GHD was reconfirmed in 28% (7/25), 10% (2/19) and 8% (1/13) patients in Group A, B and C, respectively.
Conclusion
A reduction of diagnostic cut-off at GH stimulation tests could better discriminate between "good" and "poor responders" and predict the persistence of GHD through transition. Nonetheless, GHD diagnosis solely based on provocative tests could exclude patients that might benefit of GH treatment. Group C response along with the predictive value of baseline IGF-I SDS bring back to lightNSD: should we consider an underlying hypothalamic derangement when the clinical presentation is strongly consistent with GHD-but pharmacological stimulation test is normal?

Severe heart failure in a young male patient with unrecognized hypopituitarism consequent to hemorrhagic fever with renal syndrome and undiagnosed hemochromatosis

Bojana Caric[1,2], Marko Stojanović[3,4], Ljiljana Kos[5,6], Aleksandra Grbić[6,7], Danijel Đekić[7], Gabrijela Malešević[1,6] & Dragana Miljić[3,4]
[1]University Clinical Center of Republic of Srpska, Department of Endocrinology, Clinic of Internal Diseases, Banja Luka, Bosnia and Herzegovina; [2]School of Medicine, Department of Intrenal Diseases, Banja Luka, Bosnia and Herzegovina; [3]Clinic of Endocrinology, Diabetes and Metabolic diseases, Clinical Centre Serbia, Belgrade, Serbia; [4]Faculty of Medicine, Dr Subotića starijeg 8, Belgrade, Serbia; [5]University Clinical Center of Republic of Srpska, Clinic for Cardiology, Banja Luka, Bosnia and Herzegovina; [6]School of Medicine Banja Luka, Banja Luka, Bosnia and Herzegovina

Background
The partial or complete hypopituitarism is described as late complication of hemorrhagic fever with renal syndrome (HFRS). Imaging methods of pituitary gland examination in the chronic phase showed pituitary atrophy, but a precise pathogenic mechanism that causes pituitary damage in HRFS remains unclear. While hypopituitarism in HFRS is rarely described, cardiac failure as a known complication of hypopituitarism is even more rarely described. We present a case of severe heart failure in a young male patient with unrecognized hypopituitarism consequent to HFRS and undiagnosed hemochromatosis.
Case Presentaton
42-year-old male patient was admitted at the Department of Endocrinology of University Clinical Centre of Republic of Srpska with suspected hypopituitarism. He managed to walk with the help of another person, and his speech was incoherent and with difficulties. The patient was pale, facial and body hairless with adynamia, myxedema, hypotension, and bilateral gynecomastia with decreased libido and impotency. Echocardiography verified a global reduction in myocardial contractility, dilated left atrium and ventricle, with low ejection fraction (10–15%). Results of hormone tests confirmed diagnosis of panhypopituitarism , and replacement therapy (hydrocortisone, levothyroxine and testostreone) was started. MRI of the pituitary gland was performed and it showed an "empty sella". On the third day after the therapy was introduced, the patient started to speak clearly and mental status was stabilized. The patient was independently mobile after seven days. Echocardiography performed a month after the replacement therapy was introduced showed an improvement in myocardial contractility with normal dimensions of the atrium and ventricle and estimated EF of 40%. Additionally, the diagnose of chemochromatosis was confirmed by genetic analysis of the HFE gene and presence of homozygosity for mutation pH63D (c 187>G), but the specific therapy was not initiated. At follow-up visit, 6 months after introduction of replacement therapy, the patient felt well, performed usual physical activities, male type of facial and body hair distribution recovered, his sexual function normalized, and he had a normal mental status. Echocardiography was completely normal 6 months after introduction of replacement therapy (the left ventricle with normal dimensions, EF 58%).
Conclusion
The heart failure is extremely rare complication of hypopituitarism, but it is usually reversible when hormonal therapy is replaced. According to significant relationship and a high prevalence of hypopituitarism as a consequence of HFRS, endocrinological investigation should be considered in patients with HFRS and clinical signs and symptoms suggestive of hypopituitarism.

AEP767

Severe hyponatremia revealing hypopituitarism of undetermined etiology

Asma Zargni, Ibtissem Oueslati, Wafa Skouri, Sahar Abidi, Meriem Yazidi, Nadia Khessairi, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, Department of endocrinology, Tunis, Tunisia

Introduction
Hyponatremia represents a frequent electrolyte disorder. It is defined as a serum sodium level below 135 mmol/L and it is severe when serum level is below 125 mmol/l. Endocrine disorders including adrenal deficiency and hypothyroidism are uncommon causes of hyponatremia. Secondary adrenal insufficiency is related with hyponatremia through increased ADH secretion. Herein, we report a case of severe hyponatremia revealing hypopituitarism.
Observation
A 35-year-old patient was admitted for a severe hyponatremia. His past medical history was unremarkable. He presented with headaches, weight loss and asthenia without visual disturbances or digestive signs. On physical examination, he had an altered general condition, pallor, a dry skin, a body weight of 61 kg, a body mass index of 23.5 kg/m^2, a blood pressure of 80/50 mmHg, a heart rate of 88 beats per minute, a psychomotor retardation and a dysarthria. The rest of the examination was unremarkable. On blood tests, he had a glucose level of 0.77 g/l , a sodium level of 111 mmol/l, a potassium level of 4.3 mmol/l, a creatinine level of 7 mg/l, a cortisol level of 0 ng/ml, a FT4 level of 0.48 ng/dl (nr: 0.7–1.5), a TSH level of 0.91 mIU/l (nr: 0.35–4.94), a LH level of 1.34 IU/l (nr: 1.14–8.75), a FSH level of 2.4 IU/l (norms: 1.37–21.63), a testosterone level of 14 nmol/l (nr: 10-32) and a prolactin level of1 µg/l (nr: 1.8–29.2). The diagnosis of acute pituitary insufficiency was established and the patient was put on hydrocortisone and then on L-thyroxine. The outcome was marked by the disappearance of the symptoms and the normalization of the natraemia. Initial pituitary magnetic resonance imaging (MRI) revealed a thickened pituitary stalk, an ectopic posterior lobe and an intrasellar process. The second MRI performed 18 days later, showed a pituitary necrosis and a partial empty sella with an optic chiasm ptosis. Immunological investigations revealed the presence of atypical ANCA. Other etiological tests were negative.
Conclusion
Our case represents an unusual cause of severe hyponatremia. In addition, the finding of atypical ANCA in etiologic investigations of hypopituitarism is not common. They are probably suggestive of an autoimmune disorder despite the lack of specificity.

A case of isolated ACTH deficiency and autoimmune pancreatitis associated with pembrolizumab treatment

Uğur Unluturk[1], Seda Hanife Oguz[1], Sercan Aksoy[2] & Tomris Erbas[1]
[1]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Medical Oncology, Ankara, Turkey

Background
Endocrine-related adverse effects of immune check-point inhibitors (ICIs) have been identified in growing number of cancer patients.
Case Presentation
A 49-year-old male with laryngeal cancer applied to ouroutpatient clinic with weakness, loss of appetite, weight loss, nausea and vomiting for the last three weeks. He was diagnosed with T3N1M0 laryngeal squamous cell cancer seven months before this admission and was given concurrent cisplatin and radiotherapy, and he had just received 10th cycle of his pembrolizumab (200 mg every 3 weeks) treatment. He was not given glucocorticoids alongside of pembrolizumab. Physical examination was normal except low blood pressure (90/70 mmHg). Laboratory exam revealed normal serum sodium, potassium and plasma glucose levels. Morning serum cortisol (0.47 mcg/dl) and ACTH(10.1 pg/ml) levels were low. TSH, fT4 and fT3 levels were 6.3 uIU/ml, 11.8 pmol/l and 4.7 pmol/L respectively, showing an increase in TSH from pre-treatment level of 1.6 uIU/ml. Thyroid autoantibodies were negative, and thyroid parenchyma was normal on ultrasound, displaying an incidental nodule with benign ultrasonographic characteristics. Other hormonal axes of anterior pituitary were intact. Pituitary MRI revealed enlarged pituitary gland without infundibular thickening, and loss of posterior pituitary bright spot. He had no symptoms or laboratory signs indicative of diabetes insipidus. Accordingly, a diagnosis of hypophysitis with isolated ACTH deficiency (IAD) secondary to pembrolizumab was made. Oral prednisone in a dose of 10 mg/day was started and tapered down to 5 mg/day in three days which improved symptoms dramatically. Levothyroxine was not started since thyroid function tests turned back to normal during follow up. However, the patient was admitted to our hospital one month later due to severe epigastric pain, nausea, vomiting, and elevated serum amylase, lipase and liver function tests. CT displayed oedematous pancreatic enlargement with increased density, without necrosis. Acute cholecystitis and pancreatitis due to bile duct stones were ruled out. The patient was diagnosed with autoimmune pancreatitis and started on 48 mg/day methylprednisolone which improved symptoms and laboratory signs. Pituitary MRI findings were stable 3 and 6 months after the diagnosis of hypophysitis, however local relapse of laryngeal cancer emerged 6 months following the cessation of pembrolizumab.
Conclusions
The risk of IAD has been reported to be higher in patients using ipilimumab or combined ICI therapies, but few cases were defined who were receiving pembrolizumab treatment only. Our patient also had autoimmune pancreatitis, which is reported to occur less than 1% of pembrolizumab treated patients.

AEP769

Empty sella: Who thinks of it while studying hyponatremia?

Ana Ramalho[1], Joana Costa[2], João Carvalho[1], Susana Maria Amador[1], André Resendes Sousa[1], Sofia Marques Santos[1] & Helena Cantante[1]
[1]Hospital Lusíadas (Lisbon), Internal Medicine, Lisboa, Portugal; [2]Hospital Lusíadas (Lisbon), Endocrinology, Lisboa, Portugal

Hyponatremia is a common disorder, especially among the elderly, and an important morbidity and mortality cause. Empty sella syndrome, on the other hand, is a rare entity, more common in women between their fourth and sixth decade of life, and endocrine dysfunction has been reported in 10–60% of the cases. A 68-year-old man, with a past medical history of essential hypertension and glaucoma, presented at the emergency room due to malaise, asthenia, somnolence and anorexia for the previous 2 days. He had a prior history of respiratory tract infection and had been started on amoxicillin/clavulanic acid and azithromycin six days before. At admission he was vigil but lethargic, his blood pressure was 138/72 mmHg, heart rate 78 beats/min, body temperature of 36.4 ºC. He was pale, presented with hair weakening, mainly on his eyebrows from which the external third was missing. The blood chemistry revealed severe hyponatremia (108 mmol/l), normal potassium levels (4.4 mmol/l), a reduced serum osmolarity (220 mosmol/l), and 84 mg/dl of blood glucose. While at the emergency room IV isotonic fluids were started with poor clinical response. Hyponatremia hormonal investigation revealed ACTH 9.7 pg/ml (in the afternoon) and 8.2 pg/ml (in the morning), serum Cortisol 3.61 ug/dl (in the afternoon), THS of 16.56 mUI/l and FT4 of 2.2 pmol/l. Pituitary basal function tests were completed with FSH 3.2 mUI/ml, LH 1.3 mUI/ml, Prolactin 2.0 ng/ml, Testosterone 121 ng/dl, IGF-1 27 ng/ml, and hHG < 0.05 ng/ml. Brain MRI showed an empty sella (with a flattened pituitary gland). Hypothyroidism, adrenal insufficiency and hypogonadotrophic hypogonadism were diagnosed. Patient was started on hormonal replacement treatment with prednisolone 5 mg/day and levothyroxine 0.075 mg/day, and discharged at the 8th day, asymptomatic with sodium levels of 128 mmol/l. In the follow-up visit, after obtaining normal levels of PSA and a normal prostatic ultrasound, testosterone was also initiated. Sodium levels were already within normal range (135 mmol/l) and prednisolone was titrated to 2.5 mg/day. This clinical case illustrates an unusual presentation of hyponatremia as the first sign of hypopituitarism, showing the relevance of etiology investigation of electrolyte disorder for its adequate treatment.

Massive pulmonary embolism in a newly diagnosed acromegaly patient

Sema Hepsen, Bekir Ucan, Pinar Akhanli, Ilknur Ozturk Unsal & Erman Cakal
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Acromegaly is caused by growth hormone (GH) and insulin-like growth factor (IGF-1) excess and leads to various comorbidities. However, the association between acromegaly and thromboembolic diseases is unclear. Herein, we present a newly diagnosed acromegaly patient with massive pulmonary embolism.
Case report
A 61-year-old female was hospitalized with acromegaly pre-diagnosis. She complained about extensive arthralgia and snoring. She had hypertension,

prediabetes, and vertigo in personal history. Her medications were amlodipine/valsartan and betahistidine. Her blood pressure was 130/80 mm/Hg and body mass index was 36.21 kg/m^2. The physical examination was unremarkable out of acral enlargements and macroglossia. Baseline serum IGF-1 was 538 ng/ml and GH was 2.85 ng/ml. Nadir GH level after glucose tolerance test was 1.68 ng/ml. Magnetic resonance imaging of the pituitary gland showed a 6-mm sized microadenoma. There was no pathological finding on the electrocardiogram and echocardiography. A sleep study confirmed sleep apnea syndrome. During hospitalization, she complained about a cough. Breathing sounds decreased while arterial oxygen saturation and chest radiography were normal. The patient consulted to pulmonary diseases department. The thorax tomography (CT) showed massive pulmonary embolism in bilateral main pulmonary arteries. 2 × 0.8 IU/day DMAH treatment was initiated in the acute period because she was clinically stable and followed by long-term anticoagulation therapy with warfarin. Lanreotide 90-mg was started instead of a pituitary surgery because of the high operation risk. Venous doppler ultrasonography, which was performed for excluding a deep vein thrombosis was unremarkable. Anti-nuclear antibody, protein C and S, fibrinogen, and anti-cardiolipin Ig-M and G were normal. Malignancy screening for breast, colon, and thyroid was also negative. Factor II was heterozygote and MTHFR (C677T) was homozygote in the thrombophilia screen. Bilateral pulmonary arteries were observed normally in the sixth month of warfarin therapy. We continue to follow up patient with normal GH and IGF-1 levels under lanreotide treatment.

Discussion

Although there are no clear data on whether acromegaly is a hypercoagulable condition or not, a few cases have been reported. Some studies demonstrated that serum coagulation markers altered in acromegaly. Besides active acromegaly, some comorbidities like sleep apnea syndrome and malignancies can contribute to hypercoagulability risk. Similar to our case, inherited hypercoagulability conditions accompanied by acromegaly in some of the reported cases. In conclusion, thromboembolism can be seen in acromegaly patients rarely, especially in those having additional risk factors.

Persistent hypercortisolism due to cushing disease

Natalya Volkova, Yuliya Degtyareva, Lilia Ganenko, Ilya Davidenko, Irina Dzherieva, Igor Reshetnikov, Alexander Zibarev & Julia Sorokina
Rostov State Medical University, Internal Diseases, Rostov-on-Don, Russian Federation

Background

Cushing's disease (CD) develops as a result of ACTH-secreting pituitary adenoma. Transsphenoidal selective surgery (TSS) is the first-line therapy, and success is largely determined by the experience of the surgeon. There are several reasons for the persistence of the disease, but it is almost impossible to predict such an outcome in advance, which leads to multiple interventions and has a pronounced effect on the quality of life of patients.

Clinical case

A 33-year-old female addressed the clinic with typical symptoms of hypercorticism in October 2018. From the history: in 2016, ACTH-dependent hypercortisolism was revealed, but pituitary MRI showed no pathology. It was recommended to repeat the MRI after 6 months. She returned 2 years later due to poor health, diagnosed with CD (24hr urinary cortisol – 799 nmol/day (< 400), 1 mg dexamethasone suppression test (DST): 14.20 µg/dl (< 1.8); ACTH–71 pg/ml (< 46); 8 mg dexamethasone suppression test: cortisol was suppressed from 18.67 µg/dl to 1.99 µg/dl; MRI scan: pituitary microadenoma 4 × 3.2 mm). Although treatment at an expert level institution was recommended, the patient preferred a center that doesn`t belong to the institutions with the greatest experience in treating CD, where a TSS was performed on 09/17/18. Immunohistochemically (IHC): pituitary adenoma with expression of ACTH, GH, PRL. Post-operatively, remission didn`t occur (plasma cortisol – 732 nmol/l (< 536); ACTH-76 pg/ml), secondary hypothyroidism was detected. She was offered an immediate hypophysectomy, which she refused. Ketoconazole 200 mg/d, cabergoline 0.5 mg 2 times/week, levothyroxine 50 mg/day were prescribed. After discharge, she turned to the clinic to determine further tactics. Physical examination data corresponded to CD, persistent hypercortisolism was biochemically confirmed. MRI scan: pituitary microadenoma 5×5, 5×4 mm with postoperative changes. For TSS, she was referred to an expert level center, however, on the recommendation of a neurosurgeon, the operation was postponed due to predicted inefficiency. The maximum tolerated dose of ketoconazole was selected: 600 mg/day, which didn`t allow achieving eukortisolism: plasma cortisol - 1265 nmol/l. TSS was performed after excluding ACTH-ectopic tumors according to the results of petrosal sinus sampling, post-operatively, remission didn`t occur (IHC: intensive diffuse expression of ACTH). Currently, the patient is preparing for radiation therapy.

Conclusion

Treatment of patients with CD should be carried out exclusively in an expert level center. Studies are needed aimed at determining the risk of persistent CD to optimize treatment and reduce the time of persistence of hypercortisolism, the number of hospitalizations, economic costs and improve the quality of life of patients.

AEP772

The effect of chronic glucocorticoid exposure on brown adipose tissue in patients with cushing's disease

Alev Selek[1], Berat Furkan Çayir[2], Ilhan Tarkun[3], Mehmet Sözen[1], Berrin Cetinarslan[1], Zeynep Canturk[1] & Emre Gezer[1]
[1]Kocaeli University, Endocrinology and Metabolism, Kocaeli, Turkey; [2]Kocaeli University, Internal Medicine, Kocaeli, Turkey; [3]Anadolu Sağlık Merkezi, Endocrinology and Metabolism, Kocaeli, Turkey

Objective

Various effects of glucocorticoids occur in brown adipose tissue depending on their duration of action. As a result of exposure to glucocorticoids, thermogenesis and oxygen use in brown fat tissue are reduced in animal studies. In this study, we aimed to compare the levels of UCP1 (uncoupling protein 1), Irisin, BMP 7 (bone morpogenic protein), PRDM16, which are brown addipose tissue markers, between patients with Cushing's disease and healthy controls

Methods

This study included 48 patients with Cushing's disease and 40 non diabetic controls who met the inclusion criteria. Cushing syndrome was ruled out by performing 1 mg dexamethasone suppression test to individuals in the control group. Fasting blood samples were analyzed by Enzyme-Linked Immunosorbent Assay method for UCP1, Irisin, BMP 7 and PRDM 16. Demographic and clinical information was also recorded.

Results

There were 11 men (22.9%), 37 women (77.1%) in the patient group; 9 men (22.5%) and 31 women (77.5%) in the control group. Body mass index was 31.29±5.76 kg/m^2 in the patient group, and 33.42±3.11 kg/m^2 in the control group (P<0,05). HbA1c and triglyceride levels were statistically significantly higher in patient group than in the control group (P<0,05). PRDM16, Irisin, BMP7, UCP1 levels were not significantly different between the two groups (P>0,05). Macroadenoma was detected in 19 (40.4%) patients and microadenoma in 28 (59.6%) patients in the Cushing disease group. Mean irisin, PRDM16 and BMP7 levels were similar in microadenoma and macroadenoma groups (P>0,05). However, UCP1 was significantly higher in microadenoma group than macroadenoma group (P <0.05). There was a positive correlation between serum cortisol (morning and midnight cortisol) with irisin (P<0.05), but no correlation with other markers (P>0.05). Also a positive correlation was observed between urine free cortisol and UCP1 levels (P<0.05).

Conclusion

Short term exogenous glucocorticoid administration showed decreased levels of brown adipose tissue markers in animal studies. Opposite of this in our study, there was no difference between the patient and control groups in terms of brown adipose tissue markers. However,in patients with Cushing's disease, UCP 1 and BMP7 were significantly correlated with increased cortisol levels. This finding may suggest that, prolonged exposure of high levels of endogenous cortisol causes loss of adipose tissue functionality by

creating invivo resistance. It is obvious that detailed studies are needed to explain the effects of chronic cortisol exposure.

A rare outcome after surgical removal of insulinoma- case presentation

Sandra Ghenoiu[1], Andreea Verdes[1], Anda Dumitrașcu[2], Cristina Capatina[1,3] & Catalina Poiana[1,3]
[1]"C I.Parhon" National Institute of Endocrinology, No VI, Bucharest, Romania; [2]"C.I.Parhon" National Institute of Endocrinology, Radiology, Bucharest, Romania; [3]"Carol Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
Insulinoma is a rare tumor that causes spontaneous fasting hypoglycemia in a supposedly healthy adult. Mostly these tumors are single and benign, few are malignant and a minority is represented by multiple adenomas. The treatment of choice is surgical removal of the insulinoma, which cures the condition in the majority of cases. However, after performing the surgery, less than 10% of patients either develop diabetes mellitus or continue to have persistent hypoglycemia.
Case presentation
Patient, male, 68 years old, with history of high blood pressure and ischemic stroke, presents for a month the following: diaphoresis, dizziness, altered general state, relieved by carbohydrates intake. Five days before admission in our service, he presented acute symptoms and a fingerstick blood glucose level of 25 mg/dl. During his hospital stay, he did not tolerate the fast and repeated blood samples showed low laboratory glucose and elevated plasma insulin (up to 1000 uU/ml). Further hormonal tests excluded MEN1 syndrome. The CT scan identified one small tumor located in the body of the pancreas. The patient was referred to surgery and distal subtotal pancreatectomy was performed (intraoperative ultrasound confirmed the tumor). TNM staging fits the tumor as pT1N0 and histopathological examination confirmed the neuroendocrine tumor of the pancreas, well-diferentiated (G1). After surgery the general condition of the patient was improved, but he started to present alternating episodes of mild hyperglycemia and hypoglycemia with elevated plasma insulin. The post-operative MRI scan showed no residual tumor or other pancreatic lesions. "Whole-body" somatostatin receptor scintigraphy (99mTc-Tektrotyd) with the addition of SPECT-CT was performed and it revealed a small nodule with intense uptake, in the most caudal part of the pancreas. The patient is scheduled for the second intervention.
Conclusions
The peculiarity of the case is represented by the unstable metabolic balance: the patient developed post-pancreatectomy diabetes mellitus, but in the presence of the second (previously unsuspected) insulinoma this translated into fluctuations of glycemia around normal levels (both hypo- and hyperglycemia) in the absence of treatment.

Evaluation of factors associated with presence and growth of thyroid nodules in patients with acromegaly

Eider Pascual-Corrales, Pablo Valderrabano Herrero, Jonathan Quiñones de Silva, Gonzalo Baonza Saiz, Victoria Martínez Vaello & Marta Araujo Castro
Hospital Ramón y Cajal, Endocrinology and Nutrition, Madrid, Spain

Objective
To investigate factors associated with the presence and growth rate of thyroid nodules(TN) in patients with acromegaly.
Methods
We retrospectively evaluated the medical records of 52 patients with acromegaly followed in our institution (University Hospital Ramón y Cajal). The frequencies of TN and papillary thyroid cancer (PTC) and potential factors associated with nodular thyroid disease (NTD) were investigated. In patients with NTD ($n=25$) the first and last ultrasound performed were evaluated. The mean follow up period in these patients was 62.9 (S.D.=44.4) months. The changes in nodule size comparing with the initial study and the potential factors affecting nodule growth were investigated. The statistical analysis was performed with STATA15.0.
Results
The mean age of the cohort was 50.2 years (SD=15.90) and 71% ($n=37$) were females. At diagnosis, 48.1% of the patients had TN (21 females/four males), and the mean size of the dominant nodules (MSN) was 16.1 (S.D.=13.013) mm. TN were more commonly found among women (56.8% vs 26.7%, $P=0.049$), and patients with IGF1 above the upper limit of normal (ULN) (71.4% vs 28.6%, $P=0.043$). No associations were found with age ($P=0.769$), IGF1 levels ($P=0.127$), macroadenoma ($P=0.089$), surgical cure ($P=0.76$), thyroid function($P=0.612$), obesity ($P=0.792$) or other comorbidities. No correlation was found between MSN and IGF1 or TSH levels ($P>0.05$ for r2). During follow up, the mean nodule growth was 1.5 (S.D.=8.38) mm, the mean nodule growth/year was 1.40 (S.D.=4.91) mm, and only 5 patients experienced significant growth (> 2 mm) at the end of the follow up. At last visit, nodule growth was similar in uncured vs cured patients ($P=0.317$). Neither differences were found according to thyroid function ($P=0.122$) or months with IGF1 above normal range ($P=0.057$). No correlations were found between growth and IGF1 at the time of ultrasounds($r_2=0.429$, $P=0.126$), thyroid function ($r_2=0.055$, $P=0.851$) or other parameters. At diagnosis fine needle aspiration (FNA) cytology was done in 13 patients, 11 were classified as benign (Bethesda category II, B2) and 2 as atypia of undetermined significance (Bethesda category III, B3). During follow up, FNA was repeated in 5 patients: cytology was B2 in all 3 patients with initial B2 rebiopsied due to significant growth, and remained indeterminate(one B3 and one B4) in the two nodules with initial B3 cytology. Seven patients were operated: 4 due to compressive multinodular goiter, 1 due to significant TN growth (+29 mm), and 2 due to indeterminate cytology. PTC was diagnosed only in the B3 patient (microPTC).
Conclusion
We found that NTD is frequent in acromegalic patients, especially in women and patients with elevated levels of IGF1. During follow up, TN growth was infrequent and seemed to be unrelated to acromegaly activity status and thyroid function. The prevalence of PTC was 1.9% in our acromegaly cohort.

FSH levels are related to E-cadherin expression and subcellular location in non-functioning pituitary neuroendocrine tumours

Anders Jensen Kolnes[1], Kristin Astrid Berland Øystese[1,2], Cristina Olarescu[1], Olivera Casar-Borota[3], Jens Bollerslev[1] & Anders Jørgensen[1]
[1]Oslo University Hospital, Oslo, Norway; [2], University of Oslo, Oslo, Norway; [3]Uppsala University Hospital, Uppsala, Sweden

Objectives
To study the effect of epithelial-to-mesenchymal transition (EMT) on hormone expression in gonadotroph non-functioning pituitary neuroendocrine tumours (NF-PitNET).
Background
Gonadotroph PitNETs can express FSH and LH or be hormone negative, however they rarely secrete hormones. During tumour development, epithelial cells develop a mesenchymal phenotype. This process is characterised by decreased membranous E-cadherin and translocation of E-cadherin to the nucleus. Further, oestrogen receptors (ER) regulate both E-cadherin and FSH expression and secretion. Whether the hormone status of patients with gonadotroph PitNETs are regulated by EMT and oestrogen receptors is uncertain.
Methods
Retrospective study of 105 gonadotroph PitNETs. Immunohistochemical analyses and real-time-qPCR for FSH, LH, E-Cadherin and ERα were performed. Blood samples, clinical data and radiological findings were analysed.
Results
NF-PitNET with high FSH expression had decreased immunohistochemical staining for membranous E-cadherin ($r=-0.384$; $P<0.0001$) and increased staining for nuclear E-cadherin ($P<0.0001$). Further, high FSH expression was associated with increased ERα staining ($r=0.357$; $p=0.0002$) and mRNA ($r=0.331$, $P=0.0039$). Circulating levels of P-FSH correlated with FSH staining in NF-PitNET ($r=0.360$; $P=0.0025$). Tumour size and invasiveness was not related to FSH staining, E-cadherin or oestrogen receptor. LH expression in tumours were not associated with E-cadherin or ERα. In gonadotroph PitNETs, FSH staining is associated with decreased membranous E-cadherin and nuclear translocation of E-cadherin. FSH correlates with expression of oestrogen receptors and circulating P-FSH. Further studies are needed to understand the mechanisms behind these findings.

To optimize the acute octreotide suppression test in predicting the efficacy of long acting somatostatin analogues in acromegaly

Gao Yuting, Zhihong Liao, Qin Du & Ke Cai
The First Affiliated Hospital of Sun Yat-sen University, Department of Endocrinology and Metabolism, Guangzhou, China

A 6-hour octreotide suppression test (OST) is useful in the selection of patients with acromegaly for chronic somatostatin depot analogues treatment. However, it is time consuming and that brings inconvenience to patients. We aim to simplify the blood sampling of OST, and determine the reliability of a short version of the classic 6-hour OST. The data provided in the supplementary tables of the primary manuscript were used to re-analyze the efficacies of the simplified OST tests. SPSS Software Version 25 was used for data analyses. To find the best receiver operating characteristic (ROC) curve, several analysis of the shorten-test (including 2-hour, 3-hour, 4-hour and, 6-hour's tests) were performed, and compared the parameters of ROC with that of 2-day's examination to find a proper shorten test period. After calculating, □GH (0–3 h) more than 80.51% and 91.84% provided the best predictors of a good GH response (sensitivity 96.9%, specificity 85.7%) and a good IGF-1 response (sensitivity 86.7%, specificity 81.3%). □AUC (0–3 h) more than 71.07% provided the best predictor of a good tumor size response (sensitivity 81.8%, specificity 90.6%). From these results, we conclude that OST could be simplified as the 3-hour measurements. The □GH (0–3 h) is the best optimistic parameter to predict a good GH, or IGF-1, response, while the □AUC (0–3 h) is the best for a good tumor size response to short-term efficacy of SSA in acromegaly.

Keywords: acromegaly, somatostatin analogues, remission prediction, octreotide suppression test.

Acromegaly is associated with reduced socioeconomic status and more so in female patients: A nationwide population-based study

Jakob Dal[1,2], Eigil H Nielsen[1], Ulla Feldt-Rasmussen[3], Marianne Andersen[4], Claus Feltoft[5], Peter Vestergaard[1,2], Kirstine Stochholm[6] & Jens Otto Jorgensen[6]
[1]Aalborg University Hospital, Endocrinology, Aalborg, Denmark; [2]Steno Diabetic Center Northjutland, Aalborg, Denmark; [3] Copenhagen University Hospital, Department of Endocrinology and Metabolism, Rigshospitalet,, Copenhagen, Denmark; [4]Odensen University Hospital, Endocrinology, Denmark; [5]Herlev Hospital, Endocrinology, Denmark; [6]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Denmark

Context
Acromegaly is a rare and insidious disease associated with severe somatic morbidity but data on socioeconomic status are scarce.
Objective
To study the socioeconomic status in acromegaly in a population based, nationwide follow-up study.
Patients and methods
All incident cases of acromegaly (n=576) during the period 1997–2010 were included, representing 10.116 years at risk. For every patient, 100 persons were sampled from the general population matched on date of birth and gender (comparison cohort). Cox regression and hazard ratios (HR) or conditional logistic regression with 95% confidence intervals (CI) were used.
Main outcome measures
Annual income, allocation of cash benefits, retirement, cohabitation, separation, parenthood and education level.
Results
The proportion of retirement was significantly increased in patients with acromegaly after the time of diagnosis (HR 1.43, CI95% 1.26–1.62) and also during the 5-year pre-diagnostic period (HR : 1.15, CI95% 1.03–1.28). The utilisation of cash benefits was increased in patients with acromegaly in the period preceding the time of diagnosis. Among patients who maintain a paid job, the annual income was similar to the reference population. Compared with the background population, cohabitation was less prevalent (HR : 0.69, CI : 0.50–0.95) as was parenthood (HR : 0.56, CI : 0.39–0.80), whereas neither educational level (HR: 0.61, CI : 0.35–1.06) nor the prevalence of separation (HR : 1.13, CI : 0.86–1.47) weredifferent in acromegaly. A reduced socioeconomic status was present before the diagnosis of acromegaly. Female gender was associated with a significantly worse socioeconomic status (Table 1).

Tabel 1 Hazard ratios of the various outcomes.

After diagnosis	Female	*P*-value	Male	*P*-value
Mortality	1.56 (1.27–1.91)	< 0.01	1.32 (1.09–1.61)	< 0.01
Retirement	1.58 (1.33–1.87)	< 0.01	1.30 (1.08–1.55)	< 0.01
Education	0.65 (0.34–1.25)	0.19	0.52 (0.17–1.63)	0.26
Separation	1.28 (0.89–1.83)	0.18	0.99 (0.67–1.47)	0.95
Cohabitaion	0.62 (0.38–1.00)	0.05	0.76 (0.50–1.16)	0.20
Parenthood	0.33 (0.17–0.67)	< 0.01	0.74 (0.48–1.12)	0.16
5-years pre-diagnosis				
Retirement	1.14 (0.98–1.33)	0.08	1.16 (0.99–1.36)	0.07
Cohabitaion	0.75 (0.53–1.06)	0.10	1.06 (0.79–1.41)	0.71
Parenthood	0.55 (0.34–0.87)	0.01	0.82 (0.60–1.13)	0.23

Conclusion
1. Socioeconomic status is impaired in patients with acromegaly even before diagnosis. 2. Females and patients without disease remission have significantly worse outcomes. 3. Early diagnosis and effective treatment are essential not least in female patients.

Case-control study on ACE2 expression in children with short stature

Gianluca Tornese[1], Federica Tonon[2], Francesca Nicolardi[2], Barbara Toffoli[1], Maria Chiara Pellegrin[1], Egidio Barbi[1], Bruno Fabris[2] & Stella Bernardi[2]
[1]Hospital Burlo Garofolo, Trieste, Italy; [2]University of Trieste, Department of Medical Sciences, Trieste, Italy

Background
Short stature is one of the most common presentations to paediatric endocrinologists. It is estimated that despite all the exams, in 50–90% of cases, children are labelled as having idiopathic short stature. It has been recently reported that genetic ACE2 deficiency is associated with reduced body weight as well as with impaired gestational weight gain and fetal growth restriction in pregnancy. It has been argued that ACE2 deficiency, which is usually associated with an increase of tissue Angiotensin II, could be associated with prenatal as well as postnatal changes leading to reduced growth (such as uterine artery dysfunction and IGF-1 reduction, respectively). Based on these premises, the aim of our study was to evaluate whether there was a difference of ACE2 expression in children with short stature as compared to age-matched controls.
Methods
We designed an exploratory case-control study aiming at recruiting consecutively 40 children with short stature (cases) and 40 controls presenting at the Endocrinology Service, aged 2–13 years, excluding those with acute intercurrent diseases, diabetes, renal insufficiency, syndromes and/or on medications. After signing the informed consent to participating in the study, children underwent a medical visit and a fasting blood sampling. Peripheral blood mononuclear cells (PBMC) were isolated to extract mRNA for gene expression analyses. Sera were collected for protein measurements.
Results
Children with short stature (n=17) presented with lower height and body weight as compared to controls (n=18). Our preliminary data show that children with short stature exhibited a significant reduction of ACE2 gene expression, and a significant increase of ACE/ACE2 ratio in PBMC. This was associated with a modest increase of Angiotensin II/Angiotensin 1–7 ratio. Our multivariate analysis showed that across the groups ACE2 was independently associated with height but not with body weight.
Conclusions
To our knowledge, this is the first study investigating ACE2 expression ina paediatric population. Our preliminary results, showing that ACE2

expression is significantly reduced in children with short stature, are in line with the literature. This study could representthe basis for further investigations aiming at establishing the presence of a causal relationship between ACE2 deficiency and growth reduction, with further diagnostic and therapeutic perspectives

[1]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]Humanitas Clinical and Research Center, Endocrinology, Diabetology and Andrology Unit, Rozzano (MI), Italy; [4]IRCCS Istituto Auxologico Italiano, Division of Endocrine and Metabolic Diseases and Lab. of Endocrine and Metabolic Research, Milan, Italy; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and Fondazione Luigi Villa, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy; [6]Humanitas University of Milan, Department of Biomedical Sciences, Milan, Italy

Introduction
Klinefelter syndrome (KS) is known to be associated with an increased risk of venous thromboembolism and arterial thrombosis, but the aetiology behind this prothrombotic status has not been fully elucidated. The aim of this study was to cross-sectionally investigate the coagulative state in subjects with KS compared to age-matched healthy males.
Methods
Coagulation factors assessment, clinical characteristics collection and thrombin generation test (TGT) were performed in 58 consecutive KS patients and 58 controls. TGT is based on the continuous registration of thrombin generation (mediated by procoagulants) and decay (mediated by anticoagulants) using a fluorogenic substrate. The curve of thrombin concentrations (vertical axis) by time (horizontal axis) is called *thrombogram* and is described by the following parameters: *lag-time* (time from coagulation ignition to the formation of the first amounts of thrombin); *thrombin-peak* and *time-to-peak*; *endogenous thrombin potential (ETP*, the area under the thrombin curve, measured with and without the addition of thrombomodulin); the *ETP-ratio* (ETP with/ETP without thrombomodulin), that may be considered the best parameter through which *in vivo*subtle procoagulant imbalance can be detected.
Results
No statistically significant difference was found between KS patients and healthy subjects in lag-time, thrombin-peak, time-to-peak or ETP; however, the ETP-ratio was significantly higher in KS compared to controls (0.73 and 0.66 respectively, $P<0.001$). KS patients had higher circulating concentrations of Factor VIII ($P=0.001$) and Fibrinogen ($P<0.001$) and a higher Factor VIII/Protein C ratio ($P=0.018$), while platelet count, PT ratio, aPTT ratio, Factor II, Protein C and Antithrombin were similar in the two groups. ETP-ratio was positively correlated with Factor VIII concentrations ($P=0.007$, $\rho=0.355$) and showed a trend of association with impaired fasting glucose ($P=0.069$) and Factor VIII/Protein C ratio ($P=0.072$, $\rho=0.240$). Fibrinogen levels were positively associated with age ($P=0.004$, $\rho=0.401$), body mass index ($P=0.001$, $\rho=0.468$) and fasting plasma glucose ($P=0.049$, $\rho=0.356$), while FVIII did not show any correlation with metabolic parameters as well as age. Testosterone replacement therapy and smoke were not associated with any of the coagulation parameters.
Conclusion
As clinically suggested, a procoagulant imbalance is present in KS subjects and is possibly related to higher Factor VIII concentrations here demonstrated. While testosterone replacement therapy and smoking habit did not show a significant impact, other typical factors associated with thrombotic risk such as advanced age, BMI and altered glucose metabolism could further increase this imbalance by determining hyperfibrinogenemia.

Radioidine (RAI) as a new therapy for the treatment of ovarian cancer through the sodium/iodide symporter (NIS)

Lidia Mirela Mielu[1,2], Maria Paz Lopez-Molina[1], Patricia Mingo-Casas[1], Lucía Rodal-Bravo[1], Cristina Diego-Hernandez[3], Pilar Pallarés[1], Custodia García-Jimenez[4], Pilar Martin-Duque[5] & Antonio De la Vieja[1,2]
[1]Instituto de Salud Carlos III, UFIEC, Majadahonda-Madrid, Spain; [2]Instituo de Salud Carlos III, CiberOnc, Madrid, Spain; [3]Hospital Universitario de Móstoles, Móstoles, Spain; [4]Universidad Rey Juan Carlos, Móstoles, Spain; [5]Instituto Aragonés de Ciencias de la Salud, Zaragoza, Spain

Introduction
Ovarian cancer is the most lethal gynecological malignancy. Early diagnosis has a survival rate of 90%. Unfortunately, more than 70% of cases are diagnosed when the cancer has already metastasized, and survival rates do not exceed 30% in these cases. The sodium iodide symporter (NIS) is an integral plasma membrane glycoprotein expressed in the basolateral surface of the thyroid gland, where it mediates active transport of iodide. Radioiodide therapy (RAI) through NIS is the most effective therapy in thyroid cancer. Our group has demonstrated that NIS is expressed in ovarian surface epithelium and is overexpressed in human epithelial ovarian cancer, establishing NIS as a tumor marker. The aim of this study is to determine whether endogenous expression of NIS in ovarian cancer can be used as therapeutic tool using-RAI in ovarian tumors.
Materials and methods
serous ovarian cancer cell line (SKOV3) was transfected permanently with exogenous NIS (SKOV3-hNIS) and in vitro characterized by different techniques (western-blot, PCR, flow cytometry, immunofluorescence, iodide uptake). In vivo, NIS-transfected and not transfected cells were injected into flanks of nude and NSGs mice. NIStumor expression was analyzed by different techniques and NIS functionality in animal models was measured by SPECT-CT.^{131}I treatment was tested in subcutaneous nude female mice. Human ovarian tumors samples received from the Mostoles Hospital were disaggregated and used to produce primary cultures and PDX animals.
Results
PCR and western-blot show NIS expression in both in vitro (cancer cells) and in vivo (xenotransplanted cells in animal models and human samples). Immunofluorescence and immunohistochemistry show that NIS expression occurs in plasma membrane. In vitro and in vivo (SPECT-CT) Iodide uptake assays show that the expression of NIS in plasma membrane is functional. ^{131}I treatment in subcutaneous tumors show an overall decrease in tumor size of 71% vs a 632% increase in not treated tumors. We observed that more than 37% of tumors disappear in 25 days with just a single ^{131}I dose.
Conclusion
NIS expression in human ovarian cancer cell lines is functional in vitro and in vivo, targeted to the plasma membrane, and able to accumulate iodide. A single dose of ^{131}I reduces ovarian tumor growth in NIS-expressing tumors and is more effective than conventionally chemotherapy. Patient tumors are expressing NIS in the plasma membrane, which leads us to propose NIS as a therapeutic approach to the treatment of ovarian cancer through radio iodine.

Luteinizing hormone/choriogonadotropin receptor (LHCGR) mediates different kinetics of G proteins, β-arrestins and cAMP activation

Elia Paradiso[1,2], Riccardo Benevelli[1], Clara Lazzaretti[1,2], Samantha Sperduti[1,3], Giulia Brigante[1,4], Manuela Simoni[1,3,4,5] & Livio Casarini[1,3]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]University of Modena and Reggio Emilia, International PhD School in Clinical and Experimental Medicine (CEM), Modena, Italy; [3]University of Modena and Reggio Emilia, Center for Genomic Research , Modena, Italy; [4]Azienda Ospedaliero-Universitaria di Modena. Baggiovara Hospital, Department of Medical Specialties, Modena, Italy; [5]Institut National de la Recherche Agronomique, Unitè Physiologie de la Reproduction et des Comportements, Nouzilly, France

Pituitary luteinizing hormone (LH) and placental human choriogonadotropin (hCG) are two heterodimeric glycoprotein hormones regulating reproduction. They bind the same receptor (LHCGR) expressed in gonadal cells, activating hormone-specific G protein- and β-arrestins-dependent signaling cascades, before LHCGR internalization. LH induces preferential proliferative signals, while hCG activates mainly the steroidogenic pathway,

reflecting their physiological roles. In this study,we compared the kinetics of LH- versus hCG-mediatedG proteins and β-arrestin 2 activation *in vitro*. The HEK293 cell line was transiently transfected with the LHCGR-encoding plasmid, together with that encoding G proteins- or β-arrestin 2-tagged bioluminescence resonance energy transfer (BRET) biosensors. Cells were treated by various hCG and LH concentrations (pM-nM range) and the activation of Gαs, Gαq, Gαi protein and β-arrestins was evaluated by BRET, under native conditions or after inhibition of LHCGR internalization by Dynasore. We demonstrated that LH/hCG binding to LHCGR mediates the activation of G proteins and recruitment of β-arrestin 2 in a hormone-specific manner. LHCGR-Gαs protein interaction increased upon 10 nM hCG, but not LH treatment (one-way ANOVA; $P<0.05$; $n=8$), reflecting the previously demonstrated preferential activation of intracellular cAMP signaling by the placental hormone [doi:10.1210/er.2018-00065]. These data are confirmed by kinetics analysis intracellular cAMP increase over 120-min, which achieved higher levels upon treatment by hCG than LH when hormones are administrated to cells at the 50% effective concentration (EC50; hCG=100 pM; LH=500 pM; Kruskal-Wallis test, $P<0.05$; $n=4$). On the other hand, LH was more potent than hCG in promoting LHCGR-Gαi protein and LHCGR-β-arrestin 2 interactions, thus confirming preferential activation of proliferative signals (means±SEM one-way ANOVA; $P<0.05$; $n=8$) [doi:10.1210/er.2018-00065]. Interestingly, LH and hCG mediated similar kinetics of intracellular cAMP increase between 30–120 min, when LHCGR internalization is blocked by Dynasore, while short-term (0-30) min hCG-induced cAMP levels are anyway higher than those LH-mediated (Kruskal-Wallis test, $P<0.05$; $n=4$). These results suggest that endosomal compartmentalization of LHCGR is involved in the differentiation of the long-term LH/hCG-induced cAMP signaling.
We have demonstrated that LH and hCG drive LHCGR in hormone-specific interaction with Gαs and i proteins, as well as β-arrestin 2 and endosomal compartments, and resulting in different intracellular signaling patterns.

New data in turner syndrome: Results from a long-term prospective observational study from diagnosis to adulthood

Francesca Corzani[1], Carolina Cecchetti[1], Claudia Oriolo[1], Paola Altieri[1], Annamaria Perri[2], Emanuela Scarano[2], Laura Mazzanti[2], Uberto Pagotto[1] & Alessandra Gambineri[1]
[1]Unit of Endocrinology and Prevention and Cure of Diabetes, S. Orsola-Malpighi Hospital, Department of Medical & Surgical Sciences, University Alma Mater Studiorum, Bologna, Italy; [2]Unit of Pediatric Endocrinology and Rare Disease, S. Orsola-Malpighi Hospital, Dept. of Medical & Surgical Sciences, University Alma Mater Studiorum, Bologna, Italy

Turner syndrome (TS), one of the most frequent chromosomal aberrations in females, is characterized not only by structural abnormalities (somatic and congenital) but also by acquired comorbidities, such as metabolic disorders, cardiovascular alterations, autoimmune diseases, osteoporosis, and malignancies. The prevalence of structural abnormalities that usually complicate TS at diagnosis is well known. However, the prevalence of acquired complications, that may appear at any age during follow-up, is less known, for the scarcity of data available in literature in TS during adulthood. This limit does not allow to establish an exact flow-chart on how to monitor acquired pathologies in TS. This long-term prospective observational study has been performed in a population of 139 TS diagnosed and then followed at S. Orsola-Malpighi hospital of Bologna, firstly by pediatricians and secondly by endocrinologists, using the same structured protocol of follow-up. The mean age of diagnosis of TS was 9.52±8.09 years. The average duration of follow-up was 28.4±9.7 years. Therefore, the age at the end of follow up was 38.4±8.3 years. Diabetes was diagnosed by oral glucose tolerance test in 21 patients (15.1%) with a mean age at diagnosis of 39.0±10.9 years. Hypertension was discovered in 35 patients (25.2%) with a mean age at diagnosis of 31.1±10.0 years, one of these patients complicated with aortic dissection at age 45. During follow-up we diagnosed 104 autoimmune disorders with a mean age at diagnosis of 23.8±10.5 years; in particular, we found 81 cases of thyroiditis with or without hypothyroidism, 10 cases of coeliac disease, 3 cases of Basedow-Graves disease, 3 cases of alopecia areata, 2 cases of vitiligo, 2 cases of Sjogren syndrome, 1 case of psoriasis, 1 case of chronic atrophic gastritis and 1 case of Crohn's disease. Osteoporosis was detected in 28 patients (20.1%). Finally, we found 21 cases of malignancies with a mean age at diagnosis of 31.5±13.8 years; in particular, we found 7 cases of papillary thyroid carcinoma, 5 cases of nervous system tumors, 3 cases of skin tumors, 2 cases of gonadal tumors, 1 case of kidney cancer, 1 case of breast cancer, 1 case ofacute lymphoblastic leukemia, and 1 case of aggressive hemangioma. These data reinforce the need to monitor patients with TS lifelong, focusing on endocrine, metabolic, cardiovascular and oncological complications. A specific structured protocol is useful for early detection of such important complications.

Establishing an anti-müllerian hormone (AMH) cut-off to determine polycystic ovarian morphology (PCOM) supporting diagnosis of polycystic ovarian syndrome (PCOS): The APHRODITE study

Alexandra Dietz de Loos[1], Martin Hund[2], Katharina Buck[3], Cindy Meun[1], Johanna Sillman[2] & Joop Laven[1]
[1]Division of Reproductive Endocrinology and Infertility, Department of Obstetrics and Gynaecology, Erasmus University Medical Center, Rotterdam, Netherlands; [2]Roche Diagnostics International Ltd, Rotkreuz, Switzerland; [3]Roche Diagnostics GmbH, Penzberg, Germany

PCOS is a common pathology in women of reproductive age, and ~70% of affected women remain undiagnosed. Clinical features of PCOS include ovulatory dysfunction, hyperandrogenism and PCOM (Rotterdam criteria). Replacement of transvaginal ultrasound (TVUS) with a blood test for PCOM is clinically desirable, as lack of access to TVUS may contribute to underdiagnosis of PCOS. We aimed to derive and validate a cut-off for AMH to discriminate PCOM using the Elecsys AMH Plus immunoassay. APHRODITE is a case-control study of PCOS-positive (cases) and PCOS-negative (controls) women aged 25–45 years. Cases were defined using Rotterdam criteria, showing the full phenotype A (irregular cycles/ovulatory dysfunction, clinical or biochemical hyperandrogenism and PCOM); controls had an antral follicle count (AFC)≤20, based on the new international guideline for PCOS. The discovery cohort included 484 cases and 575 controls; the validation cohort consisted of 455 cases and 500 controls. Serum levels of AMH were measured using the Elecsys AMH Plus immunoassay, and AFC was determined by TVUS. An AMH cut-off was optimised in the discovery cohort based on concordance analysis. Performance (sensitivity, specificity and area under the curve [AUC]) of the defined cut-off was evaluated in the validation cohort. Exploratory analyses in different sub-cohorts (including age groups) were performed. Compared with controls, PCOS cases were younger (median age, 29.0 vs 36.0 years), with a higher median body mass index (discovery, 28.3 vs 23.6 kg/m^2; validation, 28.1 vs 23.7 kg/m^2) and higher median AMH level (discovery, 6.13 vs 1.59 ng/ml; validation, 6.32 vs 1.58 ng/ml). Good correlation was observed between AMH and AFC in the discovery and validation cohorts, with Spearman correlation coefficients of 0.84 and 0.85, respectively. A serum AMH cut-off of 3.2 ng/ml (23 pmol/l) was determined in the discovery cohort, which achieved 86.2% sensitivity and 86.1% specificity. In the validation cohort, this cut-off achieved 88.6% (95% confidence interval [CI] 85.3–91.3) sensitivity and 84.6% (95% CI 81.1–87.7) specificity, with an AUC of 93.6% (95% CI 92.2–95.1). In women aged≤35 years, the AMH cut-off of 3.2 ng/ml showed 88.5% (95% CI 86.2–90.5) sensitivity and 80.3% (95% CI 76.6–83.6) specificity; in women aged >35 years, specificity remained high (90.1%; 95% CI 87.3–92.5) but sensitivity was lower (77.8%; 95% CI 66.4–86.7). The Elecsys AMH Plus immunoassay provides a robust method for identifying PCOM as part of PCOS diagnosis with a cut-off of 3.2 ng/mL (23 pmol/l).

Polycystic ovary syndrome is burdened with a high comorbidity rate and medication use independent of BMI: A longitudinal community based study

Linda Kujanpää[1,2,3,4,5], Terhi Piltonen[1,2,3,4,5], Riikka Arffman[1,2,3,4,5], Paula Pesonen[1,6], Laure Morin-Papunen[1,2,3,4,5], Juha Tapanainen[1,2,3,4,5,7,8], Stephen Franks[9,10] & Marjo-Riitta Järvelin[1,2,11]
[1]University of Oulu, Oulu, Finland; [2]Oulu University Hospital, Oulu, Finland; [3]PEDEGO Research Unit, Oulu, Finland; [4]Medical Research

Center Oulu, Finland; [5]Department of Obstetrics and Gynecology; [6]Infrastructure for Population Studies; [7]University of Helsinki, Finland; [8]Helsinki University Hospital, Finland; [9]Imperial College London; [10]Institute of Reproductive and Developmental Biology, London, United Kingdom; [11]Center for Life Course Epidemiology, London, United Kingdom

Objective
To investigate comorbidity rate, symptoms, overall morbidity, medication useand use of health care services among women with polycystic ovary syndrome (PCOS).
Design
Community-based prospective cohort study.
Patients
Womenreporting oligo/amenorrhea and hirsutism at age 31 and/or PCOS diagnosis by age 46 (n=280) and controls without PCOS related symptoms or diagnosis (n=1573) in the Northern Finland Birth Cohort 1966.
Main outcome measures
Self-reported diseases and symptoms diagnosed by a doctor, overall morbidity score calculated from the self-reported diagnoses, medication and supplement use and use of health care services at ages 31 and 46.
Results
The overall morbidity was increased in women with PCOS as they reported having higher occurrence of diagnosed diseases both at age 31 and 46 years. Moreover, the overall medication use was higher among affected, especially before adjustment with BMI. Women with PCOS had a higher risk for diagnosed disease at both ages [31: RR (95% CI): 1.19 (1.02 – 1.39) and 46: RR: 1.29 (1.11 – 1.50)]. Diseases more prevalent in PCOS even after adjustments both at age 31 and 46 were gastric/duodenal ulcer [OR (95% CI): 2.79 (1.02 – 7.64) and 2.12 (1.01 – 4.45), respectively], migraine [1.50 (1.05 – 2.14) and 1.58 (1.17 -2.13)] and fractures [1.63 (1.13 – 2.36) and 1.73 (1.24 – 2.41)].By age 31, women with PCOS had a higher prevalence of repeated respiratory infections, emphysema/chronic bronchitis, gynecological infections, cancer and other sickness or injury compared to control women. Furthermore, by age 46, women with PCOS had a higher prevalence of hypertension, type 2 diabetes mellitus, hypothyroidism, hyperthyroidism, salpingo-oophoritis, depression, tendinitis as well as knee, back and shoulderosteoarthritis, fibromyalgia, pre-eclampsia and endometriosis. As for infections, the women reported having more often recurrent infections, pneumonias, recurrent otitis, common colds and higher susceptibility to infections than other women. In addition, women with PCOS reported more often symptoms related to autoimmune diseases. Interestingly, use of health care services did not differbetweenthe groups either at age 31 nor 46. All results were adjusted for BMI, alcohol consumption, smoking, physical activity, education and marital status.
Conclusion
Women with PCOS are burdened with extensive comorbidity up till late fertile age independent of BMI, although higher BMI aggravates the risk for medication usage. Identification of the women with the syndrome as well as early preventive actions should be considered to alleviate health risks related to the syndrome.

Context
Androgen insensitivity syndrome (AIS) is a rare X-linked recessive disordercaused by mutations in the androgen receptor (*AR*) gene resulting in variable target tissue resistance to androgen action. The underlying molecular defect causes a spectrum of androgen dysfunction ranging from gynecomastia and/or infertility in mild AIS (MAIS) to variable degrees of ambiguous or undermasculinized genitalia in partial AIS to complete testicular feminization in complete AIS. To date, more than 800 different mutations in the*AR* gene have been identified.
Objective
We report a previously undescribed mutation in the *AR* gene associated with MAIS in two adult patients, one presenting for infertility and the other for a decrease in athletic performance. We characterize the functional impact of this mutation using 3D modeling studies.
Patients
Patient 1 was referred at the age of 38 years for infertility. He had gynecomastia and normal external genitaliaexcept for mild hypospadias. His semen analysis showed oligoasthenoteratospermia. Lab results revealed high testosterone levels, an elevated FSH, and an elevated androgen sensitivity index (ASI) suggesting AIS. The couple underwent successful *in vitro* fertilization and intracytoplasmic sperm injection resulting in a twin pregnancy. Patient 2 was referred at the age of 45 years for evaluation of a fatigue and a decrease in physical athletic performance. He had a history of gynecomastia, surgically treated during adolescencebut normal external genitalia. He alsopresented with oligoasthenoteratospermia, hightestosterone plasma levels and an elevated ASI. Despite his impairedsemen analysis, he fathered two children without assisted reproductive technology. Because of his persistent fatigue, the patient was offered a trial of high dose dihydrotestosterone therapy which improved his symptoms and his quality of life. Family history for infertility or gynecomastia was negative in both patients.
Results and conclusions
Sequence analysis of *AR* gene in the two patients revealed a common previously undescribed missense mutation, *Ala699Thr*, within the ligand binding domain. Structural analysis showed that this mutation may impact dimer stability upon ligand binding or may affect allosteric changes upon dimerization. This study highlights the usefulness of structural studies in providing a greater understanding of the functional consequences of a mutation and expands the databaseof *AR* gene mutations. The proper diagnosis of adult patients with MAIS may be helpful for the adequate counseling of infertile male patient undergoing assisted reproductive techniques. In addition, a trial of high dose androgen therapy may improve symptoms of hypogonadism in patients with MAIS.

Endogenous doping: Physical exercise acutely increases testosterone levels. Results from a meta-analysis

Daniele Santi[1,2], Giorgia Spaggiari[1], Arcangelo Barbonetti[3] & Settimio D'Andrea[3]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Ospedale Civile Baggiovara, Modena, Italy; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]Department of Life, Health and Environment Sciences, University of L'Aquila, L'Aquila, Italy

Background
Physical exercise represents the first-line therapy in the management of metabolic diseases, considering its beneficial properties on blood pressure, glyco-lipid profile, body composition and hormonal imbalances. On the other hand, testosterone is largely investigated in the setting of competitive sport, representing the main doping source. Although endogenous testosterone levels are demonstrated to be affected by both acute exercise and resistance training, the dynamic regulation of androgen production after physical activity is still a matter of debate.
Aim of the study
This meta-analysis was designed to assess whether physical exercise acutely affects testosterone levels in men.
Methods
The literature search was conducted to identify longitudinal trials evaluating the acute change of testosterone levels after physical activity in adult men published in English language until October 2019 (PROSPERO registration

ID: 157348). Data were extracted using testosterone levels before and after exercise as primary endpoint, considering sex hormone binding globulin (SHBG) and free testosterone (fT) as secondary endpoints. Sensitivity analyses were performed considering the sample collected (i.e. blood or saliva), the intensity of the physical exercise (mild, moderate or high, considering either the intensity reported in the manuscript or the percentage of the maximal exercise intensity described), and the interval between the end of the exercise and the sample collection (0–2 minutes, 3–30 minutes, and 31–60 minutes after the activity).
Results
Forty-eight studies were included in the analysis, accounting for 126 trials. A total of 569 patients were enrolled (mean age 29.7 + 13.1 years).The physical activity increased acutely total testosterone levels, considering both serum and saliva samples ($P < 0.001$, respectively). In particular, testosterone levels significantly increased after moderate ($P < 0.001$) and high intensity ($P < 0.001$) exercises, but not after mild physical activity ($P = 0.190$). Moreover, the testosterone increase was evident when measured immediately at the end of the exercise and within 30 minutes ($P < 0.001$), but not after 30 minutes ($P = 0.930$). Similar significant results were obtained considering fT, while SHBG did not change after physical activity ($P = 0.090$).
Conclusion
Albeit considering the high heterogeneity of included studies, the comprehensive evaluation of the acute physical activity effect on testosterone levels identified a clear increase after exercise, irrespective of the sample collected. The main determinant of this fluctuation was the exercise intensity, with a mechanism that seems to be mostly SHBG-independent. In particular, moderate/intense physical activity resulted able to increase endogenous androgenic production, albeit acutely and transitory.

Clinical and genetic characterization of two cases of central hypogonadism in Klinefelter syndrome

Rita Indirli[1,2], Biagio Cangiano[2,3], Eriselda Profka[2], Elena Castellano[4], Giovanni Goggi[2,3], Giovanna Mantovani[1,2], Maura Arosio[1,2], Luca Persani[2,3], Giorgio Borretta[4], Emanuele Ferrante[1] & Marco Bonomi[2,3]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of clinical sciences and community health, Milan, Italy; [3]IRCCS Istituto Auxologico Italiano, Department of Endocrine and metabolic disases and Lab of endocrine and metabolic research, Milan, Italy; [4]Endocrinology, Diabetology and Metabolism Unit, Department of Internal Medicine, A. O. Santa Croce e Carle - Ospedale S. Croce, Cuneo, Italy, Italy

Introduction
Klinefelter syndrome (KS) is generally characterized by late adolescence/young adulthood onset of primary hypergonadotropic hypogonadism. Fourteen cases have been previously reported on apparently unexplained isolated hypogonadotropic hypogonadism (IHH) in KS. Gonadotropins defect was variably associated with anosmia or other pituitary hormones deficiencies, but no cause could be clearly identified to explain the central defect. We describe the clinical and genetic features of two additional cases followed up at two clinics in Northern Italy.
Case 1
A 60-year-old Caucasian man was referred for genital infantilism and smell defect, for which he had never sought medical attention before. He had a family history of infertility and anosmia; his parents were unrelated. His past medical history included recurrent respiratory infections resulting in restrictive ventilatory defect. The patient reported he had not gone through puberty during adolescence, and eunuchoid body proportions and infantile penis were observed at physical examination. Scrotal ultrasound revealed testes hypotrophy (volume <1 ml). Cytogenetic analysis documented 47,XXY karyotype. Nevertheless, IHH was found on hormonal assessment (total testosterone 1.0 nmol/l, LH 0.1 mIU/ml, FSH 0.1 mIU/ml), while other pituitary hormones were normal.
Case 2
A Caucasian boy with prenatal diagnosis of mosaic KS (47,XXY)(46,XY) confirmed after birth,presented at 17 years of age with small and firm testes (right 6 ml, left 8 ml) and first grade obesity. As a child, he had suffered from dyslexia and incomplete pubertal development. At 20 years of age hormonal exams were obtained and unexpected results consistent with IHHwere found (total testosterone 3.7 nmol/l, LH 3.5 mIU/ml, FSH 2.3 mIU/ml), while other pituitary hormones were preserved. Smell identification test was normal and the patient had no family history of anosmia or infertility.
Diagnostic work-up
Iron overload was excluded in both patients. Sellar region was normal on magnetic resonance scans. Finally, genetic analysis performed by next generation sequencing of IHH associated genes was negative in both patients.
Conclusion
Unexplained central hypogonadism rarely occurs in KS. The mechanism by which the gonadotropin defect is determined in these patients is unknown; coexistence of KS and normosmic isolated hypogonadotropic hypogonadism or Kallmann syndrome could be possible; alternatively,chronic metabolic or systemic comorbidities may suppress the hypothalamus-pituitary-testis axis in some KS subjects resulting in central hypogonadism; finally, these patients may represent a rare variant of KS with more extensive endocrine involvement besides the testicular defect.

Clinical and genetic overlap between congenital hypogonadotropic hypogonadism and cornelia de lange syndrome

Cheng Xu[1], Andrea Messina[1], James Acierno[1], Nicolas Niederlander[1], Federico Santoni[1], Georgios Papadakis[1], Duarte Pignatelli[2], Magdalena Avbelj Stefanija[3], Kimberly Keefe[4], Ravikumar Balasubramanian[5], William Crowley[5] & Nelly Pitteloud[1]
[1]Lausanne University Hospital, Service of Endocrinology, Diabetology & Metabolism, Lausanne, Switzerland; [2]Hospital S João, Department of Endocrinology, Porto, Portugal; [3]University Medical Centre Ljubljana, Ljubljana, Slovenia; [4]Brigham and Women's Hospital, Center for Infertility and Reproductive Surgery, Boston, United States; [5]Massachusetts General Hospital, Center for Genomic Medicine, Boston, United States

Background
Congenital hypogonadotropic hypogonadism (CHH), a clinically and genetic heterogenous sydrome, is caused by >40 known loci whose mutations share the ability to cause defects in the ontogeny of the GnRH neuron network leading to absent/incomplete puberty and infertility. Cornelia de Lange Syndrome (CdLS) is similarly heterogenous disorder (distinctive facies, psychomotor delay, growth retardation and upper limb malformation) caused by mutations in 7 different genes in the cohension complex with a subset who share CHH phenotypes including cryptorchidism, micropenis, and/or delayed puberty, suggesting hypogonadism, although formal endocrine evaluation is lacking.
Methods
Given thephenotypic overlap between these syndromes, exome sequencing was performed in probands with clinical features of both CHH and CdLS or CHH alone, focusing specifically on pathogenic variants in known 7 CdLS genes (*SMC3, NIPBL, SMC1A, RAD21, HDAC8, BRD4* and *ANKRD11*). *In vitro* assays were performed on identified mutants and GnRH3:GFP zebrafish were used to explore the pathogenic role of *SMC3* and *NIPBL* in GnRH neuron development.
Results
Exome sequencing revealed rare sequencing variants (RSV) in *NIPBL* (p.P2761Cfs*4, p.R2298C) and a *de novo* missense RSV in *SMC3* (p.C549Y) in 3 patients exhibiting CHH and CdLS, all of which were absent in gnomAD controls.*NIPBL*p.R2298C has previously been reported in CdLS patients and is considered to be pathogenic. *NIPBL*p.P2761Cfs*4may escape nonsense-mediated decay, thus leading to a truncated NIBPL protein that lacksits 39 N-terminal amino acids. SMC3 C549 residue is located in the hinge domain of SMC3, and C549Y enhances the hinge binding to SMC1 *in vitro*. We also identified two novel protein truncating variants in *NIPBL* (p.E2656*& p.E2696Sfs*6) in different CHH patients without a CdLS diagnosis. Both *Nipbl* and *Smc3* are highly expressed along the migratory path of GnRH neurons from the nasal placode to the hypothalamus. Knock down of *Smc3* and *Nipbl* in GnRH3:GFP zebrafish reduced GnRH neuron numbers, indicating their implication in GnRH neuron biology.
Conclusion
Novel pathogenic variants in cohesion genes (*NIPBL* and *SMC3*) underly CHH with or without CdLS implicating the cohesion complex in GnRH neuron biology. Transcriptomic and DNA accessibility (ATAC-seq) studies in zebrafish and fibroblasts from the *SMC3*-mutated patient are underway to further explore the common mechanism of these two rare developmental diseases.

X-Linked Adrenoleukodystrophy: Report of an atypical case

Lúcia Fadiga[1], Joana Saraiva[1,2], Diana Catarino[1], Joana Reis Guiomar[1], Diana Alexandra Festas Silva[1], Mariana Lavrador[1], Sara Esteves Ferreira[3], Maria do Carmo Macário[4] & Isabel Paiva[1]
[1]Coimbra Hospital and Universitary Centre , Endocrinology Department, Coimbra,; [2]Faculty of Medicine of the University of Coimbra , Coimbra, Portugal; [3]Baixo Vouga Hospital Centre, Endocrinology Department, Aveiro, Portugal; [4]Coimbra Hospital and Universitary Centre , Neurology Department, Coimbra,

Introduction
X-linked adrenoleukodystrophy (X-ALD) is caused by a mutation in the ABCD1 gene, which encodes for a peroxisomal very long chain fatty acid (VLCFA) transporter. Clinically, X-ALD can present a wide spectrum of phenotypes, being the most frequent Adrenomyeloneuropathy, with ataxia, spastic paraparesis, sexual and sphincter dysfunction. Adrenocortical insufficiency (AI) occurs mainly in paediatric age and it can be the first manifestation of the disease in some cases.
Case report
44 year old male, with AI diagnosed at 6 years old, was referred to an endocrinology consultation. He was under hydrocortisone (HC) 20 mg+10 mg and fludrocortisone (FC) 0.1 mg od. He also mentioned complains of dizziness, gait disturbance and erectile dysfunction in the past 6 months and underwent a brain MRI (July 2015) that showed "T2 hyperintensity of internal capsule, cerebral peduncles, pons and medulla oblongata… suggestive of amyotrophic lateral sclerosis". Blood tests revealed ACTH 124 pg/ml (9–52), cortisol 27µg/dl (5-25), renin 93 µU/ml (7–76) and 21–hydroxylase antibodies 0.74 U/ml (< 1.0); other autoimmune markers were negative. Serum VLCFA were elevated and genetic test revealed a mutation in ABCD1 gene (c.1817C>T – p.S606L). One year after diagnosis, he was under HC 35 mg/day and FC 0.1 mg/day; he had grade 4 spastic paraparesis, sexual and sphincter dysfunction and he was under a rehabilitation programme. In April 2018, he had dysarthria, difficulties in fine motor skills, need for a walking aid and memory and concentration impairment. After 4 months, he had a rapid worsening of the general condition, with cognitive decline, poor understanding of speech and hearing loss. MRI (November 2018) revealed alterations typical of different phases of X-ALD, with current inflammatory activity. He was submitted to high-dose corticotherapy, with modest improvement of motor skills. In July 2019, he was admitted to the Emergency Department due to adrenal crisis, pneumonia and seizure; he was hypotensive and febrile; blood tests showed hyponatremia and hyperkalaemia; he needed non-invasive ventilation for 3 days. He was treated with ceftriaxone and azithromycin, with improvement. He was discharged to a long-term care unit. On last follow-up consultation in December 2019, he was totally dependent and aphasic; he was under HC 40 mg/day and FC 0.1 mg/day. His blood tests were normal.
Conclusion
This case demonstrates that in X-ALD, adrenocortical insufficiency can precede neurologic symptoms more than 3 decades. As was the case of this patient, clinical phenotypes of are not static. X-ALD must be considered in male patients with AI, especially if autoimmune markers are negative.

Clinical evaluation and genetic analysis of patients affected by premature ovarian insufficiency: Identification and characterization of a new mutation of the BMP-15

Francesca Orsolini[1], Eleonora Ferrarini[1], Patrizia Agretti[1], Giuseppina De Marco[1], Caterina Di Cosmo[1], Elena Benelli[1], Franca Fruzzetti[2] & Massimo Tonacchera[1]
[1]Azienda Ospedaliero Universitaria Pisana, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]Azienda Ospedaliero Universitaria Pisana, Dipartimento Materno Infantile, Pisa, Italy

Background
Premature ovarian insufficiency (POI) is an ovarian defect characterized from primary or secondaryamenorrhea, high levels of FSH (> 25 UI/l) and low levels of estrogen, which occurs before age 40.
Objective
The aim of the study was to evaluate the clinical features and genetic causes of a group of 68 patients with POI.
Methods
We performed anamnestic and clinical evaluation, hormonal and autoimmunity assessment, pelvic ultrasonography, bone densitometry (DXA) and genetic analysis in 68 women presenting with POI. Genetic analysis was performed for the research of FMR1 pre-mutation and mutations of genes involved in BMP-15 and GDF-9 folliculogenesis. DNA was extracted from peripheral white blood cells. All the exons of the BMP-15 and GDF-9 genes were amplified by polymerase chain reaction and subjected to direct sequencing. A novel heterozygous mutation in exon 2 of BMP-15 gene was identified in a patient. Functional studies were performed to assess the in vitro effect of the identified BMP-15 gene variant. For the functional study COV434 cells of ovarian granulosa were used, which consistently express BMP responsive element (BRE) by assay with luciferase.
Results
63 patients presented secondary amenorrhea, 5 primary amenorrhea. Mean age of menopause was 28 years. 9 patients (13%) had a family history of POI, 28 patients (41%) had one or more autoimmune diseases associated with POI. Pelvic ultrasound revealed the absence of ovarian follicles in 19 patients. Bone densitometry appeared dramatically reduced in 2 women. In 5 patients (7%) FMR1 pre-mutation was detected. In 1 patient we identified a new pathogenetic mutation in heterozygosis c.406G> C (V136L) of BMP-15. We found no mutations in the GDF-9 gene. After transfection in COV434 BMP-15 cells mutated V136L has a significantly reduced activity both if transfected by itself and along with the wild type gene.
Conclusion
POI is a multifactorial pathology with general health implications on affected women. Autoimmunity, familiar and genetic causes represent the most common etiology. We identified FMR1 pre-mutation in 7% of the women and a new BMP-15 mutation responsible for the observed phenotype.

A case of Swyer syndrome with successful extirpation of gonadal tissues in 70 years old women

Jana Figurova, Ivica Lazúrová
PJ Šafarik Medical faculty, 1st Department of Internal Medicine, Košice,

A 27 year old woman was examined in 1977 because of amenorrhea andhirsutism. Hormonal evaluation revealed elevated levels of gonadotrophins simoultaneously with biochemical and clinical hyperandrogenism. Cytogenetic evaluation confirmed presence of male karyotype (46XY) and Swyer syndrome (pure gonadal dysgenesis) was diagnosed. Patient underwent laparotomy, however no gonadal tissue was found during this procedure. A few years later molecular genetic evaluation demonstrated presence of Y sequencies PABY, SRY from the short arm of Y chromosome, DYZ3 sequencies from the centromeric region and sequencies SY85, SY132, SY156, DYZ1 from the long arm of Y chromosome. Patient did not visit endocrinologists for many years. She was treated by psychiatrists because of depression. In her 70-ties (2019) she was admitted to the hospital because ofabdominal pain. Imaging methods and physical examination did not confirman acute abdomen, but MRI demonstrated presence of testicular tissue and crurapenis in the pelvic region. Patient underwent laparoscopic surgery with exstirpation of gonads(testes, epididymis, d. epididymidis) and crura penis. Few months after surgery a marked regression of hirsutism, decrease in serum testosterone levels and marked improvement of depression was observed.
Conclusion
Swyer syndrome is a rare disease with a high risk of malignant transformation of residual gonadal tissue. This case study reports an unusual course of disease, where after 70 years we did not register malignant overthrow of gonads and their surgical extirpation has led to improvement of hyperandrogenism and quality of life.

Ovarian mucinous cystadenoma presenting with virilization

Maarten De Vis[1], Stefan Cosyns[2] & Brigitte Velkeniers[1]
[1]UZ Brussel, Endocrinology, Jette, Belgium; [2]UZ Brussel, Gynaecology, Ovarian Mucinous Cystadenocarcinoma Presenting with Virilization, Jette, Belgium

Background
Ovarian mucinous cystadenomas are classically considered as 'non-functional' tumors. Cystadenomas are among the most common benign ovarian neoplasms. Compared with serous cystadenomas, mucinous cystadenomas occur less frequently, are more often unilateral and can attain an enormous size. Most of these tumors are asymptomatic and found incidentally on pelvic examination or with ultrasound. We present an unusual case of a mucinous cystadenoma presenting with severe virilization in a 71-year old woman.
Case
A 71-year old female was referred to our out-patient endocrinology clinic because of rapid progressive androgenic alopecia, clitoromegaly and male pattern pubic hair growth since one year. Her medical history was unremarkable. Serum level of testosterone was 3.35 µg/l (normal range < 0.4 µg/l) and the dihydroepiandrosterone sulfate (DHEAS) level was 267 µg/l (normal range 100–800 µg/l). Magnetic resonance imaging of the abdomen revealed a 5.5 × 3 × 3 cm cystic ovarian mass. A bilateral salpingo-oophorectomy was performed without complications. Histopathology showed an unilocular cystic structure with a yellowish content and compatible with a mucinous cystadenoma. Postoperative testosteron levels quickly normalised (< 0.4 µg/l).
Discussion
Rapidly developing postmenopausal hyperandrogenism easily turns into a diagnostic challenge for the clinician. Most cases result from adrenal or ovarian tumors but atypical causes must be recognized as well. To date and to the best of our knowledge there are only five cases of mucinous adenoma causing virilization in postmenopausal women identified in the literature. This sixth case adds strength to the link between ovarian mucinous cystadenoma and severe, rapidly progressive hyperandrogenism during menopause. In this case surgical resection is the treatment of choice.

Bone mineral density in prepubertal and pubertal children with turner syndrome

Nadzeya Peskavaya[1], Anghalika Solntsava[2] & Natallia Akulevich[1]
[1]The State Center for Medical Rehabilitation, Endocrinology department, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus

Aim
To evaluate bone mineral density (BMD) in children with different karyotype variants of Turner syndrome (TS) depending on the stage and the onset of puberty (spontaneous or induced).
Methods
The total studied group consisted of 75 children with TS from 8 to 17 years (mean age 14.2±2.61), who were regularly followed-up in the University hospital (Minsk) and age matched 25 healthy controls. TS was diagnosed according to the results of karyotyping at the age of 8.2±5.16 years. 22 patients were in prepuberty (mean age 11.4±2.1 years). 53 girls had II-V stage of puberty according to Tanner (mean age 15.26±1.95 years). Spontaneous onset of puberty was observed in 14 girls aged 12.07±1.66 years. 39 patients underwent puberty initiation (the age for starting estrogen replacement therapy was 13.27±1.26 years). Depending on the karyotype, 3 groups of patients were identified: group 1 - with karyotype 45,X (n=42), group 2 - with mosaic karyotype 45,X/46,XX (n=9), group 3 - with structural anomalies of X chromosome (n=24). Body composition with evaluating of mineral component was made by DEXA with the calculation of lumbar spine (L_{1-4}) BMD (g/cm^2) and Z-test.
Results
54.5% of prepubertal patients with TS revealed low BMD of lumbar spine L_{1-4} vs 64.1% in pubertal girls. A significant increase of BMD was revealed in patients of puberty age in comparison with the group of prepubertal children (0.95 [0.85;1.02] g/cm^2 vs 0.76 [0.69;1.82] g/cm^2, P=0.0001). A statistically significant increase in the Z-test in this groups was not established (–1.25 [–1.95; –0.78] vs –1.1 [–1.7; –0.4], P=0.2). There were no differences in BMD depending on karyotype both at the prepuberty and puberty age. The BMD of the lumbar spine (L_{1-4}) was significantly lower both in patients with spontaneous puberty and in the group of girls with estrogen replacement therapy compared to the control group. In girls with TS and spontaneous puberty a low BMD was detected in 57.2% of cases (Z=–1.9±0.87), whereas in the group with stimulated puberty - in 68.4% of patients (Z=–1.8±0.62). A direct correlation of spine BMD and estrogen therapy duration (rs=0.6, P=0.0001) was found in girls with TS.
Conclusions
A significant increase in BMD without an improvement in the Z-test was found in pubertal patients with ST in contrast to prepubertal children. Decreased of BMD are more often diagnosed in patients with stimulated puberty, due to the later initiation of estrogen therapy. Long-term estrogen replacement improves BMD.

Investigating the impact of preoperative obesity-associated hyperandrogenemia in women and hypogonadism in men on weight loss following bariatric surgery

Hannes Beiglböck[1], Paul Fellinger[1], Tamara Ranzenberger-Haider[1], Bianca Itariu[1], Gerhard Prager[2], Alexandra Kautzky-Willer[1], Michael Krebs[1] & Peter Wolf[1]
[1]Medical University of Vienna, Department of Medicine III, Division of Endocrinology and Metabolism, Vienna, Austria; [2]Medical University of Vienna, Department of Surgery, Division of Metabolic Surgery, Vienna, Austria

Background
In severe obesity, hypogonadism in men and androgen excess in women are frequently observed. Sex hormones play an important role in body composition, glucose and lipid metabolism. Bariatric surgery is the most effective treatment strategy to combat morbid obesity. However, if preoperative gonadal dysfunction impacts weight loss and metabolic improvements after surgery is not known.
Methods
49 men and 104 women were included in a retrospective analysis. Anthropometric characteristics, glucose and lipid metabolism and androgen concentrations were assessed preoperatively and 17.9±11 or 19.3±12 months-postoperatively in men and women. Men with and without preoperative hypogonadism (HYPO vs CON_{male}), as well as women with or without preoperative hyperandrogenemia (HYPER vs CON_{female}) were compared.
Results
Inmen preoperative hypogonadism was present in 55%, linked to a higher BMI (HYPO 50±6 kg/m^2 vs CON_{male} 44±5 kg/m^2, P=0.001). Bariatric surgery results incomparablechanges in BMI in HYPO and CON_{male} (–16±6 kg/m^2 vs –14±5 kg/m^2, P=0.30) and similar improvements in glucose and lipid metabolism. Weight loss reversed hypogonadism in 93%. In women androgen excess was present in 22%, independent of preoperative BMI (CON_{female} 44±7 kg/m^2 vs HYPER45±7 kg/m^2, P=0.57). Changes in BMI and metabolic improvements were comparable in HYPER and CON_{female} (–15±6 kg/m^2 vs –15±5 kg/m^2, P=0.88)after bariatric surgery. Hyperandrogenemia was reversed in 61%.
Conclusions
Despite being frequently observed, hypogonadism in men and androgen excess in women have no impact on postsurgical improvements in body weight, glucose and lipid metabolism. Weight reduction resulted in reversal of hypogonadism in almost all men and of hyperandrogenemia in the majority of women.

The vulnerability of prepubertal ovarian steroidogenesis to AhR-mediated TCDD action occurs during a time-restricted window in mice

Marie Devillers[1], Florence Petit[1], Frank Giton[2], Charlotte François[1], Ludmila Juricek[3], Xavier Coumoul[3], Solange Magre[1], Joëlle Cohen-Tannoudji[1] & Celine Guigon[1]
[1]Université de Paris, CNRS, INSERM, Biologie Fonctionnelle et Adaptative UMR 8251, Physiologie de l'Axe Gonadotrope U1133, Paris, France; [2]AP-HP, Pôle Biologie-Pathologie Henri Mondor, Créteil, France, INSERM IMRB U955 eq07, Créteil, France; [3]INSERM UMR-S 1124, Toxicologie Pharmacologie et Signalisation Cellulaire, Paris, France

Background
In females, timing of puberty and fertility require estradiol (E2) action at the infantile and late juvenilestages and are tightly influenced by environ-

mental cues. A regulator of intra-ovarian E2 synthesis during reproductive life is the aryl hydrocarbon receptor (AhR). However, its action on E2 synthesis and its capacity to mediate the effect of endocrine disrupting chemicals (EDC)s has not been thoroughly evaluated during the prepubertal period.
Objectives
Determining intrinsic and EDC-induced activity of AhR on E2 synthesis at critical prepubertal stages for reproductive function programming.
Methods
The intra-ovarian expression of components of the steroidogenesis pathway, prototypical AhR target genes (*Ahrr*, *Cyp1a1*) and E2 contents were examined in the *Ahr*knockout (*Ahr*$^{-/-}$) mouse at the neonatal (7 days postnatal (dpn)), infantile (14 dpn), early (21 dpn) and late juvenile stages (28 dpn) and in the highly dioxine sensitive C57Bl/6J mouse strain treated at 14 or 28 dpn with AhR ligands, FICZ and TCDD. The expression of AhR was analyzed in both mouse and human ovaries.
Results
Intrinsic AhR pathway became active only at the end of the prepubertal period, as revealed in *Ahr*$^{-/-}$ mice *versus* *Ahr*$^{+/+}$ miceby the down-regulation in the relative intra-ovarian contents of E2, *Cyp19a1* aromatase and *Ahrr*transcripts exclusivelyat 28 dpn. AhR activation by exogenous ligands could occur at any stage, as suggested by TCDD-induced *Ahrr* and *Cyp1a1* expression at both 14 and 28 dpn, but itimpaired *Cyp19a1* expression and E2 synthesis only at 28 dpn. Although AhR is detected in the ovary throughout the prepubertal period, its nuclear localization, reflecting its activity, in granulosa cells responsible for E2 synthesis, was weak at the infantile stage.
Discussion
AhR regulation of E2 synthesis would start at the approach of puberty. We propose that AhR-mediated EDC action specifically at this stage could be particularly detrimental for reproductive function programming.

The association between hormone replacement therapy and sarcopenia in postmenopausal women: The korea national health and nutrition examination survey, 2008–2011

Sung Woo Kim, Jinu Kim, Eonju Jeon, Ji-Hyun Lee & Ho-Sang Shon
Daegu Catholic University Hospital

Objective
Menopausal transition contributes to sarcopenia, but the effects of hormone replacement therapy (HRT) on sarcopenia in postmenopausal women have not been determined. This study assessed the effect of HRT on sarcopenia in postmenopausal women.
Methods
The present study included 4,254 postmenopausal women who participated in the Korea National Health and Nutritional Examination Surveys in 2008–2011. Appendicular skeletal muscle mass divided by weight (ASM/Wt) and the prevalence of sarcopenia were analyzed in groups of women stratified by duration of HRT.
Results
ASM/Wt was higher and the prevalence of sarcopenia was lower in subjects with a history of prolonged (≥ 13 months) than in subjects without a history of HRT. After adjusting for multiple confounding factors, HRT remained significantly associated with estimated mean ASM/Wt and the prevalence of sarcopenia (odds ratio: 0.59; 95% confidence interval: 0.40–0.87; $P<0.01$). A multivariate model showed that ASM/Wt and the prevalence of sarcopenia were independently associated with age, history of hypertension, physical activity, age at menopause, and a history of HRT. Subgroup analysis showed that the association between duration of HRT and the prevalence of sarcopenia was maintained in younger (< 65 years old) and leaner (body mass index < 25 kg/m^2) postmenopausal women.

Table 1 Odds ratios for the prevalence of sarcopenia in postmenopausal women stratified by duration of hormone replacement therapy.

	No HRT ($n=3,656$)	HRT for 1–12 months ($n=302$)	HRT for ≥13 months ($n=275$)	*P* for trend
Unadjusted	1 (ref)	0.93 (0.68–1.27)	0.67 (0.47–0.95)*	0.08
Model 1	1 (ref)	0.95 (0.69–1.31)	0.64 (0.45–0.92)*	0.05
Model 2	1 (ref)	0.90 (0.66–1.24)	0.59 (0.40–0.87)**	0.03

Data were analyzed using complex samples logistic regression and are expressed as odds ratio (95% confidence interval).
Model 1: adjusted for age, age at menarche, age at menopause, and number of pregnancies.
Model 2: adjusted for age, age at menarche, age at menopause, number of pregnancies, past history of OC, past histories of DM and HTN, smoking history, physical activity, and energy intake (total, proteins, carbohydrates, and fats).
*$P<0.05$, **$P<0.01$.

Conclusions
The present study showed that prolonged HRT was associated with high muscle mass and a low prevalence of sarcopenia in postmenopausal women, suggesting that HRT may have a protective effect on sarcopenia in postmenopausal women.

Ovarian reserve and serum concentration of thyroid peroxidase antibodies in euthyroid women with different polycystic ovary syndrome phenotypes

Agnieszka Adamska[1], Agnieszka Lebkowska[2], Anna Krentowska[2], Justyna Pliszka[1], Marcin Adamski[3], Monika Leśniewska[4] & Irina Kowalska[2]
[1]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Poland; [2]Medical University of Białystok, Department of Internal Medicine and Metabolic Diseases, Poland; [3]Bialystok University of Technology, Faculty of Computer Science, Poland; [4]Medical University of Białystok, Department of Reproduction and Gynecological Endocrinology, Poland

Objective
It has been shown that women with PCOS as well as with autoimmune thyroiditis (AIT), are characterized by increased incidence of infertility. Serum anti-Müllerian hormone (AMH), which reflects ovarian reserve, is elevated in PCOS women and is decreased in women with AIT. The Rotterdam criteria recognize four clinical PCOS phenotypes,i.e.,phenotype Acharacterized by clinical and/or biochemical hyperandrogenism (HA), menstrual dysfunction (oligo/amenorrhea) (Oligo) and polycystic ovarian morphology (PCOM), phenotype B (HA+Oligo), phenotype C (HA+PCOM) and phenotype D (Oligo+PCOM). To date, there is no study evaluating ovarian reserve and TPOAbs in different PCOS phenotypes. The aim of the present study was to investigate the relation between serum concentrations of TPOAbs and ovarian reserve in different PCOS phenotypes.
Patients and methods
We examined 141 women with PCOS (phenotype A was diagnosed in 67 (47.5%) women, phenotype B in 30 (21.3%), phenotype C in 28 (19.9%), phenotype Din 16 (11.3%)) and 88 control subjects of similar age ($P>0.05$). Physical examination was performed in all women. Serum concentration of LH, FSH, estradiol, total testosterone, AMH, TSH, thyroid hormones and TPOAbs were assessed and ultrasound of the ovaries was performed.
Results
Serum concentrations of TSH, fT4 and fT3 did not differ between the studied groups (all $P>0.05$), all women were euthyroid. We observed positive serum TPOAbs in 31 (21.9%) women with PCOS and in 21 (23.9%) controls ($P=0.07$). We did not observe differences in frequency of detection of positive serum TPOAbs between phenotype A (15 women, 22.4%), phenotype B (5 women, 16.7%), phenotype C (10 women, 35.7%) and control group (21 women, 23.9%) ($P>0.05$). Interestingly, only one woman had positive serum TPOAbs (6.3%) in phenotype D. Serum AMH concentration was markedly higher in thewhole PCOS group ($P<0.01$) and in phenotype A ($P<0.01$) vs controls when serum concentration of TPOAbs was negative. However, in the groups with positive serum levels of TPOAbs, serum concentration of AMH did not differ between PCOS phenotypes and controls (all $P>0.05$). We foundrelationships between serum TPOAbs concentrations and hip circumference ($P=0.03$) and serum concentration of estradiol in the whole group ($P=0.002$).
Conclusions
Frequency of serum detection of positive TPOAbs did not differ between PCOS phenotypeswith clinical/biochemical hyperandrogenism and control group, however, phenotype D is characterized by the lowest frequency of occurrence of positive TPOAbs. We observed differences in ovarian reserve between PCOS and control group with negative TPOAbs, whereas presence of TPOAbsabolished this differences.

Comparison of three automated assays of AMH

Cindy Lauro, Aurélie Sieuw, Andrea Ion, Jean-Benoît Corcuff, Julie Brossaud & Agnès Georges
University hospital , Bordeaux, France

Anti-Mullerian Hormone (AMH) is a 140 kDa gonadal glycoprotein of the TGFβ family, with two subunits linked by two disulfide bridges. Since a first assay in 1990, three generations of assays occurred: the 1st and 2nd were manual assays. The 3rd was automated: Access AMH Kits (Beckman Coulter) and Elecsys AMH (Roche). We had the opportunity to compare two new analysers with the Elecsys AMH: Vidas (Biomérieux) and Lumipulse G (Fujirebio). The later are one-step sandwich immunoenzymatic (fluorescence detection) and two-step sandwich chemiluminescence, respectively. The population studied consisted of 50 women of reproductive age (27 [20.5–37.7] yr, median [5th-95th] percentiles; BMI 21.7 [18.2–29.1] kg/m²). The sera collected were centrifuged, aliquoted in 3 aliquots and frozen until the day of the assay. Intra-laboratory precisions reported by the suppliers were: CV < 2.1% for sample panels with concentrations from 0.41 to 22.44 ng/ml for the Lumipulse and CV < 10.6% for sample panels with concentrations from 0.22 to 7.37 ng/ml for the Vidas. The results obtained were closely correlated with no significant deviation from linearity (Passing Bablok test): Elecsys vs Vidas correlation coefficient $r = 0.976$, [Elecsys] = 0.0778767 + 1.086758*[Vidas] ng/ml & Elecsys vs Lumipulse $r = 0.913$, [Lumipulse] = 0.0308871 + 1.097997*[Vidas] ng/ml. On the Bland-Altman graphs, 3 outliers were found outside the concordance limits for the Vidas against 1 outlier for the Lumipulse. Despite these very good correlations and minor biases, an important problem rests with the proposed reference values which are not similar. For instance, for a 30-34 yr old woman: Elecsys 2.81 [0.71–7.59], Lumipulse 1.557 [0.065–10.042], Vidas 3.55 [1.19–7.00] ng/ml. A combination of reasons may explain this. Firstly, an international AMH standard is not yet used for theses assays. Furthermore, AMH concentrations can be influenced by different factors (ethnicity, tobacco, oral contraceptives, etc.). Reference values may thus be different from so-called normal values in healthy subjects. Specifics about the determination of reference ranges by the manufacturers are then critical (Ferguson, Reprod Biomed Online, 2018). Indeed, precise identification of these ranges is mandatory to assess the usefulness of determining AMH concentration with any apparatus.

Introduction
Duodenal mucosal resurfacing (DMR) is a novel therapy for T2DM. It involves the hydrothermal ablation of up to 14 cm of the duodenal mucosa through a specially designed endoscopic catheter. The procedure is performed under general anaesthesia, patients are discharged the same day and it does not involve the implantation of a foreign body. Cohort studies have demonstrated that DMR induces meaningful hbA1c reductions of 0.9–1.4% by 3 months that are largely maintained at 12 months without significant weight loss. This weight loss-independent effect on glycaemia remains elusive. Herein, we sought to investigate the effect of DMR on insulin sensitivity and menstruation of euglycaemic patients with PCOS and insulin resistance.

Methods
In this first of its kind, double-blinded RCT with a 24 week follow-up, thirty insulin resistant PCOS women were randomised at 1:1 to either DMR or sham endoscopy. Diagnosis of PCOS was based on NIH criteria. Specialist lifestyle modification was delivered to all patients. All patients underwent OGTT to measure insulin secretion and the gold standard euglycaemic hyperinsulinaemic clamps with stable isotopes to measure insulin sensitivity, at baseline, 2 weeks and 3 months after intervention.
Results

Baseline clinical characteristics

	DMR ($n = 15$)	Sham ($n = 15$)
Age (years)	30.60 ± 5.22	31.60 ± 6.94
Weight (kg)	107.76 ± 18.96	121.24 ± 12.58
BMI (kg/m²)	40.20 ± 6.63	44.71 ± 3.35
Body fat (%)	43.94 ± 3.47	46.08 ± 2.05
W/H ratio	0.87 ± 0.06	0.87 ± 0.09
Glycaemic profile		
HbA1c (mmol/mol)	39.67 ± 3.74	37.67 ± 5.33
Fasting glucose(mmol/l)	5.55 ± 0.67	5.05 ± 0.59
Fasting insulin (mIU/l)	21.99 ± 8.43	27.69 ± 13.86
HOMA-IR	6.20 ± 3.38	6.15 ± 2.93

Primary Endpoints

	DMR ($n = 15$)	Sham ($n = 15$)	*P*-value
Change in total insulin sensitivity at 12 weeks (mg/kg/min)	0.14 ± 0.97	0.24 ± 1.74	0.367
Change in insulin sensitivity by HOMA-IR at 24 weeks	-0.39 ± 1.87	-1.19 ± 4.23	0.301
Number of menses in 24 weeks	3.00 [0.00, 5.00]	2.00 [1.00, 5.00]	0.434

Conclusion
DMR didn't increase insulin sensitivity in insulin resistant women with PCOS and obesity in this trial. Thus, selecting the duodenal mucosa as a therapeutic target may only be effective in T2DM but not in euglycaemic insulin resistant states. Future studies could examine the effect of DMR on insulin sensitivity in people with T2DM. Our results are likely limited by a relatively small sample size and short duration of follow-up compared to studies done in patients with T2DM.

Early decreases in testosterone levels in healthy adult men: A longitudinal analysis.

Thiberiu Banica[1], Charlotte Verroken[1], Hans-Georg Zmierczak[1], Stefan Goemaere[1], Tim Reyns[2], Tom Fiers[2], Jean-Marc Kaufman[1] & Bruno Lapauw[1]
[1]Ghent University, Unit for Osteoporosis and Metabolic Bone Diseases, Department of Endocrinology and Reumatology, Ghent University Hospital, Ghent, Belgium, Ghent, Belgium; [2]Ghent University, Department of Clinical Chemistry, Ghent University Hospital, Ghent, Belgium

Introduction
Although it is well-known that serum testosterone (T) levels decrease in ageing men, to this date no longitudinal data are available on changes in T levels in healthy young adult men.

Objective
To investigate age-related longitudinal changes in serum levels of total T, free T and sex hormone binding globulin (SHBG) in healthy young men.
Methods
Data from 999 healthy men aged 24–46years who participated in a longitudinal population-based sibling-pair study were included. After a mean follow up of 11.6±1.9 (range 7–18) years, 709 participants were re-evaluated. SHBG, luteinizing hormone (LH) and follicle stimulating hormone (FSH) were measured using Roche e801 immuno-assays. T was measured using LC-MS/MS, free fractions and body mass index (BMI) were calculated. Linear mixed effects modelling was used for longitudinal analysis. Age at baseline and BMI were used as covariates.
Results
Men were 34.5±5.5 years at baseline and 46.4±5.8 years at follow up. During this period BMI increased from 25.1 kg/m² to 26.3 kg/m². At both time points, age and BMI negatively associated with total T and free T (all $P<0.001$), and BMI also negatively associated with SHBG ($P<0.001$). During follow up, total T levels decreased 14.4% (586.51 ng/dl vs 502.22 ng/dl at baseline and follow-up, respectively, after correction for age at baseline; $P<0.001$). The decrease in total T was less pronounced after correction for BMI and changes therein with a decrease of 10.2% ($P<0.001$). Free T decreased 17.9% (11.12 ng/dl vs 9.18 ng/dl after correction for age at baseline). The decrease in free T was less pronounced after correction for BMI and changes therein with a decrease of 16.1% ($P<0.001$). After adjustment for age and BMI, SHBG increased 5.9% (37.8 nmol/l vs 40.15 nmol/l) , LH increased 6.8% (4.465 U/l vs 4.791 U/l) and FSH increased 15.5% (4.340 U/l vs 5.139 U/l) (all$P<0.001$) during follow-up. Further, older age at baseline was associated with larger changes in SHBG ($r=0.115$; $P=0.002$) and FSH ($r=0.08$; $P=0.032$).
Conclusion
Already from the 4th decade of life, healthy men experience decreases in total and free T levels, independently from changes in BMI. Given the concurrent rise in gonadotropin levels, the decline in T in our population mostly likely arises from primary testicular dysfunction. Changes in T levels were independent from baseline age, suggesting a similar linear decrease across age within our population.

11-Ketotestosterone is the Predominant Androgen in Castration Resistant Prostate Cancer

Gido Snaterse[1], Lisanne F van Dessel[2], Job van Riet[3], Angela E Taylor[4], Jenny A Visser[1], Wiebke Arlt[4], Martijn P Lolkema[2] & Hans Hofland[1]
[1]Erasmus University Medical Center, Internal Medicine, Rotterdam, Netherlands; [2]Erasmus University Medical Center, Medical Oncology, Rotterdam, Netherlands; [3]Erasmus University Medical Center, Urology, Rotterdam, Netherlands; [4]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

Background
The treatment of metastatic castration-resistant prostate cancer (CRPC) remains dependent on Androgen Receptor (AR) mediated signalling, thus understanding all components involved in testosterone signalling in these men is of utmost importance. Recent studies have identified 11-ketotestosterone (11 KT) as a potent androgen receptor (AR) agonist present in humans. However, it is unknown if 11 KT is present at physiologically relevant concentrations in CRPC patients. In this study, we investigated the steroid hormone metabolomes of CRPC patients at baseline, during treatment with second-line therapies and after clinical progression.
Method
Plasma samples of 29 CRPC patients starting treatment with antiandrogens ($n=10$) docetaxel+prednisone ($n=10$) or cabazitaxel+prednisone ($n=14$) were selected. Five patients completed two treatments. Steroids were extracted from plasma by liquid-liquid extraction method, followed by multi-steroid profiling liquid chromatography-tandem mass spectrometry (LC-MS/MS) targeting 16 steroid hormones as well as prednisone, prednisolone and dexamethasone. Next-generation sequencing and RNAseq were performed on the tumour biopsy samples of these patients obtained at baseline ($n=20$).
Results
11 KT was the most abundant androgen in CRPC patients at baseline, with a median concentration of 0.33 nM (0.03–2.39 nM) which constituted 65.5% (43–79.1%) of the total androgen (TA) pool. Testosterone (0.13 nM; 0.03–0.64 nM) constituted 23.8% (IQR 15.0–32.3%) of the TA pool. Treatment with glucocorticoids reduced circulating 11 KT by 83.6% (IQR: 38.6–89.3%) and testosterone by 67.9% (IQR: 38.3%–79.3%) as well as 11-oxygenated androgen precursor steroids by >80%. Differential gene expression was observed between tumour biopsy samples of patients with high (>median) versus low (<median) TA concentrations. High TA concentrations at baseline were associated with longer progression-free survival ($P<0.05$).
Conclusions
This study has identified 11-ketotestosterone, a potent AR agonist, as the major circulating androgen in CRPC patients and its abundance correlates with gene expression in the tumour tissue. Thus androgen abundance in CRPC haspreviously been underestimated and routine quantification of testosterone alone may not accurately reflect the TA abundance in patients. Suppression of 11 KT and testosterone was achieved by glucocorticoid treatment, which may explain the beneficial effects of glucocorticoid treatment in CRPC patients.

Pituitary response to GnRH stimulation in patients with secondary hypogonadism is modulated by different FSHB -211 G/T genotypes

Andrea Sansone[1,2], Maria Schubert[1], Frank Tüttelmann[3], Michael Zitzmann[1], Claudia Krallmann[1], Sabine Kliesch[1] & Jörg Gromoll[1]
[1]University Hospital Münster, University of Münster, Centre of Reproductive Medicine and Andrology, Münster, Germany; [2]Sapienza University of Rome, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Rome, Italy; [3]University of Münster, Institute of Human Genetics, Münster, Germany

Background
The *FSHB* –211 G>T single nucleotide polymorphism (SNP) is known to affect pituitary FSH output by reducing the transcriptional activity of FSHB. Identifying the response of the pituitary to exogenous GnRH stimulation in subjects with *FSHB* -211 G>T SNP could provide useful information concerning the mechanisms regulating FSH synthesis and release.
Objectives
This study aimed to assess the pituitary response to a standardized GnRH stimulation test in patients with secondary hypogonadism (SH) according to the different *FSHB* -211 G/T genotypes (GG/GT/TT).
Materials and methods
67 male patients receiving a GnRH stimulation test (0.1 mg intravenously, sampling at 2 time-points after administration) during clinical workup for SH between January 1997 and October 2018 were retrospectively selected in our university-based referral centre. Linear longitudinal mixed-effect models were used to assess the effects of SNP genotype on FSH and LH levels over time via additive and recessive models.
Results
A marked increase in serum FSH and LH following administration of GnRH with a statistically significant linear trend was found ($P<0.0001$ for both models). In both the additive and recessive models, the main effect of T allele(s) did not reach statistical significance concerning changes of FSH levels ($P=0.9473$ and $P=0.9467$, respectively), albeit interaction effects over time were significant ($P=0.0219$ and $P=0.0276$). Main and interaction effects on LH-surge were significant in both the additive ($P=0.029$ and $P=0.0013$) and recessive model ($P=0.0033$ and $P=0.0016$). The peak of serum LH levels was significantly higher in TT carriers than in GT and GG carriers ($P=0.012$)
Discussion and conclusions
The promoter polymorphism *FSHB* -211 G>T affects the pituitary response to exogenous GnRH stimulation by reducing FSH and, surprisingly, increasing LH outputs in patients with secondary hypogonadism.

TU score: A new proposal for an ultrasound scoring system to predict testicular function

Francesco Carlomagno, Carlotta Pozza, Daniele Gianfrilli, Marta Tenuta, Franz Sesti, Paola Mazzotta, Andrea Lenzi & Andrea Isidori
Sapienza University of Rome, Department of Experimental Medicine, Roma, Italy

Background
Testicular ultrasound (US) is routinely employed in the evaluation of reproductive and sexual function. However, its use for characteristics other than testicular volume is hampered by a lack of information on the prognostic value of its findings, that to date have only been incorporated in a score proposed by Lenz *et al.* in 1993.
Objectives
We sought to explore whether testicular US examination can predict spermatogenesis and provide information on testicular endocrine function.
Materials and methods
We retrospectively reviewed 6210 testicular US examinations, finally selecting examinations from 2230 unique men after exclusion of individuals younger than 17 years of age and those affected by congenital disorders known to affect the testes. The following variables were considered: bitesticular volume (BTV), echotexture, echogenicity and presence of microlithiasis, solid lesions and varicocele; testicular asymmetry was derived via the testicular atrophy index. Concurrent fasting hormonal data were available for 1160 men, while 979 had a semen sample available from the same day as the US exam. We defined hypogonadism as total testosterone <12 nmol/l and LH > 8.16 mIU/ml and employed a sperm synthetic index to identify impaired spermatogenesis, defined as the total number of motile spermatozoa with a normal morphology (using a cut-off of 0.625×10^6/ejaculate, derived from the 5th centiles of the WHO 2010 reference parameters (39×10^6 spermatozoa × 40% motility × 4% normal forms).
Results
Through linear and logistic regression analyses BTV and testicular echostructure were independent predictors of sperm concentration, total sperm number, total motility, normal forms and sperm synthetic index ($P<0.001$ for all), while the addition of testicular echogenicity and presence of microlithiasis contributed in predicting total testosterone and LH values. We derived a new US score, termed TU score, that can predict both impaired spermatogenesis (AUC 0.73, sensitivity 72%, specificity 61%, $P<0.001$) and hypogonadism (AUC 0.71, sensitivity 71%, specificity 53%, $P<0.001$) more accurately than the Lenz score.
Conclusions
We describe the testicular US characteristics independently associated with impaired spermatogenesis and hypogonadism and propose the TU score as a simple screening method for use in subjects referred for testicular US.

Effects of testosterone replacement therapy on circulating resistin levels in obese hypogonadal men

Yavor Assyov[1], Antoaneta Gateva[1], Vera Karamfilova[1], Iveta Nedeva[1], Tsvetan Gatev[1], Tsvetelina Velikova[2] & Zdravko Kamenov[1]
[1]Medical University – Sofia, Internal Diseases, Sofia, Bulgaria; [2]University Hospital Lozenetz, Department of Clinical Immunology, Sofia, Bulgaria

Objective
The beneficial effects of testosterone replacement therapy (TRT) in men with hypogonadism on the body composition and metabolic parametersare well-established, but the intimate mechanisms of these effects are not fully understood. Resistin is a small protein that is involved in the regulation of glucose metabolism and is considered to be key in the development of insulin resistance and to induce proinflammatory effects. We hypothesize that TRT has an impact on the adipokine profile that mediates its positive effects on the metabolism.
Design
The aim of this pilot study was to evaluate the effects of testosterone replacement therapy (TRT) on the circulating levels of serum resistin in the study population.
Methods
A total 40 men with obesity and idiopathic hypogonadotropic hypogonadism (defined as serum testosterone concentration <12 nmol/l). Testosterone replacement therapy (TRT) with Testosterone Undecanoate (Nebido) was performed at baseline and at week 6. Serum resistin concentration was determined at baseline and at week 18 by means of ELISA.
Results
Mean age ± S.D. of the study participants was 49.4 ± 10.1 years. 50% of the subjects had type 2 diabetes mellitus. Circulating resistin was negatively associated with serum HDL concentration ($r=-0.258$, $P<0.05$), and positively with fat mass as measured by BIA ($r=0.370$, $P<0.05$). TRT has led to a statistically significant reduction in circulating serum resistin levels (8172 pg/ml vs 4816 pg/ml; paired-samples t-test $P<0.021$). This association persisted even after adjustment with potential confounders.
Conclusions
TRT in obese men with idiopathic hypogonadotropic hypogonadism has led to a significant improvement of metabolic outcomes and body composition as well as to a significant reduction in serum resistin levels. As no such data on this association has been reported in the literature thus far, further prospective studies are required to elucidate this association.

Hypogonadism and testis impairment in patients with amyloidosis due to Apo A-I Leu75Pro mutation

Paolo Facondo[1], Andrea Delbarba[2], Letizia Chiara Pezzaioli[1], Elena Di Lodovico[1], Carlo Cappelli[1], Francesco Scolari[3] & Alberto Ferlin[1]
[1]Unit of Endocrinology and Metabolism, University of Brescia, Brescia, Italy, Department of Clinical and Experimental Sciences; [2]Unit of Endocrinology and Metabolism, ASST Spedali Civili Brescia, Brescia, Italy; [3]Unit of Nephrology, University of Brescia, Brescia, Italy, Department of Medical-Surgical Specialties, Radiological Sciences and Public Health

Introduction
Amyloidosis due to Apo A-I Leu75Pro mutation is a rare form of hereditary amyloidosis with systemic involvement mainly of testicle, kidney and liver. This disease finds a wide prevalence in the province of Brescia (Northern Italy), which represents a geographic uniqueness for the spread of this amyloidosis form. Somefeatures of this disease have not yet been described.
Purpose
To describe the frequency of organ damages in this amyloidosis form and above all to define the characteristics of testicular involvement for the first time in such a wide range of cases.
Materials and methods
We have retrospectively analyzed 129 male patients >18 years of age with diagnosis of ApoA-I Leu75Pro amyloidosis. Organ involvement was assessed with scrotal ultrasound, gonadal hormone levels, glomerular filtration rate estimate and cholestasis indices evaluation.
Results
Testicular involvement is predominant with respect to liver and kidney involvement, and in younger patients it is often the first and/or only manifestation of disease. The testicle is affected in 88/129 (68.2%) of the patients and considering the younger patients (18–38 years) it turns out to be the only manifestationin 30% of cases. In older age group, gonadal involvement is associated with kidney and liver impairment in 53.3% of patients. Testicular involvement manifests itself as hypogonadism, which it is primary (reduced testosterone and increased LH)in 83% of cases. Considering also FSH-Sertoli cell axis (indirect expression of spermatogenesis function), almost all patients (96.6%) have testicular impairment of both gonadal axes. In addition, an increase in testicular volumes (>253 ml) is often found in this amyloidosis form (48.2% of cases).
Discussion
In Apo A-I Leu75 Proamyloidosis, the testicular involvement is often early and it can compromise endocrine and spermatogenic testicular function. It should be noted that ApoA-I Leu75 Pro amyloidosis manifests itself as primary testicular damage with peculiar characteristics (different from many other known forms of hypogonadism): the macroorchidism and the concomitant global involvement of testicular cell populations. Conclusions: this is the first large description of testicular involvement in this form of amyloidosis. The results of this study may have important clinical implications forearly diagnosis, screening of family membersand clinical-therapeutic follow-up of these patients.

Seasonal changes of serum gonadotropins and testosterone in men revealed by a large data set of real-world observations over nine years

Giorgia Spaggiari[1], Antonio Raffaele Michele Granata[1], Monica Setti[2], Simonetta Tagliavini[3], Tommaso Trenti[3], Manuela Simoni[1,4] & Daniele Santi[1,4]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Ospedale Civile Baggiovara, Modena, Italy; [2]Service of Clinical Engineering, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Department of Laboratory Medicine and Anatomy Pathology, Azienda USL of Modena, Modena,

Italy; [4]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background
Environmental rhythmicity seems able to affect the hypothalamic-pituitary-gonadal axis in animals to achieve reproductive advantages. However, conflicting results were obtained when assessing the environmental-dependent rhythmicity on reproductive hormone secretion in humans.
Aim of the study
This study was designed to evaluate seasonal fluctuations of the main hormones involved in the hypothalamic-pituitary-gonadal axis in men, using a big data approach.
Methods
An observational, retrospective, big data trial was carried out, including all testosterone, luteinizing hormone (LH) and follicle-stimulating hormone (FSH) measurements performed in a single laboratory between January 2010 and January 2019, using chemiluminescent microparticle immunoassay. Subjects presenting any known factor interfering with the hypothalamic-pituitary-gonadal axis were excluded from the analyses. However, according to the big data approach, no information about subjects' clinical history was available, but only the diagnostic reason for biochemical examinations. The trend and seasonal distributions were analysed using autoregressive integrated moving average (ARIMA) models.
Results
A total of 12.033 data, accounting for 7.491 men (mean age 47.46±13.51 years, range 18–91 years), were included. Mean testosterone serum levels (5.34±2.06 ng/dl, range 1.70–15.80 ng/dl) showed a seasonal distribution with higher levels in summer ($P=0.008$). A direct relationship between testosterone levels and maximum, minimum and mean temperatures (Rho:0.019, $P=0.041$; Rho:0.023, $P=0.011$; Rho:0.021, $P=0.024$, respectively) and daylight duration (Rho:0.021, $P=0.020$) was highlighted. LH (mean 4.64±2.54 IU/l, range 1.00–15.00 IU/l) presented two peaks of secretion in autumn and spring ($P=0.001$ and $P=0.001$, respectively), independently from environmental parameters. No seasonal distribution was observed considering FSH serum levels (mean 5.51±3.24 IU/l).
Conclusions
A clear seasonal fluctuation of both LH and testosterone was demonstrated in a large cohort of adult men, although a circannual seasonality of hypothalamic-pituitary-gonadal hormones in humans could be not strictly evolutionarily required. Testosterone seasonality seems independent from LH fluctuations, which could be regulated by cyclic central genes expression, and more sensible to environmental temperatures and daylight duration.

AEP807

Genetic background and previous androgenization are associated with reproductive and non-reproductive outcomes of Gonadotropin-mediated pubertal induction in Congenital Hypogonadotropic Hypogonadism (CHH)

Biagio Cangiano[1,2], Giovanni Goggi[1,2], Silvia Federici[1,2], Fabiana Guizzardi[2], Valeria Vezzoli[2], Paolo Duminuco[2], Luca Persani[1,2] & Marco Bonomi[1,2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Division of Endocrinology and Metabolism, Milan, Italy

CHH is a rare disease with a relevant genetic background, and is characterized by a failure to enter (complete forms) or to complete (partial forms) pubertal development. It requires a treatment to allow the completion of puberty, and in male this goal can be achieved either using testosterone replacement therapy or administering gonadotropins (Gn); the latter allows both testicular development and the endogenous testosterone production. There are few studies evaluating the therapy with Gn in CHH pubertal induction and there is no consensus on the protocol to be used. In this retrospective analysis we aimed to (i) investigate clinical and biochemical predictors of testicular response to Gn-induced puberty in CHH; (ii) study the non-reproductive outcomes of this treatment (height, body proportions) and their determinants. We retrospectively studied 19 CHH male patients, undergoing two years of Gn-mediated puberty induction with FSH and hCG, started between the ages of 14 and 23 years. For each patient clinical history, physical examination, hormonal evaluation, and genetic analysis using Targeted Next Generation Sequencing for CHH genes were performed; 8 patients performed a semen analysis (SA) at the end of their treatment. The Mann-Whitney test and multiple regression analysis showed a lesser increase in testicular volume after 24 months of induction, to be significantly associated with: (i) cryptorchidism; (ii) a positive genetic background; (iii) a complete form of CHH. We found no significant correlation with the cumulative dose of hCG administered in 24 months. We found no association with the results of SA, probably due to the low numerosity. The multiple regression analyses investigating the eunuchoid habitus and a measure of the difference of subject's final height from his target (deltaSDSth), found a significant relation with: (i) the age at the beginning of the induction; (ii) the duration of growth during the induction; (iii) for deltaSDSth, also the bone age before the induction. The duration of growth during induction resulted to be associated with previous testosterone priming and with partial forms of CHH. In conclusion, this study shows that genetic forms of CHH, as well as cryptorchidism, are negative predictors of testicular response. This could be because they determine a complete GnRH deficiency since intrauterine life. We also found that the eunuchoid habitus and deltaSDSth are associated not only with a delay in the treatment, but also with the duration of growth during the induction, which is apparently related to previous androgenization.

AEP808

Androgen receptor inhibition by 4, 4' DDE is reduced by mutations in the BF3 site

Andrea Lozano, Justo Torres, Tahyra Resto & Frank Dean
The University of Texas Rio Grande Valley, Edinburg, United States

Androgen receptor (AR) is an important target for inhibition by some endocrine disrupting chemicals. Some diphenyl compounds inhibit AR activity by binding to a hydrophobic surface binding site, BF3. A similar diphenyl structure is found in 4.4' DDT and its breakdown product 4.4' DDE. Previous results showed that DDT, DDE, and related compounds induced the release of bound dihydrotestosterone from the AR ligand binding domain with IC_{50} values ranging from 54 to 82 uM. We tested whetherDDE may act as an EDC by binding to BF3 and inducing allosteric changes in the AR structure. Five mutant AR genes with single amino acid changes in the BF3 site were tested for differences in the ability of DDE to disrupt AR activity. The five mutations tested were F673K, F673W, G724R, G724M, and L830D. An AR reporter system was introduced into HEK293 cells by transient transfection and AR activity was measured using a dual luciferase assay. The response of the AR protein was measured with varying concentrations of dihydrotestosterone in the presence and absence of DDE. DDE inhibited the activation of AR by dihydrotestosterone under these conditions. The inhibition of AR activity by DDE was reduced by the mutations in the BF3 site. These results suggest that DDE acts as an endocrine disrupting chemical (EDC) by interacting with the BF3 site and allosterically regulating AR activity.

DOI: 10.1530/endoabs.70.AEP808

AEP809

Computational study of the allosteric effects of the androgen receptor BF3 site mutations on steroid unbinding

Evangelia Kotsikorou, Frank Dean & Muniruzzaman Chowdhury
The University of Texas Rio Grande Valley, Chemistry, Edinburg, United States

Experimental results have shown that the presence of endocrine disrupting chemicals (EDCs) such as the diphenyl compound DDT and its analogue DDE, allosterically cause the release of the stably bound dihydrotestosterone (DHT) from the steroid binding site of the Androgen Receptor (AR) ligand binding domain. It was hypothesized that EDCs mediate this effect via binding to the Binding Function 3 (BF3) surface binding site. Mutations of three BF 3 amino acids (F673K, F673W, G724R, G724M, and L830D) showed that the ability of DDE to inhibit AR activity was reduced, suggesting that DDE binds to the BF 3 site and allosterically regulates AR activity. In this study, the Induced Fit Docking protocol of the Schrodinger software was used to dock DDE into the BF 3 site of the wild type AR ligand binding domain as well as the five mutant BF 3 sites. The docking poses generated

for each receptor were clustered and representative structures were selected. The energy of interaction between DDE and the BF 3 site amino acids was evaluated for each of the selected docks of the wild type and mutant receptors. The relationship between the energies of interaction and the experimental results for DDE inhibition of the mutant AR activities is discussed. Additionally, stochastic dynamics were run on the wild type and mutant AR receptors using the Schrodinger software and the output was analyzed using the program Caver for the identification of potential exit channels for the bound steroid ligand. This analysis assesses the stability of the wild type and mutant AR receptors and indicates ways that the steroid may be able to unbind from the receptor in the presence of DDE in the BF3 site and how the mutations in the BF3 site affect that process.

Prenatal programming of hepatic lipid metabolism: Sex, hormones and lifelong health

Katarzyna Siemienowicz[1], Panagiotis Filis[2], Chiara Talia[2], Jennifer Thomas[1], Paul Fowler[2], Colin Duncan[3] & Mick Rae[1]
[1]Edinburgh Napier University, School of Applied Sciences, Edinburgh, United Kingdom; [2]University of Aberdeen, Institute of Medical Sciences, Aberdeen, United Kingdom; [3]The University of Edinburgh, MRC Centre for Reproductive Health, Edinburgh, United Kingdom

Background
The potential for a healthy life is programmed by *in utero* development. Fetal development is impacted by perturbed hormonal signalling, with lifelong consequences. Polycystic Ovary Syndrome (PCOS), affecting over 10% of women, is an important condition linked to an altered prenatal endocrine environment. Women with PCOS have increased androgen concentrations, including during pregnancy. Increased prenatal androgen exposure is associated with a PCOS-phenotype in adult life, including insulin resistance, fatty liver and obesity. Male offspring of women with PCOS develop dyslipidaemia and hyperinsulinemia. We used an ovine model of prenatal androgen exposure, faithfully recreating PCOS offspring phenotypes, to provide crucial mechanistic understanding of metabolic disturbances programmed *in utero* manifesting in adolesence.
Methods
Ovine fetuses were directly injected with 200 µl of testosterone propionate (PA; 20 mg) or vehicle control (C) at day 62 and 82 of gestation. Male offspring (C, $n=14$; PA, $n=14$) and female offspring (C, $n=10$; PA, $n=15$) were studied during adolescence. Hepatic transcriptome and proteome were determined (Illumina RNA sequencing and LC-MS/MS respectively). Plasma proteins and analytes were measured using LC-MS/MS, ELISA and clinical biochemistry autoanalysers. Statistical analysis between C and PA groups was carried out using pairwise comparisons, with false discovery rate correction, accepting adjusted $P<0.05$ as significant.
Results
Prenatally androgenised males and females displayed multiple metabolic perturbations, including hyperinsulinemia, dyslipidaemia, fatty liver, increased fibrosis, cholestasis-like phenotype. These were not all present in both sexes, with striking sex specificity in terms of lipid handling and liver function. PA females had increased plasma free fatty acids (FA), normal plasma triglycerides (TGs) concentrations, but increased hepatic TGs accumulation. This was coupled with reduced hepatic beta and omega oxidation potential. PA males had increased plasma FA, TGs and cholesterol concentrations in the absence of increased hepatic TGs accumulation. PA males displayed increased hepatic mitochondrial uptake of FA, however, they had decreased expression of genes and proteins involved in mitochondrial oxidative phosphorylation. This mismatch between mitochondrial FA oxidation without concomitant up-regulation of mitochondrial respiratory chain activity resulted in increased hepatic content of reactive oxygen species.
Conclusion
In both sexes, but with different mechanisms in terms of altered hepatic function, lipid handling in the liver was perturbed in postnatal life, as a legacy of prenatal androgen excess. Not all of these health-relevant outcomes were found in each sex however, demonstrating that sex-specificity must be accounted for in understanding of how the prenatal environment colours lifelong health.

Urinary bisphenol A (BPA) and its relation to insulin growth factor (IGF) system in polycystic ovary syndrome

Ivica Lazúrová[1], Zora Lazurova[1], Jana Figurová[1], Beata Hubkova[2] & Maria Mareková[2]
[1]Medical faculty University Košice, Department of Internal medicine, Košice, Slovakia; [2]Medical faculty University Košice, Department of Biochemistry, Košice, Slovakia

Objectives
There is a growing evidence suggesting an impact of endocrine distrupting chemicals, including bisphenol A (BPA) on human reproduction. Insulin growth factors (IGF) play signifcant role inhuman reproduction. However the relationship between BPA and IGF system is unknown. Aim of the pilot study was to assessthe relationship between urinary BPA (U-BPA) and insulin growth factors (IGF-1, IGF-2, IGFBP 3) as well as metabolic parametersin PCOS women.
Subjects and methods
The study included 76 Caucasian womenof mean age 28.8 ± 5.7 yearsdiagnosed with PCOS. Fasting blood samples were analyzed for biochemical parameters, IGF-1, IGF-2 and IGFBP3. U-BPA was measured in the morning urine sample using high pressure liquid chromatography (HPLC). BPA level of 2.14 mg/g creatinine were usedas the cut-off for high or low levels of this xenoestrogen and served for selection of patients into two groups.
Results
PCOS women with high U-BPA had significantly higher serum insulin ($P=0.0291$) and HOMA IR ($P=0.0371$) as compared to those with low U-BPA. Both groups did not differ in parameters of lipid metabolism. There were no significant differences in the serum IGF-1 ($P=0.36$) and serum IGF-2 ($P=0.3$) between both groups. Women withlow U-BPAdemonstrated higher serum IGFBP3 ($P=0.04$). In all group of PCOS women U-BPA negatively correlated with IGF-2 ($r=-0.25$, $P=0.04$) and IGFBP3 ($r=-0.54$, $P=0.0032$).IGF-1 tended to be lowerin women with high BPA, however correlation with U-BPA was borderline ($r=-0.2$, $P=0.068$).
Conclusion
U-BPA is in negative relationship with IGF-2, IGFBP-3 and borderline with IGF-1 in PCOS women. This indicates a possible suppressive effect of BPA on ovarian function in polycystic ovary syndrome through suppression of IGF system.

Congenital adrenal hyperplasia due to 3-beta-hydroxysteroid dehydrogenase deficiency

Barbara Bromińska, Hanna Komarowksa & Marek Ruchała
University of Medical Sciences in Pozna, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland

Congenital adrenal hyperplasia due to 3-beta-hydroxysteroid dehydrogenase deficiency.
Introduction
Congenital adrenal hyperplasia is a heterogenic group of disorders. Shared feature is a deficiency of one of the enzymes which are necessary for steroid synthesis. Due to wide clinical spectrum and rarity of the disease diagnosis can be challenging. Hereby we present the case of the patient, who after prolonged period of time was finally diagnosed with 3-beta-hydroxysteroid dehydrogenase deficiency.
Case report
23-year old patient was admitted to endocrinology clinic due to hypogonadal hypogonadism. Pubic and axillary hair developed after unknown treatment commenced by urologist at the age of 11. Due to the lack of other signs and symptoms of puberty 17-year old patient was referred to endocrinology outpatient clinic. The diagnosis was not established. Patient did not continue diagnostic process. At the age of 23, he underwent appendectomy. Surgeon noticed typical features characteristic for hypogonadism and ordered endocrinologist consultation. Hypogonadal hypogonadism was diagnosed. Semen analysis results were within the norm. On physical examination performed during admission to hospital female-type fat distribution and pubic hair pattern was noticed. On ultrasonography size of testes was normal. CT of the adrenal glands revealed thickening of medial crus of left adrenal gland. Both LH, FSH and testosterone were decreased. On simulation test with GnRH, LH raised 12-times, while FSH 2-times. DHEAs and androstenedione were markedly elevated. Bone densitometry revealed osteoporosis. Urine steroid profile analysis was performed. It showed elevated levels

of: delta 5 steroids, especially pregnentriol. On the basis of laboratory and clinical findings 3-beta-hydroxysteroid dehydrogenase deficiency was diagnosed. Treatment with dexamethasone 1 mg daily and testosterone 1 injection per 3 weeks im was commenced. We noticed normalization of hormonal profile. Patient developed male secondary sex characteristics.
Conclusions
Diagnosis of non-classic form of congenital adrenal hyperplasia is challenging. In presented case proper treatment was vital to induce puberty, improve sexual function and quality of life.

Endocrinological aspects of woodhouse-sakati syndrome: Report of a new nucleotide variant DCAF17 homozygous mutation in the first family case in russia

Maria Amosova, Olesya Gurova, Irina Poluboyarinova & Valentin Fadeyev
I.M. Sechenov First Moscow State Medical University (Sechenov University), Endocrinology, Moscow, Russian Federation

Introduction
Woodhouse-Sakati syndrome (WSS) is a rare autosomal recessive disorder characterized by diabetes, hypogonadism, hypothyroidism, sensorineural hearing loss, alopecia totalis, extrapyramidal findings and specific changes on ECG. This syndrome belongs to a heterogeneous group of neurodegenerative disorders and is caused by mutations of the DCAF17 gene. Treatment is symptomatic and patients are managed by multidisciplinary teams. About 90 cases were reported since 2008 when WSS was discovered.
Case report
We describe two sisters 18- and 29 years old affected by combined endocrine disorders such as diabetes, hypergonadotropic hypogonadism (with ultrasonic signs of uterine hypoplasia), hypothyroidism with negative thyroid auto antibodies, obesity and extrapyramidal symptoms such as dyslexia, sensorineural hearing loss, mild intellectual disability and dysmorphic facial features as well as alopecia totalis. GH, prolactin and ACTH levels were normal, but it should be noted that the younger sister had a low level of IGF. On ECG both of them had specific changes in the form of T-wave flattening. Brain MRI showed multiple brain cysts. Sisters differed in severity of clinical symptoms. The severity of the diabetic state is also varied between sisters. The younger sister had intact secretion of both basal and stimulated C-peptide levels, thus, she was prescribed sulfonylurea drugs with great glucose-lowering response. The older sister had a satisfactory basal and insufficient stimulated C-peptide levels, so she was switching to basis-bolus insulin therapy in conjunction with SGLT-2 inhibitors. They did not take levothyroxine and hormone replacement therapy with estrogen before. Common genetic, metabolic and mitochondrial disorders were excluded. WSS was suspected. Sequencing of DCAF17 gene detected new nucleotide variant NM_025000.3: c.1422+3G>T in homozygous state. This nucleotide variant has not been previously described.
Discussion
In the case of combinations of several endocrine pathologies with different characteristic features, genetic testing plays an important role. Thus, we can assume the progression of the disease as well as provide an integrated personalized approach to treatment. WSS was previously described in Arabian families and this is the first case in Russian family. Since we expect that diagnostic methodology and our understanding of disease pathology, including genes, allelic variants will improve in the future, DNA banking of affected individuals should be considered.

AEP814

Early impact of cross-sex steroids on body composition and metabolic profile in young transgender subjects

Pierre Consolandi[1], Veronique Pascal[1], Caroline Samhani[2,3], Clement Larose[3], Philip Bohme[1], Klein Marc[1,3], Olivier Ziegler[1,3] & Eva Feigerlova[1,3]
[1]University Hospital of Nancy, Endocrinology, Nancy, France; [2]University Hospital of Nancy, Urology, Nancy, France; [3]University of Lorraine, Medical Faculty, Nancy, France

Background
In females transitioning to males (FtM) and in males transitioning to females (MtF), exogenous cross-sex steroids are prescribed to favour development of secondary characteristics of desired sex, while endogenous hormone production is inhibited.
Aims and design
To study early impact of cross-sex steroids on body composition, metabolic profile and pro-inflammatory parameters in young transgender persons before and after 12 months of gender-affirming hormonal treatment. Data of non-obese FtM subjects ($n=45$; 22.8±4.4 years) and MtF subjects ($n=28$; 24.8±5.9 years), followed in the University Hospital of Nancy were retrospectively analysed.
Results
In FtM subjects, testosterone administration led to a significant increase in haemoglobin (13.9±1.6 g/dl vs 15.5±0.9; $P<0.01$), and uric acid (41.2±6.2 mg/l vs 53.1±8.7; $P<0.01$), associated with a significant decrease in PRL (16.9±4.5 ng/ml vs 9.6±3.2; $P<0.05$). Pro-inflammatory indices tended to increase: AST/lymphocyte ratio (8.3±2.6 vs 9.8±3.4; $P=0.08$). An android fat distribution was enhanced with an increase in visceral adipose tissue (VAT) (260±217 g vs 368±280; $P<0.01$). There was a strong relationship between VAT and the following parameters: BMI, android fat mass, trunk/limb fat mass ratio, android/gynoid fat mass ratio; and between increase in VAT and in haemoglobin levels. In MtF subjects, a significant decrease in haemoglobin (15.4±1 g/dl vs 14.4±0.8; $P<0.05$) and in TSH (2.1±1.2 mIU/l vs 1.1±0.6; $P<0.05$) level was observed, without meaningful effects on body composition or metabolic profile.
Conclusion
Marked changes in body composition and in metabolic parameters are present in transgender subjects already after the first year of the cross-sex hormonal treatment. Significant increase in in VAT in lean transgender men may confer an increased cardio-metabolic risk in this subpopulation. Early assessment appears necessary to identify the subjects at risk and to individualise treatment regimens. Prospective long-term studies including a large sample size are needed to evaluate effects of early hormonal changes on the risk for cardiovascular diseases in MtF and FtM subjects.

AEP815

The frequency nonclassic congenital adrenal hyperplasia in adolescent girls with primary oligomenorrhea and amenorrhea

Olga Gumeniuk & Yuriy Chernenkov
Saratov State Medical University, Russian Federation

Objective
Nonclassic congenital adrenal hyperplasia (NCCAH, NCAH) or late onset congenital adrenal hyperplasia (LOCAH) is a specific type of congenital adrenal hyperplasia due to P450c21 (21-hydroxylase) deficiency with variable degrees of postnatal androgen excess, is sometimes asymptomatic (Kohn B *et al.* 2010; Speiser PW *et al.*, 2010). To study the frequency NCCAH in adolescent girls.
Patients and methods
The prevention examination of 2527 adolescents- schoolgirls (aged 12–17 yrs, mean age was 15.5±1.9 years) was carried. The main outcome measures were primary oligomenorrhea and amenorrhea. Adolescent girls without menstrual disorders formed the control group ($n=50$). A full clinical examination, hormonal analysis and pelvic ultrasound examination were conducted. CYP21A2 genotyping in girls with elevated 17-OH progesterone hormone levels (basal 17-OHP concentration ≥2 ng/ml (6 nmol/l) was performed. This study was carried out in accordance with the Helsinki Declaration. Data was analyzed using SPSS Statistics v 24.0.0.0. Data was compared using chi-square test and $P\leq0.05$ was regarded as statistically significant.
Results
Primary oligomenorrhea was present in 22%, primary amenorrhea – in 3 girls. The investigation showed that in 7 girls with oligomenorrhea was diagnosed nonclassic congenital adrenal hyperplasia due to P450c21 (21-hydroxylase deficiency). In all cases the first symptom was premature pubarche. All these girls have demonstrated hyperandrogenemia, high 17-OH progesterone hormone levels, advanced bone age, mammary hypoplasia, multifollicular ovaries. In the control group hyperandrogenemia was diagnosed in 1% and multifollicular ovaries – in 8% girls, mammary hypoplasia in 1 girls ($P<0.01$).
Conclusions
In our study nonclassic congenital adrenal hyperplasia was found in 7 (0.3%) adolescent girls. The phenotypic presentation of NCCAH in the

adolescentgirls included symptoms of hyperandrogenia such as premature pubarche, hirsutism, primary oligomenorrhea, advanced bone age, mammary hypoplasia, multifollicular ovaries.

Relapsing meningiomas in a transfemale treated with cyproterone acetate. Case and literature review

Fernando pazos[1], Laura Bertholt Zuber[2] & Roberto Oliver arias[3]
[1]Valdecilla Hospital, Endocrinology, Santander, Spain; [2]Valdecilla Hospital, Pediatrics, Santander, Spain; [3]Valdecilla Hospital, Psychiatric Department, Santander, Spain

A 40-year-old transfemale, regularly treated with oral estradiol (2 mg per day) and CPA (100 mg per day) for the last 15 years, presented with two asymptomatic intracranial lesions on compatible with meningiomas. Gender dysphoria since the age of 14, begins treatment in 2006. Paranoid schizophrenia at age 17. She referred to occasional headaches, without neurological defect. In the year 2013, a magnetic resonance imaging (MRI) scan revealed an expansive lesion over the sphenoidal planum. Prior MRI in 2007 was normal. Complete endoscopic resection was performed via intranasal of the meningioma of the sphenoidal planun. The immunohistochemical and morphological tests revealed a WHO grade I meningioma. Annual follow-up using contrast-enhanced MRI scan was performed after that. In 2018, the MRI scan showed the presence of one menigioma of 1.1 cm in the right frontal area and another of less than 1 cm at the level of the anterior clinoid processes. CPA was discontinued and was substituted with triptorelin acetate Our patient was treated for more than 10 years with cyproterone acetate with the appearance of a new menigioma again. The patient maintained high doses of CPA due to lack of alternative and severe hirsutism. It showed a recurrence of multiple of meningiomas during the follow-up. Our case confirms the clinical association between the administration of CPA and the presence of menigioma. These menigiomas appear after 5 years of treatment with high dose CPA. Proper treatment of the initial tumor does not exclude withdrawal of the CPA because of recurrence and multiple meningiomas in other brain locations. The occurrence of meningiomas in transfemale is uncommon and asymptomatic multiple tumors should be considered with the use of CPA. CPA should be removed. A literature review were done

Hutchinson – gilford progeria syndrome – a portuguese rare case

Diana Catarino[1], Margarida Bastos[1], Cristina Ribeiro[1], Lucia Fadiga[1], Diana Silva[1], Joana Guiomar[1], Mariana Lavrador[1], Inês Vieira[1], Cátia Araújo[1], Bárbara Araújo[1], Isabel Dinis[2], Alice Mirante[2] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra EPE, Coimbra, Portugal, Endocrinology, Diabetes and Metabolism Department, Portugal; [2]Pediatric Hospital of Coimbra, Portugal, Endocrinology Department

Introduction
Hutchinson-Gilford Progeria Syndrome (HGPS) is a rare disease (1:4 million) characterized by a fatal premature aging. There are 162 cases worldwide, five of them in Portugal. It is caused by a sporadic autosomal dominant mutation in LMNA gene that encodes an abnormal variant of the laminin-A protein, named *progerin*. Although most babies born looking healthy, they begin to display some characteristics of Progeria around 18–24 months of life. The earliest signs are tightness of the skin, growth failure and loss of body fat and hair. Other signs include orthopaedic, ophthalmologic and cardiovascular disease. Without Progeria-specific treatment, children die of atherosclerosis (heart disease or stroke) at an average age of 14.5 years. The intellect of children is unaffected. Pathophysiology maintains unclear. The 'Progeria Research Foundation' funds research to find new treatmentsfor Progeria. There is currently no cure for Progeria.
Case report
21-years female with HGPS caused by an 1824 C>T mutation in the exon 11 of LMNA gene. No family history of HGPS. First signs of disease at 4.5 months. Personal history of multiple fractures and dislocation of inferior members, hypermetropy, arterial hypertension, cardiac valvular disease, left ventricular hypertrophy, hypertriglyceridemia, hyperuricemia, palmar warts, subclinical hypothyroidism, multinodular goiter and secondary amenorrhea since 18 years. She is regularly monitored by orthopaedist, ophthalmologist, cardiologist, dermatologist, endocrinologist and gynaecologist. She maintains regularly follow-up at the Boston Children's Hospital and takes part of a clinical trial with Lonafarnib – a farnesyltransferase inhibitor. She is followed up in an Endocrinology-Transition consultation since the age of 18, after initial follow-up at the Pediatric Hospital, for unmedicated subclinical hypothyroidism and multinodular goiter with infracentimetric cystic nodules. At the last evaluation, patient maintains subclinical hypothyroidism (negative autoimmunity) with no need of medication, medicated hypertriglyceridemia and prediabetes. Cranioencephalic MRI was normal.
Discussion and conclusion
The clinical case intends to demonstrate the rarity of this syndrome that is associated with multiple pathologies/comorbidities, needing regular monitorization throughout the life, by a multidisciplinary team, including medical and surgical teams. Due to the rarity of the disease, research and development of effective therapies becomes more difficult. The main of drugs currently available is reducing complications of the syndrome. Supportive therapy is also extremely relevant as it improves patients' quality of life. Patient associations and international exchanges have been shown to be fundamental for families. https://www.progeriaresearch.org/

Epidemiology, clinical features and management of multiple endocrine neoplasia Type 1 – a two-center study

Stanislaw Zgliczynski[1], Tomasz Bednarczuk[1], Natalia Rogozik[1], Magdalena Kochman[2] & Zgliczynski Wojciech[2]
[1]Medical University of Warsaw, Department of Internal Diseases and Endocrinology, Warsaw, Poland; [2]The Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
Multiple Endocrine Neoplasia Type 1 (MEN1) is a rare, autosomal dominant disease characterized by the coexistence of at least two of the following: primary hyperparathyroidism (PHPT), neuroendocrine tumors (NET) and pituitary tumors. The aim of the study was to evaluate epidemiology, clinical features and management of MEN1 patients in two referral centers in Warsaw, Poland.
Material and methods
Study group consisted of 52 patients, aged from 18 to 74 (mean: 45.5, S.D. = 14), diagnosed with MEN1 and followed-up from 2015 to 2020 in two tertiary centers. 71% of patients were women, 29% were men. Data was collected using a pre-prepared form concerning demographics, medical and family history, quality of life, as well as, physical examination, laboratory, imaging, histopathological and genetic tests results.
Results
In the studied group, the first symptoms of the disease appeared on mean age of 29.6 (range: 9–60; S.D. = 12.0). The most often were: nephrolithiasis (33%), hypercalcemia (13%) and menstrual disorders (11% of women). The diagnosis of MEN1 was made on average age of 36.9 (S.D. = 13.1). Only 37% underwent genetic testing. In 52% patients the first diagnosed component of disease was PHPT, in 33% pituitary tumor, in 13% NET. 94% of subjects developed PHPT, 85% NET, 67% pituitary tumor. Every second patient manifested all three main components of the disease. Based on dual-energy X-ray absorptiometry, 76% of patients had reduced bone density and 8% of them underwent a pathological fracture. Nephrolithiasis was found in 60% of people and peptic ulcer disease in 26%. In addition to typical for MEN1, 15% of patients developed other malignancies: papillary thyroid, clear cell kidney, breast, endometrial cancers and melanoma. 85% was also diagnosed with benign neoplasms of: adrenal glands (45%), kidney/liver/spleen cysts (31%), lung nodules (13%). Up to 62% of people underwent at least one parathyroidectomy, yet 55% of them still have hypercalcemia. In the group of patients suffering from pituitary tumors 31% underwent surgery, whereas in the case of NET – 55%. Treatment with somatostatin analogues was initiated in 49%.
Conclusions
In this group, MEN1 was diagnosed with a long delay from the disease onset. The discrepancy between number of women and men being followed-up may indicate its underdiagnosis in men. PHPT was proved to be the most difficult component to manage. Frequent coexistence of other tumors, both malignant and benign, has also been demonstrated. These results suggest a need for improvement at every level of healthcare, from detection to management.

Fetal anogenital distance is longer in polycystic ovary syndrome mothers

Sharon Perlman[1,2], Yoel Toledano[3], Nufar Halevy[1], Zvi Kivilevitch[1] & Yinon Gilboa[1,2]
[1]Rabin Medical Center, Prenatal Ultrasound Unit, The Helen Schneider Women's Hospital, Israel; [2]Tel-Aviv University, Sackler School of Medicine, Israel; [3]Rabin Medical Center, Maternal-Fetal Unit, The Helen Schneider Women's Hospital, Israel

Aim
Anogenital distance (AGD) is a biomarker for the prenatal hormonal environment. Scarce evidence exists regarding the effect of prenatal androgen exposure in mothers with polycystic ovary syndrome (PCOS) on the human fetal AGD. The aim of the study was to assess the prenatal sonographic measurement of AGD in fetuses of PCO mothers vs the general population.
Materials and methods
AGD was measured prospectively infetuses at 26–37 weeks of gestation, using 2D ultrasound, in an axial view, at the level of the fetal perineum. Data was compared to fetal AGD nomograms, and the Z score was evaluated. Maternal and fetal characteristics were analyzed.
Results
27 PCOS mothers carrying singleton fetuses were recruited (12 females, 15 males). Mean gestational age at measurement was 31.2 weeks±3 days. Mean AGD, adjusted for gestational age and gender, was significantly higher in the PCOS (21.13 mm±5.9 mm) compared to the control (17.19 mm±5.45 mm) group, respectively, $P<0.001$. Mean AGD-PCOS centile was 86.04 (±18.22). Z score was not statistically different in the males (2.035±2.1950) compared to the females (2.185±1.3834). The AGD measured in fetuses of mothers with diabetes (52% of the study group) was significantly longer compared to the general population (19.74 mm±4.8 mm vs 15.11 mm±4.77 mm $P<0.001$).
Conclusions
This is the first report demonstrating a longer AGD in fetuses of mothers with PCOS. AGD may play a role as a biomarker of the intra-uterine androgen milieu, specifically in PCOS. Importantly, this might change the way we approach and treat PCOS pregnancies.

BMI may be a better predictor of cardiovascular risk than PCOS phenotype in a population of reproductive age PCOS patients

Srdjan Pandurevic[1], Carmine Pizzi[2], Flaminia Fanelli[1], Valentina Vicennati[1], Carla Pelusi[1], Guido Di Dalmazi[1], Uberto Pagotto[1] & Alessandra Gambineri[1]
[1]S. Orsola Hospital, University of Bologna, Unit of Endocrinology and Prevention and Cure of Diabetes, Department of Medical and Surgical Sciences, Bologna, Italy; [2]S. Orsola Hospital, University of Bologna, Unit of Cardiology, Department of Specialistic, Diagnostic and Experimental Medicine, Bologna, Italy

Introduction
Women with polycystic ovary syndrome (PCOS) are considered to have increased risk of cardiovascular disease (CVD), even though the syndrome encompasses hugely varying phenotypes. Research into CVD prevention demonstrated a variety of biochemical and ultrasound (US) markers predicting risk in the general population, but those are sparsely utilised for PCOS, in part due to the patients' therapeutic goals.
Aim
To evaluate if PCOS type or BMI are better predictors of cardiovascular risk, by comparing them to biochemical and US markers.
Material and methods
We recruited 138 women with PCOS in the reproductive age from the Endocrinology Unit in 2009. We subdivided them by Rotterdam criteria into 4 types (A, $n=74$; B, $n=22$; C, $n=11$; D, $n=31$), and by BMI into normal weight (18.5–24.9 kg/m^2, $n=45$), overweight (25–29.9 kg/m^2, $n=42$) and obese (>30 kg/m^2, $n=51$). Biochemical analyses measured: OGTT and fasting glycemia, fasting insulin, total cholesterol, LDL, HDL, triglycerides. Derived parameters: HOMA2 insulin resistance index, free testosterone index (Vermeulen formula, fTv). Carotid intima media thickness (cIMT), endocardial fat thickness (EFT) and brachial flow mediated dilation (FMD) were measured using B-mode US.
Results
We did not find any difference in the analysed variables among the four PCOS phenotypes. Conversely, by dividing patients in BMI categories we found increasingly higher values of systolic blood pressure ($P=2\times10^{-11}$), cIMT ($P=2\times10^{-8}$), EFT ($P=3.7\times10^{-10}$), triglycerides ($P=10^{-4}$), HOMA2 ($P=10^{-12}$) and fTv ($P=0.001$), and lower values of HDL ($P=3\times10^{-6}$) and FMD ($P=0.004$), going from normal to obese BMI categories. There was no statistical difference in the prevalence of different PCOS phenotypes based on BMI subgrouping ($P=0.633$), whereas there was a higher prevalence of diabetes in the obese BMI group with respect to overweight or normal weight groups (31.4 vs 9.8 vs 2.3%, $P=0.0002$).
Conclusion
In our group of PCOS women in the reproductive age, BMI was shown to be a better predictor of cardiovascular risk compared to PCOS phenotype categorisation.

Background
Insulin secretory defects and insulin resistance exists in women with polycystic ovary syndrome (PCOS) and are prerequisites for the development of type 2 diabetes (T2D). we aimed to determine the prevalence of T2D, impaired glucose tolerance (IGT) and impaired fasting glucose (IFG), as well as the factors associated with these dysglycemic conditions in this population.
Methods
1614 PCOS women of Caucasian origin (Rotterdam criteria) with a mean age 25.14±5.56 years and BMI 27.34±7.09 kg/m^2 comprised study group, whereas 359 normally ovulating, not hyperandrogenic women of comparable age and BMI, served as controls. This was an observational study and evaluation of biochemical/hormonal profile, ovarian ultrasound and as well oral glucose tolerance test was carried out in all studied subjects. Diabetes/intermediate hypeglycemia was categorized according to WHO criteria and PCOS subgroups was based on the Rotterdam criteria.
Results
In the PCOS group 2.2%, 9.5% and 12.4% of subjects had T2D, IGT and IFG, respectively. In control group 1.11%, 7.5% and 8.9% had T2D, IGT and IFG, respectively. When existence of T2D was stratified according to age and BMI, no difference was found among age and BMI subgroups or PCOS subgroups. In patients aged 17–22 years, T2D was detected in 3 lean and 2 obese subjects. The corresponding distribution for patients aged 22–30 years was 4 lean, one overweight and 2 obese, whereas in those older than 31 years, 2 overweight and 5 obese suffered from T2D. Free Androgen Index, waist to hip ratio and LDL levels were significantly higher in T2D compared to PCOS women with normal glucose metabolism. Diagnosis of T2D was significantly associated with Free Androgen Index (r: 0.469, $P<0.05$), while subjects with either IFG and IGT had positive association with BMI, WHR, FAI and HOMA-IR. In controls, T2D, IGT and IFG were positively associated with BMI and androgen concentrations. Conclusions: The prevalence of T2D and IGT is significantly higher in our large cohort of PCOS women compared to controls. Existence of T2D is irrespective of age and BMI, and seems to be inherent for PCOS women. Hence, evaluation of glycemic status in PCOS women using OGTT is supported.

AEP822

An assessment of the level of physiological stress in terms of release of cortisol, epinephrine, norepinephrine, prolactin and growth hormone and their relationship with ghrelin in normal and short stature children

Nighat Kausar[1], Maleeha Akram[1], Gulbin Shahid[2], Afzaal Ahmed Naseem[3], Mazhar Qayyum[1], Faheem Tahir[4], Sarwat Jahan[5], Kiran Afshan[5], Muhammad Rafi[6] & Syed Shakeel Raza Rizvi[1,7]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology, Rawalpindi, Pakistan; [2]The Children's Hospital, Pakistan Institute of Medical Sciences (PIMS), Islamabad, Pakistan; [3]University of Lahore, Sihala Campus, Islamabad, Pakistan; [4]National Institute of Health, Reproductive Physiology, Public Health Laboratories Division, Islamabad, Pakistan; [5]Quaid-i-Azam University, Department of Animal Sciences, Islamabad, Pakistan; [6]Pakistan Institute of Engineering and Applied Sciences (PIEAS), Islamabad, Pakistan; [7]University of Central Punjab, Quaid Campus, Rawalpindi, Department of Zoology, Rawalpindi, Pakistan

The short children have lower social competence and show more social problems than children with normal stature. The physical appearance has consequences in terms of how short stature children are judged and treated by others as they can be teased or bullied due to short stature, which may affect future prospects of finding a job or a spouse. These psychosocial stressors are risk factors for the psychological adjustment for children of short stature. Stress responses are activated by hypothalamo-pituitary-adrenal (HPA) axis by releasing cortisol, a marker of stress. Another hormone, ghrelin, also stimulates stress related HPA axis resulting in the release of cortisol. Both cortisol and ghrelin concentrations increase in parallel after psychological stress. The present study was designed to identify the level of physiological stress in terms of release of cortisol, epinephrine (E), norepinephrine (NE), prolactin (PRL), growth hormone (GH) and their relationship with ghrelin in normal and short stature children. ELISA was used for analysis of plasma cortisol, prolactin, E and NE and RIA was used for analysis of plasma GH of 50 normal school attending children and 35 short stature girls and boys. Data were analyzed using Student's t test, ANOVA and Pearson correlation r. The concentrations of stress hormones such as cortisol, E and NE were higher in short stature children at puberty as compared to normal school attending children. The levels of GH and PRL were significantly decreased in short stature children than controls. In addition, the levels of plasma ghrelin were positively correlated with plasma cortisol, E, NE, GH and PRL levels in normal subjects while negatively correlated in short stature children. In conclusion, this study demonstrated higher concentrations of stress hormones, cortisol, E and NE in short stature children at puberty than normal school attending children indicating that short stature children were at a higher level of stress.

Testosterone levels are the main determinant of prostate volume in men with chronic spinal cord injury

Arcangelo Barbonetti, Settimio D'Andrea, Elisa Minaldi, Maria Totaro, Antonio Parisi, Sandro Francavilla & Felice Francavilla
University of L'Aquila, Andrology Unit, Department of Life, Health and Environment Sciences, Coppito, L'Aquila, Italy

Men with spinal cord injury (SCI) exhibit a prostate volume significantly smaller compared to age-matched able-bodied men[1–3]. As men with chronic SCI (lasting more than 1 year) also display a very high prevalence of androgen deficiency[4,5], a protective role of low testosterone against prostate enlargement could be hypothesized in this population. This study aimed to identify independent determinants of prostate volume in men with chronic SCI. As assessed by trans-rectal ultrasonography, the median value of prostate volume in 138 men with chronic SCI (mean age: 53±18 years) was 23.43 ml. Men with prostate volume smaller than 23.4 ml exhibited significantly lower levels of total testosterone (TT) and calculated free testosterone (cFT), as well as a higher prevalence of biochemical androgen deficiency (TT lower than 264 ng/dl), that in the entire population was observed in 29.7% (41/138) of subjects. At the univariate analysis, a larger prostate volume was associated to higher TT ($P=0.00001$) and cFT ($P=0.001$), SCI level below T12 ($P=0.007$), more advanced age ($P=0.04$), lower body mass index ($P=0.04$), higher functional independence score ($P=0.06$), higher values of prostate-specific antigen ($P=0.12$) and shorter duration of the injury ($P=0.21$). However, at the multiple regression analyses, an independent and positive association only persisted between prostate volume with either TT or cFT levels, and, to a lesser extent, with age and a level of spinal lesion below T12. A prostate volume below the median value (23.4 ml) was observed in 91.4% (32/35) of patients with both biochemical androgen deficiency and spinal lesion level at or above T12, but in only 16.5% (2/12) of patients with both normal androgen levels and spinal lesion level below T12 ($P=0.001$). In conclusion, lower testosterone levels and, to a lesser extent, a younger age and a spinal lesion level at or above T12 represent the only variables exhibiting an independent association with a smaller prostate volume in men with SCI. It could be hypothesized that the combination of these factors could be protective against the development of proliferative prostatic diseases, including benign prostatic hyperplasia. Prospective studies might assess the validity of this hypothesis.

Transphobic attitude: In physicians who play an active role in the gender transition process

Emre Durcan[1], Serdar Sahin[1], Gizem Durcan[2], Yasin Kavla[3], HANDE MEFKURE OZKAYA[1], şenol Turan[3] & Pınar Kadıoğlu[1]
[1]Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Division of Endocrinology and Metabolism, Department of Internal Medicine, Istanbul, Turkey; [2]Bakirkoy Psychiatry, Neurology, Neurosurgery Trainee, and Research Hospital, Department of Child and Adolescent Psychiatry, Istanbul, Turkey; [3]Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Department of psychiatry, Istanbul, Turkey

Transphobia is expressed as negative attitudes, emotions and actions towards transgender individuals or transsexualism. The aim of this study is to investigate the existence of transphobic approaches towards transgender individuals in physicians in different clinics that play an active role in the gender transition process. It was planned to include physicians from the disciplines of psychiatry, endocrinology, gynecology, urology and plastic surgery. A questionnaire was sent to these physicians via internet and the participants were asked to answer ''the Genderism and Transphobia Scale'' and sociodemographic questions such as academic title, type of institution, age, gender, place of birth and residence, marital status, sexual orientation and religious belief. Also, no names and surnames were requested from these people. Increased scale scoreshows the presence of higher transphobia. The number of physicians who completed the study on the internet was 455. The mean age was 37.03±9.59 years. The male to female ratio was 1.12. Of the participants, 23 (27%) were psychiatrists, 107 (23.5%) were endocrinologists, 93 (20.4%) were gynecologists, 88 (19.3%) were urologists and 44 (9.7%) were plastic surgeon. 203 (44.6%) of the participants defined themselves as belong to a religion, 106 (23.3%) as deist, 91 (20%) as religious and 55 as atheist. And, 94.9% of the participants were heterosexual. According to disciplines, there was a significant difference between groups in term of the mean total scores of transphobia scale ($P<0.001$). In the post-hoc analysis to understand the reason for the difference, scale scores of psychiatrists were significantly lower than endocrinologists, plastic surgeons, and urologists, and did not differ from gynecologists. Morever, we found that urologists' scale scores were significantly higher than gynecologists. When the participants were categorized according to their religious self-definition; the mean total scores of scale were significantly different between groups ($P<0.001$). While the mean scores of those who define themselves as atheists and deists were lower than those who belong to a religion and religious, Psychiatrists are in an important role in the psychotherapy process, which is used to diagnose transgender individuals and to cope with the difficulties these individuals experience in society and in the gender transition process. For this reason, it can be thought that psychiatrists show less transphobic approaches than other disciplines. This study shows that transphobia may be at different levels according to the discipline of physicians and there may be differences as a result of individual characteristics.

Influence of air pollutants of vehicular origin in hormonal and seminal parameters of traffic controllers

Elaine Maria Frade Costa[1], Paulo de Nóvoa Cardoso[1], Thiago Afonso Teixeira[2,3], Mariana Kim Hsieh[4], Alessandra Renck[1], Juliana Andrietta[2], Juliana Risso Pariz[3], Jorge Hallak[2,3] & Paulo Hilario Nascimento Saldiva[5]
[1]Faculdade de Medicina da Universidade de Sao Paulo, Development Unit, Department of Endocrinology, Sao Paulo, Brazil; [2]Faculdade de Medicina da Universidade de Sao Paulo, Section of Andrology, Division of Urology, Department of Surgery, Sao Paulo, Brazil; [3]Androscience, High Complexity Clinical and Research Andrology Laboratory, Sao Paulo, Brazil; [4]Faculdade Israelita de Ciências da Saúde Albert Einstein, School of Medicine, Sao Paulo, Brazil; [5]Faculdade de Medicina da Universidade de São Paulo, Reproductive Toxicology Unit, Department of Pathology, Sao Paulo, Brazil

Sao Paulo is the most populous city in Brazil and its huge number of vehicles contributes for a higher concentration of air pollutants that may interfere in human fertility. The aim of this study was to evaluate the influence of air pollution of vehicular origin on hormonal and seminal parameters of traffic controllers. Clinical history, physical examination (testicular volume, presence of varicocele, cryptorchidism, malformations), hormonal (estradiol, LH, FSH and total testosterone) and seminal parameters (concentration, motility, morphology by WHO´s criteria and Kruger´s strict criteria, leukocytes detection test, CK, ROS and anti-sperm antibody tests) were carried out in 62 traffic controllers (exposed group) and in 210 proven fertile men from the pre-vasectomy group of Urologic Clinic at Hospital das Clinicas – University of Sao Paulo (control group). Exposition to air pollution was analyzed through the dispersion of pollutants recorded by Cetesb, generated in the software SURFER 8.0. Hormonal levels were at normal range in both groups: Estradiol ($P=0.119$), LH ($P=0.644$), FSH ($P=0.140$) and Total Testosterone ($P=0.365$). Traffic controllers presented bigger testicular volume than pre-vasectomy group ($P<0.001$). Sperm concentration was homogeneous in both groups ($P=0.395$): traffic controllers presented mean of 124.9×10^6/ml and pre-vasectomy group 110.1×10^6/ml. Exposed group presented total motility (60%) diminished than control group (65%) ($P=0.047$), as progressive motility was also diminished in the exposed group ($P<0.001$). The sperm morphologies as by WHO´s criteria (exposed group=12%; control group=20%), as by Kruger´s strict criteria (exposed group=3%; control group=6%) were significantly diminished in the exposed group ($P<0.001$). Sperm maturity marker CK was at normal range at both groups, but higher in the control one ($P<0.001$). Anti-sperm antibodies and ROS were elevated in both groups, however it was not significant ($P=0.382$ and $P=0.141$, respectively). Air pollution has a deleterious effect on sperm motility and morphology but not in male hormonal levels. It also causes elevation of ROS levels, indicating deficit in sperm function, and elevation of anti-sperm antibodies levels, suggesting that air pollutants would have transposed the blood-testis barrier. Testicular volume in the exposed group was higher than those measuredin the control group; we can suppose that it must occur due to an inflammatory reaction against the polluting agents. Although the significant difference in air pollutants concentrations between groups, no direct correlation to seminal parameters could be demonstrated.

Assessment of the status of the pituitary-gonadal axis in men who have been using androgenic anabolic steroids for a long time

Mykola Lykhonosov[1,2], Alina Y. Babenko[2], Viktor A. Makarin[1] & Yuri N Fedotov[1]
[1]University hospital of Saint-Petersburg State University, Street Petersburg, Russian Federation; [2]Pavlov First Saint Petersburg State Medical University, Street Petersburg, Russian Federation

Background
The study of the state of the pituitary-gonadal axis (PGA) in users of anabolic androgenic steroids (AAS) is important. The severity of inhibition of luteinizing (LH), follicle-stimulating (FSH) hormones, total testosterone (Tt), inhibin B may depend on the type of AAS used, its doses, the simultaneous use of several types of AAS and the duration of their administration.
Aim
To evaluate the levels of LH, FSH, Tt and Inhibin B depending on the type, dose, pattern and duration of the use of AAS.
Methods
An observational prospective study was conducted among male AAS users. During the use of AAS, LH, FSH, and Tt levels were determined by the immunochemiluminescent method, and the inhibin B level was determined by an enzyme immunoassay. Data are presented as median and interquartile range. We used the Fisher's exact test, Spearman's Rank correlation coefficient. The differences were considered statistically significant at $P<0.05$.
Results
44 male volunteers were examined, median age 29 [27.75;34] years, the duration of the use of AAS were 6 [3.52; 7] months. AAS: testosterone propionate 97.7% ($n=43$), dihydrotestoserone derivatives 65.9% ($n=29$) and 19-nortestosterone 47.7% ($n=21$). One drug were used 18% ($n=8$), 2 drugs 50% ($n=22$), 3 drugs 32% ($n=14$) participants. Doses of injectable preparations varied: from 750 mg per week 25% ($n=11$), to 1000 mg 36% ($n=16$), above 1000 mg 39% ($n=17$) men. Laboratory tests while using AAS: LH-0.2 mIU/ml [0.04; 0.47], Tt-4.34 ng/ml [1.05; 8.81]. The discrepancy between low levels of LH(0.2 mIU/ml) and normal testosterone levels is explained by exogenous testosterone. In our study, men with high levels of Tt were 29.5% ($n=13$), and the maximum value of Tt was 45.56 ng/ml (157.96 nmol/l). In the study, the number of men with a LH level <1.24 mIU/ml were 84% ($n=37$) and Tt<3.4 ng/ml was 47.7% ($n=21$) participants. Inhibin B levels during AAS use: 131.7 [72.3;166.4] pg/ml. LH was lower when large doses of AAS were used ($P=0.003$), when more AAS was used together ($P<0.001$), and in cases of dihydrotestosterone ($P=0.018$) or 19-nortestosterone ($P<0.001$). Similar data were obtained for FSH, Tt, Inhibin B. A significant correlation was established between the duration of AAS use (–0.794; $P<0.001$), the amount of AAS (–0.411; $P=0.003$), the dose of AAS (–0.726; $P<0.001$), the type of AAS (–0.602; $P<0.001$) and LH levels.
Conclusion
A significant negative effect of the type, dose, duration of use and amount of simultaneously administered AAS on the levels of LH, FSH, Tt and Inhibin B were revealed.

Testosterone (T) is poorly related to sexual desire and Erectile Dysfunction (ED) in Young/Middle Aged Human immunodeficiency virus (HIV)-Infected Men

Sara De Vincentis[1,2], Maria Chiara Decaroli[1,2], Chiara Diazzi[2], Fabio Morini[1], Davide Bertani[1], Flaminia Fanelli[3], Marco Mezzullo[3], Daniele Santi[1,2], Giulia Tartaro[1,2], Enrica Baraldi[4], Simonetta Tagliavini[4], Uberto Pagotto[3], Giovanni Guaraldi[5] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Modena, Italy; [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Endocrinology Unit and Center for Applied Biomedical Research (CRBA), Department of Medical and Surgical Sciences, University of Bologna – S. Orsola-Malpighi Hospital, Bologna, Italy; [4]Department of Laboratory Medicine and Anatomy Pathology, Azienda USL of Modena, Modena, Italy; [5]Multidisciplinary Metabolic Clinic, Unit of Infectious Diseases, University of Modena and Reggio Emilia, Modena, Italy

Background
ED is highly prevalent in HIV-infected men. T leads sexual behavior in men, but preliminary data suggests that ED is poorly related to serum T in HIV-infected men.
Aim
To explore the relationship between sexual function and gonadal function in young/middle-aged HIV-infected men.
Methodology
Prospective, cross-sectional, observational study on HIV-infected men (age <50 years). Serum TT was assessed by the gold standard LC-MS/MS. Sex hormone-binding globulin (SHBG) was measured by chemiluminescent immunoassay and calculated free T (cFT) was obtained by Vermeulen equation. Biochemical hypogonadism was defined as TT levels below 320 ng/dl and/or cFT levels below 64 pg/ml. The validated International Index of Erectile Function (IIEF)-15 questionnaire was used to identify the presence of ED (score <25) and its degree. IIEF-5 was performed to check if it is reliable as IIEF-15 in this setting.
Statistical analysis
Continuous and categorical variables were compared using ANOVA univariate and Chi-Square test. Correlations were performed using linear regression models.

Results
315 consecutive HIV-infected men were enrolled (mean age 45.3±5.3 years; mean duration of HIV-infection 16.3±8.8 years). A total of 187 patients (59.7%) had ED at IIEF-15; 59 patients (31.5%) presented a severe form of ED (score <10). Considering gonadal function, 35 patients (11.1%) had T deficiency. Scores of EF ($P=0.039$) and sexual desire ($P=0.015$) domains were higher in hypogonadal than eugonadal men. Accordingly, the prevalence of ED raised to 71.4% among hypogonadal men. By considering ED severity, patients with severe ED showed a longer duration of infection ($P=0.039$) and lower cFT levels ($P=0.041$) than patients with mild ED. No difference was found for age ($P=0.224$) and TT levels ($P=0.110$). IIEF-15 score was inversely related to duration of infection ($R^2=0.030$, beta=–0.173, $P=0.002$) and patients' age ($R^2=0.020$, beta=–0.140, $P=0.013$).No significant correlation was found between IIEF-15 score and total T ($P=0.236$) and cFT ($P=0.126$). The erectile function domain at IIEF-15 directly correlated with IIEF-5 score ($R^2=0.545$, beta=0.778, $P<0.001$).
Conclusions
In our HIV-cohort of young/middle-aged men, the prevalence of ED and T deficiency were high being of 60% and 11%, respectively. Serum TT and cFT did not correlate with sexual function parameters, even though sexual desire was lower in men with hypogonadism. ED seems to be better predicted by other factors, such as the duration of infection in this clinical setting, rather than the gonadal status. Furthermore, IIEF-5 seems to be as reliable as IIEF-15 for ED diagnosis in HIV-infected men.

Partial androgen insensitivity: A case report

Rihab Laamouri, Bchir Najla, Zouaoui Chadia, Ben Salem Maram, Jaidane Amel & Ouertani Haroun
University of Tunis Manar- Faculty of medecine, Tunis, Tunisia

Introduction
Androgenic insensitivity syndrome (AIS) is an X-linked genetic disease characterized by resistance to the actions of androgen in an individual with 46, XY karyotype. It is the most common cause of DSD in 46, XY individuals.
Case report
We report a case of a 16-year-old girl who consulted for primary amenorrhea and hirsutism. Our patient had a 9-year-old sister who was operated for an inguinal hernia and the anathomopathological study concluded to a testicular tissue. Physical examination revealed virilization signs: clitoridomegalia, deepening voice and muscle enlargement, female external genitalia and a blind ending vagina. Hormonal evaluation revealed markedly elevated testosterone (6.4 ng/ml), FSH, and LH serum levels. AMH level and dihydrotestosteronemia were low. HCG test showed an increasing testosterone level after HCG stimulation. Diagnostic imaging, including an abdominal ultrasound and a pelvic MRI, showed missing uterus and fallopian tubes and confirmed the presence of two solid structures compatible with gonads measuring 14 mm at the right and 24 mm at the left. Chromosomal analysis confirmed 46, XY karyotype with intact SRY. The patient underwent genetic testing, revealing no androgen receptor mutation. Therapeutically, the patient has benefited from a psychological support and bilateral gonadectomy is programmed especially since alpha foeto protein level was high.
Conclusion and comments
The androgen insensitivity is a rare pathology. Molecular diagnosis is achieved in almost all patients with complete AIS and in a lower frequency in PAIS individuals. In PAIS there is a risk of degenerancy in 20% of the patients, and bilateral gonadectomy is recommended in all individuals raised in the female social sex. In AIS, gender identity usually follows the sex of rearing, but sexual functioning and quality of life can be compromised, that's why it is important to keep patients in psychological care.

Gut microbiota and oral contraceptive use in polycystic ovary syndrome

Damla Eyupoglu[1], Koray Ergunay[2], Aylin Acikgoz[3], Yakut Akyon[2], Engin Yilmaz[4] & Bulent Okan Yildiz[5]
[1]Hacettepe University, Department of Internal Medicine; [2]Hacettepe University, Department of Medical Microbiology; [3]Hacettepe University, Department of Nutrition and Dietetics; [4]Acıbadem Mehmet Ali Aydınlar University, Department of Medical Biology; [5]Hacettepe University, Division of Endocrinology and Metabolism

Context
Polycystic ovary syndrome (PCOS) is a common and complex endocrine disorder. Emerging animal and human data point out to various changes in microbiota that could be linked with the syndrome. However, the effects of therapeutic approaches on gut microbial composition in women with PCOS remain unknown.
Objective
We aimed to assess whether gut microbial composition is altered in overweight/obese women with PCOS and to determine potential impact of oral contraceptive (OC) use on gut microbiota.
Materials and methods
The current study included 17 overweight/obese patients with PCOS and 15 age- and BMI-matched healthy control women. At baseline, clinical, hormonal and metabolic evaluations and gut microbial composition assessment by 16S rRNA gene amplicon sequencing were performed after a 3-day standardized diet. Patients received dienogest-ethinylestradiol (2 mg/0.03 mg) therapy along with general dietary advice for three months after which all measurements were repeated.
Results
Women with PCOS had higher total testosterone (T) and free androgen index (FAI) levels than healthy control women whereas whole body fat mass, fasting plasma glucose, insulin and lipids were similar between the groups. Alpha and beta diversity did not show a difference between PCOS and healthy controls at baseline and remained unaltered after 3 months of OC use in the PCOS group. Relative abundance of Ruminococcaceae family was higher in PCOS patients ($P=0.006$) and did not show an alteration after treatment.
Conclusion
Relative abundance of Ruminococcaceae family is increased in women with PCOS whereas short-term OC use does not alter compositional features of gut microbiota in the syndrome.

AEP830

Anti-müllerian hormone (AMH) as the primary marker for ovarian reserve in transgender male, with or without pcos, under cronic testosterone treatment

Ines Modrego Pardo[1], Marcelino Gómez Balaguer[1], Sandra Garzón Pastor[1] & Carlos Morillas Ariño[1,2]
[1]Hospital Universitario Doctor Peset, València, Spain; [2]University of Valencia, València, Spain

Background
AMH represents a marker of ovarian reserve and is used in monitoring the effects of gonadotoxic drugs. In PCOS is higher and is an indirect marker of hyperandrogenism. In transsexual man(TM), high prevalence of PCOS is described and AMH provide information about ovarian reserve after exposure to testosterone.
Objective
To assess the prevalence of PCOS in young TM previously to testosterone treatment, study the evolution of AMH levels and differentiate it response patterns according to the presence of PCOS.
Material and methods
Retrospective cohort of TMtreated with testosterone followed between 2010–2018. Levels of AMH, Testosterone, Androstenedione, LH, FSH and Estradiol at baseline and at 6 months after intramuscular testosterone were analyzed. The AMH response was evaluated based on the presence of ovariananalytic hyperandrogenism (AH) previous to treatment (testosterone ≥ 0.7 ng/ml or androstenedione ≥ 5 ng/ml) with or without clinical PCOS (Rotterdam Criteria).
Results
Of 162 HT included, the mean age was 21 years (range 13–39). Baseline AMH 3.5 ng/ml (Interquartile range (IR) 3), Testosterone 0.4 ng/ml (IR 0.1), androstenedione 3.23 ng/ml (IR 1.89), FSH 4.3 mUI/ml (IR 3), LH 5.1 mUI/ml (IR 5) and estradiol 63 pg/ml (IR 79). 8% ($n=13$) of the sample had PCOS (median age19 years (range 15–33)) and 19% ($n=31$) had AH (median age 21 years (range 15–34)), without differences. A correlation was

observed between baseline levels of AMH and Testosterone: 0.2 ($P=0.01$) in the general group, 0.479 ($P=0.006$) in AH group and 0.549 ($P=0.051$) in PCOS. Table 1 shows the baseline levels of hormones in different groups. Table 2 shows the changes in AMH throughout the follow-up in different groups.

Table 1

Baseline hormones (ng/ml) Median (IR)	PCOS		*P*-value (U Mann-Whitney)	AH		*P*-value (U Mann-Whitney)
	Yes ($n=13$)	No ($n=149$)		Yes ($n=31$)	No ($n=131$)	
AMH	4.5(5.4)	3.4 (2.9)	0.229	3.8(4.0)	3.4(2.9)	0.55
Testosterone	0.7(0.34)	0.3 (0.1)	<0.001	0.7(0.4)	0.3(0.1)	<0.001
Androstenedione	5.6(1.32)	3.5(1.56)	<0.001	5.3(1.95)	2.9(1.5)	<0.001

Table 2

	Baseline	6 months	*P*-value (Wilcoxon test)
General group ($n=118$)	3.5(3.20)	2.8(2.50)	<0.001
PCOS ($n=8$)	4.45(7.55)	4.2(3.42)	0.528
AH ($n=21$)	3.6(4.20)	3(3.05)	0.029

Conclusions
The% of PCOS is not higher in TM compared to cis-women. AMH can be a good subrogated marker of PCOS and AH. The ovarian follicular reserve measured by AMH is not significantly damaged by treatment with testosterone in the short or medium term. This response is no different in TM with PCOS or AH.

The association of serum miR-27a and miR-320 level with glucose metabolism and insulin sensitivity in young women with polycystic ovary syndrome

Anna Krentowska[1], Donata Ponikwicka-Tyszko[2], Agnieszka Lebkowska[1], Agnieszka Adamska[3], Gabriela Sokolowska[4], Maria Sztachelska[2], Justyna Hryniewicka[3], Slawomir Wolczynski[4] & Irina Kowalska[1]
[1]Medical University of Białystok, Department of Internal Medicine and Metabolic Diseases, Białystok, Poland; [2]Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Department of Biology and Pathology of Human Reproduction, Bialystok, Poland; [3]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Bialystok, Poland; [4]Medical University of Białystok, Department of Reproduction and Gynaecological Endocrinology, Bialystok, Poland

Introduction
Polycystic ovary syndrome (PCOS) is associated with an increased risk of insulin resistance. The involvement of microRNAs, small, non-coding molecules, in regulation of metabolic processes has been investigated. The role of miR-27a and miR-320 in regulation of glucose metabolism is documented. The aim of the study was to assess the level of circulating miR-27a and miR-320 in PCOS patients and to investigate its relationship with glucose metabolism.
Materials and methods
The studied group comprised 100 PCOS patients diagnosed with the Rotterdam criteria (age 24.3±3.7 years, BMI 25.2±5.3 kg/m^2), divided into phenotypes (I–33 patients; II–24 patients; III–21 patients; IV–12 patients), and 88 healthy women as a control group (age 25.4±4.3 years, BMI 23.4±3.3 kg/m^2). Anthropometric measurements, transvaginal ultrasound, assessment of sex hormones concentrations and oral glucose tolerance test (OGTT) were performed. Serum miR-27a and miR-320 levels were assessed with real-time polymerase chain reaction.
Results
The studied groups were similar in terms of age and BMI. Patients with PCOS presented higher glucose concentrations at 30 and 60 minutes of OGTT ($P=0.042$; $P=0.023$), higher insulin concentrations at 30, 60 and 120 minutes of OGTT ($P=0.049$; $P<0.001$; $P=0.013$) and lower Matsuda index ($P=0.001$) vs controls. Level of miR-27a was higher ($P<0.001$) and miR-320 was lower ($P<0.001$) in PCOS vs controls. Level of miR-27a was higher in phenotype I than in phenotype III ($P=0.021$).

Fasting glucose concentration correlated with miR-27a ($R=0.32$, $P=0.001$) and miR-320 level ($R=–0.28$, $P=0.006$) only in PCOS. In phenotype I, miR-27a level correlated with glucose at 0 and 120 minutes of OGTT ($R=0.45$, $P=0.009$; $R=0.36$, $P=0.043$), fasting insulin concentration ($R=0.44$, $P=0.011$), and Matsuda index ($R=–0.40$, $P=0.021$). In phenotype II, miR-320 correlated with glucose at 0 and 60 minutes of OGTT ($R=–0.41$, $P=0.044$; $R=–0.47$, $P=0.020$). In phenotype III, miR-27a correlated with glucose concentration at 60 minutes of OGTT ($R=0.45$, $P=0.038$). In the subgroup of women with PCOS and impaired fasting glucose (IFG)/impaired glucose tolerance (IGT), we observed higher miR-27a and lower miR-320 level, comparing to PCOS patients with normal glucose tolerance ($P=0.003$; $P=0.030$). In patients with PCOS and IFG/IGT, miR-27a level correlated with fasting insulin concentration ($R=0.50$, $P=0.029$).
Conclusions
Serum levels of miR-27a and miR-320 are altered in PCOS patients and may be linked with impaired glucose metabolism. The association of miR-27a and miR-320 with insulin sensitivity seems to be more pronounced in phenotype I. Circulating miR-27a and miR-320 could serve as potential biomarkers of glucose metabolism disturbances in PCOS.

Male hypogonadism and sarcopenia

Ceyda Dinçer Yazan, Tugce Apaydin & Dilek Gogas Yavuz
Marmara University Medical Faculty, Endocrinology and Metabolic Diseases

Background and aim
Low testosterone levels are known to be associated with unfavorable body composition and testosterone replacement is known to be associated with increased muscle mass and muscle strength. The aim of this cross-sectionalstudy is to evaluate the grip strength, appendicular muscle mass and physical performance and bone mineral densities of hypogonad male patients.
Method
75 hypogonad and 45 healthy control subjects were included in this study. The etiology of hypogonadism, follow-up and replacement durations were asked. The right and left handgrip strength were measured by a hand dynomometer to assessmuscle strength. Decreased muscle strength was defined as <27 kg in men. Appendicular skeletal muscle mass was detected with bioelectrical impedance analysis and gait speed was detected with 4 meter usual walking speed test to assess physical performance if the patient was sarcopenic. Bone mineral densities of the patient group were evaluated. Serum testosterone levels measured at 10th day of testosterone propionate injection were recorded.
Results
69 of the 75 hypogonad patients were hypogonadotrophic hypogonadism and 23 patients had panhypopituitarism. 66 of the patients were under replacement therapy but 42 of these patients had low serum testosterone levels according to reference range. The grip strength of the patient group was significantly lower than control group. 15 of the patients had muscle weakness. Appendicular skeletal muscle mass of these patients were normal. When all of the subjects were included, grip strength of the low testosterone group were lower and the BMI and Hba1c levels weresignificatly high. The total testosterone levels had a significant negative correlation with hand grip strength ($r=0.007$) but no correlation with BMD levels. When the patient group was evaluated according to testosterone reference range levels, as normal or lowthere was no significant difference of grip strength and BMD levels between groups. The grip strength of the patients with panhypopituitarism were significantly low.
Conclusion
The muscle strength of the hypogonad patients are lower than healthy population but the measured low testosterone levels of the patients under regular replacement therapy may notcorrelate directly with muscle strength.

AEP833

First in man study of oral native testosterone in hypogonadal men shows physiological testosterone levels in fed and fasted state

John Newell-Price[1], John Porter[2], Jo Quirke[2], Eleni Daniel[1], Enis Mumdzic[1] & Richard Ross[1]
[1]University of Sheffield, United Kingdom; [2]Diurnal Ltd

Introduction
Current testosterone replacement therapies have limited acceptability: gels can be messy and risk inadvertent dosing of others; injections are painful; and oral testosterone undecanoate (TU) delivers variable testosterone levels, requires concurrent ingestion of a fatty meal and may produce supraphysiological dihydrotestosterone (DHT) levels[1]. We present the first human trial of an oral native testosterone preparation formulated to deliver testosterone irrespective of food intake.
Aim
To compare the pharmacokinetics of DITEST (Diurnal Ltd Cardiff, UK) to an oil based oral TUformulation (Andriol Testocaps, MSD, UK) and explore the effect of food on DITEST bioavailability.
Methods
Single centre, phase 1b study of DITEST in 25 adult males with hypogonadism, one subject withdrawn after single period and only included in safety analysis (Clinicaltrials.gov: NCT02966652). Part 1 compared the pharmacokinetics of 80 mg TU with 120 mg DITEST after a high fat meal. Part 2 the pharmacokinetics of 200mg of DITEST administered fed and fasted. Results are baseline adjusted.
Results
DITEST showed a testosterone dose response between 120 mg and 200 mg with C_{max} 19.1 and 30.4 nmol/l and AUC (0–10 h) 59.5 and 88.6 h*nmol/l. DITEST 200 mg gave an equivalent C_{max} and AUC(0–10 h) to TU 80 mg: C_{max} 30.4 vs 31.4 nmol/l and AUC (0–10 h) 88.6 vs 102 h × nmol/l. Serum TU levels after dosing with 80 mg testosterone undecanoate were 10-fold greater than the testosterone levels generated by TU. Fed and fasted DITEST had similar pharmacokinetics C_{max} 26.5 vs 30.4 nmol/l, AUC (0–10) (87.0 vs 88.6). Both dose strengths of DITEST resulted in lower levels of DHT than TU 80 mg; C_{max} 2.9 [120 mg DITEST] vs 4.5 [200 mg DITEST] vs 6.7 [80 mg TU] nmol/l and AUC (0–10) (11.0 [120 mg DITEST] vs 16.7 [200 mg DITEST] vs 36.3 [80 mg TU] h × nmol/l). There was one serious adverse event (urinary retention) during TU dosing. There was no emerging safety concern.
Discussion
Administration of DITEST in fed and fasted states provides similar testosterone and DHT exposure. TU levels were much higher than testosterone levels suggesting a large proportion of testosterone undecanoate was not converted to testosterone. Compared to published literature on a self-emulsifying formulation of TU at 200 mg, DITEST at 200mg provides a similar testosterone C_{max} and no requirement for a fatty meal[1].
Conclusion
DITEST is an oral native testosterone formulation with anticipated advantages over current oral therapy of dosing without food and less risk of high DHT levels compared to TU therapy.

Vaginal bleeding and spotting in transgender men after initiation of testosterone therapy: A prospective cohort study (ENIGI)
Justine Defreyne[1], Yuran Vanwonterghem[2], Sarah Collet[1], Sean Iwamoto[3], Chantal Wiepjes[4], Alessandra Fisher[5], Thomas Schreiner[6], Martin den Heijer[4] & Guy T'Sjoen[7]
[1]Ghent University Hospital, Endocrinology; [2]Ghent University Hospital, Department of Endocrinology; [3]University of Colorado School of Medicine and Rocky Mountain Regional VA Medical Center, Department of Medicine, Division of Endocrinology, Metabolism & Diabetes, United States; [4]Amsterdam University Medical Center, VUmc, Department of Endocrinology and Center of Expertise on Gender Dysphoria, Netherlands; [5], University of Florence, Women's Endocrinology and Gender Incongruence Unit, Department of Experimental, Clinical and Biomedical Sciences, florence, Italy; [6]Oslo University Hospital, Department of Endocrinology, Oslo, Norway; [7]Ghent University Hospital,, Center for Sexology and Gender, Department of Endocrinology

Background
Persistent vaginal bleeding can be psychologically stressful and incongruent with gender identity in transgender men (assigned female at birth with male gender identity). Previous studieshave cross-sectionally described amenorrhea in cohorts of transgender men on intramuscular or subcutaneous testosterone injections. It remains uncertain which testosterone preparations most effectively suppress vaginal bleeding and when amenorrhea occurs after testosterone initiation. This study investigates the clinical effects of various testosterone preparations on vaginal bleeding and spotting in transgender men.
Methods
This prospective cohort study was part of the European Network for the Investigation of Gender Incongruence (ENIGI). Data on the persistence (yes/no) and intensity (continuous scale) of vaginal bleeding and spotting, serum sex steroid levels and body composition were prospectively and cross-sectionally assessed in 267 transgender men during a three-year follow-up period, starting at the initiation of various testosterone preparations. Testosterone therapy was aimed at male serum testosterone levels.
Results
After three months of testosterone, 17.9% of transgender men reported persistent vaginal bleeding and 26.8% reported spotting. The percentages reporting vaginal bleeding and spotting decreased over the first year of testosterone (bleeding 4.7% and spotting 6.9% at 12 months, respectively), with no participants reporting vaginal bleeding or spotting after 18 months of testosterone. Factors associated with vaginal bleeding or spotting included lower serum testosterone levels and being on testosterone gel, as compared to injections (e.g., esters or undecanoate preparations). If vaginal bleeding persisted, starting progestogens at three months resulted in a decrease in the intensity of vaginal bleeding and spotting.
Discussion
Testosterone therapy aimed at male physiologic ranges will result in cessation of vaginal bleeding and spotting in the majority of transgender men within three months. If not, serum testosterone levels should be measured and testosterone dose adjusted to achieve serum testosterone levels in the physiologic male range. Adding a progestin can be considered after three to six months if bleeding persists. Providers should be aware that cessation of bleeding can be more difficult to achieve in transgender men with lower serum testosterone levels or those on testosterone gel.

Autoimmune characteristics in women with addisons disease and primary ovarian insufficiency
Elinor Vogt, Marianne Øksnes & Eysetein Husebye
University of Bergen, Medicine, Bergen, Norway

Background
In women with autoimmune primary adrenal failure (AD) there is a high prevalence of autoimmune primary ovarian failure (POI). Whether the oophoritis is caused by an unknown ovary-specific autoantibodyor cross-autoimmunity with steroid hormone producing cells in the adrenal cortex is unknown. Autoimmune POI can also affect women without AD. Autoantibodies against steroidogenic enzymes are useful diagnostic markers in AD but are of uncertain value in idiopathic POI.
Aim
To compare the prevalence of steroidogenic autoantibodies in AD women with and without autoimmune POI to women with idiopathic POI.
Materials and methods
In this retrospective cross-sectional trial we identified 484 women with AD, using data from the world's largest Registry of Organ Specific Autoimmune Diseases (ROAS).POI was diagnosed based the registry's clinical and biochemical information and further validated using data from The Norwegian Prescription Database. The autoimmune status was evaluated with immunological methods of autoantibody detection against 21-hydroxylase (21 OH), side-chain cleavage enzyme (SCC), NALP5 and 17-hydroxylase (17 OH). Twenty-two women with idiopathic POI were also included.
Results
The prevalence of POI in the AD cohort was 9.1% (44/484). The AD women with POI where youngerwhen diagnosed with AD (30.9 ± 14.0 vs 36.7 ± 15.1 years) and had a subsequently longer AD disease duration (27.7 ± 15.2 vs 21.0 ± 15.5 years).More than half of AD women with POI had ≥3 positive autoantibodies. Autoantibodies against 21 OH were detected in all AD women with POI (100%) and 439 of 408 (93%) AD women without POI. SCC were positive in 35 of 44 with POI (80%) and 61 of 396 (15%) without POI. In women with idiopathic POI, only two of 22 women had positive SCC and none had detectable autoantibodies towards 21OH/NALP5/17OH.
Conclusion
POI is common in AD, and AD women have a higher frequency of positive steroidogenic autoantibodies. In these women, SCC seems to be the most specific marker for autoimmune POI. However, the prevalence of steroidogenic autoantibodies in idiopathic POI is low, suggesting either non-autoimmune cause or highlighting the need for an ovary-specific biomarker for autoimmune oophoritis.

Early menopause is associated with increased risk of arterial hypertension: A systematic review and meta-analysis

Panagiotis Anagnostis[1,2], Patroklos Theocharis[1,2], Konstantinos Lallas[1], Georgios Konstantis[1], Konstantinos Mastrogiannis[1], Julia Bosdou[1], Irene Lambrinoudaki[3], John Stevenson[4] & Dimitrios Goulis[1]
[1]Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynecology, Medical School, Thessaloniki, Greece; [2]Police Medical Centre of Thessaloniki, Department of Endocrinology; [3]2nd Department of Obstetrics and Gynecology, National and Kapodistrian University of Athens, Medical School, Athens, Greece; [4]National Heart and Lung Institute, Imperial College London, Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom

Objective
Menopausal transition has been associated with an increased risk of cardiovascular disease (CVD), mainly attributed to atherogenic dyslipidaemia, central obesity and insulin resistance. Whether arterial hypertension (AH) also contributes to menopause-associated CVD is currently unknown. The aim of this study was to systematically investigate and meta-analyze the best available evidence regarding the association between early menopause (EM) and AH risk.
Methods
A comprehensive search was conducted in PubMed, CENTRAL and Scopus databases, up to January 20th, 2020. Data were expressed as odds ratio (OR) with 95% confidence intervals (CI). The I2 index was employed for heterogeneity.
Results
Ten studies were included in the quantitative analysis (273.994 postmenopausal women, 76853 cases with AH). Women with EM (age at menopause <45 years) were at higher AH risk compared with those of normal age at menopause (>45 years) (OR 1.10, 95% CI 1.01–1.19, $P=0.03$; I^2 79%).
When women with POI were compared with those of normal menopausal age (five studies, 192.219 women), the association between POI and AH risk was not significant (OR 1.14, 95% CI 0.95–1.37, $P=0.17$; I^2 58%). Furthermore, when sensitivity analysis was restricted to studies ($n=8$) in which participants were matched for age or BMI or smoking, the direction or the magnitude of the effect observed did not changed (OR 1.13; 95% CI, 1.00–1.29; $P=0.05$). This was also the case after restricting analysis to studies ($n=2$) matched for ever use of menopausal hormone therapy or oral contraceptives (OR 1.26; 95% CI 1.05–1.52; $P=0.01$).
Conclusions
Women with EM have an increased risk for AH compared with those of normal age at menopause.

Multicentre performance evaluation of the new, fully automated Elecsys ASD immunoassay and determination of reference ranges

Barbara Obermayer-Pietsch[1], Roland Imdahl[2], Marta de Ramon[3], Claudia Reichmuth[4], Garnet Bendig[5], Stefan Hutzler[5], Judith Taibon[5], Christopher Rank[5] & Peter Findeisen[6]
[1]Medical University of Graz, Graz, Austria; [2]Labor Augsburg MVZ, Augsburg, Germany; [3]Laboratori de Referència de Catalunya, Barcelona, Spain; [4]Agent representing Roche Diagnostics GmbH, Penzberg, Germany; [5]Roche Diagnostics GmbH, Penzberg, Germany; [6]MVZ Labor Dr. Limbach & Kollegen, Heidelberg, Germany

Background
Androstenedione (ASD) levels are used to assess androgen production, adrenal gland and ovarian/testicular function, and diagnosis/monitoring of patients with hyperandrogenism from suspected cortisol-related enzyme deficiencies. According to international diagnostic guidelines, ASD can confirm biochemical hyperandrogenism in suspected polycystic ovary syndrome (PCOS) when total/free testosterone are not elevated. The Elecsys ASD assay (Roche Diagnostics) is a competitive electrochemiluminescence immunoassay for in-vitro quantitative determination of ASD in human serum/plasma. We evaluated the performance of this new, automated assay versus an ASD isotope dilution-liquid chromatography-tandem mass spectrometry (ID-LC-MS/MS) candidate reference method, and determined reference ranges in different clinical cohorts.
Methods
Elecsys ASD assay performance (cobas e 602/cobas e 801 analysers) was evaluated at three sites in Germany/Spain; method comparison was performed internally by Roche Diagnostics; reference ranges were determined at two sites in Germany. Repeatability and intermediate precision were assessed according to CLSI EP05-A3, using three control levels and five human serum pools ($n=75$ each) covering the assay measuring range (0.15–10.00 ng/ml); one run per day for 5 days. Method comparisons versus commercially available immunoassays (IMMULITE ASD [Siemens] and LIAISON ASD [DiaSorin]) and an ID-LC-MS/MS candidate reference method were conducted using 421 serum samples covering the Elecsys ASD assay measuring range; Passing-Bablok regression and Pearson's correlation were calculated. Reference ranges were determined in five clinical cohorts using samples from several sites/vendors: apparently healthy children (≤8 years [US vendor]); apparently healthy women with proven fertile cycle (US, 22–37 years [Trina Bioreactives AG, USA; Roche Wellness Center, USA]; EU/ROW, 18–37 years [UZ Brussel, Belgium; University Hospital Leipzig, Germany; Practice Dr Rohsmann, Germany]); apparently healthy men (≥18 years [Bavarian Red Cross, Germany]); post-menopausal women (55–70 years [NUVISAN GmbH, Germany]); and women with PCOS (18–45 years [Medical University of Graz, Austria]).
Results
Repeatability and intermediate precision CVs across all sites were 2.01–3.91% and 2.43–4.30%, respectively (mean ASD concentrations 2.23–9.92 ng/ml). The Elecsys ASD assay showed poor correlation with IMMULITE ASD (slope=0.459; $r=0.856$; $n=320$), moderate correlation with LIAISON ASD (slope=0.625; $r=0.984$; $n=327$), and very good correlation with ID-LC-MS/MS (slope=1.040; $r=0.996$; $n=332$). Reference ranges (5th–95th percentiles): apparently healthy children ($n=140$), <0.150–0.382 ng/ml; apparently healthy women ($n=84$), 0.490–1.31 ng/ml; apparently healthy men ($n=138$), 0.355–1.26 ng/ml; post-menopausal women ($n=140$), 0.208–0.990 ng/ml; women with PCOS ($n=125$), 0.756–3.03 ng/ml.
Conclusion
The Elecsys ASD assay demonstrated excellent precision and very good correlation with ID-LC-MS/MS. Reference ranges were established to support results interpretation in routine clinical practice.

Modifications of autoimmune markers in women with infertility and autoimmune thyroiditis

Halyna Koval, Nataliia Pashkovska, Nataliia Abramova, Ivan Pankiv, Antonina Piddubna, Yulia Marchuk & Iryna Tsaryk
HSEI 'Bukovinian State Medical University', Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Thyroid hormones affect sex hormone metabolism and reproductive function in women. Infertility in women with autoimmune thyroiditis is more difficult to treat than in women with normal thyroid function. On the other hand, immune factors are dependent on exogenous and endogenous factors, interrelated with hormones and are important regulators of fertility, autoimmune reactionsand can lead to infertility and increase the risk of pregnancy complications and miscarriage.
The aim of the study
To determine the features of changes of autoimmune markers in women suffering from infertility and autoimmune thyroiditis.
Materials and methods
The study was conducted through detailed analysis of medical records of 32 women, which were diagnosed with infertility of unexplained genesis and autoimmune thyroiditis. The control group consisted of 30 women with tubal genital infertility. The comparison group consisted of 30 healthy women. Determination of the indicators of thyroid function (thyroid-stimulating hormone, total thyroxine, free thyroxine, total triiodothyronine, free triiodothyronine, antibodies to thyroperoxidase (APO), antibodies to thyroglobulin (ATG)) was conducted by ELISA. Autoimmune markers: antisperm antibodies, antinuclear antibodies (ANA), Ro/SS-A, La/ss-B, CENP-B, Scl-70, dsDNA, Jo-1, MPO, PR3, AMA and Sm were determined out by Western Blot method.
Results
It should be noted that among all women who came to the clinic complaining about infertility for the first time, 11.34% were diagnosed with autoimmune thyroiditis. This diagnosis was the most common among all autoimmune disorders in infertile women compared to an increase in antisperm antibody levels – only 1.3% were observed, and to the proportion of all other autoimmune diseases combined – was less than 10%. The following autoimmune markers showed significant changes in women of the study group:

APO titers increased in the range of 2.4–11.2 times (P <0.001), ATG – increased in the range of 1.7–8.3 times (g <0.001), ANA – growth in the range from 1: 100 to 1: 1000 (P <0.001) compared to the control. We did not reveal significant changes of the rest of the autoimmune markers that were under the study.
Conclusion
Thus, a significant increase in the levels of thyrospecific and antinuclear autoantibodies in women with infertility on the background of autoimmune thyroiditis were revealed, which may cause fertility disorders and the search for new methods of solvation of this problem is necessary.
Keywords: infertility in women, autoimmune thyroiditis.

The diagnostic value of antimullerian hormone in polycystic ovary syndrome among Tunisian women: A case-control prospective study

Marwa Bennour[1], Ines Kammoun[1], Marouen Braham[2], Hajer Kandara[1], Manel Hamdoun[3], Anis Fadhlaoui[3], Olfa Bahri[3], Fethi Zhioua[2] & Manel Jmal[1]
[1]National Institute of Nutrition, Endocrinology and metabolic diseases, Tunis, Tunisia; [2]Aziza othmana hospital, Department of Gynécologie, obstetric et reproduction medicine, Tunis, Tunisia; [3]Aziza othmana hospital, Biochemistry laboratory, Tunis, Tunisia

Introduction
Polycystic ovary syndrome (PCOS) is a common endocrine disorder. The presence of polycystic ovarian morphologyis usually confirmed by ovarian ultrasound. However, its definition is controversial. The objective of this study was to evaluate the interest of the antimullerian hormone (AMH) in the diagnosis of PCOS, aiming to establish a threshold that would be predictive of PCOS among Tunisian women.
Patients and methods
Sixty-twoyoung women (31 with PCOS and 31 age and BMI matched healthy controls) were recruited in this case-control, prospective, cross-sectional study. All participants had physical examination, ovarian ultrasound and dosage of AMH and testosteronemia.
Results
All patients had clinical and/or biological hyperandrogenism. The mean rate of AMH was 3.6 times higher in patients (7.69 ng/ml) compared to controls (2.12 ng/ml; P < 10–3). The cut-off value for AMH which was best correlated with PCOS was 3.41 ng/ml (sensitivity = 96.8%; specificity = 90.3%; AUC = 0.977). A significant positive correlation between AMH and antral follicular number, and between AMH and testosteronemia was found. A significant negative correlation between AMH and age was also found. We noted no significant association between AMH and BMI. The most common PCOS phenotype was the A one combining the three diagnostic criteria for PCOS (52%). This phenotype had the highest rate of AMH.
Conclusions
Our results suggest that AMH may be a reliable biomarker in the diagnostic of PCOS. It may replace ovarian ultrasound if it is not available, inconclusive and/or in the absence of a qualified operator. The threshold of 3.41 ng/ml would be appropriate for Tunisian hyperandrogenic patients.

Hormonal profile of menopausal women receiving androgen replacement therapy: A meta-analysis

Daniele Santi[1,2], Giorgia Spaggiari[1], Antoan S Sojat[3], Srdjan Pandurevic[3], Elisa Maseroli[4] & Ljiljana Marina[3]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Ospedale Civile Baggiovara, Modena, Italy; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]Department of Endocrinology, Clinical Centre of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia; [4]Andrology, Women's Endocrinology and Gender Incongruence Unit, Department of Experimental and Clinical Biomedical Sciences 'Mario Serio,' University of Florence, Florence, Italy

Background
Ovarian and adrenal aging leads to a progressive decline in androgens levels and deleterious effects on the quality of life. Despite this, specific hormone replacement is not routinely recommended in the management of women with a physiological or pathological decline in their production, mainly due to the lack of long-term follow-up safety data.
Aim of the study
To evaluate and summarize the existing data about hormonal profile changes in menopausal women receiving androgen replacement treatments, considering all available androgens formulation and regimens.
Methods
The literature search was conducted to identifyall randomized clinical trials and case-control studies evaluating hormonal effects of exogenous administration of any molecule with androgenic action in post-menopausal women published in English language until May 2018 (PROSPERO registration ID: CRD42018099414).
Results
Fifty-threepapers were included in the analysis, accounting for 83 trials. Androgen administration increases testosterone serum levels (2159 treated women vs 2246 controls, P<0.001), regardless of the molecule used. Similarly, an increase of dehydroepiandrosterone (DHEA) and DHEA-sulfate serum levels was observed (P<0.001 and P<0.001, respectively), with a concomitant reduction in sex hormone binding globulin (SHBG) levels (P<0.001). However, the estrone (E1) and estradiol (E2) increase is evident only when DHEA is administered (P<0.001 and P<0.001, respectively), and not when testosterone (P=0.120 and P=0.690, respectively) or androstenedione (P=0.400 and P=0.540, respectively) where chosen.
Conclusion
Whatever androgen formulation we choose in postmenopausal women, the final result is a rise in testosterone serum levels. However, DHEA regimen shows a combined estrogenic activity. This peculiar action is crucial when choosing the best possible treatment for each patient individually taking into consideration if potential benefits outweigh the risks.

AEP841

Androgens in women – the methods for their determination

Michaela Duskova[1,2], Lucie Kolatorova[1] & Luboslav Starka[1]
[1]Institute of Endocrinology, Department of Steroids and Proteofactor, Praha, Czech Republic; [2]General University Hospital, Department of Medicine Strahov, Praha, Czech Republic

Four androgens are routinely measured in women: dehydroepiandrosterone sulfate (DHEAS), dehydroepiandrosterone (DHEA), androstenedione, and testosterone. The diagnosis of hyperandrogenemia in women is accompanied by many difficulties. One of them is the method used to measure androgens in the laboratory. In most laboratories, androgens are determined using various immuno-analytical methods. Recently, gas or liquid chromatography combined with mass spectrometry have begun to be use. These instrumental techniques should be prefered for androgen mesurement in women due to their low circulating levels. Another difficulty with androgen laboratory assays are reference ranges, which can not just be automatically taken from other references but should be tested and confirmed in each laboratory. We determined our laboratory reference range for DHEA, androstendione and testosterone quantified using newly developed LC-MS/MS method in fertile, postmenopausal and pregnant women and their newborns in plasma. DHEAS was also estimated (radioimunoassay). Moreover, we have calculated biologically available testosterone. SHBG and albumin (calculation of biologically available testosterone) and LH (phase of cycle) were measured using immunoanalysis. Reference ranges were calculated based on the 2.5th–97.5th percentiles of measured data. For calculating ranges in fertile women, 220 healthy woman samples were analyzed (average age 29.8 years). Dividing into four phases of the menstrual cycle was performed based on the day of the cycle and LH levels. Calculating of reference ranges in healthy postmenopausal woman was performed by analyzing 97 plasma samples (average age 58 years). Samples from 142 healthy women (average age 31.41 years) with physiological gravidity at the 37th week, during the first period of spontaneous labor, and from newborn mixed cord blood divided in two group according the fetal sex were used for calculating reference ranges. All probands were not using any medications, had no clinical signs of hyperandrogenemia. Androgens levels of fertile women change during menstrual cycle with higher levels in ovulation phase (for example: follicular phase testosterone: 0.10–1.53 nmol/l and ovulation phase testosterone: 0.28–2.02 nmol/l).Pregnant women at the 37th week carrying male fetus have higher levels of androgens (testosterone: 0.73–5.79 nmol/l)than pregnant women carrying female fetus (testosterone: 0.99–5.07 nmol/l). Using

LC-MS/MS methods and determination of own reference ranges for these androgens could improve the diagnostics of hyperandrogenemia in women.
Acknowledgments
The study was supported by the project MHCZ-DRO (Institute of Endocrinology-EÚ, 00023761), and by the grant MHCR 17-30528A from the Czech Health Research Council.

Evaluation of erectile dysfunction leading to a diagnosis of myotonic dystrophy

Stefanos Togias, Stefanos Stergiotis, Ioannis Kakoulidis, Ioannis Ilias & Eftychia Koukkou
El Venizelou Hospital, Department of Endocrinology, Diabetes & Metabolism, Athens, Greece

Erectile dysfunction is a common complaint of men with hypogonadism. We present the case-history of a 42-year-old man who complained of erectile dysfunction for four years. Previous paternity was mentioned in his past medical history. On clinical examination his appearance was eunuchoid with frontal balding, reduced chest hair and lipomastia. Bilateral ptosis was also noticed and after being questioned the patient admitted that he had surgically repaired eyelid ptosis one year ago. His testes measured 8 ml each. Investigations revealed hypergonadotrophic hypogonadism (testosterone 1.88 ng/ml (normal range: 2.5–8.36) FSH 35 mIU/ml (nr: 1.5–12.4) LH 26.7 mIU/ml (nr: 1.7–8.6)) as well as elevated liver enzymes (SGOT: 49 IU/l, SGPT 65: IU/l, γ-GT: 205 IU/l) and CPK: 416 IU/l. Genetic analysis confirmed the presence of an-over 150 times-expansion of CTG repeat in the dystrophia myotonica protein kinase (DMPK) gene, a finding consistent with myotonic dystrophy type 1. After diagnosis was confirmed, the patient was examined for endocrinopathies known to be related to DM1. Thyroid function tests, PTH and cortisol levels were normal and the HOMA-IR level was 2.5. This case report highlights the need of thorough examination of all patients presenting with erectile dysfunction even for rare causes of hypogonadism.

Hyperandrogenism in a postmenopausal woman secondary to an androgen secreting steroid cell tumor of the ovary

Filipa Bastos, Sara Franco, Ana Ferreira, Isabel Manita & Jorge Portugal
Hospital Garcia de Orta, Almada, Portugal

Introduction
Androgen secreting neoplasms of the ovary are rare and usually show autonomous secretion. Steroid cell tumors of the ovary represent less than 0.1% of all ovarian tumors and are a subgroup of sex cord-stromal tumors. In most cases, patients present with androgenic clinical features.
Case report
A 58-year-old woman complained of rapid onset of androgenic alopecia, excessive hirsutism and clitoromegaly. Endocrine assessment showed high levels of testosterone 293 ng/dl (4–60), with normal levels of other androgens. Abdominal magnetic resonance revealed a solid nodular lesion of the right ovary with 13×14 mm suggestive of a sex cord-stromal tumor. The patient underwent bilateral hystero-ophorectomy. The histopathology diagnosis was steroid cell tumor, not otherwise specified. Four months after surgery, hormonal evaluation demonstrated normal plasma testosterone levels and the patient refers some regression of androgenic features.
Conclusion
The rapid onset of virilization in a post-menopausal woman should lead to a search for an androgen-secreting ovarian or adrenal tumor. Surgery is the main treatment for these tumors. Although steroid cell tumors of the ovary are generally benign, there is a risk for malignant transformation and little is known about their behavior, so it is important to keep these patients under surveillance.

Severe hyperandrogenaemia and unusually large polycystic ovaries: A case report

Uzma Khan[1] & Harpal Randeva[1,2]
[1] University Hospitals Coventry and Warwickshire NHS Trust, Department of Endocrinology, Diabetes and Metabolism – WISDEM Centre, COVENTRY, United Kingdom; [2]University of Warwick Medical School, Clinical Sciences Research Laboratories, COVENTRY, United Kingdom

Introduction
Polycystic ovary syndrome (PCOS) is the most common endocrine disorder of young women and depending on the diagnostic criteria, it affects 6% to 20% of reproductive aged women. PCOS is also the most common cause of hyperandrogenism in young women with the theca cells of the ovary being the source of androgen excess. PCOS is rarely associated with severe hyperandrogenaemia and atypical features such as rapid progression, presence of virilization or very high Testosterone/ androgen levels should prompt comprehensive evaluation to exclude a sinister underlying cause.
Case report
A 19-year-old Caucasian female with background of autism presented with secondary amenorrhoea, moderate acne and recent onset mild hirsutism. Examination revealed a modified Ferriman-Gallwey score of 12, central obesity with BMI 33.9 kg/m^2 and no signs of Cushing's syndrome. Biochemical workup revealed severe hyperandrogenaemia with a Testosterone 4.9 nmol/l (<1.8), low SHBG 8.2 nmol/l (26–110) and a very high free androgen index of 59.7. Androstenedione was also significantly high 19.5 nmol/l (0.9–7.5). DHEAS was mildly elevated 11.3 µmol/l (1.8–10). 17-OHP was normal. In order to distinguish ACTH-dependent hyperandrogenism from other causes of hyperandrogenism, 1 mg overnight dexamethasone-suppression test was performed which suppressed Testosterone to less than 40% (from 3.8 nmol/l to 2.6 nmol/l); Androstenedione suppressed from 24.8 nmol/l to 12.6 nmol/l and there was enough Cortisol suppression to 13 nmol/l, excluding Cushing's syndrome. She refused a transvaginal ultrasound scan of the pelvis and had MRI of the pelvis and adrenals which excluded ovarian and adrenal neoplasm; imaging features were highly suggestive of PCOS with bilateral very large ovaries (right ovary measuring 50 cc and left ovary measuring 32 cc in volume) containing multiple (at least 20–22) small sub-centimetre sized follicles.
Conclusion
This case highlights a rare presentation of a common disorder and is unusual in that the high concentration of androgens and very high free androgen index were not associated with a sinister ovarian or adrenal pathology. Mild hirsutism despite severe hyperandrogenaemia might be explained by a relatively shorter duration of exposure to androgens, low intrinsic sensitivity of her hair follicles to androgen action or reduced local 5-alpha-reductase activity. Although her presenting features were relatively mild, significantly elevated androgens and recent onset hirsutism raised concern for non-PCOS pathology requiring suppression testing and imaging for accurate diagnosis and appropriate treatment.

The effect of diabetes mellitus on age at natural menopause: A systematic review

Eugenia Vlachou[1], Anastasia Ntikoudi[1], Georgia Fasoi[1], Vasiliki Avrampou[2], Smaragdi Boulazeri[3], Ourania Govina[1] & John Komninos[4]
[1]University of West Attica, Nursing, Athens, Greece; [1]University of West Attica, Nursing, Athens, Greece; [2]Children's Hospital 'P.&A. Kyriakou', Nursing, Athens, Greece; [3]'Skilitseio' General Hospital of Chios, Nursing, Chios, Greece; [4]Naval Hospital of Athens, Endocrinology, Athens, Greece

Introduction
Menopause marks a period of significant changes on hormones and on the women's lifestyle, which can interfere with their subsequent health. Menopause marks not only the end of the woman's reproductive life, but also the upcoming associated risks for many morbidities, as well. The increasing prevalence of diabetes (either type 1 Diabetes Mellitus (T1DM) or type 2 Diabetes Mellitus (T2DM) renders a necessity to investigate its effects on women's age of menopause.
Aim
The aim of this review was to systematically evaluate all the available literature on how diabetes affects women's age at menopause.

Method
An extensive literature search was conducted through electronic databases (Pubmed, Scopus, Cinahl and Medline) with the terms of 'age', 'menopause', 'premature' and 'diabetes mellitus', till December 2019. The search yielded 116 results, 11 of which met the inclusion criteria.
Results
Five of the included studies examined the correlation of T1DM with the age of menopause and six studies of T2DM, respectively.
In the EPIC study, menopause occurred significantly earlier among women with T1DM (WT1DM). In a sample of Finnish WT1DM the age at menopause was reported to be the same as in general population. In the OVADIA study, a similar menopausal age was reported in both groups. In the DCCT/EDIC cohort, WT1DM appeared a similar age at menopause onset compared to the average age of menopausal women in the U.S. In the FAD study, a younger age at menopause, among WT1DM was demonstrated.
In the SWAN study, women with T2DM (WT2DM) experienced their final menstrual period in a significantly earlier age than women without diabetes. Moreover, in an Indian population, the average age of menopause among diabetic women was much younger than in non-diabetic. In a Latin American study, the risk of being postmenopausal in WT2DM aged 40–44 years was found to be nearly three times higher than in those without. In contrast, in a study of Mexican WT2DM was found that they experienced a similar menopausal age with non-diabetic women. Likewise, in the EPIC study no relationship between diabetes and age at menopause was observed. Finally, the age of menopause onset in Nigerian WT2DM was found similar to the age of commonly reported in Nigerian women population.
Conclusion
The findings of this systematic review remain inconclusive regarding the effect of diabetes on age at menopause. It is important to verify that diabetes could affect the age of menopause, through future well-organized multicenter studies.

Gonadal dysfunction is associated with severity of disease in men with myotonic dystrophy type 1

Hélène hoth guechot[1], Linda Humbert[1], Florence KOHLER[1], Clara Leroy[2], Geoffroy Robin[2] & Marie-Christine Vantyghem[1]
[1]CHRU Lille, Endocrinology, Lille, France; [2]CHRU Lille, Andrology, Lille, France

Background
The myotonic dystrophy type 1 (DM1) or Steinert disease is the most common inherited, autosomal dominant neuromuscular disorder in adult. The gonadal dysfunction has been known for many years in DM1 men with description of bilateral testicular atrophy but the factors influencing the different profiles of gonadal dysfunction, and their natural evolution are not clearly established. The purpose of this study was to determine the profiles of gonadal function on men affected by DM1 followed in a single reference center and to analyse the factors influencing this gonadal profile.
Results
in the whole population, the mean age of the 75 patients was around 40 years, 57% of them being younger than 40 years old. More than half (53.3%) of these 75 patients had an adult form of the disease. The median number of CTG repeat was 450 (200–650). Forty percent of the patients had normal gonadal status. Sixty percent of patients had alteration of hormonal results. Thirty-seven percent of patients had isolated exocrine testicular lesion and 22% of patients had hypogonadism. This last, hypogonadal patients, had higher BMI and had more metabolic disorders than in patients with exocrine testicular failure or normal gonadal status. They had also more severe disease (evaluated by the number of triplets) and more severe muscular involvement (evaluated by MIRS score) than other patients, regardless of their age. Also paternity was significantly lower in hypogonadic patients than in other patients. Testosterone (t) and testosterone/SBP ratio (t/S) were inversely correlated with the age of patients (t: $r=-0.32$, $P=0.005$; t/S: $r=-0.49$, $P<0.001$) and with the MIRS score (t: $r=-0.37$, $P=0.001$; t/S: $r=-0.32$, $P=0.006$). There was not correlated with paternity and number of CTG repeats.
Conclusion
In this cohort of 75 DM1 patients aged arount 40, we observed a high prevalence of primary testicular failure with one patient out of 5 with hypogonadism. This gonadal dysfunction was significantly correlated to the number of CTG repeats, the severity of muscle involvement assessed with the MIRS score, and the metabolic syndrome regardless of the age of the patients.
The efficacy of androgen therapy on metabolic and muscular syndrome, and its acceptability by patients need to be studied, as well as the effect of an improvement of metabolic status or muscular strength through rehabilitation that might also have beneficial effects.

DOI: 10.1530/endoabs.70.AEP846

Psychological status and quality of life in men with hypogonadism and type 2 diabetes mellitus, receiving testosterone replacement therapy

Irina Khripun, Sergey Vorobyev, Natalia Kuzmenko & Ekaterina Petrovskaya
Rostov State Medical University, Endocrinology, Rostov-on-Don, Russian Federation

It is known that the presence of type 2 diabetes mellitus (T2DM) deteriorates the psychological status of patients, but its combination with a deficiency of testosterone (T) in men is not well studied. The aim of this work was to study the effect of T replacement therapy (TRT) on the levels of anxiety, depression, symptoms of androgen deficiency, diabetes and quality of life in men with T2DM and functional hypogonadism.
Materials and methods
We examined 90 men with T2DM and a T deficiency (mean age 51.5±6.3 years), which were divided into 2 groups: 1–40 patients who received TRT using transdermal T-gel (Androgel 50 mg/day) for 9 months and standard hypoglycemic therapy and 2–50 patients who were not assigned to TRT and received just antidiabetic drugs. Patients underwent clinical and psychological examinations, such as questionnaires HADS, aging male symptoms (AMS), symptoms of diabetes (DSC) and quality of life (SF-36). Statistical analysis of the data was carried out using the Wilcoxon test for time-depended parameters and Mann-Whitney U test for two independent groups using the Statistica software package (StatSoft 10).
Results
Analysis of the AMS questionnaire in men who received TRT revealed a significant ($P=0.003$) decrease in the total score of androgen deficiency symptoms from 38.5 [35; 46] to 30 [24; 39]. The diabetic symptoms according to DSC questionnaire also were decreased: the psychological scale by 0.75±0.04 points ($P=0.04$), manifestations of hyperglycemia by 0.5±0.09 points ($P=0.04$) and neuropathy scale by 0.6±0.03 ($P=0.02$) points. Moreover, the anxiety levels were significant decreased 1.8-fold ($P<0.001$) and depression level – 2-fold ($P=0.001$) in the 1st group. The quality of life according to SF-36 questionnaire were significant improved ($P<0.01$) in the physical functioning, general health, vitality, social functioning, and role-emotional scales compared to baseline in patients receiving TRT. In the control group no significant changes occurred.
Conclusion
The appointment of TRT in men with T2DM not only reduces the symptoms of androgen deficiency and diabetes, but also significantly decreases levels of anxiety and depression, which improve the quality of life in these patients.

Serum inhibin B level distinguishes congenital hypogonadotropic hypogonadism from constitutional delay of growth and puberty in males: A systematic review and meta-analysis

Gao Yuting, Qin Du, Liyi Liu & Zhihong Liao
The First Affiliated Hospital of Sun Yat-sen University, Department of Endocrinology and Metabolism, Guangzhou, China

Objective
The distinction between constitutional delay of growth and puberty (CDGP) and congenital hypogonadotropic hypogonadism (CHH) in males with delayed puberty is difficult but important for timely treatment. We aimed to summarize the sensitivity and specificity of serum inhibin B (INHB) level in distinguishing CHH with CDGPin boys.
Methods
Studies in the PubMed, EMBASE and Cochrane Library databases were systematically searched from the date of database inception to November 10, 2019.Studies incorporating INHB discriminating between CHH and CDGP were included. The quality assessment of diagnostic studies

2 (QUADAS-2) instrument was used to assess the quality of the included studies. Meta-Disc version 1.4. was used to calculate the sensitivity, specificity, summary receiver-operating characteristic (sROC) curves, and area under the curve (AUC).

Results

Six studies, comprising 328 patients (87 CHH vs 241CDGP), were eligible for this meta-analysis. For the differential diagnosis between CHH and CDGP, INHB measurement had a good diagnostic accuracy with a pooled sensitivity of 92%, specificity of 91%, pooled AUC of 0.9616. INHB performed well especially in CHH and CDGP boys with severe puberty deficiency (testes volume ≤3 ml), with sensitivity of 92%, specificity of 98% and AUC of 0.9956.Subgroup analysis weredisplayed in Table 1.

Table 1 Summary results of subgroup analysis for INHB in the diagnosis between CHH and CDGP.

Categorical variable	No. of studies	Sensitivity 95% CI	I^2(%)	Specificity 95% CI	I^2(%)
Testes volume(ml)					
≤3	3	0.92 (0.79–0.98)	67.4	0.98 (0.90–1.00)	22.3
≤4	3	0.93 (0.81–0.99)	0.00	0.85 (0.78–0.91)	53.7
≤6	2	0.90 (0.74–0.98)	0.00	0.96 (0.89–0.99)	85.6
Study design					
Prospective	4	0.93 (0.82–0.98)	51.4	0.99 (0.95–1.00)	23.7
Retrospective	4	0.91 (0.81–0.97)	0.00	0.86 (0.80–0.91)	38.2
Methodological quality					
Low risk	5	0.92 (0.83–0.97)	36.1	0.97 (0.93–0.99)	54.0
Not low risk	3	0.91 (0.80–0.98)	0.00	0.84 (0.76–0.90)	15.3

Conclusions

INHB has an excellent diagnostic performance in differentiating CHH from CDGP, retaining both considered sensitivity and specificity. INHB has better diagnostic efficacy in boys with severe puberty deficiency (testes volume ≤3 ml). (Grant/Award Number: 201604020090, Guangzhou Science and Technology Programme)

Aminoacidic residues discriminating human choriogonadotropin (hCG) and luteinizing hormone (LH) binding to the human receptor (LHCGR)

Clara Lazzaretti[1,2], Valentina Secco[1], Elia Paradiso[1,2], Samantha Sperduti[1,3], Claudia Rutz[4], Annika Kreuchwig[4], Gerd Krause[4], Manuela Simoni[1,3,5,6] & Livio Casarini[1,3]

[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Baggiovara, Italy; [2]University of Modena and Reggio Emilia, International PhD School in Clinical and Experimental Medicine (CEM), Modena, Italy; [3]University of Modena and Reggio Emilia, Center for Genomic Research, Modena, Italy; [4]Leibniz-Forschungsinstitut für Molekulare Pharmakologie, Berlin, Germany; [5]Azienda Ospedaliero-Universitaria di Modena, Department of Medical Specialties, Baggiovara, Italy; [6]Centre Inra -Val De Loire, Nouzilly, France

The human luteinizing hormone (LH)/choriogonadotropin (hCG) receptor (LHCGR) discriminates its two hormone ligands. LHCGR differs to the murine receptor (Lhr) in aminoacid residues potentially involved in qualitative discerning of LH and hCG, the latter absent in rodents. We aim to identify LHCGR residues involved in hCG/LH discrimination, indicating evolutionary determinants of human LH/hCG endocrine system. After comparing the LHCGR and Lhr sequences, we developed eight *LHCGR* cDNAs carrying 'murinizing' mutations (R247T; T48R; S149F; I83S; A57T; E270V; N35D and V37A; K225S and T226I) assumed to be interacting specifically with LH, hCG or both. HEK293 cells expressing a mutant or the wild-type receptor were treated by pM-μM LH or hCG concentrations and the kinetics of cAMP and pERK1/2 activation was analysed by BRET. A Lhr-like response was obtained in cells expressing LHCGR carrying the A57T mutation as hCG is more potent than LH in inducing both cAMP (LH EC_{50}=0.7±0.2 nM vs hCG EC_{50}=0.1±0.03 nM; Mann-Whitney's *U*-test; $P<0.05$; $n=4$; means±S.E.M.) and kinetics of pERK 1/2 activation (Kruskal-Wallis test; $P<0.05$; $n=8$). The E270V mutation located in the LHCGR hinge region decreased of 2.5 times the LH, but not hCG potency in inducing cAMP production than the wild-type (LH EC_{50}=2.8±1.4 nM vs LH EC_{50}wild-type=1.1±0.3 nM; hCG EC_{50}=0.2±0.04 nM vs hCG EC_{50}wild-type=0.15±0.03 nM; $n=4$; means±S.E.M.), suggesting this extracellular portion of the receptor is involved in LH-specific recognition. LHCGRs carrying K225S, T226I or R247T mutations mediate similar cAMP (LH EC_{50}=0.6±0.2 nM vs hCG EC_{50}=0.11±0.1 nM and LH EC_{50}=5.6±0.4 nM vshCG EC_{50}=0.4±0.02 nM; Mann-Whitney's U-test;$P>0.05$; $n=4$) and pERK1/2 response to LH and hCG (Kruskal-Wallis test; $P>0.05$; $n=8$). Via 'murinization' of LHCGR, we identified key aminoacids falling within the extracellular region of the receptor interacting with the hormone L2-β loop, which might be crucial for discriminating the two human gonadotropin ligands. We found human-specific determinants of the LH/hCG system evolution.

An investigation into the age and developmental stage related association between plasma concentrations of leptin and growth hormone, linear growth velocity, body mass index and body surface area in boys between the ages of 1 and 20 years

Afzaal Ahmed Naseem[1,2], Mazhar Qayyum[1], Maleeha Akram[1], Fahim Tahir[3], Kiran Afshan[4], Sarwat Jahan[4] & Syed Shakeel Raza Rizvi[1,5]

[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology, Rawalpindi, Pakistan; [2]University of Lahore, Sihala Campus, Islamabad, Pakistan; [3]National Institute of Health, Reproductive Physiology, Public Health Laboratories Division, Islamabad, Pakistan; [4]Quaid-i-Azam University, Department of Animal Sciences, Islamabad, Pakistan; [5]University of Central Punjab, Quaid Campus, Rawalpindi, Department of Zoology, Rawalpindi, Pakistan

Puberty, one segment of a larger developmental continuum in humans, is characterized by major transformations in body such as highest growth, sexual development and distribution of fat in different body regions. Leptin is regarded as an essential adipokine that regulates intake of food, expenditure of energy and body fat mass. It is well known that alterations in nutritional states markedly influence growth hormone (GH) secretion, which in turn regulates linear growth, muscle strength, body fat mass and lipid metabolism. Also, leptin affects bone metabolism via direct signaling from the brain. Leptin decreases cancellous bone, but increases cortical bone, which is a mechanism for increase in bone size. Leptin may also act directly on bone metabolism via a balance between energy intake and the IGF-I pathway. Therefore, this study was designed to examine possible associations between plasma concentrations of leptin and GH, linear growth velocity (LGV), body mass index (BMI) and body surface area (BSA) at different ages and developmental stages in boys between 1 to 20 years (27 boys/age group). The concentrations of leptin and GH were determined using specific ELISA, while LGV, BMI and BSA were calculated using formulae for each age/stage group. Data were analyzed using Student's *t* test, ANOVA and Pearson correlation r. Our results showed a positive correlation between plasma leptin and GH levels at 3rd, 6th, 8th, 10th, 12th, 16th to 18th and 20th year of age and at infancy, early puberty and late puberty. The leptin levels and LGV were positively correlated at 3rd, 4th, 8th to 10th, 12th and 16th to 18th year of age indicating correlation at early puberty and late puberty. Moreover, the leptin levels and BMI were positively correlated at 1st, 4th to 6th, 8th, 9th, 12th, 15th and 18th to 20th year of age demonstrating correlation at infancy and early puberty. Likewise, the concentrations of leptin and BSA were positively correlated at 1st, 2nd, 5th through 12th, 19th and 20th year of age showing relationship at infancy, pre-puberty and early puberty. In conclusion, leptin and GH, LGV, BMI and BSA were found to be positively correlated at infancy and early puberty.

Modern approaches to ovulation induction in patients with poor ovarian response

Kateryna Kondratiuk[1], Iryna Nikitina[2], Valentyna Kondratiuk[3] & Galyna Dziuba[3]

[1]O.O. Bogomolets National Medical University, Endocrinology, Kyiv, Ukraine; [2]Medical Institute of Sumy State University, Obstetrics and gynecology, Sumy, Ukraine; [3]Shupyk National Medical Academy of Postgraduate Education, Fetal Medicine, Kyiv, Ukraine

Background
Aromatase inhibitors have been introduced as a new treatment modality in controlled ovarian stimulation as they were found to elevate follicular sensitivity to gonadotropins.
The purposeof this study was to evaluate whether IVF outcomes will differ between poor responder patients who receive high doses of gonadotropins alone or low doses of gonadotropins with letrozole during ovulation stimulation.
Methods
Patients who underwent *in vitro* fertilization treatment classified as poor responder patients according. Inclusion criteria: patients being aged between 18 and 42 years, having regular menstrual cycles (between 25–32 days), having normal BMI (between 19.3–28.9 kg/m.), having normal hormone levels, having normal endometrium (evaluated with hysteroscopy). Exclusion criteria: chemotherapy and radiotherapy, ovarian surgery in anamnesis. The controlled ovarian stimulation were started on third day of the menstrual cycle. In the I Group, 24 patients were treated with 150 IU gonadotropins in combination with letrozole 5 mg/day for the first five days of the stimulation. In the II Group, 32 patients were treated with 300 IU gonadotropins. Patients were treated with 0.25 mg GnRH antagonist given from stimulation day 6 onwards. When at least three follicles were 18 mm in size, a single dose of 250 µg hCG was injected for follicular maturation. Oocyte retrieval took place for the 34–36 hours after hCG trigger. Oocytes were fertilized by conventional ICSI and cultured until the day of embryo transfer.
Results
Group I and II, there were no statistically significant difference in duration of ovulation stimulation, duration of antagonist use, number of retrieved oocytes, number of transferred embryos, implantation rate, clinical and ongoing pregnancy rates ($P>0.05$). Gonadotropin use was significantly higher in Group II (300 IU gonadotropins) compared to I Group (150 IU gonadotropins in combination with letrozole 5 mg/day), ($P<0.05$).
Conclusion
Using letrozole with low doses of gonadotropins in patients with POR does not improve the pregnancy outcomes compared to high doses of gonadotropins alone. However, the addition of letrozole can make pregnancy outcomes comparable using significantly lower doses of gonadotropins, so may be regarded as an effective adjuvant agent in POR patients.

Headache in patients with polycystic ovary syndrome

Lina Zabuliene[1,2], Edita Saukaityte Butvile[2], Vaiva Hendrixon[3], Mykolas Urbonas[4] & Dalius Jatuzis[1]
[1]Faculty of Medicine, Vilnius University, Institute of Clinical Medicine, Vilnius, Lithuania; [2]Karoliniskiu out-patient clinic, Consultants department, Vilnius, Lithuania; [3]Faculty of Medicine, Vilnius University, Institute of Biomedical Sciences, Vilnius, Lithuania; [4]Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Introduction
Polycystic ovary syndrome (PCOS) is the most frequent endocrine disorder among reproductive age women having negative impact on their health, personal and social live. In scientific literature data on headache in PCOS women are scarce.
Aim of the study
To investigate the frequency of headache and its association with metabolic parameters and diet habits in women with PCOS.
Materials and methods
114 PCOS women and 80 healthy control women took part in the study. Body weight, height, blood pressure were measured. Hormones, complete blood count, fasting glucose, fasting insulin and lipid profile tests were performed. Information about headache, nutrition habits and physical activity was collected utilizing qualitative frequency questionnaires.
Results
The mean participants' age was 27.52±3.80 years, the mean BMI was 25.08±6.20 kg/m^2. 65.5% of studied women complained on headache attacks: 68.5% of them were experiencing tension-type headache, 26.0% of them had migraine. PCOS women experienced headache more frequently than control group's women (72.8% vs 55.0%, $P<0.010$). Rate of tension-type headache were higher in PCOS women than in control group (52.6% vs 33.8%, $P=0.009$), rate of migraine didn't differ between groups. PCOS women more frequently stated, that headache affected their professional live (31.6% vs 18.8%, $P=0.046$) and everyday activities (24.6% vs 11.2%, $P=0.020$) than controls.
Overweight and obese PCOS women more frequently experienced headache than normal-weight PCOS women (81.5% vs 61.2%, $P=0.016$). Being overweight or obese increased odds ratio of having headache 2.8 times ($P=0.018$). No difference in headache frequency between healthy overweight and normal-weight women was detected.
Headache rate was lower among PCOS women every day eating whole grain bread and white flour than in PCOS women occasionally eating whole grain bread and white flour (respectively 25.3% vs 48.1%, $P=0.027$ and 15.0% vs 32.1%, $P=0.049$). Headache rate was higher among PCOS women every day eating potatoes than in PCOS women occasionally eating potatoes (18.5% vs 3.4%, $P=0.039$).
Conclusion
PCOS women more frequently have headache affecting professional live and every day activities. Overweight is associated with headache frequency in women with PCOS.

A case of swyer syndrome

Hemmat ElHaddad, Amr El Meligy, Samar Amin & Randa Salam
Cairo University, Endocrinology department, Cairo, Egypt

Introduction
Swyer syndrome is caused by abnormal sex differentiation during the embryonic period, resulting in incomplete intrauterine masculinization and undifferentiated gonads associated with a 46, XY karyotype in phenotypic females. They have normal female external genitalia and underdeveloped female internal genitalia. Such patients usually present with primary amenorrhea and delayed puberty but can also have gonadal tumors as adults. The exact incidence is unknown. The syndrome has been estimated to occur in 1 in 80.000 births.
Case report
A 18 years old child, reared as female, born of non-consanguineous marriage, presented to our Out-patient Department with primary amenorrhea with no breast development, but normal pubic and axillary hair. She is the second in her siblings, one elder brother (21 years), two younger (male 16, female 14) all achieved puberty. Her mother had her menarche at age of 15. On systematic enquiry, no symptoms suggestive of any system affection past medical, family, and developmental histories were normal.
Examination
General and systemic examinations were within normal limits; the subject had no stigmata of Turner's syndrome. Weight: 48.5 kg, Height: 149 cm (–2 S.D.), span 156 cm, US/LS ratio 0.8, mid parental height (–1.–2 S.D.).
No breast budding, pubic hairtanner stage 4, External genitalia were normal; there was no evidence of ambiguity.
Investigation
Routine biochemical and hematological investigations were within normal limits. Hormonal evaluations were consistent with primary gonadal failure: FSH 98 mIU/ml (3.5–12.5). LH42.15 IU/l (2.4–12.6), E2 less than 5, T.Testosterone 0.16 ng/dl (0.15–0.8), F.testosterone 2 ng/dl (1–5).
Normal thyroid profile
Bone age by X-ray: 13 years/Abdominal/pelvic US: infantile uterus, absent ovarian tissue replaced by fibrous tissue bilaterally (Pure gonadal dysgenesis). /MRI pelvis: hypo plastic infantile uterus, with absent ovarian Tissue. Karyotype analysis revealed 46XY, without MosaicismA FISH study revealed 95% XY that the proband was positive for SRY region 45% on Y-chromosome. She was started on low-dose continuous estrogen priming, following which she had break through bleeding. She wasthen prescribed combination of estrogens and progestogen to induce cycling bleeding. Multiple psychological counselling sessions were held. Parents werecounselled about the risk of gonadal tumor and were advised gonadectomy but they refused.
Conclusion
This case report calls attention to exclude rare Disorder of Sex Development like Swyer syndrome in a subject with primary amenorrhea, accurate and early diagnosis would allow conservative treatment and appropriate psychological counselling, which reduces emotional trauma and improve patient survival.

Age and developmental stage dependent relationship between thyroid hormones and follicle stimulating hormone, luteinizing hormone, testosterone and inhibin B in boys between the ages of 1 and 20 years

Syed Shakeel Raza Rizvi[1,2], Afzaal Ahmed Naseem[1,3], Maleeha Akram[1], Fahim Tahir[4], Kiran Afshan[5], Sarwat Jahan[5] & Mazhar Qayyum[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology, Rawalpindi, Pakistan; [2]University of Central Punjab, Quaid Campus, Rawalpindi, Department of Zoology, Rawalpindi, Pakistan; [3]University of Lahore, Sihala Campus, Islamabad, Pakistan; [4]National Institute of Health, Reproductive Physiology, Public Health Laboratories Division, Islamabad, Pakistan; [5]Quaid-i-Azam University, Department of Animal Sciences, Islamabad, Pakistan

The maturation of hypothalamo-pituitary-gonadal (HPG) axis causes the onset of puberty, which stimulates the development of secondary sex characteristics and changes in the size and composition of the body. Furthermore, the size of the thyroid gland increases and its function also changes as an adaptation to the requirements of the transformation of child to an adult. It has also been reported that the thyroid hormones including thyroxin (T4) and triiodothyronine (T3) have a facilitative action on the reactivation of the release of GnRH in pulsatile pattern at the time of puberty. In humans, it has been suggested that thyroid hormones affect reproductive functions and fertilizing ability since T3 has been demonstrated to have an essential function in testicular development by controlling the differentiation and proliferation of Leydig and Sertoli cells by binding to Sertoli cells during the development of testes. It has been reported that the proper functioning hypothalamo-pituitary-thyroid (HPT) axis is essential for proper reproductive development in human. The secretion of thyroid hormones is altered under different physiological and pathological conditions including puberty and stress. The current investigation was planned to systematically examine possible associations between plasma concentrations of T3 and FSH, LH, T and inhibin B at different ages and developmental stages in boys between 1 to 20 years of age (27 boys/age group). The concentrations of T3, FSH, LH, T and inhibin B were determined using specific ELISA systems. The data were analyzed using Student's t test, ANOVA and Pearson correlation r. The concentrations of T3 and FSH were positively correlated at 1st-3rd, 7th-12th, 14th, 18th and 19th year of age and at infancy, early, mid and late puberty. Moreover, the concentrations of T3 and LH were positively correlated at 1st, 6th, 9th to 15th, 17th and 19th year of age and at all developmental stages including infancy, pre-puberty, early, mid and late puberty. Similarly, T3 and T concentrations were positively correlated at 1st, 3rd, 6th, 8th to 15th, 17th, 19th and 20th year of age and at all developmental stages. Furthermore, T3 and inhibin B levels were positively correlated at 1st, 3rd-6th, 10th-14th, 18th and 20th year of age and at infancy, pre-puberty, early and mid-puberty. In conclusion, T3 and LH and T levels were found to be positively correlated at all developmental stages from infancy to late puberty, whereas T3 and FSH and inhibin B levels were positively correlated at infancy, early puberty and mid-puberty.

Intensive marathon running: Don't over do it!

Apurva Lunia[1] & Sathis Kumar[2]
[1]Conquest Hospital, General Medicine, Saint Leonards, United Kingdom; [2]Conquest Hospital, Endocrinology, Saint Leonards, United Kingdom

Background
Secondary hypogonadism due to intensive exercise and eating disorders are well documented in females. But there very few reports of secondary hypogonadism due to intensive exercise in male patients.
Case presentation
A 34 year old Caucasian male, presented to our clinic with impaired fertility, lack of libido and increased fatigue. On further enquiry, he mentioned that he had starting running 3–4 yrs. ago, and had been running marathons over the last couple of years since, practicing regularly, runningup to 120 miles/week. He had lost weight over this period. Moreover, he had become a vegan six months ago, and since then lost another one stone in weight. No history of any anabolic steroids or other hormonal misuse. On examination, he had adequate secondary sexual characteristics, including male pattern baldness, and testicles were normal in size bilaterally (25 3 ml). His BMI was 20. Biochemistry results showed hypogonadotropic hypogonadism (with LH 0.7 IU/l, FSH 3.7 IU/l, Testosterone 1.60 mIU/l). Other hormonal results are normal. (9 am Cortisol 453 nmol/l, Free T4 14 pmol/l, TSH 1.51 mIU/l, Prolactin 273 mu/l). MRI scan of Pituitary was normal. Sperm count showed Oligospermia. As fertility was the main concern, in view of above results and with history of intensive training (for Marathons) and also recent dietary change, he was advised to reduce his activity levels, recommended to regain some weight and was also referred to a dietician. At three months review, he had gained 10 kg in weight (and not following Vegan diet) and also reduced the running distance from 120 miles/week to just 40 miles/week and the repeat morning Testosterone has improved to 8.02 nmol/l. After following the same, at 6months review his weight was stable, and still doing only 40 miles/week of running, and the morning Testosterone levels are in normal range at 11. 83 nmol/l. He had mentioned that his Partner is now pregnant. And his libido and erectile dysfunction have improved as well.
Conclusion
Intensive training for Marathon with dietary restriction have caused hypothalamic hypogonadism in this patient, and changes in exercise intensity and duration and weight gain with appropriate dietary changes, has resolved the Hypothalamic amenorrhoea spontaneously.

Effects of perinatal exposure to 4-tert-octylphenol (OP) on brain development and behavior in mice

Dinh Nam Tran, Seon Myeong Go, Donglin Yi, Vo Thi Bich Thuy, EuiMan Jung & Eui-Bae Jeung
Chungbuk national university, College of Veterinary Medicine, Cheongju, Korea, Republic of South

Perinatal action of estrogens or aromatizable steroids at the central nervous system level is responsible for brain development. 4-tert-octylphenol (OP) is knows as an endocrine disrupting chemical (EDC) that is widespread estrogenic chemical used in the costumer produces. Thus, we hypothesis that through early contact with the central nervous system, OP could alter the processes affecting behavior. In this study, primary cortical neurons were exposure to OP (10^{-6} or 10^{-8} mol/l) from day *in vitro* 1 to 4 with/without estrogen antiestrogen ICI 182 780. In *in vivo*, we studied the negative impacts of OP on the neuro behavioral development in the offspring generation from OP-supplementation dams (10 or 50 mg/kg on GD9.5 to PND28). Primary cortical neurons were exposure to OP showed increased in the numbers of primary and secondary dendrites. There was no difference in the number ofprimary and secondary axons in OP-treated groups compared to vehicle group. OP-treated groups displayed decreased in the average length both of primary axons and dendrites. Co-treated OP with ICI reversed effect of OP. At 6–8 week-aged, off spring mice from OP-supplementation dams showed limited in acquisition of spatial reference memory and a decreased capability of locating the target in the probe trial of Morris water maze task. In addition, OP-treated groups showed cognition dysfunction in novel test. Moreover, OP-treated groups exhibited impairments in sociability and social novelty preference in three-chamber social test and social interaction test. In open field test, OP-treated groups increased anxiety-like behavior and change the locomotor activity in mice. Our results first pronounced that exposure to perinatal exposure to OP influences the neuronal development, lead to abnormal behavior in the adult off spring mice.

Association with 3-iodothyronamine improves the effect of levothyroxine on neurocognitive symptoms in a mouse model of adult-onset hypothyroidism

Grazia Rutigliano[1,2,3], Sabina Frascarelli[1], Marco Borsò[1], Lavinia Bandini[1] & Riccardo Zucchi[1]
[1]University of Pisa, Department of Pathology, Pisa, Italy; [2]Sant'Anna School of Advanced Studies, Institute of Life Sciences, Pisa, Italy;

[3]National Research Council, Institute of Clinical Physiology, Pisa, Italy

Adult-onset hypothyroidism is related to anxiety, depression, and impaired neurocognition. Guidelines from all professional societies recommend levothyroxine (LT4) monotherapy as the treatment of choice. However, ~15% hypothyroid patients do not achieve a satisfactory functional level despite TSH within the reference range. The beneficial effects of combining LT4 and liothyronine (LT3) to improve neuropsychiatric functions remains unclear. Recently, 3-iodothyronamine (T1AM), a thyroid hormone derivative, demonstrated pro-learning and anti-amnestic effects *in vivo*. Notably, decreased T1AM tissue levels were found in pharmacological rodent model of hypothyroidism, even after adequate hormonal replacement with LT4. Here, in a mouse model of adult-onset hypothyroidism, we aimed at comparing various combinations of classical and non-classical thyroid hormones on hippocampus-dependent memory, anxiety- and depression-like behaviors. Six-week-old C57BL/6J male mice ($n=41$) were given Methimazole and Potassium Perchlorate (0.20 mg/g/die and 0.30 mg/g/die) in drinking water for 49 days. As controls, $n=8$ littermates received water. At day 21, mice were implanted with subcutaneous ALZET osmotic pumps delivering replacement treatments for 28 days. We had 6 experimental groups, as follows: (1) hypothyroid, $n=9$; (2) LT4, $n=6$; (3) LT4&LT3, $n=9$; (4) LT4&T1AM, $n=8$; (5) T1AM, $n=9$; (6) euthyroid, $n=8$. T4 and T3 serum concentrations were determined, by high performance liquid chromatography coupled with tandem mass spectroscopy (HPLC-MS/MS), and confirmed the validity of our model. Mice were exposed to: (i) Elevated Plus Maze, for the assessment of anxiety-related behaviors; (ii) Open Field Test, for locomotion; (iii) Novel Object Recognition test, for hippocampus-dependent memory; (iii) Tail Suspension Test, for depression-related behaviors. Hypothyroid mice displayed significantly impaired hippocampus-dependent memory as compared to euthyroid mice (discrimination index, DI=–0.00±0.09 vs 0.28±0.08, t=2.43, $P<0.05$). ANOVA detected a global significant difference in DI among the experimental groups (F (5, 43)=4.038, $P<0.01$). In detail, LT4 monotherapy almost fully restored memory (DI=0.23±0.09). A larger improvement was observed upon LT4 & T1AM replacement, while T1AM did not induce any effect per se. Memory remained disrupted under LT4 & L-T3, possibly due to thyrotoxicosis. These findings were influenced neither by locomotor activity nor by anxiety- and depression-related behaviors, which remained unchanged. In conclusion, in our pharmacological mouse model of adult-onset hypothyroidism, LT4 & T1AM combination fared better than LT4 monotherapy in ameliorating hippocampus-dependent memory, which was disrupted in hypothyroid conditions. Future studies are needed to elucidate the molecular pathways involved in the observed effects.

3-iodothyronamine ameliorates ischemia-induced synaptic dysfunction in mouse entorhinal cortex

Francesca Tozzi[1], Grazia Rutigliano[2], Marco Borsò[2], Riccardo Zucchi[2] & Nicola Origlia[3]
[1]Scuola Normale Superiore, Pisa, Italy; [2]University of Pisa, Department of Pathology, Pisa, Italy; [3]National Research Council, Institute of Neuroscience, Pisa, Italy

Abnormalities in thyroid hormone (TH) availability and/or metabolism have been hypothesized to contribute to Alzheimer's disease (AD) and to be a risk factor for stroke. Recently, 3-iodothyronamine (T1AM), an endogenous amine putatively derived from TH metabolism, gained interest for its ability to modulate the nervous and the vascular systems. In the present work, we studied the effect of T1AM on ischemia-induced synaptic dysfunction in the entorhinal cortex (EC), a brain region crucially involved in learning and memory and early affected during AD. Moreover, we investigated the role of the trace amine-associated receptor 1 (TAAR1) and its signalling in T1AM-mediated neuroprotection. Field excitatory post-synaptic potentials (fEPSPs) were recorded in EC horizontal slices obtained from WT mice (C57bl). Slices were exposed to an oxygen-glucose deprivation (OGD) protocol for 10 min and then recorded for 50 min after reperfusion. Drugs were perfused to slices for 10 min during the application of OGD. A long-lasting synaptic depression was induced by OGD in C57bl slices (mean fEPSP amplitude in the last 10 min of recording was of 77±4% of baseline, $n=13$ slices, 6 mice). However, T1AM (5 µM) perfusion was capable of preventing the long-lasting synaptic depression after OGD (mean fEPSP amplitude 96±4% of baseline, $n=10$ slices, 6 mice). A similar protective effect was achieved by perfusion with RO5166017 (250 nM), a specific agonist of TAAR1(mean fEPSP amplitude 99±6% of baseline, $n=6$ slices, 4 mice), while T1AM protective effect was abolished in the presence of EPPTB (5 nM), a selective TAAR1 antagonist (mean fEPSP amplitude was of 81±4% of baseline, $n=9$ slices, 4 mice). Moreover, T1AM failed to protect against ischemia in the presence of a TRKB IgG capable of blocking BDNF (1 µg/ml) (mean fEPSP amplitude 55±4% of baseline, $n=12$ slices, 4 mice), or in the presence of an antibody against TRKB (1 µg/ml) (mean fEPSP amplitude 63±5% of baseline, $n=7$, 3 mice), or with a selective PI3K inhibitor, LY294002 (10 nM) (mean fEPSP amplitude 58±5%, $n=7$ slices, 3 mice), suggesting that BDNF signalling may contribute T1AM-mediated neuroprotection. Interestingly, the putative T1AM precursor, triiodothyronine (T3), and its oxidative metabolite, the 3-iodothyroacetic acid (TA1), didn't possess the same neuroprotective ability. Therefore, our results demonstrate that T1AM can ameliorate ischemia-induced synaptic dysfunction in the mouse EC and suggest that T1AM neuroprotection is mediated by TAAR1 signalling.

Importance of maternal thyroid hormone for programming the cardiovascular system in the male offspring

Mehdi Pedaran, Rebecca Oelkrug & Jens Mittag
CBBM, Center of Brain, Behavior and Metabolism, Institute of Endocrinology and Diabetes/Molecular Endocrinology, Luebeck, Germany

Thyroid hormone (TH) plays an important role for brain development. As the fetal thyroid gland only starts providing hormone at the end of pregnancy, the developing brain crucially depends on maternal thyroid hormone in early developmental periods. In previous studies, we have observed that in particular the central control of cardiovascular functions critically depends on maternal thyroid hormone for proper development; however, the precise window when the hormone is beneficial has remained to be determined. To address this question, we used mice expressing a mutant thyroid hormone receptor α1 (TRα1+m), which exhibits a reduced sensitivity to the hormone. Under physiological conditions, this leads to a receptor-mediated hypothyroid phenotype; however, the receptor can be reactivated during any given time period by raising the circulating thyroid hormone levels pharmacologically. For this study, we mated male TRα1m mice with wildtype females and treated these dams either in the first or the second half of pregnancy with thyroid hormone. We then compared the resulting TRα1+m offspring, in which TRα1 signaling had be reactivated during these developmental windows, with the resulting wildtype mice that were overexposed as embryos to thyroid hormonespecifically in these periods and untreated control offspring of both genders. In our study, we found a significant decrease of heart weight in male TRα1+m independent of the treatment, suggesting that this phenotype is an acute and not a developmental action of the mutant TRα1. Most remarkably, we found a significant increase in heart rate in the wildtype male offspring that were exposed in the second half of the pregnancy to elevated thyroid hormone, underlining our previous findings that this period is absolutely crucial for the establishment of the central control of cardiovascular functions. Taken together our findings demonstrate that maternal thyroid hormone is of particular relevance for establishing the cardiovascular set points during the second half of pregnancy. The data therefore further advocate current initiatives to routinely monitor thyroid hormone levels during pregnancy to avoid adverse health effects in the offspring.

The natural history of benign thyroid nodules: 10 years follow-up

Valeria Ramundo[1], Giorgio Grani[1], Rocco Bruno[2], Giuseppe Costante[3], Domenico Meringolo[4], Efisio Puxeddu[5], Massimo Torlontano[6], Salvatore Tumino[7], Giuseppe Lucisano[8], Antonio Nicolucci[8], Sebastiano Filetti[1] & Cosimo Durante[1]
[1]Sapienza University of Rome, 1Department of Translational and Precision Medicine, Rome, Italy; [2]Ospedale di Tinchi Pisticci, Endocrinology, Matera, Italy; [3]Institut Jules Bordet Comprehensive Cancer Center, Bruxelles, Belgium; [4]Ospedale di Bentivoglio, Bologna, Italy; [5]Università di Perugia, Perugia, Italy; [6]Istituto di Ricovero e Cura a Carattere Scientifico, Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; [7]Università di Catania, Catania, Italy; [8]Coresearch, Pescara, Italy

Background and aim
The incidental detection of asymptomatic thyroid nodules (TNs) has increased over time. Over 90% of newly diagnosed TNs are either cytologically or sonographically benign. This study aimed to determine the frequency and magnitude of changes in TNs size over time.
Methods
We performed a prospective, multicenter, observational study involving consecutive euthyroid patients with 1–4 asymptomatic, sonographically or cytologically benign TNs. The study cohort was recruited between 2006 and 2008. A yearly neck ultrasound was performed. TNs growth, defined as the first occurrence of volume increase during the follow-up, was considered significant if an increase of ≥20% was recorded in at least 2 diameters, with a minimum increase of 2 mm. After 10 years of follow-up, data were analyzed.
Results
992 consecutive patients were enrolled, and 1567 TNs were evaluated. The median follow-up was 8 years (IQR 6.2–10 years). TNs growthoccurred in 356 patients (35.9%; 95% CI, 32.9–38.9). The median time to growth was 2 years (IQR 1–4 years). Stable nodules were reported in 578 patients (58.3%; 95% CI 55.2–61.3), while 58 patients had no growing TNs and/or at least a shrunk nodule (5.8%; 95% CI 4.4–7.3). New TNs ($n=456$) appeared in 205 patients (20.7%; 95% CI 18.1–23.2). 242 (24.4%) patients finished the 10-years follow-up. Among these, the final nodule volume did not show a significant difference compared to baseline. 148 out of 242 patients showed a linear increase in TNs volume, mainly evident after the 3-years follow-up. Baseline factors associated with nodule growth were the same identified during the already published first 5-year analysis (multiple nodules, larger nodule baseline volume, male sex, age <45 years). However, the evidence of growth during the first 2 years follow-up was the strongest predictor of future growth (HR 7.43; 95% CI 5.82–9.48; $P<0.0001$). Growing nodules had a median doubling time of 3 years, while the whole cohort had a median doubling time of 26.6 years.
Conclusions
A small fraction of nodules showed a significant size increase during 10 years of serial evaluation, and it is possible to predict their behavior with early (2 years) follow-up data. These findings allow us to estimate the interval of monitoring and support the view that patients with sonographically or cytologically benign TNs can be safely followed with less frequent examinations.

How will my life with Graves' disease be? Two years of serial, longitudinal follow-up of thyroid-related quality of life in patients with Graves' disease

Diana Grove-Laugesen[1], Per Karkov Cramon[2], Eva Ebbehoj[1], Klavs Würgler Hansen[3], Lars Rejnmark[1] & Torquil Watt[4]
[1]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark; [2]Copenhagen University Hospital, Department of Endocrinology, Copenhagen, Denmark; [3]Silkeborg Regional Hospital, Department of Internal Medicine, Silkeborg, Denmark; [4]Gentofte University Hospital, Department of Internal Medicine, Gentofte, Denmark

Objectives
Quality of life (QoL) is severely affected in Graves' disease (GD) but long-term longitudinal assessment of QoL is lacking. Furthermore, whether QoL is comparable to controls after treatment of GD is unclear. For the first time, we present serial, longitudinal data on thyroid-related QoL during 24 months of follow-up in a cohort of newly diagnosed GD patients. In addition, we compare QoL in GD and controls.
Methods
All patients were treated with anti-thyroid medication according to standard care. QoL was assessed on eight occasions using the highly validated, disease-specific ThyPRO-39 questionnaire (score 0–100, higher worse). Patients were excluded from analysis in case of relapse. A matched euthyroid control group ($n=55$) also completed ThyPRO-39. All patients were enrolled in the DAGMAR study (clinicaltrial.gov NCT02384668) a randomized double-blind trial on effects of vitamin D (70 mg/d) vs placebo on the clinical course of GD. Longitudinal data were analyzed in the entire cohort using linear mixed modeling with time, intervention group (vitamin D or placebo) and their interaction term. Changes in QoL-scores are reported as the main effect of time. A 'large' change has previously been defined as >16 points difference in score. The QoL scores of placebo treated GD and controls (one assessment) were compared using Wilcoxon ranksum test.
Results
Eighty-six hyperthyroid GD-patients (86% females, mean age 41 ± 14) were enrolled. Baseline QoL scores were 50 ± 19 and 47 ± 19 on the Hyperthyroid Symptoms and the Composite QoL Scales. Compared to baseline scores, 'large' improvements were observed at six weeks on Hyperthyroid Symptoms, Tiredness, Impaired Daily Life, Composite QoL and Emotional Susceptibility Scales, whereas Cognitive Complaints showed large improvement at six months. Significant improvements of QoL beyond six months were observed on the Hyperthyroid Symptoms, Tiredness, and Composite QoL Scales. Vitamin D supplementation did not improve QoL. Compared to the controls, the QoL scores among the GD patients remained significantly worse at every assessments for the Hyperthyroid Symptoms, Tiredness and Cognitive Complaints Scales. For the Impaired Daily Life and Emotional Susceptibility Scales, QoL scores remained worse until six months.
Conclusion
These novel data demonstrate that despite marked and early improvement of QoL with anti-thyroid treatment, QoL impairments in GD were prolonged, albeit improved beyond 6 months of treatment. Importantly, compared to controls GD patients have worse mental QoL for as long as 6 or even 24 months after diagnosis, despite being euthyroid and/or in remission.

Influence of care pathway on thyroid nodule surgery relevance

Solene Castellnou[1], Lifante Jean-Christophe[2,3], Stephanie Polazzi[3,4], Lea Pascal[4], Francoise Borson-Chazot[1,3] & Antoine Duclos[3,4]
[1]Hospices Civils de Lyon, groupement Hospitalier Est, Endocrinology department, Bron, France; [2]Hospices Civils de Lyon, Centre Hospitalier Lyon Sud, Endocrine Surgery department, Pierre-Bénite, France; [3]Université Claude Bernard Lyon 1, Health Services and Performance Research Lab (EA 7425 HESPER), Villeurbanne, France; [4]Hospices Civils de Lyon, Health Data Department, Lyon, France

Objective
Guidelines recommend using fine needle aspiration cytology (FNAC) to guide thyroid nodule surgical indication, however to what extent these guidelines are followed remains unclear. This study aimed to analyze the quality of the preoperative care pathway and the influence of the care pathway on surgical indications relevance.
Design
Nationwide historical cohort study based on data from a sample (1/97th) of French health insurance beneficiaries.
Methods
Evaluation of the care pathway of adult patients operated between 2012 and 2015 during the year preceding thyroid nodule surgery. Pathways containing a FNAC were called 'FNAC' or 'FNAC+ENDO' when including an endocrinology consultation; whereasthe no FNAC pathway was called 'NO FNAC'. The main outcome was the malignant nature of the nodule.
Results
Among the 1080 patients included in the study, 'FNAC+ENDO' was found in 197 (18.2%) patients, 'FNAC'in 207 (19.2%) and 'NO FNAC' in 676 (62.6%).A cancer diagnosis was recorded in 72 (36.5%) 'FNAC+ENDO' patients and 66 (31.9%) 'FNAC' patients, against 119 (17.6%) 'NO FNAC' patients. As compared to 'NO FNAC', 'FNAC+ENDO' care pathway was significantly associated with thyroid cancer diagnosis (OR 2.67; 95% CI 1.88–3.81; *P*-value <0.001) as was'FNAC' (OR 2.09; 95% CI 1.46–2.98; *P*-value <0.001). Surgeries performed in university hospitals were significantly associated with thyroid cancer diagnosis (OR 1.61; 95% CI 1.19–2.17; P-value = 0.002).
Conclusions
Guideline compliancewas insufficient but was associated with more relevant surgical indications. A trend towards improvement in compliance with guidelines was observed over the years.

The newly created NIFTP category (non-invasive follicular thyroid neoplasm with papillary-like nuclear features) has had a notorious impact in the management of thyroid neoplasms. Its incidence appears to be higher in western countries than Asiatic, but there are few studies including more than one institution.
Objectives
To evaluate retrospectively the incidence of NITFP in a multicentre study in two adjacent countries as well as to compare the results among institutions.
Methods
Sixteen institutions from Spain (15) and Portugal (1) took part in the study. Each of them made a retrospective review of its surgical cases of Follicular Variant of Papillary Thyroid Carcinoma (FVPTC) and Well-Differentiated Tumour of Uncertain Malignant Potential (WDT-UMP) from January 1st, 2005 to December 31th, 2015. The final pathology reports were reviewed and potential NIFTPs over 5 mm were retrieved for a pathological review.
Results
Among the 3185 cases with the diagnosis of papillary thyroid carcinoma (PTC) there were 900 (28.3%) of FVPTC added to 14 cases of WDT-UMP. After the review of the archived slides of the selected cases by the own pathologist in each centre, 175 were reclassified as NIFTP, 35 of them (20%) between 5 and 10 mm of size. They included seven of 14 WDT-UMP (50%) and 168 of 900 FVPTC (18.7%). The distribution by centre varied from 0% (no NIFTP among 16 FVPTC) in the centre with the lowest incidence, to 43.5% (10 NIFTP among 23 FVPTC) in the hospital with the highest incidence. The 3 institutions with more than 100 cases of FVPTC revised had an incidence from 15.9 to 25.4%. The most frequent cause of surgery was cytological or histological study with fine needle aspiration or core needle biopsy, including 58.3% of cases. Eight glands showed two foci of NIFTPs and two of them three foci. Mean size of the main focus of NIFTP was 21.8 mm (s.d.: 14.8).
Conclusion
In our geographic area, NIFTPs comprise 5.3% and 18.7% of cases previously classified as PTC and FVPTC respectively. We found that half of neoplasms named as WDT-UMP matched to NIFTP in its histological re-evaluation. The incidence of this diagnosis varies widely between hospitals separated by a few hundred kilometres. The cause of this difference remains elusive, and we propose that it could lie in the stringency of histological criteria for assigning a tumour as PTC when each pathologist evaluates nuclear changes.

Multiple endocrine neoplasia Type 1 (Men1) – genetic variants of Men1 gene in the czech population

Petra Lukasova[1], Miloslav kuklik[1], Marketa Vankova[1], Nela Vondrkova[1], Daniela Vejrazkova[1], Jitka Moravcova[1], Josef Vcelak[2] & Bela Bendlova[1]
[1]Institute of Endocrinology, Laboratory of Molecular Endocrinology, Prague, Czech Republic; [2]Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal dominant hereditary tumor syndrome. Common manifestations include more than 20 tumors of the parathyroid, pituitary and pancreatic glands and others non-endocrine tumors. The majority of patients carry a germline mutation in a tumor-suppressor gene *MEN1*, that encodes nuclear protein menin, ubiquitously expressed. So fare, more than 600 germline or somatic mutations have been reported over the entire coding region. Approximately 70% of mutations lead to premature truncation of menin (20% nonsense, 50% frame shift).
Subjects
In years 20015–2019 we have screened 72 basic patients with suspected MEN1 syndrome from the whole Czech republic and in positive findings we have examined their 20 direct relatives.
Methods
All 10 exons with introns flanking regions and 3´and 5´ UTR regions of *MEN1* gene were analyzed by next generation sequencing (NGS) using kit Nextera XT on Miseq (Illumina).
Results
Sexteen germline mutations were identified in 18 of 72 basic patients with suspected MEN1 syndrome and in 12 of their 20 relatives. Six of detected variants have not been described yet: S113Qfs3X, D123Mfs31X, L267R, G281W, c.1049+9G>C and E392Gfs17X. In silico analysis detected these variants as pathogenic or probably pathogenic. Ten variants were previously described in families with MEN1 syndrome or familial primary hyperparathyroidism: I85Sfs32X, I85Lfs32X, T210Sfs13X, S226X, Q258X, c.784–9G>A, N374Tfs3X, D418H, C421R and R516Pfs15X. Furthermore, we have identified 3 intron variants with uncertain significance (by in silico analysis): c.–55C>T (pathogenic moderate), c.913–142C>T (likely benign) and c.913–159G>A (possible effect on splice site). We could not assess their clinical impact.
Conclusion
We confirmed the diagnosis of MEN1 syndrome in 25% of suspected basic patients and in 60% of their direct relatives. 62.5% from detected variants leaded to truncated menin (50% frame shift and 12.5% nonsense mutations), 25% were missense variants and 12.5% of the variants affected splice site. As regards newly detected genetic variants, we continue to examine other members of families to confirm the clinical impact of the variants.

Targeting RAC1 signaling to potentiate the positive effect of MAPK pathway inhibition on radioiodine uptake

Márcia Faria[1,2,3], Rita Domingues[1,4], Maria João Bugalho[1,5], Paulo Matos[2,3] & Ana Luísa Silva[1,4]
[1]Serviço de Endocrinologia, Hospital de Santa Maria- CHULN. EPE, Lisboa, Portugal; [2]BioISI- Biosystems and Integrative Sciences Institute, Faculdade de Ciências da Universidade de Lisboa, Lisboa, Portugal; [3]Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisboa, Portugal; [4]ISAMB- Instituto de Saúde Ambiental, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal; [5]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Introduction
The Sodium Iodide Symporter (NIS) is responsible for active transport of iodide into thyroid follicular cells, enabling the use of radioactive iodine (RAI) for treatment of metastatic disease. Still, a significant proportion of patients with advanced forms of thyroid cancer (TC) became refractory to RAI therapy. Defective NIS expression is the main reason for impaired iodide uptake in TC and NIS downregulation has been associated with several pathways linked to malignant transformation. Activation of MAPK pathway has emerged as a key signaling implicated in thyroid tumorigenesis and NIS downregulation has been associated with the overactivation of this pathway. Consistently, several strategies aiming at inhibiting the MAPK-pathway have been developed with the goal of increasing the uptake of iodide in refractory tumors to allow treatment with RAI. Nevertheless, the use of MAPK-pathway inhibitors only partly restored NIS expression in several experimental

models. Thus, therapeutic strategies directed to additional targets implicated in NIS upregulation could provide an additional level of adjuvant therapeutic intervention to enhance RAI uptake and increase clinical effectiveness. We have recently shown that the small GTPase RAC1 has a positive impact on TSH-induced NIS expression and iodide uptake in thyroid cells.
Objective
We evaluated whether the recovery of NIS expression induced by inhibition of the MAPK pathway can be increased by potentiating RAC1 activity in thyroid cell systems.
Methods
NRASQ61R and BRAFV600E mutantswere ectopically expressed in the thyroid follicular cell lines PCCL3 and FRTL5 by lentiviral transduction. The papillary TC-derived BCPAP cell line, in which the MAPK-pathway is constitutively activated by the BRAFV600E mutation, was also used. Cell lines were transfected with GFP-empty vector or GFP-G12V RAC1 expressing constructs, in the presence or absence of the MEK inhibitor AZD-6244. The impact of AZD-6244 treatment and ectopic overexpression of the constitutively active G12V-RAC1 mutant on NIS transcript levels was addressed by RT-qPCR.
Results
Treatment of both PCCL3 and FRTL5 cell lines with AZD-6244 consistently increased NIS transcript levels, overcoming the negative effect on NIS induced by NRAQ61R and BRAFV600E overexpression. Interestingly, inhibition of RAC1 signaling was able to partially block the AZD-6244-mediated positive impact on NIS expression. A relevant increase in NIS levels was also observed following treatment of BCPAP cancer cells with AZD-6244. Notably, this increase was considerably improved by the presence of active RAC1.
Conclusions
Overall, our data support the potential of the stimulation of RAC1 activity in enhancing NIS expression in the thyroid context.

Differentiated thyroid carcinoma (DTC) is viewed as an indolent disease but 5–15% of patients (pts) become refractory to RAI treatment. This is associated with poor prognosis, a 3–6 years life expectancy and accounts for approximately 200 deaths per year in Canada. There is no universal definition of rDCT and management evolves over time, with either monitoring or systemic therapy including LEN. In the Select Study on LEN in DTC, LEN provided a 19.4 month (mo) median PFS (progression free survival) and an objective response rate of 60.2%; however, all ptsexperienced some toxicity. In Canada, a PSP was created to offer LEN to pts with rDTC prior to public funding. We report the prescription practices and treatment patterns of these pts. Between August 2015 and January 2019, 223 pts with rDTC started LEN as part of the PSP. Prescriber information, patient demographics, start and discontinuation dates, starting/modification doses and reasons for discontinuation were ascertained whenever possible and are described in the statistics. Kaplan-Meyer method was used to estimate persistency on LEN, defined as time from first prescription to discontinuation. Treating physicians were medical oncologists ($n=141$), endocrinologists ($n=21$) or other various disciplines ($n=55$). Two-hundred twenty-three rDTC pts were analyzed (42% female, mean age 63.4 years). Median study follow-up was 15.8 mo. Mean starting dose was 21.2 mg using 24 mg for 158 pts (66%), 20mg for 35 pts (15%) and lower for 47 pts. Median KM estimate of persistency on LEN was 15.8 mo and was similar for pts starting on full or reduced dose. Treatment persistency was similar between all provinces but there was a trend favouring prescribers with more than one patient in the PSP versus those with only one patient (18.0 vs 10.2 mo) and for pts treated by endocrinologists compared to other specialties (10.4 vs 6.0 mo). There was also a trend for longer persistency in pts who had dose modifications compared to pts treated with constant doses (19.0 mo vs 9.8 mo). LEN was discontinued in 112 patients (39 deaths from disease, 23 progressive disease/palliation, 15 for medical reasons other than toxicity [including decision to pursue alternative therapy], 21 undisclosed/other reasons and only 14 from toxicity). To date, this is the largest presented real-world analysis of the treatment patterns of LEN in pts with rDTC and our estimates of treatment duration as proxy for effectiveness are comparable to the phase 3 SELECT trial.

Introduction
Pre- and postsurgical differentiation between follicular thyroid adenoma (FTA) and follicular thyroid cancer (FTC) represents a significant diagnostic challenge. Typical markers of malignancy may appear as specific genetic alterations. Next-generation sequencing (NGS) studies bring information about single point mutations, however better insight into follicular thyroid lesions genetic landscape, encompassing bigger rearrangements, is needed.
Aim
The study aimed to compare FTA and FTC using the high-resolution single nucleotide polymorphism (SNP) array and identify recurrent regions of LOH (loss of heterozygosity), which may support preoperative differentiation and a better understanding of those entities.
Material and methods
We analyzed formalin-fixed paraffin-embedded (FFPE) samples acquired from 32 patients, Caucasians (median age at diagnosis: 58), diagnosed with follicular thyroid lesions: 16 diagnosed with FTA and 16 diagnosed with FTC. Both groups were adjusted for age and gender. Genomic DNA was isolated from dissected FFPE tissues using *QIAamp DNA FFPE Tissue Kit* (*Roche*). The *OncoScan* array (*Affymetrix*, *Thermo Fisher*) was used to determine structural rearrangements and LOH utilizing the SNP markers. The obtained data from genomic experiments was subjected for analysis using dedicated *OncoScan Console 1.3* and *ChAS v4* software and compared with clinical data.
Results
The most common LOH present in both FTA (63%) and FTC (69%) was 16p12.1p11.1 LOH (7.50 Mb in size) that encompasses *TP53G3* and its several alternative splicing transcripts (*TP53G3B*, *TP53G3C*, *TP53G3D*). The only LOH present exclusively in FTA patients (56% vs 0%) was 11p11.2p11.12 (5.40 Mb), including *KAI1*, a metastasis suppressor gene. Another LOH on chromosome 20 (q11.21-q11.23, 6.89 Mb) predominated also in FTA (31% vs 6%, $P=0.172$). The alteration which tended to be detected more often in FTC (38% vs 6%, $P=0.083$) was 12q24.11q24.13 (3.99 Mb) overlapping *FOXN4*, *MYL2*, *PTPN11*, *RASAL1*genes (with a suspected role in tumor progression). Another two LOH occurred with a similar frequency in both FTC and FTA (56% vs 44%, and 56% vs 31%): 3p21.31p21.1 (6.40 Mb) encompassing *SMARCC1*, *FBXW12*, *PARP3* and 15q15.1q21.1 (3.62 Mb) including *TYRO3*.
Conclusions
The results indicate that FTA and FTC may share a common genetic background, even though differentiating rearrangements may also be detected. 12q24.11q24.13 LOH may constitute a possible marker of malignancy as it includes genes directly associated with thyroid cancer pathogenesis. Genomic screening demonstrates the complexity of follicular thyroid lesions' genetic background and enables the identification of new genetic rearrangements contributing to FTC pathogenesis.

Changes in volume of the thyroid nodule with a previous benign cytological study according to the ultrasound patterns proposed by ATA 2015

José javier Pineda, Patricia Munarriz Alcuaz, Juan Manuel Zubiría, Marta Toni García, Ander Ernaga, maria dolores ollero garcia-aulló, Joaquin de Carlos, Javier García Torres & Emma Anda Apiñariz
Complejo Hospitalario de Navarra, Endocrinology, Pamplona, Spain

Objective
To understand the factors associated with changes in thyroid nodule volume with previous benign citology.
Material and methods
This is a prospective single-center observational study. We included patients with a benign citology from March/2016 to May/2018 and ultrasound follow-up after 12–24 months. Initially we determined the nodule size (volume in ml), and its risk of malignancy was classified according to ATA 2015 criteria. Volume changes were defined as following: decrease (decrease >20%), stability (between –20% and +20%), non-significant growth (increase between 20% and 50%) or significant growth (increase >50%). We defined the nodule growth rate as the time it takes for a nodule to double its inicial volume (volume doubling time, VDT), measured in months. Statistic analysis was performed with SPSS 20.0.
Results
There were included 200 thyroid nodules (186 patients) with a mean follow-up of 18.2±6.4 months. The mean age was 50.4±13.6 years; 27 (13.5%) were males; initial TSH was 1.6±1.3 mU/l; 54 (27%) had positive autoimmunity and 142 (71%) were multinodular. Mean characteristics of node size: larger diameter 28.8±11.5 mm; volume 8.6 ml (range 0.26–69.8). Risk of malignancy according to ATA criteria: 44 (22%) very low; 119 (59.5%) low; 16 (8%) intermediate; 3 (1.5%) high and 18 (9%) not classifiable. The distribution of the nodules by volume change was: 25 (12.5%) decreased; 94 (47%) remained stable; 53 (26.5%) presented non-significant growth and 28 (14%) showed significant growth.
None of the basal characteristics of the nodules (sex, age, TSH, autoimmunity, nodularity, volume or ATA criteria) was significant in association with significant growth. However, we observed that the very low risk nodules decreased in a greater proportion than the others ($P<0.001$). From among the nodules with any growth, only 14 (10.1%) had a VDT less than 24 months. Six malignant nodules (3.3%) were detected after follow-up. Four (66.6%) did not show significant growth. Their risk of malignancy according to ATA criteria were: 3 (2.5%) low risk; 2 (12.5%) intermediate risk; 1 (33.3%) high risk.
Conclusions
1) a low proportion of thyroid nodules show significant growth after follow-up; 2) none of the variables studied are able to predict the significant growth of the nodules; 3) The ATA criteria have been useful for detecting misdiagnosed malignancy in the initial assessment.

Tocilizumab for corticoid-resistant Graves' orbitopathy: A case report

Manuel Cayón-Blanco[1], Carolina García-Figueras-Mateos[2] & Juan Carlos Anglada-Pintado[2]
[1]Universitary Hospital Jerez de la Frontera, Endocrinology and Nutrition, Jerez de la Frontera, Spain; [2]Universitary Hospital Jerez de la Frontera, Internal Medicine, Jerez de la Frontera, Spain

Introduction
Graves' ophthalmopathy (GO) is an autoimmune disorder that constitutes a major clinical and therapeutic challenge. Current treatment options for moderate-to-severe GO include immunotherapy, orbital radiotherapy and decompression surgery. Limited drugs of proven efficacy are available for the treatment of people with GO. Given the role in the pathogenesis of GO of interleukin (IL)-6 expression in adipocytes, fibroblasts and macrophages, the proposed theory is that inhibition of IL-6 by tocilizumab may be an effective treatment in GO by directly reducing the inflammatory response. We report a case of severe GO treated with tocilizumab. Efficacy and safety of the therapy is discussed.
Case report
A 48-year-old woman, former smoker and diagnosed with Graves' hyperthyroidism was referred by Ophthalmology Department to Internal Medicine Unit because of corticoid-resistant GO. She had been diagnosed with hyperthyroidism ten years ago and undergone thyroid radio ablation therapy at the onset of her disease, reaching euthyroidism since then. At the time of our evaluation, the patient had no general symptoms of thyroid disease. A biochemical profile including thyroid hormones was also normal. She presented with bilateral eyelid swelling, orbital pain, redness and tearing. Her Clinical Activity Score (CAS) was 5 out of 7. She previously received bolus of methylprednisolone with a weak response. A magnetic resonance imaging orbits scan showed intense gadolinium-enhanced images and enlargement of the extraocular muscles, more prominent of the medial and lateral recti muscles in both orbits. The patient rejected radiotherapy. 'Off-label' authorization for the use of tocilizumab was asked to Pharmacy Commission of our centre. After its approbation, she received tocilizumab 8 mg/kg monthly. Three months later, the patient was well, no side effect was documented and her CAS was 1 out of 7.
Conclusions
This clinical report confirm the relative efficacy and tolerability profile of intravenous tocilizumab in severe or corticosteroid-resistant GO.

Dietary pattern and oxidative stress markers in hashimoto's thyroiditis

Rosaria Ruggeri, Salvo Giovinazzo, Giuseppe Giuffrida, Maria Teresa Vicchio, Maria Teresa Cristani, Angela Alibrandi, Alfredo Campenni & Francesco Trimarchi University of Messina

Objective
Oxidative stress has been implicated in the pathogenesis of several immune-mediated disorders, including autoimmune thyroid disease. Aim of our study was to investigate the relationship between dietary habit and redox homeostasis, in relationship with thyroid autoimmunity.
Materials and methods
We enrolled 200 healthy subjects (173 F, mean age 35±12). None of them was under any pharmacological treatment. Exclusion criteria: any infectious/inflammatory/autoimmune comorbidity, kidney failure, diabetes, cancer. In each subject, we measured; serum TSH, free thyroxine andanti-thyroid antibodies; plasma oxidative stress markers (Table 1). A validated questionnaire on dietary habits, evaluating the intake frequencies of food groups (meat, fish, cereals, fruits and vegetables, dairy products) was submitted to each participant.
Results
Among the 200 recruited subjects, 81 (71 F, mean age 38±11 yr) were diagnosed with euthyroid Hashimoto's thyroiditis (HT), the remaining 119 (102 F, mean age 33±12 yr) served as controls. In HT subjects, AGEs, markers of oxidative stress, were significantly higher ($P=0.0001$), and anti-oxidants GPX, TRX and TEAA lower ($P=0.02$, $P=0.02$, $P=0.002$, respectively) than controls, clearly indicating a condition of oxidative stress (Table 1). In questionnaires, HT subjects reported higher intake frequencies of animal foods (meat $P=0.0001$; fish, $P=0.002$; dairy products, $P=0.030$) compared to controls, that, in turn, reported higher intake frequencies of plant foods (legumes, $P=0.010$; fruits and vegetables, $P=0.030$). Stepwise regression models demonstrated a significant dependence of oxidative stress parameters from consumption of animal foods: meat dietary intake was associated with low levels of GPX ($P=0.048$) and TRX ($P=0.007$), and dairy products intake was associated to low levels of TEAA ($P=0.020$).
Conclusions
The present study provides further evidence that oxidative stress increases in euthyroid HT. Moreover, it suggests a positive influence of low intakes of animalfoods on the oxidative/antioxidative balance, and a potential protective effect of such dietary habit towards oxidative stress-related disorders.

Catch it if you know – A rare case of impaired TSH measurement

Katja Hoskin[1], Joel Capraro[1], Peter J Neyer[2] & Sebastian Rusch[2]
[1]Kantonsspital Aarau, Department of Endocrinology and Metabolism; [2]Kantonsspital Aarau, Institute of Laboratory Medicine

Introduction
Thyreotropin (TSH) is a glycoprotein containing an alpha-subunit similar to other glycoproteins (LH, FSH, ACTH, HCG) and a unique beta-subunit which reacts with the alpha-subunit in binding to the TSH-receptor. Low TSH levels are usually evidence of primary hyperthyreoidism as in Graves diseases/ toxic goiter or thyroiditis, or a result of secondary hypothyroidism in case of diseases of the pituitary gland. This case shows a rare variant causing apparently low TSH levels in a euthyroid patient due to altered immunoreactivity with the serum TSH measurement.
Case presentation
A 37-year old patient was referred to our clinic with subclinical hyperthyroidism and a discrepancy in TSH results from his general practitioner (Abbott assay at a contract). Clinically, there were no signs of hyperthyroidism. In the initial laboratory work-up he showed repeatedly low TSH (Siemens assay), negative Anti-TPO and TRAb. After excluding all primary and secondary causes we had the serum sample analyzed for TSH (Roche assay) in a third laboratory, using a different assay, resulting in slightly elevated levels. The following genetic test revealed a homozygous variant in the TSH-beta-subunit, 223A>G (*P*.Arg75Gly), leading to a reduced immunoreactivity with our TSH assay (Siemens Dimension Vista 1500 assay). This mutation was previously described to interfere with other detection assays. With worldwide only 5 cases of homozygous carriers and none in Europe, this sequence variant is very rare, according to genome databases.
Conclusion
This report shows a case of spuriously low TSH measurement in a euthyroid patient. An arginine to glycine substitution at amino acid position 75 in the TSH-beta-subunit reduced immunoreactivity ofthe Siemens Dimension Vista 1500 assay. Generally, state-of-the-art antibody based protein quantification assays offer high sensitivity and specificity; however, missense mutations (even if physiologically irrelevant) may result in falsely low values due to impeded antibody binding. Even if rare, it is important to question conflicting results, especially if they are not in agreement with the clinical findings, as otherwise they can lead to a false diagnosis and mistreatment of patients.

*These authors contributed equally.

