The prevention of diabetic foot in emerging countries is accessible by a systematic clinical examination of all diabetic feet and the awareness of adapted footwear. Long-term studies are needed to evaluate whether the intervention of podiatrists starting at an early phase would lead to a reduction in major foot problems.

Cutaneous manifestations of diabetes mellitus

El Amri Abir[1], Nadia Ben Amor[1], Rihab Yamoun[2], Faten Mahjoub[2], Amany Amorri[3], Sirine Nsir[3], Rym Ben Othman[1], Ramla Mizouri[1], Olfa Berriche[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Tunisia; [2]Faculty of Medicine Of Tunis, Tunisia; [3]University of Tunis El Manar, Tunisia

Introduction
Diabetes mellitus (DM) is the most common endocrine disorder. The skin manifestations of diabetes can vary depending on the duration of the disease and the control of blood glucose levels. Almost all patients with DM eventually develop skin changes due to the long-term effects of hyperglycemia on microcirculation and skin collagen. This study was conducted to find the hospital based prevalence of mucocutaneous manifestations in patients with diabetes mellitus, their clinical pattern and relationship with glycemic control and duration of the disease
Methods
It was a longitudinal observational study including 200 patients aged 18 years and older with a confirmed diagnosis of type 1 and type 2 diabetes, admitted in nutrition department A for any reason between 1 August and 31 December 2021.
Results
Among 200 patients with DM, 88(44%) were males and 112(565%) were females. The mean age of the patients was 51.85 $\pm$ 18.35 years and mean total duration of diabetes was 11.87 $\pm$ 8.9 years. Of them, 135 (67.5%) had one or more dermatoses. The common skin disorders for which patients sought treatment were: xerosis (55.5%), plantar hyperkeratosis (41.3%), onychomycosis (39.2%), and inter-toe intertrigo (18.2%). Risk factors most closely associated with mucocutaneous manifestations included High Blood Pressure ($P = 0.000$), diabetic peripheral neuropathy ($P = 0.018$) and obesity or overweight ($P = 0.000$) . But there is no statistically significant relationship with nephropathy ($P = 0.14$) or retinopathy ($P = 0.58$).
Conclusion
Skin problems are quite common among diabetic population. Diabetes-related skin lesions can serve as a gateway for microorganisms and possible secondary infections. The early detection of mucocutaneous manifestations in DM is important to be able to avoid and manage the complications and prevent disability.

Dapagliflozin can Induce and Maintain Type 2 Diabetes Remission

Mahmoud Younis
Egypt Ministry of Health, Kafr Elsheikh, Egypt

Introduction
Type 2 diabetes mellitus, has gained a lot of attention in recent years as one of the most important chronic progressive diseases in the world, which slowly crawls towards longevity and which involves many chronic complications, which are dangerous to health and the economy. Sodium-glucose cotransporter-2 (SGLT2) inhibitors represent a category of newly discovered drugs that work by preventing glucose reabsorption in the proximal renal tubules. (SGLT2) Inhibitors may induce type 2 diabetes remission. Design: Randomized, -controlled trial, 6-month trial.
Materials and Methods
100 type 2 diabetes patients were randomized into 2 groups.
Results
The results show a statistically significant decrease of A1C levels after 3 and 6 months treatment with dapagliflozin and significant change in A1C levels after 3 months treatment of glimepiride but a no significant change in the next 3 months. The results also show a statistically significant decrease in BMI in the dapagliflozin group after 6 months of treatment.
Conclusion
As type 2 diabetes is one of the most disabling diseases, it is necessary to find a drug that can lead to remission. Dapagliflozin can lead to type 2 diabetes remission.KeywordsDapagliflozin, Inhibitors, Type 2 Diabetes

Double Trouble. Metformin and empagliflozin induced lactic acidosis - A case report

Bhavna Sharma, Michele Mantega, Mahesh Deore, Ian Seetho, Shivashankar Seechurn, Elaine Hui, Mushtaqur Rahman & Asjid Qureshi
Northwick Park Hospital, United Kingdom

63 years old with sarcoidosis since 2018 and type 2 diabetes was referred by GP for hypercalcemia related to likely dehydration and sarcoidosis. She was started on a weaning dose of prednisolone and empagliflozin. She had already been on metformin for several years. She was discharged after calcium improved from 2.97 mmol/l to 2.83 mmol/l. She was advised to follow up in Ambulatory care in 1 week for repeat calcium levels. On follow up, noted to have calcium levels of 2.67 mmol/l. Lactate noted to be 6.9 with a pH of 7.3 (calculated anion gap 13.1 mmol/l). Patient noted to be completely asymptomatic with normal systemic exam. Given fluids in ambulatory care , however, lactate noted to be rising at 7.7 with negative ketones and normal sugars. Empagliflozin was stopped and insulin was initiated with normalization of lactate with minimal fluid therapy. A literature review noted a similar case by Tomigana et al[1] with lactic acidosis after initiation of empagliflozin along with metformin. Cellular dehydration with inhibition of enzymes may contribute to high lactate in the patients treated with metformin and an SGLT2 inhibitor. Lactate should be checked in unwell patients on metformin and an SGLT2 inhibitor. The effect of this complication on mortality/morbidity is unclear and further research is needed.

Long-term impact of digitally administered Breathe Well-being Diabetes Reversal Program (BDRP) in individuals with type 2 diabetes mellitus

Pawan Kumar Goyal[1], Surajeet Kumar Patra[2], Aditya Kaicker[2], Rohan Verma[2], Seema Goel[2], Rupali Jangid[3], Saleha Rehman[3] & Venugopal Madhusudhana[3]
[1]Fortis Hospital, Shalimar Bagh, Delhi, India; [2]Breathe Well-Being, New Delhi, India; [3]THB (India), Gurugram, India

Introduction
Breathe Well-being Diabetes Reversal Program (BDRP) delivers personalized lifestyle management (LSM) curriculum including education, lifestyle, and health-related content, based on patient's health profile and preferences. The program assists the physicians in making clinical decisions by providing comprehensive lifestyle data, which facilitates patient adherence and aids in achieving positive health outcomes.
Objective
To estimate the long-term impact of digitally administered BDRP on lifestyle measures in individuals with T2DM in India
Methodology
BDRP provides a 4-month digitally administered LSM intervention with additional stress reduction module- a "Happiness and Lifestyle Coach" combined with meditation. Individuals with T2DM were divided in 3 cohorts (1:1:1) treated with (a) BDRP with doctor-prescribed medication ($n = 60$), (b) BDRP with doctor-prescribed medication and personalized stress reduction module ($n = 61$), (c) Only doctor-prescribed medication (control group; $n = 60$). After 4-months of intervention, cohorts 1 and 2 with high (H: $>70\%$) and medium (M: $\geq 50\%$-$< 70\%$) adherence and cohort 3 were followed up to 19 months. Informed consent was obtained.
Results
Of 60 and 61 individuals in cohorts 1 and 2, 46.7% (28) and 54.1% (33) showed H and M adherence. In H and M cohort 1, BMI (kg/m^2) reduced from 32.6 and 31.2 at baseline to 29.5 and 28.7 at 19 months ($P = 0.003$; $P = 0.000$), respectively. In H and M cohort 2, BMI reduced from 32.9 and 31.9 at baseline to 29.7 and 28.7 at 19 months ($P = 0.001$; $P = 0.000$), respectively. Body weight (kg) in H and M cohort 1 reduced from 90.2 and 85.4 at baseline to 81.6 and 78.4 at 19 months ($P = 0.003$; $P = 0.000$). For H and M cohort 2, body weight reduced from 88.1 and 88.0 at baseline to 79.8 and 79.2 at 19 months ($P = 0.001$; $P = 0.000$). In control group, BMI and body weight reduced from 32.0 and 88.1 to 31.8 and 87.5 ($P = 0.029$; $P = 0.025$). At 19 months, HbA1c levels $<6.5\%$ were observed in 78.6% and 81.8% individuals in H and M cohorts 1 and 2. Penn State Worry Questionnaire (PSWQ) score average changed from 57.5 and 55.5 to 42.1 and 42.1 for cohort 1 (H and M), and 54.9 and 59.8 to 33.9 and 41.0 for cohort 2 (H and M) at 19 months, respectively.
Conclusion
Clinically meaningful reductions in BMI, body weight, HbA1c, and stress levels were observed in both cohorts. Cohort 2 showed greater improvement in stress levels than cohort 1. Study findings supported the promising role of digitally administered BDRP on lifestyle measures of individuals with T2DM.

Sodium-glucose cotransporter-2 (SGLT-2) inhibitor-induced diabetic ketoacidosis and Fournier's gangrene

Mona Abouzaid , Chien Nee Gan & So Pye
North Tees and Hartlepool NHS Foundation Trust, Diabetes & Endocrinology Department, Stockton on Tees, United Kingdom

Introduction
The Food and Drug Administration (FDA) had issued warnings on the increased risk of diabetic ketoacidosis and Fournier's gangrene with patients using Sodium-glucose cotransporter-2 (SGLT-2) inhibitors. Herein, we report a case of simultaneous Fournier's gangrene and diabetic ketoacidosis after initiation of treatment with Empagliflozin.
Case Presentation
We report a case of a 54-year-old woman with type 2 diabetes on empagliflozin presented feeling unwell. Blood glucose level raised at 32.7 and ketones of 2.2 mmol on admission. Blood gas showed acidosis of pH 7.242 (7.35 - 7.45), bicarbonate of 21.2 mEq/l (22 - 26) and base excess of - 6.5 mmol/l (-2 to +2). She was started on diabetes ketoacidosis treatment. Empagliflozin was suspended. Blood results showed raised C-reactive protein of 353 mg/l. She reported new incontinence of both urine and faeces for 2 weeks. Examination revealed perianal fistula, extensive perineal erythema, pus with central necrotic area on left perineum, inflammation of left labia with a patch of necrosis in left groin crease. She was commenced on broad spectrum intravenous antibiotics. CT scan showed marked diffuse subcutaneous fatty infiltration and oedema on the left side of the perineum and left buttock with suspected fluid collection of the left labia measuring 29x14mm, multiple enlarged left inguinal lymph nodes. She underwent surgical drainage and debridement. Histology showed ulceration and necrotizing abscess with fat necrosis which confirmed the diagnosis of Fournier's gangrene. Humulin M3 twice daily was initiated. She then recovered well.
Conclusion
To our knowledge, only 4 cases reported in the literature worldwide presented with simultaneous Fournier's gangrene and diabetic ketoacidosis after initiation of treatment with (SGLT2) inhibitors. Health care professionals should be aware of this extremely rare but life-threatening adverse events. They should assess patients for Fournier's gangrene if suspected.

Impact of depression in type 2 diabetics with Covid 19: 38 cases

Kolsi Boulbaba[1] , Rihab Ben Abdallah Kolsi[2], Sidina Mohamed Elmoctar[1], Mohamed Dammak[1], Khouloud Boujilbéne[1], Kawthar Elarbi[1], Asma Zargni[1], Faten Hadj Kacem[1] & Mohamed Abid[1]
[1]CHU Hedi Chaker Sfax Tunisia, Endocrinology and Diabetology, Sfax, Tunisia; [2]Faculté des sciences de Sfax Tunisia, Biology, Sfax, Tunisia

Introduction
Diabetes, like any chronic disease, generates in addition to the somatic consequences, serious psychological repercussions, depression and diabetes emerging respectively in the 4th and 9th rank of the most important causes of disturbances in number of years of life corrected for the disability factor. (DALYS).
Patients and methods
Descriptive retrospective study of 38 post-Covid diabetics collected from the endocrinology – diabetology department of CHU Hédi Chaker, Sfax, Tunisia. Screening for depression using the Beck Scale (BDI).
Results
The average age of our patients was 45.5 years with a sex ratio (M / F) of 1.5. All of our patients had type 2 diabetes. The mean duration of diabetes was 9.5 years. The majority of patients (77%) had an HbA1c$>$ 7.5%. According to the Beck scale, 63.6% of our patients had experienced a feeling of sadness after Covid, of which almost 25% were unable to cope. Feelings of discouragement, failure and guilt were found, respectively, in%, 64% and 45% of cases. A state of fatigue was noted in half of our patients and 42.4% were unable to work. Overall, all of our patients experience post-Covid depression to varying degrees: it was severe in 30.3%, moderate in 54.5% and mild in the rest of our diabetic patients. None of our patients admitted to having a suicide plan and 45% felt that death would set them free. Only 25% of nurses are interested in the psychological side of post-Covid diabetics, 40% of whom encourage them to consult a psychiatric hospital.
Conclusion
All people with diabetes should be screened for symptoms of depression or anxiety. Screening for and managing the psychological consequences of diabetes is essential. Screening for and managing the psychological consequences of diabetes in adolescents is essential for improving the quality of life of these patients and better controlling their disease.

Distinct inflammatory signatures of upper- and lower-body adipose tissue in postmenopausal women with normal weight and obesity

Ioannis Lempesis[1,2,3], Nicole Hoebers[2], Yvonne Essers[2], Johan WE Jocken[2], Ellen E Blaak[2], Konstantinos N Manolopoulos[1,3] & Gijs H Goossens[2]
[1]Institute of Metabolism and Systems Research (IMSR), College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Department of Human Biology, NUTRIM School of Nutrition and Translational Research in Metabolism,, Maastricht University Medical Centre, Maastricht, Netherlands; [3]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, United Kingdom

Background
Abdominal obesity is associated with insulin resistance and increased cardiometabolic disease risk, whereas lower-body fat accumulation seems

protective against metabolic derangements. Differences in upper-body and lower-body adipose tissue (AT) function seem to underlie these opposing associations. Here, we investigated the inflammatory signature of upper- and lower-body AT in women with normal weight and obesity, as well as in human primary abdominal (ABD) and femoral (FEM) adipocytes.
Methods
Twenty-one healthy postmenopausal women (aged 50–65 years) with normal weight (BMI 18–25 kg/m^2) and obesity (BMI 30-40 kg/m^2) were recruited. The *in vivo* secretion of adipokines from ABD and FEM subcutaneous AT was determined after an overnight fast using the arterio-venous balance technique. Furthermore, adipokine expression and adipocyte size in ABD and FEM AT were examined. Finally, the expression and secretion of adipokines were investigated *in vitro* using differentiated human primary ABD and FEM subcutaneous adipocytes derived from the same individuals.
Results
Plasma leptin ($P < 0.001$) and PAI-1 ($P = 0.036$) concentrations, as well as abdominal and femoral adipocyte size were higher in women with obesity compared to normal weight. No significant differences in fat cell size and blood flow were found between ABD and FEM AT. There was significant net release of leptin and MCP-1 across ABD and FEM AT (all $P = 0.001$), and fractional release of MCP-1 was higher in ABD than FEM AT ($P = 0.023$). Gene expression of leptin ($P = 0.010$), PAI-1 ($P = 0.080$) and TNF-α ($P = 0.090$) were lower in ABD than FEM AT and increased in obesity. *In vitro*, IL-6, PAI-1 and leptin gene expression was higher, while adiponectin and DPP-4 gene expression were lower in adipocytes derived from the ABD compared to FEM region. Finally, ABD adipocytes derived from women with obesity secreted less MCP-1 compared to femoral adipocytes ($P = 0.013$).
Conclusions
The present study demonstrates for the first time that there are differences in the expression and secretion of pro-inflammatory adipokines between ABD and FEM AT and human primary adipocytes in postmenopausal women, independent of adipocyte size.

Objective
We describe two first cousins presenting with neonatal corticotropic deficiency and severe, early-onset obesity. This study aims to identify the molecular etiology of these disorders in both cases and highlights the limits of genetic investigations.
Methods
We collected the clinical-biological data of the family and, more particularly, of the two first cousins (A and B). We performed several constitutive Next-generation Sequencing (NGS) protocols focused on genes causing monogenic forms of pituitary deficits or obesity. The pathogenicity of variants was assessed via the guidelines of the American College of Medical Genetics and Genomics.
Results
Patients A and B had very early-onset obesity (> +3DS at 1year) with neonatal corticotropic deficiency and Combined Pituitary Hormonal deficiency (CPHD). The initial sequencing of three genes causing pituitary deficiency (*TPIT*, *PROP1*, *LHX3*) was negative. Then, by another targeted sequencing protocol, we found that Patient A carried a pathogenic compound heterozygous variant in *POMC* (NM_001035256.3: p.Tyr139* and p.Cys28*). However, Patient B only carried the *POMC* p.Tyr139* variant at heterozygous state, inherited from her mother (aunt of Patient A). Whole-exome sequencing in Patient B allowed us to identify a second pathogenic heterozygous variant in the proximal promoter of *POMC* (c.-11C>A) that was inherited from her father. This non-coding variant was previously reported pathogenic in the literature, with a deleterious effect on POMC activity according to *in vitro* analyses. Patient A is currently being treated effectively with an MCR4 agonist, decreasing BMI from 41.5 kg/m^2 to 25 kg/m^2 after three years.
Conclusions
We described the segregation of three different pathogenic *POMC* mutations within the same family with a CPHD phenotype and severe, early-onset obesity. One of them was challenging to identify because of the limitations of targeted NGS.

An evidence-based framework to evaluate melanocortin-4 receptor (MC4R) pathway relevance for obesity-associated genes

Megan E Vogel, Ida H Moeller, Alastair S Garfield & Bhavik P Shah
Rhythm Pharmaceuticals, Boston, United States

Introduction
The MC4R pathway is the principal regulator of mammalian energy balance through its modulation of energy intake and energy expenditure. Variants in genes associated with the MC4R pathway can result in rare genetic diseases of obesity. Clinical data in patients with certain genetic defects in the MC4R pathway indicate that setmelanotide, an MC4R agonist, may effectively reduce weight and hunger in scientifically rationalized obese subpopulations in which MC4R-pathway deficiency is a contributing factor to obesity. Here we introduce an evidence-based framework designed to evaluate various genes' relevance to the MC4R pathway to identify those genetic patient populations most likely to benefit from long-term setmelanotide therapy.
Methods
This framework utilizes a set of clinical (human genetics) and non-clinical experimental evidence to evaluate MC4R pathway relevance and is based on the core principles of the NIH ClinGen *Gene-disease Clinical Validation* approach which is the industry standard for assessing gene-disease relationships. Human genetic evidence helps define the contribution of the gene to human obesity, while experimental evidence assesses involvement of the gene in the function of MC4R pathway. The cumulative weight of this evidence is used to classify MC4R pathway genes into 4 strength-based tiers: very strong, strong, moderate, weak. The nature, quantity, and quality of evidence required for each tier builds upon that of the previous tier, with higher ranked genes being more likely to define patient populations potentially responsive to long-term setmelanotide treatment.
Results
Based on a comprehensive literature review, 118 MC4R pathway genes were identified and rank ordered: 8 "very strong", 29 "strong", 22 "moderate", 59 "weak". Importantly, clinically meaningful weight and hunger score reductions following treatment with setmelanotide have been previously demonstrated in patients with obesity due to variants in 6 genes, all initially classified as "very strong" or "strong", lending credence to this framework for the selection of patient populations most likely to benefit from long-term setmelanotide therapy.
Conclusions
This framework provides robust means of selecting MC4R pathway relevant genes and supports clinical investigation of setmelanotide responsiveness in an additional 31 "very strong/strong" genes including *LEP*, *SIM1*, *MRAP2*, and *KSR2*. A clinical trial is currently underway for patients with these gene variants.

DOI: 10.1530/endoabs.81.EP357

Reduction in Oxytocin levels predict body weight loss in patients with obesity after a very low carbohydrate ketogenic diet (VLCKD).

Rossella Tozzi[1], Sabrina Basciani[2], Rebecca Rossetti[2], Angela Balena[2], Davide Masi[2], Renata Risi[2], Gabriele Veroi[2], Elena Colonnello[2], Maria Chiara Massari[2], Mariaignazia Curreli[2], Elena Gangitano[2], Mikiko Watanabe[2], Stefania Mariani[2], Lucio Gnessi[2] & Carla Lubrabno[2]
[1]Sapienza University of Rome, Molecular Medicine, Roma, Italy; [2]Sapienza University of Rome, Experimental Medicine, Section of Medical Physiopathology, Food Science and Endocrinology, Roma, Italy

Background
Oxytocin (OXT) enhances glucose uptake and lipid utilization in adipose tissue and skeletal muscle.Dysfunction of the OXT system could underlie the pathogenesis of weight gain. Men and women with obesity were reported to have higher OXT blood levels compared to normal weight subjects. In contrast,

metabolic syndrome has been associated with reduced fasting serum oxytocin in larger scale mixed gender studies.
Aim
Data regarding the oxytocin system in rodent obesity models and human subjects with obesity appear divided. This study aimed to investigate the concentrations of OXT in a population affected by obesity before and after a very low carbohydrate ketogenic diet (VLCKD) induced weight loss.
Materials and methods
Subjects with obesity were enrolled at the Center of High Specialization for the treatment of Obesity (CASCO), Umberto I Polyclinic, Sapienza University of Rome. At baseline (t0) and after eight weeks of VLCKD (t1), all patients underwent clinical evaluation, biochemical routine assessment, DXA examination for body composition (Hologic Inc., Bedford, MA, USA, QDR 4500W) and venous blood sampling in EDTA plus 500 KIU/ml of aprotinin (Abcam ab146286) for plasma OXT determination (Abcam, Ab133050, ELISA kit). Achievement of ketosis was monitored by measuring urinary β-OH-butyrate.
Results
40 patients (26 females and 14 males) suffering from obesity were enrolled, (age $= 55.5 \pm 7$ years and BMI $= 35.7 \pm 4.3$ Kg/m^2). OXT level at baseline (t0) was 1166 ± 403 pg/ml, with no differences between males and females. At t0 OXT positively correlated with BMI and hip circumference. After VLCKD, a significant weight reduction was seen (mean BMI $= 32.7$ kg/m^2, mean weight loss $=$ -8.8 kg) and OXT (t1) significantly decreased (728.2 ± 201.7 pg/ml, $P < 0.001$). Baseline OXT positively correlated with t1urinary β-OH-butyrate, after adjustment for age ($r = 0.335$, $P = 0.046$). A strong inverse age adjusted correlation between weight loss and baseline OXT was also reported ($r = -0.458$, $P < 0.005$). A regression analysis showed that the reduction in OXT between t1 and t0, the grade of ketosis during VLCKD and baseline%fat mass were all predictors of weight loss (R20.422; $P = 0.025$).
Conclusion
Our study demonstrated that higher OXT levels associates with BMI and with ketosis induction. A lower OXT reduction during a VLCKD seems to be unfavorable for achieving weight loss. Differences in assay method used for measuring OXT, as well as expression patterns of oxytocin receptors, could explain the partial discrepancy of our results with the literature. Peripheral actions of oxytocin deserve further investigations

Response of the human gastric epithelium to sleeve gastrectomy surgery

Rachel Ben-Haroush Schyr[1], Botros Moalem[2], Dana Sender[2], Amit Elad[2], Aya Bardugo[2], Ayelet Etzyoni[2], Yhara Arad[2], Yuval Ishai[3], Ki Suk Kim[4], Ariel Benson[3], Ronit Grinbaum[3], Linda Samuelson[4], Nechemi Grinstein[3], Darleen Sandoval[5] & Danny Ben-Zvi[1]
[1]Hebrew University of Jerusalem, Israel; [2]Hebrew University of Jerusalem, Israel; [3]Hadassah Medical Center, Israel; [4]University of Michigan Medical School, United States; [5]University of Colorado, United States

The gastric mucosa is a dynamic and regenerative tissue that functions in extreme conditions of low pH, mechanical insults and bacterial exposure. The mucosa is composed of pit and neck cells which secrete protective mucus, parietal and chief cells that secrete acid and digestive enzymes, enteroendocrine cells that affect motility, secretion and satiety, rare tuft cells, and at two stem-cell compartments. We studied the response of the gastric mucosa to sleeve gastrectomy surgery: a bariatric or weight-loss surgery in which most of the stomach is removed. Histological analysis and single-cell sequencing of gastric mucosa from patients with no history of surgery, and of patients that had surgery years ago revealed that the gastric mucosa adapts to the new anatomy. We observed an increase in proliferation of the stem cells in the isthmus, in the number of cells per crypt, and a change the composition of the enteroendocrine cell population. Moreover, enterochromaffin-like cells that normally secrete histamine change their transcriptional program and express hormones and neurotransmitters that were not expressed prior to surgery. Mathematical modeling pointed to the hormone Gastrin as a main driver for this adaptation. Theoretical predictions from the model were verified using gastrin knockout mice that underwent sleeve gastrectomy. Altogether, our study reveals how the stomach adapts to a new anatomy imposed by a bariatric surgery, and identifies a new set of signals secreted from the endocrine cells of the stomach following surgery.

Background
Prader-Willi syndrome (PWS), a rare genetic neurobehavioral-metabolic condition, is characterized by hyperphagia, accumulation of excess fat, hypotonia, and behavioral/psychological complications. There are no currently approved medications to treat hyperphagia in patients with PWS; DCCR is under development as a treatment for PWS.
Objectives and Methods
The objective was to evaluate long-term safety of DCCR in individuals with PWS. 125 participants with genetically-confirmed PWS ≥ 4 years old with hyperphagia were treated with oral daily DCCR in multi-center studies conducted at 29 sites in the US and the UK: a 13-week, Phase 3, double-blind, placebo-controlled study (DESTINY PWS) and its long-term, open-label extension study (to 52 weeks and beyond). The target DCCR dose was ≥ 3.3 mg/kg (optimal dose 4.2 - 5.8 mg/kg). 103 patients received DCCR for 52 weeks and 54 patients received DCCR for at least 78 weeks.
Results
Overall, DCCR was well tolerated with the majority of adverse events (AEs), (77.6%) having grade 1 or 2 severity. Treatment-emergent adverse events (TEAEs) occurred in 98.4% of participants. Drug related TEAEs occurred in 80.0% of participants. Twenty participants experienced serious adverse events (SAEs), for which only two participants were considered drug-related (one patient with peripheral/pulmonary edema and another with fluid retention). There were no SAEs leading to death. The most common TEAEs were hypertrichosis (61.6%), peripheral edema (34.4%), and hyperglycemia (22.4%). TEAEs infrequently resulted in discontinuation of study drug (7.2% of participants). These results are consistent with the observed safety profile of DCCR from prior studies. Consistent with the expected AE of hyperglycemia, fasting glucose rose through Week 26 (mean change from baseline $\pm$ SD mmol/l $= 0.35 \pm 0.81$) and returned nearly to baseline by 15 months of treatment (0.11 ± 0.61). HbA1c followed a similar pattern, increasing at 26 weeks and returning nearly to baseline by 15 months. In participants experiencing hyperglycemia, the AE resolved with continued treatment in about half of cases. About 90% of peripheral edema cases resolved while treatment continued, requiring infrequent dose adjustment (7%) or the need for diuretic treatment (3%). Most cases of hypertrichosis ($>80\%$) were mild and only in one instance led to discontinuation. About 35% of cases of hypertrichosis were resolved/resolving at Week 52.
Conclusions
DCCR was ell tolerated beyond 52 weeks of administration. The most common treatment-emergent adverse events were expected based on prior studies of DCCR. These included hypertrichosis, peripheral edema and hyperglycemia, which were typically mild and resolved without treatment in most cases.

Menstrual cycle characteristics in women with type 1 diabetes mellitus

Maria Ilieva-Gerova[1], Presiyana Nyagolova[1], Daniela Koleva-Tiutiundjieva[1], Maria Orbetzova[1] & Ralitsa Raycheva[2]
[1]Medical University - Plovdiv, Clinic of Endocrinology and Metabolic Diseases "Sv. Georgy", University Hospital, Department of Endocrinology, Faculty of medicine, Plovdiv, Bulgaria; [2]Medical University - Plovdiv, Department of Social Medicine and Public Health, Faculty of Public Health, Plovdiv, Bulgaria

Background
Women with diabetes mellitus type 1 (DMt1) are known to have a higher prevalence of reproductive disorders, including delayed menarche, menstrual cycle abnormalities and polycystic ovary syndrome (PCOS)-like phenotype.
Objective
To evaluate the menstrual cycle characteristics of women with type 1 diabetes mellitus as well as to compare them with healthy women of reproductive age.
Methods and patients
The study included 37 women with DMt1 and 38 clinically healthy women serving as a control group. A detailed gynecological anamnesis was obtained: age at menarche, menstrual cycle interval (MC), menstruation lenght, dysmenorrhea, pregnancies, births, miscarriages. Oligomenorrhoea was defined as having a menstrual cycle longer than 35 days throughout at least the past year. Primary dysmenorrhea wad defined as painfull menstruation unrelated to a secondary pelvic disease. The metabolic control was evaluated by the glycated haemoglobin (HbA1C). Anthropometric measurements, basal levels of testosterone (T), thyroid-stimulating hormone (TSH) and serum prolactin were studied in all participants. Body mass index (BMI) was calculated.
Results
There was no statistically significant difference in terms of age ($P = 0.26$) and BMI ($P = 0.57$) in the studied population. Euthyroid function and normoprolactinaemia were reported in all participants. Women in the DMt1 group had statistically significantly higher T and HbA1C levels than healthy controls ($P = 0.000$). There was no significant difference in the age at menarche or menstruation lenght in women with DMt1 compared to the control group. The mean duration of MC in DMt1 group was (32.73 ± 5.9), comapred to the control group (30.29 ± 2.53), without reaching statistical significance ($P = 0.07$). 14 women (37.8%) with DMt1 reported oligomennorhea. A statistically significant difference between the relative proportion of diabetic women with dysmenorrhea (51.4%) compared to healthy controls with dysmenorrhea (23.7%) (z-test, $P < 0.05$) was observed. Women with DMt1 had a higher number of pregnancies ($P = 0.005$), births ($P = 0.03$) and miscarriages ($P = 0.03$) compared to healthy controls. A significant correlation was found between T and dysmenorrhea ($r = 0.508$, $P = 0.001$) and with oligomennorhea ($r = 0.664$, $P = 0.000$). There was also a positive significant relationship between dysmenorrhea and oligomennorhea ($r = 0.648$, $P = 0.000$).
Conclusion
Despite satisfactory metabolic control, women with DMt1 have higher frequency of menstrual cycle irregularities. Early and precise examination of menstrual cycle characteristics of women with DMt1 is essential for developing a better approcah towards the reproductive dissorders observed in diabetic women.
Key words
type 1 diabetes mellitus, oligomennorhea, dysmenorrhea, menstrual cycle, testosterone.

Imidazole-osmium reduces elution of lipids from cryofixed rat hepatic tissue for ultrastructural analysis

Sabine Dürr[1], Siegfried Reipert[2], Martin Kršsák[3], Cécile Philippe[4], Viktoria Ehret[3], Matthias Luft[5,6], Arno Schintlmeister[7], Thomas Scherer[3] & Clemens Fürnsinn[3]
[1]Medical University of Vienna, Wien, Austria; [2]University of Vienna, Core Facility Cell Imaging and Ultrastructural Research, Wien, Austria; [3]Medical University of Vienna, Department of Medicine III, Wien, Austria; [4]Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Wien, Austria; [5]Medical University of Vienna, Department of Plastic, Reconstructive and Aesthetic Surgery, Wien, Austria; [6]Karl Landsteiner University of Health Sciences, Department of Plastic, Aesthetic and Reconstructive Surgery, St. Poelten, Austria; [7]University of Vienna, Wien, Austria

Introduction
Transmission electron microscopy (TEM) is the main tool for studying the ultrastructural properties of metabolically diseased tissue. For impactful micrographs as well as for interpretation of TEM specimens, the integrity of cellular components is crucial. Elution of substances is a major problem in TEM preparation with no universal solution found so far. Investigating fatty liver disease in a rat model, an important factor is the depiction of undamaged lipid droplets. Imidazole, a highly polar heterocyclic compound, is hypothesized to enhance the binding ability of osmium tetroxide. This study aimed to investigate the effect of imidazole-osmium application before cryopreparation to prevent elution from lipid droplets.
Methods
Perfusion-fixed (4.5% phosphate buffered formaldehyde, pH 7) hepatic tissue from male Sprague-Dawley rats ($n = 6$; 8 weeks old) on high fat diet (60% of calories as fat; fed for 4 weeks) was processed for TEM. Prior to the procedure of high pressure freezing and freeze substitution, samples ($n = 3$) were pre-exposed to 1% OsO<ce:inf>4</ce:inf> in 0.1M imidazole for 30 min. For comparison, a control group was not subject to such pre-exposure ($n = 3$). Specimens were embedded in Agar 100 resin, and the ultrastructure was analyzed in ultrathin sections (70 nm, Leica EM UC7; ZEISS Libra 120 TEM).
Results
Screening a multitude of ultrathin sections from steatotic rat livers from three separate animals revealed expletive electron dense material within the membrane of lipid droplets in imidazole-osmium pre-treated tissue. At variance to this, the conventional approach without imidazole pre-treatment displayed translucent areas with minimal granular content.
Conclusion
The chemical bond between osmium tetroxide and imidazole obviously reduced the elution of contrastable lipid molecules from lipid droplets prior to preparation and high pressure freezing with freeze substitution. This procedure promises a major advantage in the ultrastructural study of fat accumulation in hepatic tissue. Further investigations including NanoSIMS (Nanoscale secondary ion Mass Spectrometry) will be conducted to confirm this hypothesis.

Homocysteine level in diabetic subjects with venous thrombosis

Sana Fendri[1], Boudaya Mariem[1], Ben Salah Raida[2], Jamoussi Kamel[1] & Bahloul Zouheir[2]
[1]Hedi Chaker Hospital, Laboratory of Biochemistry, Sfax, Tunisia; [2]Hedi Chaker Hospital, Internal Medicine, Sfax, Tunisia

Introduction
Homocysteine is an intermediate sulfur amino acid in the metabolic pathways of cysteine production from methionine, which is increasingly involved in various pathological processes (arterial thrombosis, depression, schizophrenia, dementia). We are interested in the course of our work to study the variation of homocysteine levels in diabetic subjects with venous thrombosis.
Materials and methods
This is an observational case-control study, comparing 47 healthy control subjects with 47 patients admitted to the internal medicine department for the management of deep vein thrombosis confirmed by radiological examination. These two groups were matched according to age, sex and body mass index. The homocysteine assay and fasting blood sugar were done by an enzymatic method. The assay of glycated hemoglobin was carried out by the reference method (high performance liquid chromatography)
Results
The mean age of patients and controls was 40.8 ± 10.5 years with ranges of 18 and 59 years. The two groups consisted of 27 men (57.5%) and 20 women (42.5%) with a sex ratio of 1.35. The diabetic subjects in our population were 14.8% in the patient group and 12.7% in the control group (without statically significant difference). Hyperhomocysteinemia was significantly correlated with the presence of diabetes with $P = 0.006$ with a mean level of 26.28 ± 10 µmol /l in diabetic subjects against a mean level of 12.3 ± 5.9 µmol /l in non-diabetic subjects.
Conclusion
Homocysteine is a sulfur amino acid involved in many cardiovascular pathological processes which should be systematically screened for in all diabetics.

Development of an electrochemical immunosensor based on competition assay for the detection of biomarkers in human urine samples

Sharmaine Reintar[1,2], Christoph Haudum[1,2], Josep Lluis Acero[3], Ciara ÓSullivan[3] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria; [2]Center for Biomarker

Research in Medicine (CBmed), Graz, Austria; [3]Universitat Rovira i Virgili, Departament d'Enginyeria Química, Tarragona, Spain

Introduction
Diabetes mellitus (DM) is a disease characterized by increased glucose levels, mostly either due to insulin deficiency (type 1 DM) or a decreasing ability of insulin receptor binding (type 2 DM) or both. Biomarker measurements such as fasting glucose and haemoglobin A1c are vital to detect and monitor DM. In addition to these parameters and antibody testing, insulin determination has been used for classifying different types of DM. However, the disadvantage of insulin measurement is a rapid degradation in the blood through hepatic metabolism. Moreover, interferences may arise from exogeneous insulin injection. In contrast, C-peptide is co-secreted along with insulin in equimolar quantity, consisting of 31 amino acids and a longer half-life of 30 minutes compared to 3-5 minutes with insulin. Therefore, it can be detected in urine samples, reflecting insulin metabolism by non-invasive samples, as this is also not subjected to exogeneous insulin interference.
Objective
We aim to validate urinary C-peptide as a reliable and sensitive biomarker for determination of the beta cell function using a point-of-care approach.
Method
The proof-of-concept for electrochemical detection of C-peptide is based on competition format. We utilize a self-assembled monolayer for covalent attachment of the coating C-peptide onto the screen-printed electrodes. Various concentrations of C-peptide were measured using an antibody against C-peptide, labelled with an enzyme to generate the signal, and a laptop/mobile phone used as the output reader.
Result
We are able to show that our proof-of-concept works for C-peptide determination. The developed sensor obtained a limit of detection of 3.5 μg/ml in spiked urine samples. In addition, the assay showed a high specificity to C-peptide with no known cross-reactivity to other related structures such as insulin.
Conclusion
Further evaluation of the assay is ongoing in our laboratory to further improve the sensitivity of the assay. Overall, our proof-of-concept for the determination of urinary C-peptide is a reliable and it can be miniaturized for easy-to-use portable assay which can be used to support diagnosis and monitoring of DM to prevent the progression of the disease and further complications.

Epidemiology, clinical and complications profile of diabetes mellitus patients hospitalized in libya: a retrospective audit

Sarah Abdulrazik[1], Ahmed Misherghi[2,3], Aida Alktounei[3] & Muhammed Elhadi[4]
[1]The Libyan Biotechnology Research Center, Genetic Engineering, Tripoli, Libya; [2]Faculty of Medicine, University of Tripoli, Medicine, Tripoli, Libya; [3]The National Diabetes and Endocrine Center, Statistics, Tripoli, Libya; [4]Faculty of Medicine, University of Tripoli, Medicine, Tripoli, Libya

Introduction
It was estimated that about one-sixth of the Libyan population have diabetes mellitus. However, there were no previous studies about the hospitalized patients and clinical presentation and outcomes. In this study.
Aim
We aimed to determine the clinical profile and complications of diabetic patients admitted to the largest diabetic center in Libya and evaluate the mortality and admission pattern.
Methods
Patients with diabetes mellitus were identified from the National Diabetes and Endocrine Center in Tripoli, Libya. A retrospective audit of diabetes mellitus cases was conducted from January 2018 to December 2019. Demographic, clinical, admission, complications, and outcome data were obtained.
Results
One thousand one hundred seventy-seven patients were included; 599 had type 1 diabetes, 575 had type 2 diabetes. The median interquartile range (IQR) of age for the patients was 40 (24 - 59) years. Of those patients, 665 (56.5%) were female and 512 (43.5%) were male. The most common causes of hospitalization were diabetic ketoacidosis (DKA) (58.6%), hyperglycemia (21.8%), uncontrolled sugar level (11%), hypoglycemia (3.4%), and several other causes. The median (IQR) of fasting blood sugar level was 231 (175 – 298) mg/dl. Approximately 18.3% have concomitant hypertension. Diabetes complications were as follows: hypertensive kidney disease (0.6%), history of cerebrovascular accident (0.8%), hypothyroidism (1.6%), and urinary tract infection (3%). All-cause mortality was 2.8%.
Conclusion
These results indicate substandard diabetic care for patients in Libya. It also outlines a high rate of diabetic ketoacidosis (DKA), a life-threatening condition for diabetic patients and requires intensive care that is lacking in Libya. Improvement in emergency care for diabetic patients in Libya is advocated to avoid future morbidity and mortality.

DOI: 10.1530/endoabs.81.EP365

Characterization of a cohort of patients with type 1 diabetes during their unstructured transition to adult care

Fernando Braca[1], Yeray Novoa[1] , Juan Carmelo Betancor Acosta[1], Paula Fernandez-Trujillo[2], Dacil Alvarado Martel[3], Josu Gonzalez Martin[4] & Ana Maria Wagner[3]
[1]Hospital Materno Infantil de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]University Hospital of Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain; [3]Instituto Universitario de Investigaciones Biomédicas y Sanitarias, Las Palmas de Gran Canaria, Spain; [4]Hospital Insular, Unidad de Investigación, Las Palmas de Gran Canaria, Spain

Background and aims
Transition of patients with type 1 diabetes (DM1) from pediatric to adult care is challenging and international guidelines recommend effective transition programs. The aim of this study is to describe our baseline situation, without a structured transition program, and to identify factors associated with worse glycemic outcome.
Materials and Methods
This is an observational, retrospective study of patients with DM1, aged 14 or more on 09/03/2020. We analyzed demographic variables and variables related with metabolic outcomes and complications. A descriptive statistical analysis was performed and comparisons were made pre- and post-transition (Studenťs t, Wilcoxoňs test), using R Core Team 2020, 3.6.3. Factors associated with changes in HbA1c and admissions were assessed (Spearmaňs R, Mann-Whitneýs test, chi-squared). A p-value < 0.05 was considered significant.
Results
We have currently included 67 patients (58.21% male), 64.2% of whom had adult-care follow-up. HbA1c was 7.7% +/- 1.1 before transition and 8.5% +/- 1.8 (P 0.007) thereafter, despite an increase in their daily insulin dose (0.84 +/- 0.3 UI/kg vs 0.92 +/- 0.3 UI/kg, P 0.008). During transition, 29.8% of patients had at least one admission to the hospital for acute complication, mainly diabetic ketoacidosis (DKA) or hyperglycemia. Patients who had a continuous glucose monitor (CGM) (24.6%) had a significant improvement in HbA1c during transition (-0.54% +/- 1.3) when compared to those without (+ 0.84% +/- 1.53%, P 0.045) and had no admissions for DKA (vs 26.1% without CGM (p 0.028)). Worse glycemic control was also associated with a lower height percentile (Spearmaňs R 0.38, p 0.0031), higher levels of triglycerides (Spearmaňs R 0.33, P 0.031), LDL-cholesterol (Spearmaňs R 0.62, $P < 0.001$) and total cholesterol (Spearmaňs R 0.59, $P < 0.001$). Admissions due to acute complications were associated with loss of follow-up (P 0.043, OR 4.29, IC 1.19 - 15.41) and a longer time between last pediatric visits and first adult appointment (191 +/- 266.18 vs 449.87 +/- 420.26 days, P 0.037).
Conclusion
Despite the small size of this cohort, we observed a worsening of glycemic and metabolic outcomes during the unstructured transition. We also observed an increased risk for acute complications in patients with loss of follow-up. The association between the use of CGM and improved glycemic control and lower risk of hospital admission has to be interpreted with care, given the retrospective nature of the study, but it could be related with the "booster" education received with the device.

Levels of IL-10 in CD4+ and CD8+ in patients with Type 2 diabetes mellitus and their correlation with mediterranean diet and anthropometric variables

Carolina Knott Torcal[1,2], Sara Jiménez Blanco[1] , Nuria Sánchez de la Blanca Carrero[1], Ana Serrano-Somavilla[1], Rebeca Martínez-Hernández[1], Jessica Jiménez Díaz[1], Alicia Justel Enriquez[1], Miguel Sampedro-Nuñez[1], Mónica Marazuela[1] & Alba Garcimartin[1,2]

[1]University Hospital La Princesa, Endocrinology and Nutrition Department, Madrid, Spain; [2]Complutense University of Madrid , Faculty Of Pharmacy, Madrid, Spain

Introduction
Type 2 Diabetes Mellitus (T2DM) is a multifactorial and complex chronic disease characterized by insulin resistance and a dysfunctional adipose tissue. T2DM patients usually present a state of low-grade inflammation due to a dysregulation of the cytokine production. Consequently, this seems to contribute to insulin resistance and beta cell failure associated with the progression of this disease.
Objective
To examine expression of Interleukine-10 (IL-10) in CD4+ and CD8+ lymphocytes in patients with T2DM compared to healthy individuals and its correlations with anthropometric parameters and Mediterranean diet.
Materials and methods
Blood samples were drawn from patients with T2DM ($n = 36$) and healthy controls ($n = 12$) from University Hospital La Princesa. Peripheral blood mononuclear cells (PBMCs) samples were obtained and incubated with monoclonal antibodies (anti-CD4, anti CD8, anti-IL10). Data were acquired in FACSCanto flow cytometer. Adherence to Mediterranean diet and electrical bioimpedance were performed. Continuous variables were examined with Spearman's rho analysis, whereas categorical variables were analysed using Student's *t*-test/Wilcoxon test o one-way ANOVA/Kruskal-Wallis. Statistical analysis was conducted with R version 4.0.3.
Results
From our cohort, 47.22% and 50% were women in patients and controls, respectively. Mean age was 34.58 ± 10.39 years in controls and 61.52 ± 8.66 years in patients. IL-10 levels were increased in patients compared to controls in both CD4+ and CD8+ populations. CD4+IL10+, normalized by absolute lymphocyte count, were three times higher ($P = 0.004$) in patients than in controls (0.499 ± 0.404 and 0.158 ± 0.187, respectively). Regarding CD8+, results showed even more differences, revealing almost four times higher levels of CD8+IL-10+ ($P = 0.002$) in T2DM than in healthy controls (1.304 ± 1.102 and 0.336 ± 0.436, respectively). Within the patient cohort, significant differences were also found regarding sex, specifically in CD4+IL-10+ ($P = 0.032$), with women showing almost double the expression compared to men (mean 0.602 vs 0.377). Interestingly, a significant inverse correlation was observed between adherence to a Mediterranean diet and both CD4+IL-10+ ($r = -0.447$, $P = 0.010$) and CD8+IL-10+ ($r = -0.536$, $P = 0.002$). Regarding body composition, a significant inverse correlation was shown between fat free mass and CD4+IL-10+ ($r = -0.434$, $P = 0.013$) and CD8+IL-10+ ($r = -0.347$, $P = 0.052$), as well as a significant direct correlation between fat mass and CD4+IL-10+ ($r = 0.434$, $P = 0.013$) and CD8+IL-10+ ($r = 0.347$, $P = 0.050$).
Conclusions
IL-10 expression was increased in CD4+ and CD8+ populations in T2DM, and significant correlations were found between Mediterranean diet and body composition.

Is MGP an inflammatory marker?

Natascha Schweighofer[1,2], Caterina Colantonio[3], Christoph W Haudum[1,2], Barbara Hutz[1], Ewald Kolesnik[3], Albrecht Schmidt[3], Andreas Zirlik[3], Thomas R Pieber[1,2], Nicolas Verheyen[3] & Barbara Obermayer-Pietsch[1]
[1]Department of Internal Medicine, Division of Endocrinology and Diabetology, Medical University of Graz, Graz, Austria; [2]CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria; [3]Department of Internal Medicine and University Heart Center Graz, Division of Cardiology, Medical University of Graz, Graz, Austria

Matrix-GLA-protein (MGP) was repeatedly associated with inflammation markers during the last decade. It is expressed in leucocytes and is a regulator of immune response. Due to posttranslational modification, there are 4 forms. The form responsible for immunomodulation is still unknown. Since the predicted active form - carboxylated, phosphorylated MGP - is not directly associated with immunomodulation, we aimed to investigate the association of dp-ucMGP (dephosphorylated, uncarboxylated) with systemic inflammation parameters and diseases with a known inflammatory component. We analysed data from the BioPersMed cohort ($n = 792$, 55.8% females, mean age 58 +/- 9 years), a prospective cohort of asymptomatic subjects at cardiovascular risk. Dp-ucMGP was measured with IDS-iSYS InaKtif MGP Kit (Immunodiagnostic Systems Holdings PLC, UK). The tertiles ranged from 0 to 410 (1st), 411 to 515 (2nd) and 516 pmol/l to highest value (3rd). C-reactive protein (CRP), cystatin C and ferritin were measured via immunotubidimetry at a Roche Cobas c system (Roche Diagnostics, Vienna, Austria). CRP: values >5 mg/ml, cystatin C: values >0.95 mg/ml and Ferritin: values >140 ng/ml (females) or >360 ng/ml (males) were defined as increased. Sarcopenia was defined by appendicular skeletal muscle mass index. Appendicular skeletal muscle mass was determined by Lunar iDXA (GE Healthcare GmbH, Austria). We defined diabetes mellitus (DM) according to ADA criteria. The presence of non-alcoholic fatty liver disease (NAFLD) was determined based on medical records. Dp-ucMGP correlates significantly with CRP and cystatin C (Rho: 0.204, 0.348, respectively; $P < 0.001$ both) but not with ferritin. CRP, cystatin C and ferritin increase significantly ($P < 0.001$, $P < 0.001$, $P = 0.028$, respectively) per dp-ucMGP tertile. Furthermore, persons with increased CRP, cystatin C or ferritin show significantly increased dp-ucMGP levels ($P = 0.002$, $P < 0.001$, $P = 0.048$, respectively). Dp-ucMGP levels are significantly higher in DM patients ($P < 0.001$) (as CRP, cystatin C, ferritin, all $P < 0.001$) and in persons with NAFLD ($P = 0.006$) (as CRP and ferritin, both $P < 0.001$) and lower in sarcopenic individuals ($P = 0.012$) as CRP ($P = 0.011$) and ferritin ($P = 0.049$). MGP might not only be an interesting biomarker for the development of diseases via regulation of calcium homeostasis but also for the modulation of immune responses. Out of the MGP subforms dp-ucMGP could be a good candidate and needs further investigation.

Development of THE allele-specific PCR method for studying insulin gene rs689 polymorphism

Talat Saatov[1], Zafar Ibragimov[1], Timur Alimov[2], Elvira Ibragimoya[1], Tokhir Ishankhodjaev[1], Zulaykho Shamansurova[1,3], Kha Karimov[2], Shakhnoza Azimova[4], Kodirjon Boboev[2] & Anton Makhnyov[4]
[1]Institute of Biophysics and Biochemistry under Mirzo Ulugbek National University of Uzbekistan, Tashkent, Uzbekistan; [2]Specialized Scientific-Practical Medical Center of Hematology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan; [3]Tashkent Pediatric Medical Institute, Uzbekistan Ministry of Education, Tashkent, Uzbekistan; [4]Academician S.U. Yunusov Institute of Chemistry of Plant Substances, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan

Background
Insulin gene (INS) is known to be responsible for production of insulin by the pancreatic β-cells. It includes variable number of tandem repeats (VNTR) of oligonucleotide consequence (ACAGGGGT (G/C) (T/C) GGGG) in the promoter region (Bell et al, 1981,1982); being the gene involved in the susceptibility to various pathologies. The allele-specific PCR allows direct diagnosis of some genetically determined disorders is rather simple and precise. However, by today, there have been no data on the use of the allele-specific PCR for the INS gene rs689 polymorphism.
Aim
The work was initiated to develop a protocol for simple, quick and precise PCR method to determine INS gene rs689 polymorphism.
Materials and methods
To study INS gene rs689 polymorphism, we used a modified method of allele-specific PCR. Original design of primers was performed by means of bioinformation analysis of NCBL database, Genome Browser with BioEdit app. The genotyping was performed using Applied Systems-2720 programmed thermocycler.
Results
To pick up the INS gene nucleotide sequence from the NCBL database is the first step of the procedure. Oligoprimers was synthetized at the Academician S.U. Yunusov Institute of Chemistry of Plant Substances, Uzbekistan Academy of Sciences. The INS gene polymorphic region (rs689) was amplified by means of allele-specific PRC. The primers synthetized as the result of the step were the basis for development of novel test-system intended for determination of INS gene rs689 polymorphism by allele-specific PCR. The efficacy of the method was assessed in the studies in the frames of research grant for patients with diabetes mellitus.
Conclusion
The modified protocol based on the allele-specific PCR intended for study on the INS gene rs689 polymorphism was developed. The protocol can be used in study on various pathologies in diabetes mellitus, insulin resistance, polycystic ovarian syndrome, adenocarcinoma esophagogastric junction, neurodegenerative disorders, etc.

Compliance and quality of life in people with type 2 diabetes

Elona Shehu[1], Anastasia Ntikoudi[1], Eleni Dokoutsidou[1], Georgia Fasoi[1], Polyxeni Mangoulia[2], Eleni Evangelou[1], Athanasios Tsartsalis[3], Andromachi Vryonidou- Bompota[4], John Komninos[3] & Eugenia Vlachou[1]

[1]University of West Attica, Nursing, Athens, Greece; [2]Evangelismos General Hospital, Athens, Greece; [3]Athens Naval Hospital, Endocrinology Department, Athens, Greece; [4]Korgialenio- Benakio General Hospital, Endocrinology Department, Athens, Greece

Introduction
Type 2 diabetes mellitus (DM2) is the most common disease in the spectrum of metabolic disorders, with its prevalence increasing significantly in recent years. It is estimated that by 2035, 592 million people will have type 2 diabetes. People with type DM2 have high rates of depression and a quality of life that is poorer than that of the general population. Another important factor in the quality of life of people with DM2 is the compliance of patients with the treatment which affects the outcome in the management of diabetes.
Purpose
The purpose of this study was to investigate the quality of life in people with DM2, the compliance with medication and other guidelines of health care professionals, and finally correlate these variables.
Material and Method
This cross-sectional study included two questionnaires, regarding the compliance and quality of life in a Greek population with DM2. The procedure was performed in two phases by distributing the questionnaires twice, three to five months apart. The convenience sample consisted of 73 adult patients with DM2.
Results
The results of the present study showed greater impact in the quality of life regarding sex life, freedom to eat and freedom to drink while less impact was observed on dependence from others. In terms of compliance with the medical instructions and medication, it was found to be statistically increased after a 15-minute nursing intervention. Regarding the glycosylated hemoglobin levels, the mean value was lower in the second measurement in a statistically significant degree after the intervention. Age, gender, lower level of education and low financial status did not seem to be associated with low quality of life scores in the present research study.
Conclusions
Health care professionals should consider not only the clinical parameters but also the lifestyle of each person with DM2 considering the physical, spiritual, cultural, social background and gender differences. Individualized care plans should be developed with a focus on patients, aiming on diet, exercise, and individual counseling to achieve optimal quality of life and compliance with the treatment.

Virulence of SARS-COV-2 in diabetic patients

Oumeyma Trimeche, Imen Zemni , Amine Hadj Mabrouk, Gara Amel, Jdira Salem, Wassim Frigui, Iyed Barbana, Anas Bouazizi, Rahma Mansour, Yosra Bouzid, Cyrine Bennasrallah, Maryem Kacem, Hela Abroug , Manel Ben Fredj, Ines Bouanene & Asma Belguith
Fattouma Bourguiba Hospital, Monastir, Tunisia

Introduction
Diabetes is a serious disease that can lead to a depression of the immune system and thereby it is incriminated in serious complications of many infectious diseases among which is Covid 19. The aim of our study is to determine the virulence of SARS-COV-2 in diabetic patients.
Methods
This is a transversal study conducted in the department of epidemiology at Fattouma Bourguiba Hospital in Monastir, in October 2020. The data was collected from calling the positive patients by phone 30 days after the initial infection.
Results
We collected the data of 1118 patients who had covid 19 in October 2020. The predominant variant in that period was the alpha variant. Forty-nine of our population were diabetic. Therefore, the prevalence of diabetes was 4,1%. Their sex ratio was 0,75. Most of our diabetic patients were aged above 65 years (13,9%). While 0,5% and 4,5% were aged between 19 to 39 years and 40 to 64 years, respectively. Diabetes was significantly associated with an increase in the rates of hospitalization in covid 19 patients ($P < 0,01$). In fact, the rates of hospitalization in this population corresponded to 22,9% versus 5,2% in non-diabetic patients. Moreover, diabetes increased the risk of oxygen therapy ($P < 0,01$). Of our 49 patients 12 (24,5%) needed oxygen therapy. As for non-diabetic patients, 68 out of 1134 (6%) needed oxygen. Two out of 48 diabetic patients died (4, 2%). However, out of 1018 non diabetic patients, only 6 were dead (0,6%). Thus, it seemed that diabetes increased the death rate ($P = 0,047$). Twenty out of 45 diabetic patients had post covid syndrome which corresponds to a prevalence of 45,5%. As for non-diabetic patients 572 out of 1124 reported symptoms related to post covid syndrome (50,9%). The association between diabetes and post covid syndrome was not significant ($P = 0,479$). The most reported Covid-19 symptoms among our diabetic patients were dyspnea (14,3%), cough (8,1%), fatigue (8%) and headaches (6%).
Conclusion
Our study demonstrates the significant impact of diabetes in hospitalization, the need for oxygen therapy and death in covid 19 patients while it dismisses the association between diabetes and post Covid-19 syndrome.

Follow-up gestational diabetes in a telemedicine system in pandemic COVID19

Esther Delgado Garcia , Paloma Perez Lopez , Marta Sanchez Ibañez, Maria Nieto , Lourdes De Marcos White , Amelia Santader Cartagena & Daniel de Luis Roman
Hospital Clinico Universitario de Valladolid, Endocrine, Valladolid, Spain

Background
Gestational diabetes mellitus (GDM) is common complication in pregnancy. During pandemic COVID-19, endocrine service iniciate telemedicine in medical care and monitoring blood glucose.
Purpose
The purpose of this study was to asses metabolic control and pregnancy outcome during pregnancy in telematic consult.
Materials and Methods
Descriptive study of 20 patients were assesed in telematic review in the first wave of the COVID-19. GDM was defined according to NDDG 1979. Glucose targets were defined by a capillary fasting glucose target <95 mg/dl and a 2-hour postprandial capillary glucose <120 mg/dl. Good control was defined as: $< 5\%$ of the glycemic values were not within the target range,
Results
20 patients (age 36,6 $\pm$ 3.0 years; HbA1c levels 5.3% $\pm$0.2).19 patient had a risk factors for predisposition to GDM include obesity (85%), history of gestational diabetes (50%) and family history of type 2 diabetes mellitus (45%). The week of the first consultation was on average at week 34 +/- 9.5. The median goal achievement was at week 37 [37-37,5] 19 had a good control and the mean dose of insulin for glycemic control was 13.05+-16.02 units. Non differences were found with respect to prolonged labor and preeclampsia with our prepandemic registration.
Conclusion
The first wave of the COVID-19 pandemic did not seem to have a negative impact on pregnancy outcomes in GDM women, despite patients with gestational diabetes were later referred to our clinics.

The benefits of breastfeeding on weight loss and glycemic control

Amal Elkhomri, Bensbaa Salma , Nassim Essabah Haraj , Siham El Aziz & Asma Chadli
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Breastfeeding has benefits for infant health, but also for maternal health, lactation has a positive impact on glucose homeostasis and weight loss. This can be explained by the needs of milk production. The mammary gland needs glucose to make lactose. The objective of this study is to evaluate the impact of breastfeeding on glycemic control and weight loss
Materials and Methods
Prospective study conducted in the department of endocrinology and diabetology including 90 patients followed for diabetic pregnancy. The analysis was carried out by SPSS version 25 software.
Results
The results had objectified a mean age of 35 years, predominantly type 2 diabetes (89%), a mean weight at conception was 80kg, Only 13% of the patients had planned their pregnancy, 57% of the patients were on insulin, 83% of the patients were breastfeeding, 36% of them were exclusively breastfeeding, the predominant duration of breastfeeding was more than 12 months (37%), postpartum weight loss was observed in 74.4%, glycemic control was observed in 60% and significantly associated with exclusive breastfeeding ($P = 0.000$), as

well as with the duration of breastfeeding of more than 12 months ($P = 0.000$), the latter was correlated with postpartum weight loss ($P = 0.02$)
Conclusion
Our results underline the positive impact of breastfeeding on weight loss and glycemic control, hence the need to systematically insist on breastfeeding in women with diabetes.

EP374

Modulation of antimony mediated therapy for an optimal insulin secretion during visceral leishmaniasis

Sukrat Sinha
Nehru Gram Bharati University, Department of Zoology, Prayagraj, India

Objective
Visceral Leishmaniasis is a macrophage associated disorder for the treatment of which antimony based drug like Sodium Antimony Gluconate has been the first choice in the recent past. About 5 percent of the patients may develop insulin dependent diabetes mellitus. It appears to have a direct action on pancreatic beta cells, resulting in initial insulin release followed by impaired insulin secretion. Within this context we looked into alternate therapies of treatment along with SAG on triggering the CD2 epitope.
Methods
We have evaluated the effect of combining CD2 with conventional antimonial (sb) therapy in protection in BALB/c mice infected with either drug sensitive or resistant strain of Leishmania donovani with 3 million parasites via-intra-cardiac route. Mice were treated with anti CD2 adjunct SAG sub-cutaneously twice a week for 4 weeks. Assessment for measurement of weight, spleen size, anti-Leishmania antibody titer, T cell and anti-leishmanial macrophage function was carried out day 0, 10, 22 and 34 post treatments. Insulin levels were also determined on the same intervals.
Results
The combination therapy was shown boosting significant proportion of T cells to express CD25 compared to SAG monotherapy. Although, the level of IFN-γ was not statistically different between combination vs monotherapy ($P = 0.298$) but CD2 treatment even alone significantly influenced IFN- γ production than either SAG treatment ($P = 0.045$) or with CD2 adjunct SAG treatment ($P = 0.005$) in Ld-S strain as well as in Ld-R strain. The influence of CD2 adjunct treatment was also documented in anti-leishmanial functions in macrophages. Interestingly insulin levels were observed to be optimal on supplementing SAG along with CD2.
Conclusion
SAG along with CD2 could be used as a potential therapy to overcome incidences of Diabetes mellitus during Visceral Leishmaniasis.

DOI: 10.1530/endoabs.81.EP374

EP375

Phenotypical variability in hepatocyte nuclear transcription factor 1 beta (HNF1β) gene mutation – A five case report

Guilherme V de Assunção[1], Liliana Fonseca[2], Catarina Mendes[3], Sofia Teixeira[2], Maria João Oliveira[3], Jorge Dores[2], Teresa Borges[3] & Helena Cardoso[2]
[1]Centro Hospitalar e Universitário do Porto, Porto, Portugal; [2]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [3]Centro Hospitalar e Universitário do Porto, Pediatric Endocrinology Unit, Porto, Portugal

Introduction
MODY 5 is a rare form of autosomal dominant monogenic diabetes with a broad phenotypical spectrum that occurs with pancreatic and extra-pancreatic clinical manifestations, such as: malformation and dysfunction of the pancreas, nephrourologic anomalies, impaired renal function, hepatopathy and neurocognitive defects. It is caused by a mutation of the gene encoding hepatocyte nuclear transcription factor 1 beta (*HNF1β*).
Case 1
Male, 8 years-old with a history of developmental delay, facial dysmorphia, macrocephaly and pielic dilatation. At the age of three a genetic test revealed 17q12 microdeletion associated with *HNF1β* mutation. Blood analysis revealed a HbA1c: 5,4% and C-peptide (C.pep): 1.09ng/ml (RR: 1.1-4.4). To date, at the age of eight, he remains euglycemic, with a HbA1c 5,5% and a C.pep 0,94 ng/ml, without any treatment.
Case 2
Male, 15 years-old, diagnosed with renal cysts and motor skills disorder. At age of 14 a genetic test revealed 17q12 deletion. To this date the patient remains euglycemic, with a HbA1c: 5,2%, without any treatment.
Case 3
Female, died at 49 years of age with sepsis, with a history of developmental delay, diabetes diagnosed at 16 years of age, kidney chronic disease and hepatopathy of unknown etiology. Started hemodialysis at the age of 43, renal transplant at 46 years-old. Genetic test revealed a 17q12 deletion associated with *HNF1β* mutation. She was on insulin therapy.
Case 4
Male, 16 years-old, diagnosed with CKD G2A2 KDIGO, multiple bilateral renal cysts and pielic dilatation. At age of six, a diagnosis of diabetes was made (insulin deficiency symptoms and no acute complications) and started insulin. Abdominal CT scan revealed pancreatic agenesis. C.pep <0.02 ng/ml. Genetic test revealed: *HNF1β* - c.301G>T(p.E101*). Currently the patient is on functional insulin therapy. HbA1c: 7.2%.
Case 5
Male, 23 years-old with progressive renal dysfunction due to bilateral renal cysts, underwent kidney transplant at the age of 19. After a few weeks diabetes was diagnosed (HbA1c 8% and C.pep. 3.89 ng/ml) and started on insulin. Genetic test revealed: *HNF1β* – variant c.443C>T (p.S148L). Last visit: HbA1c 8,3%, C.pep. 4.06 ng/ml, Cr: 2.5 mg/dl and GFR: 36 ml/min/1.73 m^2.
Conclusion
HNF1β gene mutation phenotype is variable and there are no pathognomonic manifestations, nevertheless, it should be suspected in patients with unusual diabetes and multisystem involvement unrelated to diabetes, especially, renal disease. Diabetes in these mutations can develop at any age. Neurodevelopmental disorders, diabetes, nephrourologic anomalies and hepatic abnormalities may raise suspicion of a 17q12 deletion syndrome.

The growth effects of long-term (five years) prednisone therapy in frequently relapsing nephrotic syndrome of childhood: impact on statural growth and weight gain

Ashraf Soliman[1], Noor Hamed[1], Mostafa Elbaba[1], Fawzia Alyafei[1], Maya Itani[2], Fatima Al-Naimi[2], Doaa Al Yousef[2] & Mona Shaat Dalees[2]
[1]Hamad Medical Center, Pediatrics, Doha, Qatar; [2]Hamad Medical Center, Nutrition and Dietitic Department, Doha, Qatar

Nephrotic syndrome (NS) in children usually has an onset between 2-8 years of age and steroids form the mainstay of management. Therapy may affect growth in children with relapsing NS.

Table 1 Longitudinal growth data of NS patients on LTPT

	Age years	WT kg	WTSD	HT cm	HTSD	BMI kg/m^2	BMISD
Mean	3.99	17.66	0.19	102.17	-0.38	16.67	0.65
SD	2.19	6.40	0.77	16.35	1.09	1.34	0.90
Mean	6.72	26.97	0.70	118.98	-0.35	18.29	0.97
SD	2.50	11.77	1.37	15.16	1.02	4.22	1.51
Mean	8.93	34.88	0.42	126.91	-0.79	19.98	1.10
SD	3.85	21.30	1.28	21.44	1.21	5.68	1.28

Table 2 Percent abnormalities after 3 and 5 years of LTPT

	Beginning	After 3 yr.	After 5 yr.
BMISDS > 2	2/32	7/32	8/32
% Obesity (OB)	6.25%	21.88%	25.00%
BMISDS >1<2 (OW)	6/32	7/32	10/32
% OB	18.75%	21.88%	31.25%
Total OB and OW	8/32	14/32	18/32
	25.00%	43.75%	56.25%

Aim
This study was carried out to investigate linear growth and weigh gain in children with NS and multiple relapses who receiving long-term prednisone therapy (LTPT) for 5 years.
Methods
Data of 30 children with SSNS was analysed retrospectively. They received prednisolone only in the standard dose for the initial episode at 2 mg/kg/day for six weeks followed by 1.5 mg/kg on alternate days for six weeks and relapses were treated with 2 mg/kg/day till remission followed by 1.5 mg/kg/day for four weeks. (height, HtSDS, weight, BMI and BMISDS) were recorded each clinic visit along the treatment period. Growth data were correlated with the cumulative dose of steroid.
Results
The mean cumulative prednisone = 125+/- 28 mg /kg/yr given over an average duration of 5 years. The HtSDS was not affected after 3 years (from -0.38 to -0.35 respectively) but decreased to -0.79 after 5 years (-0.4 SD loss). The BMISDS increased from 0.65 to 0.97 and 1.1 after 3 and 5 years respectively. Obesity (OB) and overweight (OW) increased from 25% pre-treatment to 59.2% after 5 years of treatment. Hypertension was detected in 12.5% and 23% of patients after 3 and 5 years of treatment.
Conclusion
Long term prednisone therapy (for 5 years) with a mean cumulative dose of prednisone = 125 +/- 28 mg/kg/yr. was associated with a small decrease in the HtSDS but significant increase in the BMISDS, OW, obesity and hypertension.

Degenerative complications after insulin therapy: are there benefits to prescribing analogue insulin compared to human insulin?

Rim Rachdi, Olfa Lajili, Hajer Moalla, Nessrine Souissi, Kamilia Ounaissa, Haifa Abdesselem & Chiraz Amrouche
The National Institute of Nutrition in Tunis, Diabetology Outpatient Department, Tunis, Tunisia

Introduction
Over the past two decades, the development of genetic engineering techniques has led to the emergence of insulin analogue that have the advantage of improving diabetics quality of life compared to human insulin. The aim of our study was to compare the frequency of occurrence of degenerative complications in two groups of patients with type 2 diabetes (T2D) on human insulin (NPH) and analogue insulin, and thus determine whether or not there are benefits to prescribing analogue insulin.
Materials and methods
Prospective comparative study involving 88 T2D patients, carried within the National Institute of Nutrition in Tunis and hospitalized for insulin therapy. Patients were divided into two groups: (G1) including 44 patients on human insulin and (G2) including 44 patients on analogue insulin. The presence or absence of degenerative complications was noted in both groups 18 months after insulin.
Results
Median age was 55,6 years in G1 versus 52,8 years in G2 (P = NS). Median diabetes duration was 7,1 years in G1 compared to 8,92 years in G2 (P = NS). Peripheral neuropathy was the most common complication in both groups (59,1% in G1 versus 68,2% in G2; P = NS). Diabetic retinopathy was present in 36,6% in G1 versus 40,4% in G2 (P = NS). Diabetic nephropathy was more present in G1 than in G2 (28,9% versus 20%; P = NS). Impaired renal function was more present in G1 than in G2 (41% versus 39%; P = NS). Coronary heart failure was the most common macrovascular complication in both groups (29,6% in G1 and 25,3% in G2). There was no statistically significant difference (P = NS) between the two groups for each of the macrovascular complications.
Conclusion
The two groups were comparable for the frequency of occurrence of different micro and macro vascular complications. In addition, patients on insulin analogue were less likely to develop diabetic nephropathy, renal failure and coronary heart failure.

Diabetes in the elderly: adherence and particularities of treatment

Ramla Mizouri, Faten Mahjoub , Rym Ben Othman , Nadia Ben Amor, Berriche Olfa & Jamoussi Henda
Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia

Introduction
Elderly diabetics are often fragile patients at high cardiovascular risk. The medical, human and socio-economic impact of diabetes is heavy in the elderly. Symptoms in this particular population are often insidious and atypical, which can delay diagnosis and the establishment of effective treatment. Indeed, management is not always easy because it must take into account multiple parameters. The objective of our study was to study the observance and particularities of treatment in elderly diabetics.
Methods
We conducted a retrospective observational study at the National Institute of Nutrition and Food Technology in Tunis, over a period from January 2018 to September 2021. Data were collected from patients' medical observation records. We prepared an information sheet which was used for the statistical analysis of the data.
Results
We collected 35 elderly diabetic patients. The age of the patients varied from 70 to 89 years with an average age of 76.2 ± 4.5 years. Our population was characterized by a female predominance (66%). The average duration of diabetes in our population was 5.89 ± 3.91 years with extremes ranging from 1 to 14 years. The average age of discovery was 70.29 ± 4.44 years with extremes ranging from 65 to 79 years. All of our patients were type 2 diabetics. Glycated hemoglobin varied between 6.5% and 13.9% with an average of 8.9 ± 1.9%. More than half of the population had an HbA1c greater than 8.5%. About half of the study population were on oral antidiabetics alone. Insulin therapy was prescribed in 54% of the population, of which only two patients were on insulin analogues. For patients on insulin therapy, the most prescribed therapeutic regimen in our population was the basal regimen (56%) with an average daily dose of basal insulin in the order of 0.47 ± 0.25 U/Kg/d. Therapeutic non-compliance was mentioned in 54% of patients. The main reasons for stopping treatment were the unavailability of drugs at local dispensaries (26%) and adverse effects (21%) dominated by digestive disorders due to metformin.
Conclusions
Diabetes in the elderly remains an area to be discovered. Few studies have been carried out to date. The field therefore remains open to many studies, especially in terms of therapy.

DOI: 10.1530/endoabs.81.EP378

Effect of iSGLT-2 on renal function and lipid spectrum in patients with type 2 diabetes mellitus

Sitora Muminova
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Diabetes mellitus (DM) is a global medical and social problem of our time, which is faced by medical science and healthcare in almost all countries of the world. The situation in Uzbekistan follows the global trend. According to 2019 data, 230 610 patients with diabetes are registered in the country: 18 349 patients with type 1 diabetes and 212 261 - with type 2 diabetes. According to screening studies, the prevalence of type 2 diabetes in Uzbekistan over the past 14 years has increased 1.6 times and, according to the latest data (2015).
Aim
To study the functional state of the kidneys and lipid metabolism while using iSGLT-2 in patients with type 2 diabetes mellitus with diabetic nephropathy.
Materials and Methods
We studied 40 patients with T2DM with DN (CKD C2, A2). The average age was 52.7 ± 3.78 years; diabetes experience - 8 years; BMI-30 ± 0.17; Hb1C-9.2 ± 0.4%; fasting glycemia –10.2 mmol/; eGFR-78 ml/min; TG-2.7 ± 0.44; total cholesterol-3.4 ± 0.72; MAU 32 ± 0.125.
Results
6 months after the start of ingestion of iSGLT-2, the patients showed an improvement in renal function and lipid metabolism. According to laboratory data, there is a significant ($P < 0.001$) decrease in creatinine levels by 7.4 μmol/l (93.8 ± 0.05) and an increase in eGFR by 5.3 ml/min /1.73 m^2. Despite the fact that the doses of statins did not change, we observed a significant ($P < 0,05$) decrease in total cholesterol levels by 1.04 mmol/l and triglycerides by 1.17 mmol/l.
Conclusion
In our study, we observed a significant decrease in the level of atherogenic fractions of the lipid spectrum. Also, the dynamics of creatinine and eGFR levels confirms the safety of the drug and some nephroprotective effect, which manifests itself with a sufficiently short observation period.