Thyroid hormones (TH)shave as a major target the heart, where they regulate many different functions, including the modulation of the heart rate and myocyte contractility. Their effects on ventricular repolarization are controversial and QT prolongation was reported both in patients with hypothyroidism and hyperthyroidism, in their overt or subclinical forms. We analyzed the effects of 3.3′,5.5′-tetraiodo-L-Thyronine (T4), 3.3′,5-triiodo-L-Thyronine (T3) and of 3.3′,5′-triiodo-L-thyronine -reverse T3 (rT3) on Field Potential Duration (FPD), the *in vitro* analog of QT interval, and on induction of arrhythmiausing a human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) cell line, namely the human iCell Cardiomyocytes (Cellular Dynamics International, Inc. Madison, WI, USA, clone 01434)and the very sensitive Maestro Pro Multielectrode Array (MEA) platform (Axion Biosystem, Atlanta, GA, USA). Treatment with T3, at slightly supraphysiological doses (1 nM), induces a significant prolongation of the FPD while, at highly supraphysiological doses (up to 100 nM), T3 is able to induce arrhythmia in our cell system. The maximum effect on FPD was a 25% increase of the FPD, corrected by Fridericia (fFPDc), observed with T3 at the dose of 1 nM, while the major effect on induction of arrythmia was observed with the dose of 100 nM. T3 induces a clear dose-dependent prolongation effect on FPD and is responsible for a dose-dependent induction of arrhythmia. Both effectsare visible long time after exposure of cells to T3, up to 24 hours for the effect on FPD and up to 4 days for those on induction of arrhythmia, suggesting that both effects are mediated by genomic actions. To test this hypothesis, FPD prolongation and induction of arrhythmia were evaluated after preincubation with rT3, the specific antagonist of T3 at the thyroid hormone receptor (TR). Preincubation with rT3 significantly reduced both effects, indicating that interaction with TR is necessary for T3-induced FPD prolongation and arrhythmia. In conclusion, we demonstrated the direct impact of THs treatment on hiPSC-CMselectrophysiology and, in particular, on FPD duration and on the induction of arrhythmia. The present study gives useful insight on the mechanism of T3-induced arrhythmias and open the way to identify new potential diagnostic biomarkers and to develop specific targeted therapies.

Treating thyroid nodules by radiofrequency: The delivered energy should be correlated with the volume reduction rate

Maurilio Deandrea[1] & Pierpaolo Trimboli[2]
[1]Ospedale Mauriziano Umberto I, Endocrinology and Metabolism, Turin, Italy; [2]Ente Ospedaliero Cantonale, Bellinzona e Lugano, Clinica di Medicina Nucleare e Imaging Molecolare, Centro di Competenza Diagnosi e Terapia delle Malattie Tiroidee, Lugano, Switzerland

Context
Radiofrequency ablation (RFA) was proven as effective in reducing thyroid nodules' volume. However, whether technical procedure aspects could influence the volume reduction rate (VRR) has not been clarified.
Objective
To analyze the correlation of RFA power, duration and energy with VRR.
Design
Prospective study from June 2018 to December 2019.
Setting
Two primary-care centers using the same RFA procedure.
Patients or other participants
Adult outpatients undergoing a single-session RFA and 1-year post-treatment follow-up.
Intervention
RFA was performed by *moving-shot* technique with internally cooled 18-gauge electrode having a 10-mm active tip. Main outcome measures The VRR was calculated. Technical parameters were the following: median power (P_{median}), effective time of treatment (T_{eff}), energy calculated as $P_{median} \times T_{eff}$ (E_{calc}), and energy delivered per ml as Kcal × 4184 × nodule's volume (E_{del}). Continuous variables were analyzed by the Mann Whitney test. The correlation of the above parameters with VRR was analyzed by linear regression.
Results
Forty-one nodules were included and their VRR 66.6%. RFA was performed with a P_{median} of 55 watts, T_{eff} 10.24 min, E_{calc} 31380 Joules, E_{del} 1473 Joules/mL. E_{del} was significantly correlated with VRR ($P=0.014$) while P_{median}, T_{eff} and E_{calc} not. A strong correlation of E_{del} with VRR was found in nodules <10 ml ($P=0.001$) while no significant correlation was observed in nodules >10 ml.
Conclusions
This study showed that the energy delivered with RFA is the only technical parameter significantly correlated with the VRR of thyroid nodules.

Changes in morphology and gene expressions of neonatally X-irradiated thyroid gland in rats

Nariaki Fujimoto[1], Mutsumi Matsuu-Matsuyama[2] & Masahiro Nakashima[3]
[1]Hiroshima University, Endo Group, Department Disease Model, RIRBM, Hiroshima, Japan; [2]Nagasaki University, Tissue and Histopathology Section, ABDI, Nagasaki, Japan; [3]Nagasaki University, Department Tumor and Diagnostic Pathology, ABDI, Nagasaki, Japan

Purpose
Exposure to ionizing radiation in childhood has been recognized as a risk factor for the development of thyroid cancer and possibly for other thyroid disorders. However, the effects of neonatal radiation exposure on thyroid

functions have never been explored experimentally despite its potential importance. We have demonstrated that neonatal rat thyroid was sensitive to ionizing radiation, developing specific morphological changes characterized by smaller thyroid follicles. In the present study, we examined the effects on the gene expression potentially related to thyroid carcinogenesis in this model.
Materials and methods
One-week-old male Wistar rats were exposed to cervical X-irradiation at 6 and 12 Gy. For comparison, 8-week-old (adult) rats were cervically X-irradiated at the same doses. Apoptosis in the thyroid follicles was evaluated by the TUNEL staining. Expressions of the gene, including Mct8, Lat4, Braf1, Oct3, CD44, and Abcg2, were measured in the thyroid by the quantitative RT-PCR method.
Results
In rats that received cervical X-irradiation at 1 week old, the colloid size of thyroid follicles decreased at 8 weeks old and afterward. The number of apoptotic cells in the thyroid follicles was increased corresponding to the reduction in follicular size. Significant increases in Braf1, CD44, and Abcg2 mRNAs were noted in neonatally irradiated thyroid at 8 weeks old, while CD44 and Abcg2 expressions were still high at 16 weeks old.
Conclusion
Our results demonstrated that neonatal rat thyroid was sensitive to ionizing radiation, developing specific morphological changes that may be caused by the increase in apoptosis. Persistent elevation of CD44 and Abcg2 expressions in the thyroid after neonatal irradiation may play a role in thyroid cancer development in childhood.

Treatment of hyperthyroidism reduces the systemic oxidative stress load, as measured by biomarkers of RNA and DNA damages

Camilla Larsen[1], Kamilla Ryom Riis[1], Kristian Hillert Winter[2], Emil List Larsen[3], Christina Ellervik[4], Laszlo Hegedüs[1], Thomas Brix[1], Henrik Enghusen Poulsen[3] & Steen Joop Bonnema[1]
[1]Department of Endocrinology, Odense University Hospital, Denmark; [2]Department of Endocrinology and Metabolism, Karolinska University Hospital, Sweden; [3]Department of Clinical Pharmacology, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark; [4]Dep. og Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Background
Increased oxidative stress has been linked to both hypo- and hyperthyroidism. Whole-body oxidative stress can be estimated by the oxidized guanine nucleosides, 8-oxo-7.8-dihydroguanosine (8-oxoGuo) and 8-oxo-7.8-dihydro-2'-deoxyguanosine (8-oxodG), derived from RNA and DNA, respectively. These biomarkers have been associated with increased morbidity and mortality in several diseases but are not well explored in humans with thyroid disorders.
Methods
We measured urinary excretion of 8-oxoGuo and 8-oxodG in 51 hyperthyroid patients (toxic nodular goiter (TNG), $n=30$; Graves' disease (GD), $n=21$) before, or shortly after, initiation of therapy and when stable euthyroidism had been achieved for at least 12 months. Patients with TNG were older (mean: 59 ± 12 s.d. years) than those with GD (50 ± 8 years). Mean follow-up time was 17.2 ± 4.6 and 22.9 ± 8.9 months for TNG and GD, respectively. All patients with TNG were treated with radioiodine, except for one who underwent thyroidectomy. GD patients were treated with methimazole andtwo of whom also received radioiodine.
Results
Both oxidative stress markers correlated positively with age (8-oxoGuo: $P<0.001$; 8-oxodG: $P=0.003$). After adjustment, the baseline urinary excretions correlated with the severity of the disease, reflected by the plasma levels ofthyroxine (8-oxoGuo: $P=0.002$; 8-oxodG: $P=0.021$), and were significantly higher in GD than in TNG ($P=0.001$ for both biomarkers). Treatment significantly affected the excretions of the oxidative stress markers. In TNG, 8-oxoGuo decreased from geometric mean (GM) 2.11 nmol/mmol (95% CI : 1.85–2.39) to 1.91 nmol/mmol (95% CI : 1.67–2.19), $P=0.001$, while 8-oxodG decreased from 1.65 nmol/mmol (95% CI : 1.41–1.93) to 1.48 nmol/mmol (95% CI : 1.27–1.74), $P=0.026$. In GD, 8-oxoGuo decreased from 2.25 nmol/mmol (95% CI : 1.95–2.59) to 1.79 nmol/mmol (95% CI : 1.63–1.97), $P=0.0003$, while 8-oxodG decreased from 2.02 nmol/mmol (95% CI : 1.73–2.38) to 1.54 nmol/mmol (95% CI : 1.63–1.97), $P=0.001$. When euthyroid, no between-group differences were found.
Conclusion
Treatment of hyperthyroidism significantly decreased the systemic oxidative stress load by 10–25%, as measured by the urinary excretion of nucleic acid metabolites. The higher values in patients with GD could be due to the more severe hyperthyroidism seen in this condition. Our findings may signify a key factor, explaining the higher morbidity and mortality linked to patients with hyperthyroid diseases, as shown in observational studies.

Diffuse Large B-cell Lymphoma of thyroid gland in an Adolescent girl with Hashimoto's thyroiditis

Mara Xatzipsalti[1], Evangelos Bourousis[1], Maria Nikita[2], Myrsini Gkeli[3], Evgenia Magkou[2], Smaragda Papachristidou[2], Dimitra Rontogianni[4], Dimitris Delis[1], Margarita Baka[2] & Andriani Vazeou[1]
[1]Children's Hospital 'P. & A. Kyriakou', Diabetes Centre, A' Department of Pediatrics, Athina, Greece; [2]Children's Hospital 'P. & A. Kyriakou', Oncology Department, Athina, Greece; [3]'Agios Savvas' – Anticancer Hospital, Department of Radiology, Athina, Greece; [4]Evaggelismos General Hospital, Department of Histopathology and Molecular Pathology, Athina, Greece

Background
Cancer of thyroid gland is rare in childhood, representing 1% of all pediatric malignancies. Primary thyroid lymphoma (PTL) is even rarer accounting for 5% of thyroid malignancies and 2% of extranodal lymphomas. The disease affects mainly adults in thesixth orseventh decade of life, with a female predominance. Most thyroid lymphomas are non-Hodgkin's lymphomas (nHL) of B-cell origin. The most common type is Diffuse Large B- cell Lymphoma (DLBCL). Patients with Hashimoto's thyroiditis (HT) are at greater risk for developing PTL.
Objectives and methods
We describe the case of DLBCL of thyroid in an adolescent girl with a history of HT. To our best of our knowledge, DLBCL in a young child has not been reported in the medical literature.
Results
A 12 -years- old girl with known HT for the last 9 years admitted to our department with a right sided painless progressive swelling of the neck. The physical and ultrasound examination revealed an enlarged thyroid gland and right lymphadenopathy. Full blood count, renal, liver and thyroid function tests were normal while anti-thyroglobulin and thyroid peroxidase antibodies were positive. She has been receiving treatment with levothyroxine since the age of 3. Two FNAs were performed showing suspected lymphoblastic lesions for nHL without precise diagnosis. A neck CT scan revealed a nodular alteration max diameter $2.95 \times 3.9 \times 5.2$ cm of the right thyroid gland and multiple lymph nodes in the neck highly suspicious of the above diagnosis. PET/CT scan confirmed these findings with SUV max = 16.5 and 2.5 in the right thyroid gland and lymph nodes respectively. Ultra-sound guided core needle biopsy was finally performed confirming the diagnosis of DLBCL. CSF analysis showed no tumor cells and the bone marrow aspiration was negative. She was treated according to LMB 2000 – group B protocol with one course COP, two courses COPADM and two courses CYM chemotherapy with no surgical removal of thyroid. The patient had a good response to the treatment with a rapid decrease in the size of the thyroid mass. She is well in herself 8 months post initial diagnosis.
Conclusion
PTLis a rare cause of thyroid malignancy and extranodal lymphomas. However, it should be considered at differential diagnosis of a thyroid mass in patients presenting with a rapidly enlarging neck mass and a history of HT. It is a treatable condition with an excellent prognosis even with the aggressive histological subtypes with no need of thyroidectomy.

Breast cancer metastasis to the thyroid gland – A case report

Aikaterini Michou, Ioannis Kakoulidis, Ioannis Ilias, Evangelia Venaki & Eftychia Koukkou
El Venizelou Hospital, Department of Endocrinology, Diabetes & Metabolism, Athens, Greece

Introduction
Metastases to the thyroid are rare (1.4–3% of malignant solid tumors). When present, metastatic cancers mimic the ultrasound image of the thyroid parenchyma, hindering diagnosis. Breast cancer rarely metastasizes to the thyroid.
Case
A 61-year-old woman was referred for goiterin the context of post-surgery evaluation for breast cancer. Thyrotropin (1.14 mIU/l), calcitonin (0.5 pg/ml) and parathyroidhormone (54 pg/ml) levels were normal. Thyroid ultrasound (US) showed a multinodular goiter with maximum nodule size of 4.2 cm at the left thyroid lobe (isoechoic with cystic degeneration areas, with few coarse calcifications and poor peripheral vascularization), scattered smaller hypoechoic nodules up to 4 mm in both lobes and few colloid cystsup to 7 mm, without abnormal lymph nodes. An US-guided FNA was performed at the largest left thyroid lobe nodule, showing benign nodular hyperplasia (Bethesda II). The patient was monitored by US and thyroid hormone testing. Elevated tumormarkers (Ca15–3) led to 18-FDG PET-CT scanning, following oncology consultation. Abnormal uptake (SUV max: 3.7) was noted in the area corresponding to the largest noduleat the left thyroid lobe. Total thyroidectomy was recommended (1.5 years after initial FNA). Histopathological examination revealed the presence of neoplastic infiltration in off-white areas of the right lower lobe of solid carcinoma with morphological and immunophenotypic characteristics compatible with breast tissue origin [CK8–18(+), CK19(+), GATA-3(+), ER(+ >80%), PGR(–), TTF-1(–), Thyroglobulin(–), p40(–), HBME-1(–), Galectin-3(–), S-100(–), Calcitonin(-), Ki67~30%].
Conclusion
In this patient, although FNA had been performed in the larger nodule that had the most suspicious featuresfor possible malignancy, it was considered that the increase in tumor markers and concomitant abnormal uptake in 18-FDG PET-CT increased the likelihood of cancer metastasis. However, histopathology after thyroidectomy revealed breast tissue metastasis in off-white areas at the right lower lobe where ultrasound had noted small hypoechoic nodules and colloid cysts. Although thyroid metastases are not very common, caution should be given especially when thyroid parenchyma lesions coexist with a recent history of malignancy.

Clinical case of autoimmune encephalopathy (Hashimoto) with a psycho-organic syndrome on the background of autoimmune thyroiditis

Mariya Rusalenko[1], Svetlana Marchenko[2], Evgeniy Pispanen[2], Svetlana Tsukanova[3] & Sergey Hadanovic[4]
[1]Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus; [2]Republican Research Center for Radiation Medicine and Human Ecology, Anestesiology, Gomel, Belarus; [3]Republican Research Center for Radiation Medicine and Human Ecology, neurology, Gomel, Belarus; [4]Republican Research Center for Radiation Medicine and Human Ecology, Transfusiology, Gomel, Belarus

Introduction
Hashimoto's Encephalopathy (HE) is an autoimmune inflammatory disease of the brain associated with the production of antithyroid antibodies.
Objective
A clinical case of treatment of severe autoimmune encephalopathy in combination with autoimmune thyroiditis and thyrotoxicosis is presented.
Results
A 59-year-old woman was transferred to the intensive care unit diagnosed with thyrotoxic crisis. Objectively: serious condition, inhibited, disoriented to personality, time and place, inadequate, productive contact is difficult, psychomotor agitation. Asymmetry of the nasolabial triangle. Swallowing is not impaired, movements in the limbs within normal. Normothermy. Heart rate 102 per minute, blood pressure 150/95 mmHg. From the anamnesis, about 5 years of thyrotoxicosis, takes thyreostatics, 3 years ago a similar episode of psycho-productive symptoms occurred, the patient was diagnosed with: 'Pseudodementia Syndrome'; mental status returned to normal without treatment. MRI of the brain: without pathology; in cerebrospinal fluid: protein 3.5 g/l, cytosis 2/3. In the blood and cerebrospinal fluid there is no DNA of herpes simplex virus, cytomegalovirus, Epstein-Barr virus. Procalcitonin and C-reactive protein are normal. Leukocytosis 10.7×10^9/l, urea 10.3 mmol/l, sodium 150 mmol/l, FT4 26.6, TSH 0.07, antibodies to TPO more than 1000. The conclusion of the council of doctors – autoimmune encephalopathy is possible, course of therapeutic plasmapheresis (No. 3) was prescribed in combination with pulse therapy with methylprednisolone (No. 5 of 1000 mg), followed by oral administration, a gradual dose reduction until complete cancellation. By the 7th day, the patient's state with pronounced positive dynamics, in consciousness, adequate, oriented to personality, time and place, some emotional lability and partial amnesia. By laboratory methods- transient hyperglycemia and protein-cell dissociation in cerebrospinal fluid. After 3 months, upon reaching the euthyroid state while taking thyreostatics, the patient underwent total thyroidectomy – without complications. Over the next 2 years, episodes of delirium and severe cognitive impairment were not observed.
Conclusion
It is necessary to consider each case of pronounced cognitive impairment with stroke-like symptoms in the prism of Hashimoto's encephalopathy, which requires timely and special treatment.

Influence of Sodium Iodide symporter expression level on recurrence rate in differentiated thyroid cancer

Uliana Farafonova[1], Marina Boriskova[1], Polina Pankova[1] & Ludmila Koloskova[2]
[1]Pavlov First medical university, endocrine surgery department, Russian Federation; [2]MedLab, Laboratory department, Sainkt-Petersburg,

The ability of thyroid cell to accumulate iodine is due to presence of sodium iodide symporter (NIS). Differentiated thyroid cancer (DTC) maintain ability to express NIS and thus it makes possible to perform RAI treatment. In case of DTC cells loss the ability of NIS protein production and cell membrane embedding that leads to RAI treatment fail.
The aim of our study was to find a relationship between the level of preoperatively defined NIS and recurrences-free survival after RAI in DTC patients.
Materials and methods
Our study included 205 patients with highly differentiated thyroid cancer. In all patients the level of NIS expression was detected by flow fluorocytometry method in a fine-needle biopsy material. The criteria for inclusion in the study were RAI therapy in the postoperative period, the ability to follow up the patient in the postoperative period up to 60 months. All patients were operated.
Results
RAI therapy was performed in 130 patientsin the postoperative period. Recurrence was detected in 50 patientsin the follow-up period of 60 months. Total thyroidectomy (TT) with central lymph node dissection (CLD) was performed in 72.5% (58/80) of cases in the group without recurrence, compared with the group of patients with detected recurrence, where this operation was performed only in 24% (12/50) of cases. Lateral neck compartment cervical lymph node dissection was performed in 40% of patients in the group with developed recurrence of the disease and in 17.5% of patients without recurrence of the disease. The liner discriminant analysis (LDA) revealed the level of NIS expression less than 1% significantly correlate with the risk of recurrence ($P=0.000037$). In the group of patients with recurrence, the level of NIS expression less than 1% was detected in 31 patients (62%), while in the group without recurrence only in 17 (21.2%).Thus, the recurrence-free survival after RAI is significantly lower in patients with NIS expression less than 1% in primary tumor compared to patients with NIS expression level more than 1%. TT with CLD was performed in all patients with low NIS expression in the group without disease recurrence and decrease in the number of recurrences is possibly associated with the volume of surgical treatment.
Conclusions
The level of NIS expression can be used as a prognostic marker of disease recurrence, particular after RAI. The level of NIS expression less than 1% in the primary tumor is suspicious of RAI-refractory DTC.

Clinical practice survey on BRAF V600E role in the therapeutic decision in indeterminate thyroid cytology

Giulia Brigante[1,2], Andrea Craparo[1,2], Elisa Pignatti[3], Marco Marino[3], Livio Casarini[1], Samantha Sperduti[1], Gisella Boselli[1,2], Gianluca Margiotta[1,2], Vincenzo Rochira[1,2] & Manuela Simoni[1,2]
[1]University of Modena and Reggio Emilia, Department Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda Ospedaliero-Universitaria di Modena, Department of Medical Specialties, Modena, Italy; [3]University of Modena and Reggio Emilia, Modena, Italy

Introduction
The use of multigene panels in thyroid nodule diagnosis is still limited, due to high costs and need for *ad hoc* sampling. Since *BRAF-V600E* is the commonest genetic alteration in differentiated thyroid cancer, this is the mostly tested genetic parameter in clinical practice.
Aim
To evaluate the use of *BRAF* mutation analysis in wash-out liquid from fine needle aspiration (FNA) in clinical practice, characterizing the cases in which it is requested, and the consequences of genetic test result on therapeutic decisions.
Methods
We considered all the subjects tested for *BRAF-V600E* among those attending the Endocrinology Unit of Modena for FNA between January 2014 and November 2018. After written informed consent, washing fluid was collected together with cytological sample and stored at –20°C. If the clinician deemed it necessary, the sample was thawed, DNA was extracted and genetic test was performed by the high-resolution melting protocol previously described[1]. We collected cytology of nodules according to the 2010 *SIAPEC-IAP* Italian Consensus, and when surgical treatment was performed, histology.
Results
Out of a total of 7112 subjects submitted to FNA, *BRAF* analysis was requested for 681 (9.6%), for a total of 898 nodules: 97% of nodules were indeterminate at cytology, mainly TIR3A (low risk); 2% suspicious or diagnostic for cancer, and genetic test was requested to estimate prognosis; 1% were suspect nodules at ultrasonography with unsuspicious cytology. Only 22 nodules were mutant (*BRAF*+).Most of them were already high risk or suspicious lesions at cytology (64%). One third were TIR3A. Considering the prevalence of *BRAF* mutation among cytological classes of the whole group, only 1% of TIR3A were *BRAF*+. Twenty *BRAF*+ patients were addressed to surgery (one lost at follow-up, one refused): 5% underwent hemithyroidectomy, 25% total thyroidectomy and 70% total thyroidectomy plus central lymph nodes dissection. They all had papillary thyroid cancer. Since 64% of *BRAF*+ were TIR3B-4-5 at cytology, they had surgical indication even before the genetic test. Among the 14 subjects treated with central neck dissection, only 2 had suspect metastasis before surgery; among those who would have had no indication, one third had metastases (only 1 among TIR3A and 2 among TIR3B).
Conclusions
Despite the development of panels, single gene tests are still requested, mainly for nodules with indeterminate low risk cytology. *BRAF* mutation in TIR3A is rare and leads clinicians to more invasive surgery, with questionable clinical utility.

The diagnostic value of basal and calcium-stimulated procalcitonin for the diagnosis of medullary thyroid cancer: Preliminary results from a multicentric experience

Simona Censi[1], Marta Di Stefano[2], Andrea Repaci[3], Jacopo Manso[1], Uberto Pagotto[3], Loris Bertazza[1], Susi Barollo[1], Mario Plebani[4], Carla Colombo[2], Laura Fugazzola[2] & Caterina Mian[1]
[1]University of Paduva, Endocrinology Unit, Department of Medicine (DIMED), Padua, Italy; [2]Division of Endocrine and Metabolic Diseases, IRCCS Istituto Auxologico Italiano, Milan, Italy; [3]Alma Mater Studiorum – University of Bologna, Endocrinology Unit and Centre for Applied Biomedical Research, Department of Medical and Surgical Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy; [4]University of Padua, Department of Laboratory Medicine, Padua, Italy

Background
Calcitonin (CT) is the most sensitive marker for MTC diagnosis. By the way, many pre-analytical, analytical and post-analytical pitfalls worsen its accuracy. Procalcitonin (proCT), a CT precursor, has been suggested as a valuable complementary test in MTC diagnosis, given its stability and the reproducibility between different assay kits.
Material and methods
basal CT (bCT) and proCT (bproCT) and stimulated CT (bCT) and proCT (sproCT) (2–5–10 and 20 minutes)were measured in 37 patients (14M, 23F; median age: 55 years, range: 5–77 years) that underwent surgical excision. At the histological report, 22 were MTC, while the others were C-cell hyperplasias (HCCs) or non-C-cell lesions. 17/37 (45.9%) were carriers of a *RET* mutation. Calcium gluconate at the dose of 25 mg/Kg based on adjusted body weight was administered. bproCT was considered positive when ≥0.04 mg/l, while CT when ≥10 ng/l.
Results
there was a correlation between bCT and bproCT ($P<0.0001$, $r=0.75$). A significant correlation was found between MTC tumor size and bproCT ($P=0.0062$, $r=0.58$), as well as with bCT ($P=0.01$, $r=0.54$).Positive bproCT showed higher specificity than positive bCT in the diagnosis of MTC with respect to non MTC lesions (CCHs or other lesions) (53% vs 40%), with higher positive predictive value (PPV) (70% vs 66.6%). The combination of elevated bCT and bproCT increased the specificity of bCT value from 40% to 67% and its PPV from 67% to 75%. bCT and bproCT showed the same accuracy in *RET*-wild-type (*RET*wt) and *RET*-mutated patients. Applying ROC curve, we could identify a cut-off of 0.07 mg/l for bproCT, able to identify a MTC (sensitivity=68%, specificity=87%, AUC=0.764, $P=0.0009$), regardless of the gender. There was a correlation between sCT and sproCT ($P<0.0001$, $r=0.64$). A positive correlation existed between MTC tumor size and sproCT ($P=0.0018$, $r=0.64$) and with sCT ($P=0.0001$, $r=0.75$). Higher values of median proCT increase were found in MTC versus non-MTC (median increase of 0.22 mg/l in MTC versus 0.02 mg/l in non-MTC, $P=0.0003$). Applying the ROC curve, a sproCT value>0.19 was able to identify an MTC (sensitivity=72%, specificity=93%, AUC: 0.806, $P<0.001$), regardless of the gender. Combining bproCT and sproCT specificity for MTC increased up to 93% (94% VPP).
Conclusions
proCT calcium-stimulated levels are significantly higher in MTC than in non-MTC and are correlate with tumour size. Basal and stimulated proCT can be used in combination with bCT and sCT to increase its specificity in biochemical diagnosis of MTC.

***In vitro* modeling of thyroid cancer cells and fibroblasts interplay**

Elisa Stellaria Grassi[1], Viola Ghiandai[2], Gabriele Pogliaghi[3], Laura Fugazzola[3,4,5] & Luca Persani[1,3,5]
[1]University of Milan, Clinical Sciences and Community Health, Milan, Italy; [2]University of Milan, Medical Biotechnology and Translational Medicine, Milan, Italy; [3]IRCCS Istituto Auxologico Italiano, Endocrine and Metabolic diseases Research Laboratory, Cusano Milanino, Italy; [4]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [5]IRCCS Istituto Auxologico Italiano, Department of Endocrine and Metabolic Diseases, Milan, Italy

Thyroid cancer (TC) is the most common endocrine tumor and its incidence has increased faster than in any other malignancy. Although TCs are usually well differentiated, disease recurrence or persistence is high, because of local and distant metastasis and therapeutic resistance. Among the different genetic alterations, BRAFV600E is the most frequent one. Several studies tried to establish a correlation between BRAFV600E and patients outcome, with controversial results. Nevertheless, the activation of different BRAF downstream pathways influences immune response, matrix remodeling and intra- and extra-cellular pH. All these alterations substantially modify tumor microenvironment and may enhance the survival of cancer-initiating cells and promote therapy resistance. The aim of the study is to investigate the role of BRAF in cancer-associated fibroblast matrix deposition and remodeling in *in vitro* 2D and 3D systems obtained from immortalized and patients-derived cells. In particular, the use of conditioned media and co-cultures of TC cells with different genetic background and fibroblasts is used to generate different extracellular matrices (ECM). The ECM themselves and their effects on cell growth and survival is then analyzed by different techniques, such as western blot, immunofluorescence, real-time PCR, colony assay, sphere formation assays and proliferation assays. Our results show that TC cells with BRAFV600E mutation can significantly increase the proliferation and activation of fibroblasts in respect with BRAF WT TC cells and normal thyrocytes; fibroblasts that have been conditioned with BRAFV600E TC cells can produce an ECM that is thicker and has a different fiber pattern than the one produced from fibroblasts conditioned with BRAF WT TC cells and normal thyrocytes. Moreover, the different matrices differentially influence the survival of BRAF mutated and WT TC cells. As second step, we are currently evaluating the effects of different drugs that acts against BRAF downstream effectors involved in matrix remodeling and metabolism alterations. In conclusion, our *in vitro* model can partially recapitulate the complex environment of human tumors and can be a useful tool for the screening of different anticancer drugs.

Description of thyroid alterations in oncological patients treated with immune checkpoint inhibitors: Experience of a tertiary hospital

Lourdes García-Blasco[1], Cortes Jimenez-Martinez[1], Blanca Riesco-Montes[2] & Ana Soler[2]
[1]Hospital General Universitario de Albacete, Endocrinology, Spain; [2]Hospital General Universitario de Albacete, Medical Oncology, Spain

Introduction
There has been an increase in the use of new drugs called immune checkpoint inhibitors (ICPI) used in advanced tumors. Clinical trials have also reported an increased risk of developing immune-related adverse events (IRAEs). Endocrine IRAEs may be particularly relevant.
Material and methods
This is a retrospective study. Patients treated with ICPI were obtained from Medical Oncology departament of the General University Hospital of Albacete from January 2016 to January 2019. We studied demographic and data related to the tumor, ICPI used, the appearance of thyroid function changes during treatment with the drug, as well as number of cycles received and time elapsed until endocrinopathy. The objective of our study was to analyze the appearance of endocrinopathies and the time that elapses until their appearance.
Results
Our sample size was 107 patients: 75 were treated with nivolumab, 19 with pembrolizumab, 8 with atezolizumab and 5 with ipilimumab. 31% were women and 69% men. The average age at diagnosis was 60 years old. The most frequent location of the primary tumor was the lung. Alteration of thyroid function was observed in 24 patients (22%) treated with ICPI. The most frequent thyroid disorder was subclinical hypothyroidism in 11 cases (46%), followed by primary hypothyroidism in 7 patients (29%) and, finally, silent thyroiditis in 6 of them (25%). The average number of cycles received until developing endocrinopathy was 6 and the time elapsed 12.4 weeks.
Conclusions
Thyroid disorders are usual in cancer patients treated with ICPI. The most frequent thyroid disorder is subclinical hypothyroidism. It is advisable to monitor thyroid function in patients treated with these drugs.

Multiple thyroid gland ectopia in a patient with hypopituitarism

Boyan Nonchev[1,2] & Antoaneta Argatska[1,2]
[1]University Hospital „Sv. Georgi' Plovdiv, Clinic of Endocrinology and metabolic diseases, Plovdiv, Bulgaria; [2]Medical University of Plovdiv, Section of Endocrinology, Second Department of Internal Diseases, Faculty of Medicine, Plovdiv, Bulgaria

Introduction
Ectopic thyroid tissue is a rare developmental abnormality resulting from aberrant embryogenesis of the thyroid gland during its passage from the floor of the primitive foregut to its final pre-tracheal position. It may be the only functional thyroid tissue or may co-exist with normally located thyroid. Most of the cases are asymptomatic but symptoms related to location, size or function may occur. Possible malignancy potential has also been discussed.
Case report
The patient is a 52-year old women with nanism who was admitted to endocrinology department in November 2014. According to her past medical record at the age of 12 she was diagnosed with hypopituitarism (GH deficiency and hypogonadism) and hypothyroidism due to growth retardation, lack of pubertal development and marked delay in bone maturation. Treatment with Sotropin H and thyroidea siccata was started and continued until the age of 18 when final height of 130 cm was achieved. She had also been found to have microspherocytic hemolytic anemia and right renal hypoplasia since early childhood. On admission to our department she was in a good physical condition, family history was unremarkable but mild intellectual disability was observed. Laboratory tests found clinical hypothyroidism with TSH level of 17.8 mIU/l (0.34–5.60), FT4 was 9.7 pmol/l (7.86–14.40) without thyroid autoantibodies. The ultrasonography of the neck showed no thyroid tissue in the front pretracheal area. Two round-shaped soft tissue masses in the right and left submandibular area were seen. Subsequent technetium 99^{m} pertechnetate scan revealed three foci of tracer concentration in the left submandibular area with no activity at the usual site of the thyroid gland. A MRI of the head and neck showed multiple thyroid ectopy – below the hard palate, at the base of the tongue and just below the hyoid bone. Thyroid functional tests performed two weeks afterwards showed significant elevation of TSH up to 31.95 mIU/l and levothyroxine treatment was initiated.
Conclusion
Review of literature reveals only few cases of multiple thyroid ectopia reported so far. Although the molecular mechanisms involved in thyroid dysgenesis are not fully known, studies have shown that mutations in regulatory genes expressed in the developing thyroid could be responsible for the abnormal thyroid migration as well as congenital abnormalities in other organs as seen in our patient.

Clinical severity score (CSS) and graves' recurrent events after therapy (GREAT) score could predict radioiodine efficacy for treatment of Graves' disease relapse

Andrea Repaci, Michelle Beleffi, Nicola Salituro, Alessandra Colapinto, Valentina Vicennati, Carla Pelusi, Paola Altieri, Alessandra Gambineri, Guido Di Dalmazi & Uberto Pagotto
U.O.C. Endocrinology and Prevention and Care of Diabetes Unit, S.Orsola Policlinic, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy

Background
Antithyroid drugs (ATDs) are the first line treatment for Graves' disease in Europe and Asia. However, their long term-efficacy is doubtful, with a high disease relapse rate after discontinuation. Radioiodine and surgery can be used as a second line therapy as definitive approaches after ATDs failure. In recent years, the GREAT and the CSS scores have been suggested to assess the risk of relapse at the time of disease onset, but no data are available about their ability to predict radioiodine treatment efficacy
Objective
To assess whether the GREAT and the CSS scores are able to predict radioiodine therapy efficacy.
Materials and methods
Our retrospective observational cohort study was conducted on 162 patients affected by Graves' disease relapse and treated with radioactive iodine from 2005 to 2013. GREAT and CSS scores were performed for all subjects, who were stratified according to the three defined classes (1 mild, 2 moderate, 3 severe). The failure of radioiodine treatment was assessed as persistence of hyperthyroidism after more than 6 months from radioiodine in the absence of L-thyroxine treatment. Chi-Square and Cox Regression Analysis were used to compare GREAT and CSS classes with treatment efficacy.
Results
Mean dose of radioiodine administered was 11.96 mCi. In 138 (86.3%) patients, radioactive iodine was effective in inducing hypothyroidism or euthyroidism. The GREAT and the CSS scores were positively correlated to each other ($P=0.001$; R2 0.445). No response to radioiodine treatment was found in 12/52 and 4/15 patients with CSS and GREAT scores class 3 respectively. In univariate regression analysis, the lack of efficacy of radioiodine therapy was positively correlated with higher thyrotropin-related antibodies (TRAb) title ($P=0.030$), higher CSS class ($P=0.011$), higher GREAT class ($P=0.039$) and larger thyroid volume ($P=0.004$). In multivariate analysis, both CSS ($P=0.004$) and GREAT ($P=0.026$) class were significantly associated with failure of radioiodine therapy. The dose of radioiodine did not influence the efficacy of the treatment ($P=0.784$). Patients displaying the highest class in both CSS and GREAT scores had the highest probability to not respond to radioiodine treatment ($P=0.029$).
Conclusions
Both scores can be useful to decide whether the patient may respond or not to radioactive iodine treatment. The concomitant class 3 in both scores likely predicts the inefficacy of radioiodine treatment suggesting in these cases a surgical approach.

Ectopic thyroid tissue presented as left adrenal mass – a case report

Vladimir Samardzic[1], Zoran Gluvic[1], Milena Lackovic[1], Jelena Tica[1], Vesna Popovic-Radinovic[1], Marina Vujovic[1], Milan Obradovic[2] & Esma R. Isenovic[2]
[1]Zemun Clinical Hospital, Endocrinology, Belgrade, Serbia; [2]Institute of Nuclear Sciences Vinca, Belgrade, Serbia

Introduction
Ectopic thyroid tissue is a rare developmental abnormality with the prevalence of 1 per 100.000–300.000 persons in the general population. It is most commonly detected in younger women and presented as lingual thyroid. Here we report a rare case of ectopic thyroid tissue in the left adrenal gland.
Case report
A 29-year old female without previous medical history was incidentally diagnosed with left adrenal gland mass detected on routine abdominal ultrasound check-up. There were no clinical findings suggestive to cortisol or androgen excess. Native abdominal CT scan revealed hyperdense (40 HU) left adrenal gland mass 4.8 × 2.5 cm in diameter, with 7% of relative washout enhancement observed in contrast scans. Abdominal MRI showed T2W phase isodense lesion demonstrating signal loss in T1W phase. Thyroid ultrasonography didn't show any thyroid abnormality. Laboratory findings obtained from thorough adrenal hormonal excess investigation (ACTH, cortisol diurnal rhythm, ODST, aldosterone/PRA, DHEAs, 24 hrs urinary EPI/NOR/DOP) were reported as normal. The patient underwent laparoscopic left adrenalectomy. The intraoperative finding was suggestive to adrenal cyst. Histology of left adrenal mass showed the cyst 15 mm in diameter, with thyroid tissue inside cyst wall. Thyroid tissue had regular cellular characteristic and expressed TTF1, thyroglobulin, CK19, CK7, and PAX8 positivity. Whole body scan with I-131 performed postoperatively didn't reveal any other additional sites of thyroid tissue.
Conclusion
We reported an exclusive case of ectopic thyroid tissue in the left adrenal cystic lesion.

Vitamin D supply influences negatively the serum IL-6 and IL-17A levels in Hashimoto's thyroiditis, while positively the serum antibody levels against thyroid peroxidase and TSH receptor in Graves' disease

Ildikó Molnár & Zoltán Nagy
EndoMed Debrecen Kft, Immunoendocrinology, Debrecen, Hungary

Vitamin D plays an important role in the adaptive and innate immunity besides its skeletal effects. Some autoimmune disease is associated with vitamin D deficiency highlighting its crucial involvement in the onset of autoimmune diseases. This study investigated the relationship between the vitamin D supply and the serum IL-6, IL-17A and antibody levels against thyroid peroxidase (TPO) and TSH receptor in autoimmune thyroid diseases. Serum IL-6, IL-17A and antibody levels against TPO and TSH receptor were measured in 80 patients with autoimmune thyroid diseases (57 cases with Hashimoto's thyroiditis, mean age of 48 ± 14 years and 23 cases with Graves' disease, mean age of 48 ± 25 years, of whom 10 cases had ophthalmopathy). Data were displayed in geometric mean (95% confidence interval). No difference was found in vitamin D levels between the two groups of autoimmune thyroid deseases, but the serum levels in vitamin D deficient patients were significantly higher in Hashimoto's thyroiditis compared with those in Graves' disease [27.72 (10.4–73.91) vs 14.37 (2.53–81.57) nmol/l, $P<0.022$]. Patients with hyperthyroid Graves' ophthalmopathy demonstrated increased vitamin D levels compared with those in euthyroid state [43.87 (28.19–68.26) vs 18.26 (2.98–111.72) nmol/l, $P<0.0467$]. The serum IL-6 [$r=-0.27$, $P<0.0423$] and IL-17A [$r=-0.3335$, $P<0.0113$] levels inversely correlated with the serum vitamin D levels and the vitamin D supply influenced them negatively in Hashimoto's thyroiditis [18.54 (4.33–79.3) vs 8.23 (0.71–95.59) ng/ml, $P<0.0248$ for IL-6 and 10.29 (3.92–27) vs 5.25 (1.44–19.22) ng/ml, $P<0.0031$ for IL-17A levels between the patients with vitamin D deficiency and sufficiency]. The serum anti-TPO ($r=0.7452$, $P<0.0054$) and anti-TSH receptor antibody levels were positively influenced by the vitamin D supply in Graves' disease, particularly in patients without ophthalmopathy [32.17 (3.24–319.28´) vs 394.97 (30.08–5186.02) IU/ml, $P<0.021$ for anti-TPO and 1.54 (0.54–4.39) vs 6.64 (2.86–15.42) IU/l, $P<0.0299$ for anti-TSH receptor antibody levels between patients with vitamin D deficiency and sufficiency]. The above mentioned relationships were also demonstrated by multivariate analysis in generalized linear model (GLM). Conclusions, the vitamin D levels influenced controversially the serum IL-6 and IL-17A levels in Hashimoto's thyroiditis and positively the antibody levels againts TPO and TSH receptor inGraves' disease demonstrating the difference in the activity of the adaptive immunity between these autoimmune thyroid diseases. The vitamin D supply can contribute to ameliorate the effects of inflammatory cytokines and amplify the antibody production against thyroid antigens.

Cumulative effects of thyroid hormones over 10 years and risk of general and abdominal obesity; tehran thyroid study

Ladan Mehran[1], Atieh Amouzegar[1], Hengameh Abdi[1], safoora gharibzadeh[3], Mohammadali mansournia[4], Maryam tohidi[5] & Fereidoun Azizi[1]
[1]Shahid Beheshti University of Medical Sciences, Endocrine Research Center, Research Institute for Endocrine Sciences, Tehran, Iran; [3]Pasteur Institute of Iran, Department of Epidemiology and Biostatistics, Research Centre for Emerging and Reemerging infectious Disease, Tehran, Iran; [4]Tehran University of Medical Sciences, Department of Epidemiology and Biostatistics, School of Public Health, Tehran, Iran; [5]Shahid Beheshti University of Medical Sciences, Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Tehran, Iran

Background
Recently many cross-sectional and a few longitudinal studies reported that thyroid hormones even within normal ranges are associated with measures of adiposity. We aim to assess if changes in TSH and Free T4 (FT4) over 10 years of follow-up would be associated with changes in BMI and waist circumference or risk of general and abdominal obesity.
Methods
4179 participants of Tehran Thyroid Study(TTS) who had attended at baseline(1999–2001) and at three subsequent follow-ups every 4 years(up to 2011) were enrolled. At baseline, participants with serum TSH < 0.1 or >10 mU/l, BMI < 18.5 kg/m^2, pregnancy or history of thyroid medication or surgery and missing data were excluded. Finally, data of 2317 subjects remained for the study analysis. The median follow up time was 9.7y. Body weight, waist circumference were measured and serum concentrations of FT4 and TSH were assayed at baseline and three follow-ups. To account for within-subject correlation, the generalized estimating equation (GEE) was usedto assess the association between a1SD change in main exposures(CE.TSH and CE.FT4) and changes in BMI; calculated scores of CE.TSH and CE.FT4 were included in models as a time varying exposure.
Results
Mean age of the study population was 43 ± 13y, of whom 59.7% were women. Cumulative excess of TSH or FT4 were not associated with increased incidence of obesity, overweight and abdominal obesity. However, in over weights, after adjusting for age, sex, smoking, education, physical activity and HOMA-IR, for each standard deviation increase in the CE.FT4(β = –0.23,95% CI : –0.34, –0.11) and CE.TSH(β = 0.13,95% CI : 0.03, 0.22), BMI was changed negatively and positively, respectively[sd(CE.TSH) = 19.27, sd(CE.FT4) = 1.72)]. In GEE analysis, however, a one unit increase in TSH was associated with 0.02 increase in BMI in the total population(β = 0.02, 95% CI : 0.008, 0.03), an increase which remained significant only in women; a one unit increase in FT4 was significantly associated with 1.7 decrease in BMI(β = –1.7.95% CI : –1.9, –1.4) in the total population which remained significant in both sexes after adjusting for age, sex, smoking, physical activity, education and HOMA-IR. After entering both exposures of TSH and FT4 to the model, only FT4 independent of TSH was inversely associated with BMI. The one unit decrease in FT4 was also associated with increase in WC(β = –3.88, 95% CI : –5.09, –2.68) in both genders.
Conclusion
Cumulative effects in thyroid hormones over time indicated no risk for general or abdominal obesity. However TSH alterations in women and FT4 in both sexes were positively and negatively associated with BMI, respectively. FT4 variations could negatively affect WC in men and women independent of insulin resistance and even TSH.

Iodine deficiency and mortality in spanish adults. Di@bet.es study

Sergio Valdes[1], Natalia Colomo[1], Cristina Maldonado-Araque[1], Eduardo García-Fuentes[2], Alfonso Calle-Pascual[3], Luis Castaño[4], Elias Delgado[5], Josep Franch-Nadal[6], Federico Soriguer[7] & Gemma Rojo-Martinez[1]
[1]Hospital Regional Universitario de Málaga, IBIMA, CIBERDEM, Endocrinology and Nutrition, Málaga, Spain; [2]Hospital Universitario

Virgen de la Victoria, IBIMA, CIBEROBN, UGC de Aparato Digestivo, Málaga, Spain; [3]Hospital Universitario S. Carlos, CIBERDEM, Endocrinology and Nutrition, Madrid, Spain; [4]Hospital Universitario Cruces, BioCruces Bizkaia, UPV/EHU, CIBERDEM, Barakaldo, Spain; [5]Hospital Universitario Central de Asturias/ University of Oviedo, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Endocrinology and Nutrition, Oviedo, Spain; [6]EAP Raval Sud, Institut Català de la Salut, Red GEDAPS, Primary Care, Unitat de Suport a la Recerca (IDIAP – Fundació Jordi Gol), CIBERDEM, Barcelona, Spain; [7]Academy of Science, Málaga, Spain

Objective
To study the association between the state of iodine nutrition, and the risk of total and cause mortality in a representative sample of the Spanish adult population.
Design
Longitudinal observational study to estimate mortality risk according to urinary iodine (UI) concentrations using a sample of 4370 subjects >18 years representative of the Spanish adult population participating in the national study Di@bet.es (2008–2010). We used Cox regression to assess the association between IU at the start of the study (<50, 50–99, 100–199, 200–299 and ≥300 µg/l) and mortality during follow-up (INE- end of follow-up December 2016) in raw models and adjusted to possible confounding variables: age, sex, educational level, hypertension, DM, Obesity, CKD, smoking, hypercholesterolemia, thyroid dysfunction, diagnosis of cardiovascular disease, cancer diagnosis, Area of residence, physical activity, adherence to Mediterranean diet, dairy intake and iodized salt.
Results
A total of 254 deaths were recorded during an average follow-up of 7.3 years. The causes of death were cardiovascular 71 (28%); cancer, 85 (33.5%) and other causes 98 (38.5%). Compared to the reference category with adequate iodine nutrition (IU 100–300 µg/l) the Hazard Ratios of all-cause mortality in the category with IU ≥300 µg/l was 1.04 (CI 95% 0.54–1.98); however, in the categories with 50–99 IU and <50 µg/l, the Hazard Ratios were 1.29 (95% CI 0.97–1.70) and 1.71 (95% CI 1.18–2.48) respectively (*P* for trend 0.004). Multivariate adjustment did not significantly modify the results.
Conclusions
Our data indicate an excess mortality in individuals with severe iodine deficiency adjusted to other possible confounding factors.

AEP890

New predictors of response to treatment with intravenous methylprednisolone in thyroid-associated orbitopathy

Sergio Roman Gimeno, Jose Jorge Ortez Toro, Carlos Miguel Peteiro Miranda, Borja Sanz Martín, Rosana Urdaniz, Ana Agudo, Laura Borau, Julia Campos Fernández & Esperanza Aguillo Gutierrez
Hospital Clinico Universitario Lozano Blesa, Endocrinology and Nutrition, Zaragoza, Spain

Introduction
Thyroid-associated ophthalmopathy is the most frequent extrathyroidal manifestation of Graves' disease. Its treatment is based on the administration of intravenous corticosteroids, and the clinical activity score (CAS), TSH-binding inhibitor immunoglobulin (TBII) and TSH-receptor antibodies (TRAb) have been classically used to measure the response to treatment. However, in recent studies [1] it has been observed that other analytical parameters such as cholesterol and triglycerides could also be related to the response to such treatment.
Methods
A retrospective observational case-control study was performed. We studied 55 patients with thyroid ophthalmopathy who have been admitted to Hospital Clínico Lozano Blesa, in Zaragoza (Spain) in the last 10 years to receive treatment with intravenous infusions of methylprednisolone. From each patient, the previous treatment received for their hyperthyroidism and different variables were taken into account in three key moments: Before the first corticoid infusion, halfway through the treatment (Sixth bolus) and after the twelfth and last bolus. Among these parameters were the CAS (Clinical Activity Score), visual acuity and presence of diplopia, and various analytical parameters (TSH, FT4, cholesterol, LDL, HDL, triglycerides, etc.). The statistical significance has been accepted for values of $P<0.05$.
Objectives
To assess whether there is a relationship between the adequate response to intravenous corticosteroid therapy in Graves' ophthalmopathy and the different analytical parameters previously mentioned.
Results
An increased risk of having poor response to intravenous corticosteroid therapy has been observed in those patients with elevated triglycerides (Odds Ratio (OR) 1.85 [IC95%=1.05–3.28]), smokers (OR 5.05 [IC 95%=1.94–27.19]) and in those with high levels of TSH-binding inhibitor immunoglobulin (OR 5.17 [IC 95%=1.11–24.04]). Moreover, a higher TBII mean (17.4 vs 8.9, $P=0.028$) and a higher triglyceride mean (127 vs 81 mg/dl, $P=0.034$) were found in nonresponders.
Conclusion
There are several factors that can serve as predictors of response to intravenous corticosteroid treatment in thyroid-associated orbitopathy, some of them are already well known, like antithyroid antibodies or smoking, and others started to gain relevance recently, such as cholesterol or triglycerides. Thus, all these factors could be used to classify Graves' orbitopathy patients prior to intravenous corticoid treatment and only start that treatment in the group of patients that could potentially have more benefit from it.

Differentiation of follicular thyroid cancer from follicular thyroid adenoma with sonographic features – results of a meta-analysis

Martyna Borowczyk[1], Kosma Woliński[1], Barbara Więckowska[2], Elżbieta Jodłowska-Siewert[1], Ewelina Szczepanek-Parulska[1] & Marek Ruchala[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznan, Poland; [2]Poznan University of Medical Sciences, Department of Computer Science and Statistics, Poznan, Poland

Introduction
According to the results of several studies and meta-analyses, certain ultrasound features are associated with increased risk of thyroid malignancy. However, most of those research papers included mainly papillary thyroid cancers (PTCs); these results cannot be simply extrapolated for the differentiation of follicular thyroid adenomas and cancers (FTAs and FTCs). The aim of the present study was to perform a meta-analysis of so far conducted research and identify sonographic features suggesting malignancy in case of follicular lesions, potentially differentiating FTA and FTC.
Material and methods
We carried out a meta-analysis following the Cochrane and PRISMA guidelines. We searched PubMed, MEDLINE, Academic Search Complete, CINAHL Complete, CINAHL, Scopus, Cochrane, Health Source: Nursing/Academic Edition, Web of Knowledge, MasterFILE Premier, Health Source – Consumer Edition, Agricola, Dentistry and Oral Science Source databases from January 2006 up to July 2018 to find all relevant, full-text journal articles written in English. The search strategy included Medical Subject Headings terms and keywords: 'thyroid and ('follicular cancer' or 'follicular carcinoma' or 'follicular neoplasm' or 'follicular adenoma' or 'follicular nodule') and (ultrasound or ultrasonography or elastography or 'color doppler' or 'power doppler')'. The pooled estimates of sensitivity, specificity, positive and negative predictive value (PPV, NPV), and odds ratios were obtained from the bivariate model.
Results
After a complete systematic review was performed, 15 studies met the inclusion criteria. They covered analyses of 15209 nodules. The overall odds ratios for particular features giving a FTC risk varied from 1.44 to 10.19. Specificity to predict FTC for individual features varied from 18 to 100%, and the sensitivity ranged from 1 to 94%. NPV was 64–92%, and PPV was 28–96%. The highest overall odds ratio in increasing the risk of malignancy was calculated for tumor protrusion (OR=10.19; 95% CI : 2.62–39.71), microcalcifictions or mixed type of calcifications (micro- and macrocalcifications): 6.10 (3.00–12.50), irregular shape: 5.89 (1.09–31.82), solid or mainly solid structure: 5.22 (1.70–16.05) and marked hypoechogenicity: 4.25 (2.57–7.05). The lowest OR was characteristic for doppler pattern 3 or more: 1.44 (0.76–2.74). The probability of FTA diagnosis suggests the oval or round shape of the lesion, presence of cystic component. Less specific features suggesting benignity are lack of calcifications and visible halo.
Conclusions
The sonographic features associated with malignancy of follicular lesions are distinct from those widely reported for all thyroid cancers, including PTC, and may be a useful tool to guide thyroid nodules management.

Anaplastic thyroid cancer arising froma patient with congenital thyroid dyshormonogenesis; A case report with a novel thyroglobulin gene mutation

Jeehee Yoon, A Ram Hong, HeeKyung Kim & Ho-Cheol Kang
Chonnam national university hwasun hospital, Endocrinology and metabolisum, Hawsun, Korea, Republic of South

Background
Concomitant thyroid cancer in patients with congenital thyroid dyshormonogesis (TD) is extremely rare and only few cases of differentiated thyroid cancer in patients with TD were reported in literature. We present the first case of anaplastic thyroid cancer (ATC) in woman with TD.
Case
A 46-year-old female patient was referred to our hospital for thyroid surgery due to rapid tumor growing and compressive symptoms. The fine needle aspiration result of a local clinic was follicular neoplasm. She and her two younger sisters had diagnosed as congenital hypothyroidism and received thyroid hormone replacement therapy from childhood. The growth and psychomotor development of three sisters were within normal range. Her serum thyroglobulin (TG) level was not detected and genetic tests for TD were performed for patient and her younger sisters. The targeted exome sequencing revealed compound heterozygous mutations in the TG gene and saner sequencing represented a c.3790T>: C (*P*, Cys1264Arg) mutation located at exon 17 and c.7070T>: C (*P*. Leu2357Pro) mutation at exon 19 in patient and one sister. The c.7070T>: C (*P*.Leu2357Pro) mutation is novel mutation. After total thyroidectomy, she was diagnosed with ATC with lung and bone metastasis. She started Lenvatinib therapy and still alive for 11months after the first diagnosis of ATC.
Conclusion
TD patients are exposed to long term hypothyroid statuswith elevated thyroid stimulating hormone, which make thyroid goiter and nodules. Genetic mutation under chronic stimulation of the thyroid gland could change nodules to aggressive natures. Further investigation is necessary to identify the association between thyroid cancer and TD.

Thyroglobulin measurement in fine-needle aspirates of lymph nodes in patients with differentiated thyroid cancer

Zamira Zuraeva, Larisa Nikankina, Galina Kolesnikova, Fatima Abdulhabirova, Pavel Rumiantsev, Vladimir Vanushko & Natalia Malysheva
Endocrinology Research Center, Moskva, Russian Federation

Backgraund
The high incidence of cervical lymph nodes (LNs) metastasis in differentiated thyroid carcinoma (DTC) and lack of effective diagnostic tools determines the need for elaboration more specific tests.
Aims
The aim of our study was to evaluate the accuracy and cut-off point of the thyroglobulin (Tg) in the washout fluid of fine-needle aspiration biopsy (FNA-Tg) in the diagnosis of DTC LNs metastasis.
Materials and methods
A retrospective studyinvolved 245 patients with recurrent DTC and suspicious cervical LNs. All patients were evaluated FNA-Tg, serum Tg levels (sTG), Tg antibodies (TgAb) and thyroid stimulating hormone (TSH). Surgical treatment was performed in 125 patients with malignant changes according to the cytology, high FNA-Tg values, sTg. Patients were divided into 2 groups with reactive ($n=23$) and metastatic ($n=102$) changes in LNs according to the histological examination. FNA for both cytology and FNA-Tg was performed with a 22-G needle. FNA-Tg was aspirated through the needle with a syringe from a test tube with 0.5 ml of normal saline. TSH levels were measured by electrochemiluminescence immunoassay (Architect), reference range 0.25–3.5 mIU/l. FNA-TG, sTg (3.5–77.0 ng/ml), TgAb (0–115 IU/ml) was performed on the automated system Cobas 601 (Roche, France). Clinical and laboratory data were compared using Mann Whitney U test, results are presented as median (25 and 75 quartiles), $P<0.05$. Diagnostic significance and the best cut-off value for FNA-Tg for the malignancy was performed using receiver operating characteristic curve analysis (ROC). All analyses were performed using the SPSSv23 Statistic (USA) and MedCalc v. 18.2.1 (Belgium) software.
Results
All patients were comparable by clinical (sex, age) and laboratory (TSH, sTG, Tg Ab) parameters. The median FNA-Tg in metastatic group was 537.0 [0.1; 1000] ng/ml while in benign group it was 17.9 [0.5; 158.0] ng/ml, $P=0.003$. The sensitivity of isolated FNA was 85%, specificity 57%, AUC=0.618, 95% CI 0.516–0.713. The sensitivity and specificity of FNA-Tg was 73% and 100%, respectively, AUC=0.865, 95% CI 0.78–0.92. The optimal cut-off point for the malignancy was >9.2 ng/ml (sensitivity 75%, specificity 100%), Youden Index 0.73.
Conclusions
Our results showed that additional measurement of the Tg in the washout fluid enhances the sensitivity of isolated FNA in evaluation of DTC lymph nodes metastasis. In our population the cut-off value>9.2 ng/ml can be proposed as a diagnostic threshold for the definition of malignancy.

Association between multifocality and aggressive histopathological findings in papillary thyroid cancer

Andoni Monzón Mendiolea, Amelia Oleaga Alday, Adela Leyre Martínez Martínez, Ignacio Merlo Pascual, Eider Etxeberria Martin & Miguel Paja Fano
Hospital Universitario de Basurto, Servicio de Endocrinología y Nutrición, Bilbao, Spain

Introduction
Papillary thyroid cancer (PTC) is usually tied to an excellent prognosis, with a 10-year disease specific survival rate of 98%. Nevertheless, some clinicopathological features are associated with a worse outcome. Therefore, a precise risk assessment is crucial for the clinicians deciding the most appropriate treatment for each tumour. Multifocal tumours (MFPTC) appear to have be a worse prognosis than unifocal tumours (UFPTC) in some series, but this aspect is disregarded by the American Thyroid Association guidelines for risk stratification on PTC. The following study tries to evaluate a possible association between MFPTC and aggressive histopathological findings.
Material and methods
We designed a retrospective cross-sectional observational study. Data regarding every histologically confirmed PTC (non-aggressive variants) larger than 2 mm operated at our centre between 2001 and 2019 was gathered. We used chi square test to evaluate the association between multifocality and several aggressive histopathological findings: extrathyroidal extension (ETE), lymph node involvement (LNI), BRAFV600E mutation and desmoplastic stromal reaction.
Results
We studied 662 patients with non-aggressive variants of PTC. 651 patients had the ETE described in their pathological reports: 404 UFPTC (19.6% with ETE) and 247 MFPTC (26.3% with ETE). From 639 patients, there were LNI in 170 histological specimens:35.8% of MFPTC (88 out of 246) and 20.9% of UFCPT (82 out of 392). 344 neoplasms had been tested for BRAF V600E mutation: 200 UFPTC (46.5% mutated) and 144 MFPTC (57.6% mutated). In 524 patients the presence or absence of desmoplastic reaction was described in their pathological reports: 308 UFPTC (34.7% with moderate to severe desmoplasia) and 216 MFPTC (46.3% with moderate to severe desmoplasia). There were no differences between groups in sex distribution, age nor tumour size (used largest focus of MFPTC). There was a statistically significant association between the following: MFPTC and ETE [$P=0.04$, OR (CI95%)=1.47 (1.01–2.14)]; MFPTC and LNI [$P<0.0001$, OR (CI95%)=2.11 (1.48–3.02)]; MFPTC and the presence of BRAFV600E mutation [$P=0.04$, OR (CI95%)=1.56 (1.02–2.41)]; and MFPTC and moderate to severe desmoplastic reaction [$P<0.01$, OR (CI95%)=1.62 (1.14–2.31)].
Conclusion
MFPTC are associated with several aggressive histopathological findings:ETE, LNI, BRAF V600E mutation and moderate to severe desmoplasia. Therefore, we suggest that multifocality should be regarded when deciding the treatment of PTC, aiming for more extensive surgical treatment when multifocality is present. The association between MFPTC and aggressive histopathological findings questions the currently proposed surgical approach for intrathyroidal PTC smaller than 4 cm (lobectomy) due to the risk of neglecting evidence of multifocality.

Cervical lymph node metastasis of a thyroid papillary carcinoma resected with detection by technetium99-nanocolloid: About an original case

Amira Bouchenna[1], Berkoune Fatma[1], Ghennam Brahim[2], Tibouk Abdelghani[3], Guidoum Adel[4], Heffaf El Mahdi[2] & Ould Kablia Samia[1]
[1]central hospital of army, endocrinology, Algeria; [2]central hospital of army, Nuclear medicine, Algeria; [3]central hospital of army, pathological service, Algeria; [4]central hospital of army, maxillofacial surgery, Algeria

Introduction
Cervical lymph node metastases from differentiated thyroid carcinomas occur mainly in the central compartment with an incidence between 20 and 90% (average 60%). The American Thyroid Association considers that the central compartment goes to the unnamed artery thus systematically including level VII to level VI. We report the case of a patient with resected level VII lymph thanks to identification by technetium99-nanocolloid.
Observation
Patient 32-year-old followed for 3 years for papillary thyroid carcinoma initially classified PT2N1bM0 who received an iratherapy treatment with a thyroglobulin (Tg) level at 71.86 ng/ml and post-therapeutic scanning: hyperfication cervical lymphadenopathy. At 3 months post-iratherapy in front of a Tg at 8.10 ng/ml, a cervical ultrasound finds a lymphadenopathy in level VII, whose fine needle biopsy returned carcinomatous with Tg in rinsing liquid highly positive. The TEP-FDG finds this lymphadenopathy without remote localization. The patient is reoperated under detection by iodine 131, unfortunately the lymphadenopathy doesn't fix the iodine, it couldn't be resected. In view of the Tg levels remained high, it was reoperated a third time under detection with in situ injection of technetium99-nanocolloid, the anatomopathological study found 2 lymphe node metastasis infiltrated and the postoperative ultrasound returned without abnormality.
Discussion
The resection of a lymph node metastasis of a thyroid papillary carcinoma by technique of in-situ injection of technetium99-nanocolloid, inspired by the technique of the sentinel node seems to be a new technique which would make it possible to act on lymphe node difficult to access on a neck modified by previous surgery and which no longer fixes iodine.

PTEN-hamartoma tumour syndrome and thyroid nodular disease: 3 case reports

Lúcia Fadiga[1], Diana Catarino[1], Joana Saraiva[1,2], Isabel Dinis[3], Rita Cardoso[3], Joana Serra Caetano[2,3], Isabel Paiva[1] & Alice Mirante[3]
[1]Coimbra Hospital and Universitary Centre, Endocrinology Department, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Coimbra, Portugal; [3]Pediatric Hospital of Coimbra, Coimbra Hospital and Universitary Centre, Department of Paediatric Endocrinology, Diabetes and Growth, Coimbra, Portugal

Introduction
Germline mutations in tumour suppressor gene PTEN cause heterogeneous phenotypes, that comprise the spectrum of PTEN-hamartoma tumour syndrome (PHTS). Manifestations include macrocephaly, developmental delay, cutaneous lesions, intestinal polyposis and increased risk of neoplasms. Thyroid nodules are identified in about 75% of patients and follicular cell-derived cancer affects 35% of cases, some of which diagnosed as early as 7 years old.
Case 1
6 year old boy, with macrocephaly and autism; genetic test revealed a heterozygous mutation in PTEN (c.359C>A – p.Ala120Glu). Thyroid ultrasound (US) at 6.5 years was normal. At 7 years, US showed 3 nodules: in right lobe (RL), 3.3 mm hyperechoic nodule and 5.8 mm hypoechoic nodule; in left lobe (LL), 3.9 mm hypoechoic nodule. TSH and thyroid antibodies were normal. At 9 years, US showed: in RL, 4.7 mm hyperechoic nodule, with irregular margins; in RL-isthmus transition, 9.3 mm hypoechoic nodule; in LL, 5.6 mm hypoechoic nodule. At 10 years and 9 months, fine-needle aspiration cytology (FNAC) of RL-isthmus transition nodule showed FLUS. Thyroidectomy was performed at 11 years; pathology revealed nodular hyperplasia.
Case 2
8 year old boy, with macrocephaly, learning difficulties, mucocutaneous lesions and lipomas; PTEN sequencing revealed a heterozygous frameshift mutation (c.412dup – p.Tyr138LeufsTer42). Thyroid US showed several hypoechoic, regular-margin nodules, the larger in LL with 9 mm; several suspicious lymph nodes. He had normal TSH, but calcitonin 15.2 pg/ml ($N<8.4$). He was submitted to thyroidectomy at 9.5 years; pathology revealed nodular hyperplasia with two follicular adenomas and reactive adenitis.
Case 3
6 year old boy with macrocephaly, developmental delay, intestinal polyposis and iron-deficiency anemia. Genome sequencing revealed a deletion on chromosome 10 (10q23.1q23.31), involving PTEN and BMPR1A genes. At 6 years and 11 months, US showed enlarged thyroid, with no nodules. At 12 years, US showed a RL nodule with 9 mm and two LL nodules, the larger with 9 mm. He had normal TSH and positive anti-thyroglobulin antibodies. FNAC of RL nodule revealed a benign lesion. At 15 years, US showed in RL a heterogeneous nodule with 21 mm; in LL, a hypoechoic nodule with 16 mm, an area of confluent nodules with 36 mm and other multiple smaller nodules; multiple enlarged lymph nodes. He is waiting for thyroidectomy.
Conclusions
PHTS patients must be evaluated annually with thyroid US, starting after diagnosis. The high risk of carcinoma in young age and the diagnostic difficulties due to multiple thyroid nodules often leads to thyroidectomy in suspicious cases.

Discordant thyroid function test in a patient with X-linked adrenoleukodystrophy

Vivek Pant[1] & Suman Baral[2]
[1]Samyak Diagnostic Pvt. Ltd., Clinical Biochemistry, Lalitpur, Nepal; [2]Nepal Mediciti Hospital, Internal Medicine, Kathmandu, Nepal

Introduction
Biotin-streptavidin detection method is used in a majority of commercial immunoassay. Biotinylated antibodies (capture antibodies) bind strongly to streptavidin that anchors those antibodies to the solid phase of the assay. Thus, high biotin concentration in the serum interferes with this bond and alters the expected results. Clinical history of patient and additional laboratory test is important for troubleshooting of discordant thyroid function test result.
Case presentation
A 52 years male was referred by an endocrinologist to our laboratory to evaluate clinic-biochemical discordance for thyroid function test. The resultsshowed a thyroid-stimulating hormone (TSH) level of 0.02 µIU/ml (0.35–5.5 µIU/ml) and a free thyroxine (fT4) level of 5.48 ng/dl (0.89–1.76 ng/dl). Similar finding was found in the report issued by second laboratory. TPO antibody, anti-thyroglobulin and TRAb were negative. Patient had normal thyroid ultrasound and low normal uptake in technitium-99 thyroid scan. This discordant TFT results prompted us to investigate for the possible interference in the TSH and fT4 assay. Patient did not have history of previous thyroid disease. There was no family history of similar TFT findings. He was recently diagnosed with X-linked adrenoleukodystrophy based on findings of long chain fatty acid test after his complaints of progressive weakness and stiffness of lower limb. For his illness, he was taking low dose hydrocortisone and was under trial of high dose biotin. Thus, biotin interference as a cause of discordant laboratory finding was suspected. We reviewed the results of previous TFT and consulted with the clinical laboratories about the design of their immunoassay. Initial results of TSH and fT4 were obtained from Vitros 3600 immunoassay. The second result was from Roche Diagnostics Modular E170. These both immunoassay systems used biotin to label the reaction. We repeated TFT in Siemens, Advia Centaur which used acridinium ester to label the reaction. The results obtained were normal. Hyperthyroidism was ruled out and high dose biotin interference was confirmed.
Discussion
The excess free biotin in sample saturates the streptavidin binding sites preventing adherence of the signal bound antibody–antigencomplex in a non competitive assay (e.g. TSH). This creates a falsely lowered TSH result by decreasingthe signal detected. For fT4 level, a competitive immunoassay principal is used where high biotin concentration causes reduction in light generated and has positive interference with fT4 assay. When an immunoassay with no biotin is used (e.g.Siemens Advia Centaur), the interference disappears.

Age and sex-specific TSH upper-limit reference intervals in the general French population: There is a need to adjust our actual practices

Véronique RAVEROT[1], Bonjour Maxime[2], Abeillon Juliette[3], Perrin Pauline[1], Roucher Florence[1], Lasolle Hélène[3], Subtil Fabien[2] & Francoise Borson-Chazot[3]
[1]Hospices Civils de Lyon, LBMMS, Lyon, France; [2]Hospices Civils de Lyon, Service de Biostatistique, Lyon, France; [3]Hospices Civils de Lyon, Fédération d'endocrinologie, Lyon, France

Background
The increasing age of the general population represents a new challenge for endocrinologists and caregivers since it is well know that the occurrence of thyroid dysfunction increases with age. It is still controversial whether or not reference values of thyrotropin (TSH) adapted to age and sex need to be used. Herein, we aimed to determine reference intervals, in males and females, suitable for thyroid disease exploration and follow-up during adult life in a tertiary center in France.
Methods
Over 11 years, 295775 TSH were measured in a single lab that used the same TSH reagent during this period. Among the 156025 TSH results available for analysis, 90 538 values were from female subjects, 82019 were from patients aged >60 years and 26825 aged >80 years. By using an indirect approach, we determined references values of TSH adapted to age and sex, and we then evaluated the proportion of patients who would have been reclassified with these reference values.
Results
The median TSH ranged from 1.2 to 1.4 mUI/l during the study period. The circannual range of the upper limit of the reference value was 4.6 to 5.4 mUI/l. By contrast, the upper limit of reference range of TSH increased with age; in females the median to 97.5th percentile values increased continuously with age from the age of 30 years to the oldest age group (90–108 years). Using new calculated reference values in patients with TSH above the conventional upper limit reference value (4 mUI/l), the proportion of results reclassified as physiologicalranged, according to age-group, from 26.3 to 65.1% in females and from 13.6 to 37.7% in males; in among those aged >60 years, 50.5 to 65.1% of females and 33.0 to 37.7% of males were reclassified.
Conclusions
The use of TSH age-specific and sex-specific upper-limitreferences values led to the reclassification of a great number of samples, notably among women. This suggests that age-specific TSH upper-limitreference intervals in daily practice should be used in order to avoid misclassification.

Thyroid hormone regulation of brain metabolism: Study in an animal model of the co-occurrence of depression and hypothyroidism

Katarzyna Glombik, Jan Detka & Boguslawa Budziszewska
Maj Institute of Pharmacology Polish Academy of Sciences, Experimental Neuroendocrinology, Cracow, Poland

Objective
Thyroid hormones are required not only for central nervous system development in the early stages of life but also play a key role in the maintenance of adult brain function. It is known that in adults, thyroid diseases can lead to various clinical manifestations i.e affective disorders, depression, memory impairment. The effects of hypothyroidism on brain functions seem particularly pronounced in depression, but until now, the mechanism underlying this relationship has not been fully understood.
Aim
The goal of the present study was to determine the effects of hypothyroidism on the brain glycolysis, citric acid cycle and oxidative phosphorylation processes in an animal model of depression.
Methods
Study was performed in an animal model of endogenous depression (Wistar-Kyoto rats) and model of coexistent depression and hypothyroidism (6-n-propyl-2-thiouracil – PTU- treatment). PTU (0.05%) was administered in drinking water for 3 weeks. The behavioral tests, enzyme-linked immunosorbent assays, colorimetric methods, immunoblots, and high-resolution respirometry were applied to investigate the changes in selected metabolic markers in the frontal cortex and hippocampus. After behavioral verification animals were sacrificed under nonstressful conditionsto dissect frontal cortices and hippocampi. The results were analyzed using the STATISTICA 13.3 software. A p-value <0.05 was considered to be significant.
Results
The applied model was verified behaviorally and hormonally. It was observed that in the model of co-occurrence of depression and hypothyroidism the pyruvate concentrations in the frontal cortex and hippocampus were downregulated and the lactate level in the hippocampus was reduced. Moreover, in the hippocampus, the aconitase activity was increased. The levels of electron transport chain complexes and pyruvate dehydrogenase activity in the frontal cortex were reduced. In the functional study, conducted with high-resolution respirometry the alternations in the oxidative phosphorylation processes in the hippocampus were demonstrated.
Conclusions
Obtained data indicate an important impact of thyroid hormones on brain metabolism in the course of depression. Furthermore, the hypothalamic-pituitary-thyroid axis hypoactivity increases brain metabolic changes observed in the model of endogenous depression. Changes in the frontal cortex may result from an observed decrease in the expression of thyroid hormone receptor alpha-1 and/or D2 deiodinase downregulation. It also seems that metabolic changes in the hippocampus may be one of the causes of long-term potentiation reduction and synaptic plasticity impairment.

Severe toxic reaction on thiamazole in a patient with hyperthyreoidism

Martina Jambrović, Andreja Maric & Maja Mikolaj Kiric
County hospital Cakovec, Endocrinology and diabetology, Cakovec, Croatia

Female patient (56 y) with hyperthyroidism (start TSH 0.01 mIU/l; fT3 15.8 pmol/l; fT4 39.4 pmol/l) one month after initiation of thiamazole therapy (10 mg 3 × 1/1 week, then 2 × 1) came to the emergency room with symptoms of sweating, palpitations, nervousness, itching, fever (37.6 C), icterus. In medical history: oesophageal achalasia surgery 5 years ago, non-smoker. Therapy: thiamazole, bisoprolol, alprazolam. Initially in laboratory findings: leukopenia (L 1.2 × 109/l), liver lesion (total bilirubin 196 µmol/l, AST 71 U/l, ALT 69 U/l, ALP 558 U/l, GGT 379 U/l) and elevated CRP (183.4 mg/l). During hospitalization a progression of pancytopenia (L 0.7 × 109/l), worsening of the liver lesion and CRP (total bilirubin up to 267 umol/l, ALP 294 U/l, GGT 153 U/l, CRP 346 mg/l) were recorded. TSH was 0.01 mIU/l with elevated fT3 10.6 pmol/l and fT4 42.7 pmol/l. Abdominal ultrasound found no signs of bile duct obstruction, there was visible splenomegaly. Gastroscopy found gastritis and oesophageal mycosis, acute tonsillopharyngitis. Cytological analysis of the bone marrow showed poor cellular bone marrow with marked neutropenia. Haemocultures, urinocultures, markers of hepatitis and serology EBV IgM were negative. She was treated with antibiotic therapy piperacillin+tazobactam, later replaced with vancomycin+meropenem+fluconazole. Despite antibiotics, filgrastim and symptomatic therapy hyperbilirubinemia persisted, leukopenia and synthetic liver function were worsening. She was transferred to a tertiary institution for further treatment, without the criteria for inclusion on the liver transplant list. Sixteen days after initial hospitalization, J-131 therapy was performed (296 mBq/8 mCi), then lithium carbonate 150 mg 1 × 1 was added to therapy for several months; euthyroidism was achieved. Sixteen months after the described toxic reaction to thiamazole, mild hyperthyroidism was noticed, followed by spontaneous euthyroidism, with a negative finding of scintigraphy and no need for therapy. In conclusion: thionamides are the most common initial therapy for hyperthyroidism. A toxic reaction is also possible with low doses of thiamazole. Regular follow up of thyroid test is required.
Keywords: thyrotoxicosis, thiamazole, toxic liver lesion.

AEP901

How various doses of iodine effect on thyroid gland in pregnant and lactating women, on the example of regional studies in russian federation?

Anastasia Rybakova, Nadezhda Platonova, Ekaterina Troshina & Fatima Abdulhabirova
Endocrinology Research Centre, Russian Federation

Relevance
Question of standards of iodine intake in pregnant and lactating women remains relevant.
Aim of study
to determine status and function of thyroid gland in pregnant and lactating women with and without antibodies to thyroid gland, on the background of taking different doses of iodine in 3 different regions of Russia with different iodine status.
Materials and methods
This study included 414 women in the different trimester of pregnancy (18–42 y.o.) and 256 newborns. They were divided into 2 groups: 1st group – women, receiving potassium iodide 200 mg/day, newborns breastfed from these women; 2nd group – women and newborns, receiving 300 mg/day.
Results
Initially, in all three regions, median iodinuria was below the threshold level (150 µg/l). After 3 months, a significant increase in the level of iodinuria in group 2 (96 µg/l at baseline and 259 µg/l at 3 months) was noted. Against the background of taking different doses, there was no increase of Anti-TPO. When comparing the iodine content of infants who are breastfed, there were no significant differences between the groups. Normal concentration of iodine in the urine was 58.6% in the newborns in the first group and 71% in the second group. The levels of TSH of newbornswere not statistically different; there were no increase above 5 mU/l.
Conclusions
We can say that in order to achieve optimal iodinuria, level of iodine intake should correspond to at least 250 µg/day. For now, initial urinary excretion of iodine does not correspond to normal iodine supply, which indicates the need for preconception treatment in regions with proven iodine deficiency.
Study was carried out by RSF grant N17-75-30 035.

Association between lipid and thyroid function parametersin premenopausal euthyroid healthy women and women on levothyroxine replacement therapy

Antoaneta Argatska[1,2] & Boyan Nonchev[1,2]
[1]Medical University of Plovdiv, Section of Endocrinology, Second Department of Internal Diseases, Faculty of Medicine, Plovdiv, Bulgaria; [2]University Hospital 'Sv. Georgi' Plovdiv, Clinic of Endocrinology and metabolic diseases, Plovdiv, Bulgaria

Introduction
The relationship between thyroid function tests and lipid parameters is still under hot discussion. According to current recommendations thyroid stimulating hormone (TSH) levels should preferably be below 2.5 mIU/l in healthy women of childbearing age as well as in women on levothyroxine treatment.
Aim
To compare lipid levels and atherogenic indices in premenopausal euthyroid healthy women and women with autoimmune thyroiditis (AIT) on levothyroxyne replacement therapy according to TSH values and evaluate their association with thyroid function tests.
Patients and methods
56 women with AIT and 195 healthy premenopausal women aged 18–40 years were included in the study. Serum levels of TSH, free thyroxine (FT4), total cholesterol, HDL and triglycerides were measured; LDL values were calculated using Friedewald formula. Castelli risk index I (CRI) and II (CRII), atherogenic coefficient (AC) and atherogenic index of plasma (AIP) were calculated. All women were euthyroid with TSH levels between 0.4–4.2 mIU/l and FT4 levels within the reference range (7.86–14.40 pmol/l), not taking steroids, metformin, lipid lowering medications or estrogen containing drugs.
Results
42.9% of the women with AIT had TSH ≥ 2.5 mIU/l compared to 28.7% of the healthy women ($P=0.052$). FT4 levels in women on levothyroxine replacement were higher than in the healthy women in both groups according to TSH levels. No differences between lipid parameteres and atherogenic indicis were found in healthy women and those on levothyroxine with TSH < 2.5 mIU/l. In the group with TSH≥ 2.5 mIU/l healthy women hadelevated levels of total cholesterol more frequently than those with AIT (51.8% vs 20.8%, $P=0.013$). In women with AIT TSH levels did not show any relation to the lipid parameteres, but there was a significant negative correlation between FT4 and total and LDL cholesterol ($P<0.01$) and I1, I2 and AC ($P<0.05$). In healthy women TSH was associated neither with lipid levels nor with atherogenic indicis. However FT4 showed significant negative correlation with HDL levels ($P<0.01$) and positive with I1, I2, AC ($P<0.05$).
Conclusion
Our results suggest that FT4 levels have different impact on lipid metabolism in healthy women and women with AIT. Whether this finding is associated with clinically significant increase in cardiovascular risk and whether intervention is reasonable remains a matter of further investigation.
Keywords: autoimmune thyroiditis, thyroid stimulating hormone, free thyroxine, lipid parameters, atherogenic indicis.

The effect of ramadan fasting on thyroid function tests: A study of patients on thyroxine replacement therapy

Budour Alkaf, Tomader Ali, Ali Bakir & Nader Lessan
Imperial College London Diabetes Centre, Research department, Abu Dhabi, United Arab Emirates

Background
Ramadan fasting entails abstinence of food and drink from dawn to sunset for 30 days. Medication timing also changes; for patients with hypothyroidism this can be a challenge as levothyroxine (LT4) is normally taken on an empty stomach and at least half an hour before breakfast. Complying with this advice during Ramadan is impractical for religious and social reasons. Adverse changes in thyroid function in patients with hypothyroidism have been observed. Whether and for how long these changes persist after Ramadan is unclear.
Aim
Investigate the short and long-term impact of Ramadan fasting on thyroid function of patients on thyroxine replacement therapy.
Methods
Patients with hypothyroidism who attended Imperial College London Diabetes Centre (ICLDC, Abu Dhabi) during 2012 and 2017, and were; (1) Arab-Emirati; (2) aged ≥ 18 years; (3) on LT4; (4) not diagnosed with type 1 diabetes; (5) had a thyroid function test (TFT) within 3 months before Ramadan (BR); and (6) had a TSH result ≤ 10 uIU/ml at that visit (BR), were initially included. Selected patients were then followed up to check if they had a TFT at; (1) 1–2 weeks post Ramadan (PR1); (2) 2–3 months post-Ramadan (PR2); and (3) 4–6 months post Ramadan (PR3). Mann-Whitney test was used to test for significant differences in TSH, FT3, and FT4 levels at BR, compared to PR1, PR2, and PR3.
Results
197 had a TFT at all 4 timepoints (BR, PR1, PR2, and PR3), and were included in the analysis. 89.9% of the cohort studied were females and the mean age was 44.7 ± 12.3 years. Prevalence rates of prediabetes and type 2 diabetes were 33.5% and 9.1%, respectively. At PR1, TSH levels were significantly higher, and FT3 and FT4 levels were significantly lower, compared to BR (Figure 1). These significant differences disappeared at PR2, and PR3, where TSH levels decrease and FT3 and FT4 levels increase.
Conclusions
Ramadan fasting leads to adverse, but temporary changes in thyroid function in patients with hypothyroidism which resolve within 2–3 months after Ramadan. Further prospective studies are needed to establish appropriate timing for thyroxine ingestion during Ramadan.

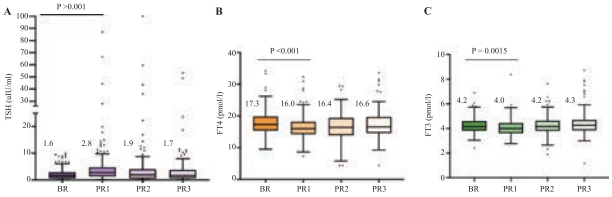

Figure 1 The impact of Ramadan on thyroid function tests. Box plots demonstrating levels of (A) TSH, (B) FT4, and (C) FT3, at within 3 months before Ramadan (BR), 1–2 weeks (PR1), 2–3 months (PR2), and 4–6 months (PR3) after Ramadan.

Numbers above each boxplot represents the median. *P* value; Related-Samples Mann-Whitney Test.

Non-thyroidal illness syndrome in patients admitted for acute disease and its relationship to survival

Evangelos Siarkos[1], Lambros Athanassiou[1], Olga-Maria Spyropoulou[1], Olga Mascha[2], Charilaos Samaras[1], Panagiotis Athanassiou[3] & Ifigenia Kostoglou-Athanassiou[4]
[1]Asclepeion Hospital, Voula, First Department of Medicine, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Biochemistry, Athens, Greece; [3]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; [4]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece

Introduction
Non-thyroidal illness syndrome or low T_3 syndrome is an alteration of thyroid hormone levels which occurs as a reaction to acute disease. It is characterized by low TSH levels and low T_3 and T_4 levels. It is transient. The severity of its expression may be related to the severity of the acute disease. It affects patients hospitalized for acute disease in the department of medicine or surgery and in the acute care unit.
Aim
The aim was to study the expression of non-thyroidal illness syndrome and its relationship to survival in the department of medicine in a general hospital in a cohort of patients hospitalized for an acute disease.
Methods
In patients hospitalized for an acute disease after admission to the department of medicine in a general hospital the levels of TSH, T_4, T_3, freeT_4 and freeT_3 were measured over a period of a calendar year. The patients were followed up until exit from the hospital or death. In the department of medicine 831 patients were admitted with acute disease during the period of a calendar year.
Results
Within this group of 831 patients, 230 patients were found to have non-thyroidal illness or low T_3 syndrome. TSH levels were lower in the group of patients with non-thyroidal illness syndrome as opposed to those who did not express the syndrome, 0.52±0.17 μIU/mlas opposed to 2.81±0.34 μIU/ml ($P<0.001$, Student's t test).T_3 levels were lower in the group of patients with non-thyroidal illness syndrome as opposed to those without the syndrome, 0.52±0.049 ng/ml as opposed to 0.57±0.036 ng/ml ($P<0.001$). T_4 levels were lower in those with the syndrome as opposed to those without the syndrome, 4.72±0.77 μg/dl as opposed to 6.53±0.43μg/dl ($P<0.001$). FT_4 levels were 1.058±0.18 ng/dl in the patients with non-thyroidal illness syndrome as opposed to 1.01±0.15 ng/dl in those without it. The probability of death was found to be higher in the group with the non-thyroidal illness or low T_3 syndrome (chi-square test with Yates correction 7.7593, $P=0.005344$).
Conclusion
It appears that the non-thyroidal illness or low T3 syndrome is frequently observed in patients in the department of medicine, who are hospitalized for acute disease of varying etiology. In the cohort described herein the expression of non-thyroidal illness syndrome was found to be related to increased probability of death.

Spurious thyroid function test results due to interference: Consider concealed biotin in health supplements

Hee Kyung Kim, Jee Hee Yoon, A Ram Hong & Ho-Cheol Kang
Chonnam National University Medical School, Internal Medicine, Gwangju, Korea, Republic of South

Biotin is used in many hormone immunoassays as an immobilizing system as streptavidin binds biotin with high affinity. Recently, cases with spurious results from biotin interference have been increasing due to widespread use of vitamin supplements containing biotin. We report two cases of erroneously high total T3 levels caused by biotin interference.
Case 1
A 88-year-old female who had total thyroidectomy for papillary thyroid cancer 10 years ago and had been taking levothyroxine 125 μg/day underwent routine follow-up thyroid function tests (TFT). Surprisingly, her serum total T3 was >651 ng/dl (60–160) and TSH 0.65 μIU/ml (0.4–4.8). Hormones were measured with a chemiluminescent immunoassay (Cobas: Roche Diagnostics, West Sussex, UK). She had no symptoms and signs of thyrotoxicosis. Subsequent detailed history revealed the culprit. Vitamin supplement (Adult multivitamin Gummies, Kirkland Signature, US) she had been taking since several months ago contained 300 μg biotin per tablet. Her serum total T3 level normalized to 110 ng/dl 1 week after stopping the vitamin.
Case 2
A 43-year-old female who had left lobectomy for papillary thyroid cancer 9 years ago and no levothyroxine replacement underwent routine follow-up TFT. Although she had no signs of thyrotoxicosis, her serum total T3 was 633 ng/dl, free T4 2.42 ng/dl, and TSH 0.786 μIU/ml. She had been taking several complex health supplements including vitamins, probiotics and diet products. Biotin was not identifiable in the label on the products. Repeated TFT results was normalized 1 week after stopping all supplements.
Biotin interference should be considered when TFT results are not compatible with clinical findings, because biotin use is widespread, and some health supplements contain concealed biotin. If biotin interference is suspected, repeating the TFT after stopping biotin supplement for one week can be a reasonable approach.

The effect of selenium supplementation and gluten-free diet in patients with subclinical hypothyroidism affected by autoimmune thyroiditis

Zelija Velija Asimi[1,2], Almira Hadzovic-Dzuvo[3,4] & Djinan Al Tawil[5]
[1]Outpatient Clinic with a Daily hospital 'Dr Al Tawil', Internal medicine – Endocrinology and Diabetology, Sarajevo, Bosnia and Herzegovina; [2]University Sarajevo School of Science and Technology, Sarajevo Medical School, Ilidža, Bosnia and Herzegovina; [3]Outpatient Clinic with a Daily hospital 'Dr Al Tawil', Research Unit, Sarajevo, Bosnia and Herzegovina; [4]University of Sarajevo, Sarajevo, Bosnia and Herzegovina; [5]Outpatient Clinic with a Daily hospital 'Dr Al Tawil', Internal Medicine – Cardiology and Angiology, Sarajevo, Bosnia and Herzegovina

Introduction
Ongoing scientific research indicates that there is a dangerous link between eating foods that contain gluten and Hashimoto's thyroiditis (HT). Gluten can be an irritant to HT by creating inflammation in the thyroid gland. Selenium, an important oligoelement, is a component of the antioxidant system. Over the last decade, it has been ever more frequently discussed in the context of thyroid disorders. The purpose of this study was to highlight the positive response of Hashimoto's patients with subclinical hypothyroidism (SH) treated with Se and gluten-free diet in restoring a normal thyroid function.
Methods
A total of 98 drug-naive women (mean age 39.60±7.36 years) with HT having Thyroid Stimulating Hormone (TSH) levels between 4 and 8 μIU/ml and normal free thyroxine (fT4) and free triiodothyronine (fT3) levels, were randomized into 2 groups: group A ($n=50$) receiving 200 μg selenium in the form of L-selenomethionine orally and gluten-free diet for 6 months and group B ($n=48$) selenium alone without any dietary treatment. Serum titers of thyroid peroxidase (TPOAb) and thyroglobulin antibodies (TgAb), as well TSH, FT4, FT3 were measured at the beginning of the study and 6 months later.
Results
At the end of the study, euthyroidism was restored in 37/50 (74%) of group A participants, and in 28/48 (58.3%) of group B participants. TSH, TPOAb and TgAb levels were significantly reduced in both group after six months of treatment. Serum TPOAb titer in group A had a more significant decrease (by 49%) than those in group B (by 34%).
Conclusions
The results suggest that the gluten-free diet with selenium supplementation is more effective in reducing of TSH, TPOAb and TgAb levels by comparing selenium supplementation alone in Hashimoto's women with SH.

Iodine sufficiency among school age children of Minsk region (Belarus) in 2018

Tatsiana Mokhort, Natalia Kolomiets, Sergey Petrenko, Alena Mokhort & Ekaterina Fedorenko
Belarusian State Medical University, Endocrinology, Belarus

Background
The problem of iodine deficiency in Belarus remains topical, due to the historical understanding of iodine deficiency in the environment. As a result,

the Republic of Belarus has developed and since 2000 implemented a strategy for iodine deficiency elimination, based on the use of iodized salt and food fortification.
Aims
To determine iodine status in children living in Minsk region.
Materials and methods
The study included 150 school children aged 9–12 years of both sexes. Questioning, determination of urinary iodine concentration and thyroid volume with ultrasound were carried out.
Results
Urine Iodine Median was 186.5 μg/l in the 150 children in Minsk region of Belarus. Thyroid volume corresponds to the normative values in children. Data are presented in the table. Thyroid volume (ml) in children depending on age According to the survey, 78.8% of households used iodized salt.

Gender	Age, y.o			
	9	10	11	12
Girls	4.288 (n=17)	5.385 (n=21)	5.701 (n=19)	5.885 (n=17)
Boys	4.267 (n=20)	5.060 (n=20)	5.763 (n=18)	6.528 (n=18)

Conclusions
The use of iodized salt and foods allows an adequate level of iodine supply in schoolchildren.

The use of different sodium/potassium perchlorate regimes could affect response time in the treatment of amiodarone-induced thyrotoxicosis

Mario Pazos[1], Martín Cuesta[1], Raquel Pallarés[1], Elvira Ramos[1], Elvira Barrio[1], Virginia Puebla[2], Paz De Miguel[1], Jose Ángel Díaz[1], Alfonso Calle[1] & Isabelle Runkle[1]
[1]Hospital Clínico San Carlos, Servicio de Endocrinología y Nutrición, Madrid, Spain; [2]Hospital Clínico San Carlos, Servicio de Farmacia Hospitalaria, Madrid, Spain

Introduction
In the treatment of amiodarone-induced type I or mixed thyrotoxicosis, sodium or potassium perchlorate is often associated to thionamides, when the latter are insufficient for a prompt control of thyroid hormone secretion. Perchlorate competes with iodine for entrance into the follicular cell, and also induces a discharge of iodine from these cells with each administration. We compare the effect of 3 different regimes of perchlorate with methimazole on control of fT4 secretion.
Methods
Retrospective. 41 patients were treated by Endocrinology of a tertiary hospital for amiodarone –induced thyrotoxicosis (AIT) with potassium/sodium perchlorate associated to methimazole (30 mg/day) over an 11-year period. Diagnosis of type I or mixed AIT was based on thyroid doppler ultrasound, fT3/fT4 ratio, MIBI scan, IL-6 levels, and response to therapy. Patients with mixed AIT initiated perchlorate following inadequate response to glucocorticoid therapy and/or methimazole. Patients with suspected type I initiated treatment with methimazole alone or combined with perchlorate. 3 perchlorate regimes were used: Group I: 150 mg 6 ×/day, Group II: 200 mg 5 ×/day, Group III: 300 mg tid, maximum of 6–8 weeks. Response was compared, analyzing the number of days necessary for initiation of a sustained fT4 descent (minimum initial descent: 2 pg/ml). [Interquartile range].
Results
26 (63.4%) men, mean age 73 (s.d.:11.7). Type I AIT: 9/41 (22%), mixed: 31/41 (75.6%), Type II 1/41 (2.4%). 5 patients were not included in the analysis: 1 patient receiving 100 mg 4 ×/day, 1 who did not take medication, 1 initially on expired perchlorate, 1 non-responder until switched from propylthiouracil to methimazole, 1 lost to follow-up. The response rate of the remaining patients was analyzed: 10 (27.7%) in Group I, 21 (58.3%) in Group II, and 5 (13.9%) in Group III.
Median baseline fT4 was 39.3 pg/ml [30.1–45.2], 24.2 [20–40.5), and 34.5 [20.4–41] in Groups I, II, and III respectively. Median duration of perchlorate therapy was 42 days [23–45]. Median number of days for response was significantly different among groups, with 3 [2–6], 7 [4–12], and 7 [4–25] in group I, II and III respectively, P=0.015. No significant side effects were observed.
Conclusions
The frequency of perchlorate administration could perhaps play a role in response time in amiodarone-induced type I and mixed thyrotoxicosis, with a more prompt response when perchlorate is administered more often. These results indicate a need for prospective trials, with larger number of patients, designed to compare the effect of different perchlorate regimes.

Plasma levels of Th17 associated cytokines in patients with autoimmune thyroid disease

Tatjana Zake[1], Ieva Kalere[2], Sabine Upmale[1], Gita Gersone[3] & Ilze Konrade[1]
[1]Riga Stradins University, Department of Internal Medicine, Riga, Latvia; [2]Riga Stradins University, Doctoral studies, Riga, Latvia; [3]Riga Stradins University, Department of Human Physiology and Biochemistry, Riga, Latvia

Introduction and aim
Cytokines play a crucial role in modulating immune response in both Hashimoto's thyroiditis (HT) and Graves' disease (GD). They may contribute to drive the autoimmune response skewing toward the Th17 phenotype and away from Th1 or Th2 phenotypes. Recent studies revealed an essential role of Th17 cells and their cytokines in the development of autoimmune thyroid diseases (AITD). However, participation of Th17 cells in the pathogenesis of GD is less evidenced. We aimed to assess the balance of Th17 immune response by analyzing plasma levels of Th17 associated cytokines in AITD patients.
Materials and methods
Fifty-four subjects were recruited into this study: 11 treatment naïve, newly diagnosed hyperthyroid GD patients, 30 patients with newly diagnosed euthyroid HT (4 out of 30 patients had mild subclinical hypothyroidism (TSH≤6 μIU/ml)), and 13 age and sex-matched healthy subjects as controls. Cytokine patterns included following groups: Th17 cytokines – IL-17, IL-22; Th17-promoting cytokines – IL-23, IL-10 and IL-6. Plasma levels of cytokines were analyzed in all 54 participants. EDTA plasma immunological markers were detected by xMAP technology (Magpix system; Luminex Corporation, USA). All tests were performed in accordance with the manufacturer's instructions (Cat#: HTH17MAG-14K; Kit Lot#: 3323752; Milliplex).
Results
The mean age of patients was 44.36±15.41 years (28–72 years; nine females and two males) in GD group, 38.55±12.54 years (23–64 years; 29 females and one male) in HT group, and 36.36±11.91 years (22–58 years; 12 females and one male) in controls. Plasma IL-17 and IL-22 levels were 13.90 (10.26, 18.31) pg/ml, 0.04 (0.01, 0.35) ng/ml in HT group, 13.53 (10.34, 16.72) pg/ml, 0.13 (0.01, 0.25) ng/ml in GD group and 17.30 (12.23, 21.06) pg/ml, 0.18 (0.04, 0.51) ng/ml in controls, respectively. Median concentrations of IL-23, IL-10 and IL-6 were 2.42 (1.30, 3.68) ng/ml, 9.71 (5.96, 11.42) pg/ml, 3.12 (0.63, 14.18) pg/ml for HT patients, 2.32 (1.71, 3.36) ng/ml, 9.51 (6.55, 11.12) pg/ml, 6.93 (0.63, 24.90) pg/ml for GD patients and 3.30 (1.96, 4.21) ng/ml, 12.75 (7.63, 16.73) pg/ml, 11.29 (1.30, 15.67) pg/ml for controls, respectively. No significant difference was found between plasma levels of cytokines among the three groups.
Conclusions
Despite recent data on involvement of IL-23/IL-17 axis in the development of thyroid autoimmunity, we did not find any significant differences regarding plasma levels of Th17 associated cytokines between patients with AITD and control group.

The use of single dose of rituximab in combination with radiotherapy, in the treatment of Graves' Orbitopathy – clinical observations

Łukasz Gojny, Agnieszka Moskwa, Marek Bolanowski & Jacek Daroszewski
Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland

The treatment of orbitopathy in the course of Graves' disease (GO, Graves' Orbitopathy) still remains a serious therapeutic challenge. Modification of risk factors is considered to be the most important and the most effective method of treatment of benign GO. Treatment with intravenous glucocorticosteroid preparations remains the first-line therapy for moderate- to severe GO but is insufficient in some patients. Radiotherapy has been used in active GO therapy for decades, but its place in the treatment remains undetermined. High hopes are associated with the administration of low doses of rituximab (RTX) – a monoclonal antibody against CD20 antigens presented by lymphocytes B. The aim of the study is to present our clinical experiences in the use of RTX in a single dose in combination with radiotherapy in patients with active orbitopathy where other available forms of treatment were exhausted. Between 2017 and 2020 a group of 8 subjects aged 35–73 with active, moderate to severe GO, not responding to methylprednisolone therapy, was included in treatment. Patients were euthyroid, L-thyroxine supplementation was used if necessary. All patients denied smoking. The follow-up period ranged from 1 to 34 months. While all of the contraindications were excluded, each patient was given a single dose of 500 mg of RTX in a slow continuous intravenous infusion, strictly according to the therapeutic protocol. There were no side effects seen, both during, and after the drug administration. After the pharmacological treatment, each of the patients was referred to a radiotherapy center, to undergo a cycle of ten fractions of the orbit radiation therapy. As the therapy was finished, a hormonal, ophthalmological and imaging reassessment was carried out. There was a significant improvement seen in patients, concerning the clinical activity score (CAS). That included the total deactivation of the inflammatory process in 62.5% of patients. The massive effect of drug administration on the decrease of TRAb level was observed. (mean 23.08 IU/l before and 18.36 IU/l after therapy). MR imaging showed a decrease in eye muscles' thickness. Our experiences with the use of single dose of RTX combined with radiotherapy indicate an efficacy of this new form of second-line treatment of GO. The reduction of activity of orbitopathy in all patients undergoing the treatment and, in some cases, its complete deactivation is very promising. Moreover, the lack of complications during the drug administration as well as the lack of infusion-related complications indicate the safety of the therapy.

Insulin resistance, lipid profile and low-grade inflammation in Hashimoto thyroiditis

Marta Afonso[1], Celestino Neves[2], João Sérgio Neves[2], Miguel Pereira[2], José Luís Medina[2], Luís Delgado[3] & Davide Carvalho[2]
[1]Faculty of Medicine of the University of Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]University Hospital Center of São João, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [3]University Hospital Center of São João, Immunology, Porto, Portugal

Background
Hashimoto thyroiditis (HT) is the most common autoimmune disease and patients may present different levels of thyroid dysfunction. The association between hypothyroidism and cardiovascular events is well established. However, it remains unclear how mild thyroid dysfunction, autoimmunity and chronic inflammation in HT contribute to an increased cardiovascular risk in euthyroid patients and in subclinical hypothyrodism. Therefore, this study aims to assess insulin resistance, lipid panel and low-grade inflammation in HT patients.
Methods
A total of 228 patients with HT were enrolled and divided into 3 groups, accordingly to TSH levels – TSH 0.35–2.49 µUI/ml, TSH 2.5–4.94 µUI/ml and TSH>4.94 µUI/ml. We assessed thyroid function tests, thyroid antibodies, lipid profile, insulin resistance indexes [homeostasis model assessment insulin resistance (HOMA-IR), quantitative insulin sensitivity check index (QUICKI), insulinogenic index (IGI), whole body insulin sensitivity index (WBISI) and hepatic insulin sensitivity index (HISI)], high-sensitivity C-reactive protein (hs-CRP), vitamin B12, folic acid and homocysteine. Statistical analysis was made using one-way ANOVA, Student's t-test, Pearson's correlations and multiple linear regression.
Results
93.9% of our population were women and mean age was 47.06±15.4 years. No significant statistical differences were found between groups, regarding age, sex and body mass index. The group TSH>4.94 µUI/ml, in comparison to the group TSH 2.5–4.94 µUI/ml, showed significant higher values of HOMA-IR (3.77±2.93 vs 1.95±1.25, $P<0.001$) and inferior values of QUICKI (0.48±0.13 vs 0.70±0.39, $P=0.049$) and HISI (41.73±29.03 vs 79.84±63.72, $P=0.026$). The group with TSH 2.5–4.94 µUI/ml, in comparison to the group TSH 0.35–2.49 µUI/ml, presented significant higher levels of Apolipoprotein B (ApoB) (102.14±33.885 vs 97.64±21.001, $P=0.036$). In the total group, positive correlations were found between TSH and both triglycerides ($r=0.206$, $P=0.002$) and HOMA-IR ($r=0.209$, $P=0.002$). Positive correlations were found between thyroid peroxidase antibodies levels and total cholesterol ($r=0.166$, $P=0.013$), LDL-cholesterol ($r=0.173$, $P=0.01$), triglycerides ($r=0.148$, $P=0.027$), ApoB ($r=0.190$, $P=0.006$) and HOMA-IR ($r=0.141$, $P=0.033$). Thyroglobulin antibodies correlated positively with triglycerides ($r=0.140$, $P=0.036$). Hs-CRP correlated positively with IGI ($r=0.156$, $P=0.024$) and negatively with WBISI ($r=-0.177$, $P=0.010$).
Conclusions
HT patients with mild thyroid disfunction present a more atherogenic lipid profile and higher resistance to insulin action. Thyroid autoimmunity also seems to be related to insulin resistance, to a less favorable lipid panel and low-grade inflammation. These findings demonstrate the importance of screening for cardiovascular comorbidities in these patients to provide an early diagnosis and better treatment decisions.

Thyroid arterial embolization for refractory amiodarone-induced thyrotoxicosis in a patient with congenital heart disease

Bruno Bouça[1], Ana Cláudia Martins[1], Paula Bogalho[1], Lídia de Sousa[2], Tiago Bilhim[3], Filipe Veloso Gomes[3], Élia Coimbra[3] & Ana Agapito[1]
[1]Centro Hospitalar Universitário de Lisboa Central, Endocrinology, Diabetes and Metabolism Department, Lisbon, Portugal; [2]Centro Hospitalar Universitário de Lisboa Central, Cardiology Department, Lisbon, Portugal; [3]Centro Hospitalar Universitário de Lisboa Central, Interventional Radiology Unit, Lisbon, Portugal

Introduction
Amiodarone-induced thyrotoxicosis (AIT) in patients with congenital heart disease (CHD) has an estimated cumulative incidence of 13–21%, and prompt reversal to euthyroidism is crucial in these patients. We present a case of refractory AIT in a patient with CHD who was treated with thyroid arterial embolization (TAE).
Clinical case
A 34-year-old male with complex cyanotic CHD (great vessels transposition, interventricular communication), had palliative cardiac surgery in his childhood and developed heart failure (HF), pulmonary hypertension, and supraventricular tachyarrhythmias. Since 2013 he was treated with amiodarone with no adverse effects. In April 2019 he was referred to our Endocrinology Department due to thyrotoxicosis, which was detected due to worsening of HF and weight loss, irritability and tremor of the extremities with 4 months of evolution. He had TSH 0.02 uIU/ml [0.35–4.94] FT4 2.12 ng/dl [0.70–1.48] FT3 5.86 pg/ml [1.88–3.18]. Analytical reassessment at 1st visit: TSH<0.01 mIU/l FT4 4.60 ng/dl FT3 14.57 pg/ml, TRAB negative. He started therapy with thiamazole 30 mg/day and prednisolone 40 mg/day. Despite a favorable initial response, the clinical and analytical condition deteriorated – ventricular tachyarrhythmia with implantable cardioverter-defibrillator placement – requiring multiple admissions, increasing doses of thiamazole (60 mg/day) and glucocorticoids (dexamethasone 10 mg/day) and initiation of cholestyramine 24 g/day and lithium 800 mg/day. On the 4th month of follow-up, due to failure of medical therapy, thyroidectomy after plasmapheresis was considered, but both were contraindicated by the patient's cardiac condition. After multidisciplinary team discussion, it was decided to perform TAE of the 4 arteries with polyvinylalcohol particles 250–300 microns, using hybrid imaging with angiography and computed tomography. There were no complications and gradual clinical and analytical improvement was obtained. On the 14th week after the procedure, the patient reached normal thyroid function on lower doses of anti-thyroid drug and no need of glucocorticoid.
Conclusion
This case was challenging, not only because it was urgent to control thyroid function due to cardiac deterioration, but also because thyroidectomy was contraindicated and AIT was refractory to medical treatment. TAE is rarely employed in AIT, but has proved to be the only therapeutic option in this patient, solely possible in a center with experienced interventional radiology unit.

Effect of increased levothyroxine dose on depressive mood in older adults undergoing thyroid hormone replacement therapy

Jae Hoon Moon[1], Ji Won Han[2], Tae Jung Oh[1], Sung Hee Choi[1], Soo Lim[1], Ki Woong Kim[2] & Hak Chul Jang[1]
[1]Seoul National University Bundang Hospital and Seoul National University College of Medicine, Department of Internal Medicine, Seongnam-si, Korea, Republic of South; [2]Seoul National University Bundang Hospital and Seoul National University College of Medicine, Department of Neuropsychiatry, Seongnam-si, Korea, Republic of South

Background
Depressive mood consequent to hypothyroidism can be reversed with levothyroxine (LT4) replacement therapy. However, it is unclear whether increasing LT4 dose confers additional mood benefits.
Methods
This was a single-blind before-and-after study of 26 patients with hypothyroidism who were aged 65 years or older and undergoing LT4 replacement therapy. Geriatric Depression Scale (GDS-K) and Hyperthyroid Symptom Scale (HSS-K) were assessed at baseline, 3 months after increasing LT4 dose by an additional 12.5 µg/day, and finally 3 months after returning to the baseline dose.
Results
Systolic blood pressure and pulse rate increased from baseline with the increased LT4 dose, and recovered after returning to the baseline dose. Serum thyroid-stimulating hormone (TSH) concentrations decreased at the higher LT4 dose (1.95±2.16 vs 0.47±1.09 mIU/l, $P<0.001$) and recovered after returning to the baseline dose. Serum-free thyroxine levels and HSS-K scores were unchanged during the study period. GDS-K scores improved on the increased dose (9.5±6.6 vs 7.5±4.7, $P=0.029$) and this improvement was maintained after returning to the baseline dose (9.5±6.6 vs 7.4±5.4, $P=0.010$). Higher serum TSH was independently associated with both higher GDS-K and depression risk among those with depressive mood (GDS-K>10) at baseline.
Conclusions
Depressive mood improves with increased LT4 dose, without significant hyperthyroid symptoms or signs, in older adults undergoing thyroid hormone replacement. These findings suggest the potential for varying hypothyroid treatment based on mood status, and that low-dose LT4 treatment may be used as an ancillary treatment in older euthyroid patients with depression.

Thyroid imaging in the management of anti-PD1/PD-L1 induced thyrotoxicosis

Alessandro Brancatella[1], Isabella Lupi[1], Nicola Viola[1], Daniele Sgrò[1], Lucia Antonangeli[1], Lucia Montanelli[1], Chiara Sardella[1], Sandra Brogioni[1], Debora Ricci[1], Francesca Bianchi[1], Paolo Piaggi[2], Ferruccio Santini[1], Claudio Marcocci[1] & Francesco Latrofa[1]
[1]Endocrine Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Obesity and Diabetes Clinical Research Section, Phoenix Epidemiology and Clinical Research Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Phoenix, AZ

Context
Thyrotoxicosis is the most common endocrine adverse event due totreatment with anti-PD1 and anti-PD-L1. The most common form is destructive thyrotoxicosis whereas persistent, supposedly autoimmune hyperthyroidism (Graves' hyperthyroidism) is rare. The possible role of thyroid imaging (neck ultrasound and scintigraphy) in the differential diagnosis has never evaluated.
Aim
To evaluate the usefulness of neck ultrasound and ^{99}Tc- scintiscan in patients with thyrotoxicosis induced by anti-PD1 and anti-PD-L1 therapy.
Patients and methods We retrospective analyzed clinical, biochemical and imaging data of 15 consecutive patients who were referred to our department for thyrotoxicosis (high levels of FT4 and FT3 and low-to-undetectable level of TSH) ensued during immunotherapy. All patients underwent neck ultrasound and ^{99}Tc-scintiscan at the onset of thyrotoxicosis and periodical tests of thyroid function (15, 30, 45, 60, 90 and 120 days).
Results
All patients were euthyroid before starting immunotherapy. At the onset of thyrotoxicosis median FT4 was 3.05 ng/dl (normal range 0.7–1.7) median FT3 was 6.30 ng/l (normal range 2.7–5.7)At ^{99}Tc- scintiscan 11 patients presented no uptake (Sci-) whereas 4 patients presented diffuse uptake (Sci+). Sci-patients had absent vascularization whereas Sci+ patients had hypervascular pattern at neck ultrasound. No differences in thyroid function tests were observed at the onset of thyrotoxicosis between the two groups. At 30 and 60 days Sci+ patients showed higher levels of FT4 and FT3 compared to Sci- patients ($P<0.005$).All Sci- patients underwent spontaneous remission, whereasall Sci+ patients required treatment with methimazole in order to control thyrotoxicosis. Among Sci- patients, a lower (< 20 ml) thyroid volume was associated with a faster remission. TSH-receptor antibodies, measured as TBI,were negative throughout the follow-up in all patients.
Conclusions
While Sci- patients showed a self limited course of thyrotoxicosis with a remission time inversely related to thyroid volume,Sci+ patients required treatment with methimazole in order to control thyrotoxicosis induced by PD1 and PD-L1 therapy.

Objective
Progesterone (P4) is essential for successful embryo implantation and preventing miscarriage. The strong connection between thyroid autoimmunity (TAI) and infertility is highlighted in literature. Follicular fluid (FF) is important for the oocyte maturation. The aim of the study was to assess the influence of FF P4 in TAI positive women on assisted reproductive technology (ART) outcome.
Methods
The study included 52 women undergoing ART. Before the initiation of protocol for the controlled ovarian stimulation,thyrotropin (TSH), free triiodothyronine (fT_3), free thyroxine (fT_4), thyroid peroxidase antibodies (TPOAbs) and thyroglobulin antibodies (TgAbs)levels were measured in serum, while TSH, fT_4, TPOAbs, TgAbsand P4 levels were measured in FF on the day of oocyte retrieval. Depending of serum TPOAbs and/or TgAbslevels patients were divided into TAI positive group included 26 patients and 26 age and body mass index matched TAI negative controls.
Results
TAI positive women had less chance to achieve pregnancy ($P=0.004$, OR=0.036, 95% CI 0.004–0.347). However, no statistically significant difference of mean P4 FF level between women with 21 724.2±12 157.3 ng/ml, and without TAI 20 676.6±11 764.9 ng/ml was found ($P=0.754$), and no statistically significant correlation was shown between FF P4 and serum and FF TPOAbs and TgAbs in groups. No statistically significant difference was found between FF P4 and the ART outcome, pregnancy per ET cycle in individual TAI positive and TAI negative groups, although, higher values of FF P4 were observed in subjects with pregnancy per ET cycle with borderline statistical significance ($P=0.060$). It was shown that FF P4 is a significant predictor of ART outcome [log FF P4 $P=0.011$, OR=56.276 (95% Cl 2.542–1245.660)].
Conclusion
To the best of our knowledge, this is the first time to demonstrate the presence of P4 in FF of TAI positive women undergoing ART, and to estimate its impact on ART outcome. FF P4 was shown to be a significant predictor of ART outcome, for both women with and without TAI. Further studies are needed to estimate possible FF P4 threshold affecting ART outcome.

Subclinical hypothyroidism and non-alcoholic fatty liver disease: A systematic review and meta-analysis

Yuli Guzman-Prado & Ondrej Samson
International centre for medical research, Dorset, United Kingdom

Introduction
Hypothyroidism has been reported as an important factor in the pathogenesis of non-alcoholic fatty liver disease (NAFLD) but studies about the relation between subclinical hypothyroidism and NAFLD have shown contradictory findings. The aim of this study was to conduct a systematic review and meta-analysis exploring the association between subclinical hypothyroidism and NAFLD.
Methods
MEDLINE, EMBASE, Cochrane Library and sources for grey literature (GreyNet international, Google Scholar, Web of Science) were searched from inception to December 2019. The results were supplemented by a manual search of the bibliographies of the articles. The Newcastle Ottawa Scale was used to evaluate the quality of included studies.
ORs were considered as the effect measure with 95% confidence interval and two sided *P* values was calculated for totals and each study. Sensitivity analysis was implemented by excluding studies with low score of quality. Heterogeneity was assessed using χ^2 test and I^2 statistic. Publication bias was evaluated by funnel plot. Review Manager software v.5.3 was used and $P<0.05$ was considered statistically significant.
Results
11 studies were included in the meta-analysis with 41.553 participants (table 1). There was association between subclinical hypothyroidism and NAFLD (OR: 1.27; CI 95%: 1.01–1.60; I^2: 79%; $P=0.04$) (Figure 1). After excluding one study with low quality, subclinical hypothyroidism was significantly correlated with NAFLD (OR: 1.28; CI 95%: 1.01–1.62; I^2: 81%; $P=0.04$). Funnel plot did not show indication of publication bias.

Table 1 Summary of the characteristics of included studies.

Author, year	Country	Study design	Number of participants	Age (years)	Quality
Bano, 2016	Netherlands	Cohort	9.419	64.7	High
Chung, 2012	Korea	Cross-sectional	4.648	48.6±11.8	High
Correa-Morales, 2014	Mexico	Case-control	145	--	Low
Eshraghian, 2013	Iran	Cross-sectional	832	48.2±12.8	Moderate
Lee,2015	Korea	Cohort	18.544	37.8±5.7	High
Lee, 2018	Korea	Cross-sectional	3.452	44.8 (44.5–45.1)	High
Ludwing, 2015	Germany	Cross-sectional	1276	40.7±12.7	High
Parikh, 2015	US	Case-control	800	44.3±3.2	High
Posada-Romero, 2014	Mexico	Cross-sectional	753	51.9	Moderate
Wang, 2014	China	Cross-sectional	806	56.99	Moderate
Xu, 2012	China	Case-control	654	–	High

Conclusion
Our meta-analysis demonstrated that subclinical hypothyroidism increases the risk of NAFLD. The treatment of subclinical hypothyroidism in patients with NAFLD might improve the progress or the occurrence of the hepatic disease and this potential benefit should be further explored by well-designed clinical studies.

Total thyroidectomy for amiodarone-induced thyrotoxicosis: Identification of the surgical candidates and preparation to surgery

Daniele Cappellani[1], Piermarco Papini[2], Agostino Maria Di Certo[1], Michele Mantuano[1], Luca Manetti[1], Gabriele Materazzi[2], Luigi Bartalena[3] & Fausto Bogazzi[1]
[1]University of Pisa, Unit of Endocrinology, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Unit of Endocrine Surgery, Department of Surgery, Medical, Molecular Pathology and Critical Area, Pisa, Italy; [3]University of Insubria, Department of Medicine and Surgery, Varese, Italy

Background
Amiodarone-induced thyrotoxicosis (AIT) is a challenging disease associated with increased morbidity and mortality. The European Thyroid Association guidelines define the role for total thyroidectomy in the management of AIT. However, these recommendations were based on small series, which often lead to heterogeneous results and, importantly, did not identify patients who may benefit from surgery.
Materials and methods
Observational longitudinal cohort study involving 207 AIT patients followed at University of Pisa over a 27-year span. Fifty-one patients received total thyroidectomy and 156 received optimal medical therapy, as defined by the most recent guidelines. Indications to surgery were revised, and surgical candidates were clustered according to the degree of urgency, thus leading to the identification of four surgical groups. Data at diagnosis of AIT and during the course of the disease were recorded. Death and its causes were assessed by telephone interview. Intergroup comparisons were performed between surgical and medical patients, and intragroup comparisons were performed according to the four identified surgical groups. Survival was estimated using the Kaplan-Meier method.
Results
Ten-years overall mortality rate and 5-years cardiovascular-specific mortality rate were lower in the surgical rather than in the medical therapy group ($P=0.04$ and $P=0.01$, respectively). This result was due to the subset of patients affected by moderate-to-severe systolic dysfunction, whereas no differences were reported for patients with normal or mildly-reduced systolic function. Compared to low-risk patients who underwent total thyroidectomy in the elective setting, high-risk patients submitted urgently to surgery due to a worsening of the underlying cardiac conditions were operated more rapidly ($P=0.018$), with a lower left ventricular ejection fraction ($P<.0001$)and with higher thyroid hormone concentrations ($P=0.0002$ and $P=0.013$ for FT4 and FT3), but without any difference in the survival rates ($P=0.486$). At Cox multivariate analysis presurgical thyroid hormone concentrations were not significant predictors of mortality.
Conclusions
Total thyroidectomy should be considered for AIT patients with moderate-to-severe systolic dysfunction, since it is associated with improved survival compared to optimal medical therapy. Patients affected by severe underlying cardiac disease should undergo surgery urgently, avoiding any possible delay aimed at a preliminary restoration of euthyroidism.

PEG precipitation of TSH in subclinical hypothyroidism. A study of 398 samples in real-world setting

Emin Mammadov[1], Cristian Bercu[2], Mihaela Dinescu[2], Bogdan Vasile Ileanu[3] & Corina Neamtu[4]
[1]Sanador Oncology Centre, Endocrine Oncology, Bucharest, Romania; [2]Sanador Hospital, Laboratory, Bucharest, Romania; [3]University of Economic Studies, Center for Health Outcome and Evaluation, Bucharest, Romania; [4]Sanador Hospital, Endocrinology, Bucharest, Romania

Background
Hypothyroidism is defined as an elevated TSH (thyroid-stimulating hormone) and/or decreased free thyroxine (FT4) levels. Levothyroxine is now one of the most widely prescribed medications. However, treatment indications are controversial in subclinical hypothyroidism, defined as high TSH with normal T4 levels.
Methods
We performed a cross-sectional study reviewing the blood samples received in our Laboratory for TSH determination during the period of 10th Jun 2019–21st Oct 2019. We did not search for access to medical background or any private information regarding the patients whose samples were analysed. Any TSH above the upper limit of normal for our laboratory (4.94 mU/l for adult patients, CMIA, Abbott Architect) and up to 20 mU/l was included to the study group. Among samples with TSH above 20 mU/l, we only included those with normal FT4 or T4 level determined from the same sample. The selected samples were treated with Polyethylene glycol (PEG) in the same manner as for high prolactin levels. We calculated the TSH recovery level (monomeric TSH) as a percentage of the initial TSH level.

For statistical analysis, we used IBM SPSS v.21 and MaxStat v.3.6. We applied non-parametric tests and defined $P<0.5$ as significant.
Results
Of 12 703 samples, 430 (3.4%) met the inclusion criteria. Of these, 398 had available serum for precipitation with PEG. Patients with initial TSH < 15 mU/l were younger than those with TSH 15 mU/l or above ($P=0.03$). The group with recovered TSH percentage of up to 24% ($n=106$) had a lower initial TSH value when compared with 25% or higher ($n=292$) ($P=0.01$). Older age (50 and older, $n=200$) was associated with a higher level of monomeric TSH ($P=0.003$). The initial TSH values of 7.77 mU/l or above had tendency towards higher value of monomeric TSH ($P=0.066$).
Conclusions
Our results suggest there could be a potential role for monomeric TSH determination prior to treatment initiation for subclinical hypothyroidism, mainly in young patients. The main strong point of our study is its real-world setting. The limitations are that we did not take into account the patients' background and treatment; we also did not have a possibility to use gel filtration chromatography which is considered a gold standard for monomeric TSH determination. At the next stage, we are planning to compare these results with a group of patients who have normal TSH values.

The effects of naringenin on NRF2 and antioxidant enzymes expressions in the thyroids of the old-aged Wistar rats

Marko Miler[1], Jasmina Živanović[1], Vladimir Ajdžanović[1], Branka Šošić-Jurjević[1], Zorica Marković[2] & Verica Milošević[1]
[1]University of Belgrade, Institute for Biological Research 'Siniša Stanković' – National Institute of Republic of Serbia, Cytology, Belgrade, Serbia; [2]Clinical Hospital Center 'Dr Dragiša Mišović-Dedinje', Department of Endocrinology, Belgrade, Serbia

Citrus flavanone naringenin (NAR) is a potent antioxidant with ability to change pituitary-thyroid function. NAR increases concentration of thyroid-stimulating hormone (TSH) in serum by increasing Sirtuin1 expression in the pituitary thyrotrophs and improves thyroid hormonogenesis capacity in old-aged rats. Thyroid hormone production is followed by generation of large quantities of reactive oxygen species (ROS) which are essential for iodine organification. A master regulator of redox status, NRF2 protein, together with antioxidant enzymes (AOE), is responsible for maintenance of redox/antioxidant balance in the cell. Considering that NRF2 expression can be affected by NAR, besides TSH, the study aim is to analyze gene and protein expressions of NRF2 and AOE in the thyroids of 24-month-old male Wistar rats. NAR was suspended in sunflower oil (vehicle) and administrated directly to the oral cavity, at a dose of 15 mg/kg b.m., during 4 weeks. Control group received vehicle only. We performed qPCR and immunoblot analyses for gene and protein expressions, respectively. Obtained results showed that NAR treatment lowered ($P<0.05$) mRNA levels of Nrf2, superoxide dismutase 1 and 2 (Sod1, Sod2) and catalase (Cat) for 42%, 32%, 45% and 35%, respectively, while it only increased ($P<0.05$) expression of glutathione peroxidase (Gpx) for 54%, all in comparison with the controls. Gene expression of glutathione reductase (Gr) remained unchanged. Also, NAR up-regulated ($P<0.05$) protein expression of NRF2 and SOD2 for 58% and 50%, respectively, and down-regulated ($P<0.05$) SOD1 expression for 48%, all when compared to the adequate control values. CAT, GR and GPx protein expressions didn't change after NAR treatment. It can be concluded that NAR changes gene and protein expression of NRF2 in old-aged rat model. Down-regulation in Nrf2 gene expression, and some AOE, is in line with previously observed TSH stimulation after NAR. Antioxidant protection in thyroid needs to be lowered in order to ensure sufficient ROS for adequate thyroid hormones production. However, due to NAR prooxidant properties, redox status in thyroid upon its application was changed, inducing accumulation of NRF2 protein in the thyrocytes. This led to increment of Gpx gene and SOD2 protein expression, helping in maintenance of fundamental antioxidant protection and disposal of excessive ROS in the thyroid gland of old-aged rats.

Retrospective analysis of low risk thyroid cancers. Total thyroidectomy or lobectomy is the optimal approach for follow up?

Zoltán Hella[1], László Vass[2], Zsolt Csapó[3] & Gábor László Kovács[1]
[1]Flor Ferenc Hospital, 1st Department of Internal Medicine, Kistarcsa, Hungary; [2]Flor Ferenc Hospital, Department of Pathology, Kistarcsa, Hungary; [3]Flor Ferenc Hospital, Department of Surgery, Kistarcsa, Hungary

Background
Differentiated thyroid cancer (DTC) <1 cm without risk factors require only lobectomy, and there is no need for radioiodine remnant ablation (RRA). The approach for surgery and RRA after surgery is less clearly defined for tumours measuring 1–4 cm.
Objectives
We aimed to evaluate the surgical approaches of DTC in stages pT1–2 in a moderate iodine deficient area. We compared our data to the current European Thyroid Association (ETA,2006) and American Thyroid Association (ATA,2015) clinical practice guidelines.
Methods
Data of 111 DTC patients treated between 2013–2018 at Flór Ferenc Hospital, Kistarcsa were retrospectively analyzed. The therapeutical response could be evaluated in 96 DTC patients.
Results
81 patients were classified with DTC in stages pT1–2. 64 patients were found in stages pT1, 17 patients were detected in stages pT2. The histological distribution of DTC was 65/81 (80.2%) papillary thyroid cancer (PTC) and 16/81 (19.8%) follicular thyroid cancer (FTC). Lymph node metastases were present in 21.5% of PTC and 0% of FTC. No distant metastases were detected. 25% of pT1 DTC was multifocal (9% limited to one lobe, 16% involved both lobes/isthmus), and 11.7% of pT2 DTC was multifocal (5.8% limited to one lobe, 5.8% involved both lobes). Thus pT1–2 multifocal DTC located in both lobes/isthmus were found in 11 patients (13.5%), all PTC, whereby 4/37 (10.8%) were in stage pT1a, 5/27 (18.5%) were in stage pT1b, 2/17 (11.8%) were in stage pT2. All of them underwent total thyreoidectomy, and in 10 of 11 were done postsurgical RRA. The tumour size in the contralateral lobe was <5 mm in 5 cases, was >5 mm in 3 cases (mean 9.6 mm) and there were no exact data in 3 cases.
Conclusions
In 13.5% of pT1–2 patients (11/81) the tumour involved both lobes, which changes the staging of the disease. The size of the tumour in the contralateral lobe is small in most cases (mean 1.4 mm), this fact makes almost impossible to detect and follow up them by ultrasound. Therefore we suggest total thyreoidectomy in moderate or low iodine supplied areas in T1b–T2 cases to improve the risk stratification, to determine the necessity of RRA and the long-term follow up, which are almost impossible if only lobectomy is being done.

Early diagnosis of medullary thyroid cancer in case of low serum calcitonin: Role of calcitonin measurement in fine-needle aspiration washout fluid

Carla Greco[1], Bruno Madeo[1], Vincenzo Rochira[1], Maria Cristina De Santis[2] & Giulia Brigante[1]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department Biomedical, Metabolic and Neural Sciences,, Modena, Italy; [2]Department of Clinical Pathology, University Hospital of Modena, Department of Clinical Pathology, Modena, Italy

Background
Screening serum calcitonin (sCT) measurement in patients with thyroid nodules is still debated. Moreover, sCt cutoffs for medullary thyroid carcinoma (MTC) are not univocally defined. Also, sensitivity of cytology by fine needle aspiration biopsy (FNAb) has been demonstrated to detect approximately half of MTCs. Ct measurement in fine-needle aspiration washout fluid (Ct-FNAb) has high sensitivity and specificity and is helpful in case of non-diagnostic cytology[1]. Recently, a series oflow sCt MTC has been collected[2].
Aim
The objectives of this retrospective observational study were to define Ct-FNAb levels in subjects with low sCt (below cutoffs diagnostic for MTC) and to evaluate their clinical, ultrasonographic (US), cytological and histological characteristics.

Methods
We selected subjects with sCt above local normal ranges but below one of the diagnostic cutoff proposed for MTC (26 pg/ml in females and 68 pg/ml in males), subjected to FNAb with Ct-FNAb measurement and then thyroidectomized.
Results
Surprisingly, 50% (8/16) had MTC at histology, 19% cellular C hyperplasia (CCH) and only 31% neither MTC nor CCH. Ct-FNAb was significantly higher in MTC compared to both no MTC no CCH (2001 vs 25.32±55.72 pg/ml; *P=0.013*) and to CCH (2001 vs 195.56±286.09 pg/ml; *P=0.008*). Even if below the diagnostic cutoff, also sCt was higher in MTC compared to no CCH and no MTC group (19±7 vs 9±4 pg/ml; *P=0.019*) but was not able to discriminate MTC from CCH. US failed to identify suspicious nodules, since MTC differed only for being solid and not haloed. At cytology nearly 90% of MTC lesions were non-diagnostic or, mainly, indeterminate. At histology, 7/8 were low risk micro MTCs.
Conclusion
HighCt-FNAb despite sCt only slightly elevated suggests: i) early detection of MTC before the onset of high secretion of Ct, ii) a peculiar variant of MTC, able to produce Ct but not to secrete it in bloodstream because of intracellular secretory pathway alteration, iii) possible methodological interferences in the dosage of sCt. In conclusion, this study demonstrates the importance of Ct-FNAb to discover early stages of MTC with sCt below diagnostic cutoffs.

Impact ofhypothyroidism on early preneoplastic changes at the transcriptomic level in mammalian cells

Karolina Hanusek[1], Monika Duda[2] & Agnieszka Piekiełko-Witkowska[1]
[1]Medical Centre of Postgraduate Education, Department of Biochemistry and Molecular Biology, Warszawa, Poland; [2]Medical Centre of Postgraduate Education, Department of Clinical Physiology, Warszawa, Poland

Introduction
Studies suggest that disturbed thyroid hormones (TH) homeostasis may lead to increased cancer risk. However, the exact role of TH in cancerogenesis is unknown. We have previously identified 15 genes linked with TH signaling in 7 cancer types and 10.967 cancer patients. Here, we investigated the influence of hypothyroidism on the expression of these 15 genes in rat tissues/organs from which the previously identified, TH-related cancer types originate.
Material and methods
Female Wistar-Kyoto rats were divided into 3 groups: i) treated with methimazole (MMI) (17 mg/kg daily for 8 weeks); ii)thyroidectomized;iii) control rats. $n=3$ rats per group. Gene expression was analyzed (qPCR) in: mammary glands, renal cortex, lungs, thyroid gland, endometrium, liver, ovary, and colon epithelium. Statistical analysis: Student's unpaired t-test, *P*-values <0.05 were considered significantly different. PanCancer analysis of co-expression of genes encoding mesenchymal stem cells (MSC) markers and genes linked to TH signaling was performed using publically available TCGA data from 10.967 cancer patients. The study was approved by the local ethics committee (Second Warsaw Local Ethics Committee for Animal Experimentation) no. *WAW2/022/2018.*
Results
The induction of hypothyroidism in rats was confirmed by serum evaluation of T4 (avg. 0.60 µg/dl) and TSH (avg. 20.23 ng/ml). In mammary and thyroid glands of MMI treated rats, strong induction of analyzed genes expression was observed, including *ARNT, THRA, THRB, SLC16A2, SLC2A1, CTNNB1, NCOA1, HDAC1, CMYC, HIF1A* upregulated in both tissues, and *VIM, CDH1 and TPO*upregulated only in thyroid glands. In the residual MMI-treated tissue types the only significant expression changes were: *HDAC1*downregulation in renal cortex and lungs, *DIO2* downregulation in endometrium, and *THRA* upregulation in colon epithelium. Expression profile in mammary glands ofthyroidectomized rats did not confirm induction of gene expression observed in MMI treated rats. Results of PanCancer TCGA data analysis revealed associations between expressions of genes linked with TH signaling and MSC functioning, including THY1/RCAN2 and ENG/RCAN2 which occurred in 11 cancer types.
Discussion
The study suggests that observed expression changes in mammary and thyroid glands are caused not only by hypothyroidism but also by MMI influence on these tissues. Elucidation of the observed expression changes requires further research. Since MMI, apart from TPO, can interact with other peroxidases like MPO, EPO and LPO,this interaction may lead to decreased selectivity of MMI inhibition and cause broader impact on gene expression.

Adverse effects of tyrosine kinase inhibitors in advanced thyroid carcinoma – a summary of 10-year experience

Jolanta Krajewska, Aleksandra Kukulska, Ewa Paliczka-Cieslik, Tomasz Gawlik, Tomasz Olczyk, Aleksandra Ledwon, Barbara Michalik, Aleksadra Kropinska, Daria Handkiewicz-Junak & Barbara Jarzab
M. Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch, Nuclear Medicine and Endocrine Oncology Department, Gliwice, Poland

Introduction
To date, only four tyrosine kinase inhibitors (TKIs) have demonstrated beneficial effect on progression free survival in advanced medullary thyroid cancer (MTC; vandetanib and cabozantinib) andradioiodine-refractory differentiated thyroid cancer (RR-DTC; sorafenib and lenvatinib). However, there is still lack of unequivocal proofs of their significant impact on overall survival. Therefore, treatment-related side effects and their potential impact on quality of life has been recently widely discussed.
Aim
We conducted a retrospective analysis to evaluate TKIs toxicity in advanced thyroid cancer. The comparison of particular drugs was not aimed.
Material and methods
The study group involved 72 patients at mean age at treatment start of 51 ± 14 years. RR-DTC was diagnosed in 32 patients, whereas MTC in 40 subjects. All side effects were evaluated according to CTCAE (*Common Terminology Criteria for Adverse Events*), V 4.03. The median treatment time was 20.6 months (range: 0.5 months–142.8 months).
Results
In total, 74 treatment courses were assessed: 27 with lenvatinib, 9 with sorafenib, 22 with vandetanib, 9 with cabozantinib, 4 with motesanib, and 3 with axitinib. Treatment-related side effects were present in 97.3% courses. The most common were skin reactions – 68.9% courses, diarrhea – 67.6% courses, hypertension – 59.5% courses, weight loss – 56.8% courses, mucositis – 48.6% courses, abdominal pain– 29.7% courses, fatigue – 29.7% courses, and nausea in 18.9% courses. Skin changes were more frequent in MTC than in RR-DTC patients ($P=0.0128$). Similarly, fatigue was reported more commonly by MTC patients than by RR-DTC patients ($P=0.0387$). Fatigue also occurred more frequently in patients ≥55 years old at treatment onset comparing to younger ones <55 years. This difference was statistically significant ($P=0.0108$). No other significant differences in the frequency of the most common TKI-related side effects were noticed regrading tumor histopathology, age of treatment start, sex, and comorbidities. Due to poor tolerability drug interruption was necessary in 70.3% treatment courses, dose reduction in 62.2% courses, whereas permanent drug withdrawal was required in 25.7% courses.
Conclusions
TKI-related side effects were present in nearly all patients treated due to advanced thyroid cancer. Early diagnosis of adverse effects as well as a supportive management and dose modifications, if necessary, allowed avoiding serious complications and making possible to keep the patient on treatment as long as it was beneficial.
The study was supported by MILESTONE – STRATEGMED 2/26 7398/4/NCBR/2015.

Octreotide and pasireotide effects on medullary thyroid carcinoma (MTC) cells growth, migration and invasion

Rosa Catalano[1,2], Federica Mangili[1], Elena Giardino[1], Anna Maria Barbieri[1], Donatella Treppiedi[1], Alessia Dolci[3], Andrea Contarino[3], Anna

Spada[1], Maura Arosio[1,3], Giovanna Mantovani[1,3] & Erika Peverelli[1]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Sapienza University of Rome; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy

Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor of the parafollicular thyroid C cells. Although somatostatin (SS) receptors (SSTs) are expressed by MTCs, treatment with octreotide, specific for SST2, has shown poor efficacy in reducing MTC proliferation, whereas pasireotide, a multi-receptor SS analogue with preferential binding to SST5, has recently demonstrated antiproliferative effects in persistent postoperative MTCs. *In vitro* data in human MTC cell line TT revealed differential responsiveness to antiproliferative and antisecretory effects of SST2 or SST5-selective agonists. Aim of this study was to test the effects of octreotide and pasireotide on MTC cells proliferation, cell cycle proteins expression, MAPK activation, apoptosis, calcitonin secretion, migration and invasion in TT cell line as well as in primary cultured cells obtained from sporadic or hereditary MTCs. Our results showed that both octreotide and pasireotide reduced TT cell proliferation (–41.7±13.8%, $P<0.001$ vs basal, and –31.3±26%, $P<0.05$ vs basal, respectively), with concomitant inhibition of ERK phosphorylation and cyclin D1 expression. This cytostatic effect was accompanied by a proapoptotic action, with an increase of caspase 3/7 activity of 1.4-fold with octreotide and 1.5-fold with pasireotide (both $P<0.001$ vs basal). Moreover, both octreotide and pasireotide inhibited cell migration (-50.9±11.3%, $P<0.01$ vs basal, and –40.5±17%, $P<0.05$ vs basal, respectively, at 10^{-8} M) and invasion (-61.3±35.1%, $P<0.05$ vs basal, and –49.7±18%, $P<0.01$ vs basal, respectively, at 10^{-8} M). No effect was observed on calcitonin secretion after octreotide or pasireotide incubation. In primary cultured cells from MTC, octreotide and pasireotide were effective in reducing cyclin D1 expression in 1 out of 3 tumors, all expressing SST2 and SST5 at similar levels. Octreotide strongly reduced cell migration in 2 tumors tested, regardless of antiproliferative and antisecretory effects and RET mutational status. In conclusion, our data demonstrated a similar efficacy of octreotide and pasireotide in reducing cell growth and invasiveness in TT cells. In contrast,they exerted variable effects in MTC primary cultured cells, independently from the expression of SST2 and SST5, suggesting the need for new biomarkers useful to stratify patients for therapeutic response to SSAs.

Basal and stimulated calcitonin: Different experience on liaison and cobas assays

Mara Băetu[1,2], Alexandru Drăghici[3], Adriana Pădure[1], Andra Caragheorgheopol[1,2] & Corin Badiu[1,2]
[1']C.I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2']Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]Mathematics and Informatics Faculty, Bucharest, Romania

Introduction
The determination of basal and stimulated calcitonin (CT) is very important for the precocious diagnosis of medullary thyroid carcinoma (MTC) and for its dynamic follow-up. Unfortunately, monitoring is difficult when using assays with different detection systems. Our objective was to identify the correction factor between the reagents for CT measurement on the LiaisonXL and Cobase 601 assays (immunochemiluminescence, respectively electro-immunochemiluminescence).
Materials and methods
The measurement rangesare 1–2000 pg/ml for LiaisonXL and 0.5–2000 pg/ml for Cobase 601. All samples above the measuring range were diluted. We selected a group of 89 patients, 28 men and 61 women, with baseline CT or calcium-stimulated CT samples dosed on Cobas, with values between 0.5–2812 pg/ml. The samples were aliquoted and stored at –20ºC, and subsequently analysed on Liaison. The agreement was obtained according to ethical norms through informed consent.
Results
After applying various statistical tests, we found a strong Spearman correlation coefficient between the two assays, of 0.992. There is a segmented linear correlation between the two assays. The general linear regression equation is: $1.108 \times +19.337$ ($P<0.05$), but for higher accuracy we identified the segmented regression equations on two disjoint intervals. The increase of the bias was observed at high CT values: for values between 200 400 pg/ml on Cobas, the linear regression equation becomes $0.807 \times +87.554$ ($P<0.05$), and for values between 400–2812 pg/ml on Cobas, the linear regression equation becomes $0.997 \times +191.094$ ($P<0.05$). We also went on and explored an alternative approach for obtaining a higher accuracy prediction model. Proceeding from the obtained data we developed a software prediction model based on Machine Learning (ML) algorithms, which by design is a prediction model that improves continuously in accuracy of the estimates as more and more data becomes available. In addition, empirical tests have shown that the ML prediction model is superior to the statistical method.
Conclusions
For the first time in literature, we identified the correction factors between Liaison and Cobas assays for CT determination. For the dynamic monitoring of a patient with MTC it is very important to quantify CT with the same method of analysis, and to apply correction factors when using different assays. The results may be influenced by the the fact that the analysys was made on stored samples. Continuing the study on a larger number of fresh samples will ensure increasing accuracy of the correction factors.
Keywords: calcitonin, liaison, cobas, correction factor.

The value of contrast-enhanced 18F-FDG PET/CT for indication of loco-regional surgery in radioiodine-refractory differentiated thyroid cancer

Pavel Koranda[1], Marketa Mocnakova[2], Zdenek Frysak[3] & Lenka Hudson[1]
[1]Palacký University and University Hospital, Department of Nuclear Medicine, Olomouc, Czech Republic; [2]Palacký University and University Hospital, Department of Surgery II, Olomouc, Czech Republic; [3]Palacký University and University Hospital, Department of Internal Medicine III, Olomouc, Czech Republic

Aim/Introduction
Contrast-enhanced ^{18}F-FDG PET/CT is an effective diagnostic procedure enabling a precise localization of remnants or recurrences in patients with radioiodine-negative differentiated thyroid carcinomas (DTCs). The detection of this lesions allows to cure patients without detectable distant metastases using a loco-regional surgical treatment. The aim of this study was to assess the influence of ^{18}F-FDG PET/CT on indication of this type of treatment.
Materials and methods
A total of 194 patients (pts) with suspicion of recurrent DTC and negative 131I scans in the period 2008–2019 underwent contrast-enhanced 18F-FDG PET/CT. Examination was performed in 32 patients (pts.) due to suspicious sonography or high-risk disease despite the low TSH-stimulated thyroglobulin (TSH-Tg<2µg/l), in 58 pts. TSH-Tg was 2<10µg/l, in 92 pts TSH-Tg>10µg/l and in 14 pts. due to persistent elevation or increasing level of anti-Tg. Only the first 18F-FDG PET/CT examinations were evaluated, all subsequent examinations of the same patient were not included in this study.
Results
Contrast-enhanced 18F-FDG PET/CT detected remnants or recurrences – usually lymph node (LN) involvement treatable with loco-regional surgery in 38 of 194 pts. In the subgroup with TSH-Tg 0<2µg/l and suspicious sonography or high-risk disease surgery was performed: 5 pts (16%) LN metastases, 2 pts. benign (parathyroid adenoma and Schwannoma) and 2 pts. malignant (spinocellular and renal carcinoma) tumors. Subgroup – TSH-Tg 2<10µg/l: 8 (14%) pts. LN metastases. Subgroup – TSH-Tg>10µg/l: 23 (25%) pts. LN metastasesor remnants (incidentally 2 another malignancies were detected using PET– lung and colorectal carcinoma) Subgroup with anti-TG pathology: 5 (36%) LN metastases.
Conclusion
Contrast-enhanced 18F-FDG PET/CT is an efficient diagnostic tool for indicating patients with radioiodine-negative DTCs to loco-regional surgery. The detection rate of treatable recurrences or remnants significantly increases with increase of TSH-Tg. Nevertheless, it is not possible to set the lower TSH-Tg limit for 18F-FDG PET/CT indication. Surprisingly, a high portion of the pathological findings also show pts. with persistent elevation or increase of anti-Tg. Incidental detections of another types of malignancies is also appreciable.

Association between multifocality and one-year post-surgery response to treatment in papillary thyroid cancer

Andoni Monzón Mendiolea, Miguel Paja Fano, Adela Leyre Martínez Martínez, Ignacio Merlo Pascual, Laura Araceli Calles Romero, Natalia Covadonga Iglesias Hernández & Amelia Oleaga Alday
Hospital Universitario de Basurto, Servicio de Endocrinología y Nutrición, Bilbao, Spain

Introduction
American Thyroid Association (ATA) guidelines suggest considering hemithyroidectomy in patients with unifocal well-differentiated thyroid tumours,smaller than 4 cm, withoutpreoperative evidence of extrathyroidal extension (ETE) nor lymph node metastases. Although multifocal microcarcinomas are considered to increase the risk of structural disease recurrence from 1%–2% to 4%–6% compared to unifocal microcarcinomas, the ATA guidelines do not suggest different risk stratification for multifocal andunifocal tumours; with the exception of BRAF V600E mutated tumours with ETE, such tumours are low risk when they are unifocal and moderate risk when they are multifocal. Our objective was to evaluate whether multifocality influences response to treatment one year after papillary thyroid cancer (PTC) surgery.
Material and methods
We retrospectively collected every histologically confirmed PTC (non-aggressive variants),larger than 2 mm, operated at our centre between 2001 and 2018. Using the Dynamic Risk Stratification system,we compared responses to therapy at one year of follow-up (1YFU) between multifocal tumours (MFPTC) and unifocal tumours (UFPTC). Using chi square test, we evaluateda possible association between MFPTCand higher risk for incomplete remission (non-excellent: biochemical incomplete, structural incomplete or indeterminate). We also stratified our sample by different variables: biggest focus size, presence of BRAF V600E mutation, treatment with I131 (RAI) and evidence of histological ETE.
Results
We studied 498 patients: 202 MFPTC and 296 UFPTC. Among MFPTC, 149 (73.8%) had an excellent response at 1YFU. Among UFPTC, 264 (89.2%) had an excellent response at 1YFU ($P<0.0001$; RR: 2.94). Higher risk for incomplete response to treatment in MFPTC was maintained when stratified by size, including those larger than 10 mm ($P<0.0001$; RR: 5.49) or 20 mm ($P<0.0001$; RR: 5.39);presence of ETE (*n*: 121, $P=0.02$; RR: 2.47); or including only PTC treated with radioiodine after surgery (*n*: 422; $P<0.0001$; RR: 3.29). A non-significant tendency to more frequent non-excellent response in MFPTC was observed when stratified by detection of the BRAFV600E mutation, with $P=0.06$ in wild type (*n*: 116) and $P=0.13$ in mutated PTC (*n*: 115).
Conclusion
MFPTC are associated with a non-excellent dynamic stratification risk at 1YFU compared with UFPTC, regardless of the size of their largest focus, the finding of ETE,or treatment with RAI. Therefore, we suggest multifocality shouldbe considered by clinicians for decision-making regarding follow-up of PTC patients. Given that total thyroidectomy allows clinicians to assess multifocality, we suggest this procedure for consideration as the routine surgery rather than lobectomy in PTC patients.

AEP928

Usefulness of tissular heterogeneity analysis measured by elastography in the characterization of tyroid nodules

Maria Sevillano Jiménez, Reyes Ravé García, Clara Socorro García García, Alberto Torres Cuadro, María Asunción Martínez Brocca & Tomas Martín Hernández
Hospital Universitario Virgen Macarena, Endocrinologia y Nutrición, Sevilla, Spain

Objectives
To assess whether the degree of heterogeneity of thyroid nodules defined by their elastographic characteristics is related to the cytological diagnosis and ultrasound classification of risk of malignancy.
Material and methods
Observational, prospective study. 101 thyroid nodules were analysed by quantitative elastographic analysis (shear-wave), measuring the stiffness of the lesion by global elastography and its standard deviation (s.d.) as an index of the stiffness heterogeneity. US-guided FNA was performed and cytological analysis was confirmed by experienced pathologist, based on the Bethesda system 2017 for reporting thyroid cytopathology.
Results
101 nodules, with an average volume of 5.02±7.01cc, average elasticity of 41.82±28.64 kPa and an average s.d. 19.81±13.61 kPa. The ultrasound characterization of malignancy risk was based on the ACR TI-RADS system 2017, obtaining 19.8% of the nodules as TR2, 26.7% as TR3, 38.6% as TR4 and 14.9% as TR5. After the cytological study 3% of lesions were characterized as non-diagnostic (Bethesda I), 80.2% as benign (BII), 1% as atypia of undetermined significance or follicular lesions of undetermined significance (BIII), 3% as follicular neoplasms or suspicious for a follicular neoplasms (BIV), 3% as suspicious for malignancy (BV) and 9.9% as malignant (BVI). Both higher mean elastographic values and greater heterogeneity of nodules (higher s.d.) were significantly correlated with the ultrasound risk of malignancy and cytological malignancy, with areas under the curve (AUC) in ROC curves of 0.83 and 0.8, respectively, and a NPV of 0.95.
Conclusions
The stiffer nodules and with greater tissue heterogeneity present a greater potential for malignancy, so that analysis of the absolute elastographic value and its intranodular variability can contribute to the differential diagnosis of malignant thyroid nodular pathology. Because of its high NPV, the analysis of tissue stiffness heterogeneity could be a useful tool in the monitoring of benign nodules.

No important salivary gland damage following radioiodine remnant ablation

Eva Krcalova[1], Jiri Horacek[2], Filip Gabalec[2], Pavel Zak[2] & Jiri Dolezal[1]
[1]Nuclear Medicine, Hradec Kralove, Czech Republic; [2]Internal Medicine IV, Hradec Kralove, Czech Republic

Radioiodine (^{131}I, RAI) has traditionally been used in thyroid cancer treatment but its benefitshould be balanced against possible risks. Among them, salivary gland dysfunction has oftenbeen discussed, although the reported data have been inconsistent. While some authors reported functional changes following higher (mostly cumulative) activities, there have been scarce data on the activity of 3.7 GBq (100 mCi) that is most commonly used for RAI remnant ablation (RRA). The aim of our prospective study was to evaluate salivary gland function in 31 thyroidectomised patients (6 men, 25 women; median age, 52 years) before and 4 to 6 months after RRA, using 3.7 GBq ^{131}I-NaI. Salivary gland uptake (reflecting parenchymal integrity) and excretion fraction (reflecting secretory function) werequantitatively assessed with ^{99m}Tc – pertechnetate salivary gland scintigraphy. Pre – and posttreatment values were compared using Wilcoxon signed rank test. No significant difference was observed in parotid (median absolute change, +0.01%; 95% confidence interval, –0.02 to +0.03%) or submandibular (0.00%; –0.02 to +0.02%) glands uptake, as well as in parotid (+0.4%; –4.6 to +6.1%) or submandibular (+3.2%; –1.0 to +8.4%) excretion fraction (absolute values in Table). The calculated power for minimum relevant (relative) difference of 25% and sample size of 31 ranged between 86 and 96% for the individual variables, making our negative results reasonably reliable. They suggest that RRA with the most commonly used ablation activity of 3.7 GBq has no important impact on salivary gland function. Therefore, the concerns about putative salivary gland functional deterioration following RRA are probably unjustified.

Variable	Before RRA	After RRA	*P*
Parotid gland			
Uptake (%)	0.14 (0.10–0.20)	0.13 (0.11–0.20)	0.268
Excretion fraction (%)	49.7 (37.1–60.0)	51.4 (42.8–57.5)	0.899
Submandibular gland			
Uptake (%)	0.15 (0.11–0.18)	0.15 (0.11–0.17)	0.855
Excretion fraction (%)	28.3 (21.9–41.1)	35.7 (22.2–42.4)	0.124

Values are expressed as median (interquartile range), *P* values from Wilcoxon signed rank test.

Graves' disease in assocation with metastatic malignant struma ovarii: A descriptive case

Ray Lai[1], Brenda Lim[1], Brenda Chiang[2] & Daniel Chew[1]
[1]Tan Tock Seng Hospital, Endocrinology, Singapore; [2]Sengkang General Hospital, Endocrinology, Singapore

Introduction
Malignant struma ovarii is a rare disease, for which risk factors and prognostic features are not well-defined. We present a patient with concomitant Graves' disease and metastatic follicular thyroid cancer arising from struma ovarii, and discuss the possible mechanism of this association.
Clinical case
A 43 year old woman undergoing follow-up for Graves' disease (GD) presented with an enlarging left lower abdominal mass. She had a prior history of a left ovarian cystic teratoma with struma ovarii (SO), which had been resected at age 34 years. There was no record of thyrotoxicosis at the time. GD was diagnosed at age 43, when she presented with weight loss, palpitations, and tremours. Free T4 was 48.5 pmol/l [11.8–24.6], TSH < 0.005 mIU/l [0.27–4.2], and TRAb 2.7 IU/l [<1.8] at diagnosis. Thyroid ultrasound (US) revealed heterogenous parenchymal echotexture and increased vascularity. She was started on carbimazole. 4 months later, she reported a sensation of lower abdominal fullness. Pelvic US showed a heterogenous left adnexal mass, measuring 13.8 × 11.6 × 7.1 cm. Left salpingo-oopherectomy followed. Intra-operatively, peritoneal nodules were visualised; histology confirmed intra-ovarian thyroid tissue housing a highly-differentiated follicular thyroid carcinoma, with metastatic peritoneal deposits. Computed tomography of the chest and abdomen did not show any gross evidence of distant metastasis. Completion hysterectomy, right salpingo-oopherectomy, omentectomy, and debulking surgery was performed. Intra-operatively, more metastatic foci were identified on the right fallopian tube and infundibulopelvic ligament, uterovaginal fold, bladder and rectal walls, and peritoneum. A total thyroidectomy followed; histology showed no evidence of intra-thyroidal malignancy. I-131 therapy was administered. The post-therapeutic I-131 whole body scan revealed multiple intra-abdominal foci of uptake, representing remnant disease. At 1 year's follow-up, the patient remains on levothyroxine therapy, with a TSH goal of <0.1 mIU/l. A repeat radioiodine scan is planned. Anti-TG titres have trended downward, and she remains clinically well.
Discussion
To our knowledge, this is the first reported case of metastatic malignant SO in the setting of GD. GD appears to be associated with an increased incidence of differentiated thyroid cancer (DTC); DTC in these situations might behave more aggressively. This association may well apply to the risk of malignant transformation in SO tissue. TSH receptor antibody and local cytokine production might contribute to the pathophysiology.

Evaluation of miRNA-222, –146b, –181b as possible diagnostic markers in patients with papillary thyroid carcinoma

Aiste Kondrotiene[1], Daina Pamedytyte[2], Vaida Simanaviciene[2], Dalia Dauksiene[1], Aurelija Zvirbliene[2], Mintaute Kazokaite[1], Raimonda Klimaite[1], Valdas Sarauskas[3], Albertas Daukša[4], Rasa Verkauskiene[1] & Birute Zilaitiene[1]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Biotechnology, Vilnius University, Vilnius, Lithuania; [3]Department of Pathology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
The sensitivity and specificity of biomarkers which have been used in clinical practice for diagnosis of papillary thyroid carcinoma (PTC) are low. It is essential to develop novel diagnostic biomarkers for PTC.
Objective
We aimed to explore the expression levels of miR-222, – 146b, –181b in PTC tissue and plasma samples and to compare with benign thyroid nodules (BTN).
Methods
We collected plasma samples from the patients just before the thyroidectomy due to PTC or BTN. Tissue samples were also collected from the subgroups of these patients. The expression levels (2^-□Ct) of plasma miR-222, –146b, –181b were measured in 48 samples from patients with PTC and 22 from patients with BTN. Expression of the same set of miRNAs in PTC and BTN tissue samples were investigated in subgroups of 19 and 9 patients, respectively.
Results
A significantly higher expression levels of miR-146b were observed in PTC tissue samples (4.433 ± 6.04), compared to BTN (0.151 ± 0.094), (P = 0.001). However, the results of plasma samples indicated that levels of miR-222, –146b, –181b had no significant differences in the PTC patients compared with BTN (P = 0.424, P = 0.641, P = 0.427, respectively).
Conclusion
Many studies are underway to discover minimally invasive method for PTC diagnostics. In our study we analyzed expression levels of miR-146b, –222, –181b and we found that only mir-146b expression levels were significantly higher in PTC than in BTN tissue samples. However, there were no significant differences while comparing expression levels of this set of miRNAs in PTC and BTN plasma samples. Unfortunately, the value of these three miRNAs is still limited in differential diagnosis of PTC and BTN from plasma samples.

Comparative assessment of several ultrasound imaging systems

Yuriy Aleksandrov[1], Elena Yanovskaya[1] & Lubov Timofeeva[2]
[1]Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation; [2]I. N. Ulianov Chuvash State University, ultrasound, Cheboksary, Russian Federation

The purpose of the study was to evaluate the diagnostic capabilities of systems for assessing ultrasound thyroid imagines. The object of the study was 754 patients with thyroid nodules. Research methods: ultrasound in the framework of image evaluation systems TIRADS, EU-TIRADS, ARC-TI-RADS, BTA, TI-RADS K. For statistical analysis of systems and criteria was performed multidimensional statistical modeling using cluster, factor, discriminant, variance, and ROC analysis. The study found that the systems have different sensitivity and specificity. Data have shown that there are more differences between systems than there are similarities. The reason for this is that there are no uniform rules for the formation of systems. The authors of the systems arbitrarily determined a set of features, their combinations, staging, accounting or not accounting for the size of thyroid nodes. According to the ROC analysis for thyroid cancer, the sensitivity of TIRADS was 91%, specificity-91%, diagnostic efficiency-91%, prognostic value of a positive result-0.92, the likelihood ratio for a positive result-10.6, the likelihood ratio for a negative result-0.03. When detecting thyroid adenomas, TIRADS sensitivity was 62%, specificity-82%, diagnostic efficiency-79%. When detecting goiter, TIRADS sensitivity was 86%, specificity-83%, diagnostic efficiency-79%. ROC analysis found that AUC = 0.972 ± 0.00 484. AUC is an integral measure of diagnostic effectiveness, it can be argued that TIRADS has good predictive capabilities in thyroid cancer, good in goiter, and insufficient effectiveness in adenomas. When comparing the systems, it turned out that the ACR-TI-RADS system, despite the decrease in the number of signs, has the highest prognostic indicators for thyroid cancer (AUC = 0.964) and slightly worse for thyroid adenomas and nodular goiter. The Korean TI-RADS-K system is a test of excellent quality (AUC = 0.959) with good prognostic indicators for various nodular thyroid pathology. In terms of specificity (97%), TI-RADS-K is superior to all other systems. When evaluating EU-TIRADS, it is established that the system is a test of high quality (AUC = 0.826), but has a predictive capability worse than TI-RADS. The BTA system has the lowest prognostic indicators of all systems (AUC = 0.823). With Multidimensional Scaling, TIRADS (coordinates: 0.80 043; 0.58 114) and ACR-TI-RADS (coordinates: 0.58 114; 0.52 5725) were close. The Correlation Analysis of a Two-Way Table confirmed the influence of empirical ranking on the results of system evaluations. Gradations related to thyroid cancer have a large diagnostic weight, and the ranking of benign pathology introduces an element of instability in the system, without significantly affecting the final result-the selection of patients for fine-needle aspiration biopsy.

Thyroid hormone resistance and succesful gestation with unaffected fetus: A case report

María Eugenia López Valverde[1], Rossana Manzanares Cordova[2], pilar rodriguez[2] & María Inés Velasco López[3]
[1]Hospital Juan Ramón Jiménez, Endocrinology and Nutrition department, Huelva, Spain; [2], Endocrinology and Nutrition department, Huelva, Spain; [3]Hospital Comarcal del Río Tinto, Gynaecology and Obstetrics department., Río Tinto (Huelva), Spain

Thyroid hormone resistance (THR) is a rare dominantly inherited syndrome characterized by a reduced response of target tissues to thyroid hormone receptor. In most cases, THR is related to mutations in the thyroid hormone receptor beta gene (THRb). Management may be challenging in cases of gestation. Here we report the case of a pregnant patient with a possible not previously described mutation and negative genotype fetus.
Case report
Thirty-two year old patient asked for consultation for free T4 elevated levels (2.42, normal values: 0.93–1.7 ng/dl) with normal TSH values (3.6, normal values: 0.5–8.9 βUI/ml). Patient was asymptomatic and neither goiter nor thryoid autoinmunity was found. Genetic test detected in heterozygosis one variant of unknown significance in THRβ (c.737T>C (p. L246P). She was asked for family members with possible thyroidopathy and THR was also diagnosed in her father. He exhibits as well the same genetic variant. Patient got pregnant being TSH and free T4 levels 3.98 mUI/ml and 3.03 ng/dl respectively. As fetal DNA obtained by amniotic fluid ruled out that fetus was affected, treatment with PTU was started in order to mantain free T4 levels lower than 20% of the upper limit of normal. Fetal ecography showed normal fetal weight and free T4 levels were in desired range with doses of 200 mg/day PTU. Caesarean section was held 3 days before the estimated day of delivery due to prelabor rupture of membranes. Masculine infant born weighted 2760 grams and APGAR was 9/10/10.

Myasthenia gravis associated with Graves' disease: About three cases

Marwa majdoub[1], Imen Rojbi[2], Sabrine Mekni[2], Nadia Mchirgui[2], Ibtissem Ben Nacef[2] & Karima khiari[2]
[1]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia; [2]Charles Nicolle Hospitalt, Tunis, Tunisia

Introduction
The coexistence of Grave disease [GD] and Myasthenia gravis [MG] may present a diagnostic dilemma especially concerning ocular manifestations. 3–10% of myasthenic patients exhibit GD, while MG is reported in only <1% of patients with thyroid disorder.
Observation
Case 1
A 32-year-old woman, with a medical history of vitiligo, was diagnosed with GD. Immunology revealed positive anti-thyroid peroxidase antibodies [TPOAb] and TSH receptor antibodies [TRAb]. Treatment with Anti-thyroid drugs was soon withdrawn because of severe eruption and the patient received radical treatment (I-131). Two months later, she reconsulted for muscle use increasing throughout the day. The diagnosis of MG was confirmed by a Prostigmine test, and positive Acetylcholine receptors [AChR] antibodies. The treatment with Pyridostigmine was immediately initiated. But, the amplification of myastenic symptoms later led to successive immuneglobulin cures.
Case 2
A 43-year-old man consulted for exophthalmia, diplopia, asymmetric ptosis and blurring of vision. Physical examination demonstrated a goiter, a resting tremor and proximal muscle weakness. Thyroid function test showed high levels of thyroid hormones, TSH<0.05. Both GD with severe ophthalmopathy and MG were suspected. Immunology confirmed the diagnoses, with positive TRAb, TPOAb and AChR antibodies. The patient was started on Thiamazol and Pyridostigmine, with a good evolution.
Case 3
A 41-year-old woman complaining of asthenia by the end of the day, diplopia and difficulty chewing. She reported a medical history of GD treated for 2 years with Benzylthiouracil, then Radioiodine at the age of 28. AChR antibodies and Anti-striated muscle Antibodies were positive confirming MG's diagnosis, with a thymic tumor revealed on chest scan. Therefore, the patient underwent a total thymectomy that in association with cholinesterase inhibitors was fairly efficient.
Conclusion
GD is associated with a number of autoimmune diseases, including myasthenia. Two out of our three patients had ocular myasthenic symptoms. Thyroid disease was found to be more frequent in ocular MG patients (40%) than in generalized MG patients (12%). Accordingly, it is important for every endocrinologist to suspect the association of MG in each GD patient especially on the presence of ptosis, exotropia, muscle weakness increasing with exercise.

Thyroglossal duct cyst papillary thyroid cancer in a 40-year-old female: Case report

Anna Dabrowska[1,2] & Jaroslaw Dudka[1]
[1]Medical University of Lublin, Department of Toxicology, Lublin, Poland; [2]Endocrinology Outpatient Clinic, Lublin, Poland

Introduction
The thyroglossal duct develops during thyroid gland formation and usually involutes at 7–10 weeks gestation. Its residue can lead to formation of cysts as well as to develop neoplasms within the mass.
Case report
A 40-year-old woman was admitted to Department of Otolaryngology because of an enlarging midline neck mass for the last few months, without other worrisome symptoms. A neck ultrasound and CT scan showed a cystic lesion with solid components measuring 20 × 18 mm in size, located above the larynx. A Sistrunk procedure was performed. On histological postoperative examination, thyroid papillary microcarcinoma with microcalcifications in the cyst wall was revealed. The lesion did not infiltrate the capsule and it was completely resected. The patient was referred to Department of Endocrine Oncology for additional testing. Thyroid ultrasound showed 6 × 8 × 9 mm lesion in the left lobe. FNAB was performed and the diagnosis of benign nodule was made (Bethesda class II). As there were no demonstrable cancer or lymph node metastases, the decision of total thyroidectomy has not been made. Levothyroxine therapy has been started with doses adjusted to achieve thyrotropin levels of 0.4 to 1.0 mU/l and further check-up has been recommended. After two years follow-up, there is no progression of thyroid left lobe nodule but in ultrasound imaging an enlarged heterogenous (with calcifications and vascularization) lymph node (32 × 10 mm) next to the left mandible angle has been observed. The patient is currently being diagnosed to confirm or exclude lymph node metastases to decide of total thyroidectomy and neck dissection as well as postoperative radioactive iodine therapy.
Conclusions
Rare prevalence of thyroglossal duct cyst carcinoma, lack of typical features distinguishing benign and malignant lesions before surgery cause the proper diagnosis can be difficult and is usually made postoperatively. The extent of treatment is also not well agreed upon. Therefore, case reports and case series are needed to determine optimal management.

Background
Thyroid storm is an extreme disorder that occurs in case of severe thyrotoxicosis. This is a life-threatening condition with mortality rates up to 10–20%. A typical dose of iodinated contrast media (ICM) contains approximately 13.500 µg of free iodide and 15 to 60 g of bound iodine, which represents an acute iodide load of 90 to several hundred thousand times the recommended daily intake of 150 µg. As a result of sudden exposure to high iodide loads, thyroid hormone regulation can be disrupted, leading to hypothyroidism (Wolff-Chaikoff effect) or hyperthyroidism (Jod-Basedow phenomenon), particularly in those with underlying nodular thyroid disease.
Case description
A 37 years old man, presented to the emergency room (ER) with clinical and ECG signs of acute myocardial infarction (AMI). Primary percutaneous coronary intervention with the administration of ICM has been performed. After the intervention, laboratory analyses reviled thyrotoxicosis, and he was given initial thyrosuppressive therapy with cardiac therapy and was discharged from the hospital. One week later, he returned to the hospital with the signs of thyroid storm. His thyroid hormones were high (FT4 260 pmol/l, undetectable TSH) and he scored 45 points on Burch-Wartofsky Point Scale. His therapy was changed into propylthiouracil 4 × 300 mg, Dexamethasone 2 × 4 mg, and Lugol's solution. His condition was further complicated with a spread of skin lesions that looked like vasculitis. Since there has been a great concern that this was propylthiouracil induced vasculitis the drug was replaced with thiamazole. It has been decided that the definitive therapy for the patent condition is surgical ablation. After prolonged hospitalization successful total thyroidectomy was performed after FT4 fall below 30 pmol/l. Pathophysiology examination of thyroid gland reviled colloid nodal goiter, which was not in correlation with the echosonography findings.
Conclusion
We presented an unusual case of thyroid storm in a patient that developed AMI and without a history of thyroid disease prior to cardiac angiography with ICM used. We aimed to raise attention on the routine evaluation of thyroid function in patients with and without previous signs and symptoms of thyrotoxicity and who had an AMI, that undergone coronary angiography. Moreover, this could be an asset as progressively more people with coronary disease will undertake this procedure. If increased thyroid hormones are detected, a patient should be carefully monitored in intensive care units.

Hashimoto's thyroiditis in a patient with IgG4 related disease

Nur Husnina Matali & Pui Lin Chong
Raja Isteri Pengiran Anak Saleha Hospital, Endocrinology, Bandar Seri Begawan, Brunei Darussalam

Introduction
Immunoglobulin G4 related disease (IgG4-RD) is an immune-mediated fibro-inflammatory condition and is a widely recognised multi-organ system disease. The prevalence of IgG4-RD is 6/100 000, but it is likely to be underestimated. IgG4-RD is characterised by elevated serum levels of IgG4 and IgG4-positive lymphoplasmacytic infiltrative lesions in the body. Recent reports suggest disease involvement in various organs including thyroid and orbital tissues. Thyroid disease described in IgG4-RD encompasses Hashimoto's thyroiditis, fibrosing variant of Hashimoto's thyroiditis, Reidel's thyroiditis and Graves disease.
Case presentation
A 47-year-old lady was referred to the Endocrine clinic with primary hypothyroidism [TSH 78.2 mIU/l (0.27–4.20), fT4 1.2 pmol/l (12–22) and fT3 < 0.4 pmol/l (3.1–6.8)].There is a family history of thyroid disorder. She had strongly positive TPOAb (>500 IU/ml) and TgAb (>5000 IU/ml), and was diagnosed with Hashimoto's thyroiditis. Thyroxine replacement was started. Initial examination revealed a small diffuse goitre with bilateral periorbital swelling on the upper lids and mild proptosis. A left thyroid nodule was palpable in subsequent visit and USS neck with FNAC was performed. Both thyroid lobes were hypoechoic and lobular in appearance with a 1.1 cm × 0.7 cm hypoechoic nodule in the medial left thyroid. FNAC of the thyroid nodule showed lymphocytic infiltration consistent with Hashimoto's thyroiditis. Serum IgG4 level was markedly elevated (2230 mg/dl; 2.4–121). She was referred to the Rheumatology clinic with suspected IgG4-RD. MRI orbit confirmed bilateral lacrimal gland enlargement. Biopsy of the lacrimal gland showed marked inflammatory cell infiltrates including lymphocytes and plasma cells. Immunostaining revealed increased numbers of IgG4 positive plasma cells among infiltrating lymphocytes. The findings were consistent with IgG4 associated ophthalmic disease. Prednisolone was started following a diagnosis of IgG4-RD.
Discussion
Our patient has Hashimoto's thyroiditis with underlying IgG4-RD. Hashimoto's thyroiditiscan be further subclassified into IgG4-thyroiditis and non-IgG4 thyroiditis. Thyroid nodule FNAC could not confirm the subtype of Hashimoto's thyroiditis in our patient. However, she has significantly elevated TPO-Ab and Tg-Ab and hypoechoic thyroid gland on ultrasonography. These features on a background of IgG4-RD suggest our patient has IgG4-thyroiditis. Bilateral lacrimal gland enlargement is in keeping with IgG4-RD manifestation in the eye which usually causes painless swelling of the lacrimal glands with chronic lid swelling and proptosis. Diagnosis of IgG4-RD can be challenging as it is uncommon and requires a combination of clinical features, serological confirmation and histological evidence with IgG4 immunostaining. The first line of treatment is usually glucocorticoid therapy. Prompt diagnosis and treatment can reduce progression of the disease.

Severe hypothyroidism secondary to Hashimoto's thyroiditis and its implications for surgery

Xinming Yu, Elaine Soong, Mengye Li & Joohi Majeed
West Suffolk Hospital, United Kingdom

Background
The prevalence of hypothyroidism is around 1–2% in the UK. Hashimoto's thyroiditis is thought to cause 0.1–2% of overt disease and 10–15% of subclinical hypothyroidism. This case presents a patient with severe hypothyroidism, secondary to Hashimoto's thyroiditis, found incidentally on a surgical admission. The case study discusses the challenges and management of severe hypothyroidism in the need for an acute surgical intervention.
Clinical case
A 72 year-old man was brought into the Emergency Department after a road traffic accident. He was found to have right tibial and fibular shaft fractures, and was incidentally discovered to have sinus bradycardia secondary to profound hypothyroidism. Thyroid function tests done on admission showed a thyroid stimulating hormone (TSH) level of 227 mIU/l (0.27–4.2 mIU/l) and free T4 level of 0.8 pmol/l (12–22 pmol/l). Anti-thyroid peroxidase antibody (anti-TPO) level was >1300 IU/ml (positive if >100 IU/ml), suggestive of Hashimoto's thyroiditis. The patient underwent two surgeries for fixation of fractures, whilst having thyroid hormone replacement. Oral levothyroxine was started and up titrated according to clinical and biochemistry response. Intravenous liothyronine was also used intraoperatively for management of bradycardia and reducing the risk of myxoedema coma.
Discussion and conclusion
Surgery and anaesthesia can precipitate complications associated with hypothyroidism, such as cardiovascular collapse, respiratory failure, and worryingly,myxoedema coma. Altered respiratory physiology and renal clearance of drugs also increase patients' sensitivity to drugs commonly used in anaesthesia. It is recommended to postpone elective surgeries until a euthyroid state can be achieved, through thyroid hormone replacement. Urgent or emergency surgical admissions should be managed with awareness of complications. Mild or moderate hypothyroidism should be managed with hormone replacement therapy and can continue with surgery. NICE Guidelines recommend treatment of hypothyroidism with levothyroxine replacement. Combination therapy with liothyronine should only be used in selective cases and directed by accredited endocrinologists. Although there is a lack of outcome data to guide management of severe hypothyroidism requiring urgent surgical management, studies support, and have shown success in, the use of combination therapy of levothyroxine and liothyronine to reduce risk of severe complications,particularly myxoedema coma. Our case demonstrates an example of an approach to the management of profound hypothyroidism associated with bradycardia and the risk of developing myxoedema coma. Whilst the patient remained bradycardic intraoperatively, he did not suffer from cardiovascular collapse or develop myxoedema coma. He subsequently recovered uneventfully from both surgeries with no serious surgical complications associated with hypothyroidism.

Cardiovascular clinical presentation of inpatients with overt hyperthyroidism – a retrospective study in 250 patients

Yael M. Szterenlicht[1,2], meir frankel[1,2], Lior Tolkin[1,2], Noa Sylvetsky[1,2] & Gabriel Munter[1,2]
[1], Internal Medicine and Endocrinology; [2]Shaare Zedek Medical Center affiliated with Hebrew University-Hadassah Medical School, Jerusalem, Israel., Internal Medicine and Endocrinology

Background
The clinical presentation of hyperthyroidism has been studied in the ambulatory caresetting. Our hospital performs a TSH test for all newly admitted patients.
Aim
To describe the clinical presentation of patients with overt hyperthyroidism during hospitalization and to study the association between thyroid hormone levels and the clinical picture.
Methods
A retrospective study of 250 hospitalized patients from an 11-year period (2008–2018) admitted to the internal medicine, geriatrics, or cardiology wards who had a confirmed diagnosis of overt hyperthyroidism.
Results
The mean age was 70±15 years, with a female:male ratio of 1:1. Out of 250 patients, 174 (69%) suffered from previous cardiovascular disease and 111 (44%) presented with a cardiovascular syndrome, including active ischemic heart disease (29, 12%) decompensated congestive heart failure (83, 32%) or new onset atrial fibrillation/flutter (14, 6%). The most common underlying etiology was amiodarone induced thyrotoxicosis (53, 21%), closely followed by overtreatment of previously known hypothyroidism (50, 20%) and toxic multinodular goiter (42, 17%), while Graves' disease was less common (18, 7%). In 51 (20%) an underlying cause could not be determined. No direct correlation was observed between the levels of fT4 and fT3 and any of the symptoms, signs or clinical syndromes; however, in the categorical analysis, elevated fT3 levels, rather than fT4, above the upper limit of normal range (ULN) was associated with cardiovascular presentation. The only symptom that was significantly related to high fT4 values was chest pain ($P<0.001$) while high levels of fT3, in contrast, were associated with palpitations ($P=0.016$), chest pain ($P<0.001$) and cardiovascular syndromes in general ($P=0.007$).
Conclusions
Most hospitalized patients with overt hyperthyroidism had cardiovascular comorbidities, while at the same time presenting with signs of active decompensated heart failure, arrhythmias or coronary artery disease as reasons for hospital admission in ±50% of the patients. Cardiovascular presentation was associated with high levels of fT3 rather than fT4.

Hyaluronan in part mediates IL-1beta-induced inflammation in human thyrocytes by up-regulating TLR-4 and CD44 receptors

Rosaria Ruggeri, Maria Teresa Vicchio, Alfredo Campennì, Salvatore Campo, Francesco Trimarchi, Salvatore Cannavo' & Angela D'Ascola
University of Messina

Background
The expression of thyroid-specific genes [thyroglobulin (Tg) and sodium iodide symporter (NIS)] is modulated by several cytokines (IL-1, IFNγ, TGF-ß) and it is down-regulated in Hashimoto's thyroiditis (HT). Also, lymphocytic infiltration and inflammation in HT results in intra-thyroidal accumulation of hyaluronan (HA). During inflammation, HA can be degraded into small fragments, able to up-regulate pro-inflammatory genes by stimulating the toll-like receptors (mostly TLR-4) and CD44, via NF-kB activation. The present study was aimed to evaluate the potential role of small HA fragments, as mediators of TLR-4 and CD44 activation, inIL-1-beta-induced inflammation in human thyrocytes *in vitro*.
Methods
Primary thyrocytes were obtained from patients undergone surgery for benign thyroid nodules. Cultured cells were treated for 24 h with IL-1β (5 ng/ml), with and without TLR-4 and CD44 blocking antibodies, and the hyaluronan binding protein (HABP), which inhibits HA activity. HA concentration was measured by ELISA, while molecular size was assayed by agarose gel electrophoresis. mRNA and related protein levels of TLR4, CD44, interleukin-6 (IL-6), matrix metalloproteinase-13 (MMP-13), thyroglobulin (Tg) and sodium iodide symporter (NIS)were evaluated by real-time PCR, Western Blot and ELISA, respectively. NF-kB activation was also assayed.
Results
IL-1beta induced an increase of HA production and accumulation, that primarily consisted of low molecular weight (LMW) fragments. TLR4 and CD44 levels were higher than controls in thyrocytes treated with IL-1beta. IL-1beta also induced NF-kB up-regulation and increased IL-6 and MMP-13, while reduced Tg and NIS expression. Treatment of thyrocytes exposed to IL-1beta with specific TLR-4 and CD44 blocking antibodies and/or HABP, reduces NF-kB activation and pro-inflammatory mediators production, while partially restore Tg and NIS levels. These findings suggest that IL-1beta exerts inflammatory activity in part via TLR-4 and CD44 by the mediation of small HA fragments derived from HA depolymerization.
Conclusion
In human thyrocytes, IL-1β promotes accumulation of LMW HA fragments anddown-regulate thyroid-specific genes expression via CD44/TLR-4/NF-kB signaling activation. Accumulation of HA pro-inflammatory fragments may play a role in the pathogenesis of thyroid inflammation and damage in autoimmune thyroid disease.

Thyroid hormone levels is not associated with non-alcoholic fatty liver disease in euthyroid subjects

Hye Jeong Kim
Soonchunhyang University, Asan-si, Korea, Republic of South

Backgroud
Recent studies have shown an association between thyroid hormone levels and non-alcoholic fatty liver disease(NAFLD). However, there have been some inconsistencies between studies. Here, we evaluated the relationship between thyroid hormone levels and NAFLDin euthyroid subjects.
Methods
A retrospective analysis of 27.719 euthyroid subjects who participated in comprehensive health examinations was performed. Subjects were grouped according to thyroid stimulating hormone (TSH) and free thyroxine (FT4). We estimated the odds ratios (OR) for NAFLD according to thyroid hormone quartiles using logistic regression models, adjusted for potential confounders.
Results
Of the study patients, 33% ($n=9.217$) had NAFLD. A lower TSH level and higher FT4 level were associated with NAFLD. The proportion of participants with NAFLD decreased across the TSH quartile categories and increased across the FT4 quartile categories. No associations were observed between thyroid hormone and NAFLD after additional adjustment for confounding variables.
Conclusion
Our study demonstrates no significant association between thyroid hormone and NAFLD.

Predictive value of free triiodothyronine within normal range on cardiovascular events in a Chinese cohort with coronary artery disease: Direct effect and mediation effect by TG

Jun Wen[1], Fei Su[2], Xuan Li[2,3], Na-Qiong Wu[1], Ying Gao[1], Geng Liu[1], Qian Dong[1], Yi-Da Tang[1], Jian-Jun Li[1] & Yuan-Lin Guo[1]
[1]Fuwai Hospital, National Center for Cardiovascular Disease, Chinese Academy of Medical Sciences, Peking Union Medical College, BeiLiShi Road 167, Beijing 100037, China, Endocrinology and cardiovascular metabolism Center, Beijing, China; [2]Beijing Hospital, National Center of Gerontology, Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Clinical Biobank, Beijing, China; [3]The Chinese University of Hong Kong, Shenzhen, Shenzhen, Guangdong, China

Background and aims
Coronary artery disease (CAD) plays an important role in global mortality worldwide. Risk assessment for patients with CAD through free triiodothyronine (FT3) remains unclear. Therefore, we aimed to investigate the impact of FT3 on the prognosis of patients with CAD.

Methods
A total of 0 patients with CAD and available FT3 data, and without overt thyroid disease were enrolled in this study and grouped by tertiles. The primary outcome was termed cardiovascular events (CVEs), including cardiovascular mortality, non-fatal myocardial infarction and stroke. Association of FT3 with 3-year CVEs was assessed through multivariate Cox regression analysis and mediation analysis.
Results
During median follow-up 2 years, 162 (2%) CVEs occurred. FT3 levels were negatively associated 5824 with incident CVEs (hazard ratio, 0.59; 95%confidence interval, 0.36–0.96). Compared with the low FT3 tertile, the high tertile had significantly lower risk of CVEs (HR, 0.59; 95% CI, 0.38–0.92). Meanwhile, triglyceride mediated the association between FT3 and risk of CVEs (HR, 0.98; 95% CI, 0.969–0.996; $P<0.05$). Moreover, FT3 significantly improved discrimination and reclassification of the Framingham secondary event model and the ABC-CHD model in our cohort. Results remained similar or became stronger in FT3 levels within the normal range.
Conclusion
Lower FT3 levels were associated with an increased risk of CVEs, partly mediated through higher triglyceride, suggesting that FT3 is a potential biomarker for a better risk stratification and perfect management in patients with CAD. Further studies are needed to confirm our findings.

Serum levels of myostatin in patients with hyperthyroidism or euthyroidism

Fen-Yu Tseng
National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan

Objective
Myostatin may negatively regulate skeletal muscle mass. Serum myostatin levels have positive associations with obesity and insulin resistance. Thyroid dysfunction may affect body weight, energy expenditure, and glucose metabolism. We evaluated the serum myostatin levels in different thyroid function statuses.
Subjects and methods
We recruited 30 newly-diagnosed hyperthyroid (HY) patients and treated them with anti-thyroid regimens as clinically indicated. Thirty euthyroid (EU) patients were recruited as controls. We measured laboratory parameters at the baseline and at 6 months, and calculated their changes. Associations between the levels of myostatin and free thyroxine (fT4), thyroid-stimulating hormone (TSH), or log transformation of TSH (logTSH) were analyzed.
Results
There were no significant difference of myostatin levels among the HY and the EU patients, both at baseline (median [Q1, Q3]: 16.25 [11.42, 20.23] vs 17.50 [11.80, 21.56] ng/ml, $P=0.599$) and at 6 months (median [Q1, Q3]: 27.27 [19.11, 32.66] vs 23.20 [16.02, 29.43] ng/ml, $P=0.306$). Serum myostatin levels had no associations with levels of fT4, TSH, or logTSH, both at baseline or 6 months. However, changes of myostatin had positive associations with changes of logTSH ($\beta=2.323$, $P=0.019$). The association between changes of myostain levels and changes of logTSH remained significant after adjustment for sex and age ($\beta=2.505$, $P=0.015$).
Conclusions
Serum myostatin levels of the HY patients were not different with that of the EU patients. In this study, changes of serum myostatin levels had positive associations with changes of logTSH. The real impact of thyroid function statuses on myostatin levels remained to be investigated.

Hypercalcitonemia in a patient with micronodular goiter and adrenal nodular hyperplasia-diagnosis challenge

Luminita Nicoleta Cima[1,2], Iulia Soare[1], Ioana Lambrescu[3], Alexandra Vadana[2], Sorina Martin[1,2] & Simona Fica[1,2]
[1]Carol Davila University, Endocrinology, Bucharest, Romania; [2]Elias University Hospital, Endocrinology, Bucharest,; [3]Babes Institute, Bucharest, Romania

Introduction
Hypercalcitoninemia has frequently been reported as a marker for medullary thyroid carcinoma (MCT). Still, several physiologic and pathologic conditions other than MCT have been associated with increased levels of calcitonin, including neuroendocrine tumors that can ectopically secrete calcitonin.
Case report
We present the case of a 78-year old female patient, incidentally diagnosed with multinodular goiter when performing Doppler ultrasound for the evaluation of severe dizziness. In the last 6 months she was admitted in the emergency room several times with paroxysmal symptoms including fronto-occipital headache, severe hypertension, diaphoresis and anxiety. She had normal thyroid function, but high serum calcitonin, carcinoembryonic antigen (CEA) and chromogranin A levels (210.5 pg/ml, 7.36 ng/ml and 159.1 ng/ml, respectively). The thyroid ultrasound revealed a micronodular goiterwith infracentimetric inflammatory lymph nodes (the largest nodule 0.78/0.83/0.9 cm having a spongiform appearance). The abdominal ultrasound showed left adrenal hyperplasia (20/25/25 mm) and an adrenaladenoma (10/10 mm). The plasmatic metanephrines and normetanephrines were in the normal range, but thedexamethasone suppression test was abnormal (6.01 microg/dl). She underwent unilateral adrenalectomy with a favourable outcome in terms of hypertension control. The histopathology report confirmed adrenocortical nodular hyperplasia. Postoperatively, hypercalcitonemia persisted (196.7 pg/ml) and she had total thyroidectomy with central neck lymph node dissection performed with a significant decrease of serum calcitonin level (46.4 ng/ml) accompanied by CEA normalisation (1.99 ng/ml).
Conclusion
Several types of neuroendocrine tumors, including paragangliomas and pheochromocytomas might be associated with increased levels of calcitonin, but the basal calcitonin values in this conditionsusually varies between 10 and 100 pg/ml. Patients with calcitonin levels > 100 pg/ml have a high risk for MCT (90%–100%) and they should be carrefully evaluated although the symptomatology may point out to a different disorder.

DOI: 10.1530/endoabs.70.AEP944

MMP-9 1562 C/T polymorphism may be associated with an increased susceptibility to develop micropapillary thyroid cancer but not more advanced tumours

Ruxandra Dobrescu[1,2], Sorina Schipor[1], Catalina Picu[1,3], Dana Manda[1], Andra Caragheorgheopol[1] & Corin Badiu[2,4]
[1]'CI Parhon' National Institute of Endocrinology, Research Laboratory, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]University of Bucharest, Faculty of Biology, Bucharest, Romania; [4]'CI Parhon' National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania

Background
Matrix metalloproteinase-9 (MMP-9) is an important mediator of invasion and metastasis in neoplasia. The single nucleotide 1562 C/T polymorphism in the promoter region of the MMP-9 genewas shown to increase gene expression and was studied as a susceptibility factor for various cancers.
Aim
We aimed to evaluate the impact of the MMP-9 promoter genotype on the risk of developing papillary thyroid cancer (PTC) and to correlate cancer patient genotype with the pre-surgery serum MMP-9 levels and clinical and pathological features of tumor aggressiveness.
Patients and methods
We evaluated 213 patients referred for thyroidectomy, divided according to pathology into: benign disease (BD) ($n=102$) and PTC ($n=111$). Genomic DNA was isolated from whole blood in all patients and the presence of theMMP-9 1562 C/T polymorphism was evaluated by PCR-RFLP analysis. Pre-surgical serum MMP-9 levels were available in 90 BD and 81 PTC patients. MMP-9 was measured by Elisa (R&D Systems).
Results
Genotype frequencies were in Hardy-Weinberg equilibrium for both patients and controls. T allele was significantly more frequent in PTC patients compared to BD: the combined CT+TT genotype was present in 37 PTC (33.3%) compared to 16 BD patients (15.7%), $\chi^2=8.86$, CI [1.384–5.219], $P=0.0029$. The 1562 C/T genotype did not significantly correlate with presurgical serum MMP-9 levels in either BD or PTC patients; in cancer patients the genotype was not associated with histological subtype, presence of invasion or risk of recurrence. However, the CT+TT genotype was significantly more frequent in tumors smaller than 1 cm compared to larger

tumors ($P=0.016$) and after excluding small intra-thyroidal micropapilllary carcinomas (MPTC) ($N=21$), the association between genotype and BD/PTC diagnosis was lost ($P=0.09$).
Conclusion
The presence of the functional 1562 C/T polymorphism in the promoter region of the MMP-9 gene may indicate susceptibility to develop thyroid cancer. However, the association between the T allele and intrathyroidal clinically non-relevant MPTC may suggest that although this may be a predisposing factor, other genetic/epigenetic events are needed for cancer progression. The 1562 C/T polymorphism might not be clinically useful as a prognostic factor.
The study was funded by UEFISCDI grant PN-II-PT-PCCA-2011-3.2 no.135/2012.

Papillary thyroid cancer with biochemical incomplete response: Clinico-pathological characteristics and disease outcome

Miriam Steinschneider[1], Mustafa Asly[1], Efrat Markus[1], Shlomit Koren[1], Inna Tkacheva[1], Carlos Benbassat[2], Limor Muallem-Kalmovich[1] & Dania Hirsch[3]
[1]Assaf Harofeh Medical Center, Zerifin, Israel; [2]Shamir medical center, Tzrifin; [3] Rabin Medical Center, Petah Tikva, Israel

Objective
Althoughmost Papillary Thyroid Cancer (PTC) patients with biochemical incomplete response (BIR) to primary therapy have a good clinical outcome, some will develop disease progression. We aim to study baseline characteristics and long-term outcomes of PTC patients with BIR.
Methods
Of 1049 PTC patients treated at 2 tertiary medical centers, 795 (75.8%) had excellent, 91 (8.7%) biochemical incomplete, 139 (13.2%) structural incomplete and 24 (2.3%) indeterminate response one year after initial treatment. Clinical features, management and disease outcome of 91 BIR patients were evaluated. Mean follow-up was 11.8±6.6 years.
Results
All patients underwent total thyroidectomy, 50.5% neck dissection and 97% RAI (122.4±49 mCi). At diagnosis mean age was 48±17 yr, 67% were females and 77% PTC. Mean tumor size was 25±9 mm, with multifocality in 59.3%, ETE 8th in 24.4%, N1 in 43%, stage 8th in I-II 96.6%, and ATA low-risk 69.7%.No patient had distant metastases. Further treatment included: reoperation 20%, additional I^{131} 52% (cumulative 278±135 mCi). During follow-up 53.8% revert to no evidence of disease, 23.1% remained BIR and 23.1% progressed to structural disease. The switch to structural disease could be predicted by older age, ETE, higher ATA risk and advanced TNM 8th stage. PostOp stTg was not a predictor in BIR patients. At the study-end there were 8 deaths (3 disease-related).
Conclusions
Our data suggest that BIR patients have a generally favorable outcome, however up to 23% may progress to structural disease. In this preliminary study we found some variables to be considered as possible predictor factors

The outcomes of thyroglobulin monitoring by high-sensitivity tests after treatment of differentiated thyroid cancer

Natalya Makolina, Nadezhda Platonova, Ekaterina Troshina & Galina Melnichenko
National Medical Research Center for Endocrinology, Moscow, Russian Federation

The goal was todetermine the optimal methods of postoperative monitoring of serum thyroglobulin (Tg) in differentiated thyroid cancer (DTC). This research intended to compare the prognostic value of immunometric methods with different functional sensitivity (FS) for Tg measurement for detecting recurrent disease.
Design
During 2010–2012 years, 76 patients with treated DTC (a total thyroidectomy and adjuvant radioiodine therapy) were included. All patients were at low-to-intermediate risk group(disease advanced was $T_{1-3}N_{0-1}M_0$), the prevalence of TgAb was 36% ($n=27$).
The study protocol contained the obtaining of samples biochemical markers twice in year: basal Tg on levothyroxine (L-T4) treatment (bTg), Tg after TSH stimulation test (stTg), TSH, TgAb.
In all cases bTg samplings were investigated with immunometric method with functional sensitivity (FS) –0.9 ng/ml and by high-sensitive assays (hs-bTg) with FS ≤ 0.2 ng/ml.
In 80% of patients, TSH stimulation tests were performed by withdrawal of LT4, in other cases through injection of rhTSH.
The observation period is not less than 6 years.
Results
During first 18 months of follow-up, 9 (12%) patients completed the study suffered from treatment failure (it was confirmed by TSH stimulation test – stTg in the range of 4.5–9.7 ng/ml). In these 9 patients the values of hs-bTg were between 0.54–0.89 ng/ml. The observation continued on 67 patients.
The high sensitivity assays confidently predict increases in stTg after withdrawal LT4 in the absence of TgAb. It appears that in TgAb-negative patients with undetectable bTg a negative TSH stimulation test (stTg ≤ 2.0 ng/ml) can be predicted if their hs-bTg ≤ 0.4 ng/ml. TSH stimulation test detected disease recurrence in two TgAb-positive patients with undetectable bTg and hs-bTg was 0.54 and 0.71 ng/ml resp. High-sensitivity Tg tests demonstrated low reproducibility for all TgAb-positive patients, while in TgAb-negative patients all results were reliable. There was no correlation between the level of TgAb and level of basal Tg and treatment failure.
Conclusions
The Tg obtained after TSH-stimulation is still excellent tumor marker.
When TgAb is absent, bTg measurement by high-sensitivity test and neck US are sufficient tools for routine follow-up of patients with DTC – to monitor the bTg trend without performing any TSH stimulation in patients with initial confirmed low-to-intermediate recurrence risk The influence of TgAb significantly reduces the diagnostic value of Tg assessment. When TgAb is present, the monitoring of bTg by high-sensitivity test can't replace completely TSH stimulating test.
Funding
This research is performed under Russian scientific fond grant (RSF) №17–75–30 035.

Introduction
Next-generation sequencing (NGS) in thyroid cancer allows for high-throughput sequencing analysis of various genetic alterations and provides a useful information of tumor biology. NGS Studies on follicular differentiated thyroid cancer have been scantyfrom Indian subcontinent. In this context, we set out study the prevalence of a genetic panel wide somatic mutations in thyroid cancer.
Material and methods
This prospective study was conducted on 40 paraffin embedded thyroidectomy surgical tissue samples. Institutional ethical committee approval was obtained. Followup details are documented and analysed. Mutation analysis with a 12-gene mutation panel using real-time PCR and ThyroSeq v2 on the Ion Torrent PGM sequencer was employed.
Results
Common single nucleotide polymorphisms (SNPs) with a minor allele frequency of >0.05, asdocumented in dbSNP; noncoding region variants; and variants in repetitive regions were excluded. Mutations were also manually checked using the Integrated Genomics Viewer v2.4.10 to filter out false positives. The analysis found mutations commonly in BRAF (30)), CDKN2A (19), NRAS (12), PI3KCA (17), RET (8), RAS (24) and TP53 (5) genes. The common mutations found in the samples was RET (M918T), NRAS (Q61R), BRAF (V600E) and missense mutation in TP53(c.217–c.1178). A mutation has also been identified in KMT2D gene in two of the patient samples. BRAF, CDKN2A, PI3KCA were more common in papillary cancer; RAS, NRAS, RET mutations were common in follicular cancer; TP53 and KMT2D were seen only in poorly differentiated cancer.

Conclusions
NGS helps in patient management, providing risk stratification and subtyping of malignancy. It can be used in molecular tumor classification, and molecular prediction of recurrence and metastasis in thyroid carcinoma. To the best of our knowledge, this is one of its kind study from Indian subcontinent

Medullary thyroid cancer follow-up in a tertiary center
Tugce Apaydin, Eren Imre & Dilek Gogas Yavuz
Marmara University School of Medicine, Department of Endocrinology and Metabolism, Istanbul, Turkey

Introduction
Although medullary thyroid cancer (MTC) constitutes 2–4% of all thyroid cancers, it is associated with higher mortality compared to differentiated thyroid carcinomas. Here we present long term clinical results of medullary carcinoma patients' follow-up in our center.
Methods and results
MTC was detected in 27 (3.73%) patients of 850 thyroid cancer cases who were followed-up between 2004 and 2020 at the Marmara University School of Medicine, Endocrinology and Metabolic Diseases Department. The mean age at diagnosis was 47.7±14. The female/male (20/7) ratio was 2.8. The mean follow-up was 7.29±4.9 years. In 16 (59.2%) patients, the diagnosis was compatible with medullary thyroid carcinoma in fine-needle aspiration biopsy, the remaining patients were diagnosed after thyroidectomy. The diagnosis was made by biopsy from the supraclavicular lymph node in 2 patients (7.4%), one had no nodule on the thyroid. None of the patients had distant metastases at the time of diagnosis. Neck lymph node metastasis was detected in 8 patients (29.6%) at the time of diagnosis. Relapse occurred in a median of 2 years (min-max: 1–14) after the first surgery in 3 patients (11.1%).
MTC was detected on the right lobe in 12 patients (44.4%), on the left lobe in 13 patients (48.1%), and bilaterally in 2 patients (7.4%). The meantumor diameter was 1.9±1.3 cm. Papillary thyroid microcarcinoma was detected in the contralateral thyroid lobe in 3 patients. The preoperative median calcitonin level was 363.5 ng/l (min-max:5–5655). Median postoperative calcitonin level was 3.3 ng/l (min-max:0.5–871), CEA level was 4.49 ng/ml (min-max: 0.45–14.6).RET mutation was heterozygous positive in 2 patients (7.4%).
Preoperative calcitonin level ($P=0.206$), presence of invasion ($P=0.516$) and tumor diameter ($P=0.581$)was not associated with response rate;on the other hand postoperative calcitonin level ($P=0.0045$) was the only effective factor on remission rate.
In the last visit, 7 (25.9%) patients had a structural incomplete response, and 3 patients (11.1%) had a biochemical incomplete response. 17 (59.3%) patients were in remission, none of the patients died of MTC or another cause.
Conclusion
We observed a higher recurrence rate compared to the literature. In previous studies, 10-year survival was associated with age, disease stage, and postoperative calcitonin levels. Postoperative calcitonin level was the only factor associated with survival in our patients.
Keywords: medullary thyroid carcinoma, calcitonin, life expectancy.

Is Poorly diffentiated thyroid cancer a bridge between well differentiated and anaplastic cancer – Genomic perspective
Ramakanth Bhargav Panchangam[1], Ramesh Bangaraiahgari[2], Rajesh Bangaraiahgari[3], Rafi Md[2], Rajkiran reddy B[4], Sabaretnam MAYILVAGANAN[5], Rakshith G[6], Lakshmi Akshaya Ramesh Devanapalli[7], Akhila Vemula[7], Shiran Shetty M[7], Shreshta T[7] & Sweeya P[7]

Introduction
Poorly differentiated thyroid cancer (PDC) is a relatively rare form of differentiated thyroid caner with intermediate prognosis between well differentiated (WDTC) and anaplastic cancers (ATC). But, this finding is debatable in literature. Genomics is the one of definitive modalities to resolve this conundrum. ATC tends to express P53 and KMT2D mutations frequently, while WDTC have no such mutations. Similar studies are scanty in PDC. In this context, we set out study the prevalence of these somatic mutations in surgical tissue samples of PDC.
Material and methods
This prospective study was conducted on surgically managed thyroid cancerpatients. Institutional ethical committee approval was obtained. Diagnosis was based on biochemical confirmation, imaging, fine needle aspiration cytology and later confirmed by histopathology. We selected 10 PDC, 3 ATC and 25 WDTC cases. Tumour tissue samples were taken from ex-vivo thyroidectomy specimen within operation theatre. After appropriate processing of samples, DNA extraction, cDNA preparation, PCR amplification, application of 2 sets of Primers were performed as part of mutational analysis of P53 and KMT2D genes.
Results
Heterozygous mutations in KMT2D gene and missense mutation in P53 genewere found in 3/10 (30%) and 5/10 (50%) of PDC cases respectively. In ATC, KMT2D mutations were seen in 2/3 (67%) and 3/3 (100%) cases. In WDTC, mutations were not seen in either of these two genes.
Conclusions
Our study shows a distinct chronological pattern of mutations in KMT2D and P53 genes suggesting correlation between the gene function and cancer cell differentiation. Further, PDC appears to be intermediate in mutation frequency, with WDTC on lower side and ATC on higher side of scale. Though our results are not robust, it sets precedent for larger multi-institutional studies to justify this observation in future.

The importance of molecular-genetic examination in a patient with sonographically suspected but cytologically benign thyroid nodule
Milos Laburda[1], Karel Vondra[2], Barbora Pekova[3], Sarka Dvorakova[3], Vlasta Sykorova[3], Jitka Moravcova[3], Eliska Vaclavikova[3], Miloslav kuklik[3], Josef Vcelak[3], Bela Bendlova[3] & Jana Drozenova[4]
[1] Institute of Endocrinology, Department of Clinical Endocrinology, Prague, Czech Republic; [2]Institute of Endocrinology, Department of Functional Diagnostics, Prague, Czech Republic; [3]Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic; [4]3rd Faculty of Medicine, Charles University and University Hospital Royal Vinohrady, Department of Pathology, Prague 10, Czech Republic

Introduction
Differential diagnosis of thyroid nodules is one of the most frequently solved problems in the endocrinological practice. It is always necessary to determine their biological nature, which will decide about further therapeutic procedure, especially about early surgery in case of proven malignancy. In addition to sonographic examination and fine needle aspiration biopsy (FNAB), now we can also use the possibilities of molecular-genetic examination.
Case report
We present a case report of a 55-year-old woman sent to our institute to examine the sonographically suspected nodule in the right thyroid lobe. In accordance with conventional procedures, fine needle aspiration biopsy of the nodule was performed. The cytological examination determined the sample as benign (Bethesda Category II). Due to sonographically very suspicious features (microcalcification, TI-RADS category 5), we performed molecular-geneticanalysis for the presence of genetic mutations associated with thyroid oncology. The somatic mutation of V600E in the 15th exon of the *BRAF* gene was proven. This mutation is associated with papillary thyroid carcinoma (PTC) and with a worse prognosis of the disease. Based on these findings, we indicated the patient to undergo total thyroidectomy. Histological examination confirmed PTC and also the mutation in the *BRAF* gene was identified in surgical tissue. The patient continues to be observed at our institute and simultaneously at the Department of Nuclear Medicine and Endocrinology in Motol University Hospital, where the first dose of radioiodine has already been given.
Conclusion
The benefit of our workplace lies in a complex diagnostic approach. Although according to the ETA guidelines molecular-genetic testing of FNAB-derived material is recommended only in Bethesda III and above,

our case report shows that a well-performed thyroid sonography leading to suspected malignancy should be complemented by a molecular-genetic examination of the nodule despite benign cytological analysis. The *BRAF* V600E mutation is specific for PTC, therefore its finding in the presented patient led directly to the diagnosis of PTC.

Intraoperative navigation of the parathyroid glands in the surgical treatment of highly differentiated thyroid cancer

Mikhail Vozdvizhenskii, Andrey Orlov, Aleksandr Makhonin, Vladimir Stadler & Yana Matyash

Samara Regional Clinical Oncology Center, Samara, Russian Federation

Topicality

The most common cancer of the endocrine system is thyroid cancer. The main method of treatment for highly differentiated thyroid cancer is surgical. A special place among the complications of surgical treatment of thyroid cancer according to the severity of manifestation and the complexity of prevention is occupied by postoperative hypoparathyroidism.

The purpose of the study.

Minimize the risk of damage to the parathyroid glands during thyroid surgery.

Inclusion criteria – patients with highly differentiated thyroid cancer T1-4aN1a-1bM0-1.

Exclusion criteria – highly differentiated thyroid cancer T1-2N0M0patients.

Materials and methods

The object of the study was 163 patients with highly differentiated thyroid cancer treated in the Samara Regional Clinical Oncology Center from July 2017 to September 2019. The average age of patients in the main group (thyroidectomy + selective cervical dissection using the pharmaceutical preparation 5-aminolevulinic acid hydrochloride) was 68.5 ± 25.6 years (18–82), 84 patients in total, in the control group (thyroidectomy + selective cervical dissection)) – 64.9 ± 24.5 years (21–78) of a total of 79 patients. In order to evaluate the effectiveness of parathyroid gland preservation, the level of parathyroid hormone was monitored on days 7, 25–30 and 55–60 after surgery and calcium, ionized calcium, phosphorus on 1, 7, 25–30, 55–60 days after surgery. Patients of the main group in the preoperative period were orally prescribed to take the 5-aminolevulinic acid hydrochloride drug twice – 3 hours before the start of surgery at a dose of 20 mg/kg (180 ± 15 min), then – 1 hour before surgery at a dose of 10 mg/kg (60 ± 10 min). Intraoperatively, to detect the parathyroid glands, an optical radiation source with a wavelength in the range from 385 to 460 nm and polarizing glasses were used, when fluorescent sites were detected, an urgent cytological study was performed to confirm parathyroid gland visualization.

Results

In the main group, transient hyperparathyroidism was observed in 2 patients (2.3%), stopped in 7 days. Persistent hypoparathyroidism was absent in patients of the main group. In the control group, transient hypoparathyroidism wasobserved in 12 patients (15.1%). Persistent hypoparathyroidism was observed in 2 patients (2.5%) in the control group.

Conclusions

Intraoperative navigation of the parathyroid glands using the pharmaceutical preparation 5-aminolevulinic acid hydrochloride can significantly reduce the number of postoperative complications associated with the removal/damage of the parathyroid glands.

Introduction

Advanced differentiated thyroid carcinoma (aDTC) – herein defined as locally unresectable or metastatic disease – is one of the most common late-stage endocrine neoplasias. However, available data about its natural history is limited. ERUDIT is a multicenter, observational, retrospective study of patients diagnosed with aDTC in Spain and Portugal. The study describes its natural history from the initial diagnosis until the advanced stages of disease, focusing on specific characteristics of this subpopulation of DTC, as well as its treatment, response patterns and medical specialties involved in its management.

Objectives

To describe diagnostic demographics of DTC patients whose disease have relapsed after initial treatment, the usage patterns and efficacy of rescue therapies, and the medical services involved in patient care.

Materials and methods

Clinical records from patients ≥ 18 y-o diagnosed with aDTC (including poorly differentiated DTC) with first evidence of advanced disease documented between January 2007 and August 2017 were retrospectively reviewed until death or lost to follow-up.

Results

213 patients were identified in 23 centres. Median age at initial diagnosis was 63 y-o, 59% were females. During the follow-up 46% progressed to advanced disease through previous relapse episodes after first treatment (surgery ± 131radioiodine [RAI]). Median (95% CI) relapse-free survival (RFS) from the initial treatment was 2.3 (1.7–2.9) years. Computed tomography (CT) and whole-body scan (WBS) were the most commonly used methods for relapse diagnosis (59% and 29%, respectively), being metastatic in 90% of the cases. Most frequent localization was lung (41%), and the rescue therapies, when indicated, were mainly RAI (62%) and surgery (14%). Specifically, 20% of the patients treated with RAI received up to 3 courses with median dose of 138 mCi each and cumulative dose of 518 mCi. Persistent structural disease was frequently reported after RAI (average 15% after three doses). Use of ablative interventions and radiotherapy was anecdotal (5%). Post relapse radiological follow-up mostly relied on CT (38%), positron-emission CT (18%), and WBS (16%). Endocrinology was the leading medical specialty responsible for patient monitoring (61%), while two thirds of the patients were evaluated by multidisciplinary committees.

Conclusions

Almost half of this cohort of aDTC tumours progressed onto advanced stage through previous relapses, with median RFS of 2.3 years and 62% being RAI-treatable. From this group, still 15% shows persistent disease after three RAI treatments. This suggests an unfavorable atypical evolution of some aDTC already since their initial treatment stages.

TNM 8th edition in thyroid cancer staging: Is there an improvement in predicting recurrence?

Miriam Cellini[1,2], Olimpia Alice Manzardo[1], Rita Indirli[3], Alessia Dolci[3], Paolo Colombo[1], Flaminia Carrone[1], Elisabetta Lavezzi[1], Giovanna

Mantovani[3], Gherardo Mazziotti[1,4], Maura Arosio[3] & Andrea Lania[1,4]
[1]Humanitas Clinical and Research Center, Endocrinology, Diabetology and Andrology Unit, Rozzano (MI), Italy; [2] 'Sapienza' University of Rome, Department of Medical-Surgical Sciences and Biotechnologies, Latina, Italy; [3]Department of Clinical Sciences and Community Health, University of Milan; Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Humanitas University, Department of Biomedical Sciences, Milan, Italy

TNM 8th edition introduces changes in the staging of patients with differentiated thyroid carcinoma (DTC). This study aims at assessing the ability of TNM 8th edition in predicting structural recurrence of DTC.480 DTC patients were retrospectively evaluated by 7th and 8th editions of TNM staging systems in relationship with risk stratification, response to therapy and recurrence of disease as defined by 2015 American Thyroid Association (ATA) guidelines. As compared to the 7th edition, TNM 8 led to downstage 136 patients (28.3%), with 97.5% of patients falling into lower stages (I-II) and only 2.5% remaining in higher stages (III-IV) ($P<0.001$). Patients who were downstaged in stages I-II by TNM 8 were classified more frequently at intermediate-high risk ($P<0.001$), had more frequently structural incomplete response to therapy ($P=0.009$) and had higher risk of structural recurrence ($P=0.002$) as compared to patients who were in the same TNM stages but were not downstaged. Specifically, the risk of structural recurrence was significantly high in patients in whom the downstaging was induced by changes in tumour classification [Hazard ration (HR) 6.18, C.I. 95% 2.20–17.40; $P=0.001$] but not in those who were downstaged for the increase in age cut-off (HR 2.80, C.I. 95% 0.86–9.19; $P=0.09$). In conclusion, TNM 8th edition did not show reliability in predicting aggressiveness of DTC. In fact, the downstaging of DTC patients especially when performed due to changes in tumour classification may overlook patients predisposed to structural recurrences, potentially causing uncertainty in the therapeutic decision-making at the time of disease's diagnosis.

AEP955

A study of the relationship between RET/PTC and Cyclin D1 expression of the thyroid under autoimmune thyroiditis and Papillary thyroid carcinoma (PTC): Clinical-pathological correlation

Tamuna Gvianishvili[1], Liana Gogiashvili[1], Zurab Tsagareli[1] & Mariam Velijanashvili[2]
[1]Iv. Javakhishvili Tbilisi State University, A. Natishvili Institute of Morphology, Clinical and Experimental Pathology, Tbilisi, Georgia; [2]Iv. Javakhishvili Tbilisi State University, Tbilisi, Georgia

Our research subject is to study the importance of some favorable molecular biological markers for prognosis of premalignant characteristics of Hashimoto's thyroiditis (HT) parenchyma. To clarify the pathogenetic link between these two pathologies (HT, PTC), we choose markers, indicating, at the one hand, on the tumor cell cycle, such Cyclin D1, at the second hand, RET/PTC rearrangement in HT, in order to determine molecular changes, connecting Hashimoto's thyroiditis with Papillary thyroid carcinoma (PTC). Basic of these concepts are follows: 1. We hypothesized, that Cyclin D1 diffuse immunoreactivites should play a role of PTC malignancies due to the mechanism of gene amplification in HT at first, while the chromosome 6p21 triggered activation of chromosome 11q23 (Cyclin D1 gene location); normal thyroid follicular cells do not show immunoreactivity for Cyclin D1 on immunohistochemistry, but Cyclin D1 is over expressed in up to 60% of PTC. 2. RET/PTC proto-oncogene is located on the long arm of chromosome 10. In the PTC pathogenesis activation of RET includes rearrangement or gene redistribution and should be typically more sensitive method of PTC detection in setting of HT. The research database includes postoperative surgical pathology material obtained 150 cases from 1065 patients, who had undergone total thyroidectomy, lobectomy, and partial resection of the thyroid gland. We reviewed all continuous thyroid histopathological reports from 2016 to 2019 years. The mean age was of 49.5 years (range 23–76). This study was reviewed and deemed exempt from written informed consent by the Ethics committee and Board of medical sciences at Tbilisi State University based on Helsinki-ethical principles declaration for medical research (2013). Immunohistochemical (IHC) studyincludes following markers: 1. Cyclin D1 (clone D-6, 1:50, Dako), 2. Ret Antibody (6E4C4, Santa Cruz Biotechnology, U.S.A.). Results were shown statistically significant correlation between RET/PTC proto-oncogene expressionin HT follicular cells nuclei and frequency of follicular epithelial dysplasia areas (χ^2-test: $P=0.091$; Fisher exact test: $P=0.119$). In terms of Cyclin D1 activity, according data, this cells cycle marker is not crucial for the detection of malignant transformation into thyroid Hashimoto parenchyma (χ^2-test: $P=0.012$; Fisher exact test: $P=0.017$). These results confirmed the importance of Cyclin D1 and RET/PTCproto-oncogene expression, suggesting their malignant transformation in the evaluation of HT behavior.

Medullary Thyroid Carcinoma (MTC); unusual metastatic sites. Two case reports

Paraskevi Kazakou, George Simeakis, Maria Alevizaki & Katerina Saltiki
'Alexandra' Hospital, Medical School, National and Kapodistrian University of Athens, Greece, Endocrine Unit, Department of Medical Therapeutics, Athens, Greece

Background
MTC tends to metastasize early in the course of the disease affecting usually regional lymph nodes; in 7–23% of patients distant metastases may be present at diagnosis (common metastatic sites:liver, lungs, bone). We present two MTC cases with unusual metastases to the breast, pancreas and mandible.
Case presentation
Patient No 1
A 48-year-old female was diagnosed with MTC in 1990. Total thyroidectomy was performed followed by neck dissection. Ten years later, cervical and mediastinum lymph node dissection took place. In 2009, disease progression was confirmed by elevated Calcitonin and CEA levels along with a positive uptake (Octreoscan) in mediastinum and liver. A bone scan revealed additional metastases in the thoracic spine and external bone radiotherapy and liver chemoembolisation were performed. In 2013, mediastinum MRI revealed a lesion in the right breast confirmed by mammography. Histology of breast tumorectomy confirmed MTC metastasis and treatment with vandetanib was initiated.
Patient No 2
A 55-year-old female was diagnosed with MTC in 2003. Total thyroidectomy with neck dissection was performed. Due to cervical nodal metastases, she underwent modified radical neck dissections. In 2014, recurrent metastatic disease in the right shoulder was confirmed by MRI and external radiotherapy was performed. Furthermore, an abdominal MRI revealed a head pancreatic tumor. MTC metastasis was confirmed by biopsy and treatment with vandetanib was initiated. Additionally, the histology of a resected painful mass in the right mandible revealed a well differentiated MTC.
Conclusions
These two MTC cases, although apparently rare, highlight the need for watchful care and prompt recognition of unexpected metastases in MTC patients.

A novel method for detecting autoantibody to wd repeat domain 1: Clinical application for differentiating papillary thyroid carcinoma with poor clinical outcome

Shoichiro Izawa[1,1], Kazuhiko Matsuzawa[1], Kazuhisa Matsumoto[1], Kenji Fukaya[1], Takahiro Fukuhara[2], Makoto Wakahara[3], Atsuro Koga[4], Tomoya Hino[5] & Kazuhiro Yamamoto[1]
[1]Tottori University Faculty of Medicine, Division of Cardiovascular Medicine, Endocrinology and Metabolism, Yonago, Japan; [2]Tottori University Faculty of Medicine, Division of Otolarygology, Head and Neck Surgery, Yonago, Japan; [3]Tottori University Faculty of Medicine, Division of General Thoracic Surgery, Yonago, Japan; [4]Tottori University, Organization for Research Initiation and Promotion, Tottori, Japan; [5]Tottori University, Department of Chemistry and Biotechnology, Graduate School of Engineering, Tottori, Japan

Background
Papillary thyroid carcinoma (PTC) is known as the most common histological subtype of thyroid carcinoma. The prognosis of PTC is generally favorable. However, small number of patients with PTC progressed with distant metastasis and invasion to adjacent organs. New diagnostic tool for early detection of PTC with poor outcome is desired. We previously reported that autoantibody to WD repeat domain 1 (AWA) in the serum was associated with the existence of undifferentiated thyroid carcinoma (UTC) and PTC (Izawa S *et al.*, Clin Endocrinol 2013). The objective of our study is todevelop this assay to be sensitive and specific for differentiating PTC with poor prognosis.
Materials and methods
A peptide library (peptide length = 12 aa, off-set = 6 aa) originated from human WDR1 isoform 1 were firstly screened (1st screening) by the serum of 3 patients with UTC and 3 normal healthy controls (N). Furthermore, 2nd screening was performed for selecting candidate peptides by using another peptide library (peptide length = 12 aa, off-set = 2 aa) designed by the result of 1st screening. Finally, candidate peptides were evaluated to be hydrophilic by bioinformatics. Sera from 16 patients with advanced thyroid carcinoma (UTC and PTC with metastasis and/or invasion to adjacent organs), 8 with not advanced PTC (without metastasis and invasions to adjacent organs), 14 with benign thyroid nodules (B), 15 with autoimmune thyroid disease (A), and 7 N were evaluated by ELISA using 12 candidate peptides.
Results
A total number of 42 peptides for detecting high titer of AWA were selected by the 1st screening. Most of these peptides were located in the C terminal of WDR1 isoform 1. After finishing 2nd screening, 12 candidate peptides with hydrophilic sequences were selected for ELISA. A peptide originating from human WDR1 isoform 1 (WDR1 2–33) presented significantly higher ($P < 0.05$) titer of AWA in advanced thyroid carcinoma (0.621 ± 0.289) than not advanced PTC (0.326 ± 0.114), B (0.255 ± 0.142), A (0.318 ± 0.164), and N (0.303 ± 0.161). The diagnostic performance of WDR1 2–33 was superior to other 11 peptides by ROC analysis.
Conclusion
We demonstrated that WDR1 2–33 could be a peptide containing the epitope of AWA. Our data suggested that evaluating AWA by WDR1 2–33 might be a new diagnostic method for early diagnosis of PTC with poor prognosis (patent pending JP2018–045806).

The profile of patients with hyperthyroidism at a tertiary health care center in the oriental region of northeastern Morrocco: – A study of 186 cases -

Salma Ben Yakhlef, Derkaoui Nada, Nisrine Bouichrat, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital, Mohammed I University, Oujda, Morocco, Department of Endocrinology-Diabetology, Oujda, Morocco

Introduction
Hyperthyroidism is characterised by an increased hormone synthesis, with non-specific and pleomorphic clinical features. Management strategy, depends entirely on the etiological status ; as part of an holistic vision. The purpose of this study is to shed light on epidemiological, clinical, etiological and therapeutic aspects of hyperthyroidism in Endocrinology & Diabetology department of Oujda's Mohammed VI university hospital.
Material and methods
Prospective data analysis of patients with hyperthyroidism followed up in Endocrinology & Diabetology department of Oujda's Mohammed VI university hospital.
Résults
186 patients were enrolled in the study. The overall mean age was 43.9 years old with a female predominance (83.9%). 18.7% of the patients had a family history of dysthyroidism. Clinicalhyperthyroidism features have been considered as the presenting complaint in 67% of all the cases, and thyroid orbitopathy have been noticed in 15.6% of patients. The mean serum concentrations of Ultrasensitive TSH and free T4 were around 0.09 mUI/l and 50.4 pmol/l respectively. Clearly elevated Thyrotropin Receptor antibodies (TRAb) and Anti-Thyroid Peroxydase antibodies (anti-TPO) were noticed in 52.4% and 45.1% of cases respectively. Grave's disease and toxic nodular goiter were identified in 61.4% of the patients, as the 2 major etiologies of thyrotoxicosis in our study. 97.8% of the patients underwent antithyroid drug therapy, and b-adrenergic blocker was added basically in 42.5% of the cases. Neutropenia was observed only in 3.9% of the patients. A total thyroidectomy was proceeded in 36.4% of cases and 31.1% preferred Radio Iodine (I-131) therapy.
Conclusion
Hyperthyroidism is considered as a frequent endocrinopathy which can be easily diagnosed. However,chosing an eminent therapeutic pathway remains a matter of debate and a challenge for every clinician.

Features of large intestinal microbiota of patients with hypothyroidism

Antonina Piddubna, Nataliia Pashkovska, Galina Koval, Ivan Pankiv, Yulia Marchuk, Nataliia Abramova & Iryna Tsaryk
HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Черновцы, Ukraine

Introduction
The prevalence of manifest hypothyroidism by various data is 0.2–2%, sub-clinical – up to 3% in men and up to 10% in women, and in people over 70 years old – 13–14%. The presence of concomitant gastrointestinal diseases significantly limits the possibility of hypothyroidism compensation; these patients need higher doses of levothyroxine. According to a number of researchers, hypothyroidism is often accompanied by small intestinal bacterial overgrowth (SIBO). The purpose of the work was to study the species composition and population level of microflora of the intestinal cavity in patients with primary hypothyroidism depending on disease compensation, as well as study of the content of the main filotypes of intestinal microbiota in these patients.
Material and methods
44 patients with hypothyroidism (19 men and 25 women) aged 30–72 years (the average age 47.3 + 8.9 years) were examined at the stageof compensation and decompensation of the disease and 51 practically healthy people who formed the control group. Due to the disease compensation, 2 groups of patients were created. The first group (20 patients) consisted of patients in the state of compensation, the second group (24 patients) – in the state of decompensation of the disease. Identification of selected cultures was carried out according to morphological, tinctoral, cultural and biochemical properties.
Results and discussion
The dysbiosis of the IV degree was established in 34 (77%) patients, the third degree — at 8 (18%) patients, II degree — in 1 patient, I degree — in 1 patient. Imbalance developed due to eliminations and deficiency of autochthonous anaerobic, obligatory bacteria (*Bifidobacteria, Lactobacteria*), contaminations of the large intestine by enterotoxigenic, enteropathogenic and hemolytic *Escherichia*, opportunistic enterobacteria and an increase of the number of the bacteriodes, peptococci, peptostreptococci, clostridia, staphylococci and yeast-like fungi of the *Candida* type.
Conclusion
It is found out that the relative content of the main microbial filotypes differed from healthy subjects compared with patients with hypothyroidism. Thus, *Firmicutes* content in patients with hypothyroidism was significantly higher and bacteroides content – significantly lower in relation to healthy individuals ($P < 0.05$). Analyzing the content of the main microbial filotypes depending on the state of hypothyroidism compensation, it was found that in patients in the state of compensation and decompensation of hypothyroidis, *Firmicutes* content was significantly higher ($P < 0.05$), and the content of *Bacteroides* – relatively lower in patients in the compensation state comparing to the group of healthy people ($P < 0.05$).

Comparative characteristics of NAD(P) – dependent dehydrogenases in blood lymphocytes and neutrophils in patients with Graves' disease

Margarita Dudina[1,2], Sergey Dogadin[1,2], Andrey Savchenko[3] & Ivan Gvozdev[3]
[1]Krasnoyarsk State Medical University named after Prof. V.F. Voino-Yasenetsky, Internal disease, Krasnoyarsk, Russian Federation;
[2]Krasnoyarsk regional clinical hospital, Krasnoyarsk, Russian Federation;
[3]Federal Research Center «Krasnoyarsk Science Center» of the Siberian Branch of the Russian Academy of Sciences, Scientific Research Institute of medical problems of the North, Laboratory of Molecular and Cell physiology and pathology, Krasnoyarsk, Russian Federation

Background
Thyroid hormones participate in maturation, differentiation and triggering of immunity, but little is known about the modulating role of thyroid hormones on intracellular enzymatic reactions of immune cells and their role in immunopathogenesis of Graves' disease (GD).
Methods
The activity of NAD(P)-dependent dehydrogenases in lymphocytes and neutrophils ofperipheral blood was studied in a group of 145 women with GD, 53 (36.5%) patients with a first episode and 92 (63.4%) with relapse of hyperthyroidism, mean age 43.14±13.81 years, and, also, 73 age- and gender matched healthy controls were determined. The diagnosis of GD had to be established by a low TSH, a high fT4 or fT3 and positive TRAb. The activity of glycerol-3-phosphate dehydrogenase (Gly3PhD), glucose-6-phosphate dehydrogenase, NAD-lactate dehydrogenase (LDH), NADH-lactate dehydrogenase (NADH-LDH), NAD–malate dehydrogenase (MDH), NADH–malate dehydrogenase, NAD-glutamate dehydrogenase (GDH), NADH-glutamate dehydrogenase (NADH-GDH), NAD(P)-isocitrate dehydrogenases (ICDH and NADP-ICDHrespectively), NADP(H)-glutamate dehydrogenases (NADP-GDH and NADPH-GDH respectively), NADP-malate dehydrogenase and glutathione reductase were measured usingbiochemiluminescence method.
Results
Studying the activity ofNAD(P)-dependent dehydrogenases in lymphocytes we found the reduction of MDH and NADPH–GDH ($P<0.001$). In neutrophils ofperipheral blood in patients with manifestation of GD increased the activity of ICDH ($P<0.01$) and reverse reaction of LDH ($P<0.05$). In patients with GD relapsing in peripheral blood lymphocytes we observed low activity of LDH ($P<0.05$), MDH ($P<0.01$), ICDH and NADPH–GDH ($P<0.01$). Studying intracellular metabolism of blood neutrophils patients with recurrence of the disease showed significantly high activity of NADP-MDH, NADP-GDH, NADP-ICDH, GDH, NADH-GDH, but inhibiting reverse reactions of LDH and MDH ($P<0.05$). The comparative analysis of the studied NAD(P)-dependent dehydrogenases demonstrate, that in group with newly diagnosed GD compared to patients with recurrent disease in lymphocytes of peripheral blood increase the level of Gly3PhD, NADH-GDH ($P<0.05$). Intracellular metabolism of blood neutrophils in patients with manifestation of GD compare to GD relapse group vary by decreasing activity of Gly3PhD,GDH and NADP-MDH ($P<0.05$).
Conclusion
The main features oflymphocyte metabolism in GD relapse patients were the reduction of intermediates formation for macromolecular synthesis reactions and aerobic processes, the low intensity of glycolysis, nitrogen metabolism,and in neutrophils – activation in the system of malate-aspartate hydrogen shunt. Further exploration of immunological mechanisms has the potential to improve treatment of GD, with more targeted treatment strategies based on the different physiopathological concepts of this heterogeneous disease.

Chronic autoimmune thyroiditis and hypovitaminosis D – mammary eco-structural implications

Ibadula Seila, Scrinic Olesea & Circo Eduard
Clinical Emergency County Hospital Constanta, Romania, Endocrinology Department, Constanta, Romania

Introduction
Benign breast disease is the most common reason for senology consultation.
Objectives
To investigate the possible involvement of thyroid autoimmunity and hypovitaminosis D in the development of mammary echo-structural lesions.
Method
The BI-RADS score was assigned to categories 1–4 characteristic of benign mastopathy, in three groups of patients: Group 1 (n=167) – with chronic autoimmune thyroiditis and normal vitamin D values; Group 2 (n=172) – patients without thyroid pathology with moderate and severe vitamin D deficiency; Group 3 (n= 181) – patients with chronic autoimmune thyroiditis and moderate and severe vitamin D deficiency respectively.
Results
In the study group 1–90% of patients had both types of antithyroid antibodies (ATPO/ATG) and 6.5% only positive ATPO, and 3.5% only positive ATG; for the patient group with both types of antibody there were significant differences ($P<0.001$) between the BIRADS score 4 and previous scores 1–2–3; statistical significance was remarkable in the ATG group ($P<0.001$) and not significant for the ATPO group. In group 2 of study – a statistical significance ($P<0.001$) was found in both groups of women investigated in terms of serum deficiency of vitamin D, for stage 4 BIRADS score, the statistical significance ($P<0.001$) also being in favor of those with very low levels of vitamin D. For study group 3 – the maximally breast density assessed in the study (BIRADS-4) was significantly increased ($P<0.001$) for patients from the group with moderately low vitamin D level with both types of antibodies and with positive ATPO only, being insignificant in the group with positive ATG – only. For the severely deficient group the statistical significance was recorded only in the group with both types of thyroid autoantibodies. Within each study group, significant percentages ($P<0.001$) for the 4-BIRADS score in the group with both antibody types present – group 1 and group 3 moderate and severe vitamin D group were observed.
Conclusions
The presence of thyroid autoimmunity and vitamin D deficiency are factors involved in the development of benign mastopathy. Additional studies may be required to fully characterize the mechanism of action. Theexpression specificities of autoimmunity and functionality of vitamin D receptor, their quantitative fluctuations in breast tissue and the specificity of bioavailability of mammary tissue components offer lesion variability with multiple individualities.

Renal malfunction in patients with primary hypothyroidism

Oksana Didushko & Iryna Cherniavska
Ivano-Frankivsk National Medical University,, Endocrinology Department, Ivano-Frankivsk, Ukraine

Aim
Study the correlation between leptin and renal malfunction in patients with primary hypothyroidism (PH).
Methods
161 patients suffering from PH took part in the investigation. Criteria of choice were as follows: patients' age from 36 to 60 and presence of PH. Presence of any acute or chronic renal disease or ischemic heart disease was the criteria of exclusion. The diagnosis was made on the basis of complaints, family history, typical clinical sign of manifested hypothyroidism and was confirmed by the results of hormonal analyses.
Results
Among 152 examined patients, barrier malfunction was found in 52.6% of patients, out of which 46.6% had albuminuria, and 6% had proteinuria. Early stage of nephropathy was found in 24% of patients. Patients diagnosed with abnormal renal function were divided into four groups taking into account their body weight index (BWI), since this factor has a significant effect on changes in mentioned above parameters. Patients with PH on the basis of Hashimoto thyroiditis with BWI<24.9 kg/m^2 and BWI>25 kg/m^2 were included to IA and IB groups correspondingly. Group II A and II B encompassed patients with postoperative hypothyroidism (PH) with BWI<24.9 kg/m² and BWI>25 kg/m^2 correspondingly. At the same time, calculating RGF by MDRD formula considering sex and age, its value was found to be quite low (77.99±2.18) and essentially differed from the data received in the control group. Patients with PH and excessive body weight showed much lower RGF in comparison to control group ($P<0.001$). Evaluating the leptin level it was noted that the bigger body weight patients with PH had the higher concentration of leptin in blood serum was revealed. Thus, patients with hypothyroidism and Hashimoto thyroiditis had leptin level two times higher in the group with BWI>24.9 kg/m^2 than in the group with BWI<24.9 kg/m^2, and in the group of patients with PH this level is three times higher. Hyperleptinemia is closely related to anthropometric indices and functional parameters of kidneys. The most distinct reverse contact was traced between leptin and RGF and direct contact–among waist circumference, BWI and albumin secretion.
Conclusion
Patients with manifested hypothyroidism have revealed renal malfunction, predisposed by such risk factor as hyperleptinemia, overweight and abdominal obesity.

AEP963

The possibilities of sonography in the diagnosis of thyroid nodules

Yuriy Aleksandrov, Ivan Belyakov & Ekaterina Sokolova
Yaroslavl State Medical University, surgery, Yaroslavl, Russian Federation

Purpose
To study the possibilities of sonoelastography (SEG) in the diagnosis of thyroid tumors. Materials and methods: in 123 patients (27 with papillary thyroid cancer, 45 with thyroid adenomas, and 51 with colloid goiter), different versions of SEG were used at the preoperative stage: compression sonoelastography (CEG) and point shear wave elastography (ARFI). Together with the staining assessment, quantitative parameters were determined: the speed of the transverse wave (M), and the Young's modulus (E). When using point elastography of the shear wave, the velocity of the transverse wave in m/s was measured.
Results
Normal thyroid tissue with CEG had slightly inhomogeneous, uneven fine-grained symmetrical staining with red-yellow tones. With nodular goiter, the staining zones of different colors and intensities were determined, depending on the' stiffness ' of the tissue in the node. Two-color (51.3%) and three-color (33.3%) staining prevailed in the CEG of colloid nodules. The ARFI in thyroid nodules was 3.11 ± 0.75 m/s, and the Young's modulus was 19.37 8.4 kPa.
The thyroid adenomas had different color characteristics and greater variety. Two-color staining occurred in 26.3% of observations, and four-color staining occurred in 47.2%. It was mostly green (58.2%). For ARFI in these tumors presented the cross-wave velocity was 3.96 ± 0.75 m/s, and the Young's modulus was 35.3 ± 7.4 kp. In most cases, purple-blue-blue staining (76.4%) was detected in the verified RSC. Four-color (26.3%) and five-color (35.2%) coloring prevailed, with a predominance of cold-tone patterns. The ARFI for thyroid cancer was 4.77 ± 0.84 m/s, and the Young's modulus was 61.22 11.3 kPa. The predictive ability of SEG in the differential diagnosis of thyroid tumors was evaluated using ROC analysis. The model took into account qualitative variables that affect the result. The index AUC = 0.811 (95% CI = 0.765–0.833), indicates that the compression sonoelastography is a test with good quality, but has limits on specificity, which is important in the diagnosis of thyroid cancer. When evaluating ARFI using ROC analysis, it was found that AUC = 0.822 (95% CI = 0.787–0.853). The sensitivity of ARVI was higher than that of KG (87.8%), and the specificity was equal (80.5%). The results obtained were better than the CEG indicators, but the differences were not reliable ($P > 0.05$). It is difficult to assess microcarcinoma and follicular thyroid cancer, in which both ARFI have low sensitivity and specificity. This reduces the diagnostic effectiveness of the test.

Efficacy & safety of total thyroidectomy as preferred primary treatment option for Graves' disease

Katlin Mallette[1], Francis Christian[1] & Gudrun Caspar-Bell[2]
[1]University of Saskatchewan, Department of Surgery, Saskatoon, Canada; [2]University of Saskatchewan, Department of Internal Medicine-Endocrinology & Metabolism, Saskatoon, Canada

Graves' disease is a common autoimmune condition, and the most common cause of hyperthyroidism. A number of definitive treatment options for this disease exist, including radioiodine (RI) and surgery. Surgery is often reserved for patients for whom RI is contraindicated or who have previously failed other treatments, including radioactive iodine ablation (RIA). The aim of this study was to assess the efficacy and safety of total thyroidectomy at our institution as a preferred primary treatment option for patients with Grave's Disease. A total of 98 consecutive cases of total thyroidectomy for the primary treatment of Grave's Disease were analyzed. Patients assessed in our retrospective study had a very low rate of complications and there was no mortality. There were no cases of voice disturbance associated with recurrent laryngeal nerve injury. The rate of hypocalcemia (transient 11.3%; persistent beyond 6 months 1%) was low and there was only one return to the operating room for evacuation of hematoma. The only patient with more persistent hypoparathyroidism recovered her parathyroid hormone levels at 18 months. Patients' symptoms, including symptoms related to hyperthyroidism, pressure related symptoms and ophthalmopathy, significantly improved in the follow up period. 17.2% of patients in this study had papillary cancer incidentally present in the surgical specimen on pathology. This study provides evidence that in selected patients with Graves' disease, surgical management with total thyroidectomy should be considered a safe and effective first line treatment. It provides complete and safe cure of disease and rapid resolution of symptoms. In addition, in our study, the simultaneous excision of incidental papillary cancer was a significant added benefit of total thyroidectomy.

Constitutive activation of Nrf2 antioxidant pathway leads to age-dependent goiter and compensated hypothyroidism in mice

Dionysios Chartoumpekis[1,2], Panos Ziros[1], Cédric Renaud[1], Massimo Bongiovanni[3], Ioannis Habeos[2], Xiao-Hui Liao[4], Samuel Refetoff[4,5,6], Peter Kopp[1], Klaudia Brix[7] & Gerasimos Sykiotis[1]
[1]Lausanne University Hospital (CHUV), Service of Endocrinology, Diabetology and Metabolism, Lausanne, Switzerland; [2]University of Patras, Internal Medicine, Division of Endocrinology, Patras, Greece; [3]Synlab, Lausanne, Switzerland; [4]University of Chicago, Department of Medicine, Chicago, United States; [5]University of Chicago, Department of Pediatrics, Chicago, United States; [6]University of Chicago, Committee on Genetics, Chicago, United States; [7]Jacobs University Bremen, Department of Life Sciences and Chemistry, Bremen, Germany

Background
KEAP1 gene (Kelch-like ECH-associated protein 1) that encodes the main inhibitor of nuclear factor erythroid 2-related transcription factor 2 (Nrf2), a central mediator of antioxidant responses, has been found to be one of the mutated genes that lead to familial multinodular goiter (MNG). The proposed association of *KEAP1* with familial MNG is based on only two loss-of-function mutations in respective Japanese families. To date, there is no experimental evidence from model organisms to support that decreased Keap1 levels can cause goiter.
Hypothesis
We hypothesized that enhanced Nrf2 signaling induced by reduced Keap1 expression in mice can lead to goiter.
Methods
Male Keap1 hypomorphic C57BL/6J male mice that express ~80% less Keap1 in their tissues (Keap1 knockdown mice:'Keap1KD') were studied at 3 and 12 months of age and compared to wild-type mice (WT).Plasma, thyroids and pituitary glands were collected for assessment of thyroid function and for histology as well as gene and protein expression by quantitative PCR and immunoblotting respectively.
Results
Keap1KD showed diffuse goiter that began to develop in early adult life and became highly prominent at the age of 12 months when the thyroids of Keap-1KD were six-fold heavier than WT. Histomorphometry assessment of thyroids showed that Keap1KD had ~three-fold larger follicle area and colloid compartment but no thyroid nodules or hyperplasia was detected. Keap1KD also showed primary hypothyroidism already in early adult life that was eventually well-compensated over time by increased TSH levels (at age of 12 months: WT TSH = 47.7 ± 9.1 mU/l, Keap1KD TSH = 460 ± 74 mU/l). This was also reflected in the pituitary gland of Keap1KD where *Tshb* mRNA was ~three-fold higher than WT. Despite a known stimulatory effect of Nrf2 on Tg gene transcription and Tg protein abundance, these measures were decreased in the thyroid of Keap1KD mice. No clear patterns were observed in the expression profiles of other thyroid hormone synthesis-specific factors, such as *Duox1, Duoxa1, Duox2, Duoxa2, Tpo, Nis, Dio1, Dio2, Dehal1* mRNA levels, with the exception of Tg-processing and Tg-degrading cathepsins, including an increase in mature forms of cathepsins D, L and S.
Conclusions
Keap1KD mice showed age-dependent diffuse goiter and compensated hypothyroidism. The precise mechanism accounting for the thyroidal phenotype remains to be elucidated, but it may involve enhanced Tg solubilization and excessive lysosomal Tg degradation. This study unravels novel roles of the druggable Keap1/Nrf2 pathway in thyroid function and economy.

Low serum IL-17A in pregnancy during second trimester is associated with an increased risk of subclinical hypothyroidism

Qian Yang, Xiaoying Li, Jun Liu & Bingbing Zha
Fifth People's Hospital of Shanghai Fudan University, Department of Endocrinology, Shanghai, China

Problem
Interleukin-17A (IL-17A) has a role in sustaining normal pregnancy. IL-17A isalso associated with thyroid autoimmunity during pregnancy. This study sought to investigate whether IL-17A is a risk factor for thyroid dysfunction during pregnancy without thyroid autoimmunity.
Methods of study
The study comprised 216 pregnant women with negative thyroid peroxidase antibody (TPOAb) andthyroglobulin antibodies (TGAb) during the second trimesterwho provided samples for serum IL-17A and thyroid function detection. To further evaluate the ratio of CD4+IL-17A+Th17 cells, we collected peripheral blood from 26 participants with thyroid-stimulating hormone (TSH) levels 2.5 mIU/l and 26 pregnant-week matching populations with TSH levels >2.5 mIU/l, along with samples from 20 participants with TSH levels ≤4 mIU/l and 20 pregnant-week matching populations with TSH levels >4 mIU/l.
Results
The serum IL-17A levels and ratios of CD4+IL-17A+cells were significantly lower in women with TSH>2.5 mIU/l than in those with TSH≤2.5 mIU/l (both $P<0.01$). Similar lower differences were noted in women with TSH>4 mIU/l (subclinical hypothyroidism) than in those with TSH≤4 mIU/l (both $P<0.01$). The IL-17A level ($\beta=-0.195$, $P=0.004$) and week of gestation ($\beta=0.284$, $P=0.000$) were significant predictors of regression, with TSH as the dependent variable in all participants during the second trimester. Logistic regression indicated that a lower serum IL-17A level was a risk factor for TSH>2.5 mIU/l [OR=0.453 (0.298–0.689),$P=0.000$] and subclinical hypothyroidism [OR=0.588(0.385–0.899), $P=0.013$].
Conclusion
A low serum IL-17A level during the second trimester is associated with an increased risk of TSH>2.5 mIU/l and subclinical hypothyroidism.

Management and outcomes of graves' disease – a retrospective audit

Elaine Soong, Myat Phoo Mon Kyaw & Joohi Majeed
West Suffolk NHS Foundation Trust, United Kingdom

Background
Graves' disease is a common cause of thyrotoxicosis,especially amongst females. In the UK,initial treatment is usually with anti-thyroid drugs, using either a 'block and replace' or a titrating regime. A meta-analysis suggests about 50% chance of relapse after the initial course of treatment and may then require definitive cure with radioactive iodine or surgery.
Method
A retrospective audit of patients with Graves' disease attending our endocrine clinics from 2016–2018 was conducted, to study our medical management of this condition and the rate of relapse. The European Thyroid Association Guideline for the management of Graves' Hyperthyroidism was used as the standard.
Results
A random selection of 36 patients with Graves' disease was audited. About 70% were female, and the age ranged 27–73 years. Almost three quarters of the audited patients had completed treatment, while the rest were still on treatment and 1 patient was lost to follow-up. Mean duration of treatment was 17 months. All but one patient had thyroid antibodies checked early during treatment, and these were elevated, however only 13 patients had them rechecked prior to stopping treatment. The titrating regime was used in 64% and the 'block and replace' regime in 36%, however a few patients were switched between the two regimes during treatment. About 38% (n= 10/26) of patients had relapsed and of these, half did not have antibodies retested prior to withdrawal of treatment. Where they were rechecked, the mean TSH receptor antibody was 9.41 IU/l (normal range <1.22 IU/l) prior to stopping treatment. Four of the ten patients that relapsed had been on a 'block-and-replace' regime while six had been on a titrating regime. Definitive treatment (radioactive iodine or surgery) was offered to 16 patients due to relapse or difficulty in stopping treatment.
Conclusions
Our relapse rates appear to be lower than in other studies, possibly because the period of follow-up was limited to the audit period. The titrating regime appears more popular amongst the six Consultants but there was no convincing evidence of superiority of either a titrating or 'block and replace' regime in preventing relapse. Many patients did not have their thyroid antibodies retested prior to withdrawing anti-thyroid medications. The importance of doing this and using it as a guide when considering withdrawal of treatment will be publicised within the team. A further audit will be performed in due course to see whether this has been successfully implemented and has influenced the rate of relapse.

Evaluation of 24-hour electrocardiogram parameters in patients with graves disease before and after anti-thyroid therapy

Gamze Akkus[1,2], Yeliz Sokmen[3], Mehmet Yilmaz[4], Ozkan Bekler[5] & Oguz Akkus[5]
[1]cukurova university, endocrinology, Turkey; [2]Cukurova university, Endocrinology department, Turkey; [3]antakya state hospital, cardiology; [4]antakya state hospital, opthalmology, Turkey; [5]Mustafa kemal university, cardiology, Turkey

Background
We aimed prospectively investigate the laboratory and electrocardiographic parameters (hearth rate, QRS, QT, QTc, Tpe, Tpe/QTc, arrhythmia prevalance) in patients with graves disease before and after antithyroid therapy.
Methods
71 patients (48 female, 23 male), age between 18–50 (mean±S.D.: 36.48±12.20) with GD were included into the study. Patients treated with antithyroid therapy (thionamids and/or surgical therapy) to maintain euthyroid status. Patients were examined in terms of electrocardiographic parameters before and after the treatment.
Results
Mean TSH, free thyroxin (fT_4) and tri-iodothyrionine (fT_3) levels of all patients were 0.005±0.21, 3.27±1.81, 11.42±7.44, respectively. While 9 patients (group 2) underwent surgical therapy, had suspicious of malignant nodule or large goiter and unresponsiveness to medical treatment; the other patients (n=62, group 1) were treated with medical therapy. Patients with surgical therapy had more increased serum fT4 ($P=0.045$), anti-thyroglobulin value ($P=0.018$) and more severe graves orbitopathy ($n=0.051$) before treatment when compared to medical therapy group. Baseline Tpe duration and baseline Tpe/QTc ratio and frequency of supraventricular ectopic beats were found to be significantly higher in group 2 when compared to group 1 ($P=0.00$, $P=0.005$). Otherwise baseline mean heart rate, QRS duration, QTc values of both groups were similar. Although the patients became their euthyroid status, group 2 patients had still suffered from more sustained supraventricular ectopics beats than group 1.
Conclusions
Distinct from medical treatment group, surgical treatment group with euthyroidism at least 3 months had still suffered from an arrhythmia (Tpe, Tpe/QTc, supraventricular and ventricular ectopic beats).

AEP969

Reducing unnecessary thyroid fine needle aspiration using ACR-TIRADS system

Mª Rosa Alhambra Expósito[1], Ana Barrera-Martín[1], Ángel Rebollo-Román[1], Pedro Segui-Azpilcueta[2] & María Ángeles Gálvez-Moreno[1]
[1]Hospital Reina Sofía, Endocrinology and Nutrition, Córdoba, Spain; [2]Hospital Reina Sofía, Radiology, Córdoba, Spain

Introduction
Thyroid ultrasound is the main technique to study this gland's pathology. ACR TI-RADS system evaluates the malignancy risk in thyroid nodules according to their sonographic features and stablishes the size in which to perform fine needle aspiration (FNA) for its cytological study. Nodules diagnosed as Bethesda category 4 (B4) means are follicular neoplasms or suspicious for follicular neoplasms.
Aim
Determine the pathology diagnosis of B4 nodules and study associations among malignancy and ACR-TIRADS sonographic features.
Material and methods
Retrospective study of thyroid nodules classified as B4 in FNA in our hospital between 2012 and 2018. Statistical analysis: SPSS v.22.0 (Student's t-test to compare means and Squared Chi/Fisher to proportions).
Results
162 nodules classified as B4 in FNA. Mean age: 54.07±14.62 years. 75.3% Women. 2.6% nodules stratified as ACR TI-RADS 2 with mean longest

diameter (MLD) of 35.25 cm. 23.9% ACR TI-RADS 3 with MLD of 31.94 mm, 66.5% ACR TI-RADS 4 with MLD of 30.19 mm and 7.1% ACR TI-RADS 5 with a MLD of 29.09 mm.

Composition		Echogenicity		Shape		Margin		Echogenic Foci	
Feature	%	Feature	%	Fea-ture	%	Feature	%	Feature	%
Cystic or almost completely cystic	**0**	Hypere-choic or isoechoic	**24.5**	Wider than tall	**94.2**	Smooth	**93.5**	None or large comet-tail artifacts	**87.1**
Spongiform	**0**	Hypoechoic	**71.0**	Taller than wide	**5.8**	Lobulated or irregular	**6.5**	Macro-calcifications	**5.8**
Mixed	**3.9**	Very hipoechoic	**4.5**			Extra-thyroidal extension	**0%**	Peripheral-calcifications	**1.3**
Solid or almost completely solid	**96.1**							Punctate echogenic foci	**5.8**

29 (17.8%) nodules met standard malignancy criteria: 15 papillary thyroid carcinomas, 12 follicular thyroid carcinomas and 2 medullary carcinomas. If ACR TI-RADS had been strictly followed, 25.2% of FNA could have been avoided. Among nodules without FNA indication, 3 were malignant (2 papillary and 1 follicular carcinoma). Of those with FNA indication 24.5% were malignant. In our cohort, ACR TI-RADS system was of 88.8% (CI 95% 1.08–0.77) and specificity of 30.2% (CI 95% 0.38–0.21). Positive predictive value was 24% and negative predictive valuewas 91%.

Conclusions

FNA performed could have been reduced in our cohort if the decision had been taken upon the strict application of ACR TI-RADS system. Given the low rate of false negative nodules, ACR-TIRADS constitutes a good screening method to determine which nodules should undergo FNA.

AEP970

Falsely elevated FT4 measurements with an electrochemiluminescent assay

Athina Pappa, Ioannis Ilias, Ioannis Kakoulidis & Eftychia Koukkou
E Venizelou Hospital, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece

Introduction

Recently Roche Diagnostics (Rotkreuz, Switzerland) introduced the third generation of its Elecsys free thyroxine (FT4 iii) assay (in Greece from February 2019 onwards). The new assay is considered to have reduced biotin interference compared to its previous version (Ft4 ii). Kits of the FT4 ii assay are still available (and valid) according to the manufacturer's expiration date. Using the FT4 ii assay per the manufacturer's instructions we noticed FT4 results that were incongruent both with thyrotropin (TSH) and subsequently with free triiodothyronine (FT3) levels and the clinical presentation of patients.

Aim – Methods – Results

Evaluation with a Bland-Altman plot of FT4 ii results vs the FT4 iii assay's results in 40 consecutive and unselected subjects showed few outliers (Figure 1). However, the results of twice as many patients (22/40 with FT4 ii vs 10/40 patients with FT4 iii) were in the hyperthyroid range (Mcnemar's $P=0.005$). From the subjects' history-taking, interference by biotin (or by other substances) was ruled out. Finally the problem was traced to the provided assay's calibration. This was communicated for assessment to the manufacturer.

Discussion

Knowledge of this is useful, particularly in the quest for recalibration of assays against reference measurement procedures[1,2].

Role of thyroid ultrasonography in egyptian patients with hashimoto`s thyroiditis; a pilot study

Hany William Z. Hanna[1], Hemmat E. El Haddad[2], Randa Salam[2], Radwa M Abdel Halim[1], C. Rizzo[3] & Hazem S. Abou-Youssef[1]
[1]Faculty of Medicine, Cairo University, Clinical and Chemical Pathology Department, Cairo, Egypt; [2]Faculty of Medicine, Cairo University, Internal Medicine Department, Cairo, Egypt; [3]Bambino Gesù Children's Hospital, IRCCS, Clinical Division and Research Unit of Metabolic Diseases, Rome, Italy

Background

Hashimoto's thyroiditis (HT) is considered the most common autoimmune disease and the predominant cause of hypothyroidism in iodine sufficient countries. HT may appear clinically in approximately 0.1–2% of the population.

Aim

The study in hand aimed at assessing the role of thyroid ultrasonography in the diagnosis of HT patients discriminating them from other causes of hypothyroidism. A scoring system of sonographic findings was aimed to be used side by side with the auto antibodies routinely used for diagnosis.

Subjects

The current study included 160 subjects with manifestations of hypothyroidism,who attended Cairo University, Kasr Al-Ainy Outpatient Endocrinology Clinic,112 patients with HT and 48 hypothyroid non-Hashimoto's controls.

Methods

All included patients were subjected to full history taking, clinical and local thyroid examination, BMI calculation, thyroid ultrasound examination (US) and a panel of assays (TSH, f.T3, f.T4, anti-TPO Ab, anti-TG Ab, calcium, alkaline phosphatase and phosphate). Regarding thyroid US scanning, the number of US findings (thyroid volume, heterogeneity, nodularity and vascularity) were counted for each studied patient. A score was given to each patient ranging from 0 (no finding) to 4 findings. Thyroid antibodies were assayed using ELISA.

Results

112 subjects were considered as HT (with anti-TPO Ab levels >75 IU/ml and/or anti-TG Ab > 110 IU/ml). 48 subjects were included as control group (withnegativeanti-TPO Ab and anti-TG Ab; <20 IU/ml and <90 IU/ml respectively). A statistically significant increase in total thyroid volume was observed in HT patients ($P=0.002$).A cutoff volume ≥4.8 ml was found discriminative with specificity (95% CL) of 60.4 (45.3–74.2)% and sensitivity of 65.2 (55.6–73.9)%. However, the remaining thyroid US features were statistically insignificant. A discriminatory cutoff for the scoring system was studied to differentiateHT patients from control group based on the number of their US findings. No significant difference was found between both groups, whether 0–1 vs 2–4 scores; ($P=0.422$), or 0 vs 1–4 ($P=0.104$).

Conclusion

All positive thyroid ultrasound findings cannot discriminate between HT and other hypothyroid non-Hashimoto's patients except thyroid volume. No scoring system based on US findings can be adopted for diagnosis of HT. However, a thyroid volume at a cutoff of 4.8 ml can be an added value to the laboratory findings to discriminate between HT and control group with specificity 60.4% and sensitivity 65.2%.

Determinants of the health related quality of life of adult filipinos with differentiated thyroid cancer

Diane Bernardo[1], Cecilia Jimeno[2] & Ralph Jason Li[2]
[1]Davao Doctors Hospital, Medicine, Davao, Philippines; [2]Philippine General Hospital, Medicine, Manila, Philippines

Objective

This study aims to investigate clinical and demographic variables associated with HRQoL as measured by the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core Questionnaire (EORTC QLQ C30) Tagalog and the Thyroid Cancer-Specific Quality of Life Questionnaire (TCS QLQ) Tagalog.

Methodology

234 adult Filipinos with histopathologic-confirmed diagnosis of DTCafter thyroidectomy with or without radioactive iodine were recruited and asked

to answerthe EORTC QLQ-C30 and TCS QLQ Tagalog versions. Demographics and clinical data were collected. Factors influencing HRQoL scales were analyzed using multivariate linear and logistic regression.
Results
Adult Filipinos with DTC showed a high a level of functionality (EORTC QLQ C-C30 functional and global domain score range 72–84) and low level of thyroid specific complaints like neck pain and hoarseness (TCS QLQ Tagalog score range 1.6–2.06). Additionally, they report a moderate level of fear about cancer recurrence and repeat treatments. Multivariate analysis identified Stage IV disease, neck dissection, comorbidity, hypothyroidism, and middle-income class being associated with lower quality of life scores in the two questionnaires.
Conclusion
Adult Filipinos with DTC following up after thyroidectomy have good HRQoL overall. Socio-economic status and a few clinical and treatment-related factors negatively influenced HRQoL in this population.

AEP973

Diagnostic value of Bethesda system for reporting thyroid cytopathology in patients with prior thyroid surgery

Sevgul Faki[1], Gulsum Karahmetli[1], Aylin Kilic Yazgan[2], Mehmet Kiliç[3], Oya Topaloglu[2], Didem Ozdemir[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Yildirim Beyazit University, Endocrinology and Metabolism, ankara, Turkey; [2]Ankara Yildirim Beyazit University, patholoji, ankara, Turkey; [3]General Surgery, Ankara Yildirim Beyazit University, ankara, Turkey

Background
Fine needle aspiration biopsy (FNAB) and Bethesda System for Reporting Thyroid Cytopathology (TBSRTC) have proven to be the most valuable diagnostic procedure for preoperative discrimination of benign and malignant thyroid nodules. Thyroid surgery may cause regional scarring and some degree of fibrotic process which may result in problems when collecting FNAB samples and evaluating the cellular abnormalities. In this study, we aimed to determine whether the Bethesda classification system in thyroid nodules is reliable in patients with a history of thyroid surgery.
Methods
We retrospectively examined outcomes of 130 patients with 260 nodules who underwent a thyroidectomy for recurrent goiter (Group 1) and compared them with 2821 patients with 5890 thyroid nodules who underwent first thyroidectomy (Group 2) in our center between 2007 and 2014.
Result
Malignancy rate was significantly lower in group B (24 (18.5%) patients) compared to group A (911 (32.3%) patients) ($P=0.016$). The most frequent operation indications in group A may explain the hight rate ofmalignancy in this group, that were giant nodule and suspicious cytology results in group B and group A respectively ($P=0.001$). Hypothyroidism was significantly higher in group B and result by a hight ratio of gaint nodules ($P=0.001$). Although a relationship between giant nodule and higher malignancy rate was reported in previous studies, we did not find a correlation between giant nodules and malignancy rate of patient in group B. Diagnostic value of Bethesda was determined in patients with primary and reoperative thyroid surgery. Benign cytology was considered negative and suspicious for malignancy and malignant cytologies were considered positive. sensitivity, specifity, PPV, NPV and accuracy of Bethesda classification in patients with primary thyroid surgery were 74.50%, 98.18%, 83.38%, 96.92% and 95.60%, respectively. In patients with reoperative thyroid surgery, sensitivity was 62.50%, specifity was 98.91%, PPV was 71.43%, NPV was 93.38% and accuracy was 97.39%.

Table 1 Diagnostic value of Bethesda classification in patients who underwent primary and reoperative thyroid surgery.

	Primary		Reoperative	
	a ($n=3710$)	b ($n=3814$)	a ($n=192$)	b ($n=199$)
Sensitivity	74.50%	76.37%	62.50%	66.66%
Specifity	98.18%	96.09%	98.91%	95.79%
Positive predictive value	83.38%	71.61%	71.43%	42.86%
Negative predictive value	96.92%	96.92%	98.38%	98.38%
False positive	16.62%	28.38%	28.5%	57.14%
False negative	3.07%	3.07%	1.62%	1.62%
Accuracy	95.60%	93.83%	97.39%	94.47%

Conclusion
FNAB is known to be the most accurate and cost-effective method that provides avoidance of unnecessary surgery in 25% of patients with benign thyroid disease. A lower frequency of malignancy was observed in patients/nodules with reoperative thyroid surgery compared to patients/nodules with primary thyroid surgery in this surgical series. Sensitivity and PPV of Bethesda were affected negatively by previous thyroid surgery. This might be considered in these patients while deciding for a recurrent surgery which has a higher risk of complications.

Humoral changes during resolution of short term severe hypothyroidism

Marin Gergics[1,2], Greta Pham-Dobor[1,2], Zoltán Horváth-Szalai[2,3], Tamás Kőszegi[2,3], Emese Mezosi[1,2] & Laszlo Bajnok[1,2]
[1]University of Pécs, Medical School, 1st Department of Medicine, Division of Endocrinology and Metabolism, Pécs, Hungary; [2]University of Pécs, Medical School, Szentágothai Research Centre, Pécs, Hungary; [3]University of Pécs, Medical School, Department of Laboratory Medicine, Pécs, Hungary

Introduction
Significant hyponatremia may evolve in hypothyroidism, when however, elevated ADH levels have not been consistently demonstrated. On the other hand, it was shown that thyroid hormone substitution suppresses ADH, and its surrogate marker copeptin secretion. The aim of our present study was to investigate the possible humoral changes in a special model of resolution of short term severe hypothyroidism in differentiated thyroid cancer (DTC) patients.
Patients
In 39 DTC patients (11 men, 28 women, mean age 50.28 ± 14.90 ys) in whom DTC was not advanced (ECOG: 0) blood samples were obtained on the day of radioiodine therapy and 10–12 weeks after thyroxine supplementation.
Results
Serum sodium (140.8 ± 2.6 vs 142.3 ± 1.8; $P=0.002$), chloride (100.8 ± 3.4 vs 102.5 ± 2.6; $P=0.012$), potassium (4.3 ± 0.4 vs 4.4 ± 0.3; $P=0.025$), eGFR (77.0 [61.0–90.0] vs 90.0 [72.0–90.0]; $P<0.001$), NT-proBNP (36.8 [20.6–73.7] vs 69.6 [37.4–194.9]; $P<0.001$), ACTH (11.9 [10.0–16.0] vs 16.4 [12.2–22.5]; $P=0.001$) and renin activity (0.7 [0.4–1.6] vs 1.6 [0.9–2.9]; $P=0.003$) were lower during hypothyroidism, while cortisol, aldosterone and copeptin were similar. Of the investigated parameters copeptin showed positive association with sodium in univariate ($r=0.226$; $P=0.046$) and to TSH in multivariate correlations (R square = 0.123; $P=0.001$). Serum sodium levels had a variance of 5.47 mmol/l and, beside copeptin, were associated to concentrations of TSH ($r=-0.321$; $P=0.004$), ACTH ($r=0.349$; $P=0.002$) and cortisol ($r=0.225$; $P=0.047$). However, none of them were independent determinants of serum sodium levels in multiple regression analyses.
Conclusion
According to our investigations, TSH is an independent predictor of copeptin level. The serum sodium level is significantly lower in short term severe hypothyroidism, but this cannot be appropriately explained by the investigated humoral parameters.

The concordance between ultrasonographic EU-TIRADS and cytologic bethesda criteria of thyroid nodules

Romena Laukiene[1,2] & Kotryna Sileikaite[3]
[1]Vilnius University hospital 'Santaros klinikos', Center of Endocrinology, Vilnius, Lithuania; [2]Vilnius University, Faculty of Medicine, Institute of Biomedical Science, Department of Human and Medical Genetics, Vilnius, Lithuania; [3]Faculty of Medicine of Vilnius University, Vilnius, Lithuania

Objective
The aim of this study was to evaluate the capability of the thyroid nodule ultrasonography criteria of the European Thyroid Imaging and Reporting Data System (EU-TIRADS) to predict fine needle aspiration cytology results categorised by The Bethesda system.
Methods
A retrospective analysis was made out of 310 cases of an outpatient clinic over a period of 1 year (2018.03–2019.03). We compared single-specialist-performed thyroid nodule ultrasonography findings categorised by EU-TIRADS to the cytopathology results of fine needle aspiration that we assigned to specific Bethesda categories. The thyroid nodules were divided into benign with ultrasonography findings of EU-TIRADS 2–3 and cytopathology of Bethesda 2 and malignant with EU-TIRADS 5 and Bethesda 5–6. Statistical analysis was performed using SPSS 23.0.
Results
We assembled cases of 310 people of which 279 (90%) were female and 31 (10%) were male. 4 patients were assigned to benign (EU-TIRADS 2), 191 low-risk (EU-TIRADS 3), 68 intermediate-risk (EU-TIRADS 4) and 47 high-risk (EU-TIRADS 5) category on ultrasonography. Overall concordance rate of EU-TIRADS and fine needle aspiration findings was 75.48%. The probability of benign pathocytology result in EU-TIRADS 2, 3, 4 and 5 was 100%, 95.3%, 72.1% and 38.3% respectively. At the same time the risk of finding a malignant cytology result was 0% with EU-TIRADS 2, 1.1% with EU-TIRADS 3, 13.2% with EU-TIRADS 4 and 38.3% with EU-TIRADS 5. Specificity and sensitivity was 91.2% and 90% accordingly. The positive predictive value was 50% and the negative predictive value was 98.9%. The association between EU-TIRADS and fine needle aspiration findings was good according to the ROC curve and the area under the curve with 0.879.
Conclusions
The categories of thyroid nodule malignancy risk in EU-TIRADS have a good correspondance to Bethesda cytopathologic categories. Concordance between the benign ultrasonography and cytology criteria is more significant compared to malignant. With every higher category of EU-TIRADS the probability of malignant cytology result increases.

Association of a medullary thyroid carcinoma, a papillary thyroid carcinoma and a renal carcinoma: Towards a new neoplastic syndrome?

Imen Halloul, Sihem Mensi, Abir Ezzine, Hajer Marzouk, Tahani Dardouri, Maha Ben Fredj, Manel Nouira & Kawthar Chatti
Sahloul University Hospital, Department of Nuclear medicine, Sousse, Tunisia

Introduction
Multiple primary cancers are a rare entity; however their incidence is increasing due to advances in diagnostic methods and surveillance strategies. The coexistence in the same patient of several primary malignant tumors has been described in the literature with a frequency varying from 5.5% to 8.5%. The aim of this observation is to report a case associating 3 neoplasias:medullary thyroid carcinoma (MTC), papillary thyroid carcinoma (PTC) and a renal carcinoma.
Case report
A 49-year-old male patient consulted for a compressive thyroid goiter. A Fine-needle aspiration biopsywas conducted, revealing a MTC. A laryngectomy with total thyroidectomy, bilateral mediastino-recurrent lymph node dissectionwith the installation of a tracheostomy was performed. The pathology study showed 2 synchronous thyroid tumors: medullary and papillary thyroid carcinoma. MTC invaded the trachea with lymph node metastases, classified as pT4a N1b, as for PTC, it was 1.8 cm in length with lymph node metastases, classifiedas pT2 N1b. The extension assessment identified costal bone metastases and a left renal tumor, which turned out to be a renal tubulo-papillary carcinoma at histological examination. For the PTC, the patient was treated with 200 mCi of iodine-131 with negativation of thyroglobulins. However, the MTC evolution was not the same; the basal serum level of calcitonin has increased, with the progression of bone metastases. As for the family history, there was no record of any thyroid or kidney tumors. The final treatment of the patient was mainly palliative.
Conclusion
The coexistence of several neoplasias is rare, and poses major diagnostic and therapeutic problems, and it requires multidisciplinary management. The role of genetic study is essential in this area to codify these different diseases into a syndromic approach.

Risk factors of disease recurrence among Filipino patients with low-risk papillary thyroid carcinoma in manila doctors hospital: A retrospective cohort study

Edrome Hernandez, Kaye Eunice Lustestica, Lou Erika Rubion & Nemencio Nicodemus
Manila Doctors Hospital, Internal Medicine, Manila, Philippines

Background
New emerging studies demonstrated that mortality from thyroid cancer and disease recurrence was significantly higher among Filipinos compared with other ethnic groups. However, exact mechanisms which could explain these findings among Filipino patients remain to be poorly understood. The risk factors associated with disease recurrence among adult Filipino patients with low-risk papillary thyroid cancer in Manila Doctors Hospital was assessed in this study.
Methods
This was a retrospective cohort study which included 39 Filipino patients diagnosed with low-risk papillary thyroid carcinoma treated at Manila Doctors Hospital. Demographic characteristics, pertinent clinical data and physical findings were extracted from the medical charts. Clinical and biochemical parameters were analyzed to determine their association with disease recurrence using Multivariate regression analysis. Cox regression analysis was done to identify significant risk factors for disease recurrence.
Results
Out of the 39 patients included in the study, 8 patients had disease recurrence (20.5%). Anti-Tg antibody level of ≤50 u/ml demonstrated significant protection against the development of disease recurrence (HR: 0.13, *P* value: 0.015). Tumor diameter of more than 4 cm (HR 34.10, *P* value 0.012) was significantly associated with disease recurrence.
Conclusion
Our study showed that the incidence of disease recurrence was 20.5%, and anti-Tg antibody level of ≤ 50 u/ml and tumor diameter of more than 4 cm demonstrated significant protection against disease recurrence and significant association with disease recurrence, respectively. The identification of risk factors for disease recurrence may help guide us in providing specific treatments tailored for low-risk PTC Filipino patients and closer follow up interval to further improve the outcome.
Keywords: disease recurrence, low-risk papillary thyroid carcinoma, Filipino.

Large 'forgotten goiter' in the thoracic cavity – a case report

Katarzyna Paczkowska, Małgorzata Rolla, Michał Elbaum, Diana Jędrzejuk, Marek Bolanowski & Jacek Daroszewski
Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland

Introduction
'Forgotten goiter' is defined as a mediastinal thyroid mass discovered after total thyroidectomy. It is a rare clinical finding, usually asymptomatic.
Case report
88-years old woman was admitted to the Endocrinology Department with a suspicion of the retrosternal goiter. In her medical history there was

thyroidectomy performed 16 years before because of multinodular goiter and she had recurrent lower respiratory tract infections in the last few months. She did not present any symptoms of impaired hormonal secretion, however thyroid function tests showed subclinical hyperthyroidism. Chest X-ray and then CT examination revealed in the thoracic cavity a mass reaching to the diaphragm and connected with the thyroid. Technetium 99 m pertechnetate scans confirmed that as a thyroid mass. Taking into consideration patient's age and contraindications to the surgery, the decision about treatment with radioactive iodine was made and patient received 20 mCi I-131. Three months after therapy patient was euthyroid, however a year after recurrence of a subclinical hyperthyroidism was found. Patient was treated with radioiodine in a dose of 20 mCi again. 15 months after the second radioiodine administration, patient remained euthyroid and a volume of the goiter has decreased.
Conclusion
In the literature there are described case reports of patients diagnosed with 'forgotten goiters', but the treatment of choice was surgery, what was contraindicated in our patient. What is more, the goiter of a size as the one diagnosed in reported patient is extremely rarely found.

DOI: 10.1530/endoabs.70.AEP978

AEP979

Primary Thyroid Teratoma – a rare diagnosis

Nádia Mourinho Bala, Sílvia Guerra, Nuno Cordeiro Raposo, Helena Oliveira, Rosa Madureira & Cristina Valadas
Hospital Beatriz Ângelo, Loures, Portugal

Introduction
A teratoma is a rare type of tumor deriving from the germ layer cells (ectoderm, mesoderm and endoderm), typically benign, more frequent in infants. Adult onset teratomas are most commonly gonadal cell tumors. Extra-gonadal teratomas generally affect the midline, most frequently anterior mediastinum, retroperitoneum, pineal and suprasellar area. Head and neck teratomas are an extremely rare entity and represent only 0.47–6% of all cases.
Case report
Female patient, 70 years old, no relevant personal or familial history. Patient is followed in Endocrinology outpatient care due to to an heterogeneous, predominantly hypoechoic nodule, 25 mm in length, located in the right thyroid lobe. Given the nodule description the patient underwent a fine needle aspiration. The result suggested a follicular lesion of undetermined significance/atypia of undetermined significance. The fine need aspiration was repeated with an inconclusive result. The third fine needle aspiration revealed the presence of a proteinaceous, amorphous tissue, with numerous vacuoles and squamous cells compatible with a branchial cyst. Due to the appearance of compressive symptoms a CT cervical scan was ordered. The image exam showed the presence of a nodular lesion, $19 \times 29 \times 25$ mm of well defined limits, heterogenous, with soft tissue, macroscopic fat and calcium fragments suggestive of a teratoma, causing tracheal and esophageal deviation, with no associated cervical adenomegalies. The patient was subjected to a right thyroid lobectomy. The pathological analysis revealed a pseudo-encapsulated nodule, occupying nearly all of the right thyroid lobe, with 30 mm of long axis, compatible with a cystic mature trigerminative teratoma, composed exclusively by well differentiated elements (grade 0).
Discussion
Thyroid teratomas represent less than 0.1% of all primary thyroid tumors. These lesions typically present as cystic or mixed lesions and the cytological result might be inconclusive. Despite being more frequent in children, teratomas do not spare any age group.

Secondary intrathyroid localization of a pulmonary papillary carcinoma

Mehdi Hasnaoui, Mohamed Masmoudi, Takwa Belaid & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Tunisia, Otolaryngology-Head and Neck Surgery, Mahdia, Tunisia

Introduction
Intrathyroid metastases are rare (less than 1% of thyroid cancers). They can be synchronous or metachronous. The origin of primary cancer is variable; the kidney, lung, stomach and breast being the most described sites. Through this case, we describe the diagnostic difficulties that the pathologist may encounter in the identification of these metastases.
Materials and methods
We report a case of intrathyroid metastasis of a pulmonary papillary micro carcinoma.
Results
She was a 73 year old patient with no particular pathological history, who presented a right spinal swelling appeared 2 months ago and gradually increasing in size. She had dyspnea and swallowing discomfort without signs of dysthyroidism. Physical examination found a free thyroid gland as well as lymph nodes. Cervical ultrasound showed multiple cervical jugulo-carotid and subdigastric lymphadenopathy associated with an isthmic thyroid nodule of 8 mm. The lymph node biopsy concluded that there was lymph node metastasis from papillary carcinoma. The patient had a total thyroidectomy with a right functional lymph node dissection and bilateral recurrent laryngeal nerve lymph node dissection with favorable operative suites. The diagnosis of lymph node metastasis from a pulmonary papillary micro-carcinoma was made on final histological examination. The thoracic CT made subsequently objectified multiple pulmonary nodules. Fibroscopy with biopsy confirmed the diagnosis of branchic adenocarcinoma in its micro papillary form. The patient had 3 chemotherapy courses with good progress.
Conclusion
The frequency of intrathyroid metastases is probably underestimated. The examination of the thyroid and a cytopuncture at the slightest doubt seems logical. Thyroidectomy is rarely indicated. The prognosis depends on the primitive.

Rhabdomyolysis from severe hypothyroidism – A case report

Adela Haxhiraj, Violeta Hoxha[1], Gerond Husi[1], Larisa Shehaj[2], Erjola Bolleku[2] & Agron Ylli[1]
[1]Mother Teresa Hospital, Endocrinology, Tiranë, Albania; [2]Mother Teresa Hospital, Nephrology, Tiranë, Albania

Introduction
Hypothyroidism can cause various degrees of muscular disorders. It can lead to symptoms such as myalgia, weakness, fatigue and in rare cases to extreme muscular damage such as rhabdomyolysis, a potential life-threatening complication. We present the case of a 53 years old patient with acute renal failure due to rhabdomyolysis from severe hypothyroidism.
Case description
The patient, a male from Albania was first admitted to the Emergency Room with complaints of severe weakness and profuse sweating. He was hospitalised in the Department of Nephrology with Acute Renal Failure from Rhabdomyolysis probably from lipid lowering medications. The patient had a short history of treatment with Statins. He was discharged after a week with moderate elevated creatine kinase level (CK 2000 UI/l) and the treatment with Statins was interrupted. The patient was re hospitalised, two weeks after being discharged with the same symptoms and elevated muscular enzymes. Blood tests were as followed: Urea 34 mg/dl, Creatinine 1.7 mg/dl, LDH 725 U/l, CK 5130 U/l. At the moment, he was not taking any lipid lowering medication and he did not have any history of extreme exercise. He had a history of several months of stiffness, feeling cold, swelling and inexplicable weight gain. Because of these clinical manifestation, a level of thyroid stimulus hormone (TSH) and anti-thyroid peroxidase antibodies (anti – TPO) were taken and they both were very high [TSH > 75 U/ml (0.4–4 U/ml) and anti TPO–1050 U/ml (<60 U/ml)]. The diagnose of hypothyroidism was later confirmed with ultrasound of the thyroid gland where it was evident a heterogeneous structure, an aspect favouring Hashimoto Thyroiditis. The patient was started therapy with Levothyroxine and the level of muscular enzymes declined, as well as his symptoms.
Conclusion
Hypothyroidism is a rare but potential cause of rhabdomyolysis when other risk factors are excluded. In order to prevent complications from rhabdomyolysis such as acute renal failure, we should always consider thyroid gland function when elevated muscular enzymes are present alongside symptoms of hypothyroidism.

Exophtalmos in a hyperthyroid patient – it's not always Graves ophthalmopathy

Sorina Martin[1,2], Theodor Mustata[1], Andrada Predescu[1] & Simona Fica[1,2]
[1]Elias Emergency University Hospital, Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Background
Hyperthyroidismcan be associated withorbitopathy that manifests as exophtalmos due to orbital tissue inflammation. Usually the diagnosis is straight forward when an autoimmune thyroid disorder is present, but conditions mimicking Graves orbitopathy can pose a diagnostic challenge.
Case report
We report the case of a 51 year old caucasian woman who was referred to our clinic with asymmetrical exophtalmos in november 2019. The patient stated that she first experienced the right eyeball protrusion after a difficult labour in 1999 but with no ophthalmologic examination until 2019 when she noticed a sudden decrease in the right eye visual acuity following, probably coincidental, blunt ocular trauma. Ophthalmological exam and visual field testing showed almost complete loss of vision in the right eye. She was reffered for endocrinological exam with asymmetrical exophtalmos (ocular protrusion of 24 mm in the right eye and 18 mm in the left eye), upper lid retraction, fine tremor of the hands and a history of palpitations and heat intolerance. Lab results revealed mild hyperthyroidism: TSH < 0.004 µIU/ml (0.4–4.0), FT_4 = 1.79 ng/dl (0.89–1.76), TT_3 = 123 ng/dl (72–179), the lack of thyroid autoimmunity: TPOAb < 10 IU, antithyroglobulin antibodies = 10 IU/ml (10–115), TRAb = 0.765 IU/l (0–1.75).The other blood tests were unremarkable, except an inflammatory syndrome, with a CRP of 34 mg/l (0.2–11). Thyroid ultrasound diagnosed a multinodular goiter. Magnetic resonance imaging and magnetic resonance angiography of the brain and orbital MRI were compatible with optic neuritis of the right eye and showed normal dimensions of the extraocular muscles: right eye – medial rectus = 3.6 mm, lateral rectus = 3.6 mm, superior rectus = 4 mm, inferior rectus = 4.7 mm; left eye – medial rectus = 3.2 mm, lateral rectus = 4.7 mm, superior rectus = 3.3 mm, inferior rectus = 5.3 mm. Moreover, orbital fat was in normal limits. Multidisciplinary team decided rheumatological and neurological check-up for differential diagnosis and a trial of salvage treatment with intravenous methylprednisolone 250 mg weekly for 6 weeks. Interestingly, follow-up perimetry test after 3 weeks showed significant improvement in the visual field of the right eye.
Conclusions
Diagnosis and treatment of orbitopathy in a hyperthyroid patient with no autoimmune thyroid disease proves to be an arduous process. Our patient's visual field improved dramatically after systemic methylprednisolone administration even though she did not meet the diagnostic criteria for Graves orbitopathy. In such instances a multidisciplinary effort is required in order to identify the underlying cause and provide adequate care.