Patient experience and outcome of teleconsultation in management of T2DM during COVID-19 Pandemic in Semi urban and village population in Kerala

Jayakrishnan B
Senior Consultant Diabetology, SafeCare Clinics, Tirur, Kerala, India

Background
Coronavirus pandemic had pushed both doctors and patients to adapt to teleconsultation for routine consultations in management of type 2 diabetes (T2DM). Telemedicine is believed to be an effective resource in health access but its experience to the patient and its outcome of management are not well understood in semi urban and village population of India. Thus, this study aims to assess the experiences and outcomes of T2DM management by tele-consultation in these population.
Methods
This Cross-sectional observational study was conducted involving 250 patients with type 2 diabetes who availed teleconsultation services in two diabetes care centers in Tirur, Kerala between March 2021 to August 2021. Patient experience was obtained through an online survey questionnaire and the glycemic outcomes are gathered from base line and end of 3 months.
Results
About 135 (54%) of the patients were male, while 115 (46%) were female. Majority of the teleconsultation occurred in the 45–65-year age group. The mean duration of diabetes was 9.1 $\pm$ 4.2. Majority of T2DM patients were on $\geq$ 2 OADs (61.2%). Around 32.8% patients were using Insulins along with oral therapy. Patient experience survey response was received from 210 patients. 190 (90.47%) of patients were happy with the quality of conversations with their physician in terms of advice and instructions. Further 175 (83.33%) were satisfied with the duration of consultation. Around 195 (92.85%) would be happy to use teleconsultation again, while 200 (95.23%) would recommend teleconsultation to their friends and family. The reduction of HbA1c was 0.7% [TCV1-9.2 $\pm$ 13 vs TCV2 -8.5 $\pm$ 2.2]. There was minimal change in BMI 0.73 kg/M2 [TCV1 -29.87 $\pm$ 4.2 vs TCV2 29.14 $\pm$ 2.5] was observed. The self-reported hypoglycemia events were less 15 (6%) patients, no documented severe hypoglycemia.
Conclusions
The patient experience and outcomes result of the study indicate that telemedicine may confer better diabetes management during and beyond COVID-19 pandemic in sub-urban and village population in Kerala

DOI: 10.1530/endoabs.81.EP380

Mistakes revealed during continuous glucose monitoring in patients with poorly controlled Type 1 diabetes

Volha Shyshko[1,2], Tatjana V Mokhort[2], Parsa Paryavi[2], Vahid Rasekhjahromi[2] & Alena Yurenia[1]
[1]Minsk City Clinical Endocrinology Center, Endocrinology, Minsk, Belarus; [2]Belarusian State Medical University, Endocrinology, Minsk, Belarus

Introduction
There is no doubt that continuous monitoring systems can improve diabetes control. The aim of the study was to determine typical deviations of glucose and mistakes in insulin treatment, self-control, predisposing to the poor blood control.
Materials and methods
30 patients with type 1 diabetes were included, mean age 21$\pm$7.8, mean age of diabetes manifestation 19.2$\pm$13.9 years, mean duration oa diabetes – 15.3$\pm$7.5. Including criteria: type 1 diabetes, basal-bolus regimen of insulin injection, HbA1c above individual target level for more than 1 year. Excluding criteria: acute diseases, failure of chronic diseases. We conducted constant glucose monitoring (CGM) using blinded system (patients didn't see results during monitoring). CGM lasted 7 days in all patients and 1988 readings were measured by the device. According to the protocol patients should have recorded in provided for them diary carbohydrates (CH) amount, doses of insulin and measure glucose levels with glucometer at least 4 times a day.
Results
We revealed statistically significant difference between HbA1c (8.9$\pm$2.1%) measured in laboratory during CGM and calculated HbA1c (7.0$\pm$1.2%) measured during monitoring (according to the results of standardized protocol) ($P < 0.05$). As far as patients were instructed to record CH, insulin doses and blood glucose levels measured at least 4 times a day it's possible to assume that one or all parts of this daily routine are lost in patients with diabetes who didn't achieve target HbA1c. Increased blood glucose levels during night (47.0$\pm$29.0%) were associated with higher HbA1c during CGM ($r = 0.5$, $P < 0.05$). The higher dose of basal insulin (21.3$\pm$9.1U) was associated with higher HbA1c measured in laboratory ($r = 0.5$, $P < 0.05$) and increased glucose during night ($r = 0.5$, $P < 0.05$).
Conclusion
1. Calculated HbA1c and laboratory HbA1c differ for approximately 2% in patients with poorly controlled diabetes. 2. Nocturnal hyperglycemia is associated with higher HbA1c level and higher doses of basal insulin.

Medication Adherence in Patients with Type 2 Diabetes

Ajili Rihab, Salah Amani, Lassoued Najoua, Boubaker Fadia, Zantour Baha, Alaya Wafa & Sfar Habib
University Hospital Tahar Sfar, Endocrinology, Mahdia, Tunisia

Introduction
Medication Adherence (MA) is the extent to which patients follow medical instructions. Poor MA is frequently encountered in the majority of chronic diseases, including diabetes. The aim of our study was to evaluate MA in patients with poorly controlled type 2 diabetes mellitus (T2DM).
Patients and methods
We conducted a cross-sectional study over a period of 2 months, including patients with poorly controlled T2DM, followed at the endocrinology department of university hospital Taher Sfar Mahdia. MA was assessed using the Morisky compliance questionnaire.
Results
A total of 59 patients were included with a mean age of 64.1$\pm$9.6 years (56.8% were females). The mean duration of diabetes was 15.7$\pm$7.6 years. Diabetes was complicated in 81.4% of cases. The average hemoglobin A1c was 10.63%. Polymedication was observed in 76.5% of patients with an average of 9.6 medications per day. Therapeutic education was performed in only 38.6% of patients. According to the Morisky score, 26.4% of patients had a good MA, 41.7% had medium MA and 31.9% had low MA. Forgetting is the first cause of this bad MA. Patients on insulin had a better MA compared to those on oral antidiabetic medications ($P = 0.001$).
Discussion and conclusion
MA is a challenge in the management of diabetes to achieve therapeutic goals and to prevent long-term degenerative complications. Hence the interest of therapeutic education, a process that must be continuous in the course of care in order to optimize this MA.

Does the insulin pump improve glycaemic control in patients with type 1 diabetes?

Messaoudi Najoua[1], Imane Assarrar[1], Nisrine Bouichrat[1], Tahri Abir[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Mohammed VI University Hospital Center, Faculty of Medicine and Pharmacy, University of Mohammed 1st, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco; [2]Faculty of Medicine and Pharmacy of Oujda, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition,Laboratory of Epidemiology, Clinical Research and Public Health, Oujda, Morocco

Introduction
Insulin pump therapy is recommended more and more in type 1 diabetic patients in order to achieve and maintain optimal glycaemic control. The objective of our study was to determine the effectiveness of insulin pump therapy in improving metabolic control in type 1 diabetic patients.
Patients-Methods
This is a retrospective, descriptive and analytical study including 20 patients with type 1 diabetes treated by insulin pump, between 2017 and 2021. All patients received a clinical evaluation, analysis of the glycaemic cycle and a dosage of HbA1c at the time of the start of insulin pump and during the evolution. Statistical analysis was performed by SPSS version-21.
Results
The mean age of the patients was 16,8 $\pm$ 8,1 years with a sex ratio (M/F) of 0,42. Thirty per-cent were children. The mean duration of diabetes was 5,8 $\pm$ 4,8 years. Seventy-five per-cent of patients practiced functional insulin therapy. The indications for insulin pump treatment were mainly hypoglycaemia and instable diabetes. During follow-up, we found a statistically significant decrease in insulin requirements, improvement in mean HbA1c and maintenance of control during

follow-up, with a marked reduction in the number of hypoglycaemia events per week.
Conclusion
Insulin pump therapy appears to be reliable and effective when used appropriately, combined with appropriate therapeutic education and glycaemic monitoring to maintain long-term glycaemic control.
Key words: Type 1 diabetes – insulin-pump – glycaemic-control

Regulation of glycemia in patients with type 2 diabetes with oral antidiabetics, insulin and combination therapy

Tatjana Bačun[1,2], Ana Damjanović[1], Ivan Lekić[1], Dunja Šojat[3] & Marko Pirić[3]
[1]Faculty of Medicine Osijek, Osijek, Croatia; [2]Clinical Medical Center Osijek, Division of Endocrinology, Department of Internal Medicine, Osijek, Croatia; [3]Osijek Health Center, Osijek, Croatia

Aim of the study
The objectives of this study were to determine the regulation of glycemia (measured by fasting glucose levels and HbA1c) in patients with type 2 diabetes and to examine whether there is a difference in therapy (oral antidiabetics, insulin, combination), age, sex and BMI.
Study design
Cross-sectional research with historical data.
Patients
The study included 102 patients of both sexes (56% women and 44% men) with a diagnosis of type 2 diabetes who were examined in the Health Center Osijek, Croatia.
Materials and Methods
The following data were collected in family medicine clinics: age, sex, body weight and height, as well as data from laboratory findings (fasting glucose levels, HbA1c, AST, ALT, urea, creatinine, total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides).
Results
HbA1c and median glucose levels were lowest in subjects on oral antidiabetic therapy (6.9% and 7.9 mmol/l), in subjects on insulin (7,4% and 8,2 mmol/l), while in subjects on combination therapy, the values were highest (9% and 9.8 mmol/l); the difference in HbA1c was also statistically significant (Kruskal-Wallis test, $P = 0.02$). An association between HbA1c and glucose values with age, sex, and body mass index has not been established.
Conclusion
A statistically significant difference was observed between HbA1c values and the type of therapy, i.e., the difference was observed between subjects on oral antidiabetics and those on combination therapy, which indicates the importance of additional education of patients on self-control and achieving fasting and postprandial glycemic targets. No statistically significant difference was observed in the parameters of glycemic regulation (fasting glucose, HbA1c) with respect to age, sex and body mass index of the subjects.Key words: type 2 diabetes; glycemia; HbA1c; insulin; oral antidiabetics

Adult-onset loss of the hepatocyte growth hormone receptor (GHR) is associated with increased autophagy in livers of male mice in the context of natural daytime fasting

Andre Sarmento-Cabral[1, 2,3,4,5,6,], Elena Gutierrez-Casado[5,6], Mercedes del Rio-Moreno[5,6], Mari C Vazquez-Borrego[5,,6,7] & Rhonda D Kineman[5,6]

Liver autophagy, as assessed by accumulation of LC3-II and p62 proteins, is positively correlated with the severity of nonalcoholic steatohepatitis (NASH) in humans. Since growth hormone (GH) is negatively associated with liver steatosis and NASH development, and our laboratory has reported that steatosis and NASH develops in a mouse model of adult-onset, hepatocyte-specific GH-Receptor knockdown (aHepGHRkd), we sought to determine if GH directly regulates the hepatocyte autophagy program, and whether this regulation is mediated via STAT5B activation. To this end, adult GHRfl/fl male mice were treated with adeno-associated viral vectors to generate GHR-intact control (AAV8-TBGp-Null), aHepGHRkd (AAV8-TBGp-Cre) or aHepGHRkd mice with constitutive activation of STAT5B (AAV8-TBGp-Cre + AAV8-TBGp-Stat5bCA). Livers were analyzed 7 days post AAV injection, a time when steatosis is observed in aHepGHRkd mice. We first evaluated the level of p62 and LC3-II proteins in liver lysosomal fractions by western blot, from mice euthanized at 1800h (end of the normal sleep cycle, natural fasting), a time of enhanced autophagy. In this condition, we did not observe any differences in p62 or LC3-II protein levels between control, aHepGHRkd or aHepGHRkd + Stat5bCA. Since p62 and LC3-II are involved in the initiation of autophagy, but are rapidly cleared in the autolysosome, we repeated the study after treating the mice with leupeptin, that blocks Cathepsin B, H and L and impairs amphysome-lysosome fusion, leading to a build-up of p62 and LC3-II. In this scenario, we observed that aHepGHRkd resulted in an increase in accumulation of p62 and LC3-II, compared with GHR-intact controls, and Stat5bCA partially reversed this effect. Current literature suggests that autophagy increases in the steatotic liver to protect against NASH progression. Therefore it is possible that the increase in autophagy observed in aHepGHRkd mice is not directly due to loss of GHR signaling but secondary to the development of steatosis, since Stat5bCA also reduces steatosis in aHepGHRkd mice. Therefore, although additional studies are required to determine if GHR/STAT5 plays a direct role in regulating the autophagy process in the liver, our data suggest this remodeling process could be altered in the context of GH signaling alteration during NAFLD development.

Predictive factors of postoperative septic complications after flexible ureteroscopy for urinary stones

Maatougui Jasser[1], Raboudi Mehdi[1], Chayma Besrour[2], Ouertani Haroun[2] & Ghozzi Samir[1]
[1]The Military Hospital of Tunis, Urology, Tunis, Tunisia; [2]The Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
The recent advent of flexible ureteroscopy made endoscopic approach to kidney and proximal ureteral calculi evolve to a real effective procedure. However, this technique is not free of postoperative complications. The aim this study was to assess the predictive factors of septic postoperative complications following flexible ureteroscopy for upper urinary tract stones.
Methods
This is a descriptive retrospective study concerning 92 patients who underwent flexible ureteroscopy for renal and proximal ureteral stones in the urology department of the military hospital of instruction of Tunis between January 2015 and December 2021. Septic complication we defined as the occurrence of postoperative fever, urosepsis, septic shock or death. We used multivariate logistic regression to assess predictive factors of septic postoperative complications.
Results
The mean age was 50 years [20 - 82]. Regarding the medical history of our patients: Diabetes was found in 29 cases (32%), occupying the first place, followed by high blood pressure in 24 cases (26%) and chronic renal failure (20%). We identified postoperative complications following 26 interventions (28%) of which 13% were septic. Predictive factors of postoperative Sepsis after flexible ureteroscopy were: Diabetes ($P = 0.032$). a history of urolithiasis ($P = 0.023$). a history of extracorporeal shock wave lithotripsy ($P = 0.009$). In our study, a quarter of diabetic patients had developed postoperative sepsis. This complication was found in only 7.9% of non-diabetic patients. Statistically, the difference was significant ($P = 0.032$).
Conclusion
In light of our studies, diabetic patients have a significantly higher risk of occurrence of postoperative infectious complications. This population may require specific perioperative preparatory measures to reduce operative morbidity.

Screening for distal and symmetric polyneuropathy in the diabetic patient: 116 cases

Mouna Elleuch, Maalej Souhir, Hsine Houda , Dhoha Ben Salah , Mohamed Abdellahi Mohamed Ahmed , Faten Haj Kacem Akid & Mohamed Abid
CHU Hedi Chaker, Endocrinology, Sfax, Tunisia

Introduction
The prevalence of diabetes in the world population is increasing day by day so that its frequency reaches epidemic proportions. As a result, the complications of diabetes are becoming more and more frequent. Diabetic neuropathy, the most common complication which affect up to half of the patients.
Purpose of the study
To establish the prevalence of distal symmetrical polyneuropathy (DSPN) in diabetic patients and demonstrate the importance of screening for this complication.
Methods
This is a descriptive cross-sectional study conducted among 116 patients during their usual appointment at the consultation. Data collection was done over a period of 2 months from August 1 to September 30, 2021. All patients had a complete neurological examination. We used the Michigan Neuropathy Screening Instrument (MNSI) and the DN4 Neuropathic Pain Diagnostic Questionnaire to establish the prevalence of the disease in our population.
Results
We included 116 participants divided into 47 men and 69 women. The mean age was 62.07 [24 - 89 years]. Type 2 diabetes was noted in 79% of the popultion. The average duration of diabetes was 12,35 years. The average blood sugar was 7,9 mmol/l. HbA1c $\leq$7% was noted in 27% of cases. The mean MNSI History score was 3.76 and 23% of patients had a score $\geq$7 indicating the presence of diabetic neuropathy in them.The mean MNSI physical score was 3.82 and 51% of patients with a score $\geq$ 2.5 had diabetic neuropathy. The mean DN4 score was 3.25. Our results showed that 42 patients (36%) had neuropathic pain with a score $\geq$ 4. Thus, PNDS was diagnosed in 57.8% of our patients. This prevalence was established on the basis of DN4 and or MNSI scores. The podiatric risk was grade 2 in 29% and grade 3 in 12%.
Conclusion
Distal and symmetrical polyneuropathy is very frequent in diabetic patients and causes a consequent morbidity. It is therefore imperative to detect it early enough for a better management.

Diabetic muscle infarction : a case study

Ons Maaoui, Sabrine Mekni, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui , Ibtissem Ben Nacef & Karima Khiari
Hospital of Charles Nicolle, Endocinology, Tunis, Tunisia

Introduction
Diabetic muscle infarction (DMI) is a rare complication of long-standing, poorly controlled diabetes, and it's more common in patients with micro-vascular complications. Herein, we present a case of DMI occurring in patient on hemodialysis.
Case presentation
A 44-year-old man on maintenance hemodialysis presented with an acutely painful and swelling in his left calf. He had a 21-year history of poorly controlled type one diabetes, with micro-vascular complications (nephropathy and retinopathy). On physical examination: his skin was pale, his temperature was 37°c , his heart rate was 80 beats per minute and his blood pressure was 150/80 mmHg. His left calf was swollen and tender with no edema or inflammatory signs. Biochemical findings showed: C-reactive protein (CRP) 42 mg/l, CPK 179 U/l (39-308) and LDH 382 U/l (140-280). A Doppler ultrasound showed no sign of deep vein thrombosis, but demonstrated edema of the superficial tissues which prompted the practice of an MRI showing thickening of the lateral gastrocnemius muscle with edema. It is the seat of a lack of enhancement extending over 3 cm with the interposition of a few fibers of marked enhancement. The thickening and muscle edema was more important in the posterior compartment of the leg. It also showed edematous infiltration of fascia and subcutaneous cellulitis without significant enhancement and minimal fatty degeneration of the different muscle compartments of the leg. The patient was put on analgesics and activity restriction in the acute phase followed by gradual mobilization.
Conclusion
Diabetic muscle infarction is a rare and under-reported condition that should be suspected in any diabetic dialysis patient who develops a painful, swollen muscle.

EP389

Gestational diabetes: a review of 64 cases

Fadwa Atfi & Imane El Abbassi
CHU Ibn Rochd, Maternity Department, Morocco

Introduction
Gestational diabetes (GD) is the consequence of an exaggerated insulin resistance associated with a defect insulin secretion. It is a high-risk pregnancy due to its maternal and foetal complications, the pathogenesis of which involves maternal hyperglycaemia.
Materials and methods
This is a retrospective study of 64 parturients, carried out from January 1, 2019 to January 1, 2020 in the gynaecology obstetrics of the Lalla Meryem maternity hospital of CHU Ibn Rochd of Casablanca.
Results
The average age of our parturients was 31 years, and they were multiparous in 81.24% of cases. Obstetrical complications were dominated by HTAG (14.06%), urinary tract infections (12.50%); while macrosomia (51%) and foetal death in utero (14.06%) are the two major foetal complications. The caesarean section rate was 75%.
Discussion
These high rates of maternal-foetal complications lead us to insist on early diagnosis of gestational diabetes in order to ensure a normal course of the pregnancy and to reduce the risk of complications, without forgetting the interest of follow-up and monitoring of complications in the far postpartum period for both the mother and the child. The improvement of obstetrical and perinatal prognosis depends above all on and multidisciplinary care involving the cooperation of different professionals, in particular diabetologists, gynaecologists, obstetricians, attending physicians dieticians, etc. The pharmacist also has a role of listening and advising, which can be useful to the patient. In addition, his involvement could be one of the solutions in the future in the screening of gestational diabetes. Through this study, we were able to identify the epidemiological and therapeutic characteristics, the risk factors involved, screening modalities and maternal-foetal morbidity, which allowed us to deduce the difficulties encountered during screening, diagnosis, and treatment
Conclusion
Gestational diabetes is a public health problem whose prevalence is increasing in our societies. Its short and long-term impact on children and mothers requires appropriate diagnosis and management.

Uricemia in hypertensive type 2 diabetics: the forgotten metabolic parameter

Faten Haj Kacem Akid, Hamdi Frikha, Cyrine Chehaider, Ameni Salah, Dhoha Ben Salah, Mouna Mnif, Nadia Charfi, Fatma Mnif, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Hyperuricemia is a common metabolic feature in patients with metabolic syndrome.
Aim
The aim of our work is to study the correlation between uric acid level and the metabolic profile in hypertensive type 2 diabetic patients.
Methods
This is a retrospective descriptive study of hypertensive type 2 diabetic patients followed in the endocrinology department of Hedi Chaker University Hospital of Sfax, Tunisia between 2019 and 2021. Hyperuricemia was defined as uric acid level $\geq$ 360 µmol/L
Results
100 patients were included. Mean age was 62.14 $\pm$ 12.7 years with a sex ratio (M/F) of 0.65. Diabetes has been diagnosed since 13.73 $\pm$ 9.6 years on average with a mean HbA1c of 11.06 $\pm$ 2.5%. Hyperuricemia was found in 23.75% of cases overall and in 29.41% of patients with diabetic nephropathy (DN). Uricemia was inversely correlated with HDL cholesterol levels (r =-0.31, P = 0.009) and creatinine clearance (r =-0.35, P = 0.05). On the other hand, uricemia was positively correlated with triglyceride levels (r = +0.7, P = 0.009), duration of diabetes (r = +0.3, P = 0.05), and albuminuria level (r = +0.45, P = 0.02). There was no significant association between uric acid and LDL cholesterol, HbA1c, BMI, total cholesterol, and blood pressure (systolic and diastolic). Uric acid was correlated primarily with renal function in type 2 diabetics. Our results also showed a significant association between uric acid levels and triglyceride and HDL levels, which could be attributed to a fructose-enriched diet.

Conclusion
Hyperuricemia has been found to correlate with major metabolic parameters in patients with diabetes notably those with DN. Its importance contrasts with the paucity of studies about its cardiovascular effects and the lack of clear guidelines regarding its management.

Cardiovascular risk in diabetic patients with chronic kidney disease: One more turn of the screw

Abdelmouhaymen Missaoui, Mnif Fatma, Asma Zargni , Kawthar El Arbi , Dhoha Ben Salah, Mouna Elleuch , Faten Haj Kacem Akid, Nadia Charfi, Mouna Mnif , Nabila Rekik Majdoub & Mohamed Abid
Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Poor glycemic control in patients with diabetes mellitus(DM) is a well-documented responsible factor for microvascular complications, especially eye and kidney damage. The onset of chronic kidney disease(CKD) marks a serious turning point in the clinical history of DM in terms of cardiovascular prognosis. Our study aims to assess the cardiovascular risk(CVR) in diabetic patients with CKD.
Method
We conducted a retrospective descriptive study on 88 type 2 diabetic patients with CKD, admitted during 2019-2020 to the Endocrinology-Diabetology Department of Hedi Chaker University Hospital, Sfax, Tunisia.
Results
The mean age was 68.7±10.9 years with a male predominance(52.3%). Active smokers represented 12.5%. We noted a family history of CKD and early cardiovascular events in 12.5% and 5.7% of cases, respectively. The mean duration of the evolution of diabetes was 13±9 years. We highlighted a glycemic imbalance in 80.2% of patients with a mean fasting plasma glucose of 2.78±1.5g/l and an average HbA1C level of 9.68±2.5%. Dyslipidemia and hypertension were encountered in 94% and 86.4% of cases, respectively. Obesity affected 35.7% of the patients with a mean BMI of 28,53 ± 5.11 kg/m^2. Macroangiopathy was documented in 29.5%, mainly ischemic heart disease (19.3%) and stroke (9.1%). Diabetic retinopathy was diagnosed in 53.5%. The mean glomerular filtration rate(GFR) was 32.2±13.81 mL/min/1.73 m^2. Most patients were Stage 3 CKD (56.8%) whereas 30.5% were stage 4 and 12.5% stage 5. Hemodialysis was undergone for 7.9%. Albuminuria was positive in 52.2% with mean proteinuria of 1.46±2.4 g/24 h. According to the European Society of Cardiology 2021 CVR assessment, all patients are among the very high CVR range.
Discussion
Diabetic nephropathy (DN) is the first leading cause of CKD in the world. Chronic hyperglycemia is responsible for the vascular damage and progression of CKD to terminal-stage and recourse to hemodialysis. In addition to traditional CVR factors, GFR impairment and albuminuria are independent markers of CVR and overall morbidity in diabetic patients. This risk is proportional to the severity of CKD and would be maximal in hemodialysis patients. We recommend screening annually for DN using a urine dipstick test and serum creatinine measurement. Achieving the best glycemic control (A1c<7%), treating high blood pressure (<130/80 mmHg or < 125/75 mmHg if proteinuria >1.0 g/24 h and increased serum creatinine), using nephroprotective renin-angiotensin-aldosterone system blockers, and treating dyslipidemia (LDL-cholesterol<0.55 g/l) are effective measures for preventing the development of microalbuminuria, delaying the progression to more advanced stages of CKD and reducing the overall cardiovascular mortality in diabetic patients.

Diabetic foot: a tunisian experience

Mouna Elleuch, Hamdi Frikha , Dhoha Ben Salah, Fatma Mnif, Mouna Mnif, Nadia Charfi , Nabila Rekik Majdoub , Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction and aim
Diabetic foot (DF) is associated with increased morbimortality and cost of diabetes management. The aim of this study is to describe the epidemiological, clinical and paraclinical characteristics and follow-up outcomes of patients with diabetic foot in a Tunisian center.
Methods
It is a monocentric retrospective study of 210 patients with diabetic foot followed at the endocrinology department of the Hedi Chaker Sfax University Hospital between 1997 and 2020.
Results
Patients were predominantly men (79.6%), aged 59.14±12.24 years on average. Over 85% of patients were type2 diabetics, 90.4% of whom had a chronically imbalanced condition. In our population, diabetes has been diagnosed since 13.21±8.2 years while DF was the revealing factor of diabetes in 7 patients (3.4%). Approximately one third of the patients lived in poor socioeconomic conditions and 24% were illiterate. Half of the patients were obese and 25.2% were smokers. The mean time to consultation was 45.83 days (median = 15 days). The most common reason for admission was major hyperglycemia associated with DF (75.1%) while ketoacidosis was found in 29 patients (14.1%). Half of patients had lower limb arterial disease (LLAD) upon admission while peripheral neuropathy was present in 81.6% of patients. The most frequent triggers of DF were unfelt trauma (26.7%) and foot-shoe conflict (12.1%). The involvement was bilateral in 51 patients. Clinical findings showed DF infection, ulceration and plantar perforation were present in 72, 62 and 59 cases respectively. Eighteen percent patients were at gangrene stage upon admission. Lab investigation showed a mean blood glucose level at 15 ± 6.81 mmol/l. The most frequently isolated germ was *Staphylococcus aureus* (29 cases). Antibiotic therapy was prescribed in 62.1% of cases for a mean duration of 19.9 ±18.6 days. Amputation was the outcome for 44 patients and the mortality rate was 1.9%. In monovariate analysis, the predictive factors for amputation were the presence of LLAD (OR=4; $P = 0.02$), osteitis (OR=34; $P < 0.001$) and gangrene (OR=18; $P < 0.001$).
Conclusion
Despite major advances in therapeutic options, DF remains a major public health issue. Therapeutic education and primary prevention are essential to reduce the frequency and severity of DF complications and ensure early management.

Diabetic nephropathy and hypertension

Meriam Dalhoum , Zohra Hadj Ali, Ines Bani, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Department C, Tunis, Tunisia

Introduction
Diabetic nephropathy is a a dreadfull complication of diabetes and it is the leading cause of chronic kidney disease worldwide. Hypertension is a major cause of progression of this complication.
Objective
To determine the prevalence of diabetic nephropathy, to search a correlation between the presence and duration of arterial hypertension and the occurrence of diabetic nephropathy.
Patients and methods
This is a retrospective study carried out about 184 type 2 diabetic patients, followed at the department C of the National Institute of Nutrition in Tunis.
Results
The mean age was 61±10 years, with a sex ratio M/F of 0.56. The mean duration of diabetes was 14±8 years, the mean glycated hemoglobin (HbA1c) was 10.6%. Nephropathy was present in 37% of cases. In the subpopulation of patients with nephropathy, it was noted that 67% of patients were at the stage of micro albuminuria, 44.2% were in renal failure, mean clearance of creatinine was 57 ml/min and 79% were hypertensive. The presence of nephropathy was correlated with the duration of evolution of hypertension (74% had a duration of evolution of more than 05 years) and 62% of patients were in blood pressure imbalance.
Conclusion
Blood pressure control is crucial in diabetic patients, it allows nephroprotection and an improvement of the cardiovascular prognosis.

DOI: 10.1530/endoabs.81.EP393

EP394

The association of hypertension and type 2 diabetes

Meriam Dalhoum , Zohra Hadj Ali, Ines Bani, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Department C, Tunis, Tunisia

Introduction
The association of hypertension and type 2 diabetes is frequent. These two pathologies constitute each a cardiovascular risk factor with a cumulative effect which increases the cardiovascular morbi-mortality of hypertensive diabetics.

Objective
To measure and compare the frequency of degenerative complications of diabetes in hypertensive and non-hypertensive diabetics.
Patients and method
The study was descriptive, retrospective and included 184 type 2 diabetic patients followed at the service C of the National Institute of Nutrition of Tunis.
Results
The mean age was 61 ± 10 years, with a sex ratio M/F of 0.56. The mean duration of diabetes was 14 ± 8 years, the mean glycated hemoglobin (HbA1c) was 10.6%. It was noted that 69.5% of patients had hypertension. The prevalence of microangiopathy was globally higher in hypertensive diabetics than in non-hypertensive patients (retinopathy: 33.6% vs 8.9%; neuropathy: 26.6% vs 17.8%; nephropathy: 43% vs 3.6%). Similarly, the prevalence of macroangiopathies was higher in hypertensive diabetics (stroke: 3.9% versus 0.54%; coronary artery disease: 18.8% versus 1.6%; and cerebral artery disease: 6.3% versus 1.8%).
Conclusion
Hypertension is often associated with type 2 diabetes. It worsens the cardiovascular prognosis and accelerates the onset of degenerative complications. Adequate management of arterial hypertension is therefore necessary to reduce the cardiovascular risk of diabetic patients.

The blood lead level is the meaningful indicator to metabolic syndrome in healthy populations

Kyu Rae Lee , In Cheol Hwang , Kyung Kon Kim , Heuy Sun Suh & Ki Dong Ko
Gachon University, Family Medicine, Incheon, Rep. of South Korea

Background
Lead is known as an environmental toxic pollutant and hormonal regulatory confounder associated with obesity. Recent China scientific report shows that blood lead level (BLL) is closely related with body mass index. Therefore, we investigated the association between the prevalence of metabolic syndrome and blood lead levels in healthy general population without hypertension, dyslipidemia, and diabetes.
Methods
We assessed the socio-demographic (height, weight, alcohol and smoking, income, education and living area, waist circumferences), cardio-metabolic variables (blood pressures, fasting plasma glucose, glycated hemoglobin and HDL cholesterol, triglyceride, high sensitivity C-reactive protein), BLL after fasting over eight hours from 1,381 healthy subjects without hypertension, dyslipidemia, and diabetes, among 8,238 subjects in 2017 KHANES (Korea Health Analysis and Nutrition Examination Survey) dataset. Chi-square tests for categorical variables, Pearson's correlation analysis, student *t*-test for continuous variables were performed. *P*-value <0.05 was considered as significant at both sided using by SPSS packages for windows (version 18, USA).
Results
As a total of 1,381 subject (43.22 +/- 0.39 years, female 55.3%), mean BMI and WC were 23.52 +/- 0.099 kg/m^2, 79.98 +/- 0.285 cm. The BLL was correlated with BMI, WC, age, sex, income, education, living location, alcohol, smoking, occupation, systolic pressures, diastolic pressures, fasting plasma glucose, total cholesterol, HDL-cholesterol. ($P < 0.05$) The BLL was very significantly correlated with BMI, WC after controlled for age, income, education, marriage, smoking, alcohol, occupation, energy intake. ($P < 0.05$, $P < 0.001$) In addition, we found hypertension, hyperglycemia, hypercholesterolemia, and hypertriglyceridemia, high sensitivity-CRP, high glycated hemoglobin, and low HDL-cholesterolemia in higher group than lower group in BLL. ($P < 0.05$) Furthermore, it was more evident for the significant difference between two groups in women than men. ($P < 0.01$)
Discussion and Conclusion
As the endocrine regulator related with metabolism, the blood lead level might be associated with body weight. However, the clear mechanism between them would not be determined. BLL was closely related with metabolic syndrome in healthy general population without diabetes, hypertension, and dyslipidemia. Further controlled longer clinical trial would be considered in the future.

Impact of bariatric surgery on body composition and cognition: a pilot study

Andreu Simó-Servat[1,2], Montserrat Ibarra[1], Mireia Libran[1], Nuria Alonso[1], Silvia Rodriguez[1], Montse Ramos[1], Veronica Perea[1], Luis García-Pascual[1], Aida Orois[1], Carmen Quirós[1] & Maria Jose Barahona Constanzo[1]
[1]Hospital Universitari Mutua de Terrassa, Endocrinology, Terrassa, Spain; [2]Terrassa, Endocrinology, Terrassa, Spain

Aim
Bariatric surgery (BS) modifies body composition. The aim of the study was to establish the first step toward the introduction of the ultrasound (US) and bioelectrical impedance analysis (BIA) in the evaluation of body composition before and after BS. In addition, as obesity was shown to be related to global cognitive decline, we aim to determine possible changes in cognitive test before and after BS.
Material and Methods
a prospective pilot study of patients with obesity who underwent BS in our hospital. Fat mass (FM) and lean mass (LM) were calculated by BIA, and skeletal muscle index (SMI) was used for estimating muscle mass. We measured thigh muscle thickness (TMT) and subcutaneous fat (SF) of quadriceps by US. In the same visit, Montreal Cognitive Assessment (MOCA) test was done. All subjects were assessed 1 month before surgery and 12 months after it.
Results
32 patients were included (75% female, mean age: 40.15 years, mean BMI: 43.79 kg/m^2). BS reduced BMI 6,63 ± 1,25 kg/m^2 on average ($P = 0.001$). About body composition, significant reductions in FM (7.26 ± 0.99 kg, CI 95% 5.23 to 9.29, $P = 0.001$) and SF (0.24 ± 0.08 cm, CI 95% 0.07 to 0.41, $P = 0.007$) were found. Conversely, although a significant increase in LM (3.76 ± 0.72 kg, CI 95% 2.29 to 5.23, $P = 0.001$) was observed, TMT (0.05 ± 0.12 cm, CI 95% -0.3 to 0.19, $P = 0.634$) and SMI (0.33 ± 0.17 kg/height^2, CI 95% -0.01 to 0.68, $P = 0.057$) did not change. When BIA and US were compared, we found a significantly correlation between the FM and SF (pre-surgical: $r = 0.42$, $P = 0.01$; post-surgical: $r = 0.52$, $P = 0.003$) and between SMI and TMT (pre-surgical: $r = 0.35$, $P = 0.04$; post-surgical: $r = 0.38$, $P = 0.03$). Lastly, MOCA score significantly increased after BS (1.13 ± 0.52, CI 95% 0.06 to 2.19, $P = 0.04$).
Conclusions
Our results suggest that US evaluation of TMT and SF may be complementary to BIA-derived SMI assessment for estimating muscle mass. Likewise, we also detected a possible improvement in the cognitive function of patients after BS.

Correlation of obesity with diminished neutralizing antibody count

Teona Nutsubidze, Lasha Uchava & Elen Giorgadze
National Institute of Endocrinology, Endocrinology, Tbilisi, Georgia

The obesity epidemic, which has persisted for more than 45 years, is now being faced concurrently with the coronavirus pandemic, with deadly effects. The complex changes caused by obesity, such as chronic inflammation, are known to be detrimental in patients with COVID-19. 33.2% of the Georgian population is obese (1). Therefore, we aimed to explore the synergistic effects between obesity and SARS-CoV-2. The objective of our study is to compare the presence of neutralizing antibodies among obese and non-obese individuals 22 weeks after COVID-19 vaccination. The findings should have important implications for fine-tuning revaccination protocols for people with obesity.
Materials and Methods
In-vitro chemiluminescence immunoassays were used to quantify the serum neutralizing antibodies to SARS-CoV-2 in 30 individuals in an outpatient setting. Only patients who had received the second COVID-19 vaccine dose at least 22 weeks earlier were included in the study. Patients were divided into two subgroups according to BMI, with 15 patients with BMI >30 kg/m^2 in the obese group and 15 patients with BMI <30 kg/m^2 in the control group. In both subgroups,40% of patients had recovered from COVID-19. The exclusion criteria for the study were the presence of autoimmune diseases, current use of immunosuppressants, or a history of COVID-19 in the prior 8 weeks. Limitations

Table 1. Values are presented as mean. BMI: body mass index.

Parameter	Control Group BMI < 30	Obese Group BMI >= 30
Gender (M/F)	3/12	6/9
Age	37	47
Duration since Second Dose (weeks)	22	22
Previous Infections		
Yes	40%	40%
No	60%	60%
nABs (μg/ml)	19,3846	1,8362

of this study include the small study population size and the lack of baseline data verifying the presence of antibodies 3 weeks post-vaccination.
Results
The serum samples of immunized patients with obesity showed lower antibody counts than those in the non-obese group. The mean amount of neutralizing antibodies in the obese group was 1,8362 µg/ml, compared with 19,3846 in the control group.
Conclusion
Our study showed a strong correlation between BMI and a sustained immune response, because most immunized patients with obesity had diminished amounts of neutralizing anti-SARS-CoV-2 antibodies after 22 week.

Berberis vulgaris: perspectives in the treatment of non alcoholic fatty liver disease

Mnif Fatma[1], Asma Zargni[1], Kawthar El Arbi[1], Dhoha Ben Salah[1], Salma Bousetta[2], Mouna Elleuch[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Faten Haj Kacem Akid[1] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Diabetology and Endocrinology, Sfax, Tunisia; [2]Institute of Biotechnology, Sfax, Tunisia

Introduction
Berberis vulgaris is a plant, of the family Berberidaceae. Berberine is the main active compound of the barberry. It is an iso quinoline alkaloid of intense yellow color. Berberis vulgaris is used in several medical purposes, including liver protection, anti-oxidant, antimicrobial agent. It also seems to reduce the level of cholesterol in the blood and triglycerides. Our study aims to investigate the effect of the dietary supplement "Berberis Vulgaris" made from the extract of the dried root bark, on the metabolic parameters in patients with hepatic steatosis (NAFLD) .
Patients and Methods
This is a double-blind randomized clinical trial conducted on 60 patients with NAFLD, divided into two equal groups: (G1) treated with berberine and (G2) treated with placebo. All patients received 3 capsules each day before meals. Weight, body mass index (BMI), Waist circumference (WC), liver transaminase levels and lipid profile were recorded in both groups before and after treatment.
Results
Our population included 17 men (28.33%) and 43 women (71.67%). The average age of patients included in G1 is 47.71 years for men and 58.48 years for women while in G 2 it is 58.9 years and 76 years respectively. The majority of patients in both groups have a family history of metabolic diseases. The majority of NAFLD patients had metabolic diseases such as diabetes in 40% of G2 patients and dyslipidemia in 40% of G2 patients and hypertension in 46.67% of G1 patients. The average weight in G1 was 80.47 kg comparable to that of G2 which was 79.55 kg. The BMI was 33.12 in G1 patients and higher in G2 patients which was 29.12 kg/m^2. On the other hand, the WC was higher in G1 than in G2 (108 cm versus 104 cm). In G1: a decrease in weight, BMI and WC was noted. Liver enzymes: ASAT and ALAT levels decreased from 18.15 to 16.5 IU/l and from 20.88 to 18 IU/l respectively. But they remained increased in G2. Cholesterol, blood glucose and especially triglycerides levels were largely decreased under treatment and remained unchanged under placebo. Abdominal ultra sound examination didn't show a significant change in steatosis.
Conclusion
Considering the decrease in liver enzymes, Triglycerides and cholesterol observed in G1 patients after the use of the dietary supplement Berberis Vulgaris, it can be said that berberine has a positive effect on hepatic and metabolic parameters and may soon be a cornerstone in the treatment of hepatic steatosis.

EP399

Impact of obesity severity on the metabolic profile of obese patients

Rim Rachdi, Berriche Olfa , Ben Ali Khaoula, Eya Safi , Nadia Ben Amor , Rym Ben Othman, Ramla Mizouri, Faten Mahjoub & Jamoussi Henda
The National Institute of Nutrition in Tunis, Diabetology Department A, Tunis, Tunisia

Introduction
Obesity is one of the major public health issues worldwide and is known to be associated with an increased risk of severe metabolic and cardiovascular complication. The aim of our study was to assess the impact of obesity severity on the metabolic profile of obese patients.
Materials and methods
Cross-sectional descriptive study involving 68 obese patients carried within the National Institute of Nutrition in Tunis. The patients were divided into two groups: 34 patients with a BMI between 30 and 34,99 kg/m^2 (G1) and 34 patients with a BMI $\geq$40 kg/m^2 (G2). Each patient underwent clinical examination, fasting blood sampling for metabolic profile and an abdominal ultrasound for fatty liver disease.
Results
Median age was 47,67 years in G1 versus 46,85 years in G2 (P = NS). A clear female predominance was noted in both groups with an F/H sex ratio of 4,66 in G1 and 16 in G2. The average BMI was 32,67 kg/m^2 in G1 compared to 44,55 kg/m^2 in G2. The average waist circumference was significantly higher in G2 than in G1 (130 cm vs 112,94 cm, $P <$ 10-3). The prevalence of diabetes was 35,29% in G1 and 23,53% in G2 (P = NS). Mean fasting blood glucose levels were comparable in both groups (7,79 mmol/l in G1 and 7,4 mmol/l in G2, P = NS). The prevalence of dyslipidemia was higher in G2 (23,53%) than in G1 (17,65%), P = NS. The mean total cholesterol level in mmol/l was comparable between the two groups (4,80 in G1 vs 4,87 in G2, P = NS). The mean triglycerides level in mmol/l was significantly higher in G2 than in G1 (1,33 in G1 vs 1,71 in G2, P = 0,0024). The average HDL cholesterol level in mmol/l was higher in G1 than in G2 (1,28 in G1 vs 1,20 in G2, P = NS). The mean uric acid level in micromol/L was significantly higher in G2 than in G1 (350,61 in G2 versus 284,64 in G1, $P <$ 10-3). Fatty liver disease prevalence was higher in G2 than in G1 (11,76% vs 5,88%) with no statistically significant difference (P = NS).
Conclusion
Our study showed that the severity of obesity is associated with a higher prevalence of metabolic disorders justifying early management of obesity in order to delay the onset of these abnormalities.

Association of chemerin and serum advanced glycation end products in patients with autoimmune thyroiditis

Sára Bak-Csiha[1], Sándor Halmi[1], David Hutkai[1], István Molnár[1], Mónika Katkó[1], Hajnalka Lőrincz[2], Mariann Harangi[2], György Paragh[2], Endre Nagy[1], Miklos Bodor[1] & Berta Eszter[1]
[1]University of Debrecen, Endocrinology, Debrecen, Hungary; [2]University of Debrecen, Metabolism, Debrecen, Hungary

Background
Hypothyroidism due to autoimmune thyroiditis leads to atherogenic lipid profile and metabolic changes. The formation of advanced glycation end products (AGEs) increases with hyperglycemia, hyperlipidemia and oxidative stress. Degradation of AGEs after AGEs-receptor 1-mediated intracellular uptake and renal clearance of soluble AGEs generated by certain cells like macrophages play a crucial role in the decrement of circulating AGEs level. Chemerin is an adipokine produced by adipose tissue and liver and acts as a chemoattractant for immune cells and promotes adipocyte differentiation. Chemerin also appears to induce insulin resistance in skeletal muscle. To date, the association of AGEs and chemerin has not been investigated in thyroid disorders.
Subjects and Methods
In our study we investigated the association between thyroid hormone levels, thyroid antibodies, the components of lipid metabolism, renal and liver function, anthropometrical parameters and AGEs. We enrolled one hundred and ten patients (9 men, 101 women, mean age 49.3 $\pm$ 16.7 years, mean BMI 27.5 $\pm$ 5.8 kg/m^2) from the outpatient clinic of Endocrine Department of University of Debrecen, Faculty of Medicine. All patients had autoimmune thyroiditis with various thyroid hormone status from hypo- to hyperthyroidism. Serum AGEs concentrations were determined by autofluorescence. Thyroid hormone levels, anti-thyroperoxidase (aTPO) concentration and lipid parameters were measured by routine laboratory methods. Chemerin levels were measured by ELISA method.
Results
Median serum AGEs level was 10.4 (9.4 – 11.8) AU/µg protein, median chemerin level was 91.2 (79.8 – 104.8) ng/ml, while mean total cholesterol level was 5.3 $\pm$ 1.1 mmol/l. Mean fT3 and fT4 were 4.56 $\pm$ 0.76 and 17.8 $\pm$ 3.7 pmol/l, respectively. Significant negative correlation was found between fT3 and log AGEs/total protein levels. There was a significant correlation between log chemerin, total cholesterol, log creatinine, log ApoB100 and log AGEs/total protein levels. However, we could not find correlation between log AGEs/total protein levels and aTPO levels.
Conclusions
The significant negative correlation between log AGEs/total protein levels and fT3 levels might be the consequence of T3 regulatory effect on metabolism. However, further clinical investigations are needed to clarify this relationship.

Efficacy of a groupal lifestyle intervention programme for weight loss in obesity

Manuel Cayón-Blanco , Dolores Cepero , M José López-Pérez , Lourdes García-García-Doncel & Maria Gloria Baena-Nieto
Jerez Hospital, Endocrinology Unit, Jerez, Spain

Introduction
Obesity is one of the most important problems worldwide in recent times. Groupal lifestyle intervention programmes are efficacious in the management of obesity. While exercise and healthy dietary habits have consistently been shown to improve various metabolic markers, adherence to these behaviors is low and methods that increase adherence to health behaviors are needed.
Objective
The primary objective of this study is to evaluate the effectiveness of a groupal weight loss programme for weight loss in obesity and its efficacy in improving health parameters related to obesity.
Materials and Methods
All participants received a groupal lifestyle intervention focused on diet, physical activity, and behavior change strategies. The duration of program was 6 months. Clinical and biochemical parameters were evaluated before and after the intervention.
Results
A total of 112 patients were included. At baseline, the mean body-mass index (BMI) for all participants was 46.1 $\pm$ 14.2 kg/m^2, and the mean weight was 125.8 $\pm$ 22.1 kg. The mean age was 46.9 $\pm$ 14.3 years and 72.5% were women. 60.4% had hypertension and 23.1% were diabetic. Of the 112 patients, 82 patients completed the follow-up (78.57%). 21.43% of the patients did not attend the appointments and left the program. The percentage of participants who lost 5% or more of their initial weight was 47.6%; In 18.8%of them the weight loss was $<$ 5% and 19.6% of patients did not lose weight. Of the 39 patients who achieved the weight loss goal, a significant decrease in BP, basal glycemia, Hba1c, uric acid, T-cholesterol, and triglycerides was observed. The patients who completed the follow-up and had the best results were the oldest and those with the most comorbidities.
Conclusions
The establishment of a groupal weight loss programmes achieves objective weight loss in most patients with a benefit in analytical parameters. Less adherence to our protocolized programme was shown in younger patients, which could be due to less interest and lack of awareness of the disease. Future studies with a longer follow-up period would be interesting.

Bariatric Surgery in Type 1 Diabetes patients: a single centre study

Tanya Chopra, Alice Wills & Foteini Kavvoura
Royal Berkshire NHS Foundation Trust, Centre for Diabetes and Endocrinology, Reading, United Kingdom

Background
Bariatric surgery significantly aids weight loss, improves glycaemic control and/or induces remission in Type 2 Diabetes patients. However, the impact of bariatric surgery in Type 1 diabetes (T1D) patients is less well-understood. With an increasing prevalence of obesity within the T1D population, it is important to identify whether bariatric surgery improves glycaemic control and prevents future complications.
Aim
To evaluate the effect on BMI, excess weight loss, HbA1c and insulin requirements over the course of a year following bariatric surgery, in patients with T1D in a large bariatric centre.
Methods
Between 2016-2020, 647 patients underwent bariatric surgery at Royal Berkshire Hospital, UK; 6 (0.9%, 83% female, mean age 49 years) had T1D and were retrospectively identified. The bariatric surgery type, BMI, HbA1c, basal insulin (BI) requirements and excess weight loss at time of referral, 6 and 12 months post-operatively were recorded. Information on short-acting insulin doses was not collected due to data inconsistencies.
Results
The majority of patients underwent a Roux-en-Y gastric bypass ($n = 5$) compared to gastric sleeve gastrectomy ($n = 1$). A sustained improvement in BMI was noted post-operatively, (-10 kg/m^2 at 6 months and -14 kg/m^2 at 12 months). A mean excess weight loss of 53.4% and 74.8% was achieved at 6 and 12 months, respectively. There was a reduction in mean daily BI requirement overall, with a 60% reduction in insulin noted at 6 months and 50% reduction at 12 months (38.8 units at referral vs 16.2 units at 6 months vs 19.2 units at 12 months post-operatively). HbA1c decreased at 6 months (mean -6 mmol/mol [-11 to +2 mmol/mol]) (pre-op mean 62mmol/mol) but this was not sustained at 12 months post-op compared to time of referral (mean -1 mmol/mol [-13 to +2 mmol/mol]).
Conclusion
Bariatric surgery resulted in a sustained improvement in excess weight loss and BMI in patients with T1D. Improvement in daily insulin requirements were noted, particularly in the short-term. However, the reduction in insulin requirements did not correspond with a reduction in HbA1c, with only short-term benefits seen. The majority of our patients had well-controlled diabetes at referral and improvement in glycaemic control was not the primary reason for surgery. The small number of patients and short follow-up may preclude definitive conclusions on the benefit of bariatric surgery in glycaemic control and complications in T1D patients in the long-term.

Covid-19 infection in an individual with Down Syndrome, obesity, and hypothyroidism: a case from the UAE

Esphie Grace Fojas[1], Shamma Al Shamsi[2], Mohamed Salah Noshi[3], Tomader Ali[1] & Nader Lessan[1]
[1]Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates; [2]Tawam Hospital, Al Ain, United Arab Emirates; [3]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates

Covid-19 infection severity has been associated with pre-existing conditions including obesity. Individuals with Down Syndrome (DS) are potentially at high risk. Reports on the outcomes of Covid-19 infection in individuals with DS are scant. Here we present such a case. MA is a 27-year old Emirati male with DS, obesity and hypothyroidism. He was brought to the ER with a history of hemoptysis (2 days), fever and cough (1 week). He tested positive for Covid-19. Initial investigations showed high CRP (44 mg/l), and mildly elevated ferritin (541 mcg/l) and D-dimer (0.93 mcg/ml). A chest CT scan showed classic Covid-19 pneumonia features with moderate severity score of 10/25. On Day 7 post-admission, his condition deteriorated; septic shock secondary to gram negative septicaemia with multi-organ failure developed. He required ventilator support and was intubated in ICU. Oliguric/anuric acute kidney injury (creatinine 882 mmol/l) followed, requiring hemodialysis; thrombocytopenia and deranged liver function tests were reported. He was prescribed full course COVID-19 regimen with multiple courses of broad-spectrum antibiotics and antifungal medication. After 10 days, MA was extubated but remained on oxygen supplementation, until finally weaned off oxygen completely. His renal function gradually recovered; his transaminitis and thyrombocytopenia resolved. His severe hypernatremia (sodium 170 mmol/l) improved on hypotonic fluid. MA was discharged after 5 weeks with a 10-day ICU stay. Post-Covid, swollen legs, uncontrolled headache, hair loss, and weight loss (9 kg) were noted. Hypothyroidism was inadequately controlled (TSH 11.72 mIU/l) 3 months post-discharge requiring thyroxine dose increase (150 to 175 mcg OD). This report highlights management challenges of COVID 19 infection in individuals with DS who often have other co-morbid conditions including obesity. Hospital admission can be prolonged and the course complicated by multi-organ failure. Specific preventative strategies including social distancing measures and vaccination schedules are needed for people with DS.

EP404

Diagnosis of sarcopenia using biomipedance analysis

Iulia Samoilova, Mariia Matveeva, Daria Podchinenova, Oxana Oleynik, Venera Mutalimi[1] & Ekaterina Choroshunova
Siberian State Medical University, Tomsk, Russian Federation

Objective
To study the peculiarities of the composition in patients over 50 years old.Materials and Methods: The study involved 136 adults aged 50 to 82 years. All subjects underwent complex examination, which included anthropometry (height, weight, body mass index (BMI)) and body composition analysis using Inbody 770 (Inbody Co.Ltd., Korea). Statistical processing of the results was performed using MedCalc Statistic software.
Results
women's age was 60[55.0;64.0] years, weight 74.5 [66.3;85.2] kg, height 159[156.0;164.0] cm, BMI 29.4 [25.0;33.8] kg/m^2. Body fat mass was

31.4[21.8;39.9] kg, body fat percentage 42.4 [37.2;48.0]%, visceral fat area 164.2 [127.7;201.5] cm^2, skeletal muscle mass 23.6[21.3;26.0] kg, appendicular muscle mass 6.48 [5.9;7.3] kg according to bioimpedanceometry. Appendicular muscle mass deficiency was found in 15.0% of the women's group. In the group of women with a normal BMI, 78.8% had changes in body composition according to bioimpedance measurements (increased body fat mass, percent body fat mass); 42.1% had visceral obesity; appendicular muscle mass deficiency was found in 52.6%. Male age was 58.5 [50.0;65.0] years, weight 92.4 [77.2;106.9] kg, height 173.5 [168.0;180.0] cm, BMI 30.9 [25.8;34.7] kg/m^2. Body fat mass was 26.5 [16.3;40.3] kg, body fat percentage 31.8 [21.8;39.5]%, visceral fat area 128.8 [83.6;189.0] cm^2, skeletal muscle mass 34.6 [29.9;40.5] kg, appendicular muscle mass 8.8 [7.9;9.2] kg according to bioimpedance measurement. The prevalence of reduced appendicular muscle mass in men was 12.5%. In the group of men with a normal BMI, 71.4% had changes in body composition by bioimpedance analysis (increased body fat mass, percent body fat mass); 42.1% had visceral obesity.
Conclusions
in some cases BMI did not reflect the actual degree of fat deposition and did not allow for differentiation between fat and muscle mass. The observed changes in body composition among those examined with a normal BMI indicate the need for more active diagnostic tactics and the use of additional tools for early detection and correction of these abnormalities, due to their association with reduced life expectancy and quality of life, as well as the risk of developing a number of metabolic disorders.

Impact of obesity on the development of respiratory abnormalities

Ramla Mizouri, Rym Ben Othman, Nadia Ben Amor, Faten Mahjoub, Rihab Yamoun, Salma Abadlia, Berriche Olfa & Jamoussi Henda
Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia

Introduction
Obesity exposes to multiple complications, including cardiovascular and metabolic ones. It can also cause respiratory problems, which are still insufficiently researched. The objective of this study was to detect respiratory abnormalities in a group of obese people followed in an obesity unit.
Methods
This was a descriptive and analytical cross-sectional study of 100 obese patients consulting at the human obesity research unit of the National Institute of Nutrition in Tunis. Each patient underwent a clinical examination (history, anthropometric parameters, eating habits, symptoms of obstructive sleep apnea syndrome) and a biological assessment.
Results
The average age of our patients was 45.08 $\pm$ 13.93 years, with a clear female predominance (88%). The average weight was 103.76 $\pm$ 17.9 kg. The average BMI was 38.95 $\pm$ 5.72 kg/m^2. The average waist circumference was 123.88 $\pm$ 13.13 cm and the average fat mass was 45.98 $\pm$ 12.22 kg. Sedentary lifestyle was noted in 60% of the study population. 44% of the subjects were overweight, 33% had class I obesity, 20% had class II obesity and 3% had class III obesity. The majority of our population (72%) had central obesity. Within this population, 53.5% had dyspnoea, 65% had nocturnal snoring, 50% described daytime sleepiness and 31.3% experienced apnea during sleep. The analytical study showed a positive association between BMI and the onset of possible nocturnal snoring. On the other hand, no positive association was found between BMI and the following factors: dyspnea, daytime sleepiness and the onset of apnea during sleep.
Conclusions
The diagnosis of obstructive sleep apnea requires a systematic and early approach to clinical screening for respiratory disorders. Better accessibility to respiratory explorations would improve the quality of care in this population.

EP406

Pregnancy in women with diabetes: A review of 100 cases

Imane El Abbassi & Fadwa Atfi
CHU Ibn Rochd , Maternity Department, Casablanca, Morocco

Introduction
Pregnancy in diabetics is one of the most frequent forms of high-risk pregnancy. It requires diabetic-obstetric-neonatalogical collaboration. Its risks affect the fetomaternal prognosis in the short and long term. Materials and methods: The aim of our work is to establish the main difficulties in the management of diabetic pregnancy. This is a retrospective study of 100 pregnant diabetic patients followed at the maternity hospital of CHU IBN ROCHD of CASABLANCA, for a period of 2 years. Results: The average age of the patients was 32 years. In 40% of the cases, it was a type I diabetes and 49% a type II diabetes. Gestational diabetes, on the other hand, represented only 11%. Gestational age at the time of the first consultation is on average 2 months, the monitoring rhythm is one consultation per month. Self-monitoring of blood glucose is performed in only 19% of cases. Diabetic pregnancy was complicated by foetal death in 14% of cases, macrosomia in 15% of cases, urinary or genital infection in 17% of cases, spontaneous abortion in 6% of cases and pregnancy toxemia in 1% of cases.
Discussion
The prognosis of pregnancy in diabetic women has improved considerably over the last few years in developed countries, thanks to better management, based on the planning of the pregnancy, justifying the use of reliable contraception, perfect glycaemic control even before conception, rigorous obstetrical, diabetic and neonatal monitoring, and the active participation of the patient. In the light of our study and its comparison with some data in the literature, we feel it is appropriate to emphasise a number of points: The importance of preconception management, in order to optimise glycaemic control before pregnancy, based on education and the implementation of insulin therapy techniques. Good management also requires the motivation of the diabetic woman who must collaborate with a multidisciplinary team. Facilitating access to material means for control and treatment is essential.
Conclusion
Diabetic pregnancy is a high-risk pregnancy for the mother and the foetus. Good medical surveillance by a multidisciplinary team from the preconceptional period until delivery allows a significant reduction in fetomaternal complications. Patient education and information are an integral part of the management of diabetic pregnancy.

Diabetes and pancreatic cancer: what link?

Faten Haj Kacem Akid, Asma Zargni, Kawthar El Arbi, Dhoha Ben Salah, Mnif Fatma, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Diabetology and Endocrinology, Sfax, Tunisia

Introduction
Pancreatic cancer is one of the digestive system cancers whose prognosis has not been improved, both in terms of early diagnosis and prognosis, despite the progress in clinical, radiological and biological investigation. A significant number of patients present at the time of diagnosis of this cancer, or just before, a relatively recent onset diabetes. The link between diabetes and pancreatic cancer is established, but it is sometimes difficult to distinguish whether its occurrence is the cause or the consequence of diabetes. Hereby we report 4 observations.
Observation
The 1st case was a 64-year-old woman. The diagnosis of a metastatic biliopancreatic adenocarcinoma was discovered fortuitously on abdominal ultrasound. Palliative chemotherapy was indicated. Diabetes was discovered during the pre-chemotherapy workup with a blood glucose level of 5 g/l. She was on insulin therapy. The 2nd and 3rd cases: Male patients aged 57 and 71 years respectively, diabetic for 1 year and 3 months on Metformin. A pancreatic adenocarcinoma was discovered in front of weight loss and jaundice. Both of them were treated surgically and put on insulin therapy. The 4th case was a man of 84 years old hospitalized for inaugural diabetic ketosis with an altered general condition. During his hospitalization, he developed jaundice associated with abdominal pain. Abdominal ultrasound revealed an extensive process at the head of the pancreas.
Discussion-Conclusion
The relationship between pancreatic carcinoma and diabetes has been shown in different studies, but whether it is a cause or a consequence of diabetes is not clear. Pancreatic tumors are three times higher in the diabetic population than in the general population. Pancreatic cancer presents problems that we do not know how to solve, especially the circumstances in which cancer should be sought in a patient with diabetes. In two of our observations diabetes preceded pancreatic cancer. The pathophysiological mechanisms of diabetes mellitus in these cases are multiple. At present, there is no systematic screening strategy for pancreatic cancer in diabetics. Particular attention should be paid to any diabetic patient with disturbances of the liver function.

Hypothroidism and cardiovascular risk in type 2 diabetic's patients

Ines Bani, Zohra Hadj Ali, Meriam Dalhoum, Yosra Htira & Feika Ben Mami
National Institute of Nutrition of Tunis, Department C, Tunis, Tunisia

Introduction
Hypothyroidism is a frequent endocrinopathy in type 2 diabetes (T2D) which can influence the cardiovascular profile in these patients. Our aim was to study the relationship between hypothyroidism and the occurrence of cardiovascular events in patients with T2D.
Method
It is a retrospective study, including 184 T2D patients, conducted in the department C of the National Institute of Nutrition of Tunis during the year 2021.
Results
The average age of our patients was 61 ± 10 years, predominantly female 64.1%, with an average duration of diabetes of 14 +/- 8 years. The prevalence of hypothyroidism was 14%. Patients with diabetes and hypothyroidism were mostly female (72%), and more than half of the patients were older than 65 years. These patients had dyslipidemia in 84% of cases. Obesity and metabolic syndrome were present in 64% and 72% of patients respectively. The average body mass index was 31 ± 6 Kg/m^2. Hypothyroidism was significantly associated with macro-angiopathy complications ($P = 0.038$) mainly coronary artery disease ($P = 0.027$). A significant association was also notified with renal failure ($P = 0.046$).
Conclusion
The coexistence of T2D and hypothyroidism predisposes to an increased cardiovascular and renal risk in type 2 diabetic's patient. This highlights the importance of early detection of this pathology.

To study the Diabetic Foot at risk using an A 60 second Foot Screening Tool and Risk classification based on the comprehensive foot examination in patients of diabetes - At a Tertiary care Center East India

Kishore Behera[1], Uttam Soren[1] & Binod Kumar Behera[2]
[1]AIIMS Bhubaneswar, Endocrinology & Metabolism, Khordha, India; [2]AIIMS Bhubaneswar, Community Medicine & Family Medicine, Khordha, India

Introduction
The aetiology of a diabetic foot ulcer is multifactorial. The three principal components that ascertain the likelihood of ulceration in a diabetic foot are peripheral neuropathy, repeated minor trauma and deformity. Aims:To find the prevalence of diabetes patients having the foot at risk using the Simplified 60-Second Diabetic Foot Screen tool (SSDFST).
Objectives
To find out the diabetic foot at risk.
1. To ascertain the dispersal of various categories of the foot at risk in patients with diabetes and the factors that modify it
2. To find out the association of neuropathy to the various diabetes risk factors.

Materials and Methods
This was a cross-sectional study comprising of 128 patients; a detailed history and examination including neurological and vascular assessment were performed attending a Tertiary Care Hospital. Patients were screened for the risk of diabetic foot using the SSDFST. The detection of loss of protective sensation (LOPS) using a simple 10-g monofilament test (10 g M) was highly predictive of subsequent ulceration had been reported by the Seattle Diabetic Foot Study. Foot at risk was correlated with demographic and clinical features. Data were analyzed using descriptive and inferential statistics, significant at $P = 0.05$.
Results
Out of 128 patients;92(72%), 36(28%) were male and female respectively. The mean duration of diabetes was 7.42 ± 6.233 years (range 1-27). The mean age, BMI, of the study population was 53.125 ± 10.997 years; 25.93 ± 4.464 kg/m^2 respectively. sOut of 128 patients, 82(64%) were normal without any risk factor for diabetic foot, and 46 (36%) patients had at least one risk factor for the diabetic foot using SSDFST. About 36% of patients were combinedly qualified for the foot at risk into (category 1, 2 and 3); among which 06 (5%) were placed under (category 1). 18 (14%) patients were classified into risk category 2 with LOPS + PAD and 22 (17%) into category 3 with a history of ulcer and /or amputation. The duration of diabetes, previous foot ulcer, deformity, absent pedal pulses, active ulcers, neuropathy, all these factors ($P = 0.05$) were significantly associated with neuropathy measured by 10 g M.
Conclusions
Our study revealed that one-third of our patients had at least one risk factor for the diabetic foot by using an SSDFST. About one-fifth of our patients had neuropathy detected by monofilaments. One-tenth of the study population were aware of proper foot care practice.

Keywords
Diabetic foot, Simplified 60-Second Diabetic Foot Screen tool (SSDFST, 10 gm monofilaments.

Cognitive decline and diabetes: what is the relationship?

Nour Hentati, Zohra Hadj Ali, Maryam Naifar, Yosra Htira & Feika Ben Mami
National Institute of Nutrition and Food Technology of Tunis, Tunisia

Introduction
The number of elderly with cognitive decline has been increasing. Several studies have shown that diabetes is a risk factor for cognitive impairment. Chronic hyperglycemia is implicated, probably by promoting the development of cerebral microvascular disease but physiopathology is complicated.
Methods
The study involved thirty-seven diabetic patients hospitalized in the department C of National Institute of Nutrition and Food Technology of Tunis and who responded to the mini-mental-status examination (MMSE) scale.
Results
We included in our study thirty-seven diabetics patients over 65 years old. The sex ratio (M/F) was 0.68. The mean age was 70.9 ± 3.5 years and the mean duration of diabetes was 15 ± 9.1 years. The mean HbA1C was 10.5 ± 2.3 and the mean BMI was 29 ± 6.9. We examined the frequency of cognitive impairment using the MMSE. An MMSE score of 26 or less was adopted as an indicator of cognitive impairment. The average MMSE score was 22 ± 6.5. The prevalence of cognitive impairment in our sample was 56.8%. The score declined with increasing age and long diabetes evolution. The cognitive impairment was associated with low level of education and the presence of hypertension and there were no significant association with the smoking.
Conclusion
Cognitive impairment is highly prevalent among the elderly. Subjects with disturbed glucose metabolism may be at risk of impaired cognitive function, as these disturbances can influence cognition through atherosclerosis, thrombosis and hypertension. That's why, routine screening of cognition in older subjects with diabetes is recommended.

Retinal vein occlusion: let's stay classic and don't forget diabetes!

Selma Massanou[1], Asma Kefi[1], Khaoula Ben Abdelghani[2], Mounira El Euch[1], Syrine Sassi[1], Sami Turki[1] & Ezzedine Abderrahim[1]
[1]Service de Médecine Interne A, Hôpital Charles Nicolle, Tunis, Tunisia; [2]Service de Médecine Interne A, Hôpital Charles Nicolle, Tunis, Tunisia

Introduction
Retinal vein occlusions (RVO) are a heterogeneous group of disorders characterized by impaired venous return from retinal circulation. RVO can be classified into branch retinal vein occlusion (BRVO), hemiretinal vein occlusion (HRVO), and central retinal vein occlusion (CRVO) depending on the site of the obstruction. Major risk factors for BRVO include systemic arterial hypertension, arteriosclerosis, and diabetes, although many associations have been reported including thrombophilia and inflammatory conditions such as Behcet disease.

Herein we report a BRVO in a young man in whom Behcet's disease was suspected.
Observation
A non-smoking 36-year-old patient, type 1 diabetic for 14 years on insulin, with no other significant medical history, presented in ophtalmology department for a brutal decrease in unilateral visual acuity of the right eye. Admission examination found visual acuity 4/10 right, 10/10 left, with skin lesions on both legs. Fluorescein angiography showed BRVO in the right, with bilateral minimal diabetic retinopathy. OCT macula scan found significant macular edema in the right eye requiring intravitreal injections of anti-vascular endothelial growth factor (anti-VEGF). Given the notion of recurrent mouth ulcers and nodular skin lesions, the patient was referred to internal medicine department for suspicion of Behcet's disease. The admission examination found no erythema nodosum, no pseudofolliculitis, no oral or genital ulcer scars. There was no neurological manifestation, no uveitis. Dermatological examination found eruptive lesions on both legs made up of multiple confluent and circumferential erythematous and brownish macules. There were infiltrated erythematous purple inflammatory nodules on the posterolateral sides of leg, some varicosities and oedema. A skin biopsy showed non-specific necrotic remodeling of the hypodermis compatible with lipodermatosclerosis. Glycated haemoglobin (HbA1c) at 7.3%. Besides, blood count ionogram, lipid and thyroid analyzes were normal. An exhaustive etiological investigation. As part of the etiological assessment, looking for Behcet's disease, coagulopathy, or connectivitis, pathergy test was negative. HLA typing didn't show HLA B27 or B51 antigen. In addition, antinuclear antibodies, anti-extractable nuclear antigen, anti-cyclic citrullinated peptides, cryoglobulinemia and antiphospholipid antibodies were all negative. In addition, thrombophilia investigation didn't reveal any anomalies. Therefore, this episode was attributed to diabetes, which is already at the stage of degenerative complications (diabetic retinopathy), and the patient was referred to his ophthalmologist and endocrinologist for follow-up.
Conclusion
Among the wide spectrum of RVO, diabetes remains one of the main causes. Until today, it still one of the leading causes of vision loss. So let's stay classic and don't forget diabetes!

The association of serum magnesium and risk of morbidity and mortality in patients admitted to the intensive care unit: A stratified analysis based on COVID-19 infection classification

Mitra Kazemijahromi[1], HamidReza Samimagham[2] & Azadeh Moradkhani[2]
[1]Endocrinology and Metabolism Research Center, Hormozgan University of Medical Sciences, Bandar Abbas, Iran; [2]Clinical Research Development Center, Shahid Mohammadi Hospital, Hormozgan University of Medical Sciences, Bandar Abbas, Iran

Background
Magnesium deficiency is a common clinical electrolyte abnormality in critically ill patients, related to the higher mortality risk, which is easily ignored. We aimed to investigate the association between magnesium levels and mortality and morbidity in patients admitted to the (ICU) based on COVID-19 infection classification.
Method
A total of 69 patients admitted to the ICU of Shahid Mohammadi Hospital were included in the study. The serum magnesium was measured in IUC patients. Data on score systems SOFA and APACHE, length of ICU stay, and duration of mechanical ventilation was determined. The mortality and morbidity were determined in patients. Also, the COVID-19 infection was detected by PCR test.
Results
The mean $\pm$ SD age of patients (34.8% male) was 52.56 $\pm$ 16.43 years. Out of 69 patients, 18 patients (26.1%) died during hospitalization, and 24 patients (34.8%) required mechanical ventilation. The prevalence of COVID-19 infection was 39.1%(27 patients). Our results showed that there is no difference in serum magnesium in patients based on mortality status. Also, no difference was found in magnesium levels in patients based on most of the morbidities status; however, the magnesium level of patients with kidney failure was significantly higher than patients without kidney failure ($P < 0.05$). Based on the COVID-19 infection classification, there was only a positive correlation between Hypomagnesemia and the length of ICU hospitalization in patients without COVID-19 ($P < 0.05$).
Conclusion
Our findings showed no difference in magnesium levels of patients based on mortality status. Based on morbidities status, patients with kidney failure had higher serum magnesium than those without kidney failure. Also, our results showed no difference in magnesium levels of critically ill patients based on COVID-19 infection status.

Prevalence of pre-diabetes and diabetes mellitus in polycystic ovarian syndrome (PCOS)

Habib Ullah[1], Kalsoom Noor[1] & Abdul Aziz[2]
[1]Sandeman Provincial (CIVIL) Hospital, Quetta, Pakistan; [2]The Aga Khan University Hospital (AKUH), Karachi, Pakistan

Objective
To determine prevalence of pre-diabetes and diabetes mellitus in polycystic ovarian syndrome (PCOS).
Study Design
Cross sectional study. Non probability consecutive sampling was done.
Sample Size
The estimated sample size was 84 women with 95% confidence level and confidence limit of $\pm$5%.
Setting
Outpatient departments of Medicine and Gynaecology & Obstetrics at a tertiary care hospital of Quetta, Pakistan.
Period
January 2021 to October 2021.
Methodology
All women of age 18-40 years who fulfilled the Rotterdam criteria of PCOS were included. Those having fasting blood sugar (FBS) $\geq$ 126 mg/dl or 2 hour blood sugar $>$ 200 mg/dl on OGTT were said to have diabetes mellitus. Those having FBS between 100-125 mg/dl were said to have impaired fasting glucose (IFG) and those having 2 hour blood sugar between 141-199 mg/dl were said to have impaired glucose tolerance (IGT). Their age, BMI and Oral glucose tolerance test (OGTT) results were documented in the proforma. For analysis SPSS version 20 was used.
Results
The mean age in our study was 29.12 $\pm$ 6.39 years and mean BMI was 30.49 $\pm$ 4.83 kg/m^2. A screening OGTT revealed that 7.1% of PCOS individuals have type 2 diabetes mellitus and 30.9% had pre-diabetes (IFG, IGT).
Conclusion
The prevalence of pre-diabetes and diabetes is high in PCOS, the main risk factor is increased BMI. Prevention and education should be undertaken in such individuals to avoid future complications.

Flash glucose monitoring in patients with type 1 diabetes

Mireia García-Ramírez, Ana María Moyano-Sánchez, Paloma Moreno-Moreno, Ángel Rebollo-Román & Maria Angeles Galvez Moreno
Hospital Universitario Reina Sofía, UGC Endocrinología y Nutrición, Córdoba, Spain

Objective
Flash glucose monitoring (FGM) allows non-invasive glucose level assessment. Our objective was to describe the characteristics of these patients and their glycemic control expressed as HbA1c and times in range.
Methods and patients
Observational longitudinal clinical study between January 2021 and December 2021 in patients with DM1 between 14 and 18 years.
Results
95 patients included. Mean age: 16.64 $\pm$ 1.25 years, with a mean DM evolution time of 6.46 $\pm$ 3.93 years. 47.4% women. Mean HbA1c 7.81 $\pm$ 1.77%. FGM metrics: 54.17 $\pm$ 21.25% time in range, 23.61 $\pm$ 9.72% time between 180-250 mg/dl, 17.05 $\pm$ 18.26% time above 250 mg/dl, 4.21 $\pm$ 4.09% time between 54-70 mg/dl, 1.06 $\pm$ 2.21% time below 54 mg/dl. Glycemic CV 38.14 $\pm$ 7.45%. Classically, patients with a HbA1c below 7% were described as well-controlled patients. 32.6% of patients in our series achieved this target. Nowadays, among users of FGM, those categorized as well-controlled patients have to achieve a TIR $>$ 70%, TAR $<$25% and a TBR $<$4% with a CV $<$33% along with an use $>$ 70% of time. 9.5% of patients in our series achieved this target.
Conclusion
- In our series, there are more patients categorized as well-controlled using HbA1c $<$ 7% (32.6%) than using the FGM metrics (9.5%).
- FMI has revealed that using HbA1c is not enough to achieve a good glucose control in our patients.

Lipid profile and deep vein thrombosis

Boudaya Mariem[1], Sana Fendri[1], Ben Salah Raida[2], Jamoussi Kamel[1] & Bahloul Zouheir[2]
[1]Hedi Chaker Hospital, Laboratory of Biochemistry, Sfax, Tunisia; [2]Hedi Chaker Hospital, Internal Medicine, Sfax, Tunisia

Introduction
Homocysteine is an intermediate sulfur amino acid in the metabolic pathways of cysteine production from methionine, which is increasingly involved in various pathological processes (arterial thrombosis, depression, schizophrenia, dementia). We are interested in the course of our work to study its implication on the lipid balance in patients with venous thrombosis.
Materials and methods
This is an observational case-control study, comparing 47 healthy control subjects with 47 patients admitted to the internal medicine department for the management of deep vein thrombosis confirmed by radiological examination. These two groups are matched by age, sex and body mass index. The homocysteine assay was done by an enzymatic method. The determination of total cholesterol and triglycerides was carried out according to an enzymo-colorimetric method. The HDLc assay was performed using an endpoint enzymatic solubilization method.
Results
The mean age of patients and controls was 40.8 $\pm$ 10.5 years with extremes of 18 and 59 years. The two groups consisted of 27 men (57.5%) and 20 women (42.5%) with a sex ratio of 1.35. Cholesterolemia did not show a significant difference (P = 0.63) between the group of patients (mean 4.33 $\pm$ 10 mmol/l) and controls (4.73 $\pm$ 0.9 mmol/l). the triglyceremia did not show a significant difference (P = 0.78) between the group of patients (mean of 1.42 $\pm$ 0.76 mmol/l) and controls (mean of 1.26 $\pm$ 0.6 mmol/l). HDLc was significantly (P <0.001) lower in patients (mean 1 $\pm$ 0.25 mmol/l) compared to controls (mean 1.33 $\pm$ 0.3 mmol/l). Homocysteine was significantly (P <0.001) higher in diseased subjects (mean 17.42 $\pm$ 5 µmol/l) compared to control subjects (mean 9.41 $\pm$ 3.1 µmol/l). Statistical analysis showed that homocysteine correlated positively with LDLc (P = 0.002; r = 0.392) and negatively with HDLc (P = 0.002; r = -0.392).
Conclusion
Homocysteine is a sulfur amino acid involved in many disease processes; this can be partly explained by the effect on lipid metabolism with a decrease in HDLc and an increase in LDLc with their toxic cellular effects.