Hurthle cell carcinoma – A case report

Rajmonda Tare[1], Ema Lumi[2], Entela Puca[3], Adriana Lapardhaja[4] & Florian Toti[5]
[1]Regional Hospital, 'Xhaferr Kongoli', Endocrinology, Internal Department, Elbasan, Albania; [2]Regional Hospital, 'Teni Konomi', Endocrinology, Internal Department, Korce, Albania; [3]Spitali Amerikan 2, Endocrinology, Tirane, Albania; [4]Poliklinic nr 2, Endocrinology, Tirane, Albania; [5]UHC Mother Teresa, Endocrinology Department, Tirane, Albania

Introduction
Hurthle cell carcinoma was considered to be a variant of follicular thyroid cancer. However, recent clinical and molecular studies clearly indicate that Hurthle cell cancer is a distinct tumor type. Histologically, it is characterized by the presence of a cell population of 'oncocytes', mostly eosinophilic oxyphilic cells and abundant cytoplasm,closely packed mitochondria, and round oval nuclei with prominent nucleoli. Unlike follicular thyroid cancer, Hurthle cell cancer has more of propensity to to spread to cervical lymph nodes. Hurthle cell cancer metastatic foci are often radioactive iodine refractory. This type of carcinoma accounts for only about 3–10% of all differentiated thyroid cancers.
Case
A 51-year-old women was presented in our policlinic with a visibile mass on the neck. She complains about difficulty swallowing and hoarseness. On physical examination we detect enlargement and stiffness of the right lobe ofthyroid gland. Thyroid ultrasonography revealed a 3 cm hypoechoic nodule with cystic degeneration on the right lobe. The left lobe and istmus were normal. Thyroid hormone tests showed normal thyroid-stimulating hormone (TSH) 2.28 uIU/ml (reference value 0.3–4.5uIU/ml), normal FT4 12.7 pg/ml (normal range 8.9–17.2 pg/ml) and normal FT3 2.1 pg/ml (normal range 1.21–4.18 pg/ml). Thyroid scintigraphy (technetium(TC)-99 m) showed enlarged right lobe,and acold nodule in the lower part of this lobe. The left lobe was non enlarged, with low homogeneous fixation, isthmusi non-homogenous. Thetotal uptake was in range. A Fine-needle aspiration (FNA) biopsy was performed and showed suspected neoplasia with Hurthle cells. The patient underwent surgical intervention. Total thyroidectomy was performed, No local lymph nodes resection. The postoperative biopsy conclude:Proliferative process of oxyphil carcinoma type. Further immunohistochemial test confirmatethe diagnosis. There were no evidence of invasion of the Hurthle cell cancer (metastasis) beyond the thyroid gland, so substitutive hormone therapy was started. Radioactive Iodine Treatment (RAI) was not performed. Periodic follow-ups every 6-months are done with ultrasound examination and hormone levels. She is free of metastases so far.
Conclusion
Hurthle cell carcinoma may be associated with poor prognosis than follicular cancer, related with the poor affinity for taking radioiodine. Hurthle cells has been shown to have an increased recurrence in local lymph nodes. Our case was a middle aged woman with a cold nodule nearly 3 cm, with no evidence of lymph node involvement.
Keywords: hurthle cell carcinoma, oxyphilic carcinoma, lymph nodes, radioactive iodine.

The flight of the thyroid- the butterfly effect

Ashutosh Kapoor
Royal Bolton Hospital, Bolton Foundation Nhs Trust, Diabetes And Endocrinology, Bolton, United Kingdom

Introduction
Dual nivolumab and ipilimumab immunotherapy has the potential of causing an immune-mediated thyrotoxicosis, precipitating thyroid storm.
Case details
A 62-year-old Caucasian woman with a history of Lung Carcinoma (Non small Cell Lung Carcinoma) presented to the emergency department, with a 3-day history of intractable nausea, severe headache, vomiting and anxiety. She had been initiated on dual nivolumab and ipilimumab therapy 6 weeks prior and received two courses of therapy thus far. Her last dose was 10 days prior to presentation.
Past medical history
a. Hypertension.
b. Depression.
c. Osteoarthritis.
d. Newly diagnosed Lung Carcinoma (NSCLC).
Investigations
- CXR-No evidence of consolidation/Pulmonary Oedema.
- Blood Cultures-Negative.
- Urine dip-Negative.
- Bloods- Revealed Leucocytosis, elevated CRP levels.
- CT Head-Nil evidence of Intracranial haemorrhage/SOL.
- Lumbar puncture-was performed and resultant Gram stain, culture, cell count, protein and glucose were all normal.
- TSH- <0.001 (0.4–4.0 mU/l).
- FT4–36.2 pmol/l (9.0–25.0 pmol/l).
- FT3–9.8 pmol/l (3.5–7.8 pmol/l).
- Thyroid peroxidase and thyroid stimulating immunoglobulin levels were within normal range.
- Scoring systems- Burch- Wartofsky Score- 55 – indicative of Thyroid storm.

Management
- Beta-blockers: propranolol 1–2 mg intravenously or 40–80 mg per os every 8 h is the drug of choice because, on the one hand, contrasts the increased binding of catecholamine to beta-adrenergic receptors, on the other hand, reduces the T4 to T3 peripheral deiodination.
- Thyrostatics: methimazole 15–20 mg every 6 h or propylthiouracil with a loading dose of 500–1000 mg followed by 250 mg every 4 h. It should be mentioned that rectal administration of both methimazole and propylthyouracyle is allowed, at a dose of 400–600 mg every 6 h and 20–40 mg every 8–6 h, respectively.

- Large iodine amount: Lugol solution or saturated potassium iodide solution (or sodium iodide 500–1000 mg daily intravenously inhibits thyroid hormone leakage by the thyroid gland. Iodine should be administered not sooner than 1 h after anti-thyroid drug administration.
- Glucocorticoids: hydrocortisone 100 mg intravenously every 6–8 h reduces the T4 to T3 peripheral deiodination

Summary

- Thyroid function tests and thyroid symptoms should be monitored in patients with undergoing nivolumab and ipilimumab immunotherapy
- Prompt treatment of thyroid storm is potentially life-saving. Close monitoring in an inpatient setting in addition to treatment with β-blockers, antithyroid agents, steroids and bile sequestering therapies are recommended.
- Thyroid storm is a clinical diagnosis, usage of Scoring tools-Burch-Wartofsky score and the Japanese Thyroid Association Scoring System recommended.

A correlation study between histological results and thyroid ultrasound findings. The EU TI-RADS classification

Mohamed Masmoudi, Malika El Omri, Mehdi Hasnaoui, Rihab Lahmar, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital mahdia, ENT department, mahdia, Tunisia

Introduction
The management of patients with nodular goiter and thyroid neoplasms is one of the most important problems in modern thyroidology. There are several classifications based on thyroid ultrasound for selecting suspected malignant thyroid nodules. The Thyroid Imaging Reporting and Data System (TI-RADS) classification is an easy to apply for thyroid lesions, which might be helpful in clinical practice for the initial assessment of the thyroid lesion risk of malignancy.
Material and methods
A retrospective study of all patients who underwent thyroid surgery at the ENT department of Tahar Sfar Hospital in Tunisia (*n*= 108) from January 2013 to December 2017. After surgery, histological results were correlated to the ultrasound findings reported.
Results
The mean age of our patients was 46 years. A clear predominance of women was found (94% of the cases). 17% of the cases were diagnosed with thyroid cancer and 83% of the cases with benign disease. Correlation of histological results with preoperative ultrasound reports showed an initial sensitivity of 95%, a specifity of 82% with positive and negative predictive values of 53% and 98%.
Conclusion
The TIRADS score is an interesting tool in the detection of malignant thyroid nodules, thus avoiding excessive surgical indications. The use of the TI-RADS scale would also allow for an adequate selection of patients amenable to fine needle aspiration of the nodule

A retrospective 5-year follow-up study on the outcomes of radiofrequency ablation for the treatment of benign thyroid nodules

Giulia Zuolo[1], Fabiola Giudici[1], Cavallaro Marco[2], Veronica Calabrò[3], Fabris Bruno[1,3], Fulvio Stacul[2] & Stella Bernardi[1,3]
[1]Department of Medical Sciences, University of Trieste – Cattinara Teaching Hospital – ASUGI, UCO Medicina Clinica, Trieste, Italy; [2]Maggiore Hospital, ASUGI, Department of Radiology, Trieste, Italy; [3]Cattinara Teaching Hospital – ASUGI, Department of Medicina Clinica (Endocrinology Division), Trieste, Italy

Background
During the last decade, radiofrequency ablation (RFA) has emerged as a reliable alternative to surgery for the treatment of benign symptomatic thyroid nodules in terms of effectiveness and safety.
Aim
The aim of this study were: (*i*) to evaluate the long-term efficacy (5 years) of RFA for the treatment of benign thyroid nodules, in terms oftechnical success and nodule regrowth, and (*ii*) to identify the predictive factors of technical failure and nodule regrowth.
Materials and methods
79 patients who underwent RFA for benign symptomatic thyroid nodules were included in this observational retrospective study. All the patients were followed up yearly for 5 years after the procedure. Regrowth was defined as a nodule volume increase greater than 50% as compared to the previously reported smallest volume after the procedure.
Results
Our analyses show that RFA led to a nodule volume reduction of 72% after one year and 76% after five years from the procedure. The technical success rate was 91%, while regrowth rate was 21.4% in 5 years. Nevertheless, in the majority of cases regrowth was not associated with symptom recurrence. Overall, only 12.7% of the patients were retreated after 5 years. In particular, 5 patients underwent surgery (all the nodules resulted benign at the final pathology), while 5 patients underwent a further session of RFA. The nodule volume reduction after one year from the second procedure was still 67%. Our results show that sex was a predictive factor of technical failure; while sex, age (with an inverse correlation), symptoms, and technical failure were predictive of regrowth.
Conclusions
RFA is effective for the treatment of symptomatic benign thyroid nodules. Overall, RFA is associated with a low rate of failures and regrowths requiring further treatments. Neverheless, if a second procedure is needed, it will further decrease nodule volume by 67%. Furthermore, our data suggest that patients should be followed up after the procedure.

Is there a place for Thyroid Scintigraphy with Technetium 99 m in the exploration of congenital hypothyroidism in the absence of Iode 123

Sihem Mensi, Imen Halloul, Abir Ezzine, Raja Sfar, Manel Nouira & Khawther Chatti
Sahloul University Hospital, Department of Nuclear medicine, Sousse, Tunisia

Introduction
With a prevalence of about one in 3000 newborns, congenital hypothyroidism (CH) is the leading cause of preventable mental retardation and growth failure. The objective of this work is to clarify the contribution of thyroid scintigraphy (TS) using technetium 99 m for the diagnosis of CH and this through the experience of the nuclear medicine department in Sahloul university Hospital.
Materials and methods
This is a retrospective study including 31 children diagnosed with CH, who were referred to the nuclear medicine department of Sahloul Hospital for a thyroid scintigraphy. The average age was 24 months (ranging from 1 month to 14 years). All patients benefited from an acquisition of images centered on the cervical region using the Pinhole collimator in anterior incidence, supplemented by a static acquisition centered on the abdomen 20 minutes after an intravenous injection of 37 to 185 MBq of technetium 99 m.
Results
The study included 18 girls and 13 boys with a sex ratio equal to 1.38. Four patients had Down's syndrome and two patients had a congenital heart defect. Twelve patients (38.7%) had thyroid dysgenesis (6 agenesis and 6 ectopia). Nineteen patients (61.3%) had a thyroid in place with a different level of thyroid fixation (normal fixation (22.6%), high fixation (16.1%) and homogeneous and weak fixation (22.6%) suggesting a disorder of hormonogenesis.
Conclusion
Technetium-99 m thyroid scintigraphy helps in the identification of thyroid dysgenesis, which is the most common cause of CH. The use of iodine 123 with a perchlorate test is particularly preferred in the diagnosis of a hormonogenesis disorder. However, in the absence of iodine 123, as for the case in our country, technetium 99 m ST can be an acceptable alternative allowing an etiological orientation of CH.

Clinical scoring systems fare poorly among elderly patients in diagnosing primary hypothyroidism

Varun Singla[1], Mary John[1] & Jubbin Jagan Jacob[2]
[1]Christian Medical College & Hospital, Department of Medicine, Ludhiana, India; [2]Christian Medical College & Hospital, Endocrine and Diabetes Unit, Department of Medicine, Ludhiana, India

Background
Clinical scoring systems were used traditionally in the diagnosis of hypothyroidism before biochemical diagnosis became the norm. There are two well validated clinical scoring systems (Billewicz and Zulewski) for diagnosing hypothyroidism. Both these scores were validated in younger patients with hypothyroidism and may not be useful in older patients. We conducted this study to determine the clinical utility of these two scoring systems among patients over the age of 60 years for diagnosing hypothyroidism.
Aims and objectives
To determine the sensitivity and specificity of the Billewicz diagnostic index and Zulewski clinical score in diagnosing hypothyroidism in elderly subjects suspected to have hypothyroidism.
Materials and methods
This observational study was conducted in the Departments of Medicine and Endocrinology at tertiary care university affiliated teaching hospital from December 2017 to September 2019. After informed consent, clinical data and scoring of the patients was collected in elderly subjects ($n=200$) with suspected hypothyroidism. A biochemical diagnosis of primary hypothyroidism was considered the gold standard (raised TSH levels with a low FT4 levels).
Results
Billewicz score was 99.32% specific and 1.85% sensitive, while specificity and sensitivity of Zulewski score was 80.82% and 37.04% respectively (considering indeterminate scores as euthyroid). After considering Indeterminate as hypothyroid, sensitivity of Billewicz and Zulewski score was 75.93% and 70.37%; and specificity was 20.55% and 36.99% respectively. Only the Zulewski score (indeterminate as euthyroid) showed weak significant agreement with final diagnosis of hypothyroidism ($K=0.185$, $P=0.009$).
Conclusion
Both scoring systems do not help in the diagnosis of hypothyroidism among elderly patients.
Keywords: thyroid gland, hypothyroidism, billewicz diagnostic index, zulewski clinical score, indeterminate.

Effect of cholecalciferol treatment on insulin sensitivity in patients with chronic autoimmune thyroiditis

Volodymyr Pankiv & Tetiana Yuzvenko
Ukrainian Research and Scientific Centre of Endocrine Surgery, Kyiv, Ukraine

Background
Effects of vitamin D on immune cells might affect diabetes mellitus (DM) development since inflammatory factors have been linked to insulin resistance (IR). The aim of this study was to investigate the effect of cholesterol treatment on insulin sensitivity metabolic markers in patients with chronic autoimmune thyroiditis.
Materials and methods
In this double-blind, randomized, placebo-controlled trial, which was conducted from May to September 2019, 45 patients with chronic autoimmune thyroiditis were enrolled. They randomly allocated into two groups to receive oral cholecalciferol (28 000 IU weekly) and placebo for 12 weeks. Serum concentration of glycated hemoglobin (HbA1c), insulin, fasting plasma glucose (FPG), calcium, phosphorus, parathyroid hormone, C-reactive protein, creatinine, triglyceride (TG), total cholesterol, and high-density lipoprotein were measured in both groups before and after investigation. Homeostasis model assessment estimates of beta cell function (HOMA-B) and HOMA-insulin resistance (HOMA-IR) were calculated before and after trial in both groups.
Results
Twenty-three and twenty-two participants were allocated to cholecalciferol-treated and placebo-treated groups, respectively. Mean (standard error) level of 25(OH)D increased significantly in cholecalciferol-treated group (34.71 [1.82] ng/ml vs 14.17 [0.72] ng/ml, $P=0.002$). Plasma parathyroid hormone decreased in the treatment group while remaining unchanged in the placebo-treated group (35.04 [2.24] ng/ml vs 46.83 [2.29] ng/ml respectively, $P=0.03$). In between-group comparison, there was significant difference between cholecalciferol-treated and placebo-treated groups regarding measures of HOMA-B, HOMA-IR ($P<0.05$). Other variables did not meet a significant change after trial ($P=$NS).
Conclusions
Weekly 28 000 IU oral cholecalciferol for 12 weeks improved IR and insulin secretion in patients with chronic autoimmune thyroiditis.

The introduction of endoscopic techniques in thyroid surgery

Igar Radziyeuski
Brest Regional Clinical Hospital, 1 Surgical Depatment, Brest, Belarus

Introduction
Endoscopic surgery has found wide application in many areas of medicine in a short: endocrinology is no exception. The main advantages of endoscopic access to the thyroid gland are the possibility of conducting endovideoscopy, a low traumatic surgical intervention, shortening of the inpatient treatment duration, periods of incapacity for work, and cosmetic effects
Goal
Determine the appropriateness of using endoscopic technologies in comparison with classical techniques in thyroid surgery procedure.
Material and methods
During last decade, more than thousand patients with diffuse and nodular thyroid disease got thyroid surgery in the surgical department of the Brest Regional Hospital (Belarus). All patients with nodular pathology of thyroid gland underwent fine needle aspiration biopsy under ultrasound control and got cytology conclusion of nonmalignant disorder. Thyroid status was investigated in all cases (TSH, free T3 and T4, TPO-Ab). TSH receptor antibodies (TSHR-Ab/TBII) were analyzed in patients with the suppression of TSH levels, thyroid scintiography was also performed in such cases. As a routine – during surgery, all patients underwent an express biopsy. All the cases of thyroid surgery were divided depending on the type (traditional or endoscopic surgery) and volume of surgical intervention (hemi or total thyroidectomy).
Results
The results of surgical treatment of patients with thyroid diseases in a traditional way and endoscopically were evaluated according to the following parameters: the duration of surgery, intraoperative volume of blood loss, drainage of the postoperative wound, the intensity of the pain in the postoperative period, complications, the duration of hospitalization in the postoperative period, cosmetic effect. In the group of endoscopic thyroid surgery, the average length of the hospital staying was reduced to a day. Intraoperative complications occurred in 1 (0.9%) patient. Postoperative complications developed in 7 (6.2%) patients. Transient paresis of the recurrent laryngeal nerve (RN) in 5 (4.4%) patients could not be avoided. The patients who underwent surgery endoscopically, the intensity of the pain in the postoperative period was much lower compared to the usual technique. Also, a decrease in the number of intra- and postoperative complications during the endoscopic thyroid surgery was reliably established.
Conclusions
The introduction of endoscopic interventions impoves the possibility of obtaining optimal clinical results in patients with thyroid nodular diseases and reduces the number of postoperative complications, shorten the length of the patient's stay in the hospital and the interval of rehabilitation in the postoperative period with good cosmetic effect in the operation area.

Efficacy of radioactive iodine in treatment of graves' disease

P Varma Buddharaju[1], Tekchand kalawat[2], Sandeep Ganta[1], Avinash patil[1], Mani Deepthi[1], Raghavendra K[1], Suresh V[1] & Alok Sachan[1]
[1]SVIMS, Endocrinology, Tirupati, India; [2]SVIMS, Nuclear Medicine, Tirupati, India

Background
Radioactive iodine ^{131}I (RAI) treatment is an effective definitive treatment of hyperthyroidism, used as a first line or second line treatment.
Aims and objectives

1. To evaluate the response of RAI therapy in Graves' disease.
2. To determine any factors predicting treatment failure.

Study design
Retrospective study
Materials and methods
Clinical records were reviewed and data were collected about hyperthyroid patients. Thyrotoxicosis was diagnosed on the basis of elevated total T4 (50–110 ng/ml) and/or total T3 (0.87–1.78 ng/ml) values with suppressed TSH. The etiology of hyperthyroidism was established with 99 mTc-pertechnetate thyroidimaging and the gland size was measured with ultrasound. Empirical single dose, approximately 10 mci of I-131 was used for ablation. Ablation was done after stoppinganti thyroid medications for at least 3 days prior to RAI therapy, and drugs were restartedafter 2 days.
Post ablation, biochemical monitoring was done once a month. Successful RAI therapy for hyperthyroidism was defined as clinical and biochemical euthyroid or hypothyroid status (group 1). Treatment failure was defined as persistent of hyperthyroidism even after 6–12 months post-RAI therapy (group 2).
Patientswho underwent RAI ablation for Graves disease and whose complete follow up records available were included in the study. Patients who had toxic adenoma and toxic MNG were excluded from the study.
Results
Total 70 patients were recruited,19 patients were excluded due to incomplete data. Fifty one patients were included. Age at diagnosis of hyperthyroidism was 38 ± 9.7 years. Men to women ratio was 1:6.3. Postablation (mean dose of I-131 9.6 ± 0.8 mci), 32 patients (62.7%) achieved remission (group 1). Among these 30 patients became hypothyroid and 2 patients became euthyroid. Nineteen patients (37.3%) failed to achieve remission(group 2). Time for response ingroup 1 was 4.9 ± 2.2 months. Thyroid gland was larger in size in the group 2 (19.9 ± 6.0 gm) as compared to group 1 (10.4 ± 3.8 gm). Mean age at diagnosis was similar among both the groups (group 1:37.3 ± 7 years vs group 2 : 39 ± 13.3 years). There was no difference in the male to female ratio and pre ablation T3, T4 levels, between the two groups.
Conclusion
Sixty three percent of the patients achieved complete remission with a single dose of I-131 with in 5 months. Larger gland size predicted the treatment failure. No other demographic, and biochemical parameters were different between two groups.

Thyroid cancer recurrence risk after transplantation: Single center experience

Özlem Turhan İyidir[1], Nazlı Gülsoy Kırnap[1], Feride Pınar Altay[1], Mahir Kırnap[2], Neslihan Başcıl Tütüncü[1] & Mehmet Haberal[2]
[1]Başkent University, Endocrinology and Metabolism; [2]Başkent University, General Surgery

Introduction
There is little data about the influence of immunosuppression on the recurrence rate of thyroid cancer. We aimed to evaluate the risk of recurrence and mortality of thyroid cancer after solid organ transplantation.
Patients and methods
We retrospectively evaluated 802 kidney and 283 liver transplant recipients who underwent transplantation between January 1999 and May 2019 in Başkent University. We identified 14 patients with thyroid cancer. Of these 14 patients, 12 were kidney transplant recipients and 2 were liver transplant recipients. Thyroid cancer was classified as low/intermediate and high risk according to the 8th pTNM (tumor, node, metastasis) classification system as well as American Thyroid Association guidelines.
Results
Fourteen patients (seven males, seven females) with a history of both organ transplantation and thyroid cancer were recruited for this study. Median age of the patients was 42 (31–70) years. All of the patients were on corticosteroid,and mycophenolate mofetil was administered to 13 patients (92.9%), cyclosporin A to 10 patients (71.8%), tacrolimus to 1 patient (7.1%), and-Mammalian target of rapamycin (mTOR) inhibitors were used in 2 patients (14.3%). All patients underwent total thyrodectomy, except one patient who underwent total thyroidectomy and lateral neck dissection. Median age at diagnosis of thyroid cancer was 34 (18–65) years. Six of the patients (42.9%) were diagnosed pre-transplantation. Thirteen of the patients had papillary and one patient had follicular cancer. Nine of the patients (64.3%) had multifocal disease. All patients had stage I disease and also were in low risk group. Median follow-up time was 6.9 (1.3–14.6) years. After initial treatment, 13 of 14 patients were in remission. One patient with had local recurrence During the follow-up period, there were no signs of local recurrence or distant metastasis in the remaining 13 patients. None of the patients were lost to thyroid cancer.
Discussion
Our results suggest that solid organ transplantation does not influence thyroid cancer prognosis, especially in low risk patients. There is a concern about the progression of a previously treated cancer after transplantation. In this study, six of the patients were diagnosed and treated before transplantation. During follow-up, all of the patients were in remission. This indicates that transplantation may not alter the outcome of differentiated thyroid cancer.
In conclusion, our study suggests that thyroid cancer outcome is not altered after kidney and liver transplantation. Further studies in a larger population are needed.

125I radioactive seed localization (RSL) in surgery of cervical metastasis of thyroid cancer

Juan Jesús García González, Tomás Martín Hernández, Rocío Domínguez Rabadán, María Reyes Ravé García & Pablo Rodríguez Vera
Hospital Virgen Macarena, Endocrinología y Nutrición, Sevilla, Spain

Introduction
The aim of this work is the evaluation of usefulness of radioactive seed localization (RSL) for the detection of cervical recurrence of thyroid cancer in order to improve the surgical outcome.
Material and method
Six patients with thyroid cancer with cervical recurrences evidenced by ultrasound, cytology/Tg-FNAB were selected for this procedure. A ^{125}I seed was placed in the metastatic lesion using a needle guided by ultrasound. During surgery, a handheld gamma probe/portable gammacamera were used for lesion localization and excision. After removing the target issue, it was verified that the seed was included in the excised tissue. Surgical intervention duration, lesion location, seed activity, thyroglobulin level, effective radiation dose, complications and the degree of surgical resection were analyzed.
Results
All the marked nodes were positive in histology. The mean duration of the ultrasound procedure was 12.8 ± 5.2 min. Seed was kept inside the patient, in average, during 4.3 days (3–7) and the average surgical time was 45 ± 37.5 min. We found 13 metastatic specimens. The mean activity of the implanted seed was 70.32 ± 22.7 MBq (42.8–105). The thyroglobulin level was 2.08 ± 1.56 ng/dl. Only one case of transient hypoparathyroidism was found.
Conclusions
The introduction of RSL in our unit has shown benefits for the patient and medical team, being a safe and effective procedure that also improves surgical programming.

Cystic cervical lymphadenopathy revealing thyroid papillary carcinoma

Mehdi Hasnaoui[1], mohamed masmoudi[2], Takwa Belaid[2] & Khalifa Mighri[2]
[1]Department of Otolaryngology-Head and Neck Surgery, Tahar Sfar Hospital, Mahdia, Tunisia, Otolaryngology-Head and Neck Surgery, Mahdia, Tunisia; [2]Tahar Sfar Hospital, Mahdia, Tunisia, Otolaryngology-Head and Neck Surgery, Mahdia, Tunisia

Introduction
Cervical lymphadenopathy is a frequent reason for ENT consultation. In most cases the diagnosis is easy based on clinical, radiological and cytopathological data. However, in some situations, the diagnosis remains pending. The objective of this work is to study the possible difficulties face to a chronic cystic cervical lymphadenopathy.
Materials and methods

It is a retrospective study bringing 4 cases of cervical cystic lymphadenopathy revealing thyroid papillary carcinoma collected over a period of 17 years (from 2000 to 2016).
Results
Our study focused on 4 cases. The sex ratio was 1 with an average age of 49 years. The reason for consultation was cervical swelling in all cases evolving for an average of 6 years. The swelling was supraclavicular in 2 cases, jugulo-carotid in one case and subdigastric in one case. Its size varied between 3 and 15 cm. The swelling was relapsing in all cases, associated with a palpable thyroid nodule in one case and multiple lymphadenopathies in one case. Cervical ultrasound, done in all patients, wrongly led to the diagnosis of a branchial cyst in 2 cases. All patients had a cervicotomy with an extemporaneous examination, suggesting a metastasis of a thyroid papillary carcinoma in 2 cases. Which examination carried the diagnosis of branchial cyst in the 2 other patients. The metastatic nature of lymphadenopathy was not confirmed until the final histological examination. It was a metastasis of papillary micro carcinoma in 3 cases and of a branchial cyst invaded by an adjacent metastatic lymphadenopathy of a thyroid papillary carcinoma in one case. The cystic nature was confirmed after immunohistochemical study.
Conclusion
Cystic cervical lymphadenopathy may be the only telltale sign of papillary carcinoma of the thyroid, hence the need to invoke this diagnosis before any cystic cervical mass.

Performance of a dual-component molecular assay in cytologically indeterminate thyroid nodules

Marialuisa Sponziello[1], Antonella Verrienti[1], Valeria Pecce[1], Luana Abballe[1], Giorgio Grani[1], Valeria Ramundo[1], Guido Fadda[2], Chiara Brunelli[2], Cosimo Durante[1] & Sebastiano Filetti[1]
[1]SAPIENZA University of Rome, Translational and Precision Medicine, Roma, Italy; [2]Catholic University of Sacred Heart, Foundation 'Agostino Gemelli' University Hospital, Division of Anatomic Pathology and Histology, Rome, Italy

Background
Deciding whether patients with a cytologically indeterminate thyroid nodule should be referred for surgery or for active surveillance is an important challenge for clinicians. The aim of this study was to evaluate the performance of a novel dual-component molecular assay as an ancillary molecular method for resolving indeterminate thyroid nodule cytology.
Methods
We selected 156 thyroid nodules from those that had undergone both FNA cytology and surgical resection between June 2016 and December 2017. The sample set included 63 nodules cytologically classified as *indeterminate*, and 93 other nodules randomly selected from those with *non-diagnostic*, *benign*, *suspicious or malignant* cytology. Nucleic acids from each nodule were subjected to next-generation sequencing analysis for mutation detection in 24 genes and to digital-PCR evaluation for miR-146b-5p expression levels.
Results
Used alone, mutation analysis in the indeterminate subset (cancer prevalence:22.5%) displayed high sensitivity (89%) and NPV (96%). In contrast, the miR-146b-5p assay offered high specificity (93%) and PPV (93%). Combined use of both analyses eliminated all the false-negative results (100% sensitivity, 100% NPV).
Conclusions
These preliminary data suggest that a dual-component molecular test can increase the diagnostic accuracy of thyroid cytology alone by reducing the number of nodules that will be classified as indeterminate and increasing those that can be reliably classified as benign. If these findings are confirmed, this test can be considered for use in clinical practice and is expected to reduce diagnostic surgery and health care costs, and to improve patient quality of life.

Comparison of therapeutic radioiodine dose to ablation response in differentiated thyroid cancer patients with cut-off serum thyroglobulin level after two weeks of levothyroxine withdrawal

Heesung SONG & Ji Young LEE
Jeju National University, Jeju National University Hospital, Nuclear Medicine

Purpose
This retrospective study is evaluated the efficacy of three doses of I-131 (1110 MBq vs 3700 MBq vs 5550 MBq) in differentiated thyroid carcinoma patients with cut-off serum thyroglobulin (TG) level after two weeks of thyroid hormone withdrawal for postoperative thyroid remnant ablation.
Methods
A total of 97 patients with differentiated thyroid cancer treated with total thyroidectomy and radioactive iodine (RAI) therapy were enrolled. Doses of 1110 MBq, 3700 MBq, and 5550 MBq were determined based on the surgical records and pathologic results of each patient. Serum TG test was performed one week before radioiodine treatment and two weeks after the thyroid hormone stoppage(preTG; ng/dl) and cut-off preTG level was below 5 ng/dl. After six months of RAI treatment, complete ablation,which defined as showing no uptake in diagnostic I-131 scan, stimulated TG of less than 1.0 ng/dl, and TG antibody of less than 100 ng/dl was investigated, and statistically analyzed.
Results
After initial therapy, 76 patients (78.4%) were in complete ablation, with 77.8% (7/9) in 1110 MBq group, 80.0% (60/75) in 3700 MBq group, and 69.2% (9/13) in 5500 MBq group. There was no statistically significant difference in complete ablation between different radiation dose groups ($P=0.681$). Serum preTG level did not show a statistically significant difference between the three groups ($P=0.091$). The serum preTG level (adjusted odds ratio (OR)=1.70, 95% confidence intervals (CI) 1.07–2.69, $P=0.024$) and stimulated TG level at the time of RAI (adjusted OR=1.4, 95% CI 1.14–1.68, $P<0.001$) were significantly independent predictors of complete ablation.
Conclusion
RAI therapy with 1110 MBq seems to besufficient for ablation if thepreTG level was below 5 ng/dl in patients with differentiated thyroid cancer.

Case report: Myocardial Infarction after 9 month treatmentwith a tyrosine kinase inhibitor (TKI) with Anti-VEGF receptor activity

Paloma González Lázaro, Cristina Contreras Pascual, Cristina Montalbán Méndez, Antonio Moreno Tirado, Francisco Javier Gomez Alfonso, Florentino del Val Zaballos, Julia Silva Fernández & Ines Gomez Garcia
La Mancha Centro Hospital Complex, Alcázar de San Juan, Spain

Introduction
TKIs including anti-VEGF receptor activity have been approved for the treatment of patients with radioiodine resistant thyroid carcinomas. For lenvatinib arterial thromboembolic events are listed as adverse events of special interest. In the phase III study of SELECT trial, arterial thromboembolic events were reported in 3% of lenvatinib-treated patients and 1% in the placebo group. Most of the patients had predisposing factors. Only one myocardial infarct was reported in the lenvatinib phase III study.
Patient
We report a 67 year-old-female with metastatic folicular thyroid carcinoma at time of diagnosis (bone, hepatic, lung and renal metastasis). Total thyroidectomy was performed. Zolendronate was started and radiotherapy was administired due to spinal cord compression caused by metastasis on L3, L4, L5. NO radioidine therapy was administired as it was considered radioiodine resistant (No RAI uptake) and treatment with Sorafenib was started. Sorafenib treatment resulted in disease progression with appearence of new hepatic and lung metastasisso treatment with sorafenib was discontinued and Lenvatinib was started with partial response. During further treatment with lenvatinib with dose reduction from initially 24 to 10 mg at 6 months of lenvatinib treatment a myocardial infarction occurred after 9 months of lenvatinib treatment. Coronary angiographydid not show significant coronary stenosis or structure abnormalities and echocardiography showed normal results with preserved ejection fraction. Treatment with lenvatinib was discontinued at the time of diagnosis of the myocardial infarction. Except for well controlled hypertension there were neither predisposing diseases like diabetes nor symptoms of cardiac ischemia on exertion

Conclusion
Our case report suggests that lenvatinib should also be added to the list of TKIs with ATE potential. So far, most of the thromboembolic events appeared after short-term treatment median duration of 10.8 months with tyrosine kinase inhibitors and mostly in patients with predisposing factors. However, our patient suffered from her first myocardial infarction aftertreatment with lenvatinib for 9 months, in absence of predisposing diseases except well controlled hypertension. Therefore, as previously proposed by Conti *et al.* for other TKIs also patients with lenvatinib treatment should be assessed for cardiovascular risk and coronary ischemia before and during the treatment

Mental health in children and adolescents with graves disease

Shakhlo Muratova
Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician E.Kh.Turakulov of the Ministry of Health of the Republic of Uzbekistan, Thyroidology, Tashkent, Uzbekistan

Aim
To study the thyroid and cognitive status and psycho-emotional health of children and adolescents with Graves' disease (GD).
Materials and methods
37 children and adolescents with GD examined in the Republican Medical Center of Endocrinology (Uzbekistan). The control group consisted of 19 healthy children and adolescents. Thyroid status was determined using a closed-type immunochemistry analyzer Cobas e411 Hitachi from Hoffman-LeRoche (Switzerland) and its reagents. To assess the level of intelligence of children, standard progressive Raven matrices were used. Spielberg Questionnaire (State-Trait Personal Inventory) was used to determine anxiety syndrome. The differences were considered statistically significant at $P<0.05$.
Results
In Uzbekistan, according to the annual statistical report for 2018, the dispensary includes 145 children and adolescents with GD. We examined 37 children with GD, which amounted to 25.5% of all children with GD in Uzbekistan. At the time of the first treatment, all children with GD had a pronounced thyrotoxicosis clinic with a reliably low TSH level (0.014±0.024, $P<0.01$), high fT4 values (5.1±0.2, $P<0.05$) and TRAbs interval was 2.5–40.0 IU/l with a median (Me) of 11.6 (17.0±1.1, $P<0.0001$). In the same group, 83.8% (31) showed high values of TPO Ab. In the control group, 8.3% (1) also showed elevated levels of TPO Ab. In a group of GD, 100% of children showed a high level of anxiety, 70.3% (26) showed a high degree of negative emotional experiences and low cognitive activity. Children with GD were dominated by indicators of insecurity, anxiety, self-distrust, a sense of inferiority and hostility, a tendency to conflict, difficulties in communication, and depression were noted. The total IQ adjusted for age in children and adolescents with GD was 73.9±14.8 (min 55, max 96, Me 75). In the control group, this indicator was 120.2±7.5 points (min 106, max 133, Me 115; $P<0.001$). In the group with GD, no children with extraordinary intelligence were detected. In 43.2% (16) adolescents, the IQ level corresponded to an average degree of intelligence, in 56.8% (21) it was below average. At the same time, 51.4% (19) of children in this group showed endocrine encephalopathy.
Conclusions
In all adolescents with thyrotoxicosis, anxiety, and negative emotional experiences prevailed, while the cognitive activity in these children was lower in comparison with the control group. Children with GD have defects in intellectual ability and impaired attention and/or perception.

Pembrolizumab inducing thyroid diseases: Are there differences between patients treated for lung carcinomas and those for lymphomas?

Valentina Lo Preiato[1], Anna Buganè[1], Beatrice Casadei[2], Stefania Salvagni[3], Lisa Argnani[2], Andrea Ardizzoni[3], Pier Luigi Zinzani[2] & Uberto Pagotto[1]
[1]Endocrinology Unit and Diabetes Care, Center for Applied Biomedical Research, Department of Medical & Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, S. Orsola-Malpighi Hospital, Bologna, Italy; [2]Institute of Hematology 'L. e A. Seràgnoli', University of Bologna, Bologna, Italy; [3]Oncology Institute, S. Orsola Hospital, Azienda Ospedaliero Universitaria, Bologna, Italy

Background
In the last years, Pembrolizumab has been used to treat solid and lymphatic neoplasms, showing improved patients' survival. Due to its mechanism of action, Pembrolizumab may be responsible of several immune-related adverse events (irAEs). The most frequent endocrine-irAEs reported are thyroid diseases.
Aims
The aim of this study was to evaluate differences in thyroid disease incidence and presentation between patients treated for lung cancer and those for lymphomas.
Materials and methods
Data of patients treated with flat dose of Pembrolizumab (200 mg/3 weeks) for lymphoma and for lung cancer, attending the Institute of Hematology Seràgnoli and the Oncology Unit of Bologna respectively, were retrospectively collected. Blood tests for thyroid function were drawn at baseline and before each injections.
Results
We included 69 patients, 37 with lung cancer (26 adenocarcinoma; 11 squamous cell carcinoma) and 32 with lymphoma (19 nodular sclerosis Hodgkin lymphoma; 13 primary mediastinal B-cell lymphoma).Pembrolizumab was administered in both cancer population for a similar amount of time (lung cancer: median of 21 weeks, lymphoma median of 25; $P=0.330$). The follow up was different according to the evolution of cancer type(lung cancer median of 21 weeks, range: 6–111; lymphomas for 115 weeks, range: 4–208; $P<0.001$). Patients with lung cancer were older than those with lymphoma (median: 33 years, range: 18–68 vs median: 70, range: 50–82; $P<0.001$). Thyroid disease prevalence was similar (10.8% for lung cancer and 9.4% for lymphoma, $P=0.844$). In particular, 3 patients developed thyrotoxicosis and 1 hypothyroidism in the lung cancer population, while 1 thyrotoxicosis and 2 hypothyroidisms were found in the lymphoma ones. In all patients, thyrotoxicosis was an early event, occurring between the 2nd and 5th administration of Pembrolizumab, while hypothyroidism arose later, between the 7th and 14th cycle. The clinical presentation and progress of thyroid diseases were equal between the two cancer populations. Thyrotoxicosis was asymptomatic and reversible, whereas the hypothyroidism was clinically mild (grade 2) but permanent, requiring long-life replacement therapy. In all subjects Pembrolizumab was continued despite thyropaties onset. No differences in TSH values before Pembrolizumab adminstration were found between patients who developed thyropathies and the remaining patients ($P=1.000$ for lung cancer and $P=0.637$ for lymphoma).
Conclusion
No differences for frequency, characteristics and evolution of thyroid diseases were shown in patients treated with Pembrolizumab in solid and hematologic malignancies. The type of tumours and age at treatment are not associated with the development of drug-induced endocrine adverse events.

Long-noncoding RAN negatively regulated by thyroid hormone to suppress tumorigenesis

Kwang-Huei Lin[1], Yang-Hsiang Lin[2], Meng-Han Wu[1]
[1]Chang-Gung University, Biochemistry, Taoyuan, Taiwan; [2]Chang Gung Memorial Hospital, Linkou, Liver Research Center, Taoyuan, Taiwan

Long non-coding RNAs (lncRNAs) are a class of non-protein coding transcripts longer than 200 nucleotides that regulate complex cellular functions, such as cell growth, differentiation, metabolism, and metastasis. Thyroid hormone (T3) and its receptor (TR) are involved in cancer progression. To identify T3/TR-related lncRNAs that are differentially expressed in HCC, lncRNA expression profile screening was performed using the SYBR Green-based quantitative reverse transcription-PCR (qRT-PCR) array in TR-overexpressing HepG2 cell lines and hepatocellular carcinoma (HCC) specimens. The deregulation of lncRNA expression has been detected in many tumor types, the mechanisms underlying specific involvement of lncRNAs in tumorigenicity remain unclear. Candidate lncRNAs that were simultaneously downregulated by T3/TR and upregulated in HCC were selected for further study, leading to the identification of lncRNA-LOC34 578. LOC34 578 was significantly upregulated in HCC compared to normal tissues. Furthermore, expression of LOC34 578 was significantly positively correlated with overall and recurrence-free survival of HCC patients. Notably, LOC34 578 expression was positively correlated with tumor type, vascular invasion, and pathological stage. These findings suggest that LOC34 578 plays an important regulator in hepatoma. Furthermore, we examined the potential effects of LOC LOC34 578 on hepatoma cell migration and invasion. HCC cells with knockdown of LOC34 578 were further

established. Overexpression of LOC34 578 enhanced cell migration ability. On the other hand, knockdown of LOC34 578 significantly suppressed cell migration and invasion, compared with that in cells transfected with control. To further confirm LOC34 578 regulated cell motility, cell migration was measured in LOC34 578-overexpressing cells simultaneously knockdown of LOC34 578. The results indicated LOC34 578 was involved in regulating hepatoma cell motility. To confirm whether the *in vitro* phenotype of LOC34 578 is reproducible *in vivo*, the effect of LOC34 578 knockdown on HCC cell tumor formation was examined in nude mice. The knockdown of LOC34 578 reduces tumor growth compared to the control group. Accordingly, LOC34 578 acts as oncogenic lncRNA in HCC. To assess whether LOC34 578 contributes to the activities of EMT, EMT-related genes were examined. The levels of p-STAT3 and MMP2 were lower in LOC34 578-depleted HCC cells relative to their control. E-cadherin, p21, and p27 were higher in knockdown of LOC34 578 cell lines. These findings suggest that LOC34 578 modulated cell migration and cell growth through regulations of EMT-related genes, cell cycle-related markers.

Obstructive sleep apnea in primary aldosteronism is associated with cortisol cosecretion

Daniel Heinrich[1], Christian Adolf[1], Laura Handgriff[1], Holger Schneider[1], Nina Nirschl[1], Elisabeth Obster[1], Lisa Sturm[1], Xiao Wang[1], Martin Bidlingmaier[1], Moritz Wildgruber[2], Roland Ladurner[3], Felix Beuschlein[4] & Martin Reincke[1]

[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Klinik und Poliklinik für Radiologie, Klinikum der Universität München, Munich, Germany; [3]Klinik für Allgemein-, Viszeral- und Transplantationschirurgie, Campus Innenstadt, Klinikum der Universität München, Munich, Germany; [4]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich, Zurich, Germany

Background
Primary aldosteronism (PA) is a secondary form of arterial hypertension that – in case of unilateral disease – can be cured by surgery. Multiple studies have shown that PA patients are at higher risk to suffer from cardiovascular events and to develop metabolic diseases. Two thirds of patients with PA suffer from obstructive sleep apnea (OSA). A bi-directional, pathophysiological interplay between OSA and PA has been proposed, with focus on overnight rostral fluid shift and the metabolic syndrome. Cortisol cosecretion – a newly identified trait of PA patients – is associated with metabolic risk parameters, independently of mineralocorticoid excess.
Objective
While the connection between the extent of cortisol oversecretion and OSA in overt Cushing's disease has been established, the role of cortisol cosecretion has not been investigated in the relationship of PA and OSA.
Methods and results
We report the results of 31 PA patients who were screened for OSA and hypercortisolism (1-mg overnight dexamethasone suppression test, 24-hour urinary free cortisol determination and late-night salivary cortisol measurement) before initiation of treatment. Serum cortisol values after dexamethasone suppression tests were significantly higher in OSA patients (1.6 µg/dl [1.3; 2.5] vs 1 [1; 1.2], $P=0.002$) and increased with OSA severity (moderate and severe OSA, 2.0 µg/dl [1.5; 2.5] in comparison to mild OSA, 1.4 µg/dl [1.2; 1.9] or no OSA, 1 µg/dl [1; 1.2], $P=0.016$). When adjusting these results for BMI, age, systolic blood pressure and HbA1c values the results remained significant ($P=0.042$).
Conclusions
The main finding of our study is the association of OSA with biochemical evidence of cortisol cosecretion in patients with PA. In this concept, PA induces fluid retention and rostral fluid shift leading to OSA in vulnerable subjects (male, obese patients), inducing increased night-time hypoxia and stress including hypothalamic pituitary adrenal axis activation. This observation can explain the strong links found between cortisol cosecretion, obesity, the metabolic syndrome and primary aldosteronism. Further interventional studies are warranted to determine long-term outcome of CPAP treatment on cortisol cosecretion for this patient cohort.

Intact endothelial epoxyeicosatrienoic acids pathway in primary aldosteronism – the route to new treatment strategies?

Laura Fruehbuss[1], Yao Meng[1], Jing Sun[1], Jair Gonzalez Marques[2], Berthold Koletzko[2], Michael Mederos y Schnitzler[3], Thomas Gudermann[3], Felix Beuschlein[1,4], Tracy Ann Williams[1,5], Daniel Heinrich[1], Christian Adolf[1], Martin Reincke[1] & Holger Schneider[1]

[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, LMU München, München, Germany; [2]Kinderklinik und Kinderpoliklinik im Dr. von Haunerschen Kinderspital, Klinikum der Universität München, LMU München, München, Germany; [3]Walther-Straub-Institut für Pharmakologie und Toxikologie, Medizinische Fakultät, LMU München, München, Germany; [4]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich, Zürich, Switzerland; [5]Division of Internal Medicine and Hypertension, Department of Medical Sciences, University of Turin, Turin, Italy

Rationale
Endothelial dysfunction (ED) is a hallmark of primary aldosteronism and paves the way for subsequent atherosclerotic disease. Past research has confirmed that one factor involved in ED is disturbed nitric oxide (NO) signalling. Since defects in NO release alone cannot explain the whole effect, we set out to address the role of endothelial CYP-expoygenase products (epoxyeicosatrienoic acids, EETs) in aldosterone-mediated endothelial dysfunction.
Objective
Todelineate aldosterone-mediated changes in expression patterns of critical genes which are necessary for the generation of EETs in endothelial cells and their action in smooth muscle cells;to assess stimulated EET release from endothelial cells after chronic aldosterone excess; and tomeasure smooth muscle calcium response to EETs after chronic aldosterone excess. To account for potential co-stimulation of mineralocorticoid receptors, are exposed to physiological levels of cortisol and pathologically relevant levels of aldosterone in parallel.
Methods and results
We show with qPCR and western blot that aldosterone excess in primary human coronary artery endothelial and smooth muscle cells does not change the expression of relevant enzymes (CYPepoxygenases, epoxide hydrolases) and channels which are deemed to be vital for an effective EET pathway. We further demonstrate BKCa channels to be mostly downregulated by physiological levels of glucocorticoids in a glucocorticoid receptor-dependent manner. Aldosterone at concentrations found in patients with primary aldosteronism (1 nM) had only minor impact on BKCa expression. Moreover, we found that stimulated endothelial EET release was unaffected by aldosterone excess. Aldosterone likewise did not induce changes in smooth muscle cell calcium transients to 14,15 EET.
Conclusions
This first systematic investigation of the EET pathway in the context of aldosterone excess demonstrates that neither the endothelial release of nor the smooth muscle response to EETs is seemingly affected by aldosterone excess. Clinical trials aiming to increase the concentration of EETs by inhibiting their breakdown are thus very likely to be effective. We also disentangle the relationship between mineralo- and glucocorticoids on BKCa channel expression. These findings have potential implications for conditions of endogenous or iatrogenic glucocorticoid excess as well as glucocorticoid co-secretion in primary aldosteronism.

Introduction
Differences in the prevalence and prognosis of cardiovascular disease have been linked with gender specific risk factors as well as the differential impact of sex hormones. Moreover, specific genetic polymorphisms may increase further the risk of cardiovascular disease development. Polymorphisms of genes encoding the NADPH/NADPH oxidase system and the endothelial nitric oxide synthase (eNOS) have been associated with atherosclerosis in the general population, but their significance in reproductively active women remains underexplored. We aimed to investigate the potential association between the C242T polymorphism of the CYBA gene and the G894T polymorphism of the NOS3 gene with the development of subclinical atherosclerosis in young women.
Methods
This cross-sectional study recruited a total of 70 healthy, normally ovulating, reproductively active women. Fasting venous blood samples were obtained for genotyping, using real-time PCR, as well as for hormonal and biochemical assessment. Sonographically assessed indices of vascular structure and function included carotid and femoral intima-media thickness (IMT), flow-mediated dilation (FMD) and carotid-femoral pulse-wave velocity (PWV).
Results
The prevalence of genotypes was as follows: for the C242T polymorphism, wild type in 38.6% (27/70), heterozygote in 31.4% (22/70), and homozygote in 30.0% (21/70); for the G894T polymorphism, wild type in 44.3% (31/70), heterozygote in 54.3% (38/70), and homozygote in 1.4% (1/70). Presence of the heterozygous genotype of the C242T polymorphism associated significantly with internal carotid IMT (b-coefficient=−0.119, $P=0.011$) and combined-IMT (b-coefficient=−0.061, $P=0.015$), after adjustment for traditional risk factors in the multivariable analysis. Values of FMD were associated with systolic blood pressure, lipids and the presence of the heterozygous C242T polymorphism (FMD, b-coefficient −1.604, $P=0.034$). In the univariate analysis, carriers of the G894T NOS3 polymorphic variant had had higher values of IMT and PWV compared to the wild-type subgroup (carotid bulb-IMT and PWV, heterozygotes/homozygotes vs wild type 0.7±0.2 vs 0.6±0.1 mm; 7.1±0.8 vs 6.6±0.7 m/s; $P=0.048$ and $P=0.029$, respectively). These differences, however, were rendered non-significant in the multivariable analysis.
Conclusion
The CYBA C242T polymorphism is associated with subclinical atherosclerosis of the carotid arteries as well as with endothelial function, in healthy reproductively active women. The NOS3 G894T polymorphic variant also associated with indices of subclinical atherosclerosis, however this association is possibly mediated by the effect of traditional cardiovascular risk factors. The significance of these findings in the clinical setting remains to be elucidated by larger prospective studies.

AEP1004

Impact of covid-19 pandemic on psychophysical stress in patients with adrenal insufficiency: The corti-covid study

Marianna Martino, Nairus Aboud, Marco Fabio Cola, Giulia Giancola, Alessandro Ciarloni, Gianmaria Salvio & Giorgio Arnaldi
AOU UNIVPM – Ospedali Riuniti Ancona, Clinica di Endocrinologia e Malattie del Metabolismo, Ancona, Italy

Background
COVID-19 pandemic is a novel, potentially adverse condition for patients with adrenal insufficiency (AI), whose life expectancy and quality of life (QoL) are impaired due to their risk of infections and stress-triggered acute events. Therapeutic usefulness of glucocorticoids in COVID-19 is debated, but infected AI patients require prompt replacement tailoring.
Objectives
In a cohort of AI patients, to assess:
– the prevalence, manifestations and outcome of COVID-19;
– the prevalence of adrenal crises and their possible association with intercurrent COVID-19 and/or pandemic-related psychophysical stress;
– the emotional impact of the pandemic-induced social distancing;
– the self-reported QoL and health status during the lockdown.
Study design
Open-label, cross-sectional, monocentric study (University Hospital of Ancona, Italy) covering the period February-April 2020.
Patients and methods
121 patients (59 males, 55±17 years) with primary ($n=40$) and secondary ($n=81$) AI underwent a three-questionnaire telematics interview:
– purpose-built 'CORTI-COVID' questionnaire (34 items, 4 domains), assessing the latest medical history and the degree of concern (score 1–5) for COVID-19-related global health, AI-specific personal health, occupational consequences, economic impact and social implications;
– AddiQoL-30;
– Short-Form-36 Health Survey (SF-36).
Results were analyzed according to AI etiology. Demography, glucocorticoid replacement and comorbidities impacting COVID-19 prognosis were also considered.
Results
COVID-19 occurred in one (0.8% prevalence) 48-year-old woman with primary AI, who promptly adjusted glucocorticoid replacement. Dyspnea lasted 3 days, without requiring hospitalization. COVID-19 was not reported among alive secondary AI patients. No adrenal crises were experienced, but pandemic-related psychophysical stress accounted for 6/14 glucocorticoid stress doses. Mean CORTI-COVID score was similar between primary and secondary AI patients. The most influencing items were 'personal health' for the former ($P=0.881$, $P=0.000$) and 'economy' for the latter ($P=0.809$, $P=0.000$). Occupational concern was higher for patients affected by working restrictions. Demography, glucocorticoid replacement and comorbidities played no significant role. Mean AddiQoL-30 score was 131±27 and 131±25 for primary and secondary AI, respectively. Global and single-item CORTI-COVID scores were all inversely correlated with QoL. SF-36 correlated directly with AddiQoL-30, inversely with CORTI-COVID. Physical pain and general health perception were influenced by glucocorticoid dose in secondary AI. Comorbidities and, for secondary AI, gender significantly impacted both AddiQoL-30 and SF-36 scores.
Conclusions
If educational efforts are made to prevent acute events, both primary and secondary AI patients seem not at particular risk of COVID-19. CORTI-COVID is a novel, reliable questionnaire assessing the strong pandemic-related emotional burden for AI patients. Even in unconventionally stressful situations, educated patients with AI preserve a good QoL.

Adrenal insufficiency at the time of COVID-19: A retrospective study

Giulia Carosi[1,2], Valentina Morelli[1], Giulia Del Sindaco[1,3], Arianna Cremaschi[1,3], Sofia Frigerio[1,3], Giulia Rodari[1,3], Rita Indirli[1,3], Andreea Liliana Serban[1,2], Eriselda Profka[3], Roberta Mungari[1], Veronica Resi[1], Emanuela Orsi[1], Emanuele Ferrante[1], Alessia Dolci[1], Claudia Giavoli[1,3], Maura Arosio[1,3] & Giovanna Mantovani[1,3]
[1]Endocrinology Unit, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [3]Department of Clinical Sciences and Community Health, University of Milan, Italy

Background
COVID-19 represents a global health emergency and infected patients with chronic diseases often present a severe impairment. Adrenal insufficiency (AI) is supposed to be associated with an increased risk of infections which could trigger adrenal crisis. Our primary aim was to evaluate the incidence of COVID-19 symptoms and complications in AI patients.
Materials and methods
We conducted a retrospective case-control study, in 279 patients with primary and secondary AI and 112 controls. By administering a standardized questionnaire by phone, we collected data on COVID-19 suggestive symptoms and consequences. As symptoms we included fever, cough, myalgia, fatigue, dyspnea, gastrointestinal symptoms, conjunctivitis, anosmia, ageusia, upper respiratory tracts symptoms, thoracic pain, headaches and otalgia. Controls were represented by patients with benign pituitary non-functioning lesions, without hormonal alterations. All patients were on active follow-up and lived in Lombardy, one of the most affected territory. All AI patients had been previously trained to modify their replacement therapy on stress doses.
Results
AI and controls' characteristics (age, sex distribution, smoking and working habit) were comparable. In February-April 2020, the prevalence of symptomatic patients (complaining at least one symptom of viral infection) was similar between the two groups (24% in AI and 22.3% in controls, $P=0.788$). Highly suggestive COVID-19 symptoms (at least two including fever and/or cough) also occurred equally in AI and controls (12.5% in both groups). No patient required hospitalization and no adrenal crisis was reported. In about 30% of symptomatic AI patients, replacement therapy was correctly increased. Few nasopharyngeal swabs were performed ($n=12$) as indicated by sanitary regulations, limiting conclusions on the exact infection rate (positive result in 0.7% of AI patients and 0% of controls, $P=0.515$).

Conclusion
AI patients who are adequately treated and trained, seem to display the same incidence of COVID-19 suggestive symptoms and disease severity as controls.

Variable mineralocorticoid function in autoimmune Addison's disease – a case report

Jonas De Rop, David Unuane & Brigitte Velkeniers
UZ Brussel, Endocrinology, Brussels, Belgium

Autoimmune Addison's disease (AAD) is widely believed to be associated with total loss of endogenous mineralocorticoid and glucocorticoid production and secretion, due to cell-mediated immune destruction. Therefore, patients with AAD are prescribed lifelong mineralocorticoid and glucocorticoid replacement therapy. We present a case of a 69 year old women known with polyglandular autoimmune disease type 2 (hypothyroidism, Addison's disease and premature ovarian failure) diagnosed 30 years ago, who required full replacement therapy with glucocorticoids, while mineralocorticoid replacement could be withheld. Several times through the disease course, replacement therapy with low dose synthetic mineralocorticoid was initiated, but had to be withdrawn due to development of hypertension, hypokalaemia and marked oedema of the lower limbs. Blood samples showed residual aldosterone secretion, albeit with high renin levels. After interruption of fludrocortisone acetate, she had persistent normal blood pressure, sodium levels and high normal potassium levels. She was recently admitted for a first severe Addison crisis due to SARS-CoV-2 infection. The patient presented with marked hyperkalaemia and low sodium levels, reacting quickly to stress glucocorticoid replacement therapy. Under three times 20 mg of hydrocortisone daily, aldosterone was not measurable and plasma renin increased to 62 ng/l (normal values: 0.1–16.1 ng/l), indicating variable residual mineralocorticoid secretion. This case highlights the possible variability among patients with AAD in residual adrenal function, questioning the dogma of total loss of function currently accepted in endocrinology. Indeed, a recent study shows variable residual mineralocorticoid and glucocorticoids levels in blood of patients with AAD. In some case reports the documentation of residual or recovered glucocorticoid secretion lead to the tapering or withdrawal of hydrocortisone substitution therapy. To the best of our knowledge, this has not been documented for mineralocorticoid substitution therapy. The clinical significance and impact of measurable steroid production by the adrenal glands on treatment remains ill defined. It does not preclude Addison crisis, as illustrated in the present case report. Regular re-assessment of adrenal function should be performed in patient with AAD, in particular in the presence of symptoms of over substation in order to identify cases that can benefit from temporary decrease of glucocorticoid or mineralocorticoid substitution therapy. Even in this setting patient should be educated to adapt or recover treatment in stress situations to avoid Addison crisis.

Testosterone levels were independently associated to sub-clinical atherosclerosis in men with chronic spinal cord injury

Settimio D'Andrea, Chiara Castellini, Maria Totaro, Antonio Parisi, Felice Francavilla, Sandro Francavilla & Arcangelo Barbonetti
Università degli Studi dell'Aquila, Dipartimento di Medicina clinica, sanità pubblica, scienze della vita e dell'ambiente, Coppito, Italy

Background
Men suffering from spinal cord injury (SCI) were at increased risk for cardiovascular diseases (CVD). SCI subjects showed an higher value of carotid intima media thickness (cIMT) at ultrasound, a surrogate markers of sub-clinical atherosclerosis. Furthermore, SCI men exhibited an higher prevalence of androgen deficiency compared to general population.
Objectives
To investigate the relationship between total testosterone (TT) levels and cIMT in men with chronic SCI.
Materials and methods
In this observational and cross-sectional study, cIMT of 60 men with chronic (> 1 years) SCI, aged 56.0 (25th–75th: 46.0–67.2) years, was evaluated with neck ultrasonography. All patients underwent a complete neurological exam, as well as biochemical and hormonal assessment. Comorbidity was scored by Charlson comorbidity index (CCI). Physical activity was assessed by self-administered tool leisure time physical activity (LTPA).
Results
At linear univariate regression analysis cIMT waspositively associated with age (β=0.09, 95% CI : 0.04, –0.15; P=0.008), calculated LDL cholesterol level (β=0.09, 95% CI : 0.03, 0.14; P=0.003) and HOMA-index (β=0.03, 95% CI : 0.001, 0.06; P=0.04). An inverse association were found between cIMT and TT serum levels (β=–0.04, 95% CI : –0.06, –0.15; P=0.001). Multivariate regression analysis, with variables identified at previous analysis, demonstrated that only TT levels were independently associatedto cIMT(β=–0.03, 95% CI : –0.04, –0.009; P=0.009). SCI men with androgen deficiency (TT < 303 ng/dl) showed an higher value of the cIMT (0.15; 25–75th : 0.12–0.24) compared to SCI men with normal androgen status (0.12, 25–75th :0.09, 0.16; P=0.03). In our group, an inverse correlation was found between TT and cIMT (r=–0.52; P=0.003).
Discussion
The relationship between androgen levels and CVD is still debated in the general population. Although, weak evidence suggested that hypogonadal able-walking men were at increased risk to develop CVD, less is known about potential putative association between endogenous testosterone and cardiovascular risk in SCI patients.
Conclusion
Lower TT levels were independently associated to higher burden of cIMT in male suffering from chronic spinal cord injury.

The association between systolic blood pressure reduction during clonidine suppression testing and the decrease in plasma catecholamines and metanephrines

Tiran Golani[1,2], Boris Fishman[1], Yehonatan Sharabi[1], Yael Olswang-Kutz[3], Avshalom Leibowitz[1], Ehud Grossman[1] & Gadi Shlomai[1,2,4]
[1]The Chaim Sheba Medical Center, Internal Medicine D and Hypertension unit, Tel Hashomer, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel; [3]The Chaim Sheba Medical Center, The Metabolic Lab, Tel Hashomer, Israel; [4]The Chaim Sheba Medical Center, Institute of Endocrinology, Diabetes and Metabolism, Tel Hashomer, Israel

Background
Borderline isolatednorepinephrine (NE) and normetanephrine (NMT) elevation is common among patients with suspected pheochromocytoma and paraganglioma (PPGL). The clonidine suppression test (CST) may help establish the etiology in these cases. Prolonged laboratory processing and/or paucity of reliable biochemical assaysmay limit the utility of CST. The aim of this study was to evaluate whether blood pressure (BP) reduction during CST is associated with alterations in plasma NMT/NE, thereby potentially providing an immediate indicationof CST results.
Methods
A cross sectional study, including all consecutive patients with suspected PPGL who underwent CST from 1st January 2014 to 31st December 2019. Linear regression models were conducted to evaluate the association between BP reduction and decrease in plasma NMT/NE.
Results
The final analysis included 36 patients (17 males). The decrease in Systolic BP (SBP) 90 minutes post clonidine was associated with a decrease inplasma NMT (R=0.668, P=0.025) and NE (R=0.562, P=0.005). A 40% decrease in NMT and NE correlated with a 9.74% and 7.16% decrease in SBP, respectively. Subgroup analyses demonstratedthat the association between SBP reductionand the decrease in plasma NMT (R=0.764, P=0.046) and NE (R=0.714, P=0.003) strengthens among patients with hypertension and among those with diabetes mellitus (R=0.974, P=0.026 for NMT).
Conclusions
SBP reduction during CST is associated with plasma NMT and NE decrease. Therefore, the decrease in SBP90 minutes post clonidine mayserve as an immediate complementary clinical tool for PPGLdiagnosis.

AEP1009

Assessment of the awareness of cancer screening in patients with diabetes mellitus

Cigdem ozkan
Izmir Bozyaka Training and Education Hospital, Endocrinology, Izmır, Turkey

Objective
Cancer is an important public health problem. Cancer screening is effective method in fight against cancer. In addition to an increased risk for cancer incidence there is some evidence in the literature reporting that patients with diabetes have a lower rate of cancer screening and survival than non-diabetic patients. In this study, we aimed to assess the awareness of cancer screening programmes in diabetic patients who admitted to our outpatient clinic.
Materials and methods
This study was carried out using a questionnaire method as a cross-sectional case-controlled study to question cancer screening awareness in patients diagnosed with diabetes who admitted to the our outpatient clinic between September 2019 and February 2020. A poll including questions regarding age, gender, educational status, smoking/ alcohol use and whether they underwent any cancer screening programme was conducted to the patients who accepted to take part in the study.
Results
83 patients participated in this study. Sixty-seven (68.6%) of 83 patientswere female,16 (31.8%) of them were male. Among all patients, the proportion of patients who had all the recommended cancer screenings appropriate for their age was determined to be 3.3%. The average age of male patients was 57. And, the rates of male patients who underwent PSA measurement, colonoscopy, fecal occult blood test were 50.0%, 25.0% and 37.5%, respectively. The average age of women was 55. It was found that women diagnosed with diabetes complied the least with HPV testing, and the most with breast examinations, mammography and breast ultrasound. The rates of female patients who underwentHPV testing, colonoscopy, fecal occult blood testing, pap-smear, mammography /breast ultrasound and breast examination were 9.1%, 29.9%, 34.3%, 65.7%, 70.1% and 70.1%, respectively.
Conclusions
In our study, it was observed that the rates of participation in cancer screening in patients with diabetes were low. It is noteworthy that despite frequent admissions of diabetic patients to hospitals for routine controls, the rates of participation in cancer screening programmes are low. Informing diabetic patients about cancer screening programmes and encouraging them to undertake necessary screening tests during their controls may be effective in terms of early diagnosis and treatment modalities.

Clinical presentation variations of pheochromocytomas

Sofia Maria Lider Burciulescu, Monica Livia Gheorghiu, Andreea Bojoga & Corin Badiu
C.I. Parhon National Institute of Endocrinology, București, Romania

Introduction
Pheochromocytoma (PCC) has a wide spectrum of clinical manifestations, from insidious disease to extreme symptoms. Various mechanisms of catecholamine and other mediators actions were related to the diversity of PCC presentation.
Aim
We describe a retrospective study, of patients with PCC from a tertiary hospital, focusing on clinical and biochemical characteristics of PCC depending on means of discovery.
Material and methods
Medical files of 67 consecutive patients diagnosed with pheochromocytoma between 1987–2018 were analysed in detail, collecting relevant clinical, hormonal and imaging data. The patients were divided in 2 groups: incidentaloma group (IG) with25 patients incidentally diagnosed with pheochromocytoma, upon imaging performed for reasons unrelated to a blood pressure abnormality or other pheochromocytoma related symptoms;symptomatic group (SG) included 42 patients diagnosed with pheochomocytoma after accusing pheochromocytoma related symptoms: arterial hypertension/hypertension paroxysms, headache, palpitation, sweating, anxiety.
Results
Mean age of diagnosis and tumor dimension were higher in incidentally discovered pheochromocytomas than in clinically suspected PCC (54.8±5.4 vs 44.0±12.2 years old respectively 5.2±2 vs 4.8±2 cm). There were no differences between gender distribution in IG, while in SG, women percentage was higher. As expected, a lower number of patients from IG had chronic hypertension (48%) or hypertension paroxysm (16%), while in SG, more than 90% of the patients reported either chronic hypertension or hypertension paroxysms. Other symptoms related to pheochromocytoma such as headache, palpitations or sweating were more intensive and more frequently reported in SG. Glicemic abnormalities were approximately equal distributed between the two groups. Arterial blood pressure normalization after surgery was reported in more patients from SG than in IG. 25 out of 31 hypertensive patients in SG had normalization of arterial blood pressure postsurgery, while 6 out of 12 hypertensive patients in IG had normal blood pressure after surgery.
Conclusion
Incidentally discovered PCCs are related to a more advanced stage of the disease (reported as higher tumor dimensions in our study) due to delayed time of the diagnosis. Incidentally discovered PCC are often asymptomatic; in half of the cases from our study, patients from IG had essential arterial hypertension rather than secondary hypertension. In case of an incidentaloma it is always required to screen for pheochromocytoma.

A case of posaconazole associated adrenal insufficiency developing in the course of acute myeloid leukemia

Ridvan Fevzi Degirmenciler[1], Gokhan Metan[2], Osman Ozcebe[3], Burcin Gonul Iremli[4] & Tomris Erbas[4]
[1]Hacettepe University Medical School, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University Medical School, Department of Infections Diseases & Clinical Microbiology, Ankara, Turkey; [3]Hacettepe University Medical School, Department of Hematology, Ankara, Turkey; [4]Hacettepe University Medical School, Department of Endocrinology & Metabolism, Ankara, Turkey

Posaconazole is a member of triazole antifungal family. It is frequently used prophylaxis and treatment in invasive fungal infections. Among the azole group antifungals, ketoconazole is well known to affect steroidogenesis through cytochrome P450 enzymes, however, posaconazole-induced adrenal insufficiency has been reported in only two cases in the literature. Here, we present our case of adrenal insufficiency induced by posaconazole.
A 54-year-old male applied to Hacettepe University Hospital with fever and weakness. The patient with anemia, leukocytosis, and thrombocytopenia was followed up with the diagnosis of standard-risk acute myeloid leukemia (AML). His history was beginning with acute retinal artery thrombosis ten years ago. The patient with JAK2V617F mutation was diagnosed with overlap of myelodysplastic syndrome/myeloproliferative neoplasm and followed up with supportive blood product replacement if necessary. Calcitriol treatment was started, who had primary hypoparathyroidism during follow-up. After four years of hypoparathyroidism, thrombosis was detected in multiple veins simultaneously with pulmonary thromboembolism and primary hypothyroidism, then hydroxyurea and levothyroxine were started. He had received posaconazole for invasive fungal infection during AML treatment. He has persistently hypoglycemia, hypothermia, hypotension18th day on posaconazole treatment. Sodium and potassium level 149 mEq/l, 3.4 mEq/l respectively, that day. We suggest that he had adrenal insufficiency, with appropriate clinical and laboratory features. After taking the tests for arterial blood gas, ACTH, cortisol, and blood culture, treatment for adrenal insufficiency was started. Cortisol 2 mg/dl, ACTH 75 pg/ml, testosterone < 13 ng/dl and DHEA-SO_4 21 mg/dl were observed in the blood sample taken at 6 PM. At the end of 12 hours, his clinical and laboratory response was dramatic. Sepsis is ruled out with this clinical and laboratory results, also no bacterial growth on the blood culture after five days. Posaconazole treatment was terminated, because it may cause adrenal insufficiency. In our patient, steroidogenesis appears to be affected as a whole under posaconazole treatment. He used steroid therapy for 45 days. His complaints did not recur during steroid dose reduction and after discontinuation of therapy. Together with the abdominal MRI and CT scans, which shows that adrenals were completely normal,and extensive iron accumulation on the liver, and we defined our patient as posaconazole-induced adrenal insufficiency on the background of hemochromatosis. We think that with the increase in prophylactic use of posaconazole, similar cases will increase. With the third case we present in the literature, clinicians should be careful in terms of adrenal insufficiency developed due to posaconazole use.

Subclinical atherosclerosis is associated with anti-mullerian hormone levels in reproductively women

Eleni Armeni[1], Stefanos Stergiotis[1], Panagiota Chatzivasileiou[1], Areti Augoulea[1], Panagiotis Anagnostis[2], Demetrios Rizos[3], George Kaparos[3], Andreas Alexandrou[1], Georgios Georgiopoulos[4], Christos Kontogiannis[4], Kimon Stamatelopoulos[4] & Irene Lambrinoudaki[1]
[1]National and Kapodistrian University of Athens, 2nd Department of Obstetrics and Gynaecology, Aretaieio Hospital, Athens, Greece; [2]Aristotele University of Thessaloniki, Thessaloniki, Greece; [3]National and Kapodistrian University of Athens, Hormonal and Biochemical Laboratory, Athens, Greece; [4]National and Kapodistrian University of Athens, Department of Therapeutics, Vascular Laboratory, Alexandra Hospital, Athens, Greece

Introduction
The prevalence of cardiovascular disease in reproductively active women has received limited attention. Recent data indicated possible adverse effect of non-typical obstetrical risk factors with regards to cardiovascular function. We aimed to evaluate the potential association between anti-mullerian hormone (AMH), a known marker of ovarian reserve, with subclinical atherosclerosis in young premenopausal women.
Methods
This was a cross-sectional study, comprising of 70 premenopausal women, aged 32.7 ± 6.5 years. Fasting blood samples were obtained to assess serum AMH levels as well as the lipid profile. Vascular studies were performed in one session and included indices of vascular structure (e.g. carotid and femoral intima media thickness, IMT) as well as vascular function (e.g. flow-mediated dilation; carotid-femoral pulse wave velocity, PWV).
Results
Serum levels of total cholesterol associated negatively with AMH concentrations. Moreover, smokers had lower levels of AMH when compared with non-smokers. Mean AMH levels associated inversely with carotid and femoral IMT values, in all of the assessed segments. The association between AMH concentrations and combined carotid IMT or carotid bulb IMT remained significant, even after multivariable adjustment for various established cardiovascular risk factors. No correlation was identified between AMH levels and indices of functional vascular disease or other markers of cardiovascular disease.
Conclusion
AMH levels are negatively and independently associated with indices of subclinical atherosclerosis as well as serum levels of total cholesterol, in this sample of young, health, normally ovulating women.

A composite pheochromocytoma inneurofibromatosis type 1: A case report

Loukil Fatma[1], Pinto Sara[2], Tatulashivili Sopio[3], Carlier Lea[4] & Bihan Helène[3]
[1]Hopital Jean Verdier, Endocrinologie, Paris, France; [2]Jean-Verdier Hospital Ap-Hp, Endocrinologie, Bondy, France; [3]Avicenne Hospital (Ap-Hp), Endocrinologie, Bobigny, France; [4]Jean-Verdier Hospital Ap-Hp, Endocrinologie, Bondy, France

Introduction
The composite pheochromocytoma is a rare adrenal medullatumour that combines a pheochromocytome and a neuroblastic tumour. We present the case of a composite phenochromocytoma discovered in a patient with neurofibromatosis type 1.
Case report
Patient aged 64 years referred to our department by his dermatologist for the exploration of a left adrenal mass discovered during the practice of a CT scan and then an 18F-FDG MRImade as part of an exploration of his neurofibromatosis. The patient hada high blood pressure and neurofibromatosis type 1 for which he is followed since 1995 The radiological characteristics at the 18F-FDG MRIwas in favor of a moderately hyper-metabolic formation fixing to SUV max 3.1 of the left adrenal of 18 × 12 mm and then the Adrenal-centered scanner was in favor of a left adrenal nodule that has a spontaneous density, an absolute and relative wash against the diagnosis of adenoma. In biology we noticed a slight rise in urinary and plasma metadrenaline on two successive samples. The patient was operated (left adrenalectomy) because we consideredthe mass as a pheochromocytoma. He had simple surgical suites with the need to stop antihypertensive treatment. Anatomopathological examination was in favour of a composite phenochromocytoma with a ganglioneuroma with no sign of malignancy
Discussion
The largest series of composite pheochromocytoma studied was published by Gupta *et al.*, it included a single case of neurofibromatosis, the mean age atdiagnosis was 67years,and the average size was 5.2 cm. The majority were functionnaly activewith a moderate elevation of catecholamines. This published case is similar to our patient in clinical and biological characteristics.
Conclusion
Pheochromocytoma, as part of a neurofibromatosis, would have more specific characteristics that need to be better studied in order to refine the management of this chronic disease.

Control of hypercorticism during paraneoplastic Cushing's syndrome secondary to atypical carcinoid tumor of the lung (about one case)

Mouna Mezoued & Said Azzoug
Algeria, Endocrinology, Algiers, Algeria

Te paraneoplastic Cushing's syndrome represents 9 to 18% of ACTH-dependent endogenous hypercorticisms; which poses, in clinical practice, two types of problems:
– on the one hand, the differential diagnosis with Cushing's disease, when well differentiated and morphologically undetectable endocrine tumors are involved.
– on the other hand, the control of hypercortism, most often major in metastatic neuroendocrine tumors, which can in itself compromise the vital prognosis.
This is the case of our young patient, aged 26 years, who presents a Cushing's syndrome of rapid onset (after 4 months), marked by the intensity of the signs of hyperandrogenism with a severe hypokalemia of the order of 1.8 mEq/l, complicated by diabetes mellitus, hypertension and psychosis. Basal endocrine (ACTH: 905 pg/l, plasma cortisol: 2589 nmol/l) and pharmacodynamic (non-blocking with Dexamethasone) exploration, as well as non-visualization of a pituitary adenoma on hypothalamic-pituitary MRI, led us to favorize the diagnostic of hypercorticism by ectopic tumor secretion of ACTH. Thoracic CT scan found a right middle lobar lung tumor; an anapathological study of the bronchial biopsy, performed under bronchoscopy, revealed an atypical carcinoid tumor of the lung with mediastinal lymph node invasion. During the etiological investigation, and in view of the significant hypercorticism, anti-cortisol therapy was instituted, namely: LYSODREN* 2 gr/day per os, FLUCONAZOLE* 600 mg/day in IV, SANDOSTATINE* 400 mg/day subcutaneously, with weekly control of the renal, hepatic and lipid balance sheet. This therapy allowed a reduction of cortisol to more than 40% (1524 nmol/l) at D15 of treatment, allowing a normalization of hypokalemia resulting clinically in an attenuation of the signs of hyper androgenism and psychosis. The study of this case illustrates the characteristics of a paraneoplastic Cushing's syndrome indicative of a carcinoid lung tumor, and the usefulness of anti-cortisol therapy in the control of hypercorticism pending etiologic treatment.

AEP1015

Primary adrenal insufficiency secondary to COVID-19 infection: A case report

Mariana Gomes Porras, Rosa García Moreno, Myriam Zapatero Larrauri, Patricia Martin Rojas & Paola Parra Ramírez
La Paz University Hospital, Endocrinology and Nutrition, Madrid, Spain

Introduction
Bilateral adrenal hemorrhage (BAH) is a rare clinical condition (estimated incidence between 0.14% –1.8%, according to postmortem studies) and life-threatening due to the development of adrenal crisis, after the destruction of 90% of each adrenal gland. A mortality rate of 15% has been reported despite treatment, but it depends on the severity of the underlying condition, reaching 90% in cases of sepsis, or even higher if it is not diagnosed quickly enough. Bilateral forms are common attributed to spasm or thrombosis of the adrenal vein. The main nontraumatic causes include

stressful situations, such as surgery, severe burns, or sepsis, bleeding diathesis (thrombocytopenia, anticoagulants therapies, especially in the setting of heparin-induced thrombocytopenia), thromboembolic disease (included antiphospholipid syndrome), adrenocorticotropic hormone (ACTH) hyperstimulation, and adrenal gland tumors, especially pheochromocytoma. The clinical suspicion of BAH is difficult because the clinical presentation is unspecific.
Case report
A 70-year-old man, with a medical history of prediabetes, went to the emergency department for presenting fever, asthenia, abdominal pain and cutaneomucosal hyperpigmentation for 15 days. Subsequently, he presented nausea, drowsiness and hemodynamic instability. The analysis reported lymphopenia, hyponatremia, hyperkalemia, elevated fibrinogen, PCR, ferritin, liver enzymes, LDH, D-dimer, and troponin-I. The cultures (blood and urine), conventional serologies and antiphospholipid antibodies were negative and the serology (IgM and IgG) for SARS-CoV-2 was positive. Imaging studies confirmed bilateral pneumonia, paralytic ileus and bilateral adrenal hemorrhage. He received hydroxychloroquine, azithromycin, thromboprophylaxis, intravenous fluid therapy, and hydrocortisone at stress doses. He was discharged at 7 days with hydrocortisone (20 mg/day) and fludrocortisone (0.1 mg/day).
Discussion
COVID-19 is a progressive endothelial thromboinflammatory syndrome, caused by the direct effects (cytokine storm, complement activation, extensive vascular deposition of C4d, C5b-9, MASP2 and fibrin) and the indirect effects of the infection (hypoxia, immobilization).Therefore, it is capable of causing vascular congestion and/or thrombosis of the adrenal vein, with the consequent increase in intraglandular pressure, collapse and adrenal bleeding.
Conclusion
There must be a high clinical suspicion of primary adrenal insufficiency in case of COVID-19 infection with abdominal pain, especially if it associates arterial hypotension refractory to fluid therapy, hyponatremia and hyperkalemia. Abdominal CT scan plays a crucial role in the confirmation diagnosis of BAH. If possible, ACTH and cortisol levels should be measured prior to corticosteroid therapy, without in any case delaying its administration. Replacement corticosteroid therapy should be started quickly.

AEP1016

Clinical and hormonal features of the manifestation of various forms of congenital adrenal hyperplasia in children

Ekaterina Rudkova & Anzhalika Solntsava
Belarusian State Medical University, Pediatric, Minsk, Belarus

Medical History of thirty five patients aged from one to sixteen years diagnosed with CAH have been analyzed in the Republican Center for Pediatric Endocrinology. Among the thirty five patients participating in the study (boys–fifty seven percent, girls –forty-three) seventy-one percent is with salt wasting form (SWF), twenty-two percent with virilising form (VF), three percent with non-classical form (NF). The mean weight SDS at birth is minus eight hundredths ± one point seventeen, the mean height SDS is twelvehundredths ± one point six. Age of diagnosis SWF is seventeen point four ± sixteen point three days, VF is one point three hundredths ± four point six years. The most frequent signs of manifestation in SWF were regurgitation, body weight loss, vomiting, dry skin, hypotension, exicosis; in VF – premature pubarche. At the time of diagnosis, seventeen-hydroxyprogesterone (SOHP) was higher than normal range in all groups: SWF –eight hundredforty ± two hundred ninety-eightnmol/l, VF – three hundred eighty-six ± eighty-one nmol/l, NF –thirty-five nmol/l; increase morning values of adrenocorticotropic hormone (seventy-four ± two pg/ml). It was revealed that before treatment there were changes in electrolytes (K, Na) only in group with SWF (six point seven ± one point six mmol/l andone hundred twenty-six ± eleven mmol/l respectively). Blood glucose and pH in children with SWF were three point two ± one point forteen mmol/l and seven point three ± sixty-seven thousandths co-responsibly. All children received hydrocortisone replacement therapy at a starting dose of sixty-four ± twenty-eight mg/m^2 in SWF group; twenty-two ± twenty-one mg/square meter in VF group; twenty-one mg/m^2 in NF group. Patients with SWF additionally took fludrocortisone at a starting dose of seven hundred eighty-seven ± one hundred thirty-one mkg/square meter. Fourteen children from the total sample have reached puberty age. Height SDS is minus point four ± one point three, weight SDS one point thirteen ± one point thirty-three, BMI twenty-four point two ± three point six kg/square meter, SOHP –thirteen point fifty-six ± thirteen point forty seven nmol/l. Late diagnosis of the disease in patients was revealed regardless of the form of AH. Metabolic acidosis, hyponatremia and hyperkalemia, high level of SOHP are registered in the SWP group at the time of manifestation There were noted compensation of metabolic parameters, achievement of target growth indices, when children receive adequate replacement hormonal therapy.

AEP1017

Clinical aging manifestations of cortisol secreting adrenal adenoma

Gulrukh Alimoukhamedova & Zamira Khalimova
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

The objective was to study clinical aging peculiarities of manifestation period of cortisol secreting adrenal adenoma.
Materials and methods
Forty five patients with cortisol-secreting adrenal adenoma served the basis for the study. In that group of patients there were 11 (24.4%) men and 34 (75.6%) women, with the average age 27.5 ± 10.5 years old. Out of forty five patients 5 (11.2%) were children. All patients had common clinical, biochemical, hormonal, and instrumental tests.
Results
Cortisol-secreting adenoma were observed in young age from 18 to 44 years old (84.4%; $\chi^2 = 40.0$; $P < 0.0001$); according to gender distribution it was more often observed in women, than in men (75.6% vs 24.4% respectively). among children and people above 44 these tumors were registered less often, in 5 (11.2%) and 2 (4.4%) cases, respectively. Only 11 (24.4%) patients were diagnosed within one years from the start of the disease, 26 (57.8%) patients needed from 1 to 5 years for the diagnosis, and 6 (13.3%) patients were correctly diagnosed in 5–10 years, and that, certainly affected the results of treatment. Finally, two (4.4%) patients spent more than 10 years before they were diagnosed. The most characteristic manifestation of cortisol-secreting adenoma was arterial hypertension (AH) observed in 18 (40%) patients. Average age of the patients in manifestation period of AH was 25.3 ± 10.2 years old. We observed positive direct correlation between the age at the moment of AH debut and systolic AP ($r = 0.35$; $P = 0.03$). Sexual dysfunctions (10–22.2%) and weight gaining (13–28.9%) had similar prevalence at the debut of the disease. Less often the pathology started with stomachache and changes in appearance. In one case cortisol-secreting adenoma diagnosis was established when patient with acute disorder of cerebral circulation was checked after long-term neuropathologist's treatment of hypertonic disease. In the majority of cases when children suffered the disease its manifestations were non-specific, and displayed in weight gaining (100%), physical and mental retardation (60%), leading to the choice of observational strategy and absence of duly diagnostics and treatment.
Conclusion
Great number and variability of early clinical manifestations of cortisol-secreting adenoma cause difficulties in diagnostics reflected in the long duration of the disease, in other words time from appearance of initial symptoms till correct diagnosis. In children the basic symptom in manifestation of cortisol-secreting adenoma is gaining weight with no growth, which should urge pediatricians to perform targeted search for the disease.

AEP1018

18 Flour-Cholin-PET-CTis the supreme tool to localize ultrasound and mibi-'negative' parathyroid adenomas – intraoperative correlation and 12 month postoperative results

Constantin Smaxwil[1], Aschoff Philipp[2], Busch Mirjam[1], Wagner Joachim[1], Altmeier Julia[1], Ploner Oswald[3] & Zielke Andreas[1]
[1]Stuttgart, Endocrine Surgery Diakonieklinikum, Stuttgart, Germany; [2]Stuttgart, Nuklearmedizin, Diakonieklinikum, Stuttgart, Germany; [3]Endokrinologie, Diakonieklinikum Stuttgart, Stuttgart, Germany

Background
To characterize the diagnostic performance of 18-Fluoroethylcholine-PET-CT (FCH-PET-CT) to localize parathyroid adenomas (PA) in primary hyperparathyroidism (pHPT) when ultrasound (US) and MIBI-Scan (MibiS) fail to localize – intraoperative correlation and one-year follow up.

Method
Beginning in 07/2017 18-FCH-PET was employed in patients with proven pHPT in whom US and MS delivered either incongruent or negative findings. All patients were offered cervical explorations with intraoperative PTH-monitoring (IO-PTH) and subjected to followed up for 12 months postoperatively.
Results
From 07/2017 to 05/2020 432 patients were operated for pHPT (17 redo-for-HPT, 62 with prior surgery to the neck). During this period 173 FCH-Pet-CTs were performed suggesting PA(s) in 162 (94%). 134 of the 173 patients of this cohort already had their surgery, confirming FCH to have accurately localized PA(s) to the respective side of the neck in 131; to have been false neg. in 2 and false pos. in 1, for a global sensitivity of 0.98; accuracy of 0.98 and PPV of 0.99. The 12-month postoperative follow up of the first 95 patients suggested that no PA(s) were missed. One patient with reoperative surgery because of persistent HPT may develop recurrent disease 10 months after surgery.
Conclusion
FCH-PET-CT is a clinically meaningful diagnostic utility when US and MibiS fail to localize a PA. FCH-PET-CT has the potential to replace MibiS. FCH-PET-CT allowes for planned unilateral and focused as opposed to bilateral explorations in almost all of our cases. We, therefore, suggest FCH-PET-CT for the localisation of negative PA(s).

A global natural history study of Fibrodysplasia Ossificans Progressiva (FOP): 12-month outcomes

Mona Al Mukaddam[1], Robert J. Pignolo[2], Geneviève Baujat[3], Matthew A Brown[4], Carmen De Cunto[5], Maja Di Rocco[6], Edward C. Hsiao[7], Richard Keen[8], Kim-Hanh Le Quan Sang[3], Andrew Strahs[9], Rose Marino[9] & Frederick S. Kaplan[1]
[1]Departments of Orthopaedic Surgery & Medicine, The Center for Research in FOP and Related Disorders, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States; [2]Department of Medicine, Mayo Clinic, Rochester, MN, United States; [3]Département de Génétique, Institut IMAGINE and Hôpital Universitaire Necker-Enfants Malades, Paris, France; [4]Guy's & St Thomas' NHS Foundation Trust and King's College London NIHR Biomedical Research Centre, London, United Kingdom; [5]Pediatric Rheumatology Section, Department of Pediatrics, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [6]Unit of Rare Diseases, Department of Pediatrics, Giannina Gaslini Institute, Genoa, Italy; [7]Division of Endocrinology and Metabolism, UCSF Metabolic Bone Clinic, Institute of Human Genetics, and UCSF Program in Craniofacial Biology, Department of Medicine, University of California-San Francisco, San Francisco, CA, United States; [8]Centre for Metabolic Bone Disease, Royal National Orthopaedic Hospital, Stanmore, United Kingdom; [9]Ipsen, Newton, MA, United States

Background
FOP is an ultra-rare, severely disabling genetic disorder characterised by cumulative heterotopic ossification (HO), often preceded by episodic flare-ups, leading to physical disability and early death. Initial misdiagnosis can occur in ~90% of individuals leading to unnecessary, often harmful interventions. FOP is diagnosed and managed by multiple specialists, including endocrinologists.
Objective
A prospective, 36-month, global natural history study (NCT02322255) was designed to investigate progression of FOP, HO, and impact on physical function. Results are described for the first 12 months.
Methods
Individuals with FOP aged ≤65 years with documented *ACVR1*^{R206H}mutation were eligible. HO volume was assessed by low-dose whole-body computed tomography (WBCT; excluding the head) interpreted at a blinded, central laboratory using pre-specified procedures. Physical function was evaluated using the Cumulative Analogue Joint Involvement Scale (CAJIS; total score 0–30 represents degree of ankylosis across 15 joints) and the FOP-Physical Function Questionnaire (FOP-PFQ; % total score); higher scores indicate more severe limitations. Changes from Baseline in HO volume, CAJIS and FOP-PFQ at Month 12 were evaluated.
Results
Of 114 participants with Baseline data, 99 (aged 4–56 years at enrolment, mean 17 years; 56% male) had a Month 12 assessment and 93 had evaluable WBCT HO data at Baseline and Month 12. Over 12 months, 40% (37/93) developed new HO and 48% (48/99) reported ≥1 flare-up. Of participants with new HO, 65% (24/37) reported≥1 flare-up (mean 2.3 flare-ups/year) and 35% (13/37) reported no flare-up. Of participants with no new HO, 43% (24/56) reported≥1 flare-up (mean 1.8 flare-ups/year). Among all participants, mean new HO volume in those who reported flare-ups was 39.718 mm^3 (SD: 91.969 mm^3; n=48) vs 5.081 mm^3 (S.D.: 14.582 mm^3; n=45) in those who did not. Mean changes from Baseline in CAJIS and FOP-PFQ were minimal (CAJIS: 0.6 [S.D.: 2.4; median: 1.0; n=99]; FOP-PFQ: 4.4% [S.D.: 11.2%; median: 3.7%; n=90]) and similar across participants with or without new HO.
Conclusions
In participants with FOP, WBCT HO volume increased over 12 months. Among those who experienced new HO, this was not preceded by a flare-up in over one third of cases. Among all participants, mean new HO volume in those who reported flare-ups was ~ 8 times higher than in those who did not. CAJIS and FOPPFQ were not sufficiently sensitive to assess disease progression over 12 months. Measuring HO may be a viable way to monitor changes in FOP over short periods of time.

Elastographic techniques in localizing parathyroid adenomas

Laura Cotoi, daniela-georgiana amzar, Borlea Andreea, Cristina Cepeha & Stoian Dana
Victor Babeş University of Medicine and Pharmacy, Endocrinology, Timişoara, Romania

Introduction
Primary hyperparathyroidism (PHPT) is the third most frequent endocrinopathy, after type 2 diabetes mellitus and thyroid disease. It is most commonly caused by an overactive parathyroid gland resulting in high serum parathormone (PTH) concentrations and consequent high serum calcium concentrations. PHPT is nowadays commonly asymptomatic, with high prevalence among postmenopausal women (female – male ration 3–4:1).
Materials and methods
We evaluated 20 consecutive patients diagnosed with primary hyperparathyroidism, from October 2018 to June 2019. All cases presented solitary parathyroid adenoma werecertified by pathology report after surgery (parathyroid adenoma excision). Pacients were evaluated clinically, biochemically and by ultrasound: 2 B ultrasound, Power Doppler, shear wave elastography with computer assisted quantitative measurement of tissue elasticity with high accuracy linear probe on Supersonic Aixplorer machine and strain elastography using Hitachi Preirus (Hitachi Medical Corporation, Tokyo, Japan) machine.
Results
We evaluated 20 consecutive patients (male to female ratio 1:19) with mean age of 57.3±13.33, mostly postmenopausal women with confirmed primary hyperparathyroidism. The parathyroid adenoma tissue was compared with the normal thyroid tissue and the surrounding muscle tissue. Using SWE elastography, we found that the mean SWE value for parathyroid adenoma is 4.74±2.745 kPa, compared to mean SWE of thyroid tissue 11.718±4.206 kPa, respectively muscle tissue 16.362±3.829 kPa. Parathyroid adenoma tissue was also evaluated with strain elastography with color maps (qualitative) and with strain ratio (semi-quantitave data). The initial qualitative analysis, found 15 out of 20 cases with score 1 on color map evaluation, according to Rago criteria. Semi-quantitative analysis using strain elastography, found a strain ratio of 1.46±1.45 for parathyroid/thyroid pair and 1.79±0.90 for parathyroid/muscle. Comparing the two elastographic methods, we have found that shear wave elastography method has a higher sensitivity and specificity, if parathyroid adenoma is compared with thyroid tissueor surrounding muscle – AUC curve 0.70, 95% CI [0.544; 0.876], compared with the specificity and sensitivity of strain elastography – AUC curve 0.646, 95% CI [0.442; 0.850].
Conclusion
To conclude, the aim of this prospective study was to quantify the value of strain elastography and 2D shear wave elastography in localizing parathyroid pathology. Although strain elastography can be a useful qualitative tool by using color mapping, 2D-SWE elastography can offer a better differentiation on tissue elasticity when diagnosing parathyroid adenomas. By using this elastographic technique, a value less than 7 kPa for mean elasticity index is suggestive for parathyroid adenoma.

Association of osteoprotegerin 1181G>C and 245T>G polymorphisms and diabetic Charcot osteoarthropathy in Egyptian patients

Basma Zakaria[1], Hanan Gawish[1], Reham Elfarahaty[2] & Manal Tarshoby[1]
[1]Mansoura University, Internal Medicine-Diabetes and Endocrinology Department, Mansoura, Egypt; [2]Mansoura University, Clinical Pathology Department, Mansoura, Egypt

Aim
Egypt is among the world's top 10 countries in terms of the highest number of people with diabetes. Charcot foot is a serious complication that affect bones, joints, and soft tissues of the foot or ankle. Although the etiology is linked to different inflammatory markers, yet not clear. Recently, an association between two polymorphisms (1181G>C and 245T>G) of the osteoprotegerin (OPG) gene and Charcot was suggested. The aim of this study was to explore polymorphisms in the OPG gene and their possible contribution to the genetic susceptibility to Charcot neuro- osteoarthropathy (CNO) in Egyptian diabetic patients.
Methods
In this case-control study, in addition to history and clinical examination, Neuropathy was assessed by Neuropathy Symptom Score (NSS) and Neuropathy Disability score (NDS). MRI was done to acute charcot patients only to confirm the diagnosis. DNA was isolated OPG gene polymorphisms from 50 consecutive patients presented with CNO in addition to another 50 patients with diabetic neuropathy without CNO. A matched 50 healthy group of persons were also tested as control group. The collected data was revised, coded and tabulated using SPSS Statistics for Windows, Version 20.0. Armonk, NY: IBM Corp. Data were presented and suitable analysis was done according to the type of data obtained for each parameter. Logistic regression analyses was used for prediction of risk factors.
Results
It was found that rs2073618 gene, C allele is significantly associated with lower frequency in charcot group i.e. seems to have protective effect against CNO development. While the rs3134069 has shown no significant association in genotypes, alleles frequencies between diabetic cases with and without charcot groups.
Conclusion
The OPG gene polymorphisms seems to play a role in protection of diabetic Charcot neuro-osteoarthropathy in Egyptian diabetic patients. This was clear fromrs2073618 gene, C allele which proved to be associated with lower frequency of CNO.

Background and aim
Obesity (Ob) is tightly associated with metabolic diseases such as type 2 diabetes (DT2) andinsulin resistance (IR). Furthermore, obesity has been identified as one of the primary causes of mood disorders (MDs) including depression. Several studies have demonstrated the link between Ob, adiposity, neuroinflammation and MDs. The Brain-Derived Neurotrophic Factor (BDNF) and its regulator, the non-coding RNA BDNF antisense RNA (*BDNFas)*, play an important role on the depression pathophysiology and therapeutic antidepressive mechanisms. However, the relation between BDNF and BDNFas, adipose tissue (AT) functionality and Ob has not yet been well defined. Preliminary, *in silico*analysis carried out by our grouphave shown that *BDNF* and *BDNFas* are validated target genes of miR-10a, miR-210, miR-182 and miR-27b. Thus, the aim of our study was to analyze the expression of these miRNAs, *BDNF*and *BDNFas* in human AT in Ob.
Materials and methods
miR-10a, miR-182, miR-210, miR-27, *BDNF* and *BDNFas* expression levels were measured by real-time qPCR from subcutaneous (SAT) and visceral (VAT) adipose tissue of normoweight subjects (NW, $n=9$) and metabolically healthy morbid obese (MHO, $n=9$).
Results
In this study, we observed that VAT miR-10a, miR-27b and *BDNFas* expression increased significantly in metabolically healthy obese subjects compared to NW individuals, while no significant changes were observed in miR-210 or *BDNF* expression. The expression levels of miR-10a, miR-27b, miR-210, *BDNF* and *BDNFas* in SAT were also higher in obese subjects compared to NW individuals. The correlative analysis has shown that the expression of miR-182 is positively correlated with *BDNFas* expression in VAT ($r=0.492$; P •0.05) whereas miR-210 expression is positively correlated with *BDNF* expression in SAT ($r=0.5089$; P •0.05).
Conclusion
Our results uncover new putative regulatory pathways involving miR-10a, miR-210, miR-182 and miR-27b in the control of the neuroinflammatory genes *BDNF* and *BDNFas* during obesity, and pave the way for future studies on the mechanisms which link obesity and mood disorders.

Vitamin D status and its associations with clinical and laboratory parameters in patients with Addison's disease

Karolina Zawadzka[1], Katarzyna Matwiej[1], Grzegorz Sokołowski[1,2], Małgorzata Trofimiuk-Müldner[1,2], Anna Skalniak[1,2] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Jagiellonian University Medical College, Department of Endocrinology, Krakow, Poland; [2]University Hospital, Department of Endocrinology, Krakow, Poland

Introduction
The autoimmune process is currently the most common cause ofthe primary adrenal insufficiency cases in developed countries. The complexity of this process consists of genetic, immunological and environmental factors. It has been proven that vitamin D (VD) inhibits the production of inflammatory cytokines and can modulate immune-regulatory mechanisms.
Purpose
The aim of our study was to evaluate the prevalence of VD insufficiencyin patients with Addison's disease (AD), as well as to evaluate associations between vitamin D levels and the various clinical and laboratory parameters of the disease.
Methods
We retrospectively analysed medical records of 31 patients adults with the diagnosis of autoimmune Addison's disease and with measured serum VD levels. We analysed correlations between serum VD and various laboratory parameters as well as AD patients symptoms collected from structured medical interviews.
Results
90.3% of the subjects had inadequate VD level – 54.8% below 20 ng/ml and 35.5% between 20 to 30 ng/ml, respectively. Furthermore, 19.3% of patients have been found to be severely deficient in VD (<10 ng/ml). There were no significant associations of serum VD level with sex, age and smoking status.

There was a significant difference in VD level between patients previously supplementing and non-supplementing VD (23.91±3.6 vs 15.29±1.77 ng/ml, $P=0.02$). In 70% of patients who supplemented 2000 IU vitamin D prior to the admission to the hospital, supplementation did not provide adequate vitamin D level. Among various laboratory variables, only serum calcium levels significantly correlated with VD status ($r=0.53$, $P=0.006$). We observed that mean level of serum VD was significantly lower in patients with severe fatigue (15.17±8.41 vs 26.83±12.29 ng/ml, $P=0.011$) and limited exercise capacity (12.38±6.9 vs 21.63±10.87 ng/ml, $P=0.016$).No associations have been found between serum VD and other clinical features (fainting, loss of appetite, weight loss, nausea, vomiting, diarrhoea, musculoskeletal pain, abdominal pain).

Conclusion

This study demonstrates a high incidence of vitamin D deficiency and a significant correlation between low levels of VD and severe fatigue as well as limited exercise capacityin AD patients. Further studies are needed to clarify if impaired vitamin D level is a causal factor in the pathogenesis of AD andto assess if VD supplementation improves the quality of life of the AD patients.

Severe hypercalcemia in infants, a report of three cases

Raoudha Kebaili[1,2], Jaballah Nesrine[1], Samia Tilouche[1,2] & Lamia Boughamoura[1,2]

[1]University Hospital Farhat Hached; [2]Ibn El Jazzar Medical Faculty of Sousse

Introduction

Hypercalcemia in newborns and infants is often iatrogenic. Clinical signs are correlated with the degree of hypercalcemia and can lead to sever complications through dehydration, neurological disorders, convulsions and cardiac rythm disorders. The objective of our work is to study the clinical, biological, etiological and therapeutic aspects of hypercalcemia in infants.

Material and methods

Retrospective study on 3 patients hospitalized in our department in which we discovered hypercalcemia defined by a total calcemia > 2.7 mmol/l.

Results

We studied the cases of two girls and one boy. The average age at diagnosis was 3 months (40 days-6 months). The circumstances of discovery were: severe vomiting (1 case), weight loss (2 cases), polyuria with dehydration stage 3 (2 cases). Neurological disorders with hyporeactivity and irritability were objectified in all the patients. The ECG was normal in all cases. The mean blood calcium level was 3.84 mmol/l (3.2–5 mmol/l). Functional renal failure as well as recurrent and deep hypokalemia were found in the 3 cases. Stage II nephrocalcinosis was found in all 3 cases. The etiologies selected were: hypersensitivity to vitamin D in 2 cases (following a single dose of 200 000 IU of vitamin D), and vitamin intoxication in a case where the parents administered by mistake an excessive dose of vitamin D. The treatment consisted in an intravenous hyperhydration with the stop of the intake of vitamin D and calcium, furosemide (3 cases), corticotherapy (1 case), 3 courses of Pamidronate (1 case) and a cure of zoledronic acid (1case). The evolution was favorable in all cases with normalization of calcemia within 4 to 45 days.

Conclusion

Infant hypercalcemia can be evoked in the face of unspecific clinical signs and must be the subject of a rigorous diagnostic process with urgent management.

Medications used by individuals with fibrodysplasia ossificans progressiva (FOP): Data from a global natural history study

Edward C. Hsiao[1], Mona Al Mukaddam[2], Geneviève Baujat[3], Carmen De Cunto[4], Richard Keen[5], Robert J Pignolo[6], Kathleen Harnett[7], Rose Marino[7] & Frederick S Kaplan[2]

[1]Division of Endocrinology and Metabolism, UCSF Metabolic Bone Clinic, Institute of Human Genetics, and UCSF Program in Craniofacial Biology, Department of Medicine, University of California-San Francisco, San Francisco, CA, United States; [2]Departments of Orthopaedic Surgery & Medicine, The Center for Research in FOP and Related Disorders, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States; [3]Département de Génétique, Institut IMAGINE and Hôpital Universitaire Necker-Enfants Malades, Paris, France; [4]Pediatric Rheumatology Section, Department of Pediatrics, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [5]Centre for Metabolic Bone Disease, Royal National Orthopaedic Hospital, Stanmore, United Kingdom; [6]Department of Medicine, Mayo Clinic, Rochester, MN, United States; [7]Ipsen, Newton, MA, United States

Background

FOP is an ultra-rare genetic disorder characterised by episodic progressive heterotopic ossification (HO) and flare-ups, causing cumulative disability and early death. FOP is diagnosed and managed by multiple specialists, including endocrinologists. There are no established disease-modifying therapies to prevent HO in FOP. Treatment guidelines for symptomatic relief of FOP have recently been published by the International Clinical Council on FOP (ICC).[1]

Objective

Report use of medications to manage FOP symptoms in a natural history study (NHS), as per standard clinical practice.

Methods

Individuals with FOP aged ≤65 years with a documented *ACVR1*^{R206H} mutation could participate in this 36-month, prospective, global NHS (NCT02322255). This analysis reports interim medication use data (cut-off: 31.08.2019). Use of medications (acute and chronic) was assessed at Baseline, by telephone at Weeks 1–3 and every 3 months thereafter, and at clinic visits (Months 12, 24 and 36). Medication prescribed for symptomatic treatment of reported flare-ups was recorded on flare-up Days 1, 42 and 84. Data were collected using a standardised list and are summarised here by preferred term (PT).

Results

73/114 (64.0%) participants had ongoing prior medications at Baseline; the most common by PT were prednisone (25.4%), ibuprofen (22.8%) and montelukast (19.3%), which are included in the ICC guidelines (Table). Pain relief medications ongoing at Baseline also included (among others): paracetamol (11.4%), naproxen (8.8%) and celecoxib (7.9%). Most participants (91/114; 79.8%) initiated treatment with new medications during the NHS; the most frequent were prednisone (31.6%), ibuprofen (28.1%) and paracetamol (21.9%). Glucocorticoids were commonly administered upon flare-up onset (155/217; 71.4%), in accordance with ICC guidelines.

Table 1 Use of medications included in the ICC FOP guidelines in the natural history study (NCT02322255).

	Ongoing prior medications at Baseline[a] *n*=114	Newly initiated medications *n*=114
Prednisone	25.4%	31.6%
Non-steroidal anti-inflammatory drugs		
Ibuprofen	22.8%	28.1%
Celecoxib	7.9%	3.5%
Indomethacin	3.5%	0.9%
Montelukast	19.3%	4.4%
Cromoglicate	5.3%	1.8%
Zoledronate	0.9%	–
Pamidronate	–	4.4%
Imatinib	–	1.8%

[a]Includes medications taken within 30 days prior to Baseline. FOP: fibrodysplasia ossificans progressiva; ICC: International Clinical Council on FOP.

Conclusions

To manage their symptoms during this NHS, individuals with FOP used various medications, which were generally consistent with current ICC guidelines. Although the study objective was not to evaluate efficacy or safety of medications used, it highlights the need for disease-modifying therapies to treat or prevent symptomatic progression of FOP.

AEP1026

Anthropometric, metabolic and immunological parameters in children with type 1 diabetes mellitus and coexisting autoimmune disorders

Natalia Volkova[1] & Anzhalika Solntsava[2]
[1]2nd Children's Clinical Hostital, Endocrinology, Minsk, Belarus; [2]Belarusian State Medical University, 1sr department of children's diseases, Minsk, Belarus

Objective
to assess the effects of associated autoimmune diseases on diabetes control, growth, lipid profile in children with type 1 diabetes mellitus (T1DM) and to determine the most predictive genetic, immune and metabolic risk factors of polyglandular autoimmunity in children with T1DM.
Material and methods
89 children with combined autoimmune pathology (main group, age 11.82±3.68 years) and 100 patients with isolated T1DM (control group, age 10.91±3.28 years) were recruited. Groups were comparable in age ($P=0.09$) and T1DM duration ($P=0.99$). Assessment of anthropometric parameters; biochemical blood parameters; glycosylated hemoglobin (HbA1c), vitamin D, thyroid hormones and antibodies to thyroid peroxidase (anti-TPO), to tissue transglutaminase IgA (tTGA) and to glutamate decarboxylase (GAD) levels was carried out. The assessment of height and body mass index (BMI) was carried out using the z-criterion (who, 2007).
Results
In the main group 42 children had combinations of T1DM with autoimmune thyroiditis (AIT), 15 - celiac disease (CD), 2 – Graves' disease, 3 – AIT and CD, 27 – elevated anti-TPO-antibodies. BMI and height z-scores in both groups corresponded to the mean age values and didn't differ significantly ($P=0.47$ and 0.28 respectively). HbA1c level in children with combined autoimmune pathology was higher than in the control group (7.99±1.74% vs 7.49±1.30%, $P=0.029$). Both groups demonstrated similar values of biochemical blood parameters: lipidogram, serum iron, and ferritin ($P>0.05$). Higher levels of anti-TPO antibodies were revealed in the main group (253.08±308.06 IU/ml) compared to the control group (32.07±28.83 IU/ml, $P=0.003$). Among the risk factors for autoimmune thyroid damage, the association of thyroid pathology with vitamin D deficiency has been established ($\chi^2=4.79$, $P=0.029$, odds ratio (OR) 3.23, 95% confidence interval (CI) 1.10–10.46). Tendency to a higher risk in female patients (OR 1.64, CI 0.87–3.12), and with a high levels of GAD antibodies (OR 2.00, CI 0.89–10.52) was detected. The analysis of risk factors for CD revealed a tendency to an increased risk in patients with autoimmune thyroid disease (OR 1.463 (CI 0.606–3.530)), elevated levels of GAD (OR 2.514 (CI 0.892–7.085)). There was no association of CD risk with age of manifestation and duration of T1DM.
Conclusions
1. Higher levels of HbA1c were detected in children with polyglandular autoimmune pathology.
2. Higher risk of autoimmune thyroid disease was found in patients with vitamin D deficiency. Potential risk factors for thyroid pathology include high levels of GAD antibodies, presence of gluten enteropathy, female gender and late puberty, and for CD – high levels of GAD antibodies.

Utilising internet of things and artificial intelligence to enable twin precision treatment for reversal of type 2 Diabetes

Paramesh Shamanna[1], Suresh Damodharan[2], Banshi Saboo[3], Rajeev Chawla[4], Jahangir Mohammed[5], Maluk Mohamed[5] & Mohamad Thajudeen[5]
[1]Bangalore Diabetes Centre, Bengaluru, India; [2]Ramakrishna Hospital, Coimbatore, India; [3]Dia Care Diabetes Care Center, Ahmedabad, India; [4]North Delhi Diabetes Center, Delhi, India; [5]Twin Health Inc, Bengaluru, India

Introduction
We evaluated Twin Precision Treatment (TPT) approach, a cluster of Internet of Things (IoT) and Artificial Intelligence (AI), validated biosensors and Continuous Glucose Monitoring (CGM) through Ambulatory Glucose Profile (AGP) integrated with machine learning algorithms, enabling physicians to empower patients to reverse diabetes.
Methods
64 T2DM (19 males, 45 female), registered on Twin Health TM service, managed by standard care of approach with TPT, were monitored for three months for change in glycemic and non-glycemic parameters with changed pharmacotherapeutic approach. Patients achieving HbA1c >6.5% and ≤6.5 were classified as responders (RG) – demonstrating reversal of diabetes and non-responders (NRG), respectively. Twin Platform was used to correlate and analyse billions of data points to understand the drivers of the glucose response to specific foods for each participant. ANOVA was utilised for statistical analysis.
Results
The mean duration diabetes was 7 years (95% CI 0.1 to 30.0), with mean duration in the RG ($n=25$) was 4 years (95% 0.1 to 15.0) as compared to the mean duration of diabetes in NRG ($n=39$) was 10 years (95% CI 0.1 to 30.0); ($P=0.009$). The rates of diabetes reversal were 10%, 75% and 41% in HbA1c tertiles of HbA1c of >9.5, 8.1–9.5, 6.5–8, respectively. HbA1c reduced by 1.9 (8.8±2.23 to 6.9±1.07) ($P<0.001$). There was non-significant, but numerically superior improvement in non glycemic parameters in the RG Vs NRG with body weight reduced by 5.8 kg to 79.7±15.90, SBP by 8.68 mmHg to 122.92±10.06. In RG, C-peptide, LBGI (Low Blood Glucose Index), FPG, and HOMA-IR decreased by 0.71 ng/ml to 1.97, 1.19 to 0.67, 21 mg/dl to 112.4, 4.26 to 3.04, respectively. Glucose Variability of patients was maintained at 17%. 45 out of 57 patients who were on at least one anti-diabetic medication at baseline, were off the medication.
Conclusion
Technology enabled precision nutrition, a combination of macro, micro and biota nutrients, along with serial HbA1c evaluation are key for reversal of diabetes. Physician enabled adoption and integration of the technology, empowers patients to achieve better glycemic control. Our study with limited dataset with short duration validates robustness of TPT approach for a precise and effective metabolic control beyond hyperglycaemia.

A call for cardiologists and diabetologists to embrace neurological investigation for diabetic neuropathy in cardiovascular risk stratification

Dragan Tesic[1], Dragica Andric[2], Milena Mitrovic[3], Bojan Vukovic[4] & Mirjana Tomic[5]
[1]Institut for Internal Diseases, Clinic of Endocrinology, Diabetes and Metabolic Disorders, Novi Sad, Serbia; [2]Institut for Cardiovascular Diseases, Clinic of Cardiology, Sremska Kamenica, Serbia; [3]Institut for Internal Diseases, Clinic of Endocrionology, Diabetes and Metabolic Disorders, Novi Sad, Serbia; [4]Institut for Internal Diseases, Clinic of Endocrinology, Novi Sad, Serbia; [5]Institut for Internal Diseases, Clinic of Hematology, Novi Sad, Serbia

Background
In the 2019 ESC Guidelines on diabetes, pre-diabetes and cardiovascular diseases, only retinopathy appears as a target organ damage as a parameter for stratification patients into very high-risk group. The aim of study was to check the strength of association between DN and isolated DR groups with cardiovascular complications.
Methods
Chronic kidney disease (CKD) was defined by eGFR ≤59 ml/min/1.73 m^2 and proteinuria (PrU) was determined (mg/24 h). Neuropathy was diagnosed by neuropathy disability score and sudomotor function using Neuropad. Presence of coronary artery disease (CAD) and cervico-cerebral ischaemic aterial disease (CCAD) was documented. Lower-extremity artery disease (LEAD) was diagnosed with ankle-brachial index (ABI) and continuous wave Doppler.
Results
Of 262 people, 49.6% were male and 71% had T2DM; 130 had DN [90 (69.2%) with retinopathy], 75 had DR without neuropathy, 57 had no evidence of retinopathy, CKD and DN (controls). All ($n=48$) CKD patients were with DR and/or DN: 15 (31.3%) with DR, 10 (20.8%) with DN, 23 (47.9%) with both DN and DR. Patients with DN compared with controls after multivariable logistic regression analysis (MVLR) significant remained model: age (OR 1.16 [95% CI : 1.07–1.25]; $P<0.01$), duration of diabetes (1.12 [1.05–1.19]; $P<0.01$), PrU (1.003 [1.00–1.005]; $P=0.06$), NeuroPad time 1.11 [1.00–1.22]; $P=0.04$). Compared with controls, those with DR were more frequently women (62.7% vs 42.1%; $P=0.01$) and older (54.8±14.6 vs 45±12.8 years; $P<0.01$), had high blood pressure (49.3% vs 26.3%; $P<0.01$), T2DM (69.3% vs 43.9%; $P<0.01$), had longer duration of diabetes (17.1±7.7 vs 10.2±7.4 y.; $P<0.01$).After MVLR only duration of diabetes (OR 1.12 [1.05–1.19]; $P<0.01$) persisted. DN group was significantly more associated with macrovascular complications (CCAD, CAD, LEAD) [$n=56$ (43.1%)] vs DR group $n=16$ (21.3%) and control group $n=9$ (15.5%); $P<0.01$. CAD ($n=43$) in univariate analysis showed association with DN (OR 2.4 [1.2–4.8]; $P=0.01$), and in MVLR anaylsis with LEAD (OR 3.4 [1.6–7.1]; $P\leq0.01$).

Conclusion
In the algorithm for cardiovascular risk stratificationwe would recommend examination of diabetic neuropathy and LEAD as the first line approach. As earlier these complications would be detected the indication for more comprehensive management of diabetic patients would be established.

EndogenousInterleukin production by the skin cells (keratinocytes and fibroblasts) cocultured with mononuclears of patients with type 2 diabetes mellitusand type 2 diabetes with chronic foot ulcers in a 3D culture model

Maryia Mashkova[1], Tatsiana Mokhort[2] & Vitaly Goranov[2]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus;
[2]Belarusian State Medical University, Minsk, Belarus

Our research focused on the role of immune mechanisms in diabetic foot ulcers development and impaired healing. The AIM of this study was to evaluate endogenous interleukin (IL1,4,6,8) production to the culture medium by the skin cells (keratinocytes and fibroblasts) cocultured with mononuclears of patients with type 2 diabetes mellitus (T2DM) and T2DM with chronic foot ulcers (DFU) in a 3D culture model.
Materials and methods
A multilayer 3D immunocompetent model of human skin comprising of keratinocytes, fibroblasts and mononuclears (peripheral blood mononuclears of 9 T2DM with DFU, 9 T2DM patients, 9 healthy controls (HC)) in an agarose-fibronectin gel was used. IL1,4,6,8 production to the culture medium was evaluated just after adding mononuclears to the system and in 24 hours of their co-cultivation with fibroblasts and keratinocytes.
Results
the initial IL1 level was significantly higher for samples with T2DM and T2DM with DFU patients mononuclears compared to HC – 54.91 [51.17;62.98] vs 51.82 [48.43; 55.92] vs 44.72 [35.37; 48.03] pg/ml, H=10.427, P=0.005. There was a significant increase in IL1 after 24-hour keratinocytes and fibroblasts coincubation with patients mononuclears – 48.91 [39.66; 51.96] vs 44.72 [35.37; 48.03] pg/ml, T=–2.666, P=0.008, 73.95 [68.13; 75.53] vs 51.82 [48.43; 55.92] pg/ml, T=–2.666, P=0.008, 85.17 [82.99; 91.51] vs 54.91 [51.17; 62.98] pg/ml, T=–2.666, P=0.008, for HC, T2DM and T2DM with DFU in 24 hours and initially, respectively. For the samples containing HC mononuclears this increase in IL1 was significantly lower than for T2DM and T2DM with DFU – 4.24 [3.65; 5.01] vs 20.21 [18.18; 23.51] vs 30.26 [26.62; 34.95] pg/ml, H=22.317, P<0.001, respectively. The increase in IL1 was significantly higher for samples with mononuclears of patients with T2DM with DFU, than without DFU – P<0.001. The initial IL6 level was slightly higher for samples with patients with T2DM and T2DM with DFU mononuclears than HC – 26.28 [20.82; 28.49] vs 27.54 [24.33; 30.03] vs 19.75 [13.57; 25.03] pg/ml, H=8.892, P=0.012, respectively. In samples with HC mononuclears, the IL6 was undetectable with the kits used (< 5 pg/ml). In the samples with patients with T2DM and T2DM with DFU mononuclears the secretion of IL6 didn't change significantly – 26.28 [20.82; 28.49] vs 23.76 [22.38; 27.58] pg/ml, T=–1.125, P=0.260 and 27.54 [24.33; 30.03] vs 26.12 [23.64; 28.90] pg/ml, T=–1.836, P=0.066 for the group of T2DM and T2DM with DFU initially and in 24-hour coincubation, respectively. The IL4 and IL8 levels were undetectable (<5 pg/ml) with the kits used.
Conclusion
An increase in IL1 and absence of a sufficient and significant decrease in IL6 production in 24-hour coincubation of skin cells with T2DM patients mononuclears indicates the activation of immune mechanisms and the maintenance of chronic inflammatory response.

Variants of hyperlipidemia in obese children are gender and insulin resistance dependent

Tetyana Chaychenko, Mariia Kharkova & Olena Rybka
Kharkiv National Medical University, Pediatrics 1 and Neonatology, Kharkiv, Ukraine

Background
Insulin resistance and dyslipidemia inobese subjectsare important for predicting future cardiovascular risk. Purpose of the study was to analyze the lipid profile of obese children depending on gender and insulin resistance status.
Subjects and methods
247 overweight and obese children (160 boys and 87 girls) aged 2 to 18 y.o. were examined in the pediatric endocrinology department. Lipids assessment included measurement of total cholesterol (TC), triglycerides (TG), low density lipoproteins (LDL), high density lipoproteins (HDL).To evaluate lipid parameters, we used recommendations of the NCEP, 2006. For assessing carbohydrates fasting blood glucose and insulin levels were measured followed by HOMA-IR calculation. Insulin resistance was determined if HOMA-IR values exceededIDEFICS charts cut-offs. Parameters were grouped by the presence (IR +) or absence (IR-) of insulin resistance. Fasting status (at least 8 hours) was required. Standard statistics used for the data analysis.
Results
Insulin resistance was detected in 69.9% of overweight children. 72% of the examined girls and 68% of the examined boys were insulin resistant.
TC level in the IR+was at borderline levels in boys (4.43 mmol/l) and in girls (4.98 mmol/l), but in girls the level was significantly higher (P=0.03). In IR- subjects TC level was within normal limits in both boys (4.38 mmol/l) and girls (4.24 mmol/l) without gender difference. TC level was higher in girls with present IR (4.98 vs 4.24 mmol/l, P<0.05). In boys, there was no significant difference. Elevated TGs were found in boys (1.54 mmol/l) and girls (1.81 mmol/l) in the IR+group, as well as in girls from the IR- group (1.63 mmol/l). TGs in IR- boys were borderline and lower than in IR +group (1.30 vs 1.54 mmol/l, P<0.05). Whereas in girls there were no significant differences. HDLs were slightly reduced in all study groups. However, HDL level was significantly lower in boys without insulin resistancethan in girls (1.11 mmol/l vs1.37 mmol/l, P=0.03). There was no deviation of LDL from references in all groups regardless of gender and the presence of insulin resistance. Meantime, average LDL level was higher in insulin resistant boys than insulin sensitive ones (2.26 vs 1.72 mmol/l, P <0.05). IR girls also had higher LDLs than insulin sensitive (2.64 vs 1.63 mmol/l, P <0.05).
Conclusions
Most of obese and overweight children are insulin resistant with deteriorated lipids. Seems, variant and degree of dyslipidemia are gender and insulin sensitivity dependent.

Type 2 diabetics with high risk of foot amputation: Role of sodium-glucose co-transporter inhibitors

Mª del Carmen Serrano Laguna, Sara León Utrero, María Hayón Ponce, Enrique Redondo Torres & Pablo José López Ibarra
Hospital Universitario Clínico San Cecilio, Endocrinología y Nutrición, Granada, Spain

Introduction
The use of iSGLT2 continues to be controversial in diabetic patients with peripheral arterial disease.
Objectives
Assess the metabolic effect and the risk of amputations of iSGLT2 in diabetic patients cared for in the Multidisciplinary Diabetic Foot Unit (MDFU) compared to a control group.
Material and methods
A retrospective observational study where patients attended at the MDFU from December 2017 to January 2020 were recruited. An iSGLT2 treatment group was selected and these data were compared with a control group. Clinical, metabolic, anthropometric variables and amputation rate were collected in both arms. Statistical analysis was performed using the SPSS program (SPSS, inc, v15.0).
Results
A total of 312 patients were recruited: 83 in treatment with iSGLT2 and 229 as a control group. The treatment group had a mean age of 65.99±10.31 vs 68.14±12.11 (P=0.12) years of the control group and a time of evolution of the disease of 17.33±10.26 vs 18.10±11.97 (P=0.52). Weight of 86.88±17.77 kg vs 82.65±15.65 kg (P=0.57) and a mean BMI 31.07±5.61 kg/m^2 vs 29.58±4.91 kg/m^2 (P= 0.03). HbA1c at baseline (iSGLT2 vs control group): 8.83±1.67% vs 7.71±1.72% (P=0.00); mean reduction: 1.04±1.32% vs 1.42±2.34% (P=0.38); Final HbA1c: 8.08±1.37 vs 7.42±1.32% (P=0.05). There were no statistically significant differences between the LDL values at baseline (96.29±38.95 mg/dl vs

98.8±40.93 mg/dl, $P=0.67$)) or between the reductions obtained in both arms (11.28±31.16 vs 12.25±31.84, $P=0.91$). Taking into account some risk factors for an amputation to occur, there was a higher proportion of hypertension (78.3% vs 72.2%), dyslipemia (74.7 vs 71.1%), smokers (58.2 vs 49.8%) in the group with iSGLT2, as well as a longer history of chronic ischemia (41 vs 38.2%) and neuropathy (74.4 vs 70.9%). The amputation rate after follow-up was 15.7% in the iSGLT2 group compared to the control group 12.3% ($P=0.55$).

Conclusions

This study shows that the treatment with iSGLT2 in a group of patients with peripheral arterial disease is effective and safe, not increasing the rate of amputations compared to the rest of the patients attended in the MDFU, despite having a higher number of risk factors for this.

Association between variants in clock genes and type 2 diabetes in an elderly greek population

Xanthippi Tsekmekidou[1], Fotis Tsetsos[2], Theocharis Koufakis[1], Maria Grammatiki[1], Marianthi Georgitsi[3], Athanasios Roumeliotis[4], Stylianos Panagoutsos[4], Elias Thodis[4], Marios Theodoridis[4], Nikolaos Papanas[5], Dimitrios Papazoglou[5], Ploumis Pasadakis[4], Peristera Paschou[2], Pantelis Zebekakis[1] & Kalliopi Kotsa[1]

[1]Division of Endocrinology and Metabolism and Diabetes Center, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Molecular Biology and Genetics, Democritus University of Thrace, Alexandroupolis, Greece; [3, 4]Department of Nephrology, Democritus University of Thrace, Alexandroupolis, Greece; [5]Diabetes Centre, Second Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece

Background

Recent data suggest that disturbances in circadian clock functioning are implicated in the pathogenesis of type 2 diabetes (T2D), through alterations in plasma glucose levels, insulin secretion and sensitivity, energy intake, and genomic expression in liver and pancreas. This study aimed to assess a potential association between variants in clock genes and T2D risk in a population of Greek elderly people.

Methods

In a case-control design, 1258 participants aged 65 and above, were categorized either as T2D patients (Group A, $n=716$) according to diabetes history, HbA1c≥6.5% and fasting plasma glucose (FPG)≥126 mg/dl, or non-diabetic controls (Group B, $n=569$). Informed consent was obtained from participants and whole blood was collected for DNA extraction. Samples were analyzed on Illumina Infinium PsychArray. After individual and SNP quality control, polymorphisms in PPARA, PPARD, PKDREJ, UTS2, CLOCK/TMEM165, VAMP2, HES6 and PER2 genes were selected and allele frequencies between groups were compared (primary analysis). For the purpose of the compound analysis, the PLINK software suite (v1.9) was used. Permutation test analysis was implemented to determine statistical significance ($P<0.05$). In order to eliminate the impact of prediabetes on the results, participants from Group B with HbA1c levels<5.7% and FPG<100 mg/dl were selected to form a control subgroup (Group $n=393$) and a secondary analysis was undertaken.

Results

In the primary analysis, a protective effect of 14 *PPARA*variants against T2D was established. A similar trend was evident for rs7291444_G/T ($P_{emp}=0.031$, OR=0.7843), rs36125344_C/G ($P_{emp}=0.043$, OR=0.758) and rs6008384_C/T ($P_{emp}=0.036$, OR=0.798) in *PKDREJ*, in both primary and secondary analyses. Interestingly, rs6744132_A/G, located downstream *HES6* and *PER2* genes was positively associated with T2D ($P_{emp}=0.044$, OR=1.183). rs2859389 in *UTS2* gene was found to be protective against T2D ($P_{emp}=0.046$, OR=0.8454). Only in the secondary analysis, rs2278637_G/T ($P_{emp}=0.015$, OR=0.784) in *VAMP2* and rs11943456 ($P_{emp}=0.018$, OR=0.787) in *TMEM165* exhibited a protective role against T2D.

Conclusion

Our data indicate a potential role of variation in clock genes in T2D genetic susceptibility in an elderly Greek population. Further studies are required to replicate our findings and clarify the complex underlying interactions between genetic, environmental and life-style components that result in the development of the disorder.

AEP1033

Prolonged Metformin intake is associated with decreased thyroid nodular growth in obese

Maxim Lushchyk[1], Artur Grigorovich[2], Hanna Tuzava[1], Maxim Ameliyanovich[3], Irma Mosse[3], Valentina Drozd[4] & Larissa I Danilova[4]

[1]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department, Thyroid Disease Research Group, Minsk, Belarus; [2]Brest Regional Endocrinological Dispensary, Brest, Belarus; [3]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk, Belarus; [4]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department,, Minsk, Belarus

Obesity and weight excess is a widespread condition all over the world, as well as thyroid nodular disease. Screening studies in different populations prove a higher frequency of nodular thyroid formations of various nature in overweight individuals.

Aim

In our study, we evaluated the dynamics of the volume of dominant and non-dominant nodular formations, as well as their sonographic structure in overweight patients with prediabetes in the groups with two-year administration of Metformin and without.

Materials and methods

We have screened 550 patients in rural areas of Belarus. Anthropometry, Endocrinologists examination, thyroid ultrasound and serum blood tests were performed. Of the screened cohort there were 183 persons with BMI over 27 kg/m^2 associated with thyroid nodules who agreed to participate with informed consent. All cases of thyroid malignancy, thyrotoxicosis, Hashimoto thyroiditis and severe hypothyroidism were excluded from recruitment. Initial consultation with the proposal of individual weight-loss, nutrition and physical activity program was made for all participants. Additionally, those, who had metabolic reasons, glucose intolerance, dislipidemia – were prescribed Metformin in the dose of 1000–2550 mg/day. Two groups were formed – Overweight with thyroid nodules ('OWTN') and Overweight with thyroid nodules and Metformin intake ('MFI'). The groups were comparable by age, BMI, metabolic characteristics and thyroid status.

Results

As a result of 2 year follow up we have observed improvement in metabolic parameters of the MFI-group, showing improved glycaemic and lipid profiles, compared to OWTN-group. But we have detected a significant increase in number and volume of thyroid nodules in OWTN-group up to 1.84±1.47 ml, comparing to 1.37±0.99 ml in the MFI-group ($P=0.0399$), with a non-significant weight reduction, in between groups. As for thyroid status – there was also a significant difference in TSH (3.94±1.0 vs 2.89±0.7, $P<0.001$) and FT4 levels (16.22±2.48 vs 16.98±2.05, $P=0.027$) accordingly.

Conclusion

The obtained results of dynamic observation indicate a significantly less active increase in the volume of nodular formations in the cases of prolonged use of Metformin. Possible mechanisms of Metformin-induced PPAR-g receptor activation and additional effects of improved insulin sensitivity as well as Metformin direct influence on TSH-receptor affinity and activity for controlling neoplastic processes and thyrocyte proliferation are discussed. Larger number cohort and prolonged observation are still desirable.

AEP1034

Characterization of dyslipidaemia and association of lipoprotein(A) plasma levels with metabolic control in young adults with type 1 diabetes

Isabel Inácio[1], Sara Ferrreira[1], Patrícia Rosinha[1], Teresa Azevedo[1], Márcia Alves[1], Rosa Dantas[1], Ana Margarida Balsa[2] & Joana Guimarães[1,3,4]

[1]Endocrinology Department, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [2]Endocrinology Department, Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal; [3]Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal; [4]Department of Medical Sciences, University of Aveiro, Aveiro, Portugal

Introduction

The 2019 European Society of Cardiology/European Atherosclerosis Society lipid guidelines changed the cardiovascular risk categories and LDL-C goals, and suggests that lipoprotein(a) [Lp(a)] measurement should be considered at least once in adult person's lifetime. Although young people with type 1 diabetes (T1DM) without major cardiovascular risk factors (CVRF) were previously considered to be at low or moderate risk, they are at least at

moderate risk based on the best available evidence. Emerging studies suggest that increased Lp(a) levels are associated with poor metabolic control in patients with T1DM. However, the knowledge about Lp(a) in T1DM is still limited.
Objectives
To evaluate the application of these guidelines and to investigate the association of Lp(a) and metabolic control in young adults with T1DM.
Methods
Observational cross-sectional study, including young adults (18–40 years) with T1DM. Patients with Lp(a) measurements were divided into two groups: very low-intermediate Lp(a) levels (≤120) vs high (>120 nmol/l).
Results
Included 75 T1DM patients (61.3% male), with median age of 30.9 (26.0–36.0) years, T1DM duration of 13.0 (6.0–20.0) years and HbA1c 7.7 (7.1–8.8)%. Median LDL-C was 105.0 (85.0–128.0) mg/dl. Among 9/75 (12.0%) patients at moderate risk (T1DM aged <35 and T1DM duration <10 years, without other CVRF), 1 (11.1%) had LDL-C above the target (≥100 mg/dl). Of the 44/75 (58.7%) at high risk (DM ≥10 years, without target organ damage or another CVRF), 38 (86.4%) had LDL-C ≥70 mg/dl. Among 22/75 (29.3%) patients at very high risk [DM with target organ damage, at least 3 major CVRF or early onset of T1DM of long duration (> 20 years)], all were above LDL-C goal (≥55 mg/dl). Median Lp(a) was 17.0 (6.0–39.0) nmol/l (n=54), no patients had extremely high levels (>430 nmol/l). Among patients not treated with antidyslipidemics, 3/48 (6.3%) had high Lp(a) levels [all at high risk and with LDL-C above the recommended goal (≥70 mg/dl)]. Patients with high Lp(a) levels had significantly higher body mass index (P=0.042), high-sensitivity C-reactive protein (P=0.041), total cholesterol (P=0.014), LDL-C (P=0.002) and non-HDL-C (P=0.003); and a trend to higher HbA1c and apolipoprotein B/AI ratio (both P=0.054). Lp(a) levels did not differ according to metabolic control (HbA1c <6.9 vs ≥6.9%). By the logistic regression method, none of the studied variables was predictive of high Lp(a) levels.
Conclusion
This study suggests that Lp(a) is a high risk marker in young adults with T1DM. Routine Lp(a) measurement in clinical practice could improve their cardiovascular risk assessment and justify intensive treatment.

Polygenic risk scorecaptures 11% of of type 2 diabetes variability in latvian population

Raitis Pečulis[1], Raimonds Reščenko[1], Valdis Pīrāgs[2,3], Ilze Konrāde[4,5] & Jānis Kloviņš[1]
[1]Latvian Biomedical Research and Study Centre, Human Genetics and Molecular Medicine, Riga, Latvia; [2]Pauls Stradiņš Clinical University Hospital, Department of Internal Medicine, Riga, Latvia; [3]University of Latvia, Faculty of Medicine, Riga, Latvia; [4]Riga East Clinical University Hospital, Department of Endocrinology, Riga, Latvia; [5]Riga Stradiņš University, Department of Internal Medicine, Riga, Latvia

Type 2 diabetes (T2D) is a multi factorial disease with increased prevalence globally. The risk of developing T2D is determined by the interaction of genetic and environmental factors. Over the decades of research, hundreds of T2D genetic susceptibility markers (mostly single nucleotide polymorphisms or SNP) have been discovered. Yet generally their contribution to increased T2D risk is small and have negligible value in clinical practice to aid T2D treatment, categorize patients or guide prognosis. To overcome the weakness of individual genetic markers, polygenic risk score (PRS) method has been developed to account for genetic background of an individual and presence of multiple T2D risk markers. T2D associated SNPs vary across populations and countries which translate into even higher heterogeneity of a PRS model. Therefore, it is important to develop PRS model for each country and population. This study performed a genome wide association study in Latvian population using 822 cases and 802 controls and developed a PRS model to capture genetic risk of T2D in Latvian population. The results indicate that seven SNPs have a statistically significant association with T2D in Latvian population after Benjamini-Hochberg false discovery rate correction and considering population stratification and other covariates. The overall correlation of effects of SNPs with recent report in meta-analysis of European populations (Mahajan 2018) is high, reaching r=0.39 when considering SNPs up to $P=1\times10^{-2}$. PRS model included 41 independent SNPs and contributes to 12% variability of T2D in the target group and 11% in the validation group with $P=1\times10^{-7}$ and AUC 0.69. Upper quartile individuals have T2D odds ratio 2.8 (CI 95% = 1.3–5.7) while lower quartile has odds ratio 0.3 (CI 95% = 0.3–0.7) when compared to the second quartile. Heritability of T2D has been determined at 26% in populations of European descent, therefore, capture of 11% variability translates to 42% of inherited variation explained in Latvian population by current PRS model. Many of the established T2D genetic risk factors were statistically significant (such as TCF7L2 gene) but failed to reach genome wide significance after correction for multiple testing, indicating that study is undepowered and larger sample size is required to improve detection of individual SNP effects and to improve PRS model. This T2D study has produced a strong PRS model explaining 11% of the diabetes variability in Latvian population and could be used in analysis with other T2D risk factors.

Insights on ghrelin immunohistochemistry: Variations between intrinsic molecular subtypes of breast cancers

Ioana Armasu[1], Delia-Gabriela Ciobanu-Apostol[2], Victor Ianole[2], Cristina Preda[3], Ioana Vasiliu[1], Bogdan Stana[1], Catalin Alexandru Pohaci-Antonesei[1], Roxana Mihaela Barbu[1], Walther Bild[1] & Ionela Lacramioara Serban[1]
[1]'Grigore T. Popa' University of Medicine and Pharmacy Iasi, Physiology, Iaşi, Romania; [2]'Grigore T. Popa' University of Medicine and Pharmacy Iasi, Pathology, Iasi, Romania; [3]'Grigore T. Popa' University of Medicine and Pharmacy Iasi, Endocrinology, Iasi, Romania

Introduction
Ghrelin, a peptide hormone produced in the stomach, stimulates secretion of growth hormone and regulates appetite and energy homeostasis. Various other effects attributed to ghrelin may contribute to many aspects of cancer development and progression.
Material and methods
Using polyclonal antibody immunohistochemistry, we assessed (by intensity scoring) the immunolocalization of ghrelin in 70 tissue samples, and described particularities within the molecular subtypes of breast cancer. Clinical and histopathological characteristics of the tumors were obtained from patients' records. Patients histological data was grouped in order to better classify the ghrelin staining characteristics and included primary tumor size (≤ 20 mm; >20 mm), lymph node invasion (with; without confirmed lymph node invasion), tumor grading, estrogen (ER) and progesterone (PgR) receptor percentage score, intensity score and status (<1%; >1% positive in tumor cells), human epidermal growth factor receptor 2 (HER2/neu) status (positive; negative or equivocal), Ki-67 index (<15%; ≥15%) and presence of fibrocystic breast disease.
Results
Ghrelin expression in breast tumor cells correlated inversely with tumor grading (ρ = –0.449, P=0.020), and positively with estrogen receptor (ER percentage scoring, ρ = 0.221, P=0.003). Dividing the study group by intrinsic subtypes, a strongly inversely association between ghrelin and tumor size (P=–0.598, P=0.007), grading (P=–0.849, P=0.003), and presence of fibrocystic breast disease (P=–0.826, P=0.033) was observed in triple negative breast cancer cases. Tumor ghrelin and ER percentage scores were positively correlated in luminal B HER2 negative tumors (ρ = 0.121, P=0.031). For luminal A tumors, a negative association was observed between ghrelin and tumor grading (ρ = –0.364, P=0.656), lymph node status (ρ = –0.230, P=0.232), ER (ρ = –0.363, P=0.188) and PgR (ρ = –0.313, P=0.241) status, Ki67 index (ρ = –0.489, P=0.087) and the presence of fibrocystic breast disease (ρ = –0.224, P=0.656), associations whichdid not reach the level of statistically significance in any of these cases.
Conclusion
Ghrelin regulates several endocrine functions with potential contributions to cancer biology. An endocrine effect of ghrelin, potentially attributable to cancer biology, is its stimulation of growth hormone secretion regulating IGF-1 levels, with subsequent pro-neoplastic effects. However, existing evidence does not strongly support contribution of ghrelin-GH-IGF1 axis to cancer development or progression, but rather prove independent effects. Previous cohort studies reported a positive prognostic significance of ghrelin immunostainings in breast cancer. Furthermore, we showed that ghrelin was linked to better tumor differentiation and proliferation especially in triple negative cases, suggesting a particular mechanism of action and a possible prognostic role of ghrelin in these cases.

Management of glucose profile throughout strict COVID-19 lockdown by patients with type 1 Diabetes prone to hypoglycemia using sensor-augmented pump

Clara Viñals, Alex Mesa, Daria Roca, Mercè Vidal, Irene Pueyo, Ignacio Conget & Marga Giménez
Hospital Clínic de Barcelona, Endocrinology and Nutrition, Barcelona, Spain

Aims
Spain has been one of the worst affected countries by the COVID-19 pandemic. A very strict lockdown at home was imposed with a tough restriction of mobility. We aimed to evaluate the impact of this exceptional scenario on glucose profile of patients with type 1 diabetes (T1D) prone to hypoglycemia using sensor-augmented pump (SAP).
Methods
Patients with T1D prone to hypoglycemia using SAP (640G Medtronic Minimed) for at least 6 months under the funding of a National Health Service were included in an observational, retrospective study. Data were collected in two periods: pre-lockdown (PL), February 23rd–March 7th and within lockdown (WL), April 1st to 14th 2020. The primary outcome was the difference in the proportion of time in target glucose range of 70–180 mg/dl (TIR). Additional glucometric data and total daily insulin were also analysed.
Results
59 patients were included: 33 women, age 46.17 ± 13.0 years and disease duration of 30.2 ± 12.0 years. TIR 70–180 mg/dl (67.6 ± 11.8 vs 69.8 ± 12.0%), time > 180 (28.1 ± 13.6 vs 25.5 ± 13.1%), time > 250 (6.9 ± 6.1 vs 5.1 ± 4.8) and Glucose Management Indicator (GMI) (6.94 ± 0.8 vs 6.75 ± 0.7%) significantly improved (PL vs WL, respectively, $P < 0.05$). Time in hypoglycemia, coefficient of variation, sensor usage and total daily insulin dose remained unchanged.
Conclusions
Lockdown conditions imposed by the COVID-19 pandemic may be managed successfully in terms of glycemic control by population with DT1 prone to hypoglycemia using SAP. The strict daily routine at home could probably explain the improvement in the time in glycemic target without increasing the time hypoglycemia.

Gestational diabetes as unusual presentation of maternally inherited diabetes and deafness (MIDD)

Uzair Akbar Ali,Muhammad Sajjad Sadiq, Dr. Elizabeth Ann Brosnan & Muhammad Aamir Shahzad
Mayo University Hospital, Castlebar, Ireland

Maternally inherited diabetes and deafness (MIDD) is rare subtype and monogenic form of adult onset diabetes caused from point mutation at position 3243 of mitochondrial DNA. The name indicates the main features of disease including diabetes and sensorineural hearing loss. About one percent of people with diabetes can have MIDD but the diagnosis can be challenging and needs high clinical suspicion on basis of family history, clinical features of diabetes, deafness and unusual neurological symptoms. We herein report an unusual presentation of MIDD in a 39 year female who presented with gestational diabetes during her 5th pregnancy. On high clinical suspicion genetic testing was done showing mutation in mitochondrial DNA (3243 A > G). She was treated with insulin during pregnancy and given Metformin and Gliclazide post-natal. After establishing final diagnosis of MIDD, her Metformin was stopped due to risk of lactic acidosis. She was continued on other oral hypoglycaemic agents with dietary changes and offered genetic counselling. MIDD is associated with co-morbidities and unique management issues. There is no definite evidence of efficacy for any specific therapy. Oral hypoglycemics can be helpful initially but patients may require insulin therapy within 2 years after diagnosis. The effectiveness of other treatment options described in literature including Co enzyme Q and thiamine requires further study.
Keywords: maternally inherited diabetes and deafness, mitochondrial DNA, mutation, gestational diabetes.

Impact of obesity on types of myocardial infarction

Julian Gin & Andrew Wilson
St Vincent's Hospital Melbourne, Cardiology, Melbourne, Australia

Introduction
Obesity is an independent risk factor of coronary artery disease, and it has also been shown to be associated with increased survival in some instances such as myocardial infarction – dubbed the 'Obesity Paradox'. However, there is a paucity of studies identifying the type of myocardial infarction – non-ST-segment elevation MI (NSTEMI) or ST-segment MI (STEMI) – that may be differentially prevalant according to BMI (body mass index) class. Indeed, STEMI has been shown to have better long-term mortality compared to NSTEMI, and may contribute towards improved survival among the obese population.
Hypothesis
We hypothesised whether STEMI or NSTEMI is greater in obese patients and if increasing BMI correlates with increased likelihood of STEMI.
Methods
We retrospectively analysed 1649 patients from a larger cohort of patients from the local cardiac surgery database collected from 2010 to 2019. BMI (weight [kg]/height^2 [m^2]) was calculated for all patients which were then assigned into groups (normal [BMI 18.5–24.9], overweight [BMI 25–29.9], and obese [BMI ≥ 30]). Baseline characteristics were assessed, including a history of cardiovascular risk factors and biochemistry. The prevalence of the MI type (as either STEMI or NSTEMI) was calculated for each BMI group. The MI type was correlated against BMI groups adjusted for cardiovascular risk factors and biochemical parameters associated with the metabolic syndrome including low-density lipoprotein (LDL), triglycerides, and fasting blood glucose.
Results
NSTEMI was more prevalent across all BMI groups compared to STEMI. NSTEMI was more prevalent (STEMI less prevalent) in both the obese and overweight groups when compared to the normal BMI group (82.4% vs 71.1%, $P = 0.001$, and 79.8% vs 71.1%, $P = 0.008$ respectively). There was no significant difference in the prevalence of NSTEMI or STEMI between obese and overweight BMI classes (82.4% vs 79.8%, $P = 0.34$). Further analysis of the type of MI with ordinal logistic regression revealed a reduced likelihood of STEMI with increasing BMI class (OR: 0.57 ± 0.16, 95% confidence interval 0.33–0.97, $P = 0.042$) and is statistically significant when adjusted for above co-variates.
Conclusion
This studied showed that NSTEMI was more prevalent relative to STEMI amongst high BMI patients. Increasing BMI was associated with reduced likelihood of STEMI. Although these findings are in contrast with our hypothesis, it highlights the impact of obesity on MI presentations. This may have clinical and/or practical implications on the management of MI in the obese population and further studies are warranted in this context.

Differences in health-related quality of life between type 1 and type 2 diabetic patients in Austria

Nawras Al-taie, Harald Stingl & Delia Maftei
Landesklinikum Mostviertel Melk, Internal medicine /Diabetes Unit, Melk, Austria

Background and aim
Improving the quality of life is one of the main goals of treating diabetic patients in addition to manage glycaemic control and diabetes complications. The study aim was to assess and compare the quality of life among Austrian patients with type 1 and type 2 diabetes mellitus using the German version of the World Health Organization Quality of Life-BREF instrument (WHOQOL-BREF).
Methods and Materials
This was an observational study that included $n = 208$ patientsfrom the Diabetes center in Melk General Hospital, Lower Austria region. Of those, $n = 170$ were diagnosed with type 2 and $n = 38$ with type 1 diabetes. Quality of life was assessed using the German version of the WHOQOL-BREF questionnaire over one year from 2018 to 2019. Consisting of questions about psychological, physical, social, and environmental topics, the WHOQOL-BREF questionnaire covers four main domains. The response to each item in the questionnaire scored from 1 to 5 (ranged from strongly disagree

to agree strongly) on the Likert scale. The raw scores in each domain were transformed into a 0 to 100 score according to the WHOQOL-BREF manual. For statistical analysis, we used R–project for statistical computing, and the Mann–Whitney U test (Wilcoxon rank-sum test) was used to compare Quality of life according to the type of diabetes.
Results
The mean HbA1c values for type 1 and type 2 patients were 61.5 mmol/mol (7.8%) and 55.5 mmol/mol (7.2%) (n.s.), respectively. 61% of all patients were male. The WHOQOL-BREF scores among both type 1 and type 2 diabetes patients were relatively high, which reflects good quality of life. Scores of the physical domain were higher in type 2 diabetes patients than in type 1 diabetes patients (64.5±20.1 vs 50.5±5.2, $P<0.001$). Similarly, scores of the environmental domain were higher in type 2 than in type1 (84.4±11.2 vs 80±3.3, P 0.04). The scores of the psychological and social domains did not differ between the two groups (71.3±18.1 vs 72.2±16.7, $P=0.88$, and 70.1±20.1 vs 71.0±19.6, $P=0.19$, respectively.
Conclusion
This study showed that type 2 diabetic patients significantly scored higher in physical and environmental domains compared to type1 diabetic patients. Further research is needed to examine this issue in detail and also the causes that may influence the quality of life in each type of diabetes.

Assessment of association between VDR variants and type 2 diabetes in an elderly greek population

Xanthippi Tsekmekidou[1], Fotis Tsetsos[2], Theocharis Koufakis[1], Maria Grammatiki[1], Marianthi Georgitsi[3], Athanasios Roumeliotis[4], Stylianos Panagoutsos[4], Elias Thodis[4], Marios Theodoridis[4], Nikolaos Papanas[5], Dimitrios Papazoglou[5], Ploumis Pasadakis[4], Peristera Paschou[2], Pantelis Zebekakis[1] & Kalliopi Kotsa[1]
[1]Division of Endocrinology and Metabolism and Diabetes Center, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Molecular Biology and Genetics, Democritus University of Thrace, Alexandroupolis, Greece; 31st Laboratory of Medical Biology-Genetics, Department of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Department of Nephrology, Democritus University of Thrace, Alexandroupolis, Greece; [5]Diabetes Centre, Second Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece

Background
Vitamin D receptor (VDR) in the presence of active calcitriol (1.25-dihydroxy vitamin D) acts as a transcription factor that modulates the gene expression oftransport proteins, which are involved in calcium metabolism. Accumulating evidence suggest apotential implication of vitamin D deficiency in the pathogenesis of diabetes mellitus. We aimed toassess whether variants in the *VDR* gene contribute to risk of Type 2 Diabetes Mellitus (T2DM).
Methods
Twenty-five polymorphisms within *VDR* gene were genotyped in 716 patients with T2DM (group A) and 569 controls (group B) of Greek origin, 393 of which withoutprediabetes (group C). Group B consisted of elderly above 65 years of age with documentedabsence of T2DM (HbA1c<6.5% and fasting plasma glucose (FPG)<126 mg/dl). Participants from group B with HbA1c levels<5.7% and FPG<100 mg/dl were selected to form a control subgroup (group C). DNA samples were collected after informed consent was obtained and they were analyzed on Illumina Human PsychArray. After quality control, polymorphisms in *VDR* gene were selectedand allele frequencies between groups were compared. Permutation test analysiswas implemented to determine statistical significance. P-values <0.05 were regarded as significant.
Results
Two analyses were undertaken. The first, between group A and group B revealed nosignificant association between T2DM and *VDR* variants with either recessive or dominant model. The second, between group A and group C showed that rs7967152 ($P=0.0276$, OR=1.234)associated significantly with T2DM. Recessive model analysis revealed that AA genotype ofrs7967152 ($P=0.027$, OR=1.543) and TTgenotype of rs12301817 associated significantly with disease ($P=0.037$, OR=0.494).
Conclusion
Our results are indicative of the complexity of T2DM geneticsusceptibility and partly reflect the controversy in the literature regarding the role of vitamin D metabolism in T2DM pathogenesis. Further studies are required to replicate our findings and clarify any complexunderlying mechanisms of action that could contribute to T2DM development.

A case of intentional overdose of insulin glargine and lispro treated with hydrocortisone

Sowmya Boddhula, Matthew Tam & Mercedes Falciglia
University of Cincinnati, Endocrinology, Diabetes and Metabolism, Cincinnati, United States

Introduction
Patients with diabetes have nearly twice the risk of depression compared to general population. Prolonged hypoglycemia can occur with insulin overdose and treatment involves correction of hypoglycemia with oral or intravenous glucose supplementation, with glucagon or octreotide in some cases. Glucocorticoids are not routinely administered but can be used as an adjunct in severe cases. We present a case of intentional insulin overdose in a young diabetic patient with hypoglycemia who responded to additive intravenous hydrocortisone after showing minimal response to repeated administrations of dextrose.
Case description
A 29 year-old female with history of secondary diabetes from chronic pancreatitis with CFTR mutation and previous autologous islet transplantation presented to the emergency department with recurrent episodes of hypoglycemia that persisted despite ingesting high carbohydrate foods. She had a history of self-harm attempts. The patient was using an insulin pump in manual-mode and continuous glucose monitor. She reported that her insulin pump malfunctioned and took reduced dose of 12 units of insulin glargine from a 24-hour basal of 16.8 units the night prior to admission. Serum glucose on presentation was 57 mg/dl requiring 10% dextrose boluses every hour in addition to a dextrose infusion. Hypoglycemia persisted for over 12 hours since admission with lowest point-of-care glucose 19 mg/dl. She eventually admitted to taking 1 full pen of insulin lispro and 1 full pen of insulin glargine; 300+300 units=600 units. For resistant hypoglycemia, a trial of IV hydrocortisone 100 mg followed by 50 mg 8 hours later resulted in subsequent improvement in glucose levels greater than 90 mg/dl. The patient later admitted that she never modified her pump settings and there was no malfunction.
Discussion/Conclusion
Our patient responded well to addition of hydrocortisone with improvement in hypoglycemia within hours after administration. Treatment with glucocorticoids has shown to counteract the resistant hypoglycemia due to insulin overdose in previous case reports. This case highlights a challenge of initial diagnosis due to patient limited disclosure and to consider high risk factors like previous suicide attempts, anxiety and depression in evaluation of hypoglycemia. Careful management of symptoms related to depression and developing a safety plan is integral to complete patient care. In conclusion, our case emphasizes the importance to recognize high risk factors for self-harm in diabetic patients and consideration for early intervention with glucocorticoids for persistent hypoglycemia if insulin overdose is suspected.

Trabecular bone score and insulin resistance in type 2 diabetes mellitus

Maria Hayon Ponce[1], Mª del Carmen Serrano Laguna[1], Maria Dolores Aviles Perez[1], Beatriz Garcia Fontana[2], Sheila Gonzalez Salvatierra[2], Diego Becerra García[1] & Manuel Muñoz Torres[1,2,3]
[1]Hospital Universitario Clínico San Cecilio, Granada, Spain; [2]Instituto de Investigación Biosanitaria de Granada, Spain; [3]Faculty of Medicine, Granada, Spain

Introduction
Trabecular Bone Score (TBS) is a new non-invasive method to evaluate trabecular bone quality at the lumbar spine. The literature has contradictory results concerning the influence of insulin resistance and adipose tissue on bone, for this reason it is of interest to evaluate factors that determine bone health and risk of fracture in patients with T2DM.
Objective
To analyze the relationship between insulin resistance and adipose tissue with bone microarchitecture in patients with T2DM.

Materials and methods
Cross-sectional observational study. We included 137 T2DM patients,mean age 65.2±7.5 years (58% male, 91% overweight/obese) and 300 non-diabetic controls. Demographic, anthropometric, clinical and biochemical variables were studied. To estimate whole-body fat percentage, we used a simple anthropometric linear equation named as the relative fat mass (RFM): 64 – (20 × height/waist circumference)+(12 × sex); sex=0 for men and 1 for women. We determined bone mineral density in the lumbar spine, femoral neck and total hip by dual X-ray absorptiometry (DXA, Hologic QDR 4500), and TBS values using TBS iNsight Software, Med –Imaps, Pessac France). Statistical analysis was performed using the SPSS program (SPSS, inc, v 25.0)
Results
Patients with T2DM show significantly lower TBS values (1.08+ 0.18 vs 1.28+0.15 $P<0.000$) despite of significantly higher lumbar BMD (LS-BMD) (1.05+0.20 vs 0.90+0.52 $P<0.001$) compared to those without diabetes. TBS values were negatively correlated with body mass index (BMI) ($P<0.000$),waist circumference ($P<0.000$) and HOMA-2IR index ($P=0.004$). However, no correlation was found between these parameters with LS-BMD. RFM was negatively correlated with both LS-BMD ($P<0.000$) and TBS ($P=0.005$) in patients with T2DM. In the multivariate analysis the association between TBS and insulin resistance parameters was maintained after adjusting for age and RFM.
Conclusions
This study shows that BMI, RFM, waist circumference, and insulin resistance are associated with lower TBS values in patients with T2DM. Our study suggests that central adiposity and its metabolic consequences negatively affect bone quality in these patients despite normal or increased bone density.

Incidence of large-for-gestational age newborns is still elevated in women with type 1 diabetes in good glycaemic control

Harold W. de Valk & Oosterwijk Lisa A
Utrecht, Internal Medicine, Utrecht, Netherlands

Introduction
Glycemic control has a major effect on fetal growth in women with type 1 diabetes mellitus (DM1), worse control leading to increased growth (large for gestational age (LGA) or very large for gestational age (VLGA) fetus). Current guidelines promote strict control (HbA1c≤48 mmol/mol) before and during pregnancy. Continuous glucose monitoring (CGM) has been instrumental in achieving this goal. We performed a retrospective chart review of pregnancy outcomes in DM1 to assess Outcome and CGM-data in well-controlled women with DM1.
Methods
Forty-eight pregnancies in 25 women were identified between 2016–2019; 19 women with a singleton pregnancy met the inclusion criterion of HbA1c≤48 mmol/mol in first and third trimester. In 8 women there were insufficient CGM-data: final CGM-study group of 11 women. LGA was defined as fetal weight>90th and VLGA>97.7th percentile. CGM-data were studied during 4 periods: 4–8 weeks gestation, 18–22 weeks, 30–34 weeks and last 8 days before delivery. Target range 3.5–7.8 mmol/l. Time in range (TIR), time below range (TBR) and time above range (TAR) were calculated.
Results
In the group of 19 women with adequate control, LGA (both LGA and VLGA) in 36.8%; simple LGA 15.7%, VLGA 21.1%.In none of the pregnancies congenital malformations were seen. Women with a VLGA child were significantly older ($P<0.03$), had higher BMI ($P<0.02$) and longer duration of DM1 ($P<0.02$). In women with normal growth fetus, LGA or VLGA, TIR was 64.1%, 63.6% and 58.5%; TAR: 24.4, 34.4 and 39.6%; TBR: 4.0, 2.2 and 2.1. Classic multivariate logistic regression analysis did not show statistical significance.
Conclusion
Our data show that current implementation of advanced technology did not have a great effect on fetal growth parameters. Mean TIR was below the recommended level in the newest guideline published in Diabetes Care in June 2019. Apparently, adaptation of endocrine care and counselling strategies are needed for improvement in outcome with technology.

The association of glomerular filtration rate with coronary artery disease in type 2 diabetic patients

Mitra Kazemijahromi[1], HamidReza Samimagham[2], Hossein Farshidi[3], Marzieh Nikparvar[3] & Mohsen Arabi[4,4]
[1]Clinical Research Center, Endocrinology, Bandar Abbas, Iran; [2]Clinical Research Center, Nephrology, Bandar Abbas, Iran; [3]Cardiovascular Research Center, Cardiology, Bandar Abbas, Iran; [4]Department of Family Medicine, Iran University of Medical Sciences,Tehran, Iran, Tehran, Iran

Background and aim
Chronic Kidney Disease and Diabetes Mellitus can influenceCoronary Artery Disease (CAD) independently. The aim of this study was to evaluate the association of Glomerular Filtration Rate (GFR) and Coronary Artery Disease in type 2 diabetic patients. (T2DM)
Methods
This cross sectional study evaluated 362 T2DM patients with clinical presentation of CAD whose documents were registered in angiography center during 18 months. GFR was measured by MDRD method and divided into 5 subgroups: GFR<15, 15≤GFR<30, 30≤GFR<60, 60≤GFR<90 and GFR≥90. Then the association of 5 subgroups of GFR with coronary angioplasty in T2DM patients was evaluated. The association between age, sex, hypertension, and dyslipidemia with 5 subgroups of GFR was also studied.
Results
Among 3624 T2DM patients, 36% had GFR<60 (ml/min/1.73 m^2).The highest frequency percentage of coronary angioplasty (53%) was observed in the GFR stage 3 (30–60) ml/min/1.73 m^2. A significant inverse association was observed between the GFR of T2DM patients and the frequency percentage of coronary angioplasty. (P-value<0.001).There was also a significant association between GFR<60 and history of hypertension and dyslipidemia. (P-value<0.001). Using regression analysis, it was shown that GFR can be an independent factor to predict coronary artery disease. (P value=0.02, $\beta=1.003$).
Conclusion
A reduced GFR in patients with diabetes increases CAD, independently of other risk factors.

AEP1047

Prediction of weight loss response to liraglutide

Anna Mosikian, Tatiana Alekseenko, Maria Martjanova & Alina Babenko
Almazov National Research Centre, Saint-Petersburg, Russian Federation

Background
Obesity is a significant risk factor for type 2 diabetes mellitus (T2D), hypertension and ischemic heart disease development. Moreover, in patients with already diagnosed T2D, obesity puts a crimp in achievement of glycemic target. Thus, body weight reduction is important both to prevent T2D and to treat it successfully. However lifestyle habits, diet and physical activity are the key factors of T2D prevention and treatment, eating disorders and disturbed appetite control decrease compliance to these efforts. Liraglutide is successfully used for such cases leading to significant weight reduction, followed by improvement of hypertension and dyslipidemia. However its efficacy varies a lot, and its cost negatively influence treatment compliance. The aim of this study was to reveal patients' parameters likely leading to higher treatment efficacy.
Methods
We tested 41 patient with obesity with mean (± S.D.) BMI of 39.63±7.59 kg/m^2: 27 injecting liraglutide up to 1.8 mg/day and 14–3.0 mg/day for 6

months. We gathered demographic and anthropometric data, parameters of glycemic control, insulin, C-peptide GLP-1, GIP and leptin blood concentration, results of Dutch Eating Behavior Questionnaire and answers to questions about hunger with the use of visual analogous scale at fasting state. We considered a therapy response as ≥7% bodyweight reduction after 6 months of treatment. We used Mann-Whitney U-test to compare responders and non-responders in terms of gathered parameters and linear regression model (LRM) to reveal parameters possibly associated with better weight-reduction response.
Results
We confirmed a dose-dependent liraglutide efficacy in routine clinical practice (more responders in 3.0 mg/day group, $P=0.007$). Responders without T2D had a 1.7-fold lower leptin concentration as compared to non-responders ($P=0.018$). LRM was not statistically significant due to a small sample ($P=0.098$), however regression coefficient was –0.50. In responders without T2D GLP-1 level before therapy initiation positively correlated with body weight reduction ($B=0.84$; $r=0.60$; $P=0.031$). Questions about hunger ('how gorged are you' and 'how much could you eat now') showed $r=0.51$ and –0.46, respectively, however were not statistically significant ($P=0.064$ and 0.097, respectively). Liraglutide was ineffective in BMI > 45 kg/m^2. Other factors were not significant for our data.
Conclusion
Lower leptin and higher GLP-1 concentrations might predict better weight-loss response to liraglutide. Questions about hunger at fasting state might be strong response predictors (need for evaluation at bigger sample). Liraglutide is probably more effective in BMI 30–45 kg/m^2.

Diabetes and COVID-19

Carlos Miguel Peteiro Miranda, Jose Jorge Ortez Toro, Borja Sanz Martín, Sergio Román Gimeno, Rosana Urdaiz Borque, Ana Agudo Tabuenca & Jose Antonio Gimeno Orna
HCU Lozano Blesa, Endocrinology, Zaragoza, Spain

Background
Although obesity and has been associated with COVID-19 mortality, the absolute and relative risks for Type 2 diabetes (DM2) is unknown. The aim of this study was to analyse metabolic characteristics of patients infected by COVID-19 hospitalised and evaluate whether DM2 have an impact in this group of patients.
Methods
We retrospectively analysed data of COVID-19 patients hospitalized to a large academic hospital system in Zaragoza between March 6st and April 02th, 2020. Data included demographics, comorbidities and biochemical parameters. The time-dependent probability of death was evaluated using the Kaplan-Meier method. Univariable and multivariable logistic regression models were performed. P value < 0.05 was considered significant.
Results
The study included 149 patients (87 men) with a mean age of 67.91 years (s.d. 17.03). Hypertension (50.3 %), dyslipidemia (23.5%) and diabetes (20.8%) were the most prevalent comorbidities. By multivariable regression analysis, both Charlson comorbidity index (CCI) (OR 1.627, CI 95% [1.183–2.321] $P=0.01$)and a neutrophil to lymphocytes ratio (NLR) > 10 (OR 4.249, CI 95% [1.419–12.724] $P=0.010$)were associated with a higher risk of COVID-19 mortality. In univariate proportional analysis DM2 (OR 4, CI 95% [1.708–9.367] $P=0.01$), was associated with mortality, but it was not significant in the multivariable analysis.
Conclusion
Our study demonstrates that hospitalized patients with DM2 are more likely to die from COVID-19. CCI and NLR were both good predictors of mortality in this population.

Diabetic emergencies during COVID-19 –A multi-centre experience

Sulmaaz Qamar[1], Umaira Aziz[2], Sadia Nasir[3], Eleni Armeni[1], Maya Zosmer[1], Tobin Joseph[1], Eleanor Crawley[1], Susan Tutty[1], Jo Lynch[1], Pierre Bouloux[4], Ahmed Yousseif[2], Sidrah Khan[3], Ravi Menon[1], Chidambaram Nethaji[1] & Efthimia Karra[2]
[1]North Middlesex University Hospital, United Kingdom; [2]Royal Free Hospital, United Kingdom; [3]Peterborough City Hospital, United Kingdom; [4]University College Hospital, United Kingdom

Introduction
Diabetes mellitus is as a major contributor to disease severity and mortality in patients with Covid-19 infection, as the estimated increase in risk of death in hospitalised patients is 3.5-times (for T1DM) and 2.03-times (for T2DM). This retrospective analysis recruited 35 patients from three London hospitals who presented with diabetic emergencies i.e. diabetic ketoacidosis (DKA), Hyperglycaemic hyperosmolar state(HHS), presence of ketoneamia (beta-hydroxybutyrate >0.6 mmol/l) as well as with positive SARS-CoV-2 PCRduring March 2020.
Results
Median age was 60 years (male 67.5%). 11 (31.4%) of patients had DKA, 13 (37.1%) patients had mixed DKA and HHS picture, 9 (25.7%) presented with hyperglycaemic ketosis and 2 (5.8%) patients had HHS. 17(48.6%) were of African origin and 6 (17.1%) mixed race.80% had T2DM and 5.7% had new diagnosis of diabetes. Across all cases the degree of ketoneamia was negatively correlated with pH (P-value = 0.035), HCO3 (P-value < 0.001) and base excess (P-value = 0.001). Time to ketone resolution was positively associated with fluid volume required (P-value = 0.047) and negatively correlated with pH (P-value = 0.025), HCO3 (P-value = 0.015) and base excess (P-value = 0.007). Median time taken to ketone resolutionfor all patients was 24 hr (IQR 14.6–36), and 35hr (IQR 24–60) for DKA. Median time to ICU admission was 3.00 ± 1.23 days, median length of stay for discharged patients was 18.0 ± 3.98 days. 13 patients were still inpatients at the time of study, 5.7% ($n=2/35$) of patient'snon-insulin treated previously, had died (DKA $n=1$; mixed DKA/HHS $n=1$).
Conclusion
This study shows overrepresentation of T2DM amongst patients admitted with DKA in the context of Covid-19 infection. Our patients, mainly of African/Afro-Caribbean background, had protracted ketoneamia and ketoacidosis with prolonged time to resolution.
These results indicate a possible effect of the ethnic background on the clinical outcome in patients admitted with diabetes emergencies in the context of Covid-19 infection. Large scale observational studies are needed to understand the insulopenic effects of COVID-19.

AEP1050

The impact of strict COVID-19 lockdown in spain on glycemic profiles in patients with type 1 Diabetes prone to hypoglycemia using standalone continuous glucose monitoring

Alex Mesa, Clara Viñals, Irene Pueyo, Daria Roca, Mercè Vidal, Marga Giménez & Ignacio Conget
Hospital Clínic de Barcelona, Endocrinology and Nutrition, Barcelona, Spain

Aims
Spain has been one of the worst affected countries by the COVID-19 pandemic. A very strict lockdown at home was imposed with a tough restriction of mobility. We aimed to evaluate the impact of this exceptional scenario on glucose profile of patients with type 1 diabetes (T1D) prone to hypoglycemia using standalone continuous glucose monitoring.
Methods
Patients with T1D prone to hypoglycemia using multiple daily injections and either a Dexcom G5 or a Free Style Libre CGM systems for at least 6 months under the funding of National Health Service were included in an observational, retrospective study. Data were collected in two periods: pre-lockdown (PL), February 23rd–March 7th and within lockdown (WL), April 1st–14th 2020. The primary outcome was the difference in the proportion of time in target glucose range of 70–180 mg/dl (TIR). Additional glucometric data were also analysed.
Results
92 patients were included: 40 women, age 42.8 ± 3.9 years, disease duration of 23.1 ± 12.6 years. Seventeen patients used Dexcom G5 and 75 Free Style Libre. TIR 70–180 mg/dl (59.3 ± 16.2 vs 62.6 ± 15.2%), time >180 (34.4 ± 18.0 vs 30.7 ± 16.9%), >250 (11.1 ± 10.6 vs 9.2 ± 9.7%) and Glucose Management Indicator (7.2 ± 0.8 vs 7.0 ± 0.8) significantly improved (PL vs WL, respectively, $P<0.05$). Time in hypoglycemia remained unchanged.
Conclusions
Lockdown conditions imposed by the COVID-19 pandemic may be managed successfully in terms of glycemic control by population with DT1 prone to hypoglycemia using CGM. The strict daily routine at home could probably explain the improvement in the time in glycemic target without increasing the time in hypoglycemia.

Clinical characteristics and outcomes of COVID-19 hospitalized patients with diabetes in the United Kingdom: A retrospective single centre study

Alamin Alkundi[1], Ibrahim Mahmoud[2], Abdelmajid Musa[3], Saima Naveed[1] & Mohammed Alshawwaf[1]
[1]William Harvey Hospital, Diabetes and endocrionology, Ashford, United Kingdom; [2]University of Sharjah, Family and Community Medicine and Behavioral Sciences department,College of Medicine, Sharjah, United Arab Emirates; [3]William Harvey hospital, kennington road Willesborough, Ashford kent, United Kingdom

Aim
To describe the clinical characteristics and outcomes of hospitalized COVID-19 patients with diabetes.
Methods
A retrospective cross-sectional study was conducted among patients admitted to the William. Harvey Hospital in England between March 10th and May10th, 2020 with a laboratory confirmed severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2), known as COVID19. Variation in characteristics, length of stay in hospital, diabetes status, duration of diabetes, control of diabetes, comorbidities and outcomes were examined.
Results
There were 232 COVID-19 presentations. Mean (standard deviation (S.D.), range) age was 70.5 (± 15.7, 30–101) years, 62.5% were male, and 37.5% were having diabetes. There were 43.4% males and 27.6 females, $P=0.016$, with diabetes admitted to our hospital due to COVID-19. Patients with diabetes were more likely to have longer length of stay (LOS) in hospital, 14.4 (S.D. ± 9.6) days, compared to the patients without diabetes, 9.8 (S.D. ± 17.1) days, $P<0.0001$. Patients with diabetic ketoacidosis (DKA) were more likely to survive (87.1%) compared to patients without DKA (50.6%), $P=0.046$.
Conclusion
Males were more likely to be admitted to hospital with COVID-19 illness than females. Hospitalized COVID-19 patients with diabetes had a longer LOS in hospital than patients without diabetes. Older age COVID-19 patients with diabetes and patients without DKA were less likely to survive compared to younger patients and patients with DKA, respectively. Further studies with large sample size are needed.
Keywords: COVID-19, diabetes, diabetic ketoacidosis, length of stay.

Characteristics and outcomes in COVID –19 with Type 2 diabetes as compared with patients without diabetes – Retrospective single center cohort study

Rajesh Gosavi, Sajal Mitra, Archana Aher, Madhuri Holay, Somraj Patil & Deepanshu Assudani
Government Medical college, Nagpur

Introduction
COVID 19 is now a global pandemic. Diabetes is postulated to be a risk factor for mortality due to COVID –19
Methods
We retrospectively evaluated the inpatient medical record data, of patients admitted over last two months in a public hospital in Central India to compare the attributes of mortality in patients without T2DM and with T2DM including their glycemic clinical characteristics. Unpaired t – test and Fisher's exact test was utilised for statistical analysis
Results
We analysed a total of 350 COVID –19 patients (204 males, 146 female). The mean age of cohort was 34 years (± S.D. 18, 95% CI 32 to 36). There were 25 (7.14 %) patients with T2DM (13 males) and 325 (92.8 %) patients did not have T2DM (noT2DM). Mean age in T2DM was 54 years (± S.D. 12, 95% CI 49 to 59, min 23, max 73) and in noT2DM was 32 years (± S.D. 18, 95% CI 30 to 34, min 0.1, max 84); $P<0.0001$. Of seven patients who expired, two had T2DM (both males), two had both hypertension with TDM and one had only hypertension. Overall mortality was 2% (7/350), 8 % (2/25) was reported in T2DM which was higher than in the noT2DM 1.5% (5/325). The relative risk of mortality in T2DM as compared to noT2DM was 0.93 (95% CI 0.76 to 0.99), $P=0.082$ (NS). The mean days of illness to mortality was 4.5 days in T2DM as compared to 5.5 days in the NoT2DM group. Among, the two T2DM patients who expired, one presented with severe acute respiratory illness and other with history of contact. Mean Random Blood Sugar (RBS) at the time of admission in T2DM was 183 mg/dl (± S.D. 71, 95% CI 154 to 212, min 78, max 296). The mean RBS in patients who expired was 255 mg/dl, with 72 mg/dl higher than the overall T2DM group. One T2DM who expired had ketoacidosis.
Conclusions
Our results are in line with the emerging global data that postulate that the mortality rates would be much lower than what was documented in the earlier studies. However, patients with T2DM and elderly are at higher risk for death. It is imperative in T2DM to achieve good glycemic control to mitigate the complication of mortality due to COVID 19

Case of steroid diabetes in a female with the hemophagocytic syndrome and panniculitis of Weber-Kristen

Olena Antonyuk
Kyiv, Medical Center 'Univeral Clinic 'Oberig', Ukraine, Ukraine

39-year old female reported usage of methylprednisolone (20–80 mg daily) for three months since the last decade of January 2020. She received methylprednisolone for controlling of panniculitis of Weber-Kristen (diagnosis was proved twice histologically in Ukraine and Austria. Before starting steroid therapy, there was no glucose impairment in her history. The patient has different complaints, including fatigue, increased body temperature, hypersensitivity of the skin, vomiting, wound on her back (after biopsy for four months), polyserositis, menometrorrhagia. The patient was hospitalized to the private medical center 'Universal Clinic 'Oberig' in May 2020 and stayed there for a week. During hospitalization condition of the patient was critical due to general inflammatory, hemorrhagic, pancytopenia, severe liver disorders, with some trend to worsening despite the therapy. The ANA-screen test was negative. Sepsis was not proved (in blood, there was no bacterial growth). She did not have any signs of infectious endocarditis on echocardiography. Results of myelography reported the absence of acute leucosis, but there were signs of aplasia and dysmonopoesis. Trepan biopsy was not performed in Kyiv as the patient disagreed. Liver tests were extremely high (data on the presence of viral hepatitis was not proved). Severe pancytopenia (leucopenia was 0.44 G/l, thrombocytopenia was 58 G/l, hemoglobin was 74–95 g/l), and coagulopathy (starting from hypocoagulation to the absence of coagulation) was observed and corrected all the time. Results of PET CT in February 2020 did not report the data of any solid tumor, except some signs of panniculitis. The usage of methylprednisolone had a temporary effect. Glycated hemoglobin was slightly increased, and during glucose monitoring, there was almost compensated diabetes (sometimes we used insulin for correcting hyperglycemia). The patient was discharged from the hospital according to her wish as she planned to be hospitalized in Austria. In Austria, she was hospitalized to the intensive care unit in some hospital and then to hematological as there were signs of hemophagocytic syndrome. Unfortunately, the patient died due to progression of the disease (hemorrhagic stroke happened). This case is rare, and it describes comorbidity of panniculitis of Weber-Kristen, hemophagocytic syndrome, and steroid diabetes.

A pilot trial for silymarin in prediabetic patients with preclinical liver disease: Focus on insulin resistance

Francisco Javier Martinez-Martin[1,2], Agnieszka Kuzior[3], Paula Maria Fernandez-Trujillo-Comenge[3], Alba Hernandez-Lazaro[3], Sara Quintana-Arroyo[4], Claudia Arnas-Leon[1], Carmen Acosta-Calero[1], Paula Gonzalez Díaz[5], Esperanza Perdomo-Herrera[5] & Alba Lucía Tocino-Hernandez[5]
[1]Hospitales San Roque, Endocrinology And Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospital Universitario de Gran Canaria Dr. Negrín, Outpatient Hypertension Clinic, Las Palmas de Gran Canaria, Spain; [3]Hospital Universitario de Gran Canaria Dr. Negrin, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [4]Hospital Insular de Gran Canaria, Endocrinology and Nutrition; [5]Gerencia de Atención Primaria

Introduction
Silymarin is a standardized extract of the milk thistle (Sylibum marianum) seeds, containing a mixture of flavonolignans: silybinin, isosilybinin, silycristin, silydianin, and others. It is used in the treatment of toxic liver

damage and as adjunctive therapy in chronic hepatitis and cirrhosis. Recent studies have shown a potential benefit in the treatment of diabetes mellitus and non-alcoholic fatty liver disease. We undertook to study the effect of silymarin on insulin sensitivity in prediabetic patients with preclinical liver disease.
Methods
For this open, uncontrolled trial, patients 18–75 years old of both sexes with prediabetes and moderately elevated transaminases or GGT (<3 × ULN) were assigned for treatment twice a day for 3 months with a capsule containing silymarin (196 mg) plus Agrimonia eupatoria extract (166 mg) plus Lamium album extract (166 mg). The main endpoint was the change in the HOMA-2 index of insulin resistance (https://dtu.ox.ac.uk/homacalculator). Secondary endpoints: effects on fasting glucose, insulin, HbA_{1C}, and the change of status from prediabetes to normoglycemia or diabetes mellitus. Tertiary endpoints: changes in AST, ALT and GGT. Additional endpoints: changes in BMI, lipid profile, blood pressure and heart rate. Security endpoints: Reported adverse effects and compliance (by questionnaire).
Results
11 patients were recruited (64% women, age 49.3±12.3 years, BMI 32.2±6.3 kg/m^2). The HOMA-2 index was significantly reduced from 3.49±0.58 to 2.96±0.49 (P=0.043, paired t-test). Fasting insulin, but not fasting glucose or HbA_{1C}, was also significantly reduced. 2 patients changed status to normoglycemia but none progressed to diabetes mellitus. AST, ALT and GGT were significantly reduced. BMI, lipid profile, blood pressure and heart rate did not change significantly, but there was a trend for reduced triglycerides and increased HDL-cholesterol. The mean reported compliance was 87% and no serious side effects were reported; no patient withdrew from the study.
Conclusions
The combined extracts of Silybum marianum, Agrimonia eupatoria and Lamium album were well tolerated and able to ameliorate the insulin resistance of prediabetic patients with preclinical liver damage, mainly by decreasing their fasting insulin. The liver enzyme profile was also improved. This combination could be expected to reduce the long term risk of progression to type 2 diabetes in these patients. The limitations of this pilot trial are obvious, but a full-scale trial seems warranted.

The effects of selective activation of kisspeptin neurons in hypothalamic arcuate nucleus on energy metabolism in mice

Qian Li[1], Qinyu Liu[1], Guifeng Huang[1], Wei Lin[1], Gang Chen[1,2] & Junping Wen[1]
[1]Department of Endocrinology, Fujian Medical University, Fujian Medical University, China; [2]Fujian Key Laboratory of Medical Measurement, Fujian Academy of Medical Sciences

Objectives
This study aims to determine which metabolic tissue is involved in the process of kisspeptin neurons regulate energy metabolism so that it may provide a novel therapy for metabolic related diseases such as obesity.
Methods
Kiss1-CreGFP mice were used in this study. And we selectively activated kisspeptin neurons by using Designer-receptors-exclusively-activated-by-designer-drugs (DREADDs) technology. Mice were bilaterally injected with the Cre-dependent adeno-associated viral (AAV) vector encoding human M3-muscarinic receptor (hM3Dq) fused with red fluorescent protein in ARC. And peripheral administration with clozapine N-oxide (CNO) leads to CNO-dependent activation of kisspeptin neurons in ARC (kiss1ARC), then, we studied metabolic phenotype of mice.
Results
Neuronal activation of kisspeptin neurons with DREADDs decreases body weight, daily average food intake, and increases energy expenditure by altering brown adipose tissue (BAT) thermogenic process and browning of white adipose tissue (WAT), which is depend on different energy states only in female mice.
Conclusions
Our results previously demonstrated that kisspeptin neurons play crucial role in controlling energy metabolism, which is sexually dimorphic.

Levels of lymphocytes subpopulations in peripheral blood among patients with diabetes mellitus type 2

Silviya Ganeva, Katya Todorova, Tsvetan Lukanov, Ginka Rayanova & Svetla Bajeva
Medical University – Pleven, Плевен, Bulgaria

Aim of the study was to investigate the lymphocytes (lymph) subpopulations as a part of immune response in peripheral blood among the patients with Diabetes mellitus type 2 (DMT2).
Patients and methods
A prospective, cross-sectional, comparative, 'case-control' study was conducted among 70 patients with DMT2. The levels of lymph subtypes[general nonspecific T-lymph (CD3+); T-helper lymph (CD4+); T-cytotoxic lymph (CD8+), natural killers [NK cells (CD3\ CD16+/CD56)] and B-lymph (CD19+)] in blood was measured and compared by flow-cytometric analisys (FAC Sort, BD).Results were compared to those of 22 patients with Diabetes mellitus type 1 (DMT1) and 21 healthy persons. The data was processed using the statistics software.
Results
No significant differences between arterial blood pressure, HвA1c levels and lipid profile among the patients with DMT1 and DMT2. No differences in the total leukocyte count between diabetic persons (DMT1–6.91±1.32.10^9/l; DMT2–7.28±1.85.10^9/l; controls-6.89±1.07.10^9/l). The results from flow-cytometric investigation showsignificantly higher absolute number of T-all lymph (CD3+), Th lymph (CD4+) and all NK (CD3\ CD16+/CD56), as well as a lower absolute number of Ts (CD8+) and B (CD19+) lymph among the diabetic patients compared to healthy subjects. The Th/Ts ratio in patients with DMT1 (2.02±0.44) and DMT2 (2.36±0.37) is also significantly higher compared to ratio of controls (1.02±0.06). No significant differences in the lymph subpopulations between the two groups with DM.
Conclusions
Changes of lymph types in peripheral blood in diabetic patients demonstrate immune activation and dysregulation among the two types of diabetes.
Keywords: type 1 diabetes mellitus, type 2 diabetes mellitus, flow- cytometry, lymphocytes.

AEP1057

Role of insulin aspart fiasp in patients with diabetes mellitus

Sara León Utrero[1], M del Carmen Serrano Laguna[1], Enrique Redondo Torres[1], Gonzalo Piedrola Maroto[2] & Miguel Quesada Charneco[1]
[1]Hospital Universitario San Cecilio, Granada, Spain; [2]Hospital Universitario Virgen de las Nieves, Granada, Spain

Introduction
Postprandial glycemic control is complex as well as insufficient. Its impact on global metabolic control (HbA1c) is controversial with various works that support its influence in terms of glycemic variability and genesis of micro and/or macrovascular complications. Fiasp due to its special formulation allows a more effective control of postprandial glycemia being an interesting alternative to the rapid-acting insulin analogavailable.
Objective
To assess the impact of FIASP insulin on global metabolic control (HbA1c) and patient adherence to this new formulation.
Materials and methods
Prospective study of 82 patients with DM followed up in two hospitals in Granada whose initial 'fast' insulin was replaced by FIASP. Two groups are theorized: 1. HbA1c>8.5% (greater influence of poor control of basal glycemia) and 2. HbA1c<8.5% (greater influence of poor postprandial control). The statistical study was carried out with the SPSS15 program.
Results
82 patients (52.4% women) with a mean age of 41.54±16.9 years. Evolution time of DM of 15.9±9.40 years. 78% of DM1 patients, all in bolus basal regimen. Average basal insulin dose of 30.47±14.89 IU (0.42 IU/kg). Basal 'fast' insulin: 8% aspart, 16.9% glulisine, 20.9% lispro and 1.2% human rapid. Baseline HbA1c and blood glucose values of 8.65±1.49% and 148.23±71.34 mg/dl respectively. After a mean follow-up of 7.9±3.5 months (67 patients with data available at follow-up), HbA1c and baseline blood glucose values were 8.20±1.22% (P<0.05) and 132, 67±62.71 mg/dl (NS) respectively. A greater decrease in HbA1c was observed in those patients with baseline HbA1c>8.5 (P<0.05). During the follow-up, 26.8% of the patients needed to decrease the doses with respect to the rapid insulin

they used previously and 12.2% decided to stop Fiasp and return to their initial rapid insulin.
Conclusions
Fiasp improved metabolic control in a large group of patients with DM, especially in the group with baseline HbA1c > 8.5. Adequate information to the patient about the characteristics of said insulin is necessary in order to increase adherence and achieve the potential benefits expected with this formulation.

AEP1058

Changes in metabolic control and body composition with Semaglutide sc in patients with type 2 diabetes mellitus

Enrique Redondo, Mª Carmen Serrano, Sara Leon, Mª Carmen Andreo, Luisa Sebastian, Miguel Quesada & Pablo Lopez-Ibarra
1San Cecilio University Hospital, Granada, Spain

Objectives
aGLP1 have been positioned as an effective and safe treatment in patients with Type 2 Diabetes Mellitus (DM2). The objective was to evaluate the changes metabolic and body composition at 6 months after initiation with Semaglutide weekly subcutaneous added to its basic treatment in patients with DM2.
Material and methods
Prospective observational study. Treatment was started in 42 patients with DM2, with weekly subcutaneous Semaglutide with a 6-month follow-up. We studied clinical, biochemical, anthropometric and body composition changes. In addition, treatment adherence, side effectsand changes in dietary habit were evaluated. The body composition study was performed with Tanita TBF-300 impedancemeter. Statistical analysis was performed through the SPSS program (SPSS, inc, v 15.0).
Results
42 patients with DM2 were recruited. Average age was 61 ± 9.7 years, 54.8% males. Baseline data: A1c 8.75 ± 1.8%, baseline blood glucose 176.55 ± 62.7 mg/dl, BMI 35.98 ± 7 kg/m^2, SBP 138.7 ± 16.8 mmHg. In basal impedanciometry, the average fat mass (%), lean mass (kg) and total water (kg) was 38.1 ± 7.94%, 60.8 ± 9.9 kg and l 44.5 ± 7.2 kg respectively. 40.4% had established CVD, preferably MI. Base treatment: 64.3% metformin, 35.7% iSGLT2, insulin: 50% basal insulin analog and 11.9% rapid insulin analogues and 71.4% statins. After 6 months of treatment there were statistically significant reductions in A1C (–1.85 ± 2.09%), baseline blood glucose (–47.9 ± 74.54 mg/dl), weight (–4.92 ± 4.2 kg), BMI (–1.88 ± 1.66 kg/m^2), SBP (–12.1 ± 15.5 mmHg), LDL (–17 ± 42.5 mg/dl), TG (–44.1 ± 118.37 mg/dl) and fat mass (–2.66 ± 4.37 kg). The presence of iSGLT2 in the treatment did not influence the results. Treatment adherence was 55%. 71.4% reported a greater feeling of postprandial fullness. We did not detect serious adverse effects. 50% of patients made changes in their habits diet after the introduction of semaglutide.
Conclusions
In our experience, Semaglutide treatment is very effective and sure producing very beneficial changes at metabolic level, in body composition, blood pressure, lipid profile and even dietary patterns in patients with Type 2 diabetes mellitus 6 months after the start of treatment. It is necessary collaboration strategies between patients, educators, and physicians to improve adherence to treatment.

AEP1059

Coronary heart disease and diabetes mellitus type↑ in emergency workers of the Chernobyl accident

David Belyi, Olena Nastina, Zhanna Gabulavichene, Gennedyi Sidorenko, Nataly Kursina & Olexander Bazyka
National Research Center for Radiation Medicine, Cardiology Department, Kiev, Ukraine

Objective
The study was focused on evaluation of coronary heart disease (CHD) and diabetes mellitus type II (DM) onset in emergency workers (EW) who took part in elimination of the Chornobyl accident in 1986 year.
Materials and methods
The EW (n = 443, males) and 172 males not exposed to ionizing radiation (the control group, CG) were involved in the study in 2013–2019. EW absorbed doses of irradiation changed from 4.3 till 710 cGy. Diagnosis of CHD and type II diabetes mellitus (DM) was established in accordance with diagnostic standards of European Society of Cardiology and European Society of Endocrinology. All study subjects had no signs of CHD, and neither of endocrine disease nor of metabolic disorders before the accident.
Results
Patients that came in our hospital had cardiovascular diseases but comorbid diseases also analyzed. DM was diagnosed in 125 EW (28.2 %) and 42 persons (24.2 %) from CG. The onset of CHD was preceded by DM development in 40 (32.0 %) EW and 16 (38.1 %) CG patients. The DM course in EW was not significantly different from non-irradiated control by both severity and such complications as retinopathy, angiopathy of lower extremities and nephropathy; insulin was administered for no one patient. Concomitant DM was associated with a higher incidence of angina pectoris, heart failure and arterial hypertension equally in both groups. There were no significant correlation between absorbed dose and time of CHD or DM onset, as well as with age of these pathology developments. According to the Kaplan-Meier survival method, CHD developed in more young age than DM in EW (56.0 ± 0.4 vs 78.8 ± 0.9 years, log-rank test χ^2 = 402.8, P = 0.000) and CG patients (60.5 ± 0.7 vs 77.5 ± 1.2 years, log-rank test χ^2 = 135.5, P = 0.000). In EW the accumulation of new DM cases occurred faster in the EW compared with individuals of CG, however with statistical significance in subjects aged until 60 years old (log-rank test χ^2 = 4.99, P = 0.026).
Conclusions
Though the terms of CHD and DM onset did not depend on the radiation dose the labor under radiation exposure can be considered as a factor accelerating the development these diseases.
Keywords: chernobyl accident, radiation exposure, emergency workers, coronary heart disease, diabetes mellitus type.

Background
Although risk factors for diabetic foot ulceration (DFU) have been extensively studied in patients with diabetes in Egypt, there is surprisingly limited evidence among those on chronic hemodialysis (CHD).
Aims
To investigate the risk factors for foot ulceration in adult patients with diabetes with end stage renal disease on hemodialysis in Dakahlia Governorate central hemodialysis units.
Patients and methods
This Cross-sectional study included all diabetic patients under CHD aged ≥ 18 years (n = 98), recruited over 7 months from the largest seven central hemodialysis units in Dakahlia governorate, Egypt. Dakahlia governorate has 18 central hemodialysis units. Data were collected on the following variables: age; gender; type and duration of DM; duration of dialysis, previous history of foot ulcers/ amputation, previous foot care education, and previous use of therapeutic footwear or custom made insoles (CMI). The feet were thoroughly examined, according to the International Working Group on the Diabetic Foot 2019 recommendations, to identify any deformities, skin or nail pathology, tenia pedis, or DFU. Footwear and foot health care behaviors were also assessed. Peripheral sensory neuropathy was detected using the 10-g (5.07 Semmes- Weinstein) monofilament. Peripheral arterial status was assessed by palpating the dorsalis pedis and posterior tibial pulses on both feet. The diagnosis of peripheral arterial disease (PAD) was further confirmed by measuring ankle pressure (Duplex; Bidop ES-100 V3 Hadeco Inc, Japan) and calculation of ankle-brachial index.
Results
The study included 57 males and 41 females. The mean age was 57.94 ± 8.93 years. The median duration of diabetes was 15 (2–33) years. 61 (62.2%) patients were on insulin therapy. The median duration of hemodialysis was 3 years. Insensate neuropathy was diagnosed in 65.3% of patients, and 15.3% of patients had PAD. The prevalence of foot deformities was 18.36%. Dry skin and plantar calluses were recorded in 62.2% and 27.6% of patients, respectively. Tinea pedis was found in 45.9%. 2 (2.04%) patients had active

foot ulcers, 9 (9.18%) patients had ulcers in remission; therefore the overall DFU prevalence was 11.22%. Ten patients (10.2%) had previous minor amputations, with no reported major amputations. 95.92% of patients had poor foot health care behaviors, and 81.63% were using inappropriate footwear. None of the included patients previously used CMI.
Conclusions
The key finding of this article suggests a high prevalence of risk factors for foot ulceration among diabetic patients receiving hemodialysis. Diabetic foot screening should be included in management strategy of those on CHD.

The first case report of Pembrolizumab inducing thyroiditis and hypophysitis

Sima abdel rahman Maraqa[1], Robert McMahon[2], anusha pinjala[2], Alheli arce gastelum[2] & mohsen zena[2]
[1]Creighton University, Internal Medicine, Omaha, United States; [2]Creighton University, United States

Pembrolizumab is a monoclonal antibody (ab) that exerts antineoplastic effects by inhibiting the immunoevasive effects PD-1 grants cancer cells. It's used to treat several forms of cancer, including melanoma and non-small cell lung cancer. Despite the promise pembrolizumab has demonstrated, it has been associated with immune-related adverse events. In this report, we describe the first case of both thyroiditis and hypophysitis occurring during active pembrolizumab therapy.
A 51-year-old male who was referred to endocrinology for subclinical hyperthyroidism. He has past medical history of hypertension, psoriatic arthritis, and poorly differentiated stage IV lung adenocarcinoma with brain metastasis. For the last 18 months, his cancer had been managed pharmacologically with pembrolizumab (200 mg every three weeks). The patient lacked a family history of thyroid disease and disclosed mild fatigue as his only symptom. Vital signs included the following: blood pressure of 92/42 mmHg, pulse of 68 beats/minute, respiratory rate of 16 breaths/minute, and body mass index of 29.94 kg/m^2. Physical examination was unremarkable. Pertinent laboratory test results included an elevated fT4 (1.6 ng/dl) and a suppressed TSH (< 0.005 µIU/ml). Thyroid stimulating immunoglobin, thyroid peroxidase ab, and TSH receptor ab tests were negative. Based on this work-up, the patient was diagnosed with pembrolizumab-induced thyroiditis and, given the mild presentation, was not prescribed anything.
At a follow-up visit two months later, the patient was found to have post-thyroiditis hypothyroidism, prompting levothyroxine initiation. After an additional four months, he complained of worsening fatigue and dry skin. TSH, fT4, FSH, LH, and total testosterone were within normal limits. 8 am cortisol, ACTH, free testosterone, and IGF-1 were reduced (0.7 µg/dl, 5.9 pg/ml, 6.1 pg/ml, and 37 ng/ml, respectively).ACTH stimulation test showed 0.5 mg/dl, 2.3 mg/dl, 3.1 mg/dl at morning, 30 and 60 minutes. A pituitary MRI was unremarkable. As a result, the patient was diagnosed with central adrenal insufficiency and started on hydrocortisone therapy. His condition improved with levothyroxine and hydrocortisone, and pembrolizumab was eventually discontinued after the patient switched to a new oncologist.
Hypophysitis occurs in approximately 1.1% of patients taking pembrolizumab. Pembrolizumab-induced thyroiditis is considered more common, though incidence estimates vary. Diagnosing these conditions involves clinical symptoms, laboratory test results, and imaging studies. With regard to imaging, pituitary MRI is the preferred study despite hypophysitis abnormalities appearing only 28% of the time. Finally, physician should keep hypophysitis diagnose in mind especially before starting patients on thyroid supplementation due to the chance of a frank adrenal crisis.

The emotional outbreak of (endocrine) cancer patients during COVID-19 pandemic

Rosa Falcone[1], Giorgio Grani[1], Valeria Ramundo[1], Rossella Melcarne[2], Laura Giacomelli[2], Sebastiano Filetti[1] & Cosimo Durante[1]
[1]Sapienza University of Rome, Translational and Precision Medicine, Rome, Italy; [2] Sapienza University of Rome, Surgical Sciences, Rome, Italy

Background
The 2019 coronavirus disease (COVID-19) pandemic is a public health emergency and raises the issue of psychological and physical resilience in more vulnerable patients. We investigated the emotional impact of the SARS-CoV-2 spread among cancer patients, followed at our Institution in Italy, after the restrictive measures imposed by the government and the disruption of planned clinical activities.
Methods
From March 18th to April 1st, 2020, we conducted an online survey among cancer patients (Group 1: with advanced/metastatic disease undergoing systemic treatment; Group 2: with metastatic thyroid cancer in active surveillance; and Group 3: patients with no evidence of structural disease in standard follow-up), sending by email two questionnaires: the COVID-19 questionnaire,specifically designed by our team for the public health emergency ongoing, and an online version of the validated Italian translation of the EORTC QLQ-C30 questionnaire.
Results
The overall COVID-19 concernedness score was higher in women than in men (8 [IQR 5–9] vs 6 [IQR 5–8]; $P=0.048$), and in younger (<65 years) than in older ones (≥65 years) (8 [IQR 5–9] vs 6 [IQR 4–8]; $P=0.013$), without differences across cancer identified groups. The score had a strong inverse correlation with the EORTC QLQ-C30 Emotional function subscale (rho –0.69; $P<0.001$).
Conclusions
Patients with cancer (even if long-standing and well-controlled) report negative feelings and fear, independently from their actual need for medical care and from the seriousness of their disease. As physicians, we should reinforce patients' education and address all these worries, to provide the best possible high-value care.

Neuromyelitis optica presenting as intractable hiccoughs and SIADH: A Case Report

Sulmaaz Qamar, Eleni Armeni, Md Mainuddin, Gary Hotton & Ravi Menon
North Middlesex University Hospital, London, United Kingdom

Neuromyelitis Optica (NMO) is a neuro-inflammatory condition usually presenting with optic nerve and spinal cord events, caused by autoimmunity to Aquaporin 4 (AQ4) channels in the central nervous system (CNS). The high density of AQ4 channels in the hypothalamus and area postrema mean that NMO can occasionally present with atypical features. We present a 56-year old South Asian man, who presented with hiccoughs and Syndrome of inappropriate antidiuretic hormone (SIADH) and was eventually diagnosed with NMO.
Clinical Case
Patient presented with 3-day history of intractable hiccoughs; physical examination including neurological, was unremarkable. On admission, serum sodium was 123 mmol/l (135–145 mmol/l), urine sodium 61 mmol/l, urine osmolality 551 mosm/kg. Thyroid function tests, cholesterol and cortisol levels were within the normal range, suggesting SIADH. The CT Head was unremarkable; CT CAP demonstrated no evidence of malignancy. In the intensive care unit, hypertonic saline was administered, and he was fluid restricted. The serum sodium normalised, and he was discharged. He re-presented 2 weeks later with tingling and numbness to the left hand. He subsequently developed weakness in both upper limbs and dyspnoea. This time serum sodium was 137 mmol/l. CSF was acellular with normal protein and glucose with absent oligoclonal bands. Paraneoplastic serology was negative, however Aquaporin4 antibodies (AQ4Abs) were present. MRI Brain demonstrated a small focus of enhancement at the lateral aspect of the right ventricle and MRI Spine demonstrated a cervical cord lesion extending from the lower medulla to C7, with contrast enhancement suggestive of transverse myelitis. 18FDG PET imaging was normal. Intravenous methylprednisolone and plasma exchange were administered. He was started on mycophenolate mofetil and the prednisolone tapered. He improved clinically and follow-up scans demonstrated resolution of the cervico-medullary enhancement and reduction of the cord swelling.
Discussion
SIADH in NMO is attributed to targeting of the hypothalamic AQ4 channels by AQ4Abs. The intractable hiccoughs are associated with inflammatory involvement of the area postrema. The combination of SIADH and intractable

hiccoughs is rare, however both regions contain relatively high levels of aquaporin 4 channels and the combination should make clinicians strongly consider NMO even in the absence of the classical neurological symptoms.

Pharmacokinetics and pharmacodynamics of macimorelin acetate (AEZS-130) in paediatric patients with suspected growth hormone deficiency (GHD)

Violetta Csákváry[1], Agota Muzsnai[2], Dmitri Raduk[3], Tetyana Chaychenko[4], Birgitte Bentz Damholt[5,6], Ekaterine Bakhtadze Bagci[5], Michael Teifel[7,8] & Nicola Ammer[7]
[1]Markusovszky Teaching Hospital, Department of Paediatrics, Szombathely, Hungary; [2]Buda Children's Hospital, Budapest, Hungary; [3]HCI 2nd Children's City Clinical Hospital, Minsk, Belarus; [4]Kharkiv National Medical University, Department of Paediatrics 1 and Neonatology, Kharkiv, Ukraine; [5]Novo Nordisk A/S, Global Development, Søborg, Denmark; [6]Novo Nordisk A/S, Stem Cell Development, Måløv, Denmark; [7]Aeterna Zentaris GmbH, Frankfurt, Germany; [8]Cleara Biotech BV, Utrecht, Netherlands

Growth hormone deficiency (GHD) in children is a rare, aetiologically diverse condition that results in growth failure and short stature. Inadequate response to two different growth hormone stimulation tests (GHST) is required for the diagnosis of GHD. Macimorelin acetate, a potent, orally administered growth hormone (GH) secretagogue, is approved by the FDA and EMA for the diagnosis of adult GHD. Study AEZS-130-P01 is the first of two studies to investigate macimorelin acetate as diagnostic test in children with suspected GHD. This was an open-label, group comparison, dose escalation trial to investigate the safety, tolerability, pharmacokinetics and pharmacodynamics of single-dose 0.25, 0.5 and 1 mg/kg oral macimorelin acetate in paediatric subjects with suspected GHD. The macimorelin GHST was administered between two standard GHST, conducted as per local clinical practice, with a recovery period of 7–28 days between tests. Blood samples were collected pre-dose (± 15 min) and 15, 30, 45, 60, 90, 120 and 360 minutes after macimorelin acetate intake. Overall, 24 paediatric subjects (8 per cohort [C1, C2, C3]) were included in the pharmacokinetic/pharmacodynamic (PK/PD) analysis. Five males and three females were observed in C1 and C2, seven males and 1 female in C3. In all three cohorts, at least 3 subjects represented Tanner stages I or II. All 24 subjects (100%) were white, with a median age of 9.8, 9.0 and 10.5 years (range 4–15 years) and a median body-mass index of 16.1 kg/m^2 (12.4–21.4 kg/m^2) at screening. Overall, 88 adverse events were reported, many related to the standard GHST; none were considered related to the macimorelin test. Maximum plasma concentrations for macimorelin were mainly observed between 30–45 min. The mean C_{max} values were 3.46, 8.13 and 12.87 ng/ml for C1, C2, and C3, respectively. The AUCs increased with dose; the mean $AUC_{0–6}$ values were 6.69, 18.02 and 30.92 h*ng/ml. The mean elimination half-lives were 1.22, 1.61 and 1.71 h, respectively. PK and PD profiles for all three cohorts were comparable, with peak GH levels mainly observed within 30–60 min following macimorelin intake. Macimorelin acetate was safe and well tolerated in all dosing cohorts. A dose-dependent increase in macimorelin C_{max} and AUC in children and adolescents correlated well with data from adultsubjects. A robust dose-proportional GH response was also achieved. PD results showed that GH response was comparable in all dose groups, with a slight shift to earlier t_{max} at higher macimorelin doses.

Efficacy and safety of long-acting pasireotide in acromegalic patients in the real life: The reappraisal of the first-dose follow-up visit

Claudio Urbani[1], Francesca Dassie[2], Benedetta ZAMPETTI[3], Agostino Maria Di Certo[1], Renato Cozzi[3], Pietro Maffei[2] & Fausto Bogazzi[1]
[1]University of Pisa, Section of Endocrinology – Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University hospital Padova, UO Internal Medicine 3, Department of Internal Medicine, Padova, Italy; [3]ASST Grande Ospedale Metropolitano Niguarda-Milano, Section of Endocrinology, Milano, Italy

Background
Pasireotide is a multi-ligand somatostatin analogue licensed in a long-acting release formulation (PAS-LAR) for the treatment of acromegaly. The real-life reports with PAS-LAR are still scanty.
Objectives
To assess the efficacy and safety of PAS-LAR in patients with acromegaly.
Patients and methods
Prospective observational multi-centre study enrolling acromegalics evaluated before (baseline) and 1, 6, 12, 24, and 36 months after PAS-LAR start. Biochemical and radiological studies have been collected. Acromegaly symptoms and drug-related adverse events (AEs) have also been recorded. Patients achieving an IGF1-index (IGF1 normalised to the upper limit of normal) ≤1.3 were considered as controlled.
Results
forty-eight acromegalics were enrolled (22 females; mean age 43 years). All patients have been previously treated with first-generation somatostatin analogues. 77% of them had received multimodal treatments for acromegaly. The PAS-LAR starting dose was 40 mg/28 days in all and was escalated to 60 mg/28 days in 16 patients and decreased to 20 mg/28 days in 3. PAS-LAR significantly decreased IGF1-index levels (baseline vs the last visit: 1.9 ± 0.6 vs 1.2 ± 0.6, $P < 0.0001$) and controlled the disease in 62% of cases at last visit. Interestingly, the effects of PAS-LAR on IGF1 have been already observed during the 1-month visit (IGF1-index 1.4 ± 0.7, $P = 0.0002$ vs baseline; disease control rate 60%, $P < 0.0001$). Only minor changes were observed by carrying on the treatment and escalating the dose, not achieving a statistical significance. PAS-LAR was associated with a rapid improvement or disappearance of headache in 50% of the symptomatic patients even after the first drug dose. MRI showed a decrease in tumour volume in 44% of subjects and no changes in 56%. Hyperglycaemia was the most common adverse event of PAS-LAR. The prevalence of diabetes increased from 33% at baseline to 54% at the last visit. Three patients developed DKA. The second most frequent AEs was mild gastrointestinal discomfort. Most glycaemic and gastrointestinal AEs was recognised in the 1st-month visit or after dose escalation. Eleven patients had discontinued PAS-LAR mainly forlack of disease control or worsening of hyperglycaemia, both occurring in eight cases.
Conclusions
PAS-LAR significantly decreases IGF1 and the size of adenoma and may quickly improve headache in a significant percentage of acromegalic patients. The beneficial effects of PAS-LAR on IGF1 levels and headache as well as its glycaemic AEs may occur even after the first administration of the drug. The 1st-month evaluation should be considered part of the standard care of PAS-LAR treated acromegalics.

AEP1066

Effect of long term rhgh treatment on bone mineral density in patients with childhood onset growth hormone deficiency

Francesca Dassie, Alice Spinazze, Lucia Russo, Matteo Parolin, Roberto Mioni, Pietro Maffei, Marco Zaccaria, Roberto Vettor & Eugenio De Carlo
University of Padua, DIMED, Italy

Background
RhGH treatment in adults with childhood onset growth hormone deficiency (COGHD) affect bone metabolism over time according to gender and age. A long-term study of bone mass density (BMD) in young-middle age hypopituitary patients with COGHD may better highlight possible benefits of therapy and improve clinical follow up.
Methods
We enrolled 40 adults (age range during follow-up: 16.8–36 years, F: 38%) with COGHD with at least 20 years of clinical follow-up. The following data were collected at baseline and during the follow-up: anthropometric parameters,hormonal data, IGF-1 values, lumbar spine and femoral neck BMD derived from DEXA. Based on IGF-1 levels patients were divided into two groups: patients with continuous sufficient IGF-1 levels (at least 60% of IGF-1 values within the normal age and gender range) and patients with discontinuous IGF-1 levels (< 60% of IGF-1 values within the normal range).
Results
At lumbar spine,at baseline 47.5%of patients were osteopenic and 17.5% of patients were osteoporotic, these percentages did not differ during the follow-up. At femoral neck, 44.7% of patients were osteopenic and 2.6% were osteoporotic at study start and after 15 years of follow-up the percentage of osteopenic patients increased significantly while the others remained stable. Regarding BMD values, at lumbar spine there was a progressive increase of BMD up to 10 years of follow-up with a following reduction

and a return to baseline after 20 years (BMD g/cm^2: baseline 0.923±0.12, 10 years 0.991±0.13 *P* baseline vs 10 years<0.05, 20 years 0.924±0.15). At femoral neck there was no changes in BMD values up to 10 years, followed by a BMD deterioration below basal values after 20 years (BMD g/cm^2: baseline 0.797±0.14, 15 years 0.704±0.12 *P* vs baseline <0.05, 20 years 0.706±014 *P* vs baseline <0.05). Men had higher BMD than women at both sites. Patients with continuously sufficient IGF-1 levels had greater lumbar spine BMD levels compared to those with discontinuous IGF-1 levels (BMD IGF-1 in range vs IGF-1 below range: 10 years 1.009±0.14 vs 0.903±0.12 *P*<0.05, 15 years 0.948±0.11 vs 0.861±0.13 *P*<0.05, 20 years 0.975±0.12 vs 0.867±0.13 *P*<0.05), no differences were found in femoral neck BMD.

Conclusion

Our data supports the need for a punctual monitoring of bone metabolism and IGF-1 levels during prolonged rhGH therapy in GHD. Tostudy the long-term effect of GH replacement therapy on risk fracture in a rare condition such as GH deficiency, a multicenter study would be needed.

DOI: 10.1530/endoabs.70.AEP1066

AEP1067

Androgen deprivation therapy for prostate cancer with GnRH agonists: Metabolic consequences

Elena Gritskevich & Tatyana Demidova
Pirogov Russian National Research Medical University, Moskva, Russian Federation

Objective

To assess metabolic disorders and thyroid function in patients with prostate cancer, who were treated with gonadotropin-releasing hormone(GnRH) agonist. Study design follow-up study.

Materials and methods

102 patients were enrolled to the study, 99 subjects were followed up till the study completion. The mean age was 69 years old (95% confidence range: 61.5–79.2 years old). To assess thyroid function, thyroid-stimulating hormone (TSH) and free T4 were measured prior to and in 12 months after androgen depriving therapy (ADT). To see metabolic disorders, waist circumference (WC), body mass index (BMI), and total cholesterol (TC) were measured prior to and 3, 6 and 12 months after ADT initiation.

Study results

The following changes were noted in test parameters: thyroid hormones (basic and 12 months later, respectively): TSH (mU/l): 1.67 506 and 1.90 684 (*P*<0.001), free T4 — 11.6266 and 11.0555 (*P*<0.001). Metabolic parameters (basic, 3, 6 and 12 months, respectively): WC (cm): 91.5, 95.4 (+4.2%), 96.1 (+5.0%), 96.4 (+5.4%) (for all differences *P*≤0.017); BMI (kg/m^2): 27.4, 28.2 (+2.9%), 28.4 (+3.6%), 28.4 (+3.6%) (*P*≤0.004 for all differences, save for differences between values in 6 and 12 months — *P*=0.995); TC (mmol/l): 5.2, 5.6 (+7.7%), 5.8 (+11.5%), 5.9 (+13.5%) (for all differences *P*≤0.001). Statistically significant positive correlation was recorded between TSH and TC dynamics (*R* v 0.285, *P*=0.004), statistically significant negative correlation — between TSH and free T4 (*R*=–0.315, *P*=0.001).

Conclusion

GnRH agonist monotherapy led to the trend of increase in WC, body mass, TSH raise and free T4 reduction one year after ADT, though mean hormone values were within acceptable range; TH demonstrated an increase. The highest increase in WC, BMI, TC was recorded within first 3 months of therapy, then the rate of increase diminished. Further study of metabolic and hormonal complications from ADT and evidence base enhancement are required in order to check the data and develop measures to prevent complications.

Growth hormone (GH) therapy (GHT) requires long-term commitment to daily sc GH injections that may present adherence challenges. Patient preference and adherence have been shown to be affected by delivery devices in association with convenience of administration, level of injection-site pain, confidence in correct dose administration and satisfaction with the device. This survey investigated if switching GH device – from NordiLet/others to NordiFlex – improved patient-reported preference, satisfaction, ease of use and adherence in paediatric patients receiving GHT in South Korea. Patients aged 4 to ≤18 years receiving GHT from paediatric clinics in South Korea between January and July 2019 were surveyed. Participants were current users of NordiFlex for 4–24 weeks who had previously used NordiLet or other GH devices for≥12 weeks before switching. Patients/caregivers compared the subjective benefits of NordiFlex vs previous device in a 25-question survey comprising four domains: *ease of use*, *self-efficacy*, *minimal disruption of daily life*, *feelings about injections*. Patients responded on a 5-point Likert scale (−2 strongly disagree, −1 disagree, 0 no difference, 1 agree, 2 strongly agree). The survey also included questions about preference for, as well as satisfaction, perceived ease of use and self-reported adherence with, NordiFlex vs previous device. 94 patients were included in the survey. 91.5% previously used NordiLet; the rest used another device. Only 8.5% self-administered GH. A significantly greater proportion of patients preferred, and were more satisfied with, NordiFlex vs previous device; mean score: 0.65 (95% CI : 0.41; 0.88) and 0.61 (95% CI : 0.36; 0.85), respectively. Similarly, patients reported greater perceived ease of use and fewer missed injections with NordiFlex vs previous device; mean score: 0.49 (95% CI : 0.26; 0.72) and 0.20 (95% CI : 0.06;0.34), respectively. Bivariate analyses showed significant associations between the four domains and preference, satisfaction, perceived ease of use and self-reported adherence for NordiFlex vs previous device (*P*≤0.005). After multivariate analyses, higher scores of *ease of use* (adjusted OR [95% CI]: 3.77 [1.04; 13.57]; *P*=0.042) and *minimal disruption of daily life* (adjusted OR [95% CI]: 5.05 [1.09; 23.25]; *P*=0.038) were still significantly associated with preference for NordiFlex. However, associations with *self-efficacy* (adjusted odds ratio 1.10 [95% CI : 0.38; 3.21]) and *feelings about injection* (adjusted odds ratio 1.63 [95% CI : 0.44–6.01]) were no longer statistically significant (*P*>0.05). Patients reported greater preference, satisfaction, perceived ease of use and self-reported adherence with NordiFlex vs previous device, suggesting that improvements in injection device features could be associated with improved patient treatment experiences.

Efficacy of lanreotide autogel for chinese patients with active acromegaly with or without prior pituitary surgery: A post hoc analysis of the Lantern study

zhenmei An[1], Ting Lei[2], lian Duan[3], Lihui Zhang[4], Su Zhou[5], Xiaofeng Shi[6] & Gu Feng[3]
[1]West China Hospital, Sichuan Universtiy, Endocrinology, Chengdu, China; [2]Tongji Hospital, Tongji Medical college of HUST, Neurosurgery, Wuhan, China; [3]Peking Union Medical College Hospital, PUMCH, Endocrinology, Beijing, China; [4]The second hospital of Hebei Medical Universty, Endocrinology, Shijiazhuang, China; [5]Ipsen Pharma, Endocrinology, Beijing, China; [6]Ipsen Innovation, Endocrinology, Shanghai, China

Background
Previous studies have yielded conflicting results on biochemical control with medical therapy in patients with or without prior pituitary surgery. The LANTERN study (NCT02493517) demonstrated that lanreotide autogel (LAN ATG) was non-inferior to lanreotide prolonged release (LAN PR) in Chinese patients with active acromegaly. This post hoc analysis of the LANTERN study aimed to explore the efficacy of LAN ATG in patients with or without prior pituitary surgery.
Design
Patients with active acromegaly were randomized to LAN ATG or LAN PR 40 mg for 32 weeks. This post hoc analysis focuses on the efficacy of LAN ATG in patients with (Group I) or without (Group II) prior pituitary surgery.
Results
There were 39 patients in Group I and 18 patients in Group II at Baseline. The median time since acromegaly diagnosis prior to Baseline was longer in Group I [median (Q1,Q3) 3.37 (0.90.4.02)] than Group II [0.44 (0.12.1.30) years; $P=0.001$]. Group I had higher age-adjusted mean Baseline IGF-1 standard deviation scores (SDS) than Group II (17.37±5.28 vs 13.65±6.11; $P=0.03$). Baseline GH level was comparable between Group I and II [10.37 (5.41.24.35) vs 18.84 (8.13.29.52); $P=0.226$]. Change in IGF-1 SDS from Baseline at Week 32 was –7.16 (95% CI 0.98.5.23) in Group I vs –4.96 (95% CI –7.84, –2.08) in group II ($P=0.218$). The proportion of patients achieving IGF-1 normalization at Week 32 in Group I (20.5%, 8/39) was almost twice that in Group II (11.1%, 2/18) ($P=0.622$). Change in GH levels from Baseline at Week 32 was comparable between Group I and II [–10.94 (95% CI –16.16, –5.71) vs –11.50 (95% CI –19.21, –3.78); $P=0.905$]. 28.2% (11/39) and 27.8% (5/18) patients in Group I and II attained GH levels ≤2.5 µg/L, respectively ($P=0.973$). Among patients with evaluable MRI both at Baseline and post-treatment, 39.4% (13/33) in Group I and 37.5% (6/16) in Group II achieved ≤20% reduction in tumor volume, respectively ($P=0.899$). The rate of treatment-emergent adverse events (TEAEs) was 94.9% in Group I and 88. 9% in Group II. The rate of severe and moderate TEAEs was lower in Group I (43.6%) than Group II (83.3%).
Conclusion
In the LANTERN study, patients with prior surgery had longer history of acromegaly and higher Baseline IGF-1 scores than those without. LAN ATG provided comparable biochemical control and tumor volume reduction in patients with or without prior pituitary surgery. The results indicate that prior pituitary surgery does not significantly affect the treatment efficacy and safety of LAN ATG.

Outcomes of pituitary apoplexy: A comparison of microadenomas and macroadenomas

Afif Nakhleh[1], Gill Sviri[2], Naim Shehadeh[1], Mai Assalia Naffaa[3] & Irit Hochberg[1]
[1]Rambam Health Care Campus, Institute of Endocrinology, Diabetes and Metabolism, Haifa, Israel; [2]Rambam Health Care Campus, Department of Neurosurgery, Haifa, Israel; [3]Rambam Health Care Campus, Department of Internal Medicine C, Haifa, Israel

Introduction
Apoplexy of pituitary microadenomas is rare and not well documented in the literature. We aimed to assess the clinical characteristics of apoplexy of pituitary microadenomas compared to that of macroadenomas.
Design
A single-center retrospective longitudinal cohort study.
Methods
We retrieved clinical records of patients over 18 years old, hospitalized in Rambam hospital (Haifa, Israel) between 1.1.2001–31.10.2017, with pituitary apoplexy confirmed by brain imaging (CT or MRI), and with a follow-up of at least one year. We compared clinical and biochemical outcomes of apoplexy among patients with microadenomas and macroadenomas. Statistical analysis was done using Fisher's exact and Mann-Whitney tests.
Results
We identified 40 patients hospitalized with pituitary apoplexy between 2001–2017. Twenty-seven patients had a follow up of at least one year and were included in the final analysis. Seven (26%) patients had microadenomas, 13 patients (48%) were female. The mean age was 40.7±12.5 years. Patients with microadenomas were younger than those with macroadenomas (29±5 vs 44±12 years, $P=0.006$). Median follow-up was 3 and 2.5 years for macro- and microadenoma groups, respectively. Twenty-one patients harbored clinically nonfunctioning pituitary adenomas (6/7 microadenomas and 15/20 macroadenomas). The hormonally functioning tumors were four macroprolactinomas, one microprolactinoma, and one growth hormone-secreting macroadenoma. Upon admission, hyponatremia, random cortisol level of <200 nmol/l and secondary hypothyroidism, were evident in 6/20, 8/18, and 4/18 patients with macroadenoma and in 1/5, 2/5, and 1/6 patients with microadenoma, respectively ($P=$NS). Hypogonadotropic hypogonadism was evident in 9/12 men with macroadenoma, but in none of the men with microadenoma. In 12 of macroadenoma patients, the tumor abutted the optic chiasm, of which eight had visual field defects. Fifteen patients with macroadenoma and two patients with microadenoma underwent transsphenoidal surgery within a median of four days. At the last follow-up visit, patients with microadenoma had lower rates of persistent corticotropic deficiency or secondary hypothyroidism compared to patients with macroadenoma (1/7 vs 13/20 respectively, $P=0.033$). The rates of persistent corticotropic deficiency or secondary hypothyroidism were comparable between patients that underwent surgery compared to patients that did not (10/17 vs 4/10, respectively, $P=$NS). 1/7 of patients with microadenoma and 3/20 with macroadenoma had persistent central diabetes insipidus ($P=$NS). Only 2 patients with macroadenomas had persistent visual field defects at the last follow-up visit.
Discussion
Long term pituitary hormone deficiencies are more common in pituitary apoplexy patients with macroadenomas. Apoplexy of pituitary microadenoma seems to carry a more favorable prognosis.

Pregnancy outcomes in acromegaly: A single tertiary center case series

Burcin Gonul Iremli, Seda Hanife Oguz, Busra Firlatan, Selcuk Dagdelen & Tomris Erbas
Hacettepe University Medical School, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Pregnancy occurs relatively rare women with acromegaly. However, in recent years, pregnancy has become more likely to occur in acromegalic women possibly due to improvements in acromegaly treatment, and advanced assisted reproduction techniques.
Methods
In this case series, we retrospectively analyzed 11 pregnancies of 8 acromegalic women followed in the university hospital in a time range between 2009–2019. Data were obtained from patient files.
Results
The median age at the time of acromegaly diagnosis was 25.5 years (range: 18–29 yrs). All patients had macroadenoma at the time of diagnosis with a maximum median diameter of 22 mm. Surgery was the primary choice of treatment in all patients. Four women had a history of radiotherapy. The median duration of time between pituitary surgery and conception was 7 years, while acromegaly was diagnosed at the 12th month of lactation from previous delivery in one patient. The median GH and IGF-1 levels at the last visit before the detection of pregnancies were 1.5 ng/ml and 307 ng/ml respectively, and the median maximum diameter of residual pituitary adenoma was 6 mm. Only five out of 11 pregnancies were planned. Three of the five planned pregnancies occurred spontaneously while two occurred with *in vitro* fertilization. One patient was able to become pregnant at the third attempt of *in vitro* fertilization. In acromegalic women planning pregnancies, somatostatin analogs ($n=5$) treatment were discontinued 17 months before conception. Six unplanned pregnancies occurred while patients were on somatostatin analogs ($n=6$) treatment. Three out of six unplanned pregnancies reached term while two were terminated due to octreotide use, and one resulted in spontaneous abortion in the first trimester. Also one out of five planned pregnancies ended in the first trimester due to spontaneous abortion. No complications such as gestational diabetes and preeclampsia were observed in seven pregnancies reaching term, cesarean section being the method of delivery in all. No congenital anomaly was observed in the babies. Increase in adenoma size of one mm was noted in one patient only. Lactation did not occur after one out of these seven pregnancies.
Discussion
There is no consensus on the follow-up of pregnancies in women with acromegaly. It is usually recommended to discontinue medical treatment as soon as pregnancy is detected. Although a majority of pregnancies occurred in acromegalic women are reported to reach term without major complications, particular attention should be paid to these women regarding gestational diabetes, hypertension and apoplexy.

A randomized-controlled trial of tesomet resulted in significant weight loss in hypopituitary patients with hypothalamic obesity

Kim Huynh[1], Marianne Klose[1], Kim Krogsgaard[2], Jorgen Drejer[2], Sarah Byberg[3], Sten Madsbad[4], Faidon Magkos[5], Abdellatif Aharaz[6], Berit Edsberg[2], Arne Astrup[5] & Ulla Feldt-Rasmussen[1]
[1]Rigshospitalet, Copenhagen University, Department of Medical Endocrinology and Metabolism, Copenhagen, Denmark; [2]Saniona, Ballerup, Denmark; [3]Copenhagen University, Copenhagen, Denmark; [4]Hvidovre Hospital, Copenhagen University, Department of Medical Endocrinology and Metabolism, Hvidovre, Denmark; [5]NEXS, Copenhagen University, Copenhagen, Denmark; [6]Slagelse Hospital, Slagelse, Denmark

Background and objective
Hypothalamic obesity is characterized by rapid and severe weight-gain with increased risk of cardiovascular and metabolic disorders. Currently, there are no approved or effective pharmacological treatments and conventional weight management remain largely ineffective in hypothalamic obesity. This trial investigated safety and efficacy of Tesomet (0.5 mg tesofensine and 50 mg metoprolol) in hypopituitary patients with hypothalamic obesity.
Methods
Twenty-one (16 females) hypopituitary patients with hypothalamic obesity were randomized double blinded 2:1 to receive daily Tesomet or placebo for 24-weeks (NCT03845075). All subjects received diet- and lifestyle counseling for weight management. The primary endpoint was safety based on heart rate, blood pressure and adverse events. Secondary endpoints included antropometrics, metabolic and pituitary hormone replacements The median age of subjects was 50 years [range 25–70], 52% had BMI 30 kg/m^2, and 38% BMI>40 kg/m^2. Almost half had a history of craniopharyngeomas, 86% had undergone pituitary/hypothalamic surgery, 52% irradiation. All patients received one or more anterior pituitary hormone replacements; 52% had diabetes insipidus.
Results
Four subjects, two in the placebo- and two in the treatment-group, discontinued treatment before the end of the 24-week period. Discontinuation in the treatment arm was secondary to anxiety ($n=1$) and dry mouth ($n=1$), both improved after drug discontinuation. Adverse events were otherwise mild to moderate and included sleep disturbances (62%), dry mouth (46%), dizziness (46%) and headache (38%), known side-effects of tesofensine or metoprolol. No significant differences in heart rate or blood pressure were observed between the two groups. Eighteen of the 21 patients completed the 24-week placebo-controlled part of the study. Compared with placebo (weight loss 0.3%), Tesomet treatment resulted in an additional mean [95%-CI] weight loss of 6.3% [1.3%, 11.3%] at week 24 ($P=0.017$); a significant increase in the proportion of patients with 5% reduction in body weight (Tesomet $n=8$; 61.5%; placebo $n=1$; 12.5%) ($P=0.046$); a significant reduction in waist circumference at week 16 and 20, approaching significance ($P=0.052$) at week 24 with a mean reduction of 5.0% [0.1%, 10.1%]. Odds-ratio of subjects achieving 5% weight loss compared with placebo was 11.2 [1.0–120.4] ($P=0.046$).
Conclusion
Tesomet treatment was generally well tolerated, did not affect heart rate or blood pressure and resulted in additional significant progressive reductions in body weight and waist circumference compared to placebo in this small cohort of hypopituitary patients with hypothalamic obesity, all receiving the same dietary guidance. These results support the continued development of Tesomet for hypothalamic obesity.

ACROCOVID: An international survey on care for acromegaly during the COVID-19 era

Andrea Giustina[1], Bruno Mario Cesana[2], Muriël Marks[3], Pietro Mortini[1], Sheila Khawaja[4], Maria Fleseriu[5]
[1]San Raffaele Hospital, Milano, Italy; [2]University of Milan, Milano, Italy; [3]World Alliance of Pituitary Organizations, Zeeland, Netherlands; [4]World Alliance of Pituitary Organizations, Trieste, Italy; [5]Oregon Health & Science University, NW Pituitary Center, Portland, United States

The COVID-19 pandemic is significantly affecting the care of chronic conditions globally. Acromegaly is a rare chronic condition with a prevalence ranging between 2.8–13.7 cases/100.000 people. Acromegaly management requires a multidisciplinary team of health care professionals (HCPs), mainly including endocrinologists, neurosurgeons, and specialized endocrine nurses. Frequent consultations, particularly during early stages of the disease, and pre/post-surgery are necessary. Furthermore, injectable somatostatin receptor ligands may require HCP support to administer, while the need for blood-test monitoring necessitates adequate laboratory provisions. All of the above treatment considerations are likely to be impacted during the current pandemic. With median diagnosis occurring during the 5th decade and a high risk of cardiovascular and respiratory diseases, the majority of people with acromegaly are likely to be at a greater risk of severe illness if infected with SARS CoV-2. Although acromegaly itself doesn't increase risk of infection, people with adrenal insufficiency on glucocorticoid replacement may be at a higher risk. Expert opinion on pandemic-concurrent management of acromegaly has been published, but the real-world impact of COVID-19 has not been established. Decreased quality of life and psychological symptoms, including apathy, blunted affected and depressed mood, are a common feature of acromegaly. The socio-behavioural measures put in place in order to control the pandemic have the potential to exacerbate these issues through the disruption of routine social and work-related activities. In addition, access to resources for vulnerable members of society may be complicated by the fact that acromegaly can often be an 'invisible disability'. In order to assess the myriad effects of COVID-19 on people with acromegaly and their HCPs, we aimed to conduct an international online survey. The survey is tailored to four audiences: people with acromegaly; endocrinologists; specialized endocrine nurses; and neurosurgeons. The survey for people with acromegaly will focus on five broad categories of questions: impact on day-to-day life; access to HCPs; access to treatment and testing; impact on emotional and financial functioning; and future management. Questions in the HCP surveys will focus on five broad categories: impact on evaluation and diagnosis; access to treatment and management; impact on monitoring; role of technology and remote communication; and future management. Development and completion of the surveys has been achieved through patient and physician specialized societies. Complete analysis will be presented at eECE 2020. Successful multidisciplinary care models implemented during this pandemic could add valuable experience for future care for people with acromegaly and physicians alike.

COVID-19 and hypopituitarism. Experience from an endocrine center in a high-impact area

Paola Ioli[1], Stefano Frara[1,2], Riccardo Pasquali[1,2], Luigi Di Filippo[1,2], Patrizia Rovere Querini[3] & Andrea Giustina[1,2]
[1]IRCCS Ospedale San Raffaele, Endocrinology Unit, Milano, Italy; [2]Università Vita-Salute San Raffaele, Chair of Endocrinology, Milano, Italy; [3]Università Vita-Salute San Raffaele, Internal Medicine, Milano, Italy

SARS-CoV-2 has rapidly spread from China throughout the world leading to a pandemic. COVID-19 can be severe enough to cause hospitalization and death. Many patients with endocrine disorders share many of the recognized risk factors for severe disease and have potential additional risks due to corticosteroid replacement therapy or alteration in blood electrolytes. We here report three cases of COVID-19 in patients with post-surgical hypopituitarism and documented hypocortisolemia. An 80 yr-old patient with hypopituitarism and diabetes insipidus after surgery for craniopharyngioma in 1990, tested positive for Sars-CoV-2 at hospital admission for cardiogenic syncope. He suffered of hypertension, mild diabetes, COPD, atrial fibrillation, vascular disease; he was on stable therapy with L-T4, high dose cortisone acetate (62.5 mg/day), intranasal desmopressin and anticoagulants. He had no symptoms nor radiological signs specific for COVID-19.Blood tests showed hyponatremia (Na^+ 128.3 mmol/l) and increased LDH (290 U/l), CRP (82 mg/l, RR. <6), IL6 (262 pg/ml, RR. <7) and D-dimer (>20 mg/ml, RR. 0.27–0.77). He received a supplemental dose of parenteral hydrocortisone, optimization of desmopressin and no specific therapy for COVID-19. He was discharged after placement of a pace-maker. A 78 yr-old male patient with hypopituitarism after surgery for suprasellararachnoid cyst was on stable therapy with L-T4, cortisone acetate (25 mg/day), testosterone and growth hormone. He presented to the ER with cough, dyspnea and fever for one week. He tested positive for Sars-CoV-2; chest CT showed COVID-19 associated pneumonia. Mistakenly, cortisone acetate therapy was missed for 40 hours while staying in ER. Blood tests showed hyponatremia (Na^+129 mmol/l) and increased LDH (230 U/l) and CRP (53 mg/l). He received low-flux oxygen, ritonavir/lopinavir and hydroxychloroquine. His clinical conditions significantly improved and he was discharged after 6 days. An 18 yr-old male with hypopituitarism after surgery for craniopharyngioma at 12 yo, severe obesity (BMI 49.5), diabetes insipidus, was on stable therapy with L-T4, hydrocortisone (25 mg/die), desmopressin, testosterone and growth hormone. He presented to the ER with fatigue and drowsinessand no respiratory symptoms. He tested positive for Sars-CoV-2. Chest X-rays showed an increase of vas-

cular pattern in both lungs. Blood tests showed increased CRP (25 mg/l), normal IL6 and D-Dimer. He received antibiotic therapy and prophylactic anticoagulant coverage with LMWH; oral hydrocortisone was doubled. No respiratory complications occurred and the patient was discharged 3 days later. In conclusion, patients with hypopituitarism may be more susceptible to COVID-19 although severity of the disease does not seem to be increased.

Outcome squares integrating efficacy and safety, as applied to functioning pituitary adenoma surgery

Friso de Vries[1], Daniel Lobatto[2], Marco Verstegen[2], Pieter Schutte[2], Irene Notting[3], Mark Kruit[4], Fasial Ahmed[1], Alberto M Pereira[1], Wouter van Furth[2] & Nienke Biermasz[1]
[1]Leiden University Medical Center (LUMC), Endocrinology, Leiden, Netherlands; [2]Leiden University Medical Center (LUMC), Neurosurgery, Leiden, Netherlands; [3]Leiden University Medical Center (LUMC), Ophthalmology, Leiden, Netherlands; [4]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands

Background
Transsphenoidal surgery is standard care in the treatment of hormone-secreting pituitary adenomas. Current clinician-reported surgical outcome measures are one-dimensional, typically focussing primarily on complete or partial resection and secondarily on complication rates. However, outcomes are best reflected by the delicate balance of efficacy and complications at patient level. This study proposes a novel way to classify outcome, integrating efficacy and safety at the patient level.
Methods
Retrospective chart review of all pure endoscopic transsphenoidal surgical procedures for acromegaly, Cushing's disease, and prolactinoma between 2010–2018 in a single tertiary referral centre. We present our results in a classic (remission and complications separate) and in a novel Outcome Square integrating intended and adverse effects (long-term complications). This resulted in four outcome groups, ranging from good to poor. We use this approach to present these outcomes for several clinically relevant subgroups.
Findings
198 surgical procedures were included (44 reoperations). Remission was achieved in 127 operations (64%). Good outcome was observed after 121 (61%), and poor outcome after 6 (3%) operations. When intended effect of surgery was applied (instead of remission), good outcome was achieved after 148 of 198 surgeries (75%) and poor outcome after 4 (2%).
Interpretation
Quality of a surgical intervention can be presented in 4 simple categories, integrating both efficacy and safety with flexibility to adapt to the individualized situation at patient, disease, and surgical strategy. Funding. No specific funding was received for this research

Table 1 Construction of the Outcome Square, a contingency table integrating efficacy with safety. Definitions of remission, intended effect and adverse effect are provided in the methods section. IOQ: integrated outcome quadrant (1–4).

Pituitary apoplexy in the elderly: About 3 cases

Meryem Drissi Oudghiri, Imane Motaib, Saloua Elamari & Asmaa Chadli
Cheikh khalifa bin zayd al nahyan Hospital-University Mohamed VI of health sciences, Endocrinology, Casablanca, Morocco

Introduction
Pituitary apoplexy is a rare clinical syndrome related to abrupt hemorrhage and/or infarction of the pituitary gland,usually occurring in patients with pre-existing pituitary disease. it is an endocrine emergency requiring rapid diagnosis and appropriate management.
Observation
We report the observation of three patients.
Case 1
This is a 72 year old patient, without any particular pathological history, who presented abruptly a ptosis of the left eye without tumour syndrome, without sensory-motor deficit associated with asthenia worsening at the end of the day, without signs of hypersecretion of the pituitary gland. Total paralysis of the left oculomotor nerve was noted. MRI showed a bleeding pituitary macroadenoma and laterosellar macroadenoma. Blood hypophysogram showed thyreotropic and corticotropic insufficiency. The patient benefited from transphenoidal excision of the tumour. The evolution was favourable, marked by the regression of ptosis after orthoptic rehabilitation. The anatomopathological study showed a non-secreting pituitary macroadenoma.
Case 2
This is an 87 year old patient admitted for afemoral neck fracture, who presented an ante-pituitary insufficiency made of asthenia without tumor syndrome or pituitary secretion syndrome and the questioning finds a notion of intense headaches for several months. The hypophysogram showed a corticotropic and thyroidotropic deficit that we substituted and a decrease in gonadotropins (FSH, LH).MRI showed a necrotic suprasellate-extension pituitary macroadenoma.
Case 3
An 82-year-old patient was admitted with severe headache and vomiting associated with paralysis of the common oculomotor nerve, without pituitary secretion syndrome. Blood hypophysogram showed a corticotropic deficit which we substituted and a decrease in gonadotropins (FSH, LH). The MRI objectified a hemorrhagic pituitary macroadenoma in favor of a pituitary apoplexy. As surgery was contraindicated in the last two patients because of their medical issues, we opted for medical treatment.
Discussion
Pituitary apoplexy is an endocrine emergency. A rapid diagnosis and appropriate management can limit the occurrence of irreversible complications. These observations illustrate the particularities of this pathology in the elderly, the symptoms may be truncated and lead to a late diagnosis with its repercussions on management, without forgetting the particularity of the fragile and multi-systemic terrain which may contraindicate the usual surgical treatment.

AEP1078

First results of a desmopressin test in forecasting of relapse acth-dependent cushing syndrome undergoing tss

Umida A Mirsaidova & Zamira Halimova
Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Hypercorticism is a syndrome caused by extended and very high exposure of glucocorticoids to the body. ACTH-dependent Cushing's syndrome develops as a result of the overproduction of adrenocorticotropic hormone by the pituitary adenoma. The main treatment for ACTH-dependent Cushing's is transnasal transsphenoidal removal of the pituitary adenoma. A the same time, the recurrence rate of Cushing syndrome is observed up to 3% during the year and up to 3%–22% of cases within 3 years. The test with the introduction of desmopressin(TD) after surgery along with other samples to determine the presence of residual neoplastic corticotrophs, that is, an increased risk of reccurence.
Objective
to analyze the prognostic value of aTD to assess the effectiveness of TSS in patients with ACTH-dependent CS in the postoperative period
Material and methods
42 patients with ACTH-dependent Cushing's syndrome were examined, operated on in the neurosurgery departments of the RSSPMCE from 2000 to 2019. Patients were divided into 2 groups: 1 gr had cortisol levels ≤138 nmol/l (18patients), and group 2 (24 patients) had cortisol levels

≥138 nmol/l in the first 1–3 days after transsphenoidal pituitary adenomectomy (TSS). The control group consisted of 20 healthy individuals of a similar age. The research methods were general clinical, instrumental,hormonal, functional test with desmopressin and statistical methods
Results
It was found that in the group of patients in remission, in 3 patients ACTH levels during desmopressin test increased significantly (on average 14.02±2.06 ng/dl), leading to a corresponding increase in the level cortisol (average 280.02±12 nmol/l) in the blood. Moreover, the peak of ACTH secretion was accounted for and held equally high at 301 and 601. As the test results show, the averaged ACTH and cortisol indicators in group I differed from the control group, although not significantly ($P>0.05$). While, a significant reaction was noted in response to desmopressin, which increased 4 times more than in the control group. In the second group, 6 patients out of 24 of patients had a positive reaction to desmopressin, as evidenced by an increase in cortisol levels and which can serve as a negative prognostic marker of the probability of a relapse.
Conclusions
Thus, according to the initial results of our studies, analysis of the results of the desmopressin test in patients withACTH-dependent Cushing's syndrome showed that desmopressin test is a sensitive tool in determining the reactivity of corticotrophic pituitary cells.

The histological structure of giant non functional pituitary adenomas with invasive growth

Urmanova Yulduz[1] & Malika Mirtukhtaeva[2]
[1]Tashkent Pediatric Medical Institute, endocrinology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, endocrinology, Tashkent, Uzbekistan

Aim of the research – to study the histological structure of non functional pituitary giant adenomas (NFPA).
Materials and methods
We observed 17 patients with giant NFPA, among them 5 male and 6 female, mean age 37.8. All patients were undergone surgical treatment by transsphenoidal access in Center of Endocrinology of MoH RU in neurosurgery department during 2019–2020 year. All patients were undergone the spectrum of analyses, including endocrine status assessment, clinical, biochemical, hormonal (GH, LH, FSH, prolactin, TSH, testosterone and others), radiological (CT/MRI of Turkish saddle), and histological study. All patients have pituitary adenoma more than 3 cm. Depending on the type of cells found on the histological study, patients with NFPA (chromophobic adenomas) were divided into 3 groups: 1st group – small cell (undifferentiated) chromophobic adenoma – 7 patients, 2nd group – large cell chromophobic adenoma – 8 patients, and 3rd group – oncocytoma (none)- 2.
Results
Preliminary analysis of the research showed that among the observed patients the most disposed to invasive total growth had patients of the 1st group with small cell histological structure of NFPA. Besides, this patients had more frequent tumor relapse in post-operative period – 3 patients (17.6%), had acute manifestation of the disease with general cerebral symptoms and neuroendocrine disturbances (secondary amenorrhea in female, potency and libido decrease in male, metabolic syndrome, visual disturbances and others). Two female patients aged 27.5 from the 1st group were undergone repeated selective pituitary adenomaectomy 3 times.
Conclusions
1. Small cell NFPA have the most aggressive growth and tumor relapse. 2. Following research is necessary to study the markers of aggressiveness in all 3 groups.

Gender differences of growth hormone and insulin-like growth factor-1 in patients with acromegaly after radiation therapy

Saodat Issaeva, Zamira Khalimova, Adliya Kholikova & Shokhsanam Safarova
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Purpose of the study
To determine the gender differences in growth hormone (GH) and insulin-like growth factor-1 (IGF-1) in patients with somatotropic pituitary adenomas after radiation therapy (RT).
Materials and research methods
The object of the study is 94 patients with acromegaly receiving RT in a total dose of 45–50 gray. Of these, 26 (27.7%) are men and 68 (72.3%) are women. The peak manifestation of acromegaly in the total sample was in the most able-bodied age for men and women (30–44 years old). Conducted hormonal, visualization, ophthalmologic, general clinical research.
Results
The level of GH before RT was increased in men 55 (37.6–81.3) mMe/l and in women 59.3 (43.3–110) mMe/l. After RT, the level of GH in men in 15.4% ($P<0.01$) of cases is not suppressed, not completely suppressed in 34.6% ($P<0.05$), reached remission of 50% ($P=0.001$) and amounted to 11 (4.15–15.3) mMe/l. In women, 22.1% ($P<.05$), 17.7% ($P<0.01$) and 60.3% ($P=0.001$), respectively, and averaged 5.8 (2.4–15.3) mMe/l. Prior to RT, IGF-1 levels in men were 767 (619–962) ng/ml and in women 784 (678–1113) ng/ml. The levels of IGF-1 after RT in men were not suppressed in 46.2% ($P<0.01$), suppressed to age norms in 53.9% ($P<0.001$) and averaged 257 (200–299) ng/ml, in women, in 39.7% ($P<0.05$) and 60.3% ($P<0.001$), respectively, it amounted to 207 (181–308) ng/ml.
Conclusion
Thus, despite the high levels of GH and IGF-1 before RT in women than in men, women achieved remission more often and had lower levels of IGF-1 and GH compared with men.

Efficacy of lanreotide autogel in Chinese patients with acromegaly according to tumor size: A post hoc analysis of the LANTERN study

Zhenmei An[1], Ting Lei[2], lian Duan[3], Lihui Zhang[4], Su Zhou[5], Xiaofeng Shi[5] & Gu Feng[3]
[1]West China Hospital, Sichuan Universtiy, Endocrinology, Chengdu, China; [2]Tongji Hospital, Tongji Medical college of Hust, Neurosurgery, Wuhan, China; [3]Peking Union Medical College Hospital, Endocrinology, Beijing, China; [4]The Second Hospital of Hebei Medical Universty, Endocrinology, Shijiazhuang, China; [5]Ipsen Pharma, Endocrinology, Beijing, China

Background
The LANTERN study (NCT02493517) has demonstrated that lanreotide autogel (LAN ATG) was non-inferior to lanreotide prolonged release (LAN PR) in Chinese patients with active acromegaly. This post hoc analysis of the LANTERN study assessed the impact of tumor size on treatment effect.
Design
In the LANTERN study, LAN ATG was started at 90 mg and subsequently titrated according to GH and IGF-1 levels for 32 weeks. Tumor diameters >10 mm were classified as macroadenoma (Group I) and ≤10 mm as microadenomas (Group II) using centralized blinded review of magnetic resonance imaging (MRI) scans. This post hoc analysis focuses on the efficacy of LAN ATG in Group I vs Group II.
Results
There were 38 patients in Group I and 14 patients in Group II. Group I had higher Baseline GH level than group II [median (Q1,Q3): 21.57(8.05, 32.06) vs 6.02 (4.27, 15.02); $P=0.004$]. Meanwhile, mean Baseline age-adjusted IGF-1 SDS was comparable between Group I and Group II [15.76±6.20 vs 13.67±6.17; $P=0.285$]. For change from Ba seline at week 32, GH levels decrease in Group I was approximately half of that in Group II [–9.39 (95% CI –14.89, –3.88) vs –16.48 (95% CI – 25.77,–7.19); $pw=0.202$]; IGF-1 SDS score decrease was significantly lower in Group I than in Group II [–4.95 (95% CI –6.81, –3.10) vs –10.01 (95% CI –13.09, –6.94); $P=0.007$]. Furthermore, a lower proportion of patents in group I attained GH level ≤2.5 µg/l vs Group II (13.16%, 5/38 vs 50.00%, 7/14, $P=0.015$); a smaller proportion of patients in Group I achieved normalized IGF-1 levels than in Group II (7.9%, 3/38 vs 35.7%, 5/14; $P=0.042$). In patients with evaluable MRI results both at Baseline and post-treatment, 36.1% (13/36) patients in Group I achieved≥20% reduction in tumor volume vs 46.2% (6/13) in Group II ($P=0.524$). The rate of treatment-emergent adverse events (TEAEs) was 94.7% in Group I and 92.9% in Group II. The rate of severe and moderate TEAEs was 57.9% in Group I and 50% in Group II. No treatment-emergent deaths were reported.
Conclusion
In this post hoc anaylsis, LAN ATG provided similar reductions in tumor volume≥20% in patients with acromegaly regardless of tumor size(i.e. marcoadenoma or microadenoma). Biochemical control appeared to be better in

patients with microadenoma than in those with macroadenoma, potentially due to imbalance in Baseline GH levels between the two groups. The safety profile of LAN ATG was consistent with previously reported data.

Somapacitan dose–IGF-I–response and impact of starting dose levels in adults with growth hormone deficiency – a model-based analysis

Rasmus Juul Kildemoes, Rune Viig Overgaard & Michael Højby Rasmussen
Novo Nordisk A/S, Søborg, Denmark

In patients with adult growth hormone deficiency (AGHD), the dose of growth hormone (GH) replacement is individualised based on clinical outcome, insulin-like growth factor-I (IGF-I) levels and adverse reactions. The aim of this analysis was to characterise dose–IGFI–response for somapacitan, a long-acting reversible albumin-binding GH derivative, and to derive expected IGF-I levels for various starting doses. Somapacitan dose–IGF-I–response analysis was conducted in 330 patients with AGHD across three phase 3 trials; GH treatment-naïve patients (NCT02229851), and patients previously treated with GH (NCT02382939, NCT03075644) were analysed using a population pharmacokinetic/pharmacodynamic (PK/PD) model. Dose titration was performed with starting doses of 1.5 mg/week, 1.0 mg/week, and 2.0 mg/week, respectively, for patients ≤60 years old, >60 years old, and female patients taking oral oestrogen. The impact of demographic covariates (weight, sex, oral oestrogen, age and race [White/other, Asian Japanese, Asian non-Japanese]) upon PK/PD parameters was investigated. Individual PK/PD parameter estimates were used to derive average IGF-I standard deviation score (SDS) at the fixed dose level after titration, and for each individual across the 0.1–8.0 mg/week dose range. Age, sex and oral oestrogen use were the most influential covariates on somapacitan dose–IGF-I–response. Higher doses of somapacitan were required to reach similar IGF-I targets in female patients, particularly those taking oral oestrogen, compared with male patients. Lower doses were required to reach similar IGF-I targets in >60 vs ≤60 year old patients. Race and body weight did not alter somapacitan dose–IGF-I–response. Mean fixed somapacitan dose after titration was 2.1 mg/week, 1.4 mg/week and 3.8 mg/week, respectively, for patients ≤60 years, >60 years, and female patients taking oral oestrogen. Based on PK/PD analysis, investigated starting doses of 1.5, 1.0 or 2.0 mg/week would result in a mean IGF-I-SDS of –0.4, with approximately 1% and 10% of patients with IGF-I-SDS >2 and <–2, respectively. Starting doses of 2.0, 1.5 or 4.0 mg/week, would result in a mean IGF-I-SDS of 0.1, with approximately 5% of patients with IGF-I SDS >2, and 5% with IGF-I-SDS <–2. This approximates the distribution of IGF-I levels in the healthy population. In conclusion, this PK/PD analysis suggests that a starting dose of 1.5 mg/week (1.0–2.0 mg/week) of somapacitan is expected to produce an IGF-I SDS in the lower range of normal, and provides an insight into the theoretical impact of higher starting doses.

AEP1083

Monitoring of weekly IGF-I levels during long-acting growth hormone therapy with somapacitan

Rasmus Juul Kildemoes, Michael Højby Rasmussen, Henrik Agersø & Rune Viig Overgaard
Novo Nordisk A/S, Søborg, Denmark

Somapacitan is a long-acting growth hormone (GH) derivative designed for once-weekly subcutaneous administration. Correct assessment of insulin-like growth factor-I (IGF-I) levels is essential during treatment of GH deficiency (GHD) and must account for fluctuations over a dosing interval. We evaluated whether reliable estimates of weekly mean and peak IGF-I could be obtained from a single IGF-I sample. A population pharmacokinetic/pharmacodynamic model was available from pharmacokinetic and IGF-I (ng/ml and standard deviation score [SDS]) profiles from phase 1 studies of healthy adults (NCT01514500), adults with GHD (NCT01706783) and children with GHD (NCT01973244). Simulation was performed to steady state at four dose levels for 26 adults (doses 0.02–0.12 mg/kg) and 23 children (0.02–0.16 mg/kg) with GHD. After 200 repetitions, 39.200 unique IGF-I profiles were simulated using a 4-hour grid from 0–168 hours after dose. Profiles with weekly average IGF-I SDS >4 were removed. For each potential sample time, a linear model was used to estimate the correlation between IGF-I SDS value at a given time and the weekly mean/peak IGF-I value. The best fit to data included a dose (mg) covariate with body weight as an interaction in adults and a logarithmic dose level (mg/kg) covariate in children. The degree of linearisation was evaluated with correlation coefficient R^2, and precision of weekly mean/peak predictions were evaluated using residual standard deviation (RSD) and 90% prediction interval (PI; calculated as ± 1.645*RSD). Strong linear correlations were found between IGF-I SDS on any day and the weekly mean across the dose ranges, as well as between IGF-I SDS on days 1–5 and the weekly peak. In children and adults, the mean was predicted with good precision based on an IGF-I sample on any day (RSD < 0.4 for adults; < 0.3 for children); the most accurate prediction was on day 4 (RSD < 0.17 [90% PI ± 0.3 SDS]). The peak was best predicted with an IGF-I sample on days 1–4 (RSD <0.4); the most accurate prediction of IGF-I peak was on day 2 (RSD < 0.10 [90% PI ± 0.2 SDS]). A linear model provided a simple and reliable tool to predict weekly mean and peak IGF-I levels based on an accurate IGF-I sample following somapacitan dosing at steady state. Mean and peak IGF-I values could be predicted by IGF-I sampling on any day after somapacitan dose. The best predictive values were on day 4 (mean) and day 2 (peak) after dose.

Diagnostic of erdheim chester histiocytosis 9 years after!

Mouna Mezoued[1], Benabes b[2] & Said Azzoug[1]
[1]Algeria, Endocrinology, Algiers, Algeria; [2]Eph Bologhine, Endocrinology, Algiers, Algeria

Erdheim Chester disease (ECD) is a non langheransian rare histiocytosis, with around 500 cases described worldwide since its discovery for the first time in 1930 by Jakob Erdheim et William Chester. It is a multivisceral disease, characterized by a proliferation of abnormal histocytes CD68 positive and CD1a negative, including a retroperitoneal and perirenal fibrosis, a peri-aortitis, an osteosclerosis of the lower limbs and sometime an exophthalmia or an diabetes insipidus. However, cases may be non-typic and confusing. We report the case of the patient B.K aged of 31 years old, followed for diabetes insipidus with an enlarged pituitary stalk evolving for 10 year, posing an etiological diagnostic problem. Sarcoidosis have been first discussed without à lot of arguments, conducing to the introduction of corticotherapy, with a morphological response (regression of the stalk enlargement on the IRM). The patient has been regularly followed and 9 years after, an expansion of the pituitary stalk led us to reevaluate him. A thoraco-abdominal CT has found a retroperitoneal infiltration (peri-pancreatic) which helped us to discuss Erdheim Chester disease. Bone scintigraphy has found multiple fixations on long bones of the lower limbs. A cutaneous localization as a xanthélasma on the lower eyelids is describe with recurrent outbreaks of headache with fever. The diagnosis of certainty was obtained by an immunohistochemical study on biopsy of the bone marrow, finding squamous histocytes expressing CD68, weakly PS100, without expression of CD1a and nuclear expression of D1 cylinder. We have introduced an antagonist interleukin 1 receptor (Anakinra) with a good clinic-biological response. The etiologic diagnostic of a pituitary stalk enlargement is often complicated, it is essential to maintain a clinical and morphological follow-up and discuss rare disease as Erdheim Chester histiocytosis.

The course and predictors of postoperative diabetes insipidus

Darya Mikhaylova, Larisa Dzeranova, Olga Yu. Rebrova, Ekaterina Pigarova, Ludmila Rozhinskaya, Andrey Grigoriev, Vilen Azizyan & Oksana Ivashenko
Endocrinology Research Centre, Neuroendocrinology, Moscow, Russian Federation

The course and predictors of postoperative diabetes insipidus.
Objectives
To evaluate the course and predictors of permanent and transient postoperative diabetes insipidus (DI).
Patients and methods
The study included 152 patients undergoing endoscopic endonasal transsphenoidal surgery aged from 18 to 65 years with median 40. 73 patients had Cushing disease, 66 – acromegaly, 4 – prolactinoma, 9 – hormonally inactive adenoma, 1 – Nelson syndrome, 1 – TSH-oma. Patients were mon-

itored for hormones, serum electrolytes, plasma and urine osmolality. The follow-up period extended over 6 years for 97 patients and 55 patients (36%) had been lost to follow-up.
Results
In 34 patients (22.4%) postoperative DI was diagnosed by discharge, among them in 16 patients disturbances later became self-limited. Self-limited disturbances occurred in 25 patients (16.4%) when discharged, among them, permanent DI occurred in 3 patients during follow-up. 91 patients did not have any disturbances when discharged but permanent DI occurred in 1 patient and transient – in 8 patients during follow-up. By the end of follow-up period, permanent DI has developed in 15 patients (15.5%), transient – in 34 (35.1%). The onset was seen on the median 5th day [1; 9.5] after surgery for the permanent DI and on the 1th median day [1; 4.5] for transient; median for transient DI's duration was 30 days [1.5; 195]. When assessing the level of osmolality and sodium, the indice of serum sodium in patients with a transient DI was significantly higher in comparison with patients without disturbances. In patients with a constant and transient DI the indices of urine osmolality and urine specific gravity were significantly lower compared to patients without disorders and sodium urine indices were significantly higher. The transient DI occurred more often in patients with corticotropinomas in comparison with other pituitary adenomas (OR 6.1 (2.3;16.1)) and in patients with microadenomas (OR 5.3 (2.0;14.2)). Adrenal insufficiency increased risk of transient DI development (OR 6.8 (2.6;18.3)) and secondary hypothyroidism – of permanent DI (OR 9. 8 (2.1;46.6)) comparing to patients without hypopituitarism. Pituitary excision increased risk of permanent DI development as well (OR 4.9 (1.3;17.6)).
Conclusions
The diagnosis of permanent or transient postoperative DI should be specified after a long-term follow-up. The onset of postoperative DI arises on the 1–5 day after surgery and rapidity of recovery varies wildly. Cushing disease, pituitary microadenomas and adrenal insufficiency can be considered as predictors of transient DI, secondary hypothyroidism and pituitary excision can be considered as predictors of the permanent postoperative DI.

Influence of radiation therapy on patients with acromegaly depending on the age of patients

Zamira Khalimova & Saodat Issaeva
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Aim
To evaluate the effectiveness of radiation therapy (RT) in patients with acromegaly, depending on the age of patients and the activity of pituitary adenomas.
Materials and methods
The subject of the study were 50 patients (women-36, men-14) with acromegaly who received gammatherapy in a total dose of 45–60 Gr of 20–25 fractions every other day. The duration of the disease was 15 years on average. In general, the age of patients ranged from 26 to 77years, on average-44.7±6.8 years. By age, the patients were divided into 3 groups: the I age group-29–44 years-23 patients (46%), the II group-45–59 year-16 patients (32%), the III group-60–79 years, 11 patients (22%). All patients underwent hormonal (GH, IGF-1) studies.
Results
The levels of hormones of GH and IGF-1 remained high in the I group in 22% of patients, and in group III in 9%. Remissions reached 64% in the III age group. The highest level of GH content occurred in the age range from 45 to 59 years and was 77.5±9.68 mMe/l, and from 26 to 44years it was 68.1±6.84 mMe/l. After RT, this indicator in both age groups was almost equally suppressed, but not up to the norm. The decrease in the GH level to normal was observed in I age group in eight patients, and in the II age group in five patients it was 2.65±2.2 mMe/l and 2.23±1.4 mMe/l, respectively. In group III, in 11 patients before RT, the mean level of GH was 46.5±8.2 mMe/l. After RT, the level of GH decreased in this way: not suppressed only in one patient and was 22.1±0.89 mMe/l, in three patients the level of GH was suppressed, but not up to the norm and amounted to 6.7±0.7 mMe/l, only seven patients were suppressed and amounted to 2.46±2.2 mMe/l.
Conclusion
In all age periods, even in the period of the most activity pituitary adenoma-at the age of 26–44 years, RT is a rather effective method of treatment and gives positive results in most cases.

Carotid ultrasound assessment in patients with acromegaly

Yawen Wang, Stefanie Hammersen & Dag Moskopp
Vivantes Friedrichshain, Neurosurgery, Berlin, Germany

Objective
Acromegaly is characterized by chronic hypersecretion of growth hormone (GH) with increased concentration of IGF-1. It is known that patients with acromegaly have a high risk of developing cardiovascular diseases. We evaluated vascular changes by performing echodoppler ultrasonography in our series of patients.
Methods
Ultrasonographywas performed on 10 patients within one week after transsphenoidal surgery. The study includes 6 male and 4 female patients with an average age of 55.2 years. Intima-media thickness (IMT) of both internal carotid arteries was measured by M-Mode ultrasonography.
Results
Mean time between symptom onset and diagnosis was estimated as 10 years. All 6 male patients showed no structural arterial changes (6/10). Mild carotid wall plaques were detected in 3 female patients (3/10), the haemodynamic assessment was within normal range. One female patient showed severe vascular abnormalities (1/10).
Conclusion
In our series, all male patients showed normal findings in the echodoppler ultrasonography. Plaques could only be detected in female patients. The prevalence for severe atherosclerosis is 10%.

Cushing's disease recurrence during peripartum period: A case report

Luiz Fellipe Carvalho Viola, Raquel Muniz, Lariana Stefanello, Maurício Massucati Negri & Leila Warszawski
Instituto Estadual de Diabetes e Endocrinologia Luiz Capriglione, Brazil

Introduction
Even with a high incidence of infertility owing to the suppressive effects of hypercortisolism in the gonadal axis, either associated or not to hyperandrogenism and ovulatory dysfunction, Cushing's syndrome (CS) during pregnancy has been reported. This could be due to a greater rate of CS among women in reproductive age; however, it is a rare condition, with fewer than 200 cases reported in the literature. In general, CS affects 2–25 people to every 1 000 000 per year. Although most cases during pregnancy are caused by autonomous cortisol secretion of adrenal glands, there are reports of Cushing's disease (CD) within this population, providing unfavorable mother-fetus outcomes. We present a case of spontaneous pregnancy in a patient in remission of CD, that recurred during peripartum period.
Case report
A 38-year-old patient presented to the endocrinology clinic with a recent diagnosis of type 2 diabetes mellitus and systemic arterial hypertension. After the initial workup, CD was diagnosed and promptly treated with transsphenoidal surgery. In the following years there was no sign of recurrence and, five years later, the patient became pregnant. In the first trimester of pregnancy, there was a worsening of blood glucose levels and insulin has been prescribed. The patient's condition did not improve and led to premature birth at 31 weeks of pregnancy. She remained with hyperglycemia, elevated blood pressure and asthenia, accompanied by flank purple striae, facial plethora and increased fat in the cervical area, up until two months post-partum. Laboratory workup after obstetric hospital discharge revealed increased late-night salivary cortisol of 9.71 ng/dl (0.8–1.2 ng/dl) and a 7.8% glycated hemoglobin. Plasma cortisol after 1 mg of dexamethasone was 12.2 mg/dl and ACTH 30.7 and 35 pg/ml. A new exam showed a pituitary microadenoma and the patient was again referred to the Neurosurgery service.
Conclusions
CS is a rare condition in pregnancy due to hypercortisolemia-induced infertility. Moreover, clinical features of CS can overlap physiological changes during the peripartum period; therefore, it is essential a high suspicion of recurrence in pregnant patients with a history of CS. Medical treatment is mandatory as deleterious peripartum outcomes may occur. Neurosurgery in the second trimester is the standard CD treatment in pregnancy. Cabergoline may be used, even though case reports with medical therapy alternatives are scarce. Our patient unfortunately had complications, without proper

treatment during pregnancy because of a low clinical suspicion by the obstetrics team.

A homozygous hypomorphic BRCA2 variant in primary ovarian insufficiency without cancer or Fanconi anemia trait

Abdelkader Heddar[1], Caburet Sandrine[2], Dardillac Elodie[3], Creux Héléne[4], Lambert Marie[4], Livera Gabriel[5], Bernard S Lopez[3] & Micheline Misrahi[1]
[1]Le Kremlin-Bicêtre, Faculté de Médecine, Université –Paris-Saclay, Le Kremlin-Bicêtre, France; [2]Université de Paris, Institut Jacques Monod, Paris, France; [3]Institut Cochin, Université de Paris, Institut Cochin, Paris, France; [4]CHU de Bordeaux, Service de Gynécologie et Médecine de la Reproduction, Bordeaux, France; [5]Université de Paris, Université Paris-Saclay,, UMR Stabilité Génétique, Cellules Souches et Radiations, Fontenay-aux-Roses, France

BRCA2, is a gene with a critical role in DNA repair and homologous recombination in somatic cells. Patients with *BRCA2* biallelic mutations develop Fanconi Anemia (FA), a severe life-threatening condition characterized by pancytopenia and multiple malformations and malignancies, while women with monoallelic alteration are at high risk to develop breast or ovarian cancer (up to 60%). Primary Ovarian insufficiency (POI) affects 1% of women under forty and is a public health problem. The genetic causes of POI are highly heterogeneous with isolated or syndromic forms. Recently, mutations in genes involved in DNA repair have been shown to cause POI. Here, using exome sequencing, we surprisingly uncovered a homozygous pathogenic variant of BRCA2 in a patient with isolated POI but without cancer or FA in all her family. The homozygous missense c.8524C>T/p.R2842C *BRCA2* variantchanges a strictly conserved residuelocated in BRCA2 DNA-binding domain. We demonstrated that this alteration only mildly altered the function of the protein usingseveral *in vitro* functional assays in primary and lymphoblastoid immortalized cells. Hence, the patient's cells showed intermediate levels of chromosomal breaks, cell proliferation and radiation-induced RAD51 foci formation compared to controls and FA cells. R2842C-BRCA2 only partially (~30%) complemented HR efficiency compared to WT-BRCA2. We show that BRCA2 is expressed in the fetal ovary in meiotic germinal cells which undergoing a high level of DNA breaks and subsequently repair. Our findings extend the phenotype of BRCA2 bi-allelic alterations to fully-isolated POI. This study has a major impact on the management of patients with POI and the genetic counsellingthat should now be addressed while keeping in mind a possible defect in a major DNA repair gene such as *BRCA2*.

Climacteric symptoms and stress management techniques in peri- and early postmenopausal women

Eleni Armeni[1], Areti Augoulea[1], Anastasia Palaiologou[1], Foteini Christidi[2], Anastasia Soureti[1], Andreas Alexandrou[1], Konstantinos Panoulis[1], Georgios Chroussos[3], Ioannis Zervas[2] & Irene Lambrinoudaki[1]
[1]National and Kapodistrian University of Athens, Aretaieio Hospital, 2nd Department of Obstetrics and Gynecology, Athens, Greece; [2]National and Kapodistrian University of Athens, Eginition Hospital, Women's Mental Health Clinic, Department of Psychiatry, Athens, Greece; [3]National and Kapodistrian University of Athens, First Department of Pediatrics and Chief Division of Endocrinology, Metabolism and Diabetes, Children's Hospital Aghia Sophia, Athens, Greece

Introduction
The hypothalamic-pituitary-ovarian and/or adrenal axis as well as the autonomous nervous system affect significantly the intensity of menopausal symptoms Pre-existing levels of stress may affect the individual perception of menopausal symptoms. We aimed to evaluate the efficacy of a structured stress management program to reduce levels of stress and severity of climacteric symptoms, in a sample of middle-aged Greek women.
Methods
The sample consisted of 61 women with varying severity of climacteric symptoms, aged 40 up to 65 years, retrieved from the Menopause clinic of Aretaieio Hospital, National and Kapodistrian University of Athens, Greece. Women were randomized into the intervention group ($N=31$) and the control group ($N=30$). An 8-week stress management program was offered to the intervention group, which included structured sessions on healthy eating, daily exercise as well as teaching of self-awareness cognitive restructuring and relaxation techniques. We evaluated the following parameters both at baseline and after the completion of the program: 1) Climacteric symptoms (Green Climacteric Scale – GCS), 2) Mood status (Depression Anxiety Stress Scale, DASS); 3) Sleep quality (Pittsburg Sleep Quality Index, PSQI); 4) Self-esteem (Rosenberg Self-esteem Scale); 5) Health locus of control (HLC). Associations were evaluated using repeated-measure mixed-model ANOVA.
Results
We found significant time × group interaction with regards to: i) GCS-Psychological symptoms ($F=144.727$; $P<0.001$); ii) GCS-Vasomotor symptoms ($F=62.917$; $P<0.001$); iii) GCS-Physical symptoms ($F=41.233$; $P<0.001$); iv) PSQI-Subjective sleep quality ($F=27.094$; $P<0.001$); v) PSQI-Sleep latency ($F=10.424$; $P=0.002$); vi) PSQI-Sleep disturbance ($F=24.186$; $P<0.001$); vii) PSQI-Daytime dysfunction ($F=10.668$; $P=0.002$); viii) DASS-Depression ($F=13.249$; $P=0.001$); ix) DASS-Stress ($F=9.546$; $P=0.003$). Scores of vasomotor symptom severity, anxiety and depression were significantly lower at follow-up compared with baseline values, only in the intervention group.
Conclusion
An alternative non-pharmacological approach to the management of climacteric symptoms. Climacteric symptoms may be effectively managed with education on stress management techniques.

Low FT3 serum values are associated with markers of disease severity, evaluated during the acute phase of COVID-19

Salvatore Sciacchitano[1], Simonetta Giovagnoli[2], Michela D'Ascanio[3], Chiara De Dominicis[4], Andrea Laghi[5], Paolo Anibaldi[6], Claudia De Vitis[1], Andrea Petrucca[7], Rachele Amodeo[8], Maurizio Simmaco[9], Christian Napoli[4], Rita Mancini[1] & Alberto Ricci[1]
[1]Sapienza University of Rome, Clinical and Molecular Medicine, Roma, Italy; [2]Sapienza University of Rome, Division of Pneumology, Roma, Italy; [3]Sapienza University of Rome, Department of Clinical and Molecular Medicine, Roma, Italy; [4]Sapienza University of Rome, Medical and Surgical Sciences and of Translational Medicine, Roma, Italy; [5]Sapienza University of Rome, Roma, Italy; [6]Sant'Andrea Hospital, Health Managment Director, Rome, Italy; [7]Sapienza University of Rome, Neuroscience, Mental Health and Sense Organs, Sapienza University, Roma, Italy; [8]Sapienza University of Rome, Flow Cytometry Unit, Clinical Laboratory, Roma, Italy; [9]Sapienza University of Rome, Neuroscience, Mental Health and Sense Organs, Roma, Italy

Low T3 syndrome is a frequent finding in patients with critical illness, particularly in those admitted to intensive care units. It is generally considered an adaptive state of thyroid hormone (TH) economy, but many evidences indicate that it may represent a negative prognostic factor too. The prevalence and clinical relevance of the Low T3 syndrome in coronavirus infections has not been evaluated yet. We have measured thyroid hormone levels and analyzed anamnestic, epidemiological, clinical, biochemical and radiologic data of 62 patients affected by COVID-19 in search of possible correlation between all these parameters and the serum FT3 values. Patients were subdivided into two groups according to their serum FT3 levels, measured during the acute phase of the disease. Group A consists of 38 patients showing low levels of FT3 (<1.7 pg/ml) and Group B consists of 24 patients with normal levels of FT3 (>1.7 pg/ml and<3.71 pg/ml). We have measured several serum markers, radiologic and clinical scores of the severity of the disease and we have searched for a possible correlation between FT3 serum values and all these markers and scores. We observe a positive correlation with many disease severity markers and scores examined. The Absolute Neutrophil Count, the related NLR and dNLR ratios are higher in Group A, compared to Group B. Reduced FT3 serum values correlates with reduced total count of CD3+ lymphocytes and with reduction of both helper-inducer and suppressor-cytotoxic T cells. Low FT3 values correlate also with increased levels of inflammation, tissue damage and coagulation serum markers. Finally, low FT3 serum levels correlated with Sequential Organ Failure Assessment (SOFA) score, Lung Inflammation Prognostic Index (LIPI) and radiological Total Severity Score (TSS). Our study demonstrates that low levels of FT3, during the acute phase of COVID-19, are associated with biomarkers of tissue damage, inflammation, coagulation and with scores,

indexes of clinical and radiological severity of the disease. Low FT3 serum levels can be considered as a novel biomarker of the severity of the disease.

Cholesterol and Graves' Orbitopathy (GO): 'A new decision-making algorithm based on baseline low density lipoprotein cholesterol (LDLc) and early GO clinical response to parenteral corticosteroids'

Adriano Naselli, Diletta Moretti, Concetto Regalbuto, Maria Luisa Arpi, Fabrizio Logiudice, Francesco Frasca, Antonino Belfiore & Rosario Le Moli
University of Catania, Clinical and Experimental Medicine – Endocrinology Unit, Catania, Italy

Introduction
Parenteral corticosteroids (PC) are effective for the treatment of active moderate to severe (AMS) Graves'orbitopathy(GO). A correlation of GO activity with cholesterol has been described. No evidences are available about cholesterol levels and the clinical efficacy of PC in AMS-GO.
Aim
Was to detect the predictive role of cholesterol on medium term clinical outcome of PC therapy in AMS-GO.
Methods
We studied 87 patients treated with PC because of AMS-GO. GO evaluation was at baseline, 6 (W6) and 12 weeks (W12) after starting PC. Patients were Improved (I) or Not Improved (NI) by the EUGOGO overall clinical criteria (CI): I or NI W6CI or W12CI and by the Clinical Activity Score (CAS): I or NI W6CAS or W12CAS.
Statistic
By univariate and binary logistic regressions analysis setting W12CAS or W12CI categories as outcome variables; independent variables included LDL cholesterol (LDLc), W6CAS or W6CI categories. For the W12 outcome by CAS (W12CAS) regression model, the best cut-off was calculated by ROC curve analysis and by Youden's test.
Results
We retrospectively studied 22 males and 65 females, median age 45 years, who received a median PC cumulative dose of 52.3 g/kg body weight. Responders at W6 (early responders) showed a 13 times greater chance to be classified as improved at week 12 when compared to early not responders (OR 13.7 and 13.1, $P<0.001$). NI-W12CAS patients had a higher baseline LDLc cholesterol than I-W12CAS patients (mean rank 40.95 vs 30.49; $P=0.045$ respectively). The regression model built for W12CAS outcome was statistically significant, $\chi^2(2)=15.985$, $P<0.001$ and both W6CAS and LDLc resulted statistically significant predictor variables. By binary logistic regression results, we built a predictive model: $\frac{1}{1+e^{-(2.95-0.025x_1+2.57x_2)}}$, where x_1=LDLc (mg/dl); x_2=W6CAS outcome ($x_2=1$ for I_{W6CAS}; $x_2=0$ for NI_{W6CAS}). ROC analysis and Youden's test identified a predicted probability of improving at W12CAS=0.664 as best cut-off. A W6CAS and LDLc based decision-making algorithm was finally elaborated: LDLc>190 mg/dl suggests to treat hypercholesterolemia before to start PC therapy being too low the chances to reach a W12CAS improvement.
Conclusions:
Early clinical response to corticosteroids is determinant of the 12 weeks AMS-GO clinical outcome when evaluated both by CAS and CI. LDLc improves the predictivity of W12CAS final outcome, LDLc baseline levels>190 mg/dl reduce the chances of improving at 12W by CAS independently of early W6CAS response.

Autoimmune thyroiditis has a protective role on papillary thyroid cancer: Insights from a new mouse model

Fabiana Pani[1], Yoshinori Yasuda[1,2], Giulia Di Dalmazi[3], Kathleen Gabrielson[4], Paulina Chalan[1], Stefano Mariotti[5] & Patrizio Caturegli[1]
[1] Johns Hopkins School of Medicine, Division of Immunology, Department of Pathology, Ross Research Building, Room 656, Baltimore, United States; [2]Department of Endocrinology and Diabetes, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Division of Endocrinology, Department of Medicine and Aging Sciences, 'G. D'Annunzio' University of Chieti-Pescara, Chieti, Italy; [4]Department of Molecular and Comparative Pathobiology, The Johns Hopkins School of Medicine, Baltimore, United States; [5]Division of Endocrinology, Department of Medical Sciences and Public Health, Cagliari, Italy

The relationship between papillary thyroid cancer (PTC) and autoimmune thyroiditis remains controversial. To gain mechanistic insights, we developed a mouse model by combining three strains: $BRAF^{V600E}$ knock-in and TPO-CRE-ER transgenic to induce PTC upon tamoxifen injection, and NOD.$H2^{h4}$ congenic to induce thyroiditis upon iodine administration.
A total of 113 mice of the desired genotype (BRAF mutant homozygous, CRE transgenic hemizygous on the NOD.$H2^{h4}$ background) were generated and separated into three cohorts. Mice in cohort 1 ($n=50$) were observed until death after tamoxifen and/or iodine treatment(s) to define the natural history of PTC and thyroiditis, while mice incohorts 2 and 3 ($n=63$) were sacrificed at a fixed time point after treatment (16 weeks after the first tamoxifen injection). Each cohort comprised six experimental groups: in Group 1 ($n=22$) tamoxifen and iodine were begun simultaneously, in Group 3 ($n=20$) tamoxifen followed iodine treatment, and in Group 5 ($n=23$) only tamoxifen was used. Each of these groups had its own control, (defined as group 2, 4, and 6 respectively) where no tamoxifen was given. In addition to survival, outcome measures included monthly assessment of thyroid ultrasound, thyroid function (TSH and T4), thyroglobulin and thyroperoxidase antibodies, and thyroid histopathology and flow cytometry at the time of sacrifice. In mice observed through their life time (cohort 1), tamoxifen induced the development of PTC in all three groups (1, 3, and 5) but with significantly different aggressiveness. While groups 1 and 5 died at 36 weeks of age, mice with preceding thyroiditis (group 3) died much later (after one year of age, $P<0.001$). In mice sacrificed at 16 weeks post tamoxifen, the incidence of PTC was significantly smaller in group 3 than groups 1 and 5 ($P<0.0001$), again indicating a 'beneficial' effect of pre-existing thyroiditis. Thyroglobulin antibodies developed, as expected, in mice treated with iodine and persisted throughout the observation time, but did not distinguish between the outcomes. On the contrary, thyroperoxidase antibodies developed later but remained elevated only in mice developing PTC. Lymphocytic infiltration in PTC lesions was greater in group 3 than group 1 ($P=0.002$) or 5 ($P=0.04$), and featured a unique expansion of CD8+ effector memory T cells ($P=0.009$). Overall, the study shows that pre-existing thyroiditis protects from PTC aggressiveness and progression, a protection that, however, disappears when thyroiditis and PTC are induced synchronously.

Identification of thyroid disease in pregnant women varies by analytical method and type of thyroid function test

Stine Linding Andersen[1,2], Peter Astrup Christensen[1,2], Louise Knøsgaard[1,2], Stig Andersen[2,3], Aase Handberg[1,2], Annebirthe Bo Hansen[1] & Peter Vestergaard[2,4,5]
[1]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark; [2]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark; [3]Aalborg University Hospital, Department of Geriatrics, Aalborg, Denmark; [4]Aalborg University Hospital, Department of Endocrinology, Aalborg, Denmark; [5]Aalborg University Hospital, Steno Diabetes Center North Jutland, Aalborg, Denmark

Objective
Physiological alterations challenge the assessment of maternal thyroid function in pregnancy. It remains uncertain how the reference ranges vary by week of pregnancy, and how the classification of maternal thyroid disease vary by analytical method and type of thyroid function test.
Method
Consecutively collectedserum samples from 6.282 pregnant women in the North Denmark Region, 2011–2013, were used for the measurement of thyrotropin (TSH), total and free thyroxine (T4), total and free triiodothyronine (T3), and T-uptake using 'Method A' (Cobas 8000, Roche Diagnostics). TSH and free T4 were also previously measured using 'Method B' (ADVIA Centaur XP, Siemens Healthineers). Pregnancy week- and method-specific reference ranges (2.5 and 97.5 percentiles) were established after the exclusion of multiple births, women who were positive for thyroid peroxidase antibodies (TPO-Ab) and/or thyroglobulin antibodies (Tg-Ab), had thyroid or other autoimmune diseases or used thyroid interfering medication. Box-Cox transformation and Tukey's fences were used for detection and exclusion of outliers. The established reference ranges were used to classify maternal thyroid function, and classifications were compared

by analytical method and type of thyroid function test. Roche Diagnostics supported the study by offering a discount for the thyroid function tests performed.
Results
The reference ranges for TSH showed a gradual decrease during pregnancy week 4–14, a gradual increase was observed for total T4, total T3, and T-uptake, whereas free T4 and free T3 showed less variation. Altogether 689 of the pregnant women had TSH outside the reference range with either method A or B, and 541 of these (78.5%) had an abnormal TSH result with both methods. For free T4, 707 of the pregnant women had a test result outside the reference range with either method A or B, and 216 (30.6%) with both methods. When both TSH and free T4 were used for classification of maternal thyroid function, Method A classified 935 with abnormal thyroid function, Method B a total of 903, and the methods agreed on 554 individuals. When TSH and total T4 were used, 947 were classified with abnormal thyroid function, and classifications by TSH in combination with either total T4 or free T4 agreed on 584 individuals.
Conclusion
Even when pregnancy week- and method-specific reference ranges were established, the classification of maternal thyroid disease varied considerably by analytical method and across the different clinical available thyroid function tests. The findings raise a concern about misclassification, particularly for the use of free thyroid hormones.

Low serum IL-17A in pregnancy during second trimester is associated with an increased risk of subclinical hypothyroidism

Qian Yang & Bingbing Zha
Fifth People's Hospital of Shanghai Fudan University, Department of Endocrinology, 閔行區, China

Problem
Interleukin-17A (IL-17A) has a role in sustaining normal pregnancy. IL-17A is also associated with thyroid autoimmunity during pregnancy. This study sought to investigate whether IL-17A is a risk factor for thyroid dysfunction during pregnancyin women negative for thyroid autoantibodies.
Methods of study
The study comprised 216 pregnant women with negative thyroid peroxidase antibody (TPOAb) and thyroglobulin antibody (TGAb) during the second trimester who provided bloodsamples for serum IL-17A, thyroid autoantibodies and thyroid function tests. To further evaluate the ratio of CD4+IL-17A+Th17 cells, we collected peripheral blood from 26 women with thyroid-stimulating hormone (TSH) levels ≤2.5 mIU/l and 26 pregnancy-week matchedwomen with TSH levels >2.5 mIU/l, along with samples from 20 women with TSH levels ≤4 mIU/l and 20 pregnancy-week matchedwomen with TSH levels>4 mIU/l.
Results
he serum IL-17A levels and ratios of CD4+IL-17A+ cells were significantly lower in women with TSH >2.5 mIU/l than in those with TSH≤2.5 mIU/l (both $P<0.01$). Similar lower differences were noted in women with TSH >4 mIU/l than in those with TSH≤4 mIU/l (both $P<0.01$). Moreover, serum TSH correlated negatively with IL-17A levels ($\beta=-0.195$, $P=0.004$), but positively with the week of gestation ($\beta=0.284$, $P<0.001$). Logistic regression indicated that a lower serum IL-17A level was a risk factor for TSH>2.5 mIU/l [OR=0.453 (0.298–0.689), $P=0.000$] and TSH>4.0 mIU/l [OR=0.588(0.385–0.899), $P=0.013$].
Conclusion
A low serum IL-17A level during the second trimester is associated with an increased risk ofTSH>2.5 mIU/l and subclinical hypothyroidism.

Limited genetic overlap between Hashimoto´s thyroiditis and Graves´ disease in Swedish twins: A population-based study

Jakob Skov[1], Jan Calissendorff[1], Daniel Eriksson[2], Jonas Ludvigsson[3], Patrik Magnusson[3], Olle Kämpe[4], Sophie Bensing[1] & Ralf Kuja-Halkola[3]
[1]Karolinska Institutet, Department of Molecular Medicine and Science, STOCKHOLM, Sweden; [2]Karolinska Institutet, Department of Medicine, Stockholm, Sweden; [3]Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden; [4]Karolinska Institutet, Department of Medicine, Stockholm, Sweden

Background
Hashimoto´s thyroiditis (HT) and Graves´ disease (GD) are known co-aggregate in families, but the magnitude and nature of a shared etiology is unknown. The aim of this study was to estimate the shared genetic influence on these diseases. In addition, we sought to examine if the heritability of HT and GD differs between men and women.
Methods
We used national health registries to identify cases of HT and GD in a cohort of 110 814 Swedish twins. By comparing intra-class and cross-twin cross-trait concordance in dizygotic and monozygotic twins, we calculated heritability and the proportions thereof shared between the diseases. Univariate estimates of heritability were calculated separately by sex.
Results
The heritability for HT and GD was 65% (95% CI, 61–70%) and 63% (95% CI, 55–72%) respectively. The genetic correlation was 0.35 (95% CI, 0.20–0.50) and shared genetic effects accounted for 8% of the variance for both HT and GD. Univariate heritability was significantly higher in men than in women for HT (90% vs 60%, $P<0.001$) but not for GD (79% vs 63%, $P<0.085$).
Interpretation
HT and GD appear to be only modestly related diseases. Hence, the term 'autoimmune thyroid diseases', commonly used to cluster these disorders, has limited validity from an etiological perspective. Moreover, the mechanisms contributing to disease are partly different for the sexes, with genetic components more important in men than in women.

Central hypothyroidism: Are patients undertreated?

Joke Marlier, Lapauw Bruno, Guy T'sjoen & Justine Defreyne
Ghent University Hospital, Endocrinology, Ghent, Belgium

Introduction
Thyroid hormone (TH) replacement therapy in patients with central hypothyroidism (CHT) cannot be reliably guided by TSH levels. Guidelines suggest substitution doses between 1.2–1.6 µg/kg body weight, aiming for free thyroxine levels (fT4) prior to intake in the upper part of normal. However, variability in TH metabolism, concomitant treatments and inaccurate interpretation of TSH levels still puts patients with CHT at risk for inappropriate substitution as compared to patients with primary hypothyroidism (PHT).
Objective
To compare levothyroxine substitution doses between patients with CHT and PTH, and to explore Quality of Life (QoL) in both groups, using two questionnaires, the SF-36 health score and the thyroid specific ThyPRO score.
Methods
This is a monocentric, cross-sectional study, performed at the Ghent University Hospital (Belgium). During 12 months, we consecutively included 70 patients, 41 patients with CHT and 29 patients with PHT. At the time of inclusion, all patients had to have a stable dose of levothyroxine during the past six months and patients with PHT needed to be euthyroid (defined as a TSH level within the reference range, 0.2–4.5 mU/l). Patients with malabsorptive disorders, malignancies or conditions affecting TH metabolism or dosing were excluded. All data was retrieved from medical files, timing of blood sampling was not specifically instructed, questionnaires were self-administered.
Results
Patients from the CHT and PHT group were comparable regarding age and BMI. There were no significant differences between patients with CHT and PHT regarding absolute dose of levothyroxine (100 [93.75–125.00] vs 107.14 [81.25–132.14] µg/day, $P=0.942$) or dose relative to body weight (1.34 [1.16–1.55] vs 1.51 [1.14–1.73] µg/kg/day, $P=0.265$). Individual doses, however, varied substantially (0.71–2.44 in CHT and 0.48–2.56 µg/kg/day in PHT). Randomly sampled serum levels of fT4 and fT3 did not differ between the two groups ($P=0.269$ and $P=0.132$, respectively) and were in the midrange for both groups. We could not demonstrate differences between both groups regarding QoL questionnaires.
Conclusion
In our patients with CHT, median levothyroxine dose was within the suggested range and although numerically somewhat lower not significantly different from patients with PTH. We neither found differences in QoL between both groups. Interindividually, however, substitution doses varied substantially in both groups, so an individual appraisal of every patient is warranted rather than a one-size-fits-all approach.

Rho-kinase (ROCK1 and ROCK2) gene polymorphisms in patients with Graves' disease

Suzan Tabur[1], Elif Oguz[2] & Tuncay Demiryurek[3]
[1]Gaziantep University, Internal Medicine, Gaziantep, Turkey; [2]Istanbul Medeniyet University, Medical Pharmacology, Gaziantep, Turkey; [3]Gaziantep University, Medical Pharmacology, Gaziantep, Turkey

Graves' disease (GD) is an autoimmune disease caused by autoantibodies binding to and activating the thyroid-stimulating hormone receptor (TSHR). Chronic stimulation of the TSHR results in a hyperactive thyroid gland and hyperthyroidism. The purpose of this study was to determine the association between Rho-kinase (*ROCK1* and *ROCK2*) gene polymorphisms and GD in a Turkish population. A total of 142 patients with HT and 163 healthy control subjects were included to this study. Genomic DNA was analyzed using the dynamic array system (Fluidigm, CA, USA). The Chi-square or Fisher's exact tests were used for calculation of the significance of differences in frequencies. Bonferroni correction for multiple testing was used for polymorphism studies, and $P<0.0083$ (0.05/6) was considered statistically significant. There were marked changes in TT genotype (0.0%, $P<0.0001$) and T allele (1.4%, $P<0.0001$) frequencies for the *ROCK1* gene rs35996865 polymorphism in GD group when compared to controls (TT 12.9%, T 14.4%). For *ROCK2* gene rs965665 polymorphism, CG genotype frequency (6.9%, $P=0.0034$) was markedly low among GD cases when compared to the controls (CG 20.0%). However, no associations were found with *ROCK1* rs73963110, *ROCK2* rs726843, *ROCK2* rs2290156, and *ROCK2* rs10178332 polymorphisms. This is the first study showing that *ROCK1* rs35996865 and *ROCK2* gene rs965665 polymorphisms were associated with GD in the Turkish population. This study was supported by a project (SBAG-213S021) from the TUBITAK, Turkey.

Data retrieval to provide thyroid hormone reference ranges and set-points upon individualized characteristics

Hadi Tabesh[1], Mostafa Hemmati[2] & Hamidreza Bazrafshan[3]
[1]University of Tehran, Department of Life Science Engineering, Faculty of New Sciences and Technologies, Tehran, Iran; [2]University of Tehran, Department of Life Science Engineering, Faculty of New Sciences and Engineering, Tehran, Iran; [3]Ludwig Maximilian University Klinikum München, Guest, München, Germany

Clinicians recognize patients persistently experience residual symptoms of thyrotoxicosis or hypothyroidism etc. despite having achieved circulating levels of TSH and FT4 within the conventional normal ranges. In fact, many pathological conditions affect preferred TSH and FT4. In addition, evidences indicate that the laboratory-quoted normal thyroid hormones as well as TSH reference range could not be always appropriate for everyone in clinical practice. In neonates, infants, children, adolescents and elderly serum concentrations of the thyroid hormones show a clear age and sex dependency. Age- and sex-specific normal reference intervals are an important prerequisite for interpreting thyroid hormone measurement. A comprehensive literature search was performed on PubMed, UPTODATE, NCBI over publications within the last 3 decades. A total number of 43 references were retrieved based on search terms including thyroid hormone reference intervals, age; sex; and related TSH intervals, thyroid disorders and optimal TSH range. We extracted data about concentration of thyroid hormones in various pathological conditions. We extracted thyroid hormones data in various physiological conditions e.g. pregnancy, menopause etc. This data was inserted in a MS Excel file and subsequently implemented into MATLAB software as a matrix. A GUI was then developed based collected data matrix to calculate individualized thyroid hormone set points based on patient input parameters comprise age, sex and several routine pathological conditions e.g. hypothyroidism, total thyroidectomy. Both euthyroid set points of patients with primary hypothyroidism, total thyroidectomy, and lobectomy etc., can be straightforwardly derived from hormone calculator App using personal indications of each patient. It can be shown that every individual has a preferred personalized set point. This software provide the preferred set points to be rationally computed using our proposed algorithm implementable for computer-aided calculations. This could facilitate precise targeted dosing of patients in personalized medicine. The proposed GUI could provide intra-individual physiological optimal ranges compared to laboratory-quoted normal ranges and assist physicians making proper decisions.

The impact of strain elastography and 4d doppler in improving the presurgical evaluation of thyroid nodules with intermediate cytology results

Andreea Borlea[1], Cristina Mihaela Cepeha[2], Ioan Sporea[1], Laura Cotoi[1] & Stoian Dana[1]
[1]Victor Babeş University of Medicine and Pharmacy, Internal Medicine II, Timişoara, Romania; [2]Victor Babeş University of Medicine and Pharmacy, Pediatrics, Timişoara, Romania

Fine needle aspiration (FNA) is recommended for diagnosing thyroid nodules with suspicious ultrasound (US) features. Bethesda categories III and IV have conflicting management approaches: follow-up or thyroidectomy. This study aimed to evaluate a multimodal US assessment of the lesions in order to clarify the therapeutic strategy in intermediate cytology cases. 64 successive Bethesda III or IV cases were included. US evaluation consisted of greyscale US, qualitative strain elastography (SE) and three-dimensional (3D) Color-Doppler. A linear multifrequency probe and a linear volumetric probe (Hitachi Preirus Machine, Hitachi Inc. Japan) were used. The nodules were described usingconventional US criteria: taller-than-wide shape, marked hypoechogenicity, irregular borders, inhomogeneity, microcalcifications and the presence/absence of suspicious lymph nodes. Lesions presenting with increased stiffness on SE (scores 3 and 4) and moderate/intense perinodular vascularization were consideredto associate an increased risk of malignancy. Based on these criteria, lesions were classified as low, intermediate, or high risk. The outcomes were compared to the pathology report post-thyroidectomy. Thyroid cancer was identified in 25% (16 cases) and borderline follicular neoplasia was found in five cases. Given the recommendation of watchful waiting in this category, it was considered together with the malignant lesions, resulting in a number of 21 cancer cases. SE alone detected thyroid cancer with an accuracy of 82.81% (54/64 cases), a proportion of 80% of the nodules displaying score 4 and 66.6% of score 3 cases proved malignant. Most of the proven malignant nodules (15/21) showed important vascularization in the surrounding tissue. The prevalence of cancergrew with the degree of stiffness (9.0%–15.0%–66.6%–80.0%), but also with the intensification of vascular perinodular pattern (18.2%–

27.7%–35.29%–50.0%). The multimodal US evaluation of intermediate cytology cases, including B-mode, SE, and volumetric Doppler demonstrated a sensitivity of 85.7%, a specificity of 88.3%, and an accuracy of 90.3% in identifying thyroid malignancy. The detection ofhighly suspicious featuresusing qualitative SE, and 3D Doppler in addition to the conventional ones, did increase the risk of cancer.

Measurement of calcitonin in nodular thyroid disease approach: The experience of a tertiary centre

Vânia Benido Silva[1], Maria Teresa Pereira[1], José Carlos Oliveira[2], Cláudia Freitas[1] & Maria Helena Cardoso[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar e Universitário do Porto, Clinical Chemistry, Porto, Portugal

Introduction
It is universally accepted that calcitonin (CT), a hormone secreted by the parafollicular cells of the thyroid, is a specific, sensitive and early marker of Medullary Thyroid Carcinoma (CMT), with higher diagnostic accuracy than fine needle aspiration biopsy(FNAB). However, the routine measurement of serum CT during assessment of nodular thyroid disease (NTD) remains controversial due to rarity of this cancer and possible false positive results.
Aim
To evaluate the frequency of hypercalcitoninemia among patients with NTD,the prevalence of MTC in these cases and the concordance with cytologic results.
Methods
We present a retrospective study including patients with measurement of serum CT during investigation of NTD between january 2010 and june 2019. Data regarding cytologic results, performance of surgery and histological diagnosis were collected. Hypercalcitoninemia was established as a serum CT value >10 pg/ml. These patients were categorized, according the CT levels, in 2 groups: G1- serum CT 10–100 pg/ml; G2- serum CT ≥100 pg/ml. Patients with personal or familial history of MTC or MEN-2 were excluded.
Results
In a total of 1124 patients with serum CT levels measured during the study of NTD, 41 (3.6%) had hypercalcitoninemia [G1: 34 (3.0%); G2: 7 (0.6%)]. The FNAB was performed in 34 (82.9%) cases of high levels of CT [G1: 27 (79.4%); G2: 7 (100%)] and a cytologic result sugestive of MTC was found in 4 (11.8%) [G1: 1(3.7%); G2: 3 (42.9%)]. Among those with hypercalcitoninemia, 15 (36.6%) underwent to surgery [G1: 9 (26.5%); G2: 6 (85.7%)] and in 9 (60.0%) it was confirmed the histological diagnosis of MTC [G1: 3 (33.3%); G2: 6 (100%)]. Among these patients, beyond the 4 cases with FNAB compatible with MTC, 1 was submited to thyroidectomy due a MTC metastasis finding, and the remaining had the following cytological results: follicular neoplasm ($n=1$), suspicious of papilar carcinoma ($n=1$), suspicious of malignancy ($n=1$) and benign result ($n=1$). The histological diagnosis distribution of the remaining 6 operated patients was as follows: follicular carcinoma ($n=2$), follicular hyperplasia ($n=3$) and C cells hyperplasia ($n=1$) and all cases belonged to G1.
Conclusion
We documented a prevalence of hypercalcitoninemia in NTD of 3.6%, quite similar to data reported in literature. It has been described a MTC rate range from 0.3 to 1.4% in patients with NTD and from 10 to 40% in hypercalcitoninemia status, which is concordant with our results (0.8% and 22%, respectively). Despite the limited number of individuals, serum CT showed higher diagnostic accuracy to MTC than cytologic study and for values of CT ≥ 100 pg/ml, the positive predictive value was 100%.

Microarray profile of B cells from Graves' disease patients reveals biomarkers of proliferation

Xiaoying Li, Bingbing Zha & Qian Yang
Fifth People's Hospital of Shanghai Fudan University, Department of Endocrinology, 閔行區, China

B lymphocytes are the source of autoantibodies against the thyroid-stimulating hormone receptor (TSHR) in Graves' disease (GD). Characterization of autoimmune B-cell expression profiles might enable a better understanding of GD pathogenesis. To reveal this, the expression levels of long noncoding RNAs (lncRNAs) and mRNAs (genes) in purified B cells from patients with newly diagnosed GD and healthy individuals were compared using microarrays, which elucidated 604 differentially expressed lncRNAs (DE-lncRNAs) and 410 differentially expressed genes (DEGs). GO and pathway analyses revealed that the DEGs are mainly involved in immune response. A protein–protein interaction network presented experimentally validated interactions among the DEGs. Two independent algorithms were used to identify the DE-lncRNAs that regulate the DEGs. Functional annotation of the deregulated lncRNA–mRNA pairs identified 14 pairs with mRNAs involved in cell proliferation. The lncRNAs TCONS_00022357-XLOC_010919 and n335641 were predicted to regulate TCL1 family AKT coactivator A (TCL1A), and the lncRNA n337845 was predicted to regulate SH2 domain containing 1A (SH2D1A). TCL1A and SH2D1A are highly involved in B-cell proliferation. The differential expression of both genes was validated by qRT-PCR. In conclusion, lncRNA and mRNA expression profiles of B cells from patients with GD indicated that the lncRNA–mRNA pairs n335641–TCL1A, TCONS_00022357-XLOC_010919–TCL1A, and n337845–SH2D1A may participate in GD pathogenesis by modulating B-cell proliferation and survival. Therefore, the identified lncRNA and mRNA may represent novel biomarkers and therapeutic targets for GD.

Application of fuzzy logic controller to optimize thyroid hormone replacement therapy

Hadi Tabesh[1], Mostafa Hemmati[2] & Hamidreza Bazrafshan[3]
[1]University of Tehran, Department of Life Science Engineering, Faculty of New Sciences and Technologies, Tehran, Iran; [2]University of Tehran, Department of Life Science Engineering, Faculty of New Sciences and Engineering, Tehran, Iran; [3]Ludwig Maximilian University Klinikum München, Guest, München, Germany

Conventionally, physicians adjust LT4 dose by clinical estimation based on their experiences and available guidelines; however, no computational algorithm exists to support their decisions. The objective of this study is to build an artificial decision support system utilizing fuzzy logic to propose a proper LT4 dosage regimen. We used THYROSIM software as the model of human thyroid hormone regulation to simulate a virtual thyroidectomized patient, setting the secretion rates of thyroid gland at 1%. A T-S fuzzy control algorithm was developed in MATLAB software to track TSH and T3 concentrations to their objective setpoints by adjusting LT4 dosage scheme. The result of our proposed LT4 dosage for the virtual patient was then compared with a conventional guideline implementing into THYROSIM software. The dosage of 165 µg LT4/day for our virtual patient results to 14 days lag time to achieve the objective setpoints of TSH and T3 while the proposed dosage by T-S fuzzy control algorithm could reach our objective in 8 days. Moreover, in contrast to fuzzy control system TSH concentraion in convetional therapy exceeded the upper bound limit for a priod of 7 days. Fuzzy logic could assist physicians by proposing a more proper LT4 dose scheme with an accuracy exceeding that of an expert provider. Therefore, a more proper treatment could be delivered by the clinicians using the decision tree of fuzzy logics.

Hypothyroidism in utero suppresses pituitary-adrenal function in the ovine fetus near term: Implications for fetal maturation and the timing of birth

Emily Camm[1], Isabella Inzani[1], Miles De Blasio[1], Katie Davies[1], India Lloyd[2], F. B. Peter Wooding[1], Abigail Fowden[1] & Alison Forhead[1,2]
[1]University of Cambridge, Physiology, Development and Neuroscience, Cambridge, United Kingdom; [2]Oxford Brookes University, Biological and Medical Sciences, Oxford, United Kingdom

Development of the fetal hypothalamic-pituitary-adrenal (HPA) axis is important for normal maturation of the fetus and the timing of parturition. In hypothyroid fetuses, gestational length may be prolonged and maturational processes delayed, although the role of the HPA axis is unknown. This study investigated the effects of hypothyroidism before birth on the structure and function of the anterior pituitary and adrenal glands in fetal sheep near term. All procedures were performed under the UK Animals (Scientific Procedures) Act 1986. In 15 twin-bearing pregnant ewes at 102–110 days of gestation (d; term ~145 d), one fetus was thyroidectomised (TX) while the other was sham-operated under general anaesthesia. At 143d, umbilical blood and fetal pituitary and adrenal glands were collected after euthanasia. Fractional volume and mass of adrenocorticotrophin (ACTH)-containing corticotrophs in the anterior pituitary gland were determined by immunohistochemistry and stereology. Adrenal zone composition, and adrenocortical and medullary mRNA abundances of key steroidogenic enzymes and growth factors, were determined by stereology and RT-qPCR, respectively. Data were assessed by Student's *t*-test ($P<0.05$). Plasma concentrations of thyroxine, triiodothyronine, ACTH and cortisol were lower in TX than sham fetuses. Fetal hypothyroidism increased absolute and relative (to fetal body weight) masses of the anterior pituitary gland (sham 22.0±1.5, TX 41.8±3.1 mg/kg) and corticotroph population (sham 6.8±0.4, TX 10.6±0.5 mg/kg).In the adrenal gland, absolute mass of the zona fasciculata was decreased (sham 117±12, TX 86±7 mg) and relative mass of the medulla was increased (sham 17.2±1.4, TX 22.4±0.8 mg/kg) by thyroid hormone deficiency, without any change in total adrenal mass. In TX fetuses, adrenocortical mRNA abundance was reduced by 42–63% for cholesterol transport protein StAR, steroidogenic enzymes CYP11A1, CYP17, 3β-hydroxysteroid dehydrogenase, CYP21 and CYP11B1, and for insulin-like growth factor-I (IGFI) and IGF type 1 receptor. Fetalhypothyroidism had no effect on adrenocortical ACTH receptor, IGFII or IGF type 2 receptor, or adrenomedullary phenylethanolamine-N-methyltransferase, IGFI, IGFII or IGF receptor mRNA abundance. Thyroid hormones are important regulators of the structure and secretory capacity of the pituitary-adrenal axis before birth. In hypothyroid fetuses, low plasma cortisol may result from impaired adrenocortical growth and steroidogenic enzyme expression, secondary to low circulating ACTH concentration. Greater pituitary corticotroph population during fetal hypothyroidism indicates compensatory cell proliferation and abnormal corticotroph capacity for ACTH synthesis and/or impaired hypothalamic input. Suppression of normal development of the fetal pituitary-adrenal axis by thyroid hormone deficiency may contribute to the delay in fetal maturation and delivery observed in hypothyroid offspring.

MTHFR C677T polymorphism frequency and DNA methylation status in Georgian population with non-autoimmune hypothyroidism

Tamar Kvaratskheliа[1,2], Elene Abzianidze[1], Mzeona Kakulia[2], Sandro Surmava[1], Ketevan Asatiani[3] & Eka Kvaratskhelia[1]
[1]Tbilisi State Medical University, Molecular and Medical Genetics, Tbilisi, Georgia; [2]Medical center 'Medimedi', Endocrinology, Tbilisi, Georgia; [3]National Institute of Endocrinology, Endocrinology, Tbilisi, Georgia

Introduction
Methylenetetrahydrofolate reductase (*MTHFR*) gene C677T polymorphism results in thermolabile, reduced functioning enzyme and predicts hyperhomocisteinemia and altered DNA methylation. On the other hand, several studies indicated a higher plasma homocysteine (Hcy) levels in patients with primary hypothyroidism than in healthy, euthyroid individuals, including some experimental studies that indicated decreased MTHFR activity in hypothyroid patients. We conducted this study to see whether there is an association between *MTHFR* C677T polymorphism, DNA methylation changes and non-autoimmune hypothyroidism (NAH) in Georgian population.
Materials and methods Study ethical approval was granted by Tbilisi State Medical University ethics committee. Informed written consent was obtained from all participants. Genomic DNA of 93 patients (mean age 51.3±15.17) and 96 healthy controls (mean age 51.6±16.65) were isolated using DNA blood Kit (Qiagen). Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis was used for genotyping *MTHFR* C677T. DNA samples underwent bisulfite modification (Qiagen) and methylation levels of Alu and LINE-1 were examined by the combined bisulfite restriction analysis-interspersed repetitive sequences (COBRA-IRS).
Results
The present study shows an association of *MTHFR* C677T polymorphism with NAH as T allele and CT genotype are more prevalent in patients then in control group (OR (CI) 3.75 (1.89 to 7.48), $P=0.0002$ and OR(CI) 5.03 (2.87 to 8.83), $P<0.0001$ respectively). On the other hand, our results suggest that hypermethylated loci (mCmC) at Alu elements are significantly lower (15%) in study group then in controls (37%) ($P<000.1$). As for LINE-1 the hypermethylated loci (mCmC) are also lower in study group (18%) then in controls (27%) ($P<000.1$).
Conclusion
The results of this case-control study suggest that the MTHFR C677T variant, was significantly associated with non-autoimmune hypothyroidism in Georgians. Also MTHFR 677TT genotype correlates with hypomethylation of Alu and LINE repetitive sequence in hypothyroid than in euthiroid individuals. All above indicates that C677T polymorphism may predispose development of non-autoimmune hypothyroidism.

Dietary interventions for the treatment and management of autoimmune thyroid disease: A systematic review and meta-analysis

Jorge Correia[1], Hafsa Meraj[2], Maaz Ahmad[3], Lucia Mariela Marroquin Ramirez[4], Laura Gómez Corral[4], Laurence Genton Graf[1] & Zoltan Pataky[1]
[1]Geneva University Hospitals and University of Geneva, Division of endocrinology, diabetes, nutrition and patient education, Geneva, Switzerland; [2]Shifa College of Medicine, Islamabad, Pakistan; [3]Sharif Medical & Dental College, Raiwind,, Pakistan; [4]Queen Mary University of London, William Harvey Research Institute, Barts & the London School of Medicine,, London, United Kingdom

Background
There is evidence that dietary interventions can reduce antibody levels in patients with autoimmune thyroid disease (ATD), which can have a beneficial effect on the clinical manifestations of the disease. The aim of this study was to review the literature regarding the different types of dietary supplementations and their effectiveness in the management of ATDs.
Methods
Using a predefined search strategy, four databases were searched (PubMed, Web of Science, CINAHL and Cochrane central register of clinical trials). Efficacy was assessed from randomized controlled trials and cluster randomized controlled trials including post-intervention mean, standard deviation and sample sizes for both the intervention and control group to calculate pooled effect sizes. Outcomes evaluated included serum levels of TSH, FT3 and FT4, levels of antibodies and change from baseline in symptoms of ATD. Risk of bias was assessed using the Cochrane tool for assessment of risk of bias.
Results
Twenty eight studies were included in the analyses, focusing on ATD ($n=9$), Graves' disease ($n=8$), Hashimoto thyroiditis ($n=7$), postpartum thyroiditis ($n=3$)and a prevention trial ($n=1$).Treatments included supplementation with Selenium ($n=15$), Vitamin C ($n=1$), Nigella sativa ($n=1$), a combination of carotene, vitamin C, Vitamin E and Selenium ($n=2$), Vitamin D ($n=4$), anatabine lozenges ($n=1$) and Myo-inositol plus L-selenomethionine ($n=1$).
Selenium supplementation improved serum TSH levels –0.48 (95% CI : –0.87 to –0.03); anti-TPO antibody –1.056 (–1.76 to –0.35); and FT4 levels –0.259 (95% CI : –0.57 to 0.05). Improvement across other outcomes was not significant. Nigella Sativa supplementation also showed an improvement in TSH –0.77 (95% CI : –1.41 to –0.13) and FT4 levels 0.67 (95% CI : 0.04 to 1.31). Myoinositol and selenium combination revealed improvement in FT4 0.54 (95% CI : 0.24 to 0.85) and Anti Tg antibody levels –0.52 (955 CI : –0.83 to –0.21). Iodine supplementation yielded a statistical significance only for anti TR antibodies –0.76 (95% CI : –0.96 to –0.56). Use of Vitamin A improved Anti Tg antibody levels 0.46 (95% CI : 0.13 to 0.79). Vitamin C and D supplementation revealed no significant effect on outcomes.
Conclusion
Dietary interventions were found to have a limited role in the management of ATDs. The evidence was generally of poor quality. We recommend that higher quality trials be conducted in the future to build a solid evidence base for use of supplements in autoimmune thyroid conditions.

Prevalence of thyroid disease in end-stage renal disease patients

Laura Cotoi, Daniela-Georgiana Amzar, Borlea Andreea, Cristina Cepeha & Stoian Dana
Victor Babeş University of Medicine and Pharmacy, Timişoara, Romania

Introduction
Chronic kidney disease is a rising cause of morbidity and mortality in developed countries, including end-stage renal disease (ESRD). Endocrine disorders are highly common endocrine complications among patients with chronic kidney disease, including those receiving dialysis. The prevalence of thyroid comorbidities in patients with chronic kidney disease is documented higher than in normal population.
Materials and methods
A cross-sectional observational single-center study was carried out in the Dialysis Center from May 2019- June 2019. One hundred twenty-three subjects were enrolled in this study. All patients were on chronic hemodialysis treatment with different primary causes of renal failure, with a mean duration of hemodialysis therapy 5.6±4.89 years. A complete clinical and biochemical profile was obtained for each patient. Conventional B-mode thyroid ultrasound was performed in all cases on Aixplorer Mach 30 (SuperSonic Imagine, France).The study aims to investigate the prevalence of morphological and functional thyroid disorders in patients with chronic kidney disease, with renal replacement therapy (hemodialysis).
Results
We evaluated 123 patients with end stage renal disease, with renal replacement therapy, with hemodialysis three times a week, mean age 62.2±11.01 years. The mean duration of hemodialysis therapy was 5.6±4.89 years. According to laboratory results we have found that 74.5% of patients from our study group were euthyroid, 24.4% percent were hypothyroid (16 females and 14 males),and 4 patients (3.3%) had subclinical hyperthyroidism. According to ultrasound results, 48.7% of patients have a normal thyroid appearance, 51.2% have a nodular goiter, defined as the presence of minimum one node in any thyroid lobe and 17.8% had autoimmune thyroiditis, with positive antibodies. The mean diameter of the nodules was 4.7±11.1 mm, the maximum size found on ultrasound was 24.6 mm and the minimum dimension was 2 mm. Thyroid disease was more prevalent among female patients, who present a 3.4 fold higher risk. We have also found that an increase of BMI with one unit raises the risk of developing thyroid disease with 1.083 times (P=0.018).
Conclusion
Chronic kidney disease and hemodialysis therapy have an impact on thyroid echo texture and morphology of thyroid gland. We have found that thyroid disease has a prevalence of 61.3% among patients with ESRD on hemodialysis, with a higher chance of developing thyroid disease for female gender, and the increase of body mass index raises the risk of developing thyroid disease by 1.083 times.

Elastographic patterns in the evolution of Graves' disease: An observational study

Cristina Mihaela Cepeha[1], Corina Paul[2], Borlea Andreea[1], Laura Cotoi[1] & Stoian Dana[3]
[1]'Victor Babes' University of Medicine and Pharmacy Timisoara, PhD School Department, Timisoara, Romania; [2]'Victor Babes' University of Medicine and Pharmacy Timisoara, Pediatrics, Timisoara, Romania; [3]'Victor Babes' University of Medicine and Pharmacy Timisoara, Endocrinology, Timisoara, Romania

Introduction
The most common cause of hyperthytoidism is considered to be Graves disease (also known as Basedow disease), an autoimuune disorder. The most recent technique developed for measuring the tissue elasticity is considered to be sonographic elastography.
Aim
This study was conducted in order to determinate if any significant changes could be encountered in the elastographic patterns of the different evolutive stages of Graves' disease.
Material
We included in the study a total number of 24 randomized patients diagnosed with Graves disease, distributed in 3 categories: Onset (O), Stable (S) and Healed (H). In the Onset category were included 6 patients (with mean age 41.5±10.1), 10 patients (with mean age 43.5±12.1) were included in Stable category and 8 patients (with mean age 49.5±9.7) were in healed phase.
Method
All subjects were evaluated by all means: clinical, hormonal, immunological and convetional US. Strain elastography was performed with a HITACHI Preirus machine, with a 5–15 multifrequency linear probe. All the included patients underwent real-time strain elastography. The strain ratio was computed evaluating the strain of each lobe compared with sternocleidomastoid muscle on the same side.
Results
The strain ratios (SRs) (mean±standard deviation) of patients included in the cathegories O, S and H were 1.9±0.83; 1.3±0.46 respectively 0.7±0.17. Ranked in ascending order, SR values were: healed<stable<onset. Statistically significant (P<0.05) differences regarding thyroid stiffness were found between the groups.
Conclusion
The existence of various degrees of elasticity in the thyroid parenchyma depending of the evolutive phase was identified using real-time strain elastography.

Keywords: graves disease, elastography, thyroid, strain ratio.

Thyroid imaging reporting and data systems (TI-RADS) and advanced ultrasound techniques: Compared stratification of the cancer risk

Andreea Borlea[1], Laura Cotoi[1], IOAN Sporea[1], Cristina Mihaela Cepeha[2] & Stoian Dana[1]
[1]Victor Babeş University of Medicine and Pharmacy, Internal Medicine II, Timişoara, Romania; [2]Victor Babeş University of Medicine and Pharmacy, Pediatrics Department, Timişoara, Romania

The prevalence of thyroid nodules is increasing in the general population, thus detecting the ones at risk represents the main concern in clinical practice. The aim of the study was to compare four important Thyroid Imaging and Reporting Data Systems (TI-RADS) and assess how elastography and 4D Color Doppler vascularity evaluation improve the estimation of the malignancy risk. 133 nodules were evaluated by means of conventional ultrasound (US), elastography and 4D Doppler. All nodules were classified using the four selected systems and our proposed improved score: The American College of Radiology (ACR), the EU TI-RADS, Horvath TI-RADS and Russ' French TI-RADS. Outcomes were compared to the pathology exam. The percentage of malignancy was of 26.31%. The ACR and EU TI-RADS showed similar results: good sensitivity of 94.28% and 97.14%, NPV of 93.33% and 95.83%, but fairly poor specificity of 31.81% and 23.46%, a PPV of 35.48% and 31.19% respectively, with an accuracy of 42.8% and 45.8%. Horvath TI-RADS displayed better accuracy of 66.9%, slightly improved specificity (62.24%), but poorer sensitivity (80%). The French TI-RADS, whichadds elastography to the algorithm, showed better outcomes (Se: 91.42%, NPV:96.42%, Sp:82.65%, PPV:65.30%, and accuracy of 84.96%). A mean strain ratio (SR) value greater than 4 was found in 80% of malignant group and in only 12% of the benign nodules. The parameter itself showedgood correlation to the response variable: the pathology report (P<0.001). Similar accuracy was achieved when considering 4D vascularity as an additional parameter to the French score, butwhen studiedby itself, it proved beneficial for predicting cancer (P<0.001), thus it may bring important extra information in uncertain cases. Adding elastography and 4D vascularity information to the standard US evaluation of thyroid nodules did improve the estimation of the malignancy risk.

The value of real-time strain elastography in the assessment of diffuse thyroid pathology

Cristina Mihaela Cepeha[1], Corina Paul[2], Borlea Andreea[1], Laura Cotoi[1] & Stoian Dana[3]
[1]'Victor Babes' University of Medicine and Pharmacy Timisoara, PhD School Department, Timisoara, Romania; [2]'Victor Babes' University of Medicine and Pharmacy Timisoara, Pediatrics, Timisoara, Romania; [3]'Victor Babes' University of Medicine and Pharmacy Timisoara, Endocrinology, Timisoara, Romania

Introduction
Autoimmune thyroid diseases are among of the most important causes of thyroid disfunction. Chronic Autoimmune Thyroiditis (CAT)and Graves' Disease (GD) are the major causes of hypothyroidism and hyperthyroidism, respectively.
Aim
The aim of this studywas to evaluate the efficiency of strain elastography in the differential diagnosis of Chronic Autoimmune Thyroiditis (CAT) and Graves' disease.
Material
In the study were included a total of 27 randomized patients with CAT (six males and 21 females withmean age 41.56±13.59), 12 patients with GD (three males and nine females with mean age 37.58±12.47) and 19 with normal-healthy thyroids (four males and 15 females with mean age 36.16±13.26).
Method: All 58 subjects underwent clinical examination, hormonal and immunological evaluation and conventional ultrasonography. For all the cases real-time strain elastography was performed by using HITACHI Preirus machine with a 5–15 multifrequency linear probe. The strain ratio was estimated by evaluating both thyroid lobes compared with sternocleidomastoid muscle on the same side.
Results
The strain ratios (SRs) (mean±standard deviation) of patients with CAT, GD and control group were 3.7±0.83; 2.15±0.28 and 0.87±0.2. Ranked in ascending order, SR values were: control group<Graves' disease<Chronic Autoimmune Thyroiditis. Statistically significant ($P<0.05$) differences regarding thyroid stiffness were found between the groups. The strain index ratio was higher both in CAT and GD than the control group.
Conclusion
Identifying different degrees of stiffness using strain elastography can help differential diagnosis of thyroid diffuse diseases.
Keywords: strain elastography, Graves disease, Chronic autoimmune tyroiditis, diffuse thyroid pathology, strain ratio.

Aldosterone to renin ratio and 24-h urine aldosterone level – suitability assessment in primary hyperaldosteronism prediction

Weronika Korzynska, Grzegorz Mazur & Anna Jodkowska
Department and Clinic of Internal and Occupational Diseases, Hypertension and Clinical Oncology, Wroclaw Medical University, Wrocław, Poland

Introduction
Primary hyperaldosteronism (PHA) is the most common hormonal cause of hypertension concerning about 5–12% of hypertensive individuals. Aldosterone to renin ratio (ARR) and 24 h urine aldosterone concentration (24-UAC) are important tools in PHA screening diagnostics. The most appropriate cutt off values predicting PHA are still being discussed. The study is to assess siutability and to determine optimal cut off values of ARR and 24-UAC for accurate PHA prediction in uniform hypertensive population.
Methods
Fifty-nine hypertensive patients (age 49.20, s.d.: ± 14.45) with clinical suspicion of PHA, following a normal salty diet underwent 24 h-urine aldosterone concentration collection and ARR measurement after 2 h of verticalization. The verification of PHA diagnosis was based on the serum aldosterone concentration after the 0.9%NaCl loading test. Statistical analysis was performed. Evaluation of the test accuracy was performed based on the receiver operating characteristic (ROC) curve analysis.
Results
According to the salt loading test PHA was confirmed in 30 patients, and in 29 essential hypertension was diagnosed. The calculated sensitivity of ARR value >20, >30, >40 was respectively 100%, 92.59%, 85.19% for PHA prediction, while the specificity of ARR value >20, >30, >40 was respectively 44.44%, 66.67%, 74.07%. The calculated sensitivity of 24UAC >10, >12, >15, >17 μg/24 h for PHA prediction was respectively 73.91% 73.91% 68.18% 65.22% and the specificity was 69.23%, 76.92%, 85.71%, 92.31% respectively.
Conclusion
The results suggest that (1) the most appropriate ARR and 24-UAC cut off values consistent with the possibility of PHA confirmation are: ARR >40 and 24-UAC>15 μg/24 h in homogenous hypertensive population.

Pregnancy during adjuvant mitotane therapy because of adrenocortical carcinoma – case report

Kamil Stępiński, Beata Jurecka-Lubieniecka, Barbara Michalik, Karolina Gorki & Barbara Jarząb
Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch, Gliwice, Poland

Introduction
Primary adrenocortical carcinoma (ACC) is a highly malignant but rare neoplasm. It can occur as a hormonally active or an inactive tumor. It is considered that about three-fourths of ACC cases are hormonally active, although they do not always give clinical symptoms. Mitotane (Lysodren) is registered by the FDA for the therapy of ACC, either for monotherapy or as a combined chemotherapy.
Case report
A 34-year-old woman, with a histopathological diagnosis of ACC (Weiss score 7 pts, Ki67-5%) after resection of the primary tumor in 2014, during the adjuvant mitotane therapy initiated in 2014 by an oncological center at the place of residence, was referred in 2017 to Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch because of the local recurrence of neoplasm with intraperitoneal dissemination. On the adimssion to our ward, the patient informed that she was pregnant. After the pregnancy was confirmed, the mitotane treatment was stopped (7 weeks' gestation). The MRI examination performed at 30 weeks' gestation revealed the progression of the disease. The patient gave birth to a healthy child in the 35 weeks' gestation (Apgar score 10/10). After the delivery the mitotane therapy was resumed and the EDP chemotherapy was performed.
Conclusion
Female patients with ACC during mitotane therapy are required to use effective contraception (mechanical preferentially). However, the mitotane belongs to the D category (embryotoxic) in the FDA Pregnancy Categories, no fetal complications were found in this case.

Advantage and trustworthy of cortisol and dexamethasone evaluation in different biological matrices in patients with adrenal masses

Luana Lionetto[1], Roberta Maggio[2], Pina Lardo[2], Donatella De Bernardini[1], Fabiola Cipolla[1], Matilde Capi[1], Maurizio Simmaco[1], Giuseppe Pugliese[2] & Antonio Stigliano[2]
[1]Mass Spectrometry Unit – Sant'Andrea Hospital, Sapienza University of Rome, NESMOS Department, Rome, Italy; [2]Endocrinology – Sant'Andrea Hospital, Sapienza University of Rome, Clinical and Molecular Medicine, Rome, Italy

Biochemical function of adrenal masses is currently based on 1 mg post-overnight dexamethasone suppression test (pDST). Several approaches are recently developed, in order to reduce false positive/negative samples, only in retrospective series. They are based on the correlation of some different parameters, i.e. late-night salivary cortisol (LNSC) vs serum and salivary cortisol pDST; LNSC vs serum and salivary cortisol and serum dexamethasone pDST; LNSC and cortisone vs serum cortisol and salivary cortisol and cortisone pDST. Although these findings offer a better diagnostic performance, several conditions are still disappointed. No information is traceable about the harvest time of diurnal salivary and serum samples and no study include neither the levels of salivary nor urinary dexamethasone pDST. Aim of our study is to combine all these strategies in order to avoid the underestimated biases and obtain more precise information about the true "cortisol condition" of the patients.
To reach this purpose we assess both cortisol and dexamethasone concentrations in several samples: saliva at 2300 h before the drug administration, diurnal saliva and serum at 0800 h and also the urine collection from 2300 h to 0800 h. Analytes levels are measured using a validated liquid chromatography–tandem mass spectrometry method. In this study we included 20 subjects without morphological adrenal alteration (MRI assessment), dyslipidemia, hypertension and impaired glucose tolerance (healthy controls) and 50 patients with adrenal incidentaloma showing different cortisol levels ranging from normal to ACTH-independent hypercortisolism. In both series, LNSC were similar to salivary cortisol pDST, even if they were greater in the patients with adrenal incidentalomas and subclinical cortisol secretion. Serum dexamethasone levels were in reference ranges, while salivary and urinary dexamethasone found in these matrices require additional sample numbers in order to establish appropriate cut-offs. Our preliminary results suggest that the combination of these findings could represent an improvement to assess the individual cortisol status.

Ectopic cushing syndrome: A cases-series in a tertiary centre in Spain

Laura Gonzalez Fernandez, Noemi Brox Torrecilla, Maria Miguelez Gonzalez, Jose Atencia Goñi, Bettina Weber, Diego Munoz, Juan Carlos Percovich, Susana Monereo Megias, & Rogelio García Centeno
Endocrinology, Gregorio Marañon University General Hospital, Madrid, Spain

Introduction
Ectopic Cushing Syndrome (ECS) is a rare disease associated with significant comorbidity. Among the causes of Cushing's syndrome (CS), ACTH-producing extrahypophyseal tumours are rarely reported. The aim of our study is to describe the clinical, diagnostic and therapeutic characteristics of patients with ECS treated in our Endocrinology department over a 15-year period.
Methods
A cross-sectional unicentric retrospective study was designed. Patients diagnosed of ECS in our hospital between 2005 and 2019 were included. Epidemiological, clinical, diagnostic, therapeutic and evolutive variables were recorded.
Results
A total of 7 patients (5 males and 2 females) with a mean age of 52 years (29–77 years) were included. The median time from the onset of symptoms to hypercortisolism diagnosis was two months. Most frequent comorbidities were hypertension in 6 patients (86%), and diabetes mellitus in 5 patients (71%). Cushingoid phenotype, oedema of limbs and proximal weakness was observed with 86%, 86% and 71% each. Regarding laboratory tests alterations, hypokalemic metabolic alkalosis, hypertransaminasemia (71%) and leucocytosis (57%) were detected. Relating to Cushing syndrome diagnosis, the mean serum cortisol was of 52.44 μg/dl (20–98), urinary free cortisol

2624.28 μg/24 h (838–6246) and ACTH 193.7 pg/ml (75–271). The ectopic origin was confirmed whether by dynamic tests in a total of 5 patients (CRH stimulation test and/or inferior petrosal sinus sampling) and/or by radiological images in 7 patients (CT, MRI, Octreoscan, FDG-PET/CT and/or 68Ga-DOTANOC PET/CT). The responsible neoplasm could be identified by histology in 6 out of 7 cases. They were mostly pulmonary neuroendocrine tumours (4 carcinoids and 2 small cell carcinoma (SCLC), and 3 of them presented metastatic dissemination at diagnosis. Regarding therapeutic management of CS, ketoconazole and metyrapone were indicated in 6 and 3 respectively. The treatment of the primary tumour included surgery in two cases, surgery combined with systemic therapy (chemotherapy and somatostatin analogues) in one case, sunitinib and somatostatin analogues in other case and chemotherapy-only in two patients. At follow-up 3 have died and 4 remain alive (3 free of disease and one with stable disease).
Conclusions
ECS is associated with significant morbidity and mortality both due to the complications derived from excess cortisol production and the tumour itself and its dissemination. Mortality differs according to the underlying primary tumour, showing SCLC the poorest prognosis. This fact highlights the importance of both hypercortisolism control and the antitumor treatment, which requires a multidisciplinary management.

The effectiveness of treatment for primary aldosteronism in Iceland 2007–2016

Hrafnhildur Gunnarsdottir[1,2], Gudbjorg Jonsdottir[1,3], Gudjon Birgisson[4] & Helga Sigurjonsdottir[5]
[1]University of Iceland, Reykjavik, Iceland; [2]Department of Internal Medicine, Landspitali University Hospital, Reykjavik, Iceland; [3]Department of Internal Medicine, University of Iowa Hospitals and Clinics, Iowa City, United States; [4]Department of Surgery, Landspitali University Hospital, Reykjavik, Iceland; [5]Division of Endocrinology, Department of Internal Medicine, Landspitali University Hospital, Reykjavik, Iceland

Introduction
Primary aldosteronism (PA) is a potentially curable cause of hypertension. In 2007, a standardized PA work-up protocol was introduced in Landspitali University Hospital (LUH), a tertiary care center for Iceland. The aim of this study is to review treatment response for patients diagnosed with unilateral and bilateral PA in LUH 2007–2016.
Methods
All charts for PA-patients aged ≥18, diagnosed 2007–2016 in LUH, were retrospectively reviewed. Saline infusion test confirmed diagnosis. Adrenal venous sampling distinguished unilateral (UD) from bilateral disease (BD). Adrenalectomy was offered for UD, otherwise patients were treated with aldosterone antagonists. Yearly follow-up consisted of monitoring blood pressure, serum-potassium and need for hypertension medication (HTM) and potassium supplementation (PS). Wilcoxon rank-sum test was used for comparison.
Results
Sixty-seven patients were diagnosed with PA during the study period; 40 BD and 27 UD. For BD, median systolic blood pressure (mSBP) at diagnosis was 160 (119–204) mmHg compared to 142 (115–189) mmHg at 1-year follow-up, $P=0.0032$. At 5-years, mSBP was 145 (121–168) mmHg, lower than at diagnosis ($P=0.012$). For UD, mSBP at diagnosis was 167 (104–214) mmHg compared to 141 (111–188) mmHg at 1-year, $P=0.0004$. For UD mSBP at 5-years follow-up was 134 (117–184), lower than at diagnosis, $P=0.0005$. Median diastolic blood pressure (mDBP) at diagnosis was 91 (64–132) mmHg for BD compared to 85 (41–106) at 1-year follow-up, $P=0.0092$. At 5-years, BD mDBP was 89 (65–100) mmHg, $P=0.15$ when compared to same group at diagnosis. For UD, mDBP at diagnosis was 102 (57–140) mmHg. At 1-year, UD mDBP was 90 (69–107) mmHg, lower than at diagnosis ($P=0.0076$). At 5-years, UD mDBP was 88 (69–100) mmHg, lower than at diagnosis, $P=0.011$. Median number of HTM at diagnosis was 3 (1–6) BD and 3 (0–5) UD. At 1-year, median HTM number was 3 (1–5) BD and 2 (0–5) UD. At 5-years, median HTM number was 2 (1–5) BD and 2 (0–6) UD. At diagnosis, 15 BD patients and 13 UD needed PS. Two from each group needed PS at 5-years.
Conclusions
In this nationwide study, we found that approximately 40% of the patients had UD. With specialised treatment, SBP and DBP reduced significantly in both subgroups. The results indicate that during the study period, only the most serious cases of PA were diagnosed as 42% of the patients in this study needed PS at baseline. The study emphasizes the importance of screening for PA in patients in Iceland.

References values for midnight serum cortisol

Cindy Lauro[1], Marine Rigo[2], Aurélie Sieuw[1], Agnès Georges[1], Magalie Haissaguerre[2], Antoine Tabarin[2], Julie Brossaud[1] & Jean-Benoît Corcuff[1]
[1]Nuclear Medicine, University Hospital, Bordeaux, France; [2]Endocrinology, University Hospital, Bordeaux, France

The loss of nychthemeral rhythm is a feature of endogenous hypercorticism that may be investigated by the assay of midnight salivary cortisol ($_{ser}$C0h) although often replaced by serum cortisol assay. However, manufacturers of cortisol immunoassays kits seldom provide reference values for this horary. We present here tentative reference values of $_{ser}$C0h with an automated imunoanalyzer (DXi800, Beckman Coulter).
The population retrospectively studied (2014–2017) consisted of in-patients mainly investigated for diabetes, hypertension, and obesity (214F/121M, 57 [25–75] years, BMI 27.5 [20.2–41.2], median [5th–95th] percentile). The patients that elicited the strongest clinical suspicion of hypercorticism were subjected to urinary sampling for cortisol assay and/or low dose dexamethasone supressing test.
$_{ser}$C0h ($n=415$) was 93 [36–251] nmol/l with a non-gaussian distribution in subjects with no confirmed hypercorticism. The upper reference limit (URL) of $_{ser}$F0 was 284 nmol/l (CLSI C28-A3 non-parametric method). Urinary free cortisol (UFC) was 17 [5–55] μg/d (ref 10–60 μg/d) Serum cortisol at 8 h ($_{ser}$C8h) was 336 [189–623] nmol/l (DXi800 reference values 185–624 nmol/l). There was no significant correlation of $_{ser}$C0h with BMI or UFC or $_{ser}$C8h.
The 10 subjects exhibiting $_{ser}$C0h>URL were diagnosed: metastatic cancer (3), pheochromocytoma (1), acromegaly (1), diabetes/alcoholism (1), stress (1), pseudoCushing syndrome (1) and adrenal incidentaloma (2). The stressed patient had normal UFC and low-dose DXM test (LDDT) 6 months later, the patient with pseudoCushing syndrome has the same status 3 years later. One patient with incidentaloma had normal UFC and LDDT 1 year later, and was later diagnosed multiple sclerosis. The other patient with incidentaloma had normal LDDT; adrenalectomy was requested because the tumour (30 mm) was heterogeneous with calcification but the patient was lost on follow-up.
We propose to use 284 nmol/l as URL for $_{ser}$C0h using the DXi800 cortisol assay. Prospective studies are pending to provide clinical specificities and sensitivities at this level. Comparisons with other immunoassays are also needed.

Case report: Ectopic Cushing syndrome as paraneoplastic manifestation of an advanced small cell lung cancer

Sebastian Schmidt[1], Christoph Werner[1], Christof Kloos[1], Olaposi Yomade[2], Karin Gabriela Schrenk[2], Andreas Hochhaus[2] & Gunter Wolf[1]
[1]Endocrinology, Clinic for Internal Medicine III, Jena, Germany; [2]Hematology and Oncology, Clinic for Internal Medicine II, Jena, Germany

Background
Ectopic Cushing Syndrom (ECS) represents approximately 12% of all patients with Cushing´s disease. Either ACTH (5–10%), CRH or cortisol is produced uncontrolled from nonpituitary tissue. Half of ECS cases are neuroendocrine lung tumors [carcinoid tumors>small cell lung carcinoma (SCLC)], but ECS is clinically apparent only in 1–5% of SCLC cases. Clinical features vary according to extent and duration of exposure to ACTH/Cortisol excess and include rounded erythematous face, acne, purple striae, proximal muscle wasting, edema, hypertension and metabolic alkalosis with hypokalemia. If possible, radical tumor excision is the treatment of choice. Ketoconazole, metyrapone, etomidate, mitotane, and mifepristrone and octreotied are second line options whereas bilateral adrenalectomy is the ultima ratio in case of pharmacological failure. Patients with ECS due to SCLC usually present at an advanced stage.
Case report
A 67-year-old male patient (BMI 26.5 kg/m²) with deterioration of known hypertension, diabetes mellitus on oral treatment (metformin/empagliflozin/

saxagliptin) and psoriasis but also hyperhidrosis, bruising, dizziness. Smoking history of 40 pack years. Severe hypokalemia with 2.17 mmol/l (3.3–4.5) and hyperglycaemia (plasma glucose: 20.3 mmol/l; HbA1c: 9.0%;) resulted from corticotropic excess [serum cortisol in nmol/l (101–536): max. 2710; profile: 2033 (0600 h) – 1266 (2400 h) – 1158 (1800 h) – 922 (1200 h); ACTH 339.8 pg/ml (4.7–48.8)]. No increase of ACTH seen in the CRH-test (−15 min: 350.0 – 0‘: 339.7 - … - 120‘ 345.9). Computed tomography (CT) scanning identified tumor lesions of the right lung, liver and bilateral adrenal glands. Liver biopsy provided histologic diagnosis for liver metastasis of a low differentiated, high proliferative SCLC (cT1bN3M1c, G3, extensive disease; MNF116 positive, AE1/AE3 positive, synaptophysin positive, CD56 positive, TTF-1 positive, KI-67-index 90%). Serum NSE was elevated: 51.5 ng/ml (0–12.5). Bradycard episodes (heart rate 35/min) due to reduced potassium levels were seen and cardiovascular surveillance and compensation of electrolyte imbalance at ICU was necessary. Cortisol excess led to susceptibility for infections and soor-esophagitis and aspergillosis of the lungs occured. Adrenostatic therapy with metyrapone (3500 mg/day) was started and serum cortisol normalized to 424 nmol/l. According to tumor board recommendation palliative systemic chemotherapy with etoposid and carboplatin was commenced. Dismissal from hospital was possible after 49 days and after 2 chemotherapy regimes. Medication at dismissal: metyrapone 3000 mg/day, spironolactone 200 mg/day, insulin therapy. Continuation of chemotherapy is planned.

Conclusions

Severe hypokalemia and cortisol excess in combination with brief disease duration should be suspected for ECS. Interdisciplinary therapy by endocrinologists, intensive care unit and oncologists is needed. Severity of hypercortisolism and tumor histology affect mortality and morbidity.

Secondary hypertension due to middle-aortic syndrome in a young adult patient

Csaba Sumánszki[1], Károly Pócsai[1], Nikolette Szücs[1], Gergely Kiss[2], Péter Sótonyi[3], Judit Tőke[1] & Miklós Tóth[1]
[1]2nd Department of Medicine, Semmelweis University, Budapest, Hungary; [2]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; [3]Heart and Vascular Center, Semmelweis University, Budapest, Hungary

Introduction

Hypertension is a severe medical condition that significantly increases mortality and disability worldwide. Most hypertensive patients are classified with essential hypertension; however, secondary hypertension is present 5–10% of all cases. Aortic stenosis is a significant cause of secondary hypertension in children and adolescents. Middle-aortic syndrome constitutes 0.5%–2% of all cases of aortic stenosis. The stenosis involves the abdominal aorta and/or distal descending thoracic aorta and can include the renal and visceral branches.

Objective

We report a case of middle-aortic syndrome in a young adult with severe hypertension.

Results

The 21-year-old female patient was referred to our tertiary referral endocrine centre with resistant hypertension diagnosed at the age of 18 years. Her blood pressure exceeded normal ranges despite a triple combination of antihypertensive drugs (ACE inhibitor, calcium channel blocker and diuretics). Physical examination revealed equally elevated blood pressure on both arms (180/100 mmHg) and significantly lower blood pressure values on both legs (150/80 mmHg). According to the 24-h blood pressure monitoring, median blood pressure was 155/80 mmHg (day time median: 137/67 mmHg, maximum systolic blood pressure 220 mmHg; night time median: 164/86 mmHg, maximum systolic blood pressure 175 mmHg). Hormonal investigations were performed after optimising antihypertensive treatment not affecting the renin–angiotensin–aldosterone system. The laboratory investigations confirmed hyperreninemic hyperaldosteronism: supine aldosterone level was 17.2 ng/dl (reference range: 0.7–15.0 ng/dl), plasma renin activity was 4.41 ng/ml per h (reference range: 0.20–2.80 ng/ml per hour). The patient was euthyroid and eucortisolemic. Both kidneys showed normal parenchymal function and ultrasound morphology. Abdominal and thoracic computed tomography–angiography revealed significant stenosis of thoracic aorta at the segment of the X–XI thoracic vertebrae. Percutaneous transluminal balloon angioplasty and stenting was performed with success as her blood pressure normalised after the intervention. Long – term blood pressure control could be achieved with low-dose doxazosin monotherapy.

Conclusion

Our case highlights that secondary hypertension should always be considered in young patients with hypertension. Middle-aortic syndrome is associated with high morbidity and mortality due to the increased risk of cardiovascular disorders. As conservative drug treatment is rarely effective vascular intervention is required to normalize blood pressure and prevent end-organ damage.

Which of the anthropometric indicators is the most useful tool in the assessement of potential inflammation in patients with non-functioning adrenal incidentalomas

Joanna Kowalska[1], Iwona Zielen-Zynek[1], Justyna Nowak[2], Ilona Korzonek-Szlacheta[2], Bartosz Hudzik[2,3] & Barbara Zubelewicz-Szkodzińska[1,4]
[1]Medical University of Silesia, Katowice, Department of Nutrition Related Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Health Sciences in Bytom, Bytom, Poland; [2]Medical University of Silesia, Katowice, Department of Cardiovascular Disease Prevention, Department of Metabolic Disease Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [3]Silesian Center for Heart Diseases, 3rd Department of Cardiology, School of Medicine with the Division of Dentistry in Zabrze, Zabrze, Poland; [4]Piekary Medical Center, St. Luke’s City Hospital in Piekary Śląskie, Department of Endocrinology, Piekary Śląskie, Poland

Introduction

Chronic inflammation is an important factor in type 2 diabetes and cardiovascular diseases development. Studies demonstrate that body fat, estimated by anthropometric indicators, correlates with inflammation indicators in chronic diseases. Ipso facto, it seems reasonable to suppose, that there would also be a correlation between anthropometric parameters and both, old and new inflammation indicators in patients with non-functioning adrenal incidentalomas.

Aim

The aim of the study was to evaluate anthropometric parameters and indicators – waist circumference (WC), BMI, WHR, WHtR, BAI, VAI, LAP, BRI, ABSI, RFM and its relationship with inflammation indicators – old one: insulin, CRP and new one: PLR (*platelet–lymphocyte ratio*), MPVLR (*MPV-to-lymphocyte ratio*), SII (*systemic immune–inflammation index*) in group of patients with non-functioning adrenal incidentalomas.

Material and methods

The study included 182 patients with non-functioning adrenal incidentalomas hospitalized in Endocrinology City Hospital in Piekary in 2014–2018. The exclusion criteria were mainly: other adrenal disorders, decompensated diabetes defined as HBA1 C% >7, kidney failure as eGFR<60 ml/min per 1.73 m^2, liver failure as bilirubin>2 mg/dl, INR>1.5 and albumins<3.5 g/dl, severe inflammation, treated cancer disease. Biochemical parameters (taken from the patient’s medical record) and anthropometric measurements were used to calculate anthropometric indicators. Patients were also analyzed with electrical bioimpedance to estimate percentage of body fat and visceral fat rate.

Results

The average age in studied group was 63 years, cortisol concentration at 0800 h was 12.05 μg/dl, CRP was 3.7 mg/l, insulin 12.8 μU/ml. There strongest correlation (P<0.05) was observed between insulin and: BRI (r=0.58), WHtR (r=0.58), BMI (r=0.58), RFM (r=−0.58). VAI correlated negatively (P<0.05) with MPVLR (r=−0.25) and PLR (r=−0.17), BAI with SII(r=−0.2). There was a positive correlation between CRP and BRI (r=0.16) as well as WC (r=0.16).

Conclusion

New anthropometric indicators, especially VAI and BRI, are more useful in the assessment of potential inflammation in studied group of patients with non-functioning adrenal incidentalomas, than the previous ones.

Malignant neuroblastoma mimicking a metastatic paraganglioma – case report

Joana Maciel, Maria Teresa Alexandre & Helder Simões
Endocrinology, Instituto Português de Oncologia Francisco Gentil de Lisboa, Lisbon, Portugal

Background
Neuroblastomas are malignant tumors that arise from sympathetic plexus or adrenal medulla. Their clinical behavior can range from spontaneous regression to aggressive disease. Like paragangliomas, they have the capacity to secrete catecholamines and to express somatostatin receptors, which is important for diagnostic and treatment purposes. However, the differential diagnosis with paraganglioma can be challenging. We present a case of a catecholamine-producing tumor whose final diagnosis was not straightforward.
Clinical case
A 24 years female presented with dorsal, lumbar and pelvic pain, pelvic paresthesia, dysuria and fever in the last 2 months. The complementary exams showed elevated inflammatory parameters, normocytic normochromic anemia and a right pleural effusion. Antibiotic therapy and several exams were performed.
The computerized tomography scan (CT) revealed several soft tissue lesions (the 2 dominant ones located in left paravertebral areas): D3-D6 measuring 48×44×32 mm and D8-12 with 46×40×46 mm, sacred vertebrae (S1−S4) and iliac bones. The magnetic resonance confirmed well defined lesions and hyperintense in T2. A CT-guided biopsy of both dominant lesions was made, suggesting a paraganglioma positive for S-100, chromogranin and synaptophysin in immunohistochemistry in the superior lesion (D3-D6) and a schwannoma in the inferior (D8-12). No immediate complications of the procedure occurred. At that point she was referenced to our endocrine oncology center. It was required a positron-emission tomography (PET) with 68Ga-dotanoc, which showed hyperexpression of somatostatin receptors in the paravertebral lesions (SUVmax 5.2 in the superior lesion and 12.8 in the inferior), in the sacrum (SUVmax 6.3), in the fourth left rib (SUVmax 4.8) and right scapula (SUVmax 7.5). The total urine metanephrines were high (38.4 mg/24 h, normal range (NR)<1) and also the vanillylmandelic acid (86.6 mg/24 h, NR<14) and chromogranin A (546 ng/ml, NR<100). She started phenoxybenzamine and palliative treatment. A PET-18Fluorodeoxyglucose was performed showing extensive metastasis in bones, muscles and lymph nodes. At that time a review of the previous histology was made: it was diagnosed a poorly differentiated neuroblastoma and a ganglioneuroma in the superior and inferior paravertebral lesion, respectively. An osteomedullary biopsy was than performed and revealed neuroblastoma infiltration in the medulla. She started chemotherapy with vincristine, etoposide and carboplatin. During chemotherapy she developed dural metastases and she is being treated with cranial radiotherapy at this point.
Conclusion
This case illustrates the importance of considering the neuroblastoma in the diagnostic workup of apparently metastatic paraganglioma in young adults, even when catecholamines are produced, 68Ga-dotanoc uptake is present and immunohistochemistry profile is compatible.

A case of coexisting carotid body paraganglioma, adrenal incidentaloma and malignant peripheral nerve sheath tumor. Coincidence or something more?

Georgiana Neagu[1], Maria-Christina Ungureanu[1,2], Irina Iftimie-Gavrilas[3], Laura Teodoriu[2], Andreea Rosu[1], Bianca Chiriac[1], Madalina Protop[1], Alina Chelaru[1] & Cristina Preda[1,2]
[1]Endocrinology, Saint Spiridon County Hospital, Iași, Romania; [2]Endocrinology, Universitatea de Medicină și Farmacie "Grigore T. Popa", Iași, Romania; [3]Regional Institute of Oncology, Oncology, Iași, Romania

Introduction
Paraganglioma (PGL) is a neuroendocrine tumor (NET) originating from the neural crest cells. Head and neck paraganglioma (HNPGL) often presents as an asymptomatic slow growing tumor and is rarely functional. Adrenal incidentaloma (AI) is defined as a silent adrenal mass detected on imaging performed for unrelated disorder. Malignant peripheral nerve sheath tumor (MPNST) is a variety of soft tissue sarcoma derived from cells of neural crest.
Case report
A 41-year-old normotensive woman with severe obesity is admitted to our endocrinology department after surgical intervention followed by radiotherapy for MPNST. Post-therapeutic follow-up MRI revealed a tumoral mass localised at the bifurcation of the right carotid artery with salt and pepper appearance, splaying of the internal and external carotid artery with approximately 31/27/35 cm. The patient underwent surgery and the immunohistological result showed typical Zellballen pattern, positive for synaptophysin, chromogranin, S100, and Ki-67 index was 5% which confirmed the diagnosis of carotid body paraganglioma. The surgical margins of resection were positive, therefore the patient was submitted to radiotherapy. In addition, a CT scan of the abdomen revealed a left adrenal gland hipodense lession with a density between −30 and −50 HU with approximately 25/20/18 mm, aspect suggestive of adrenal myelolipoma. Biochemical evaluation revealed diabetes mellitus type 2. Hormonal assessment showed slightly raised urinary metanephrines levels 387.5 (25–312 µg/24 h), normal values of NET associated markers and corticotropic axis. In order to investigate the possible existence of MEN2A syndrome we also measured calcitonin and PTH both within normal range.
Discussion
Since around half of HNPGLs are hereditary with SDH family gene (SDHx) mutations being responsible for the majority of cases, genetic testing is required. The particularity of the presented case is the association between PGL and MPNST both arising from neural crest derived cells, and AI which is found in approximately one fourth of patients with hereditary paraganglioma–phaeochromocytoma syndromes. Further studies are necessary in order to asses if there is an association between SDHx mutations and MPNST susceptibility.
Key words: head and neck paraganglioma, adrenal incidentaloma, malignant peripheral nerve sheath tumor

Altered bone mass and microarchitecture in catecholamine-secreting malignant paraganglioma

Arnaud Jannin[1,2], Amandine Beron[3], Marie-Hélène Vieillard[4], Marie-Christine Vantyghem[1], Roland Chapurlat[5], Christine Do Cao[1] & Stephanie Espiard[1]
[1]Department of Endocrinology, Diabetology, Metabolism and Nutrition, University Hospital of Lille, Lille, France; [2]School of Medicine, Lille University, Lille, France; [3]Department of Nuclear Medicine, University Hospital of Lille, Lille, France; [4]Department of Rheumatology, University Hospital of Lille, Lille, France; [5]INSERM Research Unit 831, University of Claude Bernard Lyon 1, Lyon, France

Introduction
Pheochromocytoma and most abdominal paraganglioma (PPGL) can secrete catecholamines. *In vitro* and *in vivo*, catecholamines modulate bone remodeling by stimulating bone resorption. In patients with PPGL, four studies have previously demonstrated an increase of biological markers of bone resorption, a decreased of bone density and a higher prevalence of vertebral fractures. We report two patients with malignant abdominal secreting paraganglioma presenting with osteoporosis and altered bone microarchitecture.
Case reports
Patient 1, 43 years-old, was operated for a norepinephrine-producing SDHB abdominal paraganglioma causing malignant hypertension. One year after surgery, magnetic resonance imaging (MRI) diagnosed metastases in T7 and L1 with concordant high uptake in 123I-MIBG and ^{18}F-FDG PET/CT imaging and additional multiple osteoporotic painful vertebral fractures outside the metastatic sites. A dual energy X ray absorptiometry (DEXA) showed lumbar (*T*score = −2.90) and left hip (*T*score = −2.70) osteoporosis. Patient 2, 35 years-old, had a norepinephrine and dopamine-producing SDHA paraganglioma with regional lymph nodes and liver metastases. DEXA revealed lumbar (*T*score = −3.10) and left hip (*T*score = −2.40) osteoporosis. A treatment by temozolomide and capecitabine was initiated. To evaluate bone structure, the patient underwent a high-resolution peripheral computed tomography (HR-pQCT) showing a moderate alteration of bone microarchitecture. At the right tibia, total density (Dtot) was measured at 275 mg HA/cm [normal for the age and the sex (*n*): 338 ± 51], trabecular bone density (Dtrab) at 173.3 (*n*: 199 ± 39), trabecular number (Tb.N) at 1.67 l/mm (*n*: 1.90 ± 0.33), trabecular thickness (Tb.Th) at 0.087 (0.09 ± 0.01). At the left radius, Dtot was measured at 311.4 mg HA/cm (346 ± 57), Dtrab at 179.9 (201 ± 35), Tb.N at 2 l/mm (1.97 ± 0.22), Tb.Th at 0.075 (0.09 ± 0.01). Catecholamine secretion was respectively 12-fold and 29-fold the normal values in these patients who had no other risk factors for osteoporosis than prolonged exposure to catecholamines.
Conclusion
Catecholamine excess can lead to secondary osteoporosis in secreting PPGL. We show here for the first time by the gold standard method, the HR-pQCT, an altered bone microarchitecture. Being aware of such complications is particularly important in malignant PPGL that may have progressive disease and higher catecholamine production contributing to more serious bone complications. Eventually, with bone metastasis present in approximately 70% of metastatic patients, the catecholamine-induced bone fragility can lead to fracture, pain and decreased quality of life as illustrated here.

We also believe that osteoporosis should be sought in every patient with malignant PPGL.

Distinct clinical course of neuroendocrine tumors presenting ectopic ACTH tissue expression and secretion

Michalina Oszywa, Martyna Borowczyk, Ewelina Szczepanek-Parulska, Paweł Gut & Marek Ruchała
Department of Endocrinology, Poznan University of Medical Sciences, Metabolism and Internal Medicine, Poland

Two female patients, A – 61-year-old, B – 68-year-old, were admitted to hospital with symptoms of hypercortisolemia. Both of them were diagnosed with neuroendocrine tumor (NET), patient A with pancreatic NET G3 (Ki67 – 30%), and patient B with a disease with a probable primary origin in lungs - NET G2 (Ki67 - 15%). Both women had metastases to the liver. While laboratory results were similar in both cases (high level of cortisol – up to 1750 nmol/l and 1459 nmol/l (normal value: <497 nmol/l), ACTH – up to 184.40 pg/ml and 214.90 pg/ml (normal value: <63.30 pg/ml), hypokalemia, hyperglycemia, high BP), the clinical manifestation of the disease was quite different. Examination of patient A revealed signs of hirsutism, muscular atrophy, edema of the lower limbs, easy bruising. Patient B presented psychotic symptoms, such as delusions, aggressive and inadequate behavior, confusion. MRI scan of the pituitary gland in both cases revealed no tumor. In both patients, their liver biopsy samples from metastatic foci were tested for the ACTH expression and were positive. Patient A underwent left adrenalectomy, while resection of the right adrenal gland was impossible because of the tumor infiltration. The pathomorphological examination of the removed tissues revealed lipid-poor adenoma. Patient B did not agree for surgery. In both cases, metyrapone was administered as a treatment for Cushing syndrome. Due to the limited access to the drug and its temporary withdrawal, in both patients, cortisol level fluctuations accompanied by a transient aggravation of the general condition were observed. Patient A was treated with octreotide, as well as capecitabine and temozolomide (CAPTEM) and patient B was qualified for treatment with everolimus due to lack of somatostatin receptor expression in HYNIC-TOC. Patient B died 6 months after the diagnosis, while patient A achieved partial remission of the disease and her general condition improved. Ectopic adrenocorticotropic hormone (ACTH) secretion (EAS) may be a form of ACTH-dependent Cushing syndrome in patients diagnosed with neuroendocrine tumors. The treatment of underlying disease together with the treatment of hypercortisolemia should be considered and may constitute a challenge. Metopirone might be a useful drug to reduce concentration of cortisol. However, adrenalectomy may remain basis for the treatment of EAS affecting patient's quality of life and prognosis. The assessment of ACTH expression in the neuroendocrine tumor metastases may guide the management of patients diagnosed with Cushing syndrome due to EAS.

Descriptive analysis of suprarrenal carcinoma in our center. Clinical characteristics and evolution

Miguel Damas-Fuentes, José Ignacio Martínez Montoro, Andrea Fernández Valero, María José Picón-César & Francisco J Tinahones Madueño
Endocrinology and Nutrition, Virgen de la Victoria University Hospital, Málaga, Spain

Introduction
Adrenocortical carcinoma (ACC) is a very rare entity with a variable clinical presentation.
Objective
To review the casuistry of ACC in our center in the last 15 years and to assess clinical characteristics and evolution in our patients.
Material and method
We searched cases of ACC from 2004 to December 2018 registered in the Pathology Department.
Results
Fifteen cases were found, 9 women and 6 men. The mean age at diagnosis was 49.6±12.7 years (range 27–82 years). The initial symptom was local discomfort (5), clinical hypercortisolism (4) constitutional syndrome (2), fortuitous (3), and unknown (3). Regarding location 8 were located on the right and 6 on the left gland. The size of the lesion at diagnosis was 11.15±4.1 cm (range: 5.4–21 cm). Cortisol production was found in 7 cases. At the time of diagnosis, 4 had metastases (liver and/or lung). Only one case could not be intervened due to disseminated disease. After surgery, 5 developed local recurrence and 3 distant metastases. For 2 patients we do not have data regarding post-surgical evolution. Regarding need for post-surgical treatment: 4 patients were not treated for low aggressiveness, 1 for disseminated disease at diagnosis and 1 for post-operative death. 1 patient received adjuvant treatment with Mitotane and 5 Mitotane+etoposide, doxorubicin, and cisplatin (EDP). Only 3 patients have cure criteria today after more than 10 years of diagnosis, 7 patients with a mean survival of 9.3 months (range 3–12) have died, 1 patient has lost follow-up and 4 follow-up reviews of which 2 of them have metastatic disease (at 4 and 20 months post-surgery) and the other 2 are free of disease at this time (at 7 and 38 months post-surgery).
Conclusions
ACC is a very infrequent and aggressive entity in which is necessary to maintain an important degree of alertness and, above all, multidisciplinarity.

High blood pressure due to pheochromocytoma: 8 cases

Ajili Rihab, Zantour Baha, Arfa Sondos, Boubaker Fedia, Berrich Olfa, Alaya Wafa & H Sfar Mohamed
Taher Sfar, Endocrinologie, Mahdia, Tunisia

Introduction
Pheochromocytomas are rare neuroendocrine tumors arising from chromaffincells of the adrenal gland or extra-adrenal paragangliomas. These tumors cause a hypersecretion of catecholamines, resulting in high blood pressure (HBP) and eventual cardiovascular complications. The point of this study is to go through the different clinical aspects of high blood pressure related to pheochromocytomas.
Methods
This is a retrospective study about 8 patients, hospitalized in the internal medicine department in Mahdia, having suffered from a HBP due to a pheochromocytoma , on a period of 13 years.
Results
The study concerned 4 women and 4 men with a mean age of 47.3 years old (33–64). The circumstances under which the pheochromocytoma was discovered, were adrenal incidentaloma in 4 cases and a paroxysmal HBP with adrenergic symptoms in the 4 others. A history of HBP was found in 3 patients. A grade 3 HBP was found in 7 patients with systolic hypertensive peaks reaching 250 mmHg. One out of these 8 patients had a cardiomyopathy and a hypertensive retinopathy due to HBP. The diagnosis of pheochromocytoma was made based on elevated levels of metanephrines in urine in 7 patients and in blood in one patient. CT scanning localized the tumor in 7 patients, while the eighth required an MIBG scan. The tumor was localized in the left adrenal gland in 4 cases , in the right adrenal gland in 3 cases , while an ectopic localization was found in one patient, precisely in the inferior pole of the right kidney. The mean size of the pheochromocytoma was 6.3 cm [3.6–9.8 cm]. The search for a multiple endocrine neoplasia came back negative. All the patients underwent surgery, consisting of a unilateral adrenalectomy in 7 patients. The evolution was marked by the regression of the adrenergic signs and the normalisation of blood pressure without resorting to a medical treatment.
Conclusion
Pheochromocytoma is a rare cause of HBP. The diagnosis must be suspected when faced with a severe paroxysmal HBP, with hypertensive peaks and especially when associated with adrenergic signs. Its diagnosis is based on the measuring of metanephrines in urine or in blood. The surgical treatment may heal HBP.

An unusual lesion mimicking adrenal malignancy

İlkay Çakir[1], Sema Ciftci Dogansen[1], Evin Bozkur[1], Mehmet Uhri[2], Cem Dural[3], Duygu Metin[4] & Meral Mert[1]
[1]Endocrinology and Metabolism Clinic, İstanbul SBU, Bakirkoy Dr. Sadi Konuk SUAM, İstanbul, Turkey; [2]Pathology, İstanbul SBU, Bakirkoy Dr. Sadi Konuk SUAM, Turkey; [3]Surgery, İstanbul SBU, Bakirkoy Dr. Sadi Konuk SUAM, Turkey; [4]Radiology, İstanbul SBU, Bakirkoy Dr. Sadi Konuk SUAM, Turkey

Case report
Adrenal pseudocysts are rare bening lesions that usually mimick solid tumors on imaging. Although they are asymptomatic and often discovered incidentally, distinguishing them from clinically important adrenocortical masses may be problematic before surgery. We report the case of a 50-years-old female who was referred to endocrinology outpatient clinic with a 54×58×50 mm sized mass in the left adrenal gland. Abdominal MRI which was performed because of right flank pain has revealed a Type 3 hepatic hydatid cyst and a lobulated margined adrenal lesion. A differential diagnosis of pheochromocytoma, adrenal carcinoma, and metastatic disease was suspected cause adrenal lesion showed high-signal intensity on the T2-weighted image, and an intense enhancement after contrast. The medical history was unremarkable. The patient was normotensive, no cushing or virilization sign was noted on physical exam. Hormonal work-up indicated a non-functional lesion with a suppression on 1 mg Dexamethasone test, normal aldosterone/renin ratio, and normal levels of urinary metanephrines. DHEAS levels were also in normal range. A significant FDG accumulation was not present at PET-CT imaging. An uneventful laparoscopic surgery was performed based on radiological features of the lesion suggesting a primary adrenocortical malignancy, and a 5 cm mass was excised. Histological examination reported a cyctic cavity with necrotic debris, fibrin and blood costs and a cyst wall with hyalinized fibrous tissue and atrophic adrenal tissue without a clear lining epithelium or endothelium in adrenal gland. A distrofic calcification area was also observed in the lesion. A multidisciplinary team approach is essential for the diagnosis and management of adrenal lesions; surprising results are pleasing especially in those seen really rare as in this case.

EP17

A case of ACTH-independent Cushing's syndrome caused by bilateral macronodular adrenal hyperplasia

Valentina Kalugina
Novgorod Regional Diabetes Centre, Veliky Novgorod, Russian Federation

A 40-year Caucasian female referred to Diabetes centre in November 2016. Her main complaints were 20 kg weight gain over the past 4 years, muscle weakness, high blood glucose readings, high blood pressure (up to 180/100 mmHg),menstrual irregularity.
Medical history
She was diagnosed with T2DM at the age of 39 year. She did not take any blood glucose lowering medication. Her blood glucose readings were: 12 mmol/l at fasting, 20 mmol/l postprandial. She was taking losartan 50 mg/day and bisoprolol 2.5 mg/day for her hypertension regularly. The patient had no family history of endocrine disorders.
Physical examination
Her BMI was 33 kg/m^2. Examination revealed central obesity, buffalo hump and red striae of skin located on the inner surface of the right thigh.
Laboratory findings
Her HbA1c was 9.91%
Plasma potassium level 3.47 mmol/l
Overnight dexamethasone suppression cortisol 488 nmol/l
24 h urinary free cortisol 1877.12 nmol/24 h
ACTH was less than 5 ng/ml
DHEAS 10.5 μmol/l
FSH 5.28 U/l; LH 2.99 U/l
Chromogranin A 45.8 μg/l
Aldosterone: renin ratio 0.4
Abdominal CT
Axial pre-contrast CT image of the left adrenal showed 3 masses: 30×35 mm (22 HU), 19×16 mm (16 HU), 17×17 mm (18 HU). At the right adrenal 2 masses were found: 16×18 mm (26 HU), 10×10 mm (−18 HU). The masses enhanced 60 s after rapid IV contrast bolus to +54 HU, +84 HU, +61 HU, +96 HU, +63 HU; after a 10-min delay, the contrast washed out of the masses to +38 HU, +49 HU, +49 HU, +43 HU, +32 HU (approximately 50%, 56%, 30%, 75%, 38% washout) respectively. The diagnosis of ACTH-independent Cushing`s syndrome, bilateral macronodular adrenal hyperplasia, steroid diabetes, secondary arterial hypertension, secondary amenorrhoea was established. Treatment was adjusted accordingly: glulisine 18 IU/day, glargine 100 IU/ml 20 IU/day. Losartan 100 mg/day, bisoprolol 2.5 mg/day, potassium supplements. After obtaining a satisfactory control of glycemia and blood pressure the patient was succesfully submitted to the left retroperitoneoscopic adrenalectomy (Saint-Petersburg's Clinic of High medical technologies named after N. I. Pirogov). The histology showed adrenal macronodular hyperplasia. Cortisol following the surgery was 32 nmol/l. During the first 6 months, the patient required replacement therapy (hydrocortisone 15 mg/day). The operation led to a complete clinical remission (withdrawal of hypoglycemic and hypotensive medications). Follow-up of the patient (low-dose dexamethasone suppression test annually, CT scans) showed no deterioration of the condition and no growth of masses in the right adrenal gland.

Adrenal adenoma with hyperandrogenism and virilization in a postmenopausal women

María Laura García[1], Elbio Genovesi[1], Noelia Rella[2] & Romina Speroni[1]
[1]Endocrinology, Sanatorio Méndez, Buenos Aires, Argentina;
[2]Endocrinology, Hospital Británico, CABA, Buenos Aires, Argentina

Hyperandrogenism and virilization are infrecuent in postmenopausal women and may result from androgen-producing tumors. Androgen-secreting adrenal tumors are rare in clinical practice and often diagnosed as adrenocortical carcinoma, while benign androgen-secreting adrenal tumors are even more rare.
Case presentation
A 63-year-old postmenopausal woman in follow-up for hypothyroidism reported hair loss, increased libido accompanied by deepening of the voice of more than 6 months of evolution. On physical examination she had a body mass index of 25 kg/m^2 and androgenic alopecia. There was no acne, hirsutism, clitoromegalia or other virilization signs. Findings on examination of the neck, breasts and abdomen were unremarkable. She had no signs of Cushing syndrome. Hormonal evaluation showed elevated serum androstenedione 3.2 ng/ml (reference value 0.3–2.7) and 17-hydroxyprogesterone 2.5 ng/ml (reference value 0.3–1). Nugent test, testosterone and dehydroepiandrosterone sulfate were within the normal range. Imaging examination showed nodule of 2 cm in diameter in the left adrenal gland with 13 Housfield units (HU) , wash out 98% and normal appearance of both ovaries. In addition the transvaginal gynecological ultrasound was normal. The patient develop low back pain and an adrenal CT scan was performed, showing adrenal nodule of 3 cm of 6 HU and wash out of 40% (indeterminate origin) Thus, adrenocortical carcinoma was suspected and then adrenalectomy was indicated. After two month and without surgery, she refered alleviated of manifestations of hyperandrogenism, additionally the level of androgens returned to normal range and the adrenal nodule was reduced to 2 cm (with 3.7 HU and wash out of 84%). A PET–CT with FDG confirmed a round nodule in the left adrenal gland and the SUV max of the nodule was 2, considering the possibility of benign adenoma and excluded ovarian abnormalities and other ectopic tumors. In the 3-year follow-up she was asymptomatic and the adrenal image remained unchange. In retrospect it was interpreted that she had a bleeding or necrosis in a virilizing adrenal adenoma that determined the clinical, biochemical and imaging changes.
Conclusion
The androgen source in women with hiperandrogenism and signs of virilism may be the ovary or adrenal gland. The elevated androstenedione and 17-hydroxyprogesterone indicated an adrenal origin. Despite being infrequent adrenal adenomas must be considered as a cause of hyperandrogenic syndrome.

Differences between bilateral and unilateral adrenal incidentalomas

Mehdi Kalthoum, Ibtissem Ben Nacef, Anaam Ben Chida, Imen Rojbi, Nadia Mechirgui & Karima Khiari
Hospital Charles Nicolle, Tunis, Tunisia

Introduction
Incidentally discovered adrenal incidentalomas has been reported to be as high as 5% of abdominal cross-sectional imaging performed for reasons unrelated to the adrenal gland. Although the management of bilateral and unilateral incidentalomas is the same, some studies suggest differences between the two groups.
Patients and methods
Retrospective study including 91 patients with adrenal incidentaloma at the Department of Endocrinology, Charles Nicolle hospital.
Results
Comparing the group of bilateral incidentaloma (23 patients) to the group of unilateral incidentaloma (68 patients) we found high sex ratio for the first

group (1.55 vs 0.94). The average age was the same for the 2 groups (61 years old). The first group showed more diabetes (47% vs 37%) and less hypertension and dyslipidemia (43% vs 65%). Incidentalomas were revealed more often for the first group with CT scan and less often with Ultrasound and MRI (34% vs 41%). Tumors diameter on average was less in the bilateral incidentaloma group (18.8 mm vs 23.3 mm). Bilateral incidentalomas were associated with a significantly higher prevalence of subclinical Cushing syndrome (26% vs 10%) and a lower prevalence of hyperaldosteronism (17% vs 30%), compared with unilateral lesions, while rates of pheochromocytoma were similar in both groups (4%). Only one patient with bilateral incidentaloma underwent adrenal surgery versus 5 patients with unilateral lesion.
Conclusion
Although patients with bilateral incidentalomas undergo the same management as the patients with unilateral lesions, bilateral incidentalomas are more likely to be associated with subclinical Cushing syndrome and less likely to be hyperaldosteronism.

EP20

Infertility in woman with classic congenital adrenal hyperplasia

Mihaela Stanciu
Endocrinology, University Lucian Blaga Sibiu, Clinical County Emergency Hospital Sibiu, Sibiu, Romania

Introduction
Congenital adrenal hyperplasia (CAH) represent a group of diseases in steroid biosynthesis, due to an enzyme lack in the transformation of cholesterol to cortisol. Women with menstrual dysfunction responds well to adrenocortical inhibition with prednisone, and the significant improvement of menstrual regularity is frequently noted. We report a case of successful pregnancy in a patient with CAH for the first time.
Case presentation
A 35-year-old woman with simple virilising form presented with amenorrhea and secondary infertility. Initialy, in 2013 she was diagnosed with secondary amenorrhea by polcystic ovary syndrome, and received for 3 years treatment with estrogens and progestatives. In 2016 the complete endocrine evaluation revealed a classic congenital adrenal hyperplasia based on high level of 17OH-progesteron and dynamic tests positive. The treatment was based for the next 4 years by Dexametasonum 0.5 mg/day and in September 2019 the pregnancy was confirmed by gynecologist. She was continued the treatment with prednisolone during pregnancy. Now she had 29 weeks of pregnancy and the fetus is monitorized very carefully by the gynecologist. There was a mild increase in the dose of prednisolone during pregnancy. There was no worsening of insulin resistance despite prednisolone administration. The baby is a boy on the genetic evaluation.
Conclusions
The correct diagnosis of female infertility should include the evaluation of 17OH progesterone for the application of a correct treatment that can lead to a pregnancy with normal evolution in women with 17 hydroxylase deficiency.

Singularities of the undertreatment of congenital adrenal hyperplasia in adults

Mariana Lavrador[1], Adriana Lages[1,2], Diana Catarino[1], Lúcia Fadiga[1], Diana Alexandra Festas Silva[1], Joana Reis Guiomar[1], Inês Vieira[1], Luísa Barros[1] & Isabel Paiva[1]
[1]Endocrinology Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Coimbra, Portugal

Introduction
Congenital Adrenal Hyperplasia (CAH) results from enzymatic defects caused by autossomal recessive hereditary mutations characterized by deficient cortisol synthesis and, in most cases, increased androgen synthesis. 90–95% of the cases are originated by deficits in 21-hydroxylase and, in about 75% of the cases, there is evidence of mineralocorticoid deficiency.
Case report
A 37-year-old patient was referred to an Endocrinology department due to class III obesity and insulin resistance. He had assistance in another institution for leukocytoclastic vasculitis under therapy with prednisolone 20 mg once a day, with irregular compliance. The patient had history of precocious puberty with appearance of secondary sexual characters at an early age, short stature and familiar consanguinity. Additionally, he had history of infertility. At the age of 35, the patient performed nephrectomy and right adrenalectomy for suspected renal tumour formation. Histological study revealed ectopic adrenal cortical adenoma with 3 cm and a 3 cm adrenal myelolipoma in the right adrenal gland. In the physical examination at endocrinology department, the patient had cervical and axillary acanthosis; skin hyperpigmentation; centripetal obesity; retractable, small and hard testicles; small penis with little hairiness. Initial biochemical and hormonal evaluation showed the following results: 17-OHP 57 ng/ml (0.6–3.4); renin 181 μU/ml (7–76); ACTH 1351 pg/ml (9–52), cortisol 1.7 μg/ml (5–25), Na+ 138 mEq/l e K+ 4.5 mEq/l, FSH 0.5 mUI/ml (<15); LH <0.1 mUI/ml (<9) and testosterone 0.7 ng/ml (2.7–11). These results were consistent with CAH and hypogonadotrophic hypogonadism. An abdominal CT was performed, identifying a 28 mm myelolipoma and two adenomas in the left adrenal gland. Additionally, a scrotal ultrasound revealed an 8 mm hypoechogenic nodular formation in the left testis. This finding, in association with a negative measurement of βhCG and α-fetoprotein, established the diagnosis of testicular adrenal rest tumor (TART). A genetic analysis confirmed the diagnosis of CAH with the identification of the variant g.655C>G of the CYP21A2 gene in homozygosity, with an enzymatic activity of 0–1%. The patient is monitored under hydrocortisone, fludrocortisone and testosterone replacement therapy.
Conclusion
The present case report illustrates the possibility of a late-diagnosed CAH in the context of bilateral adrenal incidentalomas and infertility. The patient developed chronic complications related to late diagnosis and undertreatment. The association of adrenal nodular lesions (mainly myelolipomas) and TART in undertreated CAH patients seems to be related with chronic hyperstimulation by elevated androgens and ACTH. Both fertility and adrenal glands could be preserved with early diagnosis and glucocorticoid treatment.

DOI: 10.1530/endoabs.70.EP21

EP22

A case of hypokalemic paralysis in a young hypertensive man

Raluca Cristina Pascu[1], Miruna Maria Popa[1], Anca Sirbu[1,2] & Simona Fica[1,2]
[1]Endocrinology, Diabetes and Nutrition Diseases Department, Elias University Hospital, Bucharest, Romania; [2]Elias' Endocrinology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Hypokalemia can be caused by decreased intake of potassium or by excessive loss of potassium in the urine or through the gastrointestinal tract. Severe and life-threatening hypokalemia is defined by levels below 2.5 mEq/l and can be associated with muscle weakness, cramping, headaches, palpitations, polydipsia and polyuria. Periodic paralysis is a very rare presentation in Caucasians.
Case presentation
A 50-year-old Caucasian man, without previous medical history, presented in the emergency department for quadriparesis with predominantly brachial diparesis and hypertensive crisis (220/100 mmHg). Native cerebral computed tomography (CT) was normal. However, biochemical testing revealed severe hypokalemia (1.4 mEq/l), hypernatremia (149.2 mmol/l), high creatine-kinase (5273 U/l), lactate dehydrogenase (2185 U/l) and transaminases (ALT = 106 U/l, AST = 191 U/l), low eGFR (60.24 ml/min per 1.73 m^2) , a raising troponin (from 0.94 ng/ml up to 1.45 ng/ml) and elevated inflammatory markers. Arterial blood gas revealed metabolic alkalosis (pH = 7.56, HCO3- = 36.7 mmol/l). Clinically, he presented with brachial motor deficit, hyporeflexia of the lower limbs, orthopnea, dyspnea and bilateral leg edema. Potassium supplementation was started both intravenously and orally and the patient was transferred to our Endocrinology department, with the suspicion of primary aldosteronism (PA). The patient admitted a long history of high blood pressure, which he had neglected and had never sought medical advice. Plasma aldosterone concentration to direct renin concentration ratio (ARR) confirmed the suspicion (plasma aldosterone = 32.3 ng/dl; direct renin = 0.8 μUI/ml; ARR = 40.3). Consequently, an abdominal non-contrast CT was performed, which showed bilateral adrenal macroadenomas (14/13 mm on the right gland and 12/10 mm on the left gland). Since adrenal venous sampling is not available in our center, we started medical therapy with Spironolactone (150 mg/day, which was gradually reduced to 50 mg/day). Because the patient presented signs of left ventricular dysfunction, we also

added Furosemide (40 mg/day). For further blood pressure control an ACE inhibitor, a calcium channel blocker and clonidine were also introduced. Six-month follow-up showed good control of blood pressure and potassium level, occasional paresthesia in the upper limbs and symmetrical gynecomastia.
Conclusion
Hypokalemic paralysis is a rare form of presentation and the suspicion of PA may be easily overlooked, as it mimics hypokalemic periodic paralysis, polymyositis, Guillan-Barre syndrome. Screening for PA is recommended for any case with spontaneous or diuretic induced hypokalemia and hypertension. Disease control can be obtained with spironolactone, however, the unpleasant side effects in men may lead to low compliance to treatment.

DOI: 10.1530/endoabs.70.EP22

Pseudoglandular myxoid adrenal cortical adenoma and secondary hyperaldosteronism

Mirjana Stojkovic[1,2], Milos Stojanovic[1,2], Biljana Nedeljkovic-Beleslin[1,2], Jasmina Ciric[1,2], Marija Miletic[1,2], Milos Zarkovic[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Deseases, Clinical Center of Serbia, Belgrade, Serbia; [2]Medical Faculty University of Belgrade, Belgrade, Serbia

Myxoid adrenocortical adenoma is a rare adenoma originated from adrenal cortex. A 51 years old male patient was admitted to our hospital due to hypertension and hypokalemia. He has a long history of nonregulated hypertension despite multiple antihypertensive medications. Hypokalemia was detected in last two years with potassium levels around 3.0 mmol/l on high supplementation dose up to 10–16 g of KCl/day. He is obese in the past 10 years. His family history was positive for diabetes (mother) and negative for hypertension. On addmition his blood pressure was 180/90 mmHg, pulse 92/min. Ambulatory blood pressure monitoring (ABPM) showed the mean blood pressure during the day of 159/88 mmHg, pulse 91/min, and during the night 158/85 mmHg, puls 79/min, without diurnal pattern. On 15 g of KCl/day, potassium level was 3.3 mmol/l, with 24 h urinary potassium 225 mmol/24 h. His urinary noradrenaline was above the upper limit (600.1 nmol/l, normal <570 nmol/24 h), while adrenaline (6.2 nmol/24 h) and dopamine (2017.3 nmol/24 h) were normal. Markers of neuroendocrine secretion CgA (23.9 ng/ml) and NSE (6.7 ng/ml) were normal. In LDDST cortisol was suppressed on 77 nmol/l. Testing of the RAAS showed high aldosterone as well as high plasma renin activity (aldosterone >1400 ng/l; PRA 12.1 ng/ml per h; K 4.0 nmol/l). Abdominal ultrasound, CT scan and MR describe hypervascular tumor in the right adrenal, 50×34×36 mm, ddg adrenal adenoma/pheochromocytoma. After premedication with phenoxybenzamine, patient was referred to surgeon who performed right adrenalectomy. Histopathological study showed several growth and distribution patterns. The dominant pattern was presented by cuboid, clear, eosinophilic cells with regular nucleus that were arranged in anastomosing and pseudoglandular patterns, within an abundant myxoid stroma. Immunohistochemical examination showed positivity of the tumour cells for CK AE1/AE3, CD56, inhibin and melanin A. Ki67 was 3%. EMA, CK20, CK7, calretinin and synaptophysin were negative. Weiss score:1. Dg: Pseudoglandular myxoid adrenal cortical adenoma. Postoperative testing showed normal urinary catecholamine levels, normal potassium and normal aldosterone levels with upper normal PRA (K 4.0 mmol/l; aldosterone 38.1 ng/l; PRA 6.49 ng/ml/h. ABPM on Ca-channel blocker, β-blocker and sartane showed normal diurnal pattern with the mean blood pressure during the day of 128/73 mmHg, pulse 69/min, and during the night 103/59 mmHg, puls 59/min. Up to present, 57 cases (24 cases of myxoid adrenocortical adenomas, 2 cases of borderline myxoid adrenocortical neoplasms and 31 cases of myxoid adrenocortical carcinomas) have been reported. Among them, 24 cases of these tumors were pseudoglandular pattern.

Case report: Heterochronous Conn's syndrome and a possible Cushing syndrome developed from bilateral adrenal masses, 5 years apart

Alexandru Morea[1], Diana Lambrinoc[1], Anda Dumitrascu[1], Ionela Florina Baciu[1,2] & Catalina Poiana[1,2]
[1]"C.I. Parhon" National Institute of Endocrinology, Pituitary and Neuroendocrine Pathologies, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Primary hyperaldosteronism or Conn's syndrome is one of the adrenocortical causes of hypertension, alongside hyperdeoxycorticosteronism, apparent mineralocorticoid excess and Cushing syndrome. The two types of hypertension-inducing adrenocortical syndromes (Conn's and Cushing) are extremely rare to be decribed in the same patient. We describe a case of a patient with clinical and biochemical evidence of Conn's syndrome due to a left adrenal adenoma, who developed, 5 years after left adrenalectomy, a potential contralateral cortisol secreting adrenal adenoma.
Case presentation
A 50 year old woman that initially presented in our clinic with severe hypertension, palpitations and headaches had undergone a CT scan 2 years prior which showed an adrenal adenoma, but no other further investigations were performed. The clinical examinantion showed severe obesity (BMI=41 kg/m^2) and uncontrolled hypertension on 4 hypotensors. Laboratory tests: potassium level=3.3 mmol/l, plasma aldosterone concentration (PAC)=188 pg/ml, plasma renin (PR)=2.6 pg/ml, with a ratio of PAC to PR of 72 (≥ 20). The patient underwent laparoscopic left adrenalectomy in 2015, the histopathological examination showing reticular and glomerular hyperplasia. Post-surgery there was a slight decrease of the blood pressure and normalisation of aldosterone and renin levels with normal basal cortisol. Two years later, in 2017, at the annual evaluation, the patient underwent another CT scan, which revealed an adenoma of 1.02 cm/ 2.01 cm on the right adrenal gland. In January 2020, at the re-evaluation, the patient described frontal headaches and also had higher blood pressure since the last visit. We discovered that the right adrenal mass had similar dimensions, but the ACTH levels decreased and the basal cortisol levels were higher (plasma cortisol at 0800 h=24.5 μg/dl). The overnight 1-mg dexamethasone suppression test (DST) was performed, which showed a level of cortisol just under the cut-off point, but close to the upper threshold of the test (1.78 μg/dl vs 1.8 μg/dl). Considering the possibility of the right adrenal mass to determine an ACTH-independent hypercortisolism, the next follow-up will be after 6 months when the 2×2 mg DST will be performed and also the 24-hour urinary free cortisol or late-night salivary cortisol will be assessed.
Conslusions
This case emphasizes the importance of long term follow-up of each patient with endocrine-related hypertension from the clinical point of view (palpitations, headaches, higher blood pressure, muscle weakness, etc.) and also from the hormonal point of view – for aldosteron, renin but mainly cortisol level.

Plasma metanephrines and normetanephrines: Alternative indices of avs in a patient with primary aldosteronism and endogenous hypercortisolemia

Spyridon Nikitas Skarakis[1], Irene Papadimitriou[1], Labrini Papanastasiou[1], Evangelos Diamantis[1], Miltiadis Gravanis[2], Georgios Karydas[2] & Theodora Kounadi[1]
[1]Unit of Endocrinology and Diabetes Centre, General Hospital of Athens "G. Gennimatas", Athina, Greece; [2]Department of Radiology, General Hospital of Athens "G. Gennimatas", Athina, Greece

Background
Adrenal venous sampling (AVS) is the gold standard method that evaluates the source of aldosterone overproduction in primary aldosteronism. During AVS aldosterone and cortisol are simultaneously measured in order to assess successful adrenal cannulation and lateralization of aldosterone overproduction. However, in patients with both adrenal cortisol and aldosterone overproduction, plasma metaneprhines and normetanephrines can be measured to overcome selectivity and lateralization problems, due to endogenous hypercortisolemia.
Aim
Measurement of metanephrine and normetanephrines during AVS to estimate correct adrenal veins catheterization and lateralization in a patient with both adrenal cortisol and aldosterone overproduction.
Case report
A 60-year-old female with bilateral adrenal adenomas of 3.7 and 4.7 cm presented with hypokalaemia and hypertension. Hormonal work-up showed autonomous aldosterone (aldosterone post-saline infusion test 1910 pmol/l) and cortisol secretion (cortisol post-dexamethasone suppression test 309 nmol/l). AVS without ACTH-stimulation was performed in order to establish the source of both aldosterone and cortisol overproduction, with concomitant measurements of cortisol, aldosterone, plasma metanephrines and normetanephrines from both adrenal veins and inferior vena cava. A

metanephrine selectivity index (SI) of ≥12 was used to determine successful catheterization[1]. A lateralization index (LI) of ≥2.0 [the ratio of the dominant over the nondominant aldosterone/cortisol (A/F) or aldosterone/metanephrine (A/M)] was used to confirmed lateralization of aldosterone excess[2]. The metanephrine-derived SI in right and left adrenal veins were 29 and 12.40, respectively, confirming the correct cannulation. When cortisol was used for lateralization, A/F ratio was similar on both sides and periphery (0.014 right vs 0.014 left vs 0.01 periphery). In contrast, with metanephrine as the denominator (A/M), aldosterone production lateralized to the left adrenal vein (4.28 right vs 11.85 left), with a ratio of 2.8. The same results occurred when plasma normetanephrines were used to calculate LI (ratio≥2.0). Furthermore, the cortisol/metanephrine (F/M) ratio was more than twice in left adrenal vein compared to the right ratio (843.3 vs 293.2), suggesting a left adrenal source of hypercortisolism.

Conclusions

Plasma metanephrines and normetanphrines on AVS are alternative useful markers for the diagnosis and subsequent treatment decision of a patient with bilateral adrenal adenomas overproducing aldosterone and cortisol.

Success rate of adrenal vein sampling: A ten-year experience

José Ignacio Martínez Montoro, Miguel Damas Fuentes, Andrea Fernández Valero, María José Picón César & Francisco José Tinahones Madueño
Endocrinology and Nutrition, Hospital Universitario Virgen de la Victoria, Málaga, Spain

Introduction

Adrenal vein sampling (AVS) is the gold standard test to distinguish between unilateral adenoma and bilateral hyperplasia in primary hyperaldosteronism. This is a technical complicated procedure with a variable success rate. Our aim was to report our 10-year-success rate and results as regards to this procedure.

Material and methods

Retrospective observational study including data from patients undergoing AVS between 2009 and 2019.

Results

Data from 15 patients, 7 women and 8 men (48.1±5.5 years old, BMI 33.7±5.23 kg/m^2, blood pressure 157.3±13.1/94±10.2 mmHg) were analyzed. Previous diagnostic imaging tests (Computerized Tomography/Magnetic Resonance Imaging) showed 5 unilateral adrenal adenomas, 2 bilateral adrenal adenomas and 8 images were normal. The success rate of AVS was 60% (9/15). AVS showed lateralization in 6 cases (left lateralization in 5 of them) Imaging test-AVS concordance was 67%. 6 patients underwent adrenalectomy, with anatomo-phatological result of cortical adenoma in 4 of them and cortical hyperplasia in 2. Blood pressure after surgery: 137.5±5.2/85±4.47 mmHg. Adrenal veins were not properly catheterized in 6 cases (5 of them due to inappropriate catheterization of right adrenal vein and 1 due to inappropriate catheterization of both right and left adrenal veins). Complications reported consisted on a unique event of adrenal hemorrhage.

Conclusion

AVS is considered to be the gold standard test to determine the subtype of primary hyperaldosteronism. Success rate of AVS is highly variable. In low-volume centres, as ours, percentage ranges between 40 and 70%, therefore our 60% success rate could be considered acceptable.

Importance of dehydroepiandrosterone sulfate assessment in males

Valentinas Matulevicius[1], Vaidotas Urbanavicius[2] & Saulius Lukosevicius[3]
[1]Department of Endocrinology, Lithuanian University of Public Health, Kaunas, Lithuania; [2]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [3]Department of Radiology, Lithuanian University of Health Sciences, Kaunus, Lithuania

Dehydroepiandrosterone sulfate (DHEAS) is a sulfated ester of dehydroepiandrosterone. Studies of large number of males with DHEAS pathology are infrequent.

Objective

To perform an investigation of significance of DHEAS assessment in males of different ages.

Subjects. Methods. Results

We analyzed clinical data of 3533 patient's (3013 females and 520 males) from DHEAS assessment lists of Vilnius and Kaunas university hospitals. For comparison purposes, a cohort of women was also clinically investigated. DHEAS was assessed 1.6 – 13.5 times more frequently in women than in men. A peak of DHEAS test for women was around 25 years. In males, referrals for DHEAS were uniform during decades, excepting being lower in 0–9 and >75 ages. DHEAS levels in 10- to 24-year-old females were higher than in males. From birth to 9 years and after 45 years, DHEAS was statistically significantly higher in males. Analysis of 491 case records showed low DHEAS in boys, aged 0–9 years and in men, aged 65 – 84. High DHEAS was detected as a peak at around 30 years, but never after 55. Double peak distribution of normal values was evident, with one peak at 10–19 years and a second large peak at 45–64 years. In patients with low DHEAS prevailed congenital adrenal hyperplasia – 31.3%, adrenal tumors (AT) – 29.8% and adrenal insufficiency – 19.3%. High DHEAS prevailed in patients with arterial hypertension – 26.4% and overweight/obesity/hypothalamic dysfunction –18.8%. We found 71 women and 117 men with adrenal tumours (AT). Higher frequency of AT was observed in women around their 30-ties. A peak of AT frequency in men was around 70-ties. We analyzed a list of 3700 consecutive abdominal only and complex abdominal, chest and pelvic computer tomographies (CT) for the age and gender of this examination. Our hypothesis, that referral for CT was much later in men than woman was strongly rejected: peak performance of CT in men and women was the same- between 65 and 74 years of age. In summary, in males, low DHEAS was found in patients with congenital adrenal hyperplasia, AT and adrenal insufficiency. AT were found in elderly and old patients with low or low normal DHEAS. Coincidence of high DHEAS and adrenal tumours was exceptionally rare. In contrary, hypertension and overweight/obesity/hypothalamic dysfunction prevailed in the group of younger patients with high values of DHEAS. This study gives some insight into gender differences of DHEAS secretion in different ages and in adrenal tumours.

Conn's adenoma in *post-partum*

Chayma Besrour, Zouaoui Chadia, Jaidane Amel & Ouertani Haroun
Endocrinology-Diabetology, The Military Hospital in Tunis, Tunis, Tunisia

Introduction

Primary hyperaldosteronism is the first cause of secondary hypertension during pregnancy. The diagnosis is too difficult due to the changes in the renin angiotensin system.

Observation

We report the case of a 37 years old women with a history of pre-eclampsia during her pregnancy who consulted the emergency 20 days after delivery for severe hypertension (23/11) and severe hypokalemia (2.2 mmol/l) resistant to intravenous treatment. The aldosterone level was at 2668 pmol/l and the renin level was <0.5 mUI/l with a high ratio at 534 (n<64) confirming the diagnosis of primary hyperaldosteronism. A CT-scaan identified an adenoma in the left adrenal gland with low density at 5 UH. The patient received spironolactone at the dose of 50 mg per day and we noticed a fully correction of hypokalemia and a normalization of the blood pressure. Then a laparoscopic adrenalectomy was performed. On the examination of the removed left adrenal gland , the adenoma appeared well circumscribed yellow, 12×18 mm in diameter.

Conclusion

Despite the fact that Conn's adenoma is a rare pathology during pregnancy, it needs to be indentified sooner to avoid maternal and foetal complications.

Testicular adrenal rest tumor (TART) in congenital adrenal hyperplasia misdiagnosed as Leydig cell tumor

İnan Anaforoglu[1] & Abdülkadir Reis[2]
[1]Endocrinology and Metabolism, Bahcesehir University Faculty of Medicine, Istanbul, Turkey; [2]Pathology, Avrasya University, Trabzon, Turkey

Congenital adrenal hyperplasia (CAH) is a common autosomal recessive genetic disorder. Impaired cortisol production leads to increased adrenocorticotropic hormone (ACTH) levels. Testicular adrenal rest tumor (TART) is a complication of CAH. It is a rare clinical condition usually presented as testicular masses. TARTs may be misdiagnosed as testicular Leydig cell tumors. We report a case of congenital adrenal hyperplasia (CAH) due to 11-beta hydroxylase enzyme deficiency who underwent left orchiectomy for testicular tumors and took a diagnosis of Leydig cell tumor. A 44 year old male born to a consanguineous marriage took a diagnosis of CAH due to 11-beta hydroxylase deficiency at age 10 while being investigated for high blood pressure and short stature. His height was 140 cm, weight was 58 kg and had left gynecomastia. He had two brothers one with CAH. He was taking 5 mg amlodipin and his blood pressure was normal. While using methylprednisolon until very recently he had been started dexamethasone for the high levels of ACTH. After using dexamethasone for 4 months he admitted to our clinic with complaint of excess weight gain. His ACTH level was 259 pg/ml. His therapy was changed to hydrocortisone. After he was started to hydrocortisone therapy his weight gain stopped. The patient came to control after 1 year. He had complaints of testicular pain and darkening of his skin at face. His ACTH level 1858 pg/ml. A scrotal ultrasonography was performed; 4 hypoechoic, highly vascularised testicular masses were detected; the biggest was 10×6 mm in diameter. His alpha-fetoprotein and beta-HCG levels were normal. The patient admitted to the urology clinic, left orchiectomy was performed. The patient came to our clinic with his pathology report which was consistent with Leydig cell tumor. Thinking possibility of a TART the pathology report was asked to be reviewed again and the report was revised as TART. In immunohistochemical study CD56 staining was focal positive, inhibin was strongly positive, calretinin was weakly positive and androgen receptors were negative supporting TART. He has been started low dose dexamethasone therapy. His ACTH level was 256 pg/ml after 0.25 mg/day dexamethasone therapy. It is important to distinguish Leydig cell tumors from TART in patients with CAH.

The utility of pre-test cortisol and other parameters in the prediction of short Synacthen test failure

Ravikumar Ravindran, Asit Kumar, Florin Capatana, Jo Carter, Mohamed Adlan & Lakdasa Premawardhana
Department of Medicine, Ysbyty Ystrad Fawr Hospital, Cardiff, United Kingdom

Introduction
Short Synacthen tests (SST) are expensive, inconvenient, time consuming and subject to Synacthen availability. Any strategy reducing the need for SSTs will improve its cost effectiveness and also improve patient satisfaction. In this regard indications for SST and assay specific pre-test cortisol levels (not all SSTs are done at 0900 h) may have clinical utility.
Methods
We retrospectively examined the indications for, time and place of testing, and the utility of pre-test cortisol concentrations of all SSTs done in the Aneurin Bevan University Health Board over a period of 12 months. Receiver-operating characteristic (ROC) curve analysis was undertaken for pre-test cortisol to obtain a cut off value for failure.
Results
We analysed 506 SSTs of which 106 (21%) were abnormal. SST failure was highest for the indications of "current therapy/weaning from steroids, and low random cortisol levels" (39.6%; $P<0.001$). There was no difference in outcome for indications such as hyponatraemia, postural hypotension and tiredness/fatigue. Median pre-test cortisol (interquartile range) were significantly different in those with abnormal SSTs compared to those with normal SSTs [147 (91–213) vs 298 (227–393), $P<0.001$]. There was a higher test failure rate in those who had an early morning SST compared to others (26.8 vs 19.5%, $P=0.001$); but there was no difference when place of testing was compared (outpatient or inpatient). ROC curve analysis indicated SST failure with 100% sensitivity with pre-test cortisol of <47 nmol/l; and a normal SST with 100% specificity with cortisol >323 nmol/l.
Conclusions
This study indicates that (i) pre-test cortisol levels of <47 predicted SST failure with 100% sensitivity and cortisol of >323 predicted a normal SST with 100% specificity; (ii) in this group 141 tests may have been avoided if these cutoffs were applied with a significant cost saving; (iii) some indications had a higher predictability for SST failure, and those with lower predictability need supporting evidence before SST is undertaken.

DOI: 10.1530/endoabs.70.EP30

Expression of CYP11B2 and CYP11B1 immunostaining in primary aldosteronism

Natalia Romanova[1], Liliya Selivanova[2], Nadezhda Platonova[1], Ekaterina Troshina[1] & Aleksander Abrosimov[2]
[1]The National Medical Research Center for Endocrinology, Therapeutic Endocrinology, Moscow, Russian Federation; [2]Department of Pathology, The National Medical Research Center for Endocrinology, Moscow, Russian Federation

CYP11B2 is a key enzyme of primary aldosteronism, and several factors are involved in the regulation of CYP11B2 expression and the overproduction of aldosterone. Somatic mutations in aldosterone-driver genes are strongly associated with CYP11B2 expression and have been only detected in the CYP11B2-positive tumor area, indicating that aldosterone producing adenoma (APA) intratumoral heterogeneity corresponds to non-uniform CYP11B2 expression in neoplastic cells. In addition, CYP11B2 can contribute to the clinical diagnosis of primary aldosteronism. CYP11B2 has the potential to synthesize hybrid steroids, which is a unique and characteristic behavior of APA that is distinctive from bilateral hyperaldosteronism (BHA). However, the pathophysiology of primary aldosteronism in both APA and non-neoplastic subtypes remains controversial.
Objective
Our aim in the present study was to compare immunohistochemical (IHC) CYP11B2 and CYP11B1 staining in adrenal slices to histological diagnosis based on H&E staining.
Materials and method
Retrospective evaluation adrenal tumors from patients with primary aldosteronism ($n=20$). According to CT unilateral macrohyperplasia was detected in 19 patients (95% of total), all of them were confirmed to have unilateral hyperproduction of aldosterone according to AVS. Both H&E and immunohistochemical expression of CYP11B2 and CYP11B1 (mouse monoclonal anti-human CYP11B2 primary antibodies and rat monoclonal anti-human CYP11B1); were analyzed in 3.5 mm thick adrenal slices in one representative slide from each case. In addition to IHC analysis of aldosterone-producing adenomas (APAs) and hyperplasia, small extranodular CYP11B2 positive cell clusters, so-called aldosterone-producing cell clusters (APCCs) were identified.
Results
Immunohistochemistry studies of the resected adrenals from 20 patients with PA operated due to unilateral production of aldosterone using CYP11B2 and CYP11B1 staining showed that 10 of those with an adenoma on CT scanning showed CYP11B2 and CYP11B1 staining in the adenoma. Furthermore, 5 cases of an unilateral adenoma, showed CYP11B2 and CYP11B1 staining in the adjacent adrenal cortex and an absence of staining for CYP11B2 in the adenoma. 5 cases showed CYP11B2 expression is heterogeneously immunolocalized throughout the tumor area.
Conclusions
Thus, the functional heterogeneity of adrenal tumors in primary aldosteronism has been proven. IHC staining of adrenal tissue improves subtype diagnostics of primary aldosteronism.

Nonfunctional adrenal adenoma in practice of the endocrinologist

Татьяна Чжен & Татьяна Киселева
Federal State Budget Educational Institution of Higher Education, "Ural State Medical University", Yekaterinburg, Russian Federation

Aims
We investigated the clinical characteristics and follow-up findings of subjects with adrenal incidentalomas (AI) in a single, tertiary-care hospital in Yekaterinburg, Russia.
Methods
This study retrospectively evaluated consecutive patients aged 18 years or older with benign AI, not treated with adrenalectomy, which were nonfunctioning (n-56). The initial and follow up evaluation, including clinical assessment, hormonal investigations and imaging were coordinated via a clinic No. 40 in Yekaterinburg.
Results
The median age in patients with *nonfunctional adrenal adenomas* (NFAI) was 64.41±10.62 years old, women – 46 (82.1%), men – 10 (17.9%). The localization of NFAI in the right adrenal gland is – 14 (25%), in the left – 28 (50%), bilaterally – 14 (25%). The plasma cortisol was 462.35±263.31 nmol/l (101.2 – 535.7 nmol/l); plasma aldosterone

–140.21±96.10 pg/ml (25 – 315 pg/ml), urinary fractionated methanephrins (MN) – 131.34±112.73 μg/day (<320 μg/day), urinary fractionated normetanephrins (NM) – 183.86±312.14 μg/day (<390 μg/day). The mean nodule size of NFAI based on computed tomography was 2.44±1.45 cm, the observation period was 5.27±3.05 years. According to CT, the density of formations in the native phase (NP) varied from −69 to +50 HU, median=6±26 HU, in arterial phase (AP) median=72±24 HU, in venous phase (VP) median=55±23 HU, in delayed (DP) (6 min) median=27±11 HU.
Conclusion
Most AIs are hormonally inactive adenomas. The low tumor density on CT scan picture may be predictive of both hormonal activity and the risk of malignancy. The risk of malignancy decreases with the size above 2.44 cm.

EP33

Pediatric retroperitoneal paraganglioma with uncommon symptom treated successfully by laparoscopic surgery: Case report and literature review.

Van Nguyen Khoa Dieu, Duc Nguyen Dinh, Linh Nguyen & Bay Nguyen Quang
Department of Endocrinology, Bach Mai Hospital, Hanoi, Viet Nam

Introduction
Pheochromocytoma and paraganglioma are rare in the pediatric population occurring in approximately 1 in 50 000 children. *The clinical presentation may range from asymptomatic to the classic triad of episodic diaphoresis, headache, and palpitations*. Among hypertensive children, the incidence of surgically confirmed pheochromocytoma or catecholamine-secreting paraganglioma ranges from 0.8 to 1.7 percent. Catecholamine-secreting paragangliomas are often located in the superior and inferior para-aortic areas (75 percent of extra-adrenal tumors); the bladder (10 percent); the thorax (10 percent); and the skull base, neck, and pelvis (5 percent). Surgery plays an important role in managing the disease. Paragangliomas usually require an open surgical approach. Meanwhiles, laparoscopic surgery may be challenging in pediatric patients with paraganglioma especially in retroperitoneal location. We herein report a case of a paraganglioma that was located retroperitoneal area successfully resected by laparoscopic surgery.
Case presentation
We report a 16-year-old male admitted to the hospital due to intermittent generalized tonic – clonic seizures. With recent history of hypertension being treated irregularly with unknown medication. Further evaluation conducted revealed his hypertension was paroxysmal and in accompanied with classic triad of adrenergic symptoms consisting of headache, palpitations, diaphoresis and elevated levels of catecholamines in the blood and urine samples. Abdominal computed tomography revealed a 4×3 cm retroperitoneal mass likely to be paraganglioma. The patient underwent laparoscopic surgery and the tumor was dissected completely with no complications.
Discussion
Incidence rates of pheochromocytoma and paraganglioma are estimated at 0.3 cases per million per year, with approximately 20 percent of cases diagnosed during childhood. In children, approximately 80 percent of catecholamine-secreting tumors are pheochromocytomas and 20 percent are paragangliomas. Seizure without any other neurological diseases is a rare symptom in pediatric paraganglioma. This condition could be a consequence of paroxysmal hypertension. Surgical resection is the primary treatment in which open surgical approach is more favorable in the management of paraganglioma. Moreover, resection of retroperitoneal paragangliomas is often a surgical challenge especially in pediatric population. However, endoscopic surgery has been properly performed in this patient without any complication.
Conclusion
Paragangliomas presented with seizure are extremely rare in pediatric population. Laparoscopic surgery which is a challenging procedure to this patient group was conducted successfully in the present case.
DOI: 10.1530/endoabs.70.EP33

Clinical, paraclinical features and outcome of adrenocortical carcinoma

Asma Zargni, Ibtissem Oueslati, Sahar Abidi, Nadia Khessairi, Fatma Chaker, Meriem Yazidi, Wafa Grira & Melika Chihaoui
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia

Introduction
Adrenocortical carcinoma (ACC) is a rare aggressive endocrine neoplasm. It's a heterogeneous malignant tumor with incompletely understood pathogenesis and poor prognosis. The aim of our study was to assess clinical and paraclinical characteristics of ACC and to determine its outcome.
Methods
In a retrospective and descriptive study, we included patients with adrenocortical carcinoma confirmed with histopathological examination. Clinical, biological, hormonal, radiological and therapeutic data were collected.
Results
We included four women and a man with an adrenocortical carcinoma. Their median age was 45.8 years [extremes: 31–60]. Their past medical history included diabetes mellitus, intellectual disability and ovarian teratoma in one case, respectively. Three patients presented with abdominal pain and were referred to our department for the exploration of an adrenal mass. One patient was admitted for clinical signs of Cushing's syndrome and the fifth patient presented with weight loss, asthenia and anorexia. On physical examination, two patients had android obesity, hirsutism, high blood pressure, muscle atrophy, skin atrophy, purple striae and facial plethora. Routine blood tests revealed dyslipidemia and diabetes in two cases and severe hypokalemia at 2.4 mmol/l in one case. Three patients had an active hormone secreting tumor with a Cushing syndrome. Cortisol levels after standard Dexamethasone suppression test were 3.5, 12.6 and 33.5 μg/dl, respectively. Among these three patients, one had mixed hormone secretion of cortisol and androgen. Two patients had hormone-inactive tumor. Adrenal computed tomography (CT) scan revealed a right tumor in four patients and a left tumor in one patient. The tumor had heterogeneous enhancement with central intratumoral calcifications in all the cases. Its diameter varied between 5 and 11 cm. A focal extension into the inferior vena cava, liver and kidney was present in one patient. Surgical treatment was performed to four patients. Only one patient had received mitotane. For the other patient, this drug was not available. Two patients died 6 and 48 months after the surgery, respectively. Two patients showed no signs of recurrence in their last CT scan and one patient was lost to follow up.
Conclusion
ACC is a rare and aggressive endocrine neoplasm that may present when hormonally active or after they have become large. The study of the clinical features could conclude to the type of the secretion. Surgical resection represents the treatment of choice in localized ACC. Mitotane, alone or in combination with other agents, remains the most effective chemotherapy.

EP35

Mediastinal malgnant paraganglioma: An atypical presentation

Sara Pinheiro, Ines Damasio, Tiago Nunes da Silva & Valeriano Leite
Instituto Português de Oncologia de Lisboa, Lisbon, Portugal

Introduction
Mediastinal paragangliomas are rare. These tumours can be associated with increased morbidity and mortality when invasive growth to the heart, great vessels, esophagus and trachea occurs. Surgical resection, if feasible, is the treatment of choice.
Case report
A 50-year-old man presented with severe and refractory left gluteal pain radiating to the posterior thigh for two months. The patient had no relevant medical history and no other symptoms. Computer tomography (CT) was performed and suggested a metastatic osteolytic lesion in the sacrum and left iliac bone (6×5 cm). Chest-CT identified a large mass involving the right atrial appendage and atrium extending from the right ventricular outflow tract to the diaphragm (13×8.7×7.9 cm). This hypervascular lesion showed close proximity with the heart and great vessels without a clear cleavage plan with these structures. An echocardiogram confirmed the presence of an extra-cardiac mass adherent to the heart without affecting myocardial or valvular function. A cardiac magnetic resonance imaging (MRI) with respiratory gating showed extensive cardiac invasion by the mediastinal tumour, excluding the possibility of surgical resection without heart transplant. A guided biopsy of the iliac mass was compatible with metastatic paraganglioma with Ki67 of 40%. The patient was then referred to the endocrinology clinic. Family history was positive for a non-functioning vagal SDHD in a half-brother, who had undergone surgey 10 years before, as well as father's death with a neck mass. Genetic testing was not performed in proband's brothers at that time. The same SDHD mutation was confirmed in the patient. Functional imaging study with 68Ga-DOTA-NOC showed intense uptake in the known lesions in the mediastinum and sacrum, and also in the left parapharyngeal space. The patient was recently proposed for chemotherapy with Capecitabine and Temozolamide and supportive cardiac treatment. The

iliac-bone lesion was treated with 20 Gray of palliative local radiotherapy (RT) and painkillers, with symptomatic improvement.
Discussion
SDHD mutation is the most frequent familial paraganglioma syndrome and is an imprinted gene, with paragangliomas occurring in patients who inherited the mutation from the father. Genetic counselling and testing of the paternal line may result in earlier diagnosis and treatment of the relatives. Malignant mediastinum paragangliomas associated with heart infiltration and SDHD mutations are extremely rare. Beyond atypical presentation, location and tumor behaviour, this case report highlights the importance of establishing a hereditary syndrome in the proband.

Paraganglioma and ulcerative colitis: A case report
Wiem Saafi, Ahmed Guiga, Wissem Chaouch, Wissal Ben yehia, Ahmed Bouker, Amira Atig & Neirouz Gannouchi
Farhat Hached University Hospital, Internal Medicine, Sousse, Tunisia

Introduction
Paragangliomas are rare endocrine tumors that represent extra-adrenal localization of pheochromocytomas. Signs of catecholamine excess are the most found manifestation of this tumor especialy hypertension. However, paragangliomas can be asymptomatic or can manifest with nonspecific signs. The association between pheochromocytomas and inflammatory diseases is exceptional.
Observation
Here we report the case of a 26 years old male that was admitted into the internal medicine unit for exploration of arterial hypertension associated with a flush syndrome. The clinical manifestation started five months before his admission. He presented a weight loss with abdominal pain and diarrhea. On the physical exam, the patient had a diffuse sensibility. The diagnosis of pheochromocytoma was highly suspected. Blood investigations revealed an elevation of metanephrines 200 times the normal level but the abdominal scan showed a bilateral retroperitoneal mass. An MIBG scintigraphy demonstrated an intense fixation in the latero-aortic region and the inter aortocaval space. The patient was operated successfully and the diagnosis of paraganglioma was confirmed histologically. However, we noted the persistence of diarrhea so a colonoscopy with biopsy was performed and the diagnosis of ulcerative colitis (UC) was posed.
Conclusion
This is the first case to demonstrate the possible association between ulcerative colitis and paraganglioma. Even though paraganglioma can manifest with diarrhea, inflammatory bowel diseases should be suspected in the absence of amelioration after surgical treatment.

Acute low members ischemia revealing a pheochromocytoma
Wiem Saafi, Ahmed Guiga, Nouha Ghriss, wissal ben yehia, Ahmed Bouker, Amira Atig & Neirouz Gannouchi
Farhat Hached University Hospital, Internal Medicine, Sousse, Tunisia

Introduction
Pheochromocytoma is a rare tumor of adrenal gland tissue that is responsible for secondary hypertension and other clinical manifestations resulting from catecholamine excess and it can result in severe damage to other body systems, especially the cardiovascular system. Here we report an atypical presentation of pheochromocytoma.
Presentation
A 40 years old female patient that was admitted into the internal medicine ward with acute ischemia of lower limbs. The patient has no particular medical history. She had a high blood pressure level (160/90 mmHg) without other signs of catecholamine excess with no hypokalemia. The Doppler ultrasound showed permeable arteries. The angioscan did not show vascular abnormalities but an 11 mm left adrenal adenoma. Biological investigations for an endocrine cause of hypertension showed elevation of plasma metanephrines 5 times the normal levels. The diagnosis of pheochromocytoma was posed and the patient was operated with a positive outcome.
Conclusion
The classic symptoms of pheochromocytoma include palpitations, headache, and generalized sweating. Those signs may occur in a paroxysmal manner. The presence of hypertension in young adults even without the typical presentation should lead us to think of the diagnosis of pheochromocytoma.

Intracardiac paraganglioma in a patient with a paraganglioma syndrome type 4. Short, medium and long-term follow-up
Pablo Lois Chicharro, Jaime Wong Martín, Belén Basagoiti Carreño, Pablo José Ferreira Ocampo & Francisca Almdóvar Ruiz
Hospital Universitario Fundación Alcorcón, Alcorcón, Spain

Introduction
Paraganglioma type 4 is the second most common hereditary paraganglioma syndrome. It is due to a mutation in the succinate dehydrogenase B (SDHB) gene. Associated with high morbimortality for presenting high penetrance (77%) and debut at an early age with a high probability of malignancy (31–71%). In terms of follow-up, annual biochemical monitoring is recommended for mutation carriers. However, the affected gene should be taken into account, for example: there is a high morbidity associated with undiagnosed paragangliomas in patients with SDHB mutations, which requires closer monitoring. In addition to biochemical testing, periodic imaging tests should be considered to detect biochemically silent tumors.
Clinical case
62-year-old male, carrier of the c166-170del CCTCA mutation of the SDHB gene. Cardiac paraganglioma is detected by octreoscan in 2015. The left ventricular tumor is resected respecting left ventricle and coronary sine. The anatomic pathology findings are compatible with subepicardial paraganglioma that affects the resection margin. Regarding follow-up, during the first year it is quarterly, using methynephrine catecholamines and methoxytyramine (negative); and with a semi-annual imaging test where a small recurrence adjacent to the coronary sinus is detected in MRI, with uptake in PET/CT, therefore ruling out cardiac surgery. -During the second and third year, semi-annual follow-up with catecholamines and methanephrines (negative) and imaging tests using PET/CT (radiological stability). During the fourth year, semi-annual follow-up by methoxytyramine, catecholamines and methanephrines (negative), and annual imaging tests, with octreoscan (negative) and PET/CT (lack of progression), and findings of a focal increase of metabolism in the right colon that turns out to be a false positive.
Conclusion
Cardiac paragangliomas are exceptional, making up 1% of all cardiac tumors. The most aggressive variant of SDH mutations is SDHB, presenting a 77% penetrance and a malignancy risk of up to 71%. Genetic study of the relatives of an affected individual is essential for an early diagnosis. Monitoring is performed by biochemical determinations of catecholamines and methanephrines and imaging tests (MRI, PET/CT), with a variable periodicity depending on the morbidity associated with the genetic mutation.

Pheochromocytoma in genetic disorders
Sabrine Mekni, Ibtissem Ben Nacef, Imen Rojbi, Mehdi Kalthoum, Nadia Mchirgui, Youssef Lakhoua & Karima Khiari
Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia

Introduction
Several familial disorders could be associated with adrenal pheochromocytoma such as Von Hippel–Lindau (VHL) syndrome, multiple endocrine neoplasia type 2 (MEN2) and, less commonly, neurofibromatosis type 1 (NF1). Herein, we report three cases of pheochromocytoma as a part of genetic syndromes.
Observations
Patient 1
A 34-year-old women with no familial history, was diagnosed with severe hypertension at 36 weeks of pregnancy. After delivery she was admitted for further exploration of an uncontrolled hypertension and palpitations. The physical examination showed café au lait spots (>6), two *neurofibromas* and clusters of freckles in the armpits and under the breast. Eye exam detected lisch nodules. The diagnosis of NF1 was made. A 24 h urinary test founded a metanephrine level of 17 572 nmol/Cr (normal range 15–120 nmol/Cr) and a normetanephrine level of 6250 nmol/Cr (normal range 40–280 nmol/Cr). Adrenal-CT reveled a right heterogeneous adrenal mass (70×73 mm) with

areas of necrosis. MIBG scintigraphy showed a right adrenal mass with a strong supporting evidence for a pheochromocytoma.
Patient 2
A 25-year-old woman with no familial history, had a surgical resection of a cerebellum hemangioblastoma. Genetic analysis identified a heterozygous germline mutation in the VHL gene consistent with VHL syndrome. Further multiple tumor screening showed bilateral adrenal masses on the CT scans and the functional nature of the adrenal masses was confirmed by a MIBG scintigraphy. Elevated urinary metanephrine level of 1200 nmol/Cr (normal range 15–120 nmol/Cr) and a normetanephrine level of 1484 nmol/Cr (normal range 40–280 nmol/Cr) confirmed the diagnosis of bilateral pheochromocytoma.
Patient 3
A 32-year-old woman with no familial history, was diagnosed with medullary thyroid carcinoma and was treated by a total thyroidectomy. Screening for further tumors revealed bilateral adrenal masses on the CT scans and the Octreoscan detected bilateral adrenal uptake suggesting bilateral pheochromocytoma. Herein, she was admitted to our department for further explorations. The patient was asymptomatic with a normal blood pressure and heart pulse. Biological finding showed an elevated concentrations of plasma chromogranin A of 100 ng/ml and elevated 24 h urinary metanephrine level of 618 nmol/Cr (normal range 15–120 nmol/Cr) and normetanephrine level of 436 nmol/Cr (normal range 40–280 nmol/Cr). We concluded to a diagnosis of MEN2. The serum calcium level, phosphate level and parathormone level was normal.
Conclusion
More than 35% of pheochromocytoma are hereditary. Early diagnosis and regular follow-up are the only means for a better outcome.

Persistent hypokalaemia leading to a diagnosis carcinoid lung cancer. A case study

Benjamin Woolner[1], Batool Rizvi[2], Jaysankar Mattappillil[2] & Ali Naqvi[2]
[1]Stroke Unit, St Mary's Hospital, Newport, United Kingdom; [2]St Mary's Hospital, Medical Assessment Unit, Newport, United Kingdom

Background
An 81-year-old gentleman presented to his GP with a 2 week history of reduced appetite, lethargy and 2–3 kg weight loss over the last month. On routine bloods, his potassium was noted to be 2.2 mmol/l. He was being treated in the community with indapamide, losartan and amlodipine for hypertension. He was admitted to hospital for IV replacement. However, he had persistent hypokalaemia (<2.9 mmol/l) for 3 days despite appropriate replacement and suspension of potential medications driving his hypokalaemia. An initial VBG on admission showed a hypokalaemic metabolic alkalosis, and a routine chest X-ray showed a suspicious looking lesion. The follow up CT chest revealed a left lower lobe lesion, consistent with a new malignancy (T2b/N3/M0), with evidence of idiopathic pulmonary fibrosis, bilateral pleural effusions and calcifications. These CT findings raised suspicions of an ACTH secreting small cell lung cancer, despite the patient not having any cushingoid features. His serum cortisol was 398 nmol/l. He had a partial response following an overnight dexamethasone test (cortisol 99 nmol/l). Cortisol levels throughout the day were 342, 357, 301, and 345 nmol/l at 0600 h. Cortisol was suppressed to 76 nmol/l following low dose dexamethasone suppression which was indicative of Cushing's Syndrome. His ACTH was not very high at 9 ng/l. He was referred to the lung malignancy MDT. A PET scan revealed significantly increased uptake of FDG in the 4 cm left lower lobe lung mass, typical of a carcinoid tumour. Tumour histology was positive for ACTH, synaptophysin, chromograffin and CD56 secretion. Proliferation index assessed with Ki67, was <1%. Further blood tests revealed an elevated chromograffin A (76 pmol/l) suggestive of a neuroendocrine tumour. Urine 5-HIAA testing which was positive with a reading of 113, suggestive of carcinoid syndrome. Repeat test was 26. Normal range (5–35). 24 h free cortisol excretion was elevated at 213 mmol/l. He has no other symptoms or signs of carcinoid syndrome: facial flushing, diarrhoea, wheezing, heart failure or Cushing's syndrome. His potassium levels remained stable following medication adjustment, and intervention with steroid synthesis inhibitors was not necessary. He was referred for surgery but unfortunately he was not a surgical candidate due to cardiac issues and anaesthetic risk. In the meantime, he has functionally deteriorated and referred to palliative team.

Primary hyperaldosteronism in Cantabria: Clinical and biochemical characterization and outcomes

Fernando Pazos[1] & Pilar Monge[2]
[1]Endocrinology, Marqués de Valdecilla University Hospital, Santander, Spain; [2]Endocrinology, Valdecilla Hospital, Santander, Spain

Introduction
Primary hyperaldosteronism (PH) is a cause of arterial hypertension (HT). The prevalence ranged from 1 to 15%. PH is associated with higher rates of cardiovascular morbidity and mortality. PH is under-diagnosed. The aims were to know the prevalence of PH, the clinical and hormonal profiles, outcomes, and prognosis of our population.
Material and methods
A retrospective review of patients with primary hyperaldosteronism in our hospital in the last 20 years (1996–2016). We analyzed motive for the screening, HT, CV risk factors and events at the time of diagnosis, aldosterone levels (ALD), plasma renin activity (ARP), RATIO ALD/PRA, and treatment outcomes.
Results
Forty-six patients, 26 men, and 20 women. Age of 52 years (29–81). In 80%, the onset was hypertension with hypokalemia, 17% was severe or resistant HTA, and 3% was hypertension with an adrenal mass. The diagnostic delay was 12 years (0–43). At presentation, 60% HVI, CVD 35%, PAD 22%. DM2 in 13%, obesity in 41%, dyslipidemia 45%. Serum ALD were 49 ng/dl (10.7–134.2 ng/ml), 6% below 15 ng/dl. Mean ARP ng/ml per h was 0.33 (<0.02–1.48). CT or/and MRI were performed at 100%. Adrenal Catheterization in 4 patients. In contrast, functional scintigraphy of the adrenal gland was performed in 35% of patients. Unilateral adenoma in 56.5% and removed surgically. Bilateral adenoma in 4%, and bilateral hyperplasia in 39.5%, both were in medical treatment.
Conclusions
The number of cases is lower than expected. The delay in diagnosis increases vascular morbidity. Our data suggest a level ALD of ≥ 10 ng /dl suspect a PA, lower than that recommended in the guidelines, in line with data from other recent studies. Adrenal catheterization is not a common practice in our environment as a pre-surgery test, instead we perform functional scintigraphy of the adrenal gland. The distribution of the etiological diagnosis is similar to other series.

Evaluation of pulmonary function and dyspnea index in Greek COPD patients with at least one metabolic comorbidity versus the population of the study without comorbidities – AEOLOS study

Stavros Tryfon[1], Nikolaos Maniakos[2], Alexandros Ginis[3] & Ioanna-Laoutselnta Markou[4]
[1]General Hospital of Thessaloniki, Pulmonary Clinic, "G. Papanikolaou", Thessaloniki, Greece; [2]Private Pulmonary Site, Private Site, Athens, Greece; [3]Medical Affairs Department, ELPEN Pharmaceutical Co. Inc., Athens, Greece; [4]Clinical Department, ELPEN Pharmaceutical Co. Inc., Athens, Greece

Introduction
Metabolic disorder has been frequently observed in chronic obstructive pulmonary disease (COPD) patients. In particular, metabolic comorbidities exert a major impact on patients' morbidity and mortality. Diabetes mellitus, dyslipidemia and osteoporosis are among the most commonly reported metabolic comorbidities in patients with chronic lung disease. COPD patients with comorbidities, such as metabolic disease, are generally more dyspnoeic and have worse health status in comparison to patients without comorbidities.
Objectives
We evaluated FEV1 (%predicted) change and MRC dyspnea score in COPD patients with at least one metabolic comorbidity versus the patients without any comorbidity, treated with a fluticasone–salmeterol fixed dose combination (FDC) for 12 months.
Methods
Prospective, multicenter, non-interventional clinical study (NCT02978703) in which 1016 patients, aged 69.54±9.57 with a mean body mass index of 28.65±5.38, were evaluated and of whom 378 (37.2%) had at least one metabolic disease and 238 (23.4%) hadn't any comorbidity. Pulmonary function was assessed by FEV1 (%predicted) changes and MRC dyspnea scores

among visits. The corresponding data were collected at 6 (V1) and 12 (V2) months, respectively.
Results
In the study population without any comorbidity there was a significant improvement ($P<0.0001$) in both FEV1 (%predicted) between baseline (V0) and final (V2) visit, as well as between consecutive visits (V0: Mean±S.D.: 49.90±8.23, V1: Mean±S.D.: 55.95±10.96, V2: Mean±S.D.: 59.16±11.84). Similar significant improvement was observed on the MRC dyspnea scale ($P<0.0001$, Kruskal–Wallis test). In COPD patients with at least one metabolic comorbidity, a corresponding but reduced improvement was observed in FEV1 (%predicted), between baseline and final visit, and between visits [FEV1%predicted: (V0: Mean±S.D.: 47.99±8.85, V1: Mean±S.D.: 54.17±11.43, V2: Mean±S.D.: 56.02±12.12), and on the MRC dyspnea scale ($P<0.0001$, Kruskal–Wallis test) as well.
Conclusions
Patients with metabolic comorbidities and COPD, although they had initially slightly worse pulmonary function and MRC dyspnea score, showed a statistically significant improvement but decreased in relation to COPD patients without comorbidities, after twelve months of fluticasone–salmeterol FDC treatment.

Pericarditis complicated with cardiac tamponade and Addison disease – A case report

Mariana Lavrador, Luís Cardoso, Diana Catarino, Lúcia Fadiga, Diana Silva, Joana Guiomar, Inês Vieira, Bárbara Araújo, Cátia Araújo, Luísa Barros & Isabel Paiva
Endocrinology Department, Coimbra Hospital and University Centre, Coimbra, Portugal

Introduction
Addison Disease is a rare condition with an estimated incidence in the developed world of 0.8 cases per 100 000 population. It is associated with relevant morbidity and mortality rates, but once the diagnosis is made it can be easily managed. When Addison Disease is associated with other autoimmune diseases, the diagnosis of polyglandular autoimmune syndrome can be set. The recognition of symptoms and signs can be challenging and clinicians should be aware of atypical presentations, since they can be fatal if not correctly identified.
Case report
A 24-year-old man was admitted to a coronary intensive care unit due to acute pericarditis complicated with tamponade and shock requiring aminergic support. After introduction of methylprednisolone 125 mg twice daily, the condition improved. The patient had history of septic shock 2 months before and episcleritis with 2 years of evolution. One month later, when the patient was on 8 mg of methylprednisolone, a new episode of pericarditis occurred, requiring a pericardial window. An exhaustive study regarding autoimmunity and serologic causes were performed, but no etiology was identified. The patient was discharged under methylprednisolone 32 mg in slow and gradual discontinuation scheme. After four months, when the patient was on methylprednisolone 8 mg, new episode of pericarditis, establishing the diagnosis of recurrent pericarditis. Because the patient had hyponatraemia (126 mmol/l) and hyperkalaemia (6.4 mmol/l), an endocrinological assessment was required. Due to suspected adrenal insufficiency, an analytical and hormonal study was requested, showing the following results: ACTH 172 pg/ml (9–52); cortisol<1 µg/dl (5–25); renin 5306 µU/ml (7–76) and anti-21 hydroxylase antibody 25.1 U/ml (<1). These findings established the diagnosis of autoimmune primary adrenal insufficiency. Moreover, additional autoimmunity assessments requested showed the following results: anti-transglutaminase IgA, anti-TPO, anti-thyroglobulin and anti-intrinsic factor antibodies negative; anti-parietal cell antibody strong positive. The study was compatible with polyglandular autoimmune syndrome. The patient started therapy with prednisolone and fludrocortisone, with clinical improvement without further pericarditis' episodes.
Conclusion
Pericarditis with tamponade was the first manifestation of Addison Disease in this patient. This association corresponds to a rare case, with few cases described in the literature. The early identification of this condition can be life-saving. This patient, after 2 years of follow-up under treatment directed to Addison Disease, did not relapse pericarditis and shock. The presence of unexplained hyponatremia and hyperkalaemia should raise the suspicious of Addison Disease, even in the existence of atypical presentations.

Introduction
Primary aldosteronism (PA) is an important cause of secondary hypertension, associated with increased cardiovascular morbidity and mortality rate compared to patients with essential hypertension.
Case report
We report the case of a 59-year-old Caucasian male with a medical history of dilatative cardiomiopathy, paroxysmal atrial fibrillation and bifascicular block who was admitted to the E.R. with shortness of breath, headache, palpitations, blood pressure at 162/117 mmHg and concomitant hypokalemia (2.5 mmol/l). The patient had no clinical signs of cortisol excess. Laboratory tests showed the following: elevated plasma aldosterone at 41.2 ng/dl, supressed renin activity (<0.10 ng AI/ml/h), elevated aldosterone/renine ratio at 420, urinary metanephrines at 141 µg/24 h, 8 h cortisol at 18.5 µg/dl and no supression of cortisol levels by low-dose dexamethasone in addition to low-normal ACTH levels (11 pg/ml). The abdominal MRI scan showed nodules in both adrenal glands (in the right medial of 23/18 mm, right lateral of 12/9 mm, left central of 13/14 mm and left lateral of 7/9 mm). Adrenal venous sampling further evidenced aldosterone secretion from the right adrenal gland (aldosterone/cortisol ratio – right/left was 3.89, 3.65 and 8.17:1). Unilateral right adrenalectomy was performed and the histopatological examination concluded the presence of right adrenal adenomas. The clinical outcome was favorable, with regression of blood pressure values and development of short-term secondary hyperkalemia.
Conclusion
Distinction between unilateral and bilateral secreting adenoma is an important stage and in such cases adrenal venous sampling is essential in diagnosis and establishing case management. In rare instances, cosecretion of aldosterone and cortisol has been reported.

GAD antibody associated stiff man syndrome in a young boy with primary adrenal insufficiency

Anusha Nadig, Alok Sachan & Suresh Vaikkakara
Endocrinology, SVIMS, Tirupati, India

Background
Stiff Person Syndrome (SPS) is an extremely rare neurological disorder, with an expected prevalence of less than 1 per million. The first described case of SPS in the literature was reported in 1959 by Moersch and Woltman. SPS is featured by progressive muscle stiffness, rigidity, and spasm involving the axial muscles, which may result in severely impaired ambulation. SPS seems to have an autoimmune basis although its exact pathogenic mechanism is still cloudy. Most SPS cases are associated with antibodies against glutamic acid decarboxylase (GAD).
Case report
We report a case of 15 years old boy presented with history of stiffness of upper and lower limbs associated with stiffness of neck with restriction of movements. Initially suspected to have spinal cord involvement or tetany. He had presented to endocrine department 9 years back with easy fatigability, weight loss, giddiness and generalised darkening of skin. He is born out of consanguineous marriage and 1st in birth order among 4 children. He was diagnosed to have primary adrenal insuffiency and was started on replacement. On evaluation, MRI brain and spine were normal. Other blood investigations were normal. GAD antibodies in serum was strongly positive.

Patient was diagnosed to have stiff man syndrome based on clinical and autoimmunity panel which showed anti GAD antibodies strongly positive and ENMG. Patient was treated with IV immunoglobulins and steroids. Recently he was diagnosed to have type 1 diabetes and started on insulin.
Conclusion
In conclusion, this case highlights that an acute gait disturbance syndrome and stiffness in children with primary adrenal insufficiency should raise clinical suspicion of autoimmune diseases and stiff-person syndrome.

EP46

Metastatic melanoma of unknown primary lesion presenting as bilateral adrenal incidentalomas

Miruna Anisia[1], Teodora Teusan[1], Mihaela Ciobotar[1], Cristina Preda[1], Maria Christina Ungureanu[1,2], Mihai Danciu[2], Cristian Lupascu[2,3] & Letitia Leustean[1,2]
[1]Saint Spiridon County Hospital, Endocrinology, Iaşi, Romania; [2]Universitatea de Medicină şi Farmacie "Grigore T. Popa", Iaşi, Romania; [3]Saint Spiridon County Hospital, Surgery, Iaşi, Romania

Introduction
Bilateral adrenal incidentalomas represent a challenge both in diagnosis and therapeutic approaches. While initial testing is similar to unilateral adrenal incidentalomas, additional investigations should be made considering the differences between the distribution of etiologies.
Case report
We report the case of a 67 years old hypertensive female, presenting with backpain; an initial abdominal ultrasound described left adrenal mass and a large right adrenal/hepatic mass. The thoraco-abdominal CT scan revealed a well circumscribed right sided adrenal mass (105/95/110 mm AP/T/CC), hypodense compared with the liver parenchima, heterogenous and of low density on pre-contrast imaging, with progressive enhancement after contrast administration and mass effect on the adjacent kidney and right hepatic lobe; also, a similar lesion on the left adrenal gland of 61/45/60 mm and a right inguinal lymph node (27 mm). Hormonal assessments showed no secretion; congenital adrenal hyperplasia and adrenal insufficiency (giving the distruction of the cortex of both glands) were also ruled out. There was a rapid increase in inguinal lymph node size, so an excisional biopsy was made; the morphologic and immunohistochemical characteristics revealed lymph node metastasis of malignant melanoma (S100 intense positive in nucleus and cytoplasm, HMB45 intense positive in cytoplasm of tumoral cells). The patient was directed to Oncology Department and lost to follow-up.
Discussion
Adrenal metastasis are the most common malignant lesions involving the adrenal gland. On the other hand, bilateral adrenal masses due to melanoma metastasis are rare, usually nonsecretory, associated with short-term survival, being uncommon for metastatic cancer to appear in the adrenal gland before the primary lesion is known.

Normotensive primary aldosteronism in a young woman taking minipill – case report

Agnieszka Łebek-Szatańska, Karolina Nowak, Wojciech Zgliczynski & Lucyna Papierska
Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland

Background
Primary aldosteronism (PA) is the most frequent cause of hormonal hypertension, typically associated with hypokalaemia. Whereas hypertension with no hypokalaemia can be present in even half of cases, hypokaleamia in normotensive patients is a very rare finding. Mechanisms that act against developing hypertension despite aldosterone excess are at least a few. Some patients with previous low blood pressure increase its values because of hyperaldosteronism, thus still maintaining them in the upper part of the normal range. When screening patients with normotension, other than antihypertensive drugs can interfere with renin–angiotensin–aldosterone system and thus alter biochemical results, with oral anticontraceptives amongst them.
Case description
34-year-old female, more than a year postpartum, was referred to Endocrinology Department because of refractory hypokalaemia of unknown origin. Kalium concentrations as low as 2.8 mmol/l were observed. Her blood pressure was within the normal range. Because of her gastric disturbances, she had her abdomen CT already performed and left adrenal incidentaloma of 15×20 mm in diameter and density of (–)20 Hounsfield Units was found. She was taking oral contraceptive minipill – desogestrel. Serum aldosterone and direct renin measurements were 11.5 ng/dl and 2.86 μIU/ml [AARR = 4.02 (cut-off level <3.7)], pointing to the possibility of primary aldosteronism. After 6 weeks of withdrawal of desogestrel, repeated screening and saline infusion test results were consistent with PA diagnosis. To assess lateralization of aldosterone production the patient underwent norcholesterol scintigraphy, because of poor availability of adrenal venous sampling and our good experience. Although the image was non-specific, the patient underwent left adrenalectomy without additional testing. Serum aldosterone, direct renin levels and kalaemia returned to normal.
Conclusions
Even in the absence of hypertension, isolated hypokalaemia itself should prompt screening for autonomous aldosterone secretion. In women of reproductive age, progestin-containing drugs can alter other hormone levels and that should be taken into account if biochemical testing is performed.

Clinical case of Takotsubo syndrome after adrenalectomy

Mariya Rusalenko[1], Alex Korotaev[2] & Elena Naumenko[3]
[1]Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus; [2]Cardiology, Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus; [3]Ultrasonography, Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus

Introduction
Described in 1990 by N Sato *et al*., Takotsubo syndrome (TS) is an acute myocardial dysfunction with the development of heart failure.
Objective
We present a description of the clinical case of ST after adrenalectomy for pheochromocytoma.
Results
Pheochromocytoma of the left adrenal gland (methanephrine 553.7 pg/ml (norm <65) and plasma normmetanephrine 458 pg/ml (norm <196) was verified in 27-year-old patient L. with hypertensive crisis. In connection with severe hypotension associated with doxazosin, 6% hydroxyethyl starch was infused. At endoscopic adrenalectomy, a transient increase in blood pressure and heart rate was observed, after compression of the left adrenal vein – severe vasoplegia, signs of acute left ventricular failure with the development of alveolar pulmonary edema. The ventilation parameters were adjusted, the left adrenal gland was removed along with the tumor. On artificial pulmanory ventilation with 100% oxygen, infusion of norepinephrine and mesatone: BP 115/75 mmHg, heart rate 138/min, central venous pressure +23 cm water column, saturation 90%, leukocytosis 18.4×10^9/l, glycemia 13.4 mol/ , CK-MB 37 U/l, hsTnl 0.671 ng/ml (<0.016). ECG: subepicardial ischemia in the anteroseptal apical segment; LV echocardiography 36×57 mm, systolic gradient at the exit of the left ventricle 2.7 mmHg, ejection fraction of 30%, akinesis of the middle segments of the septum, anterior septum, anterior, lateral, posterior, lower walls of the LV, apical segments of the septum, anterior, lateral, lower walls of the LV; X-ray signs of cardiogenic edema of the right lung. The patient was diagnosed with: Takotsubo syndrome. Acute left ventricular failure, alveolar pulmonary edema. Cardiogenic shock. Acute renal injury. Treatment: Artificial pulmanory ventilation, norepinephrine and mesatone, clexane, iso-mik before stopping the clinical signs of pulmonary edema; in-blocker. After recovering consciousness, the patient was extubated, neurological deficit was absent, the therapy for acute renal injury was administrated. Subepicardial anterior widespread changes in the type of ischemia, deepening of the T wave in leads V2–V6, inversion of the T wave in III, aVF were observed on the ECG. The global systolic function of the LV was recovered, hypokinesis subsequently persisted in the apical segment. Against the background of anticoagulant therapy, in-blockers and ing-ACE, shortness of breath decreased and exercise tolerance was recovered.
Conclusion
When conducting an adrenalectomy, it is necessary to consider the possibility of developing stress-induced myocardial dysfunction.

Ectopic ACTH syndrome presenting as pneumocystis pneumonia

Carmel Kennedy, Leanne Cussen, Michael O'Reilly & Christine Newman Newman
Beaumont Hospital, Dublin, Ireland

Ectopic adrenocorticotropic hormone (ACTH) syndrome occurs in about 5–10% of all patients with ACTH-dependent hypercortisolism. We present the case of a 35 year old gentleman who presented with a six month history of progressive 16 kg weight gain and breathlessness. Pulmonary imaging revealed bilateral infiltrates suspicious for Pneumocystis pneumonia (PCP). Physical examination was concerning for Cushing's syndrome, with facial plethora, easy bruisability and broad violaceous striae on his abdomen and thighs. Initial laboratory testing showed a profound hypokalemia (serum potassium 2.3 mmol/l (3.5–4.5 mmol/l). Endogenous hypercortisolaemia was confirmed with an overnight dexamethasone supression (ONDS) cortisol of 656 nmol/l. 24 h Urine Free Cortisol (UFC) was raised at 853 nmol/24 h. ACTH was elevated at 167 (72–63.3 pg/ml). The remainder of his pituitary profile was unremarkable with the exception of a testosterone of 3.0 (8.6–29 nmol/l). Ectopic ACTH was confirmed with Corticotroph Releasing Factor (CRF) testing failing to show a satisfactory rise in ACTH (147–175 pg/ml; 19%). Bilateral inferior petrosal sinus sampling (BIPSS) did not show a peripheral ACTH gradient and magnetic resonance imaging (MRI) pituitary was negative for an adenoma. Computed tomography of the thorax, abdomen and pelvis (CT-TAP) and Octreotide scintigraphy did not identify a culprit lesion. Calcitonin and urinary 5-Hydroxyindoleacetic acid (5-HIAA) levels were normal. His cortisol levels responded to Metyrapone with addition of Hydrocortisone to prevent adrenal insufficiency. His PCP was successfully treated with a course of co-trimoxazole. The clinical course was complicated by an admission with decompensation of congestive cardiac failure secondary to Cushing's cardiomyopathy. He is currently awaiting a 68Ga-DOTA-TATE PET/CT in the hope of localizing the ectopic ACTH-secreting tumour. This case highlights the profoundly immunocompromised state of severe Cushing's syndrome and the diagnostic challenge in localizing the offending lesion in ectopic ACTH.

Adrenal hemangioma: Unusual case of adrenal incidentaloma

Wafa Benothman, Imen Halloul, Ghada Saad, Asma Benabdelkrim, Yosra Hasni, Molka Chaieb, Maha Kacem, Amel Maaroufi & Koussay Ach
Endocrinology, Farhat Hached Hospital, Sousse, Tunisia

Introduction
Adrenal hemangioma (AH) is a benign vascular tumor of the adrenal gland. The adrenal site of an hemangioma is extremely rare occurring only in 0.01% of cases and accounts for 63 reported cases in the literature. AH are often discovered as incidentalomas either by imaging studies or histologic examination. The role of computed tomography (CT) scan and Magnetic resonance imaging (MRI) is important for the differential diagnosis.
Case report
We report a case of a 56-year-old female patient who was referred to the department of endocrinology for exploration of an adrenal incidentaloma. The mass was detected at a CT scan performed to explore chronic back pain. The patient was treated for hypertension for 10 years. Clinically, she was suffering from headache, heart palpitations, sweating. Her blood pressure was high even though she was taking 2 antihypertensive drugs. She did not present any specific skin lesion. Multiple biological exams were performed: 24-h urinary catecholamine, 4 mg dexamethasone test, aldosteronin/renin ratio. The results were all negative. Since the tumor's radiological characteristic were leading to a malignant lesion, surgical treatment was decided and a right adrenalectomy was performed. The histological results concluded to an adrenal hemangioma. During follow-up, one year after the surgery, the patient continued to have a vague abdominal pain after, for which a CT scan was performed, showing a new mass in the left adrenal gland. The hormonal work-up was normal and the tumor was benign in the last CT scan. As for her family history, her sister was admitted for exploration of bilateral adrenal incidentaloma who turned out to be a benign non secretory adenoma.
Conclusion
The adrenal hemangioma is a rare adrenal gland lesion, benign and usually asymptomatic. Imagery is the best tool to characterize these silent adrenal masses. The main risks of the hemangioma are ignorance of malignancy, abdominal mass syndrome and bleeding. In this situation comes the role of Positron Emission Tomography with 18F-FDG to distinguish the malignant tumors and therefore reassure the proper treatment.

ACTH-independent subclinical Cushing's syndrome secondary to primary bilateral macronodular adrenal hyperplasia

Maria Lavinia Popa[1] & Găloiu Simona Andreea[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and neuroendocrine pathology, București, Romania; [2]Carol Davila University of Medicine and Pharmacy, București, Romania

Introduction
Primary bilateral macronodular adrenal hyperplasia (PBMAH) is an uncommon cause (<1%) of endogenous Cushing's syndrome (CS). Recently, due to increased number of incidental imaging findings of PBMAH, the clinical expression of the disease has changed in favor of oligosymptomatic or subclinical cases, compared to those with clinically manifest CS, or rarely with secretion of mineralocorticoids, or sex steroids.
Case report
A 51-year-old overweight woman was referred to our Institute for assessment of incidentally diagnosed bilateral macronodular adrenal hyperplasia. She had a history of dyslipidemia, and paroxysmal hypertension. Physical examination revealed no typical signs or symptoms of hormonal hypersecretion, except for a slightly elevated blood pressure (140/90 mmHg). Blood test results revealed normal plasma metanephrines, normmetanephrines, and normal renin aldosterone ratio. Subnormal suppression of serum cortisol following 1-mg overnight dexamethasone suppression test (2.34 µg/dl), 2×2 mg overnight dexamethasone supression test (1.92 µg/dl) and a suppressed ACTH (2.52 pg/ml) were suggestive of ACTH independent subclinical CS. Given that in PBMAH, adrenals may have aberrant receptors that stimulate excess cortisol secretion, we followed a screening protocol, which had positive (> 50% increase of serum cortisol) results for postural, mixed meal tests, and partially positive (> 25% increase of serum cortisol) for diphereline test. In our case, taking into account the patient's preference, as well as the mild clinical expression of the disease, we recommended active surveilling with yearly imaging and hormonal monitoring.
Conclusion
Considering the increased heterogeneity of PBMAH, due to modern imaging techniques that led to early detection, a clear diagnostic criteria is required in order to better characterize this entity and develop a tailored treatment plan.

VHL-bilateral adrenalectomy with paragangliomas (A rare entity)

Sing Yang Sim & Ma'en Al-Mrayat
University Hospital Southampton, Endocrinology, Southampton, United Kingdom

Von Hippel–Lindau (VHL) disease, attributable to germline mutations in the VHL gene on the short arm of chromosome 3 (3p25-26) is an inherited condition which can give rise to paragangliomas. We present a case of 47 year old gentleman with bilateral pheochromocytomas in the past resulting in both adrenalectomies as a child in the 1980. His routine follow up subsequently picked up elevated urine Normetanephrines at 14.3 µmol/24 h 25 years postoperatively. His CT abdomen and pelvis revealed a 4.2 cm×2.8 cm mass between the IVC and right crus which was resected. His histology is reported as well-defined nests (Zellballen) bound by delicate fibrovascular stroma consistent with extra-adrenal paraganglioma. His urine metanephrines normalised post resection. He also had cryoablation to a left renal tumour in July 2008. In addition to a neuroendocrine tumour removed from the head of his pancreas in February 2009 through a Whipple's procedure which has left him diabetic. His most recent 24-h urinary metanephrines and fasting gut profile is normal. He is on hydrocortisone and fludrocortisone replacement which maintains his blood pressure around 120/80. He continues to be under annual follow up in our Joint Von Hippel–Lindau Clinic, endocrine clinic and genetics clinic aimed at early detection of any complications of his von Hippel–Lindau disease.
Conclusion
Paragangliomas are neuroendocrine tumours subdivided into parasympathetic and sympathetic paragangliomas with the formal localized to the head

and neck and the latter found in the thoracic, abdominal, or pelvic region. Clinicians treating VHL patients or having them under surveillance should be conscious about the existence of paragangliomas post adrenalectomy and be on the lookout for it post adrenalectomy.

Delayed diagnosis of Cushing's syndrome

Rada Sparavalo[1] & Sanja Borozan[2]
[1]General hospital Niksic, Department of Endocrinology, Niksic, Montenegro; [2]Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro

Because of quite variable clinical manifestations of Cushing's syndrome and overlap with more common medical problems, its diagnosis is frequently mistaken, with consequent considerable delay from the first presentation to a different primary and secondary care physicians to a final diagnosis, often made by endocrinologist. The diagnostic latency in reported studies vary from six months to ten years. We report a case of a 54-years-old female admitted to the hospital through the emergency department because of prominent stiffness and persistent, sharp pain in lumbal spine and bilateral hip region, extreme fatigue, muscle weakness, easy bruising and poorly controlled hypertension. Also, she noticed weight gain and hirsutism. Because of mentioned disturbances present over the last three years, she had seen multiple specialists including cardiologist, neurologist and physiatrist but no further diagnostic procedures were recommended. Family history was strongly positive for cancer. On examination, she was plethoric, overweight (BMI 27.3 kg/m^2) with bruises in right gluteal region and both upper and lower extremities, proximal myopathy and blood pressure of 150/95 mmHg. Laboratory findings revealed sideropenic anemia (hemoglobin 82.8 g/l), blood glucose 5.77 mmol/l, hemoglobin A1c 5.39 %, normal electrolyte status and parameters of liver and kidney function. Hormonal examination showed ACTH of 1.3 pmol/l, morning cortisol 436.6 nmol/l with loss of diurnal variation, urinary free cortisol 303.6 nmol/l (12–486 nmol/l). Catecholamines, thyroid hormones, androgens, calcitonin and PTH were all in reference range; gonadotropins within menopausal levels. No significant supression of serum cortisol was achived after low-dose and high-dose dexamethasone supression tests (cortisol 582.9 nmol/l and 501.8 nmol/l respectively). A contrast-enhanced computed tomography and magnetic resonance imaging (MRI) of the abdomen demonstrated a 30 mm well-defined solid mass in the region of right adrenal gland. The diagnosis of Cushing syndrome was established and the patient underwent laparoscopic right adrenalectomy with patohistological finding of adrenal cortical adenoma. Based on postoperative hypocorticism and maintenance of subnormal cortisol levels, a substitution with Hydrocortison is initiated and continued in full replacement dose. Since the prevalence of Cushing's syndrome is increasing, raised clinical awareness among primary and secondary care physicians could lead to early referral of selected patients and timelier diagnosis with reduced rate of complications.

Cortisol and androgens secreting left adrenal carcinoma

Emma Margarit[1], Găloiu Simona Andreea[1,2], Anda Dumitrascu[3], Andra Caragheorgheopol[4], Mircea Beuran[5,6] & Catalina Poiana[1,2]
[1]Pituitary and Neuroendocrine Disorders, C.I.Parhon National Institute of Endocrinology, Romania; [2]Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Radiology, C.I.Parhon National Institute of Endocrinology, Romania; [4]Research Laboratory, C.I.Parhon National Institute of Endocrinology, Romania; [5]General Surgery, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [6]General Surgery, Floreasca Emergency Clinical Hospital, Romania

Introduction

Adrenal carcinomas are rare tumor. It has an estimated incidence of ~0.5–2 new cases per million people per year. Just 25% of adults with hormone-secreting adrenal carcinomas present overproduction of both glucocorticoids and androgens. Women develop adrenal carcinomas more often than men.

Objectives

We report a case of 47-year-old female presented with weight gain, generalized weakness and hypertension for the last 6 months. Physical examination revealed central obesity, "moon facies" with facial plethora, facial hirsutism, and acne in the back of the chest, "bison neck", muscle weakness, hypertension and emotional lability.

Methods

The paraclinical examination showed: hypercholesterolemia, glucose intolerance, ACTH = 3.9 pg/ml (n = 5–65), 2300 h serumcortisol = 13.83 μg/dl, 0800 h serumcortisol = 25.2 μg/dl, urinaryfreecortisol (UFC) = 209.69 μg/24 h (n = 21–111), after 1 mg dexamethasoneovernight-supression – 0800 h serumcortisol = 16.63 μg/dl, testosterone = 1.14 ng/ml (n<0.75), DHEAS, plasma metanephrines and normetanephrines, aldosterone, renin are normal. Computed tomography examination showed left adrenal mass (11.5/7.7 cm) with blooming contour and hepatomegaly with subcapsular nodule on the right side.

Results

The left adrenal tumor was surgically excised by laparoscopic approach. Postoperatively the patient received hydrocortisone hemisuccinate substitution treatment with a favorable progression. Histopathological examination: adrenal carcinoma fully resected. Score Weiss = 6 points (high nuclear grade, mitotic rate 18/50 HPF, atypical mitosis, necrosis, sinusoidal invasion, capsular invasion). ENSAT stage II (T2N0M0). Postoperatively patient had secondary adrenal failure and received glucocorticoid substitution therapy; she loosed 9 kg, blood pressure and glucose levels returned to normal with no need for antihypertensive medication. She received local radiotherapy complicated with hepatic cytolysis and cholestasis (AST, ALT, GGT). 1 year postoperatively, computed tomography showed space replacing liver formation and normal right adrenal gland. She will start adrenolytic therapy with mitotane.

Conclusions

In adrenal carcinoma the prognosis was poor, but the use of adjuvant mitotane therapy increased over the 20-year time period, this improves recurrence-free and overall survival.

EP55

Case of mineralocorticoid and androgen producing adenocortical carcinoma (ACC) and thyroid papillary microcarcinoma (MPTC)

Natia Vashakmadze[1,2]
[1]Endocrinology, Georgian Association of Endocrinology and Metabolism (GAEM), Tbilisi, Georgia; [2]Department of Endocrinology, Israel-Georgian Medical Research Clinic "Helsicore", Tbilisi, Georgia

A 54-year-old female presented with muscle cramps and arterial hypertension. She was taking spironolactone 25 mg for hypertension. Her K+ level at first visit was 2.5 mmol/l. She was recommended to stop spironolactone, start potassium suplements, and measure Aldosterone, Renin, and K+ levels after 4 weeks. The Patient is a medical doctor. By her own decision CT of the abdomen was performed that showed 6.5 cm mass in left adrenal gland. The density was +28 HU. Some hypo-perfusion lesions were described in the liver. Full hormonal evaluation of the adrenal glands was performed. Metanephrines and cortisol were normal. Aldosterone – 25 ng/l (11.7–2236), Renin <1 ng/l (1.7–23.9), Aldosterone : Renin ration >25 (<20); It seemed tumor was secreting precursors of the aldosterone (deoxycorticosterone, corticosterone) and not the aldosterone itself. Testosterone – 0.66 (<0.41); Androstenedione – 5.6 (<0.82) 17(OH), Progesterone – 3.6 (<0.53); DHEA-Sulfate – 2.27 (0.5–5.5); At the same time patient was diagnosed with thyroid papillary microcarcinoma. She was advised to perform open surgery for adrenal mass and then thyroidectomy. However, she decided to undergo a simultaneous laparoscopic adrenalectomy and thyroidectomy with central prophylactic lymph node dissection. After surgery her potassium, adrenal androgens, renin, and aldosterone/renin ratio normalized. Postoperative MRI of the abdomen was unremarkable. On histologic examination, adrenal mass was 9×8×5 cm in size; Weiss score – 6; Ki67 – heterogeneous, up to 13% in hot spots. The thyroid nodule 0.5×0.4 cm – papillary carcinoma, follicular variant, sclerosing, infiltrative growth, with minimal ETE and focal lympho-vascular invasion. A total body 18F-FDG PET performed on 10/12/2019 was negative for pathologic uptakes. The stage of the ACC was defined as stage II, pT2pN0M0 low-to-intermediate risk of recur-

rence. The stage of PTC was defined as stage I, pT1apN0 M0, intermediate risk of recurrence, initial target TSH 0.1–0.5 IU/ml. Adjuvant therapy with mitotane and no RAI was recommended. Glucocorticoid replacement therapy (hydrocortisone 25 mg) was commenced simultaneously with mitotane treatment. The initial dose of mitotane was 500 mg uptitrated to 3000 mg. Mitotanemia measurement was recommended after 6–8 weeks from the initiation. Levothyroxine supressive therapy with 125 μg was prescribed. After 3 months TSH was fylly suppressed – 0.089, Tg – 0.5 (<0.2), anti-Tg <10 IU/ml. Neck US revealed a 5 mm round hypoechoic lymph node. Patient was recommended to adjust the dose of Levothyroxine to 112.5 μg and control of TSH, Tg, and Neck US in 2–3 months.

Particular course of autoimmune polyglandular syndrome

Sitorakhon Muminova[1], Khurshida Kamalova[1] & Shakhnoza Azimova[2]
[1]Endocrinology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Endocrinology, Centre Endocrinology, Tashkent, Uzbekistan

Introduction
Autoimmune polyglandular syndromes (APS) are affected by a primary lesion of 2 or more peripheral endocrine glands with the development of their insufficiency. Examination of people suffering from a disease, which may be part of combined autoimmune endocrinopathies.
The aim
To study the features of the course APS.
Materials and methods
Patient M., 11 years old with complaints of increased blood glucose, general weakness, thirst, dry mouth, dry skin, pain in the upper abdomen. Nausea, disturbed stool. Headache and dizziness. From the anamnesis: sick with type 1 diabetes for 5 years. Receives insulin therapy: NPX – 9+7 IU. Short acting – 3+3+31U. Laboratory and instrumental methods: GBA, GUA, A1C, ALT, AST, TTH, T4, cortisol, hepatitis B, C and Triglycerides.
Results
During laboratory and instrumental examinations were detected, subclinical hypothyroid and transaminase elevation. The results of laboratory studies: Hb Al c – 11.8, AST – 105 U/l, ALT 84 U/l, T4 free – 1.06 ng/dl, TTH – 7.12 mIU/l. Urinary cortisol 26.1 nmol/l, 26.8 nmol/l in blood.
Conclusion
Based on the data of anamnesis, physical examination, laboratory and instrumental studies, the following diagnosis – autoimmune polyglandular syndrome. In addition to insulin therapy, a cortef has been added to the treatment for chronic adrenal insufficiency, hepatoprotectors to eliminate the symptoms of autoimmune hepatitis.

Primary adrenal lymphoma

Fatih Kılıçlı[1], Hatice Sebile Dökmetaş[1], Göksu Biçer[2] & Meriç Dökmetaş[2]
[1]Endocrinology and Metabolism, İstanbul Medipol University, İstanbul, Turkey; [2]Internal Medicine, İstanbul Medipol University, İstanbul, Turkey

Primary adrenal lymphoma(PAL) is very rare and constitutes <1% of cases of extranodal lymphomas. Most common subtype of PAL is diffuse large B cell lymphoma. A 46-year-old male patient without any underlying disease was admitted to our hospital with a complaint of bilateral back pain, cough and fever. His laboratory tests revealed a hemoglobin: 5 g/dl (14–17.5), white blood cell: 3.8 10^3/μl (4.4–11.3), platelet: 111 10^3/μl (130–403). No pathological findings were detected in bone marrow biopsy. Abdominal MRI and chest CT revealed that bilateral adrenal mass without any lymphadenopathy. PET/CT showed a mass of 73×53 mm on the left adrenal gland and a mass of 145×90 mm on the right adrenal gland. Adrenal function was evaluated as non-functional adrenal mass. Surgical right adrenalectomy was performed. Postoperative basal cortisol level: 12.25 μg/dl (6.02–18.4), adrenal insufficiency is not detected. Histopathological examinationreported as diffuse large B cell lymphoma. R-CHOP chemotherapy was planned by consulting hematology. The 5-year cancer spesific survival rate for primary adrenal lymphoma is 38% and it should be considered as the differential diagnosis of the adrenal mass, especially when they are bilateral and grow rapidly.

Challenges in pheochromocytoma diagnosis

Luciana Pedral SD Leite
Medicine, UFS – University Federal of Sergipe, Aracaju, Brazil

Background
The clinical diagnosis of pheochromocytoma requires improved clinical reasoning due to the scarcity of symptoms and complementary tests that are not always confirmatory.
Clinical case
A 58-year-old female patient sought an endocrinology service at the University Hospital for investigation of Adrenal tumor on the right, measuring 3.8×4.5×3.8 cm, discovered during routine ultrasound. He reported vague symptoms of abdominal discomfort and had been using irregular metropolol for more than ten years, due to mild hypertension and rare palpitations. Serial laboratory studies were carried out for Adrenal Incidentaloma which showed a only slight increase in Urinary Normetanephrines (1.2 ULN). No other evidence of hormonal excess was detected. During the entire clinical investigation, with suspension of antihypertensive medication for hormonal evaluation, the patient remained asymptomatic. Clinically, there was no evidence of pheochromocytoma. He was followed up on an outpatient basis for two years with urine metanephrine levels and image monitoring. The case was discussed in a clinical session with a radiology service and the characteristics suggested as the most likely hypothesis Adrenal Hemangioma, the tumor was lobulated, defined limits, hypodense and with peripheral calcifications, with heterogeneous contrast enhancement initiated in the arterial phase, and with a tendency to homogenization in the portal and late phases. Absolute wash out 37 and relative wash out 33. After two years of follow-up, she presented paroxysmal atrial fibrillation, and amiodarone was started. Service without availability of plasma metanephrines. PET-CT-FDG was performed detecting an Adrenal nodular lesion on the right, measuring 4×3.9 cm, indicating neuroendocrine tumor and whole body scintigraphy with MIBG-SPECT CT with nodular uptake in the right adrenal. The patient underwent a right adrenalectomy after preparation with alpha adrenergic block. She underwent major bleeding in the liver bed and hypovolemic shock. After surgery, the patient remained hemodynamically stable. Immunohistochemistry study confirmed the diagnosis of pheochromocytoma.
Conclusion
The diagnosis of pheochromocytoma requires clinical skill and the use of several diagnostic resources that, combined, help to clarify the clinical situation.

Extremely rare and slow-progressive parathyroid carcinoma: Case report

Raimonda Klimaite[1,2], Simona Duzinaite[2], Virgilijus Krasauskas[2,3], Raimondas Valickas[4] & Birute Zilaitiene[1,2,5]
[1]Department of Endocrinology, Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Surgery, Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania; [4]Department of Radiology, Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania; [5]Institute of Endocrinology of Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Parathyroid carcinoma (PC) is an extremely rare, aggressive and life-threatening form of primary hyperparathyroidism (pHPT). PC accounts for less than 1% of cases of pHPT, predominantly diagnosed in the fifth or sixth decades of life. Most parathyroid carcinomas are diagnosed after surgery.
Case description
A 51-year old man was admitted to the Hospital of Lithuanian University of Health Sciences, Kaunas clinics due to leg pain and general weakness. It is known from the medical history that kidney stones were observed in 2008. Ten years later hypercalcemia and chronic kidney disease (GFR – 12.6 ml/min per 1.73 m^2 (90–120)) was confirmed.

Laboratory tests
Hypercalcemia (Ca – 2.91 mmol/l (normal range 2.15–2.50), normophosphataemia (*P* – 1.25 mmol/l (0.81–1.45), ↑ uremic measurements (creatinine – 423 μmol/l (62-106), urea – 18.30 mmol/l (1.8–8.3), anaemia (Hb – 114 g/l (130–160), significantly ↑ PTH – 260.6 pmol/l (1.26–6.74), thyroid function was normal. Ultrasound investigation of the thyroid revealed normal echogenicity, homogeneous thyroid parenchyma and heterogeneous hypoechoic focal area with micro and macrocalcifications under the right lobe. US of abdominal cavity revealed the signs of nephrocalcinosis. Spine and pelvic X-ray revealed an old compression fracture of the Th-9 vertebral body and old fracture of the right iliac wing. DXA– osteoporosis: T-score –3.0 in the spine. The diagnosis of the parathyroid adenoma was denied after performing the parathyroid scintigraphy. Conservative treatment of hypercalcemia was performed with infusion therapy. The right inferior parathyroidectomy and right thyroid lobectomy was performed. The size of the parathyroid tumour was 4.5×4×3.5 cm, the weight of the specimen- 31 g. Histologically: carcinoma of the parathyroid gland pT1 LVi1. Tumour cell mitosis was monitored (5 mitosis/10 DPRL). Ki67 proliferation index was positive up to 5% of the cells. The MEN syndrome was denied, no mutation found. No metastasis of the tumour was observed. Persistent hypocalcaemia and hungry bone syndrome lasted for about a month after the surgery. Normocalcemia was achieved after the long-term treatment with alfacalcidol and calcium carbonate. The patient came to the endocrinologists for medical check-up after one year. Renal replacement therapy with an increasing need for dialysis was started. No recurrence of parathyroid tumour was observed. Ca–P homeostasis were in normal ranges.
Conclusion
Due to lack of local symptoms and slow progression this disease is often underdiagnosed. In most of the cases the PC diagnosis is confirmed by accidental removal of the parathyroid gland or after the manifestation of multiple chronic hypercalcaemia complications.

GNAS mutation and affection of the endocrine system and bone: An analysis of 3 clinical cases

Inês Vieira[1], Diana Catarino[1], Lúcia Fadiga[1], Diana Silva[1], Joana Guiomar[1], Mariana Lavrador[1], Sara Pinheiro[2], Margarida Bastos[1], Dírcea Rodrigues[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Endocrinology, Coimbra, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal

Introduction
Activating and inactivating mutations of the GNAS gene (encoding the Gsα protein) cause McCune–Albright Syndrome and Albright's Hereditary Osteodystrophy, respectively. In both, the bone and the endocrine system are often affected. In McCune–Albright Syndrome the most common endocrine manifestation is precocious puberty, but thyroid lesions and hormonal overproduction are also described. In Albright's Hereditary Osteodystrophy there may be obesity, pseudohypoparathyroidism and other hormonal resistance.
Results (cases presentation)
Case 1: 20-year-old female patient, with McCune–Albright Syndrome. Followed in endocrinology appointments with subclinical hyperthyroidism, increased prolactin and GH/IGF-1. Currently 1.51 m, 59.2 kg, body mass index (BMI) 25.9 kg/m^2; prolactin 8.7 ng/ml (5.2–26.5) under bromocriptine; GH 7.3 μg/l (<1) and IGF-1 568 ng/ml (116–358) without therapy, having recently started lanreotide. Past medical history (PMH): Diagnosis at 2 years of age in the context of *café au lait* spots, stature acceleration, early peripheral puberty and bone dysplasia. During follow-up, she presented: elevation of GH/IGF-1 and growth >97 percentil (under sandostatin from age 10–15); hyperprolactinemia/galactorrhea (under bromocriptine from the age of 14); menstrual irregularities under combined oral contraceptive pills from age 11–19.
Case 2: 19 year-old, male patient, carrier of a GNAS mutation with suspected Albright's Hereditary Osteodystrophy. Followed in endocrinology appointments with TSH resistance hypothyroidism, currently with normal thyroid function under levothyroxine; short stature (1.43 m); normal/slightly elevated parathormone with calcium, phosphate and magnesium in the normal reference range; without other hormonal abnormalities.
PMH: primary hypothyroidism since the first year of life; genetic diagnosis performed at age 14 in the context of short stature, round face, brachydactyly and delayed psychomotor development.
Case 3: Female sex, 24 years-old with Albright's Hereditary Osteodystrophy. Followed in endocrinology appointments, currently presenting: overweight (body mass index of 28 kg/m^2), dyslipidemia and pre-diabetes (A1C 5.7%); slight elevation in parathormone 79 pg/ml (9–72) with calcium, phosphate and magnesium within the reference range and slight vitamin D deficiency; goiter with normal thyroid function; magnetic resonance with pineal cyst. Current medication: vitamin complex.
PMH: Genetic diagnosis of AHO at 12 years of age due to global developmental retardation, obesity and shortening of the 4th and 5th metatarsals and 4th metacarpals; self-injurious behaviours.
Discussion
Mutations with opposite effect on the same gene give rise to McCune–Albright Syndrome and Albright's Hereditary Osteodystrophy. Both affect the endocrine and skeletal systems differently. Due to the rarity and diversity of manifestations, they require multidisciplinary monitoring throughout life.

EP61

A case of primary hyperparathyroidism presenting with acute pancreatitis

Bengur Taskiran[1], ertaç berker[1], Dilek Beypinar[2], Mehmet Fatih Ekici[3], Sami Evirgen[4] & Kevser Onbasi[1]
[1]Endocrinology, Kutahya University of Health Sciences, Kutahya, Turkey; [2]Pathology, Eskisehir Osmangazi University, Eskisehir, Turkey; [3]General Surgery, Kutahya University of Health Sciences, Kutahya, Turkey; [4]Gastroenterology, Kutahya University of Health Sciences, Kutahya, Turkey

A 42 year old male patient was admitted to the gastroenterology unit in due to severe abdominal pain and vomiting. He denied any chronic illness and drug usage. His family history was nonsignificant for any endocrine disease. Based on biochemical studies (lipase 2280 U/l, calcium 15.0 mg/dl, phosphorus 1.7 mg/dl amylase 631 U/l, creatinine 1.16 mg/dl, ALP 735 U/l) severe hypercalcemia induced acute pancreatitis was the diagnosis. 25 OH vitamin D was 5 ng/ml and parathyroid hormone level was 2496 pg/ml, Electrolytes, liver function tests, billlirubin, CBC differential, lipid profile, Calcitonin, and TSH level were in the normal range. A left-sided atypical mass (10 mm; 17 HU on non-contrast series, 45 HU on early and 82 HU on delayed contrast enhanced series) and renal stones were detected on abdominal CT. Mild osteopenia was evident on DEXA. Neck ultrasound revealed a heterogenous hypoechoic mass with increased vascularity and measuring 34×20 mm in size in the right parathyroid lodge. Calcium level normalized after zoledronic acid administration. Calcitonin was unavailable. When diagnostic work-up was underway, severe hypercalcemia ensued again. It could not be controlled with hydration and 160 mg/day furosemide, so a second dose of zoledronic acid was administered. Mildly elevated (<x1.5 UNL) urinary catecholamine levels in 7.5 l 24 h urine was at first attributed to polyuria. Polyuria was resulted from nephrogenic diabetes insipidus induced by hypercalcemia, hydration, and forced diuresis. However since an atypical adrenal mass was present and severe hypercalcemia ensued shortly after zoledronic acid therapy, we could not spend any time for repeating catecholamine tests or performing scintigraphy such as DOTATE/MIBG. Such a small lesion (10 mm) might have been invisible on scintigraphy. We diagnosed pheochromocytoma unless proven otherwise and alpha blocker therapy was commenced. The patient underwent parathyroidectomy and unilateral adrenalectomy at the same session without any peri- and post-operative complication. Following parathyroidectomy, calcium and parathyroid hormone reached a nadir of 7.5 mg/dl and 14 pg/ml, respectively (albumin 3.6 g/dl, phosphorus 2.2 mg/dl, magnesium 1.5 mg/dl). The final pathological report whether the adrenal lesion was a pheochromocytoma and the parathyroidal lesion was an atypical parathyroid adenoma or carcinoma are pending. Genetic tests for MEN are planned. Our case was challenging in terms of timing and decision of operation. Relatively young age and absence of any accompanying chronic disease probably helped to tackle potential complications including severe hypercalcemia, acute pancreatitits, and simultaneous extraction of adrenal mass and parathyroid adenoma.

EP62

Resolution of severe primary hyperparathyroidism associated with classical skeletal complications following fine needle aspiration of suspected parathyroid adenoma

Muhammad Umer Malik & Pui Lin Chong
Endocrinology, Raja Isteri Pengiran Anak Saleha Hospital, Bandar Seri Begawan, Brunei Darussalam

Introduction
Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia, often caused by a single adenoma (85%) or four-gland hyperplasia (15%). Brown tumors are rare erosive bony lesions caused by localised rapid osteoclastic turnover resulting from hyperparathyroidism.
Case presentation
A 28-year-old lady presented to the Emergency Department with a 3-day history of fever, dry cough and generalized body aches. She reported sudden onset lower back pain radiating to her thighs and 1-month history of multiple joints pains predominantly knee joints. Biochemical investigations were consistent with PHPT: corrected calcium (cCa^2+) 3.20 mmol/l (2.23–2.50), phosphate 0.60 mmol/l (0.74–1.52) and PTH 160.3 pmol/l (1.6–6.9). Other relevant laboratory findings were: ALP 3259 U/l (40–150), 24 h urine calcium 4.75 g, normal renal and thyroid function. CT neck/chest revealed a right thyroid nodule measuring 2.5 cm and brown tumors on multiple ribs, cervico-thoracic spine and long bones. MRI spine also showed brown tumors in the right sacral alar and iliac bones. Sestamibi SPECT/CT was later performed indicating a possible hyperfunctioning parathyroid lesion on inferior pole of the right thyroid lobe. There was focal increased tracer uptake in the right iliac crest, left distal tibia and left elbow suggestive of brown tumors. Although referred for a parathyroidectomy, an ultrasound guided FNAC of the right thyroid nodule was performed prior to surgery at the request of the surgical team. FNAC findings were suggestive of parathyroid tissue. Following the procedure, the patient reported pain at the site of FNAC, and pins and needles in all limbs. On neck examination, there was a 4 cm right sided hard and tender neck lump. Laboratory tests revealed cCa^2+ 1.92 mmol/l and PTH 4.8 pmol/l. Neck ultrasound showed a 3.77×3.07 cm mixed echogenic nodule with cystic changes in the right thyroid lobe. She was treated for hungry bone syndrome requiring calcium and magnesium supplementation. Haemorrhage and apoplexy of the culprit parathyroid adenoma due to FNAC was suspected. Surgery was cancelled and she was discharged on calcium carbonate and calcitriol. At her last Endocrine clinic review, she was well and remained normocalcaemic (cCa^2+ was 2.14 mmol/l, phosphate 0.91 mmol/l) on calcium supplementation. She has not attended further endocrine follow-up thereafter.
Conclusion
Our patient with severe PHPT and significant bone disease appears to have resolution of PHPT following apoplexy of parathyroid adenoma secondary to FNAC. Spontaneous remission of PHPT due to necrosis and hemorrhage of a parathyroid adenoma, the so-called "parathyroid auto-infarction", "auto-parathyroidectomy" or "parathyroid apoplexy" is a very rare, but previously described phenomenon.

An atypical presentation of a typical aetiology

Ashutosh Kapoor[1], Sadaf Ali[2] & Furat Wahab[3]
Ashutosh Kapoor and Sadaf Ali contributed equally
[1]Royal Bolton Hospital, Bolton Foundation NHS Trust, United Kingdom; [2]Diabetes and Endocrinology, Royal Preston Hospital, Fulwood, United Kingdom; [3]Royal Blackburn Hospital, United Kingdom

Introduction
Primary hyperparathyroidism (P-HPT) is a common endocrine disorder that occurs as result of adenomas (80–85%), hyperplasia (10–15%), atypical adenoma or carcinomas (<1%). Atypical parathyroid adenoma (APA) is a rare entity and represents intermediate group of parathyroid neoplasms of uncertain malignant potential with some atypical histological features.
Case details
We report a case of a 34-year male, with a background of hypertension (HTN) & chronic kidney disease (CKD), who was urgently referred by the GP to our hospital in view of alarmingly raised Calcium (Ca) & Parathyroid hormone (PTH). Clinical history revealed vague symptoms of ongoing lethargy. Bloods PTH 146 pmol/l (1.6–6.9), adjusted Ca 3.56 mmol/l (2.2–2.6). He was treated in the day unit with intravenous (IV) fluids and referred to our team who arranged for urgent admission as his calcium levels remained refractory to the mentioned intervention. Investigations revealed Vitamin D<20 nmol/l (>50), Alkaline Phosphatase (ALP) 66 IU/l (30–130), e-GFR 58 (>90). MEN workup including MR pituitary was normal.
Management
The patient initially recieved fluids following which intravenous(IV) Bisphosphonate was administered that dropped the Calcium to <3 over the next 48 h. He was arranged to have an urgent Sestamibi Nuclear Medicine Scan(NM SPECT CT) that revealed a 4.3 cm×6.5 cm×6.7 cm retrothyroidal mass in right lower neck with significant mass effect, displacing the thyroid and carotid sheath. Following this, he was urgently referred to the Surgical Team to have surgical intervention. Histopathology of the tissue samples revealed likely to be parathyroid adenoma with atypical features, most of which pursue a benign clinical course. Post operatively, Calcium has remained stable within normal limits on the follow up bloods since then. He is planned for Long term follow up in addition to regular clinical and radiological surveillance for features of malignancy or development of overt symptoms of MEN.
Discussion
Mutations in the CDC73 and HRPT2 gene are found in cases of parathyroid Carcinoma. In approximately one-third of affected individuals with changes in these genes, the mutation is inherited from a parent and is present in all of the body's cells. On the other hand, no specific Imunohistochemical signature has been identified for APA, thus rendering the diagnosis much more challenging. Patients with APA at diagnosis have a clinical and biochemical pattern much more severe than its benign counterpart, thus warranting the need for Urgent Medical and Surgical attention, followed by a long-term Management plan with MDT input.

Malignant hypercalcemia – A rare case associated with abdominal liposarcoma

Ana Figueiredo, ines damasio, Daniela Cavaco, Helder Simões, Joana Simões-Pereira & Valeriano Leite
Endocrinology, Portuguese Institute of Oncology, Lisboa, Portugal

Background
Malignant hypercalcemia (MH) occurs in up to 30% of patients who are diagnosed with cancery, being associated with later stages of the disease and poor prognosis. The physiopathological mechanisms responsible for MH are the production of parathyroid hormone-related peptide by the tumor (PTHrp) (80% of cases), osteolytic cytokine production (20%) and excess of $1,25(OH)_2$vitamin D production (1%).
Case report
We present the case of a 60-year-old man diagnosed, after an increase in scrotal and abdominal volume, with a 25 cm retroperitoneal mass suspicious for liposarcoma. Preoperatively, a hypercalcemia of 16.3 mg/dl was detected, with a serum phosphorous of 6.3 mg/dl and an acute renal failure. He was referred to our department and immediately started intensive fluid replacement, loop diuretics and glucocorticoids. From the initial investigation: PTH <3.0 pg/ml, 25(OH)vitamin D 18 ng/ml, alkaline phosphatase 91 UI/l, PTHrp<0.5 pmol/l and $1,25(OH)_2$vitamin D 224 pg/ml (18–71). He also did a bone scan scintigraphy that was negative for metastases and multiple myeloma was excluded. He was discharged from hospital but was again readmitted 15 days later with serum calcium of 19.2 mg/dl. Since bisphosphonate treatment was contraindicated, denosumab 120 mg was administered at day 1, 8, 15 and 29, with a good response (calcium of 11.5 mg/dl). After surgery, hypercalcemia completely resolved, with serum calcium levels between 8 and 9 mg/dl and normalization of $1,25(OH)_2$vitamin D (54 pg/ml).
Conclusion
Malignant hypercalcemia due to tumoral production of 1-alpha-hydroxylase with excess of conversion of 25(OH)vitamin D to $1,25(OH)_2$vitamin D is extremely rare. Most of the reported cases are associated with granulomatous diseases like sarcoidosis and, less frequently, with Hodgkin's Lymphoma or ovarian dysgerminoma. In summary, to the best of our knowledge, we report the first case of extrarenal production of $1,25(OH)_2$vitamin D associated to abdominal sarcoma in the literature.

Differential clinical expression of primary hyperparathyroidism due to a parathyroid adenoma or hyperplasia

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Alexandros Ginis[3], Athanasios Fortis[4], Thomais Kalogirou[4] & Panagiotis Athanassiou[5]

[1]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece; [2]Department of Physiology, Medical School, University of Athens, Athens, Greece; [3]Endocrinologist, Athens, Greece; [4]Second Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [5]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Introduction
Primary hyperparathyroidism is nowadays frequently diagnosed due to routine blood calcium measured in the general biochemical profile. Primary hyperparathyroidism may be due to a parathyroid adenoma or parathyroid hyperplasia. Parathyroid adenoma may occur in the area of the parathyroid glands or may be ectopic.
Aim
The aim was to describe the differential clinical expression of primary hyperparathyroidism due to an adenoma or hyperplasia in a cohort of patients with the disease.
Methods
A cohort of 21 patient, aged 52–75 years old, 14 female and 7 male, suffering from primary hyperparathyroidism is described. Patients were diagnosed after diagnostic evaluation for various reasons which revealed an elevated blood calcium level. Subsequent evaluation revealed high PTH levels and the diagnosis of primary hyperparathyroidism was made. Further diagnostic evaluation to locate any hyperfunctioning parathyroid glands was made with neck ultrasound and scintigraphy with ^{99m}Tc-Sestamibi.
Results
In 19 of the patients a parathyroid adenoma was localized. In 17 of the cases it was in the area of the parathyroid glands, while in 2 of the patients it was in the upper mediastinum. In 2 of the patients, one male and one female the diagnostic evaluation did not reveal a parathyroid adenoma. In the cases with a parathyroid adenoma PTH levels were elevated, ranging from 121 pg/ml to 345 pg/ml. Calcium levels were also elevated, ranging from 10.8 to 13.5 mg/dl. In the cases, in which no parathyroid adenoma could not be localized, the diagnosis of parathyroid hyperplasia was made. PTH levels were only mildly elevated ranging from 75 to 88 pg/ml and calcium levels were also mildly elevated ranging from 10.6 to 10.9 mg/dl. One of the patients with the presumptive diagnosis of parathyroid hyperplasia decided to have surgery. One of the parathyroid glands was excised. The histology revealed parathyroid hyperplasia. The biochemical picture did not improve and conservative management was decided.
Conclusions
In conclusion, it appears that primary hyperparathyroidism due to a parathyroid adenoma is characterized by elevated levels of PTH and blood calcium in contradiction to parathyroid hyperplasia which is characterized by a milder clinical picture, PTH and calcium both mildly elevated. We propose that in the cases with a presumptive diagnosis of parathyroid hyperplasia, with a mild clinical picture, conservative management should be preferred along with careful follow-up.

Fahr syndrome: About a case

Sara Ijdda, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Departement of Endocrinology, University Hospital Center Mohamed VI, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
Fahr syndrome is a rare disease, characterized by bilateral and symmetrical intracerebral calcifications, localized in the central gray nucleus and by the classic association with hypoparathyroidism. We report a case of Fahr syndrome associated with postoperative hypoparathyroidism.
Case report
A 58 year old female patient with a history of total thyroidectomy 18 years ago. She complained of chronic paresthesia, muscle cramps complicated sometimes by attacks of tetany mistaken for hysterical crisis. The evolution was marked last year by the installation of a state of generalized convulsive crisis. The assessment carried out in the emergency department objectified a deep hypocalcemia at 70 mg/l, a hyperphosphoremia, associated with a low serum level of PTH on radioimmunoassay (PTH=0.001 pg/ml). On the electrocardiogram the QT was lengthened. The cerebral scanner had shown bilateral and symmetrical calcifications of the central gray nucleus of the upper and sub tentorial stages. The diagnosis of Fahr syndrome secondary to hypoparathyroidism was accepted and the patient was substituted with calcium and vitamin D.
Discussion
Fahr syndrome can complicate untreated hypoparathyroidism at any age. The pathophysiological mechanisms of intracerebral calcifications are poorly understood. In front of phosphocalcic metabolism disorders, and specially in case of associated neuropsychiatric signs, intracerebral calcinosis should be sought. Treatment is based on the correction of disorders of phosphocalcic metabolism which often leads to a marked improvement. This observation illustrates the diagnostic difficulty with the clinical heterogeneity of this pathology and the advantage of systematic research of postoperative hypoparathyroidism in order to avoid its deleterious complications.
Conclusion
Fahr syndrome is a rare entity with contrast between a rich and severe symptomatology and a simple and effective treatment. The etiologies are dominated mainly by hypoparathyroidism.

EP67

A peculiar case of primary hyperparathyroidism

Ana Rita Elvas[1], Bernardo Marques[1], Joana Couto[1], Raquel Martins[1], Jacinta Santos[1], Teresa Martins[1], Joana Guimarães[2] & Fernando Rodrigues[1]
[1]Endocrinology, Portuguese Institute of Oncology of Coimbra FG, EPE, Coimbra, Portugal; [2]Endocrinology Department, Centro Hospitalar do Baixo Vouga, EPE, Aveiro, Portugal

Introduction
Primary hyperparathyroidism (PHPT) is a common endocrine disorder characterized by hypercalcemia due to an unregulated overproduction of parathyroid hormone (PTH). PHPT is most commonly caused by a single adenoma of the parathyroid gland, usually located just behind the thyroid gland. However, in rare cases, they can have an ectopic location, including intrathyroid adenomas. In some cases, the measurement of intact PTH in the wash out fluid obtained by US-Fine Needle Aspiration (FNA) can be useful in clarifying the etiology of these lesions. Treatment of this condition usually consists of surgical removal of the adenoma.
Case report
A 48-year-old man with complaints of fatigue and malaise was diagnosed with PHPT (total serum calcium concentration, 12.4 mg/dl [reference range, 8.6–10.5 mg/dl]; PTH 462.1 pg/ml [reference range 12–67 pg/ml]) and referred to the Endocrinology department. He presented a background history of symptomatic renal stone disease. A neck ultrasound was performed and the only abnormal finding was a predominantly cystic right lobe thyroid nodule with 21 mm. The patient underwent US-guided FNA of the lesion. PTH measurement in FNA wash-out fluid was significantly elevated (PTH 7199 pg/ml). A week after the procedure he returned to our department reporting he felt neck pain following the procedure and has been noticing distal paraesthesias in the upper limbs. Blood test results showed significant hypocalcemia and supplementation with calcium and calcitriol was started. A 99 Tc-sestamibi scan was performed but did not reveal any abnormalities suggestive of parathyroid disease. An ultrasound reassessment showed a decrease in the thyroid nodule's size. The patient was closely monitored. Recurrence of hypercalcemia was later observed, nearly a month and a half after FNA. At the date of the last appointment, he was asymptomatic and was offered surgical treatment.
Discussion
We present a case of FNA induced transitory remission of PHPT in a patient with an intrathyroid parathyroid adenoma. We conjecture that intra-nodular hemorrhage might have occurred, which temporarily affected the viability of the autonomous parathyroid tissue. A few similar cases of spontaneous or induced remission of PHPT after FNA had been previously described in the literature. This remission can be transitory or permanent, depending on the degree of cellular damage, thus periodic follow-up of these patients is recommended.

Shear wave elastography role in localizing secondary hyperparathyroidism

Laura Cotoi[1], Borlea Andreea[1], Borcan Florin[1], Sporea Ioan[1], Daniela-Georgiana Amzar[1], Schiller Oana[2], Schiller Adalbert[1], Dehelean Cristina[1], Pop Nicusor[1] & Stoian Dana[1]
[1]University of Medicine and Pharmacy "Victor Babes", Timişoara, Romania; [2]Dialysis Center B Braun, Remetea Mare, Romania

Introduction
Secondary hyperparathyroidism (sHPT) is a prevailing complication of chronic kidney disease (CKD) caused by the disturbance of calcium,

phosphate, and vitamin D, with high concentrations of serum parathormone (PTH) leading to high rates of cardiovascular and bone disease. The incidence and prevalence of chronic kidney disease, including kidney failure requiring renal replacement therapies (RRT) is rising in Europe. The objective of this study is to determine using 2D shear wave elastography, the elastographic characteristics of hyperplastic parathyroid glands in patients with chronic kidney disease and determine whether the technique adds diagnostic and localization information of these glands.
Materials and methods
We evaluated patients with stage 5 CKD under hemodialysis therapy: clinical, 2B ultrasound, Power Doppler, and shear wave elastography with computer assisted quantitative measurement of tissue elasticity with high accuracy linear probe on Supersonic Aixplorer machine.
Results
We evaluated 59 patients (male to female ratio 27:32) with mean age of 56.95±10.92, mostly above 65 years old, with confirmed CKD stage 5, registered on ERSD (end-stage renal disease) program, on RRT (renal replacement therapy). A total number of 97 hyperplastic parathyroid glands were studied. Hyperplastic parathyroid glands appear as soft tissue, with a mean SWE value of 7.835±2.944 kPa and minimum value of 4.630±2.272 kPa and a maximum value of 12.956±6126 kPa. We compared the elasticity index of hyperplastic parathyroid glands with elasticity index of thyroid tissue (mean SWE=13.780±4.039) and found significant differences.
Conclusion
The aim of this prospective study was to quantify the value of 2D Shear Wave Elastography in localizing secondary hyperparathyroidism. Elastography can be a useful tool and can better differentiatiate on tissue elasticity when localizing parathyroid hyperplasia in secondary hyperparathyroidism.

Coexisting primary hyperparathyroidism and plasma cell dyscrasias – A case series

Sulmaaz Qamar, Eleni Armeni, Girish Rayanagoudar & Ravi Menon
Department of Endocrinology, North Middlesex University Hospital NHS Trust, London, United Kingdom

Introduction
Coexistence of primary hyperparathyroidism and plasma cell dyscrasias such as multiple myeloma and monoclonal gammopathy of uncertain significance (MGUS) is rare. This can cause diagnostic uncertainty regarding the aetiology and relative contribution of each disorder to hypercalcaemia. We present a series of five individuals with this combination.
Case series
All five patients were referred to the endocrine clinic with hypercalcaemia. The series consists of four women and one man with a median age at diagnosis of only 53.5 years (40–76). Presenting complaints included aches and pains at different sites and constipation (one case); one case had incidental hypercalcaemia. Median calcium level was high at 2.95 mmol/l (range 2.57–3.26; reference value 2.2–2.6 mmol/l), 25 hydroxy vitamin D: 32 nmol/l (range 19–67; reference value 50–150), Parathyroid hormone (PTH) levels: 12.77 pmol/l (range 6.2–18.7; reference value 1.9–6.8). Two patients had evidence of nephrocalcinosis and four had osteopenia on bone density scan (one patient had lytic lesions and no formal bone density assessment). Four patients had confirmed multiple myeloma simultaneously diagnosed with primary hyperparathyroidism, when investigated for hypercalcaemia. The other patient had MGUS. The patient with MGUS had negative ultrasound and radio-isotope scanning for parathyroid adenoma. Of the patients with multiple myeloma, three had localised parathyroid adenomas and two have been referred for surgery. Last patient with multiple myeloma and failed parathyroid adenoma localisation is on Cinacalcet, having declined further investigations or surgery.
Conclusion
Concomitant diagnosis of primary hyperparathyroidism and multiple myeloma is rare in the literature, even though the conditions represent common independent causes of hypercalcaemia. Median age at diagnosis was only 53 years and youngest patient with multiple myeloma was only 40 years, which is earlier than expected with either disorder. Median calcium at presentation was 2.95 mmol/l, which is higher than expected with either disorder. The diagnostic approach should always consider evaluation of the common causes of elevated calcium. A simple screening test inclusive of PTH levels, 25 hydroxy vitamin D, serum protein electrophoresis and either urinary Bence Jones protein or serum free light chains, at the first appointment, could give significant insights into the pathophysiological pathways of elevated Calcium.

Rare cause of hypercalcemia: Parathyroid carcinoma

Ursa Ksela & Miro Cokolic
Division of Internal Medicine, Department of Endocrinology and Diabetology, University Medical Center Maribor, Maribor, Slovenia

Introduction
Primary hyperparathyroidism is usually caused by parathyroid adenoma or hyperplasia. Parathyroid carcinoma is a rare cause of hyperparathyroidism with a frequency ranged from 0.3 to 2.1%. Features that increase the likelihood of parathyroid carcinoma in patients with primary hyperparathyroidism are larger tumor size, symptomatic disease, marked hypercalcemia, and very high serum parathyroid hormone (PTH) concentrations. Preoperative localization studies do not reliably distinguish carcinoma from adenoma, so the diagnosis is typically made at the time of surgery.
Case report
Sixty-five-year-old asymptomatic patient with diabetes mellitus and arterial hypertension was referred to our outpatient clinic because of a chance discovery of hypercalcemia, with calcium 2.79 mmol/l (normal range 2.2–2.6 mmol/l), ionized-calcium 1.58 mmol/l (1.12–1.23 mmol/l) and intact parathyroid hormone (iPTH) 194 ng/l (10–65 ng/l). The patient underwent an ultrasonography of neck region and a subtraction thyroid scan. Investigations did not confirm any neck mass. We performed a choline PET CT that showed a larger cystic mass on the right side of thyroid gland, suspicious for parathyroid carcinoma. Before surgery he did CT scan of neck and thorax, which showed a large tumor (4×3×5 cm in size) of parathyroid gland, without distant metastases. The patient was referred to a thoracic surgeon. Histological findings of resected tumor confirmed a parathyroid carcinoma. His serum calcium and iPTH concentrations after surgery were normal (Ca 2.12 mmol/l, iPTH 30 ng/l).
Conclusion
Primary hyperparathyroidism is often recognized as a result of biochemical screening. The majority are asymptomatic patients with mildly elevated serum calcium concentrations. Although there is an overlap in the clinical in biochemical presentation of benign parathyroid disease and parathyroid cancer, there are some features that increase the likelihood of parathyroid cancer, one of them is tumor size. So even in asymptomatic patients, localization studies can help you to determine the right management and best decision for each individual case.

Efficacy and safety of pamidronate in the treatment of parathyroid hormone-dependent hypercalcemia in hospitalized patients

Rachel Chava Rosenblum, Orit Twito, Liat Barzilay-Yoseph, Erez Ramaty, Noa Klein & Pnina Rotman-Pikielny
Meir Medical Center, Kefar Sava, Israel

Background
Bisphosphonates are effective in malignancy-related hypercalcemia and have been beneficial in parathyroid-hormone (PTH)-dependent hypercalcemia in small randomized-controlled trials. However, data regarding efficacy and safety in PTH-dependent hypercalcemia is limited, and pamidronate is not indicated for this condition.
Objective
To evaluate efficacy and safety of pamidronate in moderate-severe PTH-dependent hypercalcemia. Control groups were patients with PTH-dependent hypercalcemia who did not receive pamidronate, and patients with PTH-independent hypercalcemia who received pamidronate.
Methods
Medical charts of patients hospitalized with hypercalcemia >12 mg/dl between 2014 and 2019 were reviewed. Cases were categorized as PTH-dependent or PTH-independent. Epidemiological and clinical characteristics, laboratory findings including albumin-corrected calcium, creatinine and phosphorus levels, and treatments were extracted. Patients with PTH-dependent hypercalcemia who received pamidronate were compared with similar patients who did not receive pamidronate, and with patients with PTH-independent hypercalcemia who received pamidronate.
Results
There were 37 hospitalizations in 34 patients with PTH-dependent hypercalcemia; pamidronate was given in 24 cases (64.8%). Calcium at admission was higher in the pamidronate-treated group than in the untreated group (mean 14.4 mg/dl vs 13.0 mg/dl, $P=0.001$); baseline creatinine and phosphorus levels were similar. Nadir post-treatment calcium was similar

between groups (10.9 mg/dl vs 11.4 mg/dl respectively, $P=0.247$), however the calcium delta was higher in the pamidronate-treated group (3.5 mg/dl vs 1.6 mg/dl, $P=0.003$). Of pamidronate-treated patients, none developed hypocalcemia or renal failure; nadir phosphorus was lower than in untreated patients (1.7 mg/dl vs 2.4 mg/dl, $P=0.005$). Sixteen patients underwent parathyroidectomy in the year following hospitalization. Regarding PTH-independent hypercalcemia, pamidronate was given to 60 patients in 67 hospitalizations; 64 cases were malignancy-related. Patients with PTH-independent hypercalcemia were older than their counterparts with PTH-dependent hypercalcemia (73.9 vs 62.4 years respectively, $P<0.001$). There were no between-group differences in calcium (14.8 mg/dl vs 14.4 mg/dl respectively, $P=0.278$) or creatinine at admission; the PTH-dependent group had lower phosphorus (2.48 mg/dl vs 3.54 mg/dl, $P<0.001$). Median pamidronate dose was 60 mg in both groups. Additional treatments included fluids (97.8%), furosemide (51.6%), calcitonin (45.1%) and cinacalcet (3.3%) with no between-group differences. Of PTH-independent cases, 36 (53.7%) received glucocorticoids; few received immediate oncological therapy. Following treatment, calcium fell by 4.48 mg/dl (PTH-independent) vs 3.51 mg/dl (PTH-dependent), $P=0.048$ and by >2 mg/dl in 53 (82.8%) vs 18 (75%) respectively, $P=0.408$. Forty-eight patients in the PTH-independent group and 2 in the PTH-dependent group died within 1 year.

Conclusion

The efficacy of pamidronate was similar in PTH-dependent and PTH-independent hypercalcemia, with no significant documented side-effects in the PTH-dependent group. Pamidronate should be considered part of the treatment arsenal in moderate-severe PTH-dependent hypercalcemia.

Hypophosphatemia: Collateral damage in parenteral iron administration

Georgiana Cristina Taujan, Felicia Baleanu, Rafik Karmali & Laura Iconaru
Endocrinology, CHU Brugmann, Bruxelles, Belgium

Introduction

Iron-induced hypophosphatemia is a well-known adverse effect in patients receiving parenteral iron supplementation. Initially thought to be transient and mild, it seems that in certain cases, especially in patients who require repeated intravenous iron administrations, it can lead to spectacular symptomatology and serious complications.

Case report

A female patient, aged 61 was referred for intense muscle and bone pain, severe impaired mobility, vertigo and headaches. She has been known with Rendu–Osler syndrome which led to recurrent severe epistaxis and anemia requiring repeated administrations of intravenous ferric carboximaltose for the last 2 years. Laboratory results revealed severe hypophosphatemia (0.49 mmol/l) with hyperphosphaturia (Tmp/GFR 0.21 mmol/l) and an elevated FGF23 level (137 pg/ml). Two months before presentation, the patient was also diagnosed with vitamin D deficiency and secondary hyperparathyroidism (25 OH vitamin D 7 µg/l, PTH 114 ng/l, corrected calcium 2.01 mg/dl) which further increased phosphate renal leak. The correction of hypophosphatemia in this case was achieved after changing the parenteral formula from ferric carboximaltose to saccharated ferric oxide, oral phosphate and vitamin D supplementation confirming the literature according to which a greater risk for hypophosphatemia is associated with ferric carboximaltose through an increase of FGF23.

Discussion

Beyond the major impact on patient's quality of life, chronic and severe hypophosphatemia may lead to other serious complications such as hemolytic anemia, osteomalacia and fragility bone fractures, cardiac and pulmonary dysfunctions, delirium, seizures and coma. The mechanism in this situation seems to be a decrease in phosphate renal reabsorption and inhibition of renal 1-alpha hydroxylation due to an increase in FGF23 level, which is reported to reach a maximum in the first week after parenteral iron administration. Apparently, the risk of phosphate depletion is related to several risk factors like iron formulation, frequency of administration, renal function, previous vitamin D deficiency or hyperparathyroidism.

Conclusion

Hypophosphatemia should be sought in patients with recurrent parenteral iron administration, with monitoring of phosphate levels during 2–6 weeks after the iron administration. In addition, in order to avoid hypophosphatemia, it seems preferable to use an iron formulation devoid of ferric carboximaltose.

Vitamin D revisited: Individualized Vitamin D normal values according to PTH levels; incidence and treatment of Normocalcemic Hyperparathyroidism in children

Dimitrios T Papadimitriou[1], Eleni Dermitzaki[1], Kleanthis Kleanthous[1], Anastasios Papadimitriou[2] & George Mastorakos[3]
[1]Pediatric-Adolescent Endocrinology & Diabetes, Athens Medical Center, ATHENS, Greece; [2]Attikon University Hospital, Pediatric Endocrinology, Greece; [3]Endocrinology, Areteio University Hospital, Athens, Greece

Background

Childhood and adolescence are critical periods for the establishment of lifelong bone health. While most studies focus on vitamin-D regardless of PTH levels, Normocalcemic Primary Hyperparathyroidism (NPHPT) has been recognized more than 15 years ago as a variant of primary hyperparathyroidism (PHPT), characterized by persistently elevated PTH with normal albumin-adjusted total and ionized calcium, in the absence of secondary causes of hyperparathyroidism. PPHPT is related to an increased risk in development of osteopenia/osteoporosis, of parathyroid adenoma (15%) and hypercalcemia–hypercalciuria with renal consequences.

Aim

To redefine individual Vitamin-D sufficiency according to PTH levels, identify and treat biochemical disorders of PTH in normocalcemic children.

Methods

We performed a complete calcium metabolism evaluation (Ca, P, ALP, 25OHD, intact PTH) in all patients that visited our pediatric endocrine unit for 2 years (1 Nov 2016 until 31 Oct 2018).

Results and interventions

A total of 3060 patients – excluding those that consulted for vitamin D deficiency, Ca metabolism abnormalities or known renal pathology (i.e. Bartter syndrome). 154 patients (5.1%) had hyperparathyroidism: PTH >45 pg/ml (Horm Res Paediatr 2015;84:124–129) and normal total serum calcium levels: 51% were vitamin D replete (>30 ng/ml, group-1) and 49 % were deficient (<30 ng/ml, group-2). All received cholecalciferol (8000–16 000 IU/d)+calcium 1000 mg/day p.o. with a 3 m follow-up. In 6 patients (4 from group-1 and 2 from group-2) elevated PTH did not respond to 6 m of combined cholecalciferol/calcium therapy. These were switched to the non-calcemic synthetic 1-25(OH)2 vitamin-D analogue, paricalcitol 2 µg×1–3/day. Intact PTH (15–65 pg/ml) normalized (<35) in 5 patients by 3 m and in 1 by 10 m, with calcium in serum and urine (Ca/Cr 2-h morning sample) being normal.

Discussion

The incidence of NPHPT in childhood is high. In all normocalcemic children checked for vitamin-D, concomitant measurement of PTH is required, to individually define vitamin-D sufficiency for the given patient. Most of the cases seem to be secondary hyperparathyroidism as they are resolved with administration of cholecalciferol and calcium. Even in cases with vitamin D sufficiency, PTH fell to normal after administration of cholecalciferol and calcium.

Conclusions

Vitamin D sufficiency may not be for everybody a level >30 or 20 ng/ml, calcium intake playing also a crucial role. Subclinical Hyperparathyroidism is successfully treated with cholecalciferol (8000–16 000 IU/day)+calcium supplementation (1000 mg/day) in most cases. The non-responsive cases seem to be either primary or tertiary Hyperparathyroidism responding to Paricalcitol administration 2–6 µg/day, protecting bone and general health.

Clinical case: Complicated differential diagnosis between postsurgical and functional hypoparathyroidism.

Elena Kovaleva, Anna Eremkina, Julia Krupinova & Natalia Mokrysheva
Parathyroid Glands Pathology Department, Endocrinology Research Centre, Moscow, Russian Federation

Objective

Postsurgical hypoparathyroidism (HypoPT) is the most common etiology of disease and often occurs after thyroid surgery. However, the differential diagnosis between different forms of HypoPT in some cases remains a challenge. We present the clinical case of postsurgical and functional HypoPT combination.

Case description

A 44-year-old female was referred to the Endocrinology Research Centre. She underwent total thyroidectomy for follicular adenoma performed in

2009. Hypoparathyroidism developed after surgery, so calcium carbonate 1000 mg/day and calcitriol 0.5–1 μg/day were prescribed. She continued this therapy for 2 years and then stopped in 2011. There were no clinical symptoms of hypocalcemia. Laboratory tests revealed albumin-corrected calcium level within 2.11–2.25 mmol/l (normal value 2.1–2.55) and PTH 16.7 pg/ml (15–65). Since 2019 her condition deteriorated with seizures, muscle cramps and paresthesia recurrence. She also had a history of stomach ulcer and therapy with proton pomp inhibitors over last months. Laboratory examination showed a decrease of PTH level less 3.0 pg/ml, hypocalcaemia (1.8 mmol/l), hyperphosphatemia (1.9 mmol/l (0.74–1.52) as well as hypomagnesemia 0.6 mmol/l (0.7–1.05). 25(OH)D blood test was normal – 37 ng/ml (30–100). Calcium carbonate 1000 mg/day and calcitriol 1 mcg/day were immediately prescribed. Also she was started on magnesium supplements about 400–600 mg/day per os to control the hypomagnesaemia. After 6 months, lab. Test revealed normal magnesium (0.83 mmol/l), target calcium levels (2.32 mmol/l) and increased PTH to 24 pg/ml. There was complete symptom resolution. Step-by step the doses of calcium carbonate and calcitriol were reduced. Patient is currently receiving cholecalciferol in daily dose of 2000 IU. Her physical and laboratory examination remain normal.
Conclusion
Hypomagnesemia is recognized as a cause of hypoparathyroidism due to impaired parathyroid hormone secretion, with resultant hypocalcemia. This case demonstrates the importance of looking for all associated electrolyte abnormalities in patients with HypoPT.

Vitamin D status and parathyroid hormone serum levels in women of reproductive age in Carpathian region

Ivan Pankiv, Nataliia Pashkovska, Galina Koval, Yulia Marchuk, Antonina Piddubna, Iryna Tsaryk & Nataliia Abramova
Clinical Immunology, Bukovinian State Medical University, Allergology and Endocrinology, Chernivtsi, Ukraine

Background
Vitamin D deficiency is a major public health problem in Ukraine. The aim of this cross-sectional study was to study the status of Vitamin D and parathyroid hormone (PTH) level in women of reproductive age in Carpathian region.
Materials and methods
A cross-sectional study was carried on a total of 416 nonpregnant and nonlactating women in the reproductive age group of 19–45 years during summer 2018. Demographic, socioeconomic class, and biochemical parameters for the estimation of serum 25(OH)D and PTH levels in women of reproductive age were studied. Serum 25(OH) D and PTH levels were estimated by chemiluminescent immunoassay (chemiluminescence) and colorimetric assay (Roche Cobas) technique.
Results
The mean age of individuals was 36±8 years. The median values for serum 25(OH) D and PTH level was found to be 17.42 (8–52) ng/ml and 57.2 (27.5–83.1) pg/ml accordingly. Vitamin D level less than 30 ng/ml was detected in 389 (93.5%) of participants. Vitamin D insufficiency was found in 148 persons (38.0%), deficiency – in 241 (62.0%). Significantly higher 25(OH)D level was registered in younger age group (19–34 years) as compared to 35–45 age group. In the univariable model, vitamin D deficiency showed a significant inverse association with age and body mass index. Serum PTH level was in the normal range in 345 (82.9%) of the subjects and high level – in 17.1%. Negative correlation between levels of 25(OH)D and PTH ($P=0.02$) was revealed.
Conclusions
There is a high prevalence of hypovitaminosis D among women of reproductive age. The risk of the development of osteoporosis and pregnancy-related complications in future is higher in these women.

The importance of determining vitamin D epimers

Ludmila Macova, Markéta Šimková & Marie Bicikova
Institute of Endocrinology, Steroid Hormones and Proteofactors, Praha, Czech Republic

Vitamin D is a large group of structurally similar substances (calciferols) with diverse biological functions. Although approximately 40 different vitamin D metabolites have been determined so far, only 1,25-dihydroxyvitamin D was considered to be biologically active and the determination of 25-hydroxyvitamin D (25-OH D) served a tool to assess vitamin D supply. Recently it was found that also C3-epimers of vitamin D have their biological effect, however these effects differ from non-epimeric forms. The exact source of the epimers is not known but their proportion was found higher in mothers and newborns. The percentage of C3-epimers of the total 25-OH D range from 0% to approx. 60% for infants and from 0% to 45% for adults, respectively. Such a high percentage of epimers could lead to misclassification of vitamin D supply, as routinely used immunoanalytical methods are unable to distinguish epimers from non-epimeric forms of vitamin D and are burdened with the high proportion of cross-reactivity and interferences. Vitamin D assessment is a challenge mainly due to the low concentrations of analytes in blood, a large number of structurally similar metabolites and photo-instability of vitamin D molecules. Chromatographic separation of epimers combined with the mass spectrometry detection is recognized as the optimal method for the determination of vitamin D, however, in laboratory practice prevail immunochemical methods. In our study, we compared various methods and parameters associated with vitamin D in 80 serum samples. Surprisingly, the values of 25-OH D measured by chromatographic method and ELISA did not correlate together, but we found significant correlations between 25-OH D measured using chromatography and free 25-OH D. The choice of method is absolutely crucial when planning studies focused on vitamin D. Wide range of commercially available kits and at the same time, the unsatisfactory standardization of methods provides results that differ significantly from one another and can lead to problematic interpretation of the study outcomes. The work was supported by a grant of MH CZ – DRO (Institute of Endocrinology – EU, 00023761).

Over-supplementation of vitamin D in a patient with unknown primary hyperparathyroidism

Blertina Dyrmishi[1,2], Taulant Olldashi[3], Ema Lumi[3], ENTELA PUCA[4] & Arben Pilaca[2]
[1]Internal Medicine, Hygeia Hospital Tirana, Tirane, Albania; [2]Hygeia Hospital Tirana, Tirane, Albania; [3]Regional Hospital Korce, Korce, Albania; [4]American Hospital Tirana, Tirane, Albania

Background
Primary hyperparathyroidism is more prevalent in women and sometimes the patients are without clinical signs. Parathyroid disorders aren't uncommon in the general population.
Clinical case
A woman 68-year-old was present to the ambulatory visit with multiple joint pains and generalized weakness, constipation and weigh loss since 1 year ago. She hadn't any history of fever, anorexia, nausea, vomiting or diarrhea. She refered that since 6 months she was taken a supplementation by her selves of Vitamin D (10 000 units of cholecalciferol) every day. No history of any chronic disease.
Lab results
We found a high values of 25(OH) Vitamin D 140 ng/ml, PTH 490 pg/ml and calcium values 16.6 mg/dl (8.5–10.1 mg/dl). The other results: Creatinine 0.8 mg/dl, GFR 58 ml/min, alkaline phosphatase 179 IU/l (46–119), urinary calcium 446 mg/24 h (42–353). Thyroid ultrasound: A solid cystic nodule in the right lobe of thyroid with dimensions 2.1×1.4×2.2 cm, without imaging evidence of a typical parathyroid adenoma. Parathyroid sestamibi scan: right parathyroid adenoma She was treated with intravenous (IV) saline and furosemide. The vitamin D3 was stopped and the patient underwent surgery, excision of the parathyroid adenoma. Pathological report confirmed diagnosis: parathyroid adenoma. The PTH values return to normal range after surgery and the calcium value was 10.2 mg/dl. In the following days calcium values were below normal range. Actually the patient was in treatment with calcium supplement and bisphosfonate for the treatment of osteoporosis. She was advice to have regulary follow up and to know sign of severe hypocalcemia.
Conclusions
Our case has a unknown primary hyperparathyroidism which was complicated with severe hypercalcemia as a result of over-supplementation with very high doses of vitamin D in a patient with unknown primary hyperparathyroidism.

Keywords: Primary hyperparathyroidism, hypercalcemia, vitamin D toxicity

Hypercalcemic encephalopathy – A rare presenting manifestation of Sarcoidosis

P Kiran Kumar [1], C M Batra[1], Suganya Giri Ravindran[2] & Monika Goyal[1]
[1]Endocrinology, Indraprastha Apollo Hospital, New Delhi, India;
[2]Endocrinology, St George University Hospital, London, United Kingdom

Background
Sarcoidosis is an inflammatory granulomatous multisystem disorder commonly presenting with noncaseating granulomas in lung and lymphoid tissue. Other organs like skin, eye and joints also involved.
Case report
We present a 62-year-old diabetic woman presented to the emergency with progressive alteration in sensorium and left hemiparesis for two days. Patient had lower respiratory tract associated with recurrent hypoglycaemic attacks two weeks back and resolved after a course of antibiotics. She had neck stiffness and left gaze deviation. Biochemistry revealed blood urea – 72 mg/dl, serum creatinine – 1.8 mg/dl, HbA1C – 6.7. Corrected calcium – 15.5 mg/d and phosphorous – 4.4 mg/dl. It suggested hypercalcaemia crisis with normal phosphorous levels. Further evaluation revealed Parathyroid hormone - 19.2 pg/ml and 25hydroxy vitamin D – 45.6 ng/ml levels which were normal. CSF analysis MRI brain serum immunoelectrophoresis which were normal ruled out meningitis, stroke and myeloma respectively. PET MRI whole body was done to rule out malignancy which revealed enhanced uptake in mediastinal lymph nodes. Sr ACE levels were elevated with 87 unit/l. Fibre optic Bronchoscopy was done and biopsy of lymph nodes revealed noncaseating granulomas. Biopsy was negative for acid fast bacilli and gene expert which ruled out tuberculosis. All the above investigations suggested sarcoidosis presenting as hypercalcaemia encephalopathy. Intravenous fluids to relieve dehydration and pamidronate 90 mg infusion was given to patient. Serum calcium levels settled down to normal gradually over two days to 10.2 mg/dl and sensorium improved. Patient was started on prednisolone 60 mg with tapering doses and monitored for next three months till steroids were stopped.
Discussion
Sarcoidosis usually presents with Hypercalcaemia as either renal failure or pancreatitis however encephalopathy is a rare manifestation. In our case encephalopathy with localising signs like left hemiparesis masqueraded as cerebrovascular stroke. Common causes of Hypercalcaemia include primary hyperparathyroidism, malignancy, milk alkali syndrome etc. Increased activity of 1 alpha hydroxylase enzyme in alveolar macrophages which converts 25 hydroxycholecalciferol into active form of 1,25 dihydroxycholecalciferol is the common cause of Hypercalcaemia in sarcoidosis. Other causes include increased production of parathyroid hormone related protein which, causes upregulation of 1 alpha hydroxylase.
Conclusion
Hypercalcemia can masquerade as stroke and should be evaluated when presented as metabolic encephalopathy with normal brain imaging. Sarcoidosis is a rare cause of hypercalcemic encephalopathy and is easily treatable when compared with primary hyperparathyroidism and malignancy related Hypercalcemia.

EP79

Hypocalcemia due to pseudohypoparathyroidism diagnosed in adulthood

Carlos Antich Barceló
Nord de Palma District, Hospital Universitario Son Espases, Palma, Spain

Introduction
Pseudohypoparathyroidism (PHP) refers to a heterogeneous group of rare metabolic diseases, all characterized by end-organ resistance to the action of different hormones, primarily PTH. Main clinical characteristics are hypocalcemia and hyperphosphoremia associated with elevated parathyroid hormone (PTH) levels, frequently encompassing additional heterogeneous features, known as Albright's hereditary osteodystrophy. A molecular cause can be identified in 80–90% of patients with PHP. The most common underlying mechanisms are de novo or autosomal dominantly inherited genetic mutations within of GNAS. Most of these cases are diagnosed during childhood.
Case report
A 28-year-old male was referred by the general practitioner to study episodes of hypoglycaemia. Born in the Dominican Republic, he moved to Mallorca (Spain) at the age of 10. His medical record included active drug use (cannabis, cocaine, alcohol) and intellectual disability not clarified. He explained symptoms of weakness, dizziness and cramps in his legs since adolescence. The physical exam showed a peculiar phenotype: stocky body, rounded face, brachydactyly, obesity. A glucometer was delivered and no hypoglycemia was documented. The blood test showed normoglycemia, normomagnesemia, hypocalcemia, hyperphosphatemia, 25-OH-vitamin D levels slightly decreased and elevated levels of PTH. Calcium levels had not been carried out before. Based on these findings, a PHP was supposed and other tests were requested. CT scan showed basal ganglia calcification, HAND X-rays showed severe brachydactyly. DEXA scan revealed normal bone density. Hormonal blood test showed a subclinical hypothyroidism, low levels of IGF-1, normal testosterone and hypercalcitoninemia. An insulin-induced hypoglycemia test validated a growth hormone deficiency. The genetic study confirmed heterozygous mutation in the GNAS gene and the features are consistent with a PHP1A. Treatment was started with oral calcium and calcitriol.
Conclusions
It is important to diagnose, classify and properly treat hypocalcemia at an early age to avoid future complications. PHP requires, in most cases, a multidisciplinary approach with an endocrinologist to screen and treat the hormonal disorders.

Role of vitamin D deficiency in comorbid disorders among the Chornobyl NPP accident survivors

Irina Muraviova[1], Iryna Chykalova[1], Dmytro Afanasyev[1], Olga Kopylova[1], Oleksiy Kaminskyi[1] & Konstantin Loganovsky[2]
[1]State Institution "National Research Center for Radiation Medicine of the National Academy of Medical Sciences of Ukraine", Radiation Endocrinology, Kyiv, Ukraine; [2]State Institution "National Research Center for Radiation Medicine of the National Academy of Medical Sciences of Ukraine", Radiation Psychoneurology, Kyiv, Ukraine

Endocrine comorbidity is a hot issue in radiation medicine featuring a concomitant radiation injury of several endocrine glands.
Objective
Establishing a link of vitamin D deficiency with thyroid and pancreatic disorders among the Chornobyl nuclear power plant (ChNPP) accident survivors.
Results
A blind sample ($n=60$) of subjects treated at the Radiation Endocrinology department in 2019 were selected for the study. Study sample included the ChNPP accident survivors (group 1, $n=40$) with 20 females (50%) and 20 males (50%) among them. The comparison group included patients (group 2, $n=20$) not exposed to radiation with 11 females (55%) and 9 males (45%) among them. Age of study subjects ranged from 37 to 75 years old (60.2 ± 9.8 years at an average). Failure of compensation of type 2 diabetes was the most common reason for hospital admission (48.3%), failure of compensation of hypothyroidism was in second place (46.7%). Incidence of the increased risk of vitamin D deficiency and excessive parathyroid hormone production in the Chernobyl accident survivors was somewhat higher than in non-exposed individuals, however with no significant difference (respectively 81.08% and 78.12%; $\chi=0.257$, $P=0.612$; 31.12% and 28.08%; $\chi=0.462$, $P=0.319$). Using a multivariate analysis the reliable model was obtained confirming the relationship of increased parathyroid hormone level and early subclinical signs of the target organs damage ($F=4.294$; $P=0.042$), which proves the feasibility of clinical questionnaires application. Reliable positive relationship was found between the vitamin D and free thyroxine levels ($r=0.729$; $P=0.001$) and negative one was found with the thyroid-stimulating hormone content ($r=-0.803$; $P=0.001$) in the ChNPP accident survivors, indicating a direct impact of vitamin D deficiency on the course of hypothyroidism. Decreased vitamin D concentration in the ChNPP accident survivors having got type 2 diabetes correlated with increased duration of metformin medication ($r=-0.421$; p=0.001) and body mass index ($r=-0.787$; $P=0.001$) indicating the need for correction of such insufficiency in the given contingent of patients. It was found that the parathyroid hormone level increases along

with the duration of type 2 diabetes and increase in creatinine clearance ($r=0.724$; $P=0.001$ and $r=0.799$; $P=0.001$).
Conclusions
Vitamin D deficiency has a negative effect on the course of comorbid disorders (type 2 diabetes and hypothyroidism) and excessive production of parathyroid hormone.

Therapy of normocalcaemic primary hyperparathyroidism

Helena Šiprová & Miroslav Souček
The 2nd Department of Internal Medicine, St. Anne's University Hospital in Brno, Brno, Czech Republic

Normocalcaemic primary hyperparathyroidism (NPHPT) is becoming more common nowadays due to the increasing use of screening laboratory methods. In the care of the outpatient office of endocrinology of the 2nd Department of Internal Medicine, Faculty of Medicine, Masaryk University and St. Anne's University Hospital in Brno in the period between 1 January 2007 and 31 December 2019, there were a total of 304 patients diagnosed with primary hyperparathyroidism. At the time of diagnosis, 249 patients were normocalcaemic (serum calcium levels did not exceed 2.60 mmol/l) and 55 patients were hypercalcaemic. Any secondary causes of hyperparathyroidism were excluded. Two-thirds of patients were in their sixties and seventies at the time of NPHPT diagnosis. The high proportion of NPHPT patients can be explained by the relatively frequent examination of parathyroid hormone levels in normocalcaemia. Nearly one-fifth of all the studied patients with NPHPT had sustained or intermittent pathological increases in serum calcium within 10 years of the onset of the disease (47 patients). NPHPT can be considered a milder form of primary hyperparathyroidism or its initial form. Surgical treatment was recommended for all patients who showed marked hypercalcaemia and who had proven parathyroid adenomas. A similar practice was followed for normokalaemia patients if they also became overtly hypercalcaemic. Parathyroidectomies were also performed in five patients who remained normocalcaemic. In three of these cases, an adenoma was confirmed with MIBI scintigraphy. In two cases, thyroidectomies for nodular goitres were performed. An experienced surgeon performed a targeted search for the parathyroid adenomas in the course of the procedures and removed them after identification. In four cases, there was only a slight increase in calcaemia (up to 2.7 mmol/l) and long-term pharmacological treatment was indicated. Due to significantly reduced bone densities, bisphosphonates were administered. In one patient originally diagnosed with NPHPT, calcium serum levels increased to 3.13 mmol/l within one year of the onset of the disease. Parathyroidectomy was abandoned based on medical contraindication due to polymorbidity. Long-term treatment with cinacalcet was initiated and calcaemia decreased from 3.13 mmol/l to 2.60 mmol/l in four months. Normal calcium serum levels have been maintained for more than nine years.

NCKX3 deficiency impairs to motor function and social behavior in mice

Donglin Yi, Dinh Nam Tran, Seon Mi Park, Thi Bich Thuy Vo, Eui-Man Jung & Eui-Bae Jeung
Chungbuk National University, College of Veterinary Medicine, Cheongju-si, Republic of Sourth Korea

Ca^{2}+ homeostasis has been reported to play important roles in various cell systems. In central nerves system, the dysregulation of Ca^{2}+ homeostasis can induce the excitotoxic and neurodegeneration. NCKX3 (Sodium/potassium/calcium exchanger 3), a novel member of the family of K+-dependent Na+/Ca^{2}+ exchangers, is an important component of intracellular Ca^{2}+ homeostasis. In addition, NCKX3 highly expressed in thalamic nuclei, in hippocampal CA1 neurons, and in layer IV of the cerebral cortex in the mouse brain. Here, we examined the effects of inactivation of NCKX3 in mice. NCKX3 deficient mice at 6 week-age were used for behavior assays. In comparison to wild-type (WT) mice, NCKX3 deficient mice displayed hyperactivity in the open field test. In addition, the rotarod test revealed motor learning defects in NCKX3 knock out (KO) mice. Moreover, NCKX3 deficient mice have reduced time spent on general sniffing, anogenital sniffing, and following behavior in social interaction test compared to WT mice. In three-chamber social ability test, NCKX3 deficient mice showed spent more time in the chamber contain un-familiar mouse. However, NCKX3 deficient mice exhibited significantly lower time spent in the novel mice in social novel test. NCKX3 deficient mice showed no change in cognition function in the novel object recognition and spatial learning in Morris water maze tests. These results indicated that NCKX3 mutation causes abnormal motor functions and social behaviors in mice.

EP83

An unusual case of symptomatic hypercalcemia from Graves' disease in a young Filipino female

Diana Dimayuga & Michael Villa
Department of Medicine, St Luke's Medical Center, Philippines

Hypercalcemia in hyperthyroidism is usually asymptomatic, and related to a concurrent primary hyperparathyroidism. In this report, we describe a case of symptomatic hypercalcemia secondary to Graves' disease alone.
Case report
A 24-year-old Filipino female presented to the emergency department with generalized weakness, vomiting and abdominal pain. No other symptoms were noted. She was otherwise previously healthy. Family history was unremarkable. During physical exam, she was noted to have a non tender palpable thyroid gland without bruit. Her ECG showed sinus tachycardia. The complete blood count and electrolytes were normal however, ionized calcium was high at 1.6 mmol/l (NV 1–1.3). Renal function was normal. Hydration with saline and Furosemide 20 mg once daily was started though calcium levels remained elevated. Other causes of hypercalcemia were excluded as PTH was appropriate suppressed (8.8 ng/l; NV 14–72), vitamin D was also suppressed (15.29 nmol/LNV: >30). CT scan of chest and abdomen and bone scan did not point to any underlying malignancy nor metabolic bone disease. Medication history was also unremarkable. She was hyperthyroid with a suppressed thyroid stimulating hormone level of 0.004 pmol/l (NV:0.55–4.78), free T3 of >20 pmol/l (NV:2.3–4.2), free T4 of 8.4 pmol/l (NV:0.89–1.76). Thyroid receptor antibody levels were raised at 41.07 (NV:<1 kU/l). Supporting the diagnosis of Graves'disease. She was started on propylthiouracil 50 mg four times daily, along with propranolol 40 mg three times daily. She was subsequently seen after two weeks with normal repeat calcium level and thyroid function tests.
Conclusion
This report aims to highlight that thyroid disease should always be considered as a cause of hypercalcemia. A concomitant primary hyperparathyroidism should also be considered. The definitive treatment for the hypercalcemia is correction of thyroid function.

A case of osteopetrosis/pycnodysostosis

Bengur Taskiran, Ertaç Berker & Kevser Onbasi
Endocrinology, Kutahya University of Health Sciences, Kutahya, Turkey

A 41 year old male patient presented to the endocrinology unit due to recurrent long bone fractures and teeth decay. His past medical history was nonsignificant for any chronic disease. He was a child of consanguineous marriage; his father and mother were first degree cousins. There were no other family members with similar phenotype or history of recurrent fractures He was 154 cm in height and weighed 58 kg. The arm span was 139 cm. Upper to lower segment ratio was 1.16. He had a beaky nose and frontal bossing. The nasopalatine canal was patent and incisive foramen were present as two seperate foramina. He had bilateral fractures of the mid-portion of the tibia cortex. He had normal puberty onset and secondary sexual development. He was not mentally retarded. He had abundant patchy yellow coloured mildly plaques over the torso, but he denied itching. We suspected cafe au lait spots. The dermatologist' initial diagnosis was tinea versicolor, however fungal hyphae was absent upon potassium hydroxide examination of skin scrapings. Hepatosplenomegaly, nephrocalcinosis, and nephrolithiasis was absent. He had bilateral optic nerve atrophy and left-sided hearing loss; however temporal CT, orbita MRI, and cerebral MRI revealed no obvious entrapment. Cerebral calcification was also missing. Optic coherance tomography was compatible with optic atrophy. Pattern-reversal visual evoked

potential revealed bilaterally (left side less than the right side) prolonged P100 latency. Sclerotic bones were evident on plain films of long bones of both upper and lower extremities, vertebrae, calvarium, and mandible. There was a fistula formation of left tooth root to the mandible but evidence of osteomyelitis was missing. High bone mineral density was detected on dual energy X ray absorptiometry (T score and Z score respectively for femur neck and lumbar vertebrae 1–4; +2.8, +3.4 and +6.8, +6.9). The laboratory data were as follows: ESR 19 mm/h (UNL 15 mm/h), CBC differential within normal limits, creatine kinase 69 U/l, LDH 232 U/l, reticulocyte 1.18% (UNL 3.00%), total bilirubin 0.26 mg/dl, ALT 13 U/l, AST 28 U/l, prothrombin time/INR 1.04, aPTT 31.6 sec, ALP 88 U/l, albumin 4.4 g/dl, phosphorus 3.8 mg/dl, glucose 89 mg/dl, total protein 7.5 g/dl, vitamin B12 144 pg/ml, creatinine 0.94 mg/dl, calcium 10.3 mg/dl, TSH 1.53 mU/l, 25 hydroxy vitamin D 15 ng/ml, parathyroid hormone 20 pg/ml. We think our case shares some features of mild-intermediate form of osteopetrosis and pycnodysostosis. Genetic testing has been planned and underway.

Improvement of bone mass density in a pediatric patient with chronic kidney disease and growth failure

Iolanda Brindusa Plesuvu[1], Carmen Gabriela Barbu[2] & Simona Fica[2]
[1]Elias University Emergency Hospital, Endocrinology, Bucharest, Romania; [2]Endocrinology, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction
Multiple factors have been incriminated in growth retardation in patients with chronic kidney disease (CKD), such as metabolic acidosis, anemia, vitamin D deficiency with secondary hyperparathyroidism, under-nutrition, renal bone disease. The disease compromises vertical growth with up to one-third children having severe growth delay (below the third percentile for height). Optimal care and nutritional therapy alone, can't help the children with CKD reach their normal height without the supplemental growth hormone therapy.
Case report
An 11-year old male, known with chronic renal failure since birth, renal osteodistrophy with right renal transplant, came into our clinic for initiation of recombinant growth hormone(rGH) therapy. At the time, height was 126 cm (−3.32 DS), with a weight of 31 kg, in pubertal stage with bone age of 9 years. Predicted adult height was 165 cm, and midparental height was 180 cm. Metabolic bone parameters allowed us to initiate the rGH treatment. The additional question raised in that moment was related to the skeletal status: the patient had bilateral femoral neck fracture treated conservatively and in DXA whole body scan had a TBLH Z score of −3.84 which completed the diagnosis of osteoporosis. The patient had secondary hyperparathyroidism, in the context of CKD(GFR = 46.9 ml/min per 1.73 m^2) and previous chronic corticotherapy which recommended also byphosphonate(BF) initiation together with active vitamin D metabolites. We decided to postpone the BF therapy. Bone mass density reevaluation showed improvement under rGH treatment and 1-alpha-calcidol; thus after 1.5 years of rGH treatment, the TBLH Z score was −1.2 and without new fractures.
Conclusions
Despite not reaching the optimal height under rGH treatment period, we were able to improve bone mass density of the patient, which might be a certain benefit of it.

Edentulism and the management of osteoporosis

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Panagiotis Spyropoulos[3], Erasmia Manta[4], Pavlos Tsakiridis[5], Andreas Giannakopoulos[4], Alexandros Pastroudis[4] & Panagiotis Athanassiou[5]
[1]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece; [2]Department of Physiology, Medical School, University of Athens, Athens, Greece; [3]Endocrinologist, Athens, Greece; [4]6th Department of Orthopedics, Asclepeion Hospital, Voula, Athens, Greece; [5]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Complete or partial edentulism is common in middle age, especially in postmenopausal women. Edentulism may be the result of either dental problems or periodontitis or both. Periodontitis is characterized by systemic inflammation and may be accompanied by osteoporosis. Osteoporotic patients on treatment with anticatabolic agents may develop osteonecrosis of the jaw. The aim was to present the management of osteoporosis in an edentulous patient with severe periodontitis who developed multiple foci of osteonecrosis of the jaw. A patient, female aged 67, presented with osteoporosis, T score being −2.6 in the left hip. The patient also had severe periodontitis having already lost teeth in the maxilla. Anticatabolic treatment was administered. A year later the patient presented with severe dental problems and was completely edentulous. An extensive laboratory and clinical evaluation was performed. Osteoporosis improved and T score in the left hip was −2.4. Examination of the oral cavity revealed multiple foci of osteonecrosis of the jaw. Vitamin D and calcium were administered. Oral hygiene was taken care of and performed with the use of chlorhexidine solution. The patient was followed-up for a period of 6 months. Six months later examination of the oral cavity did not reveal foci of osteonecrosis. Thereafter, anticatabolic treatment was administered for the management of osteoporosis. In conclusion, management of osteoporosis in the edentulous patient presents unique problems. The patients are in the danger of developing osteonecrosis of the jaw. Additionally, dental implant installation may be impossible. Therefore, patients should be managed with caution. Oral examination should be performed in parallel with osteoporosis follow-up and oral hygiene should be taken care of.

Is hip geometry modified in acromegalic patients?

Elena Alexandru[1], Patricia Christina Codreanu[1], Theodor-Eugen Oprea[1,2], Irina Nistor[1], Raluca Pascu[1], Florina Andrada Predescu[1], Niculina Giurgiuman[3], Sorina Martin[1,2], Anca Sarbu[1,2], Alice Albu[1,2], Simona Fica[1,2] & Carmen Gabriela Barbu[1,2]
[1]Endocrinology, Elias Emergency University Hospital, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Elias Emergency University Hospital, Bucharest, Romania

Introduction
Besides the amount of bone mineral assesed through bone mineral density (BMD), studies have shown that neck geometry parameters as hip axis length (HAL) and neck-shaft angle (NSA) could also be reliable parameters to be included in the hip fracture assesement. On the other hand, bone geometry is known to be modified in acromegaly in flat bones, thus hip fracture is not a recognized direct complication in acromegaly neither through bone mass or long bone geometry.
Objectives
The aim of the study is to evaluate hip axis length (HAL) and neck-shaft angle (NSA) in acromegaly compared with same parameters in non-acromegalic patients.
Methods
There were analyzed examinations of DXA of the proximal femur from 19 patients with acromegaly with a mean age of 59 years compared with the same number of examinations from 19 non-acromegalic patients with a mean age of 55 years. The data was collected from the authors database retrospectively. The independent Samples t-test was used to investigate the relationships between acromegaly and HAL and also NSA. Mean HAL value was significantly greater in acromegalic patients versus control group (116.1 mm vs 104.8 mm; $P<0.01$). Mean NSA in acromegalic group didn't show any significant difference compared with non-acromegalic patients (53.63 mm vs 54.84 mm).
Results
With the limitations of the small sample of patients, our study showed a significantly greater HAL in acromegalic patients, which has been associated with a higher hip fracture risk. Considering that no significant difference was found regarding NSA, our results support an increased hip fracture risk in acromegalic patients versus non-acromegalic patients based on a modified hip geometry inspite of known exposure at GH excess in adulthood only.

Correlation of body mass index and bone mineral density in menopausal women

Snjezana Popovic Pejicic[1], Nina Pejicic[2] & Aleksandra Grbic[3]
[1]Medical faculty Banja Luka, University Clinical Center of Republic of

Srpska, Clinic for internal medicine, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Center of Republic of Srpska, Clinic for Plastic and Reconstructive Surgery, Banja Luka, Bosnia and Herzegovina; [3]University Clinical Center of Republic of Srpska, Clinic for Internal Medicine, Banja Luka, Bosnia and Herzegovina

Background /aim
Osteoporosis is a generalized bone disease, characterized by impaired bone firmness, resulting in an increased predisposition for fractures. In order to detect the subjects at risk for fractures, one should actively search for them, primarily in a group of postmenopausal women, considering clinical risk factors. Apart from others, the relevant risk factors are lack of estrogen and low body mass index (BMI <19 kg/m^2).: The aim of this study was to examine relationship between body mass index (BMI) and bone mineral density (BMD) in a group of postmenopausal women.
Methods
The study involved a group of 100 postmenopausal women, aged 46 to 70 years. (59.08±6.07). All subjects had their body mass and body height measured and BMI calculated. BMD was determined by DXA method (dual energy X-ray absorptiometry) by Lunar Prodigy Advance Unit. BMD was measured at central skeleton (lumbal spine and both hips). According to densitometry finding, the criterion for osteoporosis is T score less than –2.5 S.D. BMI values were correlated with total T score values of the lumbal spine and both hips, as well as total T score values of spine and hip.
Result
Results have shown that body mass was normal in 18% subjects, 1st grade obesity was found in 52%, 2nd grade obesity in 23%, 3rd grade obesity in 7% of subjects. Median BMI value was found in 28.27±4.12. Median lumbal spine T score was – 2.19 S.D.±1.25, and hip T score – 1.11 S.D.±0.95. A statistically significant positive correlation (r=0.01) was found between BMI and BMD of the hip, whereas between BMI and BMD of lumbal spine there was no statistically significant correlation. There was a statistically significant correlation (r=0.01) between BMD values of lumbal spine and hip.
Conclusion
BMI is a well known, significant predictor of BMD of entire skeleton. In postmenopausal women BMI is more important predictor of hip BMD, as compared to spine BMD. BMD of hip is increased with the increase of body mass and height in postmenopausal women due to considerable endocrine function of fat tissue which produces leptin and other bioactive peptides which have a protective role in bone structure. A lack of correlation between BMI and BMD of spine in postmenopausal women might be due to predominant effect of lack of estrogen and faster bone metabolism in spinal region (spongious bone).

Cortisol secreting adrenal adenoma. A clinically silent cause of osteoporosis

Ifigenia Kostoglou-Athanassiou[1], Lambros ATHANASSIOU[2], Alexandros Ginis[3], Erasmia Manta[4], Pavlos Tsakiridis[5], Andreas Giannakopoulos[4], Alexandros Pastroudis[4] & Panagiotis Athanassiou[5]
[1]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece; [2]Department of Physiology, Medical School, University of Athens, Athens, Greece; [3]Endocrinologist, Athens, Greece; [4]6th Department of Orthopedics, Asclepeion Hospital, Voula, Athens, Greece; [5]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Adrenal adenomas are nowadays frequently diagnosed in the context of abdominal imaging. Osteoporosis may be a presenting manifestation of a cortisol producing adrenal adenoma. The aim was to present two cases of patients diagnosed and treated for osteoporosis who later in the course of the disease were diagnosed with a cortisol producing adrenal adenoma. Two patients, female aged 53 and 56 years, respectively, presented with osteoporosis. T score was −2.8 and −3.0 in the left hip, respectively. Bisphosphonates were administered. During follow-up the first patient developed gastritis and vague abdominal pain. An abdominal CT scan was performed which revealed an adrenal adenoma in the left adrenal gland measuring 1.8×2.6 cm. An extensive laboratory investigation revealed increased 24 h urinary cortisol levels, marginally decreased morning ACTH levels and normal morning cortisol levels. Cortisol levels were not suppressed after an overnight dexamethasone test. The diagnosis of a cortisol secreting adrenal adenoma was made. The second patient developed anemia during follow-up and an upper abdominal MRI was performed. The MRI revealed an adrenal adenoma measuring 1.2×1.8 cm. Laboratory evaluation revealed decreased morning ACTH levels, marginally increased urinary cortisol levels while morning cortisol levels were not suppressed after a low dose dexamethasone suppression test. Both patients did not have evidence of clinical Cushing's syndrome. Both patients were treated surgically for the adrenal adenoma. A year later laboratory evaluation revealed normal cortisol, urinary cortisol and morning ACTH levels. Osteoporosis improved after the excision of the adrenal adenoma. Bisphosphonates were discontinued. In conclusion, cortisol secreting adrenal adenomas may be a silent cause of osteoporosis. Osteoporosis resolves after surgical treatment of the adrenal adenoma.

Vitamin D intake is major determinant of the concentration of 25-hydroxyvitamin D in the serum of healthy postmenopausal women.

Kiyoko Nawata[1,2], Mika Yamauchi[1], Masahiro Yamamoto[1], Toshitsugu Sugimoto[3] & Keizo Kanasaki[1]
[1]Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan; [2]Health and Nutrition, The University of Shimane, Izumo, Japan; [3]Internal Medicine, Eikokai Ono Hospital, Ono, Japan

Objectives
The serum levels of 25-hydroxyvitamin D ([25 (OH) D]) is considered to be one of the most reliable biomarkers of vitamin D (VD) nutritional status. VD deficiency/insufficiency is a risk factor for osteoporotic fractures and falls. Even though established clinical significance of maintaining an adequate level of 25 (OH) D, the level of 25 (OH) D is easily fluctuated by diverse factors such as sunlight exposure, VD intake, renal function and body fat content. In addition, Fibroblast growth factor 23 (FGF23) has been shown to suppress and induce the conversion of 25 (OH) D to 1,25(OH)2D and to 24, 25 (OH)2D, respectively. These studies suggest that many other factors can influence the level of 25 (OH) D s. In the present study, we aimed to figure out factors that influence the level of 25 (OH) D in healthy postmenopausal women.
Methods
Two-hundred healthy postmenopausal women who had undergone osteoporosis screening were analyzed in this study. Serum levels of 25(OH)D, intact PTH, CTX, and FGF23 were measured. Bone mineral density (BMD) was measured using the DXA method at the lumbar vertebrae and femoral neck (FN). Nutrient intake was calculated using a food frequency questionnaire. Motor function tests included maximum step length (MSL), and grip strength.
Results
Mean values of age was 63.4 years with the following measurements: 25(OH)D 16.2±4.3 ng/ml, serum creatinine (Cr) 0.6±0.1 mg/dl, Ca intake 656±192 mg/day, VD intake 9.9±3.9 (range: 1.3–24.6) μg/day, MSL 102±13 cm, grip strength 21.8±4.5 kg, and the mean level of outdoor activity time 1.9±1.6 h (range: 0–7.0 h). The level of 25 (OH) D was significantly associated with the age and VD intake (P<0.001); unexpectedly the length of outdoor activity appeared to be insignificant association. Multiple regression analysis demonstrated that VD intake was associated with 25 (OH) D after adjusting for age, body mass index, body fat percentage, the levels of Ca, P, PTH, Cr, CTX, FGF23, BMD(FN), length of outdoor activity, other nutrients intake, MSL and grip strength (r=0.359, P=0.003).
Conclusion
VD intake significantly influenced the concentration of 25 (OH) D after adjusting for various factors including the body fat percentage and renal function. Our findings suggest that nutritional interventions focused on VD intake are important to ensure VD sufficiency.

Vertebral fractures as first clinical manifestation of systemic mastocytosis in a young man

Elena Dragan
Endocrinology, "Regina Maria" Private Healthcare Network, Bucharest, Romania

Introduction
Systemic mastocytosis is a form of mastocytosis in which mast cells accumulate in tissues and organs such as liver, spleen, bone and small intestines. Symptoms and signs differ based on which parts of the body are affected and

vary from asymptomatic forms to highly aggresive forms with low survival rate. About 16% of patients with systemic mastocytosis have symptomatic fractures, but the presentation of systemic mastocytosis with vertebral fractures as first clinical sign in young men is rare.
Case report
A 37-year old man presented to endocrinology department after being diagnosed with two vertebral fractures (T6, T8) as a consequence of lifting an object weighing 10 kg. He was treated conservatively by the orthopedic surgeon. After endocrinological evaluation, osteoporosis was confimed by measurement of bone mineral density, with a T-score of −3.7 s.d. and a *Z*-score of −3.7 s.d. at lumbar spine. All hormonal tests for secondary osteoporosis were normal, but the level of serum tryptase was elevated. The patient was referred to the hematology department, where bone marrow biopsy and KIT D816V mutation test confirmed the diagnosis of systemic mastocytosis.
Conclusion
Non-traumatic vertebral fractures in apparently healthy young adults should raise the suspicion of an underlying pathology. Early identification and treatment of systemic mastocytosis could delay the progression of disease and prevent sequelae.

Bone mineral density in patients with human immunodeficiency virus infection. Assessment of vitamin D status, treatment and other associated risk factors

Joaquin Puerma Ruiz[1], Alba Martín González[1], Jose Napky[1], Mercedes Gutiérrez Oliet[1], Gema Villa López[1], Rafael Rubio García[2], Federico Pulido[2], David Lora[3], Gonzalo Alló[1] & Guillermo Martínez Diaz-Guerra[1]
[1]Endocrinología y Nutrición, Hospital 12 De Octubre, Madrid, Spain; [2]Departamento de Enfermedades Infecciosas, Medicina Interna, Hospital 12 De Octubre, Madrid, Spain; [3]Hospital 12 De Octubre, Estadística e Investigación, Madrid, Spain

Introduction
In patients with human immunodeficiency virus (HIV) infection, the prevalence of osteoporosis is higher in comparison with the general population. Anti-retroviral therapy (ART) use seems to be a possible risk factor there is also high prevalence of vitamin D deficiency among people living with HIV.
Objectives
To describe bone mineral density (BMD) status in HIV-infected patients as well as its associated risk factors such as vit D levels.
Materials and methods
Retrospective observational study with a sample of 107 HIV-infected patients who underwent BMD evaluation.
Results
Baseline population results are summarized on the following table:

Características Basales	*n* (%), media (DS)
Males	79 (73.83%)
Age	55±7.3 años (a)
Weight	70.74±14.03 kg
Body mass index (BMI)	25.23±4.6 kg/m^2
Smokers	47 (43.9%)
Time since HIV-infected diagnosis	17.3±7.3 a
Antiretroviral therapy:	
• Tenofovir disproxil (TED)	91 (85%)
○ Treatment years	9.9±5.04 a
• Tenofovir alafenamide (TAF)	15 (14.01%)
○ Treatment years	1.83±2.12 a
• Protease inhibitors (PI)	31 (28.97%)
○ Treatment years	7.41±5.3 a
Parathyroid hormone (PTH)	47.5±26.5 ng/dl
Serum 25-OH-vitamin D (25-OH-VitD)	27±12.6 ng/ml
• Insufficiency (20–30 ng/ml)	43(40.1%)
• Deficiency (<20 ng/ml).	29 (27%)
Femoral neck	
• *T*-score	−1.3 ± 0.9
• *Z*-score	−0.5±0.9
Hip:	
• *T*-score	−0.8±0.8
• *Z*-score	−0.3±0.9
Lumbar spine:	
• *T*-score	−1.4±1.2
• *Z*-score	−0.8±1.25
Osteopenia:	
○ Femoral neck:	74 (69.1%)
○ Lumbar spine:	45 (42%)
Osteoporosis:	
○ Femoral neck:	10 (9.3%)
○ Lumbar spine:	20(18.6%)
Osteoporosis treatment	6 (5%) solo bifosfonatos
Vit D treatment	68 (63%)
Calcium supplements	2 (1.8%)
Evaluation by osteoporosis unit	21 (19.62%)

A statistically significant association was found between combined treatment with TED+PI and lower femoral neck and hip BMD and femoral neck osteopenia. Longer duration of treatment was associated with femoral neck osteopenia and lower BMD at the femoral neck and lumbar spine. 25-OH-VitD deficiency was associated with overall lower BMD at the femoral neck and hip.
Conclusions
HIV-infected patients show a high prevalence of osteopenia and osteoporosis. Combined use of TED+PI, longer duration of ART treatment and long-standing HIV infection could be possible risk factors for this finding. There is a high prevalence of vitamin D insufficiency/deficiency despite a high prescription of supplementation.

Fibrodysplasia ossificans progressiva: Cobbling together a treatment plan for a patient with osteomyelitis

Abilash Sathyanarayanan & David Hughes
Endocrinology and Metabolic Medicine, University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom

Introduction
We describe a patient with Fibrodysplasia ossificans progressiva (FOP) who developed an osteomyelitic neuropathic toe ulcer. This was treated effectively with conservative measures, but highlighted the need for multiprofessional working in managing patients with FOP.
Case
The patient's toe ulcer occurred in 2017 and was initially managed by community podiatry and orthopaedics. The patient received multiple courses of antibiotics for recurrent infection. In 2018 they were reviewed in an endocrine clinic for a different reason whereby the osteomyeltic ulcer was highlighted. At the time the orthopaedic team were contemplating surgical debridement of the toe under spinal anaesthesia. A request for the patient to be seen in the diabetes foot clinic as an exceptional non-diabetic case was made. Initial assessment determined that there was a fixed flexion ankle deformity secondary to the FOP which was causing pressure on the first and second toes. Occupational Therapy were unable to provide a temporary device to offload such deformity and the orthotic department were asked to design a bespoke moulded insole with orthotic shoe. The infection was treated with a prolonged course of oral antibiotics and regular reviews. The combination of effective antibiotics and orthotic offloading has resolved the ulcer and osteomyelitis.
Discussion
FOP is an rare autosomal dominant condition in which there is a tendency for muscle and connective tissue to be replaced with bone, particularly in response to trauma. Specific dilemmas arose during treatment of this patient in terms of surgical and anaesthetic considerations, radiological imaging,

monitoring for flares in FOP and subsequent advise to other professionals involved in the patients care, which recently included a dentist. The learning points from the management of this case could be applied to the treatment of other patients with similar challenges.

Effect of Denosumab on bone mineral density of hematopoietic stem cell transplantation recipients

Jeonghoon Ha & Moo Il Kang
Internal Medicine, The Catholic University of Korea, Seoul St Mary's Hospital, Republic of South Korea

Purpose
Denosumab is a monoclonal antibody that prevents osteoclast development. The effect of denosumab in solid organ transplant recipients has been elucidated, but the effect of denosumab in hematopoietic stem cell transplantation recipients has not been studied yet. Thus, the aim of this study was to determine the effectiveness and safety of denosumab in hematopoietic stem cell transplantation recipients.
Methods
We retrospectively evaluated 27 patients with osteoporosis (8 males and 19 females, mean age 53.6±12.8 years) following allogeneic hematopoietic stem cell transplantation. Patients were treated with denosumab every 6 months for 12 months. The period of time since previous transplantations ranged from 2 years to 14 years (mean: 5.1±2.7 years). Osteoporosis was diagnosed using dual energy X-ray absorptiometry. Bone mineral density was evaluated for denosumab-treated patients in a 12-month interval after the first administration of denosumab.
Results
Significant increases in bone mineral density were observed in all measured skeletal sites: 4.39±6.63% for the lumbar spine ($P=0.014$), 3.11±7.69% for the femoral neck ($P=0.048$), and 1.97±6.01% for the total hip ($P=0.138$). The bone turnover marker serum cross-linked C-terminal telopeptide of type 1 collagen decreased at 12 months, without significance (−6.67±31.57%, $P=0.58$). No serious symptomatic hypocalcemia was observed. However, asymptomatic hypocalcemia was noted in 2 (7.4%) patients. Serious adverse drug reactions requiring drug discontinuation were not observed.
Conclusion
Denosumab was well tolerated. It improved bone mineral density of hematopoietic stem cell transplantation recipients.

Synchronous parathyroid carcinoma and papillary thyroid carcinoma: A case report

Mehdi Kalthoum, Ibtissem Ben Nacef, Sabrine Mekni, Imen Rojbi, Nadia Mechirgui & Karima Khiari
Hospital Charles Nicolle, Tunis, Tunisia

Introduction
In 1974, the first case of concomitant thyroid and parathyroid disease was reported. Non-medullary thyroid carcinoma has been reported in 6% of patients with Primary hyperparathyroidism. However, the simultaneous occurrence of parathyroid carcinoma along with non-medullary thyroid carcinoma is extremely rare.
Case report
We report a case of 60-year-old woman with a history of Diabetes Mellitus type 2 and hypertension. She had no family history of thyroid cancer or multiple endocrine neoplasia type 1 or 2. She presented with symptoms of severe hypercalcemia with calcium level at 13.83 mg/l (8.8–10.4 mg/l) and had increased serum parathyroid hormone level (569 pg/ml). Physical examination revealed an approximately 3 cm left nodular thyroid without recurrent nerve palsy or cervical lymphadenopathy. A bone density test performed showed no evidence osteoporosis. On ultrasound of the neck, her thyroid was multinodular with a 4–10 mm highly hypoechoic nodules associated with a large nodule at the upper pole of the left thyroid which measured 3 cm. Technetium-99 m methoxyisobutylisonitrile (MIBI) cervical and mediastinal substraction scintigraphy scans revealed increased uptake of left polar superior area of thyroid. Blood and urine tests and calcitonin levels were normal, making multiple endocrine neoplasia type 2 very unlikely. The patient received a total thyroidectomy, left parathyroidectomy, and central and lateral cervical lymph node dissection were performed in consideration of extemporaneous histological examination suggestive of a papillary micro-carcinoma of the left lobe and the suspicious aspect of the 4 cm parathyroid formation which was hard and adherent to the thyroid and difficult to dissect from the vascular axis. The definitive anatomopathological examination of the operative specimen showed a bifocal papillary micro carcinoma with vesicular component. The left parathyroid gland was the site of significant multinodular hyperplasia with central nodule involvement with vascular emboli and capsular invasion. Considering the severity of the hypercalcemia and macroscopic appearance as well as the histological aspect, the diagnosis of parathyroid carcinoma was retained. Postoperatively, the patient had normocalcemia in conjunction with PTH levels measured 30 pg/ml. Investigations showed no distant metastasis.
Conclusion
In conclusion incidence of primary hyperparathyroidism due to parathyroid carcinoma along with non-medullary thyroid carcinoma is extremely rare. In patients with severe hypercalcemia, parathyroid carcinoma should be considered a possible underlying cause, and if the operative finding supports the suspicion of parathyroid carcinoma, an en bloc resection of the parathyroid tumor and the adjacent thyroid lobe should be performed.

Epilepsy – Fahr syndrome – Primary hypoparathyroidism: A diagnostic journey

Miruna Maria Popa[1,2], Liviu Popa[3], Simona Petrescu[3], Monica-Mirela Pana[1], Anca Sirbu[1,2] & Fica Simona[1,2]
[1]Endocrinology, Elias Emergency University Hospital, Bucharest, Romania; [2]Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Neurology, Elias Emergency University Hospital, Bucharest, Romania

Background
Fahr syndrome is a rare entity characterized by symmetrical bilateral brain calcifications, involving basal ganglia (mainly), thalami, dentate nuclei and the cerebral and cerebellar white matter. Progressive neurologic dysfunction and other neuropsychiatric disorders are characteristic. Endocrine disorders which may present with Fahr syndrome include parathyroid dysfunction (hypoparathyroidism especially, but also pseudohypoparathyroidism, pseudopseudohypoparathyroidism and hyperparathyroidism) and vitamin D deficiency.
Case report
We present the case of a 22-year-old male patient, referred for evaluation from the Neurology department. He came from non-cosanguineous parents, had a healthy 15-year-old sister and the mother reported normal pregnancy, delivery and development; at age 7, he was diagnosed with epilepsy with generalized tonic–clonic seizures, following an episode of infectious meningo-encephalitis. He received various antiepileptic drugs during the following years (carbamazepine, valproic acid, levetiracetam) with weak seizure control. From the patient's medical history, we highlight recurrent episodes of hypocalcemia (e.g. 3.26 mg/dl (8.4–10.2) at age 9), right eye surgery for posterior subcapsular cataract at age 21 and mild mental impairment. Despite being advised to seek endocrinological assessment, the mother failed to do so. During neurologic evaluation, brain scan revealed extensive symmetrical calcifications, concerning basal ganglia, thalami, dentate nuclei, cerebral and cerebellar white matter, highly suggestive for Fahr syndrome. Physical examination revealed resting and intentional tremor, tetra-ataxia and cogwheel rigidity. EEG revealed non-specific changes. On admission in our clinic, calcium levels were 4.36 mg/dl (normoalbuminemia), phosphate 10 mg/dl (2.5–4.5), magnesium 1.41 mg/dl (1.6–2.6), 24 h calciuria 69 mg (5–300) and parathormone 2.66 pg/ml (15–65). Vitamin D was normal and no other hormone deficiencies, nor thyroid autoimmunity were associated. Ophtalmologic examination revealed posterior subcapsular left eye cataract, with surgical treatment indication. A diagnosis of primary hypoparathyroidism (PH) was established and treatment with alphacalcidol, calcium and magnesium supplements, along with valproic acid and levetiracetam was recommended. 6 months later, the patient demonstrated normal calcium and magnesium levels, a phosphate of 5.7 mg/dl, marked amelioration of tremor and reported seizure cessation. He received indications for gradual valproate withdrawal, but given the extensive nature of cerebral calcifications and the persistence of non-specific EEG changes, chronic levetiracetam treatment was recommended.

Discussions and conclusion
PH may associate Fahr syndrome, along with chronic hypocalcemia, both of which may trigger epileptic seizures. Diagnosing PH in an already complicated form, in context of longstanding intractable epilepsy is rare and undesirable, but timely treatment may greatly improve epileptic manifestations, in spite of extensive cerebral calcifications and is essential in order to avoid further aggravation.

Hyperparathyroidism in the internal medicine department

Wiem Saafi, Wissal Ben Yehia, Zeineb Jerbi, Ahmed Guiga, Ahmed Bouker, Amira Atig & Neirouz Gannouchi
Farhat Hached University Hospital, Internal Medicine, Sousse, Tunisia

Introduction
Hyperparathyroidism is defined by excessive secretion of parathyroid hormone (PTH) that is responsible for calcium regulation. Hyperparathyroidism can be primary in which the gland is affected and it produces PTH excessively or secondary or tertiary that cause hypersecretion of PTH as a regulatory response. The aim of our study was to describe patients with hyperparathyroidise diagnosed in internal medicine departement.
Methods
It was a retrospective descriptive study about patients hospitalized in the internal medicine ward between 2009 and 2019 and diagnosed with hyperparathyroidism.
Results
our study interested 12 patients with 3 men and 9 women. Mean age was 58 [35–80]. Three of them were hospitalized for malignant hypercalcemia. The other causes of hospitalisations were: flush Syndrom ($n=1$), severe malabsorption ($n=1$), profound anemia ($n=1$), deterioration of the general status ($n=3$) and a diagnosed systemic disease ($n=3$). Medical history included kidney failure($n=7$) ,hypertension($n=3$), diabetes($n=2$),urinary lithiasis($n=2$), cardiac rhythm disorders ($n=3$) and one of the patients had several episodes of pancreatitis.
– primary hyperparathyroidism was diagnosed in five patients.
– secondary hyperparathyroidism caused by kidney failure was diagnosed in 6 patients and the cause – was severe malabsorption due to coeliac disease in one case.
– general manifestations were the most to be found :weigh loss and asthenia ($n=10$) Digestive signs such as epigastric pain and nausea ($n=8$) with two cases of chronic gastritis.
Cervical echography showed the presence of thyroid nodule in five cases, with hypothyroidism for one of them. For one patient we found microprolactinoma and she is suspected to be a case of NEM1. Patients with primary hyperparathyroidism went through surgery with positive outcomes, when in secondary hyperparathyroidism calcium substitution was initiated.
Conclusion
Hyperparathyroidism is a common endocrine disease that can be asymptomatic or can be present with non-specific signs, but it can have severe manifestations and complications. It is frequent in adults and the elderly. This disease should be recognized at early stages to initiate optimal therapeutic strategy and have better outcomes such as reduced cardiovascular disease and improved survival.

Primary hyperparathyroidism and Gougerot disease: A case report

Sabrine Mekni, Ibtissem Ben Nacef, Imen Rojbi, Faten Cherchir, Nadia Mchirgui, Youssef Lakhoua & Karima Khiari
Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia

Introduction
Gougerot disease is an autoimmune disorder characterized by the lymphoid infiltration of salivary and lachrymal glands leading to the two most common symptoms dry eyes and a dry mouth. Primary hyperparathyroidism (PHPT), one of the most common endocrine disorders, is usually diagnosed by the association of hypercalcemia and parathyroid hormone (PTH) levels that are either elevated or inappropriately normal. The association of PHPT with Gougerot disease is rare, only few cases were reported in the literature. Herein we report the case of a female patient diagnosed with PHPT and Gougerot Disease.
Observation
A 60-year-old woman with no past medical history was admitted to our department to explore hypercalcemia and renal failure. The aboratory investigations revealed severe hypercalcemia (3.6 mmol/l), hypophosphatemia (0.54 mmol/l), and elevated PTH level (569 pg/ml). Cervical ultrasonography showed no parathyroid lesion but sestamibi sintigraphy reveled a voluminous left superior parathyroid adenoma. A surgical treatment of the parathyroid adenoma was then performed. However, the patient complained of dry eyes and a dry mouth of few month of duration. The diagnosis of Gougerot disease was confirmed by the association of xerostomy; anti-SSa- and anti-SSb-positive, and Chisholm stage IV lymphocytic sialadenitis. The etiological investigation confirmed a primary Gougerot disease.
Conclusion
The association between PHPT and Gougerot disease is reported in literature but up to date no etiopathogenetic links between the two affections were found.

Idiopathic Hypoparathyroidism – An uncommon cause of a chest pain

Stefan Zechmann, Susan Felder, Emanuel Christ & Eliska Potlukova
Universitätsspital Basel, Klinik für Endokrinologie, Diabetologie und Metabolismus, Universitätsspital Basel, Basel, Switzerland

Introduction
Hypocalcemia has been linked to a decreased myocardial performance and even congestive heart failure, while acute chest-pain as leading symptom of hypocalcemia is an unusual presentation.
Case report
A 29-year-old Caucasian man presented to the emergency department with relapsing chest-pain since several days, lasting seconds sometimes lasting several minutes, radiating to the left shoulder and combined with mild tingling in the neck. A detailed history revealed occasional muscle cramps on exercise or due to long sitting in one position. The patient also felt tired and had sleep disturbances. His medical history was unremarkable and he never underwent an operation. In the family history, nephrolithiasis in the grandfather and the great-grand father was striking. The initial physical examination revealed no pathologies, the blood pressure and heart rate were normal. The ECG showed a prolonged QTc of 465 ms but was otherwise unremarkable. The laboratory findings showed normal results (complete blood count, renal and liver function tests, markers of inflammation, high sensitive Troponin T and D-dimers) except of a severe hypocalcemia (total calcium: 1.42 nmol/l albumin-adjusted: of 1.5 nmol/l, ionized 0.76 nmol/l) and hyperphosphatemia of 2.09 nmol/l. Further tests revealed a magnesemia of 0.7 nmol/l, a Vitamin-D of 27 nmol/l and iPTH of 14.9 ng/l (reference range: 15.0–65.0 ng/l). The TSH was 1.68 mIU/l; the urinary excretion of calcium (0.8 mmol/l) was low. Based on these results, we established a diagnosis of idiopathic hypoparathyroidism and started a therapy with calcitriol (initial dose 0.25 µg twice daily, later increased to 0.25 µg three times a day) and calcium and magnesium supplementation (2 g/d and 10 mmol/d, respectively). Already the next day on the therapy, the symptoms vanished and the patient could be discharged. In further follow-up, normal calcium and phosphate values could be reached. Screening for possible associated organ-specific autoimmune diseases was negative and there were no signs of candidiasis. There were no signs of hemochromatosis or infiltrative/granulomatous disease.
Discussion
Here we present a rare case of idiopathic hypoparathyroidism which probably proceeded over years until presentation with severe relapsing chest pain. Chronic severe hypocalcemia can present like an acute coronary syndrome. The cause remains unclear; a possible autoimmune background cannot be excluded.

Nonmedullary hypercalcitoninemia in a hypocalcemic patient: Shoud we look at serum calcitonin level in the differantial diagnosis of hypocalcemia?