DOI: 10.1530/endoabs.81.EP416

EP417

Prevalence of metabolic syndrome and its correlates in young PCOS women in South India

Jayashree Gopal[1] & Madhulika Dixit Dixit[2]
[1]DiabEndoIndia, Chennai, India; [2]Indian Institute Of Technology, Biotechnology, Chennai, India

Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders in women, affecting approximately 5% to 8% of premenopausal women. Insulin resistance is believed to be a key pathophysiologic factor and increases the risk of associated metabolic syndrome (MetSyn) and diabetes. We looked at the presence of insulin resistance in young women with PCOS from South India. The data is derived from a larger study of polycystic amenorrheic women looking at endothelial progenitor cell response to a glucose challenge.
Methods
The study population included 39 women with anovulatory cycles and polycystic ovaries on USG. The control group were 20 age and BMI matched healthy volunteers, with normal menstrual cycles. Fasting and postprandial glycemic, lipid, insulin and hormonal measurements were compared between the two groups. Categorical variables and proportion estimates were evaluated for statistically significant difference (P < 0.05) using student's t-test and chi-square test as appropriate.
Results
As defined by the NCEP ATP III criteria, 41% (15 out of 36) of the young PCOS women (average age 22.5$\pm$4.7 years) had metabolic syndrome compared to none (0 out of 20) in the control group (average age 22.2$\pm$3.7 years). Both the groups were matched with respect to BMI, and waist hip ratio. Only the mean waist circumference was significantly higher ((96.6 $\pm$ 12.8 cms versus 90 $\pm$ 9.9 cms, P = 0.04840) in the PCOS women compared to control population. Both insulin resistance and insulin secretion parameters were significantly higher in the euglycemic PCOS as compared to the control group. The insulin resistance was estimated by the HOMA IR (2.94 $\pm$ 2.01 in PCOS vs 1.65 $\pm$ 0.58 in the control, P value 0.0005) and insulin secretion by the HOMA-β values (150.2 $\pm$ 56.86 in PCOS vs 110.9 $\pm$ 29.9 in control group, P value 0-001). The strongest predictor of the presence of metabolic syndrome was the waist circumference (r value 0.64), followed by the HOMA IR (r value 0.66).
Conclusions
In this study, the prevalence of MetSyn was significantly higher in young women with PCOS compared to control group. Waist circumference and HOMA IR are strong predictors of MetSyn. MetSyn is also associated with a higher HOMA-β value in the PCOS women. The high prevalence of insulin resistance and MetSyn drives home the need to screen more aggressively for the metabolic syndrome and insulin resistance in young women with PCOS.

DOI: 10.1530/endoabs.81.EP417

New-onset diabetes after transplantation (NODAT). A case report

Cristina Contreras Pascual[1], Paloma González Lázaro[1], Antonio Moreno Tirado[1], Maria Zhao Montero Benítez[1] & Susana Álvarez López[2]
[1]Hospital La Mancha Centro, Endocrinology Department, Alcázar de San Juan, Spain; [2]Alcázar de San Juan, Primary care physician, Alcázar de San Juan, Spain

New-onset diabetes after transplantation (NODAT) is a serious complication after a solid organ transplantation. It has been reported to occur in 4% to 25% of renal transplant recipients, 2.5% to 25% of liver transplant recipients, 40% to 60% of hepatitis C virus (HCV) infection and 2% to 53% of all solid organ transplantations. The diagnosis is performed using unmodified criteria for diagnosing diabetes in the general population and risk factors are the commonly recognized factors for developing diabetes: obesity, diabetes family history, dyslipidemias, etc. Recent studies suggest that hyperglycemia is associated with an increased risk of hepatitis C virus-related fibrosis development and glycemic control may reduce the risk and severity of recurrence. In addition, it is well known that liver function plays an essential role in glycemic metabolism. That's why it is important to be aware of this bidirectional relation to decrease morbidity and mortality and preserve quality of life. In this report, we describe a NODAT case after liver transplantation whose hyperglycemic state could have preceded a worsening of HCV infection. A 42 years-old woman affected by HCV infection and cirrhosis undergo liver transplantation. After the surgery, she started a posttransplant immunosuppressive treatment (prednisone). Initially her glycemic control was excellent, but five years later she asked her doctor complaining of polyuria and polidipsia. Her endocrinologist performed a blood test that shown a high glycosylated hemoglobin (HbA1c) level (11.6%) and quickly started basal insulin therapy. The study showed a normal C-peptide and negative GAD antibodies, her weight was 70 kg and she had not another diabetes risk factors. Throughout the following years, because of suboptimal control, it was necessary to add a short-acting insulin in the mayor meal (basal-plus insulin regimen) and after one year it was necessary to add insulin also in the other meals (basal-bolus regimen). HbA1c levels decreased to 7%, but some months later the patient suffered a HCV infection recurrence with stage 4 fibrosis. The Digestive System Unit quickly started Sirolimus, a direct-acting antiviral agent. Then, the patient started to lose weight and a year afterthat she had lost 12 kg. Some months later, the patient achieved sutained virological response and insulin sensitivity improved, allowing to decrease insulin therapy until it was withdrawn. In the long run, HCV infection can lead to cirrhosis, hepatocarcinoma and death in some patients. Physicians should be aware of the importance of NODAT and addressing insulin resistance to improve disease prognosis.

Latent autoimmune diabetes in adults revealed by graves' disease

Boutheina Mohamed Ali[1], Mohamed Hamid Abdillahi[2] & Aicha Ahmed[2]
[1]CHU Ibn Sina, Endocrinologie, Rabat, Morocco; [2]CHU Ibn Sina, Rabat, Morocco

Introduction
LADA (Latent Autoimmune Diabetes in Adults), is defined by the association of diabetes after 30 years, the presence of antibodies against pancreatic beta cells and the non-use of insulin therapy within 6 months of diagnosis. Graves' disease is the first cause of hyperthyroidism associating thyrotoxicosis, goiterand exophthalmos with a prevalence 5 times higher in women.
Case report
37-year-old female patient with no notable history, labeled type 2 diabetes, put on oral antidiabetics with good clinical and biological evolution. One (1) year later faced with a glycaemic imbalance, weight loss amounting to 20 kg (Patient was overweight with BMI at 28 kg/m^2) and signs of thyrotoxicosis without

orbitopathy, a thyroid assessment was made (TSH < 0.05 FT4 = 1.92 FT3 = 7.15), TSH receptor antibodies were positive confirming the diagnosis of Graves' disease. Faced with autoimmunity, weight loss and glycemic imbalance, a dosage of antibodies anti-GAD (glutamic acid decarboxylase) was done and came back positive, confirming the diagnosis of LADA in our patient for which she was put on insulin therapy with a good clinical and biological evolution.

Discussion

Epidemiological studies show that 10% of all subjects with diabetes have the characteristics of LADA. Screening with anti-GAD auto antibodies can identify with certainty. The frequency of thyroid autoimmunity in LADA varies in the literature between 20 et 30%. In the cases of patients without goiter or orbitopathy (like our patient), the dosage of TSH receptor antibodies (TRAb) or scintigraphy are useful to confirm the diagnosis of Graves' disease. This work highlights the association of LADA and Graves' disease suggesting an autoimmune poly-endocrinopathy type 2.

Conclusion

In any patient with autoimmune disease, regular monitoring is indicated to detect the outbreak of a possible autoimmune polyendocrinopathy.

Flash glucose monitoring in DM1: Our experience in a secondary referral hospital

Mª del Carmen Serrano Laguna, Ana Barrera-Martín, Ángel Rebollo-Román, Julia Silva-Fernández & Maria Angeles Galvez Moreno
Hospital Universitario Reina Sofía, UGC Endocrinología y Nutrición, Córdoba, Spain

Objective

Flash glucose monitoring (FGM) allows non-invasive glucose level assessment. Our objective was to describe the characteristics of patients in a secondary referral hospital and their glycemic control expressed as FGM targets.

Methods and patients

Observational longitudinal clinical study between January 2021 and December 2021 in patients with DM1 referred to a secondary care center in Montilla (Córdoba).

Results

101 patients included. Mean age: 42.38 ± 15.63 years, with a mean DM evolution time of 19.46 ± 12.49 years. 44.6% women. Mean HbA1c 7.75 ± 1.13%. FGM metrics: 56.57 ± 18.58% time in range, 23.5 ± 10.74% time between 180-250 mg/dl, 15.87 ± 17.05% time above 250 mg/dl, 3.90 ± 4.50% time between 54-70 mg/dl, 0.84 ± 1.90% time below 54 mg/dl. Glycemic CV 37.31 ± 7.32%. Among users of FGM, those categorized as well-controlled patients have to fulfill the following criteria: TIR ≥ 70%, TAR ≤ 25%, TBR ≤ 4% with a CV ≤ 36% as long as ≥ 70% of glucose data is obtained. In 64.4% of our patients ≥ 70% of glucose data was registered with FGM. In this subgroup 10.8% of patients fulfilled well-controlled criteria. The reason why patients did not achieve the criteria of adequate control is shown in table 1.

	Fulfill criteria		Not fulfill criteria	
Parameter	**n**	**%**	**n**	**%**
TIR	14	21.5	51	78.5
TAR	18	27.7	47	72.3
TBR	41	63.1	24	36.9
CV	28	43.1	37	56.9

Conclusion

- In our series of patients, more than a third of them (35.6%) don't present with enough FGM data. ‐ensp;Out of patients with enough FGM data, only 10.8% patients of them achieve a good control if we use FGM criteria for adequate glycemic control.
- Among the criteria of good glycemic control, TIR is the least achieved in our patients (21.5%), whereas adequate TBR was the most achieved criterium (63.1%).

The effects of Semaglutide on glycaemic control and weight, in type two diabetic patients, in our diabetic day center

Azhar Al-Shaibany [1], Olivia Mc Cabe[2,3] & Shah Shabaht[1]
[1]Our Lady's Hospital, Endocrinology and GIM, Navan, Ireland; [2]Our Lady's Hospital Navan, Co. Meath, Navan, Ireland; [3]Our Lady's Hospital, Diabetes Day Center, Navan, Ireland

Introduction

Type two diabetes is characterized by a chronic metabolic state (obesity, high blood pressure, and dyslipidemia) and insulin resistance. There is insufficient pancreatic insulin production and ineffective use of the produced insulin resulting in abnormally high blood glucose levels (hyperglycaemia). Metabolic syndrome and diabetes are associated with increased cardiovascular risk, reduced life expectancy and a reduction in quality of life. Glucagon-like peptide 1 (GLP-1) receptor agonists are used in type 2 patients whose HbA1c remains uncontrolled despite the use of multiple oral therapies. This audit was designed to evaluate the effect of Semaglutide initiation on HbA1c and weight change in patients from diabetic day centre of our Lady's hospital Navan.

Method

Patients with type two diabetes commenced on Semaglutide were identified from their medical notes from the diabetic day centre of OLHN. Patients were commenced on once weekly Semaglutide of 0.5 mg sub cutaneous once weekly and up titrated to a dose of 1mg as tolerated. In total 30 patients were identified and included in this audit. The mean age of participants was 52 years. All patients had in person review prior to commencement to identify them as candidates for treatment and have an objective weight and HbA1c recorded prior to commencement.

Results

85% patients commenced on Semaglutide achieved the Nice guidelines standard reduction in HbA1c. More than 75% of patients commenced on Semaglutide lost > 5% of their body weight and the remaining had modest weight reduction (< 5%).

Conclusion

From our snapshot audit we have demonstrated that patients in our hospital demonstrated significant reductions in both HbA1c and/or weight when commenced on either 0.5 or 1 mg of Semaglutide once weekly.

Chronic diabetes imbalance in hospitalized patients: what are the causes?

Skander Msolly, Yosra Htira, Chaima Sdiri, Maryam Cheikhrouhou, Zohra Hadj Ali, Hedfi Imene, Chaima Jemai & Feika Ben Mami
Institut De Nutrition, Tunis, Tunisia

Introduction

Diabetes balance is associated with a reduction in mortality and in cardiovascular risk in patients with diabetes [1,2]. The aim of this study was to determine the causes of chronic diabetes imbalance in hospitalized patients with diabetes.

Methods

A cross-sectional study was conducted in a department of diabetology at the Institute of Nutrition of Tunis during 3 months (from September 2021 until December 2021). Patients hospitalized for an imbalanced diabetes were included.

Results

We included 65 patients. The sex ratio (M/F) was 0.66. Among patients included,84.6% were type 2 diabetics, while 15.4% were type 1 diabetics. The mean age was 55.04 ± 16.69years [16-87]. The mean Body Mass Index (BMI) was 29.09 ± 6.95 kg/m^2 [16.63- 51.14]. The mean glycated hemoglobin (HbA1c) level was 10.88% ± 1.6 [7.5 -14]. The Mean hospital stay was 5.07 ± 2.53 days [2 -15]. Almost all the patients (92.3%) were receiving insulin. Diet deviation and therapeutic errors were found respectively in 64.6% and 40% of patients with chronic diabetes imbalance. Poor compliance and skipped injections were found in 26.2% of patients. Lipodystrophies were found in 10.8% of cases. Symptoms of insulinopenia were found in 26.2% of patients. Infections were documented in 6.2% of patients among whom urinary infections were found in 77.4% of cases. Improper handling of insulin was found in 3% of patients.

Conclusion

Any diabetes service should provide highly structured diabetes education program to help people with diabetes learn basic information about diabetes and its management, adopt healthy eating habits through nutrition education, including meal-planning.

Dietary rules in type 2 diabetic patients: degree of compliance and determining factors

Mehrez Achwak, Wafa Alaya, Selma Mohsen, Najoua Lassoued, Fadia Boubaker & Baha Zantour
Taher Sfar University Hospital, Tunisia

Introduction
Nutrition is a cornerstone of the adequate management of Type 2 diabetes mellitus (T2DM). The aims of our work are to evaluate the degree of observance of dietary rules in T2DM patients, and the factors that influence this observance.
Methods
Cross-sectional study including 84 type 2 diabetic patients followed up in the outpatient endocrinology department of Taher Sfar university hospital from September to November 2021. The data was collected in face-to-face interviews with patients.
Results
The average age was 59 $\pm$ 12 years, with a male predominance (58% of cases). The mean duration of diabetes was 9.4 $\pm$ 6.4 years. The mean HbA1c was 9.9% $\pm$ 2.4. Compliance to dietary recommendation was reported by less than half of patients (46% of respondents). Taking meals based on a dietary plan was reported in 15% of patients, having 3 meals plan per day in 88% of cases, with a regular meal time in 84% of cases, and all these factors were significantly associated to a better glycemic control ($P < 10^{-3}$). Cutting down sweets and sugary was reported in 57%, and fried food and fat intake in 71% of cases and both were significantly associated to a better glycemic control ($P < 10^{-3}$ and $P = 0.04$ respectively). Men and women were comparable in the degree of application of dietary rules. Besides, urban residents had better dietary practice than rural residents. Barriers for adherance to dietary recommendations were: cultural backround and communal network in 86% of cases, poor self-discipline and lack of motivation in 70% of cases, poor dietary knowledge and lack of education in 67% of cases, financial constraints in 51% of cases, lack of awareness in 33% of cases, lack of self-control in 21% of cases, fear of hypoglycemia in 19% of cases and eating outside home (in work) in 9% of cases.
Conclusion
Dietary compliance in T2DM patients is still far below the objectives. It is determined by several factors, in particular dietetic education which proves to be insufficient. Through the mutual efforts, health-care professionals can help their patients in achieving health goals by individualizing their nutrition interventions.

Particularities of diabetes discovered after the age of 65

Ramla Mizouri, Faten Mahjoub, Nadia Ben Amor, Rym Ben Othman, Berriche Olfa & Jamoussi Henda
Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia

Introduction
Diabetes mellitus is a disease that is progressing at an alarming rate in the world. In the elderly, the symptoms are often insidious and atypical, which can delay the diagnosis and the establishment of effective treatment. Indeed, management is not always easy because it must take into account multiple parameters. The objective of our study was to study the clinico-biological and etiological profile of diabetes discovered after the age of 65 years.
Methods
We conducted a retrospective observational study at the National Institute of Nutrition and Food Technology in Tunis, over a period from January 2018 to September 2021. Data were collected from patients' medical observation records. We prepared an information sheet which was used for the statistical analysis of the data.
Results
We collected 35 elderly diabetic patients. The age of the patients varied from 70 to 89 years with an average age of 76.2 $\pm$ 4.5 years. Our population was characterized by a female predominance (66%). Hyper-LDLemia type dyslipidemia was present in 69% of cases with an average duration of evolution of 3.35 $\pm$ 2.56 years. Hypertension was present in 40% of the study population. Diabetes was discovered incidentally in 49% of cases. The average duration of diabetes in our population was 5.89 $\pm$ 3.91 years with extremes ranging from 1 to 14 years. The average age of discovery was 70.29 $\pm$ 4.44 years with extremes ranging from 65 to 79 years. All of our patients were type 2 diabetics. Fasting blood sugar was on average 10.47 $\pm$ 4.32 mmol/l with extremes ranging from 6.1 to 29.4 mmol/l. The glycated hemoglobin varied between 6.5% and 13.9% with an average of 8.9 $\pm$ 1.9%. More than half of the population had an HbA1c greater than 8.5%. Diabetic retinopathy was present in 40% of patients. Peripheral neuropathy was present in 27% of patients with an average DN4 score of 4.3 $\pm$ 1.3. Autonomic neuropathy was mainly manifested by gastroparesis (29%) and orthostatic hypotension (11%). Macroangiopathic complications were dominated by coronary insufficiency (11%) and history of stroke (9%).
Conclusion
These results should encourage the medical community to strengthen screening for diabetes in the elderly and to systematically search for cardiovascular risk factors and, in particular, geriatric syndromes which are often overlooked.

Correlation of body mass index with random blood sugar levels in rural indians – a hospital based study

Aniket Inamdar[1], Bharat Saboo[2] & Abhisekh Shrivastav[3]
[1]Samarpan Clinic, Internal Medicine, Omerga, India; [2]Prayas Diabetes Center, Diabetology, Indore, India; [3]R & R Hormone Clinic, Endocrinology, Jabalpur, India

Background
Obesity is the most important modifiable risk factor in the pathogenesis of type 2 diabetes. Prevalence of diabetes is increasing in India, possibly due to a rise in obesity and changing lifestyles with nutrition transition. Body mass index (BMI) is positively and independently associated with morbidity and mortality from type II diabetes mellitus, hypertension, cardiovascular disease and other chronic diseases. In Caucasian and Asian populations, a strong association has been depicted between BMI and mortality. Glucose homeostasis is usually tightly regulated and when individuals' transition from normal glucose metabolism to prediabetes and diabetes, glycemic variability increases. Studies thus suggest that random blood sugar (RBS) elevations provide an early warning sign of glycemic dysregulation.
Aim
The main objective was to determine the correlation between BMI and RBS of patients in rural India.
Materials and Methods
310 patients from age 30 to 85 years who visited our hospital in rural India from January 10.2021 to February 27.2021 were included in this study. Random blood glucose was estimated using the glucose oxidase method using venous sample. BMI was calculated using standard formula using patients weight in kilograms (kg) and height (m^2). Using this, the patients were categorized as underweight ($<$ 18.5 kg/m^2), normal or lean BMI (18.5–22.9 kg/m^2), overweight (23.0 –24.9 kg/m^2) and obese ($\geq$25 kg/m^2) based on the revised consensus guidelines for India. One way ANOVA, post hoc Tukey test and Pearson's correlation test were used to analyse the data.
Results
Statistical analysis showed positive correlation between BMI and RBS. As BMI increased, there was rise in RBS with $P = 0.001$. Comparison of RBS with BMI using one way ANOVA test showed that the mean value of RBS in Obese individuals (165.92) is highest followed by overweight (143.36), normal or lean BMI (137.07) least in underweight individuals (124.34). This difference was statistically significant with a test value of 5.636 and p value of 0.001.
Conclusions
In this present study, BMI and RBS were positively correlated among the 310 subjects who participated in the study. Individuals who are overweight tend to have a detrimental and inactive lifestyle, which might also contribute to the development of adiposity, insulin resistance, hyperglycemia and other cardiovascular risk factors. Strategically, it is crucial to prevent prediabetes and diabetes by controlling risk factors, such as weight gain or excessive weight by promotion of regular physical activity and balanced diet.

Association of fasting plasma glucose levels with wake-up timings in diabetic patients in India

Aniket Inamdar[1] & Bharat Saboo[2]
[1]Samarpan Clinic, Omerga, India; [2]Prayas Diabetes Center, Indore, India

Background
The median sleep time per night has been declining in the world consistently over last 5 decades. The timing of sleep is distinct characteristic of sleep patterns that may impact metabolic disease risk independent of sleep duration, possibly through the effects of circadian rhythms on metabolism. The sleep and wake up timings are driven by both endogenous circadian rhythms that regulate sleep propensity, energy homeostasis and metabolism as well as by sociocultural factors that influence behaviour. As diabetes mellitus carries a high risk of cardiovascular-related mortality, the impact of sleep deprivation on glucose regulation suggests a mechanism whereby short sleep time might increase mortality.
Aim
Aim of our study was to determine the association of wake-up timings with fasting plasma glucose levels in rural Indians.
Materials and Methods
512 diabetic patients between age group 25 years to 75 years who visited our hospital in rural India from September 11, 2020 to June 15, 2021 were studied. Sleep timings and wake up timings were noted. Fasting plasma glucose levels were obtained by venepuncture after an overnight fast of at least 8 hours and blood glucose estimation done by the hexokinase method. One way ANOVA and post hoc Tuckey test were used for analysis.
Results
We found that fasting plasma glucose was significantly higher in patients who wake up after 0700 hours compared with patients who wake up early before 0600 hours. This difference was statistically significant with *P* value of less than 0.001. Furthermore, fasting plasma glucose values were significantly less (better) in the patients who wake up before 0500 hours.
Conclusions
Our study supports that waking up early (before 0600 hours) in the morning can lead to better fasting glucose levels compared to those who wake up after 0700 hours. One possible explanation for these associations is circadian disruption, which occurs when different endogenous circadian rhythms are not synchronized with one another and/or with the external world. Circadian disruption could occur when the timing of volitional behaviours, including sleeping and eating, are not aligned with the endogenous circadian rhythms of associated physiological processes, such as sleep propensity, insulin sensitivity, or glucose metabolism. Waking up early provides more time to do physical activity and also for recreational purpose which leads to better fasting blood glucose levels. Further research is necessary to determine whether sleep and wake up timings do in fact lead to alterations in glucose metabolism.

The role of deferoxamine (DFO) in insulin resistance and diabetes

So-Yeon Ahn[1], Min Woo Song[2], Jae Yeop Jeong[2], Tae Ho Kim[3], Sung-E Choi[4], Yup Kang[4], Hae Jin Kim[2], Ja Young Jeon[2], Seung JIN Han[2], Nami Lee[2] & Kwan-Woo Lee[2]
[1]Busan Bumin Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Busan, Rep. of South Korea; [2]Ajou University School of Medicine, Department of Endocrinology and Metabolism, Suwon, Rep. of South Korea; [3]Seoul Medical Center, Division of Endocrinology and Metabolism, Department of Internal Medicine, Seoul, Rep. of South Korea; [4]Ajou University School of Medicine, Department of Physiology, Suwon, Rep. of South Korea

Iron also plays an important role in many physiological processes, including redox balance, inflammation, and metabolism. It is reported perturbation of iron (Fe) homeostasis has also been associated with metabolic diseases. Iron reduction, with iron chelator, has preventive effects in cardiovascular remodeling and obesity. On the other hand, deferoxamine (DFO) increases hypoxia and collagen production in the kidney. Thus, the effects of DFO on metabolic disease remains controversial. As a result, we investigated the effects of DFO on obesity, inflammation, insulin resistance, and diabetes in db/db mice models with type 2 diabetes. An in vivo study was performed on 7-week-old db/db mice. Mice were treated with DFO (100 mg/ kg) or placebo every other day for 16 weeks. After treatment, an intraperitoneal glucose tolerance test and immunohistological examinations were performed. Fasting insulin and serum lipid levels were measured at the end of the study. Also, genes involved in inflammation and lipid metabolism were analyzed by real-time PCR. The DFO treated mice showed improved obesity, insulin resistance, and decreased levels of plasma inflammatory cytokines, total cholesterol, free fatty acid, and triglycerides. Fasting glucose in mice was also reduced by DFO treatment. Immunoblot analysis shows transferrin receptor 1 (TfR1) levels were increased in skeletal muscles of db/db mice models with type 2 diabetes. But DFO treatment decreased transferrin receptor 1 (TfR1) levels in skeletal muscles. DFO treatment also attenuated inflammatory cytokines and lipid deposition in the liver. Therefore, we consider the fine tuning of iron levels through DFO treatment as highly suggestive for preventing and/or treating insulin resistance and diabetes.

Assessment of hypoglycemic properties of extracts from some medicinal plants in the experimental diabetes model

Talat Saatov[1], Elvira Ibragimova[1], Sanobar Irgasheva[1], Mokhammad Mustafakulov[1], Malika Salakhutdinova[2], Tokhir Ishankhodjaev[1], Nigora Samarkhodjaeva[1] & Bakhodyr Zainutdinov[1]
[1]Institute of Biophysics and Biochemistry under Mirzo Ulugbek National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [2]A.S. Sadykov Institute of Bioorganic Chemistry, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan

Phytotherapy is the integral part of the combined treatment for diabetes mellitus. A large number of plants possessing hypoglycemic activity are described in the literature, but only small part of them is in use. Hypoglycemic effect of medicinal plants is preconditioned by the wide spectrum of compounds with biological activity in their composition. Flowers of carthamus (*Carthamus tinctorius*) and leaves of celery (*Apium graveolens*) are known to possess a number of therapeutic effects. In combination, bioactive compounds are known to amplify each other's effects. In this connection, we have studied hypoglycemic activity of aqueous extracts of carthamus flowers and celery leaves, as well as the mixture of their extracts in rats with alloxan diabetes. The extracts were administered intragastrically for 2 weeks. The experimental animals were divided into 5 groups. Intact animals were included into the 1st group, the 2nd groups consisted of animals with alloxan diabetes (alloxan controls), the 3rd one included those administered with carthamus flowers, the 4th group consisted of those administered with celery leaves; animals with alloxan diabetes administered with the mixture of carthamus flowers and celery leaves (1:1) were included into the 5th one. Our findings demonstrated the reduction in the blood glucose of all animals with experimental diabetes after a course administration of the extracts, as compared to the alloxan controls. Thus, blood glucose in rats with alloxan diabetes for 2 weeks administered with the mixture of carthamus flowers and celery leaves was found to reduce from 18.4 mmol/l to 5.7 mmol/l and 8.5 mmol/l. respectively, while in rats with alloxan diabetes it declined due to regeneration of β-cells to 13.5 mmol/l. Following the course administration of the extracts, the blood glucose in animals similarly reduced reaching the normal parameters. Hypoglycemic effect of the extracts under study increased in this order: celery extract, carthamus-celery mixture and carthamus extract.

Patient with pancreatic diabetes and insulin pump

Dimitra Pappa, Eleftheria Barmpa, Maistros Linaras, Panagiotis Tsakos, Nikolaos Zikos & Alexandra Bargiota
University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
Pancreatic diabetes is a special category of diabetes due to diseases of the exocrine pancreas, characterized by both insulin and glucagon deficiency and clinically could be very challenging to control. We present a case of a woman with pancreatic diabetes treated with sensor augmented pump therapy after undergoing total pancreatectomy for a nonfunctional pancreatic neuroendocrine tumor (NET).
Presentation
A sixty-one years old woman underwent two years ago total pancreatectomy for a non-functioning neuroendocrine tumor. Consequently she developed pancreatic diabetes and was treated with a basal - bolus insulin regime. Her diabetes was poorly controlled despite all efforts due to severe, frequent and sudden hypoglycaemic attacks, affecting her quality of life. Her HbA1c was 8.5% and

her Time in Range (TIR) was 28%, Time above range (TAR) 56%, Time below range (TBR) 16%, Glucose management Indicator (GMI) 8.5%, Glucose Variability (GV) 34.1% and Average Glucose (AG) 233 mg/dl. To achieve a better management of her diabetes, a sensor augmented pump (SAP) therapy was initiated and she was greatly improved (TIR 60%, TAR 40%, TBR 0%, GMI 7.5%, GV 30.6% and AG 173 mg/dl) and hypoglycemia was not a problem any more. Conclusion:Treating patients with pancreatic diabetes could be very challenging. Sensor augmented pump therapy can greatly improve their glycemic control, but most of all their quality of life.

Low serum epidermal growth factor level is associated with lack of diabetic control in type 2 diabetes mellitus in diabetic patients in Jordan

Ahmed Al-Dwairi & Mahmoud Alfaqih
Jordan University of Science and Technology, Faculty of Medicine, Irbid, Jordan

Background
The worldwide type 2 diabetes mellitus (T2DM) prevalence is increasing dramatically. Inflammation is involved in the pathogenesis of T2DM and development of insulin resistance. Lack of diabetic control is associated with alteration in the endocrine milieu and various health sequalae's. The aim of this research was to assess if uncontrolled T2DM is associated with increased serum levels of inflammatory cytokines and growth factors when compared with controlled T2DM in diabetic patients in Jordan.
Methods
A single institution, cross sectional study design was used in this research. One hundred and ten patients with controlled DM (HbA< ce:inf>1c<ce:inf> < 7.0%), and 105 age-, gender- and body mass index–matched patient with uncontrolled (HbA< ce:inf>1c<ce:inf> ≥7.0%) DM were recruited from the internal medicine clinic in King Abdullah University Hospital in Jordan. An antibody membrane array was used to evaluate the difference in serum levels of inflammatory cytokines, followed by enzyme-linked immunosorbent assay to confirm the results.
Results
fasting blood glucose, serum insulin, triglyceride and HOMA-IR were significantly higher in the uncontrolled T2DM group ($P < 0.01$). Antibody membrane array showed that epidermal growth factor (EGF) is lower in the uncontrolled T2DM, and this was confirmed by ELISA (158.77 + 111.7 vs 95.9 + 82.7 pg/ml, $P = 0.002$. The binary logistic model was used to predict the likelihood of being uncontrolled diabetic based on EGF levels. After controlling for age, gender, and BMI, EGF was statistically associated with diabetes control; lower EGF levels predicted uncontrolled diabetes.
Conclusion
Our data identify a novel link between serum EGF levels and the status of glycated hemoglobin indicative of diabetic control.

DOI: 10.1530/endoabs.81.EP430

EP431

Body composition and insulin resistance in type 1 Diabetes Mellitus

María Del Carmen Andreo-Lopez, María Teresa Zarco-Martín, Javier García-Sánchez , Victoria Contreras-Bolívar, Pablo López-Ibarra-Lozano & María Luisa Fernández-Soto
Granada, Clinical Nutrition Unit. Endocrinology and Clinical Nutrition Service. San Cecilio University Hospital, Granada, Spain

Introduction
DM 1 is proposed as a condition of accelerated muscle aging and mitochondrial dysfunction as a common link regulating muscle deterioration in aging and DM 1. Loss of muscle mass is associated with insulin resistance, metabolic syndrome and cardiovascular complications.
Objectives
To analyze body composition and metabolic variables related to insulin resistance in overweight/obese patients with DM1.
Material and Methods
Observational, cross-sectional study in patients with DM1 followed up in the Diabetes Clinic of the Hospital Universitario San Cecilio, Granada. Weight (kg) and height (m) were determined and BMI (kg/m^2) was calculated. The recruited individuals were classified according to BMI > or < 25. Demographic variables (age in years), metabolic variables (years of disease, insulin sensitivity factor - FSI- and glycosylated hemoglobin determined by analysis (HbA1c)) and body composition (measurement with AKERN® bioimpendanciometry of fat-free mass (FFM) in%, skeletal muscle mass (SMM) in kg. Calculation of skeletal muscle mass index (SMMI) in kg/m^2).
Results
Forty persons with DM1 were included. 48% had BMI > 25, mean age 43 ± 15 years and suboptimal glycemic control in both groups (BMI < 25: 7.3 ± 1.2 vs BMI > 25: 7.8 ± 1.1, $P = 0.21$).

	IMC < 25	IMC ≥ 25	P
Edad (años)	34.9 ± 14.8	43.2 ± 15.1	0.085
Años DM1	17.4 ± 14.7	27.1 ± 12.7	0.032
FSI	51 ± 23.4	38.4 ± 13	0.042
MLG (%)	76.3 ± 6.1	64.2 ± 9.5	0.00
SMM (kg)	23.1 ± 6.2	24 ± 5.9	0.65
SMI (kg/m^2)	6.5 ± 9	7.44 ± 0.9	0.002

Conclusions
In persons with DM 1 and overweight or obesity, parameters related to less muscle mass and higher insulin requirements are detected, a context associated with insulin resistance. It could be important to establish strategies aimed at maintaining a healthy weight (muscular strength and resistance exercise tables together with a Mediterranean pattern diet avoiding excess calories and optimizing the insulin therapy dose) to reinforce muscular behavior and increase insulin sensitivity, especially in diabetics with more years of evolution with the aim of avoiding metabolic deterioration.

Metabolic impact of flash glucose monitoring system in patients with type 1 diabetes mellitus

Jose Antonio Ariza Jimenez, Eyvee Arturo Cuellar Lloclla, Virginia Hernando Jiménez & Jose Alvaro Romero Porcel
Virgen de Valme University Hospital, Endocrinology and Nutrition, Seville, Spain

Introduction
Adequate glycemic control is essential in the diabetes prognosis. It has been described that the use of glucose monitor systems leads to an improvement in different metabolic parameters as well as facilitating decision making.
Material and methods
Retrospective observational study to evaluate the metabolic impact of flash sensor implantation in a cohort of patients with DM1 of Virgen de Valme University Hospital of Seville. All patients with implantation of the glucose monitoring system in the period 1/1/2020 to 3/31/2020 were included. Subsequently, different metabolic parameters were compared at baseline and at 3, 6 and 12 months after implantation. SPSS program was used for statistical analysis.
Results
154 patients (46.7% men and 53.3% women) have been analyzed. Mean age 40.3 ± 1.02 years. MDI treatment 87.3% vs CSII 12.7%. Previous HbA1c mean to the sensor was 8.03 ± 1.35%, with a sustained reduction observed at 12 months (8.03 ± 1.35% vs 7.68 ± 1.01%; $P = 0.036$). Number of capillary controls before sensor was 3.57 ± 0.23, with an increase in sensor scans at 12 months (3.57 ± 0.23 vs 10.62 ± 0.69; $P = 0.000$). Coefficient of variation before sensor was 47.15 ± 2.08%, with a decrease observed at 12 months (47.15 ± 2.08 vs 37.66 ± 0.63%; $P = 0.000$). Hypoglycemia percentage before sensor was 13.83 ± 1.26%, with a decrease observed at 12 months (13.83 ± 1.26% vs 5.36 ± 0.49%; $P = 0.000$). Percentage of time in range before sensor was 48.8 ± 2.38, with an increase observed at 12 months (48.8 ± 1.26 vs 59.58 ± 1.48; $P = 0.001$). Percentage of hyperglycemia before sensor was 38.08 ± 2.54, with a decrease observed at 12 months (38.08 ± 2.54 vs 35.06 ± 1.6; $P = 0.043$).
Conclusions
- The implantation of the sensor has shown, as in the literature, improvement in metabolic control in terms of HbA1c, number of controls, coefficient of variation, hypo/hyperglycemia time and time in range.
- Some parameters showed initial improvement but attenuated over time.

Why do diabetic patients fail to break the fast in hypoglycemia? About 58 cases

Nezha Raki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Ramadan fasting is associated with an increased risk of hypoglycemia in diabetics.
Purpose of the study
To assess the prevalence of diabetic patients who are unable to break the fast in the event of hypoglycemia.
Method
Descriptive prospective study, including diabetic patients followed in the Endocrinology department of the CHU Ibn Rochd in Casablanca from April to June 2021.
Results
Our study included 58 type 2 diabetic patients, all authorized to fast according to the DAR 2021 risk score. The average age was 57.4 years. Most patients were on sulfonylureas (SH) (51.7%). All our patients received pre-Ramadan education on the need to break the fast in the face of any hypoglycemia. Among the patients observing the fast, 24% presented hypoglycaemia, of which 28% did not break the fast. Hypoglycaemia occurred more frequently in patients on combination insulin and oral agents (OADs) (57%) compared to OADs alone (28%). This reluctance was explained by the occurrence of mild hypoglycaemia close to the time of breaking the fast in 57% of patients.
Conclusion
Despite the pre-Ramadan education of diabetics on the need to break the fast in the face of hypoglycemia, there is a worrying prevalence of patients who are unable to break it.