Himmet Durmaz, Cevdet Aydin, Konul Ahmadova, Ahmet Dirikoc, Reyhan Ersoy & Bekir Cakir
Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara

Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey

Background
Although high levels of calcitonin suggest neoplastic proliferations such as medullary thyroid carcinoma, C cell hyperplasia and some neuroendocrine tumors, systemic diseases and drugs may also elevate calcitonin. Although calcitonin is not as effective as PTH, it has got a role in calcium hemoastasis. Supraphysiological calcitonin level can lead to hypocalcemia.
Case presentation
A 57-year-old male patient was diagnosed with epilepsy with complaints of contraction in the body at the age of 16. Phenytoin therapy was started. He had no epileptic seizures for 13 years. Basal ganglia calcification was detected in brain CT which had been taken when he had muscle contractions while he had been hospitalized for measles in 1992. Calcium: 6.9 mg/dl phosphorus: 5.3 mg/dl albumin: 4.7 g/dl, parathormone: 499 pmol/l (219–659) calcitonin: 145 (0–50) was measured and hypoparathyroidism was diagnosed. Calcitriol and calcium carbonate treatment had been started. In another medical center it was thought that he had pseudohipoparathyroidism, because calcium was normal, vitamin D and parathormone were high while he was not taking calcium replacement treatment. He came to outpatient clinic in 2018 while he was taking 2000 mg oral calcium carbonate treatment. Calcium: 8.9 mg/dl (8.7–10.4) phosphorus:3.5 mg/dl albumin:4.5 g/dl, parathormone: 41 ng/l (18–80), 25-OH vitamin D: 41 ng/ml (25–80), 1,25OH vitamin D: 24.1 pg/ml (18–64) kalsitonin:117 ng/l (<8.4) was measured. Pseudohipoparathyroidism wasn't considered with clinical findings. The control calcitonin value was 144, and the highest calcitonin value was 323. Thyroid USG and CEA levels were normal. He had no medullary thyroid carcinoma history in the family. CDKN1B, RET, menin gene analysis were normal. 24-h urinary calcium was 55 mg/day. The heterophile antibody examined by the PEG precipitation method and heterophile antibody-coated tube was negative. No pathological lesions were detected in GA-68 DOTA peptide imaging performed for possible neuroendocrine tumor.
Conclusion
In cases of hypercalcitoninemia, C cell neoplasms should be investigated primarily. In this case, medullary thyroid carcinoma was not considered with the current findings. Due to the coexistence of hypocalcemia and endogenous hypercalcitonemia, the possibility of autosomal dominant hypocalcemia was considered in which calcium sensing receptor activation is playing a role. However, hypocalcuria was interpreted against this possibility. In case of low/normal parathormone in the etiology of hypocalcemia, it is also suggested to measure the calcitonin level.

Management of primary hyperparathyroidism in pregnancy

Nurcan Ince[1], Burçak Helvaci[2], Özgür Özçelik[2], Mehmet Kiliç[3], Cevdet Aydin[1] & Oya Topaloglu[1]
[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Cllinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Cllinics of Endocrinology and Metabolism, Ankara, Turkey; [3]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of General Surgery, Ankara, Turkey

Introduction
In pregnancy, the incidence of Primary Hyperparathyroidism is 1%; and there are 80% adenoma, 15% parathyroid hyperplasia, 3% multiple adenoma, and 1% parathyroid carcinoma in its etiology. In pregnancy, serum calcium (Ca) levels may not rise as much as expected. This is associated with hypoalbuminemia, GFR increase, placental Ca transfer, and inhibition of PTH–related bone resorption by estrogen. In pregnancy, hyperparathyroidism is asymptomatic at a rate of 25–80%. In pregnancies that are complicated with primary hyperparathyroidism, 67% maternal and 80% fetal/neonatal complications were reported in previous studies. In this case report, a pregnant patient who was followed-up due to primary hyperparathyroidism has been presented.
Case
A 34-year-old female patient, who had a history of operation in 2013 and 2018 because of nephrolithiasis, was referred to our clinic in January 2019 because of hypercalcemia. The patient had Ca:11.66 mg/dl (8.7–10.4 mg/dl), Pth:163 ng/l (18.4–80.1 ng/l), P:2.74 mg/dl (2.4–5.1 mg/dl), alb: 48 g/l (32–48 g/l). The Ca elimination in 24-hour urine was 131 mg/day. In the USG, Hypoechoic nodular formation was detected outside the left lobe inferior thyroid area (LAP? PARATHYROID ADENOMA?); and there was a finding that was consistent with adenoma in the same localization in the MIBI. The Z score of the patient was consistent with age and gender. In renal USI, 5–mm diameter stone was detected in the right kidney. Hormonal evaluation was made in terms of multiple endocrine neoplasia. Sampling was made for genetics. When the genetic results were expected, it was determined that the patient was pregnant in May 2019. The patient who had Ca: 11 mg/dl (8.7–10.4 mg/dl), alb:41 g/l (32–48 g/l), P: 2.1 mg/dl (2.4–5.1 mg/dl), was admitted to the Endocrine Service on 20/06/2019. The patient was given oral and iv hydration after which it was detected that Ca:9.910.5 mg/dl (D.Ca: 9.9–10.5 mg/dl). Parathyroid adenectomy+left thyroid lobectomy surgery was performed on 16/7/19 while the patient was still pregnant at 23 weeks. Her pathology resulted as Parathyroid Adenoma. After the operation, Ca: 8.8 mg/dl (8.7–10.4 mg/dl), dCa: 9.2 mg/dl, mg: 1.4 mg/dl (1.3–2.7 mg/dl), PTH 26 ng/l (18.4–80.1 ng/l), were detected. When the patient was at 39th week, she gave birth to a 2.500–kg girl with a caesarean section on 20/11/2019.
Conclusion
The decision to medical or surgical treatment of Primary Hyperparathyroidism in pregnant women is based on the evaluation of the risks by the endocrinologist and the obstetrician. The definitive treatment is surgery. Serum Ca: 2.75 mmol/l (11 mg/dl) and/or hypercalcemia is recommended for the treatment of maternal or fetal complications. Surgery is recommended in the 2nd trimester.

A case of hypoparathyroidism, sensorineural deafness and renal disease (HDR) syndrome in a boy carrying a novel mutation of GATA3 gene

Laura Mazoni[1], Matteo Apicella[1], Simona Borsari[1], Chiara Banti[1], Angela Michelucci[2], Maria Adelaide Caligo[2], Filomena Cetani[3] & Claudio Marcocci[1]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Molecular Genetic Unit, Pisa, Italy; [3]University of Pisa, Endocrine 2 Unit, Pisa, Italy

HDR syndrome is a rare condition with an autosomic dominant inheritance, firstly described in 1977. It is due to a mutation of *GATA3* gene, a transcription factor expressed in parathyroid, inner ear, kidney, central nervous system and T lymphocytes. The most common manifestation is neurosensorial deaf, secondary to progressive degeneration of coclear cells. Hypoparathyroidism is present in 90% of patients that can be asymptomatic or, sometimes presents with neuromuscular, cardiac or cognitive symptoms. Kidney manifestions namely renal hypoplasia, renal cysts, tubular acidosis are less common. Other rarer manifestations are neurological and genital malformations, psoriasis and intestinal, cardiac and craniofacial defects. We report the case of a 17 yrs-old boy, who was referred to our Department in May 2018 for hypocalcemia incidentally detected at routine blood tests. The clinical history was unremarkable except for sporadic paresthesia. He successfully played agonistic sport. No cognitive symptoms were present, At physical examination he appeared in good general condition without cleft palate or signs of chronic candidiasis. Trousseau and Chvosteck signs were positive. Biochemical evaluation showed a severe hypocalcemia [albumin–corrected serum calcium 5.3 mg/dl (8.6–10.2) and ionized calcium 0.62 mmol/l (1.13–1.32)], undetectable PTH levels [< 4 pg/ml (8–40)] and normal 25–OH vitamin D level [26.6 µg/l]. He had since age 12 psoriasis treated with topical therapy. Computed tomography displayed multiple cerebral calcifications. Abdomen ultrasound and magnetic resonance imaging showed multiple renal cysts, the largest of which was 6.5 cm. Audiometric examination exhibited a sensorineural hearing loss. No cardiac alterations were detected at ECG and echocardiography. Taking into account the clinical and biochemical data an *HDR* syndrome was suspected. due to a mutation of *GATA3* gene was suspected. Family history was remarkable for hypocalcemic disorders. Genetic analysis of *GATA 3* gene in the proband showed a heterozygous mutation in exon 3 (c.404dupC) leading to a frameshift and a truncated protein (p.Ala136GlyfsTer168).The mutation was not identified in the proband parent's indicating that the mutation was "de novo". In conclusion, we describe a case of sporadic hypoparathyroidism due to HDR syndrome. This condition, although rare, must be suspected on the basis of clinical evidences and confirmed with genetic analysis. Our patient in on treatment with calcium carbonate and calcitriol, with a good control of serum calcium level and 24 h–urinary calcium excretion.

Use of alfacalcidol and teriparatide for postsurgical hypoparathyroidism in a patient with gastrostomy and toxicity after systemic antineoplastic therapy: A case report

Elvira Barrio[1], Elvira Ramos[1], Clara Marcuello[1], Mario Pazos[1], Raquel Pallarés[1], Celia López[1], Natalia Pérez[1], Santiago Cabezas[2], Miguel Ángel Rubio[1] & Pilar Matía[1]
[1]Hospital Clinico Universitario San Carlos, Department of Endocrinology & Nutrition, Madrid, Spain; [2]Hospital Clinico Universitario San Carlos, Department of Oncology, Madrid, Spain

Introduction
Post-surgical hypoparathyroidism (PSHP) is a frequent complication following ENT surgery. Some patients with head/neck cancers require enteral nutrition (EN) due to dysphagia, mucositis after radiotherapy or chemotherapy, or post-surgical anatomical complications. Formulas of calcitriol are not suitable to be administered via enteral feeding tubes, and side effects of systemic antineoplastic treatment (nausea, vomiting) make calcium and phosphate serum levels difficult to maintain in the presence of PSHP.
Case Report
We present the case of a 44–year–old male with a squamous cell carcinoma of the vocal cord stage IIIB (T3N1M0) treated with radiotherapy and chemotherapy until February 2018. After eight months he presented with local relapse. Total laryngectomy, partial esophagostomy and total thyroidectomy were performed. Due to a laryngo-pharyngeal fistula with multiple failed surgical attempts of closure associating long-term dysphagia, a percutaneous radiologic gastrostomy (PRG) was placed. The Endocrinology department was consulted for management of hypothyroidism and PSHP requiring intravenous calcium supplementation, with the following laboratory results: calcium (corrected) 6 mg/dl (8.5–10.5), phosphate 4.1 mg/dl(2.5–4.5), magnesium 1.8 mg/dl (1.72.6), 25OH-vitamin D 24.8 ng/ml(30–100), iPTH 7.2 pg/ml (15–65), TSH 52.54 uIU/ml (0.38–5.33), FT4 5.4 pg/ml(5.8–16.4). Treatment via PRG was initiated with alfacalcidol 2 μg/ml (Etalpha): 2 μg/24 h; calcium acetate 500 mg–127 mg elemental calcium (Royen):1500 mg/8 h (1143 mg elemental calcium/24 h); magnesium lactate 97.24 mg/24 h; levothyroxine 150 μg/24 h. After 20 days of treatment: calcium 8.2 mg/dl, phosphate 4.1 mg/dl, magnesium 1.7 mg/dl, 25OH-vitamin D 32.7 ng/ml, calciuria 0.11 mg/ mgCr24h, TSH 4.15 uIU/ml, FT4 9.62 pg/ml. After twelve months he received chemotherapy due to local relapse, subsequently presenting with emesis and positive Trousseau sign, calcium 6.9 mg/dl, phosphate 6.2 mg/dl, magnesium 1.5 mg/dl, iPTH 5.6 pg/ml. Symptomatic hypocalcemia was persistent despite intravenous calcium supplementation. Off–label treatment was initiated with teriparatide (Forsteo):20 μg/24 h subcutaneous, initially simultaneous with intravenous calcium. After 15 days: calcium 8.5 mg/dl, phosphate 3.3 mg/dl, magnesium 1.5 mg/dl, which allowed for ceasing intravenous calcium and weaning enteral supply of calcium and vitamin D.
Discussion
Management of PSHP in patients with dysphagia is complex due to the contraindication to administer calcitriol via gastrostomy. Alfacalcidol is an active form of vitamin D with 1-hydroxlation requiring hepatic 25-hydroxilation (PTH-independent), and can be administered via gastrostomy. Despite minimal experience with its use, it was effective in our patient for the management of hypocalcemia until the later appearance of chemotherapy-related emesis. Teriparatide is recombinant human PTH (1–34) currently approved for treatment of osteoporosis in postmenopausal women. However, teriparatide may be used off-label in certain patients with hypoparathyroidism who cannot tolerate oral nor enteral calcium and vitamin D in order to achieve and maintain calcium-phosphate homeostasis.

Subtotal parathyroidectomy for the treatment of tertiary hyperparathyroidism

Nuno Cordeiro Raposo, Nadia Mourinho Bala, Sónia Pratas & Cristina Valadas
Hospital Beatriz Ângelo, Endocrinology, Loures, Portugal

Tertiary hyperparathyroidism reflects parathyroid hyperplasia, with autonomous secretion of parathyroid hormone (PTH), in spite of high plasma calcium concentration. Parathyroidectomy is an efficient therapy for stabilization of calcium and PTH metabolism in patients with end-stage kidney disease.
We report a case of a 68-year old man with end-stage kidney disease under hemodialysis for nine years, due to long-standing uncontrolled hypertension. He presented with high total plasma calcium levels (11.0 mg/dl) and high serum PTH (2638 pg/ml), regardless of therapy with cinacalcet. Parathyroid scintigraphy revealed a hyperfunctioning lower right parathyroid. Cervical CT-scan was consistent with enlargement of both right and left inferior parathyroid glands. Patient underwent successful subtotal parathyroidectomy, with reduction in intra-operative PTH from 2996 pg/ml to 364 pg/ml. After surgery plasma calcium levels fell to 7.1 mg/dl, but remained stable afterwards under supplementation with calcium carbonate and calcitriol.
Refractory hyperparathyroidism in patients with end-stage kidney disease is associated with bone and joint pain and/or fractures, muscle weakness, extraskeletal calcification and calciphylaxis. Parathyroidectomy ameliorates symptoms and stabilizes calcium and phosphorus levels, as seen in this case.

A case of hyperparathyroidism due to ntrathorcic lipoadenoma

Cristina Montalban Mendez, Paloma González Lázaro, Cristina Contreras Pascual, Antonio Moreno Tirado, Julia Silva Fernández, Francisco Javier Gómez Alfonso & Inés Gómez García
Alcázar de San Juan, Endocrinology, Alcázar de San Juan, Spain

Lipoadenoma is an uncommon benign lesión of the parathyroid gland (<1%) and it has most commonly described as non-functional, but also is a very rare cause of primary hyperparathyroidism. Since 1958 scientific literatura had described 54 cases all over the world and only six of that paratyroid lipoadenomas was extended into torax. A case of intrathoracic parathyroid lipoadenoma with hyperparathyroidism is described. A 69–year–old man was refered to our hospital for hypercalcemia and primary hyperparathyroidism. By that time he was asymptomatic and was only treated with enalapril 10 mg per day. Laboratory tests revealed hypercalcemia (11.7 mg/dl), hypercalciuria (24 h urine calcium=574 mg/day), hypophosphatemia (2.0 mg/dl), elevated serum parathyroid hormone level (PTH=284.8 pg/dl), low 25 hydroxy vitamin D (25 OH D=9 pg/ml) and glomerular filtration rate (GFR)=79 ml/min. Parathyroid technetium–99n sestamibi scintigraphy failed to detect increased activity in the right lower pole of the thyroid, and that abnormal lession was extending into the superior mediastinum. SPECT–TC showed a nodule 45×24×62 mm hyperfunctioning behind the right thyroid lobe and extended into medistinum.
The patient accepted the surgery, so the tumor was excised. His serum calcium flollowing successfull inferior right parathyroidectomy was 9.6 mg/dl. After surgery, serum Calcium and PTH normalized to 8.5 mg/dl and 41.7 pg/dl respectively.
The pathological diagnosis was parathyroid lipoadenoma with abundant adipose and nests of chief cells.

Parathyroid cancer: Clinical case

Natalya Volkova, Ilya Davidenko, Irina Dzherieva, Alexander Zibarev, Lilia Ganenko, Igor Reshetnikov, Julia Sorokina & Julia Degtyareva
Rostov State Medical University, Rostov, Russian Federation

Background
Parathyroid cancer is a rare pathology, approximately 2 cases per 10, 000, 000 people/year. The five-year survival rate for this disease ranges from 20–85%, and the ten-year survival rate is approximately 15–80%. Timely detection and compliance with algorithms for parathyroid gland cancer diagnostics allows surgical treatment and maximum positive prognosis for patient.
Clinical cаse
Patient 18 y.o., was presented with complaints to aching pains in the bones and joints, repeated fractures of the bones with a fall from the height of the body. It was found out from medical history that patient marked this complaints at 2016. Youthful osteochondrosis was diagnosed by orthopedist of the large and small tibia, symptomatic therapy was performed without improvement. A fracture of the ulnar bone of the left arm was occurred after fall from the height of his own growth. A swelling in the anterior region of 1, 2, 3 ribs on the right, when chest radiography was performed and myeloma was suspected. On the results of myelography this pathology was excluded. Intensive accumulation of the drug in the bones of the cranial vault was not-

ed on osteoscintigraphy, thus primary hyperparathyroidism was suspected.
Patient was hospitalized. Increased levels of PTH (2252 pg/ml), total calcium (3.06 mmol/l) and calcium ionized (1.66 nmol/l) were determined. At palpation, thyroid gland was enlarged, elastic volumetric formation is palpable on the right, so ultrasonography of thyroid and parathyroid glands was performed. At the result volumetric formation behind a capsule of the thyroid gland 35 × 32 mm in size was found. The tumor from the follicular epithelium was verified by fine needle aspiration biopsy, probably it was an adenoma. According to scintigraphy with 99 mTc, signs of large hyperfunction formation of parathyroid tissue / probably originating from the left lower parathyroid gland.
Thus, primary hyperparathyroidism was verified and surgical treatment was recommended.
The left lower parathyroid gland with a tumor was removed. According to histological study, parathyroid cancer was detected with foci of invasion into the tumor capsule.
Patient was discharged from the hospital with the final diagnosis of "Carcinoma of the left lower parathyroid gland" and recommendations: control of ionized calcium, phosphorus, PTH after 1 week.
Conclusion
This clinical case demonstrates that the correct interpreting of a clinical picture and keeping of algorithms of diagnostics allowed well-timed to tap parathyroid cancer of the young man and to carry out surgical treatment that allows hoping for the most positive forecast for this patient.

EP107

Ectopic parathyroid hormone secretion by a squamous cell carcinoma of the floor of the mouth with poor response to cinacalcet

Ismene Bilbao, Nerea Egaña, Jorge Rojo, Cristina Garcia, Izaskun Olaizola, Leire Agea, Maite Aranburu, Alfredo Yoldi & Miguel Goena
Hospital Universitario Donostia, Endocrinology, Spain

Introduction
Ectopic PTH secretion is rare, to our knowledge, with only 27 cases reported in the literature and 3, (a tonsil, a lung and a penile) due to squamous cell carcinoma .In the few cases reported to date it appears to be more common in males and in those over the age of 60. The management of the hypercalcemia in this setting is complicated. We are aware of 2 other case reports in which cinacalcet was used in this context, but as in our case, unsuccessfully.
Case Report
A 75 year old man, with a previous history of a stage IVA(T4a N0M0) squamous cell carcinoma of the floor of the mouth that was in progression 2 months prior to being admitted, presenting a 1 week history of malaise due to severe hypercalcemia(previous levels were normal) The patient did not have evidence of bony metastatic disease on imaging studies. Further laboratory evaluation revealed PTHrP of < 1.1 pmol/l (0–1.5), increase PTH level of 404 pg/ml (10–65), and 25-OH vitamin D level of 16 ng/ml (30–80), 1.25 Dihidroxi vitamin D 37 pg/ml (25–66), consistent with PTH dependent hypercalcemia Ultrasonography, Technetium 99 scanning, and CT examination of the neck and chest failed to identify adenoma, hyperplasia or an ectopic parathyroid gland. We therefore considered the possibility of an ectopic source of PTH. Immunohistochemical staining for PTH in cytology was attempted in our patient, however this was negative .This result may have been due to the quality of the sample .A biopsy of the primary mass was not performed as the procedure was not in the best interest of the patient due to the patient's rapidly worsening condition. Inspite of therapy with fluids, cinacalcet, zolendronic acid, the patient remained hypercalcemic, observing an increase in PTH as an "escape phenomenon" . The patient died a month after his diagnosis.
Conclusion
It is important to look for alternative etiologies in cases of hypercalcemia in the setting of malignancy including both PTHrp related and paraneoplastic ectopic secretion of PTH.
The management of the hypercalcemia in this setting is complicated and often times associated to poor prognosis. A better prognosis and management of hypercalcemia in this context, is related to the treatment of the malignancy, with surgery or chemotherapy. More studies are needed to determine whether there is a role for calcimimetics in this context.

Sequential treatment of osteoporosis: Our clinical experience

Dana Michalska & VIT Zikan
General Faculty Hospital, 3rd Departure of Internal Medicine, Prague, Czech Republic

Backgroud
When considering treatment of patients with severe osteoporosis (after previously failed antiresorptive treatment) or patients with glucocorticoid–induced osteoporosis, it is suitable to choose treatment by teriparatide (TPTD, rhPTH 1–34). In contrast to long–term treatment by bisphosphonates (BP) or denosumab (DMAB), the treatment with TPTD increases the volume of trabecular bone and the thickness of cortical bone. The recommended length of treatment is 24 months necessarily followed by an antiresorptive treatment in order to prevent loss of newly gained bone mass.
Methods
The study sample included women with severe postmenopausal osteoporosis (PMO, $n=14$) and patients with glucocorticoid-induced osteoporosis (GIO, $n=37$) who finished two-year TPTD treatment. At baseline visit (after discontinuation of TPTD treatment) were measured BMD of lumbar spine, hip and distal forearm and biochemical markers of bone turnover (serum intact amino-terminal propeptide of type I procollagen, type 1 collagen cross-linked C-telopeptide). A follow-up visit was performed anually during treatment by DMAB (Prolia 60 mg s.c. once per 6 months) or treatment by risedronate (Risendros tablets 35 mg/weekly). All patients received vitamin D substitution (cholecalciferol 1000–4000 IU/daily) and calcium (500–1000 mg/daily).
Results
Patients with PMO treated with TPTD for 2 years followed by 4 years of DMAB treatment ($n=14$) increased lumbar spine BMD +19.5% and total femur BMD+6.2% during the 6–year study period. Patients with GIO treated by DMAB ($n=10$) increased lumbar spine BMD+11.7% and total femur BMD+4.5% in the same period. The group of patients with GIO treated by risedronate ($n=27$) gained 9.7% in the lumbar spine BMD and 2.5% in total femur BMD during this period. The TPTD treatment invoked comparable increase in lumbar spine BMD and total femur BMD in both PMO and GIO patients in the first two years of the study. The following 4 years of DMAB treatment induced notably higher increase in lumbar spine BMD and total femur BMD in PMO patients compared to GIO patients. Treatment with risedronate resulted in a comparable increase in lumbar spine BMD in GIO patients, but a decrease in total femur BMD after the first year of treatment was detected.
Conclusion
Results from non-selective group of patients from ordinary clinical practice demonstrated that the response to treatment is significantly influenced by other risk factors (e.g. treatment of glucocorticoids, immobility, etc.) For patients with a very high risk of fragility fracture, the sequential treatment with TPTD should be the primary osteoporosis treatment choice.

Hip fracture and the brown tumors as clinical manifestation of primary hyperparathyroidism in late reproductive age woman: Case report.

Liubov Yanevskaya[1], Tatiana Karonova[1, 2], Karina Pogosian[1], Daria Ryzhkova[1] & Elena Grineva[1, 2]
[1]National Medical Research Center. VA Almazov, Sankt–Peterburg, Russian Federation; [2]Pavlov First State Medical University of Street. Petersburg, Sankt–Peterburg, Russian Federation

Purpose
Primary hyperparathyroidism (PHPT) is the third common endocrine disorder which often manifest with skeletal or renal disfunction. In developed countries asymptomatic form is the most common and such severe manifestations as osteofibrosis cystica are very rare.
Clinical case
We present the case of 49-years-75 × 66 old caucasian woman, with history of urolithiasis, nephrolithotripsy in 2014. In November 2016 she was diagnosed with left femur fracture. The X-ray showed multiple lesions of bone resorption in the right radius, left and right femurs, left humerus and pelvic bones. Locked intramedullary osteosynthesis was performed. In spring 2017 limitation of mobility in right forearm and severe bone pain appeared. The PTH level was 1859 pg/ml (15–65), serum ionized calcium level was 2.20 (1.11–1.32). Bone scan showed lesions of increased uptake in skull, pelvic, right forearm bones and in femurs. CT–scan showed multiple massive

tumor-like deformities of the left ilium and nadacetular region measuring 75 × 66 × 42 mm (+ 22 HU), of the right pubic bone and the right acetabulum measuring 40 × 37 × 31 mm, of the right radius distal metaepiphysis measuring 28 × 25 × 20 mm (+41 HU), in the proximal right ulna measuring 27 × 20 × 16 mm, multiple lesions of bone rarefaction in the proximal right and left femurs. The DXA showed decreased BMD (Z-score L1–L4 –1.8 SD, Neck –2.3 SD, Radius 33% –5.0 SD). Sestamibi scintigraphy showed increased uptake behind the sternum with dimention of 5 cm. Parathyroidectomy was performed, the severe hungry bone syndrome with muscle twitches, impair temperature sensivity, panic attacks, loss of taste and insomnia appeared on the fifth day after with PTH level of 23 pg/ml, total calcium level of 2.38 mmol/l. The patient started taking calcium and vitamin D supplementation and anti–resorptive treatment (denosumab). Three months after parathyroidectomy hypocalcemia was detected with normal 25(OH)D level, PTH level wasn't measured. Six months later serum PTH level increased to 280.2 pg/ml with normal calcium and 25(OH)D levels. Neck ultrasound didn't show any pathological formation. 11C-methionine PET/CT scan was also negative. The control DXA showed improving of bone remodeling (Z-score L1–L4 –0.6SD, Neck 0.1SD, Radius 33% –1.7SD).

Conclusion

The classical presentation of PHPT isn't frequent nowadays because of serum calcium screening. Brown tumors appears through rapid osteoclast turnover and can significantly decreased QoL due to the multiple fragility fractures. It's likely that the patient has a reccurent PHPT, and negative imaging data requires a more detailed analysis.

EP110

The effect of teriparatide therapy on the rate of consolidation of a leg fracture in a patient with systemic osteoporosis (description of a clinical case)

Olga Iurova[1, 2] & Larisa Marchenkova[3]
[1]National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of the Russian Federation, Department of Active Longevity and Endocrinopathy, endocrinologist, Moscow, Russian Federation; [2]SM–Clinika, endocrinologist, Moscow, Russian Federation; [3]National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of the Russian Federation, Head of Department of Active Longevity and Endocrinopathy, Moscow, Russian Federation

Patient J, b. 1963 sent to an endocrinologist by a traumatologist due to the lack of consolidation of a fracture of the right ankle with complaints of pain, restriction of movements in the right ankle joint.

Medical history

09/19/2018 suffered a combined fracture of the lower leg bones when falling from a height of their own growth after falling at home falling from a height of their own growth. Reposition was performed, a circular plaster cast was applied, immobilization in a cast until 11.24.2018. Moved with crutches. 12/24/2018 repeated fall, upon examination by a traumatologist and control radiography – no fresh fracture was detected.

Conclusion unconsolidated fracture of the external ankle, partially consolidated fracture of the medial ankle and posterior edge of the right tibia from 09/19/2018 with subluxation of the foot outward. Contracture. T–score L1–L4 = –2.61 blood electrolytes – normal, PTH 34, 25 (OH) D 13.1, B–crosslaps– 0.848, P1NP 20.3, osteocalcin <2.0, calcitonin – <2.0.

MSCT 01/07/2019:

Fractures of the distal parts of the bones of the right lower leg are determined: Unconsolidated fragmentary fracture of the lateral ankle, with diastasis of bone fragments up to 5 mm. The edges of the bone fragments are uneven, sometimes sclerotic. Improperly fused fracture of the medial ankle, with diastasis in the anterior sections up to 4 mm. The edges of the fragments are clear, sclerotic, consolidation is in the posterior sections. Consolidated fragmentary fracture of the posterior edge of the tibia, with deformation of the posterior contour of the bone, without significant displacement of fragments. Paraarticular soft tissues are swollen.

Conclusion

CT picture of a three–ankle fracture of the right ankle joint. Spotted regional osteoporosis in the bones that form the right ankle joint, bones of the right foot (Zudek syndrome).

Ds: POP complicated by a pathological fracture. Vitamin D deficiency.

Treatment

Vigantol 15 drops daily – 6 weeks.

Teriparatide 20/

Rh– control 02.17.19. A consolidated fracture of the external ankle is determined. Bone callus is formed satisfactorily, post–traumatic bone deformation at this level is noted. Consolidated fracture of the medial ankle. Consolidated fracture of the posterior edge of the tibia.

02/19/19: P1NP 41.9, B–crosslaps– 1.158, 25 (OH) D 50.3, Ca, P – norm.

Conclusion

A clinical case demonstrates the acceleration of consolidation of a complex shin fracture with delayed consolidation during therapy with teriparatide.

Bone quality is affected in acromegaly beyound insulin resistence

Patricia Christina Codreanu[1], Alexandru Elena[1], Oprea Theodor[2], Nistor Irina[1], Predescu Andrada[1], Pascu Raluca[1], Balea Ana Maria[1], Iancu Mirela[1], Giurgiuman Niculina[1], Reghina Aura Diana[1, 2], Martin Sorina[1, 2], Albu Alice[1, 2], Sirbu Anca[1, 2], Fica Simona[1, 2] & Barbu Carmen Gabriela[1, 2]
[1]Elias Emergency University Hospital, Endocrinology and Diabetes, Nutrition and Metabolic Diseases Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Farmacy, Bucharest, Romania

Introduction

Diabetes mellitus and acromegaly are both associated with an increased risk of fracture caused by altered quality of bone. TBS represents an important tool for assessment of bone microarchitecture.

Objectives

The aim of this study is to assess the bone deterioration through the trabecular bone score (TBS) and to compare TBS and Z score between 2 groups of patients: acromegaly and diabetes mellitus.

Methods

This retrospective study included 2 groups of patients diagnosed and monitored in our clinic. 17 patients with diabetes mellitus between 45–77 years old (63.88 mean age; 32.04 mean BMI) were compared with 10 patients with acromegaly between 51–77 years old (61 mean age; 29.94 mean BMI). We selected the acromegalic patients without diabetes mellitus. In acromegalic group 3 patients had osteoporosis, 3 osteopenia and 4 had a T score in normal range while in diabetes group 3patients had osteoporosis, 2 osteopenia and 11 had a T score in normal range. The One way Anova test, used to compare TBS and Z score in the 2 groups, showed a lower mean TBS and hip Z score in acromegalic patients than in diabetic patients (1.260 vs 1.358, 95% CI, $P<0.05$ and –0.4 vs 1.22, 95% CI, $P<0.01$). Mean lumbar spine Z score didn't show any significant difference between the 2 groups. The limitation of our study is the small number of patients.

Results

Our study shows that acromegaly is associated with a lower TBS and hip Z score than diabetes mellitus which means that acromegaly represents an additional risk factor for altered bone quality, added to insulin resistance, despite the older age of diabetic patients.

EP112

Complex supplementation with calcium and vitamins D3 and B6 can prolong effect of medical rehabilitation in patients with osteoporosis and high fracture risk

Larisa Marchenkova, Ekaterina Makarova & Mikhail Eryomushkin
National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Somatic Rehabilitation, Anti–Aging and Reproductive Health department, Moscow, Russian Federation

The aim of the study was to evaluate the effect of complex food supplement with calcium and vitamins D_3 and B_6 intake on muscle strength and balance function during 1-year follow-up after rehabilitation course in patients with osteoporosis and high fracture risk

Methods

The study comprised 119 men and women aged 50–80 y.o. with established osteoporosis or high probability of major osteoporotic fracture by FRAX model initiating 3-week course of rehabilitation. 41 patients who had already received anti–resorptive therapy were included in the Studied group 1 (SG1), and 78 patients who were never previously treated with anti–osteoporotic medication were randomized in SG2 ($n=39$) or SG3 ($n=39$). The food supplement containing Vitamin D_3 30 mg, Pyridoxine Hydrochloride 4 mg, Calcium Citrate 320 mg and HDBA organic complex 400 mg in daily dosage was administered to patients in SG1 and SG2 for 12 months. Changes

in dynamometry and balance tests were assessed after 3 weeks, and in 6 and 12 months as follow–up.
Results
Achieved higher levels of muscle strength during the rehabilitation course were maintained for up to 12 months in the back extensors and flexors in SG1 and SG2, and up to 6 months in the lateral back flexors in SG1 ($P>0.05$ vs 3 weeks). The effect of medical rehabilitation completely disappeared in SG3 after 6 months ($P<0.05$ vs 3 weeks). Improved vs baseline stabilometry data in balance coefficient and pressure center deviation speed were registered in SG1 and SG2 in 6 and 12 months ($P>0.05$ vs 3 weeks). Achieved during rehabilitation positive result of balance control measured with One-leg-standing test was maintained only in SG1 for 12 months ($P>0.05$ vs 3 weeks), but it significantly ($P<0.05$) worsened in SG3 at follow-up.
Conclusion
Long–term intake of food supplements containing calcium with vitamins D_3 and B_6 can help to maintain the effect of rehabilitation on muscle strength and balance in patients with osteoporosis and a high risk of fractures.

DOI: 10.1530/endoabs.70.EP112

EP113

Zoledronic acid treatment in women with postmenopausal osteoporosis; A cohort follow–up.

María Laura García, Ana Paula Lisdero, Romina Speroni, Ana Segarra, Jimena Otero, Camila Benito & Aizhar Giselle Mumbach
Sanatorio Méndez, Endocrinology, Buenos Aires, Argentina

Zoledronic acid (ZA) treatment increases bone mineral density (BMD), decreases bone turnover markers and reduces the risk of fractures in patients with osteoporosis (1).
Objective
Observe and quantify the changes in BMD and bone turnover markers in postmenopausal osteoporosis (PO) patients treated annually with zoledronic acid 5 mg intravenously.
Material and methods
Medical records (MR) of PO patients whom received ZA from 2007 to 2017 were retrospective evaluated. Parametric test (paired T-test for quantitative variable) × 2 for qualitative variable were performed following variable distribution. Kaplan Meier- log rank test, lineal and cox regression were performed. SPSS and Stata14.0 software were used for statistical analysis.
Results
130 women were included

Age (years)	68.1±9.4
BMI(Kg/m^2)	25.7±5.1
Menopause age	49±5.6
Previous fracture	45.4% (n=59/130)
Vertebral fractures	47.4% (n=28/59)
Non–vertebral fractures	61% (n=36/59
Multiple fractures	30.5% (n=18/ 59)

A percentage of 50.8% had received prior treatment with oral bisphosphonates for a time period of 1.7±2.4 years, 15 patients received others previous treatments.
The major prescription for ZA was: lack of response to oral bisphosphonates 36.2% (n=47/130), very low bone mass density (T-sc<–3.5): 31.5% (n=41/130), new fracture under treatment with oral bisphosphonates: 7.7% (n=10/130), digestive intolerance to oral bisphosphonates 24.6% (n=32/130) and previous history of fx: 45.4% (n=59/130).
From total 84 patients received 2 infusions and 45 patients, 3 infusions with ZA respectively.
Adverse events were observed in 4.6% (n=8) of patients.
One year after ZA, there was a significant increase at lumbar spine(LS) BMD in 3.7% (n=0.009) and total hip (TH) 4.5% (P=0.004), however in the following years the increase was not significant in both regions. There were no significant changes in femoral neck (FN).
There was a significant decrease 49% ($P<0.001$) in C–telopeptide of type I collagen (CTX) values, but only after the first year of infusion.
Conclusions
In our cohort the annual treatment with intravenous ZA 5 mg produced a significant increase in BMD for LS and TH and a significant decrease in CTX per year. Adverse effects were uncommon. We believe that this study despite its limitations, provides useful information regarding the effectiveness and safeness of ZA as a therapeutic option for PO treatment.

EP114

Patients characteristics with low–trauma vertebral fractures: A descriptive multi–center analysis

Eiman Alseddeeqi
Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates

Background
Vertebral fractures are the most common type of osteoporotic fractures. Prevalence of osteoporosis and osteoporotic vertebral fractures were not addressed and studied previously in the UAE. This study aims to describe for the first time the demographic and morphological characteristics of patients with fragility vertebral fractures in the UAE.
Methods
This is a retrospective medical records review of patients with low-trauma vertebral fractures from two tertiary centers during 2011–2016. Patients' gender, age at the time of fracture, nationality, BMI and the anatomical location of fracture were described.
Results
A total of 143 subjects were diagnosed with low-trauma vertebral fractures in the Emirate of Abu Dhabi during 2011–2016. Of these, 98 were women (68.5%) and 45 were men (31.5%). The overall mean age at diagnosis was 62.5. Almost half of the patients were younger than 65 years. Around 60% of the patients were UAE nationals. 51 (36.7%) patients were obese with a mean BMI of 35.3 kg/m^2. Women with vertebral fractures had statistically significant higher mean BMI compared to men (P=0.041). Nearly 40% of men had normal BMI compared to 20% of the female patients. Most of the fractures were compression fractures (77.6%) and were located in the thoracolumbar transition region.
Conclusion
Patients with vertebral fractures were predominantly females. Overweight and obesity were more prevalent specially in female patients. Male patients had lower BMI compared to females.
Keywords: Low–trauma, osteoporosis, vertebral fracture, body mass index, fragility fracture.

Tibolone effects on bone mineral density in a patient with complete androgen insensitivity syndrome, a one year follow–up

Justiene Mia Klarisse Danga[1], Mark Henry Joven[1], Karen Elouie Agoncillo[1], Maria Julieta Victoriano-Germar[2] & John Chris Gallagher[3]
[1]The Medical City – Ortigas, Internal Medicine— Section of Endocrinology, Pasig, Philippines; [2]The Medical City – Ortigas, Obstetrics and Gynecology, Pasig, Philippines; [3]Creighton University Med Center, Omaha, United States

Background
Patients with complete androgen insensitivity syndrome (CAIS) who undergo gonadectomy have evidence of reduced bone mineral density (BMD) and perhaps, higher risk of fragility fractures. Because of this, hormonal replacement therapy (HRT), usually in the form of estrogen, is used as patients with CAIS have 46, XY genotypes having androgen receptor abnormalities making them resistant to the effects of androgen. Tibolone, a "selective tissue estrogenic activity regulator" (STEAR), is a synthetic compound with estrogenic (anti-resorptive properties) on bone, preventing bone loss, increasing BMD and preventing fractures in postmenopausal women.
Case Description
A 45-year-old phenotypic woman with no prior history of fractures presents to the clinic for evaluation of primary amenorrhea. Her subsequent evaluation was consistent with a diagnosis of CAIS. She was 171 cm in height and 67 kg in weight (BMI of 29.38 kg/m^2). Physical examination was notable for scant androgen-dependent body hair, Tanner stage V breast development, and a blind vaginal pouch. Work-up showed an absent uterus on magnetic resonance imaging, a 46, XY karyotype, and hormonal evaluations consistent with male normative ranges for total testosterone estradiol. She subsequently underwent two gonadectomies (with a 10-month interval)

which showed gonads having testicular histology. Dual-energy x-ray absorptiometry revealed osteopenia based on normal female range. Baseline spine T-score was –1.7 (0.960 g/cm^2), right total hip T-score was –1.3 (0.841 g/cm^2), right femoral neck T-score was –1.0 (0.895 g/cm^2), left total hip T-score was –1.7 (0.794 g/cm^2), left femoral neck T-score was –1.2 (0.875 g/cm^2), and 33 percent left radius T-score was –0.8 (0.809 g/cm^2). Additional workups for secondary causes of osteoporosis were unremarkable. Our patient was started on tibolone 2.5 mg daily together with calcium and vitamin D3 supplementation. After one year of treatment, spine BMD increased by 2.3%, right total hip increased by 1.7%, right femoral neck increased by 3.9%, and left femoral neck increased by 1.7%. There was no significant change in the left total hip BMD. She did not experience any adverse drug events on tibolone.
Conclusion
While the efficacy of tibolone in post-menopausal osteoporosis has been demonstrated in literature, its role in the management of post-gonadectomized patients with CAIS has not been documented. We present a patient with CAIS who had increased BMD after one year of tibolone 2.5 mg treatment. A long-term study of tibolone in this rare condition is warranted so effective treatment strategies could be offered to patients to mitigate bone loss especially during early gonadectomy.

Indications of surgical treatment of secondary hyperparathyroidism in hemodialysis patients

Mehdi Hasnaoui, Mohamed Masmoudi, Takwa Belaid & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Tunisia, Otolaryngology–Head and Neck Surgery, Mahdia, Tunisia

Introduction
Hyperparathyroidism is a fairly common pathology that can cause functional and vital complications. Its treatment combines a medical component and a surgical one.
The aim of this work is to specify the surgical indications for this pathology.
Materials and methods
It is a retrospective study bringing 58 cases of secondary hyperparathyroidism collected over a period of 16 years (from 2001 to 2016).
Results
Our series includes 23 women and 25 men with a sex ratio of 1.5. The average age of our patients was 43 years (17 to 78 years).
All patients had chronic renal failure at the hemodialysis stage, progressing for an average duration of 6.77 years. They received medical treatment with calcium and vitamin D.
Bone pain was the most frequent reason for consultation (100 % of cases), followed by muscle fatigue (80 % of cases) and by a pathological fracture in 2 cases.
The diagnosis of hyperparathyroidism was made in front of high PTH figures, associated with hyperphosphoremia and a tendency to hypocalcaemia. Sixty percent of patients retained hypovitaminosis D despite well-managed supplementation.
Seventy-five patients had radiographs of the hands and skull, showing diffuse bone demineralization.
Parathyroid scintigraphy associated with cervical ultrasound, requested in all patients, showed hyper fixation of the thyroid gland in regard in 95% of the cases.
A 7/8 reduction parathyroidectomy was performed in all patients with a drop of more than 50% in PTH levels in all cases.
We noted a clear improvement in functional complaints postoperatively in all patients.
Conclusion
Secondary hyperparathyroidism remains a frequent problem in chronic hemodialysis patients. Its treatment is above all preventive. Surgery is only indicated if medical treatment fails.

Factors associated with vitamin d deficiency among adult population in carpathian region

Ivan Pankiv[1], Nataliia Pashkovska[1], Galina Koval[1], Yulia Marchuk[1], Nataliia Abramova[1], Antonina Piddubna[1] & Iryna Tsaryk[1]

[1]Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background
Vitamin D deficiency is widespread in Ukraine, particularly among older adults. Factors associated with vitamin D deficiency are not well defined.
The aim of the study was to evaluate vitamin D status and its correlatation among older adults of 5 communities in Ukrainian Carpathians.
Materials and methods
This cross–sectional study was based on study data for 1254 men and women aged 20–82 years. Anthropometric and socioeconomic data were collected in June-July 2018. Serum 25(OH)D levels were detected using a chemiluminescence immunoassay. The following socioeconomic data were obtained through self–administered questionnaires: education level, lifestyle, residency, and dietary habits. A logistic regression model was used to assess associations between anthropometric factors, socioeconomic factors and serum 25(OH)D levels.
Results
Median levels of serum 25(OH)D in men and women were 21.43 and 18.47 ng/ml, respectively. Vitamin D deficiency was common in subjects involved into the study, even though data collection was conducted during summer. The general prevalence of serum 25(OH)D levels < 20 ng/ml were 41.3% and 59.2% for men and women respectively. The general prevalence of serum 25(OH)D levels < 10 ng/ml were 3.7% and 6.4% for men and women respectively. A multivariable model indicated serum 25(OH)D level ≥20 ng/ml was significantly and positively correlated with male sex, and residency by the sea. The model also indicated that high level of physical activity was a protective factor of vitamin D deficiency for men and women. By contrast, deficient serum 25(OH)D level significantly correlated with education level (lower than primary school) or obesity for all patricipants.
Conclusion
This cross-sectional study of older adults in communities in Ukraine demonstrates that key factors positively correlated with serum 25(OH)D levels ≥20 ng/ml include male sex, residency about sea level, high physical activity and education level, maintenance of normal BMI.

Periodontitis and osteoporosis. A frequent coexistence with dangerous implications

Ifigenia Kostoglou–Athanassiou[1], Lambros Athanassiou[2], Panagiotis Spyropoulos[3], Erasmia Manta[4], Maria Mavroudi[5], Andreas Giannakopoulos[4], Alexandros Pastroudis[4] & Panagiotis Athanassiou[5]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Medical School, University of Athens, Department of Physiology, Athens, Greece; [3]Endocrinologist, Athens, Greece; [4]Asclepeion Hospital, Voula, 6th Department of Orthopedics, Athens, Greece; [5]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Periodontitis is a serious medical condition which may lead to edentulousness in middle aged patients. It is a chronic inflammatory systemic disorder which affects the oral cavity, the maxilla and mandible. It may be associated with osteoporosis. It presents unique problems in the management of osteoporosis. The patients are in the imminent danger of losing teeth. Some of the antiosteoporotic agents may induce osteonecrosis, while they may complicate the implantation of dental implants.
The aim was to describe the management of osteoporosis in patients with periodontitis.
A group of patients, 10 female and 1 male presented to the outpatient osteoporosis clinic. They had a T score of –2.8 to –3.6. They also had periodontitis. A group of 4 patients had already lost 1 to 4 teeth, and were in the process of dental implant installation. An extensive laboratory and clinical examination was performed.
Within the group of patients with osteoporosis and periodontitis, patients with osteoporosis were managed with anticatabolic treatment. The patients who were in the process of dental implant installation were managed conservatively with calcium and vitamin D until the installation of the implant was complete and a period of 3 months after installation. Thereafter, antiosteoporotic agents were administered.
Periodontitis is a chronic systemic medical disorder which affects patients in the middle age group. Postmenopausal women are particularly vulnerable. In addition, it is a systemic inflammatory disorder and may be implicated in the pathogenesis of osteoporosis. The management of osteoporosis in this group is particularly challenging. They are in danger for the development of

osteonecrosis of the jaw. Patients should be managed conservatively while in the process of dental implant installation. They should be managed with caution while care should be exercised in oral hygiene.

Systemic inflammation in primary hyperparathyroidism

Ahmet Toygar Kalkan[1], Goknur Yorulmaz[1], Bilge Başdoğan[1], Aysen Akalın[1], Elif Sevil Alagüney[2], Medine Nur Kebapçı[1] & Fatma Belgin Efe[1]
[1]Eskişehir, Eskişehir Osmangazi University Medical Faculty, Eskişehir, Turkey; [2]Konya, Endocrinology an Metabolism, Konya, Turkey

Parathyroid hormone(PTH) is a peptide hormone that regulates ionized calcium. Primary hyperparathyroidism, in which the bone-building-destruction balance is disturbed, is due to the uncontrolled secretion of parathormone. The systemic inflammation index (SSI) is a variable that has been validated in studies aimed at evaluating the inflammation that has been frequently mentioned recently. The disruption of this bone-making destruction process affects the inflammatory process in the body. For this reason, we aimed to compare systemic inflammation index and neutrophil lymphocyte ratio in hyperparathyroidism patients before and after operation in our study.
Material and methods: In the last 5 years, 28 patients who were followed-up in the endocrinology outpatient clinic for hyperparathyroidism were included in the study. Parathormone, calcium, phosphorus, alkaline phosphatase, neutrophil, lymphocyte, and platelet values were recorded before the operation and in the 6th month of the operation. Since the normal distribution was not seen, we performed the evaluation of the results with non-parametric tests.
Results: The preoperative and postoperative alkaline phosphatase, parathormone, calcium and phosphorus values of the patients were found to be significantly different. However, although their mean values differed (Table 1), the systemic inflammation index and neutrophil-lymphocyte ratio did not differ significantly. (Table 2)

Table 1

Descriptive Statistics

Pre Post Operative		N	Minimum	Maximum	Mean	Std. Deviation
Preop	SSI	28	201,67	3820,65	683,4551	698,53979
	Neutrophil Lymphocyte Ratio	28	,93	16,19	2,8830	2,84131
	Valid N (listwise)	28				
Postop	SSI	28	178,42	998,18	494,2027	221,83034
	Neutro-philLympho-cyteRatio	28	,58	5,25	2,0761	,93910
	Valid N (listwise)	28				

Table 2

Test Statistics[a]

	*P*th (pg/ml)	Ca (mg/dl)	Alp (U/l)	*P* (mg/dl)	SSI	NLR
Preoperative (median)	256,5	11,53	129	2,11	441,09	2,07
Postoperative (median)	43,5	9,28	85,5	3,35	414,40	1,92
Asymp. Sig. (2–tailed)	,000	,000	,002	,000	,646	,325

Pre–Postoperative Statistics

Discussion
Systemic inflammation index and neutrophil lymphocyte ratio are remarkable markers in recent years. In our study, the mean of preoperative and postoperative SSI was found to be 683 and 494, respectively. Mean and median values show a postoperative decrease as we expected. However, no statistical difference was found. Insufficient number of patients can cause statistical significance. Reducing the type 2 error by expanding the number of samples will show the result of this situation.

DOI: 10.1530/endoabs.70.EP119

EP120

Persistent hyperparathyreoidism due to ectopic parathyroid gland

Aleksandra Grbic[1], Gabrijela Malesevic[1], Ivona Risovic[1] & Gordana Rakita[2]
[1]University Clinical Center of the Republic of Srpska, Banja Luka, University of Banja Luka, Faculty of Medicine, Banja Luka, The Republic of Srpska, Bosnia and Herzegovina, Department of Center for Diabetes with Endocrinology, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina, Department of Center for Diabetes with Endocrinology, Banja Luka, Bosnia and Herzegovina

Sixteen percent of parathyroid adenomas can be situated in an ectopic location. Ectopic parathyroid glands result from aberrant migration during early stages of development, and lack of successful identification may lead to lack of success in parathyroid surgery. These glands are most frequently found in the anterior mediastinum, in association with the thymus or the thyroid gland. Ectopic parathyroid glands are a major cause of persistent and recurrent hyperparathyroidism.
The aim of the study was presented to patients with persistent primary hyperparathyroidism due to ectopic parathyroid adenoma in the chest.
Case Report
This is a 67–year–old woman who was presented with fatigue and was diagnosed with primary hyperparathyroidism two years ago. At the time of diagnosis, the patient had the following findings: high levels of parathyroid hormone (PTH), ionized calcium and easily reduced phosphate values. Technetium-99m–sestamibi (MIBI) scintigraphy scan was positive and detected enlarged and hyperactive upper right parathyroid gland. The ultrasound showed a multinodally enlarged thyroid gland. The patient was referred to a surgeon. The parathyroid hormone and ionized calcium levels were not normalized postoperatively. The repeated Technetium-99m-sestamibi (MIBI) scintigraphy showed this time an enlarged and hyperactive lower left parathyroid gland. After that, an exploitative cervicotomy was done but the parathyroid glands could not be enlarged in the expected projects. Even after repeated operations there was again an elevated PTH level, elevatedionized and total calcium levels with normal calciuria. The patient was again advised to do parathyroid gland scintigraphy. The third scintigraphy detected localized parathyroid adenoma/hyperplasia in superior mediastinum (an enlarged and hyperactive parathyroid gland ectopically localized behind the upper part of the left half of the sternum manubrium).The computed tomography of the chest and lower neck showed an ovoid soft tissue density area measuring about $21 \times 18 \times 13$ mm in the superior mediastinum. The patient was again referred to the surgeon. The removal of the lesion resulted in rapid improvement in serum calcium and parathyroid hormone.
Conclusion
In addition to the enlarged and hyp\eractive parathyroid glands at the typical site of the neck, the development of ectopically located parathyroid glands is also possible. Therefore, we think that the attention should be paid to this in dailyclinical practice. The neck ultrasound and 99mTc Sestamibi scan are first–line imaging modalities, although with low sensitivity and specificity. However, their combination with modern techniques, such as single photon emission computed tomography (SPECT) alone or in combination with CT (SPECT/CT) increases their diagnostic accuracy.

EP121

Teriparatide in the treatment of severe osteoporosis: Results of a case series

Iulia Florentina Burcea[1, 2], Roxana Dusceac[1, 2] & Catalina Poiana[1, 2]
[1]CI Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disease, București, Romania; [2]Carol Davila University of Medicine and Pharmacy, General Medicine, București, Romania

Introduction
Known as a potent anabolic drug, teriparatide has a stimulating effect on bone formation, increasing bone mineral density (BMD) and reducing fracture risk.
Methods
11 Caucasian women (mean age 66 years old) with severe osteoporosis treated with recombinant human parathyroid hormone (1–34) – teriparatide (Forsteo) 20 micrograms daily for 24 months were added to the study.
BMD at lumbar spine, total hip and femoral neck was measured before treatment (baseline), 12 and 24 months after initiation using dual energy x-ray absorptiometry (DXA GE Lunar). Two patients had plate osteosynthesis material at lumbar spine so DXA was performed only at total hip and femoral neck. All patients had fragility fractures, diagnosed with radiography/ vertebral MRI/ VFA: 3/11 had one vertebral fracture, 6/11 multiple vertebral fractures, 3/11 forearm fractures, 3/11 femoral fractures (one bilateral), 1/11 patella fracture and 1/11 had a pelvic fracture.
One patient had postpartum BMD below the expected range for age and vertebral fractures. 7/11 patients had previous anti–osteoporosis treatment. After 24 months of teriparatide, 10/11 patients started ibandronate 3 mg iv every 3 months, 1/11 started denosumab 60 mg sc every six months.
All received daily supplements of 500–1000 mg of calcium and 1000–2000 IU of Vitamin D. We measured osteocalcin (OC) at baseline, 12 and 24 months after initiation. We determined changes in percentage of BMD and serum OC in 12 and 24 months compared to baseline.
Results
Treatment with teriparatide determined an increase in BMD of total hip after 12 months (+ 2.18%) and significant increase after 24 months (+ 3.53%). The BMD changes at the femoral neck were 5.32% at 12 months and 3.15% after 24 months. The most significant increase in BMD was found at lumbar spine: 9.08% after 12 months and 8.36% after 24 months compared to baseline. The increase in OC was 90.47% after 12 months and 40.4 % after 24 months of teriparatide. The patient with postpartum BMD below expected for age had an important increase in BMD at lumbar spine after 12 months of 16.45% and of 24.1% after 24 months.
Treatment was well tolerated, and no serious side effects were observed.
No new fractures were diagnosed during treatment.
Conclusion
Our study suggests that teriparatide has an effective osteoanabolic effect and it is safe and well tolerated. Prolongation of follow–up is needed to see the evolution of BMD on patient treated with antiresorptive agents following teriparatide.

Failure of parathyroidectomy or PTH rebound in primary hyperparathyroidim

Loukil Fatma[1], Sopio Tatulashvili[1], Gebessoua Marie-Laure[2] & Bihan Hélene[2]
[1]Paris, Endocrinology, Paris, France; [2]Avicenne Hospital, Endocrinolgy, Paris, France

Introduction
Juvenile primary hyperparathyroidism represents more severe form of the disease, often with organ damages. Genetic mutation and paarthyroid hyperplasia are more frequent than in adults.
Case Report
20–year–old patient with familial history of kidney stone. She was hospitalized for major hypercalcemia at 3.65 mmol/l (2.2–2.6 mmol/l) discovered on daily chronic vomiting and alteration of the general condition. The biological balance was in favour of primary hyperparathyroidism with hypophosphoremia at 0.58 mml/l (0.85–1.5 mmol/l) ; hypercalciuria at 7.8 mmol/24 h (2.5–7.5 mmol/24 h), PTH at 1050 ng/l (15–60 ng/ml), Vit D at 7ng/l (30–100 ng/ml).
The morphological assessment is as follows:
–parathyroid sesta MIBI scintigraphy and cervical ultrasound were compatible with a left P3 inferior adenoma measuring 33–14–13 mm
Treatment with mimpara was instaured without success. Thus, left lower parathyroidectomy for adenoma by cervicotomy was performed, without exploration of other sites
Anatomopathology concluded to parathyroid main cell adenomas, without signs of malignancy.

	21/10/2019	24/11/2019	Surgery 2/12/2019	3/12/2019	4/12/2019	5/12/2019	6/12/2019	10/1/2020
Calcémie (mmol/l)	2.83	3.4	2.93	2.77	2.6			2.17
NV(2.2–2.6)								
PTH (ng/l)	1643	599	73		6.9	20.9	63	96
NV (15–60)								
PTH (ng/l) itraoperative			1133					

Genetic research (multiple endocrine neoplasia and Ca SR mutation were performed (results unavailable). we completed with a statistical pituitary assessment (prolactin, FT4, TSH, GH, IGF1) plasma DM) and hormonal assessment (glucagon, somatostatin, VIP) wich were normal.
Discussion
Calcemia is still normal 1 month after operation at 2.17 mmol/l . However the rapid reascension of PTH to 182 pg/ml is considered to be quite normal since it is a post–operative rebound effect linked to both the resumption of function of other parathyroids and probably increased by vitamin D deficiency despite adequate supplementation. But we may fear an hyperplasia of parathyroids and it is the genetic study and the evolution of calcemia and PTH that will predict the etiology of this hyperparathyroidism.
Conclusion
Genetic study in young patients with primary hyperthyroidism is essential given the higher risk of recurrence in familial forms. The level of calcimia may sometimes drive the time of surgery.

Severe, symptomatic hypocalcemia due to denosumab and vitamin d deficiency in a post–menopausal female with osteopenia

John Berquist, Jason Kaplan & Andrew Zazaian
Michigan State University McLaren Oakland, Internal Medicine, Pontiac, United States

Denosumab is a monoclonal antibody used in the treatment of osteoporosis to prevent bony injuries by increasing bone density. It does so by binding to RANK-L, which is then unable to activate RANK, thereby preventing osteoclast maturation and viability. Although rare, the effect of denosumab can interfere with the body's calcium homeostasis and lead to a hypocalcemic state. We present a case where a post-menopausal female developed severe, symptomatic hypocalcemia from a multifactorial etiology of a side effect from denosumab and concomitant Vitamin D Deficiency. The patient originally presented to the ED with a chief complaint of intermittent and worsening whole body numbness and confusion per her family members. Her serum calcium level on presentation was 4.3 mg/dl and attempts at improvement were refractory to multiple administrations of intravenous calcium; however, her symptoms and calcium levels improved after receiving continuous intravenous calcium and Vitamin D later during her hospital stay. Importantly, this condition could have been prevented as she was not a candidate for denosumab therapy given the results of her most recent bone scan. This case allows for insight on use of denosumab and which patients are optimal candidates for the drug and who are not, as well as the necessary testing and diagnoses to establish before initiating treatment with the drug.

The effect of PCSK9 Inhibitor EVOLOCUMAB on aldosterone among high cardiovascular risk patients

Elena Lzkhakov[1], Yakov Shacham[2], Mariana Yaron[2], Merav Serebro[2], Karen Tordjman[2], Yona Greenman[2], Naftali Stern[2] &Tomer Ziv[3]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv Univrsity, Institute ofEndocrinology, Metabolism and Hypertension, Tel Aviv, Israel; [2]Ichilov, Tel Aviv–Yafo, Israel; [3]Tel Aviv University, Tel Aviv–Yafo, Israel

Background
Proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors decrease the degradation of low–density lipoprotein (LDL) receptors, thereby increasing the removal of LDL particles from the blood and significantly reducing LDL cholesterol levels by an average of 65%. Blom et al. showed

changes in vitamin E, adrenocorticotropic hormone (ACTH), cortisol, total testosterone, and estradiol in EVOLOCUMAB (PCSK9 inhibitor)–treated patients [1]. There are currently no published data on the impact of PCSK9 inhibitor monotherapy on aldosterone.
Aim of the study
To examine the effect of EVOLOCUMAB monotherapy on LDL cholesterol reduction and steroidogenesis in high cardiovascular risk patients with statin intolerance.
Methods
Lipid profile, sodium, potassium, aldosterone, cortisol, and ACTH were analyzed at baseline and after 3 months of EVOLOCUMAB therapy. Each participant underwent two dynamic tests, a 250 mg ACTH test and an ambulation test, on two consecutive days at the beginning and end of the study.
Results
Fifteen patients were included in the study. Total cholesterol, LDL cholesterol, lipoprotein (a), and stimulated aldosterone levels were significantly lower after 3 months of EVOLOCUMAB therapy. There were no significant changes in ACTH, cortisol, or potassium levels.
Conclusions
Reduction in stimulated aldosterone secretion by EVOLOCUMAB treatment could theoretically be associated with the reduction of cardiovascular events, and that possibility warrants further investigation.

EP125

Therapeutic inertia in lipid management of diabetic patients in secondary prevention

Lorea Herráiz[1], Rona Penso[1], Teresa De Grado[1], Irene Crespo[1], Laura Mola[1], Carmen Gil[1] & María Elena Mendoza[1]
[1]Hospital Central de La Defensa Gómez Ulla, Endocrinology and Nutrition Unit, Madrid, Spain

Introduction
Dyslipidemia (DL) in diabetic patients is frequently undertreated. Even when cLDL targets have not been met, treatment remains unchanged despite the availability of alternatives approaches. This is known as therapeutic inertia (TI).The aim of this study was to evaluate the prevalence of TI in lipid management among diabetic patients and to analyse associated factors and possible causes.
Material and methods
Retrospective, cross-sectional study. Diabetic patients in secondary prevention followed up in an Endocrinology outpatient clinic, from January to June 2019. All with suboptimal cLDL levels: >70 mg/dl, according to ESC/EAS 2016 guidelines for the management of dyslipidemias. TI was considered when a lipid–lowering agent was not changed or added. Results in mean (Standard Deviation). Bivariate analysis: Pearson chi*square/Student *t* test.
Results
78 patients. 61.5% men. Age 72.2 (10) years, duration of diabetes: 16.3 (10.5) years. 94.9% DM 2. Weight 76.2 (14) kg, BMI 28.2 (4.7) kg/m^2. Mean HbA1c 8 (1.5)%, cLDL 98.5 (25.5) mg/dl, glomerular filtration rate 69.2 (24.7) ml/min. Number of chronic treatments: 10.7 (4). Complications and comorbidities: 56.4% ischemic cardiopathy (IC), 29.5% stroke, 28.6% peripheral artery disease (PAD), 23.6% diabetic nefropathy, 20.8% diabetic retinopathy (DR) and 11.5% diabetic neuropathy (DN). 29.5% with renal insufficiency and 9% with hepatopathy. Cognitive impairment in 6.4%.Type of statin: high potency in 38.8%, low-intermediate potency in 62.2%.14% without any statin. Only 10.7% received the maximum dose of statin. In 5.3% statin intolerance was reported.
cLDL levels were higher in women, hepatopathy, patients taking less than 5 chronic treatments and without statin($P<0.05$).There were no differences depending on age, renal insufficiency, cognitive impairment, HbA1c, statin intolerance, maximum dose of statin and the presence of hypertension, IC and PAD.
TI was observed in 80.7% of patients. It was not modified based on age, duration of diabetes, renal insufficiency, hepatopathy, cognitive impairment, number of chronic treatments nor number of changes in regular treatments. There were also no differences depending on other cardiovascular risk factors and type of vascular disease: tobacco, hypertension, IC, stroke, DN, PAD nor DR.
We observed less TI associated with higher cLDL and lower HbA1c levels ($P<0.05$).
Conclusions
TI was common in the lipid management of diabetic patients. We found higher cLDL and lower HbA1c levels as factors that influenced in TI, this could be due to a sequential treatment, optimizing the treatment of DL after an adequate glycemic control. The better management should be an integrated treatment of all cardiovascular risk factors.

Augmentation index in the assessment of pulse wave reflection assessment in lean and obese women with polycystic ovary syndrome (PCOS)

Krystallenia Alexandraki[1], Eleni Kandaraki[2], Theodoros Papaioannou[3], Christina Piperi[4], Antonis Argyris[5], Christos Papamichael[6], Athnasios Protogerou[5] & John Lekakis[6]
[1]Laiko University Hospital, Medical School, National and Kapodistrian University of Athens; [2]Hygeia Hospital, Department of Endocrinology & Diabetes; [3]Medical School, National and Kapodistrian University of Athens, First Department of Cardiology; [4]School of Medicine, National and Kapodistrian University of Athens, Department of Biological Chemistry; [5]Medical School, National and Kapodistrian University of Athens, Cardiovascular Prevention & Research Unit, Department of Pathophysiology; [6]Medical School, National and Kapodistrian University of Athens

Objective
Conflicting findings have been published regarding the pressure wave reflection and the arterial stiffness in young women with PCOS as opposed to the overt *ab initio* presence of endothelial dysfunction compared with controls which can be reversed six months after metformin administration. The aim of this study was to investigate arterial stiffness and wave reflections in young women with polycystic ovary syndrome (PCOS) with respects to the different weight and to evaluate the effect of metformin treatment on the aforementioned indices.
Methods
Sixty–four young women, 35 with PCOS (P) (20 lean (L), PL; 15 overweight/obese (O_{WB}), $P_{OW/OB}$) and 29 (18CL; 11 C_{OWB}) normal women were studied. Wave reflectionwas studied by the Augmentation Index (AI) as central augmentation pressure–to–pulse height ratio at heart rate (HR) 75 (C_AGPH_HR75) or without HR correctionC_AGPH and the central augmentation time index (C_ATI), bpm and biochemically by advanced glycated end–products (AGEs). Endothelial function was studied biochemically byplasma endothelin 1 (ET–1) levels. The metabolic and hormonal profile was assessed. Metformin (1700 mg daily) was administered for six months in 20 (9 lean and 11 obese) women with PCOS and the above evaluations were repeated.
Results
There was no significant difference in age among the two groups. Wave reflection sindices did not differ between PCOS and controls, but C_AGPH_HR75 significantly improved post–metformin treatment in POW/OB ($P=0.046$). AGEs differed between PCOS women groups and controls groups ($P<0.001$) but their values did not normalize after metformin treatment. Testosterone levels were higher in PCOS compared to control women and MATSUDA index values were lower in PCOS compared to control women but without normalization of their values post–metformin treatment. ET–1 levels did not differ between PCOS and controls, but significantly improved post–metformin treatment in both lean and obese PCOS groups ($P=0.01$ and $P=0.04$, respectively).
Conclusions
Wave reflections markers seem to be a covert negative predictor in PCOS but that ameliorate post–metformin treatment particularly in overweight/obese PCOS women.

Hyperuricemia in type 2 diabetes patients with atherosclerotic cardiovascular diseases.

Tinatin Akhobadze[1], Ramaz Kurashvili[2], Ana Kopaleishvili[2], Elena Shelestova[2], Ana Nikachadze[1] & Maka Moistsrapishvili[1]
[1]National center for diabetes research, Cardiology, tbilisi, Georgia; [2]National center for diabetes research, Endocrinology, tbilisi,

Background
Studies show relationship between serum uric acid (SUA) and such diseases as type 2 diabetes (T2DM), hypertension (HT) and atherosclerotic cardiovascular disease (ASCVD). There is relationship both in hyperuricemia (HU), and high–normal values of SUA. Significance of this association is unknown; there are controversial data concerning HU role in patients with T2DM/CVD.
The aim of the study was to assess SUA in T2DM patients with ASCVD.
Method
Participants were 82 hypertensive T2DM patients, treated for HT or CVD; 52 patients had established ASCVD: CAD (previous myocardial infarction/MI, or/and PCI, CABG), peripheral artery disease/PAD (ankle–brachial index < 0.9), or/and stroke (by MRI-data). At entry 83% were receiving hypotensive drugs (one or more), half of them weren't treated adequately. Statins were used in 61 patient. Participants were divided into 2 groups (Gr). G.r.1, 52 patients with ASCVD (mean age 60.1 ± 7.5yrs, 39men/13women: 35 with CAD (23 – after MI; 21 – after PCI; 11 – after GABG); 14 – with PAD (four PAD + CAD); 13 – after stroke (3 PAD + CAD). Gr.2: 30 hypertensive patients without ASCVD (mean age 58.8 ± 8.4yrs, 22men/8women). Diabetes duration (DD), SUA, HbA1c, LDL-cholesterol, triglyceride, systolic/diastolic blood pressure (SBP/DBP), body mass index (BMI) were assessed.
Results
SUA was higher, (5.77 ± 0.61 vs 4.02 ± 0.53, $P = 0.033$); DD longer (11.95 ± 2.3 vs 6.1 ± 1.8 yrs, $P = 0.04$); SBP higher (152 ± 5.3 vs 137 ± 4.9 mmHg, $P = 0.04$), and BMI was higher (33.9 ± 2.3 vs 27.4 ± 2.1, $P = 0.04$) in Gr.1 compared to Gr.2. There was not statistically significant difference in DBP (84.5 ± 6.3 vs 81.3 ± 5.1 mmHg, $P = 0.69$), HbA1c (8.3 ± 1.02 vs 8.6 ± 0.9%, $P = 0.8$); LDL–cholesterol (2.57 ± 1.09 vs 2.31 ± 1.1 mmol/dl, $P = 0.867$) and triglycerides (2.04 ± 0.8 vs 1.91 ± 0.7 mmol/l, $P = 0.902$) between two groups. BMI was higher in Gr.1 compared to Gr.2.(33.9 ± 2.3 vs 27.4 ± 2.1, $P = 0.04$).
Conclusion
T2DM + ASCVD patients have higher SUA compared to Gr.2, ASCVD patients were more hypertensive, obese and had longer DD . Further studies are necessary to assess significance of SUA as an independent risk-factor for ASCVD development in T2DM.

EP128

Asthma control and quality of life in greek patients with metabolic disorders. Results from BOREAS study

Sotiria Laparidou[1], Vasilios Seferlis[2], Maria Bertoli[3], Polyanthi Papanastasiou[3] & Alexandros Ginis[4]
[1]Mamatsio General Hospital, Pulmonary Department, Kozani, Greece; [2]General Hospital of Chalkida, Pulmonary Clinic, Chalkida, Greece; [3]ELPEN Pharmaceutical Co. Inc., Clinical Research Department, Pikermi, Attica, Greece; [4]ELPEN Pharmaceutical Co. Inc., Medical Affairs Department, Pikermi, Attica, Greece

Introduction
Asthma is often associated with various comorbidities, which may affect its clinical intensity and severity. The mechanisms of adult–onset asthma may include several metabolic and inflammatory components that are common to the other diseases such as obesity, metabolic syndrome, type 2 diabetes mellitus (T2DM), cardiovascular diseases and psychiatric diseases.
Objectives
Assessment of asthma symptom control and QoL in a subgroup of asthmatic patients with metabolic disorders (MD) residing in Greece, who were treated for 6 months with a Fixed Dose Combination (FDC) of Budesonide/Formoterol (Elpenhaler).
Methods
Multicenter, prospective, non–interventional, observational study (NCT03033758) of 1, 230 asthmatic patients, not previously treated with FDC ICS/LABA, from whom 1, 028 (83.6%) had not any MD. A subgroup of 199 patients (16.2%) with MD (i.e. obesity, type 2 diabetes mellitus (T2DM) and dyslipidaemia) among other comorbidities, was evaluated for asthma control and QoL using validated Greek versions of Asthma Control Questionnaire (ACQ) and Mini Asthma Quality of Life Questionnaire (MiniAQLQ), respectively.
Results
At baseline, the median (IQR) ACQ and MiniAQLQ score were 2.45 (1.71, 3.14) and 4.21 (3.47, 5.07) for the group of patients with MD whereas the median (IQR) ACQ and MiniAQLQ score were 2.13 (1.43, 2.71) and 4.65 (4.00, 5.47) for the group of patients without MD. After 6 months, we noticed a significant decrease in ACQ score ($Z = -11.450$, $P < 0.001$), a significant increase in MiniAQLQ score ($Z = -11.776$, $P < 0.001$) and a significant, strong, negative, linear correlation between the change in ACQ (–1.61) and MiniAQLQ (1.93) scores ($rs = -0.76$, $P < 0.001$) among visits for the group of patients with MD. In the group of patients without MD, similar results were observed.
Conclusions
At baseline, asthmatic patients with MD and especially obese patients and those who had T2DM, were less controlled and had worse QoL than patients without MD. Six months of treatment with FDC Budesonide/Formoterol, Elpenhaler resulted in a significant improvement both in asthma control and QoL in these two groups of patients.

EP129

Anthropometric and body composition indices are not predictive of cardiovascular biomarkers and estimated risk in patients with type 2 diabetes on oral antidiabetic treatment

Alexandra Markova[1], Mihail Boyanov[1], Deniz Bakalov[1] & Adelina Tsakova[2]
[1]University Hospital Alexandrovska, Medical University Sofia, Clinic of Endocrinology and Metabolism, Department Internal Medicine, Sofia, Bulgaria; [2]University Hospital Alexandrovska, Medical University Sofia, Central Clinical Laboratory, Department Clinical Laboratory and Clinical Immunology, Sofia, Bulgaria

Aims
To explore the correlations of BMI, waist circumference (WC), waist–to–height ratio (WHtR), waist–to–hip ratio (WHR) and body composition with levels of assymetric dymethylarginine (ADMA), endothelin 1(ET–1), N–terminal brain natriuretic pro–peptide (NT–proBNP), uric acid and calculated cardiovascular risks.
Methods
102 women and 67 men with type 2 diabetes on oral antidiabetic drugs participated. Serum levels of NT–proBNP were measured by electro–hemi–luminescence (Elecsys 2010, Roche Diagnostics) while enzymatic immunoassays were used for ADMA (BioVendor) and ET–1 (IBL International GmbH). Cardiovascular risks were calculated using the Framingham Risk Score (FRS), the UKPDS 2.0 and the ADVANCE risk engines. Statistical analysis was performed on an IBM SPSS 19.0 (SPSS Corp., Chicago, IL).
Results
The BMI outperformed all other indices of obesity (the WC, WHtR, WHR), as well as body composition parameters (BF%, FM, FFM and TBW) in relation to the estimated risks for CHD and stroke based on different calculators. The correlations of the obesity indices with the serum CV biomarkers were not significant except for BMI and FM vs ET–1, and for FFM and TBW vs ADMA. The correlations with serum UA were very weak.
Conclusions
The WC, WHR, WHtR, BF%, FM and FFM do apparently not add significant information related to the levels of markers of endothelial dysfunction and vascular damage or the calculated CV–risks.

Similar effect of tocilizumab, an interleukin-6 receptor antagonist, administered either intravenously or subcutaneously on lipid levels in rheumatoid arthritis

Panagiotis Athanassiou[1], Lambros Athanassiou[2], Aikaterini Tzanavari[1], Marina Gatsiou[1], Eirini Devetzi[1], Pavlos Tsakiridis[1], Maria Mavroudi[1] & Ifigenia Kostoglou-Athanassiou[3]
[1]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; [2]Medical School, University of Athens, Department of Physiology, Athens, Greece; [3]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece

Tocilizumab is an interleukin-6 receptor antagonist used in the treatment of rheumatoid arthritis (RA). It is known to induce remission and inhibit radiographic progression in RA. Tocilizumab may be administered either intravenously or subcutaneously. Its effect on lipid levels and the cardiovascular risk has not been fully investigated. The aim was to study the effect of tocilizumab administered either iv or sc on disease activity, lipid levels and cardiovascular risk in RA patients.

Tocilizumab was administered iv 8 mg/kg/ 4wks (maximum dose 800 mg) in 35 patients with RA for a period of 52 weeks. Tocilizumab was administered sc 162 mg/wk in 70 patients with RA for 52 weeks. Inflammation indices, ESR and CRP and lipid levels were measured before and 52 weeks after tocilizumab administration. The DAS 28 disease activity index was also calculated.
Inflammation indices ESR and CRP decreased significantly ($P<0.001$) after tocilizumab administration in both the iv and sc groups. The DAS 28 disease activity index decreased after tocilizumab ($P<0.001$) in both groups. Total cholesterol and HDL cholesterol increased ($P<0.001$) after tocilizumab administration, LDL cholesterol and triglyceride levels also increased in both the iv and sc groups ($P<0.001$). No acute cardiovascular events were recorded during the study or thereafter in the long–term follow–up of the patients. Tocilizumab administered either iv or sc in patients with RA was shown to decrease inflammation indices and disease activity. Lipid levels increased significantly. However, total cholesterol increased in parallel with HDL cholesterol. Cardiovascular events were not observed during the study period or in the long– term follow–up of the patients. It appears that tocilizumab may be accompanied by lipid level alterations, cardiovascular risk not increasing as the adverse effects of total cholesterol may be counteracted by HDL cholesterol.

Risk of diabetes mellitus type 2 and complications associations with atherosclerosis in the population of belarus under 40 years old

Mariya Rusalenko[1], Victor Sukristiy[2], Svetlana Pankova[3] & Irina Savasteeva[1]
[1]Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus; [2]Republican Research Center for Radiation Medicine and Human Ecology, cardiology, Gomel, Belarus; [3]Republican Research Center for Radiation Medicine and Human Ecology, The research assistant, Gomel, Belarus

Introduction
T2DM prevalence in Belarus is 3.489.5 per 100 thousand people, annual growth rate is 5–6%. STEPS study: in 2016–2017 the following risk factors prevailed: overweight and obesity (61.2%), dyslipidemia (36%), hypertension (50%); inactive lifestyle (78.2%). The study aim was to assess risk factors for metabolic disorders in a young healthy population. Objective. 253 people were examined: 22.1% of men and 77.9% of women under 40. Methods: We performed anthropometric measurements, determined glycemia and total cholesterol levels; 10–year risk of developing T2DM was assessed according to the FINDRISK scale, and 10–year fatal risk of events associated with atherosclerosis – according to the SCORE scale.
Results
Median age was 30 (24; 34), BMI – 23.7 (20.4; 26.6), systolic blood pressure – (115±14), diastolic blood pressure – (77±11) mmHg, point on the FINDRISK scale – 5 (2; 8), a very high 10–year risk of T2DM was not obtained, high – in 5.6% of women, interim – in 22.2% of women and 16.7% of men, moderate – in 5.6% of women and 16.7% of men, low – in 66.6% of women and men. Statistically significant association of risk factors for T2DM and atherosclerosis depending on gender, blood pressure, or total cholesterol was not obtained. We noted a significant correlation of the risk of T2DM with BMI ($rs=0.82$; $P<0.05$), with total cholesterol ($rs=0.77$; $P<0.05$) and glycemia ($rs=0.42$; $rs.05$). Direct significant correlation was also obtained for the visceral adiposity index: $0.77 \times$ TCHOL (CM) - 0.46 $\times$ BMI (kg/m^2) – 5.82 (model $P=0.000002$) with a risk level according to FINDRISK scale ($rs=0.71$; $P<0.05$) and glycemia ($rs=0.45$; $P<0.05$).
Conclusion
In people under 40 with no risk of fatal complications associated with atherosclerosis, there is a number of factors indicating a risk of T2DM, which should be taken into account at forming different risk groups for prevention.

Variability in the distribution of epicardial fat in young patients with type 1 diabetes

Kirill Popov[1], Elena Biryukova[2], Irina Bondarenko[1], Alexander Vorontsov[1] & Olga Shatskaya[1]
[1]Endocrinology Research Center of the Ministry of Health of the Russian Federation, Moscow, Russian Federation; [2]A.I.Evdokimov Moscow State University of Medicine and Dentistry of the Ministry of Health of the Russian Federation

Aim
To study the distribution of epicardial fat in young people with type 1 diabetes mellitus using magnetic resonance imaging (MRI) technologies.
Material and methods
60 patients (29 men, 31 women), aged 18 to 36 years old, with an experience of type 1 diabetes from 5 to 16 years old were underwent contrastive cardio MRI. Measurements of epicardial fat (EF) were carried out on basal (B), medium (M), apical (A) segments of the left (LV) and right ventricles (RV) on a 4-chamber views.
Results
The results are presented as median and interquartile range (Q25–Q75): EFBLV – 1 [0;1] mm; EFMLV – 1 [0.1] mm; EFALV–– 2 [1.3] mm; EFBRV – 2 [1.75;3] mm; EFMRV – 2 [1.3] mm; EFARV – 2 [1.3] mm. The thickness of epicardial fat is greater in the RV (50 patients – 83.3%), however this pattern is not observed in all subjects, in 8 (13.3%) patients with type 1 diabetes the thickness of EF of ventricles were equivalent and in 2 patients (3.3%) EF is thicker in the LV.
Conclusion
The variability of epicardial fat in young patients with type 1 diabetes requires further research and comparison with the data of the morphofunctional state in the myocardium.

Relationship between circulating netrin -1 levels, obesity, prediabetes and newly diagnosed type 2 diabetes

Iveta Nedeva & Zdravko Kamenov
Medical University-Sofia; University Hospital "Alexandrovska", Endocrinology, Sofia, Bulgaria

Aim
Netrin is classically recognized as a neural guidance cue that has been involved in various tissues including pancreas development. Because of Netrin's tissue regenerative, angiogenic, and inflammatory suppression properties it could play a crucial role in the development of insulin resistance and type 2 diabetes. The aim of the current study is to investigate the relation between circulating levels of Netrin-1 and the glucose continuum.
Methods
Netrin-1 level was determined using a commercially available human enzyme-linked immune sorbent assay (ELISA) kit. The homeostasis model assessment of insulin resistance (HOMA-IR) was used as an index to measure insulin resistance. The sample consisted of 163 patients with mean age 52.5±11.3 years, divided in three age and BMI matched groups-obesity without carbohydrate disturbances, prediabetes and diabetes. The control group consisted of 42 healthy individuals.
Results
The Netrin-1 levels were significantly lower in patients with obesity, prediabetes and newly diagnosed diabetes compared to the control group (0.12±0.04 vs 0.19±0.07; 0.13±0.04 vs 0.19±0.07; 0.13±0.05 vs 0.19±0.07; $P<0.001$). Logistic regression analysis showed that the level of netrin–1 were negatively correlated with LDL, TG, GGT and visceral adiposity tissue.
Conclusion
The levels of Netrin-1 were decreased in patients with obesity and carbohydrate disturbances. Further studies will shed light on the role of the biomarker in development of type 2 diabetes and its complications.

Hyperlactatemia in critically ill patients

Amina Godinjak
Eurofarm, Eurofarm Centar Private Medical Clinic Unitic, Ilidža, Bosnia and Herzegovina

Objective
The aim of the study is to describe the prevalence of hyperlactatemia and changes in lactate concentrations in critically ill patients, and the associated mortality.
Materials and methods
The study included 70 patients treated in the Medical Intensive Care Unit at the Clinical Center, University of Sarajevo, in a 6–month period. The following data were obtained: age, gender, reason for admission, Simplified Acute Physiology Score II, Acute Physiology and Chronic Health Evaluation, lactate concentrations upon admission, after 24 and 48 hours, and outcome.
Results
Hyperlactatemia upon admission was present in 91.4% patients with mean lactate concentrations of 4.13±1.21 mmol/l. Lactate concentration at 48 hours was independently associated with increased in–hospital mortality ($P=0.018$). Lactate concentration after 48 h represents a statistically significant predictive marker of fatal outcome in patients (AUC 0.874, CI 0.769–0.980 $P=0.001$) with a cut off value of 2.25 mmol/l, and sensitivity of 72.2% and specificity of 92.1 %.
Conclusion
Persistent hyperlactatemia is associated with adverse outcome in critically ill patients. Lactate concentration at 48 hours is independently associated with increased in-hospital mortality and it represents a statistically significant predictive marker of fatal outcomes of patients. Blood lactate concentrations > 2.25 mmol/l can be used by clinicians to identify patients at higher risk of death.
Keywords: hyperlactatemia, critical illness.

EP135

Comparison of two different dietetic approaches in obese and overweight patients with type 2 diabetes mellitus

Christina Balamoti & Alexandra Bargiota
[1]University Hospital of Larissa, Department of Endocrinology and Metabolic diseases, Larissa, Greece

Context
Weight reduction in obese patients with type 2 diabetes mellitus (T2DM) leads to hyperglycaemia improvement and reduces complications. Thus it is important to investigate the potential benefits of the use of different dietetic approaches on weight loss.
Objective
To examine the efficacy of two different dieting methods on weight loss in patients with T2DM.
Materials and methods
30 participants with T2DM, 18 men and 12 women, overweight or obese, aged 50.8±11.2y were categorized into two intervention groups: 1rst group ($n=15$) received a diet based on equivalent exchange list food choices (EEL) and 2nd group ($n=15$) received a point–calorie and starch equivalent system (PCS) for a 39month period. The EEL diet included carbohydrate specific pre–planned meals that the subject had to follow. The PCS diet was a free food choice system, with specific points and starch content attributed to foods listed. Subjects had individual point and starch limit daily. The recommended energy consumption was 500 Kcal less than the predicted total energy expenditure. The efficacy of each method was assessed by weight loss (weight day 0– weight day 90) and % weight loss (weight day 0– weight day 90/weight day 0 × 100). Changes in body mass index (BMI) and waist circumference (WC) were also measured.
Results
Baseline BMI was 37.0±6.5 kg/m^2 for the EEL and 40.1±11.1 for the PCS group ($P=0.3$), mean weight and WC was 108.1±22.9 and 117.8±33.6 kg ($P=0.2$) and 122.6±1.4 and 117.7±24.4 cm ($P=0.5$) for the EEL and PCS respectively. At 3-months the mean BMI was 34.3±5.4 kg/m^2 for the EEL and 37.4±10.7 for the PCS group ($P=0.3$), the mean weight was 99.9±17.4 and 109.7±32.4 kg ($P=0.3$) and the mean WC was 115.9±17.7 and 111.1±20.8 cm respectively ($P=0.7$). The mean BMI reduction was 2.7±1.9 kg/m^2 for the EEL ($P=0.001$) and 2.7±1.1 for the PCS group ($P=0.0001$). Mean weight loss for the EEL was 8.1±6.7 kg ($P=0.001$) and 8.1±3.2 kg ($P=0.001$) for the PCS group. Mean WC reduction for the EEL group was 6.6±4.8 cm ($P=0.001$) and for the PCS group 6.2±2.6 cm ($P=0.001$). At 3 months %BMI reduction in EEL and PCS groups (7.0%±3.9%– 7.1%±2.9%), %weight loss (7.0%±3.9%– 7.1%±2.9%), and %WC reduction (5.3%±3.6%– 5.3%±3.6%) were not significantly different.
Conclusion:
These preliminary findings suggest that both nutritional interventions were equally effective in weight loss in patients with T2DM. More participants and longer studies are needed for safer conclusions.

EP136

Weight gain, but not macro–nutrient intake, modifies the effect of dietary branch chain amino acids on the risk of metabolic syndrome

Somayeh Hossainpour[1], Bahar Bakhshi[1], Parvin mirmiran[1] & Fereidoun Azizi[2]
[1]Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Nutrition and Endocrine Research Center, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Endocrinology and Metabolism, Tehran, Iran

Background
The aim of this study was to investigate whether both weight change and the background intakes of macronutrients modulate the association between dietary branch chain amino acids (BCAAs) and the risk of metabolic syndrome (MetS).
Methods
This prospective study was conducted within the framework of the Tehran Lipid and Glucose Study. BCAA intakes were collected using a valid and reliable semi-quantitative food frequency questionnaire. MetS components were defined according to the modified national Cholesterol Education Program Adult Treatment Panel III. Weight change was categorized as weight gain (≥ or < 7 % over 8.9 year follow -up). Dietary fat and carbohydrate intake were categorized as above/below the median intake.
Results
Among participants with weight gain ≥ 7 % during follow–up, intakes of both dietary BCAAs and its various sources (below or above the median intake) were associated with higher risk of MetS, compared with subjects with lower intakes of BCAAs and weight change ≤ 7 %. Background dietary fat and carbohydrate did not modify the association of dietary BCAAs and its various sources with the risk of MetS.
Conclusions
Weight change, but not dietary macronutrient intake, modulates the association between dietary BCAAs and risk of MetS among adults.
Keywords: BCAA, metabolic syndrome, weight change, macronutrients, interaction.

New microbiological markers of various types of obesity (pilot study)

Natalya Volkova, Lilia Ganenko, Yulia Naboka, Oksana Oksenuk & Yuliya Degtyareva
Rostov State Medical University, Rostov–on–Don, Russian Federation

Obesity is a polyetiological and incompletely studied disease. Recent publications link the special composition of the gut microbiota not only with obesity, but also with its metabolic profile[1, 2]. To study the characteristics of the gut microbiota in patients with different phenotypes of obesity, 37 patients were examined. In addition to determining the quantitative composition of the gut microbiota by the Real-time PCR method, all participants were determined by lipid and carbohydrate metabolism and 3 groups were identified according to Wildman's criteria: 1 group ($n=11$) - healthy people without obesity and overweight, 2 group($n=13$) - patients with metabolically healthy obesity (MHO), group 3 ($n=13$) - patients with metabolically unhealthy obesity (MUHO). The results showed that the differences between the 1st group without obesity and the 2nd group with MHO is in the registration in the feces of Klebsiella spp. and Proteus spp. in amounts exceeding the formal regulatory in patients of group 2. The most significant changes were obtained in group 3 (MUHO): C.difficile was detected, a significant ($P=0.05$) decrease in F.prausnitzii and an increase ($P=0.05$) in the detection frequency of banal E.coli and a more diverse composition of gut microbiota. The data obtained as a result of our pilot study revealed compositional changes in the gut microbiota among the studied groups, which could potentially be either the cause and / or display different phenotypes of obesity. It is planned to continue further study of the composition of the microbiota of the colon in patients with various phenotypes of obesity, with

only a large number of examined in groups to obtain confirmation of the identified changes in the pilot study.

Adipokines vaspin and omentin as risk markers of disorders of carbohydrate metabolism development in overweight and obese patients

Iurii Karachentsev[1], Nonna Kravchun[1], Katerina Misiura[1], Inna Dunaeva[2] & Mohamad Hussain Alhamid[1]
[1]State Institution V. Danilevsky Institute for endocrine pathology problems National Academy of Medical sciences of Ukraine, Department of Clinical Endocrinology, Kharkiv, Ukraine; [2]Kharkiv Medical Academy of Postgraduate Education, Department of Endocrinology and Pediatric Endocrinology, Kharkiv, Ukraine

Adipokine omentin is a connecting link between obesity and type 2 diabetes mellitus. It modulates insulin sensitivity of peripheral tissues and its secretion may change in the developed inflammation of adipose tissue at its excessive accumulation. Chemokine fractalkine is a marker of the development of inflammatory processes in the body. Objective: omentin and fractalkine contents in blood circulation depending on the degree if adipose tissue accumulation, waist circumference, blood insulin level and HOMA–IR in representatives of Ukrainian population.

Materials and methods

250 individuals aged (65.48±11.86) years were examined, their waist circumferences were measured, adipose tissue mass was assessed by bio impedance method, including relatively to the total body mass; by immune enzyme method contents of insulin, fractalkine and omentin in circulation were determined; HOMA-IR index was determined.

Results

It was revealed that blood fractalkine and omentin levels show negative correlation between them (r=–0.863, P<0.001). Blood fractalkine level correlates positively with adipose mass of the body (r=0.5341, (P<0.001)); waist circumference – (r=0.4542, (P <0.001); insulinemia and HOMA–IP levels: (r=0.7798, (P<0.001) and r=0.745, (P<0.001)). Blood fractalkine level (ng/ml)=[407.478+57.1702 × HOMA-IR+2.2580 × waist circumference]; R_2=0.626; F=273.85; P<0.00001). Omentin level correlates negatively with adipose body mass (r=–0.609, (P<0.001)); waist circumference – (r=–0.397, (P<0.001); insulinemia and HOMA–IR levels: (r=–0.799, (P<0.001) and r=–0.7706, (P <0.001)). Blood omentin level (ng/ml)=[618.3103 – 25.6928 × HOMA–IR – 2.9962 × adipose tissue mass / total body mass]; (R_2=0.676; F=339.89; P<0.00001). It was proved that accumulation of adipose mass more than 25 % of the total body mass determines growth of fractalkine level up to 750 ng/ml and over; HOMA-IR>2.77, decreased level of omentin to 500 ng/ml and less. Contents of adipose tissue more than 34 % of total body mass determine increased fractalkine levels up to 900 ng/m. and more; HOMA–IR>4.00, decreased level of omenton to 400 ng/ml and lower.

Conclusion

Important role of fractalkine and omentin in pathogenesis of diabetes mellitus in obesity was proved. The correlation was established between the adipose tissue accumulation, changes in its endocrine function, development of inflammatory processes in the body, abdominal obesity, insulin resistance and type 2 diabetes mellitus onset.

Autoimmune diseases associated with T1D

Chaima Jemai[1], F Mahjoub[2], O Berriche[2] & H Jamoussi[2]
[1]National institute of nutrition of Tunis, C, Tunisia; [2]National institute of nutrition of Tunis, A, Tunisia

Introduction

Type 1 diabetes can be associated with one or more other autoimmune pathologies in case of predisposing immune background.

The aim of our study was to research the autoimmune pathologies associated with type 1 diabetes and to describe the clinical and biological characteristics of this population.

Patients and methods

This is a retrospective descriptive study including 26 patients with type 1 diabetes with at least one autoimmune pathology associated with diabetes.

Results

The average age was 35.7±8.6 years. The sex ratio was 0.23. Diabetes had evolved for an average of 17.4±6.8 years. The average body mass index (BMI) was 28.2±3.2 kg/m^2. The average HbA1C was 9.1±2.2%. The average creatinine clearance was 99.2±12.3 ml/min (CKD–EPI). The most widely described degenerative complication was retinopathy (28.1%). Hashimoto's thyroiditis was the autoimmune disease most associated with diabetes (73%) followed by celiac disease (19.2%). Only one cas of vitiligo and another case of Biermer's anemia had been found. All cases of thyroiditis were diagnosed after diabetes, as was the case with Biermer's disease. Vitiligo preceded the diagnosis of diabetes. Celiac disease preceded diabetes in the majority of cases.

Conclusion

The frequent association of autoimmune pathologies with diabetes encourages them to be screened regularly so that they are managed on time.

Awareness of patients with type 2 diabetes about their disease

Volha Shyshko[1], Alena Yurenya[1], Tatjana Mokhort[2], Iryna Bilodid[2] & Volha Lazovtseva[1]
[1]City Endicrinology Dispensary, Endocrinology, Minsk, Belarus; [2]Belarusian State Medical University, Endocrinology, Minsk, Belarus

Background

Attendance and active participation in diabetes school classes is an important element in disease management. It has been noted that self–learning and self–help predetermine the clinical outcomes of diabetes and the quality of life of patients.

Aim

To evaluate the awareness of patients with type 2 diabetes (T2D) about their disease.

Materials and methods

45 patients with T2D were included. The survey contained 5 questions: A questionnaire based on the Diabetes Care Profile (DCP) questionnaire was offered to all participants. As part of this work, the following sections have been analyzed: school diabetes, glucose self-control (which includes questions on hypo-and hyperglycemia), power supply, physical activity, prosperity, complication control, observance of the recommendations for treatment of the disease.

Results

55.5% (25) are willing to watch, observe, and only one in five (20.0% (9)) would like to communicate interactively. One in three patients with type 2 S.D. does not self–monitor glucose until 33.3% in the morning and 35.6% two hours after a meal. The presence of symptoms of hypoglycemia was indicated by patients who received either insulin treatment or insulin treatment in combination with oral drugs (44.4%). 43.2% experience hyperglycemia and 54.5% do not. 28.2% do not take any action on this issue, and 33.3% increase their short insulin dose. Only 10.3% increase the dose of prandial insulin or resort to physical activity. 12.8% and 15.4% either consume more fluid or skip staple foods or snacks, respectively. 55.8% exercise regularly. And 44.3% do not pay due attention to this recommendation.70.1% noted that their physical activity is light, 27.0% have a moderate load. 46.0% do not agree that they are healthy. 35.1% find it difficult to answer the question unambiguously and 18.9% feel healthy. According to 55.3% of patients, diabetes interferes with other aspects of life, 26.3% do not know how to answer the question, and 18.4% disagree. 41.0% of patients experience high levels of stress and one in four 25.6% are unfamiliar with these feelings by self-esteem.

Conclusion

Patients with type 2 DM are familiar with the main actions in hyperglycemia, but the practical application of these recommendations does not give proper results. Half of those interviewed do not feel healthy and the disease interferes with other aspects of their lives. Many agree that they are making efforts to control the disease, but are not aware of what this concept includes.

EP141

Frequency of hyperglycemia in screening of pregnant bulgarian women

Anna–Maria Borissova[1], Lilia Dakovska[1], Eugenia Michaylova[1, 2] & Boyana Trifonova[1]
[1]University Hospital Sofiamed, Medical Faculty, Sofia University St Kliment Ohridski, Clinic of Endocrinology and Metabolic Diseases, Sofia, Bulgaria; [2]MDL Bodimed, Clinical Laboratory, Sofia, Bulgaria

Bulgaria is also among the countries with national data on the prevalence of Diabetes published in the Diabetes Atlas of the International Diabetes Federation'2019, but did not provide data on the incidence of Hyperglycemia in pregnant Bulgarian women.
Purpose
The Bulgarian Society of Endocrinology organized and conducted screening for Hyperglycemia in pregnant women in 2019.
Material and methods
547 pregnant women from 10 regions of Bulgaria (84 settlements) were examined, with an average age of 30±5 y, an average BMI at screening 26.15±7.28 kg/m2, distributed by trimesters – I (*n* – 111, 20.3%), II (*n* – 275, 50.4%), III (*n* – 161, 29.3%). The diagnostic criteria for hyperglycemia in pregnant women were in compliance with FIGO'2015 / WHO'2013 and NICE'2015.
Results
Hyperglycemia was detected in 74 (13.52%) of the pregnant women according to oGTT screening data, with 5.66% (*n* – 31) diagnosed with early pregnancy and 7.86% (*n* – 43) – Gestational Diabetes Mellitus (GDM). There is no evidence of pre–pregnancy hyperglycemia or antidiabetic medication. Family burden with Diabetes was found in 210 pregnant women (38.4%). This family burden is present in 58.1% of all pregnant women with hyperglycemia (*n* – 43/74) – in 67.7% of pregnant women with early hyperglycemia (*n* – 21/31) and in 51.2% of pregnant women with GDM (*n* – 22/43). It appears that the risk of hyperglycemia is twice as high in the presence of familial diabetes with 20.4% (*n* – 43/210) compared to the lack of familial diabetes with 9.2% (*n* – 31/337). The average weight before pregnancy of the whole group is 63.68±14.36 kg, and during pregnancy it reaches 70.60±14.50 kg. The average weight before pregnancy is 71.00±16.30 kg of pregnant women with established hyperglycemia during pregnancy, which plays an important role in unlocking glucose intolerance.
Conclusion
The high incdence of hyperglycemia in pregnant Bulgarian women requires changes in the health system to diagnose this disorder in a timely manner.

EP142

The impact of fasting during ramadan on the sleep 9 wake rhythm in type 2 diabetics

Sara IJdda, Sana RafiI, Ghizlane Elmghari & Nawal Elansari
University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
Fasting during Ramadan is a pillar of Islam. The majority of diabetic patients at risk, practice it even if they are exempt. This practice shifts energy and hydration in the evening and reverses the sleep–wake rhythm. The aim of this work is to study the effect of fasting during the holy month on the sleep–wake clock in fasting diabetics.
Patients and methods
As part of an overall management of accompagnimant for our diabetic patients, an integral health action that aims to stratify the risk for fasting, was carried out before Ramadan in 2019. A questionnaire on sleep habits was completed one week before Ramadan and one month after. Two scales of drowsiness and tiredness were also completed.
Outcomes
Among the 176 participants in this company, 81 type 2 fasting diabetics were collected to answer the sleep quality questionnaire. The total reported sleep duration was much shorter during Ramadan. Fatigability and daytime sleepiness were present in 68% of patients during Ramadan, vs 28% after this month with no notable incidents. The duration of the revealed daily nap was much longer during the holy month with an average of 150 minutes, compared to 90 minutes outside of Ramadan.
Discussion/Conclusion
The effect of fasting during Ramadan on sleep patterns, daytime sleepiness is an interesting topic that provides a highly complex context for future research.
Our observational and analytical study shows that fasting during Ramadan leads to insufficient night sleep with a non–compensatory increase in the duration of daytime naps.
These changes could be related to lifestyle changes that accompany Ramadan fasting rather than the act of fasting itself. Larger studies that control for different confounding factors, such as environmental and cultural factors, are needed to assess the impact of Ramadan fasting on sleepiness. In addition, it is important to assess the impact of Ramadan fasting in different Islamic cultures using the same assessment methods.

Lipoatrophy in a patient with type 1 diabetes: Genetic or immunological?

Tanveer Ashraf, Nisreen Awad, Sara Suliman, Radwa Helal, Safdar Naqvi & Nader Lessan
Imperial College London Diabetes Centre, Clinical Research, Abu Dhabi, United Arab Emirates

We report the case of a 28-year-old Emirati lady with type 1 diabetes (weight 51 kg, BMI 20.82 kg/m^2) diagnosed at 3 years of age who presented to our centre with problems at her insulin injection sites. She had poor glycaemic control and her diabetes was complicated by retinopathy; other past medical history included vitamin D deficiency. All her seven siblings had diabetes and were on insulin; both parents had type 2 diabetes.
In 2017, she was switched from insulin glargine to insulin degludec and 7 months later she developed pronounced lipoatrophy (both upper frontal aspects of thigh) at the injection sites. She also developed hyperpigmented and hypertrophic reticular lesions on both axillae and neck, which were histologically proven acanthosis nigricans. She was treated with minocycline and this resulted in some improvement.
Further investigations included serum leptin and C3 nephritic factor, which were within normal range. Genetic testing showed a heterozygous variant in the Lipase E (LIPE) gene [c.746C>T p. (Thr249Met)] that was reportedly of uncertain significance. LIPE gene encodes hormone–sensitive lipase (HSL) that hydrolyzes triglycerides in adipose tissue. Mutations in this gene are associated with familial partial lipodystrophy. Attempted adipose tissue transplant was unsuccessful as transplanted tissue also atrophied within 2 weeks.
The lipoatrophy in this patient was severe and continued in spite of avoidance of injections at the lesions. It is likely that immunological factors are important in its aetiology. The heterozygous variant in LIPE gene is very rare and has not been previously described in the Emirati population. The strong family history suggests genetic cause for this patient's diabetes, which may also be relevant in the aetiology of her lipodystrophy. In the reported case here, there were also major psychological and cosmetic sequelae which contributed to her poor glycaemic control which have proved challenging to treat.

Cardiovascular diseases in people with diabetes mellitus in asturias from 2013 to 2017

Paula Morales Sánchez[1, 2, 3, 4], Raúl Rodríguez Escobedo[3], Soraya Lanes Iglesias[3], Carlos Alonso Felgueroso[3], Gema Martínez Tames[3] & Edelmiro Menéndez Torre[3, 4, 5]
[1]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Cancer Epigenetics and Nanomedicine, Oviedo, Spain; [2]Centro de Investigación en Nanomateriales y Nanotecnología (CINN), Cancer Epigenetics and Nanomedicine, El Entrego, Spain; [3]Central University Hospital of Asturias, Endocrinogy and Nutrition, Oviedo, Spain; [4]CIBER – Center for Biomedical Research Network, Rare Diseases, Madrid, Spain; [5]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Endocrinology, Nutrition, Diabetes and Obesity, Oviedo, Spain

Aim
Atherosclerotic cardiovascular disease, defined as myocardial infarction (MI), cerebrovascular accident (CVA), peripheral artery disease (PAD), is the main cause of morbidity and mortality in people with diabetes mellitus (DM) and the main cause of health expenditure in these patients.
Like in other parts of the world, a prospective study of the Asturian population showed that the mortality risk due to cardiovascular diseases was significantly higher in women with DM2 than in men.
The aim of this study is to compare the odds ratio of cardiovascular disease in people diagnosed of DM with those not diagnosed of DM based on age and sex, in the Asturian region between 2013 and 2017.
Materials and methods
Data were collected from the Primary Healthcare Clinical Database of the National Health System for the Principality of Asturias, between 2013 and 2017. The people with DM and non–DM were grouped by sex and age (35 to 64 and people over 64 years). In addition, the comorbidities both diagnosed and non–diagnosed were recorded as follows: MI, CVA and PAD.
Odds ratio, confidence intervals (95%) were calculated in R environment. Graphics were performed in GraphPad Prism 8.0.1.
Results
In all the years (2013 to 2017) it was observed that people with DM, regardless of age and sex, were more likely to suffer from any of the three cardiovascular diseases.
When analysing the data stratified by age, people with diabetes between 35 and 64 years are more likely to suffer from MI, CVA or PDA; a progressive decrease in ORs can be perceived from 2013 to 2017, in patients with DM in ages between 35 and 64 suffering from PAD (4.35 [4.06 – 4.66] and 3.09 [2.88 – 3.31] respectively).
When the data is separated by sex, the youngest age group is at greater risk of suffering from any cardiovascular disease. Diabetic women between 35 and 64 years of age were more likely than men to suffer from MI, while the opposite was appreciated for CVA and PDA. Likewise, a tendency to increase the odds from 2013 to 2017 was observed in this group.
Conclusions
Comprehensive and aggressive control of known risk factors for cardiovascular disease is needed in diabetic patients, especially those younger and females, in order to reduce the high prevalence of cardiovascular complications seen in Asturias.

Association between change of lipid profiles and early postpartum hyperglycemia risk in chinese women with prior gestational diabetes mellitus

Zeting Li, Huangmeng Xiao, Ling Pei, Xiaoyu Huang, Shufan Yue, Wenzhan Chen & Xiaopei Cao
First Affiliated Hospital, Sun Yat–sen University, Endocrinology, Diabetes and Metabolism, Guangzhou, China

Aims
Maternal dyslipidemia during pregnancy is more serve in GDM women compared with non–GDM women. The occurrence of postpartum hyperglycemia is associated with increased lipid profiles. The purpose of this study was to evaluate the relationship between lipid changes and early postpartum abnormal glucose metabolism (AGM) of women with prior GDM history.
Methods
395 patients with a history of GDM who had a postpartum OGTT were included in this retrospective cohort study. Patients' lipid levels at the gestational 2nd, 3rd trimester and early postpartum, which included total cholesterol (TC), triglycerides (TG), low–density lipoprotein cholesterol (LDL–C), high–density lipoprotein cholesterol (HDL–C) and TG/HDL–C ratio were recorded. HOMA–IR was used to evaluate insulin resistance and ISSI–2 was applied to assess pancreatic β cell functions. Logistic regression and Spearman correlation analysis were applied to determine the relationship between postpartum lipid change and glucose metabolism.
Result
Postpartum AGM patients ($n=153$) were with higher postpartum triglycerides (TG) and TG/HDL levels than women with normal glucose tolerance (NGT) ($n=242$). TG, TC, LDL–C, concentration and TG/ HDL–C ratio increased gradually during pregnancy and decreased after delivery, while HDL–C levels constantly decreased from 2nd trimester to early postpartum, the trends were similar in the postpartum AGM group and NGT group. Logistic regression analysis showed that decrease ratio of TG after delivery was associated with a decreased risk of early postpartum AGM. Correlation analysis indicated that ratio of TC, TG, LDL–C and TG/HDL–C were associated with the restoring of insulin sensitivity and pancreatic β cell function.
Conclusion
Postpartum changes in blood lipid level in GDM patients are closely related to hyperglycemia in the early postpartum, and effect of the decrease of TG was the most significant. The specific mode of action may be related to insulin resistance and pancreatic β cell function.

Uricemia and renal function in type 2 diabetics

Ramla Mizouri, Hajer Zahra, Fatma Boukhayatia, Faten Mahjoub, Olfa Berriche & Henda Jamoussi
Institut National de Nutrition de Tunis, Service A, Tunisia

Introduction:
Due to the association of hyperuricemia with conventional cardiovascular risk factors, it is difficult to determine whether uric acid is an independent risk factor for the development of renal failure. The objective of this study was to investigate the correlation between uric acid levels and kidney function in type 2 diabetics.
Methods
This was a descriptive cross–sectional study carried out from March to September 2017 on 122 diabetic patients hospitalized at the National Institute of Nutrition. Each patient underwent a clinical examination with a standard assessment including the determination of creatinine and uric acid. Creatinine clearance was calculated using the CKD–EPI formula.
Results
The average age of our patients was 52.4±7.3 years. The sex ratio was 0.96. All patients in our population were type 2 diabetics and the average duration of diabetes was 11.07±3.3 years of which 78.7% were on insulin therapy. The patients in our study were smoking at 35.2%, sedentary at 39.8%, hypertensive at 45.1% and presented with biology a hyper-LDLemia at 56.2%. Uricemia was positively correlated with creatinine level ($P=0.41$; $P<0.05$) and inversely correlated with creatinine clearance. The level of uric acid varied according to the stage of the renal insufficiency; indeed it increased if the renal function was deteriorated ($P<0.005$). Uricemia is also positively and statistically correlated with the number of cardiovascular risk factors in type 2 diabetics ($P<0.05$).
Conclusion
Our work has shown that uric acid levels are correlated with kidney function which could be an aggravating factor for this impairment. However, our population was small and not representative of the population, hence the need for large–scale studies.

Ramadan fasting affects body composition and anthropometric parameters in type 2 diabetic patients.

Fatma Boukhayatia, Ibtissem Oueslati, Meriem Cheikh, Asma Kardi, Fatma Chaker, Meriem Yazidi, Nadia Khessairi & Melika Chihaoui
La Rabta hospital, Department of endocrinology, Tunis, Tunisia

Introduction
Fasting the month of Ramadan is practiced by more than one billion Muslims worldwide, including type 2 diabetic patients. Its effects on body composition and body weight in type 2 diabetic patients are controversial.
The objective of our study was to assess the evolution of anthropometric parameters as well as the body composition in type 2 diabetic patients who fasted the month of Ramadan.
Methods
We conducted a prospective case–crossover study including 55 type 2 diabetic patients treated with metformin and / or sulphonylurea, with an HbA1c <10% and who intended to fast the month of Ramadan 2019, in the absence of a major contraindications. Body composition and anthropometric parameters (body weight, body mass index (BMI) and waist circumference (WC)) were evaluated in three sessions: T0: before the month of Ramadan, T1: just after the month of Ramadan and T2: 1 to 2 months after Ramadan month.
Results
Participants had an average age of 54.5±10.1 years and a sex–ratio of 0.89. The average HbA1c before the month of Ramadan was 7.13±0.95%.

Eighty–nine percent of patients fasted 30 days. There was a significant body weight loss after Ramadan fasting ($p<10^{-3}$). The BMI was 29.51±5.13 kg/m^2 before Ramadan, 29.22±5.42 kg/m^2 at T1 ($P=0.004$) and 29.56±5.01 kg/m^2 at T2 ($P=0.05$). The WC clearly decreased at T1 (T0=97.6±8.92 cm vs T1: 96.37±10.22 cm; $P=0.015$) but not at T2 (WC=97.13±8.03, $P=0.55$). Compared to T0, there was a decrease in the fat mass at T1 (T0=23.69±9.32% vs T1=23.28±9.5%, $P=0.043$) but not at T2 (T2=23.77±9.26%, $P=0.24$). The fat mass index varied from 8.92±3.92 at T0 to 8.82±4.12 at T1 ($P=0.04$) and to 8.93±3.76 at T2 ($P=0.24$). Body weight loss at T1 was positively correlated with the number of fasted days ($r=0.348$, $P=0.018$). However, it was not correlated with dietary intake variations and the physical activity.
Conclusion
Ramadan fasting had a favorable and a significant effect on the body composition, the body weight and the WC in type 2 diabetic patients. However, this improvement was not sustainable one month later.

Study on glutamic acid decarboxylase antibodies (Anti–GAD) in blood serum for early diagnosis of diabetes mellitus

Zafar Ibragimov[1], Timur Alimov[2], Nigora Maksutova[3], Elvira Ibragimova[1], Khamid Karimov[2], Tokhir Ishanhodjaev[1], Sanobarkhon Irgasheva[1] & Talat Saatov[1]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Biochemistry, Tashkent, Uzbekistan; [2]Institute of Hematology and Blood Transfusion, Uzbekistan Public Healthcare Ministry, Molecular Medicine and Cell Technologies, Tashkent, Uzbekistan; [3]Ya.Kh. Turakulov Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan

There are three main types of diabetes mellitus: type 1 diabetes mellitus (T1DM), type 2 diabetes mellitus (T2DM) and gestational diabetes, with the first two types making about 99% of cases.
According to its nature, type 1 diabetes mellitus (T1DM) is considered as a typical autoimmune disorder characterized with specific autoantibodies. Immunological markers of the diabetes mellitus onset can be found not only in T1DM with its specific clinical picture, but also in T2DM. Glutamic acid decarboxylase antibodies (Anti–GAD) are a DM immunological marker both of clinical and academic interest.
The work was initiated to study predictive value of specific glutamic acid decarboxylase antibodies as the immunological marker.
Anti–GAD concentrations were measured in the blood serum of a proband, a patient with type 1 diabetes mellitus. The enzyme–linked immunosorbent assay with the ELISA kit for Anti–Glutamic Acid Decarboxylase Antibody (Anti–GAD) (Cloud–Clone Corp., Houston, USA) was used for Anti–GAD qualitative determination in plasma and blood serum of the patients. Variation statistics was used for statistical processing of the results.
Anti–GAD concentrations in the probands' blood were found to be 1.54 times higher than those in blood of the apparently healthy controls ($P_1<0.0001$). The similar picture could be seen after examination of a proband's family members with Anti–GAD concentrations 1.9 times higher than those in the controls. Among other things, this seemed to be associated with the presence of the diabetics among the probands' family members. It can be explained by the genetic predisposition to DM onset and progression in some family members as well.
Identification of Anti–GAD in patients with the diagnosed DM, as well as in some of their close relatives can serve as a confirmation of predictive value of the immunological marker.

EP149

Vitamin D deficiency in children and adolescents with type 1 diabetes mellitus

Youssef Lazreg, Loukili Mohammed Aymane, Ould Cheikh Sidi Ahmed, Rouf Sihame & Latrech Hanane
UHC Mohammed VI, Endocrinology Diabetology Departement, Oujda, Morocco

Introduction
Besides its role in calcium homeostasis, vitamin D (VD) has an important immune mudulation effect. However, its role in autoimmune diseases such as type 1 diabetes is under discussion. In this study, we aimed to assess VD status in children and adolescents with type 1 diabetes mellitus (T1DM).
Material and methods
This is a retrospective descriptive study realized at the endocrinology–diabetology department of OUJDA's Mohammed VI university hospital, included 120 type 1 diabetics under the age of 19 years, with evaluation of vitamin D status.
Results
The sex ratio in our study was 1.2 (M/F) with a mean age of 13.4±4.15 years. 32.2% have a history of type 1 diabetes mellitus over 5 years. The mean HbA1c was10.97±2.42 %.
Of 120 of cases with T1DM, most had inadequate levels of vitamin D: sufficiency, 3.3% ($n=4$); insufficiency, 75 % ($n=90$); deficiency, 21.7% ($n=26$). In bivariante analyses for age, sex, visit season, z–BMI, diabetes duration, and A1c, age was most significantly associated with the level of 25OHD ($P<0.037$, r –, 191*); older age was associated with lower 25OHD concentrations.
Discussion and conclusion
Previous studies have shown that the early years of adolescence are often associated with a rapid decline in vitamin D.
Because of many risk factors that may not be modifiable due to the inherent presence of diabetes mellitus, vitamin D deficiency during childhood and during the period of peak bone mineral accumulation in this population is justified.

Effect of socioeconomic and educational status on metabolic control in patients with diabetes mellitus type 2 in republic of srpska

Snjezana Popovic Pejicic[1], Ljiljana Stanivuk[2] & Nina Pejicic[3]
[1]Medical faculty Banja Luka, University Clinical center of Republic of Srpska, Clinic for internal medicine, Banja Luka, Bosnia and Herzegovina; [2]Public Health Institute of Republic of Srpska, Banja Luka, Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina; [3]University Clinical center of Republic of Srpska, Clinic for plastic and reconstructive surgery, Banja Luka, Bosnia and Herzegovina

Aim
To determine the effect of socioeconomic and educational status on metabolic control in T2D patients in Republic of Srpska (RS)
Subjects and method
This is a cross–sectional study of 1088 subjects aged 18 or higher who were randomized from primary care physicians' T2D diabetes registries. Socioeconomic, educational, anthropometric and metabolic characteristics of T2D patients were analyzed.
Results
Highest proportion of participants were older than 65 (47.9%) with 55% women and 44.5% men. 65.3% were retirees with single monthly income (61.4%) of up to 300€ (63.2%). More than half of participants had elementary level or no education at all. Unsatisfactory HbA1c level was statistically significantly more common (61.1%:38.9%, $\chi^2=4.874$, df=1, $P=0.027$) in patients of low socioeconomic and educational status. Half of participants were obese (BMI≥30kg/m^2) and 75% had abdominal obesity with elevated levels of cholesterol (75.6%), LDL (86.0%) and triglycerides (54.3%), and low HDL levels (55.9%). Albuminuria and proteinuria were reported in 59.7% and hypertension in 88.61% of subjects.
Conclusion
High percentage of T2D patients of low socioeconomic and educational status in Republic of Srpska has not achieved target values of good metabolic control, is obese and has microalbuminuria. This could be related to low educational level, low monthly income and older age. Since most participants live with other family members it is necessary to educate those family members to take active part in realization of health guidelines for diabetes management.

EP151

Incidence of chronic diabetes complications and its association with glucoregulation quality and antihyperglycemic treatment in patients with diabetes mellitus in republic of srpska

Snjezana Popovic Pejicic[1], Ljiljana Stanivuk[2] & Nina Pejicic[3]
[1]Medical faculty Banja Luka, University Clinical center Banja Luka, Republic of Srpska, Clinic for internal medicine, Banja Luka, Bosnia and Herzegovina; [2]Public Health Institute of Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [3]University Clinical center of Republic of Srpska, Clinic for plastic and reconstructive surgery, Banja Luka, Bosnia and Herzegovina

Aim
Chronic diabetes complications are the main cause of patients' mortality, life span shortening and decreased quality of life. Aim of this study is to determine the incidence of chronic diabetic complications and their association with glucoregulation quality and antihyperglycemic treatment in diabetic patients in Republic of Srpska. (RS).
Method
This cross–sectional study included 1037 diabetic patients in RS. Immuno–inhibition test (Roche Diagnostics) was used for measurement of HbA1c. Anthropometric and blood pressure measurements, screening for chronic complications of diabetes and antihyperglycemic treatment questionnaire were included.
Results
Poor glycemic control (Hba1c ≥6.5%) was found in 61.1% of subjects (χ^2=4.874, df=1, P=0.027). The most common complication was microalbuminuria –nephropathy (48.10%), followed by polyneuropathy (42.5%) and retinopathy (25.0%). Polyneuropathy and microalbuminuria were more common in T2D (χ^2=10.217, df=1, P=0.001), while retinopathy was more common in T1D. Cardiovascular disease was recorded in 81.4%, significantly more often in women (87.0 vs 75.9%) than men (χ^2=21429, df=1, P=0.000). Significantly more men (5.5%) than women (2.3%) had diabetic foot (χ^2=7.237, df=1, P=0.007). In patients with T1D on diet and insulin treatment microvascular complications and hypertension were less common compared to patients on insulin only. In T2D the same is found with combination treatment (insulin plus diet and/or oral therapy) compared to oral only treatment.
Conclusion
High percentage of diabetic patients in RS have poor glucoregulation, hypertension, nephropathy and cardiovascular disease . Many studies from developing countries have shown similar results thus underlying the need for implementation of stronger measures for improving glucoregulation and reducing chronic complications.

Laser doppler flowmetry and fluorescence spectroscopy in assessing the state of the microvasculature and oxidative metabolism in patients with diabetes mellitus

Shinkin Mikhail[1], Zvenigorodskaya Larissa[1], Mkrtumyan Ashot[1] & Sidorov Victor[2]
[1]Moscow Medical clinical research center Loginov, , Moscow, Russian Federation; [2]Scientific Productive Enterprise Laser Medical Devies, Moscow, Russian Federation

Purpose
To study the state of the microvasculature and tissue metabolism (according to the dynamics of the FAD and NADH coenzymes) using laser Doppler fluometry (LDF) and laser fluorescence spectroscopy (LFS) in patients with diabetes mellitus.
Materials and methods
To implement the combined use of LDF and LFS methods, the Laser Diagnostic Device LAZMA ST was used (registration certificate of Roszdravnadzor No. RZN 2017/5844 of June 08, 2017).
The study was conducted on the sole of the big toe, with pre–treatment with an alcohol solution of the surface of the toe.
Criteria for non–inclusion: the presence of violations of the main bloodstream of the vessels of the lower extremities.
Control group: 30 people. Non–inclusion criteria: the presence of cancer, changes in the main blood flow of the lower extremities.
In patients, glycated hemoglobin (HbA1c) was assessed.
Results
40 patients with diabetes mellitus aged 30 to 70 years were examined using LDF and LPS using functional tests (local thermal and cold tests): 29 women and 11 men. Of these: type 1 diabetes in 3 people, type 2 diabetes in 37 people.
Patients were divided into the following groups:
1) Subcompensated violations:
1 1a – active microcirculation, oxidative metabolism reduced: 14.
2b – microcirculation is inactive, oxidative metabolism is reduced: 4.
3c – active microcirculation, oxidative metabolism reduced markedly: 9.
2) Moderate decompensated disorders of microcirculation and oxidative metabolism: 11.
3) Severe decompensated disorders of microcirculation and oxidative metabolism: 2.
Conclusions (conclusion)
A direct correlation was revealed between the HbA1c indices and the degree of microcirculatory disorders and oxidative metabolism: in group No. 1, HbA1c ranged from 6.5% to 7.2%; in group No. 2 HbA1c in the range of 7.5% – 10.2%; in group No. 3 HbA1c in the range of 10.7% – 12.1%.

DOI: 10.1530/endoabs.70.EP152

EP153

Effect of hypoglycemic therapy with forsiga on indicators of carbonyl (methylglyocal) and oxidative stress (MDA) in patients with NAFLD and type 2 diabetes

Zvenigorodskaya Larissa, Shinkin Mikhail, Petrakov Alexander & Nilova Tamara
Moscov Clinical research and practice center named after Loginov, Moscow, Russian Federation

Methylglyoxal (MG) damages arginine protein residues, inhibits enzymes, disrupts insulin signal transmission, and plays a key role in the development of insulin resistance and hyperglycemia. High glucose levels cause an increase in glycation and methylglyoxal formation. Glycation is the main cause of protein damage, leading to the production of free radicals and causing inflammation.
The purpose of the study
To Identify the relationship of methylglyoxal content with markers of inflammation (retinol–binding protein). The lipid peroxidation level was determined by the content of malondialdehyde (MDA). Determine the level of MG content by high–performance liquid chromatography.
Materials and methods
208 patients with NAFLD and type 2 diabetes were examined. There were 76 patients with type 2 diabetes and 132 with impaired glucose tolerance (NTG). The average age is 57.3±5.2 years. BMI34, 85±1.79. In 30 patients conducted hypoglycemic therapy with a medication Formiga (of dapagliflozin).
Research results
In 30 patients with NAFLD and DM, the serum MG content of 520.75±114.35 nm/l was 283.3±11.5 nm/l, in the control group of 251.3±53.6 nm/l.
Retinol–binding protein as a marker of type I and type 2 diabetes in this group of patients was increased and amounted to 55.83±2.92 mg/l compared to the control group of 26.15±1.31 mg/l (P=0.001). Hyperglycemia increases the processes of lipid peroxidation. MG and MDA are correlated (r=0.495).
Conclusions
Glucose–lowering therapy with a medication Forsiga leads to a decrease in the level of hyperglycemia, the level of MG and processes of lipid peroxidation.
MDA up to 24.12+1.64 mmol/l p/l 16.9+3.86.
MGL 192.11+16.34 nm/l

Hereditary pancreatitis as a rare cause of diabetes mellitus in the youth

Antonis Polymeris, Maria Drakou, Christina Kogia, Dimitrios Lilis & Dimitrios Ioannidis
Sismanogleio–Amalia Fleming General Hospital, Athens Greece, Department of Endocrinology Metabolism and Diabetes Mellitus, Athens, Greece

Introduction
Most cases of Diabetes mellitus (DM) in children and adolescents are autoimmune (type 1), even though recently there has been an increase in type 2 DM mainly due to the increased prevalence of obesity in this age group. However, rarely DM could be attributed to other causes such as MODY. An extremely rare cause is the hereditary pancreatitis due to activating mutations of the PRSS1 gene. This gene encodes an enzyme, cationic trypsinogen, whose hyperactivity leads to prolonged intrapancreatic effect of trypsin. This destructive process of pancreatic tissue results in diabetes, recurrent pancreatitis and pancreatic cancer. .
Case Presentation
A 16–year old male adolescent presented to our department with typical diabetic symptomatology. He was in good general condition without ketoacidosis. Fasting glucose was 266 mg/dL and HbA1c 10.9%. The antibodies for type 1 DM were negative with the exempt of those against the zinc transporter ZnT8. C–peptide was measurable although inappropriately low for his high blood glucose. Despite the high HbA1c, the patient was treated with metformin and lifestyle modification resulting in excellent metabolic control (fasting blood glucose 80–120 and 2 hours postprandially < 140 mg/dl). Further genetic investigation for MODY, especially MODY3 which is the most common form, was negative. Subsequent screening for other types of DM revealed an activating mutation of the PRSS1 gene.
Conclusion
When the diagnosis of type 1 diabetes mellitus in children and adolescents cannot be established with safety and genetic testing for MODY is negative, screening for PRSS1 gene mutations must be performed. If the result is positive, additional counseling should be pursued regarding the nature and progression of this hereditary disease as well as the future possibility of pancreatic cancer.

Two types diabetes mellitus: clinical case of HNF1B–mody and type 1 diabetes in one patient

Alla Ovsyannikova[1, 2], Oksana Rymar[2], Elena Shakhtshneider[2] & Mikhail Voevoda[2]
[1]Novosibirsk State University, Novosibirsk, Novosibirsk, Russian Federation; [2]Research Institute of Internal and Preventive Medicine – Branch of the Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Novosibirsk, Russian Federation

Hyperglycemia in a 27–year–old woman without obesity was found in the first trimester of her third pregnancy in 2015 (fasting plasma glucose – 5.8 mmol /l). Gestational diabetes was established and insulin was initiated in basal–bolus regimen. After delivery the blood glucose was normal due two months then hyperglycemia increased to 15 mmol/l. Metformin and glimepiride were prescribed within effect. Then insulin detemir (8 U/day) was prescribed with DPP–4 inhibitor sitagliptin and SGLT2 inhibitor empagliflozin. In 2016 analysis for all antibodies were negative, the fasting C–peptide was 553 pmol/l (normal: 298–2350 pmol / l) and 1129 – postprandial. Molecular genetic testing was done in 2017. Mutation in the *HNF1B* gene (rs138986885) (MODY5) was diagnosed. In addition it was found that the patient is carrier of heterozygous variant rs2476601 in the tyrosine phosphatase gene (PTPN22) which is associated with an increased risk of developing type 1 diabetes mellitus (T1DM). No other clinical phenotypes associated with mutations in *HNF1B* were found. No other cases of diabetes in relatives have been reported. The same mutation in the HNF1B gene was found in mother and daughter of a proband with normal level of glucose when examining family members. In 2018 blood glucose level was 16 mmol/l, concentration of C–peptide decreased to 83 pmol/l. Tableted therapy was canceled and baseline bolus insulin therapy was started. In 2019 HbA1c level was 7.13%. Further decrease in pancreatic cell function was noted: fasting C–peptide 33.3 pmol/l, after eating 91.9 pmol/l. The patient was transfer to pump insulin therapy. Clinical case shows a rare combination of two types of diabetes mellitus with progressive, aggressive course of disease.

What should be the cut–off age for active screening for type 2 diabetes in Uzbekistan?

Anna Alieva[1], Saydiganikhodja Ismailov[2] & Gulnara Rakhimova[3]
[1]Republican Specialized Scientific–Practical Medical Centre of Endocrinology, ICU, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Endocrinology with Pediatric Endocrinology, Uzbekistan; [3]Tashkent Institute for Postdoctoral Medical Education, Tashkent, Uzbekistan

Background
Different screening programs recommend starting active search for type 2 diabetes (DM2) at age from 35 to 45. This difference comes from variety in structure of population and weight of age as a risk factor, and also has economical background.
The aim of our study
Was to find out the most acceptable cut–off age for DM2 screening in Uzbekistan.
Material and methods
We analyzed results of type 2 diabetes screening in three regions of the Republic of Uzbekistan among 2521 people aged 35 or older without known carbohydrates metabolism disorders. A1c was tested using method of immune precipitation with anti–human and anti–mouse A1c antibodies (Human), oral glucose tolerance test was performed with 75 g glucose. Diabetes was diagnosed according to IDF recommendations.
Results and discussion
In total, DM2 had 7.9% of analyzed population. When comparing the age groups, DM2 was revealed in 0.92% (1.1% in men and 0.9% in women) at age 35–39, in 3.4% (5.1% in men and 2.9% in women) at age 40–44, and 11.8% (12.1% in men and 11.6% in women) at age 45 or older (10.5% at age 45–59; 16.5% at age 60–74; 11.9% at age 75 or older, which is 11.4%, 16.0%, and 5.6% in men, and 9.9%, 16.7%, and 14.2% in women, respectively). So, significant rise in diabetes was revealed starting from age 45.
Conclusion
Taking into account economic issues, we recommend to start screening for type 2 diabetes in Uzbek population at age 45.

Lodine saturation in Czech patients with type 1 diabetes mellitus

Michala Vosátková[1], Denisa Zdarska Janickova[2], Martin Hill[3] & Karel Vondra[4]
[1]Institute of Endocrinology, Department of Clinical Biochemistry, Prague, Czech Republic; [2]2nd Faculty of Medicine, Charles University, Prague, 2Department of Internal Medicine, Prague, Czech Republic; [3]Institute of Endocrinology, Department of Steroid Hormones and Biofactors, Prague, Czech Republic; [4]Institute of Endocrinology, Clinical Department, Prague, Czech Republic

Background of the study
There is lack of data in the Czech Republic on iodine status in patients suffering from diabetes mellitus type 1 (DM1) considered to be at risk of iodine deficiency.
Subjects and methods
A total of 54 males and 51 females Cmedian (25th, 75th percentile): age (years) 42 (31, 55); BMI 25.9 (23.3, 29.7); HbA1c (mmol/mol) 61 (51.2, 71.0) treated for DM1 were included in this cross–sectional study. In addition to iodine saturation determined as the concentration of iodine in the first urine sample of the day, we measured clinical, anthropometric, and biochemical parameters related to DM1.
Aims of the study
The main aims were to obtain for the first time information about iodine saturation in Czech patients with DM1; and to determine a) to what extent this saturation differs from the non–diabetic population, b) whether iodine saturation is related to selected clinical and laboratory parameters and characteristics of diabetic syndrome.
Results
Measured iodine levels were: median 152 μg/l, 25th percentile 117 μg/l, and 75th percentile 219 μg/l. More than 50% of iodine levels were within the optimal saturation range of 100–200 μg/l, while about 14% showed incomplete saturation (<100 μg/l), and 34% had increased saturation (>200 μg/l). Multi–dimensional regression showed significant positive relationships ($P < 0.01$; an OPLS model explaining 9% of the variability) between ioduria and male sex, body weight and height, and serum creatinine levels, which to

date have not yet been published in DM1 patients. Relationships to the other analyzed parameters (HbA1c, insulin dose, DM duration, body mass index, microalbuminuria, glomerular filtration rate, thyroid function and volume, thyroid autoimmune markers) were not significant.
Conclusions
We found that Iodine saturation in our DM1 patients were within the IC-CIDD (WHO) recommendations for optimal/good saturation for the non–diabetic population. We believe that long–term efforts to deal with iodine deficit in the general population of the Czech Republic are responsible for the satisfactory iodine status of the DM1 patients as well.
We did not find any significant relationships between iodine saturation and characteristics of diabetic syndrome, but multi–dimensional regression analysis found a new, as yet. unpublished positive relationship between ioduria and male sex, body weight and height, and creatinine levels.

Correlation between pro–inflammatory biomarkers and vitamin B12 levels in diabetes mellitus: A prospective study

Ramesh Bangaraiahgari[1], Divya K[2], Ramakanth Bhargav Panchangam[3], Rajesh Bangaraiahgari[4] & Rajkiran reddy Banala[5]
[1]Surabhi Medical College, Biochemistry; [2]Saveetha University, Physiology; [3]Endocare Hospital, Endocrine Surgery; [4]Surabhi Medical College, Anatomy; [5]Sunrise Hospital, Genetics

Introduction
Apart from genetics, autoimmunity has been implicated in pathogenesis of diabetes mellitus (DM). Further the role of vitamin B12 levels in diabetic immunomodulation is controversial. In this context, we set out study the role of Pro– inflammatory cytokines in DM with or without vitamin B 12 deficiency in South Indian population.
Material and methods
This prospective case–control study was conducted on diabetes mellitus patients. Institutional ethical committee approval was obtained. Exclusion criteria were subjects with any systemic or chronic inflammatory disease or taking B12 supplements, proton pump inhibitors or any medication which interferes with the normal function of the hypothalamic–pituitary–gonadal axis. Serum samples were collected from 100 diabetic subjects and 20 age matched healthy controls. Cases were divided in to two groups A and B with deficient and sufficient serum vitamin B12 levels respectively. Controls are considered as group C. Interleukin–6 (IL–6), Tumour necrosis factor–alpha (TNF– α) and high sensitive C reactive protein (hsCRP), leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in groups A, B and C were 17.1 ± 3.1 mg/ml, 6.3 ± 0.9 mg/ml and 5.6 ± 1.2 mg/ml respectively. The mean TNF– α, IL–6, Leptin levels in groups A and B were 278 ± 32 pg/ml, 12.8 ± 4.3 pg/ml, 2.85 ± 0.8 ng/ml and 168 ± 21 pg/ml, 4.8 ± 1.3 pg/ml, 11.85 ± 2.7 ng/ml respectively. The corresponding values in group C were 147 ± 16 pg/ml, 3.8 ± 1.1 pg/ml, 10.66 ± 1.7 ng/ml. There was statistically significant difference of all the pro–inflammatory cytokines compared between group A with B and C (P value < 0.05) with negative correlation for leptin levels. Similar comparision between group B and control group C was not statistically significant (P value > 0.05)
Conclusions
Our study showed diabetic patients with raised titers of pro–inflammatory markers – IL–6, TNF–α and hsCRP, while reduced leptin levels correlated significantly with vitamin B 12 status, suggesting its significant contributory role. But, the exact immuno–modulatory role and pathogenetic mechanism of vitamin B12 metabolism needs more research.

Serum 25-oh vitamine d level in patient with Psoriasis in Korca, Albania- A case-control study

Ema Lumi[1], Laura Ramollari[2], Ermira Vasili[3] & Agron Ylli[4]
[1]Regional Hospital, "Teni Konomi", Endocrinology, Internal Department, Korce, Albania; [2]Regional Hospital, "Teni Konomi", Dermatology, Internal Department, Korce, Albania; [3]UHC Mother Teresa, Head of Dermatology Department, Tirane, Albania; [4]UHC Mother Teresa, Head of Endocrinology Department, Tirane, Albania

Background
Psoriasis is a common chronic, inflammatory skin disease that may exhibit a variety of clinical manifestations. Psoriasis has also been identified as a multisystem chronic inflammatory disorder associated with multiple comorbidities. Recently has been reported a role for vitamin D in the pathogenesis of different skin diseases, including psoriasis.
Aim
The objective of this study was to measure the serum level of vitamin D in patients with psoriasis and compare it with the level in the control group.
Materials and Methods
The study was conducted in the department of dermatology.100 cases were included, 50 patients clinically diagnosed with psoriasis and 50 normal people. The level of Vit D was measured with k–imunofluoresence. Normal level > 30 ng/ml = vit D sufficiency, levels 11–30 ng/ml = vit D insufficiency, levels <10 ng/ml = vit D deficiency. The testing of vitamin D was done during the fall. The characteristics of the population in the study. Psoriatic patients:60% of the patients were male and 40% were female.10% of women were black skin.10 % of men were black skin.15% of women were in menopause. The average age was 44.1 years ± 17 SD (min = 11, max = 78 years old).In the control group the selection for this people is casual. These patients may or may not suffer from any other disease. 20% of them were male and 80% were females. The average age 38.54 years old ± 16.53SD (min = 1, max = 72 years old).
Results
In the psoriatic patients group the average value of vit D was 16.623 ± 6.35 SD, (min = 6.08 ng/ml, max = 37.4 ng/ml).4 patients or 8% had a Vit D level between 0–10 ng/ml, 29 patients or 58% had a Vit D level between 11–20 ng/ml, 15 patients or 30% had a Vit D level between 21–30 ng/ml. Only 2 patients or 4% had a normal Vit D level >30 ng/ml. There is no difference of the average value of vit. D between males and females in this group. In the control group the average value of vit D was 19.8 ± 6.86 SD(min = 5.61 ng/ml, max = 35 ng/ml). 4 patients or 8% had a Vit D level between 0–10ng/ml, 21 patients or 42% had a Vit D level between 11–20 ng/ml, 22 patients or 44% had a VitD level between 21–30 ng/ml. Only 2 patients or 6% had a normal Vit D level >30 ng/ml. There was a higher value of vit D in males without psoriasis, compared to women.
Conclusion
There was reduced vitamin D level in psoriatic patients when compared to healthy controls. The number of people with vit D deficiency and sufficiency was equal in both groups. The number of people with vit D insufficiency was higher in the psoriatic group.

The characteristics of carbohydrate metabolism during cushing's disease

Samira Belkacem
Faculté de Médecine Alger, Medical, Alger, Algeria

Introduction
Cushing's disease is diabetogenic due to the insulin resistance generated by the stimulating effect of glucocorticoids on neoglucogenesis and hepatic glycogenolysis.
Goal
Aim of our work is to study the frequency and characteristics of diabetes mellitus during Cushing's disease.
Material and methods
Retrospective study of a sample of 100 patients collected between (January 1983 – December 2009) in the endocrinology department of the CPMC.
Results
The frequency of diabetes mellitus in our series is 58.5%, (n = 58 p), the average age is 40 years, with a sex ratio of 3/1 (3F, 1H), diabetic inheritance is present in 75% of cases, the average BMI of our diabetic patients is 29.5 kg / m 2, the average CLU is 826 mg / 24 h, hypertension and dyslipidemia represent 80% and 52% respectively. Half of our patients (n = 29) are treated with insulin therapy (insulin alone n = 19, mixed treatment: insulin + oral treatment n = 10). The good glycemic balance under treatment was obtained in 30% (n = 17p), the average glycemic for all our diabetics is 2.33 g / l

for fasting glycemia, extremes (1.4– 3.6), and 2.56 g / l for post prandial, extremes (1.7 – 4.2).
Conclusion
The high prevalence of diabetes mellitus during cushing's disease requires rigorous monitoring with early detection of the other atherogenic risk factors which are often associated in order to improve management and to prevent complications, especially cardiovascular, which can initiate vital prognosis.

To estimate the prevalence of obesity and abdominal obesity in adult patients

Malay Parekh, Banshi Saboo, Dharmendra Panchal, Rutul Goklani, Vipul Chavda & Dhruvi Hasnani
Dia Care Clinic, Diabetes, Thyroid, Obesity & Hormone Clinic, Ahmedabad, India

Background and aims
Obese people have more risk for hypertension, Diabetes mellitus and cardiovascular disease. Obesity is a major health issue globally. So our aim is to estimate the prevalence of obesity and abdominal obesity in adult patients.
Materials and methods
In our study total 150 adults (> 20 years of age) patients were included. They were selected randomly & examined for BMI (body mass index) and WHR (waist to hip ratio).
Results
In this study out of 150 patients males were 92 and females were 58. WHR ranged in males 0.69 to 1.34 and in females 0.66 to 1.41. As per WHR, males (1.08±0.06) were more obese than their female (0.99±0.08); $P<0.001$. BMI ranged in males 16.78 to 45.34 kg/m^2 and in females 18.74 to 52.73 kg/m^2. BMI in females (29.52±5.25) was comparatively more than males (25.78±3.46); $P<0.001$. According to BMI, the overall obesity prevalence in our study population was 22.8%; obesity prevalence in males was 14.68% and in females 36.42%. The overweight prevalence was 46.7%; As per BMI, males (55.42%) were comparatively more overweight than females (41.96%). Abdominal obesity prevalence was more in females (83.76%) than in males (62.24%).
Conclusion
Obesity and abdominal obesity is a growing major health issue globally. As compared to male, female have more common both obesity and abdominal obesity. So for living a healthy life we highly suggest to control weight, blood pressure, blood sugar level.

Assessment of the reproductive system function, metabolic and immunological status in women with obesity and overweight

Kateryna Kondratiuk[1], Valentyna Kondratiuk[2], Mykola Lisyany[3] & Karine Hasparian[4]
[1]O.O. Bogomolets National Medical University, Endocrinology, Kyiv, Ukraine; [2]Shupyk National Medical Academy of Postgraduate Education, Fetal Medicine, Kyiv, Ukraine; [3]A.P. Romodanov Institute of Neurosurgery of NAMS of Ukraine, Immunology, Kyiv, Ukraine; [4]SI "IPOG nam. acad. E.M. Lukyanova NAMS Ukraine", Family planning, Kyiv, Ukraine

Background
Obesity is an excess accumulation of adipose tissue in the body, characterized by impaired lipid and carbohydrate metabolism with subsequent pathological changes. The purpose of this study was to investigate the functioning of the reproductive system, metabolic and immunological status in women of reproductive age with obesity and overweight.
Methods
We examined 110 women of reproductive age including 60 patients with obesity (group I), 25 overweight patients (group II). The control group consisted of 25 individuals without impaired body weight (group III). Evaluation of the levels of leptin, 25(OH)D, triglycerides, cholesterol, index–HOMA were performed. The concentration of cytokines (IL–6, 8 and TNF– α) was determined in serum by ELISA.
Results
In obese women, menstrual dysfunction, such as amenorrhea, dysmenorrhea, abnormal uterine bleeding, was observed in 43.3% vs 28.0% in the group of overweight women. Decrease in reproductive ability, such as subfertility and infertility, were established in 38.3% of women with obesity, vs – 24.0% of patients with overweight . Primary forms of obesity were accompanied by the most significant metabolic and immunological disorders (Table 1): severe 25(OH)D deficiency, dyslipilemia, impaired carbohydrate metabolism, and the pathological functioning of immune system (increased levels of Il–6, 8, TNF–α) which correlated with hyperleptinemia.
Conclusion
Obtained results show that obesity is a serious medical problem because it is accompanied by significant metabolic and immunological disorders, which indicates the need for their correction in order to normalize the functioning of woman's reproductive system.

Table 1 The correlations between the level of Leptine, metabolic and immunological parameters.

Group of patients	Parameters	Spearman's rank correlation coefficient, *r*
I	Leptine/ 25(OH)D	+ 0, 642
	Leptine/ Index–HOMA	+ 0, 608
	Leptine/ triglycerides	+ 0, 553
	Leptine/ cholesterol	+ 0, 534
	Leptine/ IL–6	+ 0, 403
	Leptine/ IL–8	+ 0, 508
	Leptine/ TNF–α	+ 0, 582
II	Leptine/ 25(OH)D	+ 0, 642
	Leptine/ Index– HOMA	+ 0, 628
	Leptine/ triglycerides	+ 0, 428
	Leptine/ cholesterol	+ 0, 518
	Leptine/ IL–6	+ 0, 628
	Leptine/ IL–8	+ 0, 428
	Leptine/ TNF–α	+ 0, 481

Note: If the value of the Spearman's rank correlation coefficient (r) <0, 3 – weak link, from 0, 31 to 0, 5 – moderate, >0, 5 – significant.

Bariatric surgery : About 10 cases

Abainou Lahousssaine, Idrissi Ayoub, Hamza El Jadi, Azelarab Meftah, El Barni Rachid, Qamouss Youssef & Hicham Baizri
Avicenna Military Hospital

Introduction
Bariatric surgery is the treatment which has shown the most important effectiveness in terms of weight reduction, improvement of co morbidities, quality of life and mortality on the long term, in the case of massive obesity and obesity associated with co–morbidities. The purposes of our study: clarify the place of bariatric surgery in the treatment of obesity, define the criteria of selections of patients.
Material and methods
It's a retrospective study of ten patients who underwent bariatric surgery over a period of 1 year, from 1 April 2016 to 31 March 2017 at the service of general surgery in the Avicenna military hospital of Marrakech.
Results
The average age of patients was 33.7 years, a net predominance of women with 90% and a sex ratio of 0, 11. The mean BMI of our patients was 45.15 kg/m^2 with extremes ranging from 40.67 to 54 kg/m^2. Our patients followed a standard care pathway, with a multidisciplinary assessment including a consultation in endocrinology, in psychiatry and in gastroenterology. Pre–operative assessment diagnosed comorbidities related to obesity, in our study the results were: dyslipidemia 50% cases, Obstructive Sleep Apnea Syndrome 40% cases, type 2 diabetes 30% cases, NASH 60% cases, ischemic heart disease 10% cases, hypertension 10% cases. All patients received a coelioscopic approach. The main surgery technique was the sleeve

gastrectomy. The surgical time averaged 2 h17 minutes with extremes ranging from 1 h 40 to 2 h 50 minutes. The postoperative period was uneventful for 9 patients; one patient has an infectious peritonitis, re–operated J 3 after the sleeve, it evaluated to a multiple organ failure, we deplore the death of the patient at J5. The hospital stay duration averaged 13 days with extremes ranging from 5 to 25 days.
Conclusion
These benefits of bariatric surgery are to compare with the immediate and late complications and the peri–operative mortality risk, hence the interest of an optimal preoperative evaluation, per operative monitoring and postoperative management of complications.

Prediction of Vitamin D receptor gene expression in visceral and subcutaneous adipose tissue in adults with excess weight

Golaleh Asghari[1], Emad Yuzbashian[1], Mehdi Hedayati[2], Maryam Zarkesh[2], Parvin Mirmiran[1] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Tehran Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran

In the current study, we aimed to illustrate determinants of VDR gene expression in visceral and subcutaneous adipose tissues among obese and morbidly obese adults. We gathered visceral and subcutaneous adipose tissues during an elective abdominal surgery form 33 morbidly obese (body mass index (BMI) >40 kg/m^2) and 23 obese (BMI = 30–40 kg/m^2) participants who were free of diabetes. Before the surgery, dietary intake, physical activity, anthropometric indices, and biochemical variables were collected. The gene expressions VDR in visceral and subcutaneous adipose tissue were assessed by Real–Time PCR. Multiple linear regression models were used to examine predictors of VDR gene expression among weight–based categorized participants after adjusting age, BMI, WC, 25(OH)D, HOMA–IR, calcium intake, and physical activity. The mean age of the obese and morbid obese was 42.3 and 36.7 years, respectively) and BMI of the obese and morbid obese was 34.4 and 47.7 kg/m^2. There was no significant deference between obese and morbidly obese participants in mean VDR gene expression in visceral and subcutaneous adipose tissues. Among obese participants, 25(OH) D (β = –0.103, P = 0.036) was negatively, and BMI (β = 0.292, P = 0.052) and HOMA–IR (β = 0.285, P = 0.052) were positively associated with VDR mRNA levels in visceral adipose tissue. In morbidly obese participants, the independent positive predictors of VDR gene expression in visceral fat were BMI (β = 0.309, P = 0.007) and HOMA–IR (β = 0.362, P = 0.004), and negative predictors were 25(OH)D (β = –0.114, P = 0.042) and calcium intake (β = –0.307, P = 0.008). Our findings suggested that 25(OH)D concentration is the fundamental element of VDR gene expression in visceral fat which by increasing fat depots, the subsequent insulin resistance became another predictor of VDR gene expression. Further studies will be required to unravel the physiological consequences of the different adipose tissue response of VDR gene expression depending on the degree of obesity and its relevance in clinical practice, as well as to confirm the role of VDR in glucose hemostasis.

Secular trend in dietary patterns of iranian adults from 2006 to 2017: Tehran lipid and glucose study

Maryam Aghayan[1], Golaleh Asghari[1], Emad Yuzbashian[1], maryam mahdavi[2], Parvin mirmiran[1] & Fereidoun Azizi[3]
[1]Nutrition and endocrine research center, research institute for endocrine sciences, shahid beheshti university of medical sciences, Tehran, Iran; [2]Research Institute for Endocrine Sciences, shahid beheshti university of medical sciences, obesity research center, Tehran, Iran; [3]endocrine research center, research institute for endocrine sciences, shahid beheshti university of medical sciences, Tehran, Iran

Background
By focusing on nutrition transition in the Middle East and North Africa, this study aim to investigate the general structure and secular trend of dietary patterns extracted from the Tehran Lipid and Glucose Study (TLGS) and adherence to these dietary patterns among Iranian population from 2006 till 2017.
Methods
We investigated on four examination surveys of TLGS including survey 1 (2006–2008), survey 2 (2009–2011), survey 3 (2012–2014), and survey 4 (2015–2017). The dietary intakes was gathered by a validated and reliable food frequency questionnaire. Generalized Estimating Equations was used to assess secular trends in anthropometric, biochemical, and dietary variables across the study period. To identify general structure and secular trend of dietary patterns during each survey, principle component analysis (PCA) and *K*–mean cluster analysis were used, respectively.
Results
After adjusting for potential confounders including age, sex, body mass index, and total energy intake, the carbohydrate and protein intake gradually increased and the total fat intake decreased during study period (P–value <0.001); however total energy intake remained stable. During the study period, participants consumed notable less refined grain, solid fat, dairy products, and simple sugar. Snack and dessert consumption increased and meat intake had no significant changes during a decade (all *P*–values <0.001). Three dietary patterns were extracted buy using PCA including: *Healthy dietary pattern* characterized by higher intake of vegetable, fruit, dairy products, liquid oil, nuts and seeds, and honey and jam, Western dietary pattern featured by refined grain, solid fat, meat, snack and dessert, potato, and soft drink, and the Mixed dietary pattern highlighted by tea and coffee, and simple sugar. Based on cluster analysis, 27.8% of participants in survey 4 followed a Western dietary pattern, and 34.1% followed the Mixed dietary pattern. The Healthy dietary pattern was stable among study population during the last decade.
Conclusions
The structure and the type of foods that population have chosen to eat had changed since 2006. And a new secular trend in dietary patterns including a stability of *Healthy* dietary pattern, a decline of the *Western* dietary pattern and an increase in the *Mixed* dietary pattern was presented in our investigation.

Keywords: dietary patterns, secular trend, nutrition transition, factor analysis, adults, TLGS.

EP166

Bacterial metabolism in the colon and food behavior hormones in drug therapy of obese patients.

Silvestrova Svetlana, Varvanina Galina & Zvenigorodskaya Larissa
Moscow Clinical Research Center n.a. A.S. Loginov, Moscow, Russian Federation

As known, the number of obese people in the world exceeds 50% of the total population. ☪ search the causes of obesity development many researchers pay attention to metabolites of intestinal microflora among which the main ones are short–chain fatty acids (SCFA): acetate (C2), propionate(C3), butyrate(C4). Hormones of food behavior produced by visceral adipose tissue (leptin) and cells of the gastrointestinal tract (ghrelin) also play an important role in the development of obesity
Objective
To evaluate the activity of microbial metabolism in the colon in comparison with changes in hormonal status in obese patients before and after therapeutic weight correction.
Materials and methods
The study included 17 obese patients (7m / 10f, mean age 45.7±6.2 y; BMI 36.2±03.4 kg/m^2). Patients received monoamine reuptake inhibitor in the background of hypocaloric diet. Fecal SCFA were determined by GLC–method. Leptin and ghrelin were determined using the ELISA method.
Results
The total concentration of SCFA (TSCFA) in patients before treatment varied widely (5.1–14.8 mg / g) and averaged 9.7+3.1 mg/g, (vs norm 10.6+2.4 mg/g, NS). The spectrum of metabolites showed a marked decrease of conc. C4 ($p<0.05$ vs norm) and increase of conc. C3. Leptin and ghrelin concentrations in the blood were significantly increased: 20.2±7.1 ng / ml and 68.8±18.3 ng / ml.
After therapy BMI was decreased from 36.2±3.4 kg/m^2 to 33.1±4.6 kg/m^2 and the structure of fecal metabolites underwent significant changes: conc. of C 2 was decreased. (6.43±2.86 mg / g vs 4.771.26, $P<0.05$) and increased C 3 (1.94±0.78 mg /g vs 2.35±0.58, $p<0.05$) and C4 (1.23±0.27 mg / g vs 1.65±0.78, $P<0.05$). It is likely that these modifications of the metabolite structure cause an upward trend of leptin levels (20.2±7.1 ng

/ ml vs 25.7±8.3 $P=0.07$), since C3 and C4 have been shown to stimulate leptin production (Xiong Y., 2004). An interesting fact is that there is a high degree of correlation between C3 and leptin ($r=0.643$, $r=0.05$) and TSCFA and leptin ($r=0.714$, $P=0.05$) only after treatment. There were no correlations with SCFA and leptin before treatment or with ghrelin and fecal SCFA.
Conclusion
Thus, low–molecular metabolites of the fecal microflora have a noticeable effect on the hormonal status of obese patients.

EP167

Metabolic disorders and the state of the renin–angiotensin–aldosterone system in obese patients with resistant hypertension

Anna Shalimova[1, 2], Valentyna Psarova[3], Maryna Kochuieva[4], Olena Kolesnikova[5] & Kostyantyn Prosolenko[6]
[1]GI "L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine", Complex Risk Reduction of Chronic non–Communicable Diseases, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Internal Medicine No 1, Kharkiv, Ukraine; [3]Sumy State University, Sumy, Ukraine; [4]Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine; [5]GI "L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine", Kharkiv, Ukraine; [6]Kharkiv National Medical University, Kharkiv, Ukraine

Background
The aim was to establish the features of metabolic disorders and the state of the renin–angiotensin–aldosterone system (RAAS) in obese patients with true and pseudo–resistant arterial hypertension (AH).
Material and Methods
The study included 200 patients with uncontrolled AH and obesity. Patients were initially prescribed dual antihypertensive therapy. Those patients who did not reach target blood pressure (BP) levels after 3 months on dual therapy were additionally assigned a third antihypertensive drug. Of the 98 patients who were assigned triple therapy, 48 patients did not reach target BP (27 patients had pseudo–resistant and 21 patients had true resistant AH). These patients were additionally prescribed a fourth antihypertensive drug (spironolactone). The effectiveness of the treatment was evaluated 6 months after the start of antihypertensive therapy.
Results
After 6 months of therapy, unlike patients without resistance, individuals with resistant AH differed more pronounced metabolic disorders and higher activity of the RAAS. Patients with true resistance differed from pseudo–resistant patients with significantly lower body mass index (BMI); in the absence of differences in BP levels, lipid and carbohydrate profiles, patients with true resistance had significantly higher levels of aldosterone, higher adiponectin levels, and lower leptin level.
Conclusions
Obese patients with true resistance differed from pseudo–resistant patients with significantly lower BMI, higher aldosterone levels, and less pronounced adipokines imbalance.

EP168

Evaluation of anxiety–depressive disorders in patients with metabolic syndrome

Olga Smirnova & Olga Moskalenko
Scientific Research Institute of Medical Problems of the North FRC KSC SB RAS, Clinical Pathophysiology Laboratory, Krasnoyarsk, Russian Federation

In recent years, there has been an increase in patients with metabolic syndrome (MS), which is an urgent medical problem. The severity of the clinical manifestations of MS affects the quality of life of patients, while reducing physical and mental health. Obesity leads to anxiety and depressive disorders, neurosis–like conditions, which contributes to a worsening prognosis of the underlying disease.
The aim of the work was to assess the level of anxiety, depression and quality of life in patients with metabolic syndrome.
Methods
30 patients with MS and 35 healthy volunteers were examined at the clinic of the Research Institute of Medical Problems of the North. Patients were examined, anthropometric indicators were determined (waist circumference, body weight, BMI) with an assessment of the quality of life (questionnaire SF–36, Russian version, Institute of Clinical and Pharmacological Research, St. Petersburg). The level of anxiety and depression was determined by the hospital anxiety and depression scale HADS (The hospital Anxiety and Depression Scale Zigmond A.S., Snaith R.P.).
Results
Most indicators of quality of life were statistically significantly different in patients with MS relative to the control group. A decrease in the average level of the parameters "physical functioning" by 17.3% ($P<0.05$), "role–based functioning" by 31% ($P<0.05$), and "general health" by 11.3% ($P<0.05$), "vitality" by 13% ($P<0.05$), "emotional functioning" by 50.1% ($P<0.05$). The level of anxiety and depression in patients with MS corresponded to a subclinically expressed level, the level of depression exceeded the value of the control group by 18%.
Conclusion
Patients with MS are characterized by a decrease in quality of life indicators, subclinically expressed anxiety / depression. According to MAPI Research Institute, the goal of any treatment is to improve the quality of life of patients to the level of healthy individuals, therefore, for patients with MS, along with pathogenetic therapy aimed at weight loss, correction of psychological disorders is required, which will reduce the level of anxiety–depressive disorders and improve quality of life.

Peripheral cannabinoid–1 receptor blockade potentiates the anti–obesity and anti–diabetic effects of GLP–1 mimetics

Philippe Zizzari[1], Rongjun He[2], Luigi Bellocchio[1], Camille Allard[1], Samantha Clark[1], Leste–lasserre Thierry[1], Giovanni Marsicano[1], Diego Perez–Tilve[3], Brian Finan[2], Daniela Cota[1] & Carmelo Quarta[1]
[1]INSERM, U1215 NeuroCentre Magendie, University of Bordeaux, Bordeaux, France; [2]Novo Nordisk Research Center, Indianapolis, Indianapolis (IN), United States; [3]University of Cincinnati–College of Medicine, Cincinnati, OH, USA., Department of Pharmacology and Systems Physiology, Cincinnati (OH), United States

Obesity and type–2 diabetes (T2D) represent a global health crisis. However, only a few, and often sub–effective pharmacological tools are available to treat these disorders. Though beneficial for glycemic control, GLP–1 receptor (GLP–1R) agonists show scarce weight–lowering and insulin–sensitizing efficacy.
New molecules able to selectively block the activity of the cannabinoid receptor type–1 (CB1R) in peripheral organs have been recently developed. In preclinical animal models, these non–brain penetrant drugs lead to sizable weight–loss and a global improvement in the multi–faced complications of obesity, including insulin resistance. These peripheral agents can bypass the known neuropsychiatric side–effects observed with brain–penetrant CB1R blockers.
Of note, GLP–1 release, and possibly its activity, may be negatively influenced by CB1R signalling, which implies that pharmacological inhibition of CB1R may be used as an effective approach to amplify the therapeutic benefits achieved with GLP–1R agonism.
Using genetic murine models with loss of CB1R or GLP–1R function, we found that these two metabolic receptors drive changes in food intake and body weight control via reciprocal functional interactions. CB1R knockout mice are more sensitive to the hypophagic effects of a GLP–1R agonist while a peripheral pharmacological blocker of CB1R (JD–5037) has blunted ability to lower body weight and food intake in mice lacking GLP–1R.
Such vicious interaction can be corrected pharmacologically. In diet–induced obese mice, the co–administration of JD–5037 with different types of GLP–1R agonists, including semaglutide, leads to more potent effects against obesity, insulin resistance, systemic dyslipidemia, and non–alcoholic fatty liver disease, relative to monotherapies. These benefits result from hypophagia, heightened systemic energy dissipation, and improved hepatic insulin action.
Thus, peripheral CB1R blockade may represent an effective strategy to safely amplify the anti–obesity and anti–diabetic efficacy of currently available GLP–1R agonists. Pharmacological co–targeting of CB1R and GLP–1R may help close the still–too–large gap between the anti–obesity efficacy of the available pharmacological tools relative to the efficacy of bariatric surgery, a procedure which has its risks.

Evaluation of liver fibrosis in patients with diabesity

Elena González Arnáiz[1], Begoña Pintor De la Maza[1], Lucía González Roza[1], Beatriz Ramos Bachiller[1], Raisa Quiñones Castro[2], Diana Ariadel Cobo[1], David Barajas Galindo[1], Ana Urioste Fondo[1], María Ballesteros Pomar[1] & Isidoro Cano Rodriguez[1]
[1]Centre Assistencial Universitary León, Endocrinology and Nutrition, León, Spain; [2]Centre Assistencial Universitary León, Digestive Service, León, Spain

Background
NAFLD(non–alcoholic fatty liver disease) includes; non–alcoholic fatty liver(NAFL), non–alcoholic steatohepatitis (NASH) and its complications (fibrosis, cirrhosis and hepatocellular carcinoma). These diseases are currently the most common cause of liver disease in western countries, due to the obesity and DM2 epidemic. There are scores that determine the risk of liver fibrosis in a non–invasive way.
Aims
To determine the prevalence of liver fibrosis diagnosed by FIB4 score, NAFLD fibrosis score and Hepamet fibrosis score in patients with morbid obesity. To evaluate differences in the risk of fibrosis in patients with morbid obesity with or without DM2.
Methods
Cross–sectional observational study of a sample of 95 high–risk obesity patients. Anthropometric variables (weight, size and BMI), analytical variables (glucose, insulin, AST, ALT, albumin and platelets) and non–invasive markers of liver fibrosis (FIB4, NAFLD, Hepamet) were collected. The risk of fibrosis was compared with the presence or absence of DM2.
Results
95 patients; 73.7% are women and 24.2% had DM_2. Mean age 44.22 (DE 8.34) years, weight 122.4 (RIC 84) Kg, BMI 45.82 (DE5.22) kg/m^2. 94.7% of patients have FIB4 <1.30 (without fibrosis or mild fibrosis); 3.2% FIB4 1.30–2.67 (undetermined) and 2.1% FIB4 >2.67 (advanced fibrosis). 28.4% of patients have NAFLD <–1.45 (without fibrosis or mild fibrosis), 65.3% NAFLD –1.45–0.675 (grey area) and 6.3% NAFLD >0.675 (advanced fibrosis). 85.1% of patients have Hepamet <0.12 (without fibrosis or mild fibrosis), 9.6% Hepamet 0.12–0.24 (Grey area) and 5.3% Hepamet >0.24 (advanced fibrosis). The risk scores for fibrosis in patients with obesity and DM_2 are reflected in Table 1.

Table 1

	SCORES	Diabetes	No diabetes	*P*
NAFLD	Without fibrosis or mild fibrosis	4, 3 %	36, 1 %	<< 0, 001
	Grey area	78, 3 %	61, 1 %	
	Advanced fibrosis	17, 4 %	2, 8 %	
	Total	100 %	100 %	
FIB4	Without fibrosis or mild fibrosis	95, 7 %	94, 4 %	0, 34
	Undetermined	4, 3 %	2, 8 %	
	Advanced fibrosis	0 %	2, 8 %	
	Total	100 %	100 %	
Hepamet	No fibrosis o leve	45, 5 %	97, 2 %	< 0, 001
	Grey area	36, 4 %	1, 4 %	
	Advanced fibrosis	18, 2 %	1, 4 %	
	Total	100 %	100 %	

Conclusions
There is a high prevalence of liver fibrosis in patients with morbid obesity. Patients with obesity and DM_2 have a higher risk of fibrosis estimated with NAFLD and Hepamet fibrosis score. In patients with obesity, DM_2, or other risk factors, the risk of liver fibrosis should be evaluated as it may condition the long–term prognosis.

Gender differences in image dissatisfaction and distortion in brazilian patients referred to bariatric surgery

Erika Naliato
Ricardo A T Castilho Center of Studies, Teresopolis Medical Association, Teresopolis, Brazil

Introduction
In Brazil, most patients referred to bariatric surgery are women. The literature indicates the occurrence of gender differences in body composition and body image perception.
Aim
To study body image perception and its relationship with body composition in Brazilian bariatric patients.
Methods
A total of 140 patients were evaluated using the Stunkard Figure Rating Scale (SFRS) and bioimpedance. Image dissatisfaction and distortion, body mass index (BMI), BMI excess (calculated as: [BMI – 25]), body fat percentage, muscle mass, and visceral fat were studied. Data from women and men were compared.
Results
114 women and 26 men were investigated. Seventy–six were studied before and 64 after bariatric surgery. There was no gender difference regarding age (41.73±11.52 vs 39.38±9.24 years, $P=0.3499$), prevalence of bariatric surgery prior to study inclusion (47.37% vs 38.46%, $P=0.5141$), time elapsed since surgery (27±32 vs 16±42 months, $P=0.4649$), BMI (37.78±8.6 vs 41.51±10.35 kg/m², $P=0.0573$) or visceral fat index (19.2±5.65 vs 18.8±6.27, $P=0.7784$). However, women had higher body fat percentage (46.48±7.25 vs 41.45±10.01%, $P=0.0053$) and men had higher BMI excess (18.10±10.97 vs 13.10±9.16 kg/m², $P=0.0170$) and muscle mass (40.88±5.58 vs 27.76±4.65 kg, $P=0.0001$). Based on SFRS, all subjects had image dissatisfaction (scores: women±3.7±1.6, men±3.2±1.3, $P=0.1648$), and women had higher scores of image distortion (0.99±0.86 vs 0.62±0.70, $P=0.0391$). The multiple regression model for the determinants of the dissatisfaction indicated BMI excess as the main influence ($r^2=0.8584$, $P=0.0346$), while the model for distortion suggested the impact of muscle mass ($r^2=0.3322$, $P=0.0032$).
Conclusion
Gender differences in body composition are in accordance with the literature. Most subjects in this study were women, the subgroup with the higher prevalence of image distortion, which may have contributed to their higher prevalence of obesity and, consequently, referral to surgical treatment. Present in all subjects, image dissatisfaction could have been a trigger for the search of medical treatment.

Is endothelial dysfunction the main issues in prediabetes as predictor for cardiovascular diseases?

Randa Salam[1] & Mary Fawzy[2]
[1]Cairo University, Endocrinology Departement, Cairo, Egypt; [2]Cairo University, Vascular Medicine Department, Cairo, Egypt

Background
The frequency of prediabetes is increasing as the prevalence of obesity rises worldwide. Hyperglycemia, insulin resistance, inflammation and metabolic derangements associated with concomitant obesity cause endothelial dysfunction in prediabetics, leading to increased risk of cardiovascular and renal disease.
Objective
To get a general perspective on the complex relationship between cardiovascular diseases onset, and pre–diabetes
Methodology
100 obese patients compared to 45 normal controls The study was conducted between June 2018 and april 2018 .All subjects were submitted to history taking, clinical examination including wasit circumference, BMI, Hb A1c, Fasting blood glucose, lipid profile, carotid artery duplex and Brachial artery flow media dilation (FMD)
Results:
Mean age of our patients was 30±0.3 years, BMI :30.26±3.08, cholesterol: 240±22.1 mg/dl, triglycerides : 105±12.2 mg/dl, LDL :140.7±32.1 mg/dl, HDL : 38.45±9.5 mg/dl, and A1C : 5.95±0.2. There was statistically significant difference in Carotid intimal media thickness between prediabetic and controls (0.10±0.02/0.08±0.01) (P±0.01). However, there was

no statistical significance difference between patient and control regarding FMD: (13.40±12.59 /8.63±1.01) (P=0.26).
Conclusion
Screening for prediabetes and early management is of utmost importance for prevention of cardiovascular morbidity as it is an incipient for premature atherosclerosis, endothelial dysfunction follow changes in CIMT, which highlights that screening of CVS in prediabetics should be done by CIMT and not by FMD.

Malignant insulinoma in an adult female: diagnosis and treatment challenge. A case report

Daniel Cosma[1], Cristina Alina Silaghi[2], Mihaela Mocan[3], Sorin Barbu[4] & Loan Andrei Veresiu[1]
[1]Center for Diabetes, Nutrition and Metabolic diseases, Diabetes, Nutrition and Metabolic diseases, Cluj–Napoca, Romania; [2]Endocrinology Clinic, Cluj–Napoca, Romania; [3]Clinica Medicală 1, Cluj–Napoca, Romania; [4]Spitalul Universitar C.F. Cluj, Cluj–Napoca, Romania

Insulinoma represents one of the most encountered neuroendocrine tumors, but only 4–14% is malignant. The diagnosis is suggested by high serum insulin levels during spontaneous or induced episodes of hypoglycemia and often invasion of lymph nodes and liver metastasis. A 55–year–old female was referred to our center after an episode of hypoglycemia during strumectomy for multinodular goiter. Further questioning revealed few years of Metformin treatment for hyperglycemia, which was stopped after repeated hypoglycemic episodes (3–4/week, Gl min=20 mg/dl) with remission after fast–acting carbs leading to an increase of 40 kg body weight in the last 5 years. Her family history was positive for pancreatic cancer. Post–strumectomy, the patient developed Gerhardt syndrome and hypoparathyroidism requiring daily i.v Calcium infusion. The 72–hour fast was stopped for symptomatic hypoglycemia (Gl=41 mg/dl) and an glycemia/insulinemia=2.34. The A1c=4.5% confirmed the presence of frequent hypoglycemic episodes. The CT scan revealed a tumor in the uncinate process of the pancreas for which enucleation was performed. Microscopic view was consistent with malignant insulinoma. After surgery, the patient became euglycemic with an A1c of 5.6% after 3 months and 10kg weight loss.
Despite its low incidence, the presence of insulinoma must be suspected in every person with repeated hypoglycemia after exclusion of other causes. The imaging studies and the histopathological exam are mandatory in order to establish localization and its malignant features.

Type 2 diabetes mellitus and pancreatic cancer in related family

Anila Rrupulli[1] & Brunilda Mehilli[2]
[1]Hospital of Elbasan, Endocrinology, Elbasan, Albania; [2]Hospital Mother Tereza Tirana, Laboratory, Tirana, Albania

The lifetime risk of pancreatic cancer for the average individual without a family history of pancreatic cancer is approximately 1%. Individuals with a family history of pancreatic cancer are at an increased lifetime risk for developing pancreatic cancer. This risk is likely higher for individuals from a family with FPC. The following cancer risk estimates are generalized and should be interpreted with caution since the actual risk for each individual may be different:We received a case study of two siblings of one family. The older brother was diagnosed with Type 2 Diabetes in 2017 and began insulin therapy at age 72. After one year of treatment with insulin therapy, he had symptoms such as nausea, vomiting, pruritus, weakness, weight loss. While there was no fluctuation of glycemia, with HBA1c=7%. At this moment all necessary examinations are done and results were magnetic resonance with pancreatic Ca and pulmonary meta. Ca 19–9=700.6 .After six months the patient died. In 2018 was present his brother aged 70 with typical signs of Type 2 Diabetes with polydipsia polyuria syndrome and weight loss. Glycemia=400 mg/dl and HbA1c=12%. Insulin therapy was started. During one year presented with satisfactory parameters. glycemia and HbA1C. After one year the same signs as brother, nausea, vomiting, headache, generalized pruritus began. Necessary examinations are performed and magnetic resonance results pancreas Ca and Ca19–9=1000. Actually the patient is undergoing to radiotherapy and follow–up by the oncologist. In this case, we observed that the disease appeared to be preceded by type 2 diabetes mellitus over the age of 70 and with the same symptoms. Familial pancreatic cancer (FPC) is a term to describe families with an abnormally high rate of **pancreatic cancer**. Ductal adenocarcinoma of the pancreas, which is the most common type of pancreatic cancer, starts when healthy cells lining the pancreatic ducts change and grow out of control, forming a tumor. The pancreas is a pear–shaped gland found in the abdomen between the stomach and spine. The gland makes enzymes that help the body digest food. It also makes hormones, such as insulin, that help control blood sugar. Families are considered to have FPC if there are at least 2 members of the family with pancreatic cancer who are first–degree relatives, such as a parent, child, or siblings of one another.

Very low HbA1c– a case presentation

Bethany Woodrow, Sheeba Shaikh & Edward Jude
Tameside and Glossop Integrated Care NHS Foundation Trust, United Kingdom

Background
We present an interesting case of a 56 year old male who, during pre–operative work up, was found to have a very low HbA1C 3.1% (10 mmol/mol). The patient was also noted to have mild thrombocytopenia, raised bilirubin and alanine aminotransferase and moderate splenomegaly on CT scan, with otherwise normal appearance of remaining abdominal viscera. His past medical history included alcohol excess (60–80 units/week), he was not diabetic and was taking Aspirin and Atorvastatin. It was felt his HbA1c was artefactually low due to increased red cell breakdown associated with splenomegaly.
Discussion
HbA1c is a validated, internationally recommended test for the diagnosis of diabetes, though HbA1c can become falsely lowered in clinical scenarios which lead to increased red cell turnover and therefore decreased opportunity for glycation of HbA1. Several population based cohort studies have investigated the link between very low HbA1c and mortality outcomes in non–diabetic adults, with varied results. Most agree there is a statistically significant link between very low HbA1c and all–cause mortality, though this becomes insignificant when adjusted for lifestyle and co–morbidity factors, and indeed the well–known "J–shaped curve" effect was subsequently accounted for when additional adjustment for liver function derangement was applied to their data set. Whilst very low HbA1c may not be an independent risk factor for increased mortality, there is potential for the finding to be a surrogate marker of increased all–cause mortality, and the authors would suggest this finding should not be quickly discounted as insignificant, but should prompt a thorough multi–systems assessment for potential underlying pathology. The patient in this case awaits Haematological work up of his splenomegaly, the cause of which has not yet been defined.

Diabetic ketoacidosis and continuous glucose monitoring – a case report

Diogo Ramalho, Gustavo Rocha, Helena Alves, Sara Correia, Lúcia Almeida & Maria João Oliveira
Centro Hospitalar Vila Nova de Gaia / Espinho – Unit 1, Endocrinology, Vila Nova de Gaia, Portugal

Introduction
Diabetic ketoacidosis (DKA) is characterized by the triad – ketonemia, metabolic acidosis and hyperglycemia. It is typically associated with type 1 Diabetes Mellitus (T1D) and the most common culprits are infections and poor therapeutic compliance.
Clinical Case Description
The present case deals with a 25–year–old female patient, with T1D diagnosed in 2008, without microvascular or macrovascular complications. She presented with poor metabolic control (Haemoglobin A1c (HbA1c)=11.7%) under functional insulin therapy with insulin glargine and aspart, guided exclusively by reading of the Flash Glucose Monitoring (CGM) system, which recorded values within glycemic goals.

The patient was admitted to the Emergency Room (ER) with DKA, exhibiting hyperglycemia of 578 mg/dl, severe metabolic acidemia (pH 6.9 and HCO3– not measurable – low) and ketonemia of 4.4 mmol/l. Other triggering factors were excluded.
This DKA was treated with fluid therapy and IV infusion of rapid acting insulin. Clinical and analytical resolution of DKA was achieved, progressing with oral tolerance and resuming subcutaneous insulin regimen. However, due to phlebitis of the left forearm in a site of arterial puncture and acute cystitis, DKA recurred. Standard treatment of DKA was reimposed, along with amoxicillin/clavulanic acid. After this recurrence, the patient exhibited flexion of the 4th and 5th fingers of the left hand, decreased strength in the ipsilateral hand and absence of distal pulses, consistent with left brachial artery and upper–extremity deep vein thrombosis which was treated with thromboembolectomy. At discharge, she presented good glycemic control under insulin pump therapy.
Five months later, the patient developed paracentral acute middle maculopathy, with hypovision of the left eye. For this reason, a genetic study was conducted, compatible with high prothrombotic risk (heterozygous Factor V Leiden mutation; homozygous methylenetetrahydrofolate reductase (MTHFR) mutation; Plasminogen Activator Inhibitor–1 (PAI–1) 4G/5G promoter polymorphism). Treatment with hyperbaric oxygen therapy was performed, with complete visual recovery along with rivaroxaban. Currently, under insulin perfusion pump, she presents sustained metabolic control (HbA1c=6.2%).
Conclusion
This particular case alerts us to several risks: self–monitoring of DM1 exclusively based on a flash system, failure in the self–awareness of symptoms, possibility of recurrent DKA and, finally, thrombotic events as a serious and rare complication of DKA, in genetically predisposed patients.

Effect of pilgrimage on metabolic syndrome among diabetic patients

salah ameni[1], Yosra Hasni[1], Safa Amara[2], Zomorda Kamoun[1], Saoussen Mrad[3], Asma Ben Abdelkarim[1], Molka Chadli[1], Ghada Saad[1], Maha Kacem[1], Amel Maaroufi[1] & Koussay Ach[1]
[1]University Hospital Farhat Hached Sousse, Endocrinology Department, Tunisia; [2]Higher School of Health Technicians, Tunisia; [3]University Hospital Farhat Hached Sousse, Biochemistry Department, Tunisia

Background
Hajj is one of the five pillars of Islam and is a must–do for all adult Muslims once in their life provided they are able to do it. It's estimated that pilgrims with diabetes could exceed 220000/year. Patients with diabetes are at a great risk of illness due to the nature of the disease and the altered daily routine (overcrowding, inadequate nutrition, poor access to drinking water, hot weather and physical exertion).The primary aim of this study is to evaluate the effect of pilgrimage on metabolic syndrome.
Material and methods
Cross–sectional study covered 43 diabetic patients from the city of Sousse, intending to perform the pilgrimage during 2019. The evaluation was made before and after pilgrimage and included clinical examination and biological assessment.
Results
The study covered 43 patients : 25 women (58.1%) and 18 men (41.9%) with a gender ratio (W/M)=1.8, all with type 2 diabetes. The mean course of diabetes was 12, .±9.3 years . Thirty patients were on oral anti–diabetic drugs, 2 patients were on dietary rules alone and the rest were on insulin (26.3%). The average of glycated hemoglobin (HbA1c) was 7.9±1.3 %. Fasting blood glucose, Cholesterol and LDL cholesterol significantly decreased after pilgrimage (7.8±2.88 vs 69±2.55, 4.2±1.03 vs 3.7±1.01 and 0.92±0.34 vs 0.7±0.33, respectively, $P=0.05$). Also most patients had lost weight after pilgrimage (the average of Body mass index significantly decreased 30.0±5.45 vs 28.9±4.11, $P=0.05$) with a significant decrease in waist size.
Conclusion
Although the altered daily routine of patients with diabetes during the pilgrimage, an improvement in most parameters of metabolic syndrome was observed. This enhancement is mainly due to physical activity.

Otogenic thrombophlébitis : A rare complication in diabetic patients

Meherzi Abir, Amal Kdissa, Monia Ghamam, Belakhdher Mouna, Kermani Wassim & Abdelkefi Mohamed
Sousse, ENT department, Sousse, Tunisia

Background
Otogenic cerebral thrombophlebitis is a rare intracranial complication of otitis media in the modern age of antibiotic treatment, but it is potentially a dangerous complication spatially in immune depressed patients with diabetes.
Aim
To discuss the clinical features of this complication and to analyze the impact of diabetes on its evolution as well as the management of this entity.
Methods:
We conducted a retrospective study on 10 diabetic patients with otogenic cerebral thrombophlebitis diagnosed and treated in ENT Departement of Farhat Hached Hospital from 1995 to 2019.
Results
10 poorly controlled diabetic patients were enrolled :8 men and 2 women with a mean age of 35 ans (extremes from 11 to 77 ans). The mean delay of consultation was 27 days (extremes from 7 days 3 months). Clinical presentation was made of otlagia in all patients and otorreha in 9 patients. The etiology was acute otitis media in 8 cases and cholesteatoma otitis media in 2 cases. All patients were assessed by CT Scan with contrast .The thrombosis was located in lateral sinus in 5 cases, sigmoide sinus in 2 case, Cavernous sinus in 1 case, and internal jugular vein in 30% of cases. The thrombphlebitis was on the right side in 3 cases, on the left side in 6 cases and bilateral in 1 case. The occlusion was total in 4 cases and partial in 6 cases. It was associated to other complications : mastoiditis in 5 cases, extradural empyema in 2 cases and cerebral abcess in 3 cases. The treatment was based on insulinotherapy, antibiotherapy and anticoagulation for 15 days to 3 months in alla cases. Surgical management was completed in 5 cases.
Conclusion
Otogenic cerebral thrombophlebitis in a rare and seriuos complicaion, more common in diabetic patients who are immunodepressed. Its diagnosis is based on CT Scan. It requires well controlling diabetes, antiobiotheray, anticoagulation with surgical drainge.

DOI: 10.1530/endoabs.70.EP178

EP179

Gradation of podiatric risk in a population of patients with diabetes

Chaima Jemai[1] & Sinène El Frigui[2]
[1]National institute of nutrition of Tunis, C, Tunisia; [2]Hôpital Universitaire Sahloul (CHU Sahloul), Physical medicine and rehabilitation, Sousse, Tunisia

Introduction
The American Diabetes Association (ADA) recommends an annual foot screening of patients podiatric risk for ulceration and amputation, to take effective preventive measures. However, the gradation of the podiatric risk remains insufficient, particularly in Tunisia, where epidemiological references remain missing. The aim of this study was to classify a population of diabetic patients according to the grade of podiatric risk by referring to the recommendations of the International Working Group of The Diabetic Foot (IWGDF) of 2019.
Patients and methods
This is a prospective cross–sectional descriptive study of 100 patients with diabetes. Screening for diabetic neuropathy was done by the Semmes–Weinstein monofilament test (10g). Peripheral arterial disease was assessed by palpation of the peripheral pulses.
Results
The mean age was 54±12.9 years, The sex ratio was 0.78. Diabetes was type 2 in the majority of cases (78%). The average duration of progression of diabetes was 13.62±6.29 years. 78% of the population has been unbalanced. The prevalence of sensory neuropathy was 41%. That of peripheral arteriopathy was 18%. Grade 0 was the most frequent with a frequency of 59%. Only 4% of the population had grade 3. The frequences of Grade 1 and 2 were respectively of 21 and 16%.
Conclusion
The diabetic foot is one of the most expensive and difficult to manage complications of the diabetes. The gradation of the podiatric risk is a simple means of screening making it possible to identify the subjects whose risk is high.

DOI: 10.1530/endoabs.70.EP179

EP180

Risk assessment of patients with diabetes for foot ulcers in a tunisian population

Mouna Sghir[1], Soumaya Elarem[1], Aymen Haj Salah[1], Ikram Haddada[1], Wafa Allaya[2] & Wassia Kessomtini[1]
[1]Tahar Sfar Hospital, Physical Medicine And Rehabilitation, Mahdia, Tunisia; [2]tahar Sfar Hospital, Endocrinology, Mahdia, Tunisia

Introduction
Diabetic foot is a major health problem for people with diabetes mellitus. It can cause serious complications leading to lower extremity amputations. The aim of this study was to determine the prevalence and risk factors of foot complications among diabetic patients in Mahdia, Tunisia.
Methods
Detail history and examination including neurological and vascular assessment were performed in 150 patients with diabetes mellitus attending Tahar Sfar hospital and Ezzahra primary care center in Mahdia. Foot at risk was classified according to risk classification consensus of the International Working Group on the Diabetic Foot (IWGDF). The risk level was correlated with demographic and clinical features.
Results
The mean age of patients was 56.91±12.6 years with a range of 20 to 86 years. A low level of education was found in 76% of cases and patients had a history of hypertension (41.4%), high total cholesterol (46%). Smoking was found in 13.3% of cases. Half of patients were using oral medications, 28% were using insulin therapy and 21.3% were using both oral and insulin therapies. A medical history of hypertension was found in 41.4% of patients. Only 10% of diabetics had been screened for sensory neuropathy. Forty–three per cent of patients were in group 0 of the IWGDF, 37% in group 1, 15.3% in group 2 and 4% in group 3. Patients in higher–risk groups had longer diabetes duration ($P=0.045$).Risk was higher in the presence of diabetic neuropathy ($P=0.0001$), retinopathy ($P=0.000009$) and nephropathy ($P=0.02$). Patient's BMI, smoking did not have signifcant correlation with risk of diabetic foot ulcer.
Conclusion
Despite the low prevalence of foot ulceration and amputation among the study population, a substantial proportion had potential risk factors for foot complications.

EP181

Prevalence and predictors for hypogonadism among tunisian type 2 diabetic patients with erectile dysfunction

Jenzri Haythem, Hela Marmouch, Bilel Ben Amor, Hanene Sayadi & Inès Khochteli
University Hospital–Monastir, Internal Medicine–Endocrinology Department, Monastir, Tunisia

Introduction
Testosterone levels are frequently low in men with type two diabetes mellitus, and sexual symptoms are a prominent presenting feature for these men.
Objectives
The aim of this study was to determine the frequency of hypogonadism and related risk factors among Tunisian patients with type two diabetes mellitus and erectile dysfunction.
Methods
This cross–sectional study included a total of one hundred and thirty consecutive men with type two diabetes and erectile dysfunction who attended the Internal Medicine and Endocrinology Department, Monastir University Hospital, Tunisia. Erectile function was assessed using the International Index of Erectile Function score (IIEF). All the patients submitted the fully completed Androgen Deficiency in Aging Male (ADAM) questionnaire. Hypogonadism was defined as total testosterone < twelve nmol/l.
Results
Of the one hundred and thirty total patients, twenty one per cent exhibited decreased libido, and sixty–one per cent reported more than three symptoms of ADAM. Hypogonadism was present in forty one patients. Among these patients, hypogonadotropic hypogonadism was the most prevalent form (seventy per cent). Patients with hypogonadism had lower Index of Erectile Function score compared to those with normal total testosterone. Significant negative correlation was found between total testosterone and body mass index, waist circumference, androgen deficiency symptoms, and HBA1c. In logistic regression analysis, erectile dysfunction severity and HBA1c were statistically significant risk factors for hypogonadism.
Conclusions
Considering that hypogonadism is frequent in type two diabetic subjects with erectile dysfunction, an appropriate screening should always be performed in those patients in order to detect those who have low serum total testosterone level at any early stage and to supplement testosterone accordingly.

The relationship between T2DM, nontoxic multinodular goiter and related osteoporosis/osteopenia

Lali Nikoleishvili[1], Tamta Cholikidze[1, 2] & Ziad Azzam[2]
[1]The Centre for Diabetes, Endocrine and Cardio–Pulmonary Diseases Diacori, Endocrinology, Tbilisi, Georgia; [2]New Vision University, School of Medicine, Tbilisi, Georgia

Introduction
Pathological features of T2DM – change in β–cell mass, increased intestinal glucose absorption, glucagon secretion, gluconeogenesis, enhanced catecholamines, insulin resistance – features of hyperthyroidism as well. It is known that Insulin Like Growth Factor Binding Protein (ILGFBP) is related to high insulin (possible asymptomatic hypoglycemia) as well to function and growth of the thyroid, that's why there is increased risk that patients with T2DM will develop goiter and its associaed osteopenia/osteoporosis. It's evident that TSH effects directly on bone formation and bone resorption, via the TSH receptor on osteoblast and osteoclast precursors. Association of T2DM and thyroid dysfunction is a less explored area, which may answer to various mysteries of metabolic diseases.
Methods
Retrospective cohort study.
We have studied 51 T2DM patients with nontoxic multinodular goiter and osteoporosis/osteopenia – to understand development in time and analyse possible outcomes. Age (yrs) – 63.53±9.16; 30–60=15 (29.5 %); 60≤36 (70.5%); Sex– F=42 (82.5%); M=9 (17.5%); Duration: Diabetes – 10.69±6.405; <6 yrs=16 (31.3%); ≥6 yrs=35 (68.7%); Nontoxic Multinodular Goiter – 4.41±3.56; <6 yrs=11 (21.5%); ≥6 yrs=40 (78.5%); Osteoporosis (n20) ; 1.4±0.59; <6 yrs=20 (100%); Osteopenia (n31)– 1.25±0.85; <6 yrs=31 (100%); HbA1c(%) – 7.76±2.26; <7.5%=30 (58.8%); >7.5%=21 (41.2%); TSH (μIU/ml) – 0.74±0.45; <0.4=14 (24.5%); >0.4=37 (75.5%) ; vit.D3 (OH25) (ng/ml)=14.42±7.88; i–Ca(mmol/l)=1.2±0.14; BMI (kg/m^2) –30.61±5.40; Therapy– oral anti–diabetic drugs– 39(76.5%), combined (oral+insulin) anti–diabetic therapy – 12 (23.5%).
Results
Linear regression showed correlation between HbA1c and TSH (Goodness of Fit – R square– 0.3826, P value – <0.0001, 95% confidence interval – 0.07906 to 0.1700) ; Duration of T2DM and nontoxic multinodular goiter (Goodness of Fit – R square– 0.2125, P value – 0.0007, 95% confidence interval – 0.1147 to 0.3988) Duration of goiter and osteoporosis/osteopenia (Goodness of Fit – R square– 0.08001, P value – 0.0443, 95% confidence interval – 0.001542 to 0.1192).
Conclusion
Current study shows that there is significat correlation between duration of T2DM and development of Thyroid Dysfunction and association between HbA1c levels and TSH is evident. We consider patients with T2DM as a high risk to Thyroid Dysfunctions, especially patients with possible asymptomatic hypoglycemic events and recommend to screen frequently. Thyroid Dysfunction itself effects bone health. The interface between Thyroid malfunction owing to diabetes is a matter of further investigation.

Polycysticovary syndrome (PCOS) and type 1 diabetes : A report of two cases

Ajili Rihab, Boubaker Fadia, Salah Ameni, Berrich Olfa, Alaya Wafa, Zantour Baha & Sfar Mohamed H
Taher Sfar, endocrinologie, mahdia, Tunisia

Introduction
PCOS is the most common endocrinopathy in adolescents and young women. Insulin–resistance and hyperinsulinism are its primary mechanisms,

which explains the frequency of its association with type 2 diabetes. But not many studies have been interested in the association between PCOS and type 1 diabetes.
Patients and methods
Two type 1 diabetes patients have been included in this study, aged respectively 17 and 16. The first patient had been treated by human insulin, whereas the second patient had been treated with analogues of insulin. The duration of the diabetes was of 5 and 15 years respectively and was uncomplicated in both patients. Both patients had menstrual irregularities such as spaniomenorrhea and secondary amenorrhea. Upon clinical examination, the first patient had grade 1 obesity and the other patient was slightly over weigh twith an android fat distribution. Both patients have been diagnosed with PCOS, based on Rotterdam criteria including signs of hyperandrogenism such as acne, seborrhea and a mild hirsutism, a hypertestosteronemia and polycystic ovaries on ultrasonography, after having eliminated the differential diagnosis. The therapeutic approach for both patients was dietary adjustment and a progestogen.
Discussion and conclusion
in type 1 diabetes mellitus, the prevalence of pcos is 24 to 33%. but this disease remain sunder–diagnosed. the physiopathological mechanism of this association has not been fully understood. the exogenous hyperinsulism by insulin overdose has been incriminated, which is probably the case for our two patients. the risks linked to type 1 diabetes such as neoplasic diseases, reproductive difficulties, metabolic and cardiovascular repercussions are increased by pcos. nowadays, in the absence of clea rrecommendations for the treatment of pcos in type 1 diabetes, the therapeutic approachre mains poorly codified.

Evaluation of selectins, membrane potential and antioxidant vitamins on diabetic patients attending general hospital, owerri

Joakin Chidozie Nwaokoro[1], John Kennedy Nnodim[2], Edward Ukamaka[2] & Nkiruka Oly–Alawuba[3]
[1]Federal University of Technology, Owerri, Department of Public Health, Owerri, Nigeria; [2]Imo State University, Department of Medical Laboratory Science, Owerri, Nigeria; [3]Imo State University, Department of Nutrition and Dietetics, Owerri, Nigeria

Aim
The levels of serum Selectins (P and E–Selectin), membrane potential and antioxidant vitamins were determined in diabetic patients attending General Hospital Owerri, Nigeria.
Materials and methods
A case control study involving 600 persons living with diabetes between the ages of 20 and 60 years attending General Hospital Owerri. Also, 600 apparently healthy persons within the ages of 20 and 60 years served as control. Fasting venous blood was collected for the determination of serum P–selectin, E– selectin, membrane potential, vitamins C and E. The serum selectins and vitamins were estimated using enzyme linked immunoabsorbent assay (ELIZA). While membrane potential was calculated using Nerst equation. The Independent Student t test was used for statistical analysis.
Results
The levels of P–Selectin and E–Selectin were significantly higher in diabetes ($P<0.05$), when compared with the control. The levels of membrane potential, vitamin C and Vitamin E were significantly decreased in people with diabetes ($P<0.05$), when compared with the control.
Conclusion
The result suggests that diabetes could probably be associated with increased P–Selectin and E–Selectin levels which may be useful diagnostic tool for predicting the severity of diabetes. Also the decreased membrane potential could be linked to decreased energy while reduced vitamins in diabetes could be linked to oxidative stress.
Key words: P–selectin, E selectin, membrane potential, vitamin C and E.

Complicated necrotizing otitis externa in diabetic patients

Mohamed Masmoudi, Malika Omri, Mehdi Hasnaoui, Rihab Lahmar, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Introduction
Necrotizing otitis externa (NOE) is an invasive infection. It may present with a variety of clinical findings. The most common symptoms are purulent otorrhea and exquisite otalgia resistant to analgesics. Diabetics are susceptible to microangiopathy that dulls pain perception thus predisposing them to severe complications of inctious disease.
Materials and methods
We reported ten cases of complicated necrotizing otitis externa in diabetic patients treated in ENT department of Tahar Sfar Hospital in Tunisia.
Non diabetic patients were excluded.
Results
Ten patients were diabetic occuring in 6 women and 4 men. The mean age was 64 years ranging from 58 years to 71 years. The average duration of diabetes follows up was over 10 years. All patients have received oral and local antibiotics before hospitalization. Symptoms were made of otalgia in all patients, otorrhea in 6 patients. Headache and temporo–mandibular joint pain were reported in two cases. Fever was observed in four patients. Four patients noted ipsilateral facial palsy. Stenosis of external auditory canal was observed in all patients Pseudomonas aeruginosa was t isolated in 9 cases and candidada albicans in one case. Computed tomography confirmed the NOE in all cases. CT scan showed also an extension to parapharyngeal space in 2 cases with a huge abcess in one case, to the rhinopharynx in one case, temporomandibular arthritis in two cases, lysis of the skull base in one case, lysis of the facial canal in two cases, sigmoid sinus thrombosis in one case and jugular vein thrombosis in two cases. MRI was performed for two cases with extension to parapharyngeal space and to the rhinopharynx. Diabetic control worsened with the onset of invasive external otitis in all cases. Nine patients have received intravenous anti–pseudomonal medications. Antifungual therapy was conducted in one case. One patient had a drainag of retropharyngeal abcess. Heparin was not used for the cases of septic thrombosis. A regression of symptoms was observed in 8 cases and two patients had facial palsy as sequalae.
Conclusion
Necrotizing otitis externa remains a devastating infection due to its complications. Always think about it, especially in diabetics, in order to get adequate treatment in time and prevent complication. Adequate control of diabetes in association with antibiotic therapy must be started quickly to reduce morbidity and mortality.

Complex rehabilitation of comorbid patient after acute myocardial infarction with type 2 diabetes mellitus and obesity

Valeriia Vasileva & Larisa Marchenkova
National Medical Research Center of Rehabilitation and Balneology, Moscow, Russian Federation

Rehabilitation of comorbid patients after acute myocardial infarction (AMI) with concomitant diabetes mellitus type 2 (DM2) and obesity requires application of personalized medical programs involving non–pharmacological physical methods and effective pharmacological therapy of DM2. The aim of the clinical case presentation is a description of the experience of complex medical rehabilitation of the middle–aged woman in the early period of AMI on the background of DM2 and morbid obesity using modern methods of physical therapy and liraglutide.
Case description
Female aged 51 years old was hospitalized in in–patient rehabilitation department with the diagnosis of Coronary heart disease; AIM of the left ventricle with growth of ST of 19.12.2019 (the 8th day); Stenting of the right coronary artery at 19.12.2019; DM2; Morbid obesity. The woman complained of dyspnea, increasing fasting blood glucose (FBG) up to 12 mmol/l. *Survey data*: height 165 cm, weight 152 kg, BMI 55.8 kg/m^2, waist circumference (WC) 139 cm, hips circumference (HC) 143 cm, blood pressure (BP) 148/98 mm Blood panel and routine urine analyses were without any pathological changes. HbA1c 7.6%, serum FBG 9.1 mmol/l, total cholesterol (TC) 7.4 mmol/l, triglycerides (TH) 3.08 mmol/l, low density lipoproteins (LDL) 4.8 mmol/l, high density lipoproteins (LDL) 1.2 mmol/l.
Rehabilitation program
low–calorie diet, low–intensity laser exposure #10, cardiological complex of physical exercises in a gym #10, bike exercises in a gym #10, speleotherapy #10, low–intensity kinesiotherapy #10. Due to AIM metformin has been changed to liraglutide which was initiated in a dosage of 0.6 mg/day, followed by a dose increase of 0.6 mg/day per week up to a therapeutic dose

of 1.8 mg/day. The patient was discharged in 12 days to continue her recovery in out–patient department. *In 30 days*: shortness of breath significantly decreased and tolerance to physical loads improved. Body weight 145 kg, BMI 53.3 kg/m^2, WC 132 cm, HW 140 cm, BP 124/79 mm Hg. Serum FBG 5.3 mmol/l, TH 6.9 mmol/l, TG 3.03 mmol/l, LDL 4.4 mmol/l, LDL 1.22 mmol/l. *In 3 months*: actively works, no complaints, weight 139 kg, BMI 51.1 kg/m^2, WC 128 cm, HC 132 cm, BP 125/78 mm Hg. Serum FBG 5.1 mmol/l, TH 5.9 mmol/l, TG 3.01 mmol/l, LDL 3.52 mmol/l, LDL 1.36 mmol/l, HbA1C 6.5%.
Conclusions
This clinical case demonstrates the results of complex rehabilitation of the middle–aged woman with AIM on the background of DM2 and morbid obesity using physical therapy methods and hypoglycemic pharmacological therapy with liraglutide.

Clinical presentation and course of hemichorea due to hyperglycemia: A case series

Tae Jung Oh[1, 2], Hea Eun Kim[1], Kyong Yeun Jung[3], Sung Hee Choi[1, 2] & Hak Chul Jang[1, 2]
[1]Seoul National University Bundang Hospital, Internal Medicine, Seongnam, ; [2]Seoul National University College of Medicine, Internal Medicine, Seoul, Korea, Republic of South; [3]Eulji General Hospital, Internal Medicine, Seoul, Korea, Republic of South

Introduction
Acute hemichorea due to hyperglycemia has been reported in subjects with type 2 diabetes, type 1 diabetes, and a rare type of diabetes, maternally inherited diabetes and deafness. This condition was generally subsided after adequate glycemic control, and the recurrence of hemichorea was rarely reported.
Case report
We comprehensively reviewed clinical presentation and course of hemichorea in five elderly patients with type 2 diabetes (four women and one men). Age was 69–84 years and duration of diabetes was 1–35 years. Initial HbA1c levels were 9.3–13%. They had multiple comorbidities, hypertension (n=4), dyslipidemia (n=4), and chronic kidney disease (n=4). Three patients were previously prescribed insulin but had poor compliance. Four patients undertook brain MRI and one of them performed brain FDG–PET. Three out of four brain MRI showed high signal intensities of putamen in T1–weighted images. FDG–PET scan showed hypometaboism in the corresponding lesions. Metabolic derangement or vascular insufficiency might be the pathophysiology of hemichorea in this case. Duration of hemichorea was various from 10 days to 5 months. All of them were treated with multiple daily insulin injection, and four patients were treated with dopamine–receptor blockers. One patient's hemichorea was recurred after 2 months from the time when the first event was resolved. This patient was finally diagnosed with vasculitis and followed a grave course after treatment of immunosuppressant.
Discussion and conclusion
The prognosis of hemichorea due to hyperglycemia seemed to be good, and we can easily detect typical brain MRI findings. However, we should consider other cause of hemichorea such as vasculitis when the symptom was recurred after adequate glycemic control.

Efficacy and safety of statin use in children and adolescents with familial hypercholesterolaemia: A systematic review and meta–analysis of randomized–controlled trials

Panagiotis Anagnostis[1], Konstantina Vaitsi[1], Panagiota Kleitsioti[1], Chrysanthi Mantsiou[1], Konstantinos Pavlogiannis[1], Vasilios Athyros[2], Dimitri MIkhailidis[3] & Dimitrios Goulis[1]
[1]Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynaecology, Medical School, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, 2nd Propedeutic Department of Internal Medicine, Medical School, Hippocration Hospital of Thessaloniki, Thessaloniki, Greece; [3]University College London (UCL), Department of Clinical Biochemistry, Royal Free Hospital Campus, University College London Medical School, , London, United Kingdom

Objective
Statins are the mainstay of treatment for patients with familial hypercholesterolaemia (FH). The purpose of this study was to systematically investigate and meta–analyze the best available evidence from randomized–controlled trials (RCTs) regarding the efficacy and safety of statins in children and adolescents with FH.
Methods
A comprehensive search was conducted in PubMed, Scopus and Cochrane, up to July 10, 2019. Data were expressed as mean differences with 95% confidence intervals (CI). The I^2 index was employed for heterogeneity.
Results
Ten RCTs were included in the qualitative and nine in the quantitative analysis (1.191 patients, aged 13.3±2.5 years). Compared with placebo, statins led to a mean relative reduction in total cholesterol (TC), LDL–C, triglyceride and apo–B concentrations by –25.5% (95% CI –30.4%, –20.5%; I^2 91%), –33.8% (95% CI –40.1%, –27.4%; I^2 90%), –8.4% (95% CI –14.8%, –2.03%; I^2 26%) and –28.8% (95% CI –33.9%, –23.6%; I^2 83%), respectively. HDL–C was increased by 3.1% (95% CI 1.1% – 5.2%; I^2 0%). The effect on TC, LDL–C and apo–B seems to be potency–dependent. More than half of patients may achieve the LDL–C target with high–intensity statin dose (4–14% with low–to–moderate intensity). Baseline LDL–C concentrations do not seem to predict the lipid–lowering effect of statins. Statins were well–tolerated (no effect on growth or sexual development), with no significant differences in transaminase and creatine kinase levels compared with placebo.
Conclusions
Statins are quite effective in reducing TC, LDL–C, TG and apo–B and increasing HDL–C concentrations in children and adolescents with FH. No safety issues were seen with statin use.

Risk of hospitalization for cardiovascular events associated with diabetes therapies in type 2 diabetes patients in lithuanian cohort

Zydrune Visockiene[1, 2], Roma Puronaite[1, 2, 3], Rokas Navickas[1, 2], Elena Jureviciene[1, 2] & Vytautas Kasiulevicius[1, 2]
[1]Faculty of Medicine of Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania; [3]Institute of Data Science and Digital Technologies, Vilnius, Lithuania

Background
Type 2 diabetes (T2DM) is associated with increased risk of cardiovascular (CV) complications. Although evidence suggest SGLT–2 inhibitors and GLP–1 receptor agonists to have a protective effect on CV outcomes they are still not available as a second–line therapy in Lithuania because of costs.
The aim
To examine the risk of hospitalization for CV events associated with diabetes therapies in patients with T2DM.
Methods
Lithuanian National Health Insurance Fund database, covering the period 2012 – 2014 was used to extract all diabetes cases with demographic data, information on complications, concomitant diseases, hospital admissions, prescribed medications. T2DM patients were grouped according to diabetes treatment. Nearest neighbor propensity score matching included age, gender, hypertension, chronic kidney disease, established CVD, diabetes complications, use of statins and ACEI to match the groups. Hospitalization risk for CV complications (miocardial infarction (MI), coronary heart disease (CHD), heart failure (HF), transient ischemic attack (TIA), stroke) was compared between the groups.
Results
From 124416 DM cases extracted, we excluded T1DM, treatment changes or initiation after index period. Matching of remaining 75666 T2DM cases resulted in 7089 patients in each Diet, Metformin, Sulfonylurea (SU)/Insulin and Combination therapy group with similar age – 69 years, women – 62%,

established CVD – 58%, hypertension – 87%, use of ACEI – 64% and statins – 7%. About 14% had DM complications, polyneuropathy being diagnosed most commonly in 11% of patients. In SU/Insulin group 53% were on SU, in Combination therapy – 82, 31, 97, 13, 2 and 3% – were respectively on SU, insulin, metformin, DPP–4 inhibitors, thiazolidinediones and GLP–1 receptor agonists. Compared to Metformin risk ratio (RR) for hospitalization was 1.18 [CI 1.11, 1.25] with the highest RR for TIA 1.32 [1.04, 1.67] in Diet, 1.24 [1.17, 1.32] with the highest RR for MI 1.51 [1.36, 1.66] in Su/Insulin, 1.15 [1.09, 1.22] with the highest RR for stroke 1.29 [1.07, 1.55] in Combination therapy groups. Compared to Diet RR for hospitalization was 1.06 [1.00, 1.11] with the highest RR for MI 1.29 [1.07, 1.55] in Su/Insulin. There were no difference between Diet and Combination therapy groups.
Conclusion
More than half of type 2DM subjects have established CVD in Lithuania. Only minority of them are on statins and most are treated with SU or insulin, which significantly increases the risk of hospitalization for CV events. These results strongly support the need of new antidiabetic medications with proved CV benefit for type 2 diabetes treatment.

Matrix–GLA–protein and cardiovascular parameters: uc–dp MGP vs total MGP

Natascha Schweighofer[1, 2], Moritz Strasser[3], Christoph Haudum[1, 2], Albrecht Schmidt[4], Ewald Kolesnik[4], Burkert Pieske[4], Thomas Pieber[1, 2] & Barbara Obermayer–Pietsch[2]
[1]CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria; [2] Division of Endocrinology and Diabetology, Department of Internal Medicine, Medical University of Graz; [3]Institute of Biomedical Science, Department of Health Studies, FH JOANNEUM, University of Applied Sciences; [4]Division of Cardiology, Department of Internal Medicine, Medical University of Graz

Matrix–GLA–protein (MGP), independent of its posttranslational modification(s), has been associated with bone parameters and cardiovascular risk in patients with and without type 2 diabetes mellitus (T2DM). We investigated whether uncarboxylated, dephosphorylated MGP (uc–dp MGP), total MGP or both are associated with anthropometric and cardiovascular parameters such as carotid to femoral pulse wave velocity (PWV), intima–media thickness (IMT) and relative wall thickness (RWT), in patients with and without T2DM. We analysed data from the BioPersMed cohort ($n=966$, mean age 58±9 years, 255 patients without and 71 with T2DM), a prospective cohort of asymptomatic patients at cardiovascular risk. T2DM and non–T2DM patients were defined according to ADA criteria. Uc–dp MGP was measured using the IDS–iSYS InaKtif MGP Kit and total MGP using Human MGP(Matrix Gla protein) ELISA Kit (Wuhan Fine Biotech Co., Ltd., China). Pulse wave analysis was done with a SphygmoCor device (Atcor Medical, Australia), IMT and echocardiograpy with the Vivid 9 device (GE Healthcare Austria GmbH & Co OG, Austria). Total and uc–dp MGP did not correlate with each other in both subject groups. Uc–dp MGP was associated with BMI ($P<0.001$), weight ($P=0.003$), systolic and diastolic blood pressure ($P=0.021$ and 0.004, respectively), heart frequency ($P=0.011$) and waist and hip circumferences (both $P=0.001$) in patients without T2DM and with BMI ($P=0.016$), weight ($P=0.021$) and waist and hip circumferences ($P=0.025$ and 0.046) in T2DM patients. Total MGP showed no correlations with these parameters in both patient groups. Only uc–dp MGP correlated with PWV, IMT in +patients without T2DM ($P=0.004$ and $P=0.001$, respectively). Those patients with end organ damage had elevated uc–dp MGP levels compared to patients with non–pathologic IMT ($P=0.021$). Only uc–dp MGP showed associations with RWT groups ($P=0.039$) in non–diabetic patients. Patients with eccentric cardiac hypertrophy had higher uc–dp MGP levels than patients with concentric hypertrophy. Uc–dp MGP but not total MGP was associated with cardiovascular parameters in non–diabetic patients and seems to be elevated in pathologic conditions. These findings were not seen in patients with T2DM. Our data implicate that uc–dp MGP is also an active form of MGP and not only an inactive storage form and might be a very interesting player modulating cardiovascular risk.

The serological prevalence of celiac disease (cd) in patients with type 1 diabetes (dt1)

Abainou Lahousssaine, Idrissi Ayoub, Hamza El Jadi, Sanae Elhadri, Azelarab Miftah & Hicham Baizri
Avicenna Military Hospital, Marrakech, Morocco

Introduction
Celiac disease is an autoimmune disease triggered by gluten frequently associated with other autoimmune diseases, among which is type 1 diabetes first.
Objectives
The objectives of our study are:
– To determine the serological prevalence of celiac disease (CD) in patients with type 1 diabetes (DT1)
– Compare the clinical and biological characteristics of seropositive and seronegative patients.
Methods
This is as multicenter, cross–sectional study that was carried out over a period of two years. We investigated an adult and pediatric Moroccan population comprised of 276 diabetic type 1 patients, including 144 female and 132 male (sex ratio 1: 1, mean age 14.1±8 years). The screening of CD consisted of the dosage of IgA anti–tTG antibodies, IgA–tTGA seronegative patients with IgA deficiency have been screened for IgG anti–tTG antibodies. HLA–DQ2 / DQ8 typing was performed in patients with low serum anti–tTG and EMA titers.
Results
Among the 276 participants in the study, 25 patients were found to be seropositive, making the serological prevalence 9.1%. Of whom, one patient was found to be IgA deficient and seropositive only to the IgG isotype of the anti–tTG antibodies. 5 patients were advised to perform an HLA determination as they had low titers of both tTG and EMA antibodies, 3 of whom were positive for HLA–DQ2 and 1 for HLA–DQ8. 1 patient was lost to follow up.
Conclusion
Mass screening is to be recommended. However, controlled longitudinal studies with larger samples are needed to prove any potential benefit of a gluten–free diet in similar settings, especially in asymptomatic patients.

Autoimmune hypoglycemia: Hirata disease

Marina Yukina, Nurana Nuralieva, Ekaterina Troshina, Zamira Zuraeva & Larisa Nikankina
Endocrinology Research Centre, Clinical Endocrinology, Moscow, Russian Federation

Introduction
One of the autoimmune non–diabetic hypoglycemia (NDH) causes is the formation of antibodies to insulin (AB–IRI) or Hirata disease (HD).
Objectives
To determine the prevalence of AB–IRI level increasing in patients with suspected NDH of various genesis and in healthy individuals.
Methods
96 patients aged 18–80 years with suspected NDH were included in prospective study. In all patients we determined the AB–IRI (reference 0–10 U/ml) and IRI levels at the beginning of fasting test (maximally 72h) and controlled glycemia by continuous monitoring system (CMS). According to the results, patients were divided into 4 groups: with insulinoma (group 1), with hypoinsulinemic hypoglycemia (group 2), without hypoglycemia (group 3), with HD (group 4). Also, 10 healthy individuals without hypoglycemia were included and united with patients of group 3.
Results
In group 2 the AB–IRI increasing was not revealed.
HD was revealed in 3.8% of participants (group 4), in whom we noted significantly higher levels of AB–IRI (Me 120.06 U/ml [min 61.1; max 163.55]) and IRI (Me 874.8 μU/ml [min 330.7; max 1000]) compared to other groups ($P<0.000018$). In all patients of group 4 hematological pathology was excluded, the trigger substance was identified (thioctic acid, lisinopril) and canceled. The duration of fast consisted 72h in all patients, but according to CMS the asymptomatic decrease of glycemia (2.4–3.1 mmol/l) recorded in the late postprandial period.
Increasing of AB–IRI, not reaching diagnostic values of HD (AB–IRI carriage), was detected in 2 patients of group 1 (12.81 and 15.64 U/ml) and in 3 participants of group 3 (10.1, 10.14 and 29.7 U/ml) – 4.7% of cases. After surgical treatment of insulinomas (in 2.5 months) AB–IRI remained at the same level ($P=0.94$) in all patients, as in participants №1 and №2 of group

3 when controlled the dynamics in 3 months ($P=0.87$). In participant №3 of group 3 the AB–IRI level in dynamics was normal. There were no violations of carbohydrate metabolism. We continue the patients' observation.
Conclusion
HD is not so rare disease, as seemed previously, accompanied by hypoglycemia (in most cases asymptomatic) in the late postprandial period. The IRI level more than 100 μU/ml testifies in favor of HD, and the diagnosis is confirmed when the AB–IRI level increases, and the fast test is inexpedient. AB–IRI carriage may not cause a violation of carbohydrate metabolism, however, these patients require dynamic observation.
Funding
The grant of Russian Science Foundation (project 17–75–30035).

Revision of the type of diabetes mellitus– when and why
Andreja Maric, Maja Mikolaj Kiric & Martina Jambrović
County hospital Cakovec, Endocrinology and diabetology, Cakovec, Croatia

Distinguishing type 1 from type 2 diabetes mellitus (DM) depends on clinical presentation, titers of antibodies and requirement for insulin therapy. Need for insulin per se is not a major difference between those two types. We measured the presence of antibodies for glutamic acid decarboxylase (GAD), islet–cell antibodies (ICA), insulinoma–associated protein 2 (IA–2) and the level of C–peptide in a group of 10 patients whose diagnosis of type 2 DM was established several years ago. The reasons for revision were glucose variability, elevated HbA1c in some patients, basal–bolus sheme from the beginning of diagnosis in several patients, presence of unknown hypoglycemias and need for flash glucose monitoring (FGM, "Libre") which is indicated with reimbursement of health care system in type 1 patients in our country. After revision, one male and one female patient were still type 2 DM (ICA, GAD, IA–2 negative, C–peptide 0.35 and 0.41 nmol/l), the duration of disease was 5 and 7 years, respectively. After peroral therapy for 4 and 6 yrs, basal oral regime was used. Among other 8 patients 6 patients were revised to be LADA (two males, 4 females) with positive ICA and GAD, low C–peptide. One male and one female were type 1 (DM 11 and 17 yrs, basal bolus therapy). In 2 pts with LADA, basal–bolus was started from the beginning of diagnosis (duration of DM 6–15 yrs), in 4 pts with LADA duration of DM was 5–30 yrs (peroral therapy first several years). All LADA/ type 1 patients got FGM. Conclusion: availability of FGM and new drugs for DM require that we consider revising the type of DM in some patients in order to provide them with the best care possible.
Keywords: type 1, type 2, revision, flash glucose monitoring.

Evolution of the lipidic parameters in a population of elderly subjects with type 2 diabetes who have fasted the month of ramadan
Chaima Jemai & Feika Ben Mami
National Institute of Nutrition of Tunis, C, Tunisia

Introduction
After the fast of the month of Ramadan, the lipid balance of the elderly patients with diabetes can be modified. The aim of our study was to describe the evolution of the parameters of the lipid balance after the fast of Ramadan in a population of elderly diabetic subjects.
Patients and methods: This is a prospective evaluative study conducted in a population of 20 patients with type 2 diabetes aged over 65 years. This population had benefited from an evaluation of the clinical and metabolic parameters before and after the fast and had received education and therapeutic adjustment by referring to the recommendations of the ADA 2016.
Results
The mean age was 68.2±2.4 years with extremes of 65 and 74 years. The sex ratio was 1. The average duration of diabetes was 7.7±6.2 years. The average BMI was 29.5±5.2 kg/m^2 with extremes of 23.18 and 39.87 kg/m^2. 75% were overweight or obese. 90% ($n=18$) were classified as high or very high risk related to fasting according to the classification of the ADA 2016. The days fasted were successive with an average of 26±8.7 days. The majority (80%, $n=16$) had fasted the whole month. After fasting, HbA1C increased from 8.27±1.82% to 8.29±2.1% after fasting (+0.02±1.73%, $P=0.957$) . CT, TG, HDL and LDL were 4.29±0.67, 1.43±0.68, 1.05±0.21 mmol/l, and 1±0.24 g/l respectively, before fasting. They increased respectively after fasting to 4.37±0.68 (+0.08±0.49 mmol /l, $P=0.478$), 1.46±0.46 (+ 0.03±0.43 mmol/l, $P=0.754$), 1.02±0.25 mmol / (–0.03±0.17 mmol /l, $P=0.475$) and at 1.03±0.26 g/l (+0.03±0.12 g/l, $P=0.216$). Gender and body size before fasting were not associated with changes in lipid parameters after fasting.
Conclusion
Several studies report an improvement in lipid parameters after the fast of the month of Ramadan, particularly the elderly. However, fasting in diabetics is not recommended due to the increased risk of acute complications.

Insulin therapy and weight gain in type 2 diabetes
Khadija Ben Naceur[1], Haifa Abdesselem[2], Ramla Mizouri[2], Zeineb Zemni[2], Sabrine Zribi[2], Ounaissa Kamilia[2] & Chiraz Amrouche[2]
[1]Institut National de Nutrition, Service des consultations externes et explorations fonctionnelles, Tunis, Tunisia; [2]Institut National de Nutrition, Service des Consultations Externes et Explorations Fonctionnelles, Hammam Lif, Tunisia

Introduction
Insulin therapy (IT) in type 2 diabetes(T2D) is an integral Pharmacologic Approache because of the progressive nature of the disease. Insulin improves glycemic control and reduces the risk of microvascular complications. It's however associated with weight gain as a side effect which promotes insulinoresistance and cardiovascular morbi–mortality.
In this work we evaluated long–term weight gain in insulin–treated patients with T2D.
Materials and methods
It was a retrospective, descriptive and longitudinal study includng T2D patients on IT for at least 10 years and monitored at the National Nutrition Institute of Tunis. Demographic and clinico–biological data were extracted from the medical record at the initiation of IT and 10 years after.
Results
There were 27 women and 17 men with mean age of 47.7 years old . The average duration of diabetes was 10.78±7.5 years The majority of patients (77.3%) had uncontrolled diabetes with a mean glycated hemoglobin of 9.5±2%. Half of our diabetics were under combination of insulin and oral antidiabetic drugs, 25% with metformin and 20.5% with sulfonylureas. Nearly the a third (38.1%) were on a full basal bolus regimen. Obesity was objectived in 50% of the patients at insulin intiation. the mean initial body mass index (BMI) was 30.65 kg / m^2, with an extreme ranging from 20.9 to 41.4 kg/m. After 10 years of follow–up, 79.9% of patients had unbalanced diabetes. The average weight gain was 2.21±0.8 kg. The mean BMI was 31.14 kg / m^2 with a statistically significant difference ($P<0.001$) compared to the time of insulin intiation.
Conclusions
Weight gain remains a classic side effect of insulin therapy. However, it can be limited by increasing physical activity, calorie intake restriction and concomitant metformin administration.

Adherence to anti–diabetic treatment during the fast of the month of ramadan in a population of patients with diabetes
Chaima Jemai & Feika Ben Mami
National Institute of Nutrition of Tunis, C, Tunisia

Introduction
Few studies have examined the adherence to anti–diabetic treatment in patients with diabetes during the fast of the month of Ramadan.
The aim of our study was to describe the adherence to antidiabetic treatment in patients with diabetes before and during the fast.

Patients and methods
This is a descriptive and analytical study carried out on 140 diabetics who have fasted the month of Ramadan. The risk stratification was made by referring to the recommendations of the ADA 2016. Adherence to antidiabetic treatment, was judged: good if the patient regularly takes his treatment at regular times, modertate if the patient does not take his treatment at regular times, bad if the patient does not take all of his treatment and omits some medication during the week.
Results
The majority of the population (82.8% (n=116)) had good therapeutic adherence before fasting. 17.1% (n=24) had moderate to bad therapeutic compliance. During fasting, compliance was good in 80% of cases (n=112), and moderate to bad in 20% of cases (n=28). The frequency of moderate to bad adherence was significantly more frequent in the case of high or very high risk associated with fasting (25.2% (n=25)) than in the case of low to moderate risk (7.3% (n=3)) (P=0.011, OR [95% CI]=4.27 [1.2, 15]).
We studied the association of therapeutic adherence during fasting with the following factors: age, gender, level of study, duration of progression of diabetes, therapeutic adherence before fasting.
None of these factors was significantly associated with adherence during the fasting.
Conclusion
Patients at high and very high risk are often determined to fulfill the religious duty of the fast of the month of Ramadan. Our study showed less adherence to anti–diabetic treatment during fasting in them, which increases the risk of complications, including glycemic imbalance. Thus, we propose to assess therapeutic compliance in diabetics systematically before fasting and to integrate it among the factors classifying as high and very high risk.

EP197

Real world data of Type 2 Diabetes Mellitus (T2DM) obese patients using another GLP1 receptor agonist (GLP1–RA) and switching to Semaglutide in Spain

Jersy Cardenas[1,2], Nancy Sanchez Gomez[1], Roberto Miguel Sierra Poyatos[1,3], Bogdana Luiza Luca[1], Naiara Modroño Mostoles[1,2], Teresa Montoya Alvarez[2], Maria Jesus Silva Rodriguez[1,2], Maite Ortega Juaristi[1], Diego Meneses González[1], Maria De Los Angeles Gonzalo Redondo[1], Alba Galdon Sanz–Pastor[1], Jorge Ruiz Sanchez[1], María De La Paz Gómez Montes[2], Cristina Cruces Vega[2] & Clotilde Vazquez Martinez[1]
[1]Hospital Universitario Fundacion Jimenez Diaz, Endocrinology, Madrid, Spain; [2]Hospital Universitario Infanta Elena, Endocrinology, Madrid, Spain; [3]hospital General De Villalba, Endocrinology, Collado Villalba, Spain

Objectives
Semaglutide was approved for the treatment of T2DM patients with a body mass index (BMI) > 30kg/m^2 by the Spanish National Health Service in May 2019. We evaluate clinical outcomes of patients on previous treatment with any another GLP1–RA that switch to Semaglutide.
Material and methods
Retrospective analysis. Sixty–five T2DM patients were included. Demographic data, anthropometric, systolic blood pressure (SBP), diastolic blood pressure (DBP), fasting glucose (FG), glycated hemoglobin (HbA1c) and body composition data were collected at baseline and after 6 months of switching. Statistical analysis was performed with STATA 14. Paired T–student test for comparison between baseline and 6 months and logistic regression to evaluate Semaglutide dose (≤0.5 and 1.0 mg/weekly), age, sex, duration of T2DM, BMI and HbA1c at baseline as possible predictors of Semaglutide efficacy to achieve HbA1c <7%.
Results
Of 65 patients switching to semaglutide (4.6% on 0.25 mg/weekly, 66.15% on 0.5 mg/weekly and 23.07% on 1 mg/weekly), 54.68% were males and the median age was 60.66±9.1 years. Mean duration of T2DM was 12.78±8.2 years. Regarding previous GLP1–RA: 43.0%, 38.5%, 16.9% and 1.5% switch from liraglutide, dulaglutide, exenatide and lysixenatide respectively. Seven patients discontinue treatment because of gastrointestinal intolerance and data of 2 patients were missing, including 56 patients in the final analysis. Waist circumference changed in –2.02 cm (CI95% –3.62 to –0.41) and HbA1C in –0.39% (CI95% –0.74 to –0.05) after switching. There were no changes in other analyzed variables (Table). Semaglutide dose 1.0 mg/weekly (OR: 6.69; CI95% 1.14 to 39.24) and baseline HbA1c (OR 0, 37; CI95% 0.16 to 0.83) were independent predictors to achieve HbA1c <7% after switching to Semaglutide.

	Baseline	Change from Baseline		
		0.5 mg n=39	1.0 mg n=15	Total N=56
Weight–(kg)	98.2±14.84	–0.88	–0.62	–0.58 (–1.71 to 0.54)
Waist–(cm)	116.1±9.4	–1.93	–2.33	–2.25 (–3.67 to –0.84)*
SBP–(mmHg)	133.5±14.17	–0.30	+0.77	–0.40 (–5.37 to 4.56)
DBP–(mmHg)	81.37±11.47	–0.66	–3	–1.45 (–3.78 to 0.89)
Fat–(%)	40.9±8.0	+0.25(n=12)	+3.48(n=6)	–0.57 (–5.57 to 4.42)(n=18)
Lean mass–(kg)	33.1±7.3	–1.11(n=12)	–1.55(n=6)	–1.09 (–2.84 to 0.67)(n=18)
BMI–(kg/m^2)	35.4±5.0	–0.26	–0.18	–0.17 (–0.55 to 0.21)
FG–(mg/dl)	157.4±55.1	+8.18	–9.47	+3.93 (–13.10 to 20.97)
HbA1C–(%)	7.6±1.2	–0.18	–0.99 (–1.93 to –0.03)*	–0.34 (–0.66 to –0.01)*
Insulin dose (UI/day)	50.4±33.6	–1.86(n=15)	–3.63(n=8)	–1.67 (–6.14 to 2.81)(n=24)

*P< 0.05. Two patients (semaglutide 0.25 mg/weekly) are not included in the table.
Data in mean±SD, mean(CI95%)

Conclusions
Patients with T2DM and obesity using previously GP1RA and switching to semaglutide 1 mg present better glycemic control and less waist circunference.

Relation between type 1 diabetes management and interactive diabetes education

Eka Patsatsia[1], Marina Gordeladze[1] & Elena Shelestova[2]
[1]D. Zhvania Pediatric Academic Hospital of the Tbilisi State Medical University, Endocrinological, Tbilisi, Georgia; [2]National Center for Diabetes Research, Tbilisi, Georgia

Background
Type 1 diabetesmellitus (T1DM) isthe most widespread metabolic/endocrine condition among children/adolescents in Georgia. T1DM patients aged 0–18 yrs are treated both in– and outpatiently. In 2015–2019 totally 533 patients were hospitalized, 211 of them had fresh T1DM. Special attention is paid to interactive diabetes education (IDE) of patients/their caregivers, thatis very important for adequate diabetes management. IDE is initiated from the day of admission.
Our aim was to assess the effect of continuous, structured IDE on quality of metabolic control and acute complication incidence in children/adolescentswith T1DM. Goals of IDE are– teaching about signs/symptoms, progression, acute complications (causes, signs/ symptoms, prevention and treatment) of T1DM; developing insulin injecting, self–monitoring/self–controlskills (result interpretation; bread–units; physical activity, etc).
Methods
Patients treated/supervised at our Hospital were separated into 3 groups (Gr.): 211 patients with fresh T1DM (Gr.1); 150 patients with poor (Gr.2) and 361 patients with satisfactory (Gr.3) glycemia control. Following parameters: HbA1c, hyper–/hypoglycemic coma and ketoacidosis incidence, insulin doseswere studied and compared before/after IDE course and psychologist counseling.
Results
Data obtained before IDE for Gr. 1, 2, 3: HbA1c (%) – 13.5±2.1; 12.5±2.3;7.0±2.5, respectively; hyperglycemic coma (%) – 17; 30; 5, respectively; ketoacidosis (%) – 78; 20;0, respectively; hypoglycemic coma (%) –22; 35; 0, respectively; insulin doses (U/kg) – 1.7±0.1; 1.3±0.4;0.7±0.4, respectively; QOL/Relation to Condition Questionnaire/

RCQ (%) scores were 100; 80;35, respectively. Post–education data: HbA1c (%) – 7.0±2.1; 8.0±2.2;6.4±0.8, respectively; hyperglycemic coma (%) – 0; 4;0, respectively; ketoacidosis (%) – 3; 8; 0, respectively; hypoglycemic coma (%) –0; 0;0, respectively; insulin doses (U/kg) – 0.7±0.1; 0.9±0.4; 0.7±0.12, respectively; QOL/RCQ (%) scores – 95; 87;97, respectively.
Conclusion
IDE, initiated at the moment of diagnosis, that lasts throughout in–hospital period, is regularly repeated out–patiently and tailored to individual patient needs gives knowledge, develops skills, creates motivation, helps to achieve good diabetes control, reduces and/or avoids acute complications and improvesQOL of children and adolescents with T1DM. Lately the first book for children, adolescents and their caregivers "Diabetes Mellitus for Children and Adolescent" was published in Georgian, it discusses all aspects of life with diabetes and management of the condition in a simple and attractive way. The book is delivered free of charge.

Hypothyroidism and diabetes in syrian refugees

Murad Shatnawi
International Medical Corps, Hospital Manager, Irbid, Jordan

Treating Syrian refugees with diabetes, hypertension and Hypothyroidism in Azraq refugee camp, Zarqa, Jordan
Background
Arabian Medical Relief under the donation of UNHCR has been providing primary health care for Syrian refugees at Village six in Azraq refugee camp, Zarqa, Jordan, their services include non–communicable diseases(NCDs) management, apart from other health services. The objectives of this study were to describe the method of care and management for this population, assessing treatment outcomes and challenges met at the NCD clinic.
Methods
A descriptive retrospective cohort study using routinely collected data from the medical files for all active patients attending the NCD clinic at village six in Azraq camp primary health center in 2019.
Results
Of 493 Syrian patients with NCD attending the clinic, 232 patients have hypertension, 109 patients have T2DM, 10 patients have T1DM and 47 patients have hypothyroidism, all of them are active patients visiting the clinic at least every three months in 2019. Regarding all NCD patients, they are predominantly females (57%), and mostly diagnosed before reaching the camp (67%) and most patients are from age group (40–59): 43%.
Outcome
66% of T2DM patients had controlled DM (HbA1C<7.5%) 43% of them are either without treatment or on metformin alone, 99% had controlled blood pressure (BP: <140/90 mmHg) 50% of them are either without treatment or on one medication only, 76% patients of hypothyroidism has a controlled disease (TSH: 0.5–2.5) and none of T1DM patients is controlled
Conclusions
The control rate of NCD at the level of Azraq camp is promising, especially for hypertension, using only essential drug list of the UNHCR, T1DM is very difficult to control and should be investigated more.

Remogliflozin reduces gout risk in type 2 diabetes

Hariballav Mahapatra[1, 2], Monalisa Khuntia[1] & Abhay Sahoo[2]
[1]Sevayan Diabetes Centre, Department of Endocrinology, Puri, India; [2]IMS & SUM Hospital, SOA University, Department of Endocrinology, Bhubaneswar, India

Background and aim
SGLT2 inhibitors are relatively new class of medications in the management portfolio of type 2 diabetes (T2DM). Despite their late introduction, they have gained substantial up–gradation in the treatment algorithm as suggested by various international bodies. Remogliflozin is an SGLT2i licensed in India and several other countries for the management of T2DM. We studied the effect of Remogliflozin on serum uric acid (SUA) levels in subjects with type 2 diabetes.
Methodology
In this prospective trial subjects visiting a specialized diabetes centre in Eastern India with T2DM, but without any other documented chronic diabetic complication were invited to participate. Once consented, all of them were administered Remogliflozin 100 mg twice daily for 3 months in addition to their existing antidiabetic regimen. Individuals were instructed to maintain their diet unchanged throughout the study period. During the review visit at the end of the third month, 2 subjects were lost to follow up and 1 person discontinued therapy due to hypoglycemia. Data of 44 adults (32/12 Males/Females) were considered for analysis.
Result
The mean age, weight and UA level of the sample were 49.4±8.6 years, 67.28±11.4 kg and 6.5±2.3 mg/dl respectively. After 3 months the cohort showed a significant drop in the UA level and weight (1.05±1.1 mg/dl and 1.99±2.4 kg respectively). When arranged in declining order of SUA reduction, in the upper sries 10 out of 22 subjects (45.4%) had a SUA drop of ≥1 mg/dl, whereas only 31.8% (7 of 22) had similar SUA reduction in the lower series ($P<0.05$). Mean SUA reductions in the upper and lower series were 1.13±1.3 and 0.97±1.0 respectively. Similarly mean weight loss in both the series were2.3±2.1 kg and 1.7±2.1 kg in order. A numerical drop in the level of SUA was noted in majority (95.5%) of the individuals. Overweight & obese subjects showed a greater SUA reduction when compared to those with normal BMI ($P<0.05$). Out of 16 adults with hyperuricemia (SUA >7 mg/dl), 12 (75%) could achieve normal UA without additional agents.
Conclusion
Remogliflozin reduced serum uric acid significantly, which was more prominent in overweight and obese individuals. This could be helpful while managing patients with type 2 diabetes and hyperurecemia with/ without obesity.

EP201

Hospitalization cost of diabetic foot ulcerations treated by multidisciplinary team in clinical practice: A restrospective study from Southern Turkey

Mehtap Evran[1], Bariş Karagün[1], Gamze Akkus[2], Murat Sert[1] & Tamer Tetiker[1]
[1]Cukurova University Faculty of Medicine, Endocrinology and Metabolism, Adana, Turkey; [2]Cukurova university, Endocrinology Department, Turkey

Purpose
Diabetic Foot Ulceration (DFU) is common problem throughout the world and resulting in major economic consequences for the patients and country. We aim to describe estimated cost of illness between patients with DFU in southern Turkey.
Methods
A total of 148 ($F=55$, $M=93$) patients with DFU were included in this retrospective study. We also included more than one admission of the patients with DFU. Patients characteristics, duration time of hospitalizations, biochemical parameters, having diabetic retinopathy, nephropathy, neuropathy, coronary artery diasease and peripheral artery disease were recorded from our database. The cost of each patient was recorded from financial affairs and billing department unit of our hospital.
Results
The average unit cost of each patient was £ 733.47±665.32. The major dispenses in the total cost were medication (281.2±412.5) and hospitalisation fee (74.9±54.3). 115 (77.7%) of the patients had periferic arterial diseases. While we could not determined significant correlation between the patients demographical features (age, gender, $P>0.05$), biochemical parameters (plasma glucose, HbA1c%) and diabetes mellitus year (P); lenght of the hospitalization, having periferic artery diseases and performed amputation (minor or major) were significant correlated with total expenses.
Conclusion
The study revealed that the cost of DFU could show a variability in relation with development of countries. We highlighted as similar studies in other countries, major increasing factor of total expenses were lenght of hospitalization, medication and presence of surgery.

MicroRNA-107 relation with severe insulin resistance

Diana Simoniene & Dzilda Velickiene
Lithuanian University of Health Sciences (LUHS), Institute of Endocrinology, Endocrinology, Kaunas, Lithuania

It has been shown that miR-107 regulates insulin sensitivity, but its status in severe insulin resistance (IR) patients has not been established. In this study, we investigated the expression of microRNA-107 in the sera from patients with clinically severe IR and its relationships with metabolic characteristics.
Methods
The expression of microRNA-107 was detected in the sera of 30 clinically severe IR patients and 24 gender and age-matched control group by quantitative real-time PCR. Patients that daily insulin requirements were >1 unit/kg/day and HbA1c >9% – referred as clinically severe IR group, patients that daily insulin requirements were <0.9 unit/kg/day and HbA1c <8% – referred as control group. The clinical data were collected and analyzed by statistical software.
Results
In the severe IR group, microRNA-107 level was not higher significantly in the sera (P 0.54).
Conclusions
While microRNA-107 is related with insulin sensitivity, but it is not associated with severe IR.

Association of type 1 diabetes with overlap syndrome: A case report

Ramla Mizouri, Haifa Abdesselem, Khadija Ben Naceur, Kamilia Ounaissa & Chiraz Amrouche
Institut National de Nutrition de Tunis, Hôpital Du Jour, Tunisia

Introduction: Primary biliary cirrhosis and autoimmune hepatitis are two chronic liver diseases. An overlap of the characteristic signs of these two conditions, determining an 'Overlap syndrome' can be seen. Type 1 diabetes can be associated with this syndrome due to the autoimmune predisposition.
Observation
We report the case of a young type 1 diabetic patient referred to our service for additional management of a glycemic imbalance. This is a 15 year old female patient with type 1 diabetes since the age of 4. The clinical examination showed a diffuse sensitivity of the supra-umbilical stage with a maximum in the right hypochondrium and hepatomegaly. In biology, hepatic cytolysis was found to be 17 times normal and anicteric cholestasis with high γGT (3 times normal) with correct TP. As part of the exploration of this hepatopathy, hepatitis B and C serologies and an autoimmunity assessment were requested. The anti mitochondria and anti smooth muscle antibodies were negative, on the other hand the gp 210 and SLA/LP antibodies were positive. The liver biopsy puncture objectified a chronic liver disease with septal fibrosis classified A2F2 according to Metavir framing with a primary biliary cirrhosis associated with lesions of autoimmune hepatitis (interface hepatitis) evoking an Overlap syndrome. The patient was put on ursodeoxycholic acid, corticosteroid therapy and immunosuppressant. The evolution was marked by the rapid normalization of cholestasis and cytolysis.
Conclusion
Our observation illustrates the importance of early diagnosis of autoimmune diseases that may be associated with type 1 diabetes in order to allow rapid and adequate medical care.

Primary prevention of type 2 diabetes mellitus among persons with impaired glucose tolerance in Belarus

Elena Shishko, Tatyana Mokhort, Alena Mokhort & Alena Bogomazova
Belarusian State Medical University, Endocrinology, Belarus

Aims
The aim of our study is to assess the efficacy of lifestyle modification and picolinate chromium intake in preventing diabetes mellitus type 2 (DM 2)
Materials and methods
The study included 100 patients (69 m 258 f) 25–65 years with impaired glucose tolerance (IGT) and newly diagnosed DM 2. Patients were divided into 2 groups matched by age, weight, body mass index (BMI), waist-to-hip ratio (WHR). Research group included 54 patients who carried out recommendations of a balanced diet, physical activity and picolinate chromium was taken 200 mkg per day for 1 month. Control group included 46 patients who did not lifestyle modification. The study was 24 weeks. We measured fasting plasma glycated hemoglobin (HbA1c,%) and related to fasting leptin (FL).
Results
Patients of the research group demonstrated reduction of BMI (–3.2±2.1 kg/m^2) and WHR (–0.02±0.025) (P<0.01 for all) and positive dynamics of HbA1c (P<0.001). Persons of the control group had increase BMI, WHR as also HbA1c elevation (P<0.05). The main novel finding was that median serum leptin in research group decreased on –23.9% (P<0.01) and increased in control group on +27.6% (P<0.01). Among subjects with IGT from the research group, HbA1c normalized in 49.3% (P<0.001) and serum leptin levels decreased on 26.9% (P<0.01). In control group HbA1c normalized in 4.5% (P<0.01). Among patients of the research group was a reduction of DM 2 by 11.9% and an increase in the control group by 35.1%.
Conclusion
Lifestyle modifications with picolinate chromium intake leads to the restoration of glucose homeostasis and preventing DM 2.

Influence of the time gap between appointments on type 1 Diabetes Mellitus patients' control

Sergio Roman Gimeno, Jose Jorge Ortez Toro, Carlos Miguel Peteiro Miranda, Borja Sanz Martín, Rosana Urdaniz, Blanca García García &, José Antonio Gimeno Orna
Hospital Clinico Universitario Lozano Blesa, Endocrinology and Nutrition, Zaragoza, Spain

Introduction
One of the often-discussed topics in the management guidelines for Type 1 Diabetes Mellitus (T1DM) is the ideal time gap that should exist between patient check-ups. A period of three to six months is usually recommended, which sometimes is difficult to achieve due to the high number of patients. But to what extent does the time gap between appointments in the follow-up of T1DM patients affect their diabetes' control?
Objectives
To know the average time gap between T1DM patients' appointments in our hospital; and to quantify the correlation between that time gap and HbA1c, and the correlation between those variables and severe hypoglycemia.
Methods
A retrospective cohort study of 130 T1DM patients who attended to the Endocrinology consults in Hospital Clínico Lozano Blesa, Zaragoza (Spain) was conducted, correlating the time gap between appointments with HbA1c and Clarke score, as well with the presence of severe hypoglycemia. Statistical analysis was performed using Pearson correlation coefficient and Student's T-test.
Results
A positive correlation was observed between the time gap between check-ups and the HbA1c (correlation coefficient 0.357, P<0.01), the HbA1c increase from the previous check-up correlation coefficient 0.564, P<0.01), and Clarke's questionnaire score (correlation coefficient 0.472, P=0.026), as well as between HbA1c and Clarke test score (correlation coefficient 0.387, P=0.04). Moreover, the HbA1c and time-gap mean was significantly higher in those patients who had an episode of severe hypoglycemia (8.05% and 149 days) compared to those who did not (7.32% and 109 days; P=0.017).
Conclusion
Lower HbA1c and Clarke test scores were observed when the time gap between type 1 diabetics' follow-up is shorter, thus achieving better control of their diabetes and having less risk of long-term complications. On the other hand, there is also a higher HbA1c mean in patients who presented severe hypoglycemia, which indicates the importance of time in range and glycemic variability and not only the mean glucose levels estimated by HbA1c.

Diabetic ketosis revealing a malignant tumor

Dorra Elguiche, Ibtissem Oueslati, Marwa Chiboub, Fatma Chaker, Anaam Ben Chehida, Nadia Khessairi, Meriem Yazidi & Melika Chihaoui
La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Although a strong association between diabetes mellitus and carcinogenesis is suggested, their relationship is still debated. Diabetic ketosis is an acute metabolic complication caused by absolute or relative insulin deficiency. It is rarely a revealing condition of a malignant tumor.
The aim of our study was to determine clinical and paraclinical particularities of patients with malignant tumors revealed by a diabetic ketosis.
Patients and methods
We conducted a retrospective study in patients who were admitted for a diabetic ketosis between 2015 and 2019 and in whom a malignant tumor was revealed. Clinical, biological and radiological features were collected.
Results
Our study included six patients (4 men and 2 women) with an average age of 73.6±15.6 years [Extremes: 48–89]. A family history of hypertension and diabetes was present in three patients. Three patients had type 2 diabetes mellitus. Symptoms were dominated by weight loss, weakness and anorexia in all cases and by epigastralgia in only one. On clinical examination, patients had a mean body weight of 55.3 kg, a mean body mass index of 21.36 kg/m², a mean systolic blood pressure of 106 mmHg and a mean diastolic blood pressure of 66 mmHg. Dehydration was present in one patient and only one patient had a Glasgow score of 12/15. The mean value of capillary glycemia was 4.10 g/l and all patients had ketonuria. The mean level of HbA1c was 11% [extremes: 9–14.8%]. Renal and hepatic functions were normal. Obvious precipitating factors were not present. Tumor markers CA-19–9 were elevated in one case and CA-125 in another case. Investigations revealed pancreatic carcinoma (2 cases), kidney carcinoma (1 case), hepatic carcinoma (1 case) stomach carcinoma (1 case) and brain carcinoma (1 case). Three patients had metastases.
Conclusion
Diabetes mellitus and cancer are common diseases. Their coexistence is possible and may be explained by several factors. This case series study highlights the possibility of coexisting cancer as a ketosis precipitating factor in type 2 diabetic patients and in undiagnosed diabetic patients especially in elderly with a poor general condition and in the absence of obvious precipitating factors.

Ketosis-prone diabetes: An emerging worldwide clinically important entity

Iciar Martín Timón, Inmaculada Moreno-Ruiz, Juan Jose Marin-Peñalver, Olalla Meizoso Pita, Isabel Huguet, Beatriz Ugalde-Abiega, Susana Bacete-Cebrian & Javier Modamio
Hospital Universitario INfanta Leonor, Endocrinology, Madrid, Spain

Introduction
Ketosis-prone diabetes or Flatbush diabetes has been recognized as a clinical entity since 1984. Is characterized by diabetic ketosis or ketoacidosis occurring soon after the onset of hyperglycemic syntoms (usually poyiuria, polydipsia and weight loss are present for less than 4 weeks). Unlike the insulin dependence seen in type 1 diabetes, after a few weeks (usually 2 to 12 weeks), insulin requeriments decrease, and approximately 70% of patients achieve remission and can be managed by diet alone. Most patients are overweight or obese and is reported in African-American or western Sub-Sahara-African, Hispanic descendant, and recently in Asian.
Case report
A 24-year-old male of Assian origin was admitted to our hospital in January 2014. He presented polyuria, general fatigue and a 6 kg weight loss in the preceding three weeks. Hyperglycemia had never been detected on regular check-ups.
In the emergency room his serum glucose was 323 mg/dl. Arterial blood gas analysis showeed pH 7.22, bicarbonate 19 mEq/l and ketoneuria>80 mg/dl. Islet-related autoantibodies, such us those against GAD, IA-2 and anti beta cell were all negative. On admission his body mass index was 28.29 kg/m². He received intensive insulin therapy and fluids infusion, and during the remainder of hospitalization his insulin requirement was approximately 1.5 U per kilogram of body weight per day. After discharge his treatment was adjusted form intensive insulin subcutaneous injection to only basal insulin and after 3 months to oral hypoglycemic drugs, and finally, after 20 weeks, he was managed with diet alone. He achieved and manteined remission during this 5 years.
In the last visit his plasma glucose was 112 mg/dl and HbA1c 5.4% with diet alone.
Conclusion
When an overweight or obese young patient debut with diabetes mellitus with negative auto-antibodies and diabetic ketoacidosis, with partially preserved beta cell functional reserve after the acute of diabetic ketosis we must thing in KPDM as a posibility.

Lateral thinking in new onset diabetes

Htet Htet Aung[1], Yin Yin[1], Felicity Kaplan & Aimee Hayes[2]
[1]East and North Herdfortshire NHS Trust, Diabetes and Endocricology, Stevenage, United Kingdom; [2]Royal Free London NHS Foundation Trust, Neuroendocrine Tumour Unit, London, United Kingdom

A 54-year-old gentleman presented to his GP in July 2019 with significant weight loss, polyuria and nocturia for two to three months. His HbA1c was 78 mmol/mol. He was diagnosed with diabetes and started on Metformin 500 mg BD. Upon consultant review in September 2019, he reported a 26 kg weight loss over the preceding four years, much of which was apparently intentional, and right abdominal discomfort. His paternal grandmother died of pancreatic cancer, as did his paternal aunt. His maternal grandfather had diabetes and maternal grandmother had rheumatoid arthritis. He smoked 20 cigarettes per day for thirty years and drank alcohol in moderation. His systemic examination was unremarkable. There was no significant skin rash and urine ketones were negative. Full blood count, liver function tests and electrolytes were within normal limits. The possibility of type 1 diabetes was considered in view of his initial presentation, but, GAD and IA2 antibodies were negative. Given the weight loss and family history, CA 19–9 and MRI pancreas were requested. The CA 19–9 was normal and MRI pancreas and subsequent CT chest, abdomen and pelvis revealed a 5 cm pancreatic body tumour and multiple bi-lobar liver metastases. One of the hepatic lesions was biopsied and histology reported a well differentiated neuroendocrine tumour, with Ki67 highlights up to 5% of tumour nuclei. Immunohistochemistry revealed strong positivity with cytokeratin, synaptophysin and CD56. CK7, CK20 and chromogranin were negative. Octreotide scan demonstrated avidity in the pancreatic body primarily and bi-lobar liver metastases. There was no uptake in other areas. Ga68 DOTATATE PET confirmed the diagnosis by showing high uptake in body of pancreas and liver metastases (somatostatin 2 receptor positive). His PTH and calcium level were normal, likely excluding MEN1. His fasting glucagon level was 73 pmol/l (0–50) and chromogranin A was 151 pmol/l (0–60). Chromogranin B was>250 pmol/l (0–150). Vasoactive intestinal peptide, pancreatic polypeptide, gastrin and somatostatin were normal. Somatostatin analogues were initiated as first-line therapy.
In conclusion, this case highlights the importance of careful consideration of the differential diagnosis when patients present with new-onset diabetes and atypical features, and awareness of neuroendocrine tumours (NET) of the pancreas as a cause.

Diabetic nephropathy and cardiovascular risk

Khadija Ben Naceur, Haifa Abdesselem, Ramla Mizouri, Zeineb Zemni, Fatma Boukhayatia, Ounaissa Kamilia & Chiraz Amrouche
Institut National de Nutrition, Service des Consultations Externes et Explorations Fonctionnelles, Tunis, Tunisia

Introduction
Diabetes is the leading cause of end-stage renal disease in Europe (12 to 30%). In the United States, it is the cause of more than half of the cases of this disease. Renal disease is a cardiovascular morbidity and mortality preacher which is three times more common in diabetic patients with diabetic nephropathy (DN). The aim of our study was to describe the factors of cardiovascular risk associated with ND in a group of type 2 diabetes (T2D) Tunisians.

Materials and methods
It was a transversale, retrospective and descriptive study including 75 T2D patients with a confirmed ND, collected in the Diabetology departments of the National Institute of Nutrition and Food Technology of Tunis between 2018 and 2019.
Results
There were 42 women and 33 men with mean age was 62.25±9.3 years. The body mass index was 29.67±5.43 kg/m². The average duration of diabetes was 9.48±6.88 years. In 90.6% of cases, treatment was insulin therapy. ND was at the microalbuminuria stage in 60 patients and 46.6% had renal failure (GFR <90 ml/min). High blood pressure was present in 44 patients, 81% of whom were on ACE inhibitors. Other microangiopathic complications were present, such as diabetic retinopathy in 28 patients, 6 of which had a proliferative form and peripheral neuropathy in 38 patients. Coronary artery disease was found in 9 patients and arteritis of the lower limbs in 9 patients also when two had suffered a stroke. Hyper triglyceridemia was observed in 27 patients, hypo-HDL-cholesterolemia in 35 patients and hyper LDL-emie in 65 patients. We did not found a correlation between the micro and macro albuminuria of a part and the presence of a coronary disease of another part (P=NS). We noted a positive correlation between the ND stage and the glycemic balance (P=0.04). However, no correlation has been demonstrated between the micro and macro albuminuria firestly and the triglyceride level (P=NS), HDL cholesterol (P=NS) and the LDL cholesterol level (P=NS) on the other hand.
Conclusions
Kidney damage increases the cardiovascular risk in T2D. Its prevention and management requires an optimal glycemic and blood pressure balance in order to protect not only the kidney but also the heart and thus improve the prognosis of diabetics.

Anemia in diabetic patients

bilge başdoğan, Ahmet Toygar Kalkan, Fatma Belgin Efe, Özge Özer, Medine Nur Kebapçı, Göknur Yorulmaz & Aysen Akalın
Eskişehir OSmangazi University, Endocrinology and Metabolism, Eskişehir, Turkey

Background
Anemia is a common finding in patients with diabetes mellitus which increases the progress of the diabetic complications. There are several factors which cause anemia out of renal failure in diabetics. In this study, we aimed to investigate the frequency of anemia and factors that decreases hgb levels in diabetic patients
Methods
This retrospective study includes 207 diabetic patients that were hospitalized between january 2019 and january 2020 at Eskişehir Osmangazi University Hospital, Endocrinology department. Patient's data included demographics, complicationts, medications and labaroutary results. Anemia was defined as hemoglobin (Hgb) concentrations < 13 g/dl in men and < 12 g/dl in women
Results
Of 207 hospitalized patients with diabetes 42% had anemia. Diabetic males had a higher rate of anemia compared to females (54.7% vs 34.8% respectively, P<0.008) Diabetic patients with a history of diabetic foot ulcer were more likely to be anemia. However there was no relationship between albuminuria and anemi frequency in diabetics without renal failure.
Conclusion
In this study we've found a positive correlation between diabetic foot ulcer and anemia. On the other hand there was no significant difference between macrovascular and microvascular complications with anemia. Patients with a history of diabetic foot ulcer should be considered anemia predictor and treated earlier.

Table 1

	Anemic	Non-anemic
Male(%)	45.3	54.7
Female(%)	34.8	65.2
Vitamin B12 defficiency(%)	22.1	11.2
DRP(%)	47.1	33
Diabetic foot (%)	18.1	5.8
Nöropati(%)	32.9	27.2
Metformin(%)	40.2	42.9

Charcot foot: Early diagnosis and interest in medical care: A case report

Ramla Mizouri, Radhouene Gharbi, Sonda Sellami & Ines Kammoun
Institut National de Nutrition de Tunis, Service B, Tunisia

Introduction
Charcot foot is a painless progressive osteoarthropathy of one or more joints due to an underlying neurological lesion, leading to deformities of the foot by the non-infectious destruction of bones and joints.
The interest of this observation is to show on the one hand the role that the education of diabetics plays in the early diagnosis of Charcot foot and on the other hand the need for a multidisciplinary team in the care of the foot of Charcot.
Observation
This is a 35 year old patient with type 1 diabetes, uncomplicated, from the age of 21 who presented to our emergency room for left foot edema evolving for two weeks. The clinical examination showed an edematous, hot, red and painless left foot. There is the absence of a wound or infection and the absence of general signs. The standard x-ray of the left foot was normal. Within the framework of the exploration of this localized edema, an MRI was requested objectifying an aspect related to a diabetic osteoarthropathy rather than an infectious osteoarthritis with involvement of the bone marrow of the metatarsals of the 2nd, 3rd and 5th rays as well as joint damage involving the metatarsophalangeal muscles of the 2nd and 5th rays without visible fracture or subperiosteal abscess.
The patient was referred to the physical medicine department for additional treatment, where he was provided with suitable shoes with a foot orthotic relief orthosis.
Conclusion
Our observation illustrates the value of early diagnosis of complications that may be associated with type 1 diabetes in order to allow rapid and effective management which will preserve the patient's functional or even vital prognosis.

The bidirectional link between diabetes mellitus and oral health: A study in Albanian patients with diabetes

Marjeta Kermaj[1], Arlind Myftari[2], Adela Haxhiraj[1], Edlira Elezi[1], Grej Malo[2], Redeona Collaku[2], Gresa Baboci[2], Ruden Cakonki[1], Violeta Hoxha[1], Dorina Ylli[1], Thanas Fureraj & Agron Ylli[1]
[1]UHC 'Mother Tereza', Endocrinology, Tirana, Albania; [2]UHC 'Mother Tereza', Maxillofacial Department, Tirana, Albania

Background and aims
Diabetes mellitus (DM) is a chronic, metabolic disease that is spreading rapidly around the world. Various studies have shown the association between DM and oral health. The aim of this study was to evaluate the knowledge patients with diabetes have regarding the impact of diabetes mellitus on oral health; the role of oral hygiene care and dentists follow up.
Methodology and methods
The survey research was taken in 79 Albanian patients with diabetes, hospitalized in the Endocrinology Service. A multiple-choice questionnaire was used to assess their knowledge and their habits regarding diabetes and oral health.
Results
Participants were aged from 20 to 81(mean 59.88) years old; 44(55.7%) females and 35 (44.3%) males; elementary, middle school and high education, 34 (43%), 34(43%), 11(14%) respectively. From the results of the questionnaire the following data were observed: 35 patients (44.2%) didn't know the direct link between DM and oral health; 65 patients (83.3%), females 41 (63%) and males 24 (37%), where 11 patients (100%) with high education, 32 (94.11%) patients with middle education and 22 patients (64.7%) with elementary education, knew the importance of oral hygiene in oral health. A

low number of patients 19 (24.4%) visited the dentist regularly. There was no change between ages.
Conclusions
According to the data analysis, the awareness of the link between DM and oral health, in the Albanian patients with diabetes should be improved, particularly in the patients with lower education. Incidence and severity of oral diseases in patients with diabetes can be reduced by regularly visiting dentist.

Comparative risk factors of diabetic foot complications for type 1 and type 2 diabetes mellitus

Irina Afrasinei Tenu[1], Cornelia Bala[1,2], Silvia Iancu[1] & Gabriela Roman[1,2]
[1]Cluj County Clinic Emergency Hospital, Department of Diabetes, Cluj-Napoca, Romania; [2]'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania

Objective
Diabetic foot complications are a main cause for hospital admissions and spending for patients suffering from T1DM or T2DM. The purpose of this study was to identify and compare possible risk factors for patients suffering from such issues.
Methods
We conducted a retrospective observational study analyzing data from observation charts of 324 patients, diagnosed with T1DM or T2DM as well as various foot issues, evaluated between January 2015 – December 2017 in our clinic. The patients were divided into 2 groups: T1DM and T2DM (40 and 284 patients – 25% female and 75% male, respectively 23% and 77%).
Results
The T1DM group was younger ($P=0.0000012642$), leaner ($P=0.0000000043$), had been diagnosed at a younger age ($P=0.00...01$), had a longer duration of disease ($P=0.0000200919$), more hospital admissions (1.97 vs 1.41, $P=0.015709446$), poorer glycemic control (9.69 vs 8.60%, $P=0.000124519$), but better TG and HDL-cholesterol levels (137.20 vs 165.99 and 47.65 vs 39.82 mg/dl, $P=0.030880937$, $P=0.003798103$). Statistically significant differences between patients with amputations and those only with soft tissue damage for the T2DM group: sex ($P=0.022714$), kidney impairment ($P=0.01$ 989), retinopathy ($P=0.01$ 0754), mean no. of days/hospital admission (8.06 vs 7.26 days, $P=0.029889513$), BMI (29.35 vs 30.64 kg/m^2, $P=0.04805204$), glycemic control (8.38 vs 8.86%, $P=0.040931604$), HDL-cholesterol levels (38.73 vs 41.05 mg/dl, $P=0.04$ 601). For the T1DM group: kidney impairment ($P=0.003782032$), mean no. of days/hospital admission (9.06 vs 6.12 days, $P=0.0000191641$), total and LDL – cholesterol (161.19 vs 188.15 and 88.25 vs 109.35 mg/dl, $P=0.019094005$, $P=0.013594543$).
Conclusions
Identifying risk factors should help in establishing prevention measures for diabetic foot issues.

Clinical and biological characteristics of non-reactive hypoglycemia in non-diabetic adults

Elyes Kamoun, Ibtissem Oueslati, Marwa Chiboub, Fatma Chaker, Nadia Khessairi, Wafa Grira, Meriem Yazidi & Melika Chihaoui
La Rabta hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Hypoglycemia is common in diabetic patients as an adverse effect of their medication. A minority of hypoglycemia occurs in non-diabetic patients. This spontaneous hypoglycemia defined by the Whipple's triad results from organic (non-reactive) or functional (reactive) causes, and in few cases, a factitious hypoglycemia, posing an etiological problem. The aim of our study was to assess clinical and biological features of non-reactive hypoglycemia in non-diabetic adults.
Methods
This is a descriptive, retrospective and single-center study including 65 patients with a confirmed hypoglycemia according to the presence of Whipple's triad. Patients without a precise cause of hypoglycemia, patients with factitious hypoglycemia and those with iatrogenic causes were excluded. Clinical and paraclinical features were collected and compared between patients with non-reactive hypoglycemia (group 1) and those with reactive hypoglycemia (group 2).
Results
The study population included 40 patients with a sex-ratio of 1.6 and a mean age of 45.3±16.6 years. The diagnosis of non-reactive hypoglycemia (adrenal insufficiency $n=22$, insulinoma $n=4$) was established in 26 cases (65%) and reactive hypoglycemia in 14 cases (35%). There was no significant difference between the two groups according to the age (group1: 45.9±18.3 years, group2: 44.1±13.4 years, $P=0.8$). A female predominance was found in group 1 (73% vs 43% in group 2, OR=3.6, $P=0.06$). Fasting hypoglycemia was more frequent in group 1 (66%) than in group 2 (7%) (OR=20.8, $P=0.001$). The prevalence of neuroglycopenic symptoms was 81% in group 1 vs 64% in group 2 ($P=0.22$). Group 1 had a lower body weight (65.1±16.2 kg vs 75.2±12.0 kg in group2, $P=0.03$) a lower systolic blood pressure (11.1±1.7 cmHg vs 12.2±1.6 cmHg, $P=0.05$) and diastolic blood pressure (6.9±0.9 vs 7.7±0.9, $P=0.03$). The prevalence of overweight was 48% in group 1 vs 52%, in group 2 ($P=0.06$). A blood glucose level<0.3 was found in 23% in group 1 vs 0% in group 2, ($P=0.06$)
Conclusion
Non-reactive hypoglycemia was predominant comparing to reactive causes, with a female predominance, related to the higher prevalence of adrenal insufficiency in women. The predictive factors of organicity were fasting hypoglycemia, blood glucose level<0.3, lower body weight and lower blood pressure. Fasting hypoglycemia is the most predictive and should guide etiologic investigations toward organic causes.

EP215

Decalogue of venipucture process of an experienced nurse in adult patients with prader willi syndrome

Rocío Pareja, Olga Giménez-Palop, Laia Casamitjana, Yolanda Couto, Marina Luengo, Mercedes Rigla & Assumpta Caixàs
Hospital Universitari Parc Taulí, Endocrinology and Nutrition Department, Sabadell, Spain

Background
Prader-Willi syndrome (PWS) is a genetic neurodevelopmental disorder characterized by marked hyperphagia and morbid obesity, together with hormone deficiencies, abnormal behaviour in relation to food (obsessive thinking, food foraging, stealing, etc.). Veins in patients with PWS are difficult to find due to obesity and probably to generalised hypotonia including venous tone. Since treating a patient with PWS often requires the acquisition of blood samples, an experienced nurse is mandatory in the multidisciplinary team.
Objective
On the basis of our experience, we propose some recommendations to be taken into account for blood sample collection in adult patients with PWS.
Methods
Recommendations based on grade E of evidence
Results
The following items must be taken into account: Drink a lot of water the night before, come to hospital with clothes with warm long sleeves, use local heat with hot gel, gain her/his confidence, make her/him to be comfortable, use gloves and double tourniquet 5–10 cm above venepuncture site, use alcohol pads in order to dilate the veins, use butterfly, have all the tubes to be filled near in order of priority, just in case you cannot get enough blood for all. If blood does not come out, put the arm below heart level or raise the forearm o turn the wrist so as to get more circulating blood. If you cannot get a good vein, then proceed to artery puncture (radial). Remember that they do not feel pain (high threshold) or if the patient is afraid of feeling pain, use lidocaine cream. Put an adhesive pressure strip. Use biohazard waste container. Finally, do not forget to draw and keep a map of good veins for every patient so as to check next time she/he comes.
Conclusions
Following a nurse protocol for blood collection and other care issues in adult patients with PWS is essential for the best achievement of clinical assays, investigational projects and also the routine clinical care

Relationship between high serum uric acid and postoperative central diabetes insipidus for pituitary adenoma patients

Liyi Liu[1], Qin Du[1], Yuting Gao[1], Dawei Liu[2], Haijun Wang[3] & Zhihong Liao[1]
[1]The First Affiliated Hospital of Sun Yat-sen University, Department of Endocrinology, Guangzhou, China; [2]The First Affiliated Hospital of Sun Yat-sen University, Department of Pathology, Guangzhou, China; [3]The First Affiliated Hospital of Sun Yat-sen University, Department of Neurosurgery, Guangzhou, China

Context
Postoperative central diabetes insipidus (PDI) is one of the most common complications of surgical treatment of pituitary adenoma, temporary or permanant. The diagnosis of PDI was suspicious in some occasions and inappropriate prescription of antidiuretic hormone was harmful. Generally, high level serum uric acid (HUA) was a clue for central diabetes insipidus, but we did not know its role for the brain postoperative subjects. As we know, the food intake and health condition was unstable during the acute short period after operation.
Objective
To explore whether HUA could be an indicator of PDI for those hospilized patients shortly after surgery of pituitary adenoma.
Design and patients
A total of 125 patients received resection of pituitary adenoma with pathologically diagnosed pituitary adenoma in the First Affiliated Hospital of Sun Yat-sen University from November 2017 to June 2019. A retrospective analysis of case records was done. General demographic information, daily lifestyle, anthropometric data and laboratory tests results were collected from case records. Excluding subjects without postoperative serum uric acid measurement, 43 individuals were included in the final analyses. HUA was defined as postoperative uric acid>297.5 μmol/L (5 mg/dl). PDI was defined as postoperative urine volume>4000 ml/24 h or being administrated of desmopressin such as Minirin post operation and prior to discharge. The relationship between PDI and HUA in these patients was analysed with Logistic regression analysis.
Results
The incidence of PDI in this study was 65.1%. The incidence of PDI in patients with postoperative HUA is 75.9% while it was 42.9% in patients without HUA ($P=0.046$). Logistic regression analysis result showed that PDI was a significant factor for HUA. After adjusting for gender, age, the history of hypertension, diabetes mellitus, smoking and drinking, patients with PDI had increased risk of HUA (Odds Ratio (OR)=12.13, 95% Confidence interval (CI): 1.03–142.29) ($P=0.047$).
Conclusion
PDI was a very commom complication of the pituitary adenoma surgery. PDI was associated with HUA in the patients shortly after pituitary adenoma surgery.. Postoperative HUA might be an indicator of central diabetes insipidus in these patients. The limitation here was PDI might contain other reasons of polyurea, such as excessive fluid infusion. Further well designed prospective studies are needed.

Introduction and objectives
Type 1 diabetes mellitus (T1DM) is a chronic disease with potential consequences for patients, relatives and ultimately for the healthcare system. The objective of this study is to report the incidence of DM1 in our area as well as assess the characteristics of the patients at the time of diagnosis.
Material and methods
Retrospective descriptive study. Data was collected through the registration of new diagnoses of T1DM in a third level hospital during 4 years. Medical records at patient's disease onset were reviewed. In total, data was assessed from 99 patients, including paediatric patients and adults.

Familiar history of DM	T1DM:26 T2DM:45

Conclusions
T1DM incidence in our area was 7.6/100.000 patients. There were no major changes in the incidence in the different years evaluated. Most newly diagnoses were performed before the age of 25, with a higher incidence between 6 and 10 years old. Less than 20% of patients debuted with ketoacidosis. Children are at greater risk of ketoacidosis at the diagnosis of diabetes. In almost 20% of the T1DM patients, non-insulin antidiabetic drugs were initially used. The most frequently detected autoantibodies were GAD+IA2+Zn and GAD+IA2-. Greater tendency to ketoacidosis with respect to other combinations in GAD+IA2+Zn- and GAD+IA2-Zn-. More than 80% of the patients presented positivity in any of haplotypes. The vast majority of the patients did not reported any history of autoimmune diseases. On the other hand, almost a quarter of the patients had family history of T1DM and almost half of T2DM.

Dynamics of indicators of cytolysis, carbonyl stress in patients with type 2 diabetes and non-alcoholic fatty liver disease on glucose-lowering therapies

Rodionova Svetlana, Zvenigorodskaya Larissa, Biryukova Elena, Petrakov Alexander & Nilova Tamara
Moscow Clinical Research Center Named After Loginov, Moscow, Russian Federation

Objective
To study the dynamics of cytolysis and carbonyl stress (methylglyoxal (MG)) in patients with type 2 diabetes mellitus (DM2) and non-alcoholic fat disease liver (NAFLD) on the background of various hypoglycemic therapy.
Materials and methods
The study included 48 patients, 53.8±11.14 years, with SD2 and NAFLD and 20 people in the control group. Viral hepatitis was excluded, toxic and drug-induced liver injury. Anthropometric researc included: determination of waist circumference, body weight, height, and index calculation body mass index (BMI). Indicators of cytolysis (ALT, AST) and carbonyl stress were evaluated. Patients were divided into 2 groups: 1) inhibitors sodium-glucose cotransporter type 2+Metformin (MF); 2) preparations sulfonylureas (PSU)+MF.
Results
The BMI was 35.8±8.67 kg/2 on average for the group, from 109.5±16.48 sm, which indicated abdominal type of obesity. In patients with DM2 and NAFLD, a higher concentration of MG was detected, compared with the the control group. the following dynamics of indicators: in the first group (I-NGL-2+MF) before BMI treatment was 35.1±6.66, after 12 months 33.8±6.95, in the second group ((PSM)+MF) 36.48±7.66; 39.26±7.64, respectively, the level of glycated hemoglobin (HbA1c): I-NGLT-2+MF: before treatment 8.18±1.52, after 12 months 7.37±1.76, (PSM)+MF: 8.51±1.58; 8.65±1.14 accordingly, ALT level: I-NGL-2+MF: before treatment 72.95±58.79, after 12 months 29.42±18.27, (PSM)+MF: 39.29±45.89; 36.26±23.97, respectively. After 12 month of treatment, In the first group, there was more pronounced weight loss, HbA1c, ALT, MG, as a product of excessive glycosylation, carbonyl stress index.
Conclusions
Based on the results of the preliminary analysis, we can say that inhibitors sodium-glucose cotransporter type 2+Metformin (MF) are more preferable in comparison with PSU in combination with MF, in these patients.

EP219

Determination of methylglyoxal level as an indicator glucotoxicity with nafld and diabetes 2-type

Larissa Zvenigorodskaya, Mikhail Shinkin, Alexander Petrakov & Tamara Nilova
Moscow Clinical Research and Practice Center Named After Loginov, Moscow, Russian Federation

Glycation is due to the ability of glucose to form irreversible chemical compounds with amino groups of lysine and arginine – methylglyoxal (MG).
Material and methods
98 patients with NAFLD and 52 patients with NAFLD were examined. Diabetes 2-type, and 22 healthy volunteers. Age 57.3±5.2 years. BMI 34.85±1.79. The diagnosis was established on the basis of laboratory data and examination results. The level of LPO was determinedby the content of malonic dialdehyde (MDA).
Results
In patients with NAFLD, the content of MG in the blood serum520.75±114.35, in the control-69.02±6.67 nm/l ($P=0.001$). In T2DM patients the MG content was 292.11±16.34 nm/l. Observed correlation of MG and MDA ($r=0.495$).
Conclusions
Patients with NAFLD have a significant increase in MG b serum 7 times compared to the control. MG damage arginine residues of proteins, disrupts the transmission of the insulin signal, inhibits enzymes and plays a key role in the development of insulin resistance and hyperglycemia. Quantitative determination of MG in serum by HPLC method can be used as a prognostic and diagnostic test glucotoxicity.
Keywords: NAFLD, type 2 diabetes, glycosylation, methylglyoxal.

Cubulin and Megalin gene polymorphisms in diabetes mellitus

Ramesh Bangaraiahgari[1], Rajesh Bangaraiahgari[1,2], Ramakanth Bhargav Panchangam[3] & Rajkiran reddy Banala[4]
[1]Surabhi Medical College, Biochemistry, Hyderabad, India; [2]Surabhi Medical College, Anatomy, Hyderabad, India; [3]Endocare Hospital, Endocrine Surgery, Vijayawada, India; [4]Surabhi Medical College, Genetics, Hyderabad, India

Background
Diabetes mellitus is the commonest endocrinopathy, Worldwide. Inspite of its commonality, the genetic basis of etiopathogenesis and pathophysiology are ever evolving and enigmatic. Amongst the protean genetic variations, cubulin gene and megalin gene mutations in diabetes are important in dictating genotype—phenotypic correlations and natural clinical course of diabetes. The genetic studies in this area are especially very sparse from Indian sub-continent. In this context, we analysed the prevalence of cubulin (CBN) and megalin (LRP2) gene mutations in diabetes patients visavis controls.
Methods
This is inter-disciplinary case control study conducted by collaboration between a tertiary care endocrinology hospital, biochemistry department of a teaching medical institute and genetics lab. In this prospective study, we employed 4 sets of primers and screened for cubulin; CUBN gene polymorphisms (rs1801222 and rs11254363) and megalin (LRP2) gene polymorphisms (rs3755166 and rs2544390). in subjects with type 2 diabetes mellitus.

Results
The percentages of AA, AG and GG in cases were 12.5, 62.5 and 25 while in controls it was 70, 20 and 10 respectively. The allele frequencies of A and G alleles in patients are 0.44 and 0.56 while in controls were 0.80 and 0.20 correspondingly. The percentages of CC, CT and TT in cases were 47.5, 50 and 2.5 while in controls it was 60, 30 and 10 respectively. The allele frequencies of A and G alleles in patients are 0.73 and 0.27 while in controls were 0.75 and 0.25 correspondingly. The difference was statistically significant for CUBN gene and non-significant for LRP2 gene.
Conclusions
For cubulin gene, the AA genotype along with the A allele showed an odds ratio value of 0.06 and 0.19 respectively. The AG and G allele demonstrated 7.5-fold and 5.5-fold risk. For LRP2 gene, none of the genotypes showed a protective or predisposing role.
Keywords: diabetes, cubulin gene, megalin gene, polymorphism.

Association of CAPN10, FTO, PPAR, MTHFR gene polymorphisms and obesity with type 2 diabetes mellitus: A study on the bengalee hindu caste population of west bengal, india

Pranabesh Sarkar, Diptendu Chatterjee & Arup Ratan Bandyopadhyay
University of Calcutta, Anthropology, Kolkata, India

Background
Type 2 diabetes mellitus (DM) is probably one of the non-communicable diseases with raised levels of glucose in the blood due to insulin efficacy. The aetiology of disease combines both genetic and lifestyle or environmental factors. (GWAS) studies have been identified CAPN10 (SNP-19), FTO (rs-9939609), MTHFR (rs1801133) and PPARG (rs1801282) genetic polymorphism with susceptibility to T2DM. The susceptibility will increase by independent risk of genetic polymorphism, obesity and lifestyle factors as well as combinations of these factors. On this background, the present work tried to understand the association of Calpain10 (CAPN10), FTO, PPAR and MTHFR genetic polymorphisms, fat patterning and physiological variables like blood pressure and effect of lifestyle variables with T2DM in Bengalee Hindu caste population of Eastern India.
Materials and methods
The Present study consisted of 104 clinically diagnosed Type2 diabetes Mellitus Male patients and 176 apparently healthy males denoted as control group from Bengalee Hindu caste population of West Bengal, India. Genomic DNA was isolated from mouthwash using Phenol-Chloroform method with slight modifications. Genotyping for all the SNPs/variants was performed by using standard Polymerase Chain Reaction (PCR) method and PCR- RFLP method. Data has been collected on height, weight, waist and hip circumference following standard techniques. Moreover, Percent Body Fat (PBF) and BMI were obtained by Body Scanner (Omron Karada Scan HBF-375) strictly following the manufacturer manuals. Subsequently, fasting blood glucose was also measured by Accuchek (Active) glucometer. Data on lifestyle variables has been obtained through pretested schedule.
Results
MTHFR (rs1801133) genetic variant were significantly ($P<0.05$) associated with T2DM due to increased CT genotypes among Bengalee Hindu caste group. Apart from genetic risk factor, T2DM patients had ($P<0.05$) higher central obesity (WC, WHR) as well as overall obesity (BMI, PBF) and Systolic blood pressure (SBP) compared with control group. Family history of T2DM, hypertension and family history of hypertension were significantly ($P<0.05$) enhanced the risk of T2DM.
Conclusion
The present study envisaged identification of genetic variants and anthropometric variables pertaining to obesity could be used as screening tool for early prognosis of T2DM among Bengalee Hindu caste population.

Urinary disorders revealing a wolfram syndrome: A case report

Mouna Sghir[1], Soumaya Elarem[1], Wafa Said[1], Aymen Haj Salah[1], Baha Zantour[2] & Wassia Kessomtini[1]
[1]Tahar Sfar Hospital, Physical Medicine And Rehabilitation, Mahdia, Tunisia; [2]Tahar Sfar Hospital, Endocrinology, Mahdia, Tunisia

Background
Wolfram syndrome (WS) is an autosomal recessive neurodegenerative disorder characterized by Diabetes Insipidus, Diabetes Mellitus (non-autoimmune), Optic Atrophy, and Deafness.
We report the case of a patient sent to the physical and rehabilitation department to manage urinary disorders and for whom the diagnosis of WS was retained.
Case report
A 24-year-old female patient, with history of diabetes mellitus type I from the age of 3 years, deafness, optic atrophy, presented with urinary retention. First Echo graphic and biological investigations showed no alteration of the upper urinary tracts. The urodynamic assessment found a hypo contractile retention bladder. Self-catheterization was indicated. However, the patient complained of polyuria. She was followed up in endocrinology department where diabetes insipidus was explored and the diagnosis of WS was, then, retained. The patient had also a history of and insipidus syndrome and was sent to the endocrinology department. The diagnosis of WS was, then retained. The follow-up at 4 years found an alteration of the upper urinary tract.
Conclusion
WS should be considered a differential diagnosis in patients with diabetes mellitus who present with neurogenic bladder, and it is necessary to perform a hearing test and an ophthalmological examination. The urological risk is major requiring a systematic follow-up of these patients.

The relationship between milk and dairy consumption and obesity in children between the ages of 7–10

Ferhan Mantar & Buşra Yılmaz
Bahcesehir University, Nutrition and Dietetic, Istanbul, Turkey

Introduction: There is some evidence shows daily consumption of milk/dairy products prevents obesity and many diseases. Even in adulthood, the consumption of adequate milk/dairy products in childhood is protective of obesity. Therefore, balanced consumption of milk/dairy products is thought to prevent obesity or overweight, which is an important health problem nowadays. In our study, we aimed to determine whether there is a relationship between the consumption of milk/dairy products and body mass index(BMI) among students studying at Private School and Public School. Material and Method: Our study was carried out by selecting 300 students, 126 Private School, 176 Public School 7–10 years of age. In the survey, cheese, yogurt, ayran, butter, and milk consumption was grouped separately and demographic and daily food frequency questionnaire (FFQ) was taken from the parents of students. Anthropometric measurements are the most important measures reflect nutritional status. In our study, we used the persantil curves of Turkish children (Neyzi *et al.*) which calculated by genetic variations.
Results
The frequency of those who consume milk and dairy products every day was higher among public school students. While those who consume milk every day (57.3 percent) and the majority of those who consume at least 5–6 times a week (57.1 percent) are children studying in public school, the majority of those who never consume (54.5 percent), and the majority of those who consume 1–2 times a week (57.1 percent) are children studying at the Private School. while 54.5 percent of those who consume no dairy are obese according to BMI standards of Turkey, 70.9 percent of those who consume dairy every day with normal BMI value. When we look at consumption, there is a significant difference between BMI values and dairy consumption. While 63.2 percent of those who consumed dairy products daily have normal BMI values, 55 percent of those who consumed it once a month or not at all are weak and stunted.
Conclusion
In literature, it has been shown that milk and/or dairy products added to the diet have positive effects on children's development and BMI. In our study, it supports these findings and the inclusion of milk and dairy products in the daily diet of children should be encouraged. Also, the fact that more milk consumption was detected among the students studying in the Public School was associated with regular daily milk distribution in these schools.

Efficiency of ceylon cinnamon on anthropometric indices in polycystic ovary syndrome

Salma Dghaies, Hajer Kandara, Amal Smida, Radhouene Gharbi, Manel Jemel & Ines Kammoun
National Institute of Nutrition, Department of Endocrinology, Tunis, Tunisia

Introduction
Ceylon cinnamon (CC) has shown its interest in insulin resistance, type2 diabetes and weight loss. In this study, we aimed to evaluate the effects of CC on anthropometric indices in patients with polycystic ovary syndrome (PCOS).
Methods
We performed a prospective interventional study, including 13 patients with PCOS, diagnosed according to the Rotterdam criteria, patients having received neither diet education nor Metformin. At T0 all our patients had, a dietary survey, anthropometric measurements: weight, height, waist seize, and impedance. During the intervention, they received a 500 mg capsule of CC three times a day (designed and prepared for the study), without changing their eating habits and physical activity, diabetic patients were excluded of the study.
Results
After 8 weeks (T1), we found a reduction in the mean of the waist seize (delta=–3.4±4.74 cm et $P=0.02$), a significant reduction in the waist size/height Ratio (delta=–0.22±0.03 et $P=0.02$), a non-significant reduction in the average BMI (delta=–0.32±1.34 kg/m^2) and an insignificant reduction in all components of body mass with a maximum for the fat mass at the level of the trunk (delta=–1.3±10.89 kg).
Conclusion
These results could be explained by the anti-obesogenic effect of CC and lead us to suggest it as an etiopathogenic treatment for PCOS.

Long term impact of bariatric surgery in severely obese patients in a district general hospital

Tommaso Matteucci & Estela Elías
Hospital Bidasoa, Endocrinología, Hondarribia, Spain

Introduction
The efficacy and safety of bariatric surgery (BS) are well documented, but data in our region is lacking.
Aim
Analyze the long term effect of BS on obese patients in a single district hospital. Primary outcomes: –weight change 5–10 years post BS; –patient satisfaction. Secondary outcomes: weight reduction according to type of surgical procedure, sex, public/private hospital; mortality, complications.
Materials and methods
Retrospective data collection from electronic patients record and telephone calls to patients. Study group: all patients undergoing BS before 2015. Control group: 40 obesity patients not treated with BS. Weight data collected for 5–10 years expressed as median of all available weights for each year post-op/post-entry.
Results
58 BS patients (61 procedures); 40 patients not operated. Gastric bypass (GB) 44 procedures, vertical banded gastroplasty (VBG) 7, sleeve gastrectomy (SG) 7, Scopinaro 2, adjustable gastric banding (AGB) 1. Re-operations: 3 VBG to GB, 1 SG to GB. 1 AGB removed year 2 (technical malfunction). Public procedures 88% (Hospital Universitario Donostia), Private 11% (elsewhere).
Long term weight change
Median weight 5 and 10 years post BS: 70% and 74% of pre-OP weight. Control group (no BS): 98% and 103% of initial weight. 68% of BS achieved 20% weight loss at 10 years; 39% achieved 30%. None of control group patients did. Failed operations (defined as 10-year weight loss <5%): 1 VBG patient (3%).
Patient satisfaction
Defined as not regretting having undergone BS. Data collection 67%. 37 patients (94%) did not regret their decision. 1 patient unsatisfied due to refractory hypoglycemia; 1 patient unsure. Weight change according to type of procedure, sex, public/private hospital No major differences apparent (graphs on poster).
Mortality
One death identified: over 10 years after BS, cause of death considered unrelated.
Complications
Defined as any hospital admission within 2 years of BS.
Data collection 66%.
33% of BS followed by hospital admission within 2 years: most considered 'mild', 3 (7%) considered 'serious': 2 bowel perforations requiring laparotomy, 1 Petersen´s space hernia requiring laparotomy. Favorable outcomes.
Limitations
Gaps in data collection as loss of follow-up common, reliability of data on occasions questionable as obtained by telephone calls to patients; unable to exclude unidentified deaths as patients operated as early as 1997.
Conclusion
BS is effective long term in our patients. Our results are comparable to those shown elsewhere in the literature.

DOI: 10.1530/endoabs.70.EP225

Vitamin D and selected cytokines concentrations in postmenopausal women in relation to metabolic disorders and physical activity

Anna Bohdanowicz-Pawlak[1] & Felicja Lwow[2]
[1]Wroclaw Medical University, Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw, Poland; [2]University School of Physical Education in Wroclaw, Team of Health Promotion, Faculty of Physiotherapy, Wroclaw, Poland

Introduction
Obesity and metabolic disturbances constitute an important health problem in elderly women. Due to the multifactorial background of these disorders, assessment of the interaction between risk factors is still a significant element of prevention and health promotion in this group. Studies have shown, inter alia, the relationship between low physical activity and vitamin D deficiency with obesity and its complications. Furthermore vitamin D influences production of adipokines and the inflammatory response in adipose tissue.
Subject
The aim of our study was to estimate the association between selected adipokines, vitamin D concentrations, physical activity (PA) and visceral adiposity index (VAI) in postmenopausal women.
Material and methods
The study sample consisted of 318 ethnic homogenous postmenopausal women, aged 50–60. Anthropometric (BMI, WC, WHR) and biochemical (TC, HDL,LDL, glucose, insulin, IL-6, TNFalpha, adiponectin, lutein) measurements and physical activity by IPAQ were performed. Body mass index (BMI), waist-to-hip ratio (WHR) and visceral adiposity index (VAI) were calculated using the standard formulas.
Results
We observed significant negative correlations only between BMI, WC, insulin, HOMA and categorized physical activity. We have shown a negative significant association between leptin and vitamin 25 (OH)D concentrations ($P=0.007$) and positive between adiponectin ($P=0.014$) but we didn't observe significant assiociation with TNF alpha and IL-6.
Conclusions
The results of the multiple linear regression analysis, revealed that vitamin D and HOMA were the factors influencing the concentration of adiponectin and leptin. Vitamin D and HOMA are independent factors significantly affecting leptin and adiponectin levels in contrary to VAI.

Study on effect of the tumor necrosis factor–α on onset and progression of obesity in patients with diabetes mellitus

Sanobarkhon Irgasheva[1], Zafar Ibragimov[1], Elvira Ibragimova[1], Timur Alimov[2], Nasiba Alimova[3], Nigora Maksutova[3], Khamid Karimov[2], Tokhir Ishanhodjaev[1] & Talat Saatov[1]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Biochemistry, Tashkent, Uzbekistan; [2]Institute of Hematology and Blood Transfusion, Uzbekistan Public Healthcare Ministry, Molecular Medicine and Cell Technologies, Tashkent, Uzbekistan; [3]Ya.Kh. Turakulov Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan

The fat tissue inflammation and insulin resistance formation are common in obesity and type 2 diabetes mellitus. The tumor necrosis factor–α (TNF-α), a pro-inflammatory cytokine, was found to be a key one in onset and progression of insulin resistance, blocking the insulin signaling pathway and hampering the gene expression of GLUT4, the intracellular insulin-regulated glucose transporter in body tissues. Rise in the TNF-α concentration in blood serum is believed to be associated with the excessive body mass or obesity. TNF-α can be used for diagnosis of diabetes mellitus in the obese patients. The work was initiated to identify associations between TNF-α blood serum levels in the obese patients and risk of diabetes mellitus onset. There were 3 groups of persons examined. The persons with normal body mass index (BMI) were included into the 1st group, the non-diabetic obese persons with BMI more than 28 kg/m^2 and the diabetic obese persons were included into the 2nd and 3rd group, respectively, for the anthropometric and clinical-laboratory parameters of the carbohydrate and lipid metabolism to be measured by the enzyme-linked immunosorbent assay (ELISA). The MR-96A Microplate Reader (Shenzhen Mindray Bio-Medical Electronics Co. Ltd., China) was used to perform qualitative or quantitative determination of samples by the photometric measurements. The findings demonstrated that serum TNF-α levels in the non-diabetic obese persons (3.55±0.30 pg/ml) and the obese diabetics (3.96±0.14 pg/ml) were significantly higher than those in the controls (0.79±0.30 pg/ml) and mean standard reference values. Measurements of TNF-α levels in blood sera of the obese persons are important for early diagnosis of main metabolic disorders resulting in T2DM onset.

Hyperinsulinemia does not reduce plasma sex hormone-binding globulin levels in obesity

David Martinez
Vall d'Hebron Research Institute (VHIR), Diabetes and Metabolism, Barcelona, Spain

The liver produces and secretes sex hormone–binding globulin (SHBG), which transports sex steroids and regulates their access to tissues. Body mass index is a major determinant SHBG concentration in the blood of men and women. Low plasma SHBG levels are associated with obesity and predict the development of type 2 diabetes and cardiovascular disease. The reason why obese individuals have low circulating SHBG has been attributed to hyperinsulinemia, but no mechanistic evidence has ever been described. Over the past decade we and others have contributed to gathering evidences that demonstrate that insulin does not regulate SHBG production. We have used *in vitro* (HepG2 cells) and *in vivo* (human *SHBG* transgenic mice) approaches to show that hyperinsulinemia does not reduce SHBG production. We have elucidated the molecular mechanisms by which carbohydrates and proinflammatory cytokines (i.e. tumor necrosis factor alpha and interleukin 1 beta) reduce SHBG production. Importantly we and others have corroborated these results in humans. All these evidences point to the downregulation of *SHBG* mediated by carbohydrates and proinflammatory cytokines as one explanation for the low levels of total sexual steroids that exist in chronic inflammatory diseases such as obesity and type 2 diabetes.

Hypertension and diabetic pregnancy: Epidemiological aspects and evolution

Maha Belhadj, Ramla Mizouri, Imen Sebai, Senda Sellami & F. Ben Mami
Institut National de Nutrition de Tunis, Tunisia

Introduction
High blood pressure during pregnancy is associated with various maternal and fetal complications. This risk further complicates the pregnancy of diabetic women.
Patients and methods
We carried out a longitudinal retrospective study including one hundred pregnant women with type 1 and type2 diabetes, recruited from the patients monitored at the national nutrition institute during the period from January to December 2016.
Aim of the study
Study the epidemiological characteristics of a complicated pregnancy of diabetes and hypertension in a Tunisian center, and describe the maternal and fetal outcome of these risky pregnancies.
Results
The average age of our patients was 32.87±5.3 years, the average pre-gestational BMI was 28.2±6.48 kg/m^2, 63.6% of the patients were overweight. The majority (70%) of patients had unbalanced pre-conception diabetes (HbA1c>7%). Twelve percent of the patients had a history of high blood pressure. During pregnancy, 17.6% of women were on anti hypertensive therapy (calcium antagonists: 12.4%, beta blocker: 3.1%, central antihypertensive: 2.1%). Only 2.1% of patients presented with pre-eclampsia. For the glycemic parameters, a significant improvement in HbA1c was observed in the 2nd trimester, which was maintained during the 3rd trimester. Patients had reduced their HbA1c in the 2nd trimester by 1.58% compared to pre-conceptual HbA1c ($P<10^{-3}$). The outcome of the pregnancy was favorable with full-term delivery in 72% of the cases. Premature delivery took place in 15% of cases, Therapeutic termination of pregnancy in 1% of cases, early spontaneous abortion in 8% of cases, late abortion in 1% of cases and stillbirth in 3% of cases. The majority (93.3%) of our patients delivered by cesarean. The main causes of cesarean delivery were foetal distress (29.6%), macrosomia (23%) and history of a scar uterus (18.5%). Only 2.4% of caesareans were motivated by pre-eclampsia. The average birth weight was 3577.2±0.72 kg. Macrosomia was observed in 24% of the cases. Five newborns (5.7%) presented neonatal malformations at birth: three cardiac, one urological and one polymalformative syndrome. We found five cases of early neonatal death (5.7%).
Conclusion
Diabetic pregnancy complicated by hypertension is associated with an increased risk of maternal and foetal complications. Pre-conception management and action on modifiable factors could significantly improve the prognosis.

Evaluation of neopterin levels in patients with diabetes mellitus

Goknur Yorulmaz[1], Sinem Gurcu[2], Bilge Kilicarslan[2], Gozde Girgin[2], Fatma Belgin Efe[3] & Terken Baydar[2]
[1]Eskisehir Osmangazi University, Meselik Campus, Endocrinology, Eskisehir, Turkey; [2]Hacettepe University Faculty of Pharmacy, Ankara, Turkey

Background and aims
Diabetes is an endocrinological disease with high incidence and important complications. Studies indicate that by 2030, diabetes will affect approximately 366 million people around the world. Neopterin is produced by activated monocyte-macrophages with the induction of interferon gamma and it is accepted as a biomarker of immune activation. Elevated neopterin levels in biological fluids can be observed in neurological, cardiovascular and autoimmune disorders, different types of malignancies and infections. The aim of this study was to evaluate the possible changes of serum and urinary neopterin levels in diabetes patients.
Materials and methods
36 patients with type I diabetes mellitus, 33 patients with type 2 diabetes mellitus and 30 healthy controls were recruited the study. The patients with type 2 diabetes mellitus were further subgrouped according to their drug therapy (15 metformin treatment and 18 metformin+vildagliptin treatment). Serum and urinary neopterin levels were determined by ELISA and HPLC, respectively.
Results
In all groups, serum and urinary neopterin levels were found to be correlated. All groups represented higher neopterin levels compared to controls. Although patient levels were higher, no statistical significance was observed among study groups. The highest levels were observed in metformin medicated patients with type 2 diabetes mellitus.
Conclusion
The study pointed out that neopterin levels increase in diabetes patients. The change is also possible in different types of diabetes and different antidiabetic agents. Further studies with increased number of patients are required to confirm these results.

Anxious and depressive reactions among diabetic patients in Belarus: Prevalence and impact on behavior associated with type 2 diabetes

Andrei Yaroma & Larissa I. Danilova
Belarusian Medical Academy of Postgraduate Education, Endocrinology, Minsk, Belarus

Background
The number of patients with type 2 diabetes with mental problems will increase in the coming years[1]. The fight against diabetes cannot be reduced only to the competent prescription of medications, but should be carried out comprehensively taking into account numerous barriers.
Aims
The objective of this study was to investigate prevalence and impact of anxious and depressive reactions among persons living with type 2 diabetes in Belarus to improve the support system for diabetic patients.
Method
Screening for type 2 diabetes was done in different population groups. A total of 90 participants with previously diagnosed type 2 diabetes and 90 adults without diabetes were recruited. The GAD-7 scale and the PHQ-9 scale were used to determine the level of anxious reactions and the level of depressive reactions; glycated hemoglobin was used to analyze the effectiveness of the hypoglycemic therapy.
Results
Of the 90 patients examined, more than 70% showed anxiety reactions and 45% showed depressive reactions. Patients with anxiety and depressive reactions had poor self-care skills and had poor glycemic control. Of the total diabetic patients only minority had adequate blood glucose testing practices.
Discussion
We cannot do without new pharmacological treatments for diabetes. But if you look at the entire success story of diabetology, it becomes clear that this is not enough. The North Karelia Project[2] was able to achieve results in the fight against cardiovascular diseases when pharmacological discoveries did not reach modern heights. And this means that 1) an integrated approach in the treatment of chronic diseases can bring good results; 2) the impact on society as a whole, can change the behavior of even weakly motivated patients; 3) with an integrated approach to the treatment of diabetes, it is important to consider the psychological status of patients.

The effects of hypoglycemic therapy on the sleep apnea in patients with type 2 diabetes mellitus

Ina Darashkevich[1], Tatjana V. Mokhort[2] & Tatyana Borisenko[1]
[1]Grodno State Medical University, Internal Medicine, Hrodna, Belarus; [2]Belarusian State Medical University, Endocrinology, Minsk, Belarus

Type 2 diabetes mellitus (DM2) is often associated with obstructive sleep apnea (OSA), according to the literature. Current approach in choosing the hypoglycemic therapy is based on individualization, but do not take into account the effect on OSA. The research purpose: to evaluate the effect of various hypoglycemic agents on the characteristics of OSA in patients with type 2 diabetes.
Materials and methods
The study included patients with OSA and DM2, that were divided into 2 groups depending on hypoglycemic therapy (without CPAP therapy). Group 1 ($n=12$) included patients using metformin+ gliclazide MR in treatment and group 2 ($n=14$) included treatment using empagliflozin+metformin. During the study, all patients were twice monitored for glycated hemoglobin (HBA1c), weight, body mass index (BMI), polysomnographic indicators (PSG) (SOMNOlab2, Weinmann R&K (Germany)). Patients follow-up was 6 months.
Results
Patients of groups 1 and 2 are comparable in terms of experience of DM2 (6.0 [5.0; 8.0] vs 7.5 [5.9; 8.1] years), age (43.0 [37.0; 46.0] vs 45.0 [39.0; 47.0] years), (BMI) (35.0 [33.1; 36.6] vs 34.7 [33.1; 35.1] kg/m²), HBA1c (8.0 [7.6; 8.6] vs 8.3 [7.6; 8.9]%), respectively. To assess the severity of OSA according to the results of PSG, the following was defined: apnea-hypopnea index (AHI) in group 1–25.7 [23.1; 27.2] patients vs 24.1 [21.5; 25.2] patients in group 2, which corresponded to OSA of moderate severity cases. The degree of blood oxygen saturation (SpO2) 78.0 [74.1; 80.2]% vs 84.2 [75.1; 88.2]% ($P=0.05$). Repeated investigations, after 6 months, demonstrate decreasing HBS1c in group 2 to 7.1%, BMI to 32.2 [30.1; 33.0] kg/m² and PSG characteristics. AHI parameter 26.8 [24, 1; 34.2] patients vs 12.0 [11.1; 14.2] patients ($P=0.02$), the average duration of SA is 34.7 [29.1; 38.2] vs 14.1 [12.8; 16, 2] ($P<0.01$), SpO2 –76.1 [75.1; 80.2]% vs 89.0 [88.0; 94.2]% ($P<0.02$) in comparison groups 1 and 2, respectively.
Conclusion
The administration of metformin (2500 mg/day) in combination with empagliflozin (10 mg/day) treatment in patients with DM 2 and OSA for 6 months is accompanied by reduction of episodes duration and decreasing in the severity of OSA, an increasing in SpO2 and also improvement in HBA1c, decreasing in BMI.

Diabetes and ramadan: Analysis of the behiavor of tunisian patients towards treatement

Olfa Lajili, Kamilia Ounaissa, Rim Rachdi, Emna Bornaz & Chiraz Amrouche
National Nutrition Institute, Outpatient Departement and functional explorations, Tunis, Tunisia

Introduction
Fasting during Ramadan is an obligatory practice for adult Muslims. Although exemptions exist in certain conditions,including diabetes, the majority of diabetic patients fast despite this concession with the risk of complications mainly hypoglycemic accidents. The aim of this study is to establish the relationship between hypoglycemic accidents and drug treatment, therapeutic education, clinical and biological characteristics of tunisian diabetic patients during Ramadan 2019.
Methods
A prospective descriptive observational study including 85 diabetic patients followed at the National Nutrition Institute of Tunis. Clinical and biological data are noted before four to eight weeks and after the month of Ramadan 2019.
Results
The mean age was 55.8±12.7 years. Most of the patients had type 2 diabetes (97.7%). A slight female predominance was noted (52.3%). The average duration of diabetes was 10.6±6.6 years. Two thirds of the patients are classified as high or very high risk for fasting. Only 30% of the patients were allowed to fast. Treatment with oral antidiabetics, insulin, or a combination of the two was prescribed in 50%, 12.8% and 37.2% of cases. The average of HB1AC before and after Ramadan was 8±1.2%, and 8.6±1.35% respectively. Severe hyperglycaemia (> 3 g/l) was reported in 5.8% of cases. Hypoglycemic accidents were noted in 18.6% of patients, 14.9% of whom were on insulin ($P=0.026$), either alone or in combination with oral antidiabetics, 16.27% were at high or very high risk ($P=0.128$), 87.5% with type 2 diabetics ($P=0.03$) and 13.95% uneducated for fasting ($P=0.82$). Most of patients fasted all month (72.1%). Hypoglycemic accidents were the main cause of breaking fasting (62% of cases, $P<0.01$). Half of the patients did not glycemic monitoring during the fasting but without significant impact on the incidence of hypoglycaemia. In addition, there were no hospitalized patients during this month.
Conclusions
The consequences of fasting in diabetic patients were mainly hypoglycaemia. Insulin therapy was a predictor of hypoglycemia during Ramadan. Identification of individuals who required Ramadan specific education is essentiel to prevent these complications.

Treatment goal achievement in patients with type 1 diabetes mellitus followed-up at a tertiary center in greece

Maria Christou, Maria Merkoviti, Alexandra Terzaki, Christos Zisidis, Athanasios Siolos & Stelios Tigas
Ioannina University Medical School, Department of Endocrinology, Greece

Aim
Current guidelines for type 1 diabetes mellitus (DM1) suggest a therapeutic goal for glycosylated hemoglobin (A1c) of <7.0% in adults and <7.5% in children and adolescents, while emphasizing the importance of managing dyslipidemia. We aimed to record the achievement of therapeutic goals in DM1 patients followed-up in a Greek tertiary center.
Methods
Data were included from DM1 patients who had visited the Department at least once in the previous two years. The most recent and mean A1c value over the previous two years, body mass index (BMI), systolic and diastolic blood pressure (SAP, DAP) and lipids were recorded. Results are reported as mean (standard deviation, range).
Results
Data were included for 157 out of 616 patients; 119 adults (≥18 years) and 38 children or adolescents (< 18 years). In adults, mean age was 37 years (14, 18–70), and the most recent and mean A1c were 7.6% (1.3, 4.6–12.5) and 7.7% (1.4, 4.6–11.7) respectively. A1c <7.0% was achieved in 34% of patients. Mean BMI was 25 kg/m^2 (5, 17–39), with 25% being overweight and 19% obese. Combined SAP/DAP <140/90 mmHg was observed in 78% of patients. Total cholesterol (TC) was 188 mg/dl (43, 108–391), LDL 112 mg/dl (34, 45–200), HDL 57 mg/dl (14, 25–100) and triglycerides (TG) 99 mg/dl (137, 26–1436), whereas LDL <100 mg/dl was observed in 42% of patients. The combined treatment goal of A1c <7.0%, LDL <100 mg/dl and SAP/DAP <140/90 mmHg was achieved in 6.4% of patients. In patients <18 years, the mean age was 13 years (3, 6–17), BMI 20 kg/m^2 (4, 15–35), the most recent A1c 7.4% (1.2, 5.6–11.8) and the mean A1c 7.4% (1.7, 5.4–10.3). A1c <7.5% was achieved in 69% of patients. SAP was 110 mmHg (11, 90–129), DAP 70 mmHg (7, 60–84), TC 174 mg/dl (29, 121–259), LDL 98 mg/dl (25, 49–150), HDL 58 mg/dl (13, 39–88) and TG 84 mg/dl (60, 25–298). Insulin pump therapy was used by 26% of adults and 21% of children or adolescents. In these patients, A1c improved after pump use from 8.0% (1.8, 5.1–11.7) to 7.2% (1.1, 4.6–10.2) while the most recent A1c was 7.3% (1.1, 4.6–10.5).
Conclusions
Despite recent progress, a significant proportion of DM1 patients do not reach the therapeutic goals for glycemic, lipid and blood pressure control, whilst many are overweight or obese. Insulin pump use is associated with a sustained improvement in glycemic control.

Flash glucose monitoring in type 1 diabetes: Real world data

Diana Borges Duarte, Tiago Santos, Liliana Fonseca, Sofia Teixeira, Joana Vilaverde & Maria Helena Cardoso
Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism

Introduction
Clinical trial data demonstrate improved glycemic control in individuals with type 1 diabetes (T1D),especially, reduction of time in hypoglycaemia with flash glucose monitoring (FGM);however real-life conditions can modify this scenario.
Aim
To examine real world use and glycemic control following a standardized initiation process of FGM.
Methods
Individuals aged 18 years or older with T1D were prospectively recruited from consecutive visits in our outpatient clinic. Pregnancy, diabetic ketoacidosis or use of continuous glucose monitoring (CGM) in the previous 6 months were exclusion criteria. CGM metrics from baseline (first 14 days of use) and 12 months were compared. Subgroup analysis by sex was performed. The clinical targets for CGM established in the 2019 ATTD consensus were used.
Results
Thirty individuals were included (56.7% males); mean age of 49.6±13.2 years and diabetes duration of 26.2±12.4 years; 90% were on multiple daily injections and the remainder on insulin pump therapy. Forty-seven percent (n=14) had at least one established T1D chronic complication. Mean HbA1c was 7.7±1.1% and 7.5±1.2% at baseline and 12 months, respectively (P=0.153) Mean time in range (TIR) was 50.9±17.1% and 56.5±17.3 at baseline and 12 months, respectively (P=0.113). At baseline 10.7% reached the goal of TIR >70%, rising to 20% at 12 months (P=0.003). Mean time above range (TAR) had a similar evolution, from a median of 43.6±18.2 to 38.2±19.2 at baseline and 12 months, respectively (P=0.188). At baseline, 14.3% of the individuals had a TAR <25%, compared to 23.3% at 12 months (P=0.011). There was no difference neither in time below range (TBR) nor on duration or percentage of level 2 hypoglycemia. A severe hypoglycemia event in the previous 6 months was reported by 16.7% of the patients at baseline, compared to 3.3% at 12 months. Median number of scans per day was 7.0 (IQR 5.0) and 8.0(6.0) at baseline and 12 months, respectively (P=0.066). In the analysis by sex,the percentage of male individuals attaining their TIR and TAR goals increased from 6.7% at baseline to 23.5% at 12 months (P=0.038) and from 13.3% at baseline to 35.3% at 12 months (P=0.012), respectively; no statistical difference found on TBR. In the female group no difference was found on the proportion of individuals reaching their CGM goals.
Discussion
At 12 months, there was an increasing number of individuals who reached the CGM targets for T1D while also reducing severe hypoglycemic events. Our data support the benefit of FGM on glucose control in T1D.

Type 1 diabetes and challenges ahead

Maria Batool, Abdul Qadeer, Jayant Sharma & Ma Pyeh Kyithar
Midland Regional Hospital, Portlaoise, Portlaoise, Ireland

The incidence of type 1 diabetes mellitus (T1DM) is rising. The demands of daily management, blood glucose variability and potential complications pose challenges in management of T1DM.
The aim of this study was to determine the clinical and metabolic profiles of T1DM patients attending Midland Regional Hospital Portlaoise diabetes service in 2017 and to assess their microvascular and macrovascular complications.
A retrospective analysis of data of 106 patients with T1DM was performed. Mean age of the patients was 39.9±14.4 years, 60.4% were males, and mean duration of diabetes was 15.5±12.9 years. 39.6% were overweight (BMI 25 to <30 kg/m^2) and 24.5% obese (BMI ≥30 kg/m^2). 19.8% had HbA1c <53 mmol/mol, 25.5% had HbA1c 53 to 63 mmol/mol, 30.2% had HbA1c 64 to 75 mmol/mol and 24.5% had HbA1c >75 mmol/mol. 66% were within blood pressure target (< 140/90 mmHg). 103 of patients used basal bolus insulin regime, 2 on premixed insulin and one on insulin pump. Only 10.4% did carbohydrate counting to adjust insulin doses. 20.8% had documented hypoglycaemic unawareness. 25.5% had microalbuminuria, 21.7% had background retinopathy, and 11.3% had proliferative retinopathy. Nine were at moderate risk for diabetes foot disease, four at high risk and one had active foot disease.7.5% had coronary artery disease. Our preliminary data demonstrated that overweight/obesity is common and suboptimal glycaemic control and hypoglycaemic unawareness remain significant challenges in our T1DM cohort. Resources to improve T1DM self-management education programmes are essential and use of continuous glucose monitoring and insulin pump in selected patients may overcome these challenges.

Metabolic markers of persistent hyperglycemia

Irina Savasteeva[1], Tamara Evdochkova[2], Veronika Selkina[2], Yuliya Yarets[3], Yana Navmenova & Mariya Rusalenko[1]
[1]Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus; [2]Republican Research Center for Radiation Medicine and Human Ecology, ultrasonography, Gomel, Belarus; [3]Republican Research Center for Radiation Medicine and Human Ecology, laboratory, Gomel, Belarus

Introduction
The actual prevalence of early carbohydrate metabolic disorders is associated with persistent hyperglycemia and can only be detected by targeted screening.

Objective
We examined 316 people aged 51.21(46.7;62.35) years, without DM.
Methods
We determined the 10-year risk of T2DM according to the Findrisc scale, anthropometric data, lipid profile, glycemia and HbA1c level, linear dimensions of preperitoneal and subcutenous fat by ultrasonography methods. HbA1c ≥ 6.5% was determined as persistent hyperglycemia marker.
Results
Among 316 examined, 13 patients had glycemia 5.6–6.9 mmol/l (4%), 11 patients had glycemia ≥7.0 mmol/l (3.6%), and 18 patients had HbA1c ≥6.5% (5.7%). According to Findrisc scale: below 7 points – 20%, 7–11 points – 48%, 12–14 points–13%, 15–20 points – 15%, more than 20 points – 4%. Among 60 people (≥15) after additional glycemia and oral glucose tolerance tests, T2DM was first diagnosed in 12 people (3.7%), prediabetes in 26 people (8.2%), of which impaired fasting glucose tolerance (IFG) – in 10, impaired glucose tolerance – in 16. Hyperglycemia development was significantly affected by an increase in the linear dimensions of preperitoneal fat ($b=0.62$; Exp(b)=1.86(95% CI=1.063.28); $P=0.03$); increase of LDL and LDL-C ($b=1.21$; Exp(b)=3.36 (95% CI=1.666.82) $P=0.001$) and atherogenic index (AI) ($b=0.40$; Exp(b)=1.49 (95% CI=1.131.20); $P=0.005$). Increase of BMI and triglycerides increased the risk of persistent hyperglycemia at a steady tendency level. Statistically significant risk of developing persistent hyperglycemia was obtained with LDL-C > 1.6 mmol/l:R-$R_{LDL\text{-}C\geq 1,6}$=5.51(95% CI=2.33 ÷ 13.05); AI > 2.55:$RR_{AI\geq 2,55}$=3.22(95% CI=1.36 ÷ 7.62). For the linear size of preperitoneal fat, the RR indices were at the level of steady tendecy $RR_{ППДК\geq 1,75}$=2.22 (95% CI=0.84 ÷ 5.83; 90% CI=1.00 ÷ 4.99). It is noteworthy that the critical cutoff points of all indicators of the lipid profile lay in the range of reference values.
Conclusion
For T2DM screening, a Findrisc survey is justified, in spite of normal lipid profile values, ultrasonography of adipose tissue is required.

Psychological peculiarities of parents of children with diabetes mellitus

Mariya Rusalenko[1], Oksana Pispanen[2,3] & Olga Korneeva[4]
[1]Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus; [2]The Gomel central children's polyclinic, psychology, Gomel, Belarus; [3]The Gomel central children's polyclinic, pediatry, Gomel, Belarus; [4]Republican Research Center for Radiation Medicine and Human Ecology, psychology, Gomel, Belarus

Introduction
The primary incidence of T1DM in children in Belarus is 19.27‰. It's noteworthy, modern training programs of Schools of Diabetes include questions of the psychological state.
Objective
The study included 26 parents of children diagnosed with T1DM.
Methods
we used questionnaire to assess the attitude of parents to child's disease, HADS and social adaptation self-evaluation scales (T. Holmes, R. Ray).
Results
High scores characterize anxious attitude of most parents (78%) to the child's disease. 54% of parents showed external parental control of the disease when the causes of disease are seen as something out of the parents' control. 27% of parents indicated hypernosognosia (exaggeration of the severity of disease), 13% – hyponosognosia. 15% of parents showed low indices for internal control, when parents perceive themselves as fully responsible for the child's disease. In 3 cases (1.16%) parental anxiety that exceeded subclinical indicators was revealed, in 1 case – clinically expressed depression, which was most likely not associated with the child's disease. Almost all of the studied (96%) had problems with controlling the physical activity of the child; 2% of parents, on the contrary, indicated high activity control indices characterizing the setting of maximum restrictions on the activity of the child. It should be noted that parents whose anxiety was below average (13.6%) tried to replace anxiety with something else: emotional lability, apathy, obsessions, etc., which further may negatively affect the psychological health of parents and their children.
Conclusion
When a problem raises in the family, the child and parents need the qualified help of a psychologist in order to cope with acute stress and begin to make joint decisions objectively.

Mauriac syndrome – type 1 diabetes, nanism and more

Catarina Roque, Eugénia Morgado, Rute Ferreira, Manuela Oliveira & João Sequeira Duarte
Egas Moniz Hospital C.H.L.O., Endocrinology, Lisboa, Portugal

Introduction
Mauriac syndrome is characterized by delayed growth and development, obesity, hepatomegaly and elevated transaminases in type 1 diabetes mellitus (T1DM) patients who have poor glycaemic control. Usually recognized in adolescence, when growth failure and pubertal delay became notorious.
Case Report
A 19-year-old male was referred to the Endocrinology Department due to short stature. He was severely distressed about his stature and younger appearance which were negatively impacting his search for a job. The boy was diagnosed with type 1 Diabetes Mellitus (T1DM) at age 2. Records showed no history of ketoacidosis, average A1c 9–11%, GFR 98 ml/min/BSA. He was visiting the diabetologist every 3 months. There were no other relevant antecedents. He was proportionate, had a non-syndromic phenotype and seem to be 15 years old. He measured 154 cm (–3.06 SDS WHO), BMI 19.8 kg/m^2 (–0.87 SDS WHO) at age 19. Predicted adult height was 181 cm. He was Tanner stage 4 (G4P4Ac) with testicles of 25 ml bilaterally and bone age was delayed –3.5 years. From records of the past 4 years we extracted constant bone age delay around –3 years. Puberty had started at the chronological age of 15 and progressed according to bone age but there was no growth spurt. From age 16 he grew per year 2.5 cm, 1 cm, 0.5 cm. Routine tests for the investigation of short stature were normal except for low IGF-1 for age, sex and even when adjusted for Tunner stage and bone age (92 ng/ml RR 243–527). There was an adequate response to provocative testing (GH > 10 ng/ml). Selar RMI was normal. Abdominal US confirmed steatosis and dual-energy x-ray absorptiometry documented compromised bone health with a lumbar and femoral score of –4.1 and –3.3 respectively. Despite patient education and several attempts to intensify and optimize glycaemic control, there were no significant changes on A1c nor in IGF1 levels. He grew 0 cm during the last year.
Conclusions
Our report alerts physicians for the developmental complications associated with insufficient management of diabetes mellitus. The adequate management of T1DM in adolescents is very challenging and once the struggling adolescent is confronted with severe and possibly irreversible complications of the disease the challenge is made harder. Precocious patient education with familiar involvement through childhood should be mainstream. Mauriac syndrome is severe and although reversible with good and sustained glycaemic control, the best intervention strategy is it's prevention.

EP240

Metabolic profile of adolescents with type 1 diabetes in tunisia (about 102 cases)

Sellami Sonda[1], Berriche Olfa[1], Hechaichi Aicha[2], Cherif Amal[2] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Tunis, Tunisia; [2]National Observatory of New and Emerging Diseases, Tunis, Tunisia

Background
Type1 diabetes is the third most common chronic illness in childhood following asthma and cerebral palsy. Adolescence is characterized by physical and psychological changes and there is global evidence suggesting that metabolic control deteriorates during the period of teenage.
Aims
To study the characteristics of a group of Tunisian adolescents with type 1 diabetes and describe the various metabolic complications observed.
Methods
Cross sectional study concerning 102 adolescents with type 1 diabetes hospitalized or followed at the consultation of diabetology of the Institute of Nutrition in Tunis over a one-year period between January 2017 and January 2018.
Results
The study population consisted of 102 adolescents with type 1 diabetes. 51% were female (sex ratio=0.96). Participants classified underweight (UW) were 3(2.9%), those of normal weight (NW) were 82 (80.4%), overweight (OW) 10 (9.8%) and obese (O)7 (6.9%). Abdominal obesity was present in

21.6% of our patients with a significant female predominance (girls:34.6%, boys:8%, $P<10^{-3}$).
The mean duration of diabetes was 7.1±4.3 years. The majority (78.9%) of our patients had an HbA1c level>9%. Therapeutic adherence was low in 29.4%. Insulin omission was present in 7.8% of patients (girls: 11.5% vs boys: 4%; $P=0.2$). Diabetic retinopathy, nephropathy, and neuropathy were found respectively in 3.9%, 5.9%, and 5.9%. Moderate and severe hypoglycemia rate in the past 3 months were respectively 11.8±16.2 and 1.8±7.9 per month. The average number of ketosis or Ketoacidosis decompensations in the last year was 3.6±6.3 per year. The average number of hospitalizations per year was 2.2±1.9. The average length of hospital stay was 9.2±5.1 days. Dyslipidemia was diagnosed in 30.4% of diabetics with a significantly higher frequency in girls (girls: 38.5% vs boys: 22%; $P=0.05$). The school failure rate was high (50%) in our series.
Conclusions
Metabolic control of type 1 diabetes is difficult during adolescence due to hormonal fluctuations. Ketoacidosis decompensations and severe hypoglycemia are the most common complications in adolescents with type1 diabetes and may affect the academic performance of these young people by increasing the frequency of hospitalizations. Additional efforts are needed to improve the quality of care for young diabetics.

Management of diabetic Adhesive capsulitis in physical medicine and rehabilitation

Mouna Sghir, Soumaya Elarem, Aymen Haj Salah, Ikram Haddada & Wassia Kessomtini
Tahar Sfar Hospital, Physical Medicine And Rehabilitation, Mahdia, Tunisia

Introduction
Adhesive capsulitis (AC) is a condition characterized by spontaneous onset of shoulder pain and gradual loss of active and passive shoulder motion. This condition is more common in people with diabetes. The aim of this study was to appreciate the contribution of different therapeutic means used in physical medicine and rehabilitation (PMR) in the management of AC in Diabetic patients.
Patients and methods
A retrospective study was conducted during the period from January 2015 to January 2018. Diabetic patients diagnosed with AC in PMR department were included. All patients' demographic data, dominant hand, affected hand and history of relevant co-morbidities were noted. Passive flexion, abduction, and external and internal rotation range of motion (ROM) were reported. Pain was evaluated using Visual Analog Scale (VAS). Therapeutic protocol was noted and assessments were made at baseline (before the first treatment session) and after 3 months of physical therapy.
Results
Forty diabetic patients with AC were included. The mean age was 51.2±9 years with a sex ratio of 1.6. All patients benefited from rehabilitation sessions: 1 daily session for a month followed by 3 weekly sessions with an average of 36 sessions. Intra articular corticoid injection was done in 37.5% of cases and 3 patients benefited from guided capsular distension. We noted a statistically significant improvement in pain and ROM in all sectors ($P<0.05$).
Conclusion
Rehabilitation care is beneficial among Diabetic population suffering from AC.

EP242

Assessment of podiatry risk and correlation with the level of education in diabetics

Ramla Mizouri, Maha Belhadj, Faten Mahjoub & Henda Jamoussi
Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia

Introduction
Diabetic foot trophic disorders and their complications leading to the risk of amputation remain a major public health problem. The objective of our work was to determine the level of podiatric risk in our diabetic patients according to the classification of the International Working Group of the Diabetic Foot (IWGDF) in order to reduce the rate of amputation and study their level of education and correlate it to podiatric risk.
Methods
This is a descriptive and analytical cross-sectional study including all diabetics hospitalized at the National Institute of Nutrition in Tunis for chronic diabetes imbalance, carried out over a period of two months (July – August 2019).
Results
The mean age of the patients was 55.08±14.22 years. The sex ratio was 0.67. The majority of our patients were type 2 diabetics (90.24%). During the clinical examination of the foot, plantar hyperkeratosis was the most noted manifestation (65.85%). Based on the IWGDF classification, 42.68% of patients had a grade 0 podiatric risk. Regarding the overall educational level, 76.83% poorly educated patients and 23.17% educated patients were noted. The overall educational level is significantly associated with the podiatric grade ($P<0.05$).
Conclusion
Therapeutic education or even podiatric education of the patient is important in the prevention of complications of the foot. Patient-centered training in foot care practice in public health facilities would reduce the rate of morbidity and mortality from complicated diabetic foot.

Results of the assessment of homocysteine and vitamin B12 basal levels in patients with diabetes mellitus type 1 depending on anxiety level

Yana Navmenova, Elena Makhlina & Irina Savasteeva
SI «The Republican Research Center for Radiation Medicine and Human Ecology», Endocrinology, Gomel, Belarus

Objective to assess homocysteine and B12 basal levels in patients with diabetes mellitus type 1 (DM type 1) depending on anxiety level.
Materials and methods
163 patients with DM type 1 aged 18–65 years. Diabetes duration is 11.18 [4.28; 22.33] years. The level of anxiety was assessed according to the HADS scale. The homocysteine and vitamin B12 level in serum was determined. Depending on the anxiety level according to the results of the HADS score, patients were divided into 2 subgroups.
Results
The median HC level in serum in patients with anxiety was 13.29 [8.80; 15.90] mmol/l against the median HC level in patients without anxiety – 9.80 [7.94; 11.50] mmol/l and was higher in patients with anxiety (U=15.12; $P=0.02$). The risk of developing anxiety in patients with DM type 1 is associated with a HC level of more than 15.39 mmol/l (OS=1.21; $P=0.03$; 95% CI 1.06–1.37). The median vitamin B12 level in serum in patients with anxiety was 126 pg/ml [28.0; 473.0] against the median vitamin B12 level in serum in patients without anxiety – 312 pg/ml [168.0; 602.0] and was lower in patients with anxiety (U=14.65; $P=0.04$). A negative correlation was established between the level of anxiety by HADS and the level of vitamin B12 in serum ($r=-0.19$; $P<0.05$).
Conclusion
Patients with anxiety have a higher HC level and lower vitamin B12 level than patients without anxiety. With a decrease in vitamin B12 level, an increase in anxiety level by HADS is noted. The risk of developing anxiety in patients with DM type 1 is associated with HC level in serum above 15.39 mmol/l.

Relationship between indicators of androgenic status and renal function in patients with diabetes mellitus type 1

Elena Vaschenko & Irina Savasteeva
The republican Research Centre for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus

Objective
To analyze correlation between the duration of diabetes mellitus (DM), renal function and androgenic state indicators in patients with DM type 1. 175 males with DM 1 type in the age of 18–55 years (39.75±9.69) with the duration of disease more than 1 year were examined. The control group included 25 almost healthy males in the age 21–41 years (34.60±7.80).

The compensation of DM was estimated by the level of glycosylated hemoglobin (HbA1c). Also, the indicators of lipid profile (total cholesterol, triglycerides), glomerular filtration rate (GFR) MDRD, total testosterone, luteinizing hormone/follicle-stimulating hormone (LH/FSH), prolactin, sex hormone-binding globulin, homocysteine. The statistical analysis was conducted with the use of SPSS 17.0. It was defined that there was the decrease of GFR according to the formula MDRD in the terms of the increase of diabetes duration: in the group with GFR < 60 ml/min/1.73 m^2 the duration of the diabetes was 23.72 years (± 8.04), in the group with GFR > 60 ml/min/1.73 m^2 it was12.15 years (± 8.37) ($P < 0.05$). In the terms of the decrease of GFR the increase of correlation FSH/LH was defined: in the group with GFR < 60 ml/min/1.73 m² the correlation LH/FSH was 1.82 (± 0.63), in the group with GFR > 60 ml/min/1.73 m² it was 1.37 (± 1.26) (< 0.005); the decrease of the total testosterone: in the group with GFR <60 ml/min/1.73 m² the total testosterone was 9.90 nmol/l (± 3.10), in the group with GFR > 60 ml/min/1.73 m^2 it was 10.61 nmol/l (± 8.76) ($P < 0.05$); the decrease of the homocysteine level was noticed: 11.42 ± 2.70 mcmol/l comparing with the10.32 ± 4.92 mcmol/l in the group with GFR > 60 ml/min/1.73 m^2 ($P = 0.006$). We have not revealed any differences in the level of prolactin, sex hormone-binding globulin. The revealed changes are important risk factors for development and progression of vascular complications and require appropriate arrangements.

Keywords: diabetes mellitus type 1, GFR MDRD, androgenic state.

Does 25-OH vitamin D concentration correlate with adipocytokines inpatients with non-functioning adrenal incidentalomas – preliminary study

Joanna Kowalska[1], Iwona Zielen-Zynek[1], Justyna Nowak[1], Bartosz Hudzik[1,2], Aleksander Danikiewicz[1], Patryk Szlacheta[3] & Barbara Zubelewicz-Szkodzińska[1,4]

[1]Medical University of Silesia; Katowice, Department of Nutrition Related Disease Prevention; Department of Metabolic Disease Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [2]Silesian Center for Heart Diseases, 3rd Department of Cardiology, School of Medicine with the Division of Dentistry in Zabrze, Zabrze, Poland; [3]Medical University of Silesia; Katowice, pre doc School of Medicine with the Division of Densistry; Zabrze, Poland; [4]Piekary Medical Center, Street Luke's City Hospital in Piekary Śląskie, Department of Endocrinology, Piekary Śląskie, Poland

Introduction

Vitamin D has pleiotropic effect on human body. Several studies showed that vitamin D deficiency has an influence on inflammation status in endocrine diseases (PCO-S, Graves disease, autoimmune endocrine disorders) and could reflect body fat tissue contain. Both, resistin and leptin, show pro-inflammatory effect.

Aim

The aim of the study was to asses resistin and leptin serum concentration and its relationship with 25-OH vitamin D concentration in patients with non-functioning adrenal incidentalomas.

Material and methods

25 patients hospitalized in Endocrinology City Hospital in Piekary in 2015 with non-functioning adrenal incidentalomas were inclued to the study. The exclusion criteria were: other adrenal disorders, decompensated diabetes defined as HBA1C% > 7, kidney failure as eGFR < 60 ml/min/1.73 m^2, liver failure as bilirubin > 2 mg/dl, INR > 1.5 and albumins < 3.5 g/dl, severe inflammation, cancer therapy. Patients blood was centrifuged, serum obtained and the resistin and leptin concentration determined in duplicates by ELISA method, as per manufacturer's recommendations. Data of vitamin D concentration was taken from patients medical record.

Results

In analyzed group of patients the average vitamin D concentration was 22.9 ng/dl, resistin 6.4 ng/ml and leptin 70.4 pg/ml, BMI 29.9 kg/m^2. With increasing vitamin D concentration, leptin serum concentration decreased ($r = –0.56$, $P < 0.05$) and resistin serum concentration was statistically higher ($r = 0.68$, $P < 0.05$). There was also positive correlation observed ($P < 0.05$) between leptin and anthropometric indicators: BMI ($r = 0.82$), WHtR ($r = 0.73$), BRI ($r = 0.73$), WC ($r = 0.6$), LAP ($r = 0.48$).

Conclusion

Serum 25(OH)D3 concentration in studied group was below range and defined as mild insufficiency. Vitamin D concentration correlates with leptin and resistin in patients with non-functioning adrenal incidentalomas. To confirm obtained results further studies are needed.

Metabolic abnormalities of obesity were more severe in men than in women

Elnoza Adilkhodjaeva[1], Zulaykho Shamansurova[1,2] & Ismailov Said[1]

[1]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry at NUU, Metabolomics, Tashkent, Uzbekistan

Background

Obesity is worldwide epidemics and the main risk factor for many diseases. Traditional methods of prevention and treatment of obesity often unfavorable and patients undergo to alternative treatment such as bariatric surgery. To better understanding the pathogenesis of obesity, we aimed to analyse the main abnormalities in blood serum in patients accepted to bariatric surgery.

Material and methods

27 patients (13 men and 14 women) with obesity after unfavorable treatments were accepted to bariatric surgery. In both group blood fasting and postprandial glycemia, HbA1c level, serum creatinine (Crea), fibrinogen (Fib), ALAT, ACAT, bilirubin, blood urea nitrogen levels, prothrombin index (PTI), lipids level such as Triglycerides (TG), Cholesterol Chol), LDLP, HDLP were measured and compared.

Results

Showed that even average ages were similar in men and women (37 years old), BMI was higher in men (48.09 ± 9) than in women (38.85 ± 5.85). Blood bilirubin (by 1.3 times), Crea (by 1.6 times), ALAT (by 2.1 times) levels were higher in men than in women and showed linkage with BMI. Although the blood coagulation assessed by Fib and PTI, and blood lipids assessed by TG, Chol, LDLP, HDLP levels, as well as the atherogenic coefficient were comparable in both groups, impaired glycemia was determined in 62% of man and in 46% woman. These results suggest that obesity degree, and its metabolic abnormalities were more severe in men than in women.

Conclusion

Metabolic abnormalities were more severe in men than in women with obesity accepted to bariatric surgery after unfavorable treatment and differs by higher BMI, higher blood bilirubin, Crea, ALAT level and more cases of impaired Glycemia (62% vs 42%).

Profile of diabetic patients received in the emergency department during the month of ramadan in Mohammed VI university hospital of Marrakech

Rolly Junior Louzolo-Kimbembe, Nawal El Ansari & Ghizlane El Mghari

Chu Mohamed Vi Marrakesh – Drh, Marrakech, Morocco

Ramadan is a holy month in the Muslim religion, it involves a period of daily fasting from sunrise to sunset, which means an average of fifteen hours of fasting during the day (twelve to eighteen hours depending on seasons and regions). In diabetics, this involves metabolic disorders related to fasting, food mode (quantitative and qualitative change in dietary intake). The objective of our study is to define the profile of diabetic patients seen in the emergency department and referred to the endocrinology, diabetology unit of Mohammed VI university hospital of Marrakech.

Patients and methods

It's about an observational and descriptive study which takes place from May 7th to June 6th 2019, first in the emergency department then in the endocrinology, diabetology unit when patients are referred to. Our population of study is about type 1 and type 2 diabetics, with a duration of fasting from a few hours to fifteen hours a day. The variables studied: a month before and during the month of Ramadan (age, sex, type of diabetes, duration of evolution, anti diabetic treatment, fasting, type of metabolic emergency,complications and comorbidities of diabetes mellitus).

Discussion

2 times more hospitalizations during Ramadan than before.

- Hyperglycemia with or without ketosis: the most frequent decompensation, the frequency of hypoglycemia isweak;

- 22% of T1D fasted more ketosis pdt Ramadan hypoglycaemia
- 53% of T2D fasted: same frequency of hyperglycemia and ketosis but more hypoglycaemia during Ramadan,; 2 times more patients on sulfonamides consulted during Ramadan.
  - HYPERGLYCEMIA: excessive and unjustified discontinuation or reduction of insulin doses and/or ADO; non adherence to dietary instructions, increased calorie intake and in fast sugars? 2 to 3 meals in the space of 8 hours between ftour and shour, snacking…
  - HYPOGLYCEMIA: the periods of low blood sugar are often asymptomatic so underestimatedduring Ramadan.

Clinical profile of women with gestational diabetes admitted to day hospital

Ramla Mizouri, Haifa Abdesselem, Khadija Ben Naceur, Fatma Boukhayatia, Kamilia Ounaissa & Chiraz Amrouche
Institut National de Nutrition de Tunis, Hôpital du jour, Tunis, Tunisia

Introduction
Diabetic pregnancy is a high risk pregnancy. The objective of our study was to study the clinical-biological profile of pregnant women with gestational diabetes.
Methods
It was a retrospective study of 82 pregnant diabetic women admitted to the day hospital of the National Nutrition Institute in Tunis for the management of gestational diabetes. All patients received regular follow-up until delivery.
Results
The average age of our population was 33.55±4.3 years. On admission, the mean term was 25.6±8.4 years. Pregnancy was scheduled in 12.6% of the cases. 5% were smoking and 2.6% were hypertensive. The average HbA1c was 6.2±0.5%. Hypochromic microcytic anemia requiring iron supplementation was noted in 48% of cases. The diagnosis of hypothyroidism was made in 4.4% of the population studied at an average term of 10 SA requiring the administration of 25 mg/d of L-Thyroxine. Only three of them required an increase in dose to 50 mg/day. Isolated hypothyroxinemia was noted in 5.2%. All the patients required hygieno-dietetic rules and the use of insulin therapy was noted in 26.3% of the cases.
Conclusion
Regular monitoring is essential when diagnosing gestational diabetes in order to maintain a strict glycemic balance throughout pregnancy and to prevent the appearance or worsening of any micro and macrovascular complications.

Partial androgen insensitivity syndrome with type 1 diabetes- a case report

Ibrahim El Ebrashy, Heba Moustafa, Hemmat ElHaddad, Nashwa Saeed, Samar Amin, Aya El Toraby & Randa Salam
Cairo University, Endocrinology department, Cairo, Egypt

Introduction
Androgen insensitivity syndrome (AIS), also known as testicular feminization, encompasses a wide range of phenotypes that are caused by numerous different mutations in the androgen receptor gene. where there is resistance to androgen actions influencing both the morphogenesis and differentiation of androgen responsive body structures AIS is an X-linked recessive disorder. This disorder includes a spectrum of changes ranging from male infertility to completely normal female external genitalia in a chromosomally male individual that is classified as complete, partial, or mild based on the phenotypic presentation.
Case report
An 18-year-old diabetic,phenotypic female presented to the outpatient endocrinology department with primary amenorrhea. At the age of 13,her mother noticed that our patient's voice became deep & her body hair became more excessive and in abnormal sites (especially above upper lip & chin) with acne.
Physical examination.
Normal vital signs, She had low pitched voice.
Weight: 66 kg/Height:166 cm (US/LS: 0.9) (span:170 cm)/BMI: 24 kg/m^2.
Facial acne Male distribution of body hair:Above upper lip, chin, chest, midline, back (thick, coarse, pigmented).
Breast: Tanner stage 1–2/Pubic hair: Tanner stage 5/External genitalia: clitoromegaly (2 cm).
Severe tenderness on palpation along medial side of inguinal region on both sides.
Hormonal profile: elevated FSH, testosterone with normal LH, Estradiol, PRL.
Δ4-Androstenedione 1.3 ng/ml (N: 0.4–4.5)/Testosterone 6.9 ng/ml (N: 0.1–1).
FSH 90 mIU/Ml (N: 1–12) LH 2.3 mIu/MI (N:1.9–12.5)/prolactin 10 ng/ml (N:2–29 ng/ml).
Trans-rectal US: uterus and ovaries are not visualized/MRI pelvis: Non visualized uterus & ovaries.
Bilateral inguinal ovoid structures are seen representing undescended testes (Rt 2.5 × 2 cm) (LT 2 × 2 cm). karyotyping: The case showing male genotype 100% (46XY).
Conclusion
Androgen insensitivity syndrome is distressing to the patient as well as to the family. Systemic disclosure of the diagnosis in an empathic environment with both professional and family support is encouraged. Patient will be benefited by a multidisciplinary approach including gonadectomy, detailed and repeated psychological counseling along with estrogen replacement. The medical and psychological prognosis for a woman with androgen insensitivity syndrome is excellent if she has appropriate support and counseling.

When the diagnosis of degenerative complications precedes that of diabetes

Chaima Jemai & Feika Ben Mami
National institute of nutrition of Tunis, C, Tunisia

Introduction
The diagnosis of diabetes often precedes the onset of degenerative complications.
Method
We report the case of a patient who had consulted for a poor foot plantar perforation evolving for 3 months before the diagnosis of diabetes.
Results
He is a 57-year-old active smoking patient with a family history of diabetes and hypertension who presented to the emergency department of the Tunis National Nutrition Institute for inaugural diabetic ketosis with a 'lesion' of the foot evolving for 3 months which does not heal. On examination, he had a BMI=27.4 kg/m^2, stable hemodynamic constants, an uninfected plantar neuropathic ulcer, and neuro-ischemic feet. In biology he had an HbA1C=13.1%, a clearance creatinine=102.5 ml/min (CKD-EPI). He did not have a biological infectious syndrome. The ophthalmological examination had diagnosed diabetic retinopathy. The patient was put on insulin therapy associated to metformin.
Conclusion
In our case, the appearance of the plantar neuropathic ulcer preceded the diagnosis of diabetes by 3 months. Screening for diabetes in people at risk should be systematic to avoid such cases.

Ketotic decompensation in diabetics

Ramla Mizouri, Khadija Ben Naceur, Yosra Hatira & Faika Ben Mami
Institut National de Nutrition de Tunis, Service C, Tunisia

Objective
Diabetic ketosis is very often a reason for emergency consultation in diabetics. The objective of our study was to assess the etiologies of ketotic decompensations in diabetics.
Methods
It was a descriptive cross-sectional study of 80 diabetics hospitalized at the National Institute of Nutrition for ketotic decompensation. Each patient underwent a clinical examination with a standard biological assessment.

Results
The average age of the patients was 58.36 years with a male predominance (54%). Diabetes was type 2 in 82% of the cases. The average duration of diabetes was 13.87±4.5 years of which 80.8% were on insulin therapy. The mainly found decompensation factor was an infection observed in 48% of cases. It was a bronchopulmonary infection in 36% of the cases and a urinary tract infection in 32% of the cases. Therapeutic non-compliance or discontinuation of treatment was observed in 22% of the cases. An inaugural ketosis was found in 19% of the cases and an error in the injection sites was found in 3% of the cases. Excessive deviation from diet was noted in 1% of patients. The rest of the cases remain unexplained.
Conclusion
A good education is always beneficial for the diabetic in order to survive with his chronic illness away from complications and stressful situations.

Bag of bones: Myth or reality

Sabaretnam Mayilvaganan[1], Ramakanth Bhargav Panchangam & Amit Agarwal[2]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrine Surgery, Lucknow, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Case presentation
73-year-old diabetic, hypertensive and alcoholic Male on treatment for type II diabetes for 25 years, underwent amputation of left great toe and second toe previously had sudden painless swelling of the left foot after a walk. He was diagnosed to have Charcot's foot and had the appearance of bag of bones in CT scan. He was managed conservatively with immobilization and Custom made shoes.
Discussion
Charcot foot is a sudden softening of the bones in the foot that occurs in patients with severe neuropathy and resulting bones are weakened enough to fracture, and with continued walking the foot eventually changes shape. As the disorder progresses, the arch collapses and the foot takes on a convex shape. Charcot foot is a very serious condition that can lead to severe deformity, disability, and even amputation. X-ray examination reveals the appearance of lysis of the bones with marked fragmentation, absence of bone regeneration, the tendency to disarticulation and destruction of the joints and the complete flattening of the longitudinal arch of the foot. The 'club foot' appearance in conjunction with the radiologic findings merits the appellation 'a bag of bones.'[1]

Lipid profile in type 1 diabetics

Ramla Mizouri, Faten Mahjoub, Sabrine Zribi, Fatma Boukhayatia & Henda Jamoussi
Institut National de Nutrition de Tunis, Service A, Tunisia

Introduction
The vascular risk in type 1 diabetics appears to be secondary to the premature development of atherosclerosis.
The objective of this study was to determine the characteristics of the lipid profile of a type 1 diabetic population as well as the different factors that can influence these changes.
Methodology
It was a descriptive cross-sectional study including 30 type 1 diabetic patients, followed at the National Institute of Nutrition in Tunis. Patients underwent a careful clinical examination and a standard laboratory test.
Results
The average age of our population was 26.02±7.90 years. The sex ratio was 1. The age of diabetes was 10.11±5.16 years. The average HbA1c was 10.16±2.1%. The lipid profile was characterized by: hypertriglyceridemia in 8 patients. Hypercholesterolemia in 19 patients. Hypo-HDLemia in 16 patients. We found macroangiopathic complications in 6 of our patients with coronary artery disease and lower limb arteritis; nephropathy, neuropathy and retinopathy microangiopathies were found in 11 patients. The analytical study found no correlation between microangiopathic or macroangiopathic complications and lipid abnormalities in our patients.
Conclusion
In accordance with data from the literature, our study reveals hypertriglyceridemia and hypo-HDLemia characterizing the lipid profile of type 1 diabetics. However, no correlation was found with the degenerative complications noted.

Improving diabetes care in children and adolescents with intellectual and developmental disabilities

Alba Themeli[1,1], Edmond Pistja[1], Zvjetllana Skorovoti[2] & Mirela Rexhepi[3]
[1]Medical Training Center Santa Maria, Continuing Education, Lezhe, Albania; [2]University Hospital Mother Teresa, Neuroscience Department, Tirana, Albania; [3]University Hospital Mother Teresa, Pharmaceutical Department, Tirana, Albania

Aims
To present an analysis of the evidence related to the prevalence and incidence of diabetes type 1 or type 2 in children and adolescents with intellectual and developmental disabilities, assess available support on managing their diabetes, and the services they receive, investigate the available structured education programs tailored for people with IDD.
Methods
We conducted different searches of multiple databases.
(PUBMED, MEDLINE, PsycINFO, SCOPUS, Web of Science, and Wiley Library) to find relevant articles.
Results
We identified a total of 8 studies: Four studies addressed the prevalence of diabetes in people with an intellectual and developmental disability, Three addressed the impact of diabetes on their health and well-being, and one addressed the available diabetes programs adapted for people with IDD. The prevalence of diabetes in children and adolescents with an intellectual and developmental disability is inconclusive, and the incidence of diabetes in this category is unknown. There is some evidence to support the assumption that children and adolescents with an intellectual and developmental disability might be at higher risk of developing diabetes than their peers. In general, the quality of the evidence on which to base prevention and management strategies is limited.
Conclusions
There are limited studies focused on the prevalence, incidence, and impact of diabetes among children and adolescents with an intellectual and developmental disability. Continuous research is necessary for this field, and especially further studies are necessary to develop new approaches, evaluation tools, educational resources, and diabetes care support services appropriate to the needs of children and adolescents with an intellectual and developmental disability.
Keywords: diabetes, intellectual disabilities, family support, diabetes- management, prevalence, adolescents.

Impaired fasting glucose in patients with spondyloarthritis

Ben Ali Khaoula, Maroua Slouma, Rym Dhahri & Imen Gharsallah
Military Hospital of instruction of tunis, Rheumatology, Tunis, Tunisia

Background
Spondyloarthritis is a chronic inflammatory rheumatic disease which may be associated with different comorbidities such as glucose intolerance.
Objectives
Determine the frequency of impaired fasting glucose in a population of patients with spondyloarthritis.
Methods
We performed a cross-sectional study including 50 patients with spondyloarthritis (SA) diagnosed according to ASAS criteria. Fasting glucose was measured for each patient.
Results
The mean age was 44.75±13.5 years. Sex ration(M/F) was four. Clinical phenotypes of SA were: ankylosing spondylarthritis (51.9%),psoriatis arthritis(28%), arthritis associated with inflammatory bowel disease (10%). The mean duration of the disease was 93.27 month. the mean PCR, ESR, PCR-ASDAS and fasting glucose were 29.48, 36.55, 3.38 and 5.62 respectively.

Overweight and obesity were noted in 41.5% of cases.
Eighty-four percent of the patients have a normal fasting glucose,12% of them have a fasting glucose higher than 7 mmol which needs another control to diagnose diabetes and only 4% ($n=2$) have an impaired fasting glucose.
There was no correlation between fasting glucose and these following parameters: PCR-ASDAS ($P=0.745$), PCR ($P=0.291$) and ESR ($P=0.803$).
Discussion
More than 15% of patients with SA have an incorrect fasting glucose including glucose intolerance and diabetes, this pourcentage was higher in psoriatic patients and it was equal to 28.57.
Almost the half of the population are overweight or obese. these two items associated to SA increase the cardiovascular risk.
Conclusion
Identifying glucose intolerance in SA may help physicians to minimize cardiovascular mortality also it can ensure a better quality of life if treated early.

Type 2 diabetes in patients with cirrhosis: Prevalence and clinical implications

Mrabet Soumaya, Imen Akkari & Ben Jazia Elhem
Farhat Hached University hospital, Gastroenterology, Sousse, Tunisia

Introduction
Disorders of glucose metabolism are often present in chronic liver diseases. The aim of our study is to determine the prevalence and factors associated with type 2 diabetes in patients with cirrhosis.
Methods
This is a retrospective study collecting all patients with cirrhosis between January 2010 and December 2019.
Results
During the study period, 166 patients were included. Of these patients, 47 patients had type 2 diabetes (28.3%). These were 29 women and 18 men with an average age of 61.6 years (between 17 and 84 years). Cirrhosis was metabolic in 18 cases (38.3%), viral B in 9 cases (19.1%), viral C in 8 cases (17%), autoimmune in 5 cases (10.6%), of alcoholic origin in 4 cases and of undetermined etiology in 3 cases. Cirrhosis was classified as CHILD A in 16 patients (34%), CHILD B in 23 patients (49%) and CHILD C in 8 patients (17%). Ascitic decompensation was present in 33 cases (70.2%). Six patients (12.8%) had hepatic encephalopathy. Forty-four patients (93.6%) had esophageal varices on upper gastrointestinal endoscopy. Cirrhosis was complicated by hepatocellular carcinoma (HCC) in 5 patients (10.6%). Analytic study had shown that the presence of type 2 diabetes was associated with older age ($P=0.018$), metabolic origin ($P=0.001$) and viral B origin ($P=0.04$). However, there was no association with gender, the severity of cirrhosis, and the presence of HCC.
Conclusion
In our study, type 2 diabetes was present in 28.3% of cirrhotic patients and it was associated with advanced age, metabolic and viral B origin.

Are hospitals in madrid promoting a healthy nutritional environment?

Inmaculada Moreno-Ruiz[1], Iciar Martín Timón[1], Juan Jose Marin-Peñalver[1], Isabel Huguet[1], Olalla Meizoso-Pita[1], Susana Bacete Cebrián[1], Javier Modamio[2], Beatriz Ugalde-Abiega[1] & Cristina Sevillano-Collantes[1]
[1]Hospital Universitario Infanta Leonor, Madrid, Spain; [2]Hospital Universitario Infanta Leonor, Spain

Introduction
NutriScore is a tool designed with the aim of simplifying the information of the nutritional composition obtained from the labelling. It classifies foods into five colors ranging from green (healthier) to red (less healthy). These colors are associated with five letters (A/B/C/D/E).
Objective
To examine the nutritional value of foods sold in vending machines of the public hospitals in Community of Madrid (Spain), by calculating the nutriscore.
Methods
The study was conducted during the months of January and February 2019. Snacks and beverages sold in vending machines were analyzed. These machines were located in waiting rooms of the emergency departments of every public hospital in the Community of Madrid. The NutriScore of each item was calculated, according to the amount of nutrients in 100 g of food or 100 ml of drink. One obtains the score by punctuating negative elements (caloric value, saturated fat, sugar and sodium) and substracting the positive ones (fruit content, vegetables, nuts, fiber and proteins). The higher this last score, the more unfavourable. According the final result obtained, foods are sorted into one of the five categories.
Results
258 snacks and 92 beverages available in the vending machines of 27 hospitals were analyzed. Snacks were distributed as follows: A 8%, B 5%, C 28%, D 35% y E 24% and beverages: A 1%, B 15%, C 23%, D 26% y E 35%. Category A for drinks only corresponds to water and it was found in 100% of the hospitals. There were only 2 hospitals, 7.4% of the visited, where no drink in Category E was offered. In 4 of the hospitals visited no snack in Category A was offered and in 13 of them more than a 60% were classified into Categories D and E. However, only in one hospital no product classified as E was sold.
Conclusion
Although hospitals should play a role in promoting a healthy lifestyle, the vending machines of the hospitals offer a very high number of products with low nutritional quality.

DOI: 10.1530/endoabs.70.EP257

Metabolic markers of persistent hyperglycemia

Irina Savasteeva, Tamara Evdochkova, Veronika Selkina, Yuliya Yarets, Yana Navmenova, Mariya Rusalenko & Irina Borovskaya
The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus

Introduction
The actual prevalence of early carbohydrate metabolic disorders is associated with persistent hyperglycemia and can only be detected by targeted screening.
Objective
We examined 316 people aged 51.21(46.7;62.35) years, without DM.
Methods
We determined the 10-year risk of T2DM according to the Findrisc scale, anthropometric data, lipid profile, glycemia and HbA1c level, linear dimensions of preperitoneal and subcutenous fat by ultrasonography methods. HbA1c≥6.5% was determined as persistent hyperglycemia marker.
Results
Among 316 examined, 13 patients had glycemia 5.6–6.9 mmol/l (4%), 11 patients had glycemia≥7.0 mmol/l (3.6%), and 18 patients had HbA1c≥6.5% (5.7%). According to Findrisc scale: below 7 points – 20%, 7–11 points – 48%, 12–14 points–13%, 15–20 points – 15%, more than 20 points – 4%. Among 60 people (≥15) after additional glycemia and oral glucose tolerance tests, T2DM was first diagnosed in 12 people (3.7%), prediabetes in 26 people (8.2%), of which impaired fasting glucose tolerance (IFG) – in 10, impaired glucose tolerance – in 16. Hyperglycemia development was significantly affected by an increase in the linear dimensions of preperitoneal fat ($b=0.62$; Exp(b)=1.86 (95% CI=1.063.28); $P=0.03$); increase of LDL and LDL-C ($b=1.21$; Exp(b)=3.36 (95% CI=1.666.82) $P=0.001$) and atherogenic index (AI) ($b=0.40$; Exp (b)=1.49 (95% CI=1.131.20); $P=0.005$). Increase of BMI and triglycerides increased the risk of persistent hyperglycemia at a steady tendency level. Statistically significant risk of developing persistent hyperglycemia was obtained with LDL-C>1.6 mmol/l:$RR_{LDL\text{-}C\geq 1,6}=5.51$ (95% CI=2.33 ÷ 13.05); AI>2.55:$RR_{AI\geq 2,55}=3.22$ (95% CI=1.36÷7.62). For the linear size of preperitoneal fat, the RR indices were at the level of steady tendecy $RR_{\text{ппж}\geq 1,75}=2.22$ (95% CI=0.84 ÷ 5.83; 90% CI=1.00 ÷ 4.99). It is noteworthy that the critical cutoff points of all indicators of the lipid profile lay in the range of reference values.
Conclusion
For T2DM screening, a Findrisc survey is justified, in spite of normal lipid profile values, ultrasonography of adipose tissue is required.

Personalized approach to the management of T2DM: Sibutramine+dapagliflozin – synergism at the start clinical case

Olga Iurova[1,2] & Larisa Marchenkova[3]
[1]National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of the Russian Federation, Department of Active Longevity and Endocrinopathy, endocrinologist, Moscow, Russian Federation; [2]SM-Clinika, outpatient department, Moscow, Russian Federation; [3]National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of the Russian Federation, Head of Department of Active Longevity and Endocrinopathy, Moscow, Russian Federation

Patient C., b. 1962 went to the clinic to a urologist with complaints of painful, rapid urination, dry mouth, thirst, a constant feeling of hunger in the daytime. A biochemical blood glucose(bg) level of 10.4 on an empty stomach. At the initial examination by an endocrinologist, bg at a reception of –8.0 mM/l on an empty stomach. BP-134/78 Ps-78. Height-178 Weight-101.5 BMI-32.0. HbA1c-7.4% basal insulin(bi)-28.3 (3.0–25.0) stimulated insulin(si)-56 (3.0–25.0). Basal C-peptide-4.8 (0.8–5.1). Stimulated C-peptide-7.1 (0.8–5.1). Leptin-28.0 (3.7–11.3). The diagnosis was made: T2DM with a target level of HbA1c of less than 6.5%.

Background

Obesity 1 Recommended: Dapagliflozin 10 mg Sibutramine 10 mg. After 21 days bg intake 6.4 2 hours after breakfast. GP: 5.1–4.5-5.4–5.8. Weight-93.5 (–2.5 per week) and –8.0 for the entire observation period – 3 weeks. After 30 days bi 8.3 (3.0–25.0), si 16 (3.0–25.0). Basal C-peptide-1.8 (0.8–5.1). Stimulated C-peptide-2.1(0.8–5.1) Leptin-8.0(3.7–11.3) bg at the reception is 5.5 mM/l 2 hours after breakfast. GP: 5.3–5.9–6.6–5.5 mM/l. Weight-90.0 (–11.5) per month –3.5 kg per 1 week. After 2.5 months from the start of therapy: bg at the reception – 4.3 on an empty stomach. GP: 4.1–5.2–5.3–6.1. BP-115/78 Pulse-78. Weight 79 (–11.0 per month and –22.5 for 2 months) bi-5.3 (3.0–25.0) si-7.2 (3.0–25.0). Basal C-peptide-1.1 (0.8–5.1). C-peptide stimulated-1.6 (0.8–5.1). Leptin-5.3 (3.7–11.3). HbA1c-5.7%. Patient canceled dapagliflozin 10 and sibutramine 10. Prescribed sitagliptin 100 daily morning. After 3.5 months from the start of therapy admission bg – 5.4 2 hours after breakfast. Weight-79.5 (+ 0.5) Height-178 BMI-25.09. GP: 4.9–4.6–5.5–4.8. Continued taking sitagliptin 100 mg in the morning. After 6 months from the last dose and 9.5 months from the start of therapy. BG 5.3 mM/l 2 hours after breakfast. GP 5.1–5.4–5.7–6.1 mM/l during the day. Weight 79.0 (-0.5 for 6 months) Height-178 BMI-25.01 Insulin-4.5 Leptin-1.2 C-peptide-0.9 HbA1c-5.4% BP-121/77, pulse-78 without taking antihypertensive therapy.

Conclusion

The potentiation of the effect of dapagliflozin and sibutramine at the start of treatment of T2DM contributes to the formation of proper eating behavior, a decrease in the calorie content of the daily diet and, thus, leads to the compensation of carbohydrate metabolism in a shorter time, as a result of compliance with the principle of compliance and influence on the pathophysiological mechanisms of the disease

Assessment of diabetes balance in patients on insulin analogues

skander dogui[1] & Chaima Jemai[2,3]
[1]Tunis, cnam, Tunis, Tunisia; [2]nutrition institute of Tunis, endocrinology, Tunis, Tunisia; [3]National institute of Tunis, C

Objective

The aim of this study is to assess the balance of diabetes in patients taking insulin analogues based on a recent value for their glycated hemoglobin.

Methods

2915 diabetics were evaluated for the period from March to April 2019 with as inclusion criteria a recent glycated hemoglobin and a duration of insulin treatment analogues of more than one year.

Results

Glycated hemoglobin is lower than 7 in only 8% of cases and greater than 9 in 49% of cases. No significant difference in the balance of diabetes according to the length of treatment with insulin analogues.

Conclusion

It is necessary to analyze the real benefit of insulin analogues in terms of diabetes balance as well as the cost-benefit of these molecules.

EP261

The possibilities of ultrasound in the diagnosis of latent postinjection lipodystrophies

Irina Savasteeva[1], Tamara Evdochkova[1], Veronika Selkina[1], Mariya Rusalenko[1], Elena Vashenko[1], Œena Machlina[2]
[1]The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; [2]Medical University, Gomel, Belarus

Introduction

Condition of injected skin and subcutaneous tissue is assessed by visual inspection and palpation and it has only 10–15% diagnostic value. The standard ultrasonography comparison of symmetrical skin areas is not valuable as they are usually used for injections.

Objective

We examined 143 patients, aged 43.3±3.9 years, with DM duration of 6.5±2.8 years, receiving basal-bolus insulin therapy.

Methods

Ultrasonography was performed for 78 volunteers with uninjected skin and subcutaneous tissue of the lumbar and epigastric regions. We determined correction factors that predict skin thickness at the injection site if insulin weren't administered.

Results

Ratio indices at the injection regions were calculated – the ratio of the dermis thickness of the studied to lumbar region. In the anterolateral shoulder region, normal indices were defined: for epidermis in the range of 0.9–1.0; for dermis – 0.5–0.7. In the anterolateral thigh region: for epidermis – 0.8–1.0; for dermis – 0.5–0.8. In the umbilical region: for epidermis – 0.8–1.0; for dermis – 0.6–0.8. In the upper outer quadrant of the buttock: for epidermis – 0.8–1.0; for dermis – 0.7–0.9. With values decrease, hypotrophic lipoatrophy development is expected. When performing ultrasonography and analyzing the ratios of the epidermis and dermis of the lumbar region to injection sites, changes were detected in every 4 (37 patients), which is 25%. Post-injection hypotrophic lipoatrophy was diagnosed in the umbilical region (49%), in the anterolateral shoulder (24%) and thigh (17%) regions, in the gluteal region (10%).

Conclusion

Using ratio indices during ultrasonography, it is possible to diagnose and treat post-injection lipodystrophies in the earliest time in order to achieve the highest insulin injection bioavailability.

Use of betablockers in aging patients with type 2 diabetes: Effects on glycemic control

Ben Ali Khaoula, Zeineb Zemni, Haifa Abdesselem, Olfa Lajili, Kamilia Ounaissa & Chiraz Amrouche
National instutute of nutrition, Outpatient Department and functional explorations, Tunis, Tunisia

Background

Aging patients with type 2 diabetes mellitus have a higher risk of developing hypoglycemia. Many studies show the effect of beta-blockers in hiding hypoglycemia symptoms and therefore the occurrence of a severe hypoglycemia. These agents are commonly used in diabetic patients with coronary heart disease. The aim of this study was to assess whether the use of beta-blockersdeteriorates the glycemic control.

Methods

We conducted a retrospective study involved 101 patients with type 2 diabetes mellitus followed at the National Institute of Nutrition and Food Technology of Tunis. All patients were over 65 years old.

Results

The average age was 70.69±5 years. Sex ratio were four female for one male. The majority of patients(71.1%)had a high blood pressure while 21% had a coronary heart disease. The average HbA1c was 9.55±1.92%. Seventy eight percent were treated with insulin. About a third (30.9%) of patients

was treated with beta-blockers; only 37% of them had at least one episode of hypoglycemia and only 13.3% reached the glycemic control target of less than 8% of glycated haemoglobin(HbA1c) vs 26.8% as a percentage of achieving the glycemic goal in patients not taking beta-blockers.
Conclusion
Our study indicates that the use of beta-blockersmay have a role in worsening the glycemic control, so that many physicians are reluctant to prescribe them to patients with diabetes and hypertension but their use is inevitable type 2 diabetic patientswith coronary heart disease.

Managing pregnancy in a diabetic patient with chronic kidney disease at the hemodialysis stage: An unresolved case

Chaima Jemai[1] & Hajer Kandara[2]
[1]National Institute of Nutrition of Tunis, C, Tunisia; [2]National Institute of Nutrition of Tunis, B, Tunisia

Introduction
Pregnancy in case diabetes complicated by chronic renal failure is characterized by a very high maternal and fetal risk.
Method
We report the case of a patient with diabetes and chronic renal failure at the hemodialysis stage who wishes to lead a pregnancy despite all the risks involved and of which she had been informed beforehand.
Results
This is a 39-year-old patient, with type 1 diabetes for 26 years. Her diabetes is poorly balanced (HbA1C=8.4%), multi complicated, with lasered diabetic retinopathy, diabetic peripheral neuropathy, and chronic renal failure, on hemodialysis for 8 years. The menarche was at the age of 17 years with irregular cycles. She has an obstetric history of 5 spontaneous abortions. The current pregnancy was not scheduled. The preconceptional body mass index (BMI) was 21.7 kg/m². The blood pressure were correct. She had microcytic hypochromic anemia with hemoglobin at 6.7 g/dl, a urinary tract infection and peripheral hyperthyroidism of incidental discovery whose etiological assessment is in progress. The phosphocalcic balance was correct. The glycemic balance in this patient was difficult especially on the day of hemodialysis.
Conclusion
conception in diabetic hemodialysis patients is exceptional and requires multidisciplinary management to be able to carry it through without maternal and fetal complications represented mainly by fetal loss, malformations linked to chronic hyperglycemia and anemia.

Hearing complications in diabetes – A clinical case

Catarina Ivo[1], Vitória Duarte[1], David Veríssimo[1], João Silva[1], Eurico Costa[2], Luís Lopes[1], Dolores Passos[1], Teresa Matos[2], João Jácome de Castro[1] & Mafalda Marcelino[1]
[1]Armed Forces Hospital, Endocrinology, Lisbon, Portugal; [2]Armed Forces Hospital, Otorhinolaryngology, Lisbon, Portugal

Introduction
Malignant or necrotizing external otitis (MEO) is an invasive infection between external auditory canal and skull base. It is more frequent in elderly and in diabetic patients or with compromised immune system. As MEO advance osteomyelitis can developed. It is a severe and potential mortal complication of external otitis (EO).
Clinical Case
78 years old man with history of type2 diabetes (good metabolic control) and right ear external otitis. In May 2019 initiate topic ofloxacin after diagnosis of EO. After 15 days he is admitted in emergency department (ED) with persistent otalgia in spite of treatment and was hospitalized on suspicious of MEO for IV antibiotic treatment. Analytically showed leucocytosis, elevated erythrocyte sedimentation rate (ESR) and C-reactive protein(CRP), glycemia 224 mg/dl and HbA1c 6.4%. Cultural auricular exudate: *staphylococus epidermidis*, only sensible for gentamicin, ciprofloxacin and vancomycin. Computed tomography (CT) revealed right media osteomyelitis that was confirmed by technetium scanning. Started ciprofloxacin iv 400 mg with clinical and analytical improvement and was discharged with oral ciprofloxacin and ofloxacin up to 8 weeks of total treatment. Four months later returns to ER complaining with severe otalgia with retro-auricle irradiation in RE. Right otoscopy with mesotympanic perforation without otorrhea, and painful pre and retro-auricle palpation. He has elevated both ESR and CRP. Skull base osteomyelitis recurrence was admitted, being hospitalized under iv ciprofloxacin 400 mg. Cultural auricular exudate isolated a multi-resistant *Klebsiella pneumoniae spp* only sensible for ertapenem. Antibiotic was adjusted, with clinical and analytical improvement. Gallium citrate scanning evidenced favourable evolution maintaining active inflammation. Patient is clinically improved maintaining follow-up in endocrine and otorhinolaryngology consultation.
Discussion
This case resumes a potential and severe complication present in elderly with diabetes. This group of patients are in major risk of developing this condition because macroangiopathic alterations in ear, increased pH of cerumen and phagocytic dysfunction of leucocytes from diabetes. Metabolic control of diabetes is not a risk factor for developing MEO but it is important for treatment success. Not as frequent as *pseudomonas aeruginosa*, colonization by *klebsiella pneumoniae spp* (8–19%) or commensal bacteria staphylococus epidermidis (4–9%) are described in the literature. Suspicion and alert for this pathology allows for successful diagnosis and opportune treatment.

Diabetic gastroparesis as an important comorbidity factor: About a clinical case

David Veríssimo[1,2], Diogo Faustino[2], Inês Lopes da Costa[2], Pedro Pires[2], Carmen Marques[2] & Júlio Almeida[2]
[1]Armed Forces Hospital, Department of Endocrinology, Lisbon, Portugal; [2]Hospital de São José, Department of Medicine 1.2, Lisbon, Portugal

Introduction
Gastroparesis associated with diabetic autonomic neuropathy is an underdiagnosed complication, although relatively common in diabetes. It is more prevalent in type 1 Diabetes Mellitus (DM1) with more than ten years of disease and especially in patients with poor metabolic control.
Clinical case
Female, 37 years old, DM1 with 17 years of evolution with poor metabolic control (HbA1c 9.3%) and several microvascular complications such as proliferative retinopathy with decreased visual acuity and diabetic nephropathy with end-stage renal failure, on hemodialysis for about 9 years (initially with unsuccessful living donor transplant). The patient presents an important intestinal dysautonomic component, characterized by chronic diarrhea of over 6 months and more recently with gastroparesis (2 weeks). Admitted in January 2019 after a right frontoparietal hemorrhagic stroke with mass effect and deviation of the midline, without indication for neurosurgery, resulting in left upper limb plegia, left lower limb paresis and associated left central facial paresis. During hospitalization, food intolerance was observed, with no improvement to the different prokinetic therapy instituted (metoclopramide, domperidone, clebopride, erythromycin and ondansetron), requiring total parenteral feeding. Among the tests carried, the patient was submitted to high digestive endoscopy and abdominal CT without contrast, which did not reveal relevant changes. Only after glycemic control was achieved was it possible to progressively reverse the gastroparesis condition.
Conclusion
Diabetic gastroparesis is a complex disease that is difficult to control, with diagnostic workup hampered by the extensive differential diagnosis, associated with an increased rate of hospitalization that requires a multifaceted approach.

Triple malignancy in a single patient including a medulloblastoma, a papillary thyroid cancer and a gastrointestinal adenocarcinoma: A case report

Rea Nagy[1], Anna Vágvölgyi[1], Krisztián Sepp[1], László Czakó[1], László Tiszlavicz[2], Csaba Bödör[3] & Zsuzsanna Valkusz[1]
[1]University of Szeged, Faculty of Medicine, First Department of Internal Medicine, Szeged, Hungary; [2]University of Szeged, Faculty of Medicine,

Department of Pathology, Szeged, Hungary; [3]Semmelweis University, Department of Pathology and Experimental Cancer Research, Budapest, Hungary

Second malignant neoplasm following irradiation is a rare sequelae of primary childhood malignancies. Irradiation is a well-known risk factor for the development of benign and malignant thyroid tumors. Here we present the case of a young woman with medulloblastoma, who later developed thyroid cancer and eventually was also diagnosed with a cholangiocarcinoma.
At the age of 7 the patient presented with headaches, nausea, vomiting, fatigue, somnolence and double vision and was diagnosed with a posterior scala tumor. She underwent suboccipital craniotomy with macroscopic complete removal of the tumor. Pathology confirmed medulloblastoma. This was followed by chemotherapy with intrathecal methotrexate. After chemotherapy she received complete craniospinal irradiation (36 Gy+20 Gy boost). Oncologic follow up did not reveal recurrence of medulloblastoma. Endocrinologic workup revealed GH deficiency, but no other pituitary hormone deficiency. GH therapy was not recommended since her history of malignant tumor. At the age of 15 she presented with neck lymphadenopathy and was found to have papillary thyroid cancer. She underwent total thyroidectomy and radioiodine therapy in 4 sessions with a cumulative dose of 800 MBq. Regular endocrinologic follow up with tumor markers and imaging did not reveal evidence of thyroid carcinoma recurrence. At the age of 27 she became pregnant. Her early pregnancy was complicated by gestational diabetes as well as an ovarian cyst, for which she underwent exploration laparotomy and left adnexectomy while 23 weeks pregnant. In the 37th week of her pregnancy during a routine endocrinology appointment she was found to have icterus, therefore urgent C-section was recommended. Since the icterus did not resolve after the delivery she had an ERCP and a biliary stent was placed. MRCP showed an intrahepatic tumor. Initial biopsy showed adenocarcinoma with an unknown pancreatic vs gastric vs biliary source. She had a percutan transhepatic drain placed. Subsequent exploratory laparotomy showed peritoneal carcinosis and biopsy revealed cholangiocarcinoma. Due to the extent of her disease surgical treatment was not possible, but palliative chemotherapy was planned. This had to be postponed due to bilateral pulmonary emboli. In the interim her disease has further progressed and she unfortunately passed away before she could have started her treatment.
While having thyroid cancer after irradiation for medulloblastoma could be accounted for the irradiation itself, the development of this patient's third tumor raises the possibility of a genetic abnormality leading to development of multiple tumors. We are currently conducting genetic testing to further investigate this possibility.

EP267

Raised Metanephrines in SDHB mutation- the hunt for the source

Sing Yang Sim & Ma'en Al-Mrayat
SO16 6YD, Endocrinology, Southampton, United Kingdom

We present a case of a 24 year old lady with known SDHB mutation. She was referred from the genetics clinic in view of a strong family history of premature paraganglioma at the age of 17. On initial clinic assessment she exhibits no symptoms suggestive of paraganglioma or pheochromocytoma. Her blood pressure is normal at 120/75. pulse of 60–80bpm. Physical examination was unremarkable Her Plasma normetanephrine done on two separate occasion were elevated at 1600 pmol/l and 2157.5 pmol/l (upper limit 1180) urine normetanephrine 5.7 umol/24 hours (upper limit 3), raised urine metanephrine at 6.4 umol/24 hrs. Her 123I-MIBG scan 1 year ago showed physiological distribution in the salivary glands, liver, supra renal regions and bowel with excreted activity in the urinary bladder. SPECT/CT images of the abdomen suggested some enhancement in the left pelvis in but it was felt likely to be normal activity from an ovary given her age. An MRI of the abdomen was normal and octreotide scan show no scintigraphic evidence of avid octreotide disease, tracer uptake was normal. She subsequently presented with urinary symptoms with increased frequency and constant pressure in the bladder. with persistently elevated metanephrines. An ultrasound scan of her pelvis showed an irregular solid highly vascular mass which measures $24 \times 20 \times 21$ mm. A repeat MRI neck, chest abdomen and pelvis found a 24 mm likely paraganglioma exophytic of the left wall of the bladder. Her MRI pituitary gland was normal. She was alpha and beta-blocked prior to surgery. She undergone an open excision and partial cystectomy for her paraganglioma. Her histology findings are consistent with a perivesical paraganglioma with Ki67 proliferation index of (1–2%). Her urinary function has returned to normal and she is due further follow up by the endocrinology team.
Conclusion
Urinary bladder paraganglioma is an unusual tumour arising from chromaffin cells of the sympathetic system of the urinary bladder wall accounting for<0.05% of all bladder neoplasms, often occurs in young female. (1) They are frequently located at the dome or the trigone of the bladder and may be non-functional or functional (2) Mutations in SDHB are the most commonly found gene mutations and are associated with younger ages at presentation, higher rates of metastases and poorer prognosis(1) We highlight the value of pelvic ultrasound in screening and diagnosis of bladder paraganglioma as the sensitivity for detection of familial PHEO and paranganglioma through MIBG scintigraphy is about 53–60.9%.(3)

EP268

How much time is spent on electronic prescribing in an endocrinology outpatient clinic?

Ioannis Ilias, Ioannis Kakoulidis, Stefanos Stergiotis, Stefanos Togias & Eftychia Koukkou
E Venizelou Hospital, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece

Introduction
In a US study of general practitioners, 50%-60% of their working time was found to be dedicated to paperwork and electronic medical record-keeping (including electronic prescription – EPC writing)[1].
Aim
Given the mandatory use of EPC in Greece, we wanted to assess the time required for this in the daily practice of our outpatient endocrinology clinic.
Method
In one of the outpatient (OUP) clinics of the Department of Endocrinology, Diabetes and Metabolism of a secondary women's hospital, the time corresponding to EPC was compared to the time spent in the OUP (regarding history taking, clinical examination & laboratory results' assessment). At the daytime OUP clinic, four specialists and three fellows, all with>5 years of EPC experience, examine all regular and emergency cases (there are no personal appointments). In the OUP, EPC is handled exclusively by physicians who take care of the individuals examined. The Webtime Tracker application was used to estimate EPC time, while the time required for EPC in days of general and gestational endocrinology (GE+G) clinics was compared to time spent on EPC in days of type 1 & 2 diabetes patients clinics (GE+D). Differences in EPC time were assessed by the Kruskal Wallis (KW) test, setting the statistical significance at the level of 0.05.
Results
In 101 man-hours of an OUP clinic (GE+G: 77 hours and GE+D: 24 hours), 471 subjects were examined (GE+G: 366 and GE+D: 105 subjects, respectively). The percentage of time spent on EPC was 33% overall (Q25–75: 25% –40%). More specifically, the distribution of EPC time was GE+G: 35% (Q25–75: 25% –41%) & GE+D: 32% (Q25–75: 24% –37%), respectively (KW $P>0.1$).
Discussion
A significant proportion of OUP work time was devoted to EPC, without differences on the type of clinic. In health systems, everyone is creating information that produces more bureaucracy, while doctors do not plan much of the latter[2]. Hospital doctors in Greece receive little help to serve bureaucracy and hospitals do not invest in their secretarial and administrative support. If these problems are not addressed, doctors will have less and less time to examine and treat patients.

Multiple endocrine neoplasia: A case series of 7 families

Vitória Duarte[1], Catarina Ivo[1], David Veríssimo[1], Mafalda Marcelino[1], Henrique Vara Luiz[2], Sara Franco[2], Filipa Bastos[2], Isabel Manita[2], Luisa Raimundo & Jorge Portugal[2]
[1]Hospital das Forças Armadas, Lisboa, Portugal; [2]Hospital Garcia de Orta, Almada, Portugal

Introduction
Multiple endocrine neoplasia (MEN) is a rare genetic syndrome characterized by occurrence of tumors involving two or more endocrine glands. Four types are described: MEN1, MEN2, MEN3 and the recently identified MEN4. Due to the complexity of the syndromes, it is difficult to manage these patients. Our objective was to describe the clinical features of individuals from 7 families with a diagnosis of MEN1 or MEN2 and identify current challenges in clinical practice.
Case series

1. Female, 48, presented with appendicitis at the age of 40. Pathology reported a neuroendocrine tumor (NET). Later, she was diagnosed with primary hyperparathyroidism (PH) and pituitary adenoma. The diagnosis of MEN1 was made at 44. Both her children have the mutation.
2. Female, 38, presented with prolactinoma at 18 and was prescribed dopamine agonists. Due to infertility, she was referred to assisted reproductive technology and later was diagnosed with PH and NET. The diagnosis of MEN1 was made at 37.
3. Female, 66, presented with acute pancreatitis at the age of 49. An abdominal MRI revealed nodular lesions of the pancreas. The pathology reported NET. Later, she was diagnosed with PH and pituitary adenoma. The diagnosis of MEN1 was made at 59. She has two children, 1 with the mutation.
4. Female, 50, presented with hypothyroidism. A thyroid ultrasound revealed a large nodule. The cytology reported medullary thyroid carcinoma (MTC). The diagnosis of MEN2 was made at 46. She has five children, 2 with RET mutation. Both underwent prophylactic surgery.
5. Female, 74, presented with goiter and had total thyroidectomy (TT). The cytology reported MTC. The diagnosis of MEN2 was made at 68. She has 3 children and 4 grandchildren with the mutation. One of them, 18 years, rejected prophylactic surgery. All other family members underwent TT.
6. Male, 60, presented with MTC and pheocromocytoma at 40. Genetic testing revealed no RET mutation. He has 3 children.
7. Male, 58, diagnosed with acromegaly at 36 years, had surgery and is treated with somatostatin analogs. At 46, he underwent left nephrectomy for a renal mass. At 48, he presented PH. Genetic testing revealed no MEN1 mutation. Suspicion of MEN4.

Discussion
From our series, the main clinical challenges were:
Pregnancy in MEN1 patients (case 2);
Rejection of a prophylactic surgery (case 5);
Clinical diagnosis and surveillance after a negative genetic screening (cases 6–7).
We reviewed the literature and discuss the management of these patients.

All with men 2A in one family?

Diana-Georgiana Lazar[1], Sorana L. Vasilescu[1], Sabina Elena Oros[1,2], Anda Dumitrascu[1], Romeo Smarandache[1] & Andra Caragheorgheopol[1]
[1]'C.I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania

Multiple endocrine neoplasya type 2 (MEN-2) is a rare hereditary complex disorder caused by a germline activating mutation of the RET proto-oncogene. The estimated prevalence is approximately 1:30.000. Three clinical forms have been described depending on the phenotype: MEN2A (80%), MEN2B and familial medullary thyroid carcinoma (MTC).
Clinically, MEN2A present with MTC (80–100%), unilateral or bilateral pheocromocytoma (40%) and primary hyperparathyroidism (25%) and ocasionally with cutaneous lichen amyloidosis/Hirschprung disease, within a single patient.
Case report
A 50-year-old male patient, hypertensive and diabetic, was reffered to us with MEN 2 suspicion. He presented in a general hospital with nonspecific symptoms: abdominal and low back pain, loss of appetite, vomitting and weight loss; while his 23-year-old daughter has already been diagnosed in our hospital with MEN2A syndrome with a rare high risk RET mutation (Cys634Tyr). Anterior abdominal CT scans revealed bilateral adrenal masses. Hormonal tests suggested high plasma and urinary metanephrines (MN-1.015 pg/ml, 5.806 mg/24 h) and normetanephrines (NMN-2.545 pg/ml, 7.696 mg/24 h), high cromogranin A(538 pg/ml) confirming pheocromocytoma. Thyroid ultrasound described a non-homogeneous, vascularized right lobe macronodule with calcifications. High levels of calcitonin(1858 pg/ml) and CEA (75.27 ng/ml) with bilateral pheocromocytoma confirmed MEN2A. The patient underwent bilateral adrenalectomy performed by the team of doctors Paun and Beuran and total thyroidectomy this january. Histopathological exam confirmed bilateral multifocal medullary carcinoma – T2 mNxMo. His family was invited for MEN screening, but his son is refusing and his brother is postponing the investigations. His 27-year-old nephew, with no clinical features, came for investigations. Hormonal test highlighted high plasma and urinary MN(448 pg/ml, 956 mg/24 h) and NMN(504 pg/ml, 760 mg/24 h), high calcitonin (1244 pg/ml) and CEA (42.02 ng/ml) and thyroid ultrasound that showed a left lobe nodule with calcifications. An abdominal CT scan was performed and revelead a right adrenal nodule and left adrenal hyperplasia. Both men's genetic testing highlighted the same high risk RET mutation (Cys634Tyr).
Particularities
An early onset of the syndrome and the presence of an high risk mutation in his family suggest for an highly aggressive phenotype of the syndrome. A notable intra-familial variability in disease aggressiveness was observed because her father presented with late onset of the MEN2A and developed complications.
Conclusions
Simultaneous apparition of bilateral pheocromocytoma and MTC in a patient are mandatory for further investigations and detailed genetic screening to all members of the family. Thus, early diagnosis and regular follow-up can provide a better outcome, but the prognosis in variable.

Iodine status in the Faroe Islands among adults aged 40–74 years old

Herborg Johannesen[1], Gunnar Knudsen[2], Stig Andersen[3], Pál Weihe[4] & Anna Sofía Veyhe[4]
[1]National Hospital of the Faroe Islands, Endocrinology and Internal Medicine, Thorshavn, Faroe Islands; [2]University of the Faroe Islands, Thorshavn, Faroe Islands; [3]Aalborg University Hospital, Department of Clinical Medicine, AAU Arctic, Aalborg University., Aalborg, Denmark; [4]Department of Occupational Medicine and Public Health, Thorshavn, Faroe Islands

Objective
The aim of this study was to examine the urinary iodine concentrations (UIC) in an adult population in the Faroe Islands. Iodine status in the adult population assumed to be sufficient due to the high frequency of seafood consumption1 although UIC has not been investigated previously in the Faroe Islands. World Health Organization recommends monitoring iodine status in all populations. Iodine nutrition is a key determinant of thyroid disease risk
Design
A population-based cross-sectional survey was conducted in 2011–2012 a sub-group donated a urinary sample. We measured iodine concentrations in 491 participants, 294 men and 197 women aged 40–74 years.
Methods
Urine samples were stored at minus 80 degrees Celsius. Iodine level is determined in microgram/liter (mg/l) by the ceri/arsen method after alkaline ashing.
Results
The median UIC was 101 mg/l (21 to 1870 mg/l). Severe deficiency did not occur in this study group (UIC,<20 mg/l); 10% of the participants were moderate insufficient (UIC<50 mg/l). In total 36% were in the target range (UIC, 100–199 mg/l) but 38% were mild insufficient. Nearly 15% had higher levels than recommended (UIC≥200 mg/l). Smoking habits did not affect the results. There was not significantly differences in age groups as seen in other studies. Overall UIC was significantly higher in males 115 mg/l than females 86 mg/l ($P<0\times001$).

Conclusion
It is important not only that the median iodine intake is sufficient, but also to consider the total iodine exposition in the population. With nearly half, the study population moderate to mild deficient as determined by WHO criteria especially the status in females could be a cause for concern. Health authorities need to form an opinion about and taking a position on Iodization program and regular assessment of iodine nutritional status is needed.

Effect of pregnenolone derivatives on the selective inhibition of 5α-reductase 2 activity

Marisa Cabeza[1], Lucero Bautista[1], Eugene Bratoeff[2], Juan Soriano[3] & Yvonne Heuzr[4]
[1]Universidad Autónoma Metropolitana-Xochimilco, Sistemas Biológicos, México D.F., Mexico; [2]Universidad Nacional Autónoma de México, Farmacia, México, Mexico; [3]Hospital General de México, Patología, México, Mexico; [4]Universidad Autónoma Metropolitana-Xochimilco, Producción Agrícola y Animal, Mexico D.F., Mexico

Benign prostatic hyperplasia and prostate cancer are androgen-dependent diseases. Dihydrotestosterone (DHT) is a 5α-reduced metabolite of testosterone (T), which is the causative factor for the progression of these diseases. The 5α-reductase enzyme (5α-R) converts T to DHT, which is responsible for increasing cell proliferation, and hence inhibition of this enzyme could lead to potential treatments for these afflictions. This study aimed to determine the biological activity of three series of pregnenolone derivatives as inhibitors of 5α-R. Also, these molecules evaluated as antiandrogens on androgen-dependent glands. The biological activity of these derivatives was determined by the concentration of each one needed to suppress the activity of both 5α-R types 1 and 2 isozymes by 50% (IC_{50}). The effect of these derivatives on the weight of the prostate, seminal vesicles, and diameter of the flank organs of castrated hamsters previously dosed with 1 mg/Kg T was also established. *In vitro* experiments showed that derivatives **1f**, **2b**, and **3d** were very effective inhibitors of the activity of 5α-R2, showing IC_{50} values of 21.8, 20, and 15 nM, respectively. However, derivatives **2b** and **3b** showed a lower inhibition effect on 5α-R1. The data also indicated that derivatives **2b**, **1f**, **3b**, and **3d** were very active in reducing prostate weight in the hamster model of benign prostatic hyperplasia as well as seminal vesicle weight and the diameter size of the pigmented spot of flank organs. Therefore, pregnenolone derivatives studied suppressed type 2 5α-reductase activity, and because of this, the weight and dimension of androgen-dependent organs decreased.

Testosterone modulates the corticotropin releasing hormone-induced pro-oxidant activity in macroendothelial cells

Maria Filiponi[1], Sophia Gougoura[1], Christina Befani[2], Alexandra Bargiota[1], Panagiotis Liakos[2] & Georgios Koukoulis[1]
[1]Laboratory of endocrinology and metabolic disorders, Endocrinology clinic of Peripheral University Hospital, Larissa, Larissa, Greece; [2]University of Thessaly, Larissa, Laboratory of Biochemistry, Department of Medicine, Larissa, Greece

Introduction
Limited data, support the notion that testosterone induces oxidative stress. Corticotropin-releasing hormone (CRH) participates locally in the endothelial inflammatory response by regulating the pro-oxidative mechanisms of the endothelium, inducing its adaptation to local stress. The present study was undertaken to determine whether the CRH induced pro-oxidant activity in macroendothelial cells under basal conditions, is regulated *In vitro* by androgen (testosterone-DHT).
Materials and methods
EA.hy926 endothelial cells were cultured in DMEM phenol red free without FBS for 24 hours. Growth medium was replaced and then CRH (10^{-7} M), and CRH plus testosterone (0.5nM) or DHT (0.5nM) alone or in combination with the androgen receptor antagonist flutamide (50nM), were added to the culture media and cells incubated for 2 more hours. Intracellular reactive oxygen species (ROS) content, endothelial nitric oxide synthase (eNOS) activity, nitric oxide (NO) levels, superoxide dismutase (SOD) activity, catalase activity (CAT), and glutathione (GSH) levels were measured.
Results
Testosterone and DHT abolished the CRH-dependent decrease of eNOS ($P<0.001$ vs CRH) and NO ($P<0.001$ vs CRH), as well as the increase of catalase activity ($P<0.001$ vs CRH). Moreover, both androgen amplified the CRH-dependent increase of oxidative burden ($P<0.001$ vs CRH) and SOD activity ($P<0.05$ vs CRH). All the above effects of androgens were abolished by flutamide suggesting action through the androgen receptor. Finally, testosterone and DHT had no significant effect on cellular GSH levels and the GSH/GSH+GSSH ratio in EA.hy926 cells.
Conclusion
Our findings indicate that in endothelial cells, *In vitro*, testosterone and DHT modulate the pro-oxidant effect of CRH, by relieving its inhibitory effect on eNOS and NO release and exacerbating its stimulatory effect on intracellular ROS levels as well as the SOD activity levels while restoring its stimulatory effect on catalase activity.

Poor lifestyle as a risk factor for endocrine pathology among medical students

Liza Mirkovskaya[1,2]
[1]Foothill College, Los Altos Hills, United States; [2]UNMU School of Medicine, United States

Medical students around the globe undergo serious amounts of stress related to adjustment to the rigors of medical curriculum, to change of roles, and other factors intrinsic to medical education. Research has shown that stress among medical students is associated with generally lower academic performance and lower job satisfaction once physicians. The goal of this study was to analyze the influence of healthy lifestyle practices not only on medical students' health overall, but specifically on prevalence of endocrine pathology among medical students. 235 medical students from 11 countries participated in the study. Students were both those who studied in native languages to those countries and those enrolled in English language programs. Overall, over 20 cultural and ethnic back-grounds were represented. Medical students were asked to self-report their lifestyle practices (diet, exercise, alcohol and tobacco use, sleep quality, level of stress), occurrences of endocrine disorders, and academic performance in medical school. The following standardized peer-reviewed assessment instruments were used: Simple Lifestyle Indicator Questionnaire (SLIQ), Brief Insomnia Questionnaire (BIQ), questions regarding general overall academic performance, as well as performance on standardized tests (USMLE-like) during medical school. While prevalence of endocrine disorders generally is around 5–6%, in our sample 12% of medical students experienced some form of endocrine pathologies. Students seemed to have overall higher scores on the Exercise subscale of SLIQ than on the Diet subscale, which implied that these medical students' diets are generally worse than their exercise habits. Medical students' stress and sleep scores exhibited a negative, medium-strength correlation, suggesting that that lack of sleep and higher reported stress levels are associated. On average, students with endocrine pathology reported higher academic overall performance and higher licensing exams test scores. Medical students' SLIQ and BIQ scores inversely correlated, which suggested that poorer lifestyle choices were associated with greater insomnia.

Endocrinopathy in patients with glomerulonephritis undergoing renal biopsy – single center observation

Agnieszka Gala-Bladzinska[1,2], Renata Orłowska-Florek[1,2], Joanna Sztembis[1], Katarzyna Rałowska[2], Anna Opalińska[2], Julia Nawrocka[2], Aleksandra Pich[2] & Karolina Wojton[2]
[1]St` Queen Jadwiga Clinical District Hospital No2 in Rzeszów, Department of Internal Medicine, Nephrology and Endocrinology, Rzeszów, Poland; [2]Medical College of Rzeszow University, Institute of Medical Sciences, Rzeszów, Poland

Introduction
Endocrine disorders and kidney diseases can coexist. Some of these have a common pathophysiological background. Strategies for treating endocrinopathy or glomerulonephritis (GN) may affect the function of the endocrine system and kidney.
Aim
The study was aimed to assess the correlation of kidney biopsy results performed in people with suspected GN with thyroid function, metabolic syndrome and diabetes occurrence.
Material and methods
The research consisted of retrospective analysis the data of 233 (79.8% women) patients, the age range of the group was 7–79 (44.5±17.4), hospitalized in our clinic from 2013 to 2019 (75 months) who underwent renal biopsy due to suspected GN.
Results
The most common indications for renal biopsy were: nephrotic syndrome (n=84; 36%), no nephrotic proteinuria (n=24; 10.3%), worsening renal function (n=91; 39.1%), nephritic syndrome (n=34; 14.6%). Membranous glomerulonephritis (n=33; 14%), rapidly progressive glomerulonephritis with extra capillary crescents (n=21; 9%) and focal segmental glomerulosclerosis (n=21; 9%) was the most common histological diagnosis observed in kidney biopsies. Our analysis proved higher occurrence of thyroid dysfunction: hypothyroidism (n=29; 12.4%), low FT3 syndrome (n=30; 13.1%), subclinical hypothyroidism (25; 10.7%). Diabetes coexisted in 32 (13.73%) patients, whereas diabetic nephropathy (DN) was found in renal biopsy only in 6 (2.57%) patients. Many patients had steroid-induced diabetes (14%). There wasn't higher occurrence of obesity (27.1%) and overweight (24.9%). Arterial hypertension coexisted in 108 (46.3%) patients.
Conclusions
Additional diagnosis for thyroid pathology is worth to be considered in monitoring patients with GN. A small percentage of diabetics had features of DN in kidney biopsy. There was no higher occurrence of obesity and overweight in the population with GN.

Aging, depression and movement

Marie Bicikova[1], Ludmila Macova[1], Dobroslava Jandova[2] & Zdenek Triskala[3]
[1]Institute of Endocrinology, Steroid Hormones and Proteofactors, Prague 1, Czech Republic; [2]Charles University, Third Faculty of Medicine, Prague, Czech Republic; [3]Ministry of Health of Czech Republic, Prague, Czech Republic

Old people will have to take care of themselves as long as possible. The challenge for the future is therefore not to extend human age at all costs, but to extend human self-sufficiency. Two years ago, we showed that patients with anxiety and affective disorders ('depression') felt great after a month's stay at the spa, improved in a number of endocrinologic parameters. In this work we try to explain the physiological changes of stay in a spa without pharmaceuticals or medicinal waters, without peloids (peat) 'only' climatotherapy and kinesiotherapy (movement). To some extent, the characteristics of aging are common to depression. In old age, the production of hormones such as serotonin (5-hydroxytryptamine) and melatonin (5-methoxy-N-acetyltryptamine) decreased. Important is the oxygenation of the body movement especially in healthy air, a varied diet rich in amino acids. Aging is often accompanied by loss of muscle mass – sarcopenia. No pharmacological or behavioral intervention targeting sarcopenia has been shown to be as effective as exercise. The state of mind and the emotional (limbic) system also have an impact. High blood pressure and thus cardiovascular disorders may also be caused by the formation of autonomous aldosterone-producing clusters, which were recently proven. Aerobic exercise: preferably a quick walk leads to the maintenance of baroreflex, muscle mass adjustment and thus to the strength of an aging individual. The explanation lies in function of the limbic system: control of anxiety and fear, control of social and emotional; behaviour; participation in short-term memory processes; cardiac and respiratory control (connection to the hypothalamus); secretion of endocrine glands. The hypothalamus through the limbic system (of which it is an integral part) affects movement and backwards. It connects the olfactory stimulus, eye perception, auditory perception, skin perception during movement, all information from the equilibrium and basal ganglia and movement planning (cortex, prefrontal and frontal cortex). In conclusion, it can be said that for aging people, matters the same as to patients who have undergone spa treatment. Persons who often and even moderately move in healthy air and who follow regime measures i.e.: sleep and diet rich in vitamins – hope that the positive changes that have occurred in his organism could persist for many weeks or months, long-term stabilizing and anti-progressively in terms of healthy aging.

Glioma of the optic pathways revealed by a nystagmus

Aicha Bouzid[1], salah gasri[2], Djamila Meskine[3] & Said Azzoug[4]
[1]Algiers, Medical university of algiers, Endocrinology & Métabolism Laboratory Algiers 1,EPH Beloghine, Medecine, Algiers, Algeria; [2]Annaba, Medecine, Annaba, Algeria; [3]Medical university of algiers. EPH BOLOGHINE, Medecine, Algiers, Algeria, Medecine, Algiers, Algeria; [4]Medical university of algiers, Endocrinology & Metabolism laboratory Algiers 1, Medecine, Algiers, Algeria

Abstract
Gliomas of the optic pathways are rare tumors that are mainly seen in children. We report the case of a 4 year old boy followed since the age of 6 months for a nystagmus. It is a boy born at term by vaginal way resulting from parents not consanguineous, the parents noted the nystagmus when their child was 6 months old. After opinion of the ophthalmologist, the child is treated only by optical correction, it is only at the age of 4 years following the installation of headache that a brain MRI is performed revealing a tissue damage process expansive solido cystique, supra sellaire developed at the expense of the chiasma, the cystic portion of which is posterior and the anterior solid portion measuring 31 × 38 × 36.6 mm. The child was referred to neurosurgery for treatment and then referred to our service. The ophthalmological examination finds a nystagmus without strabismus or exophthalmos. Visual acuity could not be appreciated given the age of the child. Examination of the fundus revealed a bilateral sectoral optic atrophy. The somatic examination did not find café au lait spots or other lesions that could suggest neurofibromatosis. The neurological examination is normal, in particular no intracranial hypertension syndrome. Endocrine examination is without abnormalities.
Discussion
Tumors of the optic pathways are dominated by glioma and then meningiomas. Gliomas are the most common brain tumors in children and adolescents, boys are affected twice as often as girls. These tumors include forms of very good prognosis such as pilocytic astrocytoma, and types much more difficult to treat such as infiltrating glioma of the brainstem. Low-grade (benign) gliomas are more common in younger people, while malignant gliomas affect older children or adolescents. The decrease in visual acuity is the first sign of ophthalmological appeal, however the decrease in visual acuity may go unnoticed in young children in whom the tumor may be revealed by nystagmus or strabismus.
Conclusion
The therapeutic management of gliomas of the optic pathways goes from simple clinical and radiological monitoring, to surgical treatment or chemotherapy or radiotherapy.

Physicians' attitudes towards pharmaceutical promotion: Investigation in endocrinology

Ines Kammoun[1,2], Thara Larbi[3], Hajer Kandara[1], Radhouane Gharbi[1], Skander Mrad[3] & Manel Jemel[1]
[1]National Institute of Nutrition, Endocrinology, Tunis, Tunisia; [2]University Tunis El Manar, Medical School of Tunis, Tunis, Tunisia; [3]Mongi Slim Hospital, Internal Medicine, Tunis, Tunisia

Recently, special attention has been paid to the relationship between doctors and the pharmaceutical industry. The aim of this work was to evaluate the attitude of Tunisian endocrinologists towards pharmaceutical promotion.
Methods
It was a cross-sectional study based on an anonymous 9-item survey about the attitudes and behaviors of physicians towards the pharmaceutical promotion. The study included 120 participants.

Results
One-third (34.2%) of the physicians didn't complete the survey. We analyzed the responses of 75 participants: 32 residents and 43 specialists. The inexpensive gifts were appreciated by the majority of participants. Costly gifts were judged less frequently appropriate, especially by specialists ($P<0.001$). However, these expensive gifts were received or desired by many participants, and significantly more by residents than specialists. Among residents, 9.4% and 15.6% thought that respectively their prescriptions and those of their colleagues would be highly influenced by promotion ($P=$ns). This difference was significant among the specialists: respectively 4.7% and 35.3% ($P=0.002$). Training about conflict of interest is inadequate or non-existent according to 96.8% of residents and 97.6% of specialists ($P=$ns). Contact between learners and medical visitors was to be prohibited based on 9.4% of residents and 36.6% of specialists ($P=0.007$).
Conclusions
The majority of participants confirmed that they received or wanted to receive gifts from the pharmaceutical industry, but they said that this did not affect their prescriptions. Literature shows that gifts, however small, are very effective in subtly changing the therapeutic attitudes of physicians. Awareness is needed to ensure an independent medical prescription in our hospitals.

Myasthenia gravis during anti PD-1 therapy

Katarzyna Jankowska & Wojciech Zgliczynski
Center of Postgraduate Medical Education, Endocrinology, Warsaw, Poland

A 66-year-old patient was diagnosed with lung cancer. In the interview, smoking for 40 years, about 20 cigarettes/day. Due to the intensifying cough, an x-ray of the chest was performed, a large tumor (12 cm) of the mediastinum and the right cavity was found. In the histopathological examination squamous cell carcinoma. Stage T4 N2 M0. Due to tumor inoperability, the patient was qualified for sequential chemo-radiotherapy. He received 3 cycles of chemotherapy (navelbin and cisplatin). After the chemotherapy, the lesion decreased to 6 cm, but it still infiltrated the division of the right and intermediate bronchi, and was still adjacent to the division of the right pulmonary artery and superior vena cava. Radiotherapy was used, however, in the control chest CT the dissemination of the disease was described: new changes appeared in the right lung apex up to 2.5 cm. In view of the progression of the disease, it was decided to take another type of treatment. The patient was referred to a center where immunotherapy is used. The histopathological block was examined again, immunological tests were performed. Tumor receptors have been shown to be present. The patient was qualified for anti-PD1 immunotherapy. Drug treatment brought excellent results. The lesion significantly decreased, peripheral lesions in the right lung disappeared. However, autoimmune hypothyroidism has emerged and requires levothyroxine therapy. Adrenal function remained normal. Treatment tolerance was very good. After a year of using immunotherapy, there was a significant weakness and decrease in muscle strength. The patient left home only for short walks, even clothing caused significant fatigue. It was difficult for the patient to raise their arms. Shortness of breath appeared, breathing air into the lungs was a big effort. The reason for the weakness was not adrenal insufficiency or pneumonia. Myasthenia gravis was suspected because of eyelid drooping and speech silence. Anti-acetylcholinesterase antibodies were determined. Their presence confirmed the diagnosis of myasthenia gravis. Pyridostigmine (acetylcholinesterase inhibitor) therapy was initiated. No ANA antinuclear antibodies or myositis panel antibodies were detected. Significant improvement in the patient's condition was achieved after initiating pyridostigmine treatment. The drug was used in a dose of 60 mg every 4 hours. The patient is in a very good general condition, he is continuing immunotherapy.

Rare occurence of two metachronous bladder tumours, of which one is neuroendocrine

Daniela Ioana Iulia Greere[1], Iulia Florentina Burcea[1,2], Roxana Dusceac[1,2], Luca Bottiglieri[3] & Catalina Poiana[1,2]
[1]''C.I. Parhon' National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [3]European Institute of Oncology, Divisione di Anatomia Patologica, Milano, Italy

Introduction
Neuroendocrine tumors (NETs) are rare tumors that originate in cells from the neural crest, widely distributed in the body. Genitourinary (GU) NETs occurring in the bladder represent less than 1% of these primary malignancies. We present the case of a patient with two metachronous bladder tumors, of which one is NET.
Case report
Male patient, 52–year-old, ex–smoker, known with hypertension, dyslipidemia and benign prostatic hyperplasia came to our clinic following the diagnosis of a neuroendocrine tumour of the bladder. Three years prior to presentation, after gross hematuria, transurethral resection of a bladder tumor (TURB) was performed. The histopathological examination revealed urothelial carcinoma of high grade (G3) infiltrating the lamina propria, with patterns of glandular differentiation; no invasion in the muscularis propria. After surgery, the patient developed left orchitis. 10 months later, imaging follow-up identified a second bladder tumor for which TURB was performed again. The histopathological examination revealed small cell neuroendocrine carcinoma (SCC) with immunoreaction positive for synaptophysin, chromogranin and p16 and a Ki-67 index of 95%. The patient refused radical cystectomy and underwent 4 cycles of Cisplatin and Etoposide combination chemotherapy, well tolerated. Whole body positron emission tomography was negative – the investigation was, however, inconclusive, because of the physiological urinary elimination of radiopharmaceutical. Native computed tomography of the thorax and abdomen and contrast-enhanced magnetic resonance imaging of the pelvis confirmed the absence of recurrent or metastatic disease. No preoperative neuroendocrine tumour markers values are available, but following the second surgery, serum chromogranin A, serotonin, neuron-specific enolase and urinary *5*-hydroxyindoleacetic acid are within reference range. Ecocardiography showed hypertensive cardiomyopathy. The patient denies *symptoms* of carcinoid syndrome.
Conclusion
GU NETs are very rare and usually affect women. Moreover, male GU NETs commonly involve the prostate. Last, but not least, SCC is an aggressive neoplasm that usually occurs at advanced stages, in senior population (male: female ~ 3:1) and, in approximatively 50% of cases, it is mixed with urothelial carcinoma, adenocarcinoma, squamous cell carcinoma, and/or may have sarcomatoid features. Thus, the only features in accordance with the literature are the patient's gender, history of cigarette smoking and no association with paraneoplastic syndromes. In conclusion, bladder SCC is a rare tumour whose generally poor prognosis was much improved in this case by diagnosis and treatment in the presymptomatic and presecretory stage. The peculiarity of the case further consists of the high Ki-67 index (95%) and history of urothelial carcinoma.

Inspection of the internal jugular vein pulse appears to be superior to impedance analysis for determination of volemia in a Hyponatremia outpatient clinic

Celia Lopez Nevado, Sandra Vadillo, Adriana Villareal, Jorge Ruiz, Martin Cuesta, Xavier Perez Candel, Elvira Barrio, Angelica Larrad, Alfonso Calle Pascual & Isabel Runkle
Hospital Clínico San Carlos, Servicio de Endocrinología y Nutrición, Madrid, Spain

Measurement of electrical impedance has been proposed as a way to determine whether a hyponatremic patient is hypovolemic or euvolemic. We compare the usefulness of the physical examination (PE) with bioimpedance for determination of volemia in an outpatient hyponatremia clinic.

Method
Descriptive prospective analysis. 11 patients attended at the hyponatremia clinic of a tertiary hospital were evaluated. Impedance was measured by a SECA, indicating the percent of weight corresponding to body water. Furthermore, by applying internal algorithms, SECA indicates whether total body water (TBW) and extracellular body water (EBW) are normal, increased, or reduced in a given patient, based on body composition, gender and age. Results were compared with 'gold standard' evaluation of volemia by inspection of the maximum height of the internal jugular vein pulse (PE). Patients were considered euvolemic if the pulse was 1–3 cm above the sternal angle when reclined, and hypovolemic if found below the sternal angle.
Results
2/11(18%) women. Median age: 72 [IQR 14]. Four patients were hypovolemic by PE. In 3/4, TBW was found to be low by SECA. However, impedance found low EBW in only 1 patient. In fact, in 1 patient SECA analysis found ECW to be elevated. Based on PE, in 2 patients the tolvaptan dose was reduced, in another 2 fluid intake was increased. In all 4, clinical and analytical improvement ensued. In 3 patients who were euvolemic by PE, with serum sodium ≤ 135 mmol/l, SECA found TBW to be low, normal, or high, with corresponding ECBW low, high, and high respectively. Patients were told to reduce fluid intake. All had improved at follow-up. Four patients were eunatremic, and euvolemic by PE. SECA indicated low TBW in one, normal in 3. EBW was normal in 3, and upper limits in 1. Patient therapy was not modified. Patients were well at follow-up. SECA's findings of TBW diverged from its observed EBW in 6/11 patients. SECA's TBW report coincided with the PE in 7/11 cases, whereas SECA's EBW report coincided with the PE in 6/11.
Conclusion
In a Hyponatremia clinic, physical examination of the internal jugular pulse, directly indicating volemia, provides a better tool for clinical decision-making than impedance measurement. Furthermore, given that water diffuses freely between body compartments, SECA's discrepancy as regards total and extracellular body water is surprising. SECA impedance analysis appears to be of limited value in an outpatient setting for determination of volemia.

Pituitary metastasis as a rare cause of diabetes insipidus

Mehdi Kalthoum, Hajer Kandara, Meriem Adel, Manel Jmel, Radhouen Gharbi & Ines Kammoun
Institut De Nutrition, Tunis, Tunisia

Introduction
The most common cause of diabetes insipidus is idiopathic. In some rare cases, it can be secondary to metastasis to hypothalamic–pituitary region.
Case report
We report a case of 68-years-old female patient presented to our clinic with complaints of polyuria and polydipsia. She had medical history of breast adenocarcinoma 6 years ago treated with surgery, neoadjuvant radiotherapy and 8 cycles of chimiotherapy. On physical examination she had no notable pathological findings and the evaluation of daily urine volume was at 12 l/day. Laboratory data showed normal glucose and calcium level with plasma osmolality calculated 301 mosm/kg and hypotonic urine (Urine osmolality = 90 mos/kg). Water deprivation test revealed central diabetes insipidus and desmopressin therapy was started. After the therapy complaints of polyuria and polydipsia disappeared. MRI of the brain showed infiltration of the pituitary stalk compatible with metastases and absence of posterior pituitary bright spot. Further investigation showed multiple pulmonary and hepatic metastasis and the patient was referred to the medical oncology department.
Conclusion
Tumor metastasis to the pituitary gland is a rare condition that should be noted in a cancer patient with diabetes insipidus. A better understanding of its clinical manifestations could lead to earlier diagnosis, appropriate therapy and potentially improving quality of life.

Severe hypoglycemia in diabetic patient with long lasting undiagnosed empty sella syndrome

Sintija Sausa[1,2], Dace Seisuma[1], Liva Steina[1] & Valdis Pirags[1,2]
[1]Pauls Stradins Clinical University hospital, Endocrinology, Riga, Latvia; [2]University of Latvia, Internal Medicine, Rīga, Latvia

A 45 year old female was referred to the Endocrinology department with complains of severe fatigue and weakness from basic daily activities, also irregular menstrual circle during last five years. Twelve years back she had twin pregnancy, premature delivery on 29th week, and absence of lactation. Afterwards she gradually lost 6 kg of her body weight and her menstrual circle become sparse and disappeared five years back. 1.5 years ago type 1 diabetes was diagnosed (C-peptide below range, anti-insulin antibodies elevated), and patient immediately started intensified insulin therapy scheme. Despite of adequate diabetes education she regularly experienced hypoglycemic episodes even from very low insulin doses (2–3 IU of long acting insulin, 1–2 IU of short acting insulin) and was repeatedly hospitalized with hypoglycemic coma. Due fear of hypoglycemia patient rather preferred to skip injections and her last HbA1c was elevated (75 mmol/mol, 9%). Endocrine function tests revealed disturbed pituitary function: plasma TSH was within the normal range (2.5 uIU/ml) despite of markedly decreased FT4 (0.4 ng/ml) and elevated TPO antibodies; her morning plasma cortisol was decreased (0.54 mg/dl), yet ACTH was relatively low (6.84 pg/ml); plasma LH, FSH, estradiol, progesterone, testosterone levels were decreased. MRI scan revealed pituitary gland to be thinned out to less then 1 mm in size. Substitution therapy was immediately started with levothyroxine and hydrocortisone, which led to complete disappearance of hypoglycemic episodes. Within half a year patient regained 6 kg, her BMI become optimal. Her mental and bodily strength returned and she started to menstruate again.
Discussion
We demonstrate the case of female patient having hypopituitarism due to empty sella syndrome, coexisting with autoimmune thyroiditis and type 1. diabetes mellitus. However, it was difficult to determine the primary cause of hypopituitarism. Differential diagnosis in this case is between Sheehan syndrome, lymphocytic hypophysitis or combination of both. In conclusion, our case report is showing importance of testing of pituitary function within the endocrinology setting for unclear severe hypoglycemia in diabetic patients complaining of increasing fatigue and weight loss.

Secondary amenorrhea and large uterine myomas in a patient with acromegaly

Sanja Borozan[1] & Rada Sparavalo[2]
[1]Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro; [2]General hospital Niksic, Department of Endocrinology, Niksic, Montenegro

Menstrual irregularity is common in women with acromegaly, occurring in 40–84% of patients. Its pathogenesis is still not well established although it is usually attributed to prolactin excess and/or gonadotropin deficiency. Also, since the presence of growth hormone (GH) and insulin-like growth factor 1 (IGF-1) receptors is demonstrated in the myometrium, a pathogenetic role of GH in the development of myoma is examined through different studies. Moreover, some of them particularly emphasise increased risk of developing neoplasms in patients who had been untreated for a long period of time, pointing out the significance of an early diagnosis. A 40-year-old female underwent endocrine assessment for hypertensive paroxysms characterised with sudden rise in blood pressure, up to 190/120 mmHg, over the past 4 years despite the treatment with ACE inhibitor and calcium channel blocking agent. She also reported headaches, deepening of her voice, change in facial features, enlargement of hands and feet (shoe size increased in one number) and secondary amenorrhea. Family history was positive for carcinoma and heart disease. On physical examination, typical acromegalic features were present. Hormonal examination revealed IGF-1 554 ng/ml (58.2–219 ng/ml), IGFBP3 8.23 mg/ml (3.3–6.6 mg/ml), luteinizing hormone (LH) 8.23 mIU/l, follicle-stimulating hormone (FSH) 4.38 mIU/l, estradiol 90 pg/ml, testosterone 1.42 nmol/l along with a modest increase in serum prolactin level (999.74 mIU/l). Thyroid hormones, cortisol and PTH were all in reference range. Pituitary magnetic resonance imaging (PMRI) showed a macroadenoma 21 × 17 × 18 mm with extrasellar extension into the suprasellar region. Further examination showed two large uterine myomas measuring

88 mm and 64 × 56 mm respectively. The patient underwent transsphenoidal surgery and patohistology was consistent with plurihormonal somatotrophic adenoma (GH, prolactin, TSH). After surgery, Hydrocortisone supplementation was started. On six months follow-up, control PMRI demonstrated residual tumour 18 × 8 mm, GH 0.2...0.9 ng/ml, IGF-1 157 ng/ml, IGFBP3 4.80 mg/ml, LH 5.01 mIU/l, FSH 5.59 mIU/l, prolactin 92.74 mIU/l. Amenorrhea is still present along with occasional rises in blood pressure. The patient refuses a proposed surgical treatment of uterine myomas. Concerning patient`s current clinical status, the use of somatostatin analogue is beeing considered due to its effects on tumour rest and proposed role in a reduction in uterine and myoma volume. Menstrual abnormalities should be expected in woman with acromegaly. Therefore, all of them should undergo periodic screening for endometrial neoplastic lesions.

Acromegaly and glucose metabolism – A case report

Judit Denes[1], Csenge Hargittay[2], Erika Hubina[1], Zoltán Görömbey[1], Dóra Oláh[1], László Kovács[1] & Miklós Góth[1]
[1]Health Center, Hungarian Defense Forces, Division of Endocrinology, 2nd Department of Medicine, Budapest, Hungary; [2]Semmelweis University, Department of Family Medicine, Budapest, Hungary

Acromegaly is a rare disorder caused by growth hormone (GH) and insulin-like growth factor I (IGF-I) overproduction, associated with increased morbidity and mortality. It has different complications, among which insulin resistance, prediabetes and diabetes mellitus are substantial. GH affects glucose metabolism through different mechanisms. The therapy of GH overproduction (for example surgical or radiotherapy) improves glucose metabolism, while different types of medical therapy may worsen it. We present the medical history of an acromegalic patient, diagnosed at the age of 30 years. Although his GH-producing giant adenoma had been operated twice, only partial resection was achieved with intra- and suprasellar tumour remnant. He was initially treated with dopamine agonist, followed by a high dose of first-generation somatostatin receptor ligand (SRL) octreotide LAR. In the meantime, he developed type 2 diabetes mellitus. Since the acromegaly was still active, the therapy was changed to the GH receptor antagonist pegvisomant. Despite its high dose, we couldn't achieve biochemical control. Once the second generation SRL pasireotid LAR was available, ha was given 60 mg monthly, which improved his IGF-I levels, but worsened the glycaemic control. Because of tumour concern and impaired glucose metabolism, the acromegaly is now controlled by a pasireotide LAR and pegvisomant combination therapy. His diabetes is treated with insulin, metformin, SGLT2 inhibitor and a GLP-1 receptor agonist. An overproduction of the contra-insulin GH worsens glucose metabolism. Therefore, lowering pathologically high GH levels by surgery, medical or radiotherapy improves glucose homeostasis. On the other hand, first generation SRLs might worsen glucose metabolism, while second generation SRL pasireotide causes hyperglycaemia in the majority of cases. The optimal therapy for acromegalic patients should be individually taking into account different aspects of the disease.

Macroprolactinoma in an adolescent girl with secondary amenorrhea – A case report

Evangelia Venaki[1], Ioannis Kakoulidis[1], Anastasia Linardi[1], Foteini Petychaki[1], Stefanos Togias[1], Aikaterini Michou[1], Ioannis Ilias[1] & Eftychia Koukkou[1]
[1]El Venizelou Hospital, Department of Endocrinology, Diabetes & Metabolism, Athens, Greece

Introduction
Prolactinomas are rarely found in adolescents under 15 (incidence 0.1/1.000.000). They account for 50% of all types of pituitary adenomas in childhood and adolescence (2% of intracranial tumors). The mean time from onset of symptoms to diagnosis is 2.4 years on average for girls. In cases of macroadenomas, TSH and GH deficiency may coexist. The gold standard primary therapy is dopamine agonists. In case of non-response, or the presence of large prolactinomas with compressive effects mainly in the optic chiasm, surgical treatment is recommended.

Case presentation
A14$^{+2/12}$ year-old adolescent girl (weight: 67.6 kg, height: 1.57 m, BMI: 27.4 kg/m^2), was referred for secondary amenorrhea. On physical examination, she was at Tanner stage 3–4 for both pubic hair and breast development. She had facial acne and reported occipital neuralgia. Initial laboratory results showed serum PRL at 705.4 ng/ml (normal: 4.79–23.3 ng/ml). MRI revealed a pituitary macroadenoma (16 × 13 × 15 mm) in the right pituitary lobe that encircled the right carotid artery in the cavernous sinus, while slightly pushing to the left the rest of the gland, without suprasellar projection. The visual fields examination was normal. The patient was initially started on cabergoline 0.5 mg twice weekly and gradually titrated up to 0.75 mg twice weekly, leading to menstrual cycle reappearance. Due to continuous presence of marginally high morning cortisol blood levels at 691.5 nmol/l (normal: 171–536 nmol/l), the HPA axis was assessed with overnight dexamethasone suppression test, low dose dexamethasone test and 24 h urine cortisol levels. The results were within normal limits. Fifteen months later, an MRI revealed that the macroadenoma had degenerated and significantly decreased in size (10 × 11 × 14 mm), while the remaining gland was no longer deviated to the left, nor was the internal carotid artery significantly encircled. Prolactin levels were at 43.1 ng/ml.
Conclusion
Prolactinomas are rarely found in adolescents under 15 years of age. For early diagnosis and treatment, it is very important to assess pituitary gland function in adolescent girls with menstrual disorders or amenorrhea, especially when combined with headache or vision disorders.

Obesity in endocrine connections- a finding of nonfunctional pituitary macroadenoma

Iva Jakubíková[1], Simona Kratochvílová[1], Jana Brunová[1] & Václav Hána[2]
[1]Diabetes Centre, Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [2]Third Department of Internal Medicine, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic

Introduction
Spacious sellar area predisposes to late diagnosis of nonfunctional pituitary adenomas and in males even the functional ones such as prolactinomas. Rising prevalence of obesity is mainly associated with sedentary lifestyle and excess of food intake. Only in rare cases has endocrine etiology such as Cushing disease, hypothyroidism or hypothalamic disorders.
Case-report
A 29-year-old man was admitted to our hospital for chest pain, with a highly elevated cardiovascular troponin marker. Acute coronary syndrome was excluded on echocardiography and CT coronarography and he was treated for acute perimyocarditis. Under these stress conditions random thyroid hormones were measured: TSH 1.9 mIU/l [0.35–4.9], fT3 2.5 pmol/l [2.9–4.9], fT4 6.8 pmol/l [9–19], antithyroid antibodies negative and endocrinological follow-up was recommended. Regarding patient's history – obesity since adolescence, currently BMI 38 kg/m^2, otherwise healthy. New findings covered the metabolic syndrome including dyslipidemia, arterial hypertension, and hyperuricemia. Laboratory findings after a month confirmed hypothyroidism of central etiology. Thyroid ultrasound was normal. The whole pituitary hormonal profile was screened, even though the patient was asymptomatic. Central hypogonadotropic hypogonadism and slight hyperprolactinemia were detected (LH 1.3 IU/l [1.7–3.6], FSH 1.7 IU/l [1.5–12.4], total testosterone 2 nmol/l [8.6–29], prolactin 30 mg/l [4–15]). Evident hypo- or hypercortisolism was not present (morning cortisol 298 nmol/l [166–507], ACTH 38.7 pmol/l [1.6–13.9], urinary cortisol 255 nmol/day [100–379]). Growth hormone and age-specific IGF-1 were in norm. Visual fields were intact, but the MRI scan detected sellar expansion (max. diameter 28 mm) with supra- and parasellar progression with an elevation of the optic chiasma. The patient with clinically nonfunctional sellar expansion was referred to neurosurgery for transsphenoidal tumor resection, histologically was confirmed pituitary adenoma with negative immunochemistry of pituitary hormones. Surgery and hormone replacement (currently levothyroxine and hydrocortisone) led to spontaneous BMI reduction to 36 kg/m^2. Testosterone is 4.5 nmol/l and as the patient is planning having a baby, spermiogram is now under investigation and the androgen replacement was postponed.
Conclusion
Nonfunctional pituitary macroadenomas can be found on the basis of diagnosed hypopituitarism, which can evolve slowly. The symptoms of local

compression and expansion and symptoms of partial hypopituitarism appear discreetly and late. In case of obesity and dyslipidemia the evaluation of thyroid function can lead to surprising clinical findings as shows this case report.

From visual disturbance to thyroid cancer: An unexpected journey

Florence Barker[1], Bonnie Grant[1], Nemanja Stojanovic[1], Belayat Hossain[1], Edel Casey[1], Anna Hawkins[1], Sajiv Chawda[2], Imran Syed[3], Jonathan Pollock[3,4], Antony Pittathankal[3,5] & Khash Nikookam[1,3]
[1]Barking Havering and Redbridge University NHS Trust, Endocrinology, Greater London, United Kingdom; [2]Barking Havering and Redbridge University NHS Trust, Radiology, Greater London, United Kingdom; [3]Spire London East Hospital, Greater London, United Kingdom; [4]Barking Havering and Redbridge University NHS Trust, Neurosurgery, Greater London, United Kingdom; [5]Barking Havering and Redbridge University NHS Trust, Surgery, Greater London, United Kingdom

A 28-year-old female presented to the optician with visual disturbance, lethargy and headaches, which were initially attributed to long hours of IT work. Despite a trial of eye exercises she experienced worsening colour vision and acuity in the right eye, hence a further consultation with an optometrist. Examination did not reveal a visual field defect. Visual acuity was 6/6 with 9/17 ishihara plates in the right eye and 5/6 with 17/17 ishihara plates in the left. A further referral to the ophthalmologist elicited a history of hearing changes in the right ear. MRI brain revealed a 20 × 28 × 33 mm pituitary mass, requiring an urgent referral to the endocrine team. On review in the endocrine clinic she denied any breast tenderness or galactorrhoea. As part of a general examination (including the neck), deep seated thyroid lobes (clinically not enlarged) with palpable nodules were noted. Pituitary profile showed prolactin 2229 mU/l [normal range (NR) 90–520 mU/l], TSH 0.945 mU/l (NR 0.47–4.68), freeT4 7.1 pmol/l (NR 10.1–30.2) and 9am cortisol < 100 nmol/l. She was commenced initially on cabergoline 0.5milligrams twice weekly and up-titrated to 1.5milligrams twice weekly alongside levothyroxine 100micrograms once daily and hydrocortisone 25 mg daily in divided doses. Repeat prolactin a month later on cabergoline therapy was < 10 mU/l, however pituitary MRI showed no interval change. On further assessment by the neurosurgical team and discussion with the patient, in view of ongoing visual symptoms combined with no reduction in size of pituitary mass, she underwent trans-sphenoidal surgery. Histology confirmed benign adenoma. She subsequently reported resolution of her headaches and improvement of her colour vision. Thyroid ultrasound (USS) identified a 5.4 mm × 2.7 mm U3 nodule in the right lobe and a 4.2 mm × 2.5 mm U2 nodule in the left lobe. Cytology following USS-guided fine needle aspiration of the right U3 nodule concluded papillary thyroid carcinoma (THY5). A formal referral was made to endocrine surgeon for the management of her papillary thyroid carcinoma. She made an uneventful recovery following thyroid and pituitary surgeries with acceptable thyroid function tests of TSH 0.26 mU/l, freeT4 19.6 pmol/l, freeT3 5.1 pmol/l, normal gonadotropins and prolactin 9 mU/l. She continued on levothyroxine 100 micrograms and hydrocortisone 25 mg in divided doses with cessation of cabergoline.
Conclusion
This case highlights the need for a full and thorough examination, which is the most basic but fundamental code of clinical practice and may well lead to the finding of other coexisting pathology in patients, despite singular presentation.

Clinical and endocrinological evaluation of patients with empty sella

Medine Nur Kebapci[1], Duygu Kesebi Isganderov[2], Goknur Yorulmaz[3], Aysen Akalin[4] & Belgin Efe[4]
[1]Eskisehir Osmangazi University, Endocrinology, Eskisehir, Turkey; [2]Eskisehir Osmangazi University School of Mdicine, Internal Medicine, Eskisehir, Turkey; [3]Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [4]Eskisehir Osmangazi University School of Medicine, Endocrinology, Eskisehir, Turkey

Empty sella (ES) is characterized by herniation of the subarachnoid space within the sella, compression and flattening of the pituitary gland. Stretching of the pituitary stalk may also be seen. Empty sella is a frequent finding (5–23%) in autopsy series while it is < 0.01% in persons who undergo medical attention. Meanwhile there is an increase in sellar emptiness with age. Regarding pathophysiology and etiology, it may be primary to the incompetence of the diaphragma sellae and herniation of CSF in to the sella turcica. It may be secondary to pituitary autoimmune disease, brain trauma, radiation, surgery, hemorrhage, or infarction of the pituitary gland. Primary and secondary ES can be thought of and treated as one entity. As a master gland of endocrine system, hormone secretions from the pituitary gland should be evaluated if the patients have symptoms. The most common symptom associated to ES is headache. In patients with primary ES, radiological ES is found incidentally on brain MR mostly performed because of headache. Symptoms associated with endocrine abnormalities may be seen especially in those with secondary ES. We evaluated 30 patients with ES [23 female (24–80 year-old), 7 men (32–85 years-old)]. Basal hormone levels were measured and then stimulated hormone levels were evaluated if necessary by means of insulin tolerance test. In female patients: primary and secondary ES were seen in 19 and 4 patients respectively. In male patients primary and secondary ES were seen in 4 and 3 patients respectively. In women, secondary causes were 1 Sheehan syndrome, 1 transsphenoidal operation and 1 brain trauma and 1 related to Neuro-Behcet's disease. In men, secondary causes were 1 subarachnoid haemorrhage, and 1 transsphenoidal operation and 1 brain trauma. In women with primary ES, mild hyperprolactinemia (6/19), secondary hypothyroidism (5/19), GH deficiency (2/19), and panhypopituitarim (1/19) were found. One woman had primary hypothyroidism, 3 women had adrenal adenoma (1 Conn syndrome, 2 women had nonfunctional adrenal adenomas (1 unilateral, 1 bilateral) and 2 women had intracranial hypertension with primary ES. Type 2 DM and hypertension and obesity were frequent findings in women with primary ES. In men with primary ES, 2 men had panhypopituitarism, 1 patient had mild hyperprolactinemia, 1 had secondary hypothyroidism with GH deficiency. In men with secondary ES, 2 men had hypogonadotrophic hypogonadism and one man with subarachnoidal haemorrhage had normal pituitary function. Obesity and DM were not frequent in male patients with ES.

Clinical and hormonal pecularities of acromegaly patiernts from ukrainian centre

Oksana Khyzhnyak[1,2], Mykytyuk Miroslava[1,2], Nikolaiev Roman[1], Guk Mykola[3], Karachentsev Uirii[1,2] & Gavrysh Tetiana[1]
[1]Institute for Endocrine Pathology Problems, Clinical Endocrinology, Kharkiv, Ukraine; [2]Kharkiv Medical Academy of Postgraduate Educations, Endocrinology, Kharkiv, Ukraine; [3]Romonadov' Neurosurgery Institute, Pituitary Surgery, Kiev, Ukraine

Introduction
Acromegaly (ACRO) is a rare disease of an excessive somatic growth and distorted proportions arising from hypersecretion of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). The aim Of this study is to investigate basic demographic parameters such as the age and gender related features, age at diagnosis of the disease, its clinical manifestations, biochemical control and structure of complications in Ukrainian patients with ACRO in a single neuroendocrinological centre.
Material and methods
Patients with ACRO: $n = 133$ [including 47 *de novo*]: female – 88, male – 45, and retrospective study 133 patients (female – 91, male – 42) who had neurosurgical treatment. Diagnosis of ACRO was based on the Consensus Statement on acromegaly (2018). The levels of PRL, GH and IGF-1 were measured.
Results
The study has established that 88.8% of the overall sample consist of patients aged 31 to 60 years: 26.5%/55.2% (male/female); $\chi^2 = 15.47$; $P = 0.0001$. Peak of the ACRO manifestation in the overall sample falls on the age of working efficiency (41.3 ± 12.0) yrs. Analysis of the complaints structure in patients with ACRO was: fatigability (45.5%), asthenia (43.9%), headache (43.9%), and excessive sweating (42.3%). Increasing sizes of hands and feet (60.2%) and in facial features (42.3%), which are specific morphological markers of ACRO, more than 50% of patients consider as age-related. It has been established that pre-nosological period has a linear proportional increase, related with age in patients with ACRO: ($R^2 = 3.4\%$; $P = 0.041$) and is also associated with the age of manifestation ($R = 0.24$; $R^2 = 5.96\%$; $P = 0.007$).

Conclusion
Sexual dimorphism of the clinical course ACRO is manifested at a young age at the time of manifestation of the disease and is characterized by a higher secretory activity of GH-secreting adenoma and it greater mass effect in men. Secretory and proliferative activity of the GH pituitary adenoma is associated with the age of the patient at the time of the manifestation of ACRO. High total secretory activity of GH-secreting pituitary adenoma, tumor growth rate, resistance to treatment and predisposition to relapse, which are associated with the young patient at the time of the manifestation of the disease, determine the 'fast-moving' flow of ACRO. In elderly patients, the domination of the secretory over the proliferative activity of the GH-pituitary adenoma and the satisfactory sensitivity to the treatment determine the 'slowly progressive' clinical course of disease.

Cabergoline treatment: The ethics around side effects

Risheka Ratnasabapathy, Bijal Patel, Ambreen Qayum, Shamaila Zaman, Preeshila Behary, Karim Meeran & Niamh Martin
Imperial College NHS Healthcare Trust, Department of Endocrinology, United Kingdom

Cabergoline has long been used to treat prolactinomas for symptomatic, radiological and biochemical resolution of pituitary tumours. As clinicians we are well-versed at screening for physical side effects, but are we holistic enough? We present two cases illustrating the damaging social consequences of cabergoline treatment for prolactinomas.
Case 1
A 49-year-old married father of two presented with a seizure in April 2018. MRI showed 2.3 × 2.5 × 2.5 cm sellar and suprasellar mass which compressed the optic chiasm as well as an unrelated grade 2 oliogodendroglioma which was later debulked. Prolactin levels at presentation were 50.205. The remainder of his pituitary profile showed TSH 0.75, T4 9.5, ACTH 6.9, cortisol < 28, LH 0.9, FSH 1.3, testosterone 1.7, GH < 0.05. He was started onto cabergoline 500 mg twice weekly and 4 mg prednisolone daily. His prolactin fell from 50.205 to 816 over 5 months. Eighteen months later, he reported a change in sexual behaviour, the use of escort services and sexual involvement with work colleagues. Cabergoline was discontinued in November 2019. Repeat prolactin levels in December 2019 were 583 and testosterone of 12.
Case 2
A 56-year-old man in a long term steady same- sex relationship, presented with erectile dysfunction and low energy in October 2018. His prolactin was 3.464 and testosterone 4.5. The remainder of his pituitary profile revealed TSH 1.07, T4 11.3, cortisol 189, LH 1.8, FSH 2.1, testosterone 4.5 and SHBG 41. An MRI scan of his pituitary revealed a 11 × 9 mm pituitary adenoma. He was commenced onto Cabergoline 250 mg once weekly. His prolactin fell from 2464 to 18 within 5 months, with testosterone levels of 18.9. In October 2019, his worried partner reported a change in personality and hypersexuality. Cabergoline was stopped. However, due to the patient's concerns of a return of low libido, testosterone replacement was commenced. His prolactin in November 2019 was 1942. These cases raise important ethical questions. Firstly, how much of the hypersexual behaviour observed is a direct side effect of dopamine agonist treatment and how much is a behavioural consequence of the rise testosterone? Secondly, when cabergoline treatment results in behavioural side effects such as the failure of a marriage or financially crippling gambling, who takes responsibility when huge debts emerge and family units collapse? We must be cautious when prescribing and monitoring dopamine agonist therapy to avoid social harm to patients and balance this with depriving patients of effective non-invasive treatments.

Quality of life in patients with Cushing's syndrome in remission: 10-year follow-up

Alicia Santos[1], Eugenia Resmini[1], Mª Antonia Martinez Momblan[2], Marc Medina[3] & Susan Webb[1]
[1]Hospital Sant Pau, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER, Unit 747), IIB-Sant Pau, ISCIII and Universitat Autònoma de Barcelona (UAB), Endocrinology/Medicine Departments, Barcelona, Spain; [2]Fundamental and Medico-Surgical Nursing Department, School of Medicine and Health Sciences, University of Barcelona, Bellvitge Campus, Hospitalet de Llobregat, Spain; [3]Medical student, Hospital Sant Pau Teaching Unit, Universitat Autònoma de Barcelona, Barcelona, Spain

Introduction
Cushing's syndrome (CS) has been associated with low quality of life, even after biochemical cure. However little data is available on long term follow-up. The aim of the study was to analyse 10-year follow-up of quality of life (QoL) in patients in remission of CS.
Methods
24 patients in remission of CS followed in Hospital Sant Pau were included in this study (3 men, 21 pituitary origin, 3 adrenal; mean baseline age 45.1 ± 14.1). They performed their yearly clinical follow-up visits (including clinical and analytical parameters) and the same day completed 2 QoL questionnaires (EuroQoL and CushingQoL). This was performed both basally (at least one year after cure) and after 10 years (± 6 months).
Results
After 10 years, a decrease in QoL was found. Mean CushingQoL scores at first evaluation were 64, vs 58 after 10 years (P <0.001, scores worsened in 70.8% of the patients), while for EuroQoL-VAS basal scores were 73 vs 64 after 10 years (P = 0.002, scores worsened in 58.3% of the patients). Two patients had a recurrence at 10 year follow-up, but results did not change when both patients were excluded from the analysis (P < 0.001 for both questionnaires). The percentage of patients reporting problems in the 5 dimensions of EuroQoL at both evaluations was: mobility (28% vs 40%), self-care (12% vs 20%), usual activities (32% vs 32%), pain/discomfort (52% vs 64%), and anxiety/depression (44% vs 52%). CushingQoL and EuroQoL-VAS scores after 10 years correlated with baseline scores (CushingQoL P = 0.003, R = 0.586; EuroQoL-VAS P = 0.002, R = 0.605), but did not correlate with diagnostic delay, time since surgery, current urinary free cortisol, plasma cortisol, late-night salivary cortisol, ACTH, blood pressure, BMI or age.
Conclusion
QoL in patients in remission of CS worsens after 10 years, and correlates with baseline scores. Interventions to improve quality of life at early stages may help to prevent further deterioration in the future.

EP293

Pasireotide LAR in acromegaly resistant to first generation somatostatin analogs – single-center prospective interventional study

Agnieszka Majos, Maria Stelmachowska-Banaś, Izabella Czajka-Oraniec & Wojciech Zgliczyński
Centre of Postgraduate Medical Education, Endocrinology Department, Warsaw, Poland

Introduction
The treatment of choice in persistent acromegaly after transsphenoidal adenomectomy is pharmacological treatment with first generation somatostatin analogs. They are effective in 25% to 45% of patients. Second generation somatostatin analog – pasireotide seems to be more effective.
Aim
The aim of the study was to assess the efficacy and safety of pasireotide LAR in acromegaly patients resistant to first generation somatostatin analogs.
Material and methods
Twenty eight patients (males n = 15, 53.6%, mean age 43.59 ± 13.48 years) with acromegaly after surgical debulking resistant to first generation somatostatin analogs were involved in the study. Four patients had radiotherapy performed 59, 23, 18 and 24 months before study beginning. Poor diabetes management was an exclusion criterion. All patients started with pasireotide LAR 40 mg every 28 days and had GH, IGF-1, glucose and HgbA1c measured every three months. Patients who did not achieved biochemical control of acromegaly after three-month treatment had the dose escalated to 60 mg if pasireotide tolerability and adverse events allowed. Dose reduction to 20 mg was performed in one patient with full biochemical control and difficulties with diabetes management. Within the study period 16 patients completed twelve-month treatment.
Results
After twelve-month treatment a significant decrease in GH (4.06 IQR: 1.86–6.37 μg/l vs 1.3 IQR: 0.9–2.92 μg/l, P = 0.0005) and IGF-1 concentration (605.63 ± 203.05 ng/ml vs 381.46 ± 201.82 ng/ml, P <0.0001, i.e. 2.39 ± 0.8 × ULN vs 1.51 ± 0.82 × ULN, P < 0.0001) was observed. The increase in fasting glucose concentration (106, 95 ± 13.85 mg/

dl vs 120.46±17.76 mg/dl) and glycated hemoglobin (5.91±0.44% vs 6.39±0.63%) were also significant ($P=0.002$ and $P<0.0001$ respectively). In five patients 5/16=31.3% GH concentration fell below 1 µg/l and in twelve GH concentration was below 2.5 µg/l (12/16=75%). In five patients (5/16=31.3%) IGF-1 concentration was within normal limits after twelve-month treatment and in ten patients IGF-1 concentration was below 1.5 × UNL (10/16=62.5%). Three patients (3/16=18.8%) achieved full biochemical normalization after one-year treatment with pasireotide LAR.
Conclusions
Pasireotide LAR is more effective than first generation somatostatin analogs in patients with persistent acromegaly after surgical debulking. Carbohydrate metabolism should be regularly monitored on pasireotide treatment.

Challenges in management and pharmacotherapeutic strategy in patients with a prolactinoma and neuropsychosis; a case presentation and literature review

Ahmad Moolla, David Hope, Neil Hill & Karim Meeran
Imperial Centre for Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom

A 36-year-old male presented to the emergency department with a 24-hour history of mutism, paranoia and 3-day history of social withdrawal. He was unable to engage with healthcare professionals and the history was elicited from his mother. Due to a background of mild depression, an acute psychotic diagnosis was initially pursued. A CT scan on admission revealed a large pituitary lesion. A pituitary MRI scan thereafter demonstrated a large 25 × 30 × 18 mm sellar and suprasellar pituitary macroadenoma involving the left cavernous sinus and internal carotid artery, protruding into the left cranial fossa and displacing the optic chiasm. Biochemical investigations revealed a serum prolactin level c.66.000 mIU/l with biochemical hypogonadism (testosterone 3.3 nmol/l, LH 1.7 IU/l). Clinical examination revealed no ophthalmoplegia nor visual field deficits. He was unable to engage with formal visual-field testing initially, however these later demonstrated a superior bilateral deficit. Capacity assessment on admission demonstrated a lack of mental capacity so a best interests decision for medical management was made jointly by Psychiatry and Endocrinology teams. He was commenced on the antidepressant sertraline and the antipsychotic aripiprazole (10 mg daily), a partial dopamine agonist. Aripiprazole was chosen to treat both hyperprolactinaemia and psychotic symptoms, whilst avoiding potential neuropsychiatric side effects of ergot-derived dopamine agonists. After two weeks of therapy, his prolactin fell to c.38.000 mIU/l and his mental status had improved. However, by two months, he reported weight gain, fatigue, leg cramping and stiffness, whilst blood tests showed a prolactin rise to c.55.000 mIU/l. At this point aripiprazole was not felt to be of any further benefit and was switched to cabergoline, initially 250 mg once weekly and quickly up-titrated to 500 mg twice weekly. By month six, his prolactin had fallen to c.3.500 mIU/l and his testosterone (9.8 nmol/l) and LH (0.8 IU/l) showed improvements. Repeat MR imaging demonstrated a reduction in macroadenoma size with decompression of the optic chiasm. Currently at month eight, his mood has normalised. His prolactin however has risen to c.4.500 mIU/l so cabergoline has been increased to 750 mg twice weekly. This case highlights the challenges presented by the combination of neuropsychiatric symptoms and a functioning macroprolactinoma. Initial medical management with aripiprazole monotherapy can be used to treat psychiatric disease without worsening prolactin levels. We have identified seven case reports published since 2007 of aripiprazole being used for patients with prolactinomas who have coexistent psychiatric symptoms [1–7]. These cases describe the use of dopamine agonists concomitantly or first, with aripiprazole to minimise the side effects.

Pre-operative full blood count, C-reactive protein and serum inflammation-based scores may predict aggressive or refractory disease in patients with pituitary adenomas

Pedro Marques[1,2], Friso de Vries[1], Wouter van Furth[1], Marta Korbonits[2], Nienke Biermasz[1] & Alberto M Pereira[1]
[1]Leiden University Medical Center, Leiden, The Netherlands, Center for Endocrine Tumors Leiden (CETL), Leiden, Netherlands; [2]William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, United Kingdom, Centre for Endocrinology, London, United Kingdom

Introduction
Full blood count (FBC), C-reactive protein (CRP), albumin and serum inflammation-based scores reflect systemic inflammation and predict outcomes in oncological patients. While these are increasingly used in cancer, little is known in pituitary adenomas (PAs). We aimed to characterise FBC and inflammation-based scores in patients with PAs and investigate the usefulness of such parameters in predicting aggressive/refractory disease.
Methods
We studied 424 PA patients (68 prolactinomas, 72 acromegaly, 70 Cushing´s disease, 208 non-functioning PAs (NFPAs) and 6 thyrotrophinomas), as well as 47 craniopharyngiomas (CP) and Rathke's cleft cysts (RCC). Patients who had first operation at our centre between 2006–2019 and available pre-operative biochemical data (FBC, CRP, albumin) were included. Patients with infection, malignancies, autoimmune or haematological conditions, and those on supraphysiological glucocorticoid doses at the time of blood test were excluded. The following scores were considered: Neutrophil-to-Lymphocyte Ratio (NLR), Platelet-to-Lymphocyte Ratio (PLR), Lymphocyte-to-Monocyte Ratio, Systemic Inflammation Index (SII), Neutrophil-Platelet Score (NPS), Prognostic Nutrition Index (PNI), and Glasgow Prognostic Score (GPS).
Results
PA patients had lower CRP, GPS, and higher PNI than CP/RCC patients. Cushing´s disease patients had higher mean platelet count, leucocytes, neutrophils and monocytes, and higher NLR, NPS and SII than other subtypes. FBC and inflammation based-scores didn't differ among other non-Cushing's subtypes. Serum prolactin correlated negatively with NLR among prolactinoma patients, while in acromegaly IGF-1 levels correlated positively with platelet count. Within Cushing´s disease, serum cortisol and ACTH correlated respectively with leucocyte count (positively); 24 h-urine cortisol levels correlated negatively with platelet, eosinophil and basophil counts, and were higher in patients with elevated CRP and GPS. Patients with functioning non-Cushing PAs and with suprasellar extension, cavernous sinus invasion, hypopituitarism and those requiring reoperation had higher GPS, while raised NPS was associated with suprasellar extension and active disease at last follow-up. Cushing´s patients with more invasive and refractory tumours had fewer platelets at diagnosis. NFPA patients who suffered apoplexy had more leucocytes, neutrophils and monocytes and higher CRP. NFPA patients suffering recurrence and requiring reoperation had fewer lymphocytes and higher PLR.
Conclusions
CP/RCC patients have higher systemic inflammation than PA patients. FBC and inflammation-based scores remarkably differ in Cushing´s disease comparing to other PA subtypes. The extent of pituitary hormone excess may influence, at least in part, the systemic inflammation in functioning PAs. Some inflammation-based scores may predict aggressive/refractory PA disease, namely GPS in functioning PAs (including Cushing´s disease), NPS in functioning non-Cushing PAs and PLR in NFPAs.

Prevalence of hypocortisolism and replacement treatment after transsphenoidal surgery pituitary adenomas

Maria del Mar Roca-Rodriguez[1], Jesús Manuel Cornejo-Domínguez[1], Álvaro Vidal-Suárez[1], Pedro Muriel-Cueto[2], Irene Iglesias-Lozano[3], Inmaculada Gavilán-Villarejo[1] & Manuel Aguilar-Diosdado[1]
[1]Puerta del Mar, Endocrinology and Nutrition, Cádiz, Spain; [2]Puerta del Mar, Pathological Anatomy, Cádiz, Spain; [3]Puerta del Mar, Neurosurgery, Cádiz, Spain

Aim
Evaluation of hypocortisolism and replacement treatment after transsphenoidal surgery pituitary adenomas and subsequent follow-up in Endocrinology offices.
Material and method
We conducted a retrospective intra-subject study of patients with pituitary adenomas who were undergone surgery. Clinical and analytical data were evaluated at baseline and after surgery between 2012–2018.

Results
30 patients (50% women) were analyzed. Mean age 48.6±12.1 years, mean size of adenomas 2±1.1 cm (26.7% microadenomas and 73.3% macroadenomas) and mean time after surgery 1.4±0.5 months. Before surgery, we observed 16.7% hypothyroidism, 3.3% somatotrophic hormone deficiency, no cases of hypocortisolism or hypogonadism and 33% of subjects had campimetric alterations. After surgery, we detected 34.8% hypothyroidism, 27.6% somatotrophic hormone deficiency, 40% hypogonadism and 10% insipidus diabetes (in 6.7% of cases it persisted after a year). Campymetry improved by 66% (50% complete resolution, 22% unchanged and 11% worse). Regarding post-surgery basal cortisol, 23.3%<3 mg/dl, 33.3% 3–11 mg/dl, 26.7% 11–18 mg/dl and 16.7%>18 mg/dl. Ten percent required reevaluation (66% 1 mg ACTH test and 33% insulin hypoglycemia). Mean dose of corticosteroid replacement therapy was 25.7±9.6 mg/day at hospital discharge, 16.5±12/day mg at first visit after surgery and 12.6±14.4 mg/day after a year.
Conclusions
We observed a significant incidence of hypogonadism after surgery. Campimetric affectation improved in most of patients. Hypocortisolism was present in 56.6% of subjects after surgery and they needed corticosteroid replacement therapy. Less than 50% of patients were treated unnecessarily. New strategies to select patients who need replacement steroid treatment are needed.

Treatment outcomes of acromegaly: A single-centre experience

Aiste Snieskiene[1,2], Rasa Juskiene[1], Agne Abraitiene[1,2] & Zydrune Visockiene[1,2]
[1]Vilnius, Vilnius University hospital Santaros klinikos, Vilnius, Lithuania; [2]Vilnius University, Faculty of Medicine, Vilnius, Lithuania

Introduction
The purpose of this study was to evaluate treatment options and effectiveness in patients with acromegaly.
Methods
The study involved retrospective data collection from charts of 75 patients with acromegaly who was treated at Vilnius University Hospital Santaros klinikos.
Results
Patient population consisted of 21 males (28%) and 54 females (72%), mean age at diagnosis 52±13 years. In most of the cases, macroadenoma was diagnosed (macroadenoma 68.75% vs microadenoma 31.25%). Based on GH and IGF-1 levels, disease control was achieved in 33 out of 73 (45.2%) patients (data of 2 patients is missing). Transsphenoidal surgery was performed in 49 (67.1%) patients of which disease control was achieved in 27 (57.4%): in 13 out of 19 patients without additional treatment, in 8 out of 22 with additional medical therapy and in 6 out of 7 with additional medical therapy and radiotherapy. Permanent postoperative hypopituitarism was observed in 9 (18.4%) patients. Disease control was achieved in 6 out of 24 (25%) patients who refused or had contraindications to surgical treatment. Medical therapy (somatostatin analogues (SSA), dopamine agonists (DA)) was applied in 38 of our patients: 27 patients received first-generation SSA, 3 patients received Pasireotide, 3 patients DA and 5 patients SSA with DA (control was achieved in 8 (29.6%), 1 (33.3%), 2 (66.7%) and 1 (20.0%) respectively). High-dose medical therapy are now receiving 18 out of 38 patients and in a majority (94.4%) of them complete disease control was not achieved.
Conclusions
Surgical treatment is the first-line treatment option of acromegaly, although many patients refuse or have contraindications for the surgery. Primary medical therapy with SSA±DA leads to disease control in only 25% of the patients despite availability of high-dose first generation SSAs and pasireotide. The best outcomes of acromegaly treatment were observed when treatment combinations were chosen – surgery with secondary medical treatment±radiotherapy.

Dabigatran-induced pituitary apoplexy in young patient: A case report

Iustina Cosmina Mogos[1], Andrea Mitescu[2] & Raluca Tulin[3,4]
[1]CMDT ROMA, Endocrinology, Bucuresti, Romania; [2]Cardio Clinic, Cardiology, Bucharest, Romania; [3,4]Agrippa Ionescu' Emergency Hospital, Endocrinology, Romania; [4]'Carol Davila' University of Medicine and Pharmacy, Anatomy, Bucharest, Romania

Introduction
Pituitary apoplexy is defined as the acute onset of clinical symptoms associated with hemorrhage or infarction within a normal pituitary gland or previously known pituitary adenoma.
Case report
A 47-year-old hypertensive Caucasian male patient with a known pituitary macroadenoma and family history of pituitary adenomas, was treated with thromboprophylaxis after a meniscus surgery. He was on treatment with non-steroidal anti-inflammatory medication for knee pain relief, and sartan for mild hypertension. He had been taking low molecular weight heparin for one month, but had changed the anticoagulant to dabigatran etexilate 150 mg/day, after the occurrence of deep thrombophlebitis. Over the next 3 days, the patient complained of increasing bilateral frontal headaches with the onset of binocular diplopia, drowsiness, head paresthesia and nausea. On admission, the patient was alert and had bilateral temporal hemianopia. Brain magnetic resonance imaging (MRI) showed a 1.6 cm pituitary mass with hemorrhage (apoplexy) and extension to the left cavernous sinus, with right deviation of the pituitary stalk and optic chiasm compression. Transsphenoidal resection of the tumor was done which resulted in tumor ablation and symptoms amendment.
Endocrine testing
Two weeks after transsphenoidal surgery showed thyrotroph and gonadotroph hypopituitarism. The pathology report confirmed a nonfunctional pituitary adenoma with intratumoral hemorrhage and immunohistochemistry positive for SYN and panCK, p53<1%, Ki-67<1%.
Conclusion
This case illustrates the risks of anticoagulation in patients who are already known to have a pituitary adenoma, this condition should be considered as a relative risk for anticoagulation, even with modern drugs as dabigatran.

Non-functioning pituitary adenomas – clinical presentation and management, experience of a tertiary centre in Romania

Theodor Mustata[1], Sorina Martin[1,2], Delia Mihop[3], Andrada Predescu[1], Ovidiu Parfeni[1], Anca Sirbu[1,2], Carmen Barbu[1,2] & Simona Fica[1,2]
[1]Elias Emergency University Hospital, Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background and aim
Non-functioning pituitary adenomas (NFPAs) are hormonally inactive adenohypophyseal tumors. The absence of hormone hypersecretion and the lack of clinical manifestations delay the diagnosis and therefore symptoms of mass effect are frequently seen in NFPAs. The primary endpoint of this study was to evaluate the clinical presentation of patients with NFPAs and their therapeutic management. The secondary endpoint was to identify how gender and tumor size impact the clinical presentation and therapeutic management.
Patients and methods
We evaluated 98 patients diagnosed with clinically and biochemically NFPAs between January 2013 and January 2018. Anamnestic data, symptoms at presentation, pituitary function and imaging, treatment option and outcomes were analysed.
Results
68 of the patients were female (69.39%) and 30 male (30.61%), with a mean age of 43.61±18.42 years. The most common symptom at presentation was headache (30.61%), followed by diplopia (13.27%) and bitemporal hemianopsia (13.27%), ptosis (9.18%), quadranopsia (1.02%). The prevalence of endocrine disorders caused by pituitary stalk compression was 22.9% for hyperprolactinemia and 6.9% for diabetes insipidus. GH deficiency was the most prevalent pituitary hormone deficiency (41.3%), followed by TSH deficiency (22.81%) and gonadotropin deficiency (15.31%). More than half of NFPAs were diagnosed as microadenomas (50.67%). The most used approach was conservative management (69.39%), followed by surgery (22.45%), radiation therapy (4.08%), surgery and radiation therapy (4.08%). Tumoral recurrence was seen in 6% of patients who underwent surgery, radiation therapy or both. The age at diagnosis was significantly higher in

men, compared to women (49.41±20.8 vs 41.1±16.85 years, $P=0.042$). Moreover, macroadenomas were more common in males than in females (85.71% vs 35.19%, $P<0.001$). When dividing the patients based on tumor size we found a higher age at diagnosis for macroadenomas, compared to microadenomas (51.97±17.07 vs 34.38±15.19 years, $P<0.001$), but also different treatment strategies: in microadenomas conservative management was chosen in 97.37% and surgery in 2.63% of patients, while in macroadenomas surgery was preffered in 40.54% and conservative management in 45.95% of patients ($P<0.001$).

Conclusions

NFPAs are characterized by heterogeneity in clinical presentation, patients usually presenting with symptoms of mass effect or hipopituitarism. In this regard our data showed a high prevalence of GH deficiency, while headache was the most common mass effect symptom. Although there was an overall female predominance for NFPAs, most macroadenomas were diagnosed in men. Furthermore, tumor size dictates the therapeutic management, with surgery being indicated mostly in macroadenomas.

Development of a digital patient-provider communication tool to facilitate shared decision making for patients with non-functioning pituitary adenomas: InvolveMe

Berit Seljelid[1,2], Kari Abelsen[3], Line C. Krabbe[3], Jens Bollerslev[1,3], Cecilie Varsi[2], Lise Solberg Nes[2,4] & Elin Børøsund[2]

[1]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Oslo, Norway; [2]Department of Digital Health Research, Division of Medicine, Oslo University Hospital, Oslo, Oslo, Norway; [3]Section of specialized Endocrinology, Department of Endocrinology, Morbid Obesity and Preventive Medicine, Division of Medicine, Oslo University Hospital, Oslo, Oslo, Norway; [4]Department of Psychiatry and Psychology, College of Medicine and Science, Mayo Clinic, Rochester, MN, USA, Rochester, MN, United States

Background

Patients report a variety of persisting symptoms that reduce their quality of life after treatment for non-functioning pituitary adenomas (NFPA). Digital tools have the potential to improve patient-provider communication and patient outcomes by giving opportunities for patients to report their current status, which can be helpful in recognizing symptoms and identifying needs. Mapping patients' symptoms, needs and preferences prior to the consultation can aid in preparation, set the agenda for the consultation and facilitate involvement in the decision-making processes.

Aim

The aim was to map symptoms, needs and preferences for software features that should be included in the development of a digital communication tool, *InvolveMe*, to support shared decision making in the follow-up of patients with NFPA.

Method

A combination of interviews with patients and a focus group with health care providers (HCP) was conducted. Participants were recruited from an outpatient clinic at a tertiary referral center with long lasting experience in treating pituitary patients. Data were analyzed using thematic analyses, which informed the content and software development. The development process was supported by more tool development workshops.

Results

Analyses from interviews with patients ($n=5$) and a focus group with HCPs ($n=5$) generated tree main themes: 1) Making symptoms and challenges visible, 2) Mastering a new life, and 3) Digital opportunities for follow-up. Theme 1 and 2 gave input for content development of the symptom and needs assessment part of the tool. The patients expressed need for a variety of bodily symptoms and psychosocial challenges to be addressed, including pain, fatigue, anxiety and loneliness. The patients described the need for work related support and information related to living a healthy life with the newly established condition. Theme 3 provided input for software development of the InvolveMe tool, including integration with an existing patient portal already in use by patients and providers. The HCPs perspective was in line with and elaborated on the patient perspective. Tool development workshops with patients ($n=3$) and HCPs ($n=3$) supplemented the development process and ensured that important topics were discussed and further elaborated.

Conclusion

Inclusion of content and software features relevant and meaningful for patients as well as HCPs was ensured by stakeholder involvement, from study initiation through exploration, design and development. To explore usability and potential effects of the *InvolveMe* tool, a feasibility pilot is currently in progress testing content and software features in clinical practice and context.

Can you predict the success of surgery in cushing's disease?

Paloma Moreno-Moreno[1], Alfonso Soto-Moreno[2], Carmen Fajardo-Montañana[3], Rosa Camara-Gómez[4], Raul M Luque[5] & María Ángeles Gálvez-Moreno[1]

[1]University Hospital Reina Sofía, Management Unit of Clinical Endocrinology and Nutrition, Córdoba, Spain; [2]University Hospital Virgen del Rocío, Management Unit of Clinical Endocrinology and Nutrition, Sevilla, Spain; [3]University Hospital La Ribera, Management Unit of Clinical Endocrinology and Nutrition, Alcira, Spain; [4]University and Polytechnic Hospital La Fe, Management Unit of Clinical Endocrinology and Nutrition, Valencia, Spain; [5]University of Córdoba. IMIBIC, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain

Objective

Cushing's disease (CD) is difficult to diagnose because of its rarity and because its most common symptoms can overlap with those of other more common conditions. Remission rates in the postoperative vary between 55–85%. Overall, the mean time to diagnosis was 38 months. The objective of this study was to describe whether there is any pre-surgical clinical data that predicts CD remission after TSS.

Patients and methods

Retrospective analysis of patients who underwent as TSS for CD. Variables analyzed: age, sex, time to diagnosis, tumor size, serum cortisol, salivary cortisol, urinary-free cortisol (UFC), remission of CD. Remission was defined as normalization of serum cortisol, salivary cortisol and UFC levels.

Results

67 patients with CD treated with TSS. 42.45±14 years old. Women: 82.1%. Macroadenomas 49.3%. Remission 71.6% (men: 3; women 45). Persistence 28.4% (men: 9; women 10). Presurgical treatment (76.2%): 44 patients with ketoconazole, 1 patient with cabergoline and 6 patients with combination of both (remission: 84.8%, persistence: 57.9%; $P=0.04$). Recurrence: 23.9%. Death 4.5% ($n=3$).

	Remission	Persistence	*P*
Age (years)	41.17±14.82	45.68±13.24	0.7
Time from onset of symptoms to diagnosis (months)	34.52±28.96	23.33±29.75	0.2
Time from diagnosis to surgery (months)	6.5±5.6	5.7±3.37	0.5
Tumor size (mm)	9.35±6.87	20.47±9.55	0.001
Basal cortisol (µg/dl)	23.6±10.64	22.10±9.37	0.6
Midnight plasma cortisol (µ g/dl)	14.52±5.38	34.6±32.47	0.015
Midnight salivary cortisol (µg/dl)	2.75±6.71	0.74±0.56	0.04
24-hour urinary cortisol (µg/24 h)	586.23±678.55	277.42±190.41	0.05
ACTH (p g/ml)	81.14±50.5	81.8±72.12	0.96

Conclusions

Remission is more frequent in women and in patients with pre-surgical treatment. In the presurgical study, patients in remission had smaller tumors and lower cortisol levels at midnight, however they had higher levels of CLU.

Long-term outcomes of prolactinoma-related pregnancies

Seher Tanrikulu[1], Sema Ciftci Dogansen[2], Ozlem Soyluk Selcukbiricik[3] & sema yarman[3]
[1]Haydarpasa Numune Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]Bakirkoy Sadi Konuk Training and Research Hospital, Turkey; [3]Istanbul University, Istanbul Faculty of Medicine, Turkey

Objective
The aim of the study is to evaluate both the long-term consequences of exposure to dopamine agonists (CAB and BRC) at the beginning and during pregnancy, and the effects of pregnancy on remission.
Methods
Thirty-seven prolactinoma patients who developed 58 pregnancies while receiving DAs treatment were included in this retrospective study. Age of gestation; both maximum residual tumor diameter and PRL levels before conception; the course of prolactinoma during and after pregnancy; the outcomes of pregnancies; comorbidities and complications during pregnancy and health of fetus were evaluated. Remission was defined as regained normal gonadal function with normal PRL level after discontinuation of DA therapy.
Results
58 pregnancies occurred under BRC (n:40) and CAB (n:18). The mean gestational age was 30±5 years (range 20–39), the mean maximum tumor diameter before pregnancy was 6.3±3.5 mm, and median PRL level was 32 ng/dl (range 1–15). Average treatment period until conception is 9 months for BRC and 7 months for CAB. Average cumulative CAB dose was 5mg for the first 6 weeks of gestation. BRC and CAB was discontinued in patients whose adenoma decreased significantly before conception, while the others continued throughout the pregnancy (n:13). No one had visual complaints during their pregnancy. Eighty-one percent of pregnancies resulted with live birth (15 CAB/33 BRC) and 19% with spontaneous abortion (3 CAB/8 BRC). The mean follow-up time after gestation was 7.5±5.5 years (range 1–23). Among the babies, one Down syndrome (mother's exposure was 325mg BRC during gestation) and one low birth weight baby (mother's exposure was 2 mg CAB during first weeks of gestation) were seen. Gestational diabetes was detected in 3 mothers (2 CAB/1 BRC). In the pituitary MRI after cessation of lactation, the tumor disappeared in 8 and was stable in others. Data on postpartum menstrual periods were available in 44 cases, and cycles were spontaneous in 31% of them. After delivery, 32% of the patients (4 CAB/8 BRC) were found to be in remission for 6.5 years. Other than one, all children are healthy and successful in a period of up to 23 years.
Conclusion
No side effects of DA exposure on fetus development were observed at the beginning of pregnancy or during pregnancy. Because of the possibility of spontaneous menses patients should be carefully evaluated before re-administration of DA.

Metastasis of lung cancer to two different endocrine organs

Hatice Sebile Dökmetaş[1], Meriç Dökmetaş[2], Fatih Kılıçlı[1], Ayşenur Cila[3] & Oktay Olmuşçelik[2]
[1]İstanbul Medipol University, Endocrinology and Metabolism, İstanbul, Turkey; [2]İstanbul Medipol University, Internal Medicine, İstanbul, Turkey; [3]İstanbul Medipol University, Radiology, İstanbul, Turkey

Both pituitary and adrenal gland metastases of lung cancer are very rare. A 79-year-old male patient with diabetes mellitus and hypertension was admitted to our hospital because of a mass in the lungs of the thorax CT. TSH: <0.005 UIU/ml (0.27–4.2), free T4: 0.794 ng/dl (0.93–1.7). Other pituitary hormones were also examined: FSH: 0.708 mIU/ml (1.5–12.4), LH: <0.1 mIU/ml (1.7–8.6), prolactin: 12.7 ng/ml (4.04–15.2), total testosterone: <0.025 ng/ml (1.93–7.4), cortisol: 1 µg/dl (6.02–18.4) was found to be. Pituitary MRI showed an infiltrative mass in the hypothalamus and stalk. PET/CT showed a malignant mass in the right hilar area, metastatic lymph nodes in the mediastinum, and diffuse metastasis in the left adrenal and bones. Pathological diagnosis in trucut needle biopsy from the right supraclavicular lymph node: Reported as metastasis of non-small cell lung carcinoma. The pituitary and adrenal masses were accepted as lung cancer metastasis. The patient was started on prednisolone 5mg, levothyroxine 25 µg/day. Diabetes insipitus was not considered due to lack of increase in urine volume and normal urine density and serum sodium levels. Patient oncology and radiation oncology were consulted and radiotherapy and chemotherapy were planned. Although fatigue is a common symptom in lung cancer cases, it should be kept in mind that metastasis to the pituitary and/or adrenal gland may occur in these patients

Bilateral inferior petrosal sinus sampling in a cohort of patients with acth dependent cushing´s syndrome in a tertiary hospital

Rosa María García Moreno[1], Isabel Moreno Parro[2], David Ortiz Sánchez[2], Remedios Frutos[3], Rubén Gómez Rioja[2] & Cristina Álvarez Escolá[1]
[1]La Paz University Hospital, Endocrinologý and Nutrition Department, Madrid, Spain; [2]La Paz University Hospital, Clinical Analysis Department, Madrid, Spain; [3]La Paz University Hospital, Radiology Department, Madrid, Spain

Objectives
To describe the results of the bilateral inferior petrosal sinus sampling (BIPSS) performed in our hospital for differential diagnosis between Cushing disease (CD) and ectopic ACTH secretion (EAS), and evaluate if CRH stimulation during this test improves its diagnostic accuracy.
Material and methods
We retrospectively review 29 BIPSS performed in 26 patients (4 men, 22 women), with mean age of 44.7 year-old (range 28–69), diagnosed with ACTH-dependent Cushing´s syndrome and followed in the Endocrinology and Nutrition Department of La Paz University Hospital from 2001 to 2019. All BIPSS were performed using CRH stimulation; ACTH and prolactin levels were determined at baseline and three, six and ten minutes post-stimulation. A central-to-peripheral ACTH gradient ≥2.0 at baseline or ≥3.0 after CRH stimulation was the cut-off to diagnose CD and central-to-peripheral prolactin ratio ≥1.8 was considered successful catheterization of the inferior petrosal sinus (IPS). The gold standard to confirm CD was the histological finding of ACTH-secreting pituitary adenoma and/or remission after surgery.
Results
In 17 (58.6%) of the 29 BIPSS performed, both IPS were successfully catheterized, in 8 (27.6%) only the right was catheterized, in 3 (10.3%) it was only the left and in 1 (3.4%) no IPS was catheterized. Of the 28 BIPSS with at least one IPS correctly catheterized, 24 (85.7%) diagnosed CD; 21 of these patients went to surgery and only 8 (38.1%) had histology of ACTH-secreting pituitary adenoma, 10 patients had no pathological findings and the histopathology reports of the other patients were not found. All patients with histological findings of adenoma and other 5 patients without findings got into remission; therefore in 13 patients (61.9% of operated patients) CD was confirmed. The other patients underwent computed tomography and Octreoscan that did not show any tumor suggestive of EAS, so their diagnosis remains indeterminate. Three patients with positive BIPPS result are currently waiting for surgery. Among the 4 BIPSS that ruled out a pituitary ACTH hypersecretion, EAS was confirmed in 2 patients (3 BIPSS). All patients with a positive BIPSS result and diagnosis of CD confirmed by histology and/or remission, had baseline central-to-peripheral ACTH gradient >2.0 (sensitivity 100% at baseline), and >3.0 after CRH (sensitivity 100% post-stimulation).
Conclusion
BIPSS allowed a right diagnosis in the 100% of our patients with CD or EAS subsequently confirmed by histology and/or remission, being a very highly sensitivity test. CRH stimulation did not improve the sensitivity of BIPSS in our patients.

A case series of hypopituitarism presenting as nocturnal hypoglycemia in patients with type 2 diabetes mellitus

Vishal Gupta & Vaishali Teli
Dr. Vishal Gupta's Advantage: Diabetes, Thyroid & Endocrine Center, Mumbai, India

We describe four female patients with T2DM, presenting with nocturnal dizziness (ND), low capillary blood glucose & low BP, that was partially relieved with oral glucose & salt water. C1: MB 66 years, on background of hypertension (HT, valsartan+hydrochlorthiazide (HCT)+amlodipine (AM)), hypothyroidism (T4D) (levothyroxine 700 mg/week) & IHD

(pEF) presented, 3 years into her diagnosis, A1c 52 mmol/mol, with unsteady gait, frequent falls (normal-neurology), swollen feet & generalised non-exertional fatigue. Four years into follow-up, A1c-41 & weight reduced by 3.8 kg. An evaluation was undertaken because of ND while on canagliflozin C/vildagliptin V/Met. C2: SB 64 yrs, (Met/gliclazide/Insulin treated), background of HT (nifedipine + metoprolol) & anxiety (antidepressants-AD) presented, 32 years into her diagnosis, A1c-52, with leg pains, unsteady gait (severe neuropathy) & unprovoked weight gain. After 5 year follow-up, stiffness & fatigue worsened. She lost 5 kg & A1c was 41 & evaluated for recurrent ND (RND) C3: SA 45 yrs old, C + V + Met treated, on background of HT (telmisartan + HCT), anxiety (AD) and T4D (T4 875 mg/wk) presented to us 4 years into her diagnosis, A1c-55, with complaints of generalised non-exertional fatigue and bodyache. After 1 yr of follow-up she gained 1.8 kg, A1c was 57 & evaluated for ND C4: MN 54 yr old, Met + sitagliptin + gliclazide treated, on background of anxiety (AD) & T4D (175 mg/day) presented, 6 years into her diagnosis, A1c-50, with complaints of extreme fatigue & pain in both legs (normal neurology). After 4 months she had RND despite stopping gliclazide Baseline tests suggested isolated GH deficiency (IGHD) in C1, 2, 3, C4 had panhypopituitarism, confirmed by glucagon stimulation test. MRI (pituitary) for C1, 2 & 3 was normal. C4 had non-functioning pituitary macroadenoma (removed transphenoidally). Three patients were initiated rGHT, titrated to mid-centile IGF-1 & followed for 1 year. C4 received hydrocortisone. BMI (C1:30.86–31.25; C3:39.72–40.09; C4:22.89–25.39), A1c mmol/mol (C1:43–48; C3:55–64; C4:48–82), urine microalbumin mg /mmol (C1:0.29–1.12; C3:1.36–2.45; C4:0.62–1.67) & HDL mmol/l (C1:0.93–0.98; C3:1.00–1.03, C4:1.12–1.293) increased. Hs-CRP nmol/L (C1:24.47–16.19; C3:90.57–75.14; C4:6.75–5.71), NT-ProBNP pmol/l (C1:10.40–3.33; C3:7.09–1.77; C4:8.39–2.36) & triacyglycerol mmol/l (C1:1.76–1.19; C3:1.58–1.21; C4:0.89–0.89) reduced. Hypopituitarism (IGHD) should be considered in T2DM patients presenting with nocturnal hypoglycaemia.

Clinical description and management in a series of macroprolactinomas

Lourdes García-García-Doncel, Gloria Baena-Nieto & Rosa Marquez-Pardo
Jerez University Hospital, Endocrinology Unit, Jerez, Spain

Introduction
The purpose of this study was to describe the clinical characteristics of patients with macroprolactinoma in a second level Hospital.
Methods
Retrospective data collection of patients diagnosed with macroprolactinoma between 2002 and 2017 at Jerez University Hospital.
Results
Complete Data were obtained from 22 patients. The mean age at diagnosis was 40.32 ± 18.3 years (men: 52.9 ± 14.2, women: 27.7 ± 12.4). 50% men (m) and 50% women (w). Prolactin levels at diagnosis: 856.8 ± 1139 ng/ml (m: 1253.6 ± 1332.3, w: 460 ± 779) and adenoma size at diagnosis: 20.6 ± 12.3 mm (m: 28.8 ± 12.6, w: 12.4 ± 3.2). The most common presenting symptom was hypogonadism/oligomenorrhea: 90.9% (m: 45%, w: 55), followed by headache 40.9% (m: 55.5%, w: 44.4%), galactorrhea 22.7% (w: 100%) and 9.1% with visual impairment at diagnosis. There were significant differences in tumor size at diagnosis ($P = 0.0001$), in tumor size after treatment ($P = 0.050$) and in the presence of galactorrhea ($P = 0.011$) between both sexes. Serum prolactin fell to a nadir of 31.5 ± 53.9 ng/ml and fell within normal limits in 71.4% of cases at 8.2 ± 3.9 months. An average dose of cabergoline of 1.5 ± 1.4 mg/week and bromocriptine of 5 ± 3.5 mg/d was used. Tumor size decrease was observed in 94.7% of patients, with a decrease in largest tumor diameter greater than 5.4 ± 4.7 mm (31.6 ± 34.7 months). One patient required surgery for being resistant to medical treatment. Visual disturbances at diagnosis improved after starting medical treatment. No cases of spinal fluid fistula or pituitary apoplexy were observed.
Conclusions
The response to medical treatment was adequate in the vast majority of patients with macroprolactinoma, without further complications. Diagnosis was made at an earlier age in women and tumor size at diagnosis was smaller in women than in men.

Curability rate of cushing's disease 1 year posttreatment

Andreea Verdes[1], Sandra Ghenoiu[1], Cristina Capatina[1, 2] & Catalina Poiana[1, 2]
[1]"CI Parhon" National Institute of Endocrinology, No VI, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Background
Cushing's disease is characterized by chronic ACTH hypersecretion, leading to hyperplasia of the adrenal zonae reticularis and fasciculata and, therefore, increased secretion of cortisol, androgens and DOC. Cushing's disease is the most common form of Cushing's syndrome, being responsible for approximately 80% of reported cases.
Aim
To evaluate the curability rate of Cushing's disease 1 year postoperatively.
Subjects and methods
We studied retrospectively 28 patients from our Endocrinology department, between 2016–2017, with Cushing's disease: 14 patients that were treated by transsphenoidal adenomectomy and 14 patients by bilateral adrenalectomy, with and without radiation therapy and medical treatment.
Results
77% of the subjects were women and 23% were men. Age of the patients was between: 30–40 years (13%), 41–50 years (40%), 51–60 years (16%), 61–70 years (23%), 71–80 years (8%). 29/30 patients presented clinical features suggestive of cortisol hypersecretion: red to purple striae (53%), facio-cervico-truncal obesity (83%), hirsutism (40%), hypertension (73%) and diabetes (26%). Patients treated by transphenoidal adenomectomy had the following outcome: 57% had microadenomas that were cured postoperatively, 43% remaining had macroadenomas, of which: 66% were resistant to combined treatment- surgery, gammaknife radiation therapy and medical treatment with steroidogenesis inhibitors, somatostatine analogs or dopamine agonists and 34% were cured postsurgery. Patients with bilateral adrenalectomy: 79% cured postoperatively, of which 35.7% also underwent radiation therapy and 21% controlled after bilateral subtotal adrenalectomy combined with radiation therapy and medical treatment.
Conclusions
The elective treatment for Cushing's disease is removal of the pituitary adenoma, by transsphenoidal adenomectomy, which has a high rate of curability, predominantly when dealing with microadenomas. Bilateral adrenalectomy is a secondary treatment option, that cures Cushing's disease, but at the cost of adrenal insufficiency.

Insipidus diabetes and vaginal ulcers... evidence for the diagnosis of langerhans cell hypophysitis

Sara Correia, Gustavo Melo, Helena Alves, Lucia Almeida, Maria João Oliveira & Diogo Ramalho
Centro Hospitalar de Vila Nova de Gaia, Endocrinology, Gaia, Portugal

Introduction
Langerhans Cell Histiocytosis (HCL) is a rare granulomatous disease, unknown etiology, with a wide clinical spectrum. The pituitary is affected in 25% of cases, with diabetes insipidus being the earliest and most frequent feature. Although it is more common in pediatric age, it can also be developed by adults.
Clinical case
A 39-year-old, caucasian, woman presents with polydipsia with 5L/day of water and an appetite for cold drinks, polyuria with nicturia and amenorrhea, with two years of evolution. In association, complaints of vaginal itching and dryness. She had been medicated with fluvoxamine, bisoprolol, zolpidem and alprazolam since an year ago for an anxiety disorder. On physical examination she presents with no characteristic biotipe, hemodynamically stable BMI 29.3 kg/m2. The gynecological examination revealed vesicular and ulcerated lesions of various dimensions and in different stages of healing in the vulvar region.
Analytically
A sodium of 152 mmol /l (135–145), a low urinary density (1003) and a low urinary osmolarity (108 mOsm/kg). All the other pituitary hormonal lineages were normal. A pituitary MRI revealed the absence of the hypersignal in T1 in the neurohypophysis and thickening of the pituitary stalk. Central diabetes insipidus was confirmed and she started on 0.06mg oral desmopressin 2 times/day, with improvement of symptoms. Given the persistence of

absence of menstruation, but without primary hypogonadism, we performed the LHRH stimulation test that was normal. The complementary investigation excluded autoimmune, infectious and neoplasic disease. The biopsy of a vulvar lesion and subsequent immunohistochemical revealed positivity for the CD1a and S100 markers, confirming HCL etiology. The involvement of organs such as the spleen, liver, lung and bone marrow were excluded. She started on chemotherapy with cladribine and a genital typical application of activated antifungal. The genital lesions disappeared although she remained in amenorrhea and with central diabetes insipidus in the pituitary MRI there has been no progression of the disease.
Discussion
This case intends to highlight a great heterogeneity of clinical manifestations caused by HCL, usually the definitive diagnosis is difficult to achieve. In this particular case the biopsy of the vulvar lesions gave the final diagnosis. It is not consensual that chemotherapy is beneficial for these patients although in this case seemed to help the healing of the vulvar lesions without progression of pituitary disease.

Functional gonadotroph adenoma

Chayma Besrour, Zouaoui Chadia, Jaidane Amel & Ouertani Haroun
The military hospital in Tunis, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
The pituitary adenoma is the most frequent begnin pituitary tumor. They are labeled based on their size, tumors smaller than 1 cm called microadenomas and tumors bigger than 1 cm called macroadenomas. Moreover, they can be functional or non functional. Among the functional ones, gonadotroph adenomas represent 15 to 20%.
Observation
We report the case of a 27 years old women, who consulted for secondary amenorrhea for 1 year. Further hormonal examinations showed an elevated FSH level at 170 mUI/l and an elevated LH level at 81 mUI/l with no other abnormalities in the rest of the pituitary hormones.The MRI revealed a macroadenoma 11.5 × 12.4 mm in diameter strongly enhanced with gadolinium-based contrast agents.After a few years of surveillance, the patient developed a visual field deficit and a decrease in the visual acuity. She underwent lesional resection by the endonasal transsphenoidal approach complicated with panhypopituitarism.The analysis of the tumor samples revealed an immunopositivity for both FSH and LH.
Conclusion
In women, functional gonadotroph adenomas may cause ovarian stimulation syndrome and/or menstrual abnormalities. They are mostly macroadenomas and are associated with significant morbidity.The primary therapy remains surgical which can lead sometimes to full recovery.

Familial X-linked kallman syndrome associated with ptosis, case series

Yasir Elamin[1], Mohammad Hussain Al-Qahtani[2], Fatimah Mohammed Alabdrabalnabi[3] & Zahra Abdulwahed Al Saeed[3]
[1]Imam Abdulrahman Bin Faisal University and King Fahd University hospital, Internal Medicine and Endocrinology, Khobar, Saudi Arabia; [2]Imam Abdulrahman Bin Faisal university and king Fahd University hospital, Paediatric Endocrinology, Khobar, Saudi Arabia; [3]King Fahd University Hospital, Internal Medicine and Endocrinology, Khobar, Saudi Arabia

Kallmann syndrome is a rare congenital hypogonadotropic hypogonadism with variable degrees of hyposomia to anosmia. This syndrome can be transmitted as autosomal dominant, autosomal recessive and X-linked inheritance pattern. We are reporting two cases of young male siblings (17 and 16 years old) who are the offspring of unrelated parents, presenting with delayed puberty and both were complaining of hyposmia. Their older brother, aged 24 years, was diagnosed with isolated hypogonadotrophic hypogonadism. Both patients had eunchoid habitus with small penis and testis with Tanner stage 1. They had a history of cryptorchidism which was corrected with orchidopexy at an early age. The older sibling had unilateral congeital ptosis. Upon further testing, they were found to have hypogonadotropic hypogonadism with severely low Testosterone and undetectable Luteinizing hormone and Follicle stimulating hormone. Other pituitary axes were intact. Pituitary MRI showed normal pituitary with normal olfactory nerves. Chromosomal analysis of both siblings showed 46 XY karyotype with hemizygous likely pathogenic variant was identified in Kal 1 (ANOS1) gene, consistent with a genetic diagnosis of X linked hypogonadotropic hypogonadism type 1. Androgen therapy with testosterone had been initiated for both siblings to induce secondary sexual features. Ptosis was reported by Reardon at 2007 in case series of 2 siblings with Kallmann syndrome. This was the only documented cases in literature to link ptosis to Kallmann syndrome. To our knowledge our case is the second to report this association. The presence of a family of three brothers with Kallman syndrome and the association with ptosis are unusual

The comparison of nocturnal and fasting ghrelin concentration in children with growth hormone deficiency and with idiopathic short stature

Renata Stawerska[1, 2], Marzena Kolasa-Kicinska[1], Sylwia Kołecka-Rajewska[1], Joanna Smyczyńska[1], Maciej Hilczer[1] & Andrzej Lewinski[1, 3]
[1]Polish Mother's Memorial Hospital - Research Institute of Lodz, Department of Endocrinology and Metablic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Pediatric Endocrinology, Poland; [3]Medical University of Lodz, Department of Endocrinology and Metablic Diseases, Lodz, Poland

Introduction
Ghrelin - a growth hormone (GH) secretagogue - presents a circadian rhythm with higher nocturnal concentration (similar to GH). As daily ghrelin production depended on food intake and nutritional state, we decided to assess ghrelin concentration at 60th at 90th minute after falling asleep and at 6:00 am (after 12 hours of fasting), and compare the results to determine the differences between nocturnal and morning ghrelin release in short children, both with idiopathic short stature (ISS) and with growth hormone deficiency (GHD). We also decided to correlate nocturnal and morning ghrelin concentration with the nocturnal GH concentration, measured at the same time points, as well as with the insulin-like growth factor I (IGF-I) and the maximal GH concentration during stimulating tests.
Methods
In 19 short children (aged: 10.36±3.06 years), ghrelin and GH concentration at 60' and 90' after falling asleep, as well as fasting ghrelin and IGF-I concentrations were measured. Moreover, two GH-stimulating tests were performed to establish the diagnosis: ISS or GHD.
Results
A significant correlation was observed: a) positive-between nocturnal ghrelin (both at 60' and at 90') and fasting ghrelin concentrations; b) positive - between ghrelin at 60' and nocturnal GH concentrations (both at 60'and at 90') ; c) negative - between ghrelin at 60' and IGF-I concentrations; d) negative - between ghrelin concentrations at 60' and body mass index of children.
Conclusions
1. In short children, fasting ghrelin indirectly reflects its nocturnal concentration, however it is significantly higher than the nocturnal one.
2. Despite the fact that ghrelin appears to stimulate GH secretion at night, and IGF-I is the main peripheral mediator of GH activity, it appears that in short children the lower levels of IGF-I the higher nocturnal secretion of ghrelin. This indicates inadequate GH synthesis or effects on peripheral IGF-I production in these cases.
3. Additionally, a higher nutritional state is an independent factor which influences lower nocturnal ghrelin secretion.

Multiple endocrine neoplasia 1, 4 or simple concomitance ?

Bianca Chiriac[1], Maria Christina Ungureanu[1, 2], Letitia Leustean[1, 2], Andreea Rosu[1], Georgiana Neagu[1], Madalina Protop[1], Ioana Ambarus[1] & Cristina Preda[1, 2]
[1]Emergency Hospital "Sf. Spiridon" Endocrinology Clinic, Iasi; Romania; [2]"Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Department of Endocrinology, Romania

Introduction
The association between pituitary adenoma and hyperparathyroidism is the main feature of multiple endocrine neoplasia (MEN) 1 but also for a novel MEN4 syndrome. Germline mutations in the cyclin-dependent kinase (CDK) inhibitor 1b gene (CDKN1B) were identified in patients with MEN4. The most common phenotype of the 19 established cases of MEN4 that have been described since now is primary hyperparathyroidism (PHPT) followed by pituitary adenomas. There are a limited number of cases with MEN4 and that way the association between phenotype and genotype is very difficult in order to have a positive diagnosis.
Aim
Tto present the discovery in uncommon circumstances of multiple endocrine tumors in a patient with no signs or symptoms of endocrine disorders and the difficulty to classify a possible MEN 1 or 4 syndromes.
Case presentation
We report the case of a 74-year-old female without significant family history of endocrine disease who was discovered with pituitary tumor (12/9.5 mm) and right adrenal incidentaloma (34/19 mm) at CT scan. The medical history revealed the presence of hypertension and a hip fracture at the age of 60. The patient was overweight (BMI=26 kg/m^2) with no particular signs of endocrine dysfunctions. The endocrine panel taking into account both pituitary and adrenal tumors revealed GH nadir during OGGT=23.7 pg/ml, IGF1=456 ng/ml (64–188) with central thyroid insufficiency (TSH=0.027 µUI/ml, fT4=1.39 ng/dl) and normal values for: prolactine, ACTH, plasma cortisol, free urinary cortisol, 24-hour urinary fractionated metanephrines. The ultrasound of the neck area discovered the presence of multiple thyroid macronodules and o nodular lesion located posterior to the right thyroid lobe suggestive for parathyroid adenoma. High levels of parathyroid hormone (186.2 pg/ml), hypercalcemia (11.04 mg/dl) along with osteoporosis (distal forearm T-score=–3.1 S.D.) and normal values of vitamin D were consistent with the diagnosis of PHPT. The parathyroid 99mTc-MIBI scintigraphy revealed the presence of multiple adenomas in all four glands. Regarding the thyroid the level of calcitonine was normal also the fine needle aspiration biopsy. The patient declines the surgical treatment for GH secreting pituitary adenoma and also PHPT. Somatostatin analogues and close surveillance was the decision for this patient.
Conclusion
In the absence of genetic result of possible mutation is very difficult to decide the MEN type or to conclude for simple concomitance. The phenotype otherwise extremely suggestive for MEN is not enough for delimitation between the type 1 and 4.
Keywords: MEN1, MEN4, fenotype, genotype.
DOI: 10.1530/endoabs.70.EP312

Radiotherapy in acromegaly: a single centre experience
Tanja Rezic[1], Tanja Skoric Polovina[2], Ivana Kraljevic[2], Mirsala Solak[2], Karin Zibar Tomšić[2], Anne-Marie Balasko[2], Tina Dusek[2], Zdravko Heinrich[2] & Darko Kastelan[2]
[1]Clinical Hospital Dubrava, Department of endocrinology, Zagreb, Croatia; [2]University Hospital Centre Zagreb, Department of endocrinology, Zagreb, Croatia

Background
Radiotherapy (conventional and/or radiosurgery) is an effective treatment option in patients with acromegaly when biochemical control of the disease cannot be achieved by medication and/or surgery. Purpose: The aim of our study was to evaluate the efficacy of gamma-knife radiosurgery or conventional radiotherapy in the treatment of GH-secreting pituitary adenomas.
Materials and methods
We conducted a retrospective analysis of 22 acromegaly patients treated with gamma-knife radiosurgery (n=19), conventional radiotherapy (n=2) or both methods (n=1) between 1996 and 2018 at the University Hospital Centre Zagreb. The data were analysed to assess biochemical remission defined as low or normal IGF-1 without IGF-lowering medication. Results
The median follow-up (FU) was 63.5 months (range 14–192 months). A biochemical remission was achieved in 10 patients (45.4%) with the actuarial remission rates of 13.6%, 27.2%, 40.9% and 45.4% at 1, 2, 4 and 5.5 years, respectively. The median time to biochemical remission was 21 months (range 6–66). There were no statistically significant associations between patients age, gender, tumour volume, dose of radiation or duration of FU and biochemical remission. However, there was a trend to higher remission rate in patients with lower IGF-1 before radiotherapy (P=0.053). Tumour growth control was achieved in all patients. New hormone deficiencies were found in 9 patients (40.9%) (in 6 patients one and in 3 patients two or more hormone deficiencies). This corresponds to the incidence of one new case of hypopituitarism per 5.5 patient-years. Conclusions: Radiotherapy offers endocrine remission and tumour control in a substantial proportion of patients with GH-secreting adenomas. Given a high cost of life-long medical treatment and a moderate risk of hypopituitarism, radiotherapy of GH-secreting pituitary adenomas should be considered in all patients with residual tumour.
Keywords: acromegaly, radiotherapy, gamma-knife.

Malabsorption of levothyroxine sodium tablet in a patient with neuroendocrine gastric tumor, follow-up
Olivera Boskovic[1], Brigita Smolovic[2] & Ranko Lazovic[2]
[1]Clinical Center of Montenegro, Endocrinology, Podgorica, Montenegro; [2]Montenegro, Medical School, University of Montenegro, Podgorica, Montenegro

Multiple dose adjustments can sometimes be inefficient in reaching eumetabolic state in patients with hypothyroidism treated by levothyroxine sodium tablets.
We report a case of 46-year-old female who has been on levothyroxine sodium tablet replacement therapy since 2004 without ever reaching eumetabolic state. As sellar MRI ruled out pituitary adenoma, investigation perform absorption test with 300 mg levothyroxine and test was positive in aspect of presence of selective levothyroxine malabsorption. Initial endoscopies revealed chronic atrophic gastritis without excluding possibility for tumor presence. Serum CgA level was 521 mg/l. The final third endoscopy was successful in detecting the gastric submucosal change, confirmed by endoscopic ultrasound as submucosal lesion no larger than 12 mm located in the upper part of anterior gastric wall. Histological analysis of biopsy specimen confirmed lesion to be neuroendocrine tumor–Carcinoid tumour ventriculi, Chromogranin A +, NSE+; synaptophhisin-, CK 7+with Ki67+in 2% tumour cell. Further imaging excluded its metastatic spreading, so the indication for surgical removal was established. Patient could not undergo surgery with TSH levels exceeding 100 mmU/l and free T4 lower than 5 pmol/l despite being on 300 mg of levothyroxine daily substitution regimen. Changing to a gel capsule formulation taken once a day at dose of 100 mg lead to a rapid TSH decreasement and thyroid hormones normalization, so the patient was surgically treated as eumetabolic. After six months, the patient had an unregulated thyroid status again (TSH 76.26 mIU/l, fT3 2. 7pmol/l, fT4 5, 1pmol/l). We did a control endoscopy and determined the level of gastrin (1432.0 pg/ml) and CgA (798 mg/l) and Gallium-68 Dotatate PET/CT scan thereafter (normal). We are now looking for Zollinger-Ellison syndrome and the patient is receiving 500 mg of levothyroxine sodium tablet.
This case suggests that gastric chronic inflammatory processes and neuroendocrine tumors as well may affect levothyroxine absorption.

What we found the hidden cause of SIADH?
Yin Yin, Htet Htet Aung, Giulia Simini & Samer Alsabbagh
East and North Hertfordshire NHS Trust, Endocrine and DM, Stevenage, United Kingdom

A 74-year- old gentleman was found to be hyponatraemic when he returned from birds watch trip with cellulitis of lower legs. He was generally fit and well apart from hypertension for which he had been on Amlodipine and Irbesartan. He was admitted with severe hyponatremia in July 2019 and was diagnosed with idiopathic SIADH as evidence of low serum osmolality (252 mosm/kg), high urine sodium (41mmol/l) and high urine osmolality (657mmol/kg). His Amlodipine and Irbesartan were replaced with Doxazosin. His thyroid function and adrenal function were normal. Underlying causes such as malignancy were investigated by CT Head and CT CAP showing no apparent causes. His sodium was closely monitored in Ambulatory Clinic for 2 months by liaising with endocrine specialist. Demeclocycline was initiated as he struggled with fluid restriction and the dose was adjusted later. He was seen in the endocrine clinic for further management in view of poor response to Demeclocycline. He was unfortunately re-admitted under urology team with new presentation of urinary retention, haematuria, hesitancy and frequency. Per-rectal examination showed moderately enlarged prostate. He was treated as an obstructive uropathy with

immediate catheterization. CT abdomen and pelvis showed locally invasive prostate cancer causing left-sided hydronephrosis and hydroureter, with abdominopelvic lymphadenopathy and liver metastases. Urgent urology intervention was required to relieve obstructive uropathy. There was an unclear diagnosis between prostate cancer and rectal malignancy initially due to presence of liver metastasis and normal PSA level. Hence, MRI pelvis demonstrated the high clinical suspicious of prostate cancer with liver and bone metastasis. Flexible sigmoidoscopy and rectal biopsy excluded the rectal cancer. Giving that, normal PSA level, CT scan result and unknown cause of SIADH, Prostate biopsy was performed and confirmed the diagnosis of NET neuroendocrine tumour of prostate by showing the extensive infiltration of small cell neuroendocrine carcinoma comprising 95-100% of tumour burden. Immunohistochemistry revealed diffuse CD56 and synaptophysin positivity. There was diffuse TTF1 staining and negative PSA expression. Gut hormones profile was within normal limit.
Discussion
This case highlights the importance of investigating the underlying cause of malignancy in newly diagnosed SIADH without obvious cause. Moreover, normal level PSA does not exclude neuroendocrine tumour of prostate. Therefore, close monitoring and observation for new SIADH might reveal the underlying cause and avoid missing evolving malignancy?!

EP316

Aggressive evolution of a neuroendocrine tumors of the lung (Lu-NETs) - case report

Corina Galesanu
University of Medicine and Pharmacy ”Grigore T. Popa” Iasi, Emergency Clinical Hospital “Sfantul Spiridon”Iasi, Endocrinology, Iasi, Romania

Background
Lu-NETs are a heterogeneous family of neoplasms ranging from quite indolent lesions with extremely aggressive tumors with very poor prognosis. These neuroendocrine entities are further summarized into two groups according to their biological aggressiveness: Well-differentiated: carcinoids typical (G1) and atypical (G2).Poorly-differentiate: SCLC (Combined) and LCNEC (Combined) (G3). Alarm signal on the aggressive evolution of the SCLC
Case report
Female, 60- ys. old, consult the doctor for Atrial Fibrillation. Chest x-rays: lobar atelectasis top left. CT scan: 1. lobar atelectasis top left by total obstruction from the origin of left upper lobar. 2. Lymph node metastases in hill and mediastinum. Bronchial biopsy: tumor infiltrated with insular architecture, small cells, high nuclear/cytoplasm ratio partly free chromatin, big round nuclei, bizarre cell bodies=Small Cell Lung Neuroendocrine Carcinoma (SCLC). IHC: TTF1-intensely positive in tumor cells. Cromogranin intensely positive. Synaptofizin-positive. CK7-negative. Ki67–25%positive. Treatment: Chemotherapy+radiotherapy. After nine months CT abdomen: tumoral mass in left adrenal, possible MTS. After another two months: Carcinoid syndrome: flushing, diarrhea, bronchoconstriction, tachycardia episodes. Biochemical markers: neuron specific enolase- increased chromogranin A- slightly increased. Treatment: Sandostatin LAR 20 mg/28 days. After 14 months of the diagnostic, the patient dies with cerebral MTS.
Conclusions
SCLC, is a highly aggressive disease; a young woman, with no smoking history, with a short period of stabilization after the treatment, develops quickly brain MTS and dies in short time.

Hypopituitarism and vitamin D deficiency in a patient with primary CD8+ T-cell deficiency.

Anaam Ben Chehida, Ibtissem Oueslati, Wiem Madhi, Meriem Yazidi, Nadia Khessairi, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
CD8+ T-cell deficiency is a feature of many chronic autoimmune diseases. Its association with vitamin D deficiency was described and it has been suggested that vitamin d deficiency contribute to the increase of the incidence and the progression of autoimmune diseases.
Herein we report a case of hypopituitarism and vitamin D deficiency in a patient with CD8+ T-cell deficiency.
Observation
A 28-year-old woman was admitted for a severe hypocalcaemia. She was born at term to healthy consanguineous parents and had a history of a primary CD8+ T-cell deficiency diagnosed at the age of 2 years, recurrent infectious diseases, hepatic cirrhosis and a pathological fracture of the femoral neck. She presented with constipation, abdominal pain and numbness and a primary amenorrhea. On physical examination, she had a body weight of 37 kg, a body height of 128 cm, a blood pressure of 10/6 cm Hg, a female phenotype with a female external genitalia (Tanner stage: breast development: stage 3 and pubic hair: stage 1), a dysmorphic syndrome and small hands and feet. Trousseau and Chvostek signs were positive. Electrocardiograph showed allonged QT: QTc 477 ms. The funduscopic examination revealed retinitis pigmentosa. On routine blood tests, she had a corrected calcium level of 62 mg/l, a phosphorus level of 27 mg/l, a magnesium level of 12 mg/l, a creatinine level of 4 mg/l. Hormonal investigations revealed a high PTH level of 470 pg/ml, a low 25 OH vitamin d level of 9 µg/l, a corticotropin deficiency with a peak cortisol level in response to insulin induced hypoglycemia test of 12 µg/dl and a hypogonadotropic hypogonadism. Peak GH level in response to hypoglycemia test was 33 mUI/l. Prolactin level and thyroid function were normal. Pelvic ultrasonography showed hypoplastic uterus with no visualized ovaries. Pituitary magnetic resonance imaging was contraindicated in our patient because she had a foreign metal screw. The patient was treated with hydrocortisone, vitamin d and calcium gluconate.
Conclusion
We report an unusual case of hypopituitarism and vitamin D deficiency in a patient with a primary CD8+ T-cell deficiency. It is difficult to assess the relationship between these disorders. Further investigations are needed to understand this association.

Silent corticotropic adenoma revealed by headache

Sara Ijdda, Ilham Bouizammarne, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
Silent corticotropic adenoma (SCA) is defined by the absence of clinical manifestations of Cushing’s disease despite the presence of ACTH and/or its precursors in tumor cells. It is a rare entity that represents 10% of pituitary tumors. It is known for its increasing expansion. Its clinical presentation is dominated by symptoms of tumor mass effect. We report the case of a silent corticotropic adenoma revealed by headache.
Case Report
67-year-old patient, not known to be diabetic or having hypertension; referred in our departement for post-operative monitoring of an operated pituitary macroadenoma. At clinical assessement, the patient complains of retro-orbital headaches with a decrease in visual acuity, without any signs of insufficiency or pituitary hypesecretion. A pituitary magnetic resonance imaging (MRI) is performed, showing a sellar and supra-sellar mass of $35 \times 29 \times 24$ mm in diameter. The surgical indication was retained. The patient was operated on 3 times. The histological study confirms the diagnostic hypothesis of a corticotropic pituitary adenoma. Postoperatively, the patient developed gonadotropic and thyreotropic insufficiency. A substitution with Levothyroxine at 25 µg per day is instituted. The other ante- pituitary functions are normal with a prolactin level and a cortisoluria of 24 hours in the norms; while MRI monitoring showed the persistence of the sellar and suprasellar tumor process measuring $40 \times 37 \times 22$ mm enhanced by contrast, with compression of the optic chiasm and the pituitary stalk and invasion of the right cavernous sinus. Currently, she is a candidate for surgery once again.
Discussion and conclusion
In summary, SCA is a distinct and aggressive subtype of pituitary adenomas. Preoperatively, they can be in the form of non-functioning pituitary adenomas and must be closely monitored postoperatively for the development of hypopituitarism, frequent recurrences, and more rarely for possible transformation into Cusching disease. Multimodal therapy may be necessary to adequately manage patients in whom the disease recurs, and larger clinical trials will hopefully demonstrate more effective drugs.

Endocrine pathology hidden by IUD

Malika Ichiche, Iconaru Laura
CHU Brugmann, Endocrinology, Laeken, Belgium

Introduction
Amenorrhea is a condition resulting from dysfunction of the hypothalamus, pituitary, ovaries, uterus, or vagina. Hyperprolactinemia is a relatively common endocrine disorder that produces amenorrhea by suppressing hypothalamic GnRH secretion. We describe a patient who had a Levonorgestrel intrauterine device (UID) since 5 years and who presented with amenorrhea in association with a macroprolactinoma.
Case Report
A 45 year- old -woman presented for a routine gynecologic control. She had amenorrhea since an IUD was placed 5 years earlier. A routine blood test ordered by her gynecologist showed severe hyperprolactinemia (PRL 3298 microgram/l (4.8–23.3), accompanied by hypogonadotropic hypogonadism and hypothyroidism. IGF-1, ACTH and cortisol were normal. She was referred for further work up. She didn't complain of headaches, visual disturbances or galactorrhea. On physical examination galactorrhea was found. The visual field was impaired, with superior left temporal hemianopsia. Additionally, a pituitary MRI scan showed a pituitary tumor with supra-seller extension (30 × 19× 25 mm) and compression of the left side of the chiasma opticum and deviation of the pituitary cleft to the right. Moreover a voluminous cavernoma lokated parietal paraventricul left with discrete mass effect on the corpus callosum was observed. Bone mineral density was normal. Treatment was initiated with 0.5 mg cabergoline 3 times a week and L-thyroxine. The monthly PRL concentration dropped as following to 568, 208, 52.9 (bioactive 43) and 31.1 (bioactive 27) ng/ml respectively. 6 months and 12 months later the prolactin bioactive was 27.8 and 9.5, respectively. Control MRI 1 year later showed regression (13 × 7mm) of the macro adenoma with lateralization to the left.
Discussion
The clinical manifestations of hyperproleactinemia in premenopausal women are oligo-or amenorrhea and infertility and are correlated with the magnitude of hyperprolactinemia. Less often galactorrhea occurs. Hyperprolactinemia accounts for 10 to 20% of cases of amenorrhea. Our patient presented with amenorrhea in association with a pituitary macroprolactinoma. Cabergoline treatment was effective in PRL normalization and regression of the macroprolactinoma. In this case, in the past, it was thought her amenorrhea was due to her hormonal IUD and hyperprolactinemia was not considered as a possible cause of amenorrhea and therefore had not been detected. Moreover, she had no other associated symptoms.
Conclusion
Clinicians should be aware that the amenorrhea associated with the IUD can hide a prolactinoma. Serum prolactin should be measured in every woman with amenorrhea.

Lateralized sixth cranial nerve palsy after inferior petrosal sinus sampling

Burçak Helvacı[1], Mehdi Houssein[1], Fatma Dilek Dellal[1], Gokhan Yuce[2], Şefika Burçak Polat[3] & Reyhan Ersoy[3]
[1]Ankara City Hospital, Endocrinology, Ankara, Turkey; [2]Ankara City Hospital, Interventional Radiology, Ankara, Turkey; [3]Yildirim Beyazit University, Endocrinology, Ankara, Turkey

Introduction
Inferior petrosal sinus sampling (IPSS) is the gold standard test to differentiate Cushing's disease from ectopic Cushing syndrome. IPSS may cause severe complications; however, overall rates are low. Subarachnoid hemorrhage (SAH) has been rarely reported after IPSS. Here we report a case who developed hypertensive emergency, left 6th cranial nerve palsy, and SAH after IPSS.
Case
A sixty-two years-old female patient had a history of hypertension, ischemic cerebrovascular incident, coronary artery disease, and atrial fibrillation. She was diagnosed with bilateral adrenal incidentalomas five years ago, a right-sided 20 × 13 mm and a left-sided 40 × 40 mm adenoma. She did not exhibit typical features of Cushing syndrome but had high levels of salivary and 24-hour urinary cortisol. Serum cortisol was not suppressed with low dose dexamethasone (DXM). High dose DXM testing demonstrated less than 50% suppression. Adrenal venous sampling was unsuccessful. Left adrenalectomy was performed. Pathology showed nodular hyperplasia. The laboratory evidence of hypercortisolism vanished after surgery. Her follow-up was unremarkable until 2019 when she suddenly started experiencing hypertensive episodes. The evaluation revealed biochemically recurrent Cushing. ACTH was not suppressed but was in the gray zone and increased after CRH. High dose DXM testing suggested Cushing Disease. Hypophyseal magnetic resonance imaging (MRI) revealed a right-sided 4 mm adenoma. IPSS was planned. She was on apixaban, which was switched enoxaparin. There was no technical problem during IPSS. About an hour after the procedure, she developed acutely elevated hypertension (180/100 mmHg), headache, and vomiting. Her Glasgow-coma scale point was 15, without any deficits. Her blood pressure (BP) could not be controlled with oral medication; she was transferred to the ICU for intravenous nitrate infusions. Four hours following the procedure, her BP was still uncontrolled, and she developed a left-sided 6th cranial nerve palsy without any visual disturbances. A head scan revealed widespread hyperdensities in the subarachnoid space and ventricles. Her BP treatment was intensified with subsequent successful control. Cranial MRI excluded acute cerebrovascular incident. Her symptoms gradually improved. Nerve palsy dissolved after 48 hours. Follow-up imaging on the fourth day showed that hyperdensities had entirely resolved. She was discharged without any sequel. IPSS results were lateralized to the adenoma side. She is planned for surgery.
Conclusion
Hypertensive emergency and SAH after IPSS are rare but not unexpected. To our knowledge, this is the first case of transient 6th nerve palsy after IPSS. Physicians should be prepared for these uncommon presentations after IPSS.

Infundibulo-hypophisitis with other metabolic disorders

Klodi Poshi, Agron Ylli, Adela Haxhiraj, Geri Hysi, Pranvera Spahija, Besa Hyka, Violeta Hoxha, Dorina Ylli, Marjeta Kermaj, Thanas Furrerraj, Florian Toti & Denisa Qehajaj
University Hospital "Mother Tereza", Endocrinology, tirana, Albania

Introduction
Infundibulo - hypophisitis is a rare type neuroendocrine disorder characterized by autoimmune inflammation and various pituitary disfunction. It currently has no clear diagnosis criteria.We present the 26 years–old women, first diagnosed with infundibular neurohypophisitis with clinical Diabetes Insipidus and later with other metabolic disorders.
Case description
The patient, female, 26 years old came in the emergency room with extreme fatigue, weakness, alteration of the conscience and high fever. She was first diagnosed with Limfocitar Hypophysitis in 2017, secondary Diabetes Insipidus and pituitary hypothyroidism and was being treated with Desmopresin, Levothyroxine and Dexamethasone.At the moment of the presentation, she had the following parameters: Glicemia 1062 mg/dl, Urea 126 mg/dl, Creatinine 2.0 mg/dl, Na 155 mmol/l and K 3.6 mmol/l. HbA1C 9.4% Brain CT showed no acute cerebral damages. She was first hospitalized in Intensive Care Unit and later transferred in our Department as Secondary Diabetes Mellitus and hyperosmolar hyperglycemic state. During her stay, she complained of high fever and pain in both knees. She was diagnosed with Bilateral Pneumonia, Urinary tract infection and Tendinitis for which she was administered antibiotics and non steroid anti inflammatory drugs. Her blood glucose level was rapidly normalized and although she started insulin, after a few days she didn't required anymore therapy with hypoglicemiant drugs. Dexamethasone was gradually substituted with hydrocortisone as morning blood cortisol was 0.25 ng/ml (55–230). Other parameters resulted as followed: Urinary density 1010, CRP 15.4 (1.1–8.0 ng/ml), Triglycerides 649 mg/dl and Cholesterol 336 mg/dl. A total body scan was done which resulted normal. When discharged, her parameters were stable and she was given therapy with hydrocortisone, levothyroxine, desmopresine and fibrate.
Conclusion
Infundibulo- Hypophysitis is a rare form of neurological disorder. It can show both local symptoms of inflammation and hormonal dysfunction, depending on the location and dimension of the lesion. Anti inflammatory treatment and partial or total hypopituatarism can create metabolic disorders which need a closer look and a careful follow up.

Heart failure as a first manifestation of acromegaly - A case report

Ivana Sagova[1], Dusan Pavai[1], Milan Dragula[2], Daniela Kantarova[2], Anton Vanuga & Peter Vaňuga[1]
[1]Department. of Endocrinology, National Institue of Endrocrinology and Diabetology, Ľubochňa, Slovakia; [2] Department. of Internal Medicine, University Hospital, Martin, Slovakia; [3] AlphaMedical s.r.o, Ľubochňa, Slovakia

Acromegaly is a rare disease, which is mainly caused by benign tumour of the pituitary gland. Long-term presence of elevated growth hormone (GH) and insulin like growth factor 1 (IGF-1) levels accompanying this disease is associated with rheumatologic, cardiovascular, pulmonary and metabolic complications. Cardiovascular complications of acromegaly include a cardiomyopathy, arterial hypertension, arrhytmias, valvulopathy as well as endothelial dysfunction. Cardiovascular diseases are the leading cause of mortality in patients with acromegaly. We describe a 39-year-old male with undiagnosed acromegaly presented with acute heart failure caused by acromegalic cardiomyopathy. Pacient with 3 months history of artrerial hypertension was admitted to the department of internal medicine with orthopnea and pitting edema of the lower limbs experienced over a 1-month period. He also had excessive sweating over a 1 year. Physical examination on admission showed that his height and body weight were 193 cm and 150 kg. Blood pressure was 140/95 mmHg, and heart rate was 66/ min with sinus rhythm. He showed acromegalic features such as outstanding jaw and eyebrow area, enlarged hands, feet and also nose, tongue and lips. Pulmonary auscultation revealed coarse crackles in the bilateral lower lobes. Echocardiography showed dilated and hypertrophic left and right ventricles (IVS 17 mm), restrictive filling pattern, global hypokinesia, systolic dysfunction with EF 22% without valvulopathy. Comprehensive treatment of heart failure was initiated. To rule out coronary artery disease, a coronary angiography was performed without significant stenosis of coronary arteries. Laboratory tests revealed high level of GH which was not suppressed after glucose administration, high level of IGF-1. A magnetic resonance imaging scan revealed a 14 × 14 × 12 mm macroadenoma involving the pituitary gland. A diagnosis of acromegaly was established. Treatment by somatostatin analogues was initiated at dose 120 mg every 28 days. Control magnetic resonance imaging of the sella demonstrated a decrease of macroadenoma size (13 × 11 × 12 mm). Control echocardiography after 1 year of treatment showed improvement of left ventricle systolic and diastolic function (EF 33%). Nowadays trans-sphenoidal resection of macroadenoma is in the plan

Association of an empty sella and grave's disease in a patient with acromegaly

Imen Halloul, Asma ben Abdelkarim Mzoughi, Ahlem Slim, Ghada Saad, Wafa Ben Othman, Yosra Hasni, Amel Maaroufi, Maha Kacem Njah, Molka Chaieb & Koussay Ach
Farhat Hached university hospital, Department of Endocrinology and Diabetes, Sousse, Tunisia

Introduction
Acromegaly is, in most cases, caused by growth hormone (GH) -secreting pituitary adenomas that lead to characteristic phenotypical changes. Its association with emty sella (ES) has been described and different theories has been given to explain such situation. Moreover, patients with acromegaly often develops different pathologies of the thyroid gland, however, the occurrence of grave's disease (GD) is quite a rare situation. Here we report a case of a patient diagnosed with grave's disease and acromegaly which was caused by a GH secreting adenoma and associated to an ES.
Case report
A 64-year-old female patient was referred for investigation of recent diabetes mellitus imbalance. For her personal medical history, she has been treated for hypertension and sleep apnea for 17 years now, and was operated for gonarthrosis and carpal tunnel syndrome in both hands 15 years ago. Regarding her family history, her first daughter was diagnosed with GD and the second daughter was followed for hyper prolactinemia due to an empty pituitary sella. Clinically, she was complaining of thermophobia, trembling, polyuro-polydipsic syndrome and weight loss. On examination, she had facial features of acromegaly with enlargement of her hands and feet and a goiter. Her blood pressure was often high. Biochemical testing revealed an elevated insulin-like growth factor-1 and a suppressed thyroid stimulation hormone (TSH) with positive anti-TSH-receptor antibodies. A pituitary Magnetic resonance imaging was performed, revealing an 11-mm adenoma with empty sella and no signs of local invasion. No history of pituitary apoplexy was described by the patient. A transphenoidal surgery was successfully performed and the diagnosis of GH-producing adenoma was also confirmed with immunohistochemistry. For her hyperthyroidism, she was treated with anti-thyroid drugs with a fast remission after 4 months of treatment.
Conclusion
The occurrence of an ES with a pituitary microadenoma has been described in many cases in literature; however its association with a macroadenoma is quite rare. One of the multiple physiopathological theories would be a paracrine effect of the growth hormone on the sellar bone. Moreover the combination of GD and acromegaly is not a commun situation, representing 1% of thyroid pathology in acromagalic patients.

EP324

Significant weight loss as an unusual presentation of empty sella – case report

Cristina Ene
"Dr. Victor Babes" Foundation, Endocrinology, București, Romania

Introduction
Unexplained weight loss is a cause for concern; it might indicate an underlying condition, usualy a catabolic state. In empty sella, the progressive loss of pituitary hormone secretion is usually a slow process, with symptoms varying from one person to another and depends on the underlying cause. Usually the weight remain relatively constant or we could have several arguments for weight gain.
Case report
A 57 years old man with significant weight loss–about 15 kg in the last 4 months, also associating marked physical asthenia, presented in our department to rule out an endocrine pathology, such as hyperthyroidism or primary adrenal insufficiency. All the symptoms had a sudden onset after the summer vacation and 2 weeks prior to presentation he acused musclular weekness and mialgia. The basic blood tests did not show anything wrong and he had no personal pathological background. The hormonal profile showed hypothyroxinemia with inappropriately TSH: FT4 = 0.5 ng/dl (*n* = 0.7–1.48), TSH = 4.49 micro UI/ml (*n* = 0.35–4.94) ; hypocortisolemia with low ACTH: plasma Cortisole = 1.23 microg/dl (*n* = 6.02-18.4), ACTH = 4.29 pg/ml (*n* = 7.2–63.3), low normal IGF1 level: 79.9 ng/ml (*n* = 36-200 for gender and sex), normal gonadotropic axis and normal prolactin level; the electrolytes level was normal. He also had a high level of anti-thyroperoxidase (ATPOs): 781 UI/ml (*n* <5.6), MRI of the pituitary gland was suggestive for empty sella. Substitutional treatment was established on corticotropic and thyrotropic lines, with the rapid disappearance of the symptomatology, the patient having no myalgia and gradually returning to the previous weight.
Looking for the cause of weight loss but also the explanation of empty sella syndrome, the patient also performed chest radiography and abodominopelvic ultrasound, the results being within normal limits–no sign of sarcoidosis or other granulomatous diseases, no tumor; he had no radiation or trauma, no infection and no sign of pituitary infarctisation. The presence of high ATPOs and partial hypopituitarism are suggestive for autoimmune hypophysitis.
Conclusion
Weight loss can be explained by secondary adrenal insufficiency and rarely by decreased intestinal absorption in hypothyroidism, but this is unusual and not significant in hypopituitarism. The symptomatology of our patient was suggestive of adrenal insufficiency, but the diagnosis of empty sella was a surprise. However, evolution of empty sella may be long-lasting and gradual, and rapid weight loss may be due to decompensation.

Screening for developmental neurotoxicity test using 46C cells

Seon Mi Park, Sunhwa Jeong, Jae-Hwan Lee, Eui-Man Jung & Eui-Bae Jeung
Chungbuk National University, College of Veterinary Medicine, Cheongju, Korea, Republic of South

Developmental toxicity tests have been made by embryonic stem cell tests at the European Centre for the Validation of Alternative Methods or by embryonic body test in our laboratory. However, no neuronal-specific developmental toxicity test has been made yet. Therefore, this study was carried out using a 46C cell line, mouse embryonic stem cells with an endogenous Sox1-GFP reporter, to exploit the developmental neurotoxicity test. The expression of Sox1, a marker for neural progenitor, can be detected by green fluorescence and the fluorescence density is a critical factor to achieve neuronal differentiation. 46C cells were treated for 24 hours with 5-fluorouracil, hydroxyurea, chlorpyrifos, clioquinol, diazinon, nicotine and lead acetate as developmental neurotoxicants, or saccharin, sodium bicarbonate, sodium gluconate, and penicillin G as non-neurotoxicants. CCK-8 assays were performed to determine IC50 values after 48 hours of chemical treatment. The fluorescence intensity of GFP was measured after 4 days of treatment with cells using an automated digital microscope. Through CCK-8 assay, IC50 values of developmental neurotoxicant chemicals were obtained, whereas non-neurotoxicant chemicals showed low effects. In addition, the fluorescence intensity of GFP was not decreased with non-neurotoxicants. However, neurotoxicants decreased the fluorescence intensity of GFP at higher concentrations. This decrease of fluorescence intensity indicates that the neuronal differentiation of 46C cells is inhibited by the chemicals. Taken together, this study produced a model of the developmental neurotoxicity tests used embryonic stem cells that may use to evaluate the toxicity of new chemicals or new candidate drugs.

EP326

Therapeutic difficulties in the management of craniopharyngioma

Aicha Bouzid[1,1], Amina Laloui[2] & Djamila Meskine[1]
[1]Algiers, Medical university of algiers, Endocrinology & Métabolism Laboratory Algiers 1, EPH Bologhine, Medecine, Algiers, Algeria; [2]Medical university of algiers. EPH Bologhine, Medecine, Algiers, Algeria

The craniopharyngioma is a benign tumor, curable but aggressive by its localization involving the vital and visual prognosis of the patients. Treated mainly by surgery associated with radiotherapy which allows high long-term survival but at the expense of significant side effects, it nevertheless poses a problem of therapeutic management. The aim of this study is to illustrate the therapeutic difficulties in the management of craniopharyngioma
Patients and methods
13 cases of craniopharyngiomas confirmed by hormonal and radiological investigations (cerebral CT and MRI of the pituitary region) are collected.
Results
Average age at diagnosis is 25, sex ratio: 1.6. The revealing symptoms of craniopharyngioma are mainly represented by the visual disturbances found in 38% of patients, headache in 30%, diabetes insipidus in 15%. Somatotropic insufficiency was found in 30% of the patients evaluated, gonadotropic insufficiency in 38%, corticotropic insufficiency in 53% and thyrotropic insufficiency in 53%; as for diabetes insipidus, 53% of patients suffer from it at the time of diagnosis The average size of the tumor varies from 19 to 29 mm. Therapeutically, 53% of patients underwent surgery, 3 patients received an injection of yttrium and 2 patients underwent a stereotaxic puncture. 2 ventriculoperitoneal leads have been put in place for the treatment of hydrocephalus. Simple monitoring is recommended in a patient. The postoperative morbidities are: 2 cases of diabetes insipidus, one case of breach with fever and a corticotropic deficit.
Discussion
The initial management of craniopharyngiomas depends on the clinical presentation. Signs of intracranial hypertension as well as progressive visual impairment require urgent neurosurgical treatment for hydrocephalus and/or decompression of the cystic portion or tumor. Craniopharyngioma surgery aims to have as much surgical excision as possible to remove as much of the tumor as possible and to decrease the rate of local recurrence. However, this extensive surgery is complicated by a high rate of mortality and morbidity without preventing a significant risk of recurrence since it can reach 62% at 10 years. Recurrences are one of the most common complications, thus posing management difficulties, Conventional radiotherapy being the elective treatment at this stage. Chemotherapy by injection of bleomycin and interferon alpha is reserved for cystic forms.
Conclusion
The management of craniopharyngioma requires multidisciplinary cooperation. Surgery remains the main treatment. The surgical intervention must attempt an optimal tumor reduction while respecting the integrity of the optical and hypothalamic structures. Early diagnosis remains the determining factor in prognosis

Conservative management of pituitary apoplexy – a case series

Raluca Trifanescu[1,2], Dan Alexandru Niculescu[1,2], Alexandru Cristescu[3], Georgiana Alexandra Smarandoiu[2], Ramona Dobre[2], Andra Caragheorgheopol[4], Dan Hortopan[5], Anda Dumitrașcu[5] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Pituitary tumors, Bucharest, Romania; [3]Colentina Hospital, Neurosurgery, Romania; [4]C.I. Parhon National Institute of Endocrinology, Biochemistry, Romania; [5]C.I. Parhon National Institute of Endocrinology, Radiology, Romania

Introduction
Pituitary apoplexy is a rare complication in 2%-12% of pituitary adenomas, due to sudden hemorrhage or infarction. Patients with signs of meningeal irritation, important visual field defects, ocular paresis, decreased unilateral or bilateral visual acuity or altered consciousness are treated by neurosurgical intervention, while patients without these signs could be managed conservatively.
Aim
To present a series of 4 cases with pituitary apoplexy managed conservatively.
Patients
4 patients (3 men and one woman), median age 38 years at diagnosis (range 36–65) were retrospectively reviewed. There were one patient with nonfunctioning pituitary adenoma (NFA), one with acromegaly, one with macroprolactinoma and one with Cushing's disease. There were 2 microadenomas and 2 macroadenomas (median tumor diameter 11.5 mm, range 6–41 mm). All patients but one were previously diagnosed with pituitary adenoma. No precipitating factors were identified.
Methods
FSH, LH, estradiol/testosterone, IGF1, TSH, FT4, serum cortisol and plasma ACTH, PRL were measured by chemiluminescence. Pituitary MRI and visual field assessment were performed.
Results
All patients presented with severe headaches and two patients showed ocular palsies. Signs of meningeal irritation, impaired visual field, decreased visual acuity or altered consciousness were not present in any patient. Panhypopituitarism was present in two patients. Transient aggravation of hypercortisolism was noticed in the patient with Cushing's disease, with hyperglycemia and hypokalemia. Serum natremia was normal in all patients. Conservative approach was decided in multidisciplinary team including endocrinologist, neurosurgeon, ophthalmologist and radiologist. Steroid therapy was administered. The outcome was favorable in all patients: remission of headaches and oculomotor palsies, improvement of cortisol and GH excess in patients with Cushing's disease and acromegaly, respectively. Tumor shrinkage was noticed in all cases.
Conclusion
In selected cases, without altered consciousness and absent or mild neuro-ophthalmic syndrome, conservative management could be an option for patients with pituitary apoplexy.

EP328

Radiation therapy in the management of pituitary adenomas

Aicha Bouzid[1], Abdelmoumen Maataoui[2], Abbas Harid[2] & Djamila Meskine[1]
[1]Algiers, Medical University of Algiers, Endocrinology & Métabolism Laboratory Algiers 1, EPH Bologhine, Medecine, Algiers, Algeria; [2]Medical University of Algiers. EPH Bologhine, Medecine, Algiers, Algeria

Despite advances in neurosurgical techniques, due to their size and their readily invasive nature, surgical resection of functional or non-functional pituitary macroadenomas is often only partial, justifying the use of any additional treatment (resumption of surgery, radiotherapy, treatment drug).
Patients and methods
10 patients were included in the study (7 men middle-aged 56 and 3 women middle-aged 48). 4 patients followed for non-functional pituitary adenomas and 6 for somatotropic adenomas. All patients received conventional radiotherapy (average dose 46.2 Grays) combined with drug treatment. The mode of discovery was either a cranial tumor syndrome (for non-secreting adenomas) or a dysmorphic acquired acromegaly syndrome (for somatotropic adenomas) radiotherapy combined with medical treatment has made it possible to normalize hormone secretion (GH and IGF1) in all patients with acromegaly and tumor reduction in 70% of cases and stabilization in 30% of cases. Regarding post radiotherapy complications are marked by the installation of anterior pituitary insufficiency in all cases within a variable period ranging from 1 to 3 years. The other complications (radionecrosis, stroke, radio-induced tumors) were not seen in this series.
Discussion
All studies find stabilization or a decrease in tumor volume in the majority of cases treated by conventional radiotherapy. The issue of routine radiation therapy after incomplete surgery for a non-secreting adenoma has long been debated. Success of radiation therapy in controlling tumor growth is high, 90–100% in most series, regardless of radiation technique and adenoma subtype. Success in achieving hormonal normalization in secretory tumors is more variable because of differences in patient population, radiation technique, and doses employed and variation of the definition of success. Complete biochemical remission is generally achieved in 50% of patients at 10 yr after treatment for most adenomas. Higher rates of normalization can be achieved with additional medical therapy. Hypopituitarism is an expectant result of radiation therapy. Overall rate of other treatment-related adverse effects is low. Radiation therapy should be considered in the management of patients with pituitary adenomas, particularly when medical and surgical options have been exhausted. Because response evolves slowly over many years and because hypopituitarism is likely to occur, patients should be counseled on the importance of continued endocrinological surveillance and medical management.
Conclusion
Radiation therapy retains a place in the therapeutic arsenal of pituitary adenomas, however in case of hypersecretion the period of effectiveness is a problem because it justifies another antisecretory therapy in the meantime.

A rare tumor at the adult of the hypophysis: Atipic teratoid rabdoid tumor

Hatice Sebile Dökmetaş[1], Aslı Çakır[2], Ayşenur Cila[3], Meriç Dökmetaş[4] & Fatih Kılıçlı[1]
[1]İstanbul Medipol University, Endocrinology and Metabolism, İstanbul, Turkey; [2]İstanbul Medipol University, Pathology, İstanbul, Turkey; [3]İstanbul Medipol University, Radiology, İstanbul, Turkey; [4]İstanbul Medipol University, Internal Medicine, İstanbul, Turkey

Pituitary adenomas are the most common cause of pituitary lesions. Atypical teratoid rhabdoid tumors are rare aggressive tumors of the central nervous system and are generally seen in children younger than 2 years of age, but also rarely in adults. Only 18 cases have been reported with pituitary involvement to 2018. Median survival in these tumors in adults is 21 months and the cause of death is usually tumor recurrence or leptomeningeal spread. Although surgery, chemotherapy and radiotherapy are used in treatment, a standardized treatment scheme has not been established for adults yet. A fifty-five-year-old woman presented to the hospital for a headache that started about 1 month ago. The patient also had a complaint of visual impairment that started 10 days ago. There was no additional problem in the patient's history, except for the diagnosis of diabetes mellitus, which started 1.5 years ago and regulated with metformin. On physical examination, visual acuity was decreased in both eyes with limited vision and looking down. In pituitary MRI, partial bleeding macroadenoma with 4 × 3 × 3 cm diameter filling the sellae, infiltrating the stalk and left cavernous sinus, filling the tuberculum sella, prepontine cystern and suprasellar cysternia were seen. The patient was found to have total pituitary insufficiency. She was given the operation with hydrocortisone and L-thyroxine treatment. Pathology: Macroscopically, approximately 3 cc volume tissue were examined. In microscopic sections, cellular undifferentiated tumor cells with narrow cytoplasm, vesicular nuclei, prominent nucleoli showing solid growth were seen. Necrosis and frequent mitosis were observed. Normal pituitary tissue was not seen. In immunohistochemical examination, GFAP, NSE, lymphoid (CD3, CD20, CD30), germ cell (PLAP), hormonal (LH, FSH, GH, TSH, ACTH) markers were negative. Epithelial markers (EMA, LMWK, pankeratin) were observed with focal staining and INI1 was lost. Ki67 proliferation index was found high (50%) in accordance with the mitotic index. These findings were reported as atypical teratoid rhabdoid tumor. In the PET/CT examination performed on the 15th day after the operation, a massive lesion with an intense pathological increase of SUV max. The patient was started on postoperative radiotherapy and the treatment of the vincrist, but despite this treatment, her vision disappeared in the following period, her consciousness gradually decreased. The patient died later. Atypical teratoid rhabdoid tumors of pituitary are rarely seen. they are resistant to treatment and can cause mortality by showing rapid progression.

Panhypopituitarism as first manifestation in metastatic lung cancer

Corina Homentcovschi[1, 2], Ovidiu-Dumitru Parfeni[3], Khadija Mourid[4], Luciana Craciun[5], Gabreil Becheanu[6, 7], Dan Spataru[1, 2], Luminita Weltz[8] & Ioana Tudor[1, 2]
[1]Carol Davila University of Medicine and Pharmacy, Semiology Department, Bucharest, Romania; [2]Coltea Clinical Hospital, Internal Medicine Department, Bucharest, Romania; [3]Elias Emergency Hospital, Endocrinology Department, Bucharest, Romania; [4]Fundeni Clinical Institute, Gastroenterology Department, Bucharest, Romania; [5]Doctor Carol Davila Central Military Emergency University Hospital, Bucharest, Romania; [6]Carol Davila University of Medicine and Pharmacy, Pathology Department, Bucharest, Romania; [7]Victor Babes National Institute of Pathology, Laboratory of Histopathology and Immunohistochemistry, Bucharest, Romania; [8]Coltea Clinical Hospital, Pathology department, Bucharest, Romania

Introduction
Metastases in pituitary gland are extremely rare with a reported prevalence of 1% among all pituitary tumor resections and 1 to 3.6% among post-mortem studies (1). Breast and lung cancer are the most common sites of primary tumor that have been reported to metastasize in pituitary gland and about 7% of all metastases are symptomatic (2.3).
Case report
A 62-year-old male with a 40-pack-year smoking history and no previous medical conditions presented with nausea, vomiting, fever, somnolence and a 6 kg weight loss in two weeks. Physical examination showed bradylalia, hypoacusis, drowsiness, tempo-spatial disorientation, fever (38 degrees Celsius) and an enlarged supraclavicular lymphatic nodule. No focal neurological deficits or meningeal irritation was found. Routine laboratory tests detected an elevated serum lipase (841 U/l), triglycerides (313 mg/dl), lactate dehydrogenase (994 U/l), creatinine (1.75 mg/dl), uric acid (10.69 mg/dl), c-reactive protein (10.9 mg/dl), fibrinogen (612 mg/dl), d-dimer test (1099 ng/ml), normal serum potassium and slightly elevated serum natrium (145.8 mmol/l). Additional, endocrinological work-up detected panhypopituitarism (FT4 = 4.8 pmol/l, TSH = 0.481 mIU/l, testosterone = 0.170 nmol/l, LH = 0.216 IU/l, cortisol = 47.9 nmol/l) and elevated prolactin levels (415.9 mUI/l). Proper substitutive hormone therapy was adopted. Hole body CT scan revealed the presence of a pituitary tumor, enlarged lymph nodes with necrotic areas in mediastinum and bilateral adrenal glands macroadenomas. Biopsy from supraclavicular lymphadenopathy, followed by pathological examination and immunohistochemistry uncovered a non-differentiated big cell neuroendocrine pulmonary carcinoma metastasis, staining positive for Thyroid Transcription factor 1, Synaptophysin, Chromogranin and Ki67 was positive in 90% of the tumoral cells. The patient condition deteriorated rapidly (obnubilation, tempo-spatial disorientation) with laboratory test showing elevated serum sodium and low potassium levels (Na = 159 mmol/l, K = 2.5 mmol/l). We suspected diabetes insipidus and antidiuretic hormone analogue therapy was started with a slightly improvement on patient condition and laboratory findings. Head MRI taken at three weeks after his initial admission revealed a pituitary tumor (31.4/30.6/27.5 mm) that exerted major compression on the third ventricle and determined internal hydrocephalus. The patient was relocated to neurosurgery department, where a ventriculoperitoneal shunt was placed. Unfortunately, the patient clinical condition continued to deteriorate despite correct treatment and after approximately five weeks after presentation, he passed away.

Conclusion
Panhypopituitarism and diabetes insipidus due to pituitary metastases represents a rare condition that highly complicates the diagnostic and management of patients with pulmonary carcinoma.

GH deficiency in children with sickle cell anemia: About a case

Dorra Dorraelguiche[1], Manel Jemel[2, 3], Grassa Anis[2], Hajer Kandara[2,3] & Ines Kammoun[1,3]
[1]National Institute of Nutrition and Food Technology, Tunis, Tunisia; [2]National Institute Of Nutrition And Food Technology Department of Endocrinology, Tunis, Tunisia; [3]University Tunis El Manar

Introduction
Growth retardation in sickle cell children is common and multifactorial. Recent evidence suggests damage to the somatotropic axis. We report the case of a patient followed for homozygous sickle cell anemia and in whom we discover an associated GH deficiency.
Observation
It is a 13 year old child followed for homozygous sickle cell anemia, splenectomized for 2 years, not polytransfused. We were sent to the hematology department before a delay in weight gain with a delay in bone maturation (bone age=9 years). On examination, he was 139 cm <-2DS in height and 30 kg <3rd percentile in weight. The initial assessment showed a low IGF1 level, a correct nutritional balance and a negative celiac disease serology. Endocrine exploration was in favor of growth hormone deficiency (the GH peak on catapressan test was 6.51 ng/ml and the GH peak on insulin hypoglycemia test was 3.91 ng/ml). An associated corticotropic insufficiency was eliminated by a cortisol peak at 632.8 nmol/l (during the insulin hypoglycemia test) as well as a thyrotropic insufficiency (normal thyroid balance). The pituitary hypothalamic MRI was normal.
Discussion and conclusions
Systematic growth assessment is necessary in children with sickle cell disease as stunting (CR) is common and complex in this condition. Several factors are responsible for this: hematological state (anemia), endocrine function (GH deficiency, hypothyroidism), nutritional status (iron deficiency, vitamin B12 and folates) and bone state (necrosis of epiphyses bone) and hemochromatosis (if polytransfused child). Exploring CR in this population involves evaluating all of these parameters.

Can you predict the recurrence of cushing's disease after surgery?

Paloma Moreno-Moreno[1], Rosa Camara-Gómez[2], Alfonso Soto-Moreno[3], Carmen Fajardo-Montañana[4], Raul M Luque[5] & María Ángeles Gálvez-Moreno[1]
[1]University Hospital Reina Sofía, Management Unit of Clinical Endocrinology and Nutrition, Córdoba, Spain; [2]University and Polytechnic Hospital La Fe, Management Unit of Clinical Endocrinology and Nutrition, Valencia, Spain; [3]University Hospital Virgen del Rocío, Management Unit of Clinical Endocrinology and Nutrition, Sevilla, Spain; [4]University Hospital La Ribera, Management Unit of Clinical Endocrinology and Nutrition, Alcira, Spain; [5]University of Córdoba. IMIBIC, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain

Objective
Remission of Cushing's disease (CD) in the postoperative vary between 55–85%, recurrence of up to 25%. Remission and recurrence rates vary dependent on tumor size and neurosurgical expertise. The objective of this study is to describe whether there are clinical data that help us to predece recurrence of CD after transsphenoidal surgery (TSS).
Patients and methods
Retrospective analysis of patients who underwent as TSS for CD. Variables analyzed: age, sex, time to diagnosis, tumor size, serum cortisol, salivary cortisol, urinary-free cortisol (UFC). Recurrence was defined as disturbance of serum cortisol, salivary cortisol, UFC levels and ACTH in patients in remission after TSS.
Results
67 patients with CD treated with TSS. Women: 82.1%. Remission 71.6% (men: 3; women 45). Recurrence: 23.9% (men: 2; women 14).

	Recurrence	No recurrence	*P*
Age (years)	38.56±14.82	43.03±15.33	0.32
Time from onset of symptoms to diagnosis (months)	25±22.8	37.29±30.54	0.16
Time from diagnosis to surgery (months)	3.5±3.1	7.63±5.93	0.01
Tumor size (mm)	10.42±7.34	9.99±7.81	0.85
Basal cortisol presurgery (µg/dl)	25.21±13.63	22.9±8.53	0.47
Midnight plasma cortisol presurgery (µg/dl)	14.6±3.2	14.47±6.66	0.94
Midnight salivary cortisol presurgery (µg/dl)	0.2±0.11	3.05±7.06	0.11
24-hour urinary cortisol presurgery (µg/24 h)	571.03±407.35	592.31±766.73	0.91
ACTH presurgery (pg/ml)	91.26±62.91	76.72±2.38	0.34
Basal cortisol postsurgery (µg/dl)	5.64±5.47	4.79±6.6	0.65
Midnight salivary cortisol postsurgery (µg/dl)	0.33±0.24	0.17±0.1	0.02
ACTH postsurgery (pg/ml)	24.59±42.38	22.31±32.55	0.85

Conclusions
Patients with recurrence of CD had higher levels of midnight salivary cortisol postsurgery. Recurrence of CD is similar to that described in the literature.

EP333

Pituitary metastasis from lung cancer: uncomon presentation

Grassa Anis[1], Manel Jemel[1], Salhi Salma[1], Hajer Kandara[2] & Ines Kammoun[2]
[1]National Institute of Nutrition and Food Technology, Department of Endocrinology, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology Manar University, Department of Endocrinology, Tunis, Tunisia

Background
Pituitary gland metastasis is rarely the initial presentation of metastatic cancer. Most cases of pituitary gland metastasis are asymptomatic with diabetes insipidus being the most common symptomatic presentation. It can rarely present with symptoms of hormone underproduction such as anterior pituitary deficiency. Although pituitary gland metastasis is rare, it is underestimated, as it is commonly misdiagnosed with pituitary gland adenoma due to the lack of clear radiological criteria differentiating between both.
Case Report
We present a case of a 63-year-old male known as small cell lung cancer owner for already two years, under chemotherapy and mediastinal radiotherapy. The brain scanner initially done as assessment of extension didn't show any anomaly as for the rest computed tomography scan; however four months later; the patient presented blurry vision and persistent headache. This was followed by a brain magnetic resonance imaging (MRI), which showed one unique lesion with an enhancing mass 40 mm long axis involving the right clivus, intrasellar and suprasellar cistern with mass effect on the optic chiasm and involvement of the cavernous sinus and the internal carotid artery; this was supporting both diagnosis of pituitary's macroadenoma and pituitary gland metastasis of small cell lung cancer. Further workup showed no sign of hypersecretion; but conversely showed evidence of hypopituitarism like corticotroph deficiency with (morning cortisol level 36 nmol/l), thyreotropic deficiency TSH (0.062 uUI/ml) FT4 (10.19 pmol/l), gonadotropic deficiency FSH (0.403 mUI/ml) and LH (<0.100 mUI/ml) and disconnection hyperprolactinemia PRL (32 ng/ml), however there wasn't any sign of diabetes insipidus.

Conclusion
The majority of pituitary gland metastasis cases presenting with hypopituitarism have lung cancer as their primary tumor. Many cases of pituitary gland metastasis have been misdiagnosed as pituitary adenomas due to the lack of clear radiological findings that differentiate between these two conditions. However, it is important for physicians to be familiar with the radiological findings and presentations that could favor one diagnosis over the other.

Optimal cumulative dose of cabergoline does not appear to cause fibrotic pulmonary side effects in prolactinoma

Ozlem Soyluk Selcukbiricik[1], Zuleyha Bingol[2], Sema Ciftci Dogansen[3], Neslihan Kurtulmus[4], Seher Tanrikulu[5] & Sema eryarman[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Endocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Pulmonary Diseases, Istanbul, Turkey; [3]Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [4]Acibadem University, Maslak Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [5]Haydarpasa Numune Research and Training Hospital, Endocrinology and Metabolism, Istanbul, Turkey

Introduction
Dopamine agonists (DAs) consisting of cabergoline (CAB) or bromocriptine is the primary therapy in prolactinomas. DAs are also used in Parkinson's disease and restless leg syndrome with much higher doses. As a result of reports related to doses in these patients, it is known that long term use of DAs can lead to fibrotic syndromes affecting heart and lung. Cardiac valvulopathies are the most common investigated side effects but there are case reports of pleuropulmonary fibrosis. These reports raise concern for the safety of DAs in prolactinoma due to possible pulmonary side effects. Terefore we evaluated the pulmonary functions of prolactinoma patients receiving CAB treatment.
Patients and methods
Seventy three patients who received CAB for at least 18 months are included in the study. Chest X-ray and pulmonary functions like forced vital capacity (FVC), total lung capacity (TLC) measurements and diffusion capacity monitoring with carbon monoxide (DLCO; normal range: 80-100%) were performed at the last visit of each patient. Patients with a history of pulmonary disease and using drugs which may deteriorate pulmonary function are excluded from the study. Data of the patients are reviewed retrospectively. Cumulative dose of CAB and the total time of CAB usage are calculated. All patients were evaluated by a pulmonologist and those with abnormal results were requested additional tests like high resolution computerized tomography (HRCT) of the chest if needed.
Results
The study consisted of 34 male and 39 female with a mean age of 43 years (range 22–78). The mean cumulative CAB dose was 244 mg (range 24–1298) and the mean time of CAB use was 75 months (range 18–300). Mean values of FVC, TLC and DLCO were 104±14%, 102±12%, 95±16% respectively. Among 13 asymptomatic patients (17%) with abnormal DLCO results; 2 patients had significantly decreased DLCO (mean CAB cumulative doses; 120 and 175 mg) but physical examination and chest HRCT revealed no pathology, and the others had DLCO values just below the border but also with normal physical examination and chest X-ray findings. However, these abnormal DLCO results were not related to cumulative CAB dose in these patients ($P=0.6$).
Conclusion
CAB appears to be safe for pulmonary function with mean cumulative doses of 244 mg in prolactinoma patients. But as low DLCO could be the early finding of interstitial lung disease, evaluation of pulmonary functions and follow-up according to the results may be rational during long term treatment of prolactinoma with DAs.

Complications of acromegaly regarding GH concentrations

Daniela-Georgiana Amzar[1], Balas Melania[1], Golu Ioana[1], Vlad Mihaela[1] & Laura Cotoi[2]
[1]University of Medicine and Pharmacy "Victor Babes", Endocrinology, timisoara, Romania; [2]University of Medicine and Pharmacy "Victor Babes", Timişoara, Romania

Introduction
Acromegaly is a rare disease caused by excess production of growth hormone (GH) and is associated with multiple complications. The prevalence of associated complications and the mortality rate are associated with the duration of exposure to elevated GH levels, early diagnosis being imperative. Diagnosis of acromegaly is most frequently late, after several years of evolution, with the development of cardiovascular, respiratory, metabolic complications. The presence of multiple complications in these patients contributes to an increased mortality/morbidity rate and a decreased quality of life.
Methods
The study group included 22 patients with acromegaly (women/men=15/7), aged 24 to 71 years (50.00±5.32). Patients were diagnosed and monitored at the Endocrinology Clinic in Timişoara between 2000 and present.
Results
The diagnosis was established late, 90.9% of patients had pituitary macroadenoma (preoperative adenoma dimension 25.43±12.50 mm) and 95% had complications of acromegaly at the time of diagnosis. The preoperative GH value was 21.54±25.51 ng/ml and the preoperative IGF-1 value was 666.57±346.10 ng/ml. The average number of years of illness in the studied group was 9.82±5.32 years. The studied group presented multiple complications of acromegaly. Frequency of complications presented in the group: 68.2% left ventricular hypertrophy, 54.5% sleep apnea syndrome, of which 13.6% had mild form, 13.6% had moderate form and 27.3% had severe form, 13.6% artrosic disease, 40.9% splenomegaly, 31.8% type II diabetes, 59.1% decreased glucose tolerance, 72.7% obesity, of which 31.8% grade I, 22.7% grade II and 18.2% grade III, and 8 out of 9 patients who had ophthalmological evaluation presented the narrowing of the visual field. We performed the Pearson correlation test of acromegaly complications with the preoperative GH and IGF-1 values and with the total duration in years of the disease, without statistically significant differences. The normalization of the hormonal parameters in the following years was accompanied by the improvement of the clinical picture and complications, with the improvement of the quality of life.
Conclusion
Early diagnosis and prompt assessment of acromegaly complications contribute to improving the quality of life, reducing complications and decreasing morbidity and mortality in acromegaly.

GH-secreting adenoma in peripubertal period

Adaniela-Georgiana Amzar[1,3], Melania Balas[1,3], Golu Ioana[1,3], Vlad Mihaela[1,3], Paul Corina[2] & Laura Cotoi[3]
[1]University of Medicine and Pharmacy "Victor Babes", Endocrinology, Timişoara, Romania; [2]University of Medicine and Pharmacy "Victor Babes", Pediatry, Romania; [3]University of Medicine and Pharmacy "Victor Babes", PHD student, Romania

Introduction
Gigantism represents a rare pathology in children, characterized by growth hormone (GH) excess, before epiphyseal fusion. It associates significant morbidity and decreased life expectancy, in lack of appropriate treatment.
Case presentation
O.D., a male patient, 16 years old now, has been followed in our clinic since 2016, being diagnosed with gigantism in Bega Pediatric Clinic, at the age of 12 years 9 months. In 2014, the patient presented visual disturbances, headache, soft tissue swelling, accelerated growth in height (weight 85 kg, height 171 cm, S.D.=+ 2.6). Laboratory data confirmed high values of IGF-1 and basal GH, respectively non-suppressive GH at oral glucose tolerance test. No other pituitary insufficiency was noted. Pituitary MRI revealed a 3.9 cm pituitary macroadenoma. Transsphenoidal adenomectomy was performed, but only a part of the tumor could be removed (tumor remnant volume: 34/20/30 mm). Postoperatively, somatostatin analogue treatment was started. Later, due to the incomplete response (with persistent sleep apnea and headache), dopamine agonists (cabergoline) were added. In 2016 the patient was operated again, without complete removal of the tumor. In addition, partial pituitary insufficiency (on gonadotrophs and thyrotrophs) developed. Pituitary MRI shows a tumor remnant of 1.9 cm. Pegvisomant was added to somatostatin analogues and cabergoline treatment. In 2017, due to the persistence of symptomatology and the unsatisfactory response to the medical treatment, gamma-knife radiosurgery was performed. Also, the somatostatin analogue was changed. Up to now, the disease is well controlled under treatment.
Conclusion
Advances in the pharmacotherapy and radiosurgery in patients with acromegaly and gigantism allow successful control of the disease. Precocious

diagnosis is important, many of the complications being reversible in initial stages.

The role of contrast-enhanced fast imaging employing steady - state acquisition (FIESTA) for postoperative residual tumor in pituitary adenoma

Kensaku Kamada & Takayuki Matsuo
Nagasaki University School of Medicine, Department of Neurosurgery, Nagasaki, Japan

Preoperative evaluation of pituitary macroadenoma tumor consistency is important for neurosurgery. Thus, we aimed to retrospectively assess the role of contrast-enhanced fast imaging employing steady - state acquisition (FIESTA) in predicting the tumor consistency of pituitary macroadenomas.
Objectives
In endoscopic endonasal transsphenoidal surgery of pituitary adenoma, after the removal of the lower component of the tumor, the upper component does not sag and the tumor may remain at the time of operation. We investigated whether residual tumor can be predicted from presurgical neuroimaging findings in pituitary macroadenoma retrospectively.
Subjects
Among the cases of pituitary adenomas mainly composed of solid components with a size exceeding 20 mm in which endonasal transsphenoidal surgery was performed from January 2008 to October 2019, we investigated the cases in which the residural tumor was observed in the postoperative magnetic resonance imaging (MRI) findings retrospectively.
Results
The subjects were 13 cases, 4 males and 9 females, and the median age was 72 years (39–88 years). It was difficult to predict the residural tumor after surgery from T1-weighted images, T2-weighted images, contrast-enhanced T1-weighted images, and apparent diffusion coefficiennt (ADC) map in MRI. In addition, contrast-enhanced FIESTA was performed in 12 cases. Five cases of the low signal intensity region in preoperative contrast-enhanced FIESTA almost coincided with the residual tumor. Four cases of the low signal intensity region in preoperative contrast-enhanced FIESTA partially coincided with the residual tumor. There was no correlation between both images in three cases.
Conclusion
The low signal intensity region with contrast-enhanced FIESTA is considered to be a finding suggesting the possibility of residual tumor in endoscopic nasal surgery in pituitary adenoma.

Intracranial germinoma mimicking a pituitary macroadenoma

Nanik Ram
The Aga Khan University Hospital, Section of Endocrine Department of Medicine, Karachi, Pakistan

Background
Intracranial Germ Cell Tumors (GCTs) are thought to originate from error of primordial germ cells migration during embryonic development, manifesting during first and second decade of life and accounts for 3-5% of all intracranial tumors.
Methods
We report a case of a 22-year-old patient who presented with progressive visual loss with polyuria and polydipsia, harboring an intracranial germ cell tumor.
Case Presentation
A 22 years old female presented initially to neurosurgery clinic and then referred to endocrine clinic, with history of a chronic worsening headache and recent onset visual blurring along with polyuria with polydipsia. On further inquiry she was found to have primary amenorrhea, easy fatiguability and failure of development of secondary sexual characteristics. There was no history of galactorrhea, hirsutism or any significant family history. On examination patient had bitemporal hemianopia with breast development at tanner stage II and pubic and axillary hair at tanner stage I. Her initial hormonal workup was suggestive of panhypopituitarism with diabetes insipidus. MRI Pituitary showed a seller mass with suprasellar extension inseparable from the pituitary stalk, so an initial impression of a pituitary macroadenoma vs a pituitary stalk tumor was made and patient underwent transsphenoidal surgery. The histopathology suggestive of a germinoma, a germ cell tumor and a rare cause of panhypopituitarism. She was stated on chemotherapy followed by radiotherapy, after which her tumor size has reduced significantly.
Conclusion
Pituitary stalk lesions are rare, and their definite diagnosis is challenging as different etiologies presents clinically and radiologically in a similar manner with tissue diagnosis being the gold standard.

A case report: Pituitary granulomatosis with polyangiitis

Hatice Sebile Dökmetaş[1], Güneş Çavuşoğlu[2], Fatih Kılıçlı[3], Meryem Can[3], Meriç Dökmetaş[2] & Ayşenur Cila[4]
[1]İstanbul Medipol University, Endocrinology and Metabolism, İstanbul, Turkey; [2]İstanbul Medipol University, Internal Medicine, İstanbul, Turkey; [3]İstanbul Medipol University, Rheumatolgy, İstanbul, Turkey; [4]İstanbul Medipol University, Radiology, İstanbul, Turkey

Introduction
Granulomatosis with polyangiitis (GPA) is a systemic vasculitis with necrotizing granulomatous inflammation. Any organ including the pituitary can be involved. Here we report a patient diagnosed with GPA who had nearly complete resolution of pituitary mass after cyclophosphamide and methylprednisolone treatment.
Case
46 year old female patient was admitted to the hospital after being examined by several departments for fever, severe headaches and sinusitis which she had for 2 months. Her inflammatory markers were high and she had cavities seen on her chest radiogram. Her cranial MRI showed a 12 mm-diameter adenoma of cystic and solid components at the right half of the adenohypophysis. Her hormone profile was remarkable except the prolactine [52.84 ng/ml (4.79–23.3)]. Anti-proteinase 3 antibody is also positive. She didn't have diabetes insipidus. Pulse methylprednisolone treatment was started, followed by daily methylprednisolone in decreasing doses. Monthly IV cyclophosphamide treatment was also started. 4 months later MRI showed nearly complete resolution of the adenoma and there can only be seen a microcystic focal area at the right upper side of the gland. Her hormones are remarkable including prolactine.
Conclusion
Pituitary masses can rarely be seen in GPA and our patient's mass resolved with cyclophosphamide and methylprednisolone treatment.

The galant trial: a randomised placebo-controlled trial in patients with a gallium-68 dotatate pet positive, clinically non-functioning pituitary macroadenoma on the effect of lanreotide on tumour size

Tessel M. Boertien[1], M.L. Drent[2], Jan Booij[3], Charles B.L.M. Majoie[3], Marcel P.M. Stokkel[4], Jantien Hoogmoed[5], Alberto M Pereira[6], Nienke Biermasz[6], Suat Simsek[2,7], Ronald Groote Veldman[8], Michael W.T. Tanck[9], Eric Fliers[1] & Peter H. Bisschop[1]
[1]Amsterdam UMC, University of Amsterdam, Endocrinology & Metabolism, Amsterdam, Netherlands; [2]Amsterdam UMC, VU University, Internal Medicine, Section of Endocrinology, Amsterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Radiology and Nuclear Medicine, Amsterdam, Netherlands; [4]Netherlands Cancer Institute (NKI), Nuclear Medicine, Amsterdam, Netherlands; [5]Amsterdam UMC, University of Amsterdam, Neurosurgery, Amsterdam, Netherlands; [6]Leiden University Medical Center (LUMC), Internal Medicine, Center for Endocrine Tumors Leiden (CETL), Leiden, Netherlands; [7]Northwest Clinics (NWZG), Internal Medicine, Alkmaar, Netherlands; [8]Medical Spectrum Twente (MST), Internal Medicine, Enschede, Netherlands; [9]Amsterdam UMC, University of Amsterdam, Clinical Epidemiology, Biostatistics and Bioinformatics, Amsterdam, Netherlands

Rationale
At present, there is no approved medical treatment for patients with clinically non-functioning pituitary adenoma. A number of open-label studies

suggest that treatment with somatostatin analogues may prevent tumour progression in selected patients. *In vivo* assessment of somatostatin receptor status using 68Ga-DOTATATE PET could help to select patients responsive to treatment.
Trial objective
To investigate the effect of the somatostatin analogue lanreotide as compared to placebo on tumour size in patients with a ^{68}Ga-DOTATATE PET-positive non-functioning pituitary macroadenoma (NFMA).
Design
The GALANT study is an investigator-initiated, multicentre, randomised, double-blind, placebo-controlled trial in adult patients with a suprasellar extending NFMA, either surgery-naïve or as postoperative remnant. Included patients undergo ^{68}Ga-DOTATATE PET/CT of the head and tracer uptake is assessed after coregistration with pituitary MRI. Forty-four patients with a ^{68}Ga-DOTATATE PET-positive NFMA are randomised in a 1:1 ratio between lanreotide 120 mg or placebo, both administered as subcutaneous injections every 28 days for 72 weeks. The primary outcome is the change in cranio-caudal tumour size after treatment assessed with pituitary MRI. Secondary outcomes are change in tumour volume, time to tumour progression, change in quality of life and number of adverse events. The study protocol has been approved by the medical research ethics committee of the Academic Medical Centre of the Amsterdam University Medical Centres and by the Dutch competent authority. Financial support is provided by Ipsen Farmaceutica BV.
Conclusion
The GALANT study is the first double-blind and placebo-controlled intervention trial in NFMA patients. Inclusion has been completed and results are expected in the second half of 2021. If lanreotide is effective in reducing or controlling tumour size, this would present an important new treatment option for NFMA patients.
Trial registration
EudraCT 2015–001234–22, registered 10 March 2015, and Netherlands Trial Register NL5136, registered 18 August 2015. Registration took place before start of recruitment.

Long-term-follow-up of patients with gastric bypass surgery secondary to craniopharyngioma associated hypothalamic obesity

Hannes Beiglböck, Paul Fellinger, Tamara Ranzenberger-Haider, Greisa Vila, Anton Luger, Alexandra Kautzky-Willer, Michael Krebs & Peter Wolf
Medical University of Vienna, Department of Medicine III, Division of Endocrinology and Metabolism, Vienna, Austria

Background
Patients being cured of craniopharyngioma (CP) often suffer from severe hypothalamic obesity due to tumor localization or therapeutic interventions, which has a major impact on increased mortality and reduced quality of life. Gastric bypass surgery (GBS) was suggested to be an effective therapeutic option for weight reduction in those patients. However, long-term changes in body weight and postsurgical complications are unknown.
Methods
5 patients with severe hypothalamic obesity being cured of CP, who underwent GBS, were included in a retrospective analysis (age: 20.8±4.4 years BMI: 47.3±7.7 kg/m^2). They were compared to a control group of patients with common obesity who underwent GBS, matched for preoperative age and BMI (age: 23.1±3.7 years BMI: 48.7±6.3 kg/m^2).
Results
Gastric bypass surgery led to a distinct weight loss after 1.5±1.1 years in both groups (CP: –44.0 kg±19.4, controls: –43.8 kg±14.1; P=0.176). However, in long term follow-up (6.1±2.9 years) weight regain was observed in 3 of 5 CP patients, 1 CP patient suffered from severe postsurgical malnutrition, whereas only 1 CP patient had a favorable long-term outcome comparable to controls (BMI at long-term follow-up: 42.2 kg/m^2±10.5 vs 31.2 kg/m^2±6.3). Postoperative complications requiring in-patient treatment were significantly more often in CP (CP: 4/5 (80%), controls: 5/24 (20%), P=0.022).
Conclusions
Despite promising results of weight reduction in the first years following GBS, long-term outcome is worse in patients suffering from hypothalamic obesity. Weight regain is more likely and the rate of severe postsurgical complications is higher in patients with CP compared to controls.

Cushing's disease with negative mri: an overview of the experience of the endocrinology-diabetology-nutrition department of oujda's Mohammed-VI university hospital- morocco

Imane Assarrar, Khadija Boujtat, Tahri Abir, Siham Rouf & Hanane Latrech
University Hospital Center Mohammed VI, Faculty of Medicine and Pharmacy, Mohammed 1st University, Department Of Endocrinology-Diabetology And Nutrition, Oujda, Morocco

Introduction
Cushing's disease is caused by endogenous hypercotisolism, due to the hypersecretion of the adenocorticotropic hormone (ACTH) by an ACTH-secreting pituitary adenoma. However, some patients with Cushing's disease have no visible adenoma on MRI. The goal of this study is to review the clinical features, diagnosis and medical preparation of patients with Cushing's disease.
Material and methods
A retrospective study including 6 patients with Cushing's disease and a negative MRI in the Department of Endocrinology-Diabetology of Oujda's University Hospital.
Results
The mean age of the patients was 33.6 years with a female predominance. All of the patients showed clinical signs of hypercortisolism. Elevated midnight blood cortisol and 24-hour urinary free cortisol as well as non-suppression of cortisol during 1mg overnight dexamethasone suppression test were observed in all cases. 100% of the patients had an elevated ACTH value and responded to 8mg dexamethasone suppression test. The hypothalamic-pituitary MRI was normal in all cases. The decisions considering treatment for each patient were discussed over multidisciplinary meetings. Thus, all of the patients have undergone preoperative medical therapies: 50% of the patients were treated with Metopirone, and 50% with Ketoconazole. All patients had a bilateral adrenalectomy, with a successful recovery from hypercortisolism. No case of Nelson's syndrome has been registered thus far.
Discussion and conclusion
Inferior petrosal sinus sampling (IPSS), though being invasive, is the gold standard for establishing the pituitary origin of ACTH secretion in patients with negative MRI and help guide the neurosurgical exploration using the endonasal transsphenoidal approach. However, in developping countries such as ours, this option is not available. Bilateral adrenalectomy seems more reliable and efficient in our context, but requires lifelong glucocorticoid and mineralocorticoid replacement with an increased risk of Nelson's syndrome.

EP343

Vitamin B12 deficiency associated with multiple endocrine neoplasia type 1: About a case

Yousra Cherif[1], Samar Derbal[1], Rihab Laamouri[2], Ghariani Rania[1], Ben Dahmene Fatma[1] & Abdallah Maya[1]
[1]Regional Hospital of Ben Arous, Internal Medecine, Tunis, Tunisia; [2]University of Tunis Manar- Faculty of medecine, Tunis, Tunisia

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a rare disease, defined as a tumor developing in at least two endocrine glands including the anterior pituitary gland, the parathyroid glands and the duodeno-pancreatic endocrine tissue. This is an inherited disorder. However, sporadic cases account for 8–14%. We here report a case of MEN1 revealed by vitamin B12 deficiency.
Observation
A 37-year-old young woman admitted to our department of Internal Medicine for macrocytic anemia. Physical examination was normal. The biological assessment showed a macrocytic anemia: hemoglobin: 7.4 g/dl, mean cell volume: 112.4 fl, hyperbilirubinemia: 42 µmol/l, transaminase elevation: 132 U/l. Thyroid analysis was normal, calcemia at 2.53mmol/l with elevated parathyroid hormone: 154 pg/ml (normal range: 10–65 ng/l). A vitamin B12 deficiency was diagnosed <50 pg/ml and the serum folate was normal. The oeso-gastro-fibroscopy showed gastric atrophy and a 6 mm nodule the biopsy examination after resection concluded of a neuroendocrine tumor. The thyroid ultrasound revealed an EU-TIRADS 3 nodule and a left parathyroid nodule measuring 11 × 5 mm. The assassement of chromgramine A was elevated: 150 mg/ml (normal <102 ng/ml) and the urine dosage of 5-hydroxyindolacetic acid (5HIAA) was normal: 24 µmol/24 h (normal <40 µmol/24 h). A thoraco-abdominal CT scan revealed hepatomegaly

at 21 cm and splenomegaly at 14.3 cm. Then, our patient was diagnosed with MEN1 associated with Biermer disease, she was treated with injection of vitamin B12 and she was proposed for removal oft he parathyroid nodule.
Conclusion
We report a case of a patient with who initially presented with vitamin B12 deficiency and. This case revealed the rare co-existence of MEN 1 with hyperparathyroïdism, which has rarely described in the literature. A thorough evaluation is necessary to avoid a delay in the correct diagnosis and treatment of the underlying conditions.

DOI: 10.1530/endoabs.70.EP343

Pancreatic neuroendocine tumors and pheochromocytoma in vonhippel lindau disease

Imen Halloul, Wafa Ben Othman, Maha Kacem Njah, Ghada Saad, Asma Benabdelkarim Mzoughi, Amel Maaroufi, molka Chaieb & Koussay Ach
Farhat Hached university hospital, Department of Endocrinology and Diabetes, Sousse, Tunisia

Introduction
VonHippel Lindau (VHL) disease is an autosomal dominant disorder, responsible of the occurrence of multiple endocrine and non-endocrine lesions. When it comes to this hereditary syndrom., pheochromocytoma and pancreatic neuroendocrine tumors (pNET) require special monitoring and an appropriate treatment, The object of this case report is to highlight the different clinical presentation of the same lesion in the same patient and the difficulties in decisions' making when it comes to therapeutic care.
Observation
We report a case of a 40-year-old female patient diagnosed with VHL disease 20 years ago. The first manifestation of this syndrome was a pheochromocytoma in the right adrenal gland which presented with severe hypertension at the time. Genetics tests revealed a miss sens mutation in codon 86 exon 1, which confirmed the disease. During follow up, the patient developed multiples lesions: two cerebellar hemangioblastoma, a medullary and a puituitary stalk hemangioblastoma and multiple pancreatic cysts. In the latest radiological imaging, a new tumor in the left adrenal gland and 2 pancreatic lesions suggesting a pNET were found. The first pancreatic lesion was a 3- cm tumor and the second one was 1.1 cm, located both in the head At the clinical examination, the patient was suffering of paresthesia and pain in both legs due to the growth of the medullary hemangioblastoma, her blood pressure was normal and she did not present any symptoms suggesting a fonctionnal NET. The biological exams showed an elevated 24-h urinary catecholamine levels confirming the pheochromocytoma. Surprisingly, the insulin level was high, even though the patient never presented symptoms of hypoglycemia. An octreoscan was performed and it confirmed the endocrine nature of the first pancreatic lesion. For the treatment, a surgical intervention of the medullary hemangioblastoma was rejected by the neurosurgeons due to the post operative risks on the patient. As for the pheochromocytoma, a partial tumor resection was initially proposed; however, the final decision was a total adrenalectomy, considering the possibility of recurrence of new tumors. And for the pancreas, we opted for a surgical resection of the 3- cm tumor, considering the size and the location of the mass.
Conclusion
Genetic syndrome such as VHL requires a special attention to the evolution of the different lesions. The object of the clinical surveillance will be to decide the proper timing and nature of interventions necessary, to improve early diagnosis and successful treatment of the malignancies.