Management of diabetic patients during the Ramadan fast: application of international recommendations in clinical practice About 91 cases

Nezha Raki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Fasting during the month of Ramadan is a religious rite. Fasting is not without risks in diabetic patients. Several recommendations and consensus of experts have recently made it possible to establish proposals to optimize the management of diabetes during Ramadan, and to specify the authorized population for this sacred practice.
Purpose of the study
To assess the prevalence of type 2 diabetics authorized to fast according to the DAR 2021 recommendations and to compare it with that of the old IDF 2016 classification.
Method
Descriptive prospective study, including diabetics type 2 wishing to fast, followed in the endocrinology and metabolic diseases department of the CHU Ibn Rochd in Casablanca from April to June 2021.
Results
Our study included 91 type 2 diabetic patients with an average age of 58.7 years. The average duration of diabetes was 9.5 years. The average HbA1c was 8.1%, 42% of our patients were on insulin, 43% were on sulfonylureas (SH). In order to compare the recommendations, we classified our patients into 3 groups: group 1: Authorized to fast by the 2 classifications (25.3%), group 2: Not authorized according to the 2 classifications (35.2%) and group 3: 39.5% authorized fasting only by DAR. Among the group 3, 27.7% were on insulin therapy, 33.4% on SH. Acute complications, mainly hypoglycaemia, were observed in 44.5% of these patients.
Conclusion
The latest DAR 2021 recommendations allow a very large diabetic population to fast in Ramadan compared to the old classification. Waiting for more cautious recommendations, the fasting decision must be adapted to each patient, even when the risk score is reassuring.

Dietary survey in diabetic patients during Ramadan

Sara Ragbi, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Uhc Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Ramadan is considered a sacred period during which Muslims practice fasting from sunset until dawn changing the rhythm of life and eating habits. The objective of this study is to evaluate diabetics diet during and after the holy month.
Patients and methods
Descriptive cross-sectional study, including diabetic patients, seen during the month of Ramadan, conducted at the Department of Diabetology and Endocrinology of the CHU Ibn Rochd of Casablanca. Data collection was done by interrogation, followed by an assessment of dietary intake by a 24-hour dietary survey conducted during and after Ramadan.
Results
A total of 74 patients were included, of which 51.35% were female. The mean age was 55.9 years. All patients were type 2 diabetics with a mean duration of 13.7 years and a mean HbA1c of 9.7%. Insulin-treated patients represented 81.08%. Only 24.3% of our patients have fasted. During Ramadan, the total daily caloric intake was lower in the fasting group than in the non fasting group (1658.70 kcal/d versus 1860.41 kcal/d). Among the fasting group, carbohydrate consumption was higher than among the non-fasting group during Ramadan with respectively 52.35% versus 46.59% but fat consumption was higher among the non-fasting group. Fiber and water consumption was lower during Ramadan. The diet of the fasting group during Ramadan was inadequate while that of non-fasters was excessive in lipids, putting them at risk of complications.
Conclusion
The change in lifestyle during the month of Ramadan influences the dietary practices of diabetic patients which can lead to an inadequate diet hence the interest of a nutritional education program before Ramadan.

Insulinoma with Poland Syndrome

Suhail Ahmed[1], Saba Qureshi[2], Shahzeel Raza Qureshi[2], Joshua Ajay[1], Shahid Ahmed Khan[1], George Botoros[3], Satis Kumar[1] & Umesh Kumar Dashora[1]
[1]Conquest Hospital, Endocrinology, Hastings, United Kingdom; [2]Mercy Hospital, General Internal Medicine, Hastings, United Kingdom; [3]Eastbourne District General Hospital, General Internal Medicine, United Kingdom

23-year-old scaffolder, fit and well, presented several times to A&E with episodes of fitting which comprised of an energy surge followed by typical neuroglycopenic and autonomic signs of hypoglycaemia. He was only found to be hypoglycaemic after a severe episode where paramedics were called to his home and discovered his blood sugars to be 1.8 mmol/l with a serum insulin was measurable. His symptoms were moderately relieved by eating a combination of sugary food like honey and a starchy carbohydrate. Insulinomas are the most common cause of hypoglycaemia as a result of hyperinsulinism, though only occurring in 1-4 persons per million[1] They commonly present with autonomic symptoms such as sweating, tremor and palpitations and neuroglycopenic symptoms which include disorientation, behavioural and personality changes, visual disturbances, seizure, and coma. He had multiple presentation to emergency department with shoulder dislocation, Computed Tomography (CT) imaging demonstrated absence of the right pectoralis muscle indicative of Poland syndrome. Poland Syndrome (PS), occurring only in 1 in 20000 new-borns, typically presents with missing or underdeveloped muscles on one side of the body, resulting in abnormalities that can affect the chest, breast, shoulder, arm, and hand. The extent and severity of the abnormalities vary among affected

Test	Results	Units	Reference Range
Plasma glucose (fasting)	1.8	mmol/l	4.1 – 6.1
Serum C-Peptide	612	Pmol/l	298 - 2350
Serum Insulin	4.9	mIU/l	4.4 – 26.0

Assay provided by King's Hospital.

individuals[2] Currently the aetiology of PS is unknown though likely to be genetic. Various syndromic and metabolic potential causes of hyperinsulinism hypoglycaemia have been found, one of which may be due to a sporadic mutation in the UCMA gene, causing 10p13-14 duplication in Poland Syndrome. [3,4] . This case is the first reported case of insulinoma as the cause of hyperinsulinism along with Poland syndrome both of which are rare and unique clinical presentations in themselves. Hyperinsulinism/Insulinomas can present with normal bloods and ECG once symptoms have passed. There is an association between Poland Syndrome and Hyperinsulinism, this link can help in earlier diagnosis/ruling out of one another.

Post COVID-19 complication in patient with diabetes insipidus: what we know nowadays?

Iryna Kostitska[1], Nadiia Zherdova[2], Antonina Piddubna[3], Oksana Zhurakivska[4] & Olga Zhurakivska[4]
[1]Ivano-Frankivsk National Medical University, Endocrinology, Ivano-Frankivsk, Ukraine; [2]Centre of Innovative Medical Technologies, Kyiv, Ukraine; [3]Bukovinian State Medical University, Chernivtsi, Ukraine; [4]Ivano-Frankivsk National Medical University, Ivano-Frankivs'k, Ukraine

A major cause of morbidity is post COVID-19 complications. The symptoms of carbohydrate dysfunction can be due to has relationship with coronavirus disease. In patients with chronic disorders after SARS-CoV-2 infection, aggravation of pre-existing symptoms has also been noticed. Diabetes insipidus (DI) may be at risk of dysnatraemia when developing respiratory complications of COVID-19. Particularly, the combination of two or more concurrent disorder is a major problem in patient treatment. Especially when one of the diseases is a predictor of another. This not only complicates the diagnosis but also prolongs the duration of treatment, sometimes complicating an algorithm of management and reduces its effectiveness. Thus considering the above mentioned facts, we would like to focus your attention on such comorbidities as post COVID-19 complication: diabetes melletus (DM) in patient with DI, and give a sense of this problem on the basis of clinical case study. A 69-year-old female with a past medical history of DI diagnosed five years ago treated with nasal spray desmopressin (10 µg intranasal twice daily) after COVID-19 pneumonia who later manifested DM. She was diagnosed with COVID-19 infection with nasopharyngeal reverse transcriptase polymerase reaction (RT-PCR) at an outpatient clinic 60 days ago. IgG against SARS-CoV-2 was positive. After two month for the treatment of COVID-19 pneumonia the patient complaining of polydipsia, polyuria and nocturia during the previous month. Laboratory examinations showed abnormally increased blood sodium (serum sodium -156 mmol/l) and chloride (serum chloride – 115 mmol/l) and decreased urine osmolality and specific gravity of 1.006. Thyroid function tests were normal. The level of glycosylated hemoglobin (HbA< ce:inf>1</ce:inf>C) was 7.0%, blood sugar levels ranged from 7.6 to 19.0 mmol/l. After additional examination the patient with DI was diagnosed with DM. The patient was prescribed treatment with metformin at a daily dose of 1500 mg during the meal to correct carbohydrate metabolism and added doses of desmopressin (20 µg intranasal twice daily). After 3 months, the therapy resulted in patient's improvement of the general conditions and compensation of DM was achieved: no episodes of hypoglycemia were recorded; the HbA1C level was 6.4%; glycemia levels ranged from 5.4 to 8.0 mmol/l; and normalization of electrolytic metabolism.

Conclusions

Further studies are needed to clarify the link between COVID-19 and DM in patient with DI, to provide the optimal management.

Protective effect of a marine plant on hepatic toxicity induced by a hyperlipidemic diet

Rihab Ben Abdallah Kolsi[1], Kolsi Boulbaba[2] & Noureddine Allouche[1]
[1]Faculty of Sciences, Sfax, Tunisia; [2]CHU Hedi Chaker, Sfax, Tunisia

Introduction

In recent decades, metabolic diseases have continued to increase. Several investigations concerning the origin of these diseases such as dyslipidemia, hypercholesterolemia, diabetes, etc., have been elucidated. These pathologies have been attributed to lifestyles and mainly to diet. Obesity is a serious metabolic and energy disorder, which has become a real major public health problem.

Materials and methods

We were interested in studying the effect of a high-fat diet on liver function, as well as the effect of the extract on rats receiving a hyperlipidemic diet. The variations in liver toxicity parameters in the different groups were highlighted by the study of biochemical parameters and confirmed by the study of liver histology.

Results

Under our experimental conditions, the obese had a significant elevation of serum levels of AST, ALT, LDH and CPK of 32%, 31%, 43% and 22%, respectively. While, administration of the extract to the obese improved all indices of liver toxicity. Histological sections of the livers of rats subjected to a hyperlipidemic diet for 42 days showed the appearance of lipid droplets which correspond to a deposit of fat in the hepatocytes. Whereas, CNSP and orlistat exerted a protective effect against the development of non-alcoholic hepatic steatosis in HFD-rats, objectified by a notable decrease in lipid vacuolations.

Conclusion

Finally, we noted that the result of these positive effects of the CNSP studied on hepatic toxicity was translated by restoring effects of the histological organizations of the liver, making them comparable with those of normal controls. This confirms the important role of this natural product in the fight against oxidative stress and the prevention of hyperlipidemia.

Time restricted feeding 16/8 improves metabolic parameters and fatty liver in obese mice

Camila Astudillo[1], Paula Acevedo[1], Karina Ceballo[1], Marcela Julio[2], Mauricio Dorfman[3] & Gonzalo Cruz[1]
[1]Centro de Neurobiología y Fisiopatología Integrativa (CENFI), Instituto de Fisiología, Facultad de Ciencias, Universidad de Valparaíso, Valparaíso, Chile; [2]Grupo de NeuroGastroBioquímica, Instituto de Química, Facultad de Ciencias, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile; [3]Division of Metabolism, Endocrinology & Nutrition, Department of Medicine, University of Washington, Seattle, United States

Obesity is a major health problem that is crucial in the pathogenesis of diabetes mellitus, cardiovascular diseases, and some types of cancer. Intermittent fasting is an eating pattern in which periods of fasting, lasting from 12 up to 36h, are alternated with periods of eating. Time restricted feeding (TRF) 16/8 is a type of intermittent fasting that is being used to lose weight and for treating metabolic disorders. Several studies in humans have shown a slight effect of TRF on body weight but more consistent effects on metabolic parameters. However, the molecular mechanisms by which these effects occur are poorly understood. We aimed to investigate if TRF 16/8 in mice reproduced the metabolic effects observed in human and tested if TRF 16/8 reduces inflammation in obese mice. We used C57BL/6J mice under a high fat diet for 12 weeks (60%KCal in fat) to develop obesity associated with glucose intolerance and fatty liver. Then we exposed the animals to TRF 16/8 (feeding in active phase) for 6 weeks. We found that TRF decreases body weight without changes in epididymal or subcutaneous fat, it reduces fasting glycemia, improves glucose tolerance, decreases liver weight, and decreases gut epithelial permeability. In addition, TRF increases blood ketone bodies, in particular l-hydroxybutyrate (BHB). These results show that 6 weeks of TRF are enough to produce metabolic improvements in obese mice. Since obesity is characterized by a low-grade inflammatory state and BHB may have anti-inflammatory effects, we propose that BHB induced by TRF has anti-inflammatory effects in the brain and periphery that explain why TRF improves metabolic parameters in obese mice.

Metabolic syndrome in mediterranean patients with mental illness

Salem Jdira[1], AbdelMouhaymen Missaoui[2], Oumeyma Trimeche[2], Houda Hsine[1], Wafa Abbes[1] & Ines Khochtali[2]
[1]Gabes Regional Hospital, Departement of psychiatry, Gabes, Tunisia; [2]Fattouma Bourguiba University Hospital, Endocrinology Departement, Monastir, Tunisia

Introduction

Metabolic Syndrome (MetS) represents a cluster of vascular risk factors related to insulin resistance such as abdominal obesity, hypertension, and glucose and lipid dysregulations. Multiple studies suggest an increasing metabolic risk in psychiatric patients.

Objectives
We aim to assess epidemiological and clinical features of MetS in a Mediterranean psychiatric population.
Methods
We conducted a descriptive cross-sectional study involving 126 patients attending the psychiatry department at Gabes regional hospital, Tunisia, from 2019 to 2020. MetS was diagnosed based on the 2005-IDF criteria.
Results
The mean age was 45.5 ± 12.8 years with a sex-ratio(M/F) of 1.07. The majority were married (49.2%), from urban areas(53.2%), low educational bac kgrounds (59.5%), and low-socioeconomic status households (64.3%). The rate of unemployment was 54%. Addictive behaviors were reported in 35.7% mainly tobacco (31.7%) and alcohol (3.2%). The leading mental diseases were schizophrenia and psychotic disorders (43.7%), depressive disorder (18.3%), bipolar disorder (16.7), and anxiety disorder (16.7%). Obesity was the most common metabolic comorbidity in 37.3% of patients. Dyslipidemia, diabetes, and hypertension were recorded in 17.5%, 12.7%, and 8.7%, respectively. The prevalence of MetS was 25.4%.
Conclusions
The bidirectional interplay between MetS and psychiatric disorders is due to behavioral aspects (sedentary lifestyle, smoking, unhealthy diet), somatic disturbances (chronic inflammation, hypothalamic-pituitary-adrenal axis dysregulation, and insulin resistance), in conjunction with an established metabolic-dysregulating effect of some antipsychotics. A possible shared genetic bac kground between these conditions has also been debated. Psychiatrists should screen their patients for comorbid MetS before and during treatment. Preventive and curative measures should be organized cooperatively with a multidisciplinary team (endocrinologists, diabetologists, and cardiologists) to reduce this serious cardiometabolic burden.

Low hdl cholestero and cardiovascular risk in type 2 diabetes

Ines Bani, Zohra Hadj Ali, Meriam Dalhoum, Yosra Htira & Feika Ben Mami
National Institute of Nutrition of Tunis, Department C, Tunis, Tunisia

Introduction
Low high-density lipoprotein (HDL) is a frequent metabolic abnormality, associated with diabetes, may increase the cardiovascular risk of patients with type 2 diabetes. We aimed in this study, determine the prevelence of hypo HDL cholesterol and assess the associated cardiovascular risk.
Method
It is a retrospective study, including 184 type 2 diabetic patients, conducted in the department C of the National Institute of Nutrition of Tunis during the year 2021. HypoHDl cholesterol was considred if the patients had HDLc (<40mg/dl (men); < 50mg/dl (women)).
Results
The study included 184 patients (118 women, and 66 men), with mean of age 61 +/- 10 years. The prevalence of low HDL cholesterol was 44.6%. Patients with low HDl cholesterol had a slight female predominance (52.5%). Hypertension was present in 70% of patients. Patients were obese and overweight in 56% and 31% of cases, respectively with an average body mass index of 30.63 +/- 5. In addition, they had hepatic steatosis in 28% of cases. the majority of patients had a Glycated hemoglobin out of target (92.5%), with an average HB1AC 10.5 +/- 2%. Moreover a hyper LDL cholesterolemia and hypertriglyceridemia were noted in 39 and 63.4% respectively. coronary artery disease was present in 32.9% of patients.
Conclusion
Low HDlc is a common situation in type 2 diabetes and increases the cardiovascular risk in these patients.

Regulation of glycemic variability in endothelial model: cross-talk between miRNAs and microfilaments in the activation of early fibrotic pathways

Lucia La Sala[1], Pamela Senesi[2], Daniele Capoitanio[2], Elena Tagliabue[1], Anna Ferrulli[2], Ileana Terruzzi[2] & Livio Luzi[1,2]
[1]Multimedica, Lab of Cardiovascular and Dysmetabolic Diseases, Milano, Italy; [2]University of Milan, Milano, Italy

Glycemic variability (GV), a complex phenomenon affecting subjects with diabetes, is one of the main contributors to the risk to develop both acute and long-term complications in type 1 (T1D) and type 2 (T2D) subjects. DNA double-strand breaks, apoptosis, overgeneration of reactive oxygen species (ROS) and the induction of some regulatory micro-RNAs, sustain the ominous mechanisms mainly attributable to GV. The characteristic cellular phenotype induced by GV is scarcely defined. Aims of this study are: 1) to describe a global pattern about the regulation of the major proteins differentially expressed in a cellular (human endothelial cells) model of GV and 2) the role of microRNAs on the pathways activated during the *in-vitro* long-term exposures to GV. We utilized human endothelial cells exposed for 21 days to high and oscillating glucose concentration (25 mM and 5-25 mM, respectively). The omic-based analysis integrating proteomic (2D-DIGE and MALDI/TOF) and miRNA discovery, identified a dataset of proteins and micro-RNAs differentially regulated by the oscillating and high glucose conditions. In particular, microarray of immunoprecipitated target bound to miR-146a-5p identified the main mRNA transcripts in this model. We found a protein identified both in proteomic and microarray experiments, vimentin, which is the principal protein involved in the activation of fibrotic pathways. Immunofluorescence analysis showed that the increased expression of vimentin is due to silencing of miR-146a-5p. Our set of data constitutes the "Proof of Principle" about the ability of the omic-approaches (proteomic analyses coupled with miRNome) to reveal potential biomarkers for the GV model. Future perspective is to draw the GV cellular signature along with associated functions and mechanisms.

Mediterranean diet rich in olive oil and vascular diabetes complications

Ramla Mizouri[1], El Amri Abir[1], Rihab Yamoun[2], Faten Mahjoub[2], Sirine Nsir[3], Amany Amorri[3], Rym Ben Othman[1], Olfa Berriche[1], Nadia Ben Amor[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, A, Tunis, Tunisia; [2]Faculty of Medicine of Tunis, Tunisia; [3]University of Tunis El Manar, Tunisia

Introduction
Olive oil is the most representative food of the traditional Mediterranean Diet (MedDiet) that, besides having high-monounsaturated fatty acids content, contains other minor components with biological properties. Olive oil as a food, and the MedDiet as a food pattern are associated with a decreased risk of cardiovascular disease, obesity and diabetes mellitus. The aim of this study was to determine the relationship between adherence to the Mediterranean Diet and vascular complications among diabetic patients.
Methods
It was a prospective cross-sectional study conducted over a three-month period including patients aged 18 years and older with a confirmed diagnosis of type 1 and type 2 diabetes. We completed a 14-Item MedDiet adherence screener in face-to-face interview with the participant to assess dietary habits. Three categories of adherence to the MedDiet were identified (low ≤5, median 6-9, high ≥10 points of the 14-item questionnaire).
Results
The study enrolled 109 patients, 48% were males and 52% were females. The average age of the cohort was 53.7 years ± 17.8 years. 78.7% of the patients were running type 2 diabetes. Of them, 57.4% had dyslipidemia and 68% were overweight or obese. High Blood Pressure was found in 47.2% of cases. The capillary blood glucose and glycated hemoglobin were respectively around 12.41 mmol/l and 10.55%. Diabetic patients with low, median or high adherence to the MedDiet represent 11%, 64%, and 25% respectively. We found an inverse significant relationship between the adherence to MedDiet and nephropathy ($P = 0.02$, $r = -0.15$), chronic peripheral artery occlusive disease ($P = 0.034$, $r = -0.21$), coronary artery disease ($P = 0.046$, $r = -0.2$) and body mass index ($P = 0.049$, $r = -0,15$). However, there wasn't association with retinopathy ($P = 0.9$) or diabetic peripheral neuropathy ($P = 0.32$).
Conclusions
The beneficial effects of increased adherence to a Mediterranean-type diet on the prevention of type 2 diabetes complications are now well known and may in part be mediated by weight modulation. Our study concluded that MedDiet reduces the incidence of diabetic nephropathy, chronic peripheral artery occlusive disease and coronary artery disease but it had no beneficial effect on the incidence of diabetic retinopathy or peripheral neuropathy.

DOI: 10.1530/endoabs.81.EP443

EP444

Prevalence and Risk Factors for Diabetic Lower Limb Amputation

El Amri Abir[1], Rym Ben Othman[1], Rihab Yamoun[1], Ramla Mizouri[1], Amany Amorri[2], Sirine Nsir[2], Faten Mahjoub[1], Nadia Ben Amor[1], Olfa Berriche[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Tunisia; [2]University of Tunis El Manar, Tunisia

Introduction
The progressive increase in diabetes is likely to increase the incidence of amputations. Despite a wealth of research highlighting the importance of early detection and management, prevention practices remain poor, with inconsistent patient follow-up and compliance. The aim of our study was to assess the prevalence and risk factors for lower limb amputation in a third-line hospital among diabetics.
Methods
It was a retrospective study including patients aged 18 years and older with a confirmed diagnosis of type 1 and type 2 diabetes, hospitalized in nutrition department A between 1 September and 31 December 2021. Subjects under 18 years of age and those with non-diabetic foot amputations (e.g. traumatic or neoplastic) were excluded from the study. Subjects hospitalized for conditions other than diabetes were also excluded.
Results
The study enrolled 209 patients comprising 88 males and 121 females. The average age of the cohort was 51.8 years $\pm$ 18.3 years. Lower limb amputation was twice as common in type 2 diabetics. It occurred in 4.4%, more commonly amongst men (9% versus 0.8%; $P = 0.004$). Of them, 78% had dyslipidemia, 85% were overweight or obese and 65% had high blood pressure. Risk factors most closely associated with amputation included diabetic retinopathy ($P = 0.001$), diabetic nephropathy ($P = 0.005$), diabetic peripheral neuropathy ($P = 0.002$) and chronic peripheral artery occlusive disease (PAOD) ($P = 0.01$). Although average glycosylated hemoglobin A1C (Hba1c) levels was higher amongst amputees, it was statistically insignificant.
Conclusion
Considering the correlation between amputation and other microvascular complications of diabetes, it would be justifiable to detect and manage these complications early in order to limit their aggravation and prevent the occurrence of other complications. Several factors offer potential for modification for the prevention of amputations but require further study. These include blood pressure, glycosylated hemoglobin, and smoking.

EP445

GLIM criteria and nutritional assesment in patients with heart failure

Ana María Moyano Sánchez[1], Carlos Manuel Alzás Teomiro[1], Concepción Muñoz Jiménez[1], Mireia Isabel García Ramírez[1], José López Aguilera[2], Manuel Crespín[2], María José Molina Puerta[1], María Ángeles Gálvez Moreno[1] & Aura Herrera Martínez[1]
[1]Reina Sofía University Hospital, Endocrinology and Nutrition, Córdoba, Spain; [2]Reina Sofía University Hospital, Cardiology, Córdoba, Spain

Background
Heart failure (HF) is a chronic inflammatory syndrome, with increased morbidity, mortality, and decreased quality of life. The publication of GLIM criteria has standardized the diagnosis of malnutrition. With these criteria, the nutritional status of patients with heart failure, who usually have normal weight, overweight or obesity, has acquired a new perspective, since malnutrition may affect the clinical evolution and prognosis of these patients.
Objective
To evaluate nutritional parameters including body composition using bioimpedance, adipose and muscle ultrasound in patients with HF and to determine the incidence of malnutrition using the GLIM criteria.
Methods
Thirty-eight patients with at least one hospital admission during the previous year were included. Anthropometric, biochemical, ultrasound and functional tests were collected. Statistical analysis was performed with SSPS v.24.
Results
In our cohort 72.2% were males, 75% of the patients had overweight or obesity and 58.3% presented with malnutrition according to the GLIM criteria; among them, 41.6% with BMI>25 kg/m^2. Patients with malnutrition tended to have a higher rate of hospitalization due to HF in the previous 12 months (2.1 vs 1.7; $P = 0.420$), increased length of stay in hospital (5.25 vs 4.5 days; $P = 0.43$) and increased vitamin D defficiency (58.8% vs 41.2%). There was no relation between the presence of malnutrition, serum NT-proBNP nor ejection fraction measured by echocardiogram. Altered serum nutritional parameters were observed in 65% of patients, 21% had decreased hand dynamometry values. The mean of the Up And Go test was 20.87 seconds. Median value of adipose tissue thickness in rectus femoris (measured by ultrasound) was 0.68 cm, with a median circumference of 8.8 cm and an area of 3.5 cm^2 in the referred muscle. Patients with malnutrition presented lower longitudinal axis of the rectus femoris ($P < 0.05$). Abdominal adipose tissue ultrasound revealed a total thickness of 2.19 cm, the median values were: superficial adipose tissue 0.63 cm, deep adipose tissue 0.92 cm and preperitoneal adipose tissue 0.54 cm.
Conclusions
GLIM criteria has a key role in early detection and diagnosis of malnutrition in patients with HF. The nutritional status assesed by serum parameters, body composition and muscle evaluation techniques might be related with the clinical evolution of these patients.

Prevalence of early postpartum glucose intolerance in Spanish women with gestational diabetes mellitus

Nerea Eguilaz Esparza, M Dolores Ollero, Yolanda Mayayo Remirez, Ana Irigaray, Ander Ernaga Lorea, Marta Toni García & Juan Pablo Martínez De Esteban[1]
García Orcoyen Hospital, Estella, Spain

Introduction
Women with gestational diabetes mellitus (GDM) have an increased risk for developing glucose intolerance in postpartum. The aim of our study was to describe the general characteristics of pregnant women with GDM and to assess the prevalence of glucose intolerance in early postpartum by postpartum oral glucose tolerance test (ppOGTT).
Methods
Retrospective study from January 2017 to December 2020 including patients with GDM followed at endocrinology department of Garcia Orcoyen Hospital in Estella (Spain). Relevant data of pregnancy and postpartum were recorded. Diagnosis of GDM was performed using the two-step strategy at 24–28th week of gestation. Early pregnancy screening was perfomed in women at increased risk of undiagnosed diabetes, defined by the American Diabetes Association (ADA). After delivery, a ppOGTT was performed, and prediabetes and type 2 diabetes were diagnosed according to the ADA criteria.
Results
A total of 84 women with GDM were included. The mean age was 33.7 $\pm$ 5.1 years (21 to 47 years), 42.2% were caucasian and family history of diabetes was found in 48.8% of them. 36.9% of women were primiparous ($n = 31$) and 23/53 women with previous pregnancies had history of GDM. Mean pregestational BMI was 28.2 kg/m^2 $\pm$ 6.2 (19 to 49). GDM was diagnosed in the 1st trimester in 20 women, in the 2nd trimester in 63 women and in the 3rd trimester in 1 woman During pregnancy, insulin therapy was required in 44% women. The average maternal weight gain was 8.2 $\pm$ 5.0 kg. 14.3% of fetus were above the 90th percentile and 4.8% newborns were macrosomes. After delivery, 58.3% of women ($n = 49$) performed the ppOGTT at 17 weeks postpartum, with the following Results: 33 women had a normal response; 14 women had prediabetes (8 had impaired fasting glycemia, 3 had impaired glucose tolerance and 3 women had a combination of both) and 2 women had type 2 diabetes criteria.
Conclusion
The proportion of women with GDM who underwent postpartum glucose testing is low due to high prevalence of loss of follow up after delivery. One-third of women who underwent ppOTTG after delivery had glucose intolerance.

The effect of lockdown during covid 19 pandemic on HbA1c control among diabetes patients in georgia ajara

Liana Jashi[1,2], Ketevan Dundua[3], Rusudan Kvanchakhadze[3] & Tamar Peshkova[4]
[1]Clinic Solomed, Endocrinology, Batumi, Georgia; [2]David Aghmashenebeli University of Georgia, Medicine, Tbilisi, Georgia; [3]David Aghmashenebeli University of Georgia, Medicine, Tbilisi, Georgia; [4]Batumi Shota Rustaveli State University, Medicine, Batumi, Georgia

Background
The COVID-19 pandemic changed to the daily life of individuals. These included lockdown and social distancing During COVID-19 pandemic. Healthcare providers from different institutions had to adapt to the way of supporting and managing patients with different chronic conditions including diabetes. The implementation of lockdown affected diabetes care. COVID-19 pandemic enabled healthcare professionals to apply innovation including social networks/ telemedicine/telephone clinics to manage diabetes patients and other patients needing outpatient follow up.
Aim
To assess the effect of lockdown on diabetes control among diabetes patients in Georgia Ajara Single Centre experience.

Method
Retrospective cohort study identified patients who were reviewed in the diabetes clinic before and after the pandemic and the A1C levels before December 2019 and in 2021.The data was obtained clinic notes. Demographic data were obtained including type of diabetes mellitus, gender, age. Outcomes assessed were change in HbA1C (worsening or improvement), if the patients had diabetes review during the pandemic (social networks/telemedicine) and whether HbA1C blood tests were done.
Results
In total the results of HbA1C of 78 patients were identified.37 were females, 41 were males. The patients were aged between 17-to 77 years, mean age 52 years. There was improvement in HbA1c in 19 patients (24.4%) (Despite pandemic and lockdown), and there was deterioration of HbA1c in 59 (patient) 75.6% of all patients. 9 (11.7%) Patients were type 1 diabetes patients 62(79.4%) were type 2 diabetes. 7 patients (8.9%) were Late Onset Diabetes of Adults (LADA).
Discussion
In Georgia the first lockdown measure prevented spread of prevent spread of COVID-19 was introduced in March 2020.This resulted in disruption of patients care especially those with chronic condition including diabetes. The worsening of diabetes control in these patient is explained by lack of exercise, weight gain and poor diet and probably poor compliance. The patients in this study reported anxiety and stress due uncertainty of COVID-19 pandemic and probably this contributed to worsening HbA1C. HbA1C in 75.6% of patients in this study deteriorated compared to 24.4% whose diabetes control improved. COVID-19 pandemic has helped healthcare professional to be more flexible and innovative in managing patients with diabetes and other chronic conditions.

Sudden deafness revealing type 2 diabetes: a case report

Meriam Dalhoum, Zohra Hadj Ali, Ines Bani, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Department C, Tunis, Tunisia

Introduction
Sudden idiopathic deafness is often a diagnosis of elimination. It is defined by an isolated sensorineural hearing loss (sensorineural deafness) unilateral and without obvious etiology but a vascular hypothesis is plausible. We report in this context a case of unilateral sudden hearing loss revealing type 2 diabetes (T2DM).
Observation
This is a 40-year-old man, sedentary, with no particular pathological history, a 20-pack/year smoker and occasional alcoholic, who presented with sudden deafness justifying his hospitalization in an otorhinolaryngology department. The clinical examination revealed a blood pressure of 130/80 mmHg, a body mass index of $30Kg/m^2$, and android obesity. The examination included otoscopy, tinnitus, neurological examination and audiometric examination confirming sensorineural hearing loss. The diagnosis of SBI was made in the face of a negative etiological investigation and he was treated with hyperbaric oxygen therapy. The biological workup revealed high blood glucose levels at 15.12 mmol/l, Hb1Ac at 9.3%, and hyperTriglyceridemia at 3.6 mmol/l. The diagnosis of T2DM was established and he was treated with a dual therapy (Metformin and Glimeperide) associated with hygienic-dietary rules.
Conclusion
Sudden onset deafness is a medical emergency requiring a rapid, global and adapted management of the affected patients. It is an infrequent pathology, unknown in the physiopathology is not well elucidated and which can be explained by a vascular or metabolic mechanism as we report this clinical case.

How to position Sodium Glucose cotransporter-2 inhibitors in the management of Diabetes in acromegalic patients- Another point of view

Adnan Zaina[1], Ali Abid[2], Elena Golden[2] & Eldad Arad[2]
[1]Bar-Ilan University, Azrieli Faculty of Medicine, Division of Endocrinology and Metabolism, Zvulon Medical Center, Clalit Medical Health Care Services, Safed, Israel; [2]Clalit Health Services, Division of Endocrinology and Metabolism, Zvulon Medical Center, Israel

Context
Diabetes mellitus represents one of the most frequent metabolic comorbidities and occurs in 30% to 40% of patients with acromegaly. Patients with acromegaly develop insulin resistance due to GH excess, and in those with longstanding disease, insulin deficiency may occur. Moreover, the use of second-generation somatostatin receptor ligands (SRLs) pasireotide might contribute to the increased development in new-onset diabetes and the worsening of hyperglycemia. Management of type 2 diabetes (T2DM) has been revolutionized since the introduction of sodium-glucose cotransporter 2 inhibitors (SGLT2i) with their beneficial protective cardiovascular and renal effects in patients with and without diabetes. The current treatment recommendations for diabetes management in acromegaly are similar to the general population. However, the use of incretin-based therapy such as glucagon-like peptide-1 (GLP-1) agonists and dipeptidyl peptidase-4 (DPP-4) inhibitors are more considered as second-line treatment modalities after metformin in patients with diabetes and acromegaly while the use of SGLT2i class is a less recommended option due to increased risk of diabetic ketoacidosis (DKA) in patients with acromegaly. We present our recommendations to define the position of SGLT2i in the treatment of diabetes in patients with acromegaly.
Evidence acquisition
Our recommendations are based on our experience with the use of SGLT2i in clinical practice in this subgroup of patients and the recently available published data.
Evidence synthesis
Acromegaly disease activity should be considered one of the important criteria for the management of diabetes in this subgroup of patients when considering treatment with SGLT2i. This criterion is driven by the fact that DKA was the initial manifestation in unrecognized active acromegaly according to recently published data. Thus, we recommend considering treatment with SGLT2i according to ADA, EASD, and ESC guidelines for patients with controlled acromegaly - defined as age-sex normalized IGF-1 levels, random GH $<$ 1μg/liter, nadir GH after OGTT $<$0.4 μg/liter- that was achieved postoperatively with or without pharmacological treatment such as SSAs, GH receptor antagonist and dopamine agonists as monotherapy or in combination. For patients with active acromegaly treatment with incretin-based therapy as second-line therapy is more favorable, in such cases, the use of SGLT2i is less recommended due to increased tendency for DKA.
Conclusions
we recommend a more liberal strategy in using SGLT2i among patients with controlled acromegaly and diabetes. However, for patients with active acromegaly incretin-based therapy is more favorable.

Case report of a patient with type 2 diabetes and severe hypomagnesemia

Martina Jambrović, Maja Mikolaj Kiric & Andreja Maric
General Hospital Čakovec, Department of Internal medicine, Čakovec, Croatia

Introduction
GLP-1 agonists and metformin are widely used antidiabetic drugs with excellent blood glucose-lowering effects, but patients very often develop side effects. The most common side effect of these two groups of drugs is gastrointestinal intolerance in the form of vomiting, diarrhoea, general weakness and dizziness.
Case Report
A 58-year-old male patient was hospitalised for the second time in one month due to a recurrence of dizziness, vomiting, ataxia and epileptic seizures. The patient had a history of type 2 diabetes mellitus treated with GLP-1 agonist dulaglutide 1.5 mg once weekly, metformin 2×1000 mg and glimepiride 2 mg. His medical history included arterial hypertension, hyperlipidaemia, coronary artery disease, OSA syndrome and nicotinism. Performed diagnostic procedures ruled out the neuroradiological cause of the problem and a metabolic cause of the problem was suspected. An electrolyte check was performed and severe hypomagnesaemia Mg $<$ 0.25 mmol/l (0.65-1.05 mmol/l) was found, the other electrolytes were normal (K 3.6 mmol/l, Na 143 mmol/l, Cl 95 mmol/l, Ca 2.38 mmol/l). Due to the weight loss, persistent diarrhoea and gastric discomfort, the patient was suspected of malabsorption due to severe hypomagnesaemia, but this was ruled out by comprehensive gastroenterological treatment (gastroscopy, colonoscopy and abdominal ultrasound revealed no cause of malabsorption, PHD result ruled out coeliac disease and anti-tTG test is ongoing). He was treated with parenteral magnesium supplementation, which resulted in clinical recovery and normalisation of blood magnesium levels. A malabsorption syndrome due to GLP-1 agonists and metformin was suspected. These drugs were excluded from therapy and intensified insulin therapy was introduced. At the next follow-up, the patient was subjectively better, taking oral magnesium supplements and insulin therapy was continued with the basal-bolus regimen for diabetes treatment.
Conclusion
GLP-1 agonists and metformin are excellent drugs in the treatment of diabetes, but it is necessary to pay attention to the rare side effects of these two groups of drugs and to change the therapy if severe side effects occur.

Metabolic syndrome in Cushing's syndrome

Fatima Zahra El Jaafari, Charlène-Ludwine Bifoume Ndong, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
CHU Mohammed VI Marrakech, Endocrinology, Diabetes, Metabolic diseases and Nutrition, Marrakech, Morocco

Introduction
Metabolic disorders are a relevant cause of morbidity and disability in patients with Cushing's syndrome (CS) even after a successful treatment. The aim of our study was to assess the prevalence of metabolic syndrome in our CS patients, as central obesity, dyslipidemia, diabetes, and hypertension, and to discuss the main adverse effects of CS on metabolism and emphasize the importance of long-term monitoring and treatment of these complications.
Patients and Methods
It's a retrospective and descriptive review of thirty-four patients records presenting Cushing's syndrome. They were divided according to waist circumference, lipid, glucose and tension profiles, before and after treatment.
Results
45% of our patients had dysglycemia,30% had dyslipidemia, and 23% had arterial hypertension with a pathological waist circumference, a mean age of 29.3 years old, and a female predominance. A decrease of this disorders after surgery or medical treatment were also noted.
Conclusion
Glucocorticoid excess leads to increased dysglycemia, dyslipidemia, visceral adiposity, and hypertension, which together delineate the metabolic syndrome, and increase cardiovascular morbidity and mortality. Treatment modalities and rapidity of controlling hypercortisolism is of paramount importance and have varied impacts on metabolic disorders.