Recurrent abscesses as a rare, life-threatening clinical manifestation of Cushing disease

Ewa Stogowska[1], Agnieszka Łebkowska[1], Maria Kościuszko[2], Grzegorz Zieliński[3], Irina Kowalska[1] & Monika Karczewska-Kupczewska[1]
[1]Medical University of Białystok, Department of Internal Medicine and Metabolic Diseases, Białystok, Poland; [2]Public Hospital in Łapy, Department of Internal Medicine and Diabetology, Łapy, Poland; [3]Military Institute of Medicine, Department of Neurosurgery, Warsaw, Poland

Introduction
Cushing disease, as a state of chronic hypercortisolism, causes diverse, often nonspecific symptoms, possibly delaying the proper diagnosis.
Case report
A 59-year-old woman with the history of type 2 diabetes mellitus, hypertension, osteoporosis and multiannual history of recurrent hospitalizations because of life-threatening multi-sited soft tissue and muscle abscesses, was admitted to the Department of Internal Medicine and Metabolic Diseases due to symptoms of sepsis. A month before the patient was hospitalized in the Department of Surgery because of left buttock abscess. The CT scan revealed iliopsoas and both buttocks abscesses and enlarged left adrenal gland. On admission the patient was in bad condition, lying, requiring other's help to sit. Physical examination revealed cachexia, thick, atrophic skin with a number of small scars after cutaneous abrasions, excessive chin hair, poor dental condition with severe hypodontia, facial plethora, proximal muscle wasting, arms and legs swelling, deep left buttock abscess cavity. Laboratory tests showed considerably increased inflammatory markers, normocytic anemia, hypoproteinemia with hypoalbuminemia. Blood and abscess cavity swab cultures were positive for MSSA. An abdomen and pelvis CT revealed iliopsoas and both gluteal muscles abscesses and two left adrenal gland lesions (18×22 mm and 34×22 mm) with density characteristic for adenoma. A pituitary MRI showed a 6mm lesion, described as Rathke's cleft cyst or atypical microadenoma. The treatment included antibiotics, red blood cell transfusion, negative-pressure wound therapy of abscess cavity and rehabilitation, which led to significant improvement of the patient's state. We suspected Cushing's syndrome, however, due to the patient's serious condition the hormonal diagnostics was postponed. The patient was readmitted to our Department after 3 months in order to perform diagnostics towards Cushing syndrome. The patient was in better condition, without clinical or laboratory signs of inflammation. We observed an increased midnight cortisol, the lack of cortisol suppression in low-dose dexamethasone test and cortisol suppression in high-dose dexamethasone test. The ACTH concentration was 27.98 pg/ml. CRH test revealed over twofold increase in ACTH and cortisol level after stimulation. Hormonal tests indicated Cushing disease. At the Department of Neurosurgery the bilateral inferior petrosal sinus sampling was performed, confirming pituitary source of hypercortisolism. Afterwards, the patient underwent a successful transsphenoidal pituitary surgery. Currently the patient's condition is still improving, she requires hydrocortisone supplementation.
Conclusions
Presented case shows that recurrent infections should make physicians consider the possibility of Cushing syndrome. It proves that chronic hypercortisolism is destructive and can lead to advanced disability.

The role of Octreotide in the treatment of acromegaly

Megi Lekbello, Gerond Husi & Agron Ylli
University Hospital Mother Teresa, Endocrinology, Tirana, Albania

Acromegaly is a rare disorder with a high morbidity and mortality rate. The diagnosis is typically prolonged over time due to a slow and hidden development of the disease. Current medical therapy for the treatment of acromegaly involves the administration of somatostatin analogues that effectively suppress excess hormone secretion. The objective of this study was to investigate the efficacy of octreotide therapy in acromegalic. A total of 32 patients have been treated with Octreotide since May 2015 when the medicinal was included in the reimbursement scheme in Albania. All patients have been treated every 28 days with Octreotide LAR 30 mg/2 ml. The concentration of GH and IFG1 was measured at 0 months and every 6 months thereafter. Of the 32 patients 50% received the Octreotide treatment after both surgery and Radiosurgery, another 37.5% of the patients received Octreotide treatment After surgery alone, and the remaining 12.5% received an Octreotide-only treatment. The Octreotide treatment reduced the levels of GH by 60% (significance $P=0.0072$) and IGF-1 by 12.5% ($P=0.08$) compared to the same levels measured before the treatment. For 30% of the patients the treatment achieved to bring GH and IGF-1 within normal values, 58% of the patients showed significant improvement (GH and IGF-1 reduction of 20% or more) towards the normalization of the levels, and 12% of the patients resulted resistant to the treatment. In conclusion, from the 32 patient cases treated with Octreotide we report a relevant reduction of the values of GH and IGF-1. The reduction is observed by measuring and comparing these levels before and after the treatment with octreotide. The treatment with somatostatin analogues is still the chosen treatment for acromegalic patients.

Behaviour of the long-term clinical and analytical characteristics of a series of cases with hypopituitarism

Roberto Añez, Alejandra Rivas, Juan Carlos Percovich, Jose Atencia, Bettina Weber, Noemí Brox, María Miguélez, Laura Gonzalez, Diego Muñoz, Susana Monereo & Rogelio García Centeno
H Gregorio Marañon, Endocrinology, Madrid, Spain

Aim
To describe the clinical and analytical characteristics of patients with hypopituitarism in the Endocrinology Department.
Materials and methods
This was a descriptive, retrospective study with 70 patients diagnosed with hypopituitarism in the Endocrinology Department´s outpatient consultations with a follow-up of up to 44 years. The qualitative variables were expressed in frequencies and the quantitative variables showed a normal distribution expressed in means±S.D.
Results
Out of the 70 patients, 44.3% were women and 90% Spanish. The age at diagnosis was 42.94±21.79 years with an average follow-up of 11.79±10.56 years. The BMI mean was 28.56±5.04 kg/m^2; of which 42.1% were obese, 31.6% overweight and 26.3% normal weight. The most frequent cause was non-functioning macroadenoma surgery with 47.1%. The most prevalent hormonal deficits were TSH with 92.9%, ACTH 91.4%, FSH/LH 87.1%, GH/IGF-1 54.3%, and ADH 45.7%. The following means were observed in the last blood sample: Glucose 88.59±27.30 mg/dl; HbA1c 5.86±0.73%; Cholesterol 180.27±37.47 mg/dl; HDL 57.35±19.47 mg/dl; LDL 100.57±31.22 mg/dl; TAG 138.51±65.37 mg/dl; T4L 1.02±0.21 ng/dl; IGF1 99.40±58.39 ng/ml. Hydrocortisone daily mean was 21.09±6.93 mg, and a dosage of three times a day was 67.2%. The average dose of levothyroxine according to weight in subjects under 65 years was 1.30±0.32 mg/kg/day and in subjects 65 years or older 1.04±0.31 mg/kg/day. The number of drugs used as chronic treatment was 6.75±3.16. Regarding comorbidities, dyslipidemia was observed in 60% of patients, hypertension 37.1%, and diabetes mellitus 15.7%. Alterations in bone densitometry were observed in 42.8% (osteopenia 25.7% and osteoporosis 17.1%). The majority was asymptomatic (68.1%) in the last visit and 21.7% reported asthenia. After diagnosis, 54.3% had readmissions (24.3% more than 3 times). The mortality was 7.1%, being the most frequent oncologic cause.
Conclusions
Surgery on the selar area represents an important cause of hypopituitarism. Most of them had excess weight, dyslipidemia, and decreased bone mass. Mortality was mainly secondary to oncological causes.
Keywords: hypopituitarism, pituitary, adenoma.

EP348

A rare cause of ectopic cushing syndrome: Prostate cancer

Murat Atmaca[1], Cansu Temiz[2], Hatice Sebile Dökmetaş[1], Meriç Dökmetaş[2] & Fatih Kiliçli[1]
[1]Istanbul Medipol University, Endocrinology and Metabolism, İstanbul, Turkey; [2]Istanbul Medipol University, Internal Medicine, İstanbul, Turkey

Objective
To report a rare cause of ectopic adrenocorticotropic hormone (ACTH) secretion leading to Cushing syndrome.
Methods
We describe the clinical presentation and management of a case of Cushing syndrome attributable to ectopic ACTH secretion from small cell cancer of the prostate.
Results
In a 74-year-old man developed hypocalemia and heart failure. He was found to have severe hypokalemia (serum potassium, 2.37 mEq/l). Hormonal evaluation revealed a high serum cortisol level of 56.57 microg/dl and a high 24 hour-urine free cortisol excretion of 3218.5 microg/dl (reference range, 4.3 to 176), confirming the diagnosis of Cushing syndrome. A serum ACTH level was elevated at 416 pg/ml (reference range, 0 to 46). An overnight high-dose (8 mg orally) dexamethasone suppression test was positive (serum cortisol levels were 50.3 and 55.1 microg/dl before and after suppression, respectively), and magnetic resonance imaging of the pituitary gland disclosed no abnormalities. Thorax and abdomen CT for ectopic ACTH secreting tumor disclosed no abnormalities too. In PET CT scan, 18 FDG uptake was detected in prostate. Transurethral biopsy of the prostate showed features of small cell prostate cancer. A prostate biopsy specimen showed small cell prostate cancer with highly positive staining for ACTH. The tumor was found to be resectable, but he was in intensive care unit and orotracheal intubated. He was treated with ketoconazole 600 mg/day, which yielded good temporary control of his Cushing syndrome (serum cortisol level was 19.72 microg/dl and serum potasium level was 4.8 mmol/l). After diagnosis, he died 1 month later as a result of influenza pneumonia sepsis.
Conclusion
Ectopic ACTH secretion accounts for 10 to 20% of all causes of endogenous cushings syndrome and is usually associated with neuroendocrine tumors and small cell carcinoma of the lung (up to 50%).
Small cell prostate cancer is a rare subtype that can be associated with ectopic secretion of ACTH and severe Cushing syndrome. With this subtype of prostate cancer, Cushing syndrome should be considered and appropriately managed.

Intravenous dexamethasone suppression test in cushing syndrome diagnosis: Three cases

Urcan Ince[1], Cevdet Aydin[1], Hilal Yildirim Deryol[2], Nagihan Bestepe[2], Oya Topaloglu[1] & Dilek Berker[3]
[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Cllinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Cllinics of Endocrinology and Metabolism, Ankara, Turkey; [3]Saglik Bilimleri University, Ankara City Hospital, Cllinics of Endocrinology and Metabolism, Ankara, Turkey

Introduction
Dexamethasone Suppression Test (DST) is a useful approach in diagnosis and differential diagnosis of Cushing Syndrome (CS) despite its limitations. One of the major limitations is the difficulty to provide standard suppression dose depending on the variability of gastrointestinal absorption. One solution is for this testing serum Dexamethasone levels or test it with intravenous (iv) Dexamethasone In this case, we examined 3 patients to whom we applied intravenous DST in our clinic in 2019.
Case1
The patient who underwent left surrenalectomy and two pituitary surgeries due to Cushing Syndrome was referred to us. The Pituitary gland was showed as a thin line at pituitary MRI. Abdominal MRI was normal. The Diurnal Rhythm was preserved. The 24-hour urine cortisol was normal. 1mg DST suppression wasn't detected. The patient had low st4 level (0.63) whe thought it might be because of intestinal edema-induced absorption disorder and whe did IV overnight DST. (1mg/st iv DXM infusion between 23:00 and 03.00) CS was not considered in the patient who have cortisol suppression.
Case2
A 49-year-old female patient who had weight gain complaint had central obesity and proximal muscle weakness. Her cortisol rhythm was impaired. Night saliva cortisol and 24-hour urine cortisol were normal. There were no 1mg DST, 2-day 2 mg DST, and 2-day 2 mg DST+CRH suppressions. A 7 × 8 mm nodular lesion was detected at Pituitary MRI. The patient with longterm diarrhea underwent IV DST considering that she might have absorption disorder. The 0 th-24 th-hour ACTH and cortisol values were used in diagnosis. The results were interpreted in favor of Cushing Syndrome (CS).
Case3
A 58-year-old female patient with surrenal adenoma didn't have 1 mg DST, 2-day 2 mg DST suppression. Her cortisol rhythm was preserved. The 24-hour urine cortisol and saliva cortisol were normal. The 0th-24th-hour ACTH and cortisol values were used in the diagnosis (1 mg/S.D × m infusion between 1100 h and 1500 h) Since there were no suppression in the cortisol levels, sub-clinical CS was considered.
Discussion:
There are limited studies on IV DST Test. There is no complete consensus on the application protocol and the diagnostic threshold value yet.
The efficiency of the IV DST Test was interpreted as an expected result because the two case both had gastrointestinal malabsorbsiyon. The third case, hadn't malabsorbsiyon. The serum dexamethasone levels couldn't be tested during oral DST was performed.
IV DST should be remember as patient with absorption disorders or use drugs that affect the dexamethasone metabolism.

Case report: the combination of acromegaly, primary hyperparathyroidism and colon cancer

Leyla Akdoğan[1], Muzaffer Serdar Deniz[2], Muhammed Saçikara[2], Narin Nasiroğlu[2], Abbas Ali Tam[1] & Neslihan Çuhaci Seyrek[1]
[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey

Introduction
Acromegaly is a chronic disease caused by excess growth hormone (GH) release from an adenoma caused by somatotroph cells of pituitary gland.In acromegaly, it is known that the risk of thyroid and colon cancer is increased 8 and 4 times, respectively, compared to the normal population.Moderate hypercalcemia, due to vitaminD activation, is seen in acromegaly, but overt hypercalcemia, generally secondary to primary hyperparathyroidism, is rare. Combination of acromegaly and primary hyperparathyroidism, often related with MEN-1 (Multiple endocrine neoplasia-1), has been reported in few cases.In this study, we wanted to share a newly diagnosed acromegaly with diabetes mellitus, multinodular goiter, primary hyperparathyroidism, and colon cancer.
Case
A 60-year-old male with hypertension and coronary artery disease was referred to our endocrinology clinic because of supressed TSH (thyroid stimulating hormone) level.As a result of examinations, he had been diagnosed with diabetes mellitus, multinodular goiter, and primary hyperparathyroidism.Because of his enlarged hands, feet and acromegalic face IGF-1 (insulin-like growth factor-1) was evaluated.Due to high IGF-1 level, glucose growth hormone suppression test (GGHST) was performed.GH was not supressed, compatible with acromegaly.Pituitary magnetic resonance imaging (MRI) revealed 14 × 10 mm nodular lesion in inferior part of pituitary gland, no cavernous sinus and optic chiasm compression were observed. Thyroid USG (ultasonography) revealed diffuse hyperplasic thyroid gland, with multinodular goiter, and a 22.8 × 12.8 × 57.8 mm hypoechoic lesion, suggested parathyroid adenoma, adjacent to the right superior thyroid lobe. Thyroid scintigraphy revealed active multinodular lesions on the upper left lobe of the thyroid gland, and parathyroid scintigraphy showed activity retention in the area that fit the thyroid gland in the right upper-middle section that could be compatible with parathyroid pathology.Fine needle aspiration biopsy (FNAB) of recommended thyroid nodules were reported as benign and nondiagnostic.Bone mineral densitometry was compatible with osteopenia, nephrolithiasis was reported on abdomen USG.Due to co-existence of acromegaly and primary hyperparathyroidism, MEN-1 was evaluated, genetic test was normal.His colonoscopy revealed 3–4 cm ulcer in rectum, and the biopsy result was adenocarcinoma.The patient was evaluated in terms of current diagnoses, operation for acromegaly and primary hyperparathyroidism was planned, but since it was stated by the oncology department that the operation for colon cancer is a priority for patient survival, the operation for colon cancer was planned first.Lanreotide for acromegaly, zoledronic acid for primary hyperparathyroidism were given.Since the patient wanted to be operated in the another center, he was discharged to apply after the operation.
Conclusion
Acromegaly causes an increased morbidity and mortality with metabolic effects caused by GH over-secretion and the mass effect due to compression of the pituitary adenoma.In the course of acromegaly, patients should be examined appropriately for possible complications.Acromegalic cases with hypercalcemia should be evaluated for parathyroid adenoma and possible MEN-1-syndrome, although it is not common.

Cardiovascular risk factors in acromegaly: comparison between successful surgery with medical treatment

Nerea Egaña Zunzunegui, Ismene Bilbao, Cristina García, Maite Aramburu, Leire Agea, Izaskun Olaizola, Jorge Rojo, Alfredo Yoldi & Miguel Goena
Hospital Universitario Donostia, Endocrinology, Spain

Introduction
Acromegaly is an insidious disease caused by chronic GH and IGF-I hypersecretion associated with increased morbidity and mortality, mostly from cardiovascular complications. The aim of this study is to compare cardiovascular risk factors, between patients with medical treatment vs cured.
Materials and methods
This is a retrospective study of 37 acromegalic patients, 21 well controlled with medical treatment (IGF-I within the normal range for age and sex) and 16 cured after successful surgery and/or radiotherapy. Studied cardiovascular risk factors are: BMI, glucose metabolism, dyslipemia and hypertension. Of those on medical treatment, 57% received depot somatostatin analog (SST), 5% pegvisomant, 5% cabergoline, and rest SST with cabergoline. No cardiovascular event was observed.
Results
There is no significant differences in age at diagnosis, GH and IGF-I levels, and current IGF-I index. There are more hypopituitarism in the cured group despite no differences in radiotherapy. The number of macroadenomas, patients with dyslipemia and basal glycemia disturbances are significantly higher in the "not cured" group, however there is no differences in diabetes mellitus.

	Curados	TTO Medico	*P*
Age	57.7	59.86	ns
Age at diagnosis	39.6	45	ns
Sex (F/M)	56.3/43.8	47.6/52.4	
Macro/Micro	75/25	90.5/9.5	$P<0.05$
Surgery	100%	81%	$P<0.05$
Radiotherapy	37.5%	33.3%	ns
Hypopituitarism	62.5%	42.9%	$P<0.05$
GH at diagnosis	22.5	21.3	ns
IGF-I at diagnosis	750.17	811.88	ns
IGF-I index at diagnosis	5.61	5.93	ns
Current IGF-I index	1.52	0.97	ns
BMI	27.47	28.7	ns
Hypertension	43.8%	38.1%	ns
Dyslipemia	50%	71.4%	$P<0.05$
Basal glycemia disturb	6.25%	23.8%	$P<0.05$
DM	18.8%	14.3%	ns

Conclusion
A good hormonal control can be achieved with current medical treatments. We demonstrated that cardiovascular risk is similar in both groups. Therefore, strict hormone control is required to improve the cardiovascular prognosis in patients with acromegalia.

Hypercortisolism in a patient with previous medullary thyroid carcinoma–is it paraneoplastic or co-existent cushing's disease?

Diandra Carmen Giuca[1], Delia-Maria Varlan[1], Georgiana Alexandra Smarandoiu[1], Dan Hortopan[2], Andra Caragheorgheopol[3], Dana Terzea[4], Ionela Baciu[1,5], Raluca Trifanescu[1,5] & Catalina Poiana[1,5]
[1]"C.I. Parhon" National Institute of Endocrinology, Pituitary and Neuroendocrinology, Bucharest, Romania; [2]"C.I. Parhon" National Institute of Endocrinology, Radiology, Bucharest, Romania; [3]"C.I. Parhon" National Institute of Endocrinology, Biochemistry, Bucharest, Romania; [4]"C.I. Parhon" National Institute of Endocrinology, Morphopathology, Bucharest, Romania; [5]"Carol Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
Medullary thyroid carcinoma (MTC) accounts for 3-9% of all thyroid cancers and only 0.7% develop paraneoplastic Cushing's syndrome. However, incidence of endogenous Cushing's syndrome is also low (1–3/million population/year), with a female preponderance, pituitary mediated ACTH production being responsible for up to 80% of these cases.
Aim
To present the difficulties in the differential diagnosis of ACTH dependent hypercortisolism in a patient with previous medullary thyroid carcinoma.

Patient and methods
A 53 year old woman with thyroidectomy for MTC in 2009 (preoperative calcitonin levels >2000 pg/ml; negative CEA), without biochemical or imagistic evidence of recurrence 9 years after, presented in our department for significant weight gain, peripheral edema and high blood pressure (SBP~190 mmHg).
Methods
TSH, FT4 and calcitonin were measured by chemiluminescence. Serum cortisol and plasma ACTH were measured by electrochemiluminescence. We also performed: 1-mg overnight dexamethasone suppression test (1-mg DST) and 48-h, 2mg/d low-dose DST (LDDST) ; immunohistochemistry of thyroid tumor for calcitonin, CEA, SSTR2, SSTR5, TTF1, Ki67 and ACTH; pituitary and adrenal imaging by MRI, cervical and thoracic imaging by CT scan.
Case report
Clinical examination showed gynoid obesity (BMI=41.95 kg/m^2), BP=175/100 mmHg, normal visual field, but no purple striae or hirsutism; galactorrhea or extremities enlargement were absent. There were no palpable cervical masses. Hormonal assessment revealed increased 8 AM serum cortisol (22.38 μg/dl) and plasmatic ACTH (72.66 pg/ml), loss of nocturnal nadir of serum cortisol at 11 PM (9.76 μg/dl), without adequate suppression of 8 AM serum cortisol either after 1-mg DST (3.93 μg/dl) or LDDST (4.59 μg/dl), normal prolactin and IGF1. ACTH dependent Cushing's syndrome was therefore diagnosed. There was no diabetes or osteoporosis. MRI showed a pituitary adenoma (9.5/5.5/6.5 mm) and bilateral adrenal hyperplasia. IPSS was not technically available, but there wasn't any sign of recurrence of MTC (persistent normal calcitonin and CEA, negative ACTH immunohistochemistry of the thyroid tumor, negative imaging study for local regrowth/distant metastases–ultrasonography, CT scan), neuroendocrine markers were normal (Cromogranin A, 5-HIA, plasmatic metanephrines and normetanephrines) and there were no pulmonary nodules on CT scan. Therefore, Cushing's disease was the most probable diagnosis. Treatment with 2 mg/week of Cabergoline was started. Pituitary surgery is pending.
Conclusion
The reported case is uncommon because previous MTC (with high rates of recurrence/metastases and probability to develop paraneoplastic Cushing's syndrome) was later associated with pituitary ACTH secreting microadenoma. Immunohistochemistry of pituitary adenoma and hormonal postoperative assessment are mandatory for diagnosis confirmation.

Diagnosis of panhypopituitarism in adulthood - diagnostic and therapeutic challenges

Livia Celia Lasca[1], Vera Lozovanu[1], Antonia Kiraly[2], Carmen Georgescu[1] & Cristina Alina Silaghi[1]
[1]County Clinical Emergency Hospital Cluj, Cluj-Napoca, Romania, Endocrinology Department, Romania; [2]Regina Maria, Endocrinology Department, Cluj-Napoca, Romania

Introduction
Combined pituitary hormone deficiency (CPHD) is characterized by impaired production of pituitary hormones. A possible cause are PROP-1 mutations (prophet of Pit-1 protein). It plays an essential role in the evolution of pituitary cells secreting GH, TSH, LH, FSH, prolactin; some patients may develop late ACTH deficiency. PROP 1 gene mutation is manifested with variable degrees of phenotype-genotype correlation, with growth failure as the first sign detected in early childhood. Central hypothyroidism, delayed or absent sexual maturation and ACTH insufficiency occur progressively. On magnetic resonance (MR) imaging, the anterior lobe is usually hypoplastic but may be normal or even enlarged; the posterior lobe and the pituitary stalk are normal.
Case Description
We report a case of a 45 years old romanian man who, was admitted for decreased libido, asthenia. Physical examination–normal stature, overweight (BMI=28.73 kg/m^2, 89 kg), normal blood pressure, without orthostatic hypotension, regression of sexual secondary characteristics, no syndromic abnormalities. No similar diseases in the family history. Serum hormones revealed panhypopituitarism (IGF-1=40 ng/ml, TSH=0.2 mU/ml, fT4=0.60 ng/dl, 8 AM Cortisol=4 mg/dl, FSH=0.24 U/l, LH=0.04 U/l, Testosterone=0.63 ng/ml) and an initial elevated Prolactin (39.2 ng/ml) but after precipitation the prolactin was also low. Pituitary MR imaging showed a normal aspect of the pituitary (LL=14.5/AP=8.7/CC=4 mm), without enhancement after contrast infusions. The stalk and the neurohypophysis appear in normal position. Blood DNA analysis for PROP-1 gene defects are in progress.
Conclusion
The findings illustrates combined pituitary hormone deficiency at adult age–this is quite exceptional, but further investigation is considered - DNA analysis of PROP-1 gene defects. The PROP-1 mutations are currently the most frequently recognized genetic cause of CPHD. Substitutive hormone treatment is introduced to this patient with 75 μg oral Levothyroxine, 10 mg oral Hydrocortizone and Testosterone gel, with a good clinical and biological result.

Crooke's cell adenoma and cushing disease: A severe case report

Miguel Vasques[1], Lurdes Matos[1], Amets Sagarribay[2], Carlos Pontinha[3], Manuela Mafra[3], Luís Cerqueira[4] & Ana Agapito[1]
[1]Centro Hospitalar Universitário Lisboa Central, Endocrinology, Lisbon, Portugal; [2]Centro Hospitalar Universitário Lisboa Central, Neurosurgery, Lisbon, Portugal; [3]Centro Hospitalar Universitário Lisboa Central, Pathology, Lisbon, Portugal; [4]Centro Hospitalar Universitário Lisboa Central, Neuroradiology, Lisbon, Portugal

Introduction
Cushing's disease (CD) is a potentially fatal disease caused by corticotrophic adenoma of the pituitary gland. Crooke Cell Adenomas (CCA) are a rare variant characterized by cytoplasmic ring deposits of cytokeratin filaments. They are usually aggressive macroadenomas with a higher rate of recurrence and malignancy.
Clinical case
A 36 year old man, with 34 kg weight gain and uncontrolled hypertension for 4 years presented at the Emergency Department In September 2018 with new onset dyspnea for small exertion, orthopnea and paroxysmal nocturnal dyspnea, BP 201/152 mmHg, heart rate 135 bpm, normal cardiopulmonary auscultation and hepatomegaly. Laboratory workup: metabolic alkalosis, hypoxemia, normocapnia and hypokalemia, serum creatinine 3.9 mg/dl and a troponin rise from 262 ng/dl to 624 ng/dl (VR <34.2 ng/dl). ECG without changes. Acute heart failure was admitted with an AMI without ST elevation and acute kidney injury. Coronary angiography was postponed. Echocardiogram: concentric ventricular hypertrophy, LVEF 40% with lateral segmental hypokinesis. Fundoscopy: severe hypertensive retinopathy. In the ward, hypertension persisted despite 5 antihypertensive drugs and also refractory hypokalemia. When observed by the Endocrinologist it was noted his central obesity (IMC 36 kg/m2), moon face, thin skin, violaceous striae, and decreased proximal muscular strength. Laboratory tests: baseline cortisol and ACTH, 13.2 mg/dl and 57.7 pg/ml, respectively; Cortisol after DXM low dose–7.2 mg/dl and after high dose–7.2 mg/dl. Pituitary MRI: 7 mm posterior intrasellar lesion with slight lateralization to the right, probably cystic". Inferior petrosus sinus catheterization: basal ACTH central/ peripheral gradient of 33.2 and after CRH stimulation 40. Metyrapone 750mg/day was instituted, with progressive improvement in blood pressure control. Submitted to endoscopic transphenoidal surgery with removal of the pituitary lesion without complications. Serum cortisol 17 h after intervention–0.7 mg/dl. Discharged under hydrocortisone 40 mg, amlodipine 10 mg, carvedilol 25 mg and enoxaparin 40 mg/day, with controlled arterial tension and stable renal dysfunction. Histology: solid large cell tumor with abundant cytoplasm, without atypia. ACTH+on the surface and ring cytokeratin in the cytoplasm; Ki67 <3% - Crooke Cell Adenoma. Over the next 15 months, progressive improvement in blood pressure control and kidney function. Hidrocortisone was stopped on the 13 month, and he remains without biochemical evidence of hypercortisolism
Discussion
This case illustrates the serious consequences of prolonged endogenous hypercortisolism. The posterior location of the pituitary lesion raised doubts about its causal relationship with CD and the best neurosurgical approach. Albeit in remission, a careful follow up is indicated, namely considering the histologic type of the corticotrophic adenoma.

Craniopharyngiomas: experience of the endocrinology department EPH bologhine west of algiers

Aicha Bouzid[1], Salah Gasri[2], Amina Laloui[3] & Djamila Meskine[4]
[1]Algiers, Medical university of algiers, Endocrinology & Métabolism Laboratory Algiers 1, EPH Bologhine, Medecine, Algiers, Algeria; [2]Annaba, Medecine, Annaba, Algeria; [3]EPH Bologhine, Medecine, Algiers, Algeria; [4]Medical university of algiers. EPH Bologhine, Medecine, Algiers, Algeria, Medecine, Algiers, Algeria

Craniopharyngioma is a slow growing benign epithelial tumor, growing from the pituitary stalk or pituitary gland in the sellar and/or parasellar region. Despite its benignity, the quality of life of patients is most often altered, due to the endocrine, visual and neuro-intellectual sequelae linked to the tumor itself and/or its treatment, as well as a high rate of recurrence. local. Early diagnosis remains the determining factor in prognosis. The objective of this study is to report the experience of the Endocrinology service of EPH Bologhine through the analysis of 31 records of patients hospitalized for craniopharyngioma.
Materials and methods
This is a retrospective study including 31 patients (15 women and 16 men) including 13 children and 18 adults, average age 23 years.
Results
Neurological manifestations are the predominant mode of disclosure 54.8% (17/31) with a picture of intracranial hypertension (42%). On the endocrine level, the somatotropic deficit is found in 25% of patients, the same portion is noted for the gonadotropic deficit. The corticotropic and thyrotropic deficit each represent 41.9% of cases. Stress delay was found in 6.7% of patients and diabetes insipidus 41.9%. Visual disturbances are found in 74.2% (23/31) of patients with blindness in 16.1% of cases. On the radiological level, the suprasellar localization is found in 32% of the cases, calcifications are found in 13% of the cases. The size of the lesion ranged from 18 mm to 63 mm.
Discussion
Craniopharyngioma is a benign, curable tumor, but due to its intimate relationship with critical structures of the central brain such as the optic structures, the pituitary gland, the hypothalamus, intracranial vascularization, the brainstem and the temporal lobes, its grip in charge introduces the risk of long-term morbidity of treatment. Today, the most common therapeutic approach is conservative subtotal resection followed by radiotherapy, and the goal is to limit long-term toxicity. Many recent advances in the treatment of craniopharyngioma are attributable to improvements in surgical techniques and radiotherapy technologies.
Conclusion
The management of craniopharyngioma requires multidisciplinary cooperation. Surgery remains the main treatment.. Today, the most common therapeutic approach is conservative subtotal resection followed by radiotherapy, and the goal is to limit long-term toxicity. Many recent advances in the treatment of craniopharyngioma are attributable to improvements in surgical techniques and radiotherapy technologies.

Panhipopituitarism due to inoperable cavernous sinus meningioma

Florina Andrada Predescu[1], Theodor Mustata[1], Elena Alexandru[1], Carmen Sorina Martin[1, 2] & Fica Simona[1, 2]
[1]Elias Emergency University Hospital, Bucharest, Romania, Endocrinology Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania

Panhypopituitarism refers to decreased production of all of the pituitary hormones of the adenohypophysis with or without deficiency of neurohypophysis function. The development of the disorder is frequently insidious and the manifestations often depend on the etiology of the condition.
Case report
In October 2019 a 57-year-old man collapsed in front of the hospital after being discharged from the cardiology clinic. The day before, he had undergone angiographic control for a bicoronary lesion treated in 2018 with Angioplasty with no evidence of restenosis or new lesions. After spontaneously recovering he described previous dizziness without chest pain or palpitations preceding the syncope. On physical examination presented with pale sweaty skin, absent facial hair, blood pressure 100/60 mmHg, heart rate 52/ min raising to 64/min under atropine. No evidence of hematoma, no changes on the EKG nor on the ultrasound, no arrhythmia or sinus pauses were detected on 24 h Holter. Blood sample showed a mild normochromic normocytic anemia and hyposodemia. Brain CT scan described an expansive intracranial process 36/43 mm axial and 33 mm cranio-caudal, with intense iodophilia, involving the right cavernous sinus with intra- and suprasellar extension, plated to the duramater of the large wing of the right sphenoid, invading the sphenoidal sinus, extending in plaque at the prepontin level and including the right: internal carotid artery, Meckel cavity, the orbit apex and right optic nerve. Re-interrogated, the patient declared having suffered several lipothymia episodes, for which a head MRI was performed on August 2018 describing the exact same lesion. Due to the extensions of the lesion the diagnosis of inoperable right cavernous sinus meningioma was reached. The suspicion of Hypopituitarism is raised for the first time and he is referred for endocrinological exam. Lab results revealed: TSH=3.97 uUI/ml (0.27–4.2), FT4=4.2 pmol/l (10.6–22.7), FSH=1.8 mUI/ml (1.512), LH=0.4 mUI/ml (1.7–8.6 mUI/ml), Testosteron=2.50 ng/dl, 8 AM Plasma cortisol=247.9 nmol/l (171–536 nmol/l), ACTH=33.29 pg/ml, Prolactina=555 uUI/ml (98–456), GH <0.05 ng/ml, IGF 1=68.6 ng/ml (81–225). Substitution treatment with prednisone and levothyroxine was initiated, with testosterone substitution being further considered.
Conclusions
Diagnosis and treatment of hypophysis insufficiency can sometimes be delayed. This case emphasises the importance of a thorough anamnesis and data integration in the investigation process. Screening of hypopituitarism in a defined risk populations may prevent under-diagnosis and reduce the severity, extent and duration of the condition.

Pituitary apoplexy

Aicha Bouzid[1], Imane Aribi[2] & Djamila Meskine[2]
[1]Algiers, Medical university of algiers, Endocrinology & Métabolism Laboratory Algiers 1, EPH Bologhine, Medecine, Algiers, Algeria; [2]Medical university of algiers. EPH Bologhine, Medecine, Algiers, Algeria

Introduction
Pituitary apoplexy is a rare and potentially life-threatening endocrine and neurosurgical emergency, most often linked to hemorrhage or necrosis of a pituitary adenoma.
Observation
We report the case of a 45 year old patient, with a history of chronic headache, hospitalized in the emergency setting for the management of meningeal syndrome with severe headache associated with vomiting, a significant drop in visual acuity, exophthalmos and ptosis of the left eye. Patient treated with antibiotic therapy, benefited from a normal income brain scan. Faced with the finding of a typical dysmorphic syndrome of acromegaly, it is directed to the endocrinology department where the diagnosis of acromegaly is confirmed biologically, the pituitary imaging revealed a necrotic pituitary adenoma.
Discussion
Pituitary apoplexy is defined by the occurrence of a massive necrotico-hemorrhagic reorganization within a pituitary adenoma, the clinical presentation of which varies according to the extent of the hemorrhage, necrosis and edema. It associates brutal headaches, disturbances of consciousness, sometimes severe visual disturbances (this is the case of the patient), and signs of meningeal irritation with in two thirds of cases signs of endocrine deficits often corticotropic. Its prevalence is 6.2 cases/100.00 inhabitants.
Diagnosis of pituitary apoplexy should be considered in all patients with acute severe headache with or without neuro-ophthalmic signs. The initial hormonal and ophthalmological assessment is essential to allow appropriate management. Magnetic resonance imaging (MRI) is the imaging test of choice to confirm diagnosis. Surgery is indicated in the event of severe visual disturbances. The evolution is generally favorable to often depends on a transient pituitary deficit.
Conclusion
Pituitary apoplexy is a rare complication of pituitary adenomas, it must be suspected in the presence of sudden headache with ophthalmological disorders. Its management must be multidisciplinary.

Unexpected diagnosis of ACTH dependent cushing syndrome in an old patient with hypertension, osteoporosis and newly diagnosed diabetes mellitus

Delia-Maria Varlan[1], Diandra Giuca[1], Andra Caragheorgheopol[2], Delia Acsinte[3], Iulia Grigore[4], Raluca Trifanescu[1,5] & Catalina Poiana[1,5]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrinology, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Biochemistry, Bucharest, Romania; [3]C.I. Parhon National Institute of Endocrinology, Radiology, Bucharest, Romania; [4]C.I. Parhon National Institute of Endocrinology, Diabetes, Bucharest, Romania; [5]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
Cushing syndrome could be missed initially, especially when the presenting features are common in the general population. Before proceeding to the hormonal tests we have to consider that recent studies have shown that up to 50% of patients with CD have different degrees of altered glucose metabolism, up to 80% of CS patients have hypertension independently of their age and sex and hypercorticism changes bone structure and causes vertebral fractures in approximately 70% percent of patients.
Aim
To present a patient with ACTH dependent Cushing syndrome with many complications of Cushing disease but no specific clinical signs.
Patient and methods
A 68 year old obese woman (BMI = 30.4 kg/m^2), known with hypertension, osteoporosis, multinodular goiter presented in 2019 for endocrine assessment and was diagnosed with diabetes mellitus and ACTH dependent Cushing syndrome.
Case report
Physical examination showed central obesity, without facial plethora, without easy bruising, without reddish purple striae, with minimal hirsutism on the upper lip, BP = 140/85 mm Hg despite treatment with 4 antihypertensive drugs. Visual field was normal. Thyroid examination detected a dominant nodule in a multinodular gland, about 4 cm in size (TIRADS 4, BETHESDA 2). Diabetes mellitus was diagnosed and there was no improvement in bone mineral density (BMD) after 2 years of antiresorbtive therapy (Lumbar BMD 2018–0.791 g/cm^2, lumbar BMD 2019–0.767 g/cm^2). Laboratory tests revealed increased basal serum 0800 h cortisol (28.62 µg/dl) and plasmatic ACTH (137.3 pg/ml), increased serum 2300 h cortisol (13.56 µg/dl), unsuppressed 8 A.M serum cortisol after 1 mg dexamethasone overnight test (27 µg/dl) and after two-day, low-dose dexamethasone suppression test (6 mg/dl).The tests suggested ACTH dependent Cushing syndrome. CT scan showed a pituitary macroadenoma and unilateral adrenal hyperplasia. NET markers (5 HIA, serotonin) were normal, apart Cromogranin A which was mild elevated but the patient was taking proton pump inhibitors. Metanephrines and normetanephrines were normal. There were no pulmonary nodules on chest X-Ray scan. Therefore, Cushing disease was suspected. Pituitary surgery is pending.
Conclusion
Simultaneous development and increasing severity of Cushing Syndrome complications such as diabetes, osteoporosis, hypertension in older patient, it's a clinical clue that should trigger the screening, despite the fact that this disease is often diagnosed at younger ages (25 to 45 years).

DOI: 10.1530/endoabs.70.EP358

EP359

Ex juvantibus diagnosis of undifferentiated diffuse connective tissue disease

Lola Daminova[1], Olga Skosyreva[1], Makhsud Sabirov[1] & Sitorakhon Muminova[2]
[1]Tashkent State Dental Institute, Therapy, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

The term "undifferentiated connective tissue disease" (UCTD) represents a stage of disease where clinical symptoms and serological abnormalities suggest autoimmune disease, but they are not sufficient to fulfill the diagnostic criteria of any well-established connective tissue disease (CTD). A 73-year-old man was referred to the 3rd hospital of Tashkent Medical Academy with signs of kidney lesion and the history of treatment at two other medical settings.

Complaints on admission
Exertional dyspnea, productive cough, high temperature (38° C) with chill and perspiration, palpitation, dryness in the mouth with no saliva, pain in joints, including the maxillary ones, nausea and vomiting, anorexia, 10 kg weight loss for 3 months, and expressed general asthenia.

Indicator	Before treatment	day 10	day 24
Blood:			
Hb	87.0	101	109
RBC	3.0	3.1	3.3
Color index	0.8	0.86	0.9
WBC	10	6.3	8.9
Platelets	3.l	3.5	3.55
Stab neutrophils	4%	-	3
Segmented neutrophils	78%	72	74
Eosinophil%	3	4	4
Lymphocytes%	15	16	18
Basophiles%	0	0	0
Monocytes%	4	8	5
ESR mm/h	35	22	18
Blood coagulation time	H–3.4	K–4.10	H-3.6
ALT U/l	20	23	
Total bilirubin µmol/l	13.5	10.8	
Conjugated bilirubin µmol/l	–	–	
Unconjugated bilirubin µmol/l	13.5	10.8	
Glucose mmol/l mmol/l	4.0	5.1	
Urea	16.9	13.6	10.3
Creatinine µmol/l	427.2	214.9	188.3
Total protein g/l	65.0	69.5	68.8
Potassium mmol/l	4.2	4.0	
Haematocrit	29	32	
Fibrinogen/ antithrombin g/l	6.3	4.1	3.9
Prothrombin ratio/index%	105	90	93
MHO	1.2	1.0	1.1

Examination of the patient 2 weeks later: the general condition is satisfactory, slight general weakness; sometimes coughing with light sputum, 2 kg weight gain. Further recommendations for 1 month: prednisolone (8 tab./day), vitamin E (1 caps. by 200 mg twice a day), clopidogrel 75 mg/day. in the evening after meals, calcium D3 (1 tab. twice aday), omeprazole 20 mg/day. Conclusion: This clinical case is of interest in terms of late diagnosis of undifferentiated diffuse connective tissue disease, that, most likely, was difficult to make due to underestimation of multi-organ manifestations of the disease, including the Sjogren's syndrome which is characteristic for collagenosis, as well as due to refusal of the patient from biopsy. The pulse therapy under the umbrella of the antibiotic have rendered a pronounced positive effect and confirmed the main diagnosis on the basis of the effect of treatment (diagnosis ex juvantibus).

Carcinoid crisis after peptide receptor radionuclide therapy in patient with midgut neuroendocrine tumor.

Dorota Brodowska-Kania, Marek Saracyn, Maciej Kolodziej, Lukasz Kowalski & Grzegorz Kaminski
Military Institute of Medicine, Department of Endocrinology and Isotope Therapy, Warsaw, Poland

Background
Carcinoid crisis (CC) may rarely occur as a complication of general anesthesia/surgery or peptide receptor radionuclide therapy (PRRT) in patients with neuroendocrine tumor (NET). The incidence of CC as a complication of PRRT is underestimated and comes to 10% of all radioisotope therapies. Progressive organ dysfunction, decrease or increase in blood pressure SBP <80 mmHg or >180 mmHg, unexplained tachyarrhythmia with heart rate >120/ min, bronchoconstriction and facial flushing are criteria for CC.
Clinical case
We present a 75-year-old patient who developed a life-threatening cc on the second day after prrt. he had a midgut neuroendocrine tumor (synaptophysin (+), chromogranin (neuroendocrine tumor (synaptophysin), ki67 5%), with metastates to liver, bones, abdominal nodules and right orbit. a long-acting somatostatin analog (saa)–octreotide was administered. the ct follow-up after 8 months showed progression. the patient was qualified for radioisotope therapy with 177 lu-dota-tate. the patient received the first activity of 200 mci177lu-dota-tate without significant complications. after three months, a second activity of 200 mci 177 lu-dota-tate was given. at admission, the patient was in a good general condition. In additional testsslightly increased CRP–12.5 mg/dl, creatinine-1.4–1.5 mg/dl were found. Urine culture was ordered, and Amoxicillin\Clavulanic were administered. On the next day, intravenous 1000 ml 10% Nephrotec was given for kidney protection, followed by 200 mCi 177Lu-DOTA-TATE. 24 hours after administration of PRRT, the general condition worsened. A syncope, atrial flutter with a rapid ventricular rate of up to 200/min, a tendency to hypotension with a systolic pressure of up to 90 mmHg occured and inflammatory parameters increased (CRP-37 mg/dl, procalcitonin 20 ng/ml). The patient was significantly weakened, with edema, short breath, oliguria, abdominal pain, without diarrhea. Facial flushing dominated. The ciprofloxacin and ceftriaxone, fluids, diuretics, metoprolol and amiodarone were administered. Due to persistent facial flushing and mentioned above signs, CC was diagnosed. Intravenously bolus of 200 μg octreotide, then 100 μg every 6h were given. Daily urine collection showed significantly increased excretion of 5-HIAA-69 mg/24 h (N:2–9 mg/24 h) before and 76 mg/24 h after octreotide injection. No bacterial growth was found in the blood and urea. Treatment with short-acting somatostatin analogues was continued. On the fifth day after PRRT administration, the sinus rhythm returned and the patient's condition improved.
Conclucion
Potential causes of carcinoid crisis in this case might be: injection of last SAA dose 3 months before PRRT, tumor lysis syndrome after PRRT, overproduction of serotonin from lysine and arginine given as nephroprotection or partially all of them.
The next PRRT, should be proceeded with use of short-acting somatostatin analog immediately after PRRT as the protection against the CC.

The management of acromegaly: experience of the endocrinology–diabetology department of oujda's mohammed vi university hospital, morocco

Soumiya Berrabeh, Ouafae Elmahraoui, Houda Bouali, Siham Rouf & Hanane Latrech
Mohammed Vi University Hospital, Department of Endocrinology-Diabetology-Nutrition, Oujda, Morocco

Introduction
Acromegaly is a rare disease characterized by somatotropic hypersecretion. The disease is associated with multiple significant comorbidities and increased mortality. The purpose of this study is to describe the epidemiological, clinical, para-clinical and therapeutic features of Acromegaly disease.
Patients and methods
This is a retrospective study including 12 patients with acromegaly in the Endocrinology Diabetology Department of Oujda's Mohammed VI University Hospital, MOROCCO.
Results
The mean age at diagnosis was 55 years with a female predominance. The median diagnosis delay was 8 years. Acrofacial dysmorphic syndrome was the most frequent mode of revelation. Pituitary adenoma was the etiology in all cases: macroadenoma in 11 patients and microadenoma in one patient. All our patients had complications at the moment of diagnosis: ante-pituitary insufficiency in 100% of cases, ophthalmological disorders in 75%, cardio-respiratory complications in 60%, diabetes mellitus was found in 58% and dyslipidemia in 25% of cases. All our patients had goiter. Colic polyps were observed in 41.6%, bone deformities in 50% and arthralgia in 50%. 75% of patients underwent transsphenoidal pituitary surgery. Surgery reduced the level of IGF1 by 41% and the size of the pituitary adenoma by 33%. 83.3% have been treated by somatostatin analogs SSAs (Lanreotide LP 120 mg), given before surgery in 4 cases with non-invasive adenoma and in 5 cases as a second line therapy after incomplete tumor resection associated to radiotherapy (25%). Treatment with SSAs has allowed IGF1 to be normalized in 62.5% of cases.
Conclusion
Acromegaly is a serious condition, associated with multiple comorbidities and increased mortality. Early identification of the signs and symptoms of the disease by health care professionals knowledgeable about acromegaly may help to mitigate this delay. Treatment can then be initiated promptly, with the potential to reduce mortality. Its management should be discussed among multidisciplinary meetings.

Management and outcomes of prolactinoma: follow-up of 40 patients

Inga Alikhanian, Elena Grineva, Uliana Tsoy, Lidiya Belousova, Anna Dalmatova, Vladislav Cherebillo & Natalia Gussaova
The National Medical Research Center n.a. V.A. Almazov

Introduction
Prolactinomas are the most common pituitary adenomas. Dopamine agonists (DAs) are the treatment of choice for prolactinomas. Patients with prolactinomas normally are treated in ambulatory. In some patients there are challenges in therapy, and they need to be hospitalized.
Objective
To study the clinical features and outcomes of in-patients with prolactinoma.
Materials and methods
A retrospective analysis of 40 hospitalized Patients with prolactinomas was done. MRI-findings, type and the effect of therapy have been analyzed.
Results
Forty patients (18 (45%) men, 22 (55%) women) were included into the study. Eight patients (20%) had microprolactinomas and 32 (80%) harbored macroprolactinomas. The main reasons for hospitalization were: 30 (75%) patients were referred from different regions of Russian Federation due to ineffectiveness of routine treatment, 8 (20%) were transferred from the neurosurgery department after adenomectomy and 2 (5%) were hospitalized due to the suspicion on MEN1 syndrome. 11/40 (40%) patients used cabergoline in dose less than 2 mg/week with prolactin levels normalization and adenoma volume reduction. This group of patients can be considered as sensitive to DAs. Due to an allergic reaction, cabergoline therapy was discontinued in one patient; after that was performed adenomectomy followed by normalization of prolactin levels. 2/40 patients were initially treated with bromocriptine (7.5–12.5 mg/day) and led to the normalization of prolactin and a decrease in adenoma volume. 16/40 (40%) patients used cabergoline in dose more than 2 mg/week without prolactin levels normalization. This group of patients can be considered as resistant to DAs. In 8/16 (50%) patients doses were increased (to 3.5–4.5 mg/week), in 4 patients it led to normalization of prolactin levels. In 2/16 (12.5%) patients cabergoline was changed to bromocriptine (7.5–10 mg/day), in 1 patient it led to normalization of prolactin levels. Adenomectomy was performed in 6/16 (38%) patients; however, surgery did not lead to normalization of prolactin in 3 cases. 10/40 patients (25%) underwent adenomectomy without achieving the maximum tolerated doses of DAs, only 3 of them had emergency indications for surgery.
Conclusions
The use of high doses of DAs can lead to normalization of prolactin levels, as well as a reduction of more than 30% of the tumor volume with long-term treatment. The increasing of doses of DAs to the maximum tolerated, using a combination of non-selective and selective DAs can lead to prolactin levels normalization and reduce the number of surgical interventions among patients with prolactinomas.
Keywords: bromocriptine, cabergoline, prolactinoma, resistance.

Metastatic neuroendocrine tumor of unknown primary site with associated carcinoid syndrome in a young patient–a case report

Sima Antonia, Burcea Iulia Florentina, Sorohan Mădălina Cristina, Dușceac Roxana & Poiană Cătălina
National Institute of Endocrinology CI Parhon, Pituitary and Neuroendocrine Pathology, Bucharest, Romania

Background
Neuroendocrine tumors (NETs) are relatively uncommon, accounting for 10 to 14 percent of all neuroendocrine neoplasms. Twelve percent to 22% of patiens are metastatic at presentation. The most frequent primary sites are the gastrointestinal tract (62–67%) and the lung (22–27%).
Case presentation
We report the case of a 36-year-old female patient diagnosed with metastatic disease, with liver, lung and lymph nodes metastasis with unknown primary tumor site, diagnosed on magnetic resonance imaging (MRI) at the age of 34. At her first evaluation in our clinic, she presented both clinical and paraclinical signs of carcinoid syndrome, with hot flashes, increase in stool frequency and with increased neuroendocrine markers (Chromogranin A = 100 ng/ml, Serum Serotonin = 1187 ng/ml, Neural Specific Enolase = 11.6 ng/ml). Further imaging studies showed progression of the metastatic disease, with the increase both in size and number of the liver metastasis (the largest from 9 cm in December 2017 to 14 cm in August 2019) and a lung tumor increasing in size, from 1.71 cm to 8.57 cm withing the last year. She was put on somatostatin (SS) analogues (Octreotide) with increasing doses, up to 60 mg every 28 days. We mention a twin pregnancy lost at 17 weeks in July 2019, on the course of which the patient stopped treatment with Octreotide. In December 2019 she received 7.4 GBq177-Lu-DOTATOC withing the first session of peptide receptor radionuclide therapy (PRRT), with the arousing of suspicion that the primary tumoral site might be the lung lesion, as seen of PET-CT.
Conclusion
We presented the case of a 36-year-old patient with a neuroendocrine tumor of unknown site, with rapidly progressing metastatic disease, with poor response to SS analogues, with a very poor prognosis for tumor-free survival.

Insulinoma localized by Ca-stimulation angiography: A case report

Sándor Halmi, Eszter Berta, Annamária Erdei, Inez Lengyel, Endre V. Nagy & Miklós Bodor
Debreceni Egyetem, Debrecen, Hungary

Introduction
Insulinoma is a rare tumor of the beta cells of the pancreas. The clinical manifestation is diverse with hypoglycemia and autonomic neurological symptoms. For diagnosis the Whipple's triad needs to be present: signs of hypoglycemia, glucose level under 3 mmol/l and the cessation of symptoms after administration of iv. glucose. The fasting test confirms the diagnosis. The most commonly used imaging techniques that may localize the tumor are the abdominal ultrasound and CT scan; however, in some cases further procedures are necessary.
Case report
A 27 years old male patient without any other significant disease in his history presented with symptoms lasting for one year involving dizziness, fatigue, confusion, sweating and tremor. Blood glucose under 2 mmol/l was found on multiple occasions while presenting specific symptoms, which ceased every time after administration of iv. glucose. During the fasting test a low glucose level with consecutively elevated insulin and C-peptide levels were measured. In order to localize the tumor different imaging techniques were performed. Abdominal sonography, endoscopic ultrasound and spiral CT couldn't find the suspected pancreatic tumor. Finally selective arterial angiography was performed with Ca-stimulation. After selective catheterization of the arteria lienalis, mesenterica superior and gastroduodenalis Ca-stimulation was performed. After administration of iv. calcium blood samples were collected from the right hepatic vein after 0.30 and 60 seconds. During the stimulation administered in the a. lienalis the 1-minute sample showed a significant rise in the insulin and C-peptide levels while after performing the stimulation on the other two arteries no remarkable differences were noticed. The concomitant arteriography showed a small, 1 cm diameter hyper vascularized nodule, characteristic for insulinoma.
Discussion
After establishing the diagnosis, the precise localization of the tumor within the pancreas can become a serious problem. According to the literature 10–27% of the insulinomas cannot be evidenced by the available imaging techniques. The selective Ca-stimulation technique can shrink the possible tumor localization to the region of the pancreas that is supplied with blood by the specific catheterized artery. With this procedure the majority of the pancreas can be saved. Although newer techniques, like GLP1 scintigraphy or sensitive intraoperative ultrasound became available recently, the selective Ca-stimulation can still be used for the identification of insulinomas non-detectable by less expensive noninvasive methods.

Acromegaly in young patients - treatment challenges, case presentation

Laura Cotoi, Balas Melania, Golu Ioana, Vlad Mihaela & Daniela-Georgiana Amzar
Victor Babeş" University of Medicine and Pharmacy Timişoara

Introduction
Acromegaly is a debilitating, indolent disease that develops over several years due to extended exposure to elevated growth hormone (GH) levels. It is most commonly caused by somatotropinomas. It represents a rare pathology with an incidence of 3–14 cases per 1 million inhabitants and a prevalence of 40 to 90 cases per 1 million inhabitants. Pituitary adenomas respresent a challenging disease in young patients. Transphenoidal surgery is the best therapeutic option, but in many cases complete biochemical control is difficult to obtain, often requiring adjuvant therapy.
Materials and methods
We present the case of a male patient, 22 years old, diagnosed in 2014 with somatotropinoma. Clinically, on admission, the patient presented drug resistant headache, decreased visual acuity, extremities enlargement and arthralgia. Biological, the patient had elevated IGF–11 (726.9 ng/ml) and basal GH (116 ng/ml) levels and gonadal insufficiency. The MRI evaluation revealed the presence of an invasive macroadenoma (32/36/26 mm), with the inclusion of the optic chiasm and severe bitemporal hemianopsy. The recommendation at diagnosis was transphenoidal adenomectomy, performed in the same year. Postoperatively, the patient presented multiple postoperative complications with the development of global pituitary insufficiency. Postoperative biochemical profile improved, but with GH secretion (10.2 ng/ml) persistence and elevated IGF-1 concentrations (712.6 ng/ml). Treatment with somatostatin analogs and dopamine agonists was initiated after surgery, but GH secretion pursued (6.73 ng/ml). GH receptor antagonist therapy was added to the initial regimen, normalizing IGF-1 concentration (388.00 ng/ml), but with persistent GH secretion (7.78 ng/ml). Radiation therapy with conventional fractionated photons or radiosurgery with proton beam is recommended in this case.
Results
The patient presented a GH secreting pituitary macroadenoma with multiple acute postoperative complications, not responsive to drug therapy. The patient developed multiple complications of acromegaly, impairing quality of life and darkening long term prognosis.
Conclusions
Treatment of acromegaly is challanging in pituitary macroadenomas, especially in young patients. Early diagnosis with therapeutic interventions can improve disease complications, improving quality of life.

Recurrent cushing's disease and pregnancy: A case report

Wafa Benothman, Ghada Saad, Imen Halloul, Asma Ben Abdelkrim, Yosra Hasni, Molka Chaeib, Maha Kacem, Amel Maaroufi & Koussay Ach
Farhat Hached Hospital, Endocrinology, Sousse, Tunisia

Introduction
Cushing's disease (CD) is reported in 60-70% of all patients with Cushing's syndrome (CS), but occurs only in approximately 33% of the reported CS cases in pregnancy. Nevertheless, despite its rarity, pregnancy in patients with CS can be troublesome because of the risk of maternal-fetal complications.

Observation
A 28-year-old female patient was referred to our endocrinology department for a suspected CS with morphological alterations and recent diagnosed diabetes mellitus. The clinical, laboratory, and imaging findings were compatible with CD and a secondary hypogonadotropic hypogonadism due to pituitary macroadenoma of 17 mm. The patient underwent transsphenoidal resection of the adenoma. No complications arose during the operative and postoperative period. The anatomopathological study disclosed a corticotroph-cell adenoma. Postoperatively, the patient had normal adrenalism. Five and seventeen months after the surgery, respectively, she had two pregnancies with successful maternal-fetal outcomes. The patient remained in remission with no clinical symptoms of CS. Biochemical workup after 5 years and 10 months was as follows: 24 h UFC 150 µg; ACTH 156 pg/ml and serum cortisol measured at 0800 h. after 1 mg dexamethasone administration at midnight 20 ng/ml. Pituitary MRI revealed an adenoma remnant invading the cavernous sinus. Thus, recurrent CD was confirmed. Just a month later, the patient got pregnant. She is now in her first trimester. After a thorough discussion of the risks and benefits to both her and the baby, she elected to proceed with no medical nor surgical treatment.
Conclusion
Pregnancy in women with a diagnosis of CD is an extremely rare event and its diagnosis and treatment are a real medical challenge. The impact of achieving biochemical remission on fetal outcomes is unknown.

Diagnosis of multiple endocrine neoplasia type 1 in a patient with hypercalcemia and hyperprolactinemia

Hatice Sebile Dökmetaş[1], Ayşegül Yıldırım[2], Fatih Kılıçlı[1] & Ayşenur Cila[3]
[1]İstanbul Medipol University, Endocrinology and Metabolism, İstanbul, Turkey; [2]İstanbul Medipol University, Internal Medicine, İstanbul, Turkey; [3]İstanbul Medipol University, Radiology, İstanbul, Turkey

Multiple endocrine neoplasia type 1 is a rare autosomal-dominant disorder. The most common endocrine tumors are parathyroid tumors, which cause hyperparathyroidism and hypercalcemia. Other tumors of MEN 1 include pituitary tumors for example prolactinomas and enteropancreatic tumors such as gastrinomas, insulinomas, VIPomas, carcinoid tumors. We report a case of a 31 year old male with MEN 1 presenting hypercalcemia with complaints of fatigue and weakness. On further questioning, the patient reported to headache and decreased libido. Laboratory results revealed: serum calcium: 11.27 mg/dl (8.6–110), intact parathormone: 101.1 pg/ml (15–165) phosphor: 2.64 mg/dl (2.6–14.5), prolactin: 1597 ng/ml (4.04–115.2), gastrin 17 pg/ml (13–1115), insulin: 19.79 uU/ml. A cranial MRI revealed 3 cm diameter cystic macroadenoma on the center of pituitary gland. The upper abdominal MRI was scanned for exploratory purpose and did not revealed any tumors. Hyperparathyroidism and pituitary macroadenoma were accepted as MEN 1 components. The patient underwent the operation for resectomy of the pituitary mass. Parathyroidectomy and profilactic thymectomy operations were planned. Although hypercalcemia with hyperprolactinemia is a a rare condition, it should be kept in mind that finding of hyperparathyroidism and hyperprolactinemia togetherness may be the signs of the Men 1 syndrome.

ACTH-dependent cushing's syndrome: an overview of the clinical features, diagnosis and treatment in the endocrinology-diabetology and nutrition department of oujda's mohammed vi university hospital - morocco

Imane Assarrar, Khadija Boujtat, Wahiba Abdellaoui, Siham Rouf & Hanane Latrech
University Hospital Center Mohammed Vi, Faculty of Medicine and Pharmacy, Mohammed 1st University, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Introduction
Cushing's syndrome is a rare condition, resulting from chronic exposure to excessive circulating levels of glucocorticoids. This condition is highly associated with complications such as cardiovascular and metabolic disorders. This study aims to review the clinical characteristics, diagnosis and treatment of patients with ACTH-dependent Cushing's syndrome.
Material and methods
A descriptive and comparative study carried out in the Endocrinology-Diabetology-Nutrition department of Oujda's Mohammed VI University Hospital, Morocco. The population study included 15 patients with ACTH-dependent Cushing's syndrome.
Results
The mean age of the patients was 31.7 years (extreme ages 14–151 years) with a female predominance. All patients showed symptoms of hypercortisolism. All patients had elevated midnight blood cortisol, loss of cortisol circadian rhythm and non-suppression of cortisol during 1mg overnight dexamethasone suppression test. All patients responded to 8mg dexamethasone suppression test. The mean ACTH value at the moment of diagnosis was 141.9 ng/l. The hypothalamic-pituitary MRI revealed a pituitary microadenoma in 46.7% of the cases, a macroadenoma in 20% and was negative for 33.3% patients. 7 patients out of 15 received preoperative medical therapies: 42% were treated with Metopirone, and 58% were treated with Ketoconazole. 42.8% of the patients have undergone transsphenoidal surgery for their pituitary adenoma, while 50% had a bilateral adrenalectomy. Fifteen percent of patients needed post-operative conventional radiotherapy and one patient underwent radiosurgery. Meanwhile, one patient refused treatment. The remission rate was around 33.3%. However, 50% experienced an adenoma recurrence.
Conclusion
Cushing's disease is caused by a pituitary ACTH-secreting adenoma, causing endogenous hypercortisolism. The management of Cushing's disease and its complications should be discussed over multidisciplinary meetings, including endocrinologists, neurosurgeons and radiologists in order to choose the best treatment plan for the patient.

Family case of multiple endocrine neoplasia type 1 in belarusian population

Maxim Lushchyk[1], Elena Kuzmenkova[2], Galina Korolenko[3], Dmitri Raduk[1] & Larissa I. Danilova[1]
[1]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department, Minsk, Belarus; [2]Republican Center of Medical Rehabilitation and Watertherapy, Endocrinology Department, Minsk, Belarus; [3]Minsk City Clinical Hospital Nr.10, Endocrinology Department, Minsk, Belarus

Introduction
Multiple endocrine neoplasia type 1 (MEN-1) is a rare, autosomal dominant inherited disorder, characterized by a high predisposition to develop a wide spectrum of endocrine and nonendocrine tumors, mostly of parathyroids, endocrine pancreas, and anterior pituitary.
Methods
Analysis of clinical and laboratory data, family history of multiple endocrine neoplasia.
Results
A 19-year-old woman with autoimmune thyroiditis and hypothyroidism was routinely examined in outpatient Endocrine Department in Minsk (Belarus). Replacement therapy with levothyroxine 50 mg was prescribed 2 yrs ago. She complained sickness, in the anamnesis–eating behavior disorders with body mass fluctuations during last year. Occasionally low levels of serum potassium were revealed and she was hospitalized in Medical Academy Clinic. It appeared that her mother had pituitary macroadenoma (somatotropinoma) and primary hyperparathyroidism with hypercalcemia, verified in 2019 yr. She was prescribed aledronic acid medication to control the levels of serum calcium. Parathyroid surgery was postponed because of unclear reason. Mother's sibling and nephews are living in Germany and MEN-1 mutation was verified in their family. Their MEN-1 phenotype was characterized by primary hyperparathyroidism, pituitary adenoma. Pancreas tumor was diagnosed in one family member 48 years old. New anamnesis data influenced the diagnostic protocol in our patient - increased levels of PTH were diagnosed (255.0 ng/l, reference range, 10–65 ng/l). Routine biochemistry revealed near normal Calcium level of 1.35 mmol/l (reference range, 1.12–1.32 mmol/l). She had no symptoms of hypercalcemia. Parathyroid scintigraphy was normal. Serum potassium levels became near normal

on infusion therapy (3.9 mmol/l). Screening for parathyroid, pancreas endocrine tumors and pituitary adenoma started.
Conclusion
Primary hyperparathyroidism is the most frequent and usually the earliest expression of MEN-1, with typical age of onset at 20–25 years. Early detection of the disease and correct treatment are therefore of great importance. Education of members of families with MEN-1 is worth doing as well as molecular screening for MEN-1 mutation to individualized their diagnostic and treatment protocols.

Latrogenic cushing syndrome owing to topical steroids

Veysel Nijat Baş
Kütahya Health High School, Department. of Pediatric Endocrinology, Kütahya, Turkey

Topical steroids are widely used by dermatologists and other physicians for the treatment of skin diseases such as diaper dermatitis. Iatrogenic Cushing syndrome may occur as an undesirable outcome of high-dose glucocorticoids treatments. This may also cause hypothalamus–hypophysis– adrenal axis suppression. While this situation may be caused more frequently with oral and topical glucocorticoid therapy, iatrogenic. Here, we report a 6 month-old boy with Cushing syndrome that was developed secondary to potent topical corticosteroid (diflucortolon valerate) use 3 to 4 times daily for 4 months. We tried to warn the physicians about the warning signs of Cushing syndrome in patients who suffer from regional obesity, and emphasized the importance of explanation of the usage, and duration of treatment while prescribing topical steroid creams especially during infancy.

EP371

ACTH-secreting pituitary macroadenomas about tow cases

Karima Chafai, Hamida Oumbiche, Coralie Amadou, Anne Deburge, Armelle Pochat, Rabah Bensbaa & Alfred Penfornis
Service D'endocrinologie Diabétologie Du Centre Hospitalier Sud Francilien, Essonne, Corbeil Essonne, France

Introduction
Cushing's disease is a rare condition observed in about 8–10% of patients with pituitary tumor. In the majority of cases, corticotroph adenomas are small, intrasellar and less than 10mm in diameter, while macroadenomas occur in 4–10% of the patients. An observation of two clinical cases is reported.
The observation
Case number 1: a female patient aged 31, hospitalized for suspected Cushing's disease. Diagnosis mentioned in the context of an exploration for fracture osteoporosis. The 24-h urinary free cortisol (UFC): 560 nmol/l, ACTH: 148.9 pg/ml, midnight cortisol: 350 nmol/l. With pituitary MRI: pituitary macroadenoma of 19 × 10 × 13 mm, extending to the level of the right cavernous sinus, arriving in contact with the right internal carotid artery without invading it. High-dose dexamethasone overnight suppression test, and a corticotrophin releasing hormone (CRH) test, were positive. The patient had a trans-sphenoidal adenomectomy with histological confirmation, corticotropic adenoma KI67 at 7%. The post-operative evaluation at 3 months is in progress. Case number 2: 60 year old male patient with a history of hypertension, type 2 diabetes, sleep apnea syndrome. Diagnosis is supected in front of the clinical aspect suggestive of a cushing syndrome. The 24-h urinary free cortisol (UFC): 5760 nmol/24 h, ACTH: 183.3 pg/ml. Pituitary MRI: macro adenoma of the anterior pituitary gland measured at 14 × 15 × 15 mm, developed mainly on the right side without invasion of the pituitary stem without invasion of the optic chiasm or carotid arteries. High-dose dexamethasone overnight suppression test was negative, but corticotrophin releasing hormone (CRH) test was positive. Patient referred in neurosurgery.
Conclusion
Cushing's disease is rare, even rarer in corticotropic macro adenomas, the latter can be secreting and clinically symptomatic, are often associated with less glucocorticoid suppression than micro adenomas, and pose a problem of management since they are often severe and aggressive.

Pasireotide therapy in a patient with pituitary macroadenoma and asymptomatic acromegaly resistant to first generation somatostatin analogues

María Concepción Terroba-Larumbe[1], Jose Maria Palacio-Mures[1], Cristina Crespo-Soto[1], Marta Ventosa-Viña[1], Luis Cuellar-Olmedo[1], Manuel Acuña-Garcia[2], Itziar Anacabe-Goyogana[3], Danay Areli Ticona-Spinoza[4], Jose Maria Delgado-Sanz[1] & Javier Angel Rodriguez Garcia[1]
[1]Hospital Rio Hortega, Endocrinologia y Nutrición, Valladolid, Spain; [2]Hospital Rio Hortega, Otorrinolaringologia, Valladolid, Spain; [3]Hospital Rio Hortega, Radiologia, Valladolid, Spain; [4]Hospital Rio Hortega, Nefrologia, Valladolid, Spain

Introduction
Acromegaly increases morbidity and mortality and should be treated even in the asymptomatic phase. It is almost always caused by a GH-producing pituitary adenoma and although transsphenoidal surgery is the treatment of choice in most cases, in others, primary medical therapy is indicated.
Clinical case
A 36-year-old female with a family history of thyroid functional pathology and diagnosed with micronodular goiter was evaluated in February 2015 for a transient minimal galactorrhea, unrelated with drugs and without other associated symptoms or signs. In the biochemical tests the following was observed: IGF-I 640 ng/ml (100–330), GH 1.4 ng/ml (0–4.3). Prolactin, FSH, LH, estradiol, cortisol, T4-free and TSH, calcium, phosphorus, renal and hepatic functions were normal. Pituitary magnetic resonance (MR) detected an increase in pituitary size at the expense of a 20 × 12 × 15 mm-sized lesion, bilaterally predominantly left, minimally hyperintense in T2, with some microcyst, hypointense in T1 and hypocaptant with respect to the rest of the gland. It partially invaded the left cavernous sinus and slightly bulged the upper contour of the gland without compromising the suprasellar structures. The pituitary stalk was discreetly horizontal and somewhat lateralized to the right. Given the existence of a macroadenoma that did not compress the optic chiasma and impossible to eliminate completely due to the extension to the cavernous sinus, Sandostatin LAR IM was prescribed, initially 20 and then 30 mg/month. One year later, the patient remained asymptomatic but, given the absence of a biochemical (IGF-I 674 ng/ml, GH 3 ng/ml) and morphological response we agreed to suspend this therapy and reassess the results of IGF-I with another methodology and performing oral glucose overload (baseline GH 5.2 ng/ml, nadir 2 ng/ml). After confirming acromegaly, in July 2017, we started treatment with Pasireotide-LAR IM 40 mg/month and 3 months later the IGF-I was within normal range. The October 2018 pituitary MR showed a reduction in size of the adenoma to 12 × 9 × 8 mm and that it contacted the left internal carotid artery without extending to the walls of the cavernous sinus. To date, with this therapy, the patient maintains biochemical normality with no significant side effects.
Discussion
In this patient with pituitary macroadenoma without surgery indication and null response to first generation somatostatin analogues, it was not possible to personalize the initial medical therapy. Pasireotide-LAR, chosen as second option, produced a biochemical and morphological response.

Pituitary macroadenoma (co-secreting GH and Prolactin)

Faiza Qari
King Abdulaziz University Hospit, Endocrine, Jeddah, Saudi Arabia

A 16 years old boy referred to neurosurgery due to sellar and suprasellar mass. He had a history of retro orbital headache in the last three years. he noticed increase in his height, enlargement of hands and feet. He had one year history of progressive decrease in vision mainly in the left. He did not enter puberty.

Physical examinations
BMI 36 kg/m^2 (more than 95 percentile), Tall height 190 (more than 97 percentile), Weight 130 kg (more than 97 percentile).
He had coarse features, with large hand and feet, oily skin. His visual field examination revealed left temporal hemianopia. He is still Pre pubertal.
Laboratory
GH 40 ng/ml, IGF1 1220 ng/ml (107–584).
FT4 10.0 pmol/l, TSH 0.458 miu/ml.
Cortisol 100 nmol/l, Post ACTH stimulation: Cortisol 300 nmol/l.
Testosterone index 7 (33–106), LH<0.1 IU/l, FSH <0.1 IU/l.
Prolactin 888032 miu/l (86–324).
Diagnosis of Pituitary macroadenoma (co-secreting GH and Prolactin) was made.
Patients was treated initially with cabergoline 0.5 mg po once week with dose escalation. Follow up 2 weeks Octreotide 30 mg IM/4W.
His headache improve, as well Visual field improve.
Follow up Prolactin was 30300 miu/l, After three months follow up, he showed marked Improvement in his visual field, and no more headache disappear. The Prolactine level was 6000 miu/l and IGF1 800 ng/ml (107–584).
MRI showed Minimal regression of the mass
After 6 months follow up.
The Visual field was normal, Prolactin 3000 miu/l, IGF1 650 ng/ml (107–584).
He is still on Cabergoline 1.5 mg twice per weeks and Octreotide 40 mg/4 weeks.
Conclusion
Young patient present with sellar and suprasellar mass. The diagnosis was Pituitary macroadenoma (co-secreting GH and Prolactin) was made.

Androgen modulate the pro-oxidant and antioxidant activity of macro-endothelial cells

Maria Filiponi[1], Sophia Gougoura[1], Christina Befani[2], Alexandra Bargiota[1], Panagiotis Liakos[2] & Georgios Koukoulis[1]
[1]Laboratory of Endocrinology and Metabolic Disorders, Endocrinology Clinic of Peripheral University Hospital, Larissa, Larissa, Greece; [2]University of Thessaly, Larissa, Laboratory of Biochemistry, Department of Medicine, Larissa, Greece

Introduction
Limited data exist on testosterone and oxidative stress induction. The present study was undertaken to evaluate, in vitro, the role of physiological concentrations of androgens (testosterone-DHT) in modulating the pro-oxidant and antioxidant activity of intact endothelial cells.
Materials and methods
EA.hy926 macroendothelial cells were cultured in DMEM phenol red free without FBS for 24 hours. Growth medium was replaced and then testosterone (0.5 nM), and DHT (0.5 nM) alone or in combination with the androgen receptor antagonist flutamide (50nM), were added to the culture media and cells incubated for 2 more hours. Intracellular reactive oxygen species (ROS) content, endothelial nitric oxide synthase (eNOS) activity, nitric oxide (NO) levels, superoxide dismutase (SOD) activity, catalase activity (CAT), and glutathione (GSH) levels were measured.
Results
Testosterone and DHT significantly increased eNOS activity ($P<0.001$ vs CTL) and NO production ($P<0.001$, $P<0.01$ vs CTL accordingly), while they augmented the intracellular ROS content ($P<0.001$ vs CTL) in EA.hy926 endothelial cells. Moreover, they increased the antioxidative system of SOD ($P<0.001$, $P<0.01$ vs CTL accordingly) and significantly decreased catalase activity ($P<0.001$ vs CTL). All the above effects of androgens were abolished by flutamide suggesting that they act through the androgen receptor. Finally, testosterone and DHT had no significant effect on cellular GSH levels and the GSH/GSH+GSSH ratio in EA.hy926 cells.
Conclusion
Our findings indicate a pro-oxidative role of testosterone and DHT in EA.hy926 endothelial cells, suggesting that the androgens upregulate the endothelial oxidoreductase homeostasis to a higher functional level.

[1]"Grigore T. Popa" University of Medicine and Pharmacy, Medical Genetics, Iasi, Romania; [2]"Cuza Voda" Obstetrics and Gynecology Hospital Iasi, Medical Genetics, Iasi, Romania; [3]"Victor Babes" University of Medicine and Pharmacy Timisoara, Medical Genetics, Timisoara, Romania; [4]"Sfantul Spiridon" Emergency Hospital Iasi, Endocrinology, Iasi, Romania

We made a retrospective study of X monosomy cases identified in our laboratory in the last 10 years. The aim of study was to establish a correlation between different forms of X monosomy, and age for confirmation of cytogenetic diagnosis. Between 2010 and 2019 we confirmed 81 cases of Turner syndrome in our laboratory. We found different forms of X monosomy and the most frequent was X homogenous X monosomy. We found 24 cases (29.62%) of X homogenous monosomy (median age of diagnosis–7 years) 14 cases (17.28%) of 45, X/46, X, I (Xq) (median age of diagnosis–14 years) 11 cases (13.58%) of with deletions on chromosome X (median age of diagnosis–10.5 years) 9 cases (11.11%) with 45, X/46, XX (median age of diagnosis–25 years) 9 cases (11.11%) with complex forms of chromosomal mosaics that included a line with X monosomy (median age of diagnosis–23 years) 7 cases (8.64%) with ring chromosome X (median age of diagnosis–8.75 years) 3 cases (3.7%) with X monosomy and the presence of a marker chromosome (median age of diagnosis–3.75 years) and 5 cases (6.17%) with other unbalanced structural anomalies of chromosome X (median age of diagnosis–6.25 years). We confirmed the diagnosis at a small age in cases with X homogenous monosomy, ring chromosome X or a marker chromosome. For example, in 10 of 24 cases with X homogenous monosomy the age for confirmation of diagnosis was before 1 year. In opposition, the presence mosaic forms were correlated with a high median age (more than 20 years). The chromosomal analysis in our cohort was imposed by different clinical suppositions: Turner syndrome–58 cases (71.6%) amenorrhea or feminine sterility–8 cases (9.87%) short stature–7 cases (8.64%) plurimalformative syndrome–4 cases (4.93%) loss of pregnancies–2 cases (2.46%) and intersexuality–2 cases (2.46%). A feature or a complete pattern of Turner syndrome was discovered in 73 cases (90.01%) and such situation was identified in all cases with homogenous X monosomy or ischromosome X. Our study confirmed the importance of a good collaboration between geneticists and endocrinologists in management of Turner syndrome. Also, we confirmed the importance of cytogenetic analyses that are mandatory in management of Turner syndrome.

Thyroid peroxidase antibodies in women with polycystic ovary syndrome and type 1 diabetes

Agnieszka Lebkowska[1], Agnieszka Adamska[2], Anna Krentowska[1], Aleksandra Uruska[3], Anita Rogowicz-Frontczak[3], Aleksandra Araszkiewicz[3], Justyna Hryniewicka[2], Monika Leśniewska[4], Katarzyna Ożegowska[5], Ewa Wender-Ożegowska[6], Dorota Zozulinska-Ziolkiewicz[3] & Irina Kowalska[1]
[1]Medical University of Bialystok, Department of Internal Medicine and Metabolic Diseases, Poland; [2]Medical University of Bialystok, Department of Endocrinology, Diabetology and Internal Medicine, Poland; [3]Poznan University of Medical Sciences, Department of Internal Medicine and Diabetology, Poland; [4]Medical University of Bialystok, Department of Reproduction and Gynecological Endocrinology, Poland; [5]Poznan University of Medical Sciences, Department of Infertility and Reproductive Medicine, Poland; [6]Poznan University of Medical Sciences, Department of Reproduction, Poland

Objective
Polycystic ovary syndrome (PCOS) is more prevalent among women with type 1 diabetes (T1DM) than in general population. Autoimmune thyroiditis (AIT) is the most common autoimmunological disease in young women in reproductive age, especially in T1DM. Data in literature indicate the possible role of thyroid autoimmunity in PCOS pathogenesis. It has been suggested that positive concentration of thyroid peroxidase antibodies (TPOAbs) is associated with increased prevalence of PCOS. Data in women with PCOS

and T1DM are not known. The aim of this study was to evaluate the presence of TPOAbs and its relationships with clinical and laboratory parameters in women with PCOS and T1DM.
Patients and methods
We studied 83 women with T1DM (age 26±5 years, BMI 24±3 kg/m^2): 41 with PCOS and 42 without PCOS. PCOS was diagnosed using the Rotterdam criteria. Anthropometric measurements, clinical parameters, ultrasonographic evaluation of the ovaries, assessment of serum concentrations of sex hormones, TPOAbs, TSH, free triiodothyronine and free thyroxine were performed for all women.
Results
In PCOS women, we found 12 women with positive serum concentration of TPOAbs (T1DM+PCOS+TPOAbs) and 29 women with negative serum TPOAbs (T1DM+PCOS+noTPOAbs); in the group without PCOS, 18 had positive serum TPOAbs. The prevalence of positive TPOAbs concentration did not differ between women with and without PCOS. Groups T1DM+PCOS+TPOAbs and T1DM+PCOS+noTPOAbs did not differ in anthropometric measurements, daily dose of insulin, or HbA1c. TSH and free thyroid hormones, as well as hormonal profile were comparable in T1DM+PCOS+TPOAbs and T1DM+PCOS+noTPOAbs. In all PCOS women, TPOAbs concentration correlated significantly with hirsutism score (r=0.48, P=0.001) and ovarian volume (r=0.33, P=0.037).
Conclusions
In T1DM women, PCOS is not related to higher prevalence of positive serum TPOAbs detection.

Is there relationship between serum Igf-1 and thyroid nodule, thyroid or ovarian volume in polycystic ovarian syndrome?

Ömercan Topaloğlu[1], Bahri Evren[2], Mehmet Uzun[3], Saim Yoloğlu[4], Emek Güldoğan[4] & İbrahim Şahin[2]
[1]Kocaeli Derince Training and Research Hospital, Endocrinology, Derince/Kocaeli, Turkey; [2]Inonu University Medical Faculty, Endocrinology, Malatya, Turkey; [3]University of Health Sciences, İzmir Suat Seren Chest Diseases and Surgery Training and Research Hospital, Intensive Care Unit, İzmir, Turkey; [4]Inonu University Medical Faculty, Biostatistics, Malatya, Turkey

Introduction
Studies investigating the association between serum IGF-1, and thyroid nodule, ovarian or thyroid volume in polycystic ovarian syndrome (PCOS) are limited. We aimed to analyze the association between serum IGF-1 level, and ovarian or thyroid volume, or thyroid nodule in PCOS.
Materials and methods
The study was performed between June 2017 and August 2019 as prospective design. The patients referred to our medical faculty were included. Adult females with new-onset PCOS were included. The patients having comorbid illness, or using medication were excluded. Basic laboratory tests, thyroid and ovarian sonography were performed. The patients were grouped according to thyroid nodule (absent/present) and ovarian volume (<10 ml/≥10 ml). We planned to find a positive association between IGF-1, and thyroid nodule, thyroid or ovarian volume in PCOS.
Results
Of total 118 patients, 11 (9%) had thyroid nodule. The patients with thyroid nodule had a higher thyroid and ovarian volume (P=0.026, P=0.006; respectively). No correlation was found between GH or IGF-1, and thyroid or ovarian volume. IGF-1 was not a predictor for thyroid nodule or higher ovarian volume. The higher DHEAS and thyroid nodule were found as significant predictor for higher ovarian volume.
Conclusions
To our knowledge, our study is the first to analyze the association between IGF-1 and thyroid nodule in PCOS. We found that thyroid nodule was associated with thyroid and ovarian volume, but IGF-1 was not associated with thyroid nodule, thyroid or ovarian volume. It should be kept in mind that metabolic screening is essential but we do not recommend routine measurement of IGF-1 in PCOS.

Clinical experience in puerta del mar university hospital anttending transsexual people (2015-2019)

Almudena Lara-Barea, Isabel Mateo Gavira, Laura Larrán Escandón, Cristina López Tinoco & Manuel Aguilar Diosdado
Puerta del Mar University Hospital, Endocrinology and Nutrition, Spain

Introduction
Transsexuality is defined as discordance between one's assigned sex at birth and that individual's gender identity. Hormonal, anatomical, legal and psychosocial adaptations are present in most cases. Following recent changes to the Spanish legal framework, modifications have instaured to the model of attention for transsexual people in Andalusia. The aim of this study was to evaluate healthcare demand evolution in Trans People Attention Unit of Puerta del Mar University Hospital (Cádiz) from April 2015 to December 2019.
Methodology
We conducted a retrospective and longitudinal-descriptive case series study to evaluate healthcare demand evolution in Transsexual People Attention Unit of Puerta del Mar University Hospital (Cádiz) from April 2015 to December 2019. We analyzed demographic characteristics and the percentage of people reciving gender-affirming treatments (hormonal and/or surgery). Rate of loss of clinical follow-up and the psychological support demand are analyzed.
Results
We attended 353 transsexual people: 194 transsexual men and 159 transsexual women. The number of people assessed per year increased from 49 in 2015 to 91 in 2019. The median age at the 1st visit was 19 (17–25) years. 335 people (94.9%) started gender-affirming hormonal treatment (HT). We observed 28.9% mastectomy and 20% hysterectomy plus double anexectomy in transsexual men. 13.7% transsexual women were underwent for feminizing genitoplasty surgery and 15.8% are on surgical waiting list. 18.4% transsexual people (n=64) have required psychological support and 16.5% (n=56) were lost to follow-up.
Conclusions
In our setting, care is provided to a growing number of transsexual people in last years. In most cases, gender-affirming hormonal treatment is performed and psychological support is occasionally demand. No cases of regretted have been detected gonadectomy yet.

Semen quality improvement after weight loss by very low-calorie ketogenic dietary: A report of two cases

Alessandra Renck[1], Thiago Afonso Teixeira[2, 3], Juliana Risso Pariz[2], Ericka Barbosa Trarbach[4], Jorge Hallak[2, 3] & Elaine Maria Frade Costa[1]
[1]Hospital das Clinicas, Universidade de Sao Paulo, Developmental Endocrinology Unit, Sao Paulo, Brazil; [2]Androscience, High Complex Clinical and Research Andrology Laboratory, Sao Paulo, Brasil, Sao Paulo, Brazil; [3]Universidade de Sao Paulo, Section of Andrology, Division of Urology, Sao Paulo, ; [4]Universidade de Sao Paulo, Laboratory of Cellular and Molecular Endocrinology LIM-25, Sao Paulo, Brazil

Considered as the biggest public health problem, the pandemic growth of obesity is associated to decline of male fertility potential over the last 50 years. Thus far, the effect of weight loss on semen parameters is still controversial and poorly understood. In this study we report the effect of significant weight loss on semen parameters of two obese men with metabolic syndrome. The patients followed to a very low-calorie ketogenic diet (VLCKD) according to a commercial weight loss program (Pronokal® Method), wich includes lifestyle and behavioral modification support. Seminal analysis was performed in according to World Health Organization guidelines, using Maklef counting chamber. Sperm morphology was analized by WHO guidelines and strict criteria (fabric for sperm concentration, motility and morphology). Clinical and hormonal data pre- and *post*-dietary intervention are presented below. Patient 1, weight: 127.8/*101.4* kg, BMI: 42.7/*33.9* kg/m^2, body fat 41.9/*33.9%*, triglycerides 286/*157*, HOMA-IR 11.6/*3.0*; total testosterone 256/*623* ng/dl. Patient 2, weight: 99.5/*90.3* kg, BMI: 31.4/*28.5* kg/m^2, body fat 21.2/*26.3%*, triglycerides 197/*88* mg/dl, HOMA-IR 2.63/*1.29*; total testosterone 388/*351* ng/dl. All semen characteristics expressively improved in both patients. The sperm total and progressive motility increased respectively by 46.4% and 62%% in Patient 1 and by 2.63% and 24.5% in Patient 2. Normal sperm morphology increased from 5% to 8% in patient 1 and from 1% to 5%, in patient 2. In addition, total motile sperm count

increased by 20% and 40% in patients 1 and 2, respectively, after dietary intervention. In conclusion, besides the significant improvement in metabolic and hormonal profiles, our results seem to support the potential benefit of weight loss by VLCKD in improving sperm motility and morphology of obese patients. Further cohort studies involving a larger number of patients should be performed to verify this hypothesis.

DOI: 10.1530/endoabs.70.EP379

Effect of significant weight loss by very low calorie ketogenic diet on male obesity secondary hypogonadism and sexual function

Alessandra Renck[1], Thiago Afonso Teixeira[2,3], Marcio Roberto de Souza[1], Paulo de Nóvoa Cardoso[1], Ericka Barbosa Trarbach[4], Jorge Hallak[2,3] & Elaine Maria Frade Costa[1]
[1]Faculdade de Medicina da Universidade de Sao Paulo, Unit of Development, Department of Endocrinology, Sao Paulo, Brazil; [2]Faculdade de Medicina da Universidade de Sao Paulo, Section of Andrology, Division of Urology, Department of Surgery,, Sao Paulo, Brazil; [3]Androscience, High Complexity Clinical and Research Andrology Laboratory, Sao Paulo, Brazil; [4]Faculdade de Medicina da Universidade de Sao Paulo, Laboratory of Cellular and Molecular Endocrinology LIM-25, Sao Paulo, Brazil

Obesity is the single most significant risk factor for testosterone deficiency in men, with a reported prevalence up of 60% of male obesity secondary hypogonadism (MOSH). Several studies have shown that significant weight loss due to bariatric surgery have significant metabolic and endocrine improvement in obesity, however the results achieved with conventional diet and lifestyle change are poor and not able to reverse this condition. As an alternative to bariatric surgery, we aimed to evaluate the effect of very low-calorie ketogenic dietary (VLCKD) on hypogonadism reversion and sexual function in obese patients. Ten men aged 31–47 years with BMI between 31.7–48.7 kg/m^2 were assigned to the VLCKD intervention following a commercial program of weight loss Pronokal Method. Body weight, visceral fat, HOMA-IR, triglycerides, HDL and testosterone levels were measured at baseline and after two months. International Index of Erectile Function (IIEF–5) questionnaire was used to assess erectile dysfunction at baseline and after six months. Statistical analysis was performed by repeated-measure multivariate ANOVA using STATA 14.2. Results demonstrated mean weight loss of 18.0±3.2 kg (15±2.1%) with a significant improvement in TT levels (150.4±127 ng/dl corresponding to 53±38.9% of the basal; $P=0.005$). IIEF-5 score of six patients was calculated. Four had erectile dysfunction that improved from mild to normal ($n=3$) and from severe to mild/moderate ($n=1$). Furthermore, a significant improvement in metabolic parameters as HDL, triglycerides, HOMA-IR and visceral adiposity were also reported. Compared to data found in meta-analysis (increase of 254 ng/dl/32% of weight reduction), the VLCKD diet seems to increase more significantly baseline testosterone levels. In conclusion, VLCKD significantly increases testosterone levels, improves metabolic parameters and erectile function in men.

46, XX male syndrome- testicular disorder of sexual differentiation

Derya Köseoğlu & Nafiye Helvaci
Erol Olçok Education and Research Hospital, Department of Endocrinology and Metabolism, Çorum, Turkey

Introduction
46, XX male syndrome–testicular disorder of sexual differentiation (DSD) is a rare condition, that was first described by la Chapelle et al. in 1964. The phenotypes of 46, XX testicular DSD include males with normal phenotype, males with genital ambiguities or males with true hermaphrodites. The diagnosis may be more difficult in adults with normal gender development than in children. Here, we present hormonal and cytogenetic conditions of an adult male who was diagnosed as primary hypogonadism with 46, XX male syndrome.
Case
A 39-year-old male presented with erectile dysfunction, decreased sexual desire and infertility. His height and weight were 163 cm and 75 kg, respectively, with a body mass index of 28.3 kg/m2. On physical examination, he had bilateral painless gynecomastia. His testicles were in the scrotum, but they were small and soft. The size of the penis was small. In laboratory analysis, FSH and LH levels were over the upper normal limit, and total testosterone level was below the normal limit (Table 1). Hormonal analyses showed hypergonadotropic hypogonadism. Scrotal ultrasonography showed small testicles localized in the scrotum (right testicle was 80 × 15 mm, left testicle was 9 × 10 × 17 mm). Spermiogram was performed and it was found to be compatible with azoospermia. Karyotype analysis was performed and 46, XX was detected. FISH analysis and molecular analysis for SRY gene was performed, but the result has not been released yet. After testosterone replacement therapy, the patient's complaints decreased at follow-up.
Conclusion
Hypergonadotropic hypogonadism that develops due to genetic causes is rarely seen. One of them is 46, XX karyotype testicular DSD disorder, which is an uncommon sex reversal syndrome characterized by a female karyotype in discordance with a male phenotype. Diagnosis depend on karyotype, molecular and cytogenetic analysis. Klinefelter's syndrome and mosaic forms should be considered in the differential diagnosis of these rare syndromes, which are differentiated by karyotype analysis. Proper treatment with the timely diagnosis will contribute positively to bone mineral density and their sexual development.

Table 1 Laboratory variables of the patient.

FPG (ng/dl)	82
Creatinin (0.6–1.3 mg/dl)	0.6
ALT (5–50 U/l)	21
AST (5–50 U/l)	26
FSH (1.4-18.1mIU/ml)	31.27
LH (1.5–9.3 mIU/ml)	15.63
Total testosterone (2.49–8.36 ng/ml)	0.569
Estradiol (0–39.8 pg/ml)	16.93
Prolactin (4.04–15.2 ng/ml)	8.75
TSH (0.27–4.1) µIU/ml	1.49

FPG: Fasting plasma glucose, ALT: alanine aminotransferase, AST: aspartate aminotransferase, FSH: Follicle-stimulating hormone, LH: luteinizing hormone, TSH: thyroid-stimulating hormone.

TSH levels vis-à-vis total sperm count and testosterone levels

Ioannis Kakoulidis, Ioannis Ilias, Stefanos Stergiotis, Stefanos Togias, Aikaterini Michou, Anastasia Lekkou, Vaso Mastrodimou, Athina Pappa, Evangelia Venaki & Eftychia Koukkou
E Venizelou Hospital, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece

Introduction
The role of thyroid hormones is important in testicular development and function (involvement in Sertoli cell proliferation and functional maturation control and postnatally in Leydig cell differentiation and steroidogenesis). Additionally, thyroid hormone receptors are found in testicular cells throughout development and in adulthood. Our aim was to study thyroid hormone effects on testicular function.
Materials and methods
We retrospectively analyzed data from a large series of outpatients who were evaluated for couple subfertility in our andrology clinic. Men with thyroid or pituitary disorders, azoospermia or obstructive azoospermia (diagnosed by history, normal FSH levels and, in most subjects, testicular biopsy), previous surgery operation for varicocele, or receiving medications that altered testicualr or thyroid physiology were excluded. A series of 106 unselected men from the records of the clinic were included (mean age±S.D: 34.3±6.1 years, mean BMI±S.D: 27.63±4.64 kg/m^2). Thirty-six subjects had total sperm count <5 × 10^6, forty had 5–20 × 10^6, eleven had 20–40 × 10^6 and nineteen were normozoospermic (>40 × 10^6). Mean±S.D TSH levels were 1.51±0.85 mIU/l; mean testosterone: 4.51±1.81 ng/ml; total sperm count: 20.6±28.5 × 10^6, semen volume: 3.3±1.4 ml; mean FSH: 6.1±4.8 mIU/ml; mean LH: 4.3±2.5 mIU/ml; mean PRL: 7.1±5.1 ng/ml. Total sperm count, semen volume and testosterone levels in relation to TSH levels were

evaluated using Pearson's correlation (age and BMI were also considered as possible confounding factors).
Results
A weak correlation was found between logTSH levels and the log total sperm count with marginal statistical significance ($r=+0.16$, $P=0.09$). The other parameters showed no correlation with TSH.
Conclusions
We noticed a weak association between TSH levels and sperm count. With larger series maybe this relationship can be stronger. Further studies are needed to draw more reliable conclusions that would be useful in daily clinical practice.

Could omentin concentration be an indicator of cardiovascular risk in PCO-S

Iwona Zielen-Zynek[1], Joanna Kowalska[2], Justyna Nowak[1], Karolina Kulik-Kupka[3], Ilona Korzonek-Szlacheta[1], Aleksander Danikiewicz[3], Bartosz Hudzik[1,4] & Barbara Zubelewicz-Szkodzińska[3,5]
[1]Medical University of Silesia; Katowice, Department of Cardiovascular Disease Prevention, Department of Metabolic Disease Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [2]Medical University of Silesia; Katowice, Department of Metabolic Diseases Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [3]Medical University of Silesia; Katowice, Department of Nutrition Related Disease Prevention; Department of Metabolic Disease Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [4]Silesian Center for Heart Diseases, 3rd Department of Cardiology, School of Medicine with the Division of Dentistry in Zabrze, Zabrze, Poland; [5]Piekary Medical Center, St. Luke's City Hospital in Piekary Śląskie, Department of Endocrinology, Piekary Śląskie, Poland

Introduction
There have been described that about 50% of women diagnosed with PCO-S, present lipid metabolism disorders, insulin resistance and incorrect blood pressure. They suffer not only from fertility disorders, but also present a risk of metabolic complications such as: obesity, type 2 diabetes and hypertension, which increase diet-related cancers and cardiovascular risk.
Aim
To explore if serum omentin concentration could be an indicator of cardiovascular risk in PCO-S, lipid panel, SBP, DBP and QUICKI values, also predisposing CVD factors were assesed.
Material and methods
33 women, aged 18-39, with PCO-S were included in the study. The patients were hospitalized in Endocrinology City Hospital in Piekary in 2015-2019. The predisposing CVD factors were: BP different from <120/80 mmHg, TC > 190 mg/dl, LDL > 135 mg/dl, HDL < 50 mg/dl, TGC > 150 mg/dl, HOMA-IR > 1.5, glucose > 100 mg/dl, BMI > 24.9, smoking and reduced physical activity and assigned 1 point for every existed factor. Anthropometric measurements were conducted and blood parameters from the medical patients records were taken. To determine the serum omentin concentration ELISA method was used. Statistically significant value $P<0.05$ was assumed.
Results
The average serum omentin concentration in examined women was 274 ng/ml (± 78), TC concentration was 193 mg/dl (± 45), BP value 121/76 mmHg (± 12) and QUICKI value was 0.3 (± 03.05). Statistically significant negative correlation between serum omentin concentration and SBP and DBP was shown ($P=0,03$; $P=0,002$). As the concentration of omentin increased, an increase in QUICKI value was observed ($P=0.001$). Negative correlation was observed between serum omentin concentration and predisposing CVD factors ($P=0.008$). There were no correlation between serum omentin concentration and lipid panel values.
Conclusion
Serum omentin concentration could be an useful tool to demonstrate the risk of CVD in women with PCO-S. Further studies in a larger group are required to confirm the CVD risk diagnostic value of omentin.

Cardiac defects in turnerian patients

Nisrine Bouichrat, Ikram Mahroug, Achwak Alla, Rouf Siham & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Introduction
Turner syndrome is one of the most common chromosomal abnormalities, with a reported prevalence of one in every 2.500 live-born girls. The phenotype includes short stature, primary ovarian failure, and other characteristics resulting from the consequences of fetal lymphedema and skeletal abnormalities. Turner syndrome can be associated with multiple defects: cardiovascular, renal, auditory, and skeletal. The aim of our study was to detect the prevalence of cardiac defects in our Turner patients.
Material and method
This is a retrospective descriptive study realized in 15 patients followed for a Turner syndrome at the Endocrinology-Diabetology and Nutrition Department of the Mohammed VI University Hospital Center of Oujda, Morocco.
Results
The mean age of diagnosis was 12.2 ± 13 years [3–41 years]. 40% were diagnosed in adulthood. The reason for consultation was dominated by short stature in 40% of cases with a height under -3DS in 60% of patients, followed by primary amenorrhea in 26.7% of cases. Six patients had a history of low weight for gestational age. Dysmorphia was present in all of our patients. Cardiac exploration revealed a median heart with levocardia and situs salitus in 3 patients, one of whom also had aortic bicuspid and the other had mitral leakage. The analysis of caryotype objectified two cases of monosomy, and one case of mosaic.
Conclusion and discussion
Cardiac abnormalities are common in Turnerian girls and are found in about 50% of cases. Early identification of congenital cardiac defects is crucial as they are a major cause of morbidity and mortality in Turner syndrome, hence the importance of systematic screening at diagnosis followed by strict long-term monitoring.

Hyperandrogenism caused by a leydig cell tumor of the ovary: A case report

Fernando Mendonça[1], Selma Souto[1], Daniela Magalhães[2], Ana Sofia Fernandes[3], Ana Rita Coelho[4], Raquel Portugal[4], Vera Falcão[3], Sara Tavares[3], Jorge Beires[3] & Davide Carvalho[1]
[1]Centro Hospitalar e Universitário de S. João, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Hospital da Luz, Clínica do Porto, Porto, Portugal; [3]Centro Hospitalar e Universitário de S. João, Department of gynaecology, Porto, Portugal; [4]Centro Hospitalar e Universitário de S. João, Department of Pathology, Porto, Portugal

Introduction
Leydig stromal cell tumors are a subtype of steroid tumors that make up to less than 0.1% of the ovarian tumors. These neoplasms can affect women from all ages but are more frequent after menopause, being usually unilateral, benign and small sized. In around 75% of cases, these tumors produce androgenic hormones, causing oligomenorrhea and virilization.
Case report
A 39-year-old woman, nulligravid, with complains regarding androgenic alopecia, acne and hirsutism, associated with weight gain for the last 8 months. She referred menstrual irregularities with oligomenorrhea after stopping taking oral contraceptive 9 months ago. The objective examination revealed an androgenic facies and alopecia, dorsocervical adiposity, acanthosis nigricans and clitoromegaly. Blood analysis revealed total testosterone 10.52 ng/ml (0.06–0.82), estradiol 41.8 pg/ml (1.3–266), androstenedione 5.13 ng/ml (0.3–3.3), DHEA-S 246.6 µg/dl (60.9–337.0), prolactin 32.7 ng/ml (4.8–23.3), LH 0.61 mUI/ml (2.4–12.6), FSH 0.87 mUI/ml (2.1–12.6), with normal thyroid function and free 24 h urinary cortisol. The gynaecological transvaginal ultrasound revealed an heterogenous solid lesion in the left ovary with 15 × 15 × 16 mm of smooth margins. A pelvic magnetic resonance showed globosity of the central stroma of the left ovary and the abdominal CT did not reveal any adrenal pathologic findings. The patient was submitted to laparoscopic left adnexectomy that proceeded without complications. A microscopic analysis of the surgical specimen revealed

a Leydig cell ovarian tumor. During the follow-up medical consultations 1 month and 4 months after surgery, there was a notorious improvement of the clinical hyperandrogenism (hirsutism, androgenic alopecia), with regularization of the menstrual cycles and normalization of the serum androgens.
Conclusion
Ovarian tumors that produce androgens are a diagnostic challenge that must be considered in the differential diagnosis of severe hyperandrogenism. This case report of a woman presenting with virilization signs, shows the importance of undertaking a careful gynecological exam, followed by measurements of serum androgens and abdominopelvic imaging to exclude androgen producing tumors of the ovaries or adrenals. The virilizing tumors of the ovaries are surgically treated, usually having good prognosis.

A nonpalpable leydig cell tumor and gynecomastia: A case report

Wafa Benothman, Imen Halloul, Asma Ben Abdelkrim, Ghada Saad, Yosra Hasni, Molka Chaeib, Maha Kacem, Amel Maaroufi & Koussay Ach
Farhat Hached Hospital, Endocrinology, Sousse, Tunisia

Introduction
Leydig cell tumors (LCTs) are uncommon neoplasms arising from gonadal stroma, accounting for 1–3% of all testicular tumors in adults. The etiology of LCT remains unclear. About 25% of LCTs secrete predominantly estrogens, which produce gynecomastia.
Observation
We report a case of a 53-year-old male patient who sought evaluation for bilateral gynecomastia. He had a long-term use of amitriptyline and benzodiazepine. The physical examination of the testicles was normal. A left testicular tumor was found on echographic analysis. The serum germ cell tumor markers showed no significant abnormalities. Radical left orchidectomy was performed by an inguinal approach. The anatomopathological study disclosed a LCT as the immunostaining showed that the tumor cells were positive for inhibin and calretinin. There were no cytological signs of malignancy or evidence of metastasis. Two years and a half after the surgery, the follow-up CT-scan did not reveal any local recurrence and distant metastases. Hormonal investigations showed moderately elevated estradiol level and low level of testosterone at 2.3 ng/ml, while tumor markers AFP and β-hCG were still negative. The gynecomastia persisted as well.
Conclusion
In the last few years, the incidence of LCTs seemed to increase well above the literature predictions. A hormonal study and scrotal ultrasound evaluation should be performed even in the absence of palpable testicular tumors. Complete recovery of both endocrine and exocrine testicular function is not guaranteed. This may be secondary to a slowly reversible (or irreversible) estrogen-induced damage to tubular and leydig cells.

Clinical and etiological aspects of hirsutism

Nisrine Bouichrat, Salma Farih, Imane Assarrar, Rouf Siham & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Introduction
Hirsutism is a condition featuring an excessive growth of terminal hair at the woman's androgen-dependent areas, which develops in a distribution model similar to that of men. It is one of the most common disorders in women during reproductive age. It affects up to 1 in 7 women. The objective of this work was to study the clinical and etiological aspects of hirsutism.
Material and methods
This is a retrospective descriptive study involving 59 patients followed for hirsutism in the endocrinology-diabetology and nutrition department.
Results
We collected 59 patients with a mean age of 24.8±6.9 years. 28.8% had a family history of hirsutism. The history of male stillbirths was reported in 12.5% of cases. Forty percent of patients had onset symptoms at puberty. Hirsutism was severe in 44.1% of cases, moderate in 35.6% and light in 20.34% of cases, with an average of Férriman and Gallway score at 17.95±6.32. It was associated with acne in 44.07% of cases, seborrhea in 16.95% of cases, and menstrual disorders in 66.1% of patients. Four patients presented signs of virilization: clitoridomegaly (1 case), frontal gulfs with muscular hypertrophy (2 cases), alopecia (1 case). Overweight was found in 32.2%, while obesity was found in 25.42% of cases. The results showed elevated testosterolemia in 35.09% of cases with a mean of 1.10±1.93 ng/ml. The etiologies were dominated by polycystic ovarian syndrome (PCOS) (60.34%), followed by idiopathic hirsutism in 24.14% of cases, and cushing disease in 8.62% of patients, adrenal tumour (1 case), 21 hydroxylase block (1 case), 11 betahydroxylase block (1 case), and drug use (1 case).
Conclusion and discussion
Polycystic ovarian syndrome is the most common cause of hirsutism in our study, which is consistent with the data reported in the literature. Hirsutism is a frequent reason for consultation; it not only reflects circulating androgen levels, but is also influenced by peripheral androgen metabolism, the sensitivity of the hair follicle to androgens, and insulin resistance. Women suffering of hirsutism often have low self-esteem and altered quality of life, which can lead sometimes to depression, hence the interest of a global therapeutic and psychological management.

Probable role of KLK3 in menstrual cycle of young women

Mariacira Gentile[1], Francesca Donnarumma[1], Giusy Esposito[1], Tommaso Gentile[1], Ida Ferrara[2], Claudia Crescenzo[3], Mariangela Palmieri[3], Salvatore Raimondo & Luigi Montano[4]
[1]Laboratory "Gentile s.a.s.", Field of Research "Gentile s.a.s.", Gragnano (NA), Italy; [2]Günè Centro Medico, Acerra, Italy; [3]Clinica HERA, Giugliano in Campania, Italy; [4]Hospital San Francisco de Asis, Oliveto Citra, Italy

Introduction
Recent studies report the presence of KLK_3 in women serum, KLK_3 is excreted by Skene glands, it is involved in the production of cervical-vaginal fluid (CVF). Activation of KLK_3 is pH depending, it has been hypothesized to have antimicrobial, immuno-regulator activity and vaginal and cervical epithelial desquamation. We intend to verify if KLK_3 is present in female serum, in which menstrual cycle phases KLK_3 increases and its main role.
Materials and methods
They were enrolled voluntary young women aged between 21 and 44 years with specific requirements: no professionally exposed, no alcohol, no smoking, no drugs, no use of oral contraceptives for at least 2 years and regular menstrual cycles.To the participants was asked the age of the menarche, if they are nulliparous/multiparous and if they have had spontaneous/volunteer abortions. BMI (body mass index) and the Ferriman-Gallwey score were calculated. Blood samples were taken in three periods of the cycle (days: 5/6; 12/13; 19/20) for the plasma assay of total KLK_3 and in the third sample the Progesterone test was performed. The method used is "Access Hybritech PSA" test. The total KLK_3 values are expressed in ng/ml.
Results
KLK_3 showed a non-homogeneous behaviour, in fact out of 82 participants, 27, equal to 32.9%, can't be measured in any of the three samples, 55, equal to 67.1% gave values measurable. The comparison of total KLK_3 values with the anamnestic data and semeiotic evaluations didn't give significant correlations. We subdivided the Progesterone values into two bands: band A with Progesterone values >14.5 ng/ml and Band B with Progesterone values <14.5 ng/ml. In band B, from the values of the first sample there is a decrease in the second sample and then a constant decrease in the third one. Instead in band A, there is a continuous increase. The curve of the total KLK_3 values for multiparas is comparable to that of Progesterone (band A). This could demonstrate an interaction between the total KLK_3 and Progesterone.
Conclusion
The transition between the ovulatory and the lutein phase is the key to understanding the quality of ovulation. Measuring KLK_3 in the days before ovulation, it would give us indications on how ovulation will be. KLK_3 values variation, as in the Profile A, indicates an excellent ovulation that could be different from the one with decreasing values (Profile B). In fact, the curve of KLK_3 in Profile A is comparable with that of the multiparas.

The genetic background of coagulation factors can predict the presence of oligo- or amenorrhea in girls with anorexia nervosa: A pilot study

Areti Augoulea[1], Eleni Armeni[1], Stavroula A. Paschou[1], Evangelia Deligeoroglou[1], Emmanuel Economou[2], Georgios Papadimitriou[1], Evgenia Stergioti[1], Vassilios Karountzos[1], Artemis Tsitsika[3], Konstantinos Panoulis & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Clinical Laboratory of Therapeutic Individualization, National and Kapodistrian University of Athens, School of Medicine, Aretaieio Hospital, Athens, Greece; [3]Adolescent Health Unit, Second Department of Pediatrics, National and Kapodistrian University of Athens, School of Medicine, P. and A. Kyriakou Children's Hospital, Athens, Greece

Introduction.
The aim of this study was to investigate the association between the genetic background of coagulation factors and the presence of oligo- or amenorrhea in adolescent girls diagnosed with anorexia nervosa compared with controls.
Patients and methods
A total of 40 adolescent girls diagnosed with anorexia nervosa aged 14–17 years, as well as 10 age-matched girls, were included in the study. We recorded anthropometric parameters and calculated body mass index (BMI) z-scores adjusted for age, as well as duration of amenorrhea. Blood samples were obtained for genotyping and hormonal assessment. Genetic polymorphisms of MTHFR (methylenetetrahydrofolate reductase C677T and A1298T), GpIIb/IIIa (glycoprotein IIb/IIIa) and prothrombin were investigated.
Results
Presence of the GpIIIa Leu33/Pro was evident almost solely in the subgroup of anorexic girls (cases vs controls, 27.6% vs 5.9%, P-value = 0.073). Anorexic girls had higher odds than controls to carry: i) the GpIIa leu33/pro or G20210A mutation (34.5% vs 5.9%, P-value = 0.028) ; ii) the GpIIIa Leu 33/Pro mutation or the MTHFR A1298C (62.1% vs 29.4%, P-value = 0.032). Furthermore, girls with oligo- or amenorrhoea compared with girls presenting with normal menses had significantly higher prevalence of: i) the GpIIIa Leu33/Pro mutation (30.3% vs 5.9%, P-value = 0.048) ; ii) GpIIIa Leu33/Pro or the G20210A mutation (36.4% vs 5.9%, P-value = 0.020) ; iii) any mutation from the panel, consisting of the GpIIIa Leu33/Pro or MTHFR A1298C (60.6% vs 29.4%, P-value = 0.037). Logistic regression analysis proved that the presence of any mutation from the panel, consisting of G20210A or the GpIIIa Leu33/Pro mutation, as well as levels of estrogen, predict the development of amenorrhoea (OR 15.618, P-value = 0.043), in a model adjusted for age, BMI z-score and diagnosis of anorexia nervosa.
Conclusions
Genetic background of coagulation factors can predict the presence of oligo- or amenorrhea in girls diagnosed with anorexia nervosa.

Quality of life questionnaires in PCOS- the impact of hirsutism

Zoran Gluvic[1], Milena Lackovic[1], Vladimir Samardzic[1], Marina Vujovic[1], Vesna Popovic-Radinovic[1], Jelena Tica[1], Milan Obradovic[2], Emina Sudar-Milovanovic[2] & Esma R. Isenovic[2]
[1]Zemun Clinical Hospital, Endocrinology and Diabetes, Zemun, Serbia; [2]Institute of Nuclear Sciences Vinca, Laboratory for radiobiology and molecular genetics, Belgrade, Serbia

Introduction
Polycystic ovary syndrome is the most frequent ovarian dysfunction during the reproductive period. Its presence significantly impacts on the final scores of various Quality-of-Life (QoL) questionnaires. This pilot study aims to analyze the impact of hirsutism (H), as the component of PCOS, on the scores of determined generic (General Health Questionnaire-12, GHQ12) and disease-specific questionnaires (Polycystic Ovary Syndrome Questionnaire, PCOSQ) in PCOS subjects.
Material and methods
A pilot cross-sectional study involved 30 age- and BMI-matched subjects recruited at the Outpatient Endocrinology Department. The examinees are divided into two groups depending on the H- distribution score, determined by Ferriman-Gallwey (FG) scale (group 1: FG ≤ 8 and group 2: FG > 9). Examinees independently fulfilled both questionnaires (GHQ12 and PCOSQ), and the responses are rank-transformed and presented as scores. Statistical analyses were performed by SPSS for Windows 18.0.
Results
Mean GHQ12, overall, and H-domain of the PCOSQ score of the study population were 12 ± 7 (2–26), 5 ± 1 (2–7), and 6 (2–7), respectively. GHQ12 and overall PCOSQ scores statistically negatively correlated as well as the H-domain of PCOSQ and FG scores. Concerning the study groups, the GHQ12 score is higher in the FG > 9 group along with PCOSQ and H domain of PCOSQ scores, which are less in FG > 9 comparing to FG ≤ 8 group.
Conclusion
Our results suggest that H associated with PCOS directly impacts on general and disease-specific aspects of QoL. Therefore, it is of particular interest to assess the patient's attitude about H presence.

Diagnostic value of anti mullerian hormone for detecting polycystic ovary syndrome in Tunisian morbidly obese women

Rym Belaid[1], Ibtissem Oueslati[1], Hana BelhadjHassen[1], Bassem Hammami[2], Seif Boukriba[3], Meriem Yazidi[1], Wafa Grira[1], Fatma Chaker[1], Habiba Mizouni[3], Moncef Feki[2] & Melika Chihaoui[1]
[1]La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta Hospital, Laboratory of Biochemistry, Tunis, Tunisia; [3]La Rabta Hospital, Department of Radiology, Tunis, Tunisia

Introduction
The level of anti-Mullerian hormone (AMH) is considered by several authors as a marker of polycystic ovary syndrome (PCOS). However, data are lacking regarding the real role of AMH and its cut-off value for predicting the existence of PCOS in women with morbid obesity.
The aim of this study was to analyze the performance of the AMH assay in the diagnosis of PCOS in women with morbid obesity.
Patients and methods
We conducted a cross-sectional study including 50 women of reproductive age with morbid obesity. Each patient underwent a clinical examination, biological and hormonal assays and an ovarian ultrasound between the third and fifth day of the menstrual cycle. PCOS was diagnosed according to the Rotterdam criteria.
Results
Participants had an average age of 34.2 ± 7.5 years. PCOS was diagnosed in 20 women (40%). No statistical differences were found between women with and without PCOS regarding age and anthropometric parameters. The mean AMH level was significantly higher in women with PCOS (3.4 ± 3.6 ng/ml vs 1.3 ± 1.2 ng/ml, P = 0.01). It was positively correlated with the Ferriman and Gallwey score (r = 0.49, P = 0.01), total testosterone levels (r = 0.52, $P < 10^{-3}$) and the LH/FSH ratio (r = 0.29, P = 0.04). Furthermore, AMH level was not correlated with anthropometric parameters, nor the HOMA index, nor the volume of the ovaries nor the number of antral follicles. The area under the ROC curve of AMH in the diagnosis of PCOS was 0.71 ± 0.07, P = 0.01. An AMH level ≥ 5 ng/ml had a sensitivity of 20% and a specificity of 100%. In contrast, an AMH level ≥ 1 ng/ml was significantly associated with PCOS with an Odds Ratio of 4.9 (P = 0.02).
Conclusion
Our results showed an association between PCOS and AMH level in women with morbid obesity. However, specific thresholds for this population must be determined in order to improve the sensitivity and specificity of this hormonal marker.

Turner's syndrome: Clinic, therapeutic and evolutive particularities in a tunisian center

Dorra Dorraelguiche, Kamoun Ines, Hajer Kandara, Kalthoum Mehdi, Madhi Wiem & Manel Jemel
National Institute of Nutrition of Tunisia, Endocrinology, Tunisia

Introduction
Turner's syndrome (TS) affects 1/2500 female births and it is characterized by growth retardation, dysmorphic syndrome and gonadal dysgenesis. Our objective was to describe the clinical, therapeutic and evolutive features of Tunisian patients with TS.

Patients and methods
It was a retrospective study including 23 patients with TS diagnosed between 1993 and 2019.We noted clinical, therapeutic and evolutive data for each patient.
Results
The average age at diagnosis was 17 years (10–33 years). The karyotype showed a 45 × 0 monosomy ($n=13$), a mosaicism without structural abnormality ($n=6$) or a mosaicism with structural anomaly ($n=3$). Our patients consulted for growth retadration ($n=9$) and amenorrhea ($n=14$). Twenty-eight percent of them had an history of otitis. Dysmorphic syndrome was present in 20 patients with a pathological cardiovascular examination in 2 patients. Hypothyroidism was noted in 6 patients, celiac disease and hyperthyroidism (Graves' disease) in one patient. Growth hormone (GH) therapy was started in 9 patients, for other patients advanced age was a limiting factor for treatment. The final height was greater in the patients having received GH treatment ($P=0.01$). The mean age of induction of puberty was not delayed in the patients who received GH ($P=0.384$). Spontaneous menarche was noted in one patient who had a mosaic karyotype without structural abnormalities.
Conclusions
The diagnostic of TS is very late in our country. GH treatment has a significative effect on the final height but it must be established in childhood. We have to think about TS in case of dysmorphic syndrome or statural delay in young girls.

Acquired nonreversible hypogonadotropic hypogonadism and impaired wound healing in diabetic foot syndroma of type 2 diabetic patient - Case series

Dragan Tesic[1], Tijana Icin[1], Milena Mitrovic[1], Dragica Andric[2] & Mirjana Tomic[3]
[1]Clinical Centre and University of Novi Sad, Clinic of Endocrinology, Diabetes and Metabolic Disorders, Novi Sad, Serbia; [2]Institut for Cardiovascular Diseses and University of Novi Sad, Clinic of Cardiology, Sremska Kamenica, Serbia; [3]Clinical Centre and University of Novi Sad, Clinic of Haematology, Novi Sad, Serbia

Introduction
The fact that up to 33% with type 2 diabetes develop hypogonadotropic hypogonadisms (HH), are still not catching enough attention. More futher ''the 5-year mortality of somebody who has got diabetes, who has had a myocardial infarction is actually lower than the diabetic patient who has developed a diabetic foot ulcer, which is around 48%''.
Case description
We describe male patient, 47 y. (on 2016y), newly diagnosed type 2 diabetes mellitus (already established background retinopathy; BG 18 mmol/l, pH 7.45) and amputation of digit V (infection cum necrosis). BP 170/90 mmHg, HR 110/min, on CW doppler noncompressible aa., in B mode calcified atherosclerotic plaques. BH 153 cm, BW 46.2 kg (BMI 19.6 kg/m2). CRP 116.8 mg/l, HbA1c 9.6%, TG 1.71, HDL chol. 0.81, cholest 4.91 mmol/l, US abdomen steatosis hepatis. 3 yrs ago he was anaemic. FSH 3.1 IU/l, LH 2.3 IU/l, testosteron (T) 5.82 nmol/l. In the next 3 months all small digits (II-V) were amputated, but still with nonhealed wounds. On twicely given premix insulin HbA1c 6.1%. In the time period 2016–2020y.: T 8.9±3.1 nmol/l and estradiol (E) 33.75±3.3 pg/ml while on clomiphene Tx T 21.9±4.3 nmol/l and E 56±8.5 pg/ml. On clomiphene, maximal FSH have been 8.1 and LH 5.6 mIU/ml. During 2017.y. wound on his foot heald. The only improved symptom of normal T level has been better erectile function (''rigidity of penis''). During low testosterone, a distinctive redness of cheekbones, and during both phases, testicles were with normal size and hardness. As a control patient we used Type 1 diabetic, with diabetic ketoacidosis, as a result of 4 day omission of insulin therapy, in december 2019. 7th day after admitance in Clinic T 6.9 nmol/l, FSH 4.1 and LH 8.15 miu/but on 14th day T rised lspontaneously on 14.27 nmol/l (FSH 7.57 and LH 6.86), E 25 and 35 pg/ml.
Discussion
We conclude that our patient do have insulin resistance of neuronal cells that secrete GnRH but these cells are functional when we eliminate suppressive effect of estrogen by clomiphen. At the periphery it might have been positive effect of estrogen on wound healing in diabetic foot syndroma. Mild anemia that preceded diabetic foot wounds might be in relation to low testosteron. In second case, simple insulin therapy reestabished the function of neuronal cells that secrete GnRH.

EP394

The relationship between TRAB and inhibin-B in male with graves disease

Hakan Kursat[1], Meral Mert[2] & Sema Ciftci Dogansen[2]
[1]University of Health Sciences, Bakirkoy Training and Research Hospital, Internal Medicine, İstanbul, Turkey; [2]University of Health Sciences, Bakirkoy Training and Research Hospital, Endocrinology, İstanbul, Turkey

Introduction and aim
Graves' disease which is the most common cause of hyperthyroidism is an autoimmune disease presenting with goitre, orbitopathy and dermopathy. The disease is caused by stimulant type TSH receptor antibodies (TRAB). TSH receptor (TSHR) has been shown in different tissues other than thyroid. Testis is one of the extrathyroidal tissues with TSHR. The aim of this study was to investigate relationship between TRAB and inhibin-B, which is an indicator of spermatogenesis.
Materials and methods
After approval of the Clinical Ethics Committee of Bakırköy Dr. Sadi Konuk Training and Research Hospital, 53 male patients who were admitted to the outpatient clinics aged 18 to 65 with Graves disease positive for TRAB and 34 male controls with no infertility problems, autoimmun diseases and medications whic may affect Hypotalamo-pituitary-gonadal axis were included the study. Sociodemographic data form was applied to all patients included in the study and TSH, fT3, fT4, Anti-TPO, Anti-Tg, TRAB values were recorded. For inhibin B assay, 5 ml venous blood was collected in a plain bottle without anticoagulant between hours 08:00–11:00 and serum was separated by centrifugation. The serum aliquots were stored at -80 °C untill analysis. Inhibin-B studied with ELISA (E-EL-H0313 Detection Range: 7.81~500 pg/ml, Sensitivity: 4.69 pg/ml)
Results
Mean age was 39.5±11.8 years in patient group and 40.17±12.1 in control group. Mean duration of disease was 31 months. Mean TSH was 3.5±13.8 this is because of high TSH values of hypothyroid men among patients and median TSH was 0.02 in patient group. Mean TSH was 1.3±0.69 in control group. There were 35 hyperthyroid, 14 euthyroid, 4 hypothyroid men in patient group and all men in control group were euthyroid. Serum inhibin-B was negatively correlated with body mass index (BMI) ($r=-0.217$, $P<0.01$) and positively correlated with existing of thyroid nodules ($r=0.255$ $P<0.05$) in patient group; on the other hand we did not observe relation between TRAB, TSH, Anti-TPO, Anti-Tg, fT4, fT3 and inhibin-B in patient group. Studies demonstrated that inhibin-B is lower in TRAB positive Graves patients than control group ($P<0.0001$).
Conclusion
This study showed inhibin-B is significantly low in TRAB positive Graves patients but no significant relationship between TSH, fT3, fT4, TRAB, duration of disease and inhibin-B. Therefore, all patients with Graves disease should be consulted on their reproductive health.

Leydig cell tumor of the ovary: a rare cause of postmenopausal virilization

Anastasia-Konstantina Sakali, Pinelopi Thoda, Dimitra Pappa, Eleftheria Mparmpa, Eleni Georgiou, Ioannis Gountios & Alexandra Bargiota
University Hospital of Larissa, Faculty of Medicine, University of Thessaly, Department of Endocrinology, Metabolism and Diabetes, Larissa, Greece

Introduction
Postmenopausal virilization with acute onset and rapid progression requires a thorough investigation for the presence of adrenal or ovarian tumor. We present here a challenging case of a radiologically not visible and rare androgen-hypersecreting ovarian tumor.
Case report
A 71-year old postmenopausal woman presented to our department for the investigation of terminal hair growth, of recent onset and rapid progression, on the upper lip, chin and thighs. Physical examination revealed hirsutism

(Ferriman-Gallway score of 11) and signs of virilization with clitoromegaly. On hormonal evaluation she had high levels of serum testosterone (4 ng/ml), while androstenedione (Δ4-A: 1.5 ng/ml), dehydroepiandrosterone sulfate (DHEA-S: 150 µg/dl) and 17 (OH) progesterone (17 (OH) PRG: 1 ng/ml) were within nomal range. MRI imaging of the pelvis was unremarkable, while adrenal CT imaging demonstrated a small left adrenal hypodense lesion of 1 cm diameter. She underwent laparoscopic left adrenalectomy and histopathology was indicative of a non-secreting adrenocortical adenoma. Postoperatively, clinical and biochemical hyperandrogenism persisted. Subsequently, she had a laparoscopic bilateral salpingo-oophorectomy and histopathological examination revealed the presence of a small Leydig cell tumor of the right ovary of approximately 1.2 cm diameter, with no features indicating malignant potential. Postoperatively, serum testosterone levels dropped and were within normal range (0.025 ng/ml) and remain so at her 3 month follow up accompanied by clinical improvement.
Conclusion
Hyperandrogenism in the menopause may be challenging. Rapid development and the presence of virilization signs are usually indicative of a tumor of either adrenal or ovarian origin. When the tumor is radiologically not visible and the adrenal origin of the hyperandrogenism is excluded, laparoscopic oophorectomy might be needed, despite the negative radiological results. Sertoli-Leydig cell tumors are extremely rare; typically, they are unilateral and confined in the ovary. Unlike our case, most patients are premenopausal and the tumor size is large. Prognosis relies on the degree of differentiation of the tumor and is usually favorable.

Unusual manifestation of an endocrine-active testicular tumor

Anna Steighardt[1], Rüfer Axel[2], Högger Dominik[3], Henzen Christoph[1] & Fischli Stefan[1]
[1] Luzerner Kantonsspital Luzern, Department of Endocrinology/ Diabetes, Switzerland; [2], Luzerner Kantonsspital Luzern, Department of Hematology, Switzerland; [3], Luzerner Kantonsspital Luzern, Department of Urology, Switzerland

Introduction
Leydig cell tumors (LCT) are rare testicular tumors, characterized by mostly benign etiology. Due to their secretory activity androgen- and/or estrogen-excess can occur.
Case report
A 42-year old patient with recent history of cerebrovascular incident was admitted to the hematology department for diagnostic work-up of new-onset erythrocytosis (hemoglobin 185 g/l [reference 127–163], hematocrit 0.53 [0.37–0.46]). Myeloproliferative neoplasia and other common causes of secondary erythrocytosis (i.e. obstructive sleep apnea, smoking) could be excluded. Remarkably, gonadotropin levels were suppressed on repetitive measurements (LH <0.1 U/l [1.7–8.6], FSH <0.1 U/L [1.5–12.4]). Total testosterone-/SHBG levels were in the mid-normal range (17.9 nmol/l [8.64–29] and 38.6 nmol/L [18.3–54.1], respectively) and estradiol was high-normal (154 pmol/l [41.4–159]). DHEA-S, androstendione, 17-OH-progesterone, AFP, beta-HCG and LDH were normal. The patient denied use of anabolic steroids and biochemical features of steroid abuse (i.e. low SHBG- and HDL-levels) were absent. Clinical examination was normal without gynecomastia, normal pattern of secondary hair and normal-sized, bilaterally descended testes without a palpable mass. Three months after initial presentation estradiol levels rose slightly above the upper limit of normal (198 pmol/l) whereas LH/FSH remained suppressed. Testicular ultrasound found a nodular structure of 1.5 cm in diameter. Tumor enucleation was performed, histologically proving Leydig cell tumor (LCT) without signs of malignancy. Postoperatively, hormone metabolism and hematocrit normalized completely during the following months.
Comment and conclusion
Up to 30% of LCT are associated with endocrine hypersecretion leading to a variety of clinical (i.e. gynecomastia, erectile dysfunction and loss of libido) and laboratory (i.e. erythrocytosis) findings which can gradually evolve–as seen in our patient. LCT exhibit specific patterns of endocrine alterations: enhanced aromatase activity leading to higher intratesticular and peripheral estradiol concentrations and secretion of inhibin causing a decline in FSH. However, most of the patients presenting preoperatively with testicular LCT have low-normal but unsuppressed LH-/FSH-levels. In our case the initial finding of suppressed gonadotropins, normal testosterone/estradiol and severe erythrocytosis is striking and the presence of unmeasured paraneoplastic secretion of other sex-steroids with LH-/FSH-suppressing and hematopoiesis-stimulating properties has to be postulated.

The autoimmune profile of turnerian patients

Nisrine Bouichrat, Ikram Mahroug, Messaoudi Najoua, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department Of Endocrinology-Diabetology And Nutrition, Oujda, Morocco

Introduction
Turner Syndrome is a genetic disorder linked to the total or partial absence of an X chromosome. The clinical presentation is heterogeneous, associating a small stature with a dysmorphic syndrome that varies from one person to another.
The aim of this study was to determine the prevalence of autoimmune diseases in our Turnerian patients.
Material and method
This is a retrospective descriptive study collecting 15 cases of Turnerian patients followed in the Endocrinology-Diabetology and Nutrition Department of the Mohammed VI University Hospital Center of Oujda, Morocco.
Results
The mean age of diagnosis was 12.2 13.1 years. Only 33.3% of cases were diagnosed in childhood. Short stature was objectified in 40% of cases, followed by primary amenorrhea in 26.7% of cases. Four patients had peripheral hypothyroidism (26.7%). Hashimoto was noted in 2 cases. Celiac disease was diagnosed in 2 patients, and type 1diabetes in one case. Psoriasis was diagnosed in one patient.
Conclusion and discussion
Autoimmunity has been recognized as one of the most important characteristics of Turner syndrome. Turner patients have an increased risk of developing in particular: Hashimoto's autoimmune thyroiditis, celiac disease, type 1 diabetes, psoriasis and rarely Basedow's disease. The results of our study are consistent with those reported in the literature; the frequency of these pathologies requires systematic screening at the time of diagnosis and during surveillance.

DOI: 10.1530/endoabs.70.EP397

Prevalence and awareness of anabolic-androgenic steroids use among male bodybuilders in the eastern province, saudi arabia

Yasir Elamin, Ali Al-Khars & Noor Bumarah
Imam Abdulrahman Bin Faisal University, King Fahd University Hospital, Internal Medicine and Endocrinology, Khobar, Saudi Arabia

Purpose
The use of anabolic androgenic steroids (AAS) to improve fitness and increase muscle mass is widespread among athletes. Information regarding self-administered AAS used to enhance athletic performance or improve physical appearance is sparse and poorly documented in Saudi Arabia. The purpose of this study is to investigate the prevalence and motivation of AAS use and knowledge of its adverse effects among fitness centres visitors in Eastern Province, Saudi Arabia.
Methods
A cross-sectional survey was conducted among 541 male bodybuilders visiting fitness centres in the Eastern Province region of Saudi Arabia. Information on demographics, use of AAS and awareness about its adverse effects were collected using a self-administered questionnaire.
Results
The prevalence of AAS among bodybuilders in Eastern Province was 21.3%. The percentage was highest among those in the 21–30 years age group and those who received higher education (63.8% and 66.4% respectively). The most common types of AAS used were Oxandrolone (Anavar) (61.9%), Methandienone (Dianabol) (46%) and Nandrolone-decanoate (Deca-Durabolin) (45.1%). Participants were not aware of the adverse effects of anabolic steroids use. Side effects experienced by 77% AAS users; includes depression in 47%, acne was reported in 32.7%, hair loss in 14.2% and sexual dysfunction in 10.7%. On the other hand, 88.5% of the AAS users reported fast muscle gain, and more than half of them noticed increasing in

muscle strength. Despite experienced some side effects, 40% of the users has recommended others to use anabolic steroids.
Conclusion
AAS abuse is a common problem among young bodybuilders associated with lack of knowledge regarding its adverse effects. Health educational programs are needed to increase the awareness of the community towards this problem. The information provided in this study should help clinicians to develop appropriate intervention strategies for AAS abuse.

The role of E2/P ratio in the etiology benign breast disease and mastopathy

Milena Brkic[1] & Svetlana Vujovic[2]
[1]Faculty of medicine University of Banja Luka, Banja Luka, Bosnia and Herzegovina, BanjaLuka, Bosnia and Herzegovina; [2]School of Medicine, University of Belgrade, Belgrade, Serbia, Department of Endocrinology, Clinical Center of Serbia, Beograd, Serbia

The aim of the study was to assess the role of the estradiol and progesterone relationship during the late luteal phase and the occurrence of fibrocystic breast disease (FBD). The concentration of E2/P was measured in the group of women with FBD as study group and healty control group. All women had regular ovulation cycles. Blood samples for E2, P and prolactin determination were obtained in the morning at 8 am on days 21 and 24 of menstrual cycle. Significant mastalgia and mastodynia history in women with FBD was obtained with yes or no questionnaire. FBD diagnosis was confirmed with ultrasound. In the control group, a reduced E2/P ratio was noticed from day 21 to day 24 of the cycle, which was not recorded in the group of women with FBD (study group). Even the slightest disturbance of the E2/P ratio may contribute to the occurrence of benign breast disease with clinical manifestations of mastalgia and mastodynia.

Efficiency of ceylon cinnamon on insulin resistance parameters in polycystic ovary syndrome

Zeineb Jenouiz, Hajer Kandara, Nedra Bendag, Radhouan Gharbi & Manel Jemel, Ines Kammoun
National Nutrition Institute of Tunis, Department of Endocrinology, Tunis, Tunisia

Introduction
Insulin resistance (IR) is the main pathogenic factor in polycystic ovary syndrome (PCOS) and its complications. Ceylon cinnamon (CC) is an herb with an insulin-sensitizing effect reported in diabetic patients.The aim of our study was to assess the efficiency of CC on the parameters of the IR in patients with (PCOS).
Methods
We conducted a prospective interventional study, we included 13 patients with PCOS diagnosed according to the Rotterdam criteria, having received neither dietetic education nor metformin, and diabetic patients were excluded. At T0, all of our patients had a food survey, anthropometric measurements: weight, height, waist size (WS), to calculate the WS/height ratio (IR indicator), and a biological assessment: Insulinemia and fasting blood sugar to calculate the HOMA-IR index. During the intervention, our patients received a 500 mg capsule of CC (designed and prepared for the study) three times a day, without changing their eating habits and physical activity.
Results
After 8 weeks (T1), we found a significant reduction in the WS/height ratio (Delta=–0.22±0.03 and $P=0.02$), a non-significant decrease in the average fasting blood sugar, going from 5.35±0.54 to 5.26±0.4 mmol/l (P±NS), the average insulinemia decreased from 20.25±11.93 to 18.91±10.54 µ IU/ml, (P±NS), the average HOMA-IR index was reduced from 4.96±3.22 to 2.75±1.88 (Delta of –0.46±2.85 and P±NS).the reduction in the HOMA-IR index was greater but not significant in patients with IR (Homa-IR index ≥ 2.5) at T0, in this group, the HOMA-IR index fell from 6.25±3.08 to 5.51±2.73 (Delta at –0.74±3.44).
Conclusion
These findings can be attributed to the ability of CC to stimulate the translocation and synthesis of GLUT4 at the cellular level, which improves the cellular response to insulin at its target cell level. Further studies are needed to suggest the therapeutic impact of CC in PCOS.

Probable role of KLK3 in menstrual cycle of young women

Mariacira Gentile[1], Francesca Donnarumma[1], Giusy Esposito[1], Tommaso Gentile[1], Ida Ferrara[2], Claudia Crescenzo[3], Mariangela Palmieri[3], Salvatore Raimondo[1] & Luigi Montano[4]
[1]Laboratorio Analisi Cliniche 'Gentile S.A.S.', Field of research 'Gentile S.A.S.', Gragnano, Italy; [2]Günè Centro Medico, Acerra, Italy; [3]Clinica HERA, Giugliano in Campania, Italy; [4]Hospital San Francisco de Asis, Oliveto Citra, Italy

Introduction
Recent studies report the presence of KLK_3 in women serum, KLK_3 is excreted by Skene glands, it is involved in the production of cervical-vaginal fluid (CVF). Activation of KLK_3 is pH depending, it has been hypothesized to have antimicrobial, immuno-regulator activity and vaginal and cervical epithelial desquamation. We intend to verify if KLK_3 is present in female serum, in which menstrual cycle phases KLK_3 increases and its main role.
Materials and methods
They were enrolled voluntary young women aged between 21 and 44 years with specific requirements: no professionally exposed, no alcohol, no smoking, no drugs, no use of oral contraceptives for at least 2 years and regular menstrual cycles.To the participants was asked the age of the menarche, if they are nulliparous/multiparous and if they have had spontaneous/volunteer abortions. BMI (body mass index) and the Ferriman-Gallwey score were calculated. Blood samples were taken in three periods of the cycle (days: 5/6; 12/13; 19/20) for the plasma assay of total KLK_3 and in the third sample the Progesterone test was performed. The method used is 'Access Hybritech PSA' test. The total KLK_3 values are expressed in ng/ml.
Results
KLK_3 showed a non-homogeneous behaviour, in fact out of 82 participants, 27, equal to 32.9%, can't be measured in any of the three samples, 55, equal to 67.1% gave values measurable. The comparison of total KLK_3 values with the anamnestic data and semeiotic evaluations didn't give significant correlations. We subdivided the Progesterone values into two bands: band A with Progesterone values > 14.5 ng/ml and Band B with Progesterone values < 14.5 ng/ml. In band B, from the values of the first sample there is a decrease in the second sample and then a constant decrease in the third one. Instead in band A, there is a continuous increase. The curve of the total KLK_3 values for multiparas is comparable to that of Progesterone (band A). This could demonstrate an interaction between the total KLK_3 and Progesterone.
Conclusion
The transition between the ovulatory and the lutein phase is the key to understanding the quality of ovulation. Measuring KLK_3 in the days before ovulation, it would give us indications on how ovulation will be. KLK_3 values variation, as in the Profile A, indicates an excellent ovulation that could be different from the one with decreasing values (Profile B). In fact, the curve of KLK_3 in Profile A is comparable with that of the multiparas.

Inhibin-B and FSH – the best male fertility report

Katarzyna Jankowska[1,2] & Michał Rabijewski[3]
[1]Bielanski Hospital, Endcorinology, Warsaw, Poland; [2]Center of Postgraduate Medical Education, The Department of Reproductive Health, Warsaw, Poland; [3]Center of Postgraduate Medical Education, Reproductive Endocrinology, Warsaw, Poland

Objective
Sperm cells are produced in the testes by the Sertoli cells. These cells produce Inhibin B and they are stimulated by FSH. Can Inhibin B be a good marker of spermatogenesis? Should we use other marker (FSH?, testosterone?)

Design
Prospective study.
Patients
We examined 71 patients with infertility.
Methods
Semen analysis and hormonal analysis was performed. Semen analysis was performed according to World Health Organization guidelines (WHO 2010). Hormone analysis include: FSH (follicle stimulating hormone), LH (luteinizing hormone), testosterone, prolactin, TSH and inhibin B. We analysed the dependencies between semen parameters and hormons, especially inhibin B.
Results
The sperm count was significantly and positively correlated with Inhibin B ($r=0.4$, $P<0.0001$). The Inhibin B was negatively correlated with FSH ($r=-0.6$, $P<0.0001$). The lower was the concentration of inhibin B, the lower was the number of sperm in the semen. There was also a relationship between seminogram and FSH – the higher was the FSH, the lower was the number of sperm. There was no relationship between the number of sperm and the concentration of LH, testosterone, TSH, prolactin.
Conclusions
It seems that we can use the value of inhibin B and FSH to assess the intensity of spermatogenesis. The decreased concentration of inhibin B correlates with the number of sperm (the lower the concentration of inhibin B the lower the efficiency of spermatogenesis) and with FSH (the higher FSH, the lower the sperm count). High levels of FSH and reduced levels of inhibin B clearly indicate impairment of spermatogenic function in addition to the testes. The concentration of testosterone is not good predictor of spermatogenesis. (Inhibin B and testosterone are produced from different types of cells in the testis).
FSH and inhibin-B can be used if the doctor wants to assess spermatogenesis and the patient does not want to perform sperm analysis (for example, in young boys).

EP403

Aspects of reproductive state in women after kidney transplantation

Anastasia Kudrytskaya[1], Olga Doronina[2] & Oleg Kalachik[3]
[1]Belarusian state medical university, Obstetrics and gynecology, Minsk, Belarus; [2]Peoples' Friendship University of Russia, Obstetrics, gynecology and, Moscow, Russian Federation; [3]GU 'Minsk Scientific-Practical Center of Surgery, Transplantation and Hematology', Republican center of nephrology, renal replacement therapy and kidney transplantation, Minsk, Belarus

Chronic kidney disease (CKD) is a global burden, with prevalence of 11–13%. CKD usually remains asymptomatic until later stages, but is strongly associated with increased risks of cardiovascular morbidity, premature mortality and decreased quality of life. Kidney transplantation (KT) is a treatment of choice for end stage CKD. KT was performed 350 times from dead donor and 6 times from living donor in the GU 'Minsk Scientific-Practical Center of Surgery, Transplantation and Hematology' in 2018. Objective – Evaluate menstrual function and reproductive state in women after KT. Patients' history was collected by interview and physical examination, hormone levels were determined by ELISA. Ethics Committee approved the study. All patients signed written informed consent. Research group includes 34 women of age 36.4±5.8 who had undergone KT within last 6 years. Patients have adequate graft function confirmed by serum creatinine, urea, cystatine C levels and GFR and are observed by nephrologist regularly. Patients get immunosuppressive medications (Medrol-Ciclosporin/Azathioprin/Tacrolimus- Mucophenolate mofetil) in 2 or 3 component treatment regime and had no complications or concomitant diseases at the time of the study. Women who had severe infections, were pregnant or had complications in graft functioning were excluded from the study. Control group consisted of 27 healthy women. Measures showed 27 patients had menstrual disturbances, the most common oligo- and amenorrhea that depended from age and time that a patient had spent on the dialyses. Average levels of estradiol, Ingibin B, Antimullerian hormone, progesterone, LH and FSH measured in the luteal phase were comparable with no significant difference between two groups. Serum prolactin levels were higher in kidney recipients that in controls ($P=0.01$) with the ranges 693.5±267.7 mIU/l (KT) and 510.0±271.8 mIN/l (healthy women). Testosterone and free testosterone levels we significantly lower in women after KT than in control ones. 25(OH)D status remained below recommended threshold in both groups that was explained by the autumn/winter time of the study. Significant difference was found in levels of LH mediana and FSH mediana in the follicular phase. Women after transplantation suffer from irregular menses, hyperprolactinemia, low levels of testosterone. Different hypotheses suggest connection between immunosuppressive therapy, dialyses time, graft function and obtained data that needs further investigation.

DHEA in infertility – can you reverse the flow of time?

Katarzyna Jankowska[1], Radoslaw Maksym[2] & Wojciech Zgliczynski[2]
[1]Center of Postgraduate Medical Education, Endocrinology, Warsaw, Poland; [2]Center of Postgraduate Medical Education

We study the impact of the dehydroepiandrosterone (DHEA) by the women with diminished ovarian reserve and very low DHEA-S in the blood.
Patients
We present a description of 7 patients with diminished ovarian reserve (DOR). Patients reported because of problems with getting pregnant. Infertility lasted for several years. The patients disagreed on IVF for ethical and religious reasons. All of the presented patients were diagnosed with diminished ovarian reserve (very low AMH or high FSH, elevated estradiol concentration on day 3 of the cycle). We found also a very low DHEA-S concentration.
Interventions
The patients were given dehydroepiandrosterone.
Main Outcome Measures
After several months of treatment (3–6 months), the patients became pregnant. None of them had procedures for *in vitro* fertilization.
Results
Seven patients gave birth to healthy children. Our experience with DHEA is much bigger, but these 7 cases are very well documented. The obtained results indicate that DHEA supplementation in conditions of its deficiency improves the functioning of the ovaries and increases the chance of pregnancy.
Conclusions
1. In some cases the aging of the ovaries can be delayed by administering of dehydroepiandrosterone (DHEA).
2. This effect occurs specially when the endogenous concentration of DHEA-S is reduced.
3. In the case of reduced ovarian reserve, DHEA-S concentration should be determined.
4. The question remains open as to whether we should not mean DHEA in the blood of infertile men (does DHEA-S deficiency interfere with sperm maturation?)

Table 1 Patients with infertility and DHEA-S below the reference rage.

Ip	Age	Duration of infertility	FSH – 3rd day of cycle IU/ml	AMH ng/ml	Estradiol 3rd day of cycle	DHEA-S ug/dl	Testosteron ng/ml	The result of treatment	After what time of DHEA application did pregnancy appeared?

The occurrence of the hypogonadotropic hypogonadism as a prediagnostic finding for HIV Infection in a patient with klinefelter under testosterone replacement therapy

Mariana Costache Outas
Coltea Clinical Hospital, Endocrinology Outpatient Clinic, Bucharest, Romania

Background
Hypogonadism is common among human immunodeficiency virus (HIV)-infected men. The actual prevalence remains poorly defined and ranges from less than 10% to over 50% in different studies. Secondary hypogonadism is the most common cause of hypogonadism among HIV-infected men. In hypogonadal HIV-infected men, naive of highly active antiretroviral therapy (HAART), around 75% have secondary hypogonadism due to the suppression of gonadotropins by the active inflammation and disease. Hematologic neoplasias, occurring in 1.6% of Klinefelter patients could develop in the pituitary region. Gonadal and extragonadal germ cell tumours (mediastinal germ cell tumours, teratoma, teratocarcinoma, choriocarcinoma) may occur.
Case presentation
We followed a thirty-five-year-old male patient diagnosed in our Endocrine outpatient department with Klinefelter Syndrome for appropriate replacement therapy with intramuscular testosterone. Nine months following his diagnosis of hypergonadotropic hypogonadism, endocrine laboratory testing revealed suppressed gonadotrophins despite lengthening of periods in testosterone administration. The patient was well-nourished and asymptomatic for a pituitary tumour. The patient reported no opioids abuse or steroids. Serum levels of free testosterone and SHBG were in the normal range when we tested it after 14 weeks from the last administration of testosterone. We excluded the reversible causes of hypogonadotropic hypogonadism. Serum prolactin was in the normal range. Ultrasound of the testis and normal values for HCG, AFP and LDH excluded a germinal tumour. Blood tests were positive for HIV infection with normal CD4 count. The patient started HAART with Triumeq (dolutegravir 50 mg/abacavir 600 mg/lamivudine 300 mg). Restauration of normal gonadotrophins secretion after ART initiation will explain the HIV-related cause of hypogonadotropic hypogonadism in this patient.
Conclusion
We report the occurrence of the secondary hypogonadism in a Klinefelter patient under testosterone replacement that drove specific tests that revealed an early stage of HIV infection without advanced degrees of immunosuppression (CD4 > 100 cells/mm^3). Undernutrition, severe illness, drugs, pituitary dysfunction, were excluded in our patient. The endocrinologists frequently overlook HIV infection as a cause of hypogonadotropic hypogonadism. Yet, it must be considered between causes of unexplained gonadotrophins suppression in these patients.

Idiopathic childhood cliteromegaly: Testosterone gel and its sensitivity

Bonnie Grant[1], Yousaf Razzak[2] & Khash Nikookam[1,3]
[1]King George Hospital, Barking Havering and Redbridge University NHS Trust, Endocrinology, Greater London, United Kingdom; [2]King George Hospital, Barking Havering and Redbridge University NHS Trust, Pharmacy, Greater London, United Kingdom; [3]The Holly Private Hospital, Essex, Greater London, United Kingdom

We present a 37-year-old gentleman (Mr. A) who self-referred to the endocrine clinic for review of his testosterone replacement therapy.
He required testosterone replacement therapy aged 11 years old following surgical removal of underdeveloped testes of unknown aetiology. He was prescribed testosterone injections until the age of 22 years old when testosterone patches were trialled, which he did not tolerate. He commenced testosterone replacement gel (TESTOGEL 50 mg/5 g sachets) with good effect for 15 years. His biochemical hormone profile was in keeping with primary hypogonadism; LH 33.2 U/l [normal range (NR) 1.7–8.6 U/l], FSH 93.4 IU/l (NR 1.5–12.4 IU/l), testosterone 10.5 nmol/l (NR 8.6–29.0 nmol/l), SHBG 57 nmol/l (NR 14.5–48.4 nmol/l) with a free androgen index of 18 (NR 30–150). Genital examination identified prosthetic testicles with an unremarkable examination of all other systems. Despite good replacement with TESTOGEL he sought alternatives due to ongoing medical complications with his 18-month-old adopted baby girl (Child X) who had concurrently been referred to the paediatric endocrinology team with increased downy hair in the pubic region and an enlarged clitoris. Examination by a paediatric endocrinologist identified dark hair in the pubic region and mild clitoromegaly of approximately 1 cm. There was no axillary hair nor breast development. Child X was born weighing 7lbs and healthy. As minimal information was available regarding her genetic background, further investigations were sought. Child X' genetic karyotyping confirmed 46XX (genetically female) without mosaicism. Full biochemical profile included; testosterone 10.5 nmol/l with undetectable androgen precursors, LH, FSH and HCG with an AFP level in the normal range; suggestive of exogenous testosterone exposure. On further questioning, Mr. A confirmed he only applied TESTOGEL to the upper arms and shoulders, washed his hands fully with soap and covered himself with clothes in the morning prior to attending to Child X, in accordance with manufacturing guidance. TESTOGEL was immediately stopped and testosterone injections commenced. Within two weeks, Child X' testosterone levels improved to 4.5 nmol/l and further fell to 0.9 nmol/l a few weeks later. TESTOGEL 50 mg/5 g is licensed for transdermal testosterone replacement in men with hypogonadism due to androgen deficiency. The manufacturer' Summary of Product Characteristics (SmPC) states the percutaneous absorption of testosterone ranges from 9% to 14% of the applied dose. Application of one TESTOGEL 50 mg/5 g sachet produces an average plasma testosterone concentration increase of 2.5 ng/ml (8.7 nmol/l).
Conclusion
Despite following manufacturing guidelines there was still evidence of testosterone transmission. Do we need to advise and educate against light clothing despite adequate hand washing?

The long way to unravel the reasons for differences in phenotypes among MEN1 patients

Anna Skalniak, Agata Jabrocka-Hybel, Dorota Pach & Alicja Hubalewska-Dydejczyk
Uniwersytet Jagielloński Collegium Medicum, Kraków, Poland

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a monogenic, dominantly inherited disorder caused by mutations in the *MEN1* gene. Unfortunately, the outcome and the patients' prognosis are unpredictable even among members of one family. It seems clear that other factors influence the individual outcome of the disease. However, it is still unclear what kind of factors (genetic or environmental) would be responsible for the observed differences.
Aim
We have planned a number of connected studies that aim at identifying the direction in which the reasons for the observed differences in MEN1 outcomes should be searched for. The aim of this work is to present the first part of this study, which is based on evaluating the patients' genetic background, i.e. the variants in the patients' genomes. This part of our study focuses on classical genetics.
Methods
We performed high-throughput sequencing that encompassed the whole exomes of 16 patients grouped depending on the outcome of their disease. This patient group included first-degree relatives with different outcomes despite a common underlying *MEN1* mutation. Because of the very limited number of patients, the analyses were based on pathways rather than single gene variants.
Results
We present the premise, methods, analyses, and initial results of the first part of our planned multi-step study on the reasons for phenotype differences in MEN1 patients.
Perspectives
In addition to basic genetic factors, the next part of the analyses will encompass also epigenetic and environmental factors, which will be evaluated all together in one final analysis.

Preservation of fertility in men with benign and malignant brain tumors

Ludmila Astafyeva & Yuliya Sidneva
N.N. Burdenko National Medical Research Center of Neurosurgery, Pituitary, Moscow, Russian Federation

Brain tumors are on the 3rd place in terms of growth rates of incidence among oncological diseases. By virtue of the improvement of neurosurgical treatment methods, with the use of modern chemotherapy and radiation therapy, the survival of patients with benign and malignant brain tumors is increasing. A significant proportion of patients with such tumors are young

people of reproductive age who are interested in maintaining their fertility. Neurosurgical removal of tumors, which are mainly located in the hypothalamic-pituitary region, as well as the applying of chemotherapy and radiation treatment of malignant brain tumors of any localization may be complicated by the development of hypogonadism and infertility. A simple and reliable method of preserving male fertility is currently cryopreservation of sperm. We recommend carrying out a cryopreservation of sperm in young patients, as well as in patients interested in the reproductive potential:
1) in benign tumors of the hypothalamic-pituitary region (invasive, large pituitary adenomas, craniopharyngiomas, etc.):
– with intact gonadotropic function prior to surgery and a high risk of developing hypopituitarism (including hypogonadism);
– with hypogonadotropic hypogonadism after surgical, radiotherapy or drug treatment during the course of gonadotropin therapy.
2) in the case of malignant brain tumors of any localization:
– before radiotherapy and/or chemotherapy
Neurosurgeons, as well as oncologists, radiologists should inform patients with brain tumors about the possible risk of hypogonadism development, infertility and the possibilities of sperm cryopreservation, which increases the chances of having future genetic progeny.

Characteristics of true precocious puberty in children over last three years

Rukhsora Sayfullaeva & Yulduz Urmanova
Tashkent Pediatric Medical Institute, Department of endocrinology, pediatric endocrinology, Tashkent, Uzbekistan

The aim of investigation to examine characteristics of true premature sexual development in children and adolescents over three years.
Material and methods
We observed 9 children with true premature sexual development (including boy – 1, girls –8), which had treatment in the pediatric department of the Center of Endocrinology in the period from September 2016 to July 2018 years. Patients were measured height, weight, considered a lack of growth, weight, performed a palpation of the thyroid gland and an objective examination of sexual development' stages by Tanner.
All patients underwent a set of studies, including the clinical (General blood and urine analysis), biochemical, hormonal (LH, FSH, prolactin, estradiol, progesterone, free testosterone). Besides that, we performed pituitary MRI and ultrasound investigation of endocrine organs.
Results
It was established that growth excess occurred in all (100%) patients examined. Hormonal disorders were characterized by an increase in average levels of peripheral sex hormones on the radiographs of the brush in all children, an advance of bone age of 3–4 years was revealed No changes in brain MRI were detected. In 3 patients, isolated telarch was noted. All patients received dipherelin therapy.
Conclusions
In the structure of premature sexual development in children, true is relatively rare. A special screening is required to identify this pathology in children

DOI: 10.1530/endoabs.70.EP409

The prevalence rate of true precocious puberty in children by region of the Republic of Uzbekistan (as of December 1, 2018)

Yulduz Urmanova & Rukhsora Sayfullaeva
Tashkent Pediatric Medical Institute, Department of endocrinology, pediatric endocrinology, Tashket, Uzbekistan

The aim of investigation to study the prevalence rate of precocious puberty (PP) in children by region of the Republic of Uzbekistan (as of December 31, 2018). The prevalence rate of premature sexual development in children by region of the Republic of Uzbekistan (as of December 1, 2018).
Material and methods
We observed 173 children with true precocious puberty (including boy – 51, girls – 122), which had treatment in regional endocrinology clinics in the period from January 1, 2018 to December, 31, 2018 year. Patients were measured height, weight, considered a lack of growth, weight, performed a palpation of the thyroid gland and an objective examination of sexual development' stages by Tanner. All patients underwent a set of studies, including the clinical (General blood and urine analysis), biochemical, hormonal (LH, FSH, prolactin, estradiol, progesterone, free testosterone). Besides that, we performed pituitary MRI and ultrasound investigation of endocrine organs.
Results
It was established that as of December 31, 2018 in Andijan region was registered 8 children with PP, in Bukhara region – 32, Djizakh region – 5, Kashkadarya region –2, Navoi region–2, Namangan region-2, Samarkand region –11, Surkhandarya region –42, Tashkent region –9, Fergana region –11, Khorezm region –39, Tashkent city – 5 patients.
Conclusions
The largest number of patients was registered in Surkhandarya region.

Severe hypothyroidism causing acute ileus and polyserositis

Aiste Kondrotiene[1,2], Arturas Jacinavicius[3], Lina Barsiene[2], Rasa Verkauskiene[1,2] & Birute Zilaitiene[1,2]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Endocrinology, Kaunas clinics, Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Cardiology, Medical Academy, Lithuanian University of Health Sciences, Kaunas

Introduction
Hypothyroidism is associated with a spectrum of symptoms affecting almost all bodily functions. We present a case of severe hypothyroidism with multiple body cavity effusions, volvulus of sigma creating ileus.
Case report: A 70 year old female was admitted to emergency department with dyspnea, and acute abdominal pain. Physical examination was notable for anasarca, abdominal fluid wave, lower extremity pitting edema, hypotension. She did not have any comorbidities. Anamnesis of hypothyroidism left unknown during admission. Diagnostic CT scan revealed a volvulus of sigma creating bowel obstruction. Ascites, bilateral pleural effusion, cardiac tamponade were also diagnosed. Sigmostoma was applied for decompression of ileus during urgent laparatomy. Pericardial, pleural and peritoneum drainage was performed. Antibiotics were started due to inflammation (CRP 120 mg/l). Abundant secretion from the peritoneum, pleura and pericardium continued. Polyserositis differential diagnostic tests were done: ANCA –negative, AntiDNA 25.2kU/l, albumine 23.2–16.3 (n–35–52) g/l, liquid from pleura, peritoneum and pericardium had no signs of cancer, tuberculosis. Thyroid function tests showed hypothyreosis: TSH 100 (0.4–3.6) mU/l, FT4 0.1 (9–21.07) pmol/l, FT3 1.17 (3.34–5.34) pmol/l, AntiTPO 63.73kU/l (0–3.2). Adrenal insufficiency was denied: ACTH 7.7 (3–14) pmol/l, morning cortisol 441 nmol/l. Ultrasound of the thyroid gland revealed small lobes and isthmus. Treatment with levothyroxine 50 μg/day was started, human albumin transfusions were applied. Expanded anamnesis revealed that patient had been on levothyroxine replacement but had defaulted treatment for 15 years. Following hospital course was uncomplicated with steadily rising dose of levothyroxine from 50 to 100 μg/day. After 26 days of treatment with levothyroxine TSH was still high (87.5 mIU/l), though FT4 reached 6.73 pmol/l. Abatement of ascites, pleural effusion, tissue oedema and pericardial effusion were observed. Patient continued on a maintenance dose of 100 μg/day levothyroxine with regular follow up.
Conclusion
Isolated ascites (< 4% cases), pericardial effusion (3–6% cases) or pleural effusion is not unusual in hypothyroidism. Volvulus and bowel obstruction were also described as probable rare consequences of hypothyroidism. Multiple body cavities effusions, tissue edema, motility dysfunction causing volvulus and acute ileus and all occurring simultaneously due to hypothyroidism is extremely rare. Due to rarity of these conditions, diagnosis is often difficult and delayed.

Late-onset endocrine opthalmopathy due to activation of occult Graves' disease in a patient with toxic adenoma treated with radioiodine (Marine-Lenhart syndrome)

Dimitrios Askitis[1] & Athanasios Zissimopoulos[2]
[1]Private Practice for Endocrinology, Alexandroupolis, Greece; [2]Democritus University of Thrace, Medical School, University Hospital of Alexandroupolis, Department of Nuclear Medicine, Alexandroupolis, Greece

Introduction
Hyperfunctioning thyroid nodules (toxic adenomas) comprise one of the most common causes of hyperthyroidism and are usually treated with therapeutic radioiodine administration (RAI). Coexistence of such nodules with Graves' disease (GD) is a rare disorder (Marine-Lenhart syndrome) with a reported prevalence of approximately 2.7–4.1% in GD patients. We present a rare variant of this condition, featuring the case of a patient with hyperfunctioning nodular thyroid disease and development of post-RAI endocrine opthalmopathy due to activation of occult autoimmune thyroid component with an excessive elevation of thyroid-stimulating autoantibodies (TRAb).
Case report
A 48-year old smoking female patient with newly detected subclinical hyperthyroidism and related symptoms presented for endocrinological evaluation. She reported no signs/symptoms of orbitopathy. The neck ultrasound revealed 3 heteroechoic nodules of the right thyroid lobe; the adjunctive ^{99m}Tc- scintigraphy was diagnostic for a toxic adenoma and functional suppression of the rest thyroid parenchyma. The patient underwent radioiodine therapy with administration of 12.5 mCi J^{131}. Iatrogenic hypothyroidism developed 3 months post-therapeutically and was treated with oral administration of levothyroxine over a period of 5 months before cessation of therapy due to tendency of supplementation-induced TSH suppression. The patient presented after 2 months with bilateral eye-lid swelling and redness, as well as lacrimation. An evaluation of TRAb showed high titers of >40 IU/l (reference range <1.75 IU/l). The patient was treated with selenium administration over a period of 6 months and reported a progressive remission of her eye symptoms. Due to concomitant relapse of overt hypothyroidism she was started on levothyroxine and remained euthyroid under 62 μg daily.
Conclusion
Radioiodine for the treatment of hyperthyroidism due to nodular thyroid disease may trigger endocrine opthalmopathy in terms of autoimmune activation in patients with undiagnosed occult Graves' disease, especially in active smokers. Therefore, an estimation of TRAb should be considered in every patient with a diagnosis of toxic adenoma and thyroid scintigraphy non suggestive for concomitant Graves' disease. In such rare cases, a careful follow-up should be conducted for the early detection of post-RAI orbitopathy and where indicated a prophylactic post-therapeutic corticosteroid coverage should be administered.

Treating TSH or patient? A case of misleading TSH in a young patient

Emin Mammadov[1] & Cristian Bercu[2]
[1]Sanador Oncology Centre, Endocrine Oncology, Bucharest, Romania; [2]Sanador Hospital, Laboratory, Bucharest, Romania

Background
Primary hypothyroidism diagnosis is mainly based on the TSH (thyroid-stimulating hormone) and free thyroxine (T4) levels. Following treatment initiation, the main lab test used for dose adjustment is TSH. However, there could be potential issues with TSH measurement.
Case report
A young lady, 36, presented to our clinic in January 2019, being treated with Levothyroxine 175 mg daily, and having clinical signs and symptoms of thyrotoxicosis: tachycardia, palpitations, excessive sweating, tremor, increased gut motility, hair thinning and nail softening, menstrual irregularities, insomnia. She was also taking Propranolol PRN to reduce the heart rate. Her personal history was unremarkable until Feb 2009, when she was diagnosed with primary hypothyroidism at age 26, based on high TSH, 16.8 mU/l, and T4 not sampled at the time of diagnosis. She started Levothyroxine therapy, 100 mg daily, her TSH was followed up periodically and was high (> 10 mU/l) on multiple occasions, apparently not responding to treatment, leading to Levothyroxine dose escalations.
At the time of presentation to our clinic, she got her thyroid function tests sampled and, despite the abnormal TSH value (5.79 mU/l), the Levothyroxine dose was reduced to 125 mg daily, which led to significant improvement in her symptoms, and she stopped Propranolol completely.
Two months later, her TSH was 4.3 mU/l, we then performed a PEG (polyethylene glycol) precipitation of the sample, and the monomeric TSH was obtained at the level of 0.58 mU/l. Since then, we further reduced the dose of Levothyroxine to 100 mg daily, her last TSH was 3.34 mU/l (normal), and she feels well.
Discussion
Our case reminds of the fundamental principle 'Primum non nocere'.
Treating the blood test result and continuing to increase the dose aiming to normalise the TSH value, without taking into account the clinical presentation, can lead to overtreatment and cause iatrogenic thyrotoxicosis.
We could only hypothesise that the laboratory testing could mislead due to the presence of interfering macromolecules, taking into account that we did not have possibility to perform a gel filtration chromatography, which is considered a gold standard to identify the monomeric TSH. We could speculate that, in some cases, PEG precipitation is a useful tool to identify patients with falsely elevated TSH levels.

Myxoedema ascites: An unusual situation revealing Hypothyroidism

Sabrine Mekni, Ibtissem Ben Nacef, Imen Rojbi, Chedi Mhedhebi, Nadia Mchirgui, Youssef Lakhoua & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Clinical presentation of hypothyroidism is frequently insidious. Of the many non specific clinical signs of hypothyroidism, ascites is one of the less common manifestations reported and the diagnosis is often made late with this condition. Herein, we present the cases of isolated ascites revealing hypothyroidism in order to drow attention to hypothyroidism as an etiology of an unexplained isolated ascites.
Observation
A 61-year-old diabetic women presented with abdominal distention, constipation and ascites of three months duration. On physical examination, blood pressure was 130/70 mmHg and the pulse rate was 80/min. The abdomen was distended with marked ascitic fluid. Neither the liver nor spleen were palpable. The thyroid gland was also not palpable. There were no signs of congestive heart failure and the electrocardiogram was normal. The initial exploration of ascites could not suggest any etiology: hemogram, bilirubin level, Liver function, protein electrophoresis and creatinine level were normal. There was no proteinuria. Viral serologies B and C and immunoassay were negative. The intradermal reaction to tuberculin was negative. The ascites puncture revealed a transparent fluid, its cell count was 141/mm^3 with 95% lymphocytes, its protein concentration was 36.5 g/l and cultures were negative. Both diuretics (spironolactone) and a sodium restricted diet were prescribed with no improvement. Few month later, the patient developed profound weakness, bradycardia (pulse rate 60/min) and hypoacousia suggesting the diagnosis of hypothyroidism. Thyroid function tests showed a low serum FT4 (1.4 pg/ml reference range :6.6–14 pg/ml) and an elevated serum TSH (75 μU/ml: reference ranges 0.2–3.5 μU/ml). The patient was treated initially with levothyroxine (L-T4) 25 μg/day and gradually increased to 200 μg/day. The ascites rapidly disappeared about 1 month and a half after the start of replacement therapy.
Conclusion
Ascites can be an early clinical magnifestation of hypothyroidism. It is rapidly reversible after hormone replacement therapy, therefore evaluation of thyroid functions should be performed in all patients with unexplained ascites.

EP415

Iodine status in a group of pregnant women with chronic autoimmune thyroiditis having as provenience perimarine area of Romania

Scrinic Olesea[1], Ibadula Seila[1], Delia Corina[2] & Circo Eduard[1]
[1]Clinical Emergency County Hospital Constanta, Romania, Endocrinology Department, Constanta, Romania; [2]The National Institute for Mother and Child Health 'Alessandrescu-Rusescu', Bucharest, Romania, Bucharest, Romania

Objectives
Assessment of the utility of supplementing the iodine intake during pregnancy in women with chronic autoimmune thyroiditis (CAT) coming from the perimarine territory of Romania.
Material and method
The study included 28 pregnant women in the first trimester of pregnancy, diagnosed with CAT. The following variables were evaluated: TSH, FT4, ATPO. The iodine status of pregnant women was analyzed by 2 methods: 1 – the value of the urinary iodine concentration (UIC) from the spontaneous urine sample and 2 – the iodine concentration corrected after the urinary creatinine (UIC/Ucr).
Results : Most of the pregnancies came from the urban area (79%). The gestational age between 8 and 13 weeks predominated in proportion of 82%, whilst only 19% of pregnant women were evaluated in the first 2 months of pregnancy. The median value of TSH was 16.22±23.82 mUI/l and for FT4 the median value was 14.70±3.65 ng/ml. Pregnant women with TSH>2.5 mUI/l were indicated for thyroxine replacement therapy. The median UIC in our study was 113, 74 mg/l (insufficient iodine intake according to WHO recommendations<150 mg/l). Adjustment of iodide after urinary creatinine is necessary to eliminate the interference of increased diuresis specific to the pregnancy period due to the increased glomerular filtration rate. The median value of the UIC/UCr ratio was 170, 51 mg/g, placing pregnant women in the category with sufficient iodine intake. It should be mentioned that 2 patients had excessive iodine values (> 500 mg/l), both intermittently taking iodine supplements, the reassessment of iodide investigations after the UIC/UCr report found normal values.
Conclusions
The recommendation of iodine content supplement administration in pregnant women with CAT should be adjusted depending on the level of urinary iodine assessed during early pregnancy. The method of dosing iodine without reporting to urinary creatinine may suggest iodine supplementation in pregnant women without iodine deficiency, with a potential aggravation of thyroid autoimmune pathology. Normal or supplemented iodine intake in the perimarine area of Romania does not, however, exclude individual cases with urinary iodine variations.

Grave' disease and Systemic lupus erythematosus association

Wiem Saafi, Ahmed Guiga, Abir Mtira, Wissal Ben yehia, Ahmed Bouker, Amira Atig & Neirouz Gannouchi
Farhat Hached University Hospital, Internal Medicine, Sousse, Tunisia

Introduction
Graves' disease is an autoimmune disease that affects the thyroid gland and leads to a state of hyperthyroidism. This disease is caused by the production of antibodies that bind to and activate the thyroid-stimulating hormone (TSH) receptor. In some cases, Grave' disease may be associated with other organ-specific or systemic autoimmune disorders. One of the most frequent multisystemic autoimmune disorders is Systemic lupus erythematosus (SLE). Many studies have described the association between SLE and thyroïde disease but mostly hypothyroidism. However, a limited number of cases of Graves' disease have been also reported in SLE patients.
Observation
We describe a case of a 29 years old female without a particular medical family history, with a history of two precocious miscarriages who has been diagnosed with LES associated with Sjogren syndrome in July 2019.
The patient presented a deterioration of the general status and a tumoral syndrome, a biological inflammatory status with pancytopenia and complement consumption. The diagnosis was confirmed by the presence of positive antinuclear antibodies. She was treated with Hydroxychloroquine and corticoids.
In August 2019, the patient was addmitted with a fever, tachycardia and a continuous loss of weight that was initially attributed to an acute episode of her disease. We noticed the presence of a minor exophthalmia and fine tremors but there was no palpable goiter.
The hormonal tests showed a status of hyperthyroidism ; a suppressed thyroïde stimulating hormone (<0.15 mUI/l) and a high FT4 level (64.8 pmol/l). Measurement of TSH receptor antibody was positive and the thyroid Ultrasonogram with Doppler showed an heteromultinodular hypervascular gland. The diagnosis of Grave' disease was posed and the patient was treated with Antithyroid drugs.
Conclusion
The clinical manifestations of LES and Grave' disease can be similar. This association even if not frequent should be suspected in the presence of subtle signs of hyperthyroidism. Since both are autoimmune diseases that can have severe complications.

Refractory hypothyroidism: What else should be done?

Nursah Ozum, Adnan Yay, Miray Yaman, Levent Ozsari, Ferhat Deniz & Arif Yonem
Sultan Abdulhamid Han Training and Research Hospital, Adult Endocrinology, Istanbul, Turkey

The treatment of hypothyroidism is straightforward,replacing with orally L-thyroxine(LT4).However,some factors including malabsorption,pancreas and liver disorders,drug interactions,etc.,may impair the absorption of LT4,and cause therapy failures.In these circumstances,high doses of different oral formulae or parenterally given LT4 may be a solution. Here,we present a case of primary hypothyroidism,resistant to high doses of oral LT4 replacement but,responsive parenteral LT4 administration.
Case
A thirty-eight years old female patient with effort precipitated fatigue,constipation and hair loss was admitted to endocrinology clinic in Jan. 2019. History revealed that she had bilateral total thyroidectomy for papillary thyroid cancer in May 2018. She was given radioactive iodine,100 mCi, in July 2018. Physical exam showed that she had a puffy face,dry skin,decreased hair,and bilateral nonpitting pretibial edema. She was not given any other medications that interact with LT4. At the admission,serum levels of her thyroglobulin,anti-thyroglobulin antibody,freeT4, and TSH were 0.20 ng/ml,3.79 IU/ml,<0.40 ng/dl and 175 mIU/ml,respectively. She has been given high doses of oral LT4, 1000 mg/day. Antibodies against endomysium and tissue transglutaminases were also negative. Endoscopic examination of upper gastrointestinal tract and biopsies of the duodenum also showed no abnormality. Echocardiographic examination revealed pericardial effusion but normal cardiac output. Dose of LT4 was increased to 1500 mg/day,and added 25 mg T3 thrice a day. A few days later, serum levels of thyroid hormones and TSH were repeated,still showing high TSH and low T4, and pointing therapy failure. Hence, we decided to begin intravenous LT4 therapy. Intravenously,1000 mg/day LT4 was applied and observed no unwanted effects. Thereafter,400 mg/day LT4 was given for three days. Therapy, then, was switched to another regime consisting of 200 mg/day LT4 intramuscularly once a week. This approach resulted in normalization of serum TSH and T4 levels. Abnormalities on physical exam at the admission also improved significantly.
Discussion
Our case is refractory hypothyroidism since unresponsive to very high doses of oral thyroid hormone replacement,approaching totally 1500 mg/day T4+75 mg/day T3. We were not able to find such a case report, requiring so high doses in the literature. Currently LT4 is available in tablet, soft gel, liquid and ampul formulations,being mostly used oral tablets. However,this treatment is not sufficient in some patients due to a variety of conditions such as autoimmune gastritis,malabsorption,pancreatic and liver diseases,drug interactions,noncompliance to the prescription,etc. In such situations, in which oral liquid or gel formulations are ineffective,parenteral forms of LT4 should be undertaken. Parenteral form of LT4 is, however,not available in every country. Though it is a very rare condition,it causes great challenges for both the patients and the care providers. Therefore,the health authorities of every country should provide parenteral form of LT4.

3-iodothyronamine (T1AM) is taken up and rapidly metabolized in cell culture medium only at low concentration

Federica Saponaro, Marco Borsò, Sara Verlotta, Lavinia Bandini, Alessandro Saba, Sandra Ghelardoni & Riccardo Zucchi
Institute of Biochmistry, Department of Pathology, Pisa, Italy

3-iodothyronamine (T_1AM) is rapidly catabolized to iodothyroacetic acid after few hours by serum proteins. To avoid a rapid metabolism during any treatment, DMEM devoid of FBS has been used, inducing changes in the cell culture environmental. We evaluated the uptake and the metabolism of different concentrations of T1AM, in presence of supplemented medium,

and the presence of 3-iodothyroacetic aldehyde (Ald), a putative intermediate of T1AM catabolism to TA1.
DMEM supplemented with 10% FBS was spiked with T1AM at concentration 0.1–10 μM and provided to NG108–15 cells or U-87 MG (24-well plates). The medium was removed at specific time points (1,2,3,4, 24 h), and media and cell lysates were analyzed by HPLC-MS/MS to evaluate T1AM and TA1. To assess the endogenous production, cells were incubated with DMEM + 10%FBS or human serum without T1AM. To evaluate the presence of Ald, T1AM (100 μM) was incubated with bovine plasma amine oxidase (0.33 mg/ml). After protein precipitation (CAN?? ACN?), samples were centrifuged and supernatants analyzed by HPLC-MS/MS operating in Full Scan mode to detect ions of interest.
In NG108–15 and U87MG cells, in medium, T1AM at 0.1 and 1 μM rapidly decreased and became undetectable after 2–3 h. Differently, in the infusion with 10 μM, T1AM was measurable after 24 h. T1AM was taken up by cells and catabolized to TA1 which was detectable from the beginning of treatment (1 h), exceeding T1AM concentration after 24h. In cells incubated only with medium, neither T1AM nor TA1 were detected, in this way excluding any endogenous production by neuronal cells.
Putative aldehyde ion (m/z 353) was detected in negative ion mode without the formation of TA1. The fragmentation of this ion led to iodine loss, which reinforced the hypothesis that the detected molecule was a T1AM derivative.
In conclusion T1AM was taken up by cells and catabolized to TA1. The detection of the putative intermediate 3-iodothyroacetic aldehyde still needs to be confirmed by further studies.

Subclinical hyperthyroidism as a cause of atrial fibrillation

Lambros Athanassiou[1], Evangelos Siarkos[1], Athanasios Fortis[2], Thomais Kalogirou[2], Panagiotis Athanassiou[3] & Ifigenia Kostoglou-Athanassiou[4]
[1]Asclepeion Hospital, Voula, First Department of Medicine, Athens, Greece; [2]Asclepeion Hospital, Voula, Second Department of Medicine, Athens, Greece; [3]Street Paul' Hospital, Department of Rheumatology, Thessaloniki, Greece; [4]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece

Introduction
Subclinical hyperthyroidism is a syndrome with vague clinical symptoms. It may cause tachycardia, loss of weight or no symptoms at all. Subclinical hyperthyroidism may occur in middle age and in the elderly. It may be related to the occurrence of atrial fibrillation. Subclinical hyperthyroidism may be the result of an autonomous goiter, may occur in the course of follow-up of hypothyroidism, as the needs for treatment may vary over time and substantially diminish in middle and old age and may occur in the context of autoimmune thyroiditis.
Aim
The aim was to present a cohort of patients presenting with atrial fibrillation who were subsequently diagnosed with subclinical hyperthyroidism.
Methods
A cohort of 31 patients, 20 male and 11 female, aged 48–72 years presented with atrial fibrillation. Levels of blood TSH, freeT_4, freeT_3, anti-TPO ab and anti-Tg ab were measured and a thyroid ultrasonogram was performed.
Results
TSH levels were found to be diminished. FreeT_4 and freeT_3 levels were found to be normal. Anti-TPO and anti-Tg ab were positive in 18 and 15 patients, respectively. In 20 of the group hypothyroidism was diagnosed as the underlying thyroid illness. Treatment was adjusted to the needs of the patients. In 7 of the patients a multinodular goiter was diagnosed. Antithyroid agents were administered in this group. In 4 patients within the cohort autoimmune thyroiditis was diagnosed. After treatment adjustment in the hypothyroid group episodes of atrial fibrillation decreased in frequency and in two of the patients they were almost eliminated. After antithyroid drug administration in the goiter group episodes of atrial fibrillation were attenuated.
Conclusions
Atrial fibrillation may be the presenting symptom of subclinical hyperthyroidism. Subsequent diagnosis and proper management of subclinical hyperthyroidism may aid in the management of atrial fibrillation. We propose that patients with atrial fibrillation should be screened and appropriately treated for an underlying thyroid disorder.

Autoimmunity in thyroid nodules referred for FNAB

Irina Nistor[1], Theodor-Eugen Oprea[2], Simona Gabriela Duta[1], Albu Alice[1,2], Carmen Sorina Martin[1,2], Anca Sirbu[1,2], Carmen Gabriela Barbu[1,2] & Fica Simona[1,2]
[1]Spitalul Universitar de Urgență Elias, Endocrinology, București, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, București, Romania

Introduction
The aim of the study was to evaluate the relevance of autoimmunity in the cytological results for the thyroid nodules referred to FNAB (fine-needle aspiration biopsy).
Materials and methods
Our study included 590 patients who underwent FNAC in 615 nodules between December 2015 and January 2019. Besides demographic data and routine endocrine investigations (thyroid hormonal status, presence of autoimmunity, the actual or past use of levothyroxine or inhibitors of the synthesis of thyroid hormones), we retrospectively collected data regarding localization, ultrasonographic (US) Ti-RADS (Thyroid Imaging Reporting and Data System) evaluation and Bethesda based cytology findings. We analysed the obtained data using IBM SPSS Statistics 20.
Results
We investigated 590 patients, from which 77 men (mean age 54.91 ± 14.902 years old) and 513 women (mean age 52.05 ± 13.635 years old). Our analysis revealed that 10 male patients had thyroid autoimmunity (12.98%) and 155 out of 513 female patients (30.21%, $P = .002$, $r = .129$). The Bethesda based results were: 70 (11.16%) category I, 459 (72.17%) category II, 75 (11.79%) category III, 16 (2.52%) category IV and 15 (2.36%) category V. Autoimmunity was present in 6 cases of Bethesda V (6.66%), 1 case of Bethesda IV (18.75%, 23 cases of Bethesda III (12.5%), 123 cases of Bethesda II (12.66%) and 22 cases of Bethesda I (12.85%), with no statistical significance in neither of these categories, nor comparing malignant – benign or diagnostic – non-diagnostic results. Also, important to mention, the presence of autoimmunity did not interfere with the TI-RADS score, and it was present in only 3 of the 29 cases that were confirmed after surgery as thyroid cancer and in 2 of the 23 patients that were diagnosed with benign thyroid nodules post thyroidectomy (the rest were lost to follow-up).
Conclusions
Considering the lack of information of how the presence of autoimmunity could interfere with the cytological results of nodules referred for FNAB, we tried to demonstrate the the simultaneous diagnostic of thyroid autoimmunity does not tamper with the beneficial outcome of FNAB. Further research is needed in order to assign a more radical conclusion.

DOI: 10.1530/endoabs.70.EP420

Screening of thyroid function in pregnant women in Bulgaria

Anna-Maria Borissova[1,2], Lilia Dakovska[2], Eugenia Michaylova[2,3] & Boyana Trifonova[1,2]
[1]University Hospital Sofiamed,;Sofia University St Kliment Ohridski, Clinic of Endocrinology and Metabolic diseases, Medical Faculty, Sofia, Bulgaria; [2]UMHAT Sofiamed, Clinic of Endocrinology and Metabolic diseases, Medical Faculty, Sofia, Bulgaria; [3]MDL Bodimed, Clinical Laboratory, Sofia, Bulgaria

In Bulgaria there are epidemiological data for the population of 20–80 years for the frequency of thyroid dysfunction – 6.3% hypothyroidism and 3.7% hyperthyroidism (Bulgarian Society of Endocrinology, 2012). So far, there is no national data on the incidence of thyroid disorders in pregnant women, which is a major lack of the health care system and the purpose of this study is to fill this gap.
Material and methods
We studied 547 pregnant Bulgarian women from 10 regions of the country, with mean age 30 ± 5 y. The prevalence of subclinical (SHT), overt (OHT) hypothyroidism, subclinical (SHyperT), overt (OHyperT) hyperthyroidism was determined. TSH, FT4 were measured and ultrasound of thyroid was performed.
Results
Screening find in 20.1% of pregnant women (n-110) SHT, 6.2% (n-34) OHT, 0.9% (n-5) SHyperT and 0.4% (n-2) OHyperT. In 79 (55%) pregnant women hypothyroidism has been known and has been treated – 76 with SHT and 3 – with OHT. There are 65 (45%) pregnant women with newly discovered hypothyroidism – 34 with SHT and 31 with OHT. Thus, of

all 144 pregnant women with hypothyroidism, only 55 (38.2%) under the Levothyroxine treatment achieved an euthyroid state, but the remaining 89 (61%) were hypothyroid (55 with SHT and 34 with OHT), although some were under hormonal treatment. During pregnancy, the proportion of women undergoing treatment with Levothyroxine increased: I trimester – 42%, II trimester – 45%, III trimester – 57%.
Conclusion
The presence of 16.3% of hypothyroid pregnant women (89 of the 547 studied) is a poor certificate for maternal and child health care. In the presence of verbally established risk factors for thyroid disease early diagnosis, timely inclusion of an adequate dose of Levothyroxine and regular monitoring are needed.

DOI: 10.1530/endoabs.70.EP421

EP422

Ultrasound guided percutaneous laser ablation of thyroid nodules

Nataša Bedernjak Bajuk, Simona Gaberscek, Edvard Pirnat & Katja Zaletel
University Medical Centre Ljubljana, Department of Nuclear Medicine, Ljubljana, Slovenia

Background
Thyroid nodule is the most common endocrine disorder with the prevalence of more than 50% in adults. Majority of nodules are small in size and can be detected only by various imaging methods. Thyroid nodules are usually benign, asymptomatic, and do not need treatment. Growing and large symptomatic thyroid nodules are usually treated with thyroidectomy. Novel minimally invasive ablation techniques can be alternative to surgery. Percutaneous laser ablation is causing irreversible thermal destruction of tissue by conversion of the absorbed laser light into heat. Method is only applicable in benign thyroid nodules.
Aim
To evaluate efficiency and safety of ultrasound (US) guided percutaneous laser ablation of thyroid nodules.
Patients and methods
In our prospective study, we included two male and four female patients with a mean age of 50.5±10.9 years with US isoechoic homogeneous thyroid nodule larger than 3 cm in diameter and 5 ml in volume, which was scintigraphically 'cold' and two times benign on cytology examination (Bethesda 2). Under US guidance optical fiber(s) were inserted percutaneously directly into the nodule through inserter using cranio-caudal approach. In order not to damage surrounding tissue the optical fiber(s) were positioned at least 10–15 mm from nodule border. Depending on nodule volume and size we applied from 1800 J to 8400 J of energy. We used one or two fibers and zero to two 'pull backs'. Outcome was evaluated one week, one month and three months after the procedure. Results are reported as mean±standard deviation. T-test was used for statistical analysis.
Results
Initial mean volume of thyroid nodules was 20.6±7.6 ml (range, 9.4–31.6 ml). Volume of nodules decreased to 14.6±6.6 ml (reduction of 29.1%) at one week, 13.0±5.7 ml (reduction of 36.9%) at one month and 10.8±5.6 ml (reduction of 47.6%) at three months after the procedure ($P=0.0573$, $P=0.0005$, $P=0.0003$, respectively). Regarding adverse effects, one patient reported periprocedural pain in the nodule (VAS score, 3/10), which was not observed after the procedure. In the first week after the procedure two patients reported tension in nodule and headache. No voice changes or other adverse events were observed.
Conclusion
In our initial experience, US guided percutanoues laser ablation of thyroid nodules is effective and safe procedure. Inclusion of a larger group of patients and follow-up for a longer period of time is needed in order to obtain more reliable results regarding efficiency and safety of the procedure.

EP423

Risk of developing hypothyroidism during pregnancy in women with autoimmune thyroid disease

M Dolores Ollero, ana iriarte beroiz, Patricia Munarriz Alcuaz, Nerea Eguilaz Esparza, Juan Zubiría Gortázar & Javier García Torres
Complejo Hospitalario de Navarra, Endocrinology and Nutrition, Pamplona, Spain

Women with positive thyroid autoimmunity are considered at risk of developing hypothyroidism in pregnancy, so monitoring thyroid function is recommended.
Objective
To assess the risk of gestational hypothyroidism in pregnant women with autoimmune thyroid disease and normal thyrotropin (TSH) at the beginning of pregnancy.
Methods
Retrospective review of data from pregnant women attended between April 2016 and October 2019. Women with positive anti peroxidase (anti-TPO) and/or anti thyroglobulin (anti-Tg) antibodies, and normal TSH level in the first trimester (TSH 0.1–4.0 mIU/l) were selected. Thyroid function was monitored throughout pregnancy to assess the development of gestational hypothyroidism, defined as TSH ≥4 mIU/l.
Results
Ninety-nine pregnant women were included, aged 34.2±4.7 years (18–43), 40.4% nulliparous, with mean baseline TSH 1.91±1.05 mIU/l (9th gestational week).
Anti-TPO antibodies were positive in 86.9% of women. All anti-TPO negative women were positive for anti-Tg antibodies. Twelve women were lost during follow-up.
Only 2 women developed hypothyroidism (2%). These women had baseline TSH levels>2.5 mIU/l and reached TSH 4.01 and 4.23 mIU/l respectively in the 15th gestational week, starting treatment with levothyroxine.
Conclusion: In our population, women with positive thyroid autoimmunity and normal TSH levels in the 9th week, appears to have very low risk of developing gestational hypothyroidism. These women would need no additional follow-up during pregnancy.

Amiodarone induced thyrotoxicosis

Marianna Bystrianska[1], Adrian Bystriansky[2] & Iveta Wildova[1]
[1]F.D. Roosevelt University Hospital in Banská Bystrica, Department of Internal Medicine, Banská Bystrica, Slovakia; [2]Central Slovak Institute for Cardiovascular Diseases Banska Bystrica, Department of Arythmology, Banska Bystrica, Slovakia

Background
Amiodarone induced thyrotoxicosis (AIT) is one of the most important and severe complications caused by amiodarone therapy. The multidisciplinary medical cooperation and combined therapeutic strategies are necessary in some cases.
Aim
Analysis of patients suffered from AIT with focus on clinical picture, laboratory findings and possible therapeutic options.
Methods and Results
We performed retrospective analysis of 35 consecutive patients with AIT, (27 men and 8 female, mean age 61.91±9.5 years) who were examined and long-term monitored on Department of Internal Medicine University Hospital Banska Bystrica (Endocrinology section) during the period 2005–2018. All of analysed patients ($n=35$) have been treated for arterial hypertension, 49% ($n=17$) ischaemic heart disease, 63% ($n=22$) had heart failure and 23% ($n=8$) had implantable cardioverter defibrillator. The atrial fibrillation was the most frequent indication for amiodarone therapy (in 71%) and in 29% of patients it was ventricular tachyarrhythmias. The mean time of amiodarone administration was 980±566 days, median 866 days. Mean TSH in the time of diagnosis was 0.024±0.06 mIU/l and mean free T4 was 46.2±16.71 pmol/l. The prevalence of different types of AIT was: AIT type 1 (34%, $n=12$), AIT type 2 (49%, $n=17$) and mixed type AIT (17%, $n=6$). Twenty four patients (69%) had been hospitalized and four patients (11%) developed thyrotoxic crisis. All of patients ($n=35$) have been treated with antithyroid drugs and 13 of them (37%) with corticoids co-administration. The mean time to achieve AIT remission (defined as free T4 decrease to physiological ranges) was 112±52 days, median 99.5 days. In 12 patients (32%) thyroidectomy was performed, in five patients urgently and seven electivly. The thyroid papillary microadenocarcinoma was histologically confirmed in two of observed patients.
Conclusion
Amiodarone induced thyrotoxicosis is one of the most severe complications caused by amiodarone therapy. Thorough knowledge of its adverse effects allow us to perform appropriate therapeutic mesures in care of patients

Upregulation of HLA class I and antiviral immune responses in graves' disease

Therese Weider[1,2], Sarah Richardson[3], Noel G. Morgan[3], Trond H. Paulsen[4], Knut Dahl-Jørgensen[2,5] & Sara S. Hammerstad[5]
[1]Oslo University Hospital, Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo, Norway; [2]University of Oslo, Faculty of Medicine, Oslo, Norway; [3]University of Exeter Medical School, Islet Biology Exeter, Institute of Biomedical and Clinical Sciences, Exeter, United Kingdom; [4]Oslo University Hospital, Department of Breast and Endocrine Surgery, Oslo, Norway; [5]Oslo University Hospital, Department of Pediatric Medicine, Oslo, Norway

Background
Graves' disease (GD) is a common autoimmune disease of unknown origin. Evidence of an association between autoimmune thyroid diseases and viral infections is, however, emerging. Human leukocyte antigen (HLA) class I presents both virally and self-derived antigens to circulating immune cells and plays a crucial role in the defense against viral infections. This study aimed to investigate the presence of enterovirus and HLA class I expression in a large GD cohort, with both newly diagnosed and chronic GD patients. In addition, the presence of the coxsackie and adenovirus receptor (CAR) and the viral immune response proteins signal transducer and activation of transcription 1 (STAT1) and protein kinase R (PKR) were examined.
Methods
Thyroid tissue samples from 48 GD patients were obtained from core needle biopsies and thyroid surgery specimens. Thyroid tissue collected from 24 patients during neck surgery for other reasons than thyroid autoimmunity served as controls. Standard immunohistochemistry on formalin-fixed and paraffin-embedded tissue samples were used to detect HLA class I, enteroviral capsid protein 1 (VP1) and CAR. STAT1 and PKR were examined with combined immunofluorescence staining in a subset of the samples.
Results
Significantly more HLA class I positive samples were found in the GD group (25 out of 48 [52.1%]) than in the control group (5 out of 24 [20.8%]) ($P=0.011$). Moreover, the semi-quantitative score (ranging from 0 to 8) assessing the grade of HLA class I expression was significantly higher in the GD group (3.1±3.3) than in the control group (0.5±0.9) ($P<0.001$). VP1 was detected in both controls and GD samples, but with significantly more VP1 positive thyroid cells in the GD samples (50.1±30.5%) than in controls (14.9±10.5%) ($P<0.001$). Nuclear, as well as cytosolic, STAT1 was found in thyroid cells, and was co-localized with HLA class I. In addition, PKR and VP1 were also found co-localized within thyroid cells. Finally, we demonstrate the presence of CAR in thyroid cells.
Conclusion
The current study confirmed that HLA class I upregulation is a defining feature of GD and that enterovirus protein can be found in thyroid tissue. Thyroid cells express CAR, thus confirming a susceptibility to enterovirus infection. The co-localization of HLA class I with STAT1 and VP1 with PKR indicates an intracellular, antiviral host response. These findings support the concept of a firm link between viral infection and autoimmune thyroid diseases.

A rare case of isolated central hypothyroidism with thyroxine malabsorption

Amit Badshah, Irfan Khan & Parag Singhal
Weston General Hospital, Diabetes and Endocrinology, Weston Supermare, United Kingdom

Introduction
Hypothyroidism remains a global problem with prevalence of 1–2% in iodine replete areas of the world. Primary or Autoimmune Hypothyroidism remains the most common type of hypothyroidism worldwide. Central (secondary) hypothyroidism (CH) because of pituitary/hypothalamic disorders is a rare cause of hypothyroidism with reported prevalence of 1:20.000 to 1:80.000 in the general population[1]. This makes CH about 1000 fold rarer than primary hypothyroidism. We present an interesting case of a young female who initially presented with biochemical features of autoimmune primary hypothyroidism and subsequently developed isolated central hypothyroidism (ICH) with concomitant Thyroxine malabsorption.
Case report
A 45-year old female patient presented with clinical features of hypothyroidism. Biochemistry showed TSH 5.29 mIU/l & free T4 11.4 pmol/l with strongly positive TPO antibodies (> 1000) suggesting primary autoimmune hypothyroidism. Despite being on increasing doses of Levothyroxine, she remained symptomatic. Serial TFTs showed suppressed value of both TSH & free T4. The results were cross checked by sandwich Delfia assay in a different laboratory which showed consistent pattern of TFTs ruling out assay interference. Further investigations, including full pituitary hormones profile, Short Synacthen Test and MRI pituitary were normal apart from suppressed TSH and low T4 which is indicative of Isolated Central Hypothyroidism. Despite adequate Thyroxine replacement, her free T4 level remained low. Her Coeliac and malabsorption screens were normal. She had supervised Oral Thyroxine absorption test (with 700 mg of Levothyroxine) but subsequent serial measurements of free T4 levels failed to rise above 8.7 pmol/l (Normal range 12–22 pmol/l). As a consequence, patient was offered even higher dose Thyroxine replacement and planned for trial of intravenous thyroxine but she chose to move her care to a different hospital.
Discussion
This is a very rare case of primary hypothyroidism which later transformed into central hypothyroidism of unknown aetiology and also developed Thyroxine malabsorption. If relied solely on the TSH level, the primary care practitioners can be caught out by the persistently low TSH being perceived as Thyroxine over replacement and potentially inadvertently reducing the Thyroxine dose and delay in diagnosis of central hypothyroidism. This leads to a question whether T4 should be routinely tested even for diagnosis and monitoring of all patients with suspected hypothyroidism.

Thyroid function in pregnancy and atmospheric pollution

Ioannis Ilias, Ioannis Kakoulidis, Stefanos Togias, Stefanos Stergiotis, Aikaterini Michou, Anastasia Lekkou, Vaso Mastrodimou, Athina Pappa, Evangelia Venaki & Eftychia Koukkou
E Venizelou Hospital, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece

Introduction
Exposure to air pollution and in particular to nitrogen dioxide (NO_2) or particulate pollutants less than 2.5 μm (PM2.5) or 10 μm (PM10) in diameter has been linked to thyroid (dys)function in pregnant women. The environmental degradation that has occurred in recent years in the region of Athens led us to a local study of air pollution against thyroid function in pregnant women in Athens. We hypothesized that there may be a dose-effect relationship between air pollutants and thyroid function parameters.
Methods
We retrospectively evaluated thyroid function with thyrotropin (TSH) in 293 women, mean±S.D.: 30.9±5.5 years, vs the mean of the previous 9 months of NO_2, PM2.5 and PM10 levels of five atmospheric air quality measurement stations in the greater Athens area (2013–2017). All the women had no prior thyroid disease and were diagnosed with hypothyroidism for the first time during their pregnancy (mean±S.D. gestational age at diagnosis 19.4±8.6 weeks, weight gain 5.1±5.6 kg, TSH: 4.54±1.66 mIU/l). We only included women with TSH>2.5 mIU/l or>3.0 mIU/l if the initial thyroid assessment was done in the first or the second trimester of pregnancy respectively. Exposure to air pollution for each woman was considered according to her place of residence (permanent residence for at least one year) within a reasonable distance of one of the five air quality measuring stations. Statistical analysis of age, pregnancy weight change, and air pollutants vs TSH was performed with ordinary least squares regression (OLS-R) and quantile regression (Q-R).
Results
Using OLS-R, a significant (positive) correlation for logTSH was found only with PM2.5 ($r=+0.13$, $P=0.02$). Analysis with Q-R showed that each incremental unit increase (for the 10th to the 90th response quantile) in PM2.5 increased TSH (± S.E.) between+0.029 (0.001) to+0.025 (0.001) mIU/l ($P<0.01$). Other pollutants (PM10 and NO_2) had no significant effect on TSH.

Conclusion
Our results indeed show a relationship between PM2.5 and TSH. The mechanisms involved in the pathophysiological effects of atmospheric pollutants, in particular PM2.5, are being investigated.

The hypothyroid adrenals, transient thyro – adrenal failure – functional or real?

Swaraj Waddankeri
MR Medical College, Division of Diabetes & Endocrinology, Department of Internal Medicine, Gulbarga, India; Asst. Prof. Department of Medicine, M R Medical College, Gulbarga and Consultant Anugraha Diabetes and Endocrinology Center, Gulbarga

Background
Primary hypothyroidism is one of the most common endocrine disorder, prevalence is in the ranges of 3.8–10.9%. It has been estimated that about 42 million people in India suffer from thyroid diseases. At one end,with easier availability of the assays and better affordability we are now able to diagnose and treat hypothyroidism much earlier. At the other end, we are seeing patients with TSH > 100 at diagnosis, most of them done as a part of routine screening often with no other comorbidities.
Materials and methods
The present case series is a descriptive and observational case control study of 25 consecutive cases diagnosed on routine screening with TSH > 100. We assessed the Zulweski clinical score, BMI, goitre grading as a part of the clinical examination. Biochemical evaluation included an 8 AM cortisol, prolactin and T_3, T_4 TSH. LT_4 replacement was started in all.
Results
The median age of presentation was 26.76 years and 96% were women. Weight gain was a presenting feature only in less than one third of the cases. The commonest feature of presentation was easy fatigability. Prolactin was elevated in 64% of the cases. 0800 h cortisol levels were normal in two-thirds of the cases. Three (12%) cases presented within 72 hrs of taking LT_4 with fatigue, tiredness, headache and hypotension (all had low cortisol). They were managed with intravenous followed by oral hydrocortisone. On follow up, we could withdraw Hydrocortisone within a period of three months.
Conclusion
In this series severe primary hypothyroidism was not associated with weight gain in most. Twelve percent of the cases had clinical and biochemical hypoadrenalism after levothyroxine therapy. Routine replacement with steroid is not indicated in all cases of severe hypothyroidism but when dealing with severe primary hypothyroidism as in our cases, a check on Cortisol is worth considering along with a careful watch for the clinical symptoms of hypoadrenalism in the first few days after starting levothyroxine treatment. Baseline 8 AM cortisol may help in predicting the precipitation of adrenal failure post levothyroxine.

An audit of monitoring of fetus in pregnant women with hyperthyroidism

Monzoor Quader[1], Ananth Nayak[2], Geraldine Masson[2], Saada Usman[2] & Lakshminarayanan Varadhan[1]
[1]University Hospitals of North Midlands NHS Trust, Diabetes and Endocrinology, Stoke on Trent, United Kingdom; [2]University Hospitals of North Midlands NHS Trust, Obstetrics and Gynaecology, Stoke on Trent, United Kingdom

Aim
Hyperthyroidism can affect pregnancy outcomes based on activity of the disease, ongoing use of anti-thyroid drugs (ATD) and TSH receptor antibody (TRAB) positivity. The aim of our audit was to analyse the outcomes of fetal monitoring in pregnant women with previous or current history of active hyperthyroidism
Methods
The data on all patients with hyperthyroidism and pregnancy over 3 years was collected. The local guidelines recommend TRAB check at 20 weeks. If TRAB + and/or patient continuing on ATD into third trimester, fetal medicine scan(FM Scan), serial growth scans in third trimester and a neonatal alert for a new-born review were arranged.
Results
N = 56. This included women with active Graves' (*n* = 34); previous hyperthyroidism currently in remission (*n* = 15) and post radio-iodine or thyroidectomy induced hypothyroidism(*n* = 7). Of the Graves' patient, 19 required ATD continuing into 3rd trimester, with the rest withdrawing ATD during the course of early pregnancy
TRAB ±
N = 31; FM Scan normal in 30 patients-1 patient had an abnormal scan (hydronephrosis) which was likely unrelated to the thyroid disease. Serial growth scans were done in 26/31 women– 20 normal; 3 had large for gestational age (1 on thyroxine, 2 were euthyroid on no ATD) – one had normal birth weight, one was born preterm at 30 weeks, other baby was 3.7 kg at birth. 3 had small for gestational age (1 on thyroxine, 2 were euthyroid on no ATD)- one had twin pregnancy, one had pre-eclampsia with known hypertension and the third baby was well after delivery. On looking at the women who did not have growth scans (due to recent change in local guidelines), 4 had only weakly + TRAB and 1 had premature rupture of membranes attributed to likely placental issues.
Patients on ATD
N = 19; FM Scan was normal in all 19 women and were normal. Serial growth scans (*n* = 18) were normal in 16/18 women-2 had small for gestational age which is not consistent with ATD use and both had normal TFT. (1 patient who did not have the growth scan was the patient with premature rupture of membranes).
Conclusion
The study shows generally good outcomes for patients with hyperthyroidism. Serial growth scans can be used as a preliminary screening to guide further monitoring during pregnancy to monitor for TRAB or ATD or active Graves' related impact to pregnancy. Fetal medicine scans may be reserved for patients with high TRAB as they have generally been normal.

Antithyroperoxydase autoantibody evolution in Hashimoto thyroiditis. Comparison between all re-evaluated patients and those over 10 years observation. January 2020

Dan Peretianu[1], Dana Cristina Staicu[1] & Bogdan Oprisan[2]
[1]Medical Center Povernei, Endocrinology, Bucharest, Romania; [2]Iassi faculty of Medicine 'Gr. T. Popa', Byophisics and Medical Physics, Bucharest, Romania

Aim
Most research teams analyze the evolution of patients with Hashimoto thyroiditis (HT) on syndromic basis (e.g., the thyroid function), not on pathogenic basis (the autoantibodies). Thus, most researchers refer to thyroid hormone evolution. In this study we re-analyzed (first in 2018) how evolve the antithyroid autoantibodies. Therefore, we analyzed the antithyroperoxydase antibodies (ATPO) evolutive patterns in patients with HT.
Method
1. ATPO levels were analyzed in several accredited Bucharest laboratories. 2. Only patients with minimum 3 investigations were considered for interpretation. 3. We considered 5 ATPO evolutive patterns: a. undulatorious; b. decreasing; c. increasing; d. unmodified, e. normalization. 4. Unmodified pattern was considered if ATPO level did not differed by 5%. 5. normalization pattern was considered if ATPO decreased under the *cut off* level (= 34 IU/ml).
Results.
A. All Patients: 893; women – 831, men –62 (7.46%).
B. Patients re-evaluated over 10 years: 97; woman: 89; men: 8 (8.99%).
C. The reinvestigation final time for all patients: average: 4.28 years; median: 3; minimum: 2 months, maximum: 24.5 years.
D. For patients with over 10 years observation; average: 12.56 years; median: 12; minimum: 10 years, maximum: 24.5 years
E. ATPO level at onset (at diagnostic time) for all patients re-analyzed: average: 789.55 IU/ml, standard deviation: 2129.
F. For patients observed over 10 years: average; 607.86 IU/ml, S.D.: 941.
G. The evolution patterns for all patients: a. undulatorious – 425 patients (47.59%); 12 without thyroid (3 = TXT/total thyroidectomy, 3 = 131-I, 6 = atrophy); b. decreasing but with ATPO over the *cut off* limit – 233 (26.09%); 6 without thyroid (3 = atrophy, 2 = TXT, 131-I = 1); c. increasing: 156 (17.47%); 1 = TXT; d. unmodified: 58 (6.49%), 2 no thyroid (1 = 131-I, 1 = TXT); e. normalization: 21 patients (2.35%), 5 no thyroid (2 = atrophy, 3 = TXT).

H. ATPO patterns in patients seen after 10 years observation: a. undulatorious: 76 (78.35%), vs all, $P << 0.001$; b. decreasing: 14 (14.43%), vs all, $P << 0.001$; increasing: 1 (1.03%); unmodified: 1 (1.03%); e. normalization: 5 (5.15%).
Conclusions
1. When performed more ATPO analysis (over 10 years), the evolutive pattern become undulatorious, around 80% patients. 2. When thyroid is missing, ATPO decreased level were registered till normalization.

DOI: 10.1530/endoabs.70.EP430

EP431

Treatment of benign thyroid nodules in Spain with HIFU. Importance of its size, situation and painful sensation in the results. 18 month follow-up

Pedro Pablo Ortiz Remacha[1] & Joan Vidal Jové[2]
[1]University of Zaragoza, Human Anatomy and Embriology Department, Zaragoza, Spain; [2]University Hospital Mútua Terrassa, Terrasa, Barcelona, Spain

Objectives
Assess the response of benign thyroid nodules to HIFU treatment depending on their volume and localization. Know if the treatment is painful when sedation is not used.
Methods
66 patients with benign thyroid nodules (Bethesda Category II) were treated with HIFU (Echopulse Theraclion). They were grouped in 3 categories by maximal nodule diameter as assessed by echography. Group 1: nodule diameter between 14 and 20 mm; Group 2: between 21 and 30 mm; Group 3: over 30 mm. Follow-up at 8 weeks, 6, 12 and 18 months was done under echography. Nodules are described as superficial or deep taking the center line of the trachea as a reference. We define therapeutic success when the nodule size, after 8 weeks of the last treatment, is inferior to 50% of its initial size. All patients followed the same pre-treatment oral analgesia protocol: Lorazepam 1 mg+Paracetamol 1.000 mg+Dexketoprofene 25 mg. Assessment was made using a categorical 6-grade scale (CS).
Results
Results from groups 1 and 2 are significantly different from those from Group 3. 81% of Group 1 cases reach therapeutic success with a single treatment. Groups 2 and 3, have respectively 58% and 42% of success. In cases from Groups 2 and 3 treatment is repeated up to 4 times. Deeper nodules and nodules located on the isthmus can only be treated partially. There has been no recurrence or enlargement of treated nodules after 18 months. Patients describe pain as 'tolerable' in 68% of cases. In 23% of cases pain is marked as 'almost intolerable', which needed to lower the delivered power by 5–10 W. Lastly, in 9% of cases pain was marked as 'intolerable' leading the treatment to finalize without being totally performed. Pain sensitivity is less and less tolerated for Group 3 nodules of longer treatment durations, as oral analgesia efficacy decreases in time.
Conclusions
The treatment of benign thyroid nodules with HIFU is safe and effective. The size of thyroid nodules is an important factor to design of the treatment strategy with HIFU. Nodules under 30 mm diameter are the best choice in terms of treatment speed, efficacy and obtained results. For bigger nodules, several sessions and a follow-up over 18 months are necessary to obtain satisfactory results. Deeper nodules and nodules located on the isthmus need a previous simulation treatment to assess the expected reduction. Our protocol for oral analgesia is successful for nodules that do not require long treatment times, and on patients that feel relaxed and have a better self-control management.

DOI: 10.1530/endoabs.70.EP431

EP432

Clinical approach after a Bethesda 4 result in a thyroid cytology

Mª Rosa Alhambra Expósito[1], Ana Barrera-Martín[1], Ángel Rebollo-Román[1], Pedro Segui-Azpilcueta[2] & María Ángeles Gálvez-Moreno[1]
[1]Hospital Reina Sofía, Endocrinology and Nutrition, Córdoba, Spain; [2]Hospital Reina Sofía, Radiology, Córdoba, Spain

Introduction
Thyroid nodules are a very common finding in sonographies (20–75% people). Criteria for clinical management and for cytological diagnosis (Bethesda system) are well standardized. In spite of this, a gap of knowledge exists as far as management of Bethesda 4 is concerned.
Aim
Evaluate the clinical approach of Bethesda 4 (B4) result in a thyroid cytology.
Material and methods
Retrospective study of thyroid nodules classified as B4 in FNA in our hospital between 2012 and 2018. Statistical analysis: SPSS v.22.0 (Student' t-test to compare means and
Squared Chi/Fisher to proportions).
Results
162 nodules classified as B4 in FNA. Mean age: 54.07±14.62 years. 75.3% Women. 138 (85.2%) were surgically removed: 11.6% of them were part of a multinodular goitre; 55.8% follicular adenomas; 10.9% follicular carcinomas; 8.7% papillary carcinomas; 1.4% medullary carcinomas; 11.6% NIFTPs. In 24 cases there were not a surgical treatment: In 12 of them active surveillance was decided in accordance to patients' preferences, in 10 of them surgical treatment was put off because of an intercurrent neoplasia and 1 patient died of an unrelated cause.
Conclusions
In our cohort, proportion of B4 thyroid nodules and carcinoma result after surgery doesn't differ from previously published results. Although the use of this category seems correct, it gives rise to a surgical overtreatment in hyperplasic nodules.

DOI: 10.1530/endoabs.70.EP432

The effectiveness of the thyroid disease screening program in pregnant women in the slovak republic 2016 compared to 2011

Matej Bielik[1], Jan Bielik[2], Vladimira Kmečova[3] & Marian Faktor[3]
[1]KAMEAT, S.R.O., Endocrinologic out Patients Department, Nové Mesto nad Váhom, Slovakia; [2]Faculty of Healthcare, Trencin Universit, Trencin, Slovakia; [3]Health Insurance Company Dovera, Bratislava, Slovakia

Objectives
Thyroid screening in pregnancy has in Slovakia started in 2009 on the basis of a ministerial guidance for diagnosis and therapy of autoimmune diseases of thyroid gland in pregnant women. (source: Vestník MZ SR 39., 2009, pp. 33–39). Its effectiveness was analysed in 2016 and compared with a similar analysis from 2011. The analysis was aimed to verify the implementation rate of the Guidance in practice.
Methods
Records from pregnant women registered in the Health Insurance Company Dôvera (28% share in Slovakia) were evaluated. Included were women with documented first visit at gynecologist who confirmed pregnancy in 2016. Examination of blood sample for TSH and APTO followed by examination by endocrinologist with negative anamnesis of appointments with endocrinologists in 2015 were including criteria for the analysis. All women were monitored till the end of 2017.
Results
16 891 women were included. Out of them 5 901 (34.9%) underwent a „mandatory 'examination for TSH and ATPO. Out of these 526 (i.e. 8.9% of 5 901) were subsequently examined and followed up by endocrinologist also in 2017 for thyroid pathology of TSH and/or ATPO. 210 women (39.9% of 526) in the latter group needed medicament treatment: 6 women (2.9%) for hyperfunction and 204 women (97.1%) for hypofunction of thyroid gland with average daily dose 74.5 mg thyroxin. Thyroid disease screening in pregnant women implemented by gynecologists in 2016 was low reaching 34.9%, however, surprisingly it was even lower than in 2011 when it reached 37.1%. Newly diagnosed thyreopathy reached only 3.1% in the whole group of 16 891 women, and thyreopathy with needed treatment only 1.2%. The overall screening costs amounted to 135 922 €, i.e. 23€ per one woman. Average costs of one identified thyreopathy were 258.4 € and of one treated thyreopathy 647.3 €.
Conclusions
The high proportion of laboratory thyreopathies in 2016 requiring long-term follow up by endocrinologist (8.9% in the group with examined TSH and ATPO) and necessity of a long-term therapy in this group (39.9%) allow to conclude that this screening is clinically as well as cost effective and should be performed on the whole population of pregnant women. The Low implementation of the screening by out-patient gynecologists despite the ministerial guidance has been in force for seven years is a critical weakness.

Alteration in thyroid function in a sample of Egyptian female patients with breast cancer receiving adjuvant chemotherapy

Hany Khairy, Mohamed Saad, Laila Mahmoud & Walid Mohamed
Ain Shams University Faculty of Medicine, Internal Medicine, Cairo, Egypt

Introduction
Chemotherapy, as a systemic therapy, is one of the most effective modalities for cancer treatment. However, the use of chemotherapeutic drugs in patients with breast cancer can lead to thyroid dysfunction. The aim of our work is to determine the influence of adjuvant chemotherapy on thyroid function in female patients with breast cancer after radical mastectomy and before radiotherapy.
Materials and methods
Our study was conducted on 40 Egyptian female patients(18–60) years of age who received adjuvant chemotherapy with 5-flourouracil, epirubicin and cyclophosphamide for breast cancer after mastectomy and before radiotherapy. Free T3, Free T4, TSH, anti-thyroglobulin antibody and thyroid peroxidase antibody were measured before treatment and after the 6th cycle (six months) of chemotherapy.
Results
On comparing the results of the studied group before and after chemotherapy, there were high significant difference in TSH value $P=0.005$ being higher after chemotherapy (2.42 mU/l before chemotherapy vs. 2.87 mU/l after chemotherapy), significant difference in free T4 values $P=0.025$ being lower after chemotherapy(1.32 ng/dl before chemotherapy vs. 1.23 ng/dl after chemotherapy), but there was no significant difference in free T3 value $P=0.051$, Concerning both anti-thyroglobulin and anti-peroxidase there was no change in values before and after chemotherapy.
Conclusion
Receiving adjuvant chemotherapy in breast cancer patients was associated with significant elevation of TSH and decrease in fT4 levels which in spite of still being in the normal range, it may lead to overt hypothyroidism with longer duration of follow up.

DOI: 10.1530/endoabs.70.EP434

EP435

Significance of serum thyroglobulin levels in differentiated thyroid carcinoma patients with distant metastasis

Yen-Hsiang Chang
Kaohsiung Chang Gung Memorial Hospital, Nuclear Medicine, Kaohsiung City, Taiwan

Background
Distant metastases develop in approximately 5–10% of patients with differentiated thyroid cancer (DTC). Nearly 70% of this subset will become radioiodine refractory (RAI-R) with a poor prognosis. Recently, the multikinase inhibitors (MKIs) showed promising results of treating these patients. It has become crucial to identify RAI-R DTC early. This study was conducted to identify the predictors of RAI-R disease in patients with distant metastasis secondary to differentiated thyroid carcinoma (DTC).
Methods
A retrospective review of 1665 patients with DTC treated at a regional tertiary hospital in Kaohsiung, Taiwan between 1986 and 2010 was performed. Medical records relating to a total of 207 patients with pathologically verified DTC were studied, and all of whom were found to have distant metastasis at diagnosis or during follow-up. Predictor analysis included age, sex, histology, cancer stage, site of metastatic foci, thyroglobulin (Tg) level and accumulated therapeutic dose of radioiodine (RAI). Cases with positive anti-Tg antibody were excluded from analysis.
Results
Approximate 80% of this cohort had papillary carcinoma or its variants whereas others reported follicular carcinoma. The mean age at diagnosis of distant metastasis was 46 years. The female to male ratio was 2:1. The independent predictors of radioiodine refractory disease were old age (> 55 yr) and high TSH-stimulated Tg level (> 400 mg/l) at the discovery of metastasis.
Conclusion
High level of TSH-stimulated serum Tg levels can be used as a indicator in DTC patients with distant metastasis to predict RAI-R disease. Old age is also a risk factor of RAI-R disease.

EP436

Coexistent thyroid and lung cancers resembling flip flop phenomenon

Daniela Cavaco, Joana Simões-Pereira & Valeriano Leite
Instituto Português de Oncologia de Lisboa, Endocrinoloy, Lisboa, Portugal

Introduction
Differentiated thyroid cancer (DTC) prognosis is usually favorable, even when metastatic radioiodine avid disease is present. Radioiodine-refractory disease, usually a sign of higher aggressiveness, can be detected by ^{18}F-FDG-PET/CT. There is a reverse relationship between iodine and FDG accumulation in thyroid cancer lesions, the so-called ''flip-flop'' phenomenon: when thyroid cancer cells dedifferentiate they tend to lose their radioiodine avidity and start uptaking FDG. We present a case of advanced DTC with heterogeneous uptake of iodine and FDG.
Case presentation
A 69 years-old woman with a past history of right hemithyroidectomy 8 years before, due to a 70 mm hyperplastic nodule, was referred to our center. The patient had a painful lesion in the right acromion whose biopsy suggested papillary thyroid cancer (PTC) metastasis. Histological review of slides of the previous right thyroidectomy revealed PTC (encapsulated follicular variant) with vascular invasion. Neck ultrasound from the remaining thyroid showed irrelevant findings. However, CT scan documented extensive metastatic disease in the upper mediastinum, lungs with micronodules and a large lesion with 49 mm in the left lower lobe, chest wall and right acromion. The patient was submitted to radiotherapy (20Gy) with improvement of the shoulder pain. The histological piece of the remaining thyroidectomy revealed no neoplastic lesions. Then, she was submitted to radioiodine therapy with 150 mCi. Stimulated thyroglobulin was > 300000 ng/ml and the whole-body scintigraphy revealed metastatic disease in the right shoulder, chest wall, pelvis and left femur but no uptake in the lungs and mediastinum. ^{18}F-FDG-PET/CT was performed and revealed several lesions with elevated metabolism in the mediastinum, pulmonary left hilum and lower left lobe with 61 mm (SUV 22) and contralateral lung, while the lesions referred in the previous 131 I scintigraphy only showed a slight to moderate metabolism (maximum SUV of 7). Due to ^{18}F-FDG uptake discrepancy within the lungs, the larger left lobe and mediastinic lesions were biopsied by bronchoscopy; the immunohistochemistry was negative for thyroglobulin and PAX 8 and positive for TTF1, suggesting lung adenocarcinoma. The patient was referred to a second radioiodine therapy with 150 mCi and also for lung-directed chemotherapy.
Conclusion
In the presence of flip flop phenomenon, a well-described characteristic of progessive DTC, a high suspicion index must be maintained when the findings are discordant, in order to provide an appropriate differential diagnosis and management of the disease.

The learning curve of a new thyroid fine-needle aspiration facility

Dan Alexandru Niculescu[1,2], Dana Terzea[3], Laura Deacu[2] & Catalina Poiana[1]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]C. I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [3]C. I. Parhon National Institute of Endocrinology, Pathology, Bucharest, Romania

Fine-needle aspiration (FNA) is the best available technique for preoperative diagnosis of malignancy in thyroid nodules. Although its efficiency has been well described, the learning curve is underreported. We aimed to describe the learning curve of a new FNA facility (endocrinologist/pathologist) in a university based hospital.
Methods
In February 2018 a new FNA facility was formed in our hospital comprising an endocrinologist with high experience in thyroid ultrasound but without any experience in FNA and a pathologist with occasional activity in thyroid FNA. We assessed all FNA procedures of thyroid nodules until December 2019 (791 nodules). The nodules were chronologically grouped in 4 groups of 200 nodules (191 in the last group).
Results
The number of slides per nodule decreased from 5 ± 1.6 in the first group to 4.9 ± 1.4, 4.3 ± 1.0 and 4.1 ± 1.1 in the second, third and fourth group respectively (ANOVA $P<0.001$) while the nodule greatest dimension remained constant (around 26 mm). The percent of Bethesda 1, 3 and 4 decreased

from 14.5%, 12.5% and 31.5% in the first group to 10.5%, 10% and 18.5% in the second, 5%, 5.5% and 9.5% in the third and 10.5%, 3.7% and 10.5% in the last group. In surgically treated nodules the risk of malignancy 100%, 100%, 92.3% and 100% respectively for Bethesda 5/6 and 30.6%, 36.3%, 22.2% and 60% respectively for Bethesda 4 categories.
Conclusion
The efficiency parameters of a new thyroid FNA facility continue to improve at least until 800 procedures. However, most parameters are within the literature reported range after 200–400 procedures.

Determination of daily iodine consumption amount of people with nodular goitre and relationship with papillary thyroid cancer

Ferhan Mantar & Feriha Dökücü
Bahcesehir University, Nutrition And Dietetic, Istanbul, Turkey

Objective
There is a risk of malignancy in 5–10 percent of all thyroid nodules. The most common type of thyroid cancer is papillary thyroid cancer (PTC).There are some risk factors has been found in differentiated thyroid cancers like high iodine intake. However, in people with severe or moderate iodine nutritional deficiency (<75 μg/day),an increased risk of thyroid cancer was found 2.6 times higher than those with optimal iodine nutrition (150–299 μg/day) in a research. In another one, PTC was found related relatively low or excessive iodine intakes in an adequate area of iodine. In our study we aimed to find daily iodine consumption amounts in patients with nodular goitre (NG) and PTC. We searched the frequency of consumption of iodine-rich foods and goitrogen foods. Anthropometric measurements, some blood values and the properties of nodules on ultrasonography were also investigated and compared the in these two groups.
Material and method
The study was designed on the basis of patients with 64 benign NG group and 50 malignant PTC group according to the result of the fine needle aspiration biopsy (FNAB) of the thyroid nodules whose applied to Endocrinology Outpatient Clinic of a private medical center in Istanbul between October 2015 and November 2019. The data of the research taken by demographic and daily food consumption questionnaire (FFQ). Daily consumption of iodine from the FFQ questionnaire calculated with the Nutrition Information System (BEBIS-BESLENME BİLGİ SİSTEMİ) version 8.2 developed for Turkey. Iodized salt amount using with meals calculated from demographic questionnaire has also been added the total iodine consumption in the survey. Results are evaluated according to WHO criteria. TSH, TPOAb, TgAb, fasting glucose, insulin, total cholesterol, LDL cholesterol were examined in the participants. In addition, the number and properties of nodules were examined with ultrasonography and anthropometric measurements were taken
Results
At the end of the study, daily iodine consumption in the PTC group were significantly higher than the benign group. TSH, TgAb and TPOAb were higher in PTC groups, while total cholesterol and HDL cholesterol were significantly higher in the benign group. The foods like shellfish, eggs and cheese, rich in iodine, are consumed significantly more in the benign group. In conclusion, we can say that excess iodine taken is associated with papillary thyroid cancer,but not with iodine-rich food consumption. However large number case studies would give us to chance reveal more precise results about the potential relationship PTC with higher iodine intakes.

Next generation sequencing of 12 gene panel in differentiated thyroid cancer

Ramesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Chakrapani B[3], Sabaretnam Mayilvaganan[4], Rajesh B[5], Rafi Md[1], Rakshith G[6] & Lakshmi Akshaya Ramesh D[7]
[1]Surabhi Medical College, Biochemistry, India; [2]Endocare Hospital, Endocrine Surgery, India; [3]Chakri Neuro Hospital, Neurology, India; [4]SGPGIMS, Endocrine Surgery, India; [5]Surabhi Medical College, Anatomy, India; [6]Apollo Hospital, Medicine, India; [7]Surabhi Medical College, mbbs, India

Introduction
Next-generation sequencing (NGS) in thyroid cancer allows for high-throughput sequencing analysis of various genetic alterations and provides a useful information of tumor biology. NGS Studies on follicular differentiated thyroid cancer have been scanty from Indian subcontinent. In this context, we set out study the prevalence of a genetic panel wide somatic mutations in thyroid cancer.
Material and methods
This prospective study was conducted on 40 paraffin embedded thyroidectomy surgical tissue samples. Institutional ethical committee approval was obtained. Followup details are documented and analysed. Mutation analysis with a 12-gene mutation panel using real-time PCR and ThyroSeq v2 on the Ion Torrent PGM sequencer was employed.
Results
Common single nucleotide polymorphisms (SNPs) with a minor allele frequency of >0.05, as documented in dbSNP; noncoding region variants; and variants in repetitive regions were excluded. Mutations were also manually checked using the Integrated Genomics Viewer v2.4.10 to filter out false positives. The analysis found mutations commonly in BRAF (30)), CDKN2A (19), NRAS (12), PI3KCA (17), RET (8), RAS (24) and TP53 (5) genes. The common mutations found in the samples was RET (M918T), NRAS (Q61R), BRAF (V600E) and missense mutation in TP53(c.217 – c.1178). A mutation has also been identified in KMT2D gene in two of the patient samples. BRAF, CDKN2A, PI3KCA were more common in papillary cancer; RAS, NRAS, RET mutations were common in follicular cancer; TP53 and KMT2D were seen only in poorly differentiated cancer.
Conclusions
NGS helps in patient management, providing risk stratification and subtyping of malignancy. It can be used in molecular tumor classification, and molecular prediction of recurrence and metastasis in thyroid carcinoma. To the best of our knowledge, this is one of its kind study from Indian subcontinent
Keywords: thyroid cancer, BRAF gene, RAS gene, genomics, mutation

The relationship between clinicopathological factors and recurrence risk of papillary thyroid cancer

Raimonda Klimaite[1,2], Dalia Dauksiene[3], Albertas Dauksa[4], Valdas Sarauskas[2,5], Rasa Verkauskiene[3] & Birute Zilaitiene[3]
[1]Department of Endocrinology, Hospital of Lithuanian University of Health Sciences, Kauno klinikos, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [5]Department of Pathological Anatomy, Hospital of Lithuanian University of Health Sciences, Kauno klinikos, Kaunas, Lithuania

Introduction
Papillary thyroid carcinoma (PTC) is the most common type of differentiated thyroid cancer, accounting for about 80% of all cases of thyroid cancer. 20 – year survival rate is about 90%. However, PTC can be aggressive – up to 30% of the patients have local renewal or systemic spread.
Our objective was to evaluated the clinicopathological factors of recurrence in completely resected PTC patients.
Methods
A retrospective review of a prospectively maintained thyroid cancer database was performed. Study included 102 patients with histopathologic diagnosis of PTC, treated at Hospital of Lithuanian University of Health Sciences, Kaunas clinics between 2004 and 2017. Patients were divided into: remission group – patients who had no recurrences for at least 1 year after total thyroidectomy and postoperative I^{131} therapy; recurrence group – patients who had local or systemic tumour recurrences for at least 1 year after total thyroidectomy and postoperative I^{131} therapy. Multivariate analyses were performed to identify predictive factors of PTC recurrence patterns. Descriptive statistics was performed, Student´s t test or Mann-Whitney U test for independent samples, Chi-Square for qualitative data.
Results
Study included 51 patients in each group. Average age at diagnosis was 63.51±6.47 years in remission and 53.16±15.6 years in recurrence group ($P<0.001$). The higher rate of recurrence was statistically significant among younger than 55 years old patients ($P<0.001$). There was no significant difference between gender, multifocality, Hashimoto' thyroiditis and rate of PTC recurrence ($P>0.05$). Most common histologic type of recurrence was

classic PTC 80.5% ($n=33$) ($P<0.001$). Classic PTC histology was associated with greater incidence of AJCC tumour stage and lymph node metastasis ($P<0.001$).
Conclusion
This analysis included comparison of the associations between clinicopathologic factors, histological sub-types and recurrences of PTC. We found evidence that younger age and classic PTC sub-type is associated with increased recurrence rate of PTC. Our study lend support to recent data indicating that classic PTC confers a worse prognosis. But further studies are also warranted to expand upon our findings.

Management difficulties in nodular goiter associated with hypopharynx infiltration – case report

Laura Teodoriu[1], Andreea Magdalena Boboc[2], Georgiana Neagu[3], Bianca Ioan[3], Andreea Rosu[3], Maria Christina Ungureanu[1,3] & Cristina Preda[1,3]
[1]University of Medicine and Pharmacy Gr. T Popa, Endocrinology, Iasi, Romania; [2]Regional Institute of Oncology, Otorhinolaryngology, Iasi, Romania; [3]Emergency Clinical Hospital of Street Spiridon, Endocrinology, Iasi, Romania

Introduction
The connection between the pharynx and thyroid is close, so in the situations of concomitance: thyroid nodules and pharynx infiltration is very difficult to establish the primary lesion. Extralaryngeal spread of laryngopharyngeal cancer to the thyroid gland can occur by three pathways: direct extension, lymphatic spread or hematogenous spread. Of these three mechanisms, direct extension is the main mechanism because of the close anatomical relationship of the thyroid gland to the laryngopharyngeal region. In the same way the thyroid cancer spread to laryngopharyngeal region also mainly by direct infiltration of the tumor.
Aim
To present a rare case of hypopharyngeal cancer (typical for men aged 55–70 years with a history of tobacco use and/or alcohol ingestion) in a relative young female patient with nodular goiter as first symptom.
Case report
A 48 years old woman with dysphagia and throat pain for past 4 months presented at clinical examination a large goiter (nodules over 2 cm in size in both lobes). Neck ultrasound outlines two round thyroid nodule (one for each lobe) situated in the superior poles close to the thyroid capsule: ACR TI-RADS score 5 points. The indirect laryngoscopy described total left and partial right vocal cord paralysis and computer tomography investigation revealed massive hypopharynx infiltration. Due to the ACR TI-RADS score, a fine needle aspiration biopsy from both thyroid nodules was performed and the histological result displayed only squamous cells with no thyreocites. Hypopharynx biopsy confirmed squamous cell carcinoma and the patient underwent tracheostomy and enteral feeding due to the important and rapid local obstruction. In addition she underwent palliative radiotherapy and chemotherapy.
Conclusion
Thyroid gland involvement is not common in hypopharyngeal squamous cell carcinoma. Cases that involved the post-cricoid area, subglottic extension, extralaryngeal spread are associated with a higher risk of thyroid gland invasion. The particularity of our case consist in the presence of hypopharyngeal cancer in a relativ young female alredy with local metastases in the thyroid gland. Besides the two options: thyroid cancer with hypopharyngeal infiltration or hypopharyngeal carcinoma with thyroid metastasis a third hypothesis would have been plausible: papillary thyroid cancer coexisting with squamous cell carcinoma of the upper aerodigestive tract.

Anaplastic thyroid carcinoma: About 6 cases

Mohamed Masmoudi, Mehdi Hasnaoui, Malika El Omri, Wadii Thabet, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital mahdia, ENT department, Tunisia

Introduction
Anaplastic thyroid carcinoma also known as undifferentiated carcinoma is a rare and highly aggressive malignant tumor. It continues to rank as one of the deadliest diseases worldwide and carries a very poor prognosis. It is an aggressive locoregional disease with a high metastatic capacity. There is no agreement with regards to the best treatment.
Material and methods
We reporteded 6 cases of anaplastic thyroid carcinomas treated in the ENT department of Tahar Sfar Hospital in Mahdia. Clinical manifestations and treatments were analysed during a period of 26 years (1996–2018).
Results
The median age was 65 ranging from 47 years to 78 years. Females were more affected, 5 cases occurred in women and one male. The common manifestation was neck enlargement which is associated to hoarseness in two cases. Duration before diagnosis ranged from 4 weeks to 20 weeks with an average of 14 weeks. ALL the cases had lymph node metastases, 4 cases had trachea invasion, 4 cases had subhyoid muscle invasion. One patient had bone metastasis. Histological findings were consistent with the diagnosis of anaplastic carcinoma. Histological examination was performed in total thyroidectomy specimens in 2 cases, and in a microbiopsy of the thyroid gland in 4 cases. A tracheostomy was performed for 3 cases. Four patients underwent total thyroidectomy and 2 patients had inoperable cancer. All patients received Radiation Therapy. All the *patients died within* the follow-up period of 11 months (ranged from 8 to 13 months).
Conclusion
Complete surgical resection is associated with better survival but is very difficult to achieve due to aggressive biological behaviour. Multimodal therapy is associated with better survival and a better quality of life. There is a need for more effective systemic treatments as extensive surgical resections have little overall benefit in highly invasive and metastatic disease.

Medullary thyroid cancer, papillary thyroid microcarcinoma and Sarcoidosis: a curious association

Wafa Benothman, Amani Salah, Maha Kacem, Amel Maaroufi, Asma Ben Abdelkrim, Ghada Saad, Yosra Hasni, Molka Chaeib & Koussay Ach
Farhat Hached Hospital, Endocrinology, Sousse, Tunisia

Introduction
Medullary thyroid carcinoma (MTC) represents 3–10% of all thyroid cancer. The presence of papillary thyroid microcarcinoma (mPTC) in patients undergoing thyroidectomy for multinodular goiter has been reported as 3–7%. The occurrence of multiple thyroid cancers of different origin in one individual patient is a rare event. We report the case of synchronous papillary and medullary thyroid cancer developed in heterogynous recurrent goiter of a patient with sarcoidosis.
Observation
A 68-year-old female patient was followed up in our endocrinology department for a heterogynous recurrent goiter for 7 years. The biggest nodule measured 10 mm and was assessed as EU-TIRADS 3. She reported a history of a thyroid nodule(s) operation 2 decades ago and a cutaneous and pulmonary sarcoidosis 5 years ago. Due to a recent size increase of the left thyroid nodule, becoming in EU-TIRADS 4 class, a fine needle aspiration (FNA) and plasma calcitonin (PC) were indicated. Although the cytology exam was benin, high PC levels were noted (266 and 803 ng/l). A second FBA classified the nodule as Bethesda 4. MTC was highly suspected as calcitonin in FNA biopsy and plasma carcinoembryonic antigen (CEA) were elevated (2000 ng/l and ng/ml, respectively). We could not find any sign of an accompanying multiple endocrine neoplasia syndromes and the metastatic work-up was negative. A total thyroidectomy and bilateral mediastino-recurrent lymph node dissection were performed. The anatomopathological study disclosed a MTC and a mPTC. The PC and CEA were normal postoperatively.
Conclusion
The particularity of our case are, besides the simultaneous coexistence of 2 types of thyroid cancer, their slow evolution and their nonmetastatic invasion. The carcinogenic transformation can be due to a potential neoplastic sarcoidosis effect. Further investigations are needed in order to understand and validate the pathogenetic link between sarcoidosis and thyroid neoplasia.

Can platelet and neutrophil to lymphocyte ratios be used as predictive markers for malignancy in thyroidectomy patients?

Oana Stefana Enache[1], Sorina Martin[1,2], Theodor Mustata[2], Oana Ion[3], Andreea Chifulescu[4], Ovidiu Parfeni[1], Anca Sirbu[1,2], Carmen Barbu[1,2], Cosmin Giulea[5,6], Adrian Miron[5,6], Florin Andrei[7] & Simona Fica[1,2]
[1]Elias Hospital, Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [3]Fundeni Clinical Institute, Nephrology, Bucharest, Romania; [4]Fundeni Clinical Institute, Gastroenterology, Bucharest, Romania; [5]Carol Davila University of Medicine and Pharmacy, Surgery, Bucharest, Romania; [6]Elias Hospital, Surgery, Bucharest, Romania; [7]Elias Hospital, Pathology, Bucharest, Romania

Objectives
In recent studies, neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) are being investigated as prognostic and diagnostic markers for many malignancies, including thyroid cancer. The aim of our study was to investigate if a relationship exists between NLR and PLR and thyroid cancer.
Materials and methods
We retrospectively analysed the files of 953 patients who underwent thyroidectomy in our surgery department between January 2012 – December 2017. In the study were included 205 patients with differentiated thyroid carcinoma (DTC) and 108 age- and gender-matched patients with benign thyroid pathology. Anthropometric, biologic and imagistic data, indication of thyroid surgery, surgical procedures and pathology results were recorded.
Results
Age at diagnosis was 52.06±13.22 years for DTC patients (83.4% women) and 52.07±12.902 years for patients with benign thyroid pathology (83.3% women). Before surgery, NLR and PLR were similar in both groups (2.40±1.03 in the DTC patients vs 2.41±1.38 in benign pathology patients, $P=0.958$, respectively 137.6±47.29 vs 130.69±44.22, $P=0.209$). Younger DTC patients had significantly higher PLR than those with benign pathology (under 45 years: 145.79±49.67 vs 45 years and older: 116.50±34.26, $P=0.006$; under 55 years: 142±47.97 vs 55 years and older: 125.30±42.26, $P=0.030$). In the DTC group, men had significantly higher NLR compared to women (2.75±1.10 vs 2.33±1, $P=0.029$). Post surgery, NLR was 2.65±1.37 vs 2.17±0.89 ($P=0.063$), while PLR was significantly higher in the DTC group than in the benign pathology group (147.96±54.47 vs 125.05±34.95, $P=0.025$).
Conclusions
In our study, men with DTC had higher NLR than women, while PLR was higher in the cancer group, but statistical significance was obtained only for younger patients (< 45 and<55 years) before surgery and after surgery for all DTC patients compared to benign pathology group. This could be explained by the changes in immunity that appear with aging, but the relationship between NLR and PLR and thyroid cancer needs to be further investigated.

Clustering techniques for thyroid nodules malignancy inference in the era of personalized medicine

Andrea Giani[1], Patricia Borges de Souza[2], Stefania Bartoletti[1], Flavio Morselli[1], Andrea Conti[1] & Maria Chiara Zatelli[2]
[1]University of Ferrara, Wireless Communication & Localization Networks Laboratory, Department of Engineering, Italy; [2]University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Italy

Introduction
Thyroid nodules (TN) are common entities usually discovered during a physical exam or by chance with ultrasound (US) procedures performed for reasons different from thyroid check. The majority of nodules are benign, notwithstanding the growing incidence of thyroid cancer (TC), which increases much largely as compared to all other tumours each year and will be, presumably, the most incident malignancy in women after breast cancer. The clinical challenge relies on the accurate identification of malignant nodules needing attention since the very beginning of the diagnostic process from nodules that will follow an indolent course of disease. Therefore, pre-surgical assessment of TN should improve in order to advance into the era of personalized medicine and identify the best way to manage what has been defined as a 'tsunami of thyroid nodules'.
Aims
The present study has focused on the development of an algorithm capable of inferring TN state of malignancy in order to improve patient' management and avoid inappropriate use of diagnostic procedures.
Materials and methods
Information regarding epidemiological, clinical, biochemical, ultrasound, molecular and cytological data of over 12.000 TN with known histological diagnosis was collected and analyzed with Machine Learning techniques. Specifically, TN were grouped into clusters with similar characteristics using partition clustering algorithms such as K-means e K-medoids, being the latter more flexible to outliers deviations.
Results
The designed algorithm was able to accurately identify malignant and benign TN showing malignant and benign US characteristics, respectively, confirming US high predictability for these categories. Moreover, the majority of TN belonging to malignant or suspected malignant cytological classes showed malignant histology.
Discussion
Our algorithm did not achieve the capability of inferring TN malignancy belonging to the grey zone of indeterminate nodules, where US and/or cytology are not accurate enough. However, it was able to confirm that US is essential since it provides the majority of information and is highly predictive for benign TN and for TN having a cytological diagnosis associated to US characteristics highly suspicious of malignancy. In conclusion, the mathematical model built herein brings insight for future tools that could be used to improve TN management and estimate malignancy probability that underlies the discovery of a TN.

Prognostic factor of medullary thyroid carcinoma: Experience of one endocrine center

Andrey Kvachenyuk
Institute Endocrinology and Metabolism, Endocrine Surgery, Kiev, Ukraine

Based on the medical records of 311 patients with medullary thyroid carcinoma (MTC) treated in the period 1979–2018, using the Kaplan-Meier method, it was found that the sporadic form and male patients are negative predictors of disease. Other is essential for patients with sporadic form of MTC, because sex has no prognostic value in patients with hereditary forms of the disease. The presence of metastases in regional lymph nodes or distant metastases is a poor prognostic factor and analyzes the significance of the severity of the disease showed that patients belonging to the male sex are also a negative factor on prediction. In determining surgical treatment is necessary to consider the size of the tumor: the presence of carcinoma larger than 2 cm (even proved the absence of metastasis) increases mortality and reduces the survival of patients with MTC. In order to determine the need for prophylactic lateral neck lymph node dissection in patients with MTC with tumors of various sizes a retrospective analysis of the incidence of recurrence and mortality of patients depending on the amount of surgery. The study confirmed the idea that dominates the literature regarding mandatory extrafascial thyroidectomy even for tumors less than 2 cm. When the thyroidectomy and lateral (unilateral or bilateral), the frequency of neck dissection lymph node recurrence and mortality of patients were very high, due to frequent metastasis primarily in the central compartment lymph nodes neck. Rate of recurrence and mortality in patients after an isolated central dissection is low, and all cases of complications or death focused exclusively on patients with tumors larger than 2 cm. In case of the combined thyroidectomy and central and lateral lymph node dissection also observed a small amount of recurrence and death in patients: they were significantly lower compared to the group of patients who underwent thyroidectomy and lateral neck dissection, and is comparable with the group of patients who underwent central neck lymph node dissection. This is most clearly observed in the group of patients with tumors up to 2 cm. Based on the analysis concluded that the MTC larger than 2 cm, even in the absence of lymph node metastasis (from a survey of methods of topical diagnosis) is appropriate in conjunction with thyroidectomy and central spending also bilateral lymphadenectomy.

Mixed medullary-papillary thyroid carcinoma with mixed lymph node metastases

Vanessa Guerreiro[1], Cláudia Costa[2], Joana Oliveira[2], Ana Paula Santos[2], Mónica Farinha[3], Paula Freitas[1] & Isabel Torres[2]
[1]Centro Hospitalar Universistário de São João, Serviço de Endocrinologia, Diabetes e Metabolismo, Porto, Portugal; [2]Instituto Português de Oncologia do Porto Francisco Gentil, Serviço de Endocrinologia, Porto, Portugal; [3]Instituto Português de Oncologia do Porto Francisco Gentil, Serviço de Anatomia Patológica, Porto, Portugal

Introduction
Medullary thyroid carcinoma (MTC) and papillary thyroid carcinoma (PTC) are two distinct neoplasms originating from follicular and parafolicular-C cells, respectively. These pathologies have always been considered different from each other in terms of their incidence, their cell origin and their histopathological features. Concurrent occurrence of MTC and PTC in the same patient is an unusual event and its occurrence as true mixed medullary-follicular-derived carcinomas is extremely rare.
Case report
We are presenting a case of 60-year-old man, with history of atrial fibrillation who was referred to an endocrinology consultation after diagnosis of thyroid nodules on cervical ultrasound. At neck examination, thyroid was palpable, without palpable thyroid nodules or cervical adenopathy. Ultrasonographically, a solid nodule with 22 mm (the largest dimension) located in the left lobe (in a multinodular thyroid gland) with irregular margins and microcalcifications; supraclavicular suspicious adenopathy was also noticed. The fine-needle aspiration (FNA) of the thyroid nodule suggested the possibility of medullary carcinoma. FNA of the supraclavicular adenopathy was compatible with medullary carcinoma metastasis. The serum calcitonin thus performed was elevated (428.5 pg/ml; NL: < 14.3), with normal urinary normetanephrines and metanephrines. Patient underwent total thyroidectomy with regional cervical lymph node excision. Histopathologically, the diagnosis of mixed medullary-papillary carcinoma of the thyroid was made, with papillary and medullary component metastases in 12 of the 38 isolated lymph nodes in left region and 8 of the 10 isolated lymph nodes at central region. He underwent ablative treatment with I131 and awaits Genetic consultation.
Conclusion
Mixed medullary-follicular-derived carcinomas are a very rare event in clinical practice, and there is a constant debate whether this event should be considered coincidental or rather the result of a common genetic alteration. It is of extremely importance to make the correct diagnosis due to its prognostic and treatment implications. For papillary thyroid carcinoma, radioactive iodine therapy and TSH suppression therapy may be recommended; the treatment of medullary thyroid carcinoma is essentially based on a radical surgical approach, requiring only levothyroxine replacement therapy. The genetic study of these patients is also pertinent to exclude multiple endocrine neoplasia type 2.

Relationship between basal thyroglobuline level before radioiodine treatment and therapeutic response in differentiated thyroid carcinoma

Marta Toni García, Javier García Torres, Joaquín de Carlos, Juan Manuel Zubiría, Ander Ernaga, Patricia Munarriz Alcuaz, Javier Pineda Arribas & Emma Anda
Complejo Hospitalario Navarra, Endocrinología, Pamplona, Spain

Objectives
We studied whether the postoperative serum thyroglobulin (TG) basal levels before treatment with I131 (baseline TG) could be related with the response to treatment. We consider the excellent response as the absence of clinical, biochemical disease (undetectable TG and anti-thyroglobulin antibodies AcTG negative) and/or structural disease.
Material and methods
This is an observational study that includes 100 patients with differentiated thyroid carcinoma (CDT) who underwen total thyroidectomy and radioiodine therapy as initial treatment, during 2017 and 2018 in our center, with a minimum follow-up of 12 months. Clinical, radiological and biochemical data have been analyzed during the administration of I131 (after rhTSH stimulation) and in the follow-up (at 3, 6 and 12 months).
Results
It is a cohort of 100 patients (74% women) with an average age of 50.9 (range 23–82) years. Total thyroidectomy was performed in 56% and 44% required lymphadenectomy. 38% of patients diagnosed with Ac antiTg at diagnosis. The most frequent histology in our sample was papillary carcinoma (87%). The TNM classification is: stage 1: 75%, stage 2: 17%, stage 3: 5% and stage 4: 3%. According to the ATA classification, 41% of patients present a low risk of recurrence, 27% an intermediate risk and 22% a high risk. The average mean Tg level in patients with negative AcTg was 10 ng/ml. The 83% of these patients showed an excellent response to treatment, 12 months after treatment. They all presented a baseline TG equal to or less than 3.3 ng/l.
Conclusion
In our study, presenting a baseline TG value greater than 3.3 ng/ml implies an absence of excellent response one year after treatment with I131.

EP449

Esophageal perforation due to thyroid lymphoma

Panagiotis Anagnostis[1], Konstantina Vaitsi[1], Keraso Tzelepi[2] & Efstratios Kalaitzis[2]
[1]Department of Endocrinology, Police Medical Center of Thessaloniki, Thessaloniki, Greece; [2]Panorama Surgery Center, 'Aghios Loukas' Hospital, Thessaloniki, Greece

Introduction
Primary thyroid lymphoma (PTL) represents about 1–5% of thyroid malignancies and < 2% of extra-nodal lymphoma. The most common subtype is diffuse large B-cell lymphoma (DLBCL) (~ 50% of cases), followed by mucosa-associated lymphoid tissue (MALT) lymphoma, both non-Hodgkin' lymphomas. sophageal perforation is a very rare complication during the course of PTL, characterized by poor prognosis.
Case presentation
A 65-year-old Caucasian woman was admitted to our department due to anterior neck enlargement and compressive symptomatology (dysphagia and hoarseness) during the preceding two months. Her medical history was remarkable for rheumatoid arthritis, treated with methotrexate. On physical examination, she had a stiff, non-tender and diffuse goitre. Thyroid ultrasound showed a heterogeneous sub-sternal goitre, including a 34 mm hypoechoic nodule of irregular margins, in the middle of right thyroid lobe. Fine-needle-aspiration (FNA) biopsy was inconclusive (Bethesda III). A computerized tomography (CT) scan showed severe trachea compression, esophageal dilatation and air bubbles in the surrounding structures (Panel A, arrow). The patient' swallowing capacity was progressively deteriorating and, subsequently, she underwent a total thyroidectomy, which revealed esophageal perforation (Panel B, arrow). Histological diagnosis was compatible with large B-cell thyroid lymphoma of high malignancy grade, in the right lobe. The patient was transferred to the intensive care unit, but she developed acute renal failure and repeated respiratory infections, with a progressive thrombocytopenia and normocytic anemia. Bone marrow biopsy showed infiltration by lymphoma cells, but chemotherapy was not feasible due to the patient' clinical state. She died one month later.

EP450

Total thyroidectomy can still remain the method of choice in some Bethesda III FNAB cases

Jindrich Lukas
Na Homolce Hospital, Prague, Department of Otolaryngology and Head and Neck Surgery, Praha, Czech Republic

Background
Nonivasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) and hyalinizing trabecular tumor (HTT) are a rare follicular- derived thyroid neoplasmas with indolent clinical behavior. These tumors are encapsulated or clearly delimited and distinguished by detail using histopathological criteria.

Method
Description of two cases of these rarer tumors, classified on FNAB Bethesda III AUS/FLUS in the BSRTC 2017 and diagnosed after total thyroidectomy. Results. Two cases of classified Bethesda III with ultrasonography guided FNAB were investigated using molecular genetic methods and histopathology verification: In a 61-year-old man following the category Bethesda III system histopathology investigation detected nonivasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTPs) in the terrain of polynodous nodular goitre. There was only minimum of colloid in the microfolliculles but nuclei were slightly enlarged, non-round and ovrlapping. Molecular genetic investigation found c.182A>G p.(Gln61Arg) in the exon 3. somatic mutation of the gene *NRAS*. In a second patient, a 48-year-old man solitary isthmic nodule classified Bethesda III. The postoperative histological finding expressed suspicion of medullary carcinoma. But angioinvasion was not shown and amyloid staining was negative. Supervision by an experienced thyroid pathologist was required. Immunohistochemistry: calcitonin, CEA- negative; thyroglobulin TTF1-positive, NES dispersive positive. Ki-67 unique pattern of membranous positivity characterizing hyalinizing trabecular tumour. (HTT). Molecular genetic analysis c.394G>Ap.(Glu132Lys) in the exon 4. somatic mutation of the gene *NRAS*. Conclusions. In these two rarer tumours with Bethesda III diagnosis total thyroidectomy was chosen as the best option due to risk of possible multifocal involvement in the terrain of nodular goitre, age and male sex with a longer duration and size progression of the nodules. In case of postoperative histological finding of thyroid malignancy, completion thyroidectomy bears higher risk of postoperative complications and the patient is exposed to greater psychological stress.

EP451

When levothyroxine is not enough- combination therapy with liothyronine

David Veríssimo[1,2], Luís Reis de Almeida[2], Manuel Monteiro[2] & Luís Dias[2]
[1]Armed Forces Hospital, Department of Endocrinology, Lisboa, Portugal; [2]Hospital de São José, Department of Medicine 1.2, Lisboa, Portugal

Introduction
The treatment of central hypothyroidism with a combination of levothyroxine (T4) and liothyronine (T3) is not recommended for most patients since it does not show an advantage over T4L monotherapy. However, in certain patients who remain symptomatic under replacement therapy with T4L and thyroid stimulating hormone (TSH) within the reference values, combined treatment with T4 and T3 can be tested.
Clinical case
Male, 39 years old, medical history of craniopharyngioma, submitted to surgical intervention with subsequent panhypopituitarism. Medicated with 125 mg levothyroxine, 10 mg hydrocortisone, 0.12 mg desmopressin and monthly dose of testosterone. The patient was admitted for septic shock due to Klebsiella pneumoniae cellulitis, aggravated by pyelonephritis due to Morganella morganni, with acute kidney injury and metabolic acidemia, requiring aminergic support and non-invasive ventilation, being submitted to several cycles of antibiotic therapy. Despite the reversal of the infectious condition and improvement in renal function, the patient remained in comatose state, hypotensive (89–65 mmHg), bradycardic (51bpm) and hypothermic (33.4ºC). Blood test showed hyponatremia (130 mEq), normoglycemia (78 mg/dl), free T4 within the reference values (1.10 ng/dl), but with non-dosable free T3, despite 40 days of 150 mg levothyroxine therapy. A deficient conversion of T4 to T3 was assumed and treatment with 75 mg of T3 was started, showing a remarkable improvement in consciousness after 1 day of therapy and normalization of temperature (37.2ºC), blood pressure (112–60 mmHg) and heart rate (60bpm) after 3 days, having gradually discontinued liothyronine. At the date of suspension with 1.52 ng/dl of free T4 and 2,72 pg/ml of free T3.
Discussion
The patient presented hypothyroidism decompensation secondary to sepsis. Initially, the patient' recovery was expected after normalization of the clinical status and normalization of T4 levels. However, the patient maintained a weakened clinical condition, disagreeing with the analytical data, so a combination of thyroid hormone therapy was implemented. This combination therapy should be performed under close monitoring, given the potency of T3 (3 times more potent than T4). The present case highlights that in patients with severe hypothyroidism, including coma, with poor response to T4 replacement, the combination with T3 may be useful, although not recommended.

Ectopic thyroid nodules: Unusual localization

Rihab Laamouri[1], Ben Nacef Ibtissem[1], Boudaya Mohamed Sadok[2], Rojbi Imen[1] & Khiari Karima[1]
[1]Charles Nicole Hospital, Endocrinology, Tunisia; [2]Charles Nicole Hospital, General Surgery A21, Tunisia

Introduction
Thyroid ectopy is uncommon pathology. The lingual area is the most frequent localization. The medaistinal localization is rare. We report in this article two cases illustrating this location.
1st clinical case
66-year-old woman operated on for benign breast cysts consulted for progressive chest pain. The clinical examination was without abnormalities. The standard biological assessment was normal. Cervicothoracic CT scan showed two heterogeneous enhancement tissue mediastinal masses, a heterogeneous thyroid gland of normal volume. The surgical procedure consisted of a thymectomy and the anatomopathological study concluded to an intra-thymic ectopic thyroid adenoma.
2nd clinical case
57-year-old woman consulted for a chronic cough. No anomaly objectified at the clinical examination. The biological assessment including thyroid was normal. The CT scan showed formation of the cervicothoracic orifice whose density evoked a thyroid or parathyroid nodule. The mass was excised and the antomopathological study found a thyroid parenchyma with no signs of malignancy.
Comments and conclusion
Transcription factor mutations are implicated in thyroid ectopy. Several locations have been described. The mediastinal localization is exceptional. The presence of a eutopic thyroid is frequently associated with the mediastinal location of ectopia. Clinical-biological euthyroidism is as well. Therapeutically, surgery may be indicated in dyspnoea or other disabling symptoms.

Epidemiological aspects of medullary thyroid cancer as a component of multiple endocrine neoplasia type 2 in the Republic of Belarus

Yuliya Dydyshka[1], Alla Shepelkevich[1], Victor Kondratovich[2], Tatiana Leonova[2], Anna Portyanko[3], Alena Subach[3], Alexandra Sosedkova[2], Alena Yurenia[4], Tatsiana Chakhovich[3] & Sergey Smirnov[3]
[1]Belarusian State Medical University, Endocrinology Department, Belarus; [2]Public Health Institution Minsk City Clinical Oncologic Dispensary, Belarus; [3]N.N. Alexandrov National Cancer Centre of Belarus, National Molecular Genetics Centre of Cancer Research, Belarus; [4]Minsk Endocrinology Medical Center, Belarus

Multiple endocrine neoplasia type 2 (MEN2) is a hereditary condition with an autosomal dominant type of inheritance. It is evident that MEN2 is characterized by the presence of Medullary Thyroid Cancer (MTC) as a permanent symptom, the combination of which with pheochromocytoma and parathyroid syndrome is referred to as MEN-2A syndrome. The aim of our study was the creation of a database of patients with MTC and analysis of the data.
Materials and methods
The study is carried out in the framework of the State Program 'Oncological diseases' on the task 'To develop and implement effective technologies for the diagnostic detection and observation of patients with multiple endocrine neoplasia type 2A'. The selection of participants for inclusion was carried out from the Cancer Register of the Republic of Belarus and the medical documentation of the Republican Center for Thyroid Tumors. Patient' data from 1987 to 12/31/2019 were included.
Results
A database of patients with MTC has been compiled containing information on 591 patients, of which 183 patients died. Currently included 420 (71.1%) women and 171 (28.9%) men. The average age at the moment of diagnosis was 53.1 (43.2–61.8) years; 53.2 (43.7–62.6) years for women

and 52.5 (41.6–59.4) for men ($U=32944$, $P=0.115$). Significant differences in age weren't found among men and women. 76.1% patients (450 people) lived in the city and 23.9% – (141 people) in the countryside. The second tumor was discovered in 7.8% patients (46 people). Based on gender, 8.8% (37 people) of women and 5.3% (9 people) of men had the second tumor ($\chi^2=2.13$, $P=0.145$). A concomitant endocrine tumor was present in 1.7% patients (10 people); 1.4% of women (6 people) and 2.35% of men (4 people) ($F=0.61$ $P=0.433$). *Retrospective died patient' data analysis (183 patients).* Life expectancy after diagnosis was 4.5 (1.4–9.5) years. In a woman (108 people) 4.9 (1.2–10.2) years and in men (75 people) 4.1 (1.5–7.8) years no significant differences were found ($U=3746.5$ $P=0.389$). 18.6% patients (34 people) died within 1 year, 19.7% patients (35 people) lived for more than 10 years. Five-year survival rate is 44.6% (79 patients).

Conclusions

Medullary thyroid cancer is more common in women, the average life expectancy after diagnosis is 4.5 years. A concomitant tumor in 7.8% of patients requires genetic verification of the MEN.

Features of the radical treatment of medullary thyroid cancer in the republic of belarus

Yuliya Dydyshka[1], Alla Shepelkevich[2], Victor Kondratovich[3], Tatiana Leonova[3], Alexandra Sosedkova[3], Anna Portyanko[4], Alena Subach[4], Tatsiana Chakhovich[4], Sergey Smirnov[4] & Alena Yurenia[5]

[1]Belarusian State Medical University, Endocrinology Department, Belarus; [2]Belarusian State Medical University, Belarus; [3]Public Health Institution Minsk City Clinical Oncologic Dispensary, Belarus; [4]N.N. Alexandrov National Cancer Centre of Belarus, Belarus; [5]Minsk Endocrinology Medical Center, Belarus

The medical and social significance of the Multiple Endocrine Neoplasia type 2 (MEN2) is due to the severity of the manifestations of the disease components, namely the tumor process progression, a high risk of vascular accidents, pathological fractures of the femoral neck/spine, gastrointestinal bleeding, chronic renal failure. Late detection of pathology is associated with high mortality due to medullary thyroid cancer (MTC). Thus, the aim of the study was to establish the characteristics of the clinical course and management of patients with MTC.

Materials and methods

The study is carried out within the framework of the State Program 'Oncological diseases' on the task 'To develop and implement effective technologies for the diagnostic detection and observation of patients with multiple endocrine neoplasia type 2A'. A retrospective analysis of patient data from 1987 to December 31, 2019 was performed. The information was obtained from the Cancer Register of the Republic of Belarus and the medical documentation of the Republican Center for Thyroid Tumors.

Results

A database of patients with MTC has been compiled containing information on 591 patients, of which 183 patients died. Currently included 420 (71.1%) women and 171 (28.9%) men. The average age at the time of diagnosis is 53.1 (43.2–61.8) years; 53.2 (43.7–62.6) years for women and 52.5 (41.6–59.4) for men ($U=32944$, $P=0.115$). In general, 95.6% of cases (565 people) underwent surgical treatment, 32.9% (195 people) radiation therapy and 25.9% (153 people) chemotherapy. Given the severity of the disease and the progression of the tumor process, 14.7% of patients (87 people) had combined surgical, chemotherapeutic and radiation treatments. 10.0% of patients (59 people) were operated and had chemotherapy, 17.2% of patients (102 people) had combined treatment – surgical and radiation therapy. Only surgical treatment was performed in 53.6% (317 patients). Less than one percent had only chemotherapy (4 people), only radiation therapy (3 people), complex radiation and chemotherapy treatment. 16 patients (2.7%) didn't receive radical therapy. In this group the average life expectancy after diagnosis was 0.3 (0.7–0.03) years.

Conclusions

In the Republic of Belarus, surgical treatment is the preferred method for the radical treatment of medullary thyroid cancer. However, a high percentage of combined treatment requires optimization of the early diagnosis of medullary thyroid cancer.

EP455

Features of thyroid state in patients with type 1 diabetes and chronic kidney disease receiving renal replacement therapy

Alena Sazonava[1,2], Tatiana Mokhort[1] & Natalia Karlovich[1,2]

[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Republican Center for Medical Rehabilitation and Balneotherapy, Endocrinology, Minsk, Belarus

Aims

Thyroid function changes are common endocrine disturbance among patients with chronic kidney disease (CKD), including those receiving renal replacement therapy (RRT). The purpose of the study was to study the effect of RRT on thyroid function in patients with type 1 diabetes (T1D).

Materials and methods

Thyroid hormone examination was performed before and after hemodialysis procedures (HD) in 9 patients with T1D (3 men and 6 women). Mean age was 41.21±11.09 yrs, duration of T1D was 28.17±9.64 yrs, duration of CKD was 12.98 (4.41–14.98) yrs. The terms of receiving RRT were 16.8 (8.25–59.34) months. There was a marked decompensation of T1D (HBA1s 8.28±1.57%). Nonparametric statistical methods were used. A P-value <0.05 was considered significant.

Results

TSH levels were higher after HD, but not statistically significant. FT4 levels before the HD procedure were low normal 12.25 (11.38–13.0) pmol/l and significantly increased towards normalization after HD 15.66 (13.59–16.22). FT3 levels before HD were low 3.75 (3.54–3.83) pmol/l and significantly increased after the HD procedure 4.00 (3.82–4.60), however, stayed in low normal range. Before HD 78% patients had low FT3 and 33% low FT4, changing after HD to 33% of low FT3 to and 11%. FT4. Patients differed by AbTPO (54.51 (12.05–74.74) IU/l vs 19.10 (8.61–55.62). TG was significantly lower after HD (10.37 (6.87–30.84) ng/ml vs 9.71 (5.66–32.68). Despite the fact that the levels of AbTG significantly decreased after HD159.02 (25.11–336.35) IU/l vs 156.80 (51.59–352.90), its median values remained in the diagnostic interval confirming the presence of autoimmunity. Ab-R-TSH were lower after HD (0.3 (0.30–0.65) IU/l vs 0.30 (0.30–0.30). No relationship between thyroid hormones and HbA1c in T1D patients with RRT, as well as between the duration of CKD and RRT with thyroid profile were noted. The age of T1D manifestation correlated with levels of FT3 ($\rho=0.493$), AbTPO ($\rho=-0.565$). Duration of T1D correlates with TG levels ($\rho=0.627$).

Conclusion

Revealed changes predetermine the need to assess serum levels of free fractions of peripheral thyroid hormones, as well as hormonal studies immediately after the HD procedure. Low levels of AbTSH-R confirms the absence of influence of autoimmunity on the genesis of thyroid disorders in patients with CKD and RRT.

EP456

Anxiety disorders in patients with autoimmune thyroiditis

Iuliia Onofriichuk[1] & Maksym Prystupiuk[2]

[1]Kyiv City Clinical Hospital #4, Kyiv, Ukraine; [2]Bogomolets NMU, Kyiv, Ukraine

To date, up to 35% of the young population (25–60 years) in developed countries are subject to anxiety disorders. The use of anti-anxiety agents in clinical practice does not always lead to a lasting effect. The study included patients who initially consulted a neurologist or psychotherapist. With panic attacks. On the Anxiety and Depression Rating Scale (HADS), all patients received 11 points or more. The use of anti-anxiety drugs gave a short-term effect with subsequent deterioration. The study group included 76 patients with anxiety disorders, men-29 (age 33.9 years), women-47 (age 31.7 years). The whole patient an ultrasound of the thyroid gland; to assess the state of thyroid function, the levels of thyroid-stimulating hormone, free T3 and T4 in serum were studied. In all patients, titers of antibodies to tyrnoglobulin and to thyroid peroxidase were determined. According to the results of ultrasound, it was revealed that the total thyroid gland in 55 (72%) patients was within the age norm, in 21 (28%) patients it exceeded the norm by no more than 20%. In 71 (95%) patients, an increase in the intensity of blood flow in the gland was recorded. According to laboratory results, 76 (100%) patients had free T3 (2.5–4.3 pg/ml) and free T4 (0.93–1.7 ng/dl), which is an indicator of the norm. The level of TSH in 44 (58%) patients was within the normal range (0.4–4.0 μMU/ml) and in 32 (42%) it was

within the range of 4.1–6.5 μMU/ml. Tiroglobulin was normal in all patients. All patients had anti-TPO (35–1000 IU/ml). Patients with increased blood flow in the gland, but with normal TSH, 39 (44%) people were prescribed NSAID (ibuprofen 200 mg) twice a day for 14 days. NSAID (ibuprofen 200 mg) twice a day for 14 days and thyroxine at a dosage of 25–50 μg were prescribed to patients with increased blood flow in the gland and increased TSH 32 (42%). for 8 weeks. After that, an ultrasound of the thyroid gland and laboratory tests were performed. During the control, the blood flow in the gland decreased in 60 (79%) patients. TSH levels normalized in 30 (39%) patients. With the HADS scale in 71 (95%) patients, the anxiety level ranged from 4–8, which is a normal indicator, while patients did not receive anti-anxiety drugs. All patients with anxiety disorders need to check the function of the thyroid gland, since its disorders can lead to psycho-emotional disorders.

The evaluation of hepcidin in patients with graves' disease

Aleksandra Hernik, Ewelina Szczepanek-Parulska, Dorota Filipowicz & Marek Ruchala
Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland

Introduction
Hepcidin is an acute-phase protein and a key regulator of iron homeostasis. Anemia frequently occurs in patients with hyperthyroidism, while hepcidin may be a potential link.
Objectives
Prospective evaluation of hepcidin serum concentration and other parameters related to Fe homeostasis in group of hyperthyroid patients in the course of Graves' disease (GD) at diagnosis and after restoration of euthyroidism.
Patients and methods
42 (32 women, 10 men) patients met inclusion criteria, aged 42.5±15.1 years. Clinical and biochemical assessment, including hepcidin measurement by ELISA method was performed at baseline (T0) and in remission state (T1). The follow-up was presented for 24 patients.
Results
Hepcidin concentration at T0 was significantly higher if compared to the value during euthyroidism [28.7 (8.1–39.4) ng/ml vs. 7.9 (4.3–12.9) ng/ml, $P<0.001$]. Hepcidin level most statistical significantly correlated with ferritin (rho=0.723) in women at T0. In both men [377 (171–411) vs. 165 (84–237) ng/ml, $P=0.001$] and women [84 (23–104) vs. 35 (16–64) ng/ml, $P=0.001$] a significant decrease in ferritin level was demonstrated following therapy.
Conclusions
Hepcidin level decreases significantly during transition from hyperthyroid state to euthyroidism in patients with GD. The observed changes occur presumably in parallel to iron homeostasis fluctuation, which is expressed by ferritin level decrease.

DOI: 10.1530/endoabs.70.EP457

Suspicious thyroid nodule in subacute thyroiditis

Ricardo Fonseca, Catarina Roque, Ana Germano, Raquel Sousa & Fernando Aldomiro
Hospital Fernando Fonseca, Amadora, Portugal

Background
Subacute thyroiditis is an inflammatory condition, most likely of viral origin, which typically presents wit low anterior neck pain, fever and transient thyrotoxicosis. Ultrasonography (US) usually shows a diffuse thyroid enlargement with ill-defined hypoechoic areas.
Case
A 55-year old women was admitted in the emergency room, with 2 weeks of anterior neck pain, cervical compressive symptoms of dysphagia, fever and palpitations. On physical examination a firm 4 cm neck anterior mass was palpable. Thyroid US showed a highly suspicious thyroid nodule in the isthmus/left lobe with 38 mm, apparent extrathyroidal extension, microcalcifications, with absence of intranodular flow in Doppler. A fine needle aspiration (FNA) was performed, with a benign result (follicular cells without nuclear atypia and macrophages). Laboratory results: TSH 0.01 mMUI/l (0.4–4.0), Free T4 3.19 ng/dl (0.93–1.70), Free T3 7.2 (2.0–4.4), erythrocyte sedimentation rate 110 mm (< 20), C-reactive protein (CRP) 26.1 mg/dl (< 20), Thyroid peroxidase antibody (TPO) and TRAb were negative. The patient was hospitalized, there wasn't other site of infection, and the Endocrinology department was contacted due to suspicion of Subacute Thyroiditis and discrepancy between US thyroid nodule description and FNA result. Thyroid scintigraphy wasn't performed due to recent contrast exposure (Neck Computed tomography). The patient was treated with Prednisolone with normalization of thyroid function, fever and apparent involution of thyroid nodule, with resolution of cervical compressive symptoms. After 3 months, Thyroid US showed a massive reduction of the thyroid nodule, with 12 mm, without the worrying aspects of first US. Transient hypothyroidism was noted without the need for Levothyroxine replacement, due to absence of symptoms, with normalization of thyroid function after 8 weeks.
Discussion
We present a case with an atypical presentation of Subacute Thyroiditis with a high suspicious 38 mm solitary nodule, with apparent extrathyroidal extension, mimicking thyroid malignancy. The presence of thyrotoxicosis and the symptoms of neck pain and fever were very suggestive of this disease, and after Prednisolone treatment, the thyroid nodule markedly reduced.

Variation of parameters of thyroid function during pregnancy

Violeta Mladenovic[1,2], Marija Andjelkovic[3,4], Zoran Gluvic[5,6] & Milena Mitrovic[7,8]
[1]Clinical Center «Kragujevac», Serbia, Center for Endocrinology, Diabetes and Metabolic Diseases, Kragujevac, Serbia; [2]2 Department of Internal Medicine, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia; [3]Faculty of Medical Sciences, University of Kragujevac, Serbia, Department of Biochemistry, Kragujevac, Serbia; [4]Clinical Center «Kragujevac», Serbia, Department of Laboratory Diagnostics, Kragujevac, Serbia; [5]School of Medicine, University of Belgrade, Serbia, Belgrade, Serbia; [6]Division of Internal Medicine, Department of Endocrinology, Zemun Clinical Hospital, Belgrade, Serbia; [7]Clinic for Endocrinology, Clinical Center Vojvodina, Novi Sad, Serbia, Novi Sad, Serbia; [8]Faculty of Medicine, University of Novi Sad, Serbia, Novi Sad, Serbia

Introduction
The basic characteristics of metabolism in pregnancy are changes from anabolic to catabolic conditions. During early gestation, the fetus is dependent on maternal thyroid hormones that cross the placenta. Thyroid disease in pregnancy is a common clinical problem, at least 2–3% of women have thyroid dysfunction. Pre-conceptual education and appropriate diagnosis and treatment of thyroid dysfunction in early pregnancy are of great importance, with the aim of preventing complications during pregnancy and offspring. In the first trimester, the 'normal' range for TSH is reduced to 0.1–2.5 mIU/l, and in the second and third trimester is 3.0 mIU/l.
Aim
The aim of this study is to analyse concentration of thyroid parameters and variations of thyroid function during pregnancy.
Matherial and methods
This study included 77 healthy pregnant women in the first trimester of pregnancy registered in the Center for endocrinology of Clinical Center Kragujevac. Blood samples were collected for fT4, TSH and TPOAb and measured by RIA method.
Results
The mean age of 77 patients was 30.8±4.7 years. The prevalence of autoimmune thyroid disease was 25.9% and positive family history for thyroid disorder was in 9%. When we excluded patients with disorders of glicoregulation, the average serum level for fT4 in first trimester was 10.68±2.16 pg/ml, for TSH was 2.09±1.11 mIU/l, the average serum level for fT4 in the second trimester was 7.58±2.11 pg/ml, for TSH was 2.59±1.47 mIU/l, and the average serum level for fT4 in the third trimester was 7.18±1.48 pg/ml, for TSH was 2.48±1.18 mIU/l. For the first time, we shown reference range for thyroid parameters in our population in trimesters:

parameter *(min-max)*	1. trimester	2. trimester	3. trimester
fT4 (pg/ml)	8.52–12.84	5.47–9.69	5.7–8.66
TSH (mIU/l)	0.98–3.2	1.12–4.06	1.3–3.66

Conclusion
It has been shown that as pregnancy progresses, the value of thyroid parameters decreases.
Keywords: thyroid function, pregnancy.

Volume changes of thyroid gland in Graves'disease after radioactive iodine treatment

Jitka Cepkova
The Univerzity Hospital in Hradec Kralove, 4th Internal clinic, Hradec Kralove, Czech Republic

Introduction
The study describes volume changes of thyroid gland in patients with Graves'disease (GD) after radioactive iodine treatment in the University hospital in Hradec Kralove.
Patients and methods
Retrospectively, we analyzed 66 patients with GD (57 women and 9 men, mean age 52±13.4 years). Volume of thyroid gland was measured before and 1 year after application of radioactive iodine.
Results
Total decrease of thyroid gland' volume was 56% ($P \leq 0.001$). For detailed analysis we divided our cohort into three subgroups according to the function status one year after treatment: 1. hypothyroidism ($n=39$), 2. euthyreoidism ($n=19$), 3. continues hyperthyroidism ($n=8$). The decrease of 69% ($P \leq 0.001$) was found in the first subgroup, of 58% ($P=0.003$) in the second subgoups and of 15% ($P=0.309$) in the third subgroup, respectively.
Conclusion
The successful therapy respond resulted into significant decrease of thyroid gland volume.

Università Cattolica del Sacro Cuore – Fondazione Policlinico Gemelli IRCCS, Endocrinology, Rome, Italy

Background
Immune checkpoint inhibitors (ICI), anticancer therapy blocking specific molecules expressed in tumor microenvironment, are associated to several endocrine side effects. In particular, the use of PD-1/PD-L1 inhibitors is related to a higher incidence of thyroid dysfunction. The most frequent form of thyrotoxicosis is a destructive thyroiditis, which can evolve into hypothyroidism.
Patient findings
We report the case of an 85 years-old patient, affected by metastatic melanoma and treated with Nivolumab, which experienced a severe ICI-related thyrotoxicosis. The diagnosis was complicated by a biochemical interference on thyroid hormones assay, probably induced by Nivolumab.
Summary
Laboratory examination performed before starting anticancer therapy showed normal thyroid function test. Few days after the second administration, the patient developed a severe thyrotoxicosis. According to destructive thyroiditis, in a short period TSH levels normalized and rapidly increased, but FT4 levels resulted inappropriately elevated. A possible analytical interference has been suspected: the sample has been analyzed with a different immunoassay, which confirmed a severe hypothyroidism with appropriately low FT4 levels. Furthermore, we processed the same blood sample after polyethylene glycol (PEG) 6000 precipitation to remove the macromolecules and after this evaluation, FT4 levels resulted appropriately low. Nine months after starting anticancer therapy, the patient stopped Nivolumab administration. Thyroid function tests performed one month later with the first immunoassay showed normal and appropriate FT4 levels.
Conclusions
The peculiarity of this case is represented by the possible biochemical interference of Nivolumab on FT4 immunoassay. In our hypothesis, Nivolumab should determinate interference on FT4 dosage by a mechanism similar to that reported for anti-FT4 autoantibodies. In our case, the interference detected with the one step immunoassay has not been confirmed using a two-step immunoassay. However, further studies will be necessary to prove the biochemical mechanisms which cause this interference.

Thyroid nodules during connective tissue diseases

Rihab Laamouri[1], Samar Derbal[2], Yousra Cherif[2], Jridi Mayssem[2], Ben Dahmene Fatma[2] & Abdallah Maya[2]
[1]University of Tunis Manar- Faculty of medecine, Tunisia; [2]Regional Hospital of Ben Arous, Internal Medecine, Tunis, Tunisia

Introduction
The association of thyroid nodules and connective tissue diseases (CTD) is not uncommon. The purpose of our work was to describe the clinical, biological and ultrasound characteristics of thyroid nodules during CTD.
Materials and methods
It was a retrospective study (2015–2019) including records of patients with CTD and thyroid nodule in an internal medicine department at Ben Arous regional hospital. Informations regarding thyroid function tests and imaging were recorded.
Results
We included eight female patients among patients presenting connective tissue disease (4% of connective tissue disease which are Sjôgren' Syndrom ($n=127$), Rheumatoid arthritis ($n=35$), Scleroderma ($n=17$), systemic lupus erythematosus ($n=22$) and inflammatory myositis ($n=4$)). The thyroid nodule was diagnosed at a mid age of 54 years old. The diagnosis of CTD and thyroid pathology was done concomitantly in four cases. Seven patients had Sjogren syndrome and one had rheumatoid arthritis. The circumstance of nodule discovery was accidental ($n=4$), in front of clinical thyroid dysfunction ($n=2$), biological thyroid dysfunction ($n=1$) and in another case the nodule was palpable. Four cases were associated with hypothyroidia while the rest patients were in a clinical and biological euthyroid state. Immunologic testing was performed in these four patients and thyroperoxidase antibodies were positive in one case. The diagnostic means was in all cases thyroid ultrasound. The number of nodules was an average of two. The size was less than one centimeter in half of the cases and exceeded one centimeter in the rest with a maximum size of 2.4 cm. The nodules were bilateral in one case, isthmic in another, lower site in the rest of patients. Two thirds of the cases were classified as Eutirads 3, one third as Eutirads 2. All nodules were monitored with a good evolution after 1.9 years follow-up.
Conclusion
Thyroid nodules are a common pathology. Their presence during CTD can be a manifestation of the disease or a simple association. Physiopathology is not yet clear. That' why it is necessary to search them in front of CTD so that we won't miss a nodule which can hide a carcinoma.

Radioiodine therapy outcome in patient with toxicmultinodular goiter with concomitant hereditary hasharon hemoglobinopathy

Dali Dzeytova[1], Stanislav SHklyaev[1], Pavel Rumyantsev[1], Marina Sheremeta[1], Alexey Trukhin[1], Nina Cvetaeva[2] & Evgenij kozhedub[1]
[1]Endocrinology Research Centre, Moscow, Russia, Moscow, Russian Federation; [2]National Research Center for Hematology, Moscow, Russian Federation, Moscow, Russian Federation

Aim/introduction
The main purpose of this work was to describe a clinical case of thyrotoxicosis with concomitant HASHARON hemoglobinopathy scrutinizing whether the latter could hinder radioiodine therapy (RIT).
Materials and methods
Patient H., 53 years old, diagnosed with moderate toxic diffuse multinodular goiter. Clinical manifestation of the disease were in summer 2018 (TSH – 0 mIU/ml). Medication with thyrozole (20 mg) was initiated. Thyrotoxicosis recurrence in case of discontinuation antithyroid drug therapy proved.