Keywords
Cushing's syndrome; Metabolic syndrome; Dysglycemia; Dyslipidemia; Hypertension; Obesity.

"Characteristics of cerebral hemodynamics in patients with type 2 diabetes on program hemodialysis"

Urmanova Yulduz[1], Alisher Kholikov[2] & Mekhinbonu Khalimova[3]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Department of Hemodyalisis, Tashkent, Uzbekistan; [3]Tashkent Pediatric Medical Institute, Department of Endocrinology, Tashkent, Uzbekistan

The goal is to study the changes in the parameters of cerebral hemodynamics in patients with diabetes mellitus of type 2 receiving program hemodialysis.
Material and methods of research
We have been viewed and surveyed in just a period from January 1, 2019 to June 1, 2021 g - 117 patients suffering from type 2 diabetes mellitus, with chronic kidney insufficiency V stage on program hemodialysis. Of these, women were 58, men -62. The average age of men amounted to 67 $\pm$ 4.2 years, and the average age of women is 64 $\pm$ 5.6 years. 20 patients of the relevant age amounted to a group of control. The number of hemodialysis sessions in patients varied from 2 to 162. All patients were carried out by all studies that included generally crystal biochemical, hormonal blood tests, an ultrasound of internal organs, dopplerography of the main arteries of the head, consulting narrow specialists.
Results
It was revealed that as the degree of the degree of brain ischemia decreased and the Linear blood flow rate in all the main arteries of the head were decreased: carotid artery, internal carotid artery, vertebral artery on both sides (- $P < 0.05$, $P < 0.001$). At the same time, differences in the LSK from healthy individuals were significant. The most often stenosis of the lumen of the vessels of the magician met in patients with 3 groups, while they most often observed multiple stenosis of vessels.
Conclusions
1) Doppler of the main arteries of the head is informative to determine the forecast of brain ischemia in patients with type 2 diabetes with chronic kidney disease. 2) Linear blood flow rate was reduced in all groups of patients with type 2 diabetes with chronic kidney disease.

"The prognostic efficiency of the N-terminal fragment of the Brain natriuretic peptide in the diagnosis of chronic heart failure in patients with type 2 diabetes"

Zamira Khalimova[1] & Shakhnoza Yusupova[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Department of Neurendocrinology, Tashkent, Uzbekistan; [2]Andijan State Medical Institute, Department of Endocrinology, Andija, Uzbekistan

The purpose of the study is to study the prognostic role of NT¬proBNP in patients with diabetes mellitus type 2 associated chronic heart failure (CHF).
Material and research methods
For the period 2015-2021, 185 patients were identified as an object of study, and 185 patients based on the materials of their preparations into therapeutic and prophylactic institutions of Andijan from 30 years and older. Patients were distributed to 3 groups: 1 Group are patients with DM 2 type + CHF - 65 patients, 2 Group are patients with DM 2 type without CHF - 60 patients, 3 Group - these are patients with CHF without DM 2 type - 60 patients Patients were fulfilled with general, biochemical, hormonal, genetic blood tests, as well as ECG, ECHC and other instrumental research.
Results of the study
The average values of NT-proBNP were significantly different in all groups and at the same time they were significantly higher in the group of patients with DM2 + CHF compared with the parameters of the patients with insulated CHF. We selected median levels of NT-proBNP in increasing NT-proBNP treads ranging from 125 to 250 pg / ml, from 250 to 500 pg/ml and above 500 pg/ml.
Conclusions
Increasing the concentration of NT-proBNP in all patients of DM 2 with CHF, as well as the high sensitivity and specificity of the test dough, the value of this marker for the diagnosis of CHF in patients with a 2-type diagnosis. The dynamics of their concentration, mainly NT-proBNP, can help in assessing the effectiveness of the therapy and the need for dose of drugs.

"Hormonal characteristic of patients with diabetes mellitus 2 types of associated chronic heart failure"

Shakhnoza Yusupova[1] & Zamira Khalimova[2]
[1]Andijan State Medical Institute, Hospital therapy and endocrinology department,, Andijan, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov,, Tashkent, Uzbekistan

The purpose of the study is to study the clinical and hormonal features of diabetes mellitus 2 (DM) associated chronic heart failure (CHF).
Material and research methods
For the period 2015-2021, 185 patients were identified as an object of study, and 185 patients based on the materials of their preparations into therapeutic and prophylactic institutions of Andijan from 30 years and older. Patients were distributed to 3 groups: 1 gr. are patients with DM 2 type + CHF - 65 patients,2 gr. are patients withDM 2 type without CHF - 60 patients, 3gr - these are patients with CHF without DM 2 type - 60 patients. Patients were fulfilled with general, biochemical, hormonal, genetic blood tests, as well as ECG, ECHC and other instrumental research.
Results
The average values of the N-terminal fragment of the Brain natriuretic peptide (NT-proBNP) were reliably different in all groups, and at the same time they were significantly higher in the group of patients with DM 2 + CHF compared with the parameters of patients with insulated CXN. In the study of the aldosterone, elevated average values were found in all groups, in patients with CHF, the indicators are reliable higher than in the group of patients with DM 2 type, in the group of patients with DM 2, in combination with CHF, the indicators were the highest, reliably distinguish from indicators of patients with DM 2 type and unreliable in comparison with the CHF Group. Renin levels in groups were significantly higher than the upper limit of the norm lying. However, it should be noted that in the DM 2 + CHF group, the indicators statistically significantly exceeded the indicators in the first two groups.

Conclusions
1) Chronic hyperglycemia and activation of RAAS are pathogenetic factors that are aggravated by chronic heart failure in patients with 2-type diabetes. 2) Increasing the concentration of NTproBNP in all patients of the 2-type diabetes with concomitant CHF, as well as high sensitivity and specificity of the test proves the value of this marker for the diagnosis of CHF.

"The Level of awareness of the risk of developing coronary heart disease of patients with type 2 diabetes mellitus complicated by cardio-renal syndrome"

Kamola Alimova
Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

The purpose of the study is to study the Level of awareness of the risk of developing coronary heart disease (CHD) of patients with type 2 diabetes mellitus complicated by 4 type cardio-renal syndrome.
Material and methods
We examined in total for the period from October 1, 2021 to December 1, 2021 - 25 patients suffering from type 2 diabetes mellitus with chronic renal disease (CRD) and chronic cardial insufficiency (CCR). The average age of 33.3% of patients was within 50-59 years, and in 46.7% - from 60 to 69 years. The research methods included: 1) general clinical (study of endocrine, neurological status, anthropometry, height (sm), weight (kg), BMI, waist circumference (WC), hip circumference (HC), waist-hip ratio 2) instrumental (ECG, roentgen of thorax, ultrasound of internal organs 3) biochemical tests (Hb1AC, glycemic profile, urea, creatinine, lipid spectrum, coagulogram),4) hormonal blood tests (insulin, C-peptide etc.)
Results
When patients learned about the risk of CHD: before the diagnosis of DM 2 is 20%, in the process of investigation the diagnosis of DM 2 - 6.7%, shortly after the DM 2 was revealed - 20%, a few years after the DM 2 was identified in 40%, when the diagnosis of cerebro-vascular disease (CVD) is 6.7%, does not know - 6.7%. The risk levels of the development of the heart complications (HC) were the following: low -20%, average - 33%, more average - 27%, high - 13%, below average - 7%. Among the suffering diseases were: arterial hypertension - 53.3%, arrhythmia -40%, kidney disease -13.7%, stroke -6.7%.
Conclusion
1 of the 3 respondents suffering from the DM 2 rated their level of risk of developing CVD low, while diabetes a history of already high risk of CVD. 40% of the respondents received information on the risk of the development of the CVD several years after the diagnosis of the diagnosis of the DM 2. All respondents talked with the attending physician about the DM 2 and the risk of CVD. Nevertheless, at the time of the survey, all of them had CVD.

Plasmalogen levels are associated with the severity of diabetic neuropathy

Nilufar Akhrarova[1], Talat Saatov[2], Munojat Salimova[3], Mehriniso Khamraeva[4], Bakhodir Zaynutdinov[2] & Zulaykho Shamansurova[2,5]
[1]City Specialised Outpatients Clinic, Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophisics and Biochemistry at the NUUz, Metabolomics, Tashkent, Uzbekistan; [3]City Specialised outpatients Clinic, Physiotherapy, Tashkent, Uzbekistan; [4]City Specialised Outpatients Clinic, Cardiology, Tashkent, Uzbekistan; [5]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Backgrounds
Diabetes mellitus is a complex disease accompanied by the development of complications. In addition to the classic hyperglycemia and dyslipidemia, a number of other factors are involved in the pathogenesis of complications. Plasmalogens disturbances participates in nerve tissue degeneration.
Materials and methods
In 76 people with DM2 plasma and erythrocytes membranes plasmalogenes measured and compared according to diabetic neuropathy.
Results
Blood plasma plasmalogenes and erythrocytes membranes plasmalogens level shown decreased in patients with DM2 in compare with people without diabetes. When results analysed according to severity of diabetic nephropathy Blood plasma and erythrocytes membranes plasmalogens levels showed linkage. Blood plasma plasmalogens level were significantly differs between the groups and shown in 2.4 and 3.1 times lower in DN1 and DN2 groups. Whereas erythrocytes membranes plasmalogenes were more lower and showed lowering in DN1 groups in 3.6 times and DN2 groups in 4.2 times.
Conclusion
Blood plasma and erythrocytes membranes plasmalogens have linkage with severity of DN and involved into pathogenesis of neuropathy by neurodegeneration.

Lipid metabolism in patients with type 1 diabetes mellitus accompanied by ischemic heart disease

Gulnora Artykbaeva & Talat Saatov
Institute of Biophysics and Biochemistry under MirzoUlugbek National University of Uzbekistan, Laboratory of metabolomics, Tashkent, Uzbekistan

Cardio-vascular disorders (CVD), ischemic heart disease (IHD) and myocardial infarction (MI) heading the line are the main cause of death among patients with diabetes mellitus (DM). DM has been proved to be an essential risk factor for IHD and MI to be instrumental in regarding all patients as belonging to the CVD high risk group. Dysfunction of adipocytes, insulin resistance, hyperinsulinemia, hyperglycemia and dyslipidemia seen in DM are the triggers for the cascade of hemodynamic and neuro-humoral responses underlying the atherosclerotic damages of vessels of various location with clinical manifestation in the form of IHD. The work was initiated to study lipid metabolism parameters in patients with the IHD- accompanied type 1 diabetes mellitus.
Materials and methods
We examined 10 patients with type 1 DM and 14 patients with type 1DM and IHD. 12 donors were included in the control group. Concentrations of lipids, triglycerides (TG), total cholesterol (TC) and high density lipoproteins (HDP) cholesterol were analyzed in all groups.
Results and discussion
Significant increase in concentrations of total lipids and TC could be seen in all patients being more pronounced in the IHD-accompanied type 1 DM. Concentrations of total lipids in patients with the accompanied pathology were the highest (11.42 $\pm$ 0.61 versus 5.2 $\pm$.33 g/l in the controls). Total cholesterol concentrations were approximately equal in all groups of patients to be 226.0 $\pm$ 11.3 mg% in patients with type 1 DM and 223.0 $\pm$11.8 mg% in those with DM and IHD ($P < 0.05$) while the concentrations of TG and HDL cholesterol changed by presence of IHD. The most pronounced changes in the serum TG concentrations could be seen in patients with IHD-accompanied type 1 DM (232.8 $\pm$ 26.0 mg%), as compared to those in patients with DM but not IHD (211.3 $\pm$ 14.3 mg%)($P < 0.05$) and the controls (137.8 $\pm$ 1.9 mg%). The reduction in HDL cholesterol could be seen both in patients with type 1 DM (36.3 $\pm$ 2.26 mg%, $P < 0.05$) and those with the pathology-accompanied disease (33.9 $\pm$ 1.8 mg%, $P < 0.001$) to significantly differ from the parameters in the controls (59.7 $\pm$ 0.8 mg%). Thus, the increase in concentrations of total cholesterol, TC, TG paralleling reduction in HDL cholesterol could be seen characteristic of patients with type 1 DM. IHD was demonstrated to be the confounding factor for DM course due to metabolic and pro-atherogenic changes, as well as formation of risk factors, to name arterial hypertension, obesity and dyslipidemia.

Are diabetes mellitus and parkinson's disease linked?: a case report

Gorgi Khaoula, Echchad Lamya, Rifai Kaoutar, Iraqi Hinde & Gharbi Mohamed El Hassan
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Parkinson's disease is considered the most common chronic neurodegenerative disease that often affects the elderly, rarely the young. Meanwhile, Diabetes mellitus is the most common chronic metabolic disease. Because of the increase

in the prevalence of diabetes and neuro-vegetative diseases, we can wonder about the relationship between the two diseases. We report the case of a patient with type 2 diabetes mellitus associated with young onset Parkinson's disease
Case
A 44-year-old female patient, has been followed for type 2 diabetes mellitus for 5 years under Metformin and insulin with a history of Parkinson disease diagnosed 2 years ago in front of resting tremor, slowness of movements and muscular rigidity. She was put on L-Dopa with favorable clinical evolution.
Discussion & conclusion
The possibility of a relationship between Parkinson's disease and T2DM has been well studied. A few epidemiological studies have shown that diabetes is a major risk factor that accelerates the deterioration of motor function or cognitive status. T2DM shares some common pathogenic traits with PD. For example, high levels of immune cells, cytokines and chemokines have been described in pancreatic islets of patients with T2DM, while microglia activation seems to play a central role in PD progression. Similarly, the role of mitochondrial dysfunctions and oxidative stress in both T2DM and PD is now well established.

An inaugural diabetic ketoacidosis revealed by Fournier's gangrene

Gorgi Khaoula, Echchad Lamya, Rifai Kaoutar, Iraqi Hinde & Gharbi Mohamed El Hassan
Ibn Sina University Hospital, Endocrinology and Metablic Diseases, Rabat, Morocco

Introduction
Fournier's gangrene (FG) is a rare but life-threatening disease. Although originally thought to be an idiopathic process, FG has been shown to have a predilection for patients with diabetes, HIV, alcoholism and other immunocompromised states. We report the case of a patient who presented an inaugural diabetic ketoacidosis revealed by Fournier's gangrene
Observation
A 38-year-old male patient with a smoking history, presented to the emergency department for intense perineal pain associated with a fever. The physical assessment had revealed a tachycardia of 120 bpm, blood pressure 110/60 mmHg, a high respiratory rate 24 per minute & a temperature of 39°C. The perineum was swollen and necrotic. An abdominal CT scan was performed which showed air bubbles at the perineal area extended to the retroperitoneal space and to the scrotal region. In the other hand the biological assessment was in favor of an elevated plasma glucose level of 4 g/l, metabolic acidosis and urine ketones.C-reactive protein level was at 235 mg/l with white blood cell count 18 per mm^3. The diagnosis of a Fournier's gangrene associated with an inaugural diabetic ketoacidosis was made. Management with intravenous fluids, insulin infusion and aerobic/anaerobic broad-spectrum antibiotics were started followed by surgical debridement without any complications.
Discussion & conclusion
Fournier's gangrene is a fulminant form of infective necrotizing fasciitis of the genital, perianal and perineal regions, which commonly affects men, but can also occur in women and children. Diagnosis should be prompt with early surgical intervention, along with antibiotics and good supportive care. Proactive management of diabetic and immunosuppressed patients with perineal infections is of extreme importance to prevent the development of the condition in the first place as this condition in the presence of such comorbidities is associated with high mortality

Long-term diabetes complications

Chaima Sdiri, Yosra Htira, Skander Msolly, Maryam Cheikhrouhou, Zohra Hadj Ali, Hedfi Imene, Chaima Jemai & Feika Ben Mami[1]
Institut De Nutrition, Tunis, Tunisia

Introduction
The chronic hyperglycemia related to inadequately controlled diabetes is involved in the onset of degenerative complications, responsible for disabilities. The objective of the present study was to determine the long-term complications observed in hospitalized patients with diabetes.
Methods
We used a prospective study conducted in the department of diabetology in the National Institute of Nutrition (Tunisia). This work was carried out on the medical records of hospitalized patients. Diabetics with less than 10 years of diabetes evolution were not included.
Results
We collected 48 patients: 18 men and 30 women. the majority have type 2 diabetes (79%). For the type 1 diabetic group, the mean age was 35.2 ± 10 years and the mean glycated hemoglobin (HbA1c) level was 9 ± 1%. The mean age of type 2 diabetes (T2DM) was 65.7 ± 8.4 years and the mean HbA1c level was 10.7 ± 1.5%. Almost the half of T2D patients (49%) had diabetic retinopathy. It was minimal, moderate and proliferative in 35%, 18% and 47% of the cases, respectively. In type 1 diabetics (T1DM), retinopathy was observed in 70% of patients. In this case, minimal, moderate and proliferative retinopathy were found in 58%, 28% and 14% of the cases, respectively. Diabetic nephropathy was present in 47% of T2DM and in 10% of T1DM. Peripheral neuropathy was mentioned in 26% of T2DM and in 10% of T1DM. For the T2DM group, macroangiopathy affected 39% of hospitalized patients: 21% had coronary artery disease, 13% had chronic arterial occlusive disease of the lower extremities and 5% had a history of ischemic stroke. We did not found similar anomalies in the T1DM group. In the present data, no significant correlation was observed between the onset of chronic diabetic complications and the HbA1c level or age of diabetes (P = NS).
Conclusion
The prevalence of diabetes-related complications is increasing but often underestimated. Early screening of these complications may allow a better management.

Correlation between pulse wave velocity and retinopathy in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
Diabetic retinopathy (DR) is a serious complication of diabetes that affects 50% of patients with type 2 diabetes. It represents the first cause of blindness. The aim of this study was to examine the relationship between diabetic retinopathy and arterial stiffness.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications, between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 $\pm$ 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years. Diabetic retinopathy (DR) was found in 24.1% of the patients. Among them 26.7% had proliferative DR. CfPWV $>$ 10 m/s was found in 95% of the patients with DR. In this group, cfPWV was at 15.34 $\pm$ 2.94 m/s VS 13.10 $\pm$ 2.56 m/s in patients without diabetic retinopathy ($P < 0.001$). Moreover, in patients with DR, we did not find a correlation between cfPWV and the stage of the retinopathy ($P = 0.108$).
Conclusion
Arterial stiffness is often increased in type 2 diabetes. And It is more increased in the presence of retinopathy. Microvascular disorders of the retina including DR were associated with cardiovascular disease, highlighting the relationship between microvascular abnormalities and atherosclerosis specifically and arterial stiffness overall.

Correlation between pulse wave velocity and neuropathy in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
Diabetic neuropathy (DN) is the most common complication of diabetes affecting up to 50% of patients with type 2 diabetes. Carotid to femoral pulse wave velocity (cfPWV) is an independent cardiovascular marker of morbidity and mortality and is considered the gold standard in the assessment of arterial stiffness. The aim of

this study is to examine the relationship between diabetic neuropathy and arterial stiffness.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications, between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 ± 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years. Diabetic neuropathy (DN) was found in 27.7% of the patients. CfPWV > 10 m/s was found in 94.2% of the patients with DN. In this group, cfPWV was at 14.56 ± 2.99 m/s VS 13.29 ± 2.68 m/s in patients without DN ($P = 0.001$).
Conclusion
This study shows that arterial stiffness is higher in type 2 diabetic patients with diabetic neuropathy than in those without diabetic neuropathy. Indeed, increased aortic stiffness can directly damage microcirculation, including vasa nervorum, by increasing the transmission of larger and harmful pulsatile pressure waves due to loss of normal aortic buffer function. More importantly, diabetic neuropathy has been shown to be a major risk factor for cardiovascular disease. Thus, diabetic neuropathy and macroangiopathy might have common pathogenic mechanisms.

EP463

Correlation between pulse wave velocity and hypertension in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
People with high blood pressure have a greater risk of developing diabetes, and people with diabetes also have an increased risk of high blood pressure. These two associated pathologies can increase cardiovascular risks and cause other repercussion such as arterial stiffness. The aim of this study is to examine the relationship between pulse wave velocity and hypertension in type 2 diabetes.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications, between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 ± 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years. The mean systolic blood pressure was at 138.9 ± 17.2 mmHg and the mean diastolic blood pressure was at 78.7 ± 9.8 mmHg. High blood pressure was found in 54.2% of the patients. Among them 33.3% had a controlled blood pressure under treatment. In this group, cfPWV was at 14.66 ± 2.83 m/s VS 12.43 ± 2.29 m/s in patients without hypertension ($P < 0.001$). Moreover, the presence of arterial stiffness multiples by 8 the risk of hypertension (Odds Ratio = 8).
Conclusion
Both diabetes and hypertension are known to be causes for arterial stiffness and their association increases more this risk. Therefor a well-controlled blood pressure and glycemic level is necessary to slow down this process.

Predicting factors of insulin requirement in gestational diabetes mellitus

Zeineb Zemni[1], Daii Raja[2], Haifa Abdesselem[1], Emna Bornaz[1], Chaima Sdiri[1], Nadia Alaya[1], Kamilia Ounaissa[1], Fatma Boukhayatia[1], Imen Sebaii[1], Ryme Yahyaoui[1], Asma Ben Brahim[1] & Chiraze Ammrouche[1]
[1]National Institute of Nutrition of Tunis, Outpatient Department and Functional Explorations, Tunis, Tunisia; [2]National Institute of Nutrition of Tunis, Department C, Tunis, Tunisia

Background
The management of gestational diabetes mellitus (GDM) is based on nutrition therapy associated to insulin therapy in second intention if glycemic targets are not achieved. The aim of this study was to assess predictive factors of insulin requirement in a group of pregnant women with GDM.
Methods
We conducted a retrospective study at the Outpatient Department and functional explorations, in the National Institute of Nutrition of Tunis, between April and June 2021. Clinical and biological data were collected from medical observation records.
Results
The study included 110 pregnant women with GDM. Mean age of patients was 33.4 ± 5 years. Diagnosis of GDM was based on pathological 75 g oral glucose tolerance test (OGTT) in 60% of patients and pathological fasting blood glucose in 40%, with a mean term of discovery of 22.75 ± 7.55 weeks of gestation. Nearly to one-third (33.6%) of the patients required initiation of insulin therapy. The mean term of insulin therapy instauration was 27.27 ± 5.55 weeks of gestation with a mean time between diagnosis of GDM and insulin therapy of 4.76 ± 3.94 weeks. Insulin therapy was initiated during the first week of follow-up in 16.6%. Insulin therapy was initiated with short-acting insulin, NPH insulin and basal bolus pattern in 54.1%, 13.5% and 32.4% of cases respectively. Univariate analysis showed a significant association between level of education ($P = 0.031$), sedentarity ($P = 0.013$) and the need for insulin therapy. Glycated hemoglobin (A1c) was higher in women with insulin therapy ($P = 0.018$). We did not find a statistically significant association between insulin use and history of GDM, early discovery of GDM, maternal age, and fasting blood glucose. Multivariate analysis showed that predictive factors for insulin therapy were A1c (OR = 4.34) and personal history of miscarriages (OR = 3.67).
Conclusion
Pregnant women who develop gestational diabetes treated with insulin are at increased risk of developing type 2 diabetes in the future. That's why postpartum management is essential based on long-term screening and diabetes prevention strategies.

Are type 2 diabetic insulin-requiring elderly satisfied?

Fatma Zaouali, Najoua Lassoued, Arfa Sondos, Alaya Wafa & Sfar Mohamed Habib
Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
Glycemic control in elderly diabetics is a challenge. Treatment Satisfaction reflects this control.
Objectives
To assess insulin treatment satisfaction and to determine the factors associated with insulin treatment satisfaction among type 2 diabetic elderly.
Methods
A cross-sectional study on 86 type 2 diabetic insulin dependent elderly recruited from the outpatient endocrinology consultation during June and July 2021.We applied the Diabetes Treatment Satisfaction Questionnaire (DTSQ) and geriatric assessment scores.
Results
Three quarters of the patients were satisfied with the insulin therapy. Satisfied patients had significantly less history of hospitalization and more regular follow-up. Diabetic neuropathy medications were significantly less taken by satisfied patients. The number of daily insulin injections was significantly higher among unsatisfied patients. Diabetic foot was significantly more frequent among unsatisfied patients. Satisfied patients were significantly less depressed, more independent in both basic and instrumental activities of daily living, without memory impairment, in better nutritional status and not falling. Higher DTSQ scores were associated with regular follow up (β 7.92, 95% CI 1.83 to 34.3). Lower DTSQ scores were associated with the history of hospitalization (β 0.12, 95% CI 0.02 to 0.58), the taking of medications for diabetic neuropathy (β 0.07, 95% CI 0.09 to 0.51), the high number of insulin injections (β 0.43, 95% CI 0.19to 0.97) and the presence of diabetic foot (β 0.17, 95% CI 0.01 to 0.38).
Conclusions
Risk factors for patients' insulin dissatisfaction should be detected early and managed appropriately to improve patients'satisfaction and consequently their well-being.

Insulin analogs: do patients know their treatment advantages and modalities?

Emna Bornaz, Radhouen Gharbi, Lina Ghram, Marwa Chiboub, Hajer Kandara, Manel Jemel & Ines Kammoun
Institut De Nutrition, Tunis, Tunisia

Introduction
In Tunisia, the prescription of insulin analogs is increasingly « automatic » by practicians, convinced by this treatment superiority over human insulin in diabetes management. The aim of our study is to determine whether the analogs prescription modalities and advantages are known by the patients, and to assess the factors associated with this knowledge.
Patient and Methods
We conducted a retrospective study including 65 diabetic patients attending the National Institute of Nutrition and on insulin analogs. Information was extracted from medical record and patients interviews.
Results
Fourteen patients had type 1 diabetes, and 51 had type 2 diabetes. Prescription of analogs (primary or switch from human insulin) was the doctor initiative in 86.2% of cases, and was the patients' in 13.8%. The motivation of this prescription (ie advantages over human insulin) was explained to the patients by the practician in 60.7% of cases. In 58.5% of cases, the patients knew that analogs are more flexible,% 49.2 knew that analogs cause less hypoglycemia, and 10.8% that its injection (insulin pen, solely available to analogs in Tunisia) was less painful than syringe. The percentage knowing the fast analog latency and action duration were respectively 74.2% and 48.5%. There was a statistically significant association between the patient knowledge about hypoglycemia risks and the doctors explanations ($P = 0{,}00$). This knowledge was associated with a better diabetes management: less hypoglycemia ($P < 0{,}001$) a better HbA1C. (9.62 vs 8.81, $P = 0{,}019$). 98.5% of patients manifested their satisfaction with analogs and their desire to keep their prescription.
Conclusion
A substantial proportion of diabetics on analogs didn't know their advantages and characteristics. This ignorance was partly due to lack of communication with their doctors. Improving this knowledge will lead to a better management of this treatment, and will help to have a better glycemic control.

EP467

Metformin adherence and its impact on diabetes control

Elyes Kamoun[1,2], Meriem Yazidi[1,2], Sahar Abidi[1,2], Nadia Khessairi[1,2], Yasmine Mouelhi[1,2], Ibtissem Oueslati[1,2] & Melika Chihaoui[1,2]
[1]Hospital Rabta, Department of Endocrinology, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia

Introduction
Metformin is the first-line treatment of type 2 diabetes mellitus. Poor adherence can be lead to poor glycemic control. The aim of our study was to determine the level of metformin adherence and its link with glycemic control in type 2 diabetic patients.
Methods
We performed a cross-sectional study including 273 patients with type 2 diabetes taking metformin for at least three years. We assessed metformin adherence using the Girerd questionnaire in its Tunisian version. The level of adherence was considered good, medium or poor. Diabetes was considered controlled when HbA1c was less than 7%.
Results
The mean age was 60 ± 8.22 years. Mean duration of metformin treatment was 10 ± 5.5 years, with extremes ranging from 3 to 40 years. Mean HbA1c was 8.7 ± 1.8% with extremes ranging from 5.6% to 15.7%. The diabetes was controlled in 18.3% of patients. The compliance was good in 7.3% of patients, medium in 48% of patients and poor in 44.7% of patients. When comparing mean HbA1c in all three adherence categories, there was a near statistically significant difference between the three categories ($P = 0.058$). HbA1c was higher in patients with poor treatment adherence compared to patients with good or medium level of adherence (8.98 ± 1.96% vs 8.46 ± 1.7%, $P = 0.02$). Duration of diabetes was lower in patients with poor adherence (9.7 years vs 11.1 years, $P = 0.045$).
Conclusion
Poor adherence to metformin treatment is frequent in type 2 diabetic patients. It is associated with a poorer glycemic control and should be targeted in therapeutic education programs.

Painful fat necrosis as a consequence of insulin application - an unsolvable problem?

Sanja Borozan, Emir Muzurovic & Snezana Vujosevic
Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro

We report a case of 39–year-old female presented with painful, scaling skin lesions on insulin application sites. She was diagnosed with type 1 diabetes mellitus (T1DM) at the age of 21 years and treated with intensified conventional insulin therapy. Three months before hospital admission, she suddenly started to feel pain at insulin injection sites, followed by oval subcutaneous deposits and skin ulcer in the further course. Identical local changes repeated after subcutaneous use of every available type of both human insulin and insulin analog. Patient past medical history was significant for surgically treated cervical cancer, cervical disc herniation and unilateral hip replacement due to femoral head osteonecrosis. On physical examination, multiple skin lesions in a form of scabs with maximal diameter of 7 mm, were present in bilateral upper arm and anterior abdominal region, and along the thighs. Her insulin injection technique was observed and estimated as adequate. Clinical, biochemistry and radiological assessment was performed as the biopsy of skin lesions. An insulin pump was inserted, but after a few days the same changes occurred at the site of catheter application. She is currently being treated with insulin parenterally.

Impact of COVID-19 lockdown on glycemic control in diabetic patients hospitalized in emergency months

Rim Rachdi, Nadia Ben Amor, Olfa Lajili, Faten Mahjoub, Ramla Mizouri, Rym Ben Othman, Berriche Olfa & Jamoussi Henda
The National Institute of Nutrition in Tunis, Tunisia, Diabetology Department A, Tunisia

Introduction
The global pandemic spread of SARScov2 has led to a heavy medical and socio-economic toll since December 2019. Patients suffering from chronic diseases were particularly affected during the lockdown period due to difficulties in accessing care. The aim of our study was to evaluate the impact of the 2-month lockdown introduced in Tunisia in March 2020 on diabetic patients' glycemic control.
Materials and methods
Retrospective study involving 54 diabetic patients hospitalized through the emergency room in June 2020, one month after lockdown, in the diabetology department "A" at the National Institute of Nutrition in Tunis. Glycemic control, lipid balance as well as microvascular complications of diabetes were noted for each patient before and after lockdown (in January 2020 and June 2020).
Results
Median age was 54.72 years [20-87 years]. The sex ratio (M/F) was 0,5. 74% of patients had type 2 diabetes and 26% had type 1 diabetes. Median diabetes duration was 15.5 years [2-38 years]. 20.37% of patients were on oral antidiabetic drugs (ADO), 59.26% were on insulin, and 20.37% were on a combination of insulin and ADO. 53.7% were hypertensive and 66.66% had dyslipidemia. Patients were hospitalized for unbalanced insulin-deficient diabetes in 59.27%, for switching to insulin in 20.37%, diabetic ketosis in 16.66% and for unstable type 1 diabetes with severe hypoglycemia in 3.7%. Average fasting blood glucose increased from 9.35 mmol/l before lockdown to 13.24 mmol/l ($P < 10^{-3}$). Mean HbA1C value of lockdown (10.92%) was much higher than of pre lockdown (8.5%; $P < 10^{-3}$). 3.7% of patients had developed mild nonproliferative retinopathy and 1.85% saw their pre-existing retinopathies worsen. 18.52% of patients had worsened their 24-hour microalbuminuria and developed at least moderate renal impairment. Worsening of LDL cholesterol levels was observed in 38.88% of patients. The main diabetes complications aggravating factors found were non-compliance with hygienic-dietary measures during the lockdown period (83.33%), as well as non-compliance and non-availability of medications related to patients' absenteeism at the consultation (61.11%).
Conclusion
COVID-19 lockdown was associated with a deterioration in glycemic control and diabetes complications mainly due to non-adherence to the diet and lack of access to care.

Mitochondrial diabetes: from diabetes to syndrome

Celia Gallego Díaz, Álvaro Romero Porcel, E Arturo Cuellar Lloclla & María Victoria Cózar León
Hospital Virgen de Valme, Endocrinología y Nutrición, Sevilla, Spain

Anamnesis
We report the case of a 54-year-old man who consulted for weight loss. He had been diagnosed with diabetes more than 20 years ago with good glycemic control (currently HbA1c 6.9%), no obesity, hypertension, or dyslipidaemia. A history of chronic pancreatitis and retinitis pigmentosa with eyelid ptosis. He maintains regular treatment with metformin, sitagliptin, repaglinide, ASA, Kreon and Pregabalin.
Complementary test
In reference to the chief complaint, there had not been any changes in his eating habits, his glycaemic control was in range, there were not abnormalities in CT scans, abdominal ultrasound, and faecal occults blood test. Subsequently, he was admitted for constitutional syndrome, and an echoendoscopy was requested where a hypoechogenic lesion measuring 28x27 mm was observed in the head of the pancreas with FNA showing signs of cytological atypia. A radical pancreaticoduodenectomy was performed with a diagnosis of pancreatic adenocarcinoma with areas of squamous differentiation (G3pT4 N0, Mx). During hospitalisation the patient presented palpitations, with paroxysmal EKG conduction with right bundle branch block, and a permanent pacemaker was implanted.
Discussion
We assessed the different clinical profile and discussed a mitochondrial disease known as Kearns-Sayres Syndrome. It starts in childhood with a classic triad of palpebral ptosis, retinitis pigmentosa and progressive external ophthalmoplegia, associated with sensorineural deafness, myopathies (progressive neuralgic pain and generalised muscle weakness), cardiac conduction disturbances, CNS involvement (cerebellar ataxia, bilateral facial weakness, etc.), digestive disorders (pancreatitis, diarrhea, etc.), and endocrinopathies (diabetes, delayed puberty...) and kidney failure. The aetiology of diabetes is due to an A3243g mutation affecting the mitochondrial MTTL1 gene. This gene encodes Leucine transfer RNA, which results in an attenuation of cytosolic ADP/ATP levels, resulting in a resetting of the glucose sensor in the pancreatic B-cell, producing less insulin. There is a high clinical variability based on the percentage of mutated DNA. In the beginning, usually under 40 years of age, there is insulin reserve, but it usually progresses to insulin dependence and treatment with metformin is not recommended due to the risk of lactic acidosis.
Conclusion
Our patient underwent a muscle biopsy, which was positive for specific alterations of fibres with mitochondrial proliferation.

Correlation of knowledge and self-care with glycemic control in people with diabetes

Smaragdi Boulazeri[1], Anastasia Ntikoudi[1], Anna Kavga[1], Martha Kelesi[1], Polyxeni Mangoulia[2], Eleni Evangelou[1], Athanasios Tsartsalis[3], John Komninos[3], Andromachi Vryonidou- Bompota[4] & Eugenia Vlachou[1]
[1]University of West Attica, Nursing, Greece; [2]Evangelismos General Hospital, Athens, Greece; [3]Athens Naval Hospital, Endocrinology Department, Athens, Greece; [4]Korgialenio- Benakio General Hospital, Endocrinology Department, Athens, Greece

Introduction
Diabetes mellitus (DM) is a disease that shows a rapid increase over the recent years and is a major cause of morbidity and mortality. Thus new ways of prevention and treatment are needed and constantly being developed. As a lifelong challenge, DM is likely to affect one's life in a variety of ways. It requires daily planning and decision making. Self-care is a vital component of the disease. Knowledge consists of information about the disease and its management, which makes people with DM capable to carry out self-care activities. Knowledge about DM, its course and its treatment and how all of these factor work together are prerequisites for an sufficient level of self-care.
Aim
The aim of this study was to investigate the relationship between knowledge and self-care of people with DM in accordance with their glycemic control.
Materials and Methods
This is a cross-sectional study with a sample of 98 people with type 1 and type 2 DM, aged 18-50 years old. A convenience sample was used, and the data were collected through anonymous questionnaires.
Results
The average score of people's knowledge regarding the diabetes disease showed a good level of knowledge. The results showed a moderate level of knowledge of the participants in insulin use. People with better knowledge of insulin use, younger people, people with lower body mass index, and people with shorter duration of diabetes appeared to have better level of knowledge in physical activity. Regarding the level of care of the lower extremities, a moderate level of care was observed. The average overall medication score showed a fairly good level of compliance with the treatment. It was also found that the average overall nutrition score was relatively good. In terms of physical activity, it was found that the average overall score was low, which indicates a low level of physical activity of the participants.
Conclusion
These results indicate the need to improve education of people with diabetes, in subjects related to the disease in order to enhance their capacity for self-care. Factors that have been shown to influence both the level of knowledge and the self-care activities need to be considered in the individualized diabetes education.