Instrumental methods of diagnostics was performed prior to RIT: ultrasound signs of nodular goiter (TIRADS 2) mixed with thyroiditis, thyroid volume – 8.6 ml; 99 mTc-pertechnetate scintigraphy shows increased thyroid uptake index – 2.7%. In 2000 patient was diagnosed with some unclear abnormal hemoglobin. Complete blood count was prescribed prior RIT: RBC 4.33 × 10 12/l, Hb 131 g/l, MCV 85 fl, RTC 1.04%; biochemical blood analysis: total bilirubin 24.2 μmol/l, bound 4.8 μmol/l, free 19.4 μmol/l, iron 10.2 μmol/l; according to ultrasound examination of the abdominal cavity and kidneys – no signs of pathology; hemoglobin electrophoresis revealed pathological HbS fraction of 17%. DNA diagnostics of the globin alpha chain genes showed the presence of the missense mutation (Asp47His) in the HBA2 gene, resulting in a heterozygous state, resulting in to the formation of abnormal hemoglobin Hb Hasharon. Thus, the diagnosis of hereditary hemoglobinopathy with the presence (17%) of unstable Hasharon hemoglobin in a heterozygous form was verified.
Results
02.07.2019, RIT with 131I activity of 400 MBq. RIT follow up: monthly monitoring of the level of TSH, free T3, free T4 as well as the levels of red blood cells, hemoglobin, total, indirect and direct bilirubin; the level of TRAb and ultrasound of the thyroid gland – after 3 and 6 months. Hypothyroidism was established at the end of 2 months after RIT. Over the entire observation period (6 months), the patient' condition remained satisfactory. There were no episodes of any anemia or significant increase in bilirubin level. Thus, no side effects after RIT were observed.
Conclusion
Clinical case illustrates the approach of patient' preparation prior to RIT and follow up after RIT in the presence of unstable hemoglobin Hasharon. Taking everything into consideration there is no influence on safety of RIT thyrotoxicosis in patients with similar hemoglobinopathies, however, it individual approach in each case can not be excluded.

EP464

Functional and autoimmune implications in a group of patients with chronic autoimmune thyroiditis associating periodontal disease

Circo Razvan, Ibadula Seila, Gosu Cristina, Scrinic Olesea & Circo Eduard
Clinical Emergency County Hospital Constanta, Romania, Endocrinology Department, Constanta, Romania

Introduction
Periodontal disease (PD) is a disease with infectious determinism, initiating inflammatory and autoimmune processes, in intricate evolutionary stages, affecting 10% to 60% of adults.
Objectives
Between chronic autoimmune thyroiditis (CAT) and PD there are observations regarding pathogenic interconditioning.
Material and method
Group 1 ($n=109$ patients) comprised 84 women and 25 men. The mean age was 36±9 years for women and 41±7 years for men. All patients had CAT and PD. Group 2 – was composed of 91 patients with PD, 62 women and 29 men, with an average age of 31±11 years for women and 43±12 years for men, without associated thyroid pathology.
Results
Monofactorial linear regression (Pearson' coefficient) tested the dependency ratios between the simplified oral hygiene index (OHI-S) and the parameters determined in the study group (Group 1): the age of the patients and the paraclinical characteristics of thyroid autoimmunity – TSH, ATPO, ATG.
In terms of patient age, an average interdependence was established between the OHI-S and age ($r=0.62$, $P=0.018$). Thyroid function, estimated by the mean value with the serum TSH level recorded above the normal maximum levels (> 4.2 mUI/ml), determined in terms of hypothyroidism an average interdependence between OHI-S and TSH ($r=0.55$; $P=0.0003$). Taking into account the average values of ATPO and ATG considered individually in the patients of Group 1, there was not shown a proportional relation to the value of OHI – S. Analyzing the relationship between the parameters obtained in the study of CAT characteristics in the patients of the study group by multifactorial linear regression, we found a directly proportional relation between OHI-S and TSH, ATPO, ATG – ab. ($r=0.56$; $P=0.001$). Along with these parameters, their interdependence was much closer considering the age of the patients ($r=0.78$; $P<0.001$). This finding is in agreement with the particularities of expression of the evolution duration of PD, but also of the altered thyroid function during the destructive thyroid autoimmune process.
Conclusions
A unitary concept regarding the etiopathogeny and the interconditioning of periodontal disease in patients with chronic autoimmune thyroiditis remains to be specified, taking into account the individualized expression features of the two diseases with inflammatory/autoimmune mechanism.

Down syndrome & metamorphosis of thyroid autoimmunity

Catarina Roque, Cátia Ferrinho, Clotilde Limbert, Luís Raposo & João Sequeira Duarte
Egas Moniz Hospital C.H.L.O., Endocrinology, Lisboa, Portugal

Introduction
Patients with Down syndrome are vulnerable to autoimmune thyroid disease and progression from Graves' disease (GD) to Hashimoto' thyroiditis or vice-versa may be more frequently seen in this population, specially at a younger age. In the last years questions have been raised regarding the distinction of this metamorphic scenario from a single entity: autoimmune thyroiditis with TRAbs that trigger opposite functional actions.
Case Report
A female patient with trisomy of the 21st chromosome was evaluated at age 14 due to thyrotoxicosis. She was diagnosed with GD based on clinical signs/symptoms, elevated FT4/FT3 and supressed TSH with TRAb positivity (TRAb 19.7<1.5 UI/ml) and absence of thyroid nodularity in the US. She was given appropriate dosages of methimazole to maintain euthyroidism until age 18 when treatment was stopped due to raising TSH. Given the sustained hypothyroid pattern she was started on levothyroxine. Primary hypothyroidism due to Hashimoto' thyroiditis was diagnosed at age 20 based on the hypoechogenic thyroid pattern and positivity for serum thyroglobulin and thyroid peroxidase autoantibodies. During the 10 years of follow up, thyroid function tests showed marked fluctuations from supressed to high TSH (< 0.02 to 33 μUI/ml) despite the relatively stable dosages of levothyroxine, FT4 and FT3 within reference range and recurrent denial of non-adherence to treatment. More interestingly, TRAb titres ranged from 71–529 (< 1.5 UI/ml) without clear association of titres with severity of thyroid function status. She is now 32 years old and has been euthyroid for the last year with a stable dosage of 88 mg of levothyroxine, positive TPOAb, TgAb and TRAb. Last US showed a small 5 ml hypoechoic gland with fibrous septa (RL 11 × 9.4 × 24 mm and LL 13 × 11 × 26 mm, AP × T × L), suggesting chronic atrophic thyroiditis.
Conclusions
Autoimmune TRAb positive atrophic thyroiditis is being increasingly recognized. Fluctuations in TSH due to shifting/competing stimulatory and inhibitory TRAbs are typical. We postulate that given the current low thyrocyte mass reserve the patient will maintain a more stable thyroid function. Additional tests as scintigraphy (specially I-123) and functional TRAb assays, unfortunately not widely available, shall be helpful to a better understanding and categorization of autoimmune thyroid disorders.

Quality of life in patients with Graves' orbitopathy

Georgios Boutzios[1], Sofia Kouvelioti[2], Eleni Papaoiconomou[2], Eleni Koukoulioti[2], Myrto Miliou[2] & Athanasios Tzioufas[3]
[1]Medical School, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [3]Department of Pathophysiology, Medical School, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Introduction
Graves' disease (GD) is an autoimmune thyroiditis frequently associated with development of Graves' orbitopathy (GO). As a consequence, patients with GO experience impairment of quality of life (QoL) and social function. The aim of our study was to assess quality of life in patients with GO.
Methods
This is a single-center observational study in an outpatient clinic of autoimmune endocrinopathies at a Tertiary, General, University Hospital. Patients with GO and increased levels of thyroid-stimulating immunoglobulin (TSI>1.75 IU/l) were included in the study. Clinical activity score (CAS score) was evaluated by a single ophthalmologist. The patients were asked to complete a QoL questionnaire at their first visit in the outpatient clinic, before initiation of any treatment. Laboratory tests for TSH, T3, FT4, TSI,

TgAbs, TPOAbs, blood count, liver enzymes and thyroid sonography were performed to all patients.
Results
A total of 17 patients were analyzed, of whom females were 82.4% (14/17). The mean age of the patients was 52.3±11.6 years, median TSI levels were 8.36 IU/l, mean CAS score was 3.12±1.22. Diplopia appeared in 41.2% of the patients (7/17). 23.5% (4/17) of the patients had undergone total thyroidectomy, 11.8% (2/17) had thyroid cancer, and 47.1% (8/17) had other autoimmunities. QoL was not significantly associated with gender, age, diplopia, TSI levels, thyroidectomy, and thyroid cancer (P=NS), but there was a trend with the presence of other autoimmunities (P=0.07). QoL was significantly associated only with CAS score (Pearson correlation was –0.59, P=0.013).
Conclusion
This study showed that the quality of life in patients with Graves' orbitopathy depends on their symptoms severity as expressed with clinical activity score.

Diagnostic difficulties in patients with large goiter

Ivan Belyakov, Yuri Aleksandrov & Artem Dyakiv
Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation

The purpose was to study the possibility of various diagnostic methods in patients with large goiter. In 2016–2018 years 628 people with thyroid diseases was operated. In 69 cases the volume of the thyroid was 100–1200 cm^3. The correlation between thyroid volume and age is weak (0.074033), the duration of the disease is high (0.732455). Evaluation of clinical signs was not difficult, but the examination data and symptoms did not give a adequate picture of the thyroid volume. The diagnostic value of the clinical examination (ROC analisis) was low (AUC=0.743; 95% CI=0.715–0.811; sensitivity=72.1%, specificity=74.0%). All patients underwent ultrasound. The possibilities of US was low: the size, location of the thyroid and its ratio to the surrounding tissues in 84.5% did not correspond to the operating data, especially of chest goiter. In most cases, there was no assessment of tracheal and esophageal compression. There were difficulties in assessing the pathology using the TIRADS, sonoelastography and US with contrasts. The ROC analysis revealed that US was not informative for large goiter (AUC=0.793; 95% CI=0.735–0.832; sensitivity=85.5%, specificity=72.4%). The traditional approach to US as a universal method for diagnosing thyroid pathology has limitations. In this regard, for the clarifying topical diagnostics were used magnetic resonance imaging or multispiral computed tomography. The resolution was increased by bolus image enhancement. The study showed that the discrepancies between MRI and operational data in the size and volume of the thyroid were 13.3%. It was practically possible to establish the capsule and the contours of the thyroid and assess the surrounding tissues (including the esophagus, trachea and lymph nodes) in all patients. Densitometric characteristics of the thyroid were different, which gave additional opportunities for differential diagnosis based on the type of contrast accumulation and removal curve, the time of peak achievement, and the degree of maximum contrast. In multi-node goiter and adenoma, a heterogeneous structure was determined on T1 and T2 VI with a predominance of signal amplification with a gentle decrease. In thyroid cancer, the structure was heterogeneous due to hypointensive inclusions on T2 VI with early signal intensity amplification with an early peak and a long phase of contrast elimination. MRI sensitivity in thyroid pathology was 94.4%, specificity-88.7% (AUC=0.915; 95% CI=0.843–0.974). Based on the study, it was concluded that MRI/MSCT is mandatory for patients with large goiter when planning an operating aid.

Etiological profile of hypothyroidism in Nepalese patients

Ansumali Joshi, Priyadarshini Yonzon & Sabeena Tamang
Kathmandu Diabetes and Thyroid Center, Kathmandu, Nepal

Background
Hypothyroidism is a common endocrine disorder. Common causes are autoimmune disease such as Hashimoto' thyroiditis, surgical removal of the thyroid, drug induced and radioactive iodine (RAI) ablation.
Aim
The aim of our study was to determine the etiology of hypothyroidism in Nepalese patients.
Method
This is a retrospective study conducted in our opd from May 2015 to April 2019 in which data was collected from the patient record files of the subjects diagnosed with hypothyroidism. A total of 1000 patients with hypothyroidism were enrolled for this study.
Result
The findings of the study revealed that, out of 1000 hypothyroid patient, 83.2% were female and 16.8% were male. Among them 11.9% (n=119) had a family history of hypothyroidism, 0.6% (n=6) had undergone RAI Ablation and 0.4% (n=4) had total thyroidectomy. 0.8% (n=8) cases were congenital and out of them 0.7% (n=7) had thyroid agenesis and 0.1% (n=1) had ectopic thyroid (lingual thyroid). 50% (n=500) cases were autoimmune with antiTPO antibody positivity. In 36.3%(n=363), cause could not be determined.
Conclusion
The most common etiological diagnosis of hypothyroidism in Nepalese patients was autoimmune (Hashimoto' thyroiditis). However, cause could not be determined in many patients.

Nivolumab induced relapse of graves' disease: A case report

Berna Evranos Ogmen, Abbas Ali Tam, Cevdet Aydin, Ahmet Dirikoç, Husniye Baser, Reyhan Ersoy & Bekir Cakir
Ankara Yildirim Beyazit University, Endocrinology and Metabolism, Ankara, Turkey

Background
Immune checkpoint inhibitors, including anti-programmed cell death-1 (PD-1) antibodies, have become promising treatments for a variety of advanced malignancies. Nivolumab, an anti–PD-1 monoclonal Ab, is an effective treatment of unresectable metastatic melanoma, non–small cell lung cancer, renal cell carcinoma, head and neck cancer, Hodgkin lymphoma, and gastric cancer. These medicines can cause immune-related adverse events (irAEs), including endocrinopathies. Thyroid dysfunction (TD) is a common irAE induced by nivolumab. The TD includes hypothyroidism and thyrotoxicosis, which are generally mild to moderate. The most common endocrine adverse event with anti-PD-1 therapy is hypothyroidism (around 5.9% cases). Thyrotoxicosis is related to destructive thyroiditis in most of the cases. Patients with TgAbs or TPOAbs are prone to develop destructive thyroiditis after initiation of nivolumab treatment. The development of hyperthyroidism owing to Graves' disease is virtually very rare, with only 4 cases reported so far. Here we aimed to present the 5th case of Graves' disease after Nivolumab therapy.
Case presentation
A 75-year-old woman with primary malignant urethral melanoma received three courses of nivolumab at a dose of 240 mg every two weeks. Laboratory tests performed before the 4th course due to the patient' palpitation. Thyroid-stimulating hormone (TSH), free triiodothyronine and free thyroxine level were<0.015 (normal range [NR]: 0.55–4.78) mU/l, 7.44 (NR: 2.3–4.2) ng/l and 2.4 (NR: 0.89–1.76) ng/dl, respectively. Her thyroglobulin (Tg-Ab) and thyroid peroxidase antibody (TPO-Ab) were both positive, while TSH receptor antibody (TRAb) was negative. Thyroid ultrasonography showed enlargement of both thyroid lobes with low echogenicity and increased vascularity. Thyroid scintigram showed an increased and diffuse uptake.
She had been diagnosed with Graves' disease approximately eight years ago and treated medically. Tg-Ab and TPO-Ab were both positive, and TRAb was negative like now. After medical treatment was over, the patient was euthyroid in follow-up and even before PD-1 treatment.
Conclusion
While antibody positivity often causes destructive thyroiditis, differently caused Graves' disease in this case. Also, this is the first case-reported that nivolumab therapy induced a relapse of Graves' Disease.

Thyroid Dysfunction in patients with HIV infection

Nikolaos Kalogeris[1], Eleni Herolidi[1], Melpomeni Moustaki[1], Alexandros Dermetzoglou[1], Vasilikh Loi[1], Eleni Vakali[2], Athina Lioni[2], Vissaria Sakka[2], Nikolaos Mangafas[2], Maria Chini[2] & Andromahi Vryonidou[1]
[1]Red Cross General Hospital, Endocrinology, Diabetes & Metabolism, Athens, Greece; [2]Red Cross General Hospital, Infectious Diseases Unit, Athens, Greece

Background
The incidence of endocrine complications among patients with HIV infection has decreased over the last years owing to widespread administration of combined Antiretroviral Therapy (cART) at early stages of the disease. We conducted a prospective observational study aiming to characterize the effects of cART on thyroid function in a cohort of newly diagnosed treatment-naive male patients.
Materials and methods
Male subjects diagnosed with HIV infection at the Infectious Diseases Unit during the period from 2015 until 2017 participated in the study after informed consent. Thyroid hormones, free thyroxine (fT4) and triiodothyronine (T3), thyroid stimulating hormone (TSH) and anti-thyroid antibody levels were measured at baseline, 12 and 24 months post-CART initiation. CD4 lymphocytes were assessed, as appropriate. SPSS 22.0 was used for the statistical analysis of the results.
Results
Fifty-five men attended their first and second year follow-up visits. All subjects had Caucasian ethnic background; the average age was 36.3±10.3 years, and median duration of HIV infection was 20.5 months (2–132). Two subjects (3.6%) had co-infection with hepatitis B, while 5 subjects (9.1%) had a positive family history for autoimmune thyroid disease. From 30 patients in whom anti-thyroid antibodies were measured, only 4 had positive values (13.3%). Two years after cART initiation, CD4 number increased significantly (578±315 vs 840±332, $P<0.001$) and fT4 level decreased (1.00±0.11 vs 0.96±0.12, $P=0.028$), while no change in TSH levels was demonstrated (2.14±1.33 vs 2.42±1.75, $P=0.145$). The incidence of subclinical hypothyroidism at two-year follow up increased 2.5-fold compared to baseline (4 vs 2 subjects). None of the subjects with subclinical hypothyroidism at baseline progressed to clinical hypothyroidism. Interestingly, subjects with subclinical hypothyroidism had negative anti-thyroid antibodies and no family history for thyroid or other autoimmune disease. Finally, 2 subjects developed clinical hyperthyroidism with positive anti-TSH receptor antibodies (TRAB) at 2 years, one of them presenting a relapse of Graves' Disease.
Conclusions
In patients with HIV infection, an isolated decrease in fT4 levels is observed after cART initiation; yet, no fT4 value falls below the normal range. Subclinical hypothyroidism is the most frequent thyroid disorder while GravesC Disease is the most clinically important, usually as a result of Immune Reconstitution Inflammatory Syndrome (IRIS).

Risk factors in graves' disease recurrence after treatment with radioactive iodine

Joana Reis Guiomar[1], Luís Lemos[2], Carolina Moreno[1], Diana Catarino[1], Lúcia Fadiga[1], Diana Silva[1], Inês Vieira[1], Mariana Lavrador[1], Gracinda Costa[2] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, EPE., Endocrinology, Diabetes and Metabolism Department, Coimbra, Portugal; [2]Coimbra Hospital and University Center, EPE., Nuclear Medicine Department

Introduction
Radioactive iodine (131I) therapy is a safe and cost-effective choice in Graves' disease (GD). Usually only one treatment with ^{131}I is sufficient, however, individual characteristics of the disease can lead to its recurrence. The aim of this study is to determinate the risk factors that influence the recurrence of GD after ^{131}I.
Materials and methods
Retrospective cohort study in 528 patients with GD who did ^{131}I therapy between January/2003 and May/2019. From this sample, 78 relapsed after the first therapy with ^{131}I (cases). 78 patients with therapeutic success (euthyroidism/hypothyroidism 36 months after ^{131}I) were randomly selected, adjusted for age and sex (controls). Statistical analysis in SPSSv.23, with the variables: disease progression, family history of thyroid disease, thyroid function tests, antithyroid antibodies, previous therapy with antithyroid treatment, ^{131}I uptake at 24 h (RAIU-24 h), functioning parenchyma mass and administered activity.
Results
A total of 528 patients were enrolled, out of which 82% ($n=433$) were female and 9% ($n=95$) were males, with an average age of 44±12 years. The recurrence rate was 14.8%($n=78$), on average 11±9 months after the first treatment. With regards to previous therapy, propylthiouracil (PTU) compared to thiamazole, was used more often in patients with recurrence (31.4% vs 6.5%; $P<0.01$), with an odds ratio of 6.67 (95% CI: 2.14–20.41). Recurrent patients had significantly higher T3l (14.9±10.5 vs 8.9±6.3; $P=0.001$), TPO Ab (1107±1505 vs 549±666; $P=0.04$), RAIU-24 h (65±11 vs 61±12; $P=0.02$) and functioning parenchyma mass (75±30 vs 48±19; $P<0.01$). There was a tendency to prolonged illness in recurrent patients (months) (32±10 vs 24±8; $P=0.064$), but without statistical significance. There were no difference between: family history of thyroid disease, TRABs and administered activity.
Conclusion
In this study, the recurrence rate of GD submitted to therapy with ^{131}I was 14.8%, on average one year after the first treatment. The recurrence is significantly associated with higher: T3l, TPO Ab, functioning parenchyma mass and RAIU-24h. Previous therapy with PTU was associated with a significant increased risk of recurrence. The longer the duration of the disease, the greater the tendency for recurring disease.

Aberrant cervical thymus mimicking thyroid on ultrasonography: A case report

Mohamed Masmoudi, Malika El Omri, Mehdi Hasnaoui, Wadii Thabet, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital mahdia, ENT Department, Mahdia, Tunisia

Introduction
An abnormally positioned thymus may either be aberrant or ectopic. Aberrant cervical thymus (ACT) is located along the normal pathway of descent of the thymus, with an attachment to mediastinal thymus via thymic tissue or fibrous cord in 50% of the cases. ACT is usually diagnosed within the first and second decade of life, and most lesions are cystic.
Case report
We report a case of 9-year-old woman was referred to our hospital for the operation of thyroid nodule. He did not have any neurological symptoms. During the ultrasonographic evaluation for thyroid thyroid, an incidental solid mass was found, which was located at the lower pole of the left thyroid, without remarkable interface echo to the thyroid parenchyma. Computed tomography (CT) showed a mass located at the lower pole of the left thyroid too. On the surgical field, the mass was found under the left thyroid. The mass was a yellowish soft mass. The mass was confirmed as the thymic tissue without any cystic component.
Conclusion
Its very important to recognize an aberrant cervical thymus as a differential diagnosis of paediatric neck masses, such as cervical lymphadenopathy, branchial anomalies, vascular malformations, inflammatory lesions and neoplasm. Ultrasound and CT scan can help to establish the etiological diagnosis.

EP473

Pseudomalabsorption as a cause of persistent hypothyroidism

Elyes Kamoun, Ibtissem Oueslati, Rym Belaid, Meriem Yazidi, Fatma Chaker, Nadia Khessairi & Melika Chihaoui
La Rabta hospital, Department of endocrinology, Tunis, Tunisia

Introduction
Levothyroxine is the treatment of hypothyroidism, achieving normal thyroid stimulating hormone (TSH) levels. The optimal dose of Levothyroxine may

be affected by several factors such as age, gender, body weight, patient' compliance, some medical disorders and drugs intake. Persistent hypothyroidism secondary to non compliance is rare and represents a diagnostic challenge.
The aim of this study was to describe cases with refractory hypothyroidism due to pseudomalabsorption of Levothyroxine.
Observations
We report three patients who presented with persistent primary hypothyroidism despite high doses of Levothyroxine. All patients confirmed the good compliance with the hormone replacement therapy. An oral dose of 600 µg of Levothyroxine was administered under medical supervision. Baseline thyroid function tests were performed and repeated after 2, 4, 6 and 24 hours. The first case was a 33-year-old man with a hypothyroidism diagnosed 19 years ago. He presented with a refractory hypothyroidism on 300 µg/d of Levothyroxine. The oral lévothyroxine test revealed a persistent high TSH level and low FT4 level consisting with the diagnosis of lévothyroxine malabsorption. The serology of celiac disease was negative. Gastroscopy revealed H. pylori gastritis. After treatment, the patient presented with a persisting refractory hypothyroidism with a TSH levels of 1068 mIU/l and a FT4 level of 0.46 ng/dl on 500 µg of Levothyroxine. The second patient was a 27-year-old woman who was treated with radioactive iodine for Graves' disease. She was on lévothyroxine replacement therapy since 3 years. She presented with a TSH level superior to 100 mIU/l and a FT4 level of 0.51 ng/dl on 250 µg of Levothyroxine. The third patient was a 45-year-old woman who had a thyroidectomy and radioactive iodine for a thyroid papillary carcinoma 4 years ago. She had a TSH level of 26.144 and a FT4 level of 1.04 ng/dl on 400 µg of Levothyroxine. Oral lévothyroxine absorption challenge test revealed a correct increase in FT4 levels and a decrease in TSH levels in all patients. They were diagnosed with pseudomalabsorption, and were advised about compliance. The mean TSH after 3 months was 10.3 mUI/l under lower doses for two patients and same dose for the second one, secondary to a persistent non-compliance.
Conclusion
In the absence of evident causes of persistent hypothyroidism despite optimal doses of lévothyroxine, the oral absorption test under medical supervision is useful to diagnose pseudomalabsorption.

Association of the rs12976445 MIR125A polymorphism with the clinical course of Graves' disease in Russian population

Natalia Peikrishvili, Anna Volkova & Svetlana Dora
Pavlov First State Medical University of Street Petersburg, Endocrinology, Sankt-Peterburg, Russian Federation

Introduction
Graves' disease (GD) is an autoimmune disorder of the thyroid gland, which is characterisied by a breakdown in immune tolerance. The lymphocytic infiltration of the thyroid leads to production of autoantibodies targeting thyroid stimulating hormone receptor (TSHR). The clinical course of GD varies among patients and it is difficult to predict the relapse risk after antithyroid therapy withdrawal. It is believed that GD occurs due to genetic suspectibility in combinaton with external factors. According to recent studies, microRNAs (miRNAs), which are small noncoding RNAs, also can play crucial role in the regulation of the immune system and development of autoimmunity. The aim of this study was to identify the association between single nucleotide polymorphism (SNP) rs12976445 in *MIR125A* gene and GD recurrence risk in Russian population.
Methods
We enrolled 270 patients with GD (210 women, 60 men) and 200 adults without autoimmune disorders. The mean age of GD onset was 41±13.6 years. In our study we mesuared the levels of TSH, free T4, T3, TRAb before and after 12–18 months of antithyroid drug treatment. Also the ultrasound examination of the thyroid gland was performed. Genotypes of SNP rs12976445 *MIR125A* were identified using direct sequencing and polymerase chain reaction–restriction fragment length polymorphism method. Alleles and genotypes frequencies were compared between groups using the Chi-square or Fisher' exact probability test.
Results
In our study the relapse rate estimated 33%. Only 13% of patients achieved remission of GD. The levels of TSH, freeT4, T3, TRAb did not differ significantly among patients. In this study significant differences in the distribution of alleles and genotypes between GD patients and control group were not revealed ($P>0.5$). Among the patients with the reccurence of GD the CC genotype carriers were significantly more frequent ($P=0.001$, OR=5.5, 95% CI 1.8–13.8) than in patient with GD in remission.
Conclusion
Our results suggest that SNP rs12976445 *MIR125A* is associated with the risk of GD relapse but not with the severity of hyperthyroidism. At first time in Russian population with GD genotypes and allele frequencies of the rs12976445 *MIR125A* were identified.

Peculitaries of markers of thyroid homeostasis in patients with liver cirrhosis of non-viral ethiology

Krystyna Chympoi[1], Nataliia Pashkovska[2], Oksana Olinyk[1] & Jana Teleki[1]
[1]HSEI 'Bukovinian State Medical University', Department of Internal Medicine and Infectious Disease, Chernivtsi, Ukraine; [2]HSEI 'Bukovinian State Medical University', Department of Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

The aim of this study was to assess thyroid homeostasis in patients with liver cirrhosis (LC) of non-viral etiology and analyze the association between serum thyroid parameters and A/C polymorphism in the deiodinase type 1 (DIO1) gene in these patients.
Material and methods
The study was conducted on 70 subjects: 50 patients with (LC) and 20 healthy controls. The thyroid homeostasis was evaluated by using «thyroid function tests», measurement of serum free thyroxine (fT_4), free triiodothyronine (fT_3) and thyroid stimulating hormone (TSH). A/C polymorphysm in the DIO1 gene was studied using a polymerase chain reaction.
Results
The level of fT_3 was reduced by 12.1% ($P<0.01$) in patients with (LC), fT_4 level was increased by 15.1% ($P<0.01$) in group of patients with (LC) compared to healthy controls. These changes, obviously, are the result of a decrease in the activity of DIO1 and inhibition of T_4 to T3 transformation. The theory might be confirmed by significantly reduced fT_3/fT_4 ratio (by 21.6%, $P<0.001$), that decreased below the reference range in 78% patients with (LC). At the same time, fT_4/fT_3 ratio increased by 24.1% ($P<0.001$) compared to healthy controls, that can be attributed to the non-thyroidal illness syndrome in these patients. Elevation of TSH level by 28.7% and TSH/fT_3 ratio by 45.7% were determined in patients with (LC) compared to healthy controls ($P<0.05$). The study did not reveal an association between the genotypes of DIO1 gene and the level of TSH in serum. However, it has been established that the presence of the C-allele was associated with elevation of fT_3 level and fT_3/fT_4 ratio, decreasing of fT_4/fT_3 ratio and fT_4 level, while the presence of A-allele resulted in a decrease in fT_3/fT_4 ratio and serum fT_3 with the increase in T_4 level in patients with chronic hepatitis.
Conclusions
Liver cirrhosis is accompanied by the development of non-thyroidal illness syndrome with a reduction in free triiodothyronine level (by 12.1%, $P<0.01$), an increase in free thyroxine and thyroid stimulating hormone levels (by 15.1%, $P<0.01$ and 28.7%, $P<0.05$ respectively), a decrease in fT_3/fT_4 peripheral conversion rate (by 21.6%, $P<0.001$). Pathological changes in thyroid metabolism are associated with A/C polymorphism in the DIO1 gene.

Inaugural cardiothyreosis

Chayma Besrour, Zouaoui Chadia, Jaidane Amel & Ouertani Haroun
The military hospital in Tunis, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
Cardiothyreosis or thyrotoxic heart disease is the most dangerous complication of hyperthyroidism. This rare complication can be revealing and occurs mostly to fragile patients ; eldery or individuals with preexisting cardiac troubles.

Observation
We report the case of a 59 years old male without medical history, who consulted the emergency for dyspnea and palpitations due to atrial fibrillation (ACFA) not well tolerated with both respiratory and neurological distress. The patient had amyotrophia, bilateral exophtalmos and a homogeneous goiter with high level of FT4 (48.7 pmol/l) and low level of TSH (< 0.005 µUI/ml). The thyroid ultrasound showed a giant multinodular goiter hyperechoic heterogeneous and hypervascular. The diagnosis of grave' disease was confirmed. We completed the investigation with a cardiac ultrasound that revealed an infero-septo-basal hypokinesia with a left ventricular ejection fraction (LVEF) at 50%. The patient received antithyroid medication associeted to B-blockers with progressive decrease in the doses after clinical and biological control. Two weeks later, the patient was no more in an acute condition and he was discharged.
Conclusion
Hyperthyroidism is a frequent disease, revealed after cardiothyreosis can be associeted with higher morbidity and mortality. The ACFA is its most common clinical form and underlying cardiac disease is often present.

Thyrotoxicosis and Tuberculosis (TB) related cervical lymphadenopathies: A case report

Lucia Almeida, Ana Sousa, Gustavo Melo, Diogo Ramalho, Sara Correia, Helena Alves & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, Endocrinology, Vila Nova de Gaia, Portugal

Introduction
Grave´s disease (GD) is the most prevalent cause of hyperthyroidism, leading to inflammation of the thyroid gland and sometimes to an enlargement of the nearest lymph nodes caused by that same inflammatory process. Peripheral lymphadenopathy of doubtful cause presents a diagnostic dilemma. There are many potential causes: biopsy is sometimes the best way to reach a definitive diagnosis. Tuberculous adenitis is usually regional and mainly affects nodes of the head and neck.
Clinical case
A 21 year-old male patient, with no significant past medical history besides rhinitis and active smoking, is sent to Endocrinology clinic (2016) in the setting of laboratory workup alterations: thyroid-stimulating hormone (TSH)<0.008 uUI/ml (0.27–4.2); Free thyroxine (FT4) 3.26 ng/dl (0.7–1.58). He presented to the hospital complainning about sudden weight loss (15 kgs in 2 months), anxiety, palpitations, insomnia and trembling hands for over a year. He denied any prior history of similar symptoms.
Physical examination showed signs of goiter, cervical bilateral lymphadenopathies (III/IV region) and otherwise unremarkable and tiamazol 5 mg bid wasprescribed. Six weeks later, thyroid function tests showed a TSH of 0.12 µIU/ml, FT4 of 0.41 ng/, free triiodothyronine (FT3) 2.3 pg/ml (2.57–4.43), TSH receptor antibodies (TRabs) 15.9 IU/l («1) and thyroid peroxidase antibodies 2902.0 UI/ml (0–34). Thyroid ultrasound was significant for an enlarged, heterogeneous, and-hypervascular gland, consistent with an autoimmune or inflammatory thyroiditis. Multiple cervical lymphadenopaties consistent with reactive nature, probably secundary to the inflammatory thyroiditis. At this point, our patient showed a remarkable clinical improvement but a new onset of excessive tiredness, nocturnal fever and further enlargment of painless cervical lymphadenopathies, led to further testing: cervical-thoracic Computer Tomography (CT-scan) showed cervical, supraclavicular and mediastinum lymphadenopathies; serologies were all negative; peripheral blood immnunophenotyping was negative for proliferative disease; aspiration biopsy cytology of one of the lymphadenopathies was performed (Immunophenotyping was negative for proliferative disease; bacteriological and mycobacteriological were also negative). One of the cervical lymph nodes along with adenoid tissue were surgically removed and the cultural test came out positive por Mycobacterium Tuberculosis. Sputum examination was negative for this agent. The patient initiates TB still under treatment for his now assymptomatic Graves disease (tiamazol 5 mg bid). The latest blood tests revealed: Trabs 9 IU/l, TSH 0.13 uUI/ml, FT4 1.72 ng/dl and FT3 4.01 pg/ml.
Conclusions
This cases teaches us how to never overlook all the possible differential diagnosis associated with lymphadenopathies. Tuberculous adenopathies can ecographycally simulate many other conditions.

EP478

Recurrent subacute thyroiditis case of an elderly patient

Sema Hepsen, Bekir Ucan, Pinar Akhanli, Muhammed Kizilgul & Erman Cakal
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Subacute thyroiditis (SAT) is the inflammatory disease of thyroid gland, which commonly affects middle-aged females. SAT is rarely seen in extreme age groups. Herein, we reported an 82-year-old patient presenting recurrent SAT.
Case report
An 82-year-old female patient presented fever, neck pain, weakness, and dizziness. She had hypertension and peripheral vascular disease. She had a 2-week of symptom history and admitted to emergency service before being referred to our clinic. Her body temperature was 38.6 °C and the heart rate was 105beats/minute. The thyroid gland was painful in palpitation. Hyperthyroidism and elevated acute phase reactants were observed. Thyroid ultrasonography showed bilateral hypoechoic heterogeneous areas. The patient having diagnosed SAT was started to use 48-mg methylprednisolone. The dose tapering protocol was 48–32–24–16–8–4 per week respectively. The severity of symptoms was decreased after three days of the initiation of the treatment. After 6-week of the treatment, laboratory and ultrasonography findings were resolved. 2 weeks after the completion of SAT treatment, the neck pain relapsed. Laboratory tests and thyroid ultrasonography were compatible with SAT. 48-mg methylprednisolone was started again with the same tapering protocol. At the end of the second treatment, TSH was 5.82 mIU/l while thyroid autoantibodies were negative. We presently continue to follow up the patient in the second month of SAT resolution.
Conclusion
In the evaluation of large patient groups, SAT was reported in very small numbers in patients whose ages were over 80. Although, the most well-known reasons for the SAT recurrence are short treatment period and genetic background, decreased immune response may be a possible risk factor for elderly patients. The symptoms of SAT can be more exaggerated and the management can be more challenging in elderly patients. Therefore, clinicians should be more careful about the treatment and follow-up of elderly patients with SAT.

Table 1 Laboratory parameters in SAT processes.

	1. SAT	After treatment	2. SAT	After treatment	Reference range
Sedimentation, mm/h	62	6	42	18	0–20
CRP, mg/l	107	1.8	103	2.7	0–8
WBC	9500	10.100	7500	9700	3.57–
TSH, mIU/l	0.12	0.32	1.11	5.82	0.38–5.33
fT4, ng/dl	1.79	0.94	0.93	0.94	0.58–1.6
fT3, ng/dl	4.67	3.1	4.1	4.22	2.66–4.37
anti-TPO, IU/ml	0.3	0.3	0.3	0.2	0–9
anti-TG, IU/ml	0.9	0.9	0.9	0.9	0–4

SAT subacute thyroiditis, CRP C-reactive protein, WBC white blood cell, TSH thyroid-stimulating hormone, fT4 free thyroxin, fT3 free triiodothyronin, anti-TPO anti-thyroid peroxidase, anti-TG anti-thyroglobulin.

Investigation of aggregation disorders before and after levotyroxin therapy in patients with hashimato thyroiditis

Nanişe Gizem Fener[1], Hatice Sebile Dökmetaş[2], Fatih Kılıçlı[2], Burçin Çakan Demirel[1] & Zeynep Kaya[1]
[1]İstanbul Medipol University, Internal Medicine, İstanbul, Turkey; [2]İstanbul Medipol University, Endocrinology and Metabolism, İstanbul, Turkey

Objective
Thyroid hormones are powerful mediators of numerous physiological and metabolic processes, including blood clotting, and thyroid dysfunction can adversely affect various stages in the coagulation cascade. Mean platelet volume (MPV) is used to measure platelet size and may indicate platelet activity. Studies have reported that increased MPV is associated with atherosclerotic lesions and cardiovascular diseases, and conflicting results have been reported for the relationship between thyroid function and MPV. In this study, in the healthy control group and patients with hypothyroidism due to Hashimoto' thyroiditis, L-thyroxine treatment was given to euthyroid after at least 6 months of treatment. We investigated its effect on platelet aggregation.
Materials and methods
We evaluated 72 patients diagnosed with Hashimato thyroiditis between March 2013 – May 2018 and who were followed for at least 6 months of L-thyroxine treatment.
Results
A total of 72 patients (61 males, 11 females) were included in the study. The control group consisted of 32 healthy individuals (25 female and 7 male). hemoglobin (Hb), mean erythrocyte volume (MCV), MPV and platelet count (PLT) and thyroid function tests were studied in the patient and control groups. There was no significant difference between patient and control groups in terms of mean Hb, MCV, MPV and PLT ($P>0.05$). There was no significant difference between the pre- and post-treatment Hb values ($P=0.651$) and the mean MCV, MPV and PLT values before and after treatment ($P>0.05$).
Conclusion
Hb, MCV, MPV and PLT values of patients with Hashimoto thyroiditis before and after at least 6 months of L-thyroxine treatment were not significantly different. There was no significant difference between the Hb, MCV, MPV and PLT values of the patient group before and after L-thyroxine treatment for at least 6 months.

Laboratory and USG thyroid examinations in the period of 2010 to 2017 in the Slovak Republic

Jan Bielik, Pavol Spano & Matej Bielik
Faculty of Healthcare, Trencin University, Trencin, Slovakia

Objectives
Between 2010 to 2018, the number of patients with thyroid disease in the Slovak Republic grew by 43.4%. We investigated the development of physical, laboratory, USG thyroid examinations and economic costs over the period 2010–2017.
Methods
The study was conducted using data from patient records of the General Health Insurance Company, which registered approximately 3,497,265 policyholders (66.13%) in 2010 and 3,238,500 policyholders (62.01%) in 2017. Laboratory (fT3, fT4, TSH, aTPO, aTG, thyreoglobulin, TRAK) and USG thyroid examinations were evaluated in relation to E00-E07 ICD diagnosis.
Results
The number of patients with these diagnoses had a constant growth tendency: 2010–258 622, 2011–272 936, 2012–284 086, 2013–304 213, 2014–341 496, 2015–349 498, 2016–368 393, 2017–370 745. The same tendency was observed in laboratory examinations and as well USG examinations: 2010–5 407 687 resp 1 382 937, 2011–5 303 433 resp 1 453 508, 2012–5 194 163 resp 1 526 951, 2013–5 391 737 resp 1 629 922, 2014–6 183 108 resp 1 751 184, 2015–6 024 153 resp 1 812 302, 2016–6 361 716 resp 1 913 681, 2017–6 158 735 resp 1 941 145. The total costs of endocrinology, laboratory and USG examinations were: 2010–11 355 988 €, 2011–11 214 956 €, 2012–11 132 859 €, 2013–11 654 875 €, 2014–12 917 370 €, 2015–13 100 799 €, 2016–14 104 543 € and in 2017–14 052 674 €. The average number of laboratory and USG examinations per patient was: 2010–3.57 resp 1.19; 2011–3.48 resp 1.19; 2012–3.29 resp 1.18; 2013–3.16 resp 1.19; 2014–3.10 resp 1.20; 2015–3.04 resp 1.20; 2016–3.01 resp 1.20; and 2017–2.96 resp 1.19.
Conclusions
The possibilities of influencing cost reduction without compromising the quality of health care will be focused on a stricter indication of laboratory examinations, in particular fT4, fT3, aTG, aTPO, TbG, based on the new expert guidelines for diagnosis and treatment of thyroid diseases issued by the Ministry of Health of the Slovak Republic.

Is there genetic linkage between benign adenoma and papillary cancer of thyroid: A linkage study through braf and ras gene mutation study

Ramesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Rajesh Bangaraiahgari[1], Rajkiran reddy Banala[3] & Rafi Mohammad[3]
[1]Surabhi Medical College, Biochemistry, India; [2]Endocare Hospital, Endocrine Surgery, Vijayawada, India; [3]Sri Rishika LifeSciences Pvt Ltd, Genetics, India

Introduction
The adenoma- carcinoma sequence in thyroid nodules is an enigmatic phenomenon. Genomics is the only definitive modality to resolve this hypothesis. Adenomas and papillary carcinomas tend to have mutations in RAS and highly specific BRAF gene respectively. In this context, we set out study the prevalence of these somatic mutations in surgical tissue samples.
Material and methods
This prospective study was conducted on surgically managed thyroid nodule patients. Institutional ethical committee approval was obtained. Diagnosis was based on biochemical confirmation, imaging, fine needle aspiration cytology and later confirmed by histopathology. We selected 28 benign thyroid adenomas (BTA) and 24 papillary thyroid carcinoma (PTC) cases. Tumour tissue samples were taken from ex-vivo thyroidectomy specimen within operation theatre. After appropriate processing of samples, DNA extraction, cDNA preparation, PCR amplification, application of 4 sets of Primers were performed as part of mutational analysis of RAS (H-,K-,N-) and BRAF genes.
Results
Homozygous mutations in N-RAS were found in 10/28 (36%) of BTA and 1/25 (4%) of PTC cases. No H-RAS or K-RAS mutations were found in both groups. Homozygous mutations were found in BRAF gene in 3/28 (11%) of BTA cases and 11/24 (46%) of PTC cases. The differences were statistically significant.
Conclusions
N-RAS and BRAF mutations were prevalent in both benign and malignant thyroid nodules giving some evidence for linkage between them. Though not robust, we opine that there is possibility of adenoma- carcinoma sequence in thyroid nodules. BRAF and RAS mutations appear to be specific to PTC and BTA respectively. We need larger multi-institutional studies to justify this observation in future.

Treatment with tyroisine kinase inhibitor in thyroid cancer: A single centre experience

Diana Catarino[1], Cristina Ribeiro[1], Joana Saraiva[1,2], Miguel Melo[1,2], Lucia Fadiga[1], Diana Silva[1], Joana Guiomar[1], Mariana Lavrador[1], Inês Vieira[1], Sara Ferreira[3], Cátia Araújo[1], Bárbara Araújo[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra EPE, Coimbra, Portugal, Endocrinology, Diabetes and Metabolism Department; [2]Faculty of Medicine – University of Coimbra, Portugal; [3]Centro Hospitalar Baixo Vouga, Aveiro, Portugal, Endocrinology, Diabetes and Nutrition Department

Introduction
Tyrosine kinase inhibitors (TKI) demonstrated clinically significant activity in radio iodine (RAI)-refractory differentiated thyroid cancer (DTC) and in locally recurrent, unresectable and metastatic medullary thyroid cancer (MTC). The natural history of MTC and DCT is quite variable with rates of disease progression ranging from a few months to many years. TKI can be associated with progression-free survival, but is not curative and the side effects may have a significant effect on patient' quality of life.
Objective
Characterization of patients with thyroid carcinoma treated with TKI, followed at the endocrine department of a hospital centre, between 2001 and 2019.
Methods
Retrospective cohort study, based on clinical records of patients with DTC and MTC treated with TKI. Statistical analyses with SPSS.
Results/Conclusion
We obtained 14 patients: 71.4% ($n=10$) female, mean age at the diagnosis: 45.93±13.56 years. 35.7% ($n=5$) papillary carcinoma, 35.7% ($n=5$) follicular carcinoma and 28.6% ($n=4$) medullary carcinoma. One patient with MTC had a genetic confirmation of MEN2. All patients performed total thyroidectomy at diagnosis, five of them performed lymph nodes resection too. Three patients had distant metastases at diagnosis. All patients with DTC ($n=10$) underwent RAI-therapy (cumulative mean dose: 566.4±354.6 mCi). These patients had disease progression with metastases (cervical lymph nodes: $n=7$; distant lymph nodes: $n=4$; pulmonary: $n=7$; cerebral: $n=2$; bone: $n=2$), a median of thyroglobulin-721 ng/l (reference range:1.6–60) and non-radioiodine avid disease. It was decided to perform TKI therapy: sorafenib in 9 patients (800 mg/day) and lenvatinib in 1 patient (24 mg/day). Four patients died due to disease progression; five patients performed a second TKI therapy-lenvatinib [4 dues to disease progression (mean Tg:698 >3682.7 ng/l) and 1 due to side effects of sorafenib], one patient maintains the initial TKI with stable disease. Actually, four patients with DTC are alive, three of them with stable disease. Relative to patients with MTC ($n=4$), it was decided to perform ITK Therapy due to disease progression, namely the presence of metastases (absence at diagnosis): cervical lymph node: $n=3$; distant lymph node: $n=2$; pulmonary: $n=2$; liver: $n=1$; bone- $n=1$). Three patients perform therapy with vandetanib (300 mg/day) and one with sorafenib (800 mg/day). Three patients are actually alive. Side effects of TKI were frequent, mainly gastrointestinal (anorexia-47%; transaminases' elevation-37%, diarrhea-32%), hypertension-47% and dermatologic effects 37%; needing dose reduction (36.8%) or even therapy suspension (10.5%). Optimal management of side effects is essential because they have a significant effect on quality of life and this should be factored into treatment decisions.

Thyroid metastases from clear cell renal carcinoma: Presentation of two unusual cases and literature review

Cristina Corina Pop-Radu
University of Medicine, Pharmacy, Science and Technology, M4, Endocrinology, Tirgu Mures, Romania

Clear cell renal carcinoma (CCRC) is a tumor with great metastatic capacity, although the presence of metastases in the thyroid gland is very uncommon. Therefore it is important to know the oncological background of the patient and to perform a complete immunohistochemical analysis of the thyroid lesion to obtain a correct diagnosis. Thyroidectomy can be considered in patients with no other metastasis or in those who present compressive symptoms as a palliative measure. We present two cases of patients with clear cell type renal cell carcinoma, without a previously known another metastasis of renal origin and symptomatic goiter containing a nodule that was found to be a metastatic lesion.
Keywords: thyroid gland, renal cell carcinoma, metastatic disease, immunohistochemistry.

DOI: 10.1530/endoabs.70.EP483

Clinical presentation and prognosis of patients with medullary thyroid cancer

Federica de Cicco[1], Roberta Modica[2], Livia Barba[2], Filomena Bottiglieri[2], Roberto Minotta[2], Antongiulio Faggiano[3] & Annamaria Colao[2]
[1]Endocrinology Unit 'Federico II' University, Naples, Italy, Department of Clinical Medicine and Surgery, Napoli, Italy; [2]Endocrinology Unit, 'Federico II' University, Department of Clinical Medicine and Surgery, Napoli, Italy; [3]Sapienza University, Department of Experimental Medicine, Roma, Italy

Medullary thyroid carcinoma (MTC) is a rare type of tumor that originates from parafollicular C-cells and accounts for 3–4% of all malignant thyroid neoplasms. MTC presents as sporadic (75–80%) or inherited tumors (20–25%). Hereditary MTC is part of multiple endocrine neoplasia type 2 (MEN2). Aim of the study was to describe clinical presentation, prognosis and therapy of sporadic MTC patients. Sixty-seven patients (pts) with histologically confirmed MTC referred to ENETS Center of Excellence of Naples, Endocrinology Unity of Federico II University between 2010–2018 were evaluated. MEN-2-inherited MTC were excluded. Clinical-pathological data, therapy and survival were retrospectively reviewed. Mean age at diagnosis was 51.4±15.1 years. Mean calcitonin concentrations at diagnosis were 4101±7801 pg/ml, resulting above the upper limits of the normal range in all cases, 11% with a slight increase of basal calcitonin had a calcium-stimulated test. Thyroid FNC was positive in 59.6%. Disease stage was I in 37.3%, II in 29.8%, III in 22.4% and IV in 7.4%. First-line therapy was surgery in all cases, radical surgery in 75%. Disease relapse occurred in 20 of those who had radical surgery (29.8%) while a second surgey or more was performed in 8.9%. Systemic therapy included pasireotide in 28.3%, everolimus in 10.4%, vandetanib in 13%. Median PFS was 132 months (95% CI, 61–203). Median survival was not reached. Calcitonin concentrations were increased in all cases at diagnosis but highly variable. MTC patients have substantially a favorable and long-time survival. In patients with metastases many different systemic therapies can be considered.

Anaplastic transformation of well differentiated carcinoma of the thyroid gland with muscle metastasis

Justiene Mia Klarisse Danga & Ruben Kasala
The Medical City – Ortigas, Internal Medicine Section of Endocrinology, Pasig city, Philippines

Introduction
Anaplastic thyroid carcinoma (ATC) is the most aggressive and invasive histological type of thyroid carcinomas. Frequently, upon diagnosis obstructive symptoms and loco-regional metastasis have already occurred. Presence of distant metastasis in the skeletal muscle in ATC is rare; and there are less than five documented cases reported worldwide.
Case
A 68-year-old Filipino Male, presents with two-month history of pain on the right thigh. He has previous history of Papillary thyroid carcinoma and underwent total thyroidectomy with post-operative radioactive iodine treatment. He was asymptomatic until 11 months post thyroidectomy, when he complained of progressive swelling and tenderness on his right thigh. On initial consult, CT scan of the right lower extremity showed a possible angiosarcoma. Biopsy revealed undifferentiated metastatic carcinoma and immunohistochemical stain is positive for CK7, PAX 8 and TTF-1; denoting anaplastic thyroid carcinoma. Due to the findings, he eventually consulted our institution, on examination there' notable firm non-tender mass about 4 × 4 cm at the left supraclavicular area, and erythematous 6 × 8 cm firm

mass on the posteromedial aspect of the right thigh. Repeated excision biopsy of both masses was performed, during the surgery an invasion of necrotic tissue surrounding the mass was seen. Histopathology of both masses presented anaplastic tumor cells. Total hip disarticulation was done due to severe infection and tumor invasion. Further plans for chemotherapy was not executed due to severe sepsis, and eventually patient succumbed to death.
Conclusion
In patients with previous history of well differentiated thyroid carcinoma, a rapidly enlarging neck mass or even a new mass of unknown origin should be suspected for a more aggressive histologic type of thyroid cancer. Aggressive diagnosis should be immediately performed on these patients, due to the risk of de-differentiation to anaplastic thyroid carcinoma. Keen knowledge is needed for clinicians to prevent misdiagnosis and to avoid delay of treatment.

EP486

Clinical and epidemiological characteristics of thyroid papilar carcinoma at jerez hospital during a 3 years period (2017–2019)

Maria Gloria Baena-Nieto, Rosa Marquez-Pardo & Lourdes García-García-Doncel
Jerez University Hospital, Endocrinology Unit, Jerez, Spain

Introduction
Papillary carcinoma is the most common form of well-differentiated thyroid cancer (80% of the total). In recent years there has been a significant progressive increase in prevalence.
Objectives
The aim of the study was to evaluate the clinical characteristics of the newly diagnosed papillary thyroid carcinoma at the Sanitary Area of Jerez, as well as to analyze its incidence in recent years.
Material and methods
An observational, descriptive and retrospective study of patients diagnosed with papillary thyroid carcinoma in the Health Management Area of Jerez during a 3 year period (2017–2019). Epidemiological and clinical characteristics were analysed and The American Thyroid Association (*ATA*) classification was used for initial risk classification.
Results
During the study period, a total of 63 patients with papillary thyroid carcinoma were diagnosed: 26 in 2017 (5.83/100,000 inhabitants/year); 20 in 2018 (4.48/100,000 inhabitants/year) and 17 (3.81/100,000 inhabitants/year) in 2019. Of these, 5 cases (7.93%) were microcarcinomas. 74% were women with a mean age at diagnosis of 48.89 ± 14 years. 31% of the patients were obese and 28.8% were overweight. The health area was identified: 47.6% area of Jerez, 44.4% area of Jerez-Sierra and 6.3% of Jerez-Costa. 20.6% were smokers. Regarding the clinical characteristics, 50.8% were symptomatic with a 76.2% of single nodules and an average size of 19.8 ± 10 mm. After surgery, based on the 2015 ATA risk classification, 50.6% were low, 27% were intermediate and 12.7% were classified as hig risk of recurrence. Postoperative RAI ablation was used in 81% of patients.
Conclusions
In our area we found an incidence of papillary thyroid cancer similar to other published series. In most cases the diagnosis is made in early stages.

The association between thyroid anaplastic carcinoma and papilar carcinoma folicular version – longer life expectancy?

Mirela-Claudia Nechita[1], Anca-Georgiana Tudurean-Olteanu[1], Teodora Dumitru[1], Alexandru Florescu[2] & Maria Christina Ungureanu[1,2]
[1']Sf.Spridon' Emergency Clinical Hospital, Endocrinology, Iasi, Romania; [2']Grigore T. Popa' University of Medicine and Pharmacy, Iaşi, Iasi, Romania

Introduction
Anaplastic thyroid carcinoma are highly aggressive solid tumors, with a median survival of less than 6 months after diagnosis. They typically occur in patients who are 65 years of age or older. On the other hand, papillary thyroid carcinoma and follicular thyroid carcinoma are generally indolent, with very few progressive cases.
Case report
A 64-year-old patient with no significant pathological history, known with goiter for about 40 years but without endocrinological evaluation, presented in our department for progressive dysphonia. A total thyroidectomy was performed. Histopathological examination revealed aplastic thyroid carcinoma that associates papillary thyroid carcinoma follicular form. The patient received radioiodine therapy (June 2015) and external, cervical beam therapy (July 2016). Post-surgery, CT scan describes multiple cervical, less than 1 cm, lymph nodes, and two straight pulmonary nodules too small to be characterized, stationary imaging aspect at subsequent examinations. In March 2019, he performed a PET-CT scan that detects a left rib (C6-C7) tumor with high FDG activity – surgery was performed, and papillary metastasis was confirmed. In August 2019, it was treated with a complementary dose of radioiodine. Bone scintigraphy and CT scan performed afterward described small, nonspecific rib injuries: secondary or old post-traumatic or arthritic lesions. In this case, thoracic radiotherapy was postponed due to the high risk for secondary lung fibrosis and the uncertainty of secondary injuries. After iodine therapy, the values of thyroglobulin were undetectable both in suppression and without. It was bisphosphonate treatment and possible SORAFENIB – timed for the moment (normal thyroglobulin). In 3 months, a new CT scan, costal biopsy, or better a PET-CT scan are considered.
Conclusion
Anaplastic thyroid cancer is the rarest yet most aggressive thyroid cancer. Most patients present with a rapidly enlarging thyroid mass, and the majority die within six months of diagnosis. In our patient case, it is considered the association between anaplastic and papillary-follicular variant, with a good, unexpected evolution for the anaplastic component but with secondary dissemination for the differentiated part.

Keywords: thyroid carcinoma, management, secondary injury.

Simultaneous papillary and medulary thyroid carcinoma – how to approach?

Diana Martins[1,2], Daniela Guelho[1], Nuno Vicente[1], Mara Ventura[1,3] & Alexandra Vieira[1]
[1]Serviço de Endocrinologia e Nutrição do Centro Hospitalar de Leiria, Portugal; [2]Faculdade de Medicina da Universidade de Coimbra, Portugal; [3]Faculdade de Ciências da Saúde da Universidade da Beira Interior, Covilhã, Portugal

Introduction
Papillary thyroid carcinoma (PTC) and medullary thyroid carcinoma (MTC) are distinct neoplasms, associated with different histological findings. Their coexistence in the same patient is a rare event, requiring a different clinical approach.
Clinical case
A 72-year-old patient with no family history of thyroid disease, underwent total thyroidectomy in February 2019, due to toxic multinodular goitre, with no evidence of postoperative complications. The anatomopathological study of the surgical specimen revealed aspects of follicular nodular hyperplasia, with a 6 mm papillary microcarcinoma evident in the right lobe, with areas of classical pattern and a 4 mm medullary microcarcinoma in the left lobe (positive immunohistochemistry for calcitonin). Both lesions did not present foci of lymphovascular permeation or extension to the surrounding soft tissues. Two months postoperatively, patient was revaluated under 125 µg sodium levothyroxine id and presented: TSH 3.13 µUI/ml (0.38–1.33), fT4 12.8 pmol/l (7.9–14.4), Tg 0.31 ng/ml (1.15- 130.77), Anti-Tg Ab 8.7 IU/ml (5.0–100.0), Calcitonin 1.9 ng/l (<9.8) and CEA 1.9 ng/ml (<3.0). At this stage, a therapeutic change was made to 137 µg id levothyroxine sodium. In the cervical ultrasound study, a small amount of tissue, compatible with thyroid residue, was evident in the left locus. At 6 months postoperatively, the patient was revaluated again, showing clinical stability, with analytical study revealing: TSH 1.58 µUI/ml, fT4 14.2 pmol/l, Tg 0.24 ng/ml, Anti-Tg Ab 8.7 IU/ml, Calcitonin 1.8 ng/l (<9.8), CEA 2.0 ng/ml (<3.0), PTH 50.6 pg/ml (12.0–88.0) and assays of urinary catecholamines and metanephrines within the reference limits. The ultrasound study revealed at this stage that residual tissue remained in the left surgical bed, with maintained dimensions. Given the stability, patient continued therapy with 137 mg sodium levothyroxine, with indication for clinical, analytical and ultrasound reassessment in consultation.

Conclusions
The simultaneous occurrence of PTC and MTC is an unusual finding. The follow-up should consider the individual characteristics of both, as they consist in entities with different histological patterns and different clinical evolution. The aetiology of this entity is not clear, however, the possibility of a common tumour pathway should be placed and evaluated in series with a higher number of patients.

Thyroglobulin vs imaging in late recurrent metastatic thyroid carcinoma

Amalia Ioana Arhire, Carmen Gabriela Barbu & Oprea Theodor
Elias Hospital, Endocrinology, Diabetes, Nutrition and Metabolic Diseases, Bucharest, Romania

Introduction
As the incidence of thyroid cancer is increasing, so are the cases of recurrence with RAI refractory metastasis of thyroid differentiated cancer. We present such a case
Case report
A 77-year-old female with a medical history of papillary thyroid carcinoma recurrence 10 years after surgery with successful 3 RAI sessions and normal thyroid cancer markers after treatment until her recurrence a year ago, with TSH unstimulated thyroglobulin of 199 ng/ml. She had extensive cervical surgery with en-block resection and jugular grafting because of laterocervical adenopathies with Bethesda V suspicion of papillary carcinoma. After surgery we referred her to radio iodine treatment.
Laboratory: thyroglobulin of 255 ng/ml, on stimulated TSH of over 100, thyroglobulin antibodies of 5.8.
Whole body I131 scintigraphy: anterior thyroid recurrence.
She received 160 mCi of I131 and as the thyroglobulin remained high the nuclear imagist ordered more imagining.
The cervical and thoracic CT revealed multiple bilateral secondary lesions in the lungs and large supraclavicular adenopathies, with no other primary tumor.
The abdominal and pelvic IRM was normal.
The oncologist repeated the thyroglobulin and the thyroglobulin was 38.9 ng/dl with a TSH of 16, 6 weeks after radioiodine treatment and the decision was to repeat the CT in 2 months.
The new cervical and thoracic CT showed a progression of the pulmonary lesions so the patient was referred to the nuclear imagist with a suspicion of RAI resistant metastasis.
Conclusion
Typically differentiated thyroid cancer has a good prognostic with 5-year survival rate of over 98%, but almost one third of recurrences become RAI resistant with a 5-year survival of only 19%. There is a BRAF mutation that promotes NIS silence in these cases so it is very important to identify these patients as to avoid unnecessary irradiation and waist precious time that could be used with trying new individualized treatment.

Solitary fibrous tumour of the thyroid, features of a very rare tumour: A case report

Teodora Dumitru[1,2], Anamaria Hrisa[1,2], Mirela-Claudia Nechita[1,2], Delia Ciobanu[2,3], Radu Danila[2,4] & Maria-Christina Ungureanu[1,2]
[1]Emergency University Hospital 'Sf. Spiridon', Endrocrinology; [2]University of Medicine and Pharmacy 'Grigore T. Popa', Iasi; [3]Emergency University Hospital 'Sf. Spiridon', Anatomopathology; [4]Emergency University Hospital 'Sf. Spiridon', Surgery

Introduction
Solitary fibrous tumor (SFT) is a sporadic tumor, commonly found in the pleural cavity. It is like a large well-circumscribed mass, arising from mesenchymal tissue, with spindle cells proliferation, arranged in various patterns. SFT of the thyroid is exceptionally rare, with only about 28 cases being reported in the international literaterature.
A 34-year-old woman presented in the Department of Endocrinology with the diagnosis of a multinodular goiter. She had no clinical signs or symptoms at that moment. Biological and thyroid function tests were normal. We performed an ultrasonographic examination of the thyroid, which described a solid hypoechogenic nodule in the left lobe (12.13 ml); close imagistic surveillance was recommended. In the next presentations,we noticed the same euthyroid status but an increase in the nodule dimensions ($4.9 \times 5.5 \times 3$ cm) and compression symptoms. Fine needle aspiration biopsy (FNAB) under ultrasound guidation was performed with a favorable result after the Bethesda system. Duet o increasing in nodular size, a total thyroidectomy was done, and thyroid hormone replacement therapy was started. Immunohistochemistry revealed positivity for CD34 marker, CD99, BCL-2, CD 68, negativity for desmin and SMA, and a KI-67 index $<1\%$. The diagnosis was benign SFT arising from the thyroid gland. IGF-2 value was normal; the patient remains well 12 months after excision.
Discussions
Our case is a rare case of SFT of the thyroid, where the patient presented with an asymptomatic slowly increasing thyroid mass in the presence of a benign FNAB. There was no evidence of SFT before immunohistochemistry; the exam highlighted SFT characteristic features, very useful in the differential diagnosis that includes undifferentiated (anaplastic) carcinoma.

Incidentally discovered thyroid microcarcinomas in patients undergoing thyroid surgery for benign disease

Emma Anda Apiñariz, Ander Ernaga Lorea, Marta Toni García, Patricia Munarriz Alcuaz, Javier Pineda Arribas, Juan Pablo Martínez De Esteban, Nerea Eguilaz Esparza & Ana Irigaray
Complejo Hospitalario de Navarra

Objective
Incidentally discovered thyroid microcarcinomas (TMc) are tumors with a maximal diameter ≥1 cm, indetified during a detailed histopathology examination following a thyroidectomy performed for reasons not pertaining to malignancies of the thyroid gland.
Methods
We included 1555 patients who underwent a total thyroidectomy for benign disease between January 2005 and December 2018. Patients with post-surgical pathology consistent with thyroid cancer with a maximal tumor diameter ≥1 cm were excluded. The incidence of TMc was identified and compared between the different subgroups.
Results
The mean age of the 1555 patients was 53.5 ± 13.8 years and the proportion of women was higher (82.5%, $n=1283$). 1206 patients (77.6%) had a preoperative diagnosis of nodular goiter. 136 cases of TMc were identified (prevalence 8.7%). The majority of cases were papillary TMc (91.2%, $n=124$).
There were no differences in prevalence according to sex (women 8.6% vs. men 9.6%, $P=0.601$) or age (mean age 54.4 ± 12 years in patients with TMc vs. 53.4 ± 14, $P=0.415$).
The prevalence was significantly lower in patients with Graves' disease (5.2% vs. 9.6% in nodular goiter and 9.3% in chronic lymphocytic thyroiditis, $P=0.037$).
Conclusion
In our study the prevalence of TMc in patients who underwent total thyroidectomy for benign disease was 8.7%.
The prevalence was significantly lower in patients with Graves'disease.

Clinical profile of patients with solitary thyroid nodules attending tertiary endocrine centre in Kathmandu, Nepal

Ansumali Joshi, Priyadarshini Yonzon & Pavitra Rai
Kathmandu Diabetes and Thyroid Center, Endocrine, Kathmandu, Nepal

Background
Thyroid nodules are common with annual increasing trends worldwide. 5% to 15% of the thyroid nodules is thyroid cancer. The prevalence of thyroid nodule is 3%–7% prevalence by palpation and 19%–67% by high resolution ultrasound. Thyroid nodules are more prevalent in women and older age group. More than 95% of all thyroid nodules are benign.

Aim
The aim of this study is to assess the clinical profile of patients with solitary thyroid nodules in our center
Method
This is a retrospective study conducted in our opd in which data of patients with solitary thyroid nodules was collected from the patient record files. A total of 161 patients were enrolled for this study from April 2018 to April 2019.
Result
The findings of the study revealed that out of 161 patients, 82.20% were females and 16.56% were males, mean age was 47.27(±12) years, mean BMI was 26.85 (±5) kg/m^2. 94.4% were non-smokers and remaining 5.5% were smokers. 46.58% had right thyroid nodule and 50.93% had a left thyroid nodule and 2.48% had nodule in the isthmus. The largest dimension of thyroid nodule was 20.70(±12) mm. The cytological diagnosis distribution as per Bethesda nomenclature were 73.29% benign, 18% malignant (all Papillary Carcinoma), 5.59% non-Diagnostic or unsatisfactory and 1.2% suspicious for malignancy and 1.24% AUS (atypia of undetermined significance) or FLUS (follicular lesion of undetermined significance) respectively.
Conclusion
Prevalence of solitary thyroid nodules was significantly higher in females and obese.
Most of the nodules were benign. 18% solitary thyroid nodules were malignant and all were papillary carcinoma in our study.

Prevalence of incidentally finding of papillary thyroid cancer among patients with sporadic medullary thyroid cancer

Georgios Boutzios[1], Nefeli Tomara[2], Evgenia Kotsifa[2], Eleni Koukoulioti[1], Alexis Terra[2], Stylianos Kykalos[2], Eleftherios Spartalis[2], Konstantinos Vagianos[2] & Gerasimos Tsourouflis[2]
[1]National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]National and Kapodistrian University of Athens, Second Department of Propedeutic Surgery, Athens, Greece

Introduction
The coexistence of papillary thyroid cancer (PTC) and medullary TC (MTC) is rare. Previous retrospective studies have shown a prevalence up to 19%. The aim of our study was to assess the prevalence of PTC in patients with sporadic MTC.
Methods
This is a single-center retrospective study of an endocrinology outpatient clinic at a Tertiary, General, University Hospital. Patients who had undergone total thyroidectomy with central neck compartment and had histologically confirmed MTC were included in the study. Also, a RET oncogene analysis was performed in all patients. Patients with positive RET were excluded from the study.
Results
A total of twenty-seven patients were analyzed, of whom females were 40.7% (11/27). The mean age of patients was 58.19±13.1 years. The prevalence of PTC was 33.3% (9/27). 22.2% (6/27) of the patients underwent re-operation for lymph node invasion. Distal metastases appeared in 14.8% of the patients (4/27).
Conclusion
According to our data the prevalence of PTC as incidental finding in patients with MTC is higher compared to previous studies. The cause underlying the phenomenon of MTC and papillary PTC is still unclear.

EP494

Clinical profile of thyroid cancer patients attending a tertiary endocrine center in Nepal

Ansumali Joshi, Priyadarshini Yonzon & Thuma Sharma
Kathmandu Diabetes and Thyroid Center, Endocrine, Kathmandu, Nepal

Background
Thyroid cancer is the most common malignant disease of the endocrine system. Thyroid cancer represents above 1% of all malignancies. There is a paucity of data on thyroid cancer in Nepalese patients.
Aim
The aim of this study is to explore clinical profile of thyroid cancer patients diagnosed and managed in our center.
Methods
A total of 70 patients with thyroid cancer were included in the sample from March 2013 to December 2019. The OPD records of these patients were reviewed for their clinical profiles including age, sex, operation procedure, location of tumor, TNM staging, ATA risk category, RAI ablation and dose of RAI ablation. The collected data was analyzed by using descriptive and inferential statistical with SPSS version 20.
Result
The findings of the study revealed that 81.4% were females and 18.6% were males. The mean age was 37.3(±9) years and mean BMI was 27(±4) kg/m^2. Location of tumor in left lobe was 34.28%, right lobe was 52.85% and both lobes were 12.87%. Among those patients 25.71% had righthemithyroidectomy, 10% left hemithyroidectomy and 64.29% total thyroidectomy. All had papillary thyroid carcinoma. According to American Thyroid Association (ATA) Risk Stratification System, 62.85% had low risk category, 35.71% of patients intermediate risk category and 1.44% high risk category. According to TNM classification, 14.2% patients had stage T1a, 38.5% stage T1b, 32.8% stage T2, 11.5%, stage T3a, 1.5% stage T3b, 1.5% stage T4a respectively.18.5% of patients underwent RAI ablation. Doses of RAI given to patients were 100 mCi (5.7%), 121 mCi (1.42%), 150 mCi (1.42%), 64 mCi (1.42%), 65 mCi (4.28%), 80 mCi (1.42%) and 95 mCi (1.42%). Mean dose of RAI was 96.42 mCi.
Conclusion
Thyroid cancer was mostly seen in females and young age. Most patients had right lobe cancer. More than half of the patients had total thyroidectomy. Most patients had low risk category. Only 18.5% patients underwent RAI ablation.

EP495

Risk stratification of Bethesda III category thyroid nodules: Tertiary centers experience

Eiman Alseddeeqi
Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates

Background
AUS/FLUS (atypia/follicular lesion of undetermined significance) carries a malignancy risk reaching up to 50%. Based on the reported malignancy rate in a given population, the clinical practice towards such a category varies. We hereby identify clinical parameters for risk stratification to aid in decision making for either surgical referral or a clinical follow up.
Our aim is to calculate the malignancy risk in Bethesda III category and to identify clinical parameters that guided both clinicians and patients at our institutions to reach a clinical decision.
Methods
A retrospective review of patients with Bethesda III category thyroid nodules from tertiary centres in the Emirate of Abu Dhabi during January 2011 through December 2015 was carried out. Malignancy risk in Bethesda category III nodules and repeat FNA utility were calculated. Parameters guided referral to surgery were studied.
Results
Two hundred and two cases were included in the study. Of these, 101 cases underwent surgery initially following the first FNA and 10 cases following FNA repeat. Histology confirmed malignancy in (41%) of cases that went initially to surgery and in (40%) of cases that underwent a repeat FNA. Repeat FNA resulted in, 17 (44.74%) cases being re-classified into benign category, 10 (26.3%) being AUS/FLUS category, 6 (15.7%) being both suspicious and malignant, and 5 (13.16%) being unsatisfactory. Repeating FNA resulted in a definitive diagnostic utility in 50% of the cases.
Conclusion
The relatively high malignancy rate in our institutions, the suspicious radiographic features and the repeat FNA predictive value stratified Bethesda III category nodules for appropriate referrals to surgery.

Thyroid malignancy among patients with thyroid nodules in the united arab emirates: A five-year retrospective tertiary centre analysis

Eiman Alseddeeqi
Sheikh Khalifa Medical City, Endocrinology, Abu Dhabi, United Arab Emirates

Objectives
Thyroid malignancy constitutes the sixth common cancer type in the United Arab Emirates (UAE). There are no epidemiological data outlining the prevalence of cancer in thyroid nodules, nor previous analysis of ultra-sonographic features correlating with thyroid malignancy in the UAE. This study aimed to estimate the prevalence of thyroid malignancy in patients with thyroid nodules and to describe the ultra-sonographic characteristics of thyroid nodules harbouring malignancy.
Methods
A retrospective electronic medical records review of all thyroid nodules in patients (aged 18 to 80 years) with normal thyroid-stimulating hormone (TSH) levels, who underwent ultrasound guided fine needle aspiration cytology (UG-FNA) at Sheikh Khalifa Medical City (SKMC) during 2011–2015.
Results
436 patients with normal TSH underwent UG-FNA cytological examination of thyroid nodules ($n=555$ nodules). The overall crude prevalence of thyroid cancer among patients was 10.1% (95% CI 7.5–13.3). The age-adjusted prevalence of thyroid cancer among UAE nationals, Arabs, Far East Asians, and Caucasians were 9.6% (3.6–15.6), 10.0% (6.2–13.8), 16.8% (4.5–29.0) and 16.3% (1.7–30.9), respectively. The crude prevalence was 14.5%(95% CI 6.2–22.8) in men, and 9.3%(95% CI 6.3–12.2) in women. The echogenicity features were significantly different between the cancerous and noncancerous nodules ($P=0.025$). Cancerous nodules were relatively more hyper- and hypo-echoic, while noncancerous nodules were mostly complex.
Conclusion
We report a higher prevalence of thyroid malignancy among patients with thyroid nodules relative to that reported in other parts of the world. The rate of thyroid malignancy was higher in patients of Far-East Asian and Caucasian ethnic background.

EP497

Mandibular metastasis revealing a vesicular carcinoma of the thyroid: A case report

Amira Bouchenna[1], Guidoum Adel[2], Tibouk Abdelghani[3], Berkoune Fatma[4] & Ould Kablia Samia[4]
[1]Central Hospital of Army, Endocrinology, Algeria; [2]central Hospital of Army, Maxillofacial Surgery, Algeria; [3]central Hospital of Army, Pathological Anatomy, Algeria

Introduction
Oral metastases are exceptional, representing about 1% of cancers of the oral region. The most common primary tumors are the lung in men and the breast in women. Thyroid carcinoma accounts for approximately 3% of all oral metastatic carcinomas.
We are reporting a case.
Observation
65-year-old woman, followed for 35 years for a toxic large goiter at the expense of the right lobe under medical treatment, which consults following a bulky left mandibular mass. The scanner of the face finds an hypervascular tumor process of the lysing left masticatory space completely the rising branch of the mandible, the biopsy of which returns in favor of a secondary localization of papillary carcinoma of the thyroid TTF1 + TG +. The cervical ultrasound shows a voluminous right nodule classified EU-TIRADS III, the fine needle aspiration of which is an income in favor of papillary carcinoma. The extension report doesn't find other locations. The patient benefits at one time from a total thyroidectomy and resection of the mandibular mass. The pathology study returns in favor of a vesicular thyroid carcinoma of 6.5 cm with mandibular metastasis classified PT3N0M1.
Discussion
Distant metastases from differentiated thyroid carcinomas are rare, the most common being the lung and bone (vertebrae, pelvis and ribs). Oral metastases are exceptional, affecting the mandible more often than the maxilla and are rather the plume of vesicular carcinomas due to hematogenous spread. These metastases cloud the prognosis with a 5-year survival rate of 40% and a 10-year survival rate of 27%.

A case of graves disease with hepatic dysfunction, thrombocytopenia and paralysis

Mehdi Houssein[1], Kubra Turan[1], Berna Evranos Ogmen[1], cevdet aydin[1], Didem Ozdemir[1] & Sevgul FAKI[1]
[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of Endocrinology and Metabolism, Endocrinology and Metabolism, Ankara, Turkey

Background
Graves' disease is an autoimmune disease that is characterized by production of excess thyroid hormones by thyroid gland, which is called hyperthyroidism. Generally, clinical presentations of Graves' disease range from asymptomatic disease to overt symptomatic hyperthyroidism with heat intolerance, tremor, palpitation, weight loss, and increased appetite. Single-cell lineage haematological abnormalities, such as anemia, leukopenia, and thrombocytopenia, although uncommon, could be part of the clinical manifestations in patients with Graves' disease. Another rare clinical manifestation of hyperthyroidism may occur in the gastrointestinal system, including liver function tests, particularly high serum alkaline phosphatase concentrations. Thyrotoxic patients also may have numbness and weakness in lower limbs.
Case presentation
A 37-year-old male patient admitted to our clinic with palpitation, tremor, abdominal pain, nausea, vomiting, weight loss and dysphagia. Also, he had numbness and weakness in lower limbs. He was afebrile, had tachycardia (110 beats/min), and had a normal blood pressure of 116/65 mm Hg. He had a fine tremor and palpable goitre on physical examination. There were no signs of ophthalmopathy or pretibial myxedema. Laboratory investigations revealed suppressed thyrotrophin (< 0.008 mu/l) and elevated free thyroxine (6.75 ng/dl), mild thrombocytopenia (131×10^9), normal serum electrolytes except mild hypokalemia (3.4 meq/l). The alkaline phosphatase and the gamma glutamyl transferase levels were elevated approximately 3–4 times the upper limit of normal with high bilirubin levels while aspartate aminotransferase and alanin aminotransferase were normal. Thyroid ultrasonography revealed chronic thyroiditis compatible with Graves disease. Thyroid receptor antibody was positive. Other causes of liver dysfunction and thrombocytopenia were ruled out. The patient was started on methimazole 20 mg/day and propranolol 40 mg/day. Complaints of the patient regressed with the improvement of cholestatic enzymes and thrombocytopenia.
Conclusion
Rare clinical manifestations of Graves' disease such as thrombocytopenia, liver dysfunction, muscle weakness in the lower extremities, and mild hypokalemia were present in this patient. All of these findings improved with anti-thyroid therapy.

Endocrinopathies related to immune checkpoint inhibition: A clinical case presentation

David Veríssimo, Matilde Jácome de Castro, Catarina Ivo, Vitória Duarte, Mafalda Marcelino & João Jácome de Castro
Armed Forces Hospital, Department of Endocrinology, Lisbon, Portugal

Introduction
In the area of Immunotherapy, immunological checkpoints, such as CTLA-4, PD-1 or PD-L1, are membrane proteins involved in the immune response that, when inhibited, cause an increase in T cell activity and a consequent anti-tumor effect. However, this inhibition can also cause adverse effects, including endocrinopathies, such as thyroid dysfunction and hypophysitis.
Clinical case
59-year-old man, diagnosed with lung cancer, treated with nivolumab (anti-PD-1), with complaints of fatigue, decreased muscle strength, anorexia, constipation and depressed mood a month after treatment initiation. Laboratory evaluation revealed autoimmune hypothyroidism and secondary adrenal insufficiency (thyroid stimulating hormone: 7.81 μU/ml; free thyroxine: 0.65 ng/dl; anti-thyroid peroxidase antibodies: 185 U/ml; adrenocorticotropin < 0.1 pg/ml; cortisol: 0.5 μg/dl). It was made a magnetic

resonance imaging that revealed an enlarged pituitary gland, without associated lesions. Following the diagnosis of primary hypothyroidism and adrenal insufficiency secondary to hypophysitis, the patient received replacement therapy with clear clinical and laboratory improvement.
Discussion
The clinical case describes an uncommon association of hypothyroidism and hypophysitis associated with anti-PD-1 therapy and aims to highlight a recent and often underdiagnosed clinical entity: endocrinopathies related to immune checkpoint inhibition.
In cancer patients receiving anti-PD-1, anti-PD-L1 or anti-CTLA-4 drugs, regular endocrine assessment is recommended to make early diagnosis and treat appropriately. The endocrine laboratory evaluation should be performed before starting to immune checkpoint inhibition therapy as well as during the treatment cycle. The hypothalamic-pituitary-thyroid and hypothalamic-pituitary-adrenal axis are the most frequently affected. The remaining assessment of the pituitary function will depend on the clinic of each patient. The therapeutic approach consists of hormonal replacement of the deficient endocrine axis.
Conclusion
The early diagnosis of endocrinopathies as well as the timely institution of adequate therapy can have a significant impact on the prognosis and quality of life of these patients.

Is it Graves orbitopathy?

Ricardo Firme, Pedro Morato, Luiza Morato & Julia Morato
Endocrinologica, Itaúna, Brazil

Graves' orbitopathy, is a rare and potentially sight-threatening ocular disease that sometimes occurs in patients with euthyroid or hypothyroid chronic autoimmune thyroiditis. We relate a case of a man with 53 years that have diabetes and hipertension and regular clinical exams with endocrinologist and oftalmologist. He developed a bilateral exoftalmia, larger at right eye, in 3 months of follow up, without another signs of thyrotoxicosis. After 2 years of follow up, the thyroid function was normal but the levels of thyrotropin (TSH) receptor (TSHR)-stimulating autoantibodies was insistently in very high levels. It was not observed clinical activity on eyes and more involvement of the muscles of eye motility. We discuss the possibility of thyroid-associated ophthalmopathy and some new described causes as IgG4-related disease, neoplasias and others.

Early diagnosis of acromegaly in chronic thyroiditis-case report

Ana-Maria Stancu[1,2], Alexandra Gabriela Marin[1], Monalisa Beatrice Preda-Ivascu[1], Daniel Mihai[1], Cristina Stancu[1] & Corin Badiu[1,2]
[1]National Institute of Endocrinology, 'C.I.Parhon', Thyroid II, Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', General Medicine, Bucharest, Romania

Introduction
Acromegaly is characterized by a pituitary adenoma with excess secretion of GH and IGF-1 hormones. More than 90% of the cases are diagnosed as macroadenomas, after 5 to 10 years of clinical manifestation.
Case report
We present the case of a 49 years old man with minor thalassemia, hospitalized in endocrinology department for a routine check of chronic autoimmune thyroiditis. A careful anamnesis showed that in the last year the patient was dizzy, the ring was not fitting on his finger and the shoes were tight. Laboratory findings: elevated IGF1 (617 ng/ml, normal range: 67–225 ng/ml), lack of GH suppression with oral glucose tolerance test (GH = 6.332 ng/ml, normal less than 1 ng/ml), HbA1c = 6.1% (4.8–5.7). MRI of the pituitary gland showed a 7.3 × 5 mm pituitary adenoma. Pituitary-gonadal axis was not affected nor optic chiasm. A thyroid ultrasonography was performed and a 1.48/1.01/1.29 cm nodule was discovered in the left lobe. The thyroid function was in normal range without medication, except thyroid peroxidase antibodies which were elevated. The patient underwent transsphenoidal adenomectomy with good result after surgery (IGF-1 = 259.50 ng/ml –postoperative and 3 months after surgery IGF-1 = 180 ng/ml with GH suppression with oral glucose tolerance test). The diagnosis of acromegaly was also confirmed histopathological. A fine needle aspiration biopsy of the thyroid nodule was performed and it was classified as Bethesda III. Also, the patient underwent screening for cardiomegaly, colon cancer, diabetes and sleep apnea and all were negative.
Conclusion
Diagnosis of GH-secreting pituitary adenoma as microadenomas increases the chance to cure the disease and improves the quality of life. In addition, patients do not develop other complications associated with excess of growth hormone. Early diagnosis is the key in the treatment of acromegaly.

Size does it matter?

Yasmin Nikookam[1,2], Bonnie Grant[2], Yunni Lee[2], Imran Syed[1], Antony Pittathankal[1,2], Anna Hawkins[1,2] & Khash Nikookam[1,2]
[1]Spire London East Hospital, Greater London, United Kingdom; [2]King George Hospital, Barking Havering and Redbridge University NHS Trust, Greater London, United Kingdom

Introduction
Thyroid cancer is the most common malignant endocrine tumour and represents 1% of all malignancies. Cancer Research UK in 2015 reported 3528 new cases and 382 deaths with annual incidence of 5.1 and 1.9 per 100,000 women and men respectively. The incidence is increasing globally, mostly due to papillary thyroid cancer.
Ultrasound is the preferred examination with recommended U1-U5 grading system +/- fine-needle aspiration cytology (FNAC).
Results
We present a case of a 28-year-old female with a long history of seizure-free epilepsy who was referred to an endocrinologist with a 3-month history of hot flushes, night sweats and difficulty losing weight. Clinically there was no signs or symptoms of infection, inflammation or any endocrinopathies, expect for palpable nodules on both lower poles of the thyroid. There were no thyroid or carotid bruits audible. She was clinically euthyroid.
A series of investigations showed normal full biochemistry, haematinics, thyroid function, inflammatory markers however, a raised serum basal cortisol which was likely related to the oral contraceptive pill. Subsequently, ultrasound of the thyroid showed nodules in the right lower lobe and a dominant nodule in the left lower lobe measuring 21 mm × 8 mm with moderate vascularity and no macro or microcalcification. Several small cervical lymph nodes on the right side of the neck level III were seen, likely reactive. FNAC of the left dominant thyroid nodule confirmed Thy2.
On subsequent visit, repeat ultrasound of thyroid and FNAC was advised in view of the size of the left thyroid nodule, which confirmed Thy5.
She underwent a total thyroidectomy with an uneventful recovery and was commenced on levothyroxine.
Conclusion
This case highlights the size of a thyroid nodule may well correlate to the likelihood of malignancy. This has been emphasised in American Thyroid Association management guidelines, but not in the United Kingdom.

'Thank you for giving me my wife back' – the role of liothyronine (T3) in primary hypothyroidism

Bonnie Grant, Nirupam Purkayastha, Raj Tanday, Anna Hawkins, Nancy Enriquez, Augustine William, Edel Casey & Khash Nikookam
King George Hospital, Barking Havering and Redbridge University NHS Trust, Endocrinology, Greater London, United Kingdom

The British Thyroid Association executive committee advised in 2015 that there was insufficient evidence that levothyroxine(T4) and liothyronine(T3) combination therapy was superior to levothyroxine monotherapy, which remains the standard treatment of primary hypothyroidism. It was considered an experimental approach in symptomatic patients on T4 therapy with a TSH level within normal range.
We present a 47-year-old lady who had been diagnosed with primary hypothyroidism for three-and-a-half years under the care of her General Practitioner. Despite treatment with levothyroxine 25 and 50 micrograms on alternate days she had ongoing lethargy, generalised weakness, a lack of concentration and 'brain fog'. She gained over 10 kg in weight over the

previous 5 years despite adhering to calorie intake recommendations, increased exercise regimes and seeing a nutritionist.
On clinical examination, she had a body mass index (BMI) of 36 with a slow relaxing phase of bicep reflexes, an otherwise normal examination of all systems with no overt features of Cushing's Syndrome. She was clinically and biochemically euthyroid with TSH 4.49 mU/l [Normal range (NR) 0.35–5.5], free T4 17.3 pmol/l (NR 10–19.5) and free T3 5.1 pmol/l (NR 3.55–5.44) with positive TPO antibodies. An overnight dexamethasone suppression test excluded a Cushing's syndrome with an appropriate serum basal cortisol suppression at 24 nmol/l.
She was reviewed a number of times over the following 12 months with ongoing symptoms as per patient; feeling tired, worn out, unable to keep awake and 'at her wit's end'. She remained clinically and biochemically euthyroid with free T3 4.3 pmol/l at lower half of the normal range, normal TSH 3.96 mU/l and a normal free T4 15.7 pmol/l, hence no changes to levothyroxine dose were made.
The pros and cons of T3 therapy were discussed in detail and subsequently liothyronine 10 micrograms daily was initiated. At further clinic reviews four and eight months later, she reported a significant improvement in her energy levels, hair growth at her eyebrows and weight reduction of 3 kg with no change in her lifestyle. Liothyronine 10 micrograms daily in combination with levothyroxine 25 and 50 micrograms alternate days was continued with subsequent further improvement in her general wellbeing.
Conclusion
We present a case of significant improvements in a patient's symptoms, well-being and quality of life on commencement of T3 in addition to T4 despite prior normal thyroid function tests on T4 alone.

The relationship between thyroid function and lipid metabolism – is it so obvious?

Szymon Suwala & Roman Junik
Collegium Medicum in Bydgoszcz, University of Nicolaus Copernicus in Torun, Department of Endocrinology and Diabetology, Poland

Introduction
Thyrotropic hormone (TSH), triiodothyronine (fT3) and thyroxine (fT4) affect adipocytes and HMG-CoA hepatic reductase, indirectly regulating the body's lipid metabolism. This mechanism is already known, however the principles of regulating lipid metabolism through thyroid metabolism constitute an important and a desirable element of scientific research in thyreology. Thyrotropic hormone (TSH), triiodothyronine (fT3) and thyroxine (fT4) affect adipocytes and HMG-CoA hepatic reductase, indirectly regulating the body's lipid metabolism. This mechanism is already known, however the principles of regulating lipid metabolism through thyroThe aim of the study was to assess the relationship between TSH, fT3 and fT4 concentrations and lipid parameters, as well as to identify differences in individual thyroid gland dysfunctions.m constitute an important and a desirable element of scientific research in thyreology.
Material and methods
The medical records of 1470 patients were analyzed (gender, TSH, fT3, fT4, total cholesterol, HDL-C, LDL-C, triglycerides as well as the percentage of HDL-C and LDL-C relative to total cholesterol level). Patients receiving statin therapy were excluded from the study. The collected data was statistically analyzed using the STATISTICA 13.3 statistical package
Results
TSH correlated with total cholesterol ($r=0.10$), LDL-C ($r=0.08$), and triglycerides ($r=0.10$), but not with HDL-C ($P=0.43$). fT3 correlated with total cholesterol ($r=0.13$), LDL-C ($r=0.12$), HDL-C ($r=0.29$), but not with triglycerides ($P=0.16$). Correlations regarding TSH were stronger in men, while those related to fT3 and fT4 – in women. Hypothyroidism is associated with a 37% higher risk of triglyceridemia and a 41–62% risk of atherosclerosis compared to the euthyroid population. Full results will be presented during Congress.
Conclusion
The function of the thyroid gland has a significant impact on the lipid metabolism. Correlations between thyroid and lipid parameters show significant diversity based on gender. Full conclusions will be presented during the Congress.

Hypothyroidism, a rare complication of nephrotic syndrome: A case report

Hind Asbar, Rolly Junior Louzollo-Kimbembe, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Mohammed VI University Hospital, Marrakech, Marrakesh, Morocco

Introduction
During nephrotic syndromes, thyroid function abnormalities may be observed. Hypothyroidism due to loss of thyroid hormones or their binding proteins can be seen but remains a rare complication of nephrotic syndrome. We report the case of 22 year old patient admitted for massive proteinura with nephrotic syndrome that was complicated with hypothyroidism.
Case report
We report the case of 22 year old patient who presented with generalized edema. The patient was diagnosed with nephrotic syndrome with massive proteinuria at 15 g/24 h. He was found to have a hypothyroidism with a TSH level at 6 mUI/l. Thyroid ultrasound was normal with negative anti-thyroperoxidase antibodies. A kidney biopsy revealed features consistent with minimal change renal disease. Given the massive proteinuria and etiology investigations of hypothyroidism that were negative, the patient was not put on thyroxine therapy. The evolution was favorable with regression of proteinuria to 5 g/24 under symptomatic treatment and normalization after a month as well as thyroid function.
Discussion
Excessive loss of urinary proteins due to nephrotic syndrome leads to loss of albumin and thyroxine binding globulin (TBG) through urine and can affect thyroid function. It also damages renal tubules and reduces the reabsorption of low-molecular-weight proteins, including free thyroid hormones. In most cases, the loss of thyroid hormones is compensated by an increase in TSH. Hypothyroidism, which remains a rare event during nephrotic syndrome, is seen mainly in massive and prolonged proteinuria.
Conclusion
The occurrence of hypothyroidism in nephrotic syndrome in adults is rarely described. Its exact prevalence is not well known. It seems useful to systematically assess thyroid function in the nephrotic syndrome especially if the proteinuria is massive and prolonged.

Hashimoto's tiroiditis, quervain's disease and a suspicious nodule

Catarina Roque[1], Clara Cunha[2], Carlos Bello[3], Catarina Saraiva[3] & João Sequeira Duarte[3]
[1]Egas Moniz Hospital C.H.L.O., Endocrinology, Lisboa, Portugal; [2]Egas Moniz Hospital C.H.L.O., Lisboa, Portugal; [3]Egas Moniz Hospital C.H.L.O., Endocrinology, Lisboa, Portugal

Introduction
The Quervain's disease is an infrequent subacute thyroiditis (ST) that results in granulomatous infiltration of the gland's parenchyma. Is usually diagnosed clinically based on cervical pain, systemic symptoms, altered thyroid function tests (TFTs) and history of upper respiratory tract infection. It is a benign self-limited condition that may share US features with malignancy which may result in improper therapy, including lobectomy.
Case report
A 47-year-old female was evaluated due to the identification of a macronodule not present in the previous year US. She had primary hypothyroidism substituted with 100 mg of levothyroxine. Previous exams (2018) showed negativity for anti-thyroid antibodies and a small sized gland without nodularity, suggestive of chronic thyroiditis. The ultrasound performed in the context of mild cervical pain (5/2019) revealed relative enlargement of the right lobe and a taller-than-wide 28 mm markedly hypoechoic, heterogenous nodule with poorly defined margins.
During medical interview (9/2019) she denied risk factors for thyroid cancer or history of respiratory infection. She complained of right-sided cervical moderate pain exacerbated by touch, that started 4–5 months before and lasted 2–3 weeks. She denied any other local signs/symptoms, viral or thyroid dysfunction associated systemic symptoms apart from a period of exacerbated anxiety in these previous months.
Upon inspection and palpation there were no inflammatory signs, the gland had normal size, no palpable node and was freely movable.
Hashimoto's thyroiditis and a presumptive diagnosis of ST was made despite the subtleness of the history and clinical findings. Thyroid function

and inflammatory parameters resulted normal. Due to the lesion's suspicious features US guided FNA was requested. An asymmetric gland with a heterogeneous hypoechoic right lobe without individualized nodules was the only finding (11.2019).
Conclusion
ST is usually diagnosed clinically but the history/symptoms may be heterogenous, vague and the characteristic triphasic pattern of TFT may not be identified. US characteristics are focal heterogenous (markedly) hypoechoic areas of irregular and hill-defined borders. Lesions may be taller-than-wide and oedematous disruption of the perithyroidal capsular echogenic line may suggest extrathyroidal extension. Lack of microcalcifications or suspicious ganglia and a centripetal reduction in echogenicity have been reported to be the most distinctive features for ST. FNA may pose challenges to the cytopathologist and follow up US (after 2–5 months) may indetify resolution. In doubtful scenarios deliberation between FNA vs follow-up US may be considered to document normalization of echogenicity and uncover any suspicious thyroid nodules obscured by the inflammatory changes.

What is responsible for subacute thyroiditis? Virus or immune system: A case report

Dilek Geneş, Zafer Pekkolay, Mehmet Güven, Mehmet Şimşek, Hüsna Saraçoğlu & Alpaslan Kemal Tuzcu
Dicle University Faculty of Medicine, Adult Endocrinology, Diyarbakır, Turkey

Background
Subacute thyroiditis (SAT) is a transient thyrotoxic state characterized by suppressed TSH and low uptake of iodine 123 on thyroid scanning. SAT is a self limiting, possibly viral and inflammatory thyroid disorder that is usually associated with thyroid pain and systemic symptoms. Many factors can cause SAT. Infections are considered the most common cause. Vaccines can also lead to SAT.
Case report
A 46-year-old male with a history of type 1 diabetes mellitus admitted to the hospital with fatigue, weight loss, myalgia and mild anterior neck pain. In November 2019, about four weeks before admission to our hospital, the patient received the seasonal influenza vaccine [VaxigripTetra- Quadrivalent influenza vaccine; batch number T3J232V, Sanofi Pasteur, Val de Reuil, France, containing the following strains: A/Brisbane/02/2018 (H1N1) pdm09; A/Kansas/14/2017 (H3N2); B/Colorado/06/2017; and B/Phuket/3073/2013], and at the time of vaccination, there was no prior history of thyroid disease or symptoms to suggest a recent viral infection. However, one week following the vaccination, the patient developed fever, sore throat, fatigue, myalgia and muscle weakness. He received antibiotherapy for two weeks. The patient had no symptoms or physical examination findings of upper respiratory system infection, and he had no obvious fever at the time of admission to the hospital. His heart rate was 112/min and regular. He had tenderness in both thyroid lobes. His laboratory tests showed a white blood cell (WBC) count of 9.12/µl (normal, 4.6–10.2), His kidney and liver functions were normal. Tests for thyroid autoimmune antibodies (thyroperoxidase and thyroglobulin) were negative. Ultrasonographic imaging and thyroid scintigraphy confirmed diagnosis of SAT. The table presents the time-varying laboratory parameters at admission and after steroid treatment (Table 1). The patient was started on 32 mg/day oral methylprednisolone treatment. His symptoms improved with treatment. With the two-month treatment period, the steroid dose was gradually reduced and discontinued. The patient asymptomatic in the third month of follow-up.

Table 1 Laboratory parameters following influenza vaccine.

	4. week	7. week	9. week	15.week	Referance range
TSH	0.01	4.15	10.08	5.82	0.5–5.5 mIU/l
FT4	2.17	0.78	1.09	1.22	0.89–1.76 ng/ml
FT3	4.81	1.94	2.67	3.25	2.3–4.2 pmol/l
ESR	21	9	5	3	0–15 mm/h
CRP	<0.34	0.02	<0.34	<0.34	0–0.5 mg/dl

TSH; thyroid-stimulating hormone, FT4; free thyroxine, FT3; free triiodothyronine,
ESR; erythrocyte sedimentation rate, CRP; C reactive protein

Conclusion
SAT should be suspected if influenza-like symptoms and pain in the thyroid region develop after influenza vaccination.

DOI: 10.1530/endoabs.70.EP507

The place of radioactive iodine remnant ablation in papillary thyroid microcarcinoma

Mohamed Masmoudi, Mehdi Hasnaoui, Malika El Omri, Rihab Lahmar, Khalifa Mighri & Nabil Driss
Tahar Sfar Hospital mahdia, ENT Department, Mahdia, Tunisia

Introduction
Thyroid papillary microcarcinoma is a subtype of papillary carcinoma that included tumors with less than 10 mm diameter. Its therapeutic management is still a subject of controversy.
Material and methods
We conducted a retrospective study over 20 cases of papillary thyroid microcarcinoma at the ENT department of Tahar Sfar Hospital in Mahdia over 17 years (2000–2017).
Results
We report 20 cases of papillary thyroid microcarcinoma occuring in 18 women and 2 men. The mean age was 42 years ranging from 24 years to 75 years. A family history of thyroid pathology was noted in three cases and no prior history of cervical radiation or thyroid surgery was found. The ultra sound of the neck showed benign thyroid nodules in 18 cases and lateral lymph node associated to a suspect infracentimetric nodule in two cases. Lymph node metastases of papillary carcinoma were detected by fine needle aspiration cytology in these two cases. Total thyroidectomy was performed for 8 cases of multinodular goiters, thyroid lobectomy for 10 cases of a thyroid nodule. The intra operative pathologic examination was benign for these cases. Total thyroidectomy associated to central and lateral lymph node dissection was undergone in two cases. All the cases of thyroid microcacinoma were found during final pathologic examination. Lymph node metastases were noted in nine cases. Completion thyroidectomy following lobectomy that was associated to a central lymph node dissection was performed for 8 cases. Two cases of lobectomy did not perform this procedure since the size of microcacinoma was successively 1 and 2 mm. Radio-active Iodine remnant ablation treatment was indicated in 15 patients: 9 cases of lymph node metastases, extra thyroidal invasion in 5 cases and bilateral microcarcinoma in one case. A six years mean follow-up revealed no recurrence or death.
Conclusion
Papillary thyroid microcarcinoma have favourable long-term prognosis. Its management is multidisciplinary. A controversy exists regarding the role of radioactive iodine remnant ablation in this type of tumor. The indication of it depends on histological data.

Chronic lymphocytic thyroiditis

Mehdi Hasnaoui, Mohamed Masmoudi, Takwa Belaid & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Tunisia, Otolaryngology-Head and Neck Surgery, Mahdia, Tunisia

Introduction
Chronic lymphocytic thyroiditis is an autoimmune pathology affecting 5% of the population. Treatment is most often medical based on hormone treatment. Sometimes thyroiditis will be associated with benign or malignant nodular pathologies requiring the use of surgery. The objective of this study is to describe the diagnostic, therapeutic and evolutionary features of this entity.
Materials and methods
It is a retrospective study bringing 28 cases of chronic lymphocytic thyroiditis collected over a period of 15 years.
Results
The average age of our patients was 44 years (23 to 70 years) with a clear female predominance (26 women and 2 men). Anterior cervical swelling was the reason for consultation in all cases, associated with dysphagia in 4 patients and dyspnea in 2 patients. Cervical ultrasound, performed in all patients revealed a multinodular goiter in 53% of the cases, an isolated nodule

in 42% of the cases and an appearance of thyroiditis in 0.3% of the cases. Thyroid scintigraphy performed in 3 patients, objectified a hetero-nodular goiter in 9 cases and a cold nodule in 4 cases. Hypothyroidism was noted in 6 patients. All the patients were operated, having had a lobo-isthmectomy in 36% of the cases and a total thyroidectomy in 64% of the cases. The final histological examination showed Hashimoto thyroiditis in 14 patients, lymphocytic thyroiditis associated with an adenoma in 8 patients, a multinodular goiter in 4 patients, a papillary carcinoma in one case and a lymphoma in one case.
Conclusion
The frequency of the lymphocytic thyroiditis association with a multinodular goiter, an adenoma, a thyroid cancer has prompted several etiopathogenic studies in order to clarify the peculiarities of this coexistence.

Case report of a very unusual thyroid nodule

Rona Penso[1], Irene Crespo[2], Juan José Dominguez Cañate[3], Laura Mola[2], Teresa de Grado[2], Lorea Herraiz[2], Maria Elena Mendoza[2]
[1]Hospital Central de la Defensa Gomez Ulla, Endocrinología, Madrid, Spain; [2]Hospital Central de la Defensa: Gomez Ulla, Endocrinología, Madrid, Spain; [3]Hospital Central de la Defensa: Gomez Ulla, Anatomía patologica, Spain

Background
Branchial cleft cysts account for almost 20 percent of pediatric neck masses. They are usually present in late childhood or early adulthood, when a previously unrecognized cyst becomes infected. First branchial cleft cysts typically appear on the face near the auricle. Second branchial cleft cysts are the most common and they are usually located just inferior to the angle of the mandible and anterior to the sternocleidomastoid muscle. Third branchial cleft cysts are typically located lower in the neck than the second one. First step in management is controlling infection, if present. Once the infection has been resolved, the mass is usually excised to prevent future complications.
Case presentation
A 72-year-old man was incidentally found to have a nodule in left thyroid lobule (LTL) during the performance of a carotid doppler ultrasound. The patient had personal history of transient ischemic attack in 2016, type 2 diabetes, dyslipidemia, arterial hypertension, Wolf-Parkinson-White syndrome and prostate carcinoma (in remission). He followed treatment with aspirin, metformin, atorvastatin and ramipril). There was no family history of thyroid carcinoma. Palpation of the neck was normal. He presented normal thyroid hormone levels with positive autoimmunity. Thyroid ultrasound reported a normal size gland with 2 hyperechoic micronodules without suspicions characteristics in right lobule and one solid nodule (13 mm, markedly hypoechoic, heterogeneous with lobulated surroundings) in LTL, suggesting a malignant nodule (TIRADS4c). Ultrasound guided fine-needle aspiration cytology was performed, which revealed four times insufficient specimen (Bethesda I) describing: protein hemorrhagic background with abundant anucleated cytoplasms and mature flat pavement cells, as well as crystalline deposits, without thyroid elements or with 3–4 follicular groups insufficient for diagnosis. With these results, a left hemithyroidectomy was performed.
Examination of the pathology sample reported an intrathyroidal branchial cleft cyst with collapsed light, microscopically, presented occasional anucleated laminates and cellular detritus, which were coated by squamosian epithelium without grain, lacking of atypia. Also, an incidental 1 mm papillary carcinoma was found, with free resection margins.
Conclusion
This report represents a rare case of branchial cleft cyst because of the location and the age of our patient. The literature review reveals the existence of only 6 cases of intrathyroidal branchial cleft cyst. There are not specific ultrasound or cytology characteristics, resulting in the need for surgery to reach a diagnosis.

Concurrent central diabetes insipitus and thyroid hormone resistance syndrome

Sheng-Fong Kuo & Bie-Yui Huang
Chang Gung Memorial Hospital, Endocrinology and Metabolism, Keelung, Taiwan

A 47-year-old male farmer presented to our endocrinology clinic in 2001 with progressive polyuria for half a year. He had a past history of left intracranial hemorrhage with right hemiparesis due to traumatic injury in November 1998 but recovered thereafter. He complained of urine output more than 10 000 c.c. per day. Routine urine check with SP. GRAVITY < 1.005 was noted (Normal range: 1.005–1.030). Serum osmolality was 299 mosm/KgH_2O (Normal range: 275–295) while urine osmolality was 86 mosm/KgH_2O (Normal range: 50–1400). We also checked his serum ADH level which was 0.13 pg/ml (Normal range: 0.4–2.4), and therefore central diabetes insipidus (DI) was impressed. In addition, serum level of pituitary hormones, including luteinizing hormone (LH), follicle-stimulating hormone (FSH), prolactin, growth hormone (GH), adrenocorticotropic hormone (ACTH) were normal. However, elevated serum FT4 level (FT4: 2.22 ng/dl) (Normal range: 0.85–1.86 ng/dl) with higher serum TSH level (TSH 13.7 ulU/ml) (Normal range: 0.25–4 ulU/ml) was noted. Serum TBII level was 4.45% (Normal < 15%). Repeated thyroid function test revealed similar results with slightly higher serum FT4 level and normal to higher serum TSH level. Brain magnetic resonance imaging (MRI) was performed and revealed no pituitary mass. The patient did not have any symptoms and signs of hyperthyroidism, such as weight loss, heat intolerance, hand tremor and tachycardia. Thyroid ultrasonography was performed and showed a normal thyroid. Thus, thyroid hormone resistance syndrome was suspected. Except a large amount of DDAVP (nasal spray) (10 mg/ds, 25 ds/bot) 5 bottles per months, he did not receive any treatment for abnormal thyroid function. Serum FT4 level has been continued to be higher than normal with a normal to higher serum TSH level. In conclusion, our patient had been diagnosed with central diabetes insipitus and thyroid hormone resistance syndrome.

A rare complication of thyrotoxicosis: diabetic ketoacidosis

Dorina Condurache[1] & Dr Vinit Shah[2]
[1]Northwick Park Hospital, London, United Kingdom; [2]East & North Hertfordshire NHS Trust, Stevenage, United Kingdom

Graves' disease is the most common cause of hyperthyroidism. It is well established that hyperthyroidism promotes a hypermetabolic state characterized by increased resting energy expenditure, increased lipolysis and gluconeogenesis. We describe a rare complication of thyrotoxicosis in a patient with type II diabetes on insulin, with no previous thyroid history. An 83 year old woman with type 2 diabetes on biphasic insulin presented with symptoms of polyuria, polydipsia and fatigue. She was tachycardic and tachypneic but normotensive and apyrexial with no obvious focus of infection. Her clinical examination revealed no abnormalities and initial investigations showed blood glucose of 26 mmol/l, ketones 4.8 mmol/l, pH 7.19 and bicarbonate of 14 mmol/l confirming diagnosis of Diabetic Keto-Acidosis (DKA). A thyroid function panel was ordered which showed her thyroid stimulating hormone was < 0.003 with a free T4 level of 64.1 mg/l. A diagnosis of Graves' disease was made based upon her positive thyroid stimulating hormone receptor antibody (TSH-R). The patient improved upon starting management for DKA with resultant closure of anion gap and resolution of DKA. Treatment for thyrotoxicosis was also initiated with propranolol and carbimazole to manage her thyroid state with good response. She was discharged on biphasic insulin and newly commenced on anti-thyroid medication. Our case emphasizes that inadequately treated thyroid disease can negatively impact diabetes control. Increased glucose uptake and increased insulin clearance in hyperthyroidism creates a relative insulinopenic state that can manifest as DKA. Graves' thyroid patients with diabetes can have suboptimal blood sugar control in hyperthyroid state and they should be warned about DKA as a potential complication.

Graves' disease and papillary thyroid cancer: Clinical case

Natalya Volkova, Ilya Davidenko, Irina Dzherieva, Alexander Zibarev, Lilia Ganenko, Igor Reshetnikov, Julia Sorokina, Julia Degtyareva & Snezhana Brovkina
Rostov State Medical University, Rostov, Russian Federation

Background
Graves' disease in combination with thyroid nodules is more common in women. However, more than one in three patients has carcinoma.

Unfortunately, thyroid cancer is most frequently detected accidentally after a thyroidectomy for Graves' disease, despite the wide possibilities of modern diagnostic methods.
Clinical case
A 55-year women complained of discomfort in the neck, sweating, irritability, palpitation. From anamnesis: in 2012 she was diagnosed with thyrotoxicosis syndrome. For 5 years, the patient was treated with thyrostatics, but when trying to reduce the dose, the syndrome of thyrotoxicosis recurred. In March 2017, the patient's condition worsened, at the time of treatment she took Thyrosol 30 mg/day.
Objectively
Hypersthenic body type, BMI 33 kg/m^2. Thyroid gland visually was increased in volume, dense with palpation, homogeneous, mobile. Elevated titer of antibodies to the TSH receptor was discovered, according to the ultrasound – increase thyroid gland 30.2 cm^3, hyperechogenic formation of the left lobe 10×10×9 mm with hypoechoic rim, clear smooth contours, intranodular blood flow. As a result, the Graves' disease, goiter grade 2, manifest thyrotoxicosis was verified, surgical treatment was recommended. Thyroidectomy, histological examination was performed: Graves' disease was confirmed, papillary microcarcinoma with metastasis to 1 regional lymph node was revealed. Diagnosed: papillary thyroid cancer I st (pT1aN1aM0x), 2 clinical group. The patient was prescribed suppressive therapy with L-thyroxine 100 μg/day, against which after 3 months TSH reached the target values (0.2–0.5 Mme/l). Taking into account the histological characteristics of the tumor, the nature and volume of the lesion, age, the patient belongs to the group of intermediate cancer risk of progression of cancer. According to scintigraphy residual functioning thyroid tissue (20 × 15 mm) was detected. Radioiodine therapy was carried out in a specialized hospital. Suppressive therapy of L-thyroxine 150 μg/day, target values of TSH 0.1–0.5 Mme/l was recommended. After 6 months, TSH reached target values, and according to the results of ultrasound of thyroid gland no data for structural relapse was found.
Conclusion
Long-term recurrent Graves' disease with a dubious effect of conservative therapy, in the presence of nodular formation, should alert the doctor to the presence of thyroid cancer. Such patients are needed in carefully examination, as necessity for surgery should be determined.

Management and evolution of papillary thyroid carcinoma in a patient with acromegaly

Mihaela Vlad[1], Marioara Cornianu[2], Melania Balas[1,2], Ioana Golu[1], Daniela-Georgiana Amzar[1] & Flore Varcus[3]
[1]Victor Babeş University of Medicine and Pharmacy, Endocrinology, Timişoara, Romania; [2]Victor Babeş University of Medicine and Pharmacy, Timişoara, Romania; [3]Victor Babeş University of Medicine and Pharmacy, Surgical Department, Timişoara, Romania

Background
Acromegaly is a chronic rare disease induced by persistent hypersecretion of growth hormone (GH) and insulin-like growth factor 1 (IGF-1) in adult patients. Several studies have associated acromegaly with an increased risk for developing different benign or malignant tumors.
Case presentation
A 33-year old female patient was diagnosed with acromegaly due to a large pituitary macroadenoma, in 2009. In the same period, she was also diagnosed with a very large and compressive nodular goiter with retrosternal extension and underwent a subtotal thyroidectomy. The pathological exam established that it was a papillary thyroid carcinoma (PTC). Therefore, two further surgeries were performed for the complete removal of the thyroid tissue. The pituitary adenoma was treated 6 months later through endoscopic transsphenoidal surgery, but a residual tumor mass remained in the left cavernous sinus, that was managed by external radiotherapy, followed by the administration of Somatostatin analogues (SMA) for six years. The patient developed thyrotropic and gonadotropic insufficiency after the neurosurgical intervention. Radioiodine therapy was necessary for thyroid carcinoma, but the administration of Thyrogen was mandatory due to the suppressed TSH induced by pituitary insufficiency. The evolution of the case was favorable under therapy and the patient is now in a satisfactory condition, with a good quality of life. The Thyroglobulin level is undetectable (0.04 ng/dl) and the last IGF-1 value, four months after discontinuation SMA, was normal (103, NV 58–219 ng/ml).
Discussion
This case present one patient from our acromegalic series, who was detected with PTC in the moment of diagnosis. Many studies reported a high prevalence of thyroid cancer, between 1.2–11% among acromegalic patients. Sustained exposure to high serum IGF-1 levels seems likely to play a role in the development of the malignant disease, by stimulating the proliferation of different cells and by inducing an antiapoptotic effect on thyroid follicular cells. Some studies suggested a role for different factors like pituitary radiotherapy, obesity, insulin resistance, IGF-binding proteins, in development of thyroid cancer.
The diagnosis and the management of this case were difficult and challenging, but the evolution of this case was favorable, with cure of diseases, PTC and acromegaly.
Conclusion
A careful evaluation and management allow a favorable evolution in this case. Patients with acromegaly should be routinely screened for thyroid pathology at first evaluation, to allow an earlier detection of associated thyroid disease.

Grave's disease as a rare cause of pericardial effusion

Charlene Ludwine Bifoume Ndong[1,2], Sana Rafi[3,] Ghizlane El Mghari[4], Nawal el ansari[4] & Mohamed Akrim[5]
[1]CHU Mohammed VI, Endocrinology, Diabetes and Nutrition, Marrakech, Morocco; [2]Marrakesh, Endocrinology, Diabetes and Metabolic Diseases, Marrakesh, Morocco; [3]CHU Mohammed VI, Endocrinology, Diabetes and Metabolic Diseases, Marrakech, Morocco; [4]Centre Hospitalo-Universitaire Mohammed Vi Marrakech, Endocrinology, Diabetes and Metabolic Diseases, Marrakech, Morocco; [5]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Heart Department, Marrakech, Morocco

Introduction
The auto immune's diseases are also involved in the heart's failure. Grave disease(GD) is an autoimmune thyroid disease that often linked by pericarditis. We report a case of an acute pericarditis that was also presumed to be associated with GD.
Case report
A 59 years old who 10 pack years smoker. admitted for chest pain and shortness breathstage 3NYHA. At the investigation there was a progessive emaciation of 12 kg within 7 months with palpitations and repeated diarrhea. 4 days ago he presented a progressive setting dyspnea with orthopnea with intense chest pain. At the examination, skinny patient, radiance to the eye. There was a homogeneous thyroid enlargement with thrill and neck vein engorgement. There was no foot 's oedema,pulse rate of 109 beats per minute and a normal blood pression at 120/80 The heartbeat was regular and no cardiac murmur including precordial friction rub could be identified. Laboratory results showed a stunted TSH at 0,005 μg/ml( ), T4L: 70 pmol/l(12–22), a neck echography hypervascularized with a homogeneous goiter, the thyroid's antibody were positive by anti RTSh on 38(*N*<1.75). Transthoracic echocardiography showed circumferential effusion with hemodynamic consequences. The blood count and liver's enzymes were normal and the remaining part of the immunologic and serology is featureless. The management consisted in 3 pericardial drainage and etiological treatment under ATS in offensive trend of 60 mg of carbimazole, propranolol 40 mg ½ cp*3/d.
The favorable development with the pericardium drying and clinic stabilization and biological and hyperthyroidicism.
Discussion
The pericarditis with effusion in GD can happen by autoimmune mechanism involving a direct or indirect interaction between the Ac anti receptor and the pericardium. The thyrotoxicosis affects the metabolism of the pericardial's brown fat. The well taken ATS treatment must be completed by a radical treatment because of the high recidivism risk. The ATS choice is crucial because of pericarditis drug risk due to PTU.
Conclusion
The etiology research to a pericarditis must always involve a thyroid check not just to a research of a hypothyroidism commonly associated but also a hyperthyroidism notably in more frequently form which is the GD.

Treatment of hypothyroidism does not affect whole-body oxidative stress, as measured by biomarkers of RNA and DNA damage

Kamilla Ryom Riis[1], Camilla Larsen[1], Kristian H. Winther[1], Emil L. Larsen[2], Christina Ellervik[3], Laszlo Hegedüs[1], Thomas Brix[1], Henrik E. Poulsen[2] & Steen J. Bonnema[1]
[1]Odense University Hospital, Endocrinology, Odense, Denmark; [2]Rigshospitalet, Department of Clinical Pharmacology; [3]Copenhagen University, København, Denmark

Background
Hyperthyroidism as well as hypothyroidism have been associated with oxidative stress, caused by an imbalance between pro-oxidants and anti-oxidants. Oxidative stress may damage the genomic apparatus and other cellular structures. Urinary excretion of 8-oxo-7.8-dihydroguanosine (8-oxoGuo) and 8-oxo-7.8-dihydro-2'-deoxyguanosine (8-oxodG), respectively, represent global RNA and DNA oxidation, thus reflecting oxidatively generated modification of nucleic acids in the entire organism. While these biomarkers have been associated with increased morbidity and mortality in various diseases, they have only sparsely been explored in patients with thyroid disorders.
Method
Twenty-eight hypothyroid women (overt: $n=6$; subclinical: $n=22$) were included in a prospective cohort study. Mean age was 48.4±10.8(s.d.) years at diagnosis. Urinary excretion of 8-oxoGuo and 8-oxodG, corrected for creatinine, were measured shortly after initiation of levothyroxine (LT4) supplementation [mean 38±26 days between start of treatment and first study visit], and after a minimum 12 months of stable euthyroidism.
Results
Before treatment, TSH was 9.40±4.97 mIU/l and total T4 was 75.0±18.4 nmol/l. Mean follow-up time was 604±251 days. When euthyroid, the mean LT4 dose was 112±36 μg, and TSH had decreased to 2.48±2.08 mIU/l. As 8-oxoGuo and 8-oxodG were not normally distributed, a logarithmic transformation was applied. Compared to baseline, none of the biomarkers changed significantly after 12 months of euthyroidism. 8-oxoGuo: geometric mean (GM) 1.82 (95% CI: 1.62–2.03) nmol/mmol creatinine at baseline and GM 1.88 nmol/mmol creatinine (95% CI: 1.67–2.11) at euthyroidism, $P=0.51$. 8-oxodG: GM 1.37 nmol/mmol creatinine (95% CI: 1.15–1.64) at baseline and GM 1.45 nmol/mmol creatinine (95% CI: 1.23–1.70) at euthyroidism, $P=0.44$.
Conclusions
To the best of our knowledge this is the first study to evaluate the impact of LT4 treatment in hypothyroid patients on the excretion of the nucleic acid metabolites 8-oxoGuo and 8-oxodG. We found no significant effect of restoration of euthyroidism on these biomarkers of whole-body oxidative stress. However, the negative finding may be explained by most of our patients having subclinical rather than overt hypothyroidism. Thus, larger studies of patients with more severe thyroid failure are needed to further explore the relationship between hypothyroidism, its treatment, and whole-body oxidative stress.

Frequency of circulating antithyroid antibodies among the patients with thyroid diseases

Dinara Urinbaeva[1], Zulaykho Shamansurova[1,2] & Said Ismailov[1]
[1]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry at NUU, Metabolomics, Tashkent, Uzbekistan

Background
Increasing of the level of circulating Antithyroid autoantibodies suggested about autoimmune destruction in thyroid gland and not always depends from thyroid status. We aimed to study the frequency of circulating antithyroid autoantibodies (ATAB) in people with the different thyroid diseases.
Material and methods
In 25 people with high level of circulating ATAB blood serum TSH, T3, T4, glucose, ALAT, protein, albumin levels were measured. Thyroid gland ultrasound and ECG were performed. HR and BP were assessed.
Results
According to thyroid function in 64% were determined euthyreosis (TSH 1.6 ng/ml), in 24% with hyperthyroidism (TSH 0.1 ng/ml) and 12% with hypothyroidism (TSH 15.4 ng/ml). The average levels of ATAB were comparable between the groups and were four times higher than in healthy subjects. There were no significant differences in blood Calcium, Phosphorus level and alkaline phosphatase activity, whereas blood total protein, albumin, ALAT levels were oppositely linked with thyroid function. Interestingly, higher level of ATAB were accompanied with impaired glycemia in 56% patients with ecthyreosis, in 17% with hyperthyrosis and no glycemia impairments were detected in patients with hypothyreosis.
Conclusion
In patients with higher circulating ATAB mostly detected euthyreosis (in 64%) than hyperthyreosis (in 24%) and hypothyreosis (in 12%). In people with higher ATAB the glycemia impairments were determined in those with euthyreosis (56%) and hyperthyreosis (17%).

Management of subclinical hyperthyroidism presented by several cases

Valentina Velkoska Nakova[1], Brankica Krstevska[2], Gordana Pemovska[3], Irfan Ahmeti[3], Tatjana Milenkovic[3,4]
[1]Clinical Hospital, Faculty of Medical Science, University Goce Delchev, Internal medicine, Shtip, Macedonia; [2]Medical Faculty, University Cyril and Methodius, PHO Center of Internal Medicine 'Srce', Skopje, Macedonia; [3]Medical Faculty, University Cyril and Methodius, University Clinic of Endocrinology Diabetes and Metabolic Disorders, Skopje, Macedonia; [4]Medical Faculty, University St Cryl and Methodius, University Clinic of Endocrinology, Diabetes and Metabolic Disirders, Skopje, Macedonia

Subclinical hyperthyroidism (ScHyper) is a condition with suppressed TSH, and normal free T3 and free T4 hormones, affecting 10% of the population. There are two subgroups of patients, the first group with TSH lower than 0.1 U/l, and the second group with mildly suppressed TSH between 0.1 and the lower assay reference limit. The patients from the first group should be treated, but there is no evidence for therapy for the second group of patients. We present a three cases from the second group of patients with ScHyper and their different management of the disease. The pregnant women in the first trimester of pregnancy wasn't treated, just observed. The TSH spontaneously normalized in the second trimester of pregnancy. Patient with ScHyper caused by Graves' disease was treated only with beta blocker because of tachycardia. And, older women with multinodular goiter, who refused iodine 131 therapy, was treated with low doses of antithyroid drug and beta blocker. All three were without any complications from the disease. Treatment options of ScHyper are: antithyroid drugs, iodine 131 therapy, and surgery. Which of these will be chosen, or patient will be observed without therapy, depends to the specific causes.
Keywords: subclinical hyperthyroidism, Graves' disease, TSH reference values.

The Role of Selenium and Iodine on thyroid status in the first trimester of pregnancy

Sabine Upmale[1], Vija Veisa[1], Ieva Kalere[2], Andrejs Šķesters[1], Marina Makrecka- Kūka[1], Ieva Strēle[1], Maija Dambrova[1,3] & Ilze Konrāde[1]
[1]Riga Stradins University, Riga, Latvia; [2]Riga Stradins University, RIga, Latvia; [3]Latvian Institute of Organic Synthesis, Riga, Latvia

Introduction
Pregnant women are at risk for selenium deficiency, which is known to maintain adequate function of immune system and thyroprotective enzymes. Same, iodine is an essential micronutrient for thyroid hormone synthesis and important endocrine regulator of early brain development. Our previous study revealed that 81% of pregnant women in Latvia have insufficient levels of iodine. The aim of the present study was to evaluate iodine and selenium supply during pregnancy in recent years, and to analyze its association with thyroid function and autoimmunity.
Methods
123 pregnant women during the first trimester were included in a cross-sectional study in 2017–2019. Urinary iodine concentration(UIC) was

measured using the ammonium-persulfate method. Thyroid status was assessed by measuring thyroid stimulating hormone(TSH), free T4(FT4), thyroid peroxidase antibodies(TPO-ab). Serum selenium level was detected in 111 participants.
Results
Out of 123 participants(age 29.23±4.568;(min 17; max 40)) 65(52.8%) had UIC below the WHO recommended level of ≥150 μg/g during the first trimester of pregnancy. Furthermore, 34 patients(27.6%) were iodine deficient (UIC<100 μg/g). The median UIC was 147.21 μg/g Cr(IQR 89.99–248.1), which is regarded as suboptimal. There was no statistically significant correlation between UIC and TSH (0.047; $P=0.618$), FT4 (–-0.028; $P=0.769$) or TPO-ab (0.012; $P=0.895$). In addition, suboptimal iodine status did not have significant impact on thyroid function, as median TSH was 1.1 (IQR 0.676–1.45) mU/l in patients with suboptimal UIC(Group 1) and 1.0 (IQR 0.7–1.5) in patients with sufficient levels of UIC(Group 2), $P=0.816$. Mean FT4 was not affected either: group 1 mean FT4–14.2 pmol/l (95% CI 13.36–15.03) and 14.14 pmol/l(95% CI 13.62–14.65) in Group 2 ($P=0.911$). Moreover, it had no effect on TPO-ab levels: 28 (95% CI 27–40) vs 27 (95%CI 27–39, $P=0.612$). The mean serum selenium concentration was 102.07±37.01 μg/l (min 26.5; max 212.31). Furthermore, selenium concentration showed a statistically non-significant tendency of negative correlation with TPO-ab(0.027, $P=0.783$) and TSH(–0.120, $P=0.217$). 15 participants with increased TPO-ab(> 60) were characterized by lower levels of selenium as compared to those 93 with normal TPO-ab levels (≤ 60): 91.15(95% CI 71.07–111.23) vs. 103.10 μg/l (95% CI 95.62–110.58). There was no impact of selenium status on mean FT4(0.0, $P=0.996$).
Conclusions
More than half of pregnant women had UIC below the WHO recommended level of adequate iodine supply. However, mean serum selenium level was detected to be sufficient in the first trimester of pregnancy. Yet a negative correlation between TSH, TPO-ab and serum selenium levels was found. There was no significant association between UIC, selenium status and thyroid function.

Magnitude of increase in levothyroxine requirements during pregnancy in women with pregestational hypothyroidism in navarra (Spain)
Patricia Munarriz Alcuaz, Nerea Eguilaz Esparza, Ander Ernaga, Maria Dolores Ollero Garcia-Aulló, Emma Anda Apiñariz, Ana Iriarte Beroiz, Ana Irigaray Echarri & Amaya Sainz De Los Terreros Errea
Complejo Hospitalario de Navarra, Spain

Introduction
Hypothyroidism during pregnancy has been asociated with adverse maternal and neonatal outcomes. During pregnancy, maternal levothyroxine (LT4) dose requirements increase. The aim of this study is to determine the increase of LT4 doses during pregnancy in pregestational hypothyroid women.
Methods
We included 76 hypothyroid pregnant women. We analyzed analytical and clinical characteristics of these patients, as well as the increase of LT4 requirement during pregnancy. We used the statistical software SPSS version 20.
RESULTS
Fifty-two women had autoimmune hypothyroidism (68.4%). The mean prepregnancy TSH was 2.46±1.25 mU/l and the prepregnancy LT4 requeriment was 75.3±32.3 μg/d. An increase in the LT4 dose was necessary in 64 women (84.2%). The mean LT4 requirement increased 44±45 percent. Women with LT4≤50 μg/d increased LT4 by 63%, those between 51–100 μg/d and>100 μg/d increased by 33% and 25% respectively ($P=0.008$). Women with higher levels of anti-Tg antibodies required a higher LT4 dose (70% vs. 37%, $P=0.025$). There is also a higher dose increase in women with prepregnancy TSH>2.5 mU/l, but these differences were not statistically significant.
Conclusion
Most pregestational hypothyroid women require an increase in daily substitutive doses of LT4 during pregnancy. The mean LT4 requirement increased 45% percent during pregnancy. Women with lower prepregnancy LT4 requirement and women with higher levels of anti-Tg antibodies needed a higher dose increase.

Radioiodine therapy and Graves' disease
Abainou Lahousssaine, Hamza El Jadi, Ayoub Idrissi, Sanae Elhadri, Azelarab Miftah & Hicham Baizri
Avicenna Military Hospital, Endocrinology, Marrakech, Morocco

Used for the first time in 1941 in the United States by Hertz and Roberts for the treatment of hyperthyroidism in Grave's Disease, radioactive active therapy (RAI) has been able to gain its place within the already existing therapeutic arsenal by being efficient, easy to use and minimally invasive. Our work is a retrospective study of 46 patients collected at the Department of Endocrinology, over a period of 7 years and half from January 1, 2011 to June 30, 2018. The purpose of this study is to determine the place of radioiodine therapy in the treatment of Graves' disease in our context, and to evaluate its results. We defined 2 groups of patients: An 'A' group corresponding to all 46 patients followed for Graves' disease (the average age was 43 years and the sex ratio (F/M) was 0.84), including a subgroup 'B' corresponding to the 17 patients treated with RAI (the average age is 41 years and the sex ratio (F/M) was 1.12). All patients in group 'A' received first-line medical treatment, 37% of whom resorted to RAI because of either resistance to treatment in 70.6% of cases, relapse in 23.5% of cases, or serious side effects (severe leukoneutropenia and cholestatic hepatitis) caused by antithyroid drugs (ATD) which required an immediate interruption of the treatment in 5.9% of cases. Thirteen patients in group 'B' received a single dose of radioiodine (76.5%), 3 patients received 2 doses (17.6%) and only 1 patient received 3 doses of treatment (5.9%). The administered activities were between 8 and 15 mCi. The average activity administered in the first dose of treatment was 9.7 mCi (41.2% received 8 mCi, 52.9% received an activity between 10 and 12 mCi and 5.9% received an activity>12 mCi). The average activity of the 2nd dose of treatment was 9.2 mCi. The additional doses were justified by either resistance to ATDs or persistence of hyperthyroidism. The administration of iodine was very well tolerated. Only one case of xerophthalmia and ocular pain was noted in the short term.
The long-term results were as follows:
– 29.4% benefited from a return to euthyroidism.
– 47.1% went into hypothyroidism.
– 23.5% are still hyperthyroid.
Overall, the treatment was successful in 76.5% of cases and failed in 23.5% of cases. Despite the limited number of patients and the short period we had in order to evaluate this therapy, the results seem encouraging.

Autoimmune polyglandular syndrome type 3
Chayma Besrour, Ben Nacef Ibtissem, Rojbi Imen, Lakhoua Youssef, Mchirgui Nadia & Khiari Karima
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
Autoimmune polyendocrine syndrome (APS) is a rare, inherited disorder, characterized by autoimmune thyroiditis with another organ specific autoimmune disease.
Observation
We report the case of 55 years old woman, descendant of a first degree consanguineous marriage, who presented at the age of 35 a premature ovarian insufficiency and alopecia. Eight months later, she developed a goiter with hyperthyroidism and the diagnosis of Grave's disease was confirmed in front of high level of anti TSH receptor antibodies. During her hospitalization, we discovered a pancytopenia with severe anemia that needed a transfusion. Then she presented a diarrhea and the diagnosis of coeliac disease was confirmed. The procedure to follow was to put the patient under gluten free diet, and she was treated for her Grave's disease with radioactive iodine. This patient present an autoimmune polyglandular syndrome type 3C which is the association of autoimmune thyroiditis with alopecia and other organ-specific autoimmune disease.
Conclusion
APS is an autoimmune condition that affects the body's endocrine glands, the cause is still unknown. Type three is more often seen in women in middle age. The morbi-mortality is determined by the specifics of each syndrome. It is important to assure the follow up of the patients to detect and diagnose the other autoimmunes disorders at an early stage.

Low TSH level and twin pregnancy. A case report

Marjeta Kermaj[1], Thanas Fureraj[1], Violeta Hoxha[1], Klodiana Poshi[1], Dorina Ylli[1], Besa Hyka[1], Sara Zavalani[1], Irsa Zaimi[2], Klotilda Resuli[3], Adela Shkurti[4] & Agron Ylli[1]
[1]UHC 'Mother Tereza', Endocrinology, Tirana, Albania; [2]Regional Hospital Fier, Endocrinology, Fier, Albania; [3]Regional Hospital Vlora, Endocrinology, Vlora, Albania; [4]Hospital 'Vila Maria', Endocrinology, Tirana, Albania

Introduction
Thyroid physiology changes during pregnancy so the use of pregnancy-specific reference ranges for TSH and FT4 in order to adequately diagnose gestational thyroid disease is necessary. According to literature, in twin pregnancy, TSH can be in low levels during first trimester due to a much higher and more sustained peak of hCG (TSH-like activity of human chorionic gonadotropin) but it will be normalized at the end of the second trimester or within 22 weeks. Hyperemesis gravidarum (HG) is reported to occur in 0.3% to 1.0% of pregnancies.
Case report
Our patient, Caucasian female, 42 years old, pregnant 22 weeks, hospitalized at maternity hospital for being under close medical care. Before current pregnancy she had had 5 abortions (2 natural pregnancies and 3 pregnancies under IVF treatment). The current pregnancy has also been assisted by in vitro fertilization techniques. During the first 16 weeks of pregnancy she had been having hyperemesis gravidarum. In following she was without nausea and vomitus. She complained anorexia and fatigue. Familiar history and her life history not related to thyroid disease. She had normal weight body, mild hands tremor, and palpitations with a pulse rate of 100 beats per minute. Laboratory examinations reveled a TSH 0.006 IU/l. She was evaluated for thyroid diseases. FT4=14.2 pg/ml (7–18), FT3=3.9 pg/ml (2–4.25), T4 11.2 μg/ml (5.1–14.1) R-TSH ac 0.37UI/ml (<1). Thyroid ultrasound resulted normal. She was followed by repeating TSH, T3, T4 every month until delivering. It was noted that TSH stood in low levels (0.001 Ulu/ml) until delivering but FT4 and T4 in normal value. She was very stressed during her pregnancy because of fear of losing the pregnancy again. She underwent section cesarean at 35 weeks and she gave birth a healthy male child 2000 gr and a hypotrophy female child 1400 gr.
Conclusion
Every medical physician who takes care of a twin pregnancy, must recognize that a TSH level that keeps standing quite low (more than 22 weeks of pregnancy), does not always correspond with thyroid dysfunction and may be caused by other conditions such as hyperemesis gravidarum, higher level of hCG during twin gestation than pregnancy with a baby and maternal chronic stress. We thought that a combination of all these conditions have kept quite low TSH level until the end of pregnancy.

Oncological disease mimicking endocrine pathology – a challenging case report

Linda Kundzina-Steinberga
Riga East Clinical University Hospital, Endocrinology, Rīga, Latvia

Introduction
Patient with co existing oncological disease can easily be misunderstood by endocrinological pathology as hypothyroid, both representing similar appearances. The aim of this case report is to stress the importance of multidisciplinary teamwork, meaning of follow up, and increase knowledge about side effects of hormonal therapy which could affect endocrine system.
Case report
A patient 55 years old female complaining about weakness, dry skin, hair loss, constipation and headaches was referred to general practitioner and by examining autoimmune thyroiditis with elevated TSH-11 mU/l and anti TPO – 900 IU/ml, low fT4–7 pmol/l were found and Levothyroxine 25 mg OD was started. Few months after euthyroid state was reached, patient was diagnosed with infiltrative (Grade 2) ductal carcinoma (HER2 – positive) and left mammary gland sectoral resection with sentinel node biopsy was performed shortly afterwards. After the surgery surgeon and immunologist relying to a year-old lab results cancelled therapy of Levothyroxine, calling it useless. Chemotherapy by EC-T scheme, including Epirubicin 140 mg, Cyclophosphamide 1000 mg and Paclitaxel 300 mg was started with continuous hormonal therapy including Trastuzumab 600 mg by scheme and Tamoxifen 20 mg OD. Nine months after cancellation of thyroid hormone therapy patient with recurrent complaints about weakness was examined and high TSH – 25 mU/l, low normal fT4–12.4 pmol/l and clinically significant dyslipidemia (total cholesterol 6.45 mmol/l (< 5.0); LDL 3.88 mmol/l (< 3.0); Non HDL – 4.95 mmol/l (< 3.4); triglycerides – 3.37 mmol/l (< 2.0)) was found. Head MRI revealed multiple vascular lesions with hemosiderin deposition in basal ganglia. Initiation of Levothyroxine 25 mg OD followed, as well as continuation with Trastuzumab 600 mg by scheme and Tamoxifen 20 mg OD. Patient is now followed up by multidisciplinary team including endocrinologist and oncologist.
Conclusions
This case report reveals lack of multidisciplinary teamwork in patients with oncological disease receiving hormonal therapy, as well as treatment options in patients with subclinical thyroiditis causing severe dyslipidemia and importance of consideration of screening imaging of the brain for patients with HER2-positive subtypes.

Continuous enteral feeding in a extremely refractory dumping syndrome

Mikel Gonzalez Fernandez, Maria Elena Lopez Alaminos, Karol Almendra Alvarado Rosas, Leticia Serrano Urzaiz, pablo trincado & Patricia De Diego Garcia
Hospital Universitario Miguel Servet

Introduction
Dumping syndrome is a phenomenon produced by the alteration of the pyloric sphincter. It occurs in 20% of pyloroplasty or distal gastrectomies. The syndrome is attributed to the rapid emptying of the chyme in the intestine. The osmotic gradient attracts fluid to the intestine, and this releases vasoactive hormones, such as serotonin or vasoactive intestinal polypeptide.
Case report
We present a 82-year-old woman with gastric intervention in 1985 with pyloroplasty and vagotomy with early and late dumping syndrome. This situation was refractory to nutritional and medical treatment conditioning with frequent and severe hypoglycemia events. A hypoglycemia study was performed with a fasting test, anti-insulin antibodies and C-peptide that were normal. The possibility of home parenteral nutrition was ruled out because of the risk of infection and also surgical intervention because her comorbidities. The placement of a nasoyejunal catheter was chosen. Given the good tolerance it was decided to perform a radiological yejunostomy to definitely avoid hypoglycemia.
Discussion
Dumping syndrome is defined by a group of symptoms caused by rapid emptying of nutrients from the stomach into the small intestine. First line of the treatment includes dietary modifications. A small group of patients may require medical therapy with acarbose or octreotide. Nevertheless is extremely rare the use of continuous enteral feeding to avoid hypoglycemia symptoms.
Ethical aspects
The case has the informed consent of the patient.

Central hypothyroidism secondary to oxcarbazepine therapy in children-a clinical case report

Alexandra Mirica[1], Radu Mirica[2], Diana Monica Preda[3] & Diana Loreta Paun[4]
[1]Grigore Alexandrescu Spitalul Clinic de Urgenta Pentru Copii, Paediatric Endocrinology, Bucharest, Romania; [2]Saint John Emergency Hospital, General Surgery, Romania; [3]Grigore Alexandrescu Spitalul Clinic de Urgenta Pentru Copii; [4]C.I. Parhon National Institute of Endocrinology, Romania

Introduction
The change in thyroid parameters is described in the case of antiepileptic treatment in the pediatric population, due to interferences within the hypothalamo-pituitary-thyroid axis and due to the increase in the rate of hepatic metabolism of thyroid hormones.

Case presentation
We present the case of a 10-year-old boy who addressed our outpatient pediatric endocrinology department for endocrine evaluation in the context of weight growth about 10 kilograms, dry skin, poor growth velocity and low school performance, that developed progressively over the last 3 months. The patient associated a history of partial seizures and motor tics controlled with treatment with oxcarbazepine 900 miligrams per day for 1 year. The parents denied daily administration of biotin, corticosteroids, etc. On physical examination the child was overweight (87 percentile body mass index), had a normal height for his age (+0.16 s.d.) without active stretch marks, without hirsutism and with Tanner I prepubertal status.
Thyroid hormone profile indicated central hypothyroidism with low levels of thyroid stimulating hormone of 0.56 microUi/ml (normal range 0.6–4.5 microUi/ml) and decreased values for free thyroxine (FT4) and free triiodothyronine(T3) of 0.82 pmol/l and 75 ng/dl (normal range 0.89–1.34 pmol/l, respectively 80–200 ng/dl). The patient had normal laboratory evaluation, including liver and kidney function, complete blood count, prolactin and cortisol levels. The thyroid ultrasound indicated a homogenous structure, normal dimensions of thyroid gland and a normal vascularization. The magnetic resonance of the brain and the hypothalamo-pituitary region was within normal limits. The patient was started on levothyroxine therapy and clinical symptoms have improved together with the increase of free thyroxine values.
Conclusions
In conclusion, we present the case of a patient diagnosed with central hypothyroidism associated with oxcarbazepine treatment, emphasizing that oxcarbazepine can interfere with thyroid hormones axis.
Keywords: central hypothyroidism, oxcarbazepine.

Thyroid diseases and mastopathy
Irina Vasyhina[1] & Larisa Danilova[2]
[1]The Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Belarus; [2]Belarusian Medical Academy for Postgraduate Education, Endocrinology, Belarus

Aim
To assess the thyroid and reproductive system status in 222 women with normal menstrual cycles.
Material and methods
Patients were referred for thyroid ultrasonography and concurrent breast ultrasonography. The 160 women were divided into two groups, based on the nature of the thyroid pathology.
Results
The 1st group included 90 women with autoimmune thyroiditis (AIT), the median age was 36.00 [25.00; 50.00] years, the 2nd group – 70 women with nodular goiter, median age was 37.00 [31.00; 45.00] years. Women with AIT showed inverse significant correlations between age and testosterone level ($\rho=-0.32$; $P<0.001$), age and DHEAS level ($\rho=-0.38$; $P=0.001$), as well as BMI and FT_4 ($\rho=-0.24$; $P=0.04$). Direct significant correlations were established between progesterone and estradiol levels ($\rho=0.30$; $P=0.01$), progesterone and FT_3 levels ($\rho=0.24$; $P=0.04$). Testosterone had a direct significant correlation with the FT_3 level ($\rho=0.24$; $P=0.04$). DHEAS level had a direct significant correlation with the TSH level ($\rho=0.33$; $P=0.004$). Prolactin levels also had a direct significant correlation with estradiol levels ($\rho=0.23$; $P<0.05$). Age had a direct significant correlation with BMI ($\rho=0.50$; $P=0.001$). In the group of women with nodular goiter, age had an inverse significant correlation with progesterone levels ($\rho=-0.37$; $P=0.002$); testosterone levels ($\rho=-0.39$; $P=0.002$) and DHEAS levels ($\rho=-0.47$; $P<0.001$). An inverse significant correlation was established between progesterone and FSH levels ($\rho=-0.32$; $P=0.01$). In this group, a direct correlation was established between age and prolactin level ($\rho=0.31$; $P=0.01$) and BMI ($\rho=0.53$; $P<0.001$). The progesterone and testosterone levels had a direct significant correlation ($\rho=0.36$; $P=0.004$).
Conclusion
The obtained results indicate that the presence of thyroid pathology can be considered as one of the risk factors for the development of mastopathy.
DOI: 10.1530/endoabs.70.EP527

Thyroid disorder in patients with spondylarthritis
Ben Ali Khaoula, Maroua Slouma, Rym Dhahri, Leila Metoui, Imen Gharsallah & Bassem Louzir
Military Hospital of Instruction of Tunis, Rheumatology, Tunisia

Background
The association between spondylarthritis and thyroid diseases is unclear. Few studies have examined this association and results remain unknown. We aimed to assess the frequency of thyroid disorders among patients with spondylarthritis.
Methods
We performed a cross-sectional study including 50 patients with spondyloarthritis (SA) diagnosed according to ASAS criteria. The disease activity was assessed using ASDAS Free Thyroxine(FT4) and thyroid stimulating-hormone (TSH) were measured for each patient.
Results
The mean average was 45.75±13.18 years. The sex-ratio was 3. Clinical phenotypes of SA were: ankylosing spondylarthritis (60%), psoriaticarthritis (22.5%), arthritis associated with inflammatory bowel disease (12.5%). The mean duration of the disease was 91.6±61.17 months. The mean C-reactive protein and erythrocyte sedimentation rate were 32.21±43.09 mg/l and 34.36±24.9 mmH1 respectively. The mean ASDAS-CRP and BASMI were 3.83±2.33 and 2.11±2.23. The mean FT4 and TSH levels were 12.23 and 1.89 respectively. There is no Correlation between ASDAS, BASMI, inflammatory markers, and Thyroid hormone (FT4 and TSH). Disorder of at least one thyroid function test (FT4 or TSH) was noted in 27.5% of cases ($n=11$). Among these patients: 10% of patients ($n=4$) had a central hypothyroidism(low FT4 level and normal TSH level), 2.5% of patients ($n=1$) had a subclinical hyperthyroidism (n ormal FT4 level and low TSH level), and 2.5% of patients ($n=1$) had acquired hyperthyroidism (high FT4 level and low TSH level). A normal TSH associated with high FT4 was found in 12.5% of ($n=5$). This finding may correspond to thyroid hormone resistance, an artifact or a thyrotropic microadenoma.
Conclusion
Our study showed that thyroid disorder is not uncommon in patients with SA. The main disorder observed in our study is a high free T4 associated with normal TSH level. Our study suggests that the screening of thyroid disorder is mandatory in patients with SA.

Recurrent subacute thyroiditis associated with microscopic polyangiitis (ANCA positive vasculitis)
Adam Lawrence Townsend, Indrajit Talapatra, David James Tymms & Mohit Kumar
Royal Albert Edward Infirmary, WWL Foundation Trust, Department of Diabetes and Endocrinology, Wigan, Greater Manchester, United Kingdom

A 56 year old lady was investigated by her GP for arthralgia and found to be thyrotoxic (TSH<0.01 mU/l, free T4 34.8 (10–20 pmol/l), TPO 50 (<35 IU/ml)). She gave a history of anterior uveitis some 20 years earlier. She was commenced on carbimazole and referred to the endocrinology clinic, where her thyroid function rapidly normalised and a biochemical diagnosis of subacute thyroiditis was made. Thyroid pertechnatate scan showed reduced uptake throughout the gland. TSH receptor antibodies were negative. It was noted she had had a similar episode 11 years earlier. Investigations for breathlessness revealed some ground glass appearances on CT. Two further episodes of thyroiditis occurred, each one asymptomatic. She was found to be MPO-ANCA positive, for which prednisolone and subsequently mycophenolate mofetil was commenced for a diagnosis of microscopic polyangiitis. Eleven years later she developed hypothyroidism, presumed following another episode of thyroiditis, and levothyroxine commenced with normalisation of thyroid function, and a plan for radioiodine treatment if further episodes occurred. Microscopic polyangiitis is a small vessel necrotising vasculitis typically affecting the lungs, kidneys, eyes and other vascular beds, and most commonly associated with MPO-ANCA positivity. The understanding of the relationship between the thyroid and vasculitis is evolving. It is well recognised that ANCA positivity (MPO, PR3 or both) can occur frequently with thiouracil derivates more often than MMI derivatives, and that 15% of

these patients can exhibit a clinical vasculitis, though presentation is heterogeneous. In addition, thyroid disease seems to occur more frequently in patients with vasculitis, perhaps up to 40% with ANCA positive vasculitis. Those of MPO positivity and female sex and are more likely, with the most common outcome being hypothyroidism. The link is not established, though theories include genetic predisposition, loss of tolerance to peroxidases and cross reactivity of TPO and MPO. Unfortunately studies lack details about the specifics of hyperthyroid episodes so the frequency of thyroiditis over other causes is not clear. There is also a lack of pathological data looking at the thyroid in patients with vasculitis. Recurrent thyroiditis is rare, with cases associated with amiodarone, suppurative thyroiditis and postpartum thyroiditis. To our knowledge this is the first case reported of recurrent thyroiditis associated with vasculitis.

Choice of diagnosis of solid form of papillary carcinoma in pathological investigation rather than fine needle aspiration

Lali Tigishvili[1], Keti Tsomaia[2], Khatuna Khachapuridze[3], Nino Kekelidze[4], Giorgi Mchedlishvili[5] & Maya Mchedlishvili[6]
[1]ENMEDIC, endocrinology, T'bilisi, Georgia; [2]Al.Natishvili Institute of Morphology, Tbilisi, Georgia; [3]Al. Natishvili Institute of Morphology, Tbilisi, Georgia; [4]Al.Natishvili Instuitute of Morphology, Tbilisi, Georgia; [5]Al.Natishvili Insitute of Morphology, Tbilisi, Georgia; [6]ENMEDIC, T'bilisi, Georgia

Thyroid cancer in children at the age of 0–14 year is a rare case and according to 2018 y. sta-tistics, it comprise 4% of total endocrine system cancer. This article describes clinical case of 14 years old boy with the solid form of thyroid carcinoma and the diagnosis was based on the surgical tissue examination. According to planned ultrasound investigation 2 cm nodule was revealed in the left lobe of thyroid gland without involvement in lymph nodules. Blood test of TSH,FT4 hormones was in normal range. Fine needle aspiration (FNA) of the nodules shows thyroid follicular neoplasia. Microscopic investigation revealed a well-surrounded nodule with vascular invasion in capsule. Tumor was composed of round solid nests resembling filled up follicules,surrounded by fibrous/hyaline stroma. Focally nuclear features of papillary carcinoma was presented. Normal follicular structures was revealed arroud the capsule, but in the center of the nodule there was atypical cells with brisk miotoc activity. In the center of the tumor a solid but focally papillary structures was marked. It was performed an additional immunohistochemically (IHC) investigation using 'dako' antibodies : CEA,Calcitonin,Chromogranin A was negative. TTF1, Thyroglobulin and AE1/AE3-positive. It should be signed that poor expression of of the markers is revealed in the mitotic active areas, HBME1 –negative, CD56(-)negative. According to IHC analysis the medullary carcinoma has been excluded, although due to high mitotic activity of tumor cells differntial diagnosis was still followed between poorly differentiated carcinoma vs solid form of papillary carcinoma. It should be noted thyroid papillary carcinoma diagnosed according to nuclear signs of folliculocytes, which is better shown in FNA investigation. The IHC marker with high specifi-city and sensitivity doesn't exist. The morphological criteria performed during investigation, because the cancer was well-surrounded and necrotic areas was not revealed. As the tumor was well-surrounded, there was no necrosis nuclear features of papillary carcinoma detected and given the patient's age, we suggested a solid form of papillary carcinoma. A solid variant of papillary carcinoma may misdiagnosed by FNA investigation which shown more normal cells than tumor cells in smear. That is the first choice of pathological investi gation rather than FNA.

Hurtle cell carcinoma: A case report

Meherzi Abir, Amal Kdissa, Belakhdher Mouna, Mouna Khalifa, Monia Ghamam, Kermani Wassim & Abdelkefi Mohamed
Sousse, ENT departement, Sousse, Tunisia

Background
Hürthle cell carcinoma or oncocytic carcinoma of the thyroid gland is an unusual and relatively rare type of differentiated thyroid cancer. It accounts for only about 3–10% of all differentiated thyroid cancers. Its diagnosis as well as its management remains a subject of controversies.
Aim
The purpose of this paper is to describe clinical presentation as well as the difficulties we can affront within the diagnosis and the treatment of this entity.
Method
We report a case of hurtle cell carcinoma of thyroid gland operated and followed in ENT department of Farhat Hached hospital.
Observation
A 54 year old male with no medical history who undergone thyroidectomy in 2012 for enormous goiter which size have been increasing for 3 years. The anatomopathological examination objectivated oncocytic adenoma on multinodular goiter. the patient was lost to follow up. He presented 5 years later with swelling of the right base of the neck, associated to multiple firm swollen cervical lymph nodes, dyspnea and hemoptysis. A cervico thoracic ct scan showed glottic and supra glottic laryngeal tumor with locoregional extension to thyroid and lungs. An histologic re evaluation redressed the diagnosis to concocytic variant of follicular thyroid carcinoma. The patient has undergone a tumorectomy with an histological examination confirming the diagnosis. A radioiodine therapy and hormone suppressive treatment were completed. Unfortunately the patient was lost to follow up again.
Conclusion
Oncocytic carcinoma is rare with metastatic potential. There are no standard guidelines for its optimal management as few institutions have extensive experience with Hürthle cell neoplasms.

The functional state of the parathyroid glands among patients with autoimmune thyroiditis with the presence of calcifications in the thyroid glands

Emma Badalyan[1] & Maria Badalyan[2]
[1]'Avagyan' medical center, Endocrinology, Yerevan, Armenia; [2]'Izmirlyan' medical center, Endocrinology, Yerevan, Armenia

Thirty five patients (33 women, 2 men) age 26–67 who had calcifications in the thyroid gland in a result of ultrasound examination, the levels of parathyroid hormone, vitamin D and microliters (Ca^{++}, Mg^{++} and Phosphorus) have been determined as well. The level of 25(OH) in the studied groups were significantly reduced and was within the following range; 14 ± 7 ng/ml. Twenty five patients had hyperparathyroidism, which indicated an increased functional state of the parathyroid gland, and 14 patients had the upper limits of the requirement norm ($55 += 5$). Changes in electrolyte metabolism were not determined among examined patients. The possible increased activity of the Parathyroid glands on the background of a low content of 25(OH) is the cause of calcifications in the thyroid gland.

Hot Topics (Including Covid-19)

EP533

The renin–angiotensin system blockers and the risk of COVID-19

Tahir Omer[1,2]
[1]University of South Wales, Cardiff Campus, United Kingdom; [2]Northampton General Hospital, United Kingdom

Introduction
The year 2020 has witnessed a new global pandemic caused by an encased single-stranded RNA virus identified as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The exceptionally infectious capability of the virus, along with case fatality rate ranging from 0.99% to above 3%, have raised major global concerns.
COVID19 and Risk factors
Evidence from several observational studies suggests risk factors for poor COVID-19 patients' outcome. Among these, both Diabetes and hypertension are associated with increased risk. hypertension was the most frequent comorbidity with an estimated prevalence of 15% – 30%.
The renin-angiotensin-aldosterone system (RAAS)
The renin-angiotensin-aldosterone system plays an important role in controlling blood pressure. Angiotensin-converting enzyme (ACE) inhibitors or blockers (ARBs) are highly recommended for the management of patients with cardiovascular diseases. They are also widely used to slow the progress of renal insufficiency in Diabetic patients. These medications together with NSAIDs and Thiazolidinediones can cause upregulation of ACE2

(Angiotensin-converting enzyme 2). Evidence showed increased cardiac ACE2 activity with ACEi/ARBs and increased urinary ACE2 with Olmesartan. ACE2 has been recognized as SARS-CoV-2 binding site to cells. It is not clear if this upregulation of ACE2 is beneficial or harmful. It has been argued that this upregulation could lead to increased patient susceptibility to viral dissemination. Conversely, there is a suggestion that ARB treatment helped reversing the lung injury due to reduction in ACE2 caused by SARS-CoV (the cause of the 2003 pandemic) in mice. A preliminary trial of ACE2 administration to individuals with acute respiratory distress syndrome demonstrated no improvement in lung function. This is a review of the most recent relevant literature on the matter examining several recent observational studies that examined the relationship between ACEI/ARB and COVID19. The reviewed 8 observational studies (with risks of confounding factors) reached the conclusion that there is no sufficient data to advocate stopping ACE/ARB treatment in patients with COVID-19. There were some contradictory findings regarding possible different effects of the two drug classes.
Conclusion
The strong beneficial effects of ACEI/ARB for some patients currently outweigh the theoretical risks. This review supports the British cardiovascular society recent statement that 'Patients should continue treatment with ACEi and ARBs unless advised to stop by their medical team'. This also echoes the American Heart association view on the subject.

EP534

Prevalence of adrenal tumors in various age groups

Gulrukh Alimoukhamedova & Zamira Khalimova
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

The objective of the research was to study the prevalence of adrenal tumors in various age groups.
Materials and methods
Clinical observation of 282 patients with various adrenal tumors. Among the examined patients there were more women 169(59.9%), with 113 (40.1%) men. The age of patients at the moment of the first application to a doctor varied from 4 months to 74 years old, with average 39.8±15.7 years old. Average age of men was 37.4±16.7 years old, and average age for women was 41.4±14.9 years old. According to WHO age classification presented in 2017 the age under 45 is considered to be young. In relation to that, we distributed the patients to two groups, where we compared clinical case parameters. The first group included 178(63.2%) patients under 45, while the second group involved 104(36.8%) patients ≥45 years old. All patients with adrenal tumors had common clinical, biochemical, hormonal, and instrumental tests.
Results
Adrenal tumors were presented by the following nosological forms: 45(16%) cortisol-secreting tumors, 51(18.1%) pheochromocytoma,16(5.6%) aldosterone-secreting adenoma, 9(3.2%) androgen-secreting tumors, 5(1.8%) adrenal cortical cancer, 11(3.9%) adrenal metastases, and 145(51.4%) incidentaloma. Basic clinical manifestation at the moment of application was arterial hypertension (AH), which was observed in 218 (77.3%) patients and had various expression degrees. Cases of adrenal tumors with increased arterial pressure (AP) did not depend on the age. The average age at the moment of AP rise in the group of patients under 45 was 28.2±8.5 years old, and in the group of ≥45 years old it was 50.0±9.4 years old. Debut of the disease in the group of patients under 45 differed by its sudden start (9.6%), with development of early complications of AH (3.3%). In the group of patients under 45 prevalent duration of AH was less than 5 years, while in the group of patients ≥45 the duration of AH was 5 years and more.
Conclusion
Prevailing majority of patients (55.3%) with adrenal tumors were young at their 18–44 years, in other words in their active workable period, which in its turn, conditions early invalidation and pre-term lethality of the patients in any workability age. In the group of patients under 45 there were more often hormonal active tumors, such as pheochromocytoma (19.1%), cortisol-secreting tumors (23.6%), aldosterone-secreting adenomas (6.2%), androgen-secreting tumors (5.1%), while in the patients of ≥45 years' old there were more incidentalomas (66.4%), metastases (7.7%), and adrenal cortical cancer (2.9%).

Pathohistological diagnosis of adrenal tumors: experience of a single center

Tatjana Bačun[1,2], Ivan Lekić[3], Veronika Banović[3], Ksenija Marjanović[4,5], Ivan Feldi[3,6] & Borna Kovačić[7]
[1]Faculty of Medicine, University of Osijek, Department of Internal Medicine, Osijek, Croatia; [2]Clinical Medical Center Osijek, Department of Endocrinology, Osijek, Croatia; [3]Faculty of Medicine, University of Osijek, Osijek, Croatia; [4]Faculty of Medicine, University of Osijek, Department of Pathology and forensic medicine, Osijek, Croatia; [5]Clinical Medical Center Osijek, Clinical department of Pathology and forensic medicine, Osijek, Croatia; [6]General Hospital Našice, Department of Internal medicine, Našice, Croatia; [7]Clinical Medical Center Osijek, Department of Abdominal surgery, Osijek, Croatia

Research Objectives
To investigate adrenal tumors of patients operated on at the Osijek Clinical Hospital from 2016 to 2019 to examine the location and histopathological findings of the tumors, and to determine whether there is a difference in the age and gender of the subjects.
Study design
Cross-sectional study with historical data.
Patients and Methods
The subjects were patients of both sexes diagnosed with adrenal tumors who underwent surgery at KBC Osijek in the period 2016–2019. The archive was used in the Clinical Hospital Center Osijek. The results were processed by the statistical program STATISTICA 12.5.192.7.
Results
Adrenal tumors were more often unilateral than bilateral (18 cases, 78%). No differences were found in the localization of tumors of the right and left adrenal glands (9 cases were on the right side, 50%; 9 cases were on the left side, 50%). Benign tumors were more common than malignant and were the most common adenoma (22 cases, 96%). Operated women were on average 10 years older (61.6 years). There were no significant differences with respect to patient age. Benign tumors were more common in women, but the difference was not statistically significant. In the histopathological findings, women were more likely to have adenoma and hyperplasia, while men had more frequently benign tumors and metastatic tumors, but the difference was not statistically significant.
Conclusion
In patients operated on for adrenal tumors, there were more unilateral tumors compared to bilateral ones, but there was no difference in tumor localization (left and right). More common were benign tumors, the most common of which were adenomas. There were no significant differences with respect to age and gender.

Primary aldosteronism: follow up of 17 cases

Wafa Benothman[1], Ghada Saad[1], Imen Halloul[1], Asma Benabdelkrim[1], Yosra Hasni[1], Maha Kacem[1], Molka Chaieb[1], Amel Maaroufi[1] & Koussay Ach
Farhat Hached Hospital, Endocrinology, Sousse, Tunisia

Introduction
Primary and nonsuppressible hypersecretion of aldosterone is an increasingly recognized, but still underdiagnosed, cause of hypertension. Our objective is to determine the evolution features of primary aldosteronism (PA) patients.
Patients and Methods
Retrospective study of 17 patients with PA confirmed biochemically and histologically when operated.
Results
The mean age was 41.9±9.3 years at PA diagnosis, and 6 of them (35.3%) were male. Twelve patients had adenoma producer of aldosterone (APA), 3 had bilateral adrenal hyperplasia idiopathic (HIA), 1 had familial PA and the last one had primary unilateral adrenal hyperplasia (PUAH). Patients were followed for a period between 6 months and 21 years, with an average of 4.3 years. Eleven out of twelve APA, 1 HIA and 1 PUAH had unilateral adrenalectomy using laparoscopic technique. Of postoperative complications, we noted hypertensive spikes in 5 patients and severe hypokalemia in 2 cases. Eight patients had a remission without antihypertensive drug except

one case with biological 'normo-aldosteronism' and essential hypertension. Familial aldosteronism was treated with dexamethasone. Hypertension was controlled with 2.9±1.2 antihypertensive drugs. An average reduction of 0.9 (range: –1 and 3) in the number of these drugs was obtained in post-therapy; both medical and surgical. All patients had normokalemia. Morbidity was independent of the etiology and the treatment.
Conclusion
The overall treatment goal in patients with PA is to prevent the adverse outcomes. Individualization of treatment according to the anatomo-clinic type determined an improvement of the patients' prognosis without however a significant effect on the morbidity.

EP537

Peculiarities of clinical progression of aldosterone producing adrenal adenoma

Gulrukh Alimoukhamedova & Zamira Khalimova
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Introduction
Aldosterone-producing adenoma (APA) in adrenals is relatively rare but diagnostically the most complex hormonal active formation in adrenals. Difficulty of APA diagnostics is that clinically these states are hardly distinguishable from essential hypertonic disease. Besides, it is difficult to differentiate them from several symptomatic arterial hypertensions (AH), such as nephrogenic AH, some types of vascular AH or continuous and mixed pheochromocytoma.
The objective of the research was to study clinical aging characteristics of APA.
Materials and methods. Among the studied patients with various formations in adrenals (n=282), who received out-patient and in-patient treatment in the Republican Specialized Scientific Practical Medical Center of Endocrinology of the Uzbekistan Public Healthcare Ministry within the period from 2000 to 2018, there were 16 patients with APA (5.6%). Among them there were 11(68.8%) women and 5(31.2%) men. The age of patients varied from 20 to 65 years old, with the average age 42.4±12.4 years old. All patients had common clinical, biochemical, and instrumental tests.
Results
Majority of the patients (68.8%) with APA were young workable people, while 18.8% and 12.4% were people of middle and old age, respectively. in relation to gender distribution, APA was 3 times more often observed in female patients. Leading clinical manifestation in all patients with APA in 100% of the cases was AH, which was constant in 75% of the patients, mixed in 12.5%, and in 12.5% of the cases it had constant malignant character. It should be noted, that most often registered among the patients with APA was AH stage I (50%) and AH stage II (37.5%), while only 12.5% had AH stage III. AP values varied from 130/90 to 240/140 mmHg. Maximal level of SAP varied from 160 to 240 mmHg (average value 186.3±28.3 mmHg), DAP from 100 to 140 mmHg (average 111.9±14.7 mmHg). In our observations classical clinical triad including combination of three basic syndromes (AH, neuromuscular, and renal) was noted only in 62.5% of the patients with APA.
Conclusion
Thus, summarizing the obtained data, it can be concluded that, APA was more often met in young workable age with higher prevalence rate among women. Leading clinical manifestation in all patients with APA was AH. It should be noted that, combination of AH, especially in young people, and familiar history of AH and its complications in the closest relatives should serve to be the basis for exclusion of APA diagnosis.

Manifestation characteristics of adrenal tumors according to application records in the republic of uzbekistan

Gulrukh Alimoukhamedova & Zamira Khalimova
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

The objective of the research was to study clinical manifestations and characteristics of manifestations of adrenal tumors.

Material and methods
We followed 282 patients with adrenal tumors, who received in and out-patient care in the Republican Specialized Scientific Practical Medical Center of Endocrinology of the Uzbekistan Public Healthcare Ministry within the period from 2000 till 2018. Among them there were 169(59.9%) women and 113 (40.1%) men. The age of the patients at the moment of the first application to doctor varied from 4 months to 74 years old, with average 39.8±15.7. Male average age was 37.4±16.7 years old, while female average age was 41.4±14.9. Adrenal tumors were presented by the following nosological forms: 51(18.1%) pheochromocytoma, 45(16%) cortisol-secreting tumors,16(5.6%) aldosterone-secreting adenoma, 9(3.2%) androgen-secreting tumors, 5(1.8%) adrenal cortical cancer, 11(3.9%) adrenal metastases, and 145(51.4%) incidentaloma.
Results
Adrenal tumors were characterized by heterogeneous non-specific manifestations, such as lumbar pain 12.8%, gaining weight 7.8%, stomachache 5.7%, menstrual cycle disorders 5.7%, losing weight 2.8%, stroke 1.8%, polyuria 1.4%, headache 1.1%, pre-term maturation 1.1%, excessive hair growth 0.7%, cardialgia 0.7%, hypertonic crisis 0.7%, compression fractures 0.7%, neuromuscular disorders 0.4%, with prevalence of arterial hypertension (AH), which was observed in 52.5% of the cases. In 4.1% of the cases there were no symptoms. Taking into account heterogeneity of clinical symptoms, including AH, associated with tumors, most patients first applied to different specialist. Primarily, these patients were treated by other specialists, among them 17.7% of the patients applied first to cardiologist, 14.2% to physician, 8.9% to neuropathologist, 5.7% urologist, 3.5% to gynecologist, 1.8% to oncologist, 1.8% to pediatrician, 0.7% to traumatologist, 0.4% to rheumatologist, and only 18.8% of the patients initially applied to endocrinologist, while in 26.2% of the cases the diagnosis was established by functional diagnostics specialists. In the careful study of the history of the disease we revealed the following: 64.2% of the patients did not link the start of the disease with any reason, 22.7% associated it with stress, 4.6% with pregnancy, 2.8% related it to various surgical interventions, 2.1% with over-cooling, 1.1% with the start of climax period, 0.7% with delivery, infectious diseases, and application of hormonal agents, and, finally, 0.4% with abortions.
Conclusion
Heterogeneity of clinical symptoms, including AH, associated with tumors, inhibit in-time diagnostics due to initial application of patient to other specialists

Seizure and coma secondary to Conn's syndrome: A case report

Eiman Alseddeeqi
Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates

Background
Conn's syndrome is a curable condition if identified properly. It is characterized by autonomous secretion of aldosterone from the adrenal gland cortex. Its morbidity is related to the increased risk of cardiovascular diseases.
Case presentation
We report the case of a 48 years old male presenting with generalized tonic-clonic seizure and coma secondary to hypertensive encephalopathy. The biochemical evaluation revealed a very high aldosterone level and an undetectable renin level, both are compatible with primary aldosteronism. The presentation of the following: spontaneous hypokalemia, an undetectable renin level, and a high aldosterone level confirms the diagnosis of primary aldosteronism. Abdominal computed tomography revealed a left adrenal adenoma. Adrenal venous sampling confirmed lateralization of aldosterone excretion from the left adrenal gland. The patient underwent left laparoscopic adrenalectomy that confirmed a left functional adrenal adenoma. After 12 months of follow up, the patient's hypertension was controlled on only one antihypertensive drug down from four drugs preoperatively.
Conclusion
Conn's syndrome, in this case, was complicated by coma secondary to seizure. Adrenalectomy has normalized the hypokalemia and improved resistant hypertension. Potassium supplementation and several antihypertensives were discontinued as the patient became normokalemic and normotensive on one antihypertensive agent.

Hyperaldosteronism in a female with chronic hypokalemia

Olena Antonyuk
Medical Center 'Univeral Clinic 'Oberig', Kyiv, Ukraine

Introduction
Hyperaldosteronism is not so common in middle-aged groups. But it should be concerned in the case of unclear hypertension, fatigue, or dyspepsia.
A 61-year-old female was hospitalized in the private clinic 'Oberig' in December 2019. She had non-specific complaints such as weakness, dyspepsia, constipation, vomiting, losing an appetite, decrease in body weight. She has been treated for a long time out-patiently and had some episodes of hospitalization, including the surgical unit. She had severe electrolyte disorders, such as hyponatremia (106 mmol/l), hypokalemia (1.8 mmol/l), hypochloremia (62.8 mmol/l), hypophosphatemia (0.54). Magnesium was normal (97 mmol/l). AKSH and cortisol were in the normal range. She has arterial hypertension since being 25–30 years old. She was reported to have multinodular goiter for four years. She received levothyroxine 50 mg daily, but we detected that TSH was slightly less than average (0.36). There was a decision to decrease the dosage to 25 mg with further TSH control in 1 month. After normalization of the potassium level in the blood, we checked aldosterone and renin. Aldosterone was normal, renin was less than average, and their correlation was increased up to 37 (normal range is lower than 18.7). Adrenal hyperplasia was not detected on CT. We prescribed eplerenone 50 mg. Soon in 1 month, all symptoms regressed, and the patient felt much better.
Conclusion
Electrolyte screening is essential for diagnostic unclear dyspepsia and hypertension.

DOI: 10.1530/endoabs.70.EP540

How to treat primary hyperparathyroidism in pregnancy? A case series

Alheli Arce Gastelum[1], Azka Latif[1], Kinaan Farhan[2], Sangeeta Mutnuri[3]
[1]Creighton University, Internal Medicine, Omaha, United States; [2]Jinnah Medical and Dental College, Medicine, Karachi, Pakistan; [3]Creighton University, Nephrology, Omaha, United States

Primary hyperparathyroidism (PHPT) is rare in pregnancy, with an incidence of 1%. It is associated with maternal, fetal, and neonatal complications. Treatment options include both medical and surgical approaches. Parathyroidectomy is the definitive and preferred treatment, especially when serum calcium level is higher than 10.8 mg/dl and with a prior history of pregnancy loss. Herein, we present two cases of gestational primary hyperparathyroidism with different treatments.
Case one
A 40-year-old lady G5P3023 at 30 weeks of gestation who presented with epigastric. Initial workup revealed serum lipase of 1256 u/l and serum calcium of > 15 mg/dl with normal serum albumin. Further workup for hypercalcemia showed an elevated ionized calcium level of 2.04 mmol/l, PTH of 350 pg/ml, Vitamin D 1–25 dihydroxy level of 43.1 pg/ml, vitamin D 25 hydroxy level of 15.9 ng/ml. She received intravenous fluids for acute pancreatitis. Ultrasound of the neck revealed a 1.9 × 1.6.1.7 cm nodule suspicious for parathyroid adenoma. The patient received aggressive IV fluid resuscitation, two intramuscular injections of 300 units of calcitonin, and 60 mg of cinacalcet twice daily. Despite medical management, her serum calcium level remained elevated for a week, requiring and a right inferior parathyroidectomy. After surgery, her serum calcium level normalized.
Case two
A 30-year-old lady G1P1001 at 40 weeks of gestation who presented with concerns of decreased fetal movements. She underwent emergent cesarean due to non-reassuring fetal heart tones. The infant was born with hypoglycemia. Initial workup was significant for serum calcium of 14.1 mg/dl with normal serum albumin. Given the hypercalcemia, the patient received aggressive intravenous fluid resuscitation, 200 units of subcutaneous calcitonin twice daily, 30 mg of cinacalcet twice daily. Further workup for hypercalcemia showed ionized serum calcium level of 1.61 mmol/l, PTH of 302.6 pg/ml, vitamin D 25 hydroxy level of 20.4 ng/ml. Her hypercalcemia manifested as several episodes of coarse upper and lower extremity tremors. An ultrasound of the neck illustrated a 2.5 × 2.5 cm parathyroid nodule consistent with a parathyroid adenoma. Despite medical management, serum calcium levels remained high after a week. She underwent left inferior parathyroidectomy, and her calcium levels normalized after the surgery.
Compared to conservative management, surgical treatment with parathyroidectomy is associated with better maternal and fetal outcomes, as it has shown a decreased incidence of pre-eclampsia and preterm delivery. Hence, gestational hyperparathyroidism is a clear indication for an early parathyroidectomy in both symptomatic and asymptomatic patients.

EP542

COVID-19 infection in a patient with life-treatening hypercalcaemia and sickle cell disease

Desiree Seguna[1], Henry Marshall[1], Filipa Barroso[2], Laila Parvanta[3], Ashok Adams[4], Daniel Berney[5], Scott Akker[1] & Dominic Cavlan[1]
[1]St Bartholomew's Hospital, Department of Endocrinology, London, United Kingdom; [2]St Bartholomew's Hospital, Department of Haematology, London, United Kingdom; [3]St Bartholomew's Hospital, Department of Surgery, London, United Kingdom; [4]St Bartholomew's Hospital, Department of Radiology, London, United Kingdom; [5]St Bartholomew's Hospital, Department of Pathology, London, United Kingdom

A 21-year-old woman with homozygous sickle cell disease, presented to A&E with vomiting and diarrhoea, and was noted to be hypercalcaemic (corrected calcium 3.00 mmol/l [ref. 2.2–2.6]; phosphate 0.48 mmol/l [ref. 0.8–1.5]). She reported polyuria and polydipsia, but no other symptoms of hypercalcaemia. There was no history of renal stones, renal impairment, or fragility fracture. A maternal aunt required parathyroidectomy in middle age. Bloods revealed PTH 138.4 pmol/l (ref. 1.6–6.9), magnesium 0.6 mmol/l (ref. 0.7–11.0), Vit D <13 nmol/l and normal pituitary function. 24-hour urinary calcium was elevated at 9 mmol/day (2.5–7.5). A calcium creatinine clearance ratio of 0.0131 ruled out familial hypocalciuric hypercalcaemia. The hypercalcaemia responded to intravenous fluids and she was discharged on cinacalcet and cholecalciferol. Three days later she represented with a further sickle cell crisis. Bloods showed persistent hypercalcaemia 2.67 mmol/l, with an acute haemoglobin drop from 82 to 58 g/l (ref. 120–150). The patient was transfused and restarted IV fluids. Following transfusion, hypercalcaemia worsened, peaking at a level of 3.77 mmol/l, refractory to IV fluids, withdrawal of cholecalciferol, and an increase in cinacalcet dose, but responded to IV bisphosphonates. Admission was compounded by a delayed haemolytic transfusion reaction. Localisation studies were performed: there was no abnormal parathyroid tissue on neck ultrasound, but CT and Tc99m-sestamibi scanning both suggested a 4.4 cm upper mediastinal parathyroid mass. Emergency parathyroidectomy was planned, but postponed when pre-operative COVID-19 screening returned a positive nasal swab. Surgery was further delayed by an admission with hyperhaemolysis, but was performed 4 weeks later. The post-operative course was complicated by severe, symptomatic hypocalcaemia, and sickle chest crisis. Imaging was consistent with COVID-19 pneumonia, despite a then negative nasal swab. Management of hypocalcemia with IV calcium infusions worsened the degree of haemodilution and increased the potential for precipitating a crisis. Conversely, blood transfusion increased the risk of hyperhaemolysis. Hungry bone syndrome is likely to underly the intractable hypocalcaemia, which was exacerbated by vitamin D deficiency. Additionally, COVID-19 pneumonia increased the risk of precipitating a crisis. Histology was in keeping with an atypical parathyroid adenoma, with scattered mitoses and a Ki-67 of 20%.
Discussion
– Role of vitamin D replacement in hyperparathyroidism.
– Concerns about malignancy in a young patient with very elevated calcium and PTH.
– Complications of GA, surgery, and post-operative calcium replacement in sickle cell patients.
– Surgical planning in times of COVID-19 and dealing with COVID-19 sequelae.
– Role of genetic studies.

Are women with osteoporosis treated with denosumab at risk of severe COVID-19?

Anna Maria Formenti, Erika Pedone, Luigi Di Filippo, Fabio Massimo Ulivieri & Andrea Giustina
Vita-salute San Raffaele University and IRCCS San Raffaele Scientific Institute, Institute of Endocrine and Metabolic Sciences, Milan, Italy

Coronavirus disease 2019 (COVID-19), is a primarily respiratory infection which can lead to severe syndrome needing hospitalization and assisted ventilation with high lethality. In a recent meta-analysis of 33 RCTs increased risk of severe infections on treatment with Denosumab, widely used for treatment of osteoporosis, was found specifically for ear, nose, and throat. In fact, by inhibiting the receptor activator of nuclear factor κ-B ligand, denosumab acts as an immune system modulator. However, despite these findings calling for caution, several recently published opinions recommended maintaining treatment with denosumab during the COVID-19 outbreak, We report on the incidence of symptomatic respiratory infections in denosumab vs other available drug treated osteoporotic population attending our bone clinic in Milano one of the centers of COVID-19 pandemic in Italy. We conducted a telephone interview on a sample of 85 patients (aged ≥18 years) regularly followed in our bone center for post-menopausal osteoporosis ($n=75$) or under aromatase inhibitors (AI) for breast cancer ($n=10$). We excluded patients with comorbidities and concomitant therapies potentially influencing COVID-19 morbidity such as chronic kidney disease and glucocorticoid treatment. All patients were asked the following questions concerning the 3 month period from February 21 to May 24.2020: 1. clinical symptoms of upper airway infection or diagnosis of pneumonia, 2. COVID-19 positive testing, hospitalization and related clinical course; 3. Falls. A total of 50 patients responded to the survey. Fifteen were treated with oral bisphosphonates (BP; mean age 68.8±11.4), 29 with denosumab (D; mean age 79.2±8.6) and 6 with teriparatide (T; mean age 75.0±10.4). Median duration of treatment was 7, 26 and 10 months respectively. In the BP and D group: one patient reported self-limited fever and cough, none of the patients was hospitalized and two and one patient respectively reported one episode of fall without clinical consequences; in T group no patients reported symptoms of infection, hospitalization or falls. Our preliminary data suggest that denosumab may not represent specific risk factor for COVID-19. Our data give some initial real life evidence support to opinions which recommended to continue denosumab during COVID-19 pandemic. Interestingly, it can be hypothesized that female sex may have exerted a relevant protective effect. Finally, it can not be excluded a selection bias in the choice of our patients for denosumab treatment excluding a priori those with recurrent or at increased risk for respiratory infections.

Frequency of musculoskeletal complications in patients with acromegaly in the Ferghana Valley

Shokhsanam Safarova, Zamira Khalimova, Adliya Kholikova, Saodat Issaeva
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

The aim of the study was to study the incidence of osteo-articular complications in patients with acromegaly in the Ferghana Valley.
Materials and methods
129 patients with acromegaly in the Ferghana Valley who were included in the national register of acromegaly were examined. Of these, men – 46 (35.7%), women – 83 (64.3%). The average age of the patients was (48±8.7 years). By age, patients were divided into three groups: 1 group – up to 30 years, 2 gr. –30–44 years, 3 gr. – 45 years and older. The diagnosis of acromegaly was established on the basis of the clinical manifestations of the disease and was confirmed by high serum levels of GH, IGF-1 levels
Results
According to the national register of patients with acromegaly, 2019(Republic of Uzbekistan), the incidence of osteoarticular neuromuscular complications was 82.9%, osteoarticular neuromuscular complications were most common among patients with acromegaly – arthropathy (57.4%), followed by carpal tunnel syndrome (49, 6%) and osteoporosis (48.9%). At the time of diagnosis, in most cases (more than 2/3 of cases) macroadenomas are detected, which may be associated with a delayed diagnosis and imposes difficulties in surgical treatment of these tumors. As the results showed, the examined patients had a high frequency of macroadenomas, with their prevalence in the Andijan (47.5%, $P<0.05$) region. In general, macroadenomas and giant pituitary adenomas are more often identified in patients of Ferghana Valley.
Conclusion
In the Ferghana Valley, acromegaly prevails among women, while acromegaly is common over the age of 45 ($P<0.05$) years in all regions of the Ferghana Valley. The highest frequency of MSC was identified in the Ferghana region, followed by the Namangan region and the frequency of MSC in Andijan region is relatively lower. Macroadenomas were more often present in patients with acromegaly of the Ferghana Valley, with their prevalence in Andijan region.

An unexpected cause of severe hypocalcemia

Rym Belaid[1], Yazidi Meriem[2], Oueslati Ibtissem[3], Grira Wafa[2], Chaker Fatma[2] & Chihaoui Melika[2]
[1]Avenue Mohamed 5 Beni Khiar Nabeul, Tunisia; [2]La Rabta Hospital, Nabeul Tunisia; [3]Department of Endocrinology, La Rabta Hospital, Nabeul,Tunisia

Background
Common Variable Immunodeficiency syndrome (CVID), the most common symptomatic immunodeficiency in aduIts, is characterized by diminished levels of IgG, IgA and/or IgM, and recurrent bacterial infections. The gastrointestinal (GI) manifestations of CVID are rare and variable. We herein report the case of a patient with a severe hypocalcemia secondary to digestive tract involvement of the CVID syndrome.
Case report
A 32 year-old female patient with a history of CVID and recurrent lung infections was admitted to our department for exploration of deep hypocalcemia. She complained of weight loss, asthenia and paresthesia of the lower limbs.She also reported abdominal pain and diarrhea. The physical examination revealed a weight a body mass index of 17.6 kg/m^2 and a a homogeneous hepatosplenomegaly. Trousseau sign was elicited. Biochemical tests noted hypocalcemia of 57 mg/l, hypophosphoremia of 10 mg/l, hypokalemia of 2.7 mmol/l, hypomagnesemia of 10 mg/l and hypoalbuminemia of 25.8 g/l. Hypochromic microcytic anemia of 7.9 g/dl was also found. The hormonal assessment revealed hyperparathyroidism secondary to vitamin D deficiency. Thyroid assessment and coeliac disease serology were normal. Electrocardiogram showed sinus tachycardia, an elongated QT space and diffuse negative T waves. Upper endoscopy and duodenal biopsy were normal. Computed tomography enterography didn´t show any thickening of the bowel wall. Colonoscopy showed a normal appearance of colonic mucosa but colonic histology revealed a chronic colitis with moderate activity related to its CVID syndrome.
Conclusion
GI manifestations in CVID are mainly dominated by chronic diarrhea. This diarrhea can be due to chronic infections with Giardia lamblia but also resulting from specific lesions of the intestinal mucosa such as villous atrophy mimicking celiac disease.

Maternal and foetal outcomes associated with medical and surgical treatment of primary hyperparathyroidism in Pregnancy

Muhammad Fahad Arshad[1], Maulee Arambewela[2], William Bennet[3], Monique Sterrenburg[3] & Saba P Balasubramanian[3]
[1]University of Sheffield Medical School, Oncology and Metabolism, Sheffield, United Kingdom; [2]University of Sri Jayewardenepura, Nugegoda, Sri Lanka; [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Background
The management of Primary hyperparathyroidism (PHPT) during pregnancy is challenging due to lack of robust guidelines. Various studies have suggested an increased risk of various maternal and foetal complications, however there is no clear consensus in the literature about medical treatment vs surgery during pregnancy. The aim of this study was to review the maternal and foetal outcomes of pregnant women treated for PHPT at a single tertiary care centre and compare our findings with similar studies in the literature.
Methods
Data on relevant clinical parameters, demographics, management strategies, maternal and foetal outcomes were collected from pregnant patients with PHPT between 2012 and 2019.
Results
Of 15 pregnancies with PHPT that were reviewed, 6 were managed medically and 9 patients underwent surgery during pregnancy. The median age at

index pregnancy was 28 years (range 19–42). The median highest recorded adjusted calcium in the medical group was 2.90 mmol/l (2.61–3.25) while it was 3.11 mmol/l (2.78–4.95) in the surgical group. There was one miscarriage and stillbirth of a twin pregnancy in the medical group, but none in the surgical group. The median gestational age at delivery (excluding miscarriage) was 39+3 (24+2–41+2) and 39+4 (37+1–39+5) in the medical and surgical groups respectively. There was one emergency C-section in each group. None of the live births in either groups were complicated with neonatal tetany or convulsions. All the surgeries were successful with no reported post-operative complications.
Conclusion
This study and the review current literature suggests that more complications appear to occur in the medically treated pregnant PHPT patients, however the evidence is not conclusive. Most surgeries during pregnancy are performed during the second trimester with good outcomes. Multi-centre prospective studies are required to ascertain the exact risk of various complications for PHPT during pregnancy.

Familial Isolated Hypoparathyroidism caused by AIRE gene mutation

Muhammad Aamir Shahzad, Dr. Elizabeth Ann Brosnan & Muhammad Sajjad Sadiq
Mayo University Hospital, Endocrine and Diabetes, Castlebar, Ireland

Hypoparathyroidism is an uncommon condition characterized by reduced parathyroid hormone production resulting in hypocalcaemia with its clinical manifestations. A minority of cases are familial and exist as either isolated disease or as part of well described, multisystem syndromes. Mutation in the Autoimmune regulator gene (AIRE) results in Autoimmune Polyglandular Syndrome type 1 featuring hypoparathyroidism as a part of the syndrome. This case reported herein describes a mutation in AIRE leading to Isolated hypocalcaemia with an otherwise normally functioning endocrine glands.

Teriparatide treatment in a patient with resistance hypoparathyroidism

Muhammed Erkam Sencar, Murat Calapkulu, İlknur Ozturk Unsal, Sema Hepsen, Mustafa Ozbek & Erman Cakal
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Turkey

Background
Hypoparathyroidism is an uncommon disorder of calcium metabolism characterized by hypocalcemia, hyperphosphatemia, and reduced level of parathyroid hormone (PTH). The most common cause of hypoparathyroidism is accidental damage to the parathyroid glands during thyroid surgery. There are no formal guidelines for hypoparathyroidism management. The main goal of treatment is to improve the symptoms of hypocalcemia, to keep the serum calcium within the low normal range, and to avoid hypercalcemia. Herein we report a case of hypoparathyroidism, which was successfully treated with subcutaneous teriparatide.
Case report
A 38-year-old woman presented to our clinic with tetany. The patient had symptoms of perioral numbness, paresthesias of the hands and feet, muscle cramps, and Chvostek's sign was positive. It was learned that one year before admission, the patient underwent a total thyroidectomy due to multinodular goiter, and treatment was given for hypoparathyroidism related to post-surgical hypoparathyroidism. The patient, who received 6 gr calcitriol and 12 gr calcium carbonate treatment, was hospitalized with the diagnosis of resistant hypoparathyroidism. The laboratory values were PTH:1 pg/dl, Ca:6.1 mg/dl, phosphorus: 5.1 mg/dl. Normocalcemia was achieved, and hypocalcemia signs and symptoms regressed with intravenous calcium treatment. 25(OH)D and hydrochlorothiazide treatment were added to the treatment of the patient, and calcium carbonate treatment was started to be given as 2 g at 4-hour intervals. Despite treatment changes, the patient's calcium level was found to be 7.8 mg/dl. Teriparatide treatment was started for the patient who stated that using high dose calcium treatment affects the quality of her life. The patient was started on 2*20 mg teriparatide treatment, and daily serum calcium level control was performed. Calcitriol treatment was discontinued within two weeks, while Ca treatment was reduced to 1 g. Although the patient described mild bone pain lasting up to 1 hour with teriparatide treatment, the patient's symptoms and signs of hypocalcemia did not recur. The patient, whose treatment was adjusted as 2*20 mg teriparatide and 2 g calcium carbonate, did not need intravenous calcium treatment for six months. Before starting teriparatide treatment, the patient's 24-hour urinary calcium level was 231 mg/day, and after three months, it decreased to 91 mg/day with teriparatide therapy. Although the patient states that mild bone pain persists, she describes that the quality of life has improved greatly.
Conclusion
Teriparatide is an effective alternative treatment for patients with hypoparathyroidism, which may avoid the potential side effects of conventional therapy.

Precocious pseudopuberty with central progression due to McCune-Albright Syndrome: case report

Ionela Lungu[1], Carmen Emanuela Georgescu[2], Camelia Al-Khzouz[3], Carmen Asavoaie[4] & Cristina Alina Silaghi[2]
[1]Cardiomed Medical Center, Endocrinology, Cluj-Napoca, Romania; [2]Iuliu Hatieganu University of Medicine and Pharmacy, Endocrinology, Cluj-Napoca, Romania; [3]Emergency Clinic Hospital for Children, Iuliu Hatieganu University of Medicine and Pharmacy, Medical Genetics, Cluj-Napoca, Romania; [4]Emergency Clinic Hospital for Children, 1st Pediatric Clinic, Imaging and Radiology, Cluj-Napoca, Romania

McCune-Albright Syndrome (MAS) is a rare congenital sporadic disorder due to an embryonic post-zygotic somatic mutation in the GNAS1 gene, defined by the triad of peripheral precocious puberty (PPP), unilateral café-au-lait spots and fibrous dysplasia (FD) of bone. PPP or precocious pseudopuberty is the most common endocrinopathy seen in MAS. Other hyperfunctioning endocrinopathies include hyperthyroidism, acromegaly, FGF23-mediated hypophosphatemia and neonatal hypercortisolism. A 2.6-year old girl with history of a recent 15 mm left ovarian cyst was admitted for repeated vaginal bleeding and slightly elevated growth rate. Physical examination: bilateral thelarche Tanner stage 3, menarche, advanced stature+0.94 s.d. towards the mean, lumbosacral, café-au-lait spots without axillary-pubic hair or bone deformities. MAS was assessed. Hormonal evaluation: basaline estradiol (E2) values fluctuated between 10.7–71.5 pg/ml, with reduced serum gonadotrophin (LH≤0.13 mUI/ml, FSH≤0.21 mUI/ml), normal TSH, FT4, PRL, IGF1, basal cortisol, testosterone, DHEAS, 25-OH vitamin D, slightly elevated 17-OH progesterone (2.6 ng/ml), low PTH (14 pg/ml) associated with normal serum phosphorus and calcium, high alkaline phosphatase (599U/l) and osteocalcin (66.7 ng/ml). The first Diphereline stimulation test (DST) 0.1 mg SC showed LH=0.68 mUIm/l at 4 h. The 6 month DST was positive with an increasing tendency of gonadotrophin suggesting central puberty (LH and FSH at 4 h were 4.5 mU/ml respectively 7.19 mU/ml) and E2=68.8 pg/ml at 24 h. Abdominal ultrasound: enlarged uterus of 7.5 cc, 41 mm, thickened endometrium, no ovarian cysts, normal adrenal glands. Breast ultrasound: 13.6/15.8 mm right and 16.7/15.5 mm left breast buds. Bone age: 4 years old. Cranial CT scan and pelvic, bilateral femur and knee X-rays: polyostotic fibrous dysplasia of the neuro- and viscerocranium, bilateral iliac and femoral neck and left proximal tibial osteosclerosis areas. Pituitary MRI and thyroid ultrasound were normal. The prescribed treatment consisted of Letrozole 1.5 mg/m^2/day associated with Diphereline 1.87 mg/28 days and 1-alphacalcidol 0.25 µg/day. One month later, follow-up revealed: disappearance of vaginal bleedings and normal E2. PPP in girls results from autonomous ovarian tissue activation with recurrent estrogen-secreting ovarian cysts. Due to prolonged exposure to high E2 levels with maturation of the hypothalamic-pituitary axis, PPP may progress to central precocious puberty (CPP). Treatment includes aromatase inhibitors alone or in combination with gonadotropin-releasing hormone agonists. FD is associated with increased osteoclastic activity and elevation of biochemical markers of bone turnover. Bisphosphonates have been alleged to improve FD symptoms in MAS. As the age of onset and the severity of the MAS clinical manifestations are variable, close long-term follow-up and periodical screening are required. Therefore MAS management is challenging and involves a multidisciplinary team.

Introduction
Parathyroid gland proliferative disorders include adenoma, hyperplasia and carcinoma. Adenoma and hyperplasia are found more commonly in women, while carcinoma, which is very rare, is found in both sexes equally. The aim of this study was to investigate parathyroid gland tumors surgically removed at University Hospital Centre Osijek between 2016 and 2019. Also to review tumor location, size and histopathology and compare sex difference.
Patients and methods
Patients of both sexes undergoing parathyroidectomy for parathyroid gland tumor in University Hospital Centre Osijek between 2016 and 2019 were included in the study. Parathyroid gland tumor samples were histologically analyzed, their size and histopathology were noted. Existing documentation on patients with parathyroid gland tumor was used. Analyses was done on archived histologic material stained with hematoxylin – eosin stain. Statistical analysis was done on MedCalc Statistical Software version 18.9.
Results
Overall 19 samples of parathyroid gland tumor were included in this study. Tumors of the parathyroid glands are most commonly localized on the lower left parathyroid (8 cases, 42%), and most rarely on the upper right (2 cases, 11%). The histopathological diagnosis was most commonly determined by adenoma (11 cases, 58%), followed by hyperplasia, while no cancer was diagnosed. Tumors were operated more frequently on women than on men (17 vs 2 cases). There was no correlation in histopathology of parathyroid tumor and sex (Fisher's Exact Test, $P=1$). And there was also no correlation in tumor location and sex (Fisher's Exact Test, $P=1$).
Conclusion
The most common locations of tumors of the parathyroid glands were the lower glands, the more frequent was the lower left parathyroid and most often it was an adenoma. Women are more frequently operated on than men.
Keywords: parathyroid glands, primary hyperparathyroidism, histopathology, staining and labeling

Metabolic profile of a diabetic population on statins

Eya Safi[1], Yosra Htira[2] & Faika Ben Mami[2]

[1]National Nutrition Institute, Tunisia; [2]National Nutrition Institute, C, Tunisia

Introduction
Dyslipidemia is a frequent pathology, especially in diabetics, which may require the use of lipid-lowering drugs such as statins. Our goal is to determine the impact of these molecules on the metabolic profile of a diabetic population with dyslipidemia.
Methods
This is a retrospective study including 150 patients followed at the Tunis nutrition institute for diabetes and dyslipidemia.
Results
The average BMI was 31.4±6.1 kg/m². Waist circumference was high especially among women. Over three-quarters (76%) of the patients were hypertensive. Average fasting glucose was 13.12 mmol/l with extremes ranging from 5.3 to 24.9 mmol/l. The average HbA1c level was 9.62±2.16%. The mean duration of statin therapy was 2.2±2.6 years. After being put on statins, the average BMI and waist circumference both increased significantly ($P=0.007$ and $P=0.029$ respectively). Both systolic and diastolic blood pressure increased but not significantly. Fasting blood sugar became significantly higher ($P=0.039$). The average HbA1c decreased but this decrease was not significant. Regarding lipid parameters, total cholesterol decreased by 1.02±1.25 mmol/l ($P<0.001$). Triglyceridemia decreased but not significantly ($P=0.15$). HDL cholesterolemia decreased by 0.035±0.27 mmol/l without this being significant. The uricemia also decreased under statins but not significantly.
Conclusion
Statins have modified the metabolic profile of our population, especially anthropometric and biological parameters, which underlines the importance of clinical and biological monitoring after taking these molecules.

Vitamin D deficit in type 2 diabetes patients during COVID-19 lockdown with and without supplementation

Alba Hernández Lázaro[1,1], Paula Maria Fernandez-Trujillo-Comenge[1], Agnieszka Kuzior[1], Manuel Esteban Nivelo-Rivadeneira[1], Ana Delia Santana-Suarez[1], Sara Quintana-Arroyo[2], Carmen Acosta-Calero[2], Claudia Arnás León[2] & Francisco Javier Martinez-Martin[2]

[1]Hospital Universitario de Gran Canaria Dr Negrín, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales San Roque, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain

Introduction
Low vitamin D status has been associated to COVID-19 risk, and type 2 diabetic patients are a vulnerable group. Even though the Canarian archipelago is one of the sunniest spots in Europe, our prevalence of vitamin D deficit is known to be very high. The mandatory lockdown may have worsened this deficit, increasing the need for vitamin D supplementation.
Objectives
Our main objective was to assess and compare the prevalence of vitamin D deficit in supplemented and unsupplemented type 2 diabetic patients from Northern Gran Canaria during the 12 week lockdown started on March 15th 2020. A secondary aim was to correlate the strike rate of COVID-19 with the calcifediol status of the patients.
Methods
Plasma calcifediol levels were sampled in an unselected type 2 diabetic population, along with age, gender, vitamin D supplementation status and confirmed COVID-19 status.
Results
Data were obtained from 239 consecutive patients, 140 female (58.6%), mean age 57.9±16.7. 97 (40.6%) were taking vitamin D supplements years. Mean plasma calcifediol was 30.1±13.2 ng/ml; but it was lower than recommended (<30 ng/ml), in 57.3% of the patients, deficient (<20 ng/ml) in 22.2% and severely deficient (<12 ng/ml) in 5.0%. In supplemented patients, calcifediol was mostly adequate (mean 41.0±12.4 ng/ml, with 22.7%<30 ng/ml, 4.1%<20 ng/ml, none<12 ng/ml and none>80 ng/ml) but low in unsupplemented patients (mean 22.7+7.3 ng/ml, with 81.0%<30 ng/ml, 34.5%<20 ng/ml and 8.5%<12 ng/ml). Plasma calcifediol was significantly higher in supplemented patients (unpaired t-test, $P<0.0001$) and the proportions of low, deficient and severely deficient patients were significantly lower (Fisher's exact test, $P<0.0001$, $P<0.0001$ and $P=0.0062$, respectively). The strike rate of COVID-19 was fortunately very low in this population (1.26%) with 3 confirmed cases (all of them mild, 2 in unsupplemented and 1 in supplemented patients), and though numerically lower in supplemented patients (1.03% vs. 1.41%) it could not be meaningfully analyzed.
Conclusions
With a mandatory lockdown right after the winter months, the prevalence of low calcifediol levels in our unsupplemented type 2 diabetic population is extremely high. On the other hand, when taking vitamin D supplements their vitamin D status is satisfactory with<5% deficient patients and none severely deficient. We cannot conclude that vitamin D supplements were associated with protection from COVID-19; however, their use was effective to prevent the deprivation associated with lockdown.

EP553

Higher HbA1c increases mortality in COVID 19 swab positive hospital inpatients with diabetes

Mohit Kumar

WWL Teaching Hospitals NHS Foundation Trust, Department of Diabetes and Endocrinology, Wigan, Greater Manchester, United Kingdom

Introduction
In the UK, the North West of England is one of the worst affected regions by COVID 19, with over 275 cases/100,000. We retrospectively looked at the diabetes characteristics of consecutive patients at our trust admitted with COVID 19 and had known diabetes, and assessed whether there was a correlation with the outcome, Clinical Frailty Score (CFS) and age.
Methods
88 continuous patients with a prior diagnosis of diabetes and COVID 19 swab positive requiring inpatient stay were included. Primary care records provided information on HbA1c. Inpatient records were interrogated to obtain information on CFS (1–9), diabetes drugs and outcome. A Cox's proportional hazards regressional model was used to evaluate the results.
Results
One patient was excluded. Male:female ratio 54:33. Mean age 75.9 years. Mean CFS 5.06. At time of analysis, 43 patients had died, 39 discharged and 5 still inpatients. 68 patients had a history of hypertension. No obesity data was available. Mean HbA1c was 53.2 mmol/mol. 38 patients took metformin, 22 DPP4-inhibitors, 12 sulphonylureas, 6 GLP-1 analogues, 5 SGLT2-inhibitors, 1 pioglitazone, and 12 insulin. 2 patients were admitted with glycaemic emergency (1 DKA, 1 hypoglycaemia). An increase in HbA1c ($P=0.034$) and a CFS<5 ($P=0.0285$) were associated with an increased risk of mortality. A 1 mmol/mol increase in HbA1c was associated with a 10.8% increase in mortality (CI 1.008–1.2192). No correlation between age and HbA1c, and CFS and HbA1c were found.
Discussion
This study adds to the evidence base regarding the importance of diabetes control and COVID outcome. A number of questions arise however, including the role of non-diabetic hyperglycaemia and outcome, and the balance of very tight control vs hypoglycaemia. Prospective interventional studies are also required to look the impact of various levels of inpatient glucose control and outcomes. There was insufficient data to look at the impact of individual diabetes drug classes. The unexpected finding of a lower CFS score (ie less frail people) having a higher mortality (converse to expectation) may be explained by a number of factors, including a low number of patients with low CFS, subjectivity regarding the CFS by many different clinicians on assessment, and a small sample size. It is also possible that those less frail patients who need hospital admission are generally very unwell, as compared to older multimorbid frailer patients who may be admitted with lower levels of illness.
Many thanks to Luigi Sedda, Alison Unsworth & Abdul Ashish

Patient reported changes in metabolic health during COVID-19 induced lockdown – a cross sectional digital connect survey in type 2 diabetes

Rajiv Kovil[1], Tejas Shah[2], Manoj Chawla[3], Shefali Karkhanis[4], Dakshata Padhye[5], Ami Sanghvi[6], Mayura Kale[7], Purvi Chawla[3], Nikhil Prabhu[8], Vinay Dhandhania[9] & Kiran Shah[10]
[1]Dr. Kovil's Diabetes Care Centre; [2]IVA Diabetes Center; [3]Lina Diabetes Care Center; [4]Karkhanis Hospital, India; [5]Conquer Diabetes Center; [6]Sanghvi Eye and Diabetes Care Centre; [7]Dr.Kale's Diabetes and Psychiatry Clinic; [8]Dr Nikhil Prabhu's Diabetes Clinic; [9]Bombay Medical Hall; [10]Diabetes and Thyroid Care Centre

Introduction
During the COVID-19 induced lockdown it is imperative that people with T2DM be aware, disciplined, and sensitive to achieve glycemic control to mitigate the risks of COVID 19.
Methods
We conducted a cross sectional survey to map the overall short-term impact of nationwide lockdown on the metabolic parameters and change in healthful behaviour patterns among patients from pooled practices of 21 diabetologists across 343 patients, with 30 questions designed to assess the current health status, perceived health status and behaviour before the lockdown and change observed in health status after 21 days of lockdown.
Results
Mean age was 55 years ± 13.0 (95% CI 52 to 55). Participants in aged 18–60 years were more often primary earning members ($n=176$) as compared to age group >60 years ($n=57$) (OR 2.48, 95% CI 1.53 to 4.02; $P<0.0003$) and less likely to have duration of diabetes >10 years ($n=80$) (OR 0.10 95% CI 0.06 to 0.17, $P<0.0001$). Almost half were non-hypertensives ($n=157$) between age group of 18–60 years (OR 5.46 95% CI 3.28 to 9.06, $P<0.0001$). There was not much change in number of participants aged >60 years, that had adequate sleep duration even during lockdown (32 vs 33) (OR 0.32 95% CI 0.17 to 0.62, $P<0.0009$), whereas almost one fourth ($n=88$) who had adequate sleep duration during lockdown were aged 18–60 years. There were less proportion of females ($n=51$) on insulin as compared to males ($n=65$) (OR 0.44 95% CI 0.28 to 0.71, $P<0.0009$). There was dramatic drop in females (105 vs 5) ordering food from eatery as compared to males (205 vs 28) (OR 0.34 95% CI 0.14 to 0.9, $P=0.03$). Fasting glucose reported by SMBG >140 mg/dl, by 32.6% before lockdown, changed to 18%, during lockdown. Participants reporting decrease in weight (16.3%) were more than those reporting increase in weight (14.8%), despite 7.7% less participants reporting daily physical exercise during lockdown. There were 81% and 74% increase in people who were unable to SMBG for fasting and post prandial glucose, respectively.
Conclusions
Our study highlights the dynamic impact of the lockdown which enabled a situational, self-automated patient empowerment driven despite limited resources, to enable control of diabetes. The results need corroboration with a longer follow up to evaluate changes with the evolving COVID 19 environment.

Maturity-onset diabetes of the young type 5 (MODY 5): A case reporte

Cristina Contreras Pascual[1], Paloma González Lázaro[1], Cristina Montalbán Méndez[1], Antonio Moreno Tirado[1], Julia Silva Fernández[1] & Inés Gómez García
Hospital La Mancha Centro, Endocrinología y nutrición, Alcázar de San Juan, Spain

The diagnosis of atypical non-autoimmune forms of diabetes mellitus, such as maturity onset diabetes of the young (MODY) presents several challenges, in view of the extensive clinical and genetic heterogeneity of the disease. In this report we describe a case of atypical non autoimmune diabetes associated with a damaging HNF1β mutation. A 39-years-old woman with normal weight (BMI 20'8 kg/m^2), endometriosis, ex-smoker, fatty liver and uterus bicornis unicollis surgery performed 10 years before was consulted to the emergency department complaining of fever and tachycardia. The blood test evidenced leukocytosis, high inflammation markers (fibrinogen and C-reactive protein) and glucose levels (487 mg/dl), without venous blood gas alterations. Urine test showed positive nitrites, ketone bodies and bacteriuria, and a urinary tract infection was diagnosed. The patient was admitted to Internal Medicine department for antibiotics and to perform a complete study. It revealed high glycosilated hemoglobine (HbA1c) levels (11'8%), and revieweing last 10 years blood tests, impaired fasting glycemia was found. Ecography revealed multiple renal cysts. Asking about symptoms of hyperglycemia, the patient referred polyuria, polydipsia and weightloss over the last 3 months. Six days later, there was no sign of infection neither complication, glucose levels became normal and she felt better. The patient performed a short-term diabetes education program and was discharged with multiple-dose insulin injection therapy. Two weeks later, negative antibodies for GAD and islet cell antibodies (ICA) and low C-peptide leves were obtained, suggesting a low insuline secretory reserve, and she was diagnosed with a type 2 diabetes. The patient referred a paternal history of diabetes (grandfather, grandmother and uncle) but she could not specify the type of diabetes neither the establishment age. Because of that multiple-dose insulin injection therapy was replaced by a basal insuline dose and a combination of metformin and dipeptidyl peptidase-4 inhibitor (iDPP4) was introduced. Three months later the patient reduced 60 percent of the total daily insuline dose, HbA1c levels became normal (5'2%) and fasting capillary blood glucose were under 100 mg/dl. Because all of that we applied for a genetic testing for MODY, that shown a HNF1β de-novo mutation (her mother and sister were negative for the mutation, her father would not perform the test). The optimal care for patients with MODY-5 is multidisciplinary and involves obstetricians, endocrinologists, geneticists and nephrologists. That's why from our point of view all of them should be aware of this condition due to its potential complications.

GABA from medical nutrition to pancreatic beta-cell regeneration

Mahmoud Younis
Egypt Ministry Of Health, Internal Medicine, Kafr Elsheikh, Egypt

GABA from medical nutrition to pancreatic beta-cell regeneration.
Introduction
Type 1 diabetes is considered as one of the most widespread chronic diseases in the world, which happens due to autoimmune damage of beta cells in islets of langerhans in the pancreas. It is the most widespread type of diabetes in young age below 18 years(1.2).The beginning or progress of autoimmune cellular injury of pancreatic beta cells could occur through the presence of many auto-antigens which are detected in the pancreatic beta cells(12).it was found that GABA promoting proliferation of beta cells which may have good impact on type 1diabetes(21).
Design
Randomized, controlled trial, 6 month trial.
Materials and Methods: 100 type 1 diabetes patients were randomized into 2 groups.
Result
The results exhibited a statistically significant decrease of anti-gad antibodies and a statistically significant increase of c peptide levels after 6 months of treatment with GABA.
Conclusion
GABA may be used for decreasing anti-gad antibodies and beta-cell regeneration.

Use of metformin in patients with type 2 diabetes mellitus

Mehrez Achwak, Sebai Imen, Ben naceur khadija, Zribi Sabrine, Saafi Eya, Hkiri Ghofran, Yahyaoui Rim, Ben brahim Asma, Abdesslam Hayfa, Ounaissa Kamilia & Amrouche Chiraz
National Institute of Nutrition, Tunis, Tunisia

Background
Metformin is the most known oral glucose-lowering medications. It is considered to be the optimal first-line treatment for patients with type 2 diabetes mellitus.
Goal
The aim of the study was to describe the clinical and biological profile of patients with type 2 diabetes mellitus treated with metformin.
Methods
This was an observational study conducted among 57 patients with type 2 diabetes mellitus. It was performed between January and March 2020 in the outpatient department of the national institute of nutrition. Patients with creatinine clearance less than 30 ml/min were not included.
Results
The mean age was 61.3±8.65 years. Sixty-three percent were women, 37% were smokers or ex-smokers and 91% were having high blood pressure. The mean duration of diabetes was 16.2±7.5 years. The average HbA1c was 10.5±1.5%. Thirty-nine patients (68%) were taking metformin. One third of patients treated with insulin were not taking metformin. Patients treated with metformin had significantly shorter duration of diabetes (14.7±7.1 vs 19.3±7.8; p=0.044), higher creatinine clearance (96.1±19.2 ml/mn vs 81.9±21.1 ml/mn; P=0.010)and higher fasting blood sugar (2.49±0.7 g/l vs 2.07±0.6 g/l). Age, gender, body mass index and HbA1c values were comparable in patients using metformin or not using metformin.
Conclusion
It seems to be that metformin was not regularly prescribed in patients with type 2 diabetes mellitus after insulin initiation. However, a combination of insulin with metformin is indeed associated with better glycemic control and less weight gain than treatment with insulin alone.

EP558

SGLT-2 inhibitors as adjunctive therapy in type 1 diabetes: Short experience from a center

Daniela Salazar, César Esteves & Davide Carvalho
Centro Hospitalar Universitário de São João, Endocrinology, Diabetes and Metabolism, Porto, Portugal

Background
Sodium-glucose cotransporter-2 (SGLT-2) inhibitors were recently approved as adjunctive treatment for type 1 diabetes (T1D), contributing to better glycemic control, cardiovascular and renal protection. Aim: access the efficacy and safety of these antidiabetic agents in selected T1D patients.
Methods
Evaluation of medical records of T1D patients starting SGLT-2 inhibitors between August 2018 and October 2019.
Results
24 T1D patients (58.3% females, n=14), 41.5±12.32 years, on multiple daily injections (n=23) or insulin pump therapy (IPT; n=1), initiating metformin/dapagliflozin 850/5 mg od (n=16), metformin/dapagliflozin 1000/5 mg od (n=5), and empagliflozin 10 mg od (n=3). Body mass index (BMI) was 27.6±3.6 kg/m^2. Diabetes duration was 17.5±9.95 years, 25% with high blood pressure, 45.8% dyslipidemic, 33.3% had retinopathy, 13% nephropathy, 1 patient neuropathy, and 2 (8.7%) history of coronary heart disease. Mean glycated hemoglobin (HbA1c) was 8.3±0.88%, systolic blood pressure (SBP) 132.0±15.32 mmHg, diastolic blood pressure (DBP) 76.7±12.56 mmHg, serum creatinine 0.7±0.16 mg/dl, glomerular filtration rate (GFR) 110.7±25.5 ml/min. Three (12.5%) patients abandoned therapy in the first 3 months due to side effects (genital infection, diuretic effect, diarrhea). One male stopped the medication temporarily (genital infections that eventually ceased). The patient on IPT suspended SGLT2 inhibitor for difficult compliance on ketone bodies surveillance and desire to keep IPT. No episodes of DKA were reported. 20 patients were followed for 10.1±3.56 months: there was a reduction of 0.7% in HbA1c (8.2±0.94% vs 7.5±0.72%; p<0.001), loss of 3.0±3.19 kg (75.8±13.99 vs 72.8±13.77 kg; P=0.001), improvement in BMI (27.4±3.68 vs 26.4±3.72 kg/m^2; P=0.001), and reduction of 6.8±8.80 IU in total daily dose (TDD) of insulin (n=11; 62.7±22.22 vs 55.9±22.00 IU; P=0.028). Overall reduction occurred in basal insulin dose (total basal dose 31.0±12.35 vs 26.7±12.08 IU; P=0.075), with no statistical significance. Despite overall reduction, the differences were not significant for SBP (P=0.127), DBP (P=0.363), total cholesterol (P=0.132), and LDL cholesterol (P=0.077), probably due to the sample size. Renal function was preserved during the follow-up: no changes in serum creatinine (0.73±0.16 vs 0.73±0.13 mg/dl; P=0.872) and GFR (110.9±25.65 vs 109.6±23.9 ml/min; P=0.741). There were no changes in patient's blood count (hemoglobin 13.7±2.11 vs 13.9±2.22 g/dl, P=0.550; erythrocyte count 4.8±0.51 vs 4.8±0.58, P=0.605).
Conclusion
SGLT-2 inhibitors are an effective adjunct therapy to insulin in T1D, improving glycemic control but also patient's metabolic profile. Careful selection of patients ensures safety of this therapy. Longer follow-up would improve our knowledge of its real-life benefits.

Effects of Orthodox fasting on cardiometabolic risk factors: a comparative evaluation between lay fasters and Athonian monks

Spyridon Karras[1], Theocharis Koufakis[1], Andrea Petróczi[2], Dirk Folkerts[3], Maria Kypraiou[1], Maria Grammatiki[1], Hilda Mulrooney[2], Declan Naughton[2], Dimitrios Skoutas[4], Lilian Adamidou[5], Pantelis Zebekakis[1] & Kalliopi Kotsa[1]
[1]Division of Endocrinology and Metabolism, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]School of Life Sciences, Pharmacy and Chemistry, Kingston University London, Penrhyn Road, Kingston upon Thames, Surrey, KT1 2EE, United Kingdom; [3]Department of Sport Psychology, Institute of Sport and Exercise Sciences, University of Muenster, Germany; [4]Sarafianos Private Hospital, Thessaloniki, Greece; [5]Department of Dietetics and Nutrition, AHEPA University Hospital, Thessaloniki, Greece

Background
Orthodox fasting (OF), a periodical vegetarian subset of the Mediterranean diet, has been shown to exert beneficial effects on human health. Athonian fasting is a pescetarian OF variation, where red meat is restricted throughout the year. Previous studies have examined the OF nutritional synthesis and health impact in general population fasters (GF) and Athonian monks (AM), separately. This is the first study to comparatively evaluate the characteristics and effects of this nutritional pattern between the two populations, with a special interest in cardiometabolic risk factors.
Methods
43 general population male fasters (aged 20–45 years) and 57 age-matched male monks following OF were included in the study. Dietary intake data

were collected in both groups during a restrictive (RD) and a non-restrictive (NRD) day. Nutritional, cardiometabolic and anthropometric parameters were compared between the two cohorts.
Results
AM presented lower daily total caloric intake for both RD (1362.42±84.52 vs 1575.47±285.96 kcal, $P<.001$) and NRD (1571.55±81.07 vs 2137.80±470.84 kcal, p<.001) than GF. They also demonstrated lower Body Mass Index (23.77±3.91 vs 28.92±4.50 kg/m^2, $P<.001$), Body Fat mass (14.57±8.98 vs 24.61±11.18 kg, p=.001) and Homeostatic Model Assessment for Insulin Resistance values (0.98±0.72 vs 2.67±2.19 mmol/l, $P<.001$), compared to GF. Secondary hyperparathyroidism (Parathyroid Hormone concentrations: 116.08±49.74 pg/ml), as a result of profound hypovitaminosis D [25(OH)D: 9.27±5.81 ng/ml], was evident in the AM group.
Conclusions
These findings highlight the unique characteristics of Athonian fasting and its value as a health-promoting diet. The impact of limitation of specific vitamins and minerals during fasting warrants further investigation.

[1]Firat University, Elazig, Turkey., Department of Internal Medicine (Endocrinology and Metabolism Diseases), Faculty of Medicine,; [2]Firat University, Elazig, Turkey., Department of Nuclear Medicine, Faculty of Medicine; [3]Firat University, Elazig, Turkey., Department of Internal Medicine (Rheumatology) Faculty of Medicine; [4]Firat University, Elazig, Turkey, Department of Internal Medicine, Faculty of Medicine; [5]Fethi Sekin City Hospital, Health Science University, Elazig, Turkey., Cardiovascular Surgery Department,; [6]Firat University, Elazig, Turkey., Department of Anatomy, Faculty of Medicine; [7]Pamukkale University, Denizli, Turkey, Department of Nuclear Medicine, Faculty of Medicine

Purpose
Diabetes mellitus is a complicated disease that is associated with bone mineral density, depression, and anxiety in addition to its association with carbohydrate metabolism. The present study is intended to assess the biochemical measurements, depression and anxiety scores, and bone mineral densities (BMD) of diabetic patients with diabetic foot (DF) compared with those of diabetic patients without DF.
Materials and methods
A total of 37 patients diagnosed with DF and 40 non-DF diabetic patients who were admitted to the Fırat University Hospital Endocrinology and Metabolic Diseases Outpatient Clinic were included in this study according to their Hospital Anxiety Depression Score (HADS). Serum hemoglobin A1c (HbA1c), magnesium (Mg), albumin, urea, creatinine, calcium (Ca), phosphorus (P), parathyroid hormone (PTH), and vitamin D levels were measured along with body mass indexes (BMI). Patients with DF were also assessed according to Wagner's classification. In addition, BMDs were measured from the lumbar and femoral head regions of the patients using dual X-ray absorptiometry.
Result
Depression and anxiety scores were significantly higher in female patients of both groups with and without DF, and the BMD value was also significantly lower in women than in men. Depression and anxiety scores increased as BMI increased in both groups but not to significant levels. BMD results were not significant but trended lower in the DF group. BMI and BMD were found to be positively correlated. Ca, P, and Mg levels related to bone metabolism were significantly lower in the DF group compared with those of the non-DF group.
Conclusion
According to the available data, anxiety, depression, and BMI increase as BMD decreases in DF patients, and this requires a multidisciplinary approach that integrates endocrine and metabolic treatment with psychiatric treatment for these patients.

Diabetic neuropathy: Prevalence and risk factors in a type 2 diabetic population

Eya Safi[1], Yosra Htira[2] & Faika Ben Mami[2]
[1]National Nutrition Institute, Tunis, Tunisia; [2]National Nutrition Institute, C Tunisia

Introduction
Diabetic neuropathy is a degenerative complication of diabetes mellitus which can be restrictive. The objective of our work is to determine the prevalence of this complication in a type 2 diabetic population as well as its different risk factors
Methods
This is a retrospective study including 100 Tunisian type 2 diabetic patients followed up in the 'C' department at the National Nutrition Institute in Tunis.
Results
The average age of our population was 56.79 years. A female predominance was noted with a sex ratio of 1.9. The average duration of progression of diabetes was 11.28 years. The average HBA1C was 10.83±2.26%. Almost a third of the population had diabetic neuropathy (31%) with no significant difference between the two sexes. The frequency of this complication was significantly correlated with the age and the duration of progression of diabetes ($P=0.025$ and $P=0.002$ respectively). It was best noted in the presence of diabetic retinopathy ($P=0.008$). Diabetic neuropathy was correlated to higher HBA1C and microalbuminuria levels, but this was not significant. It was more common in hypertensive patients who represented more than half of the population. It was more noted in patients with dyslipidemia without this being significant. The uric acid level was significantly higher in the presence of diabetic neuropathy ($P=0.037$). Twenty-three percent of the population was smoking with no statistical relationship to the onset of neuropathy.
Conclusion
As risk factors for diabetic neuropathy, we noted the age, duration of progression of diabetes, poor glycemic control, uricemia, hypertension and dyslipidemia. Being a potential source of invalidity, the screening of the risk factors of this complication and their control are essential.

A comparative evaluation of late effects of Orthodox religious fasting vs time restricted eating on metabolic profiles of overweight adults

Spyridon Karras[1], Theocharis Koufakis[1], Lilian Adamidou[2], Maria Grammatiki[1], Stergios Polyzos[3], Paraskevi Karalazou[4], Katerina Thisiadou[4], Pantelis Zebekakis[1], Kali Makedou[4] & Kalliopi Kotsa[1]
[1]Division of Endocrinology and Metabolism, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Dietetics and Nutrition, AHEPA University Hospital, Thessaloniki, Greece; [3]First Laboratory of Pharmacology, School of Medicine, Aristotle University of Thessaloniki, Greece; [4]Laboratory of Biological Chemistry, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece

Background
Previous research has demonstrated positive effects of Orthodox fasting (OF) and time restricted eating (TRE) on body weight (BW). However, little is known about the late, metabolic effects of the two diets.
Methods
29 overweight adults followed a hypocaloric diet based on OF. A hypocaloric, TRE plan (eating between 08:00 to 16:00 h) was followed by 16 BW-matched participants. Anthropometric, glycemic and inflammation markers and serum lipids were assessed at baseline, at the end of the intervention (7 weeks) and 6 weeks after the cessation of diets (13 weeks).
Results
Both groups demonstrated a decrease in total energy intake at week 13, compared with baseline (OF: 1988±339 vs 2124±315 kcal, $P<0.001$; TRE: 1960±433 vs 2217±350 kcal, $P<0.001$). There was a trend of weight loss in both groups, which was evident at week 7 (TRE: –2.1±1.0; OF: –2.0±0.5 kg, $P<0.001$ from baseline) and remained significant at week 13 (TRE: –2.9±0.7; OF: –2.6±0.3 kg, $P<0.001$ from baseline). In the OF group, lipid concentrations decreased at week 7 and increased at week 13, compared with baseline. Neither group manifested differences in glycemic parameters.

Conclusions
These findings suggest that OF and TRE plans result in significant reductions in BW among overweight adults, which are sustainable even after the cessation of the diets. OF also promotes a decrease in plasma lipid concentrations, which is not evident 6 weeks after its end.

Pseudoxanthoma elasticum: About a case report

Zohra Hadj Ali, Yosra Htira & Feika Ben Mami
National Nutrition Institute, C, Tunis, Tunisia

Introduction
Pseudoxanthoma elasticum (PXE), a multisystem heritable disorder, is characterized by ectopic mineralization of soft connective tissues. It is an autosomal recessive disorder in which mutations in the ABCC6 gene result in low levels of inorganic pyrophosphate (PPi).
In its classic form, PXE is a late-onset, slowly progressing disease, and the major clinical problems relate to development of vascular complications, including hypertension, intermittent claudication, occasional rupture and bleeding of gastrointestinal blood vessels, and, rarely, early myocardial infarcts and strokes. We report a case of PXE.
Observation
A 18 year-old female patient presented a 1 year history of yellow papules on the lateral sides of the neck. She denied systemic symptoms and family history of similar findings. Her medical history included type 1 diabetes treated with insulin evolving since 11 years. Physical examination revealed white-to-yellowish millimetric non-follicular papules on the lateral aspects of the neck, blood pressure at 120/80 mmHg, heart rate at 76 bpm, peripheral pulse was weak and body mass index (BMI) was 25.84 kg/m^2. The electrocardiogram was normal. In biology: creatinine was correct (45 umol/l), microalbiminuria was negative (6 mg/24 H), total cholesterol: 3.22 mmol/l, HDL-cholesterol: 0.94 mmol/l, trigyceride: 0.62 mmol/l, LDL-cholesterol: 0.77 g/l. Transthoracic heart ultrasound showed myocardial involvement with the presence of intramyocardial calcification. Ophthalmological investigation performed was unremarkable.
Conclusion
The association of PXE and diabetes can be harmful because of cardiovascular complications which can be worsening in a reciprocal way. The cause of PXE remains unclear, and some etiopathogenic theories have been proposed: ultraviolet radiation, intrinsic aging, abnormal elastogenesis, and genetic or inheritable factor.

Hyperosmolar Hyperglycaemic State (HHS) and SARS-COV-2 coronavirus- an unusual presentation in a well controlled type 2 diabetic

Ashutosh Kapoor[1], Dr. Ambar Basu[1,2] & Aye Aye Thant[1]
[1]Royal Bolton Hospital, United Kingdom; [2]University of Bolton, Bolton, United Kingdom

Introduction
Hyperglycaemic Hyperosmolar State (HHS) is characterised by Hypovolemia, marked hyperglycaemia, Osmolality of 320 mosmol/kg or more with the absence of acidosis and hyperketonaemia (Ph>7.3, bicarbonate>15 mmol/l). This is a presentation usually found in people with poorly controlled Type 2 Diabetes Mellitus (T2DM). During the current pandemic of COVID-19, there have been atypical and unusual presentations of Diabetic Emergencies, in patients with well controlled Diabetes having inter-current COVID-19 infection.
Case details
We report the case of an elderly gentleman, with a history of T2DM which was adequately controlled solely by Dietary measures. He was admitted with symptoms of feeling generally unwell and was found to be biochemically in HHS. On examination, he was found to be severely dehydrated with no obvious focalising signs of any infection. Biochemically, he was hyperglycaemic, Serum Osmolality of 361(Sodium- 165, Urea- 17.9) and Ketones were 0.1.On the Full Blood Count, the only marker of note was Lymphocytopenia. As an inpatient, he had consistent spikes of temperature and new Oxygen requirements, which raised the suspicion of COVOD-19 infection following which he had a SARS-COV2-RNA swab which was positive. Radiological evidence was indeterminate for COVID-19.
Management
In accordance with the HHS guidelines, the patient was initially treated with IV Fluids. Following this, he was transferred to the Diabetic ward, where he was started on Insulin, due to persistently raised Blood Glucose levels, despite the fluids. He required high doses of Insulin to alleviate his Blood Glucose levels and was subsequently established on twice a day Insulin regime. In view of his symptoms and the acuity of deterioration in his Diabetes control, COVID-19 swabs were sent off, which confirmed inter current Coronavirus infection.
Summary
This case focuses on the atypical effects and implications that COVID-19 can have in the context of Diabetics, for even those who are well controlled. Infection of SARS-CoV-2 in those with diabetes possibly triggers higher stress conditions, with greater release of hyperglycaemic hormones namely Cortisol and Glucagon, thus leading to increased blood glucose levels and abnormal glucose variability. Among different cytokines found significantly higher in patients with diabetes compared to those without, Interleukin-6 (IL-6), may play a more deleterious role in Covid-19 infection. Even in patients whose Diabetes is well controlled, COVID-19 infection can possibly precipitate an inflammatory response and Cytokine storm, thus resulting in a Diabetic emergency to be the presenting feature.

Effects of COVID-19 lockdown on physical activity among adults in Tunisia

Manel DRIDI, Imen Sebai, Ghofrane Hakiri, Kamilia Ounaissa, Eya Safi, Sabrine ZRIBI, Reem Yahyaoui, Asma Ben Brahim & Chiraz Amrouche
National Institute of Nutrition, Outpatient Department, Tunis, Tunisia

Introduction
In order to avoid the spread of the Corona Virus disease, Tunisia has imposed strict confinement measures. The lockdown may change Tunisian's physical activities.
The aim of this study was to evaluate the impact of COVID-19 lockdown on physical activity among adults in Tunisia.
Methods
It was a transversal study conducted from 31th of May to 06th of June 2020. The target audience was adults aged between 18 and 65 years old. Online questionnaire was published and shared via social media. To assess the physical activity before and during the lockdown, surfers were asked to answer anonymously the Ricci-Gagnon self-questionnaire.
Results
A total of 562 provided valid responses to the questionnaire. Women represented 93.4% of the participants. The mean age was 36.96±8.61 years. More than 92% had completed higher levels of education. Almost 15% were smokers. The majority were married (69.4%). The study population was from Great Tunis region in 62.8% of cases.
The mean score of Ricci-Gagnon self-questionnaire was 18±7.2 before the lockdown and 14.4±6.5 during the lockdown (P=<10^{-3}). The decrease of the score was related to gender (–6.2±8.02 among men vs –3.43±7.54 among women; P=0.029). Before the lockdown 60.1%; 38.8% and 1.1%of responders are considered inactive, active and very active, respectively. Home confinement increased significantly the rates of sedentary among adults in Tunisia (74.6% during lockdown vs 60.1% before; P=<10^{-3}). About 31.5%of people were no more motivated to practice sports regularly since gym closure.
Conclusion
Before the COVID-19 confinement, the majority had a sedentary lifestyle. Physical activity was more decreased by lockdown.

Comparison of the characteristics of COVID – 19 Patients with and without type 2 diabetes – single center perspective

Prabhat Agrawal, Ashish Gautam, Nikhil Pursnani, Ajeet Chahar, Ruchika Garg
SN Medical College, Agra

Introduction
COVID 19 is now a global pandemic. Oxygen saturation (SpO2), male gender and diabetes have been associated as risk factors for critical care admission, intubation, and prolonged intubation in hospitalised patients. Bacillus Calmette-Guérin (BCG) vaccine may have protective role of against COVID-19
Methods
We retrospectively evaluated inpatient records, of patients admitted over last three months in a public hospital in Northern India to compare attributes and characteristics in COVID-19 patients with and without T2DM. Unpaired t – test, ANOVA and Fisher's exact test was utilised for statistical analysis
Results
We analysed a total of 318 COVID – 19 patients (178 males, 140 female). Mean age of cohort was 42 years (± s.d. 18, minimum 2, maximum 82, 95% CI 40 to 44). There were 47 (14.7%) patients with T2DM (36 males, 11 female) and 271 (85.2%) patients (142 males, 129 females) did not have T2DM (NT2DM). Mean age in T2DM was 54 years (± s.d. 11, 95% CI 51 to 57, min 31, max 76) and in NT2DM was 40 years (± s.d. 18, 95% CI 38 to 42, min 2, max 82); $P<0.0001$. There were 76.6% males in T2DM group as compared to 52.4% males in the NT2DM group (OR 2.97 95% CI 1.46 to 6.13); $P=0.0023$. The mean peripheral capillary oxygen saturation at the time of admission (SpO2) in cohort was 91% (± s.d. 9, 95% CI 90 to 92). Mean SpO2 in T2DM was 89% (± s.d. 7.6, 95% CI 87 to 91, min 65, max 98) and in NT2DM was 91% (± s.d. 7.6, 95% CI 90 to 92, min 45, max 99); $P=0.11$ (ns). Overall, 239 (75.1%) had BCG vaccine. There were 29 (9.12%) T2DM who had BCG vaccination, 210 (66%) NT2DM and had BCG, 18 (5.6%) T2DM- No BCG and 61 (19.1%) NT2DM – No BCG. (OR 0.46, 95% CI 0.24 to 0.9) p = 0.27 (NS). 61.7% (29/47) of T2DM and 77.4% (210/271) of NT2DM had BCG vaccination.
Conclusions
We observed that patients with T2DM were significantly older by 14 years, with a greater number of males in T2DM than in NT2DM. SpO2 was numerically less by 2% in T2DM and with relatively less vaccination coverage. The varied differences in T2DM group would make them more vulnerable to severe COVID-19.

Health-related quality of life in children with type 1 diabetes: A multicentric prospective study

Raoudha Kebaili[1,2], Jaballah Nesrine[1,3], samia Tilouche[1,2], Amel tej[1,2] & Lamia Boughamoura[1,2]
[1]Ibn El Jazzar Medical Faculty of Sousse, Sousse, Tunisia; [2]university hospital Farhat Hached; [3]university hospital Farhat Hached, pediatrics, Sousse, Tunisia

Introduction
Type 1 diabetes mellitus (T1DM) is one of the most common endocrinological chronic diseases in children that may affect the physical and mental health of children by causing a deep upheaval in their life. Children with type 1 diabetes mellitus (T1DM) have to deal with a complex and demanding daily treatment regime which can have a negative impact on the quality of life (QoL) of these patients. The goal of our study was to evaluate the quality of life of school-age children with T1D.
Material and methods
We conducted a multicentric prospective study collecting diabetic children aged 6 to 12 years. We used the PedsQL3.2DM scale translated into Tunisian dialect and which assesses the following items: symptoms of diabetes, barriers and adherence to treatment, anxiety and communication. The scores obtained were scored from 0 to 100 (100 corresponding to a better quality of life).
Results
Our study concerned children followed in 5 different centers. We interviewed 91 children aged 10.1 ± 2 years on average, whose diabetes started at an average age of 6.3 ± 3 years. A female predominance was noted. All the children were in school. Half were hospitalized at least once, and all children received daily insulin injections (1–5 injections/day). The mean score of the children according to the measurement scale used was 68.26 ± 14.31. Multivariate analysis revealed that the improvement in the score was linked to the decrease in HbA1C, the low number of injections and advanced parental age.,df;f
Conclusion
Quality of life assessment is an essential health outcome measure in pediatric medicine it should be an integral part of caring for children with diabetes. Psychological support is often necessary in order to optimize their daily life and their prognosis in the medium and long term.

Analysis of diabetic patient's visits to private medical center in the context of reforming of ukrainian medical system

Olena Antonyuk
Kyiv, Medical Center 'Universal Clinic 'Oberig', Ukraine

Diabetes mellitus is a global social and medical problem. In the world, there are 463 million diabetic patients, and in 2045 it is expected to be 700 million (IDF DIABETES ATLAS, Ninth edition 2019). In Ukraine, diabetes affects 7.6% of the Ukrainian population, which is 2.5 million people. According to changes in the public health system, we have separate registration of people with diabetes who receive insulin, but it does not include all diabetic patients. Previous years we used special diabetic register SYNADIAB (2001, Tronko M.D.), but nowadays, in the absence of adequate financing, this project can not answer all epidemiological questions. In the context of reforming medical care, visits to a doctor are registered in the system #helsi.me. The problem is that this information is usually received mainly from governmental clinics and rarely involves private medical centers.
Results
We retrospectively analyzed 522 visits to the endocrinologist in one private medical center in Kyiv to find out the structure of visits (primary/secondary, state of compensation of diabetes, a complication of diabetes, age, and gender of the patients). All information was received from the database of the clinic, and all patients signed an agreement on using their personal information. No personal data (including name and others) was published. Some of the patients visited the clinic out patiently, and endocrinologist consulted others during hospitalization to the in-patient department and the stroke department. Few of them were diagnosed as diabetic patients after severe complications, such as stroke or myocardial infarction. We analyzed visits not only to an endocrinologist, but also results of laboratory tests or instrumental findings, or consultations by other colleagues (including cardiologist, neurologist, ophthalmologist). There was a retrospective observational analysis that was focused on important information about the compensation of diabetes, its complication, and the quality of life. We tried to answer whether our data from the private medical center can be useful for providing a special national diabetic register, which will help us to improve the quality of medical care in the national context. This information is necessary, especially nowadays (COVID-19 in the world, changes in the financing of medical care in our country, etc.).
Conclusion
We propose to recreate a diabetic register for the improvement of communication between different medical facilities.

The effectiveness of group training course in the obesity treatment in adult women in the Republic of Belarus

Yuliya Dydyshka[1,2], Alla Shepelkevich[1], Volha Vadzianava[3] & Veranika Lobashova[2]
[1]Belarusian State Medical University, Department of Endocrinology, Minsk, Belarus; [2]Republic Center of Endocrinology and Medical Rehabilitation, Minsk, Belarus; [3]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus

Background and aims
According to the risk factors study for noncommunicable diseases STEPS 2016, carried out under the auspices of the World Health Organization, in 2016–17 years 60.6% Belarusians had overweight (BMI > 25 kg/m^2); 25.4% had obese (BMI > 30 kg/m^2), and the proportion of women with obesity (30.2%) was 1.5 times higher than men (20.2%). Thus, the project aim was to develop a methodology for group non-drug treatment of overweight and obesity and evaluate the effectiveness.
Materials and methods
Inclusion in the project was based on the results of filling out an online questionnaire (from 11.02 to 25.02), posted on social networks. 44 young women aged 20–45 years (34.5 (29.0–42.0)) with BMI ≥ 25 kg/m^2 were selected. At the first meeting, growth 1.65 (1.57–1.80) m, weight 75.0 (67.2–135.8 kg,

BMI – 29.6 (25.6–35.7) kg/m^2, waist circumference 80 (78–129) cm, fasting glycemia 4.9 (4.4–5.7) mmol/l, total cholesterol 4.2 (3.8–5.7) mmol/l were estimated. The project is joint initiative of the Belarusian Women's Union and Belarusian Public Medical Association 'Endocrinology and Metabolism'.
Results
Using the Dutch Eating Behavior Questionnaire (DEBQ) 59% (26 women) had restrained eating behavior, 45% (20 women) had emotional eating behavior, 41% (18 women) had external eating behavior, any eating disorder – 81% (35 women). The food diary led 91% (40 women) to the second meeting, 56.8% (25 women) to the third. BMI decreased by 7% (became 27.5 (25.2–33.4). In the first three months of work, total weigh became easier by 46 kilograms. A decrease in body weight was noted in 81% (36 women), in 19% (7 people) unchanged. After training course, the proportion of patients with eating disorders decreased to 68% (30 women). A group of dynamic observation was formed, the purpose of which is to maintain optimal body weight and the formation of healthy habits.
Conclusions
A high proportion of people with eating disorders among women with overweight and obesity in the Republic of Belarus is determined. The application of group training meetings is effective in reducing body weight.

Neurological characteristics of patients with diabetic nephropathy V st.

Urmanova Yulduz[1] & Alisher Kholikov[2]
[1]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry Named by Acad. Ya.Kh. Turakulov, Hemodialysis, Tashkent, Uzbekistan

The aim of investigation
To study neurological characteristics of patients with type 1 and type 2 diabetes who received hemodialysis
Material and research methods
We for the period from January, 01.2017 to December, 31, 2017 year 102 patients with type 1 and type 2 diabetes mellitus were examined. Of these, men – 45 (44.1%), women – 57 (55.9%). Average age: men amounted to 57.12 years, women – 58.15 years. 20 of them were urgently received hemodialysis. The research methods included: 1) general clinical (study of endocrine, neurological status, anthropometry 2) instrumental (fundus, visual acuity, ECG, densitometry, Ultrasound of internal organs and dopplerography of the main arteries of the head, etc.), 3) biochemical tests (Hb1AC, glycemic profile, urea, creatinine, lipid spectrum, coagulogram),4) hormonal blood tests (insulin, C-peptide etc.)
Research results
Depending on the degree of diabetic encephalopathy, all observed patients were divided into 3 groups:1 gr – 23 patients with diabetic nephropathy of 4–5 stages with CBI 1 st (chronic brain ischemia); 2 gr. – 45 patients with diabetic nephropathy of 4–5 stages with CBI 2 st; 3 gr. – 34 patients with diabetic nephropathy of stages 4–5 with CBI 3 st.
Analysis of neurological status showed various disorders. Patients of the 1st group had headaches, noise in the head, memory loss, and in the neurostatus the disappearance of surface reflexes, anisoreflexia. Patients of the 2nd group experienced headaches, noise in the head, memory loss, depression, sleep disturbances, attacks of transient ischemic attacks, and the appearance of pathological Babinsky symptoms from 2 sides was characteristic in the neurostatus. In the 3 group of patients, we observed a history of stroke in 5 cases (14.7%), in neurostatus hemiparesis in 5 patients(14.7%), dysarthria – 4 cases (11.7%), pseudo-bulbar syndrome – 6 patients (17.6%), increased muscle tone in spastic and plastic type – 11 patients (32.3%).
Conclusions
1) Among the examined 102 patients, patients with a 2 degree of chronic cerebral ischemia prevailed; 2) Severe neurostatus disorders were detected in patients of group 3.

Inaugural diabetic ketosis in iatrogenic cushing syndrome

Elyes Kamoun[1,2], Nadia Ben Amor[1,2], Olfa Berriche[1,2], Faten Mahjoub[1,2], Olfa Lajili[1,2], Dorra El Guiche[1,2] & Henda Jamoussi[1,2]
[1]Medical School of Tunis, Tunis, Tunisia; [2]Institut De Nutrition, Tunis, Tunisia

Introduction
The main widespread type of diabetes are type 1 and type 2 diabetes, and secondary causes must always be assessed if there is any suspicion.
Cushing Syndrom is one of the main causes of endocrine disorders causing diabetes, though it is rarely revealed by a ketosis.
We herein report the case of inaugural ketosis in a patient with an iatrogenic Cushing Syndrom.
Observation
A 27-year-old man was referred to us for inaugural diabetic ketosis. There is a family history of type 1 diabetes in the brother, and no personal medical history. He reported the cardinal signs of diabetes with weight loss, asthenia, polyuria and polydipsia. Physical examination showed a normal blood pressure, a body mass index of 27.42 kg/m^2, and no signs of neuropathy or complications of diabetes. He had thin skin, purple stretch marks and multiple bruises. The patient was taking 2.25 milligrams of betamethasone daily for four years in order to fain weight, resulting in a Cushing Syndrom with iatrogenic corticotropin deficiency. On complementary exams, there were no signs of infection, the electrocardiogram was normal, the glycated hemoglobin was at 10.7%, kidney and liver testings were normal, and thyroid-stimulating hormone levels were at 2.32 μIU/ml. The ketosis was cured after one injection of ten international Units of fast-acting insulin, and he was put under a basal-bolus injection regimen and 60 milligrams per day of hydrocortisone with gradual tapering.
Discussion
In this patient, the type of diabetes is unclear as the inaugural ketosis is rarely observed in glucocorticoids induced diabetes, and type 1 diabetes is less likely considering the fast response to insulin, and must be excluded first before concluding to an endocrine disorder. For further investiations, testing was realized for Glutamic Acid Decarboxylase 65 and protein tyrosine phosphatase antibodies, the results are still in progress. Follow up on this case and his insulin needs after glucocorticoid tapering and discontinuation will lead to the etiologic diagnosis of diabetes mellitus.

'Clinical characteristics of patients with type 1 and type 2 diabetes mellitus who received hemodialysis in 2017 year'

Urmanova Yulduz[1] & Alisher Kholikov[2]
[1]Tashkent Pediatric Medical Institute, endocrinology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, hemodialysis, Tashkent, Uzbekistan

The aim of investigation
To study clinical characteristics of patients with type 1 and type 2 diabetes who received hemodialysis in 2017 year
Material and research methods
We for the period from January, 01.2017 to December, 31, 2017 year 102 patients with type 1 and type 2 diabetes mellitus were examined. Of these, men – 45 (44.1%), women – 57 (55.9%). Average age: men amounted to 57.12 years, women – 58.15 years. 20 of them were urgently received hemodialysis. The research methods included: 1) general clinical (study of endocrine, neurological status, anthropometry 2) instrumental (fundus, visual acuity, ECG, densitometry, Ultrasound of internal organs and dopplerography of the main arteries of the head, etc.), 3) biochemical tests (Hb1AC, glycemic profile, urea, creatinine, lipid spectrum, coagulogram),4) hormonal blood tests (insulin, C-peptide etc.)
Research results
Depending on the degree of diabetic encephalopathy, all observed patients were divided into 3 groups:1 gr – 23 patients with diabetic nephropathy of 4–5 stages with CBI 1 st (chronic brain ischemia); 2 gr. – 45 patients with diabetic nephropathy of 4–5 stages with CBI 2 st; 3 gr. – 34 patients with diabetic nephropathy of stages 4–5 with CBI 3 st. Analysis of clinical and medical history studies showed that the duration of the disease prevailed in patients of the 3rd group – 22.5 years, while in patients of the 2nd group – 15.6 years, and in patients of the 1st group – 11.7 years. 22 patients were died during year. Stage 5 diabetic nephropathy was detected in all patients
Conclusions
1) Among the examined 102 patients, patients with a 2 degree of chronic cerebral ischemia prevailed; 2) The duration of the disease prevailed in patients of the 3rd group – 22.5 years

Pregnancy induced hypertension in women with gestational diabetes mellitus (GDM)

Zamira Khalimova[1], Nilufar Ibragimova[1,2], Feruza Khaydarova[1] & Iroda Tojieva[1]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, endocrinology, Tashkent, Uzbekistan; [2]Charity Association of persons with disabilities and people with diabetes mellitus, UMID, Tashkent, Uzbekistan

The aim
To define the prevalence pregnancy induced hypertension (eclampsia, severe preeclampsia, mild preeclampsia, and gestational hypertension) among women with gestational diabetes in Uzbek population.
Material and methods
The epidemiological study involved 1812 pregnant women from 6 pilot regions (Kashkadarya, Samarkand, Fergana, Surkhandarya, Namangan, Khorezm). GDM was screened for the first time among 1812 pregnant women in the period of 20–32 weeks of pregnancy, aged 18–40 years. We extended gestation age beyond the recommended 24–28 weeks to provide flexibility for women who did not exactly remember the date of their last menstruation. Screening included: an anamnesis (presence of risk factors, number of births, etc.), anthropometry (height, weight, calculation of BMI), a study of fasting venous blood glucose and after OGTT (75 g glucose). Women were excluded from the study if they were previously diagnosed with diabetes and/or were taking medications that affect their blood glucose levels.
Results
A total of 196 women were diagnosed as having GDM according to IADPSG diagnostic criteria which resulted in a GDM prevalence of 10.5%. The two groups were similar with respect to BMI, gravidity and parity. The GDM subjects had significantly higher fasting-and 2-h glucose values during OGTT compared to controls. Gestational age at OGTT was similar in the two groups. The frequencies of preterm birth, previous delivery of a macrosomic infant and age ^ 35 years were significantly higher in GDM patients than in controls, whereas a family history of diabetes, the frequencies of prepregnancy overweight, previous unexplained stillbirth were similar in the two groups.
Conclusions
Hypertensive disorders were more frequent in GDM subjects than in controls (19.6% vs. 10.5%).Women with gestational diabetes mellitus were initially thought to have borderline significantly increased risk of preeclampsia (relative risk 1.47; 95% confidence interval 0.92–2.05) and of pregnancy-associated hypertension (relative risk 1.08; 95% confidence interval 0.96–3.22). These findings suggest that women with gestational diabetes mellitus do indeed have an increased risk of preeclampsia.

Perception regarding acceptance of telemedicine in urban and suburban population of central india during COVID-19 lockdown

Bharat Saboo[1], Raka Sheohare[2] & Shikha Jaiswal[3]
[1]Prayas Diabetes Center, Diabetology, Indore, India; [2]Lifeline Madhumeet Diabetes Hospital, Diabetology, Raipur, India; [3]Pt. Jnm Medical College, Pharmacology, Raipur, India

Introduction
India has a huge population of 1350 million and most of it has a patchy availability of healthcare services, where specialist care is not available at most parts of the country. Telemedicine has been recently approved in India by government of India to be implemented during the COVID-19 lockdown as most of the patients will not be able to have the routine in clinic opd consultations.
Aim and objectives
We tried to see the impact and perception of telemedicine in people of central India as to how they perceive this newer concept, how satisfied they felt with it and how they want to go ahead with it. There are no previous studies of this regard in this population.
Materials and methods
374 subjects from central India who have opted for telemedicine consultation during this COVID-19 lockdown period from 1st April 2020 to 15 may 2020 were surveyed. All the respondents were novel users of telemedicine. responses were recorded and analysed by simple mathematical calculations.
Result
Most of the respondents 54% used Telephonic consultation only as compared to 46% who used online video consultation, highest number of patient 47.5% took consultation for DM, 80.5% respondents were happy with teleconsultation, 66.7% respondents found teleconsultation better during pandemic but 77.2% said they would like to have in clinic consultation once the lockdown eases and 36.8% don't like to pay for teleconsultation.
Conclusion
Telemedicine is not the answer to all the healthcare problems, but it can be very important in addressing a vast number of issues. There is a need to spread awareness about this tech-tool to the common man so that they can avail quality healthcare services. We also need to further study the perception of telemedicine as the lockdown eases and its impact in societies with lower education levels.

Clinical manifestations of musculoskeletal complications of acromegaly

Shokhsanam Safarova, Zamira Khalimova, Adliya Kholikova & Saodat Issaeva
Republican Specialized Scientific and Clinical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Summary
Objective
To study the clinical manifestations of musculoskeletal complications (MSC) of acromegaly, to improve the early diagnosis of the disease.
Materials and methods
150 patients with acromegaly were examined who were observed at the RSSPMC of Endocrinology during the period from 2000 to 2020. The age of patients ranged from 19 to 76 years and averaged 43±8.6 years. Of these, 65 (43.3%) were men and 85 (56.7%) women. Moreover, the duration of the disease ranged from 1 year to 23 years.
Results
An analysis of the complaints of our patients showed that the most common complaints of deformation of MSC are an increase in the size of the fingers (96.7%), hands (100%) and feet (98.7%), an increase in the nose, lips (93.3%), changes in facial features (86.7%), swelling of the face and hands (85.3%). More than half of the patients complained of pain (in the spine (73.3%) and in the knees – 56%, in the thigh area – 56.7%). All this led to general weakness and reduced ability to work (88%). As the results of the study showed, in more than half of our patients, different MSCs can be detected by X-ray analysis. So, in 92% of patients, deformation of the phalanges of the hands, feet, thickening of the bones of the skull (92.7%) and signs of osteoporosis of the spine (90%) were detected; 80% have expansion of the periarticular space and deformity of the lower jaw, an increase in sinuses (84%) and signs of osteoporosis of the femurs (80.7%).
Conclusions
1. Among the clinical manifestations of complications of the musculoskeletal system in our patients were enlarged hands and feet (100%), swelling of the joints (93.3%), expansion of the distal phalanges (92%), swelling of the face (90.6%), prognathism (80%) and diastema (72%), limited mobility of the knee joints (70%) and polyarthralgia (66%). 2. Radiography, being one of the available methods for the diagnosis of MSC of acromegaly, allowed the detection of deformation of the phalanges of the hands in 92% of patients, feet, thickening of the bones of the skull (92.7%) and signs of osteoporosis of the spine (90%); 80% have expansion of the periarticular space and deformity of the lower jaw, an increase in sinuses (84%) and signs of osteoporosis of the femurs (80.7%).

Challenges in hyponatremia etiology and management in a child with a suprasellar tumour

Sara Donato, Ana Figueiredo & Joana Simões-Pereira
Instituto Português de Oncologia de Lisboa, Endocrine Department, Portugal

Introduction
Hyponatremia is the most common hydroelectrolytic disturbance in clinical practice. Multiple causes exist for its occurrence, being the etiological diagnosis sometimes complex. In patients with suprasellar tumours it is even harder due to several confounding factors. Management of these patients is difficult as it conflicts with chemotherapy-associated hyperhydration protocols. We present a case that exemplifies this.
Clinical case
Four year-old female born in Angola diagnosed with a suprasellar pilomyxoid astrocytoma. She was submitted to a ventriculoperitoneal shunt and started chemotherapy with vinca alkaloids. Due to hypoosmolar hyponatremia, she was first diagnosed with secondary adrenal insufficiency and started therapy with hydrocortisone and, given the persistency, also fludrocortisone. When she was first seen in Endocrine department she was under 30 mg/day of hydrocortisone and 0.075 mg/day of fludrocortisone. She was clinically euvolemic and maintained hypoosmolar hyponatremia (sodium 130 mmol/l; osmolality 258.8 mOsm/kg) with low uric acid concentration and normal renal function. She presented with stage 2 pubic hair, probably due to iatrogenic pubarche. The pituitary axis evaluation was normal (ACTH 23.1 pg/ml; cortisol 15.2 μg/dl – without morning dose of hydrocortisone; TSH 0.75 μUI/ml; free T4 1.44 ng/dl; LH 1 mUI/ml; FSH 6.5 mUI/ml; estradiol 42 pg/ml). She started weaning off hydro and fludrocortisone and a syndrome of inappropriate antidiuretic hormone secretion (SIADH) due to brain tumor and/or vinca alkaloid therapy was suspected. She started hydric restriction and 0.25 g/kg of urea. Sodium levels were difficult to manage but documented as normal whenever the medication was strictly followed. She is now seven years old, Tanner stage 1, her tumor is stacionary in size (55 × 36 mm) under chemotherapy with a third line vinca alkaloide. She still needs medication to control hyponatremia.
Conclusion
The etiology of hyponatremia in this child was particularly challenging. Hyponatremia in this context is difficult to manage. We emphasize the potential complexity of correctly diagnosing and treating these patients.

'Neuro-visualization characteristic of the chiasmal-sellar region of the pituitary gland in patients with neuroendocrine diseases'

Urmanova Yulduz[1] & Malika Mirtukhtaeva[2]
[1]Tashkent Pediatric Medical Institute, Endocrinology, Тошкент, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry Named by Acad. Ya.Kh. Turakulov, Department of Neuroendocrinology and Pituitary Surgery, Endocrinology, Tashkent, Uzbekistan

The aim of investigation
To study the tomographic characteristic of the chiasmal-sellar region (CSD) in patients with volumetric formations of the hypothalamic-pituitary region.
Material and research methods
We for the period from 2018 to 2020. 34 patients with various pituitary adenomas were examined. Of these, men – 15 (44.1%), women – 19 (55.9%). Average age: men amounted to 37.12 years, women – 38, 15 years. The research methods included: 1) general clinical (study of endocrine, neurological status, anthropometry 2) instrumental (perimetry for all colors, fundus, visual acuity, ECG, densitometry, CT/MRI of the Turkish saddle, etc.), 3) hormonal blood tests (STH, IGF-1, LH, FSH, PRL, TSH, ACTH, prolactin, etc.)
Research results
Among the 34 patients examined, various formations of the Sellar region were identified: non-functional pituitary adenoma (NFPA) – 21 patients, prolactinoma – 3, Itsenko-Cushing's disease – 4, craniopharyngoma –2, acromegaly –4. Depending on the size of the pituitary adenoma, the following pituitary changes were found on CT/MRI: microadenomas (<10 mm) – 2 patients (5.8%), mesoadenomas (11–20 mm) – 3 patients (8.8%), macroadenomas (up to 30 mm) – 4 patients (11.6%), giant – (more than 30 mm) – 25 patients (73.5%) Distribution of patients according to topographic anatomical classification of the growth side of the pituitary adenoma B. Kadashev (2007) showed that the most frequently observed pituitary adenomas with endosuprasellar growth – 13 bx (38.2%), with infracellular growth – 2 (5.8%), with laterosellar growth – 3 (8.8%), with an antesellar growth of –1 (2.9%), with a retrocellular growth – 1 (2.9%), with a total growth option – 14 bx (41.1%).
Conclusions
1) Among the examined 34 patients with volumetric formations of the sellar region, patients with giant pituitary adenomas (more than 3 cm) predominated – 25 cases (73.5%). 2) The most common endo-suprasellar growth of the neoplasm was 13 cases (38.2%).

Complete growth hormone deficiency associated with solitary median maxillary central incisor syndrome (SMMCI)

Raoudha Kebaili[1,2], Jaballah Nesrine[1,2], Hajer Ben Belgacem[1,2], Jihene Bouguila[1,2], Najla Soyah[1,2] & Lamia Boughamoura[1,2]
[1]University Hospital Farhat Hached, Sousse, Tunisia; [2]Ibn El Jazzar Medical Faculty of Sousse, Tunisia

Introduction
Solitary median maxillary central incisor syndrome (SMMCI) is a complex disorder consisting of multiple, mainly midline defects of development resulting from unknown factors and an uncertain etiology. Its incidence is estimated at 1/50.000.
Material and methods
We report 2 cases of patients with SMMCI associated with GH isolated deficiency in one case and multiple pituitary hormone deficiency in the other one.
Case 1
A 4-year-old girl with no significant medical history consulted for growth retardation at –3.5 s.d. She had a particular physionomy with blond hair, fair skin (contrasting with the skin tone of the parents), baby face and a single maxillary median central incisor. Psycho-motor development was normal. Hormonal investigations concluded to a complete GH deficiency, a central hypothyroidism and a central corticotropic deficit. Hypothalamic MRI showed a pituitary stalk interruption syndrome without any other cerebral anomaly. No other malformation (cardiac, renal, vertebral) was found. She was treated by growth hormone, L-thyroxine and hydrocortisone with satisfying heigt gain and improvement of general condition.
Case 2
The second observation is about a 7-year-old girl with a complete and isolated GH deficiency discovered at the age of 3. She was receiving GH regularly with good results. She had the same particular physionomy than the first girl : blond hair and baby face. This made us re-examine her, so we found also the same dentar anomaly : a solitary median maxillary central incisor. Notice, the parents didn't pay attention to this anomaly in the two cases.
Conclusion
The SMMCI is a rare condition that may be associated with midline anomalies, hypopituitarism, holoprosencephaly and other visceral malformations. It constitues also an eshtetic problem that requires interdisciplinary intervention, generally after the eruption of the permanent teeth.

Successful pregnancy after pituitary surgery: A case report

Amir Bahrami-Ahmadi[1], Professor Dr G.K. Stalla[2], Hadi Tabesh[3] & Hamidreza Bazrafshan[4]
[1]Iran University of medical sciences, Occupational medicine research center, Tehran, Iran; [2]Ludwig Maximilian University of Munich, Medicover Neuroendocrinology and Medizinische Klinik und Poliklinik IV, München, Germany; [3]University of Tehran, Department of Life Science Engineering, Faculty of New Sciences and Technologies., Tehran, Iran; [4]Ludwig Maximilian University Klinikum München, Guest, München, Germany

Background
current studies reported that pregnancy in women with hypopituitarism is rare and several obestristics and endocrinologic complications must resolve for successful pregnancy among these women. Here we report one woman with hypopituitarism who became pregnant after hormonal replacement therapy.
Method
A therapeutic strategy for 34 years old pregnant women as known case of pituitary surgery and completed pan hypopituitarism was designed. We

performed one hormonal replacement strategies including HCG, HMG, prednisone and levothyroxine hormones and after that, we stimulate ovulation process with growth hormone.
Results
After therapeutic time, our patient could achieve a successful pregnancy and delivered her son in due course.
Conclusion
Pregnancy is possible for females suffering from hypopituitarism due to total hypophysectomy by an individualized therapeutic strategy using growth hormone for ovulation stimulation.

Internet search engine queries on abortion and miscarriage peak after a query on missing a dose of oral contraceptive

Irit Hochberg[1,2] & Elad Yom-Tov[3,4]
[1]Rambam Health Care Campus, Institute of Endocrinology, Diabetes and Metabolism, Haifa, Israel; [2]The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel; [3]Microsoft Research, Herzliya, Israel; [4]Technion – Israel Institute of Technology, Faculty of Industrial Engineering, Haifa, Israel

Objective
Oral Contraceptives (OCs) are a unique chronic medication where a slip of memory may be experienced as a threat that could change the life course of a person. Internet search engine queries provide a unique access to concerns and information gaps in a large number of internet users. We sought to quantitate internet search engine queries on missing one or more doses of an OC and subsequent queries on emergency contraception, abortion and miscarriage. We also quantified their rate of reporting a pregnancy timed to the cycle of missing an OC.
Study design
We extracted all Bing English-language queries submitted in the US during 2018 mentioning a missed OC, and further queries by the same users on miscarriage, abortion, emergency contraceptives and week of pregnancy and analyzed temporal trends and query frequency in different age groups.
Results
We identified 26.395 Bing users in the US who searched Bing on missing OC pills and the subfraction who queried about miscarriage, abortion, emergency contraceptive and week of pregnancy after their initial missed OC query. Users under the age of 30 who asked about forgetting an OC dose were more likely to ask about abortion (× 1.5) and emergency contraception (× 1.7) (P-value = 0.00 006 and 0.00 001, respectively), while at ages 30–34 queries about pregnancy (× 2.1) and miscarriage (× 5.4) were more likely (P-value = 0.000002 and 0.000004, respectively).
Conclusion(s)
A large number of women ask about missing a dose of OC, either because they have not have received sufficient information from their healthcare providers or because they preferred to obtain information online. Queries about abortion and miscarriage peaking in subsequent days may indicate a common worry of possible pregnancy.

Oral antioxidants improve sperm motility, sperm concentration and reduce oxidative stress in males with oligoasthenozoospermia

Vegim Zhaku[1], Sheqibe Beadini[2], Nexhbedin Beadini[3], Vjosa Xhaferi[1] & Tatjana Milenkovic[4]
[1]Тетовски Универзитет, Department of Physiology, Тетово, Macedonia; [2]Тетовски Универзитет, Department of Biochemistry, Тетово, Macedonia; [3]Тетовски Универзитет, Department of Molecular Biology, Тетово, Macedonia; [4]Ss. Cyril and Methodius University, University Clinic of Endocrinology, Skopje, Macedonia

Male infertility is a worldwide healthcare issue, which has driven developed countries to take the necessary steps in detecting and treating the problem. While transition countries such as North Macedonia and most of the surrounding states belonging to the Western Balkans, usually blame the female partner for infertility, thus male factor is underestimated. The term 'milieu intérieur' means also a perfect equilibrium between reactive oxygen species (ROS) and antioxidant capacity (AC), crucial for physio-pathological effects on sperm maturation and capacitation, but not only. Oral antioxidants have been shown to diminish oxidative stress (OS) and improve semen parameters, mostly sperm motility and concentration. For this purposes we enrolled 37 infertile males. First semen sample was collected at the time of enrollment in the study. From this 0.5 ml was used for standard semen analysis, while 1.2 ml for evaluating OS parameters such as malonedialdehyde (MDA) and protein carbonyl (PC). A second sample was collected after 6 months of antioxidant treatment. Mean, Standard Deviation, the Pearson Correlation and paired student t-test (since normal distribution was tested by Shapiro-Wilk test) were used for statistical analyses. Levels of MDA are negatively correlated with sperm motility (r = –0.53) and sperm concentration (r = –0.19), so show and levels of PC with sperm motility (r = –0.36) and sperm concentration (r = –0.12). After six months of treatment the semen parameters such as concentration and motility, improve significantly (P < 0.001), MDA also decreases significantly (P < 0.001), PC was also lower after the treatment, but was not statistically significant (P = 0.0554). Antioxidants improve semen parameters in terms of concentration and motility, and dramatically reduced the oxidative stress markers. Considering cost-efficiency of oral antioxidant administration to infertile men, the potential advantages that such treatment offers cannot be ignored. Our suggestion is that Antioxidants should be used on a routine basis in cases of idiopathic male infertility. Anyway, further randomized controlled trial on larger sample size for standardization of doses and duration of supplementation are needed.
Keywords: male infertility, semen parameters, malonedialdehyde, protein carbonyl, antioxidants.

Graves' disease following Hashimoto's thyroiditis. Case report

Leonard Nduwayo[1] & Niyitegeka Marie Florence[2]
[1]Centre hospitalier Genevieve de Gaulle Anthonioz, Haute Marne, Saint Dizier, France; [2]Hôpital de Saint Dizier, Service d'Endocrinologie, Diabétologie, Nutrition, Saint Dizier, France

Hyperthyroidism in Graves' disease (GD) is caused by thyroid-stimulating autoantibodies to the TSH receptor. Hypothyroidism in Hashimoto's thyroiditis (HT) is associated with thyroid peroxidase and thyroglobulin autoantibodies. Transformation of HT to GD has been rarely reported. We report a woman with history of HT, who then developed GD.
Case presentation
A 50-year-old female with a past history of hypothyroidism due to HT treated with Levothyroxine from 2016 to 2018, presented in March 2020 with palpitations, dyspnea on slightest effort and dizziness. Thyroid gland was symmetrically normal, without any bruit. There were no ocular manifestations. Initial thyroid function tests revealed: TSH: < 001 mUI/l (0.27–4.20), FT4:37 pmol/l (12–22), TPO antibodies: 216 UI/ml (<34), TG antibodies: 202 UI/ml (< 34); TSH receptor antibodies: 10 U/l (< 1). Thyroid ultrasonography showed a multinodular gland with a nodule of 17 mm located in the left lobe. 99 m Tc pertechnetate scan showed a normal sized gland with increase uptake of radiocontrast, typical image of GD.
Comment
HT and GD represent the main two types of autoimmune thyroid disease. The conversion to GD from HT is a rare phenomenon which needs further immunological and genetic studies to explain this unusual autoimmune disorder and the time between hypothyroidism and the occurrence of hyperthyroidism. In our case, hyperthyroidism appeared 4 years after hypothyroidism due to HT.

Myxedema: How a lack of follow up can lead to a medical emergency

Jonas De Rop[1], Wannes Baeten[2], Frederic Camu[2] & Katleen Devue[2]
[1]UZBRUSSEL, Endocrinology, Brussels, Belgium; [2]ASZ Aalst, Emergency medicine, Aalst, Belgium

Myxedema coma is a potentially lethal presentation of severe hypothyroidism. It is a rare condition in the Western society. We present a 72-year-old woman with a myxedema coma precipitated by a urinary tract infection. The patient was admitted to the emergency ward in a subcomatose state featuring hypothermia, hypotension, bradycardia and hypoxia. Diagnosis of myxedema by the attending Emergency Physician was suggested based on clinical presentation. The consulting endocrinologist questioned the diagnosis due to the lack of thyroid related disease at initial review of her medical history and because of its rare incidence. Thyroid tests confirmed the diagnosis of myxedema and subsequent treatment with levothyroxine and liothyronine intravenously resulted in a rapid amelioration of the patient's physical and mental state. During the patient's stay in the hospital it became clear that she had previously been on radioactive iodine therapy for Graves' disease, but that follow-up had been neglected. The case presented here highlights the importance of knowledge of low incidence endocrine disease in the emergency department. Patient who undergo treatment with radio-active iodine should be actively encouraged and reminded to follow up the effects of the treatment. This statement is of particular importance in the current COVID-19 lock down period. Patients are scared to pursue their regular follow-up. Tele-consultations and video consultations may be an alternative to face to face consultations in order to avoid loss to follow-up and detect timely overt thyroid dysfunction.

EP584

Acute thyroiditis treated with Levofloxacin in overall healthy young woman – after subacute thyroiditis

Nino Abesadze
ქირურგიის ეროვნული ცენტრის კლინიკა „ახალი სიცოცხლე' – axali sicocxle, Ambulance, T'bilisi, Georgia

Introduction
Acute thyroiditis is rare disease and it affects mainly immunocompromised patients. First line antibiotics for treatment are Ampicillin and Cephalosporin.
Case report
30 y/o woman presented with neck pain and according clinical-laboratory tests was diagnosed with subacute thyroiditis.

- TSH-0.018(0.350–4.940 μIU/ml);
- FT4–32, 32 (9, 01–19, 05 pmol/l)
- CRP-151.25 (<5 mg/l)
- WBC-10.81(3.50–10.00) 10^9/l
- E.S.R 48(<20 mm/h)
- Thyroid ultrasonography- Left lobe –10.7 cm^3, right lobe 10, 9 cm^3. With autoimmune thyroid disease signs.

Treatment with methylprednisolone 16 mg was started and after releasing of pain, gradually lowered. After withdrawal of hormone in about 8 weeks, patient's pain returned. NSAID was initiated, but treatment did not help and patient began to take again methylprednisolone. After second withdrawal of hormone in 6 weeks, more acute pain came back, with swollen left side of neck, dysphagia and dysphonia. Patient decided to take 4 mg methylprednisolone for 2 days, which did not help and she came for evaluation. Thyroid ultrasonography – Left lobe enlarged –14.6 cm^3, right lobe reduced-6.7 cm^3. In left lobe was infiltrate-like appearance lesion.

- TSH-0, 39 (0.27–4.2 μIU/Ml)
- WBC- 11.87 (4.4–11.3 10^3/mm^3)
- Neutrophils% 85.3%(50–75)
- ESR 3 mm/hr<25ESR.

Patient refused to take additional tests- CT and FNA, due to financial reasons. Treatment for acute thyroiditis with Amoxicillin/clavulanic acid 2000 mg daily was started and methylprednisolone stopped. Patient had-allergic rash and itching on face. She remembered, that she had previously allergy on cephalosporin. Because of that Amoxicillin was replaced with Levofloxacin 500 mg and after 1 week patient presented without symptoms.

- WBC-8.63 10^3/mm^(3 4.4–11.3)
- Neutrophils% 67.6%(50–75)
- ESR 7 mm/hr<25ESR
- Thyroid ultrasonography-left lobe was reduced in size twice.

We continued treatment for 1 more week and patient was fully recovered. After 2 months she reports to feel great.
Conclusions
Notwithstanding, that we had limited diagnostic resources and we did not know real pathogen, after good result on antibacterial therapy we can confirm, it was acute thyroiditis. Was it due to glucocorticoids, was it acute thyroiditis from beginning, or some other anatomic reason – we could not find out. It is unusual case, because of patient's young age and overall health. Also it is interesting, because Fluoroquinolone is not widely used in acute thyroiditis and we can suggest it as an effective treatment option.

Alopecia universalis as clinical manifestation of hashimoto's thyroiditis: A case report

Canggih Dian Hidayah[1], Dicky Tahapary[2] & Dante Harbuwono[2]
[1]Faculty Of Medicine Universitas Indonesia, Department Of Internal Medicine, Dr. Cipto Mangunkusumo National General Hospital, Central Jakarta, Indonesia; [2]Faculty Of Medicine Universitas Indonesia, Division Of Metabolism And Endocrinology, Department Of Internal Medicine, Dr. Cipto Mangunkusumo National General Hospital, Central Jakarta, Indonesia

Background
Thyroid hormone has an important role for skin growth and development. Alopecia is one of the clinical feature of autoimmune hypothyroidism or systemic autoimmune disease
Case Illustration
A 18-year-old Indonesian woman presented with alopecia universalis. It started with a patchy hair loss which then progress to all of her body. At the age of 15 she had complaints of neck enlargement, palpitation, weight loss, and heat intolerance. Physical examination revealed alopecia universalis and diffuse thyroid goiter. She had high TSHs level and positive TPO-Ab. Thyroid ultrasound characteristics were in concordance with thyroiditis. She was then diagnosed with Hashimoto's thyroiditis and given low dose levothyroxine (LT4), but without any improvement in the alopecia. Screening for other systemic autoimmune disease yielded negative results. She had also toxoplasmosis and has already been given full treatment course.
Discussion
Alopecia areata (AA) is an organ-specific auto-immune disease with genetic predisposition, environmental trigger such as infection, and associated with increased overall risk of autoimmune thyroid disease (TAI) especially those with alopecia universalis (AU). Thyroid autoantibodies were found in AU patients and seem to dysregulate TSH secretion and inflammatory state could mediate its clinical manifestation. The standard treatment of LT4 leads to TSH suppression and reduction of exaggerated inflammatory response in thyroid gland, skin, and decreasing TPO-Ab level.
Conclusions
This indicates the necessity screening for thyroid abnormalities, thyroid autoantibody, and further systemic autoimmune in patients with AU, which is of benefit for early diagnosis and treatment.

Hypoparathyroidism incidence in patients operated on papillary thyroid carcinoma — are there any changes in a 20 year time-lapse?

Maxim Lushchyk[1], Hanna Tuzava[1], Natallia Dudzik[2] & Larissa I. Danilova[2]
[1]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department, Thyroid Disease Research Group, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department, Minsk, Belarus

Introduction
Today, thyroid papillary cancer remains to be the most frequent diagnosed malignancy. Despite highly positive outcomes, treatment protocol still requires surgical intervention, which, in turn often affects not only thyroid and regional lymph nodes, but also recurrent nerve and parathyroid glands. The aim of our study was to compare the metabolic compensation of calcium and thyroid metabolism improvement in patients operated on thyroid cancer recently and 20 years ago.

Material and methods
We have examined two groups of patients (in total 104 men and women with the age of 21 to 43 years old at the moment of operation) treated on highly differentiated thyroid carcinoma in different time periods (1998–2000 and 2018–2029). The first one, analyzed retrospectively, consisted of 44 patients aged 22.16±7.51at the moment of operation, the second one recently selected included 60 patients with mean age 22.16±7.5 years. Both groups did not differ significantly by the age at the moment of operation, as well as by staging – all were marked as stage 2 by pTNM. Daily prescribed amount of levothyroxin was recorded. Tests for TSH, FT4, TG, Parathormone were made using ELISA-DRG (USA) kits and serum calcium levels were estimated on Cormay-Diana biochemical analyzer (Poland).
Results
As a result, comparing two groups we have seen no significant difference in FT4 levels, though significant decrease in mean TSH levels was observed in between groups (0.6420±0.74 mUI/l in group 1 vs 0.3275±0.62 mUI/l) ($P<0.05$) on the almost similar amounts of thyroxin intake 160.14±28.89 vs 153.95±31.21 mg/day respectively, showing significant improvement in compliance and target TSH suppression levels achievement over time. As for the calcium levels – they have also significantly improved over the time of surgical experience – 1.97±0.17 in group 1 vs 2.37±0.12 in group 2 ($P<0.05$) – two decades later. Alongside with the positive shifts – a worrying difference in TG levels was determined –1.91±3.30 ng/ml vs 2.49±3.96 ng/ml ($P=0.03$) That can be explained either by different reagent sensitivity or higher relapse tendency in more sparing surgical techniques.
Conclusion
Improvement of surgical techniques and reduction of postoperative hypoparathyroidism is obvious, but still the minimally invasive approach requires more clinical observation and follow up.

RHO gene polymorphisms in patients with Graves' disease

Suzan Tabur[1], Elif Oguz[2] & Tuncay Demiryurek[3]
[1]Gaziantep University, Internal Medicine, Gaziantep, Turkey; [2]Istanbul Medeniyet University, Medical Pharmacology, Istanbul, Turkey; [3]Gaziantep University, Medical Pharmacology, Gaziantep, Turkey

Graves' disease (GD) is an organ-specific autoimmune disorder of the thyroid due to the presence of circulating anti-thyroid-stimulating-hormone receptor stimulating autoantibodies that lead to hyperthyroidism. Involvement of the genetic variants of *RHO* genes in GD has not been examined yet. Therefore, the aim of this study was to investigate possible associations between RHO gene polymorphisms and GD in a Turkish population. A total of 128 patients with GD and 163 healthy control subjects were included to this study. Genomic DNA was extracted from whole peripheral blood samples and analyzed using the dynamic array system (Fluidigm, South San Francisco, CA, USA). The Chi-square or Fisher's exact tests were used for calculation of the differences in frequencies. The Bonferroni correction for multiple testing was used for polymorphism studies, and $P<0.0071$ (0.05/7) was considered statistically significant. We investigated 7 *RHO* gene polymorphisms. Neither genotype distributions nor the allele frequencies for the *RHOA* rs6784820, *RHOA* rs974495, *RHOA* rs2177268, *RHOC* rs11102522, *RHOD* rs2282502 (Asp88 Glu), *RHOD* rs34270544 (Arg144 Gln), and *RND3 (RHOE)* rs816890 polymorphisms showed a significant association between the groups. This study showed for the first time that there were no associations between studied *RHO* gene polymorphisms and the risk of developing GD in the Turkish population.
This study was supported by a project (SBAG-213S021) from the TUBITAK, Ankara, Turkey.

Table 1 The genotype and allele distrubition of *RHO* gene polymorphisms in Graves patients and control group.

Gen/SNP	Genotype/ Allel	Control	*n**	Patient	*n**	*P*
RHOA	AA/AG/GG	65/63/30	158	56/38/28	122	0.3109

Amiodarone induced thyroid disorders – would you miss them?

Hnin Yu Sanda[1] & Gideon Mlawa[2]
[1]Queen's Hospital, Acute Medicine, Romford, United Kingdom; [2]Queen's Hospital, United Kingdom

Introduction
Amiodarone is a well-established class III antiarrhythmic drug used in the treatment of arrhythmias and atrial fibrillation.
Case Report
History
A 68 year old gentleman who has background history of persistent Atrial fibrillation, dilated cardiomyopathy, took digoxin 125 mg, bisoprolol 2.5 mg and warfarin 2 mg, simvastatin 40 mg, Ramipril 10 mg. Digoxin was discontinued due to the nocturnal pauses, bradycardia on 24 hour holter and Aamiodarone 200 mg was started on April 2015. Following four months commencement of Amiodarone, he developed nausea, palpitation, fatigue, unintentional weight loss and found to have thyrotoxicosis. No iodine-containing contrast agents had been recently administered and family history was negative for thyroid disorders.
Diagnosis
Amiodarone induced thyroiditis [AIT] was made. TSH<0.01 [0.35–5.50 mu/l], Free T4–30 [10–19.8 pmol/l], TSH receptor Antibody –negative, TPO antibody negative. Routine blood tests are unremarkable.
Treatment and Follow up
Amiodarone was stopped and carbimazole was started. His thyroid function test back to baseline, clinically and biochemically euthyroid after two years of treatement.
Discussion
A diagnosis of AIT can be considered at any time in a patient who develops clinical signs of thyrotoxicosis after taking amiodarone. The main mechanism is iodine-induced hyperthyroidism (type 1 AIT), a form of Jod Basedow, or destructive thyroiditis (type 2 AIT), caused by amiodarone itself and its high iodine content. The risk of hyperthyroidism also increases with increased dosage. The effects of amiodarone on the thyroid can be seen as early as a few weeks after startingtreatment and or up to several months after its discontinuation as Amiodarone is lipophilic and has a long half-life in the body.
Conclusion
Patients with cardiac disease receiving amiodarone treatment should be monitored for signs of thyroid dysfunction, which often manifest as a reappearance of the underlying cardiac disease state. Because thyroid dysfunction is relatively common in amiodarone therapy,all patients should have free thyroxine and thyroid-stimulating hormone (TSH) levels measured before starting therapy, at three- month intervals during treatment and for at least one year after the amiodarone is discontinued.

Serious progressive risk of Basedow's disease: Thyroid storm

Sara Ijdda[1], Rafi Sana[1], Ghizlane EL Mghari[1] & Nawal EL Ansari
University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
Thyroid storm is an acute exacerbation of hyperthyroidism, responsible for significant mortality despite treatment.

Case report
We report the observation of a 43-year-old diabetic patient with basedow's disease with poor therapeutic adherence; admitted for convulsions and loss of consciousness. The diagnosis of acute thyroid storm on drop out of treatment was mentioned, in front of the detection of peripheral hyperthyroidism with low TSH; T4 at 67.75 pmol/l, T3 at 45 pmol/l, hepatic cytolysis and high creatine phosphokinase. Other clinical parameters included bilateral exophthalmos, vascular goiter, tachycardia at 180 beats/minute, dehydration and hyperthermia. Management consisted on intubation-ventilation, re-administration of carbimazole 50 mg and propranolol 60 mg, with bolus of corticosteroid therapy and rehydration. The patient died within 24 hours despite symptomatic intensive care measures.
Discussion/Conclusion
The thyroid storm is a rare and potentially fatal entity. Low socio-economic backgrounds promote its occurrence. The main difficulty is recognizing its varied presentations, and offering appropriate treatment when the doctor faces a failure, or against contraindications of conventional therapy.