Oral health related behavior and knowledge in adult patients with diabetes: a questionnaire study

Meriam Dalhoum, Zohra Hadj Ali, Bani Ines, Htira Yosra & Ben Mami Faika
National Institute of Nutrition, Department C, Tunis, Tunisia

Diabetes is a common disease with concomitant oral manifestations that impact dental care.
Purpose
To investigate oral health awareness, oral hygiene and behavior in adults with diabetes.
Subjects and methods
This study involved interviews with a sample of 30 patients with diabetes type 2 followed in the C department of the National Institute of Nutrition in Tunis using a questionnaire study on oral health behavior and awareness.
Results
The mean age of our patients was 53 ± 7 years, with a sex ratio M/F = 0.43. The average duration of diabetes was 10 ± 8 years. The majority of respondents (59.4%) visited a dentist once a year, but oral care varied: 67.2% reported brushing at least once a day, whereas only 4.3% flossed daily. Awareness of oral health risks was limited, only 22% of the participants answered correctly about oral health knowledge items related to diabetes and 74.1% had never received any oral health advice related to their diabetes.
Conclusions
Many adults with diabetes have poor awareness of oral care and health complications associated with diabetes, and are receiving limited advice. Health professionals should take the opportunity to educate patients with diabetes and to promote proper oral health behaviors.

Daytime sleepiness in patients with diabetes

Meriam Dalhoum, Zohra Hadj Ali, Bani Ines, Htira Yosra & Ben Mami Faika
National Institute of Nutrition, Department C, Tunis, Tunisia

Excessive daytime sleepiness (EDS) is commonly considered a cardinal sign of sleep apnea; however, the mechanism underlying the association is unclear.

Purpose
The purpose of this study is to investigate the daytime sleepiness in patients with diabetes.
Methods
Participants were 30 adults with type 2 diabetes (T2DM) followed in the C department of the National Institute of Nutrition in Tunis. Subjective sleepiness was assessed using the Epworth Sleepiness Scale (ESS).
Results
The mean age of our patients was 60±11 years, with a sex ratio M/F=0.48. The average duration of diabetes was 17±4 years. Obesity was present in 83.4% of patients. The mean glycated hemoglobin was 10.8% and the frequency of hypertension was 73%. This study showed that most patients (43.2%) presented a mild daytime sleepiness. People who scored highly on the ESS (4.9%) were more likely to have poor glycemic and blood pressure control and a higher body mass index than those with low scores (34.1 vs 31.8 kg/m^2).
Conclusions
Sleep abnormalities and daytime sleepiness are frequent in T2DM and it is associated with decreased diabetes self-management. We suggest that diabetic patient should be more thoroughly investigated for symptoms of daytime sleepiness.

Prophylactic gonadectomy in A young phenotypic female with turner syndrome 45,XO/46,XY mosaicism: a case report

Sofia Ouhessaine, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Turner syndrome is a chromosomal disorder that affects an estimated 1/2500 female live births. An estimated subset of 6-12% of all Turner Syndrome patients will be a mosaic with Y-chromosomal elements. It is recognized that a Turner female possessing Y chromosome material has an increased risk of developing gonadoblastoma, a precursor to dysgerminoma. Consequently guidelines recommend prophylactic gonadectomy in Turner females.
Obsevation
We present the case of a 17-year old female, followed for mosaic turner syndrome, who underwent prophylactic gonadectomy. Patient was followed for 4 years, the diagnosis was initially suspected in front of a failure to thrive, presence of Nevi on the face, and primary amenorrhea. Karyotype study was ordered and revealed a mosaic pattern of 46,X/45,X—70% of the cells containing Y chromosome material. The clinical examination finds the stigmata of the classic Turner Syndrome, wide neck with a low hairline, a high palate and a bradymetacarpus. An exploratory laparoscopy performed showed bilateral ovarian strips. Prophylactic gonadectomy was organized, by laparoscope. The post-operative follow-up was simple, with anapath, bilateral ganadic dysgenesis without signs of malignancy.
Conclusion
Early gonadectomy has been recommended in mosaic Turner females with Y-chromosomal material as a consequence of high risk of gonadoblastoma in infants as early as 5 months old.

Can Alopecia Areata predict the appearance of autoimmune diabetes in a patient with autoimmune polyglandular syndrome type 2?

Ana Silvia Corlan & Mihaela Vlad
University of Medicine and Pharmacy "Victor Babes", Endocrinology, Timisoara, Romania

Autoimmune polyglandular syndrome type 2 can be associated with alopecia areata. We present herein a case of a female patient, 42 years old, who suffered from autoimmune thyroid disease with hypothyroidism and autoimmune adrenalitis and who was recently diagnosed with alopecia areata. She accused sudden, asymptomatic hair loss, which she noticed 3 months ago, accompanied by a burning sensation in her scalp. Her menstrual cycles were normal. The clinical examination identified smooth, circular, discrete areas of complete hair loss on her scalp. Her physical exam was otherwise normal. Her medication included 88 mcg Synthroid/day and 20 mg hydrocortisone daily. The laboratory investigations identified normal thyroid function, decreased levels of cortisol (the patient was feeling well, her blood pressure was normal), normal electrolytes, normal renal and hepatic function, normal levels of serum testosterone (in the female normal range). The glycemic profile showed normal fasting glucose, with a HbA1c of 5.2%. A suspicion of alopecia areata was raised and the patient was sent to a dermatological evaluation. The dermoscopy confirmed the diagnosis of alopecia areata. Data in the literature point to the fact that there are human leukocyte antigen alleles, that are high risk for alopecia areata. Epidemiological studies show that a history of autoimmune disease increases the risk of alopecia areata. Specific associations mentioned in the literature are: alopecia areata with thyroid disease, vitiligo, rheumatoid arthritis. Given the fact that autoimmune polyglandular syndrome type 2 (as is the case of our patient) associates autoimmune diabetes in 30-52% of cases, we decided to test for diabetes autoantibodies. The test detected increased levels of glutamic acid decarboxylase (GAD-65). Studies point to the fact that antibodies, in particular antibodies anti-GAD, are also present in a percentage of nondiabetic patients, that do not develop diabetes over many years. But given the association with multiple other autoimmune diseases, the patient must be carefully followed, to detect diabetes onset in an early stage, preventing life-threatening complications. Literature data suggest that alopecia areata protects against type 1 diabetes in predisposed individuals (it is the reason, why our patient at risk didn't develop clinical diabetes). In conclusion, the appearance of alopecia areata in a patient with autoimmune thyroid and adrenal disease, who is at increased risk of autoimmune diabetes, could protect against the development of rapidly progressive type 1 diabetes.

Globoid cell leukodystrophy: case report and literature review

Fatima Zahra Outtaleb[1], Amal Tazzite[2], Bouchaib Gazzaz[2,3] & Hind Dehbi[2,4]
[1]Ibn Rochd University Hospital, Laboratory of Medical Genetics, Casablanca, Morocco; [2]Faculty of Medicine and Pharmacy. Hassan II University, Cellular and Molecular Pathology Laboratory, Casablanca, Morocco; [3]Royal Gendarmerie, Genetics Analysis Institute, Rabat, Morocco; [4]Ibn Rochd University Hospital, Laboratory of Medical Genetics, Casablanca, Morocco

Krabbe disease, also known as globoid cell leukodystrophy, is an autonomic recessive genetic disorder caused by *GALC* mutations. *GALC* gene codes for galactosylceramidase, which is a lysosomal enzyme. This disorder can occur during early childhood, between the ages of 1 and 8 years old (later onset form) or during adulthood; its prevalence is estimated at 1/100 000. Nevertheless, in most cases, this disorder occurs during childhood. With this case report, our aim is to attempt to describe both clinical features and evolution of this rare defect. A 5-year-old non-consanguineous female with a good psychomotor development has been showing psychomotor regression including generalised hypotonia, loss of both speech and walking since age 3. This patient no dysmorphia and no organomegaly and she had no fever. Genetic testing revealed the presence of a compound heterozygote mutation in *GALC* gene— c.865G>C and c.195G>C confirming diagnosis of globoid cell leukodystrophy. Both parents received genetic counselling in order to determine the risk of reiteration and to offer prenatal diagnosis in case of any future pregnancy. Regarding patients with later onset globoid cell leukodystrophy (occurrence between 1 and 8 years of age), as is the case we are currently reporting, initial symptoms usually include eating difficulties and irritability. Then hypertonic episodes including myoclonic seizures occur in association with development regression. During the final stage of this disorder, hypotonia, blindness and deafness appear. Diagnosis can be stablished based on reduced galactosylceramidase enzymatic activity or by genetic testing for mutations in *GALC* gene. Death usually occurs 2 to 7 years after initial symptoms begin. For patients with either early childhood or later onset forms of this disorder, the only therapeutic option is hematopoietic stem-cell transplantation which slows down development of this disease. These facts provide new light on the need for genetic cancelling in order to provide pre-symptomatic diagnosis to at risk relatives. Furthermore, reporting of new cases will help to better unravel the phenotype-genotype correlation of *GALC* gene variants.

Metabolic and hemodynamic disorders in obese patients with true and pseudo-resistant hypertension

Anna Shalimova[1,2], Ganna Isayeva[1], Olena Burakoska[1], Iryna Komir[1], Maryna Vovchenko[1] & Kostyantyn Prosolenko[2]
[1]L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Complex Risk Reduction of Chronic non-Communicable Diseases, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Internal Medicine N1, Ukraine, Ukraine

Objective
to conduct a comparative assessment between metabolic and hemodynamic parameters in obese patients with true and pseudo-resistant (due to different causes) hypertension.
Materials and methods
The study included 302 patients with uncontrolled hypertension and obesity. Initial treatment efficacy was assessed 3 months after dual therapy was administered. Those patients who did not reach target blood pressure (BP) in dual therapy were transferred to triple therapy. Among patients who received triple therapy, 69 people did not reach target BP (they received the fourth drug spironolactone). All patients were additionally examined 6 months after the initiation of antihypertensive therapy.
Results
A comparative assessment of office BP, ambulatory BP monitoring (ABPM) and home self-measurement of BP was carried out between non-resistant and resistant patients: at the initial stage of enrolling patients, there was no significant difference in BP levels between non-resistant and subsequently resistant patients; after 3 months of follow-up (after prescribing double fixed combinations), there was a significant difference in the indicators of both office and out-of-office BP in resistant and non-resistant patients; despite the achievement of target BP levels after 6 months of therapy (double or triple fixed combinations in non-resistant patients and triple therapy + spironolactone in resistant patients), in the presence of resistance, both office, home and most ABPM indicators were significantly higher than in non-resistant patients. If at the stage of enrolling patients into the study and 3 months after the start of therapy there was no significant difference in BP levels between patients with true and pseudo-resistance, then after 6 months of antihypertensive therapy, patients with true resistance had significantly higher levels of office systolic BP (SBP, $P < 0.01$) and 24 h average SBP according to ABPM data ($P < 0.05$) compared with pseudo-resistant patients. Obese patients with true resistance had also significantly lower body mass index (BMI) and low-density lipoprotein cholesterol (LDL-cholesterol, $P < 0.05$) as well as higher levels of aldosterone and SBP ($P < 0.05$) compared with pseudo-resistant patients.
Conclusions
Even when target BP levels in antihypertensive therapy are achieved, obese resistant patients are characterized by higher levels of office and out-of-office BP, compared with non-resistant patients. Compared with pseudo-resistance, the presence of true resistance in obesity is associated with higher SBP and aldosteron levels, as well as lower BMI and LDL-cholesterol.

EP479

A new rehabilitation complex for muscle strength deficit correction and movement disorders in case of obesity

Valeriia Vasileva & Larisa Marchenkova
National Medical Research Center for Rehabilitation and Balneology, Department of Somatic Rehabilitation, Reproductive Health and Active Longevity, Moscow, Russian Federation

Aim
The Aim of the study was evaluation of effectiveness a new complex included aerobic and physical training, kinesiohydrotherapy, balance therapy on changes in muscle strength and movement disorders in patients with obesity.
Materials and methods
The study group included 40 patients aged 58 [53;66] y.o. with a BMI $\geq$ 30 kg/m^2. The control group included of 40 people aged 57 [54;63] y.o. with BMI $\geq$ 30 kg/m^2. Study methods included anthropometry, functional tests, and dynamometry.
Results
In research it was a significant decrease in body weight (from 106.03 [83;145] to 102.8 [80;141] kg), BMI (from 39.2 [30.12;49.1] to 38.1 [29.4;46.7] kg/m^2), decreased WC (from 109 [105;125.8] to 107 [98.8 12] cm), HC (from 127 [112.3;139.8] to 121 [109.5;133.5] cm), decreased pain syndrome (from 5 [3;7] to 2.5 [1;4.75] points), increased arm strength (in right arm from 20 [14.25;34] to 30 [19;42], in left arm from 19.5 [14.25;29.5] to 22 [18;30.75] daN). Conditioning and coordination abilities improved significantly in the main group according to the functional tests: "Up and go test" (from 7.9 [7.1;8.9] to 7.4 [6.5;8.3] sec.), back muscle strength (from 5[5;5] to 5[5;5]), static and dynamic abdominal muscle endurance (from 12.04 [9.47;17.13] to 16.07 [10.69;27.7] sec. and from 31[21;37.25] to 39 [29.5;46.5] sec, and back and (from 14.94 [5.8775;22.205] to 18.41 [9.745;31.335] times and from 8 [5;14] to 10 [8;23], times, respectively); Fukuda test scores (from 65 [56;76.75] to 72 [61;82] reps), One leg standing test (from 13.9 [5.38;32.15] to 18.61 [8.6125;38.1575] sec. for the left) and closed eyes (from 3.45 [2.16;6.38] to 3.975 [2.715;5.82] seconds for the right and from 4.12 [1.3;8.61] to 4.31 [2.16;8.13] seconds for the left).
Conclusions
A new complex including aerobic and strength training, kinesiohydrotherapy, and balance therapy showed significant effects on body weight reduction, body volume reduction, and muscle strength improvement in obese patients. A new integrated method results in a longer maintenance of the achieved effect when controlling the long-term results after 3 months and 1 year compared with the group that received only the 2-component program.

Keywords
obesity, kinesiohydrotherapy, balance, rehabilitation, coordination training, muscle strength.

Age aspects and body mass index in patients with toxic hepatitis

Oksana Prokopchuk[1,2], Ihor Hospodarskyy[2], Nadiia Gavryliuk[2], Svitlana Danchak[2] & Olha Kozak[2]
[1]Ternopil National Medical University, Department of Higher Nursing Education, Patient Care and Clinical Immunology, Ternopil, Ukraine; [2]Ternopil National Medical University, Ternopil, Ukraine

Background
Over the last year the social consequences of obesity has become significant, with weight-based stigmatization and prejudiced common outcomes. Toxic hepatitis is one of those diseases that has obese as comorbidity in different age groups. The pervasiveness of prejudice toward obese in patients with toxic hepatitis makes it imperative that scientists have access to valid and reliable measures to assess weight bias.
Objectives
Age groups structuring and examination of patients with toxic hepatitis for obesity detection as one of the hepatic fibrogenesis triggers.
Methods
124 patients with toxic liver disease were examined. The body mass index (BMI, Kettle index) was calculated using anthropometric indicators. For all our patients BMI was interpreted using standard weight status categories (classification of BMI adopted by the WHO (1997). The value of BMI in the range of 18.5-24.9 kg/m^2 should be considered optimal - normal or healthy weight; reduced BMI or underweight $\geq$ 18.5; overweight - 25.0-29.9; obesity I degree - 30,0-34,9; obesity II degree - 35,0-39,9; grade III obesity - $\geq$ 40 (kg / m^2). The age standards were interpreted using adopted by the WHO/Europe, according to which the young age is 25-44, the average age - 44-60, the older age - 60-75, the elderly age - 75-90, people aged 90 and over considered as long-lived. However, it should be noted that the last age category among the examined patients was not presented.
Results
The examination revealed that the following changes were observed in BMI: 52.8% of patients were with normal weight, 39% were overweight, obesity I degree was detected in 8.1% of patients. Age structuring of BMI is given in the table.

Characteristics	Young age n = 8(%)	Average age n = 56(%)	Elderly age n = 52 (%)	Old age n = 7 (%)
1	**2**	**3**	**4**	**5**
BMI kg/m^2 18,5-24,9	7(87,5)	31(55,4)	24(46,2)	3(42,9)
BMI kg/m^2 25,0-29,9	1(12,5)	22(39,3)	23(44,2)	2(28,6)
BMI kg/m^2 30,0-34,9	-	3(5,4)	5(9,6)	2(28,6)

Conclusions
Obesity of varying degrees was found in 47.2% of patients with toxic hepatitis in all age groups. The most numerous was group of average age ($n = 56$), the smallest in number was group of old age patients ($n = 7$). These data should be taken into account when choosing and prescribing adequate treatment, nutrition should always be considered among physicians in the liver and obesity fields, who have an important role to play in improving the quality of life for so many individuals afected by these pathologies.

DOI: 10.1530/endoabs.81.EP480

EP481

Prevalence of non alcoholic fatty liver disease and fibrosis in morbidly obese patients undergoing bariatric surgery

Rahma Khalaf, Faten Mahjoub, Nadia Ben Amor, Olfa Berriche & Henda Jamoussi
National Institute of Nutrition, Department A, Tunisia

Background
Patients undergoing bariatric surgery have a higher prevalence of non alcoholic liver fatty disease (NAFLD) than the general population; however, its assessment and the accurate staging of fibrosis are often complicated because noninvasive tests are not very accurate in patients with morbid obesity, and liver biopsy cannot be performed as a routine exam.
Aim
The aim of this study was to determine the prevalence of non alcoholic fatty liver disease and fibrosis in patients undergoing bariatric surgery.
Methods
This is a monocentric prospective descriptive study including 40 morbidly obese patients before bariatric surgery. NAFLD was diagnosed by ultrasound and alterations in liver enzyme levels (aspartate aminotransferase (ASAT), alanine aminotransferase(ALAT) and yGlutamylTransferase (yGT)). Fibrosis score used was the fibrosis-4 (FIB-4) index.
Results
The mean age was 38.18 $\pm$ 10.03 years, 35 (87.5%) were females, mean body mass index (BMI) was 47.13 $\pm$7.73 kg/m^2 and mean waist circumference was 134.64 $\pm$ 20.39 cm. Mean triglyceride level was 1.8 $\pm$ 1.67 mmol/l [0.41-7.67]. Mean serum levels of liver enzymes ASAT, ALAT and yGT were respectively 25.29 $\pm$ 12.11 UI/l [10-54], 26.82 $\pm$ 14 UI/l [14-58] and 28.11 $\pm$ 15.6UI/l [8-55]. Mean 25 OH vitamin D level was 17.02 $\pm$ 13.61 ng/ml [8.1-64.8] .Ultrasound was abnormal in 26 patients (65%). NAFLD was associated with triglyceride levels ($P = 0.034$). However, age ($P = 0.5$), body mass index ($P = 0.44$), hypertension ($P = 0.7$), diabetes ($P = 0.4$), ASAT levels ($P = 0.6$), ALAT levels ($P = 0.1$),ASAT/ALAT($P = 0.053$) and yGT levels ($P = 0.4$) and Vitamin D levels ($P = 0.05$) were not associated with NAFLD. Mean FIB-4 index was 0.74 [0.19-3.76]. Of the study population, 92.1% of patients had a FIB-4 index <1.3, 5.3% had a FIB-4 index between 1.4 and 2.67 and 2.6% of patients had a FIB-4 index >2.67. FIB-4 index >1.3 was associated with ALAT levels ($P = 0.005$), vitamin D levels ($P = 0.038$) and yGT($P = 0.03$).However, no association was found with ASAT levels ($P = 0.1$), yGT ($P = 0.3$), HOMA2-insulin resistance ($P = 0.9$), age ($P = 0.3$), BMI ($P = 0.56$) and waist circumference ($P = 0.4$).
Conclusion
Vitamin D status were associated with NAFLD and advanced fibrosis in morbidly obese patients. Therefore, routine screening of 25OH vitamin D deficiency have important therapeutic implications in this population. FIB-4 index ruled out advanced fibrosis in most of our study cases.

The effect of laparoscopic mini-gastric bypass on the compensation of carbohydrate metabolism in patients with morbid obesity and type 2 diabetes

Natalya Mazurina, Ekaterina Ershova, Kseniya Komshilova & Ekaterina Kim
Endocrinology Research Centre, Therapeutic Endocrinology, Moscow, Russian Federation

Objective
Sustained weight loss is a highly effective strategy to treat and prevent the development of type 2 diabetes (T2D). Bariatric surgery leads to significant weight loss, which ensures the achievement of remission of diabetes mellitus and other obesity-related comorbidities.
Aim
The aim of this study was to estimate glycemic profile of patients with morbid obesity and T2D after laparoscopic mini-gastric bypass (LMGB).
Methods
We conducted a retrospective study of obese patients admitted to the Endocrinology Research Center between February 2019 and December 2020. We included 45 adults (41 women and 4 men, median age 57.5 years) with diabetes mellitus type 2 (median duration of disease 8 years, 5 newly diagnosed) and morbid obesity (BMI>40 kg/m^2). Anthropometric (BMI) and metabolic (fasting plasma glucose (FPG), glycosylated hemoglobin (HbA1c), C-peptide) parameters were determined before surgery and at 6, 12 months after. Statistical analysis was performed with the use of Statistica v. 13.3 (TIBCO Software Inc., Palo Alto, CA, USA). Data is presented by medians and interquartile ranges (Median, (25;75)). There were carried out a comparative analysis of three dependent groups for quantitative data using the Friedman criterion, pairwise comparison of groups for quantitative data using the Wilcoxon criterion. The initial critical level of significance in testing statistical hypotheses was assumed to be 0.05.
Results
In the studied group the baseline median BMI was 51 kg/m^2 (44.3; 55.6), FPG 7.4 mmol/l (6.6; 9.0), HbA1c 7.2% (6.5; 8.5), C-peptide 4.5 ng/ml (4.3; 5.1). 6 months after LMGB the median BMI was 38.6 kg/m^2 (35.5; 42.1), FPG 5.3 mmol/l (4.9; 6.2), HbA1c 5.5% (5.3; 6.2), C-peptide 2.5 ng/ml (2.3; 3.9); 1 year after - BMI 31.6 kg/m^2 (28.65; 34.2), FPG 4.9 mmol/l (4.4; 5.3), HbA1c 5.7% (5.1; 5.9), C-peptide 2.2 ng/ml (1.9; 3.2). Comparing three groups differences in HbA1c levels were revealed ($n = 11$, $P < 0.001$). Difference between groups of 6 and 12 months after LMGB ($n = 10$, $P > 0.05$) was significantly less than before LMGB and 6 months after ($n = 23$, $P < 0.001$), before and 12 month after LMGB ($n = 18$, $P < 0.001$) in further pairwise comparison.
Conclusion
Weight loss was accompanied by a significant improvement of carbohydrate metabolism. A more pronounced decrease in body weight and improvement of metabolic parameters were observed in the first 6 months after surgery.

Hypoglycemia after gastric bypass

Coskun Ates, Erhan Hocaoglu, Ensar Aydemir, Filiz Mercan Saridas, Özen Öz Gül, Soner Cander, Canan Ersoy & Erdinc Erturk
Uludag University Faculty of Medicine, Endocrinology and Metabolic Diseases, Bursa, Turkey

Introduction
Today, approximately 33% of the world population is either overweight or obese. National Health and Nutrition Examination Survey (NHANES) results show that, when 20 years and older American adults are examined, it is seen that 33% of them are overweight, 35.7% of them are obese, and 6.3% of them are morbidly obese (1). Roux-en-Y gastric bypass is a restrictive and malabsorptive combined method and is a complicated operation. Cases of endogenous hyperinsulinemic hypoglycemia developing an average of 5-6 years after the operation have been reported (2). We aimed to present a case of severe hypoglycemia after Roux-en-Y gastric bypass.
Case
A 27-year-old female patient had a sleeve gastrectomy in 2015 and a Roux-en-Y gastric bypass operation in 2018. She lost 76 kg after the operation. His hypoglycemia started one year after Roux-en-Y gastric bypass. The patient, who has tremors, sweating, and palpitations, especially 2-4 hours after the meal, states that his capillary blood sugar is 24 mg/dl. Therefore, the patient sometimes applied to the emergency room. The patient was interned at Bursa Uludağ University in 2019. At the 15th hour of the 72-hour fasting test, blood glucose was: 20 mg/dl Insulin: 19.2 pmol/l c-peptide: 7 ng/ml. At the 2nd hour of the mixed meal test, blood glucose was 47 mg/dl while insulin: was 43.4 pmol/l. Computed tomography (CT) was performed on the patient. The pancreas was normal in CT. Islet abnormalities after Roux-en-Y gastric bypass surgery were considered in the patient. The patient received acarbose and metformin treatments for three months, but to no avail. Then liraglutide was started. After a month, the controlled hypoglycemia continued, and isoptin and acarbose were added to his treatment. However, the patient's complaints continued. Thereupon, Octreotide LAR 20 mg was started. The patient whose hypoglycemia improved is being followed up.
Conclusion
It is necessary to be careful about hypoglycemia developing after Roux-en-Y gastric bypass. Also, we should consider the long-term results of bariatric surgery

when making an operational decision. Octreotide therapy may be an alternative to pancreatectomy in hypoglycemia developing after gastric bypass.

Quality of life, anxiety-depressive disorders and their assessment in patients with metabolic syndrome

Olga Moskalenko & Eduard Kasparov
Federal Research Center «Krasnoyarsk Science Center» of the Siberian Branch of the Russian Academy of Sciences, Russian Federation

This article discusses the assessment of quality of life, psychological state and anxiety-depressive disorders in patients with metabolic syndrome. It is known that the prevalence of metabolic syndrome in different countries is about 30% and varies from included criteria. The problem of the quality of life of obese and overweight patients is relevant and socially significant.

Research Methods

The authors present the results of a study of 70 patients with MS and 36 apparently healthy volunteers who do not have concomitant diseases and are not obese. The study was conducted on the basis of the clinic of the Federal Research Center. Patients were examined, anthropometric parameters were determined (waist circumference, body weight) with an assessment of the quality of life (SF-36 questionnaire). The level of anxiety and depression was determined by the hospital anxiety and depression scale HADS.

Results

Analysis of the results revealed that most of the quality of life indicators were statistically significantly different in patients with metabolic syndrome relative to the control group. Thus, the indicators of the level of QoL are significantly higher in healthy individuals than in patients with obesity. Differences in all groups are significant ($P \leq 0.05$). It was found that the average level of parameters "physical functioning" decreased by 19.2% ($P < 0.05$), "role functioning" by 34.2% ($P < 0.05$), "general health" by 14.7% ($P < 0.05$), "vitality" by 16% ($P < 0.05$), "emotional functioning" by 53.1% ($P < 0.05$). The assessment of the level of anxiety and depression in patients with MS corresponded to the subclinically expressed level, and the level of depression exceeded the control group by 19%. The level of QoL in patients with obesity is significantly lower than in healthy individuals.

Conclusion

Assessment of the quality of life of patients with obesity and overweight is one of the most important factors in the integrative assessment of the condition of such patients. I would like to note that the higher the patient's body weight, the lower his physical condition and the more pronounced concomitant diseases. Patients with MS are characterized by a decrease in quality of life indicators, subclinically expressed anxiety-depression. Patients require correction of psychological disorders, which will reduce the level of anxiety and depressive disorders, which will further improve the quality of life.

Correlation between Type-1 diabetes and obesity

Subhash Kumar[1], Anand Shankar[2], Shaibal Guha[3] & Amit Kr Das[4]
[1]Diabetes and Obesity Care Center, Diabetes, Patna, India; [2]Shankar Diabetes Care and Research, Patna, India; [3]Positive Health Care Center, Patna, India; [4]SHMC Muzaffarpur, Diabetes, Muzaffarpur, India

Introduction

Increase in global childhood obesity is considered to be one of the detrimental problems all across the world. It is well known that about every 1 in every 300-500 infants suffers from Type-1 Diabetes Mellitus. Obesity has been directly associated with elevation of blood sugar and HbA1c.

Objective

This study investigates the prevalence of obesity in Type-1 DM and the distribution of sex, age and its correlation with HbA1.

Methods

Transversal revision of Type-1 DM anthropometric measurements from patients at a selected general hospital in Bihar. Sex, age, weight, values of HbA1c were reviewed.

Results

Among the selected 60 subjects, 6 (10% participants) were underweight with BMI below 15 kg/m^2, 18 (30% participants) were also underweight, however, their BMI falls between 15 to 16 kg/m^2. 9 (15% of participants) were also underweight but in between BMI 16-18.5 kg/m^2. 24 (40% of participants) were in the normal range and their BMI was between 18.5-25 kg/m^2. HBA1c median was 9.44% with a standard deviation of 2.45%. Only one patient had a normal HbA1c value below 7%. Out of 60, 8% had between 7-8%, 22% patients had 8-9%, 22% had 9-10, 16% had 10-11, 4% had 11-12%, 14% had 12-13%, 10% had between 13-14% and 1 patient had A1c level between 14-15% which was elevated.

Conclusion

This study showed that overweight and obesity were not big issues in the Type-1 diabetic population. Both these cases are rare when the HbA1c level is high.

Manifistation of psoriasis in patients with type 2 diabetes

Elena Brutskaya-Stempkovskaya [1], Alla Shepelkevich[2] & Yuliya Dydyshka[2]
[1]Belarusian State Medical University, Jeneral Medicical Practice, Minsk, Belarus; [2]Belarusian State Medical University, Endocrynology, Minsk, Belarus

Background

It is known that the prevalence of skin diseases in patients with type 2 diabetes (T2D) is increased including psoriasis. Patients with T2D and psoriasis have an increased risk of psoriasis exacerbations. The study of the psoriasis manifestation features in patients with T2D can help to reduce the number of exacerbations, their severity and duration.

Aims

To study the influence of T2D on the psoriasis manifestation and exacerbation.

Materials and Methods

We studied hospitalized patients with T2D and psoriasis in dermatological clinic during 5 years ($n = 47$) - the main group. Comparison group 1- patients with psoriasis without T2D ($n = 40$), comparison group 2 - patients with T2D without psoriasis ($n = 37$). Patients were excluded: with the psoriatic arthritis, GFR ≤ 45 ml/min/1.73 m^2.

Results

Patients of the main group (women-53.2%, men-46.8%, mean age 61.0$\pm$7.7 years), comparison group 1 (women-55%, men- 45%, mean age 60.5$\pm$7.5 years), comparison group 2 (women-54%, men-46%, mean age 62.0$\pm$7.8 years) were same in clinical, anthropometric, anamnestic and laboratory data (AST, ALT, total cholesterol, creatinine, $P > 0,05$). Patients of the main group and comparison group 1 differed in serum glycaemia ($P = 0.005$), HbA1c ($P = 0.009$). Patients of the main group had an increase HbA1c (11.8 (7.9-12.3)) compared with the comparison group 2 (6.8(6.1-7.3), $P = 0.006$) in the exacerbation of psoriasis period. All patients of the main group were ranked into groups depending on the HbA1c level. HbA1c $<$ 7.0% was detected in 8.5% ($n = 4$) of patients with T2D and psoriasis, HbA1c 7.0-8.5% -in 31.9% ($n = 15$), HbA1c $>$ 8.5% - in 59.6% ($n = 28$) cases. Thus, result of the study indicates a decrease in glycemic control in 91.5% patients of the main group for a period of at least 3 months before the psoriasis exacerbation.

Discussion

Result of the study indicates a decrease in glycemic control in patients with T2D and psoriasis before the psoriasis exacerbation. There is probably a correlation between psoriasis exacerbation and low glycemic control in patients with T2D and psoriasis.

Neurodegeneration type and severity have linkage with plasma insulin in DM patients

Talat Saatov[1], Timur Alimov[2], Elvira Ibragimova[1], Takhir Ishankhodjaev[3], Zafar Ibragimov[3], Gulnora Artikbaeva[3], Mukhammadjon Mustafakulov[1], Dilnoza Saidova[3] & Zulaykho Shamansurova[1,4]
[1]Institute of Biophisics and Biochemistry at the NUUz, Metabolomics, Tashkent, Uzbekistan; [2]Republican Specialised Scientific Practical Medical Centre of Hematology, Tashkent, Uzbekistan; [3]Institute of Biophisics and Biochemistry at the NUUz, Tashkent, Uzbekistan; [4]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Background
In Pathogenesis of Neurodegeneration in Diabetes Mellitus (DM) addition to insulin resistance, glycemic control and blood plasma lipid levels existing other mechanisms were proposed. We investigated plasma insulin level in patients according to severity of diabetic neuropathy.
Materials and methods
In 32 people with DM2 glycemia, HbA1c, blood plasma insulin, blood total cholesterol, triglycerides, Low Density Lipoproteins (LDLP) levels were measured and compared regarding to DN severity by stages in DN1 and DN2 groups.
Results
People with DN1 and DN2 have the same age and disease duration. Glycemia and HbA1c level were also comparable between groups. Although, body weight and BMI (in 1.32 times), blood total cholesterol (in 1.3 times), triglycerides (in 1.32 times), LDLP (in 1.4 times) levels were significantly higher in DN2 group than DN1, blood plasma insulin was higher in DN2 group and suggested about involvement of insulin resistance into pathogenesis of DN. However, people in DN2 group used metformin with combination of sulfonilureas, whereas DN1 group mostly used metformin for lowering blood sugar.
Conclusion
DM2 patients with severe DN have higher BMI, blood lipids and plasma insulin level. Plasma insulin level have a linkage with DN severity in DM2 and play a role in the development of neurodegeneration.

Salvage nephrectomy for a severe acute emphysematous pyelonephritis with septic shock: a case report

Maatougui Jasser[1], Raboudi Mehdi[1], Chayma Besrour[2], Ouertani Haroun[2] & Ghozzi Samir[1]
[1]The Military Hospital of Tunis, Urology, Tunis, Tunisia; [2]The Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Emphysematous pyelonephritis is associated with high mortality rate. It is seen in patients with a long-standing diabetes. We report a case of a women presenting a septic shock following a severe acute right emphysematous pyelonephritis and requiring salvage nephrectomy.
Case report
A 52-year-old female presented fever with right flank pain. She had a long history of uncontrolled diabetes. Physical examination revealed a with high fever (39°) with tender right loin. Basic investigations reported high blood sugar (33 mmol/l) with HbA1c at 13.2%. Urinary labstix showed negative results for ketones. Biology found renal failure (Creatinine 243 μmol/l) with an hyperleukocytosis (23 × 109/l) and thrombocytopenia (85 × 109/l). kidney, ureter, and bladder (KUB) X-ray revealed no significant abnormality. Ultrasonography showed a right kidney with hydronephrosis upon a 8 mm lumbar ureteral calculus. Left kidney was normal. The diagnosis of acute obstructive right pyelonephritis has been established and antibiotherapy using cefotaxime, amikacin injection and insulin has been immediately started. A double J stent has been also inserted to drain right renal cavities. Despite those measures, our patient continued to be febrile, without improvement of biological parameters. Rapidly, she became sleepy with persistent hypotension, tachycardia and deterioration of renal function. Computed tomography, urgently performed, showed a right emphysematous pyelonephritis (stage III) with gas replacing almost all renal parenchyma and extrarenal extension to pararenal space (Figures 1). Based on the clinical and radiological features, Urologists has performed an urgent right salvage nephrectomy. The removed kidney was gangrenous. She had an uneventful recovery during 5 days in intensive care unit. She received imipenem for 21 days. Renal and tests and CBC normalized. Blood sugar became normal with insulin.
Conclusion
Emphysematous pyelonephritis occurs mostly in patients with diabetes and a predilection for females. It has a high fatality rate. Therefore, aggressive medical with early surgical intervention is recommended.

Ptosis and type 1 diabetes: fortuitous association?

Ramla Mizouri, Rym Ben Othman, Nadia Ben Amor, Faten Mahjoub, Selma Mohsen, Rihab Yamoun, Berriche Olfa & Jamoussi Henda
Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia

Introduction
Diabetes is the cause of ophthalmological complications that are all the more severe when the balance of diabetes is precarious. Among the non-retinal ocular targets of diabetes is damage to the optic nerve. The diagnosis of diabetic mononeuritis should only be made after excluding other causes of neuropathy.
Observation
We report the case of a patient referred to our service for equilibration of diabetes. This is a 59-year-old patient, type 1 diabetic for 30 years, coronary stent 6 years ago. In addition, the patient presents a ptosis of the right eye which appeared two weeks ago. As part of the exploration of this symptomatology, a brain scan and a brain MRI were requested. The scan came back with no abnormalities. MRI showed moderate thickening of the optic nerve consistent with optic neuritis. The etiological investigation was continued by serological, enzymological and immunological tests. CMV and HIV serologies were negative. The angiotensin converting enzyme level was normal. Polymorphonuclear anti-cytoplasm antibodies and native anti-DNA antibodies also came back negative. On biology, he had a fasting blood sugar level of 25.1 mmol/l and a glycated hemoglobin of 12.9%. The patient was put under hygieno-dietetic rules, metformin and insulin therapy. The evolution was marked by the normalization of the glycemic figures after one week of hospitalization.
Conclusions
Optimal glycemic control reduces the risk of diabetic retinopathy but also of the occurrence of other ocular pathologies, in particular oculomotor damage and damage to the optic nerve responsible for reduced visual acuity.

Association between severe COVID-19 pneumonia and characteristics of type 2 diabetes patients

Olfa Lajili, Zouaoui Chadia, Rim Rachdi, Bchir Najla & Haroun Ouertani
The Military Hospital of Tunis, Endocrinology and Nutrition Department, Tunis, Tunisia

Introduction
COVID-19 caused by SARS-COV-2 infection can lead to multi-organ injuries and significant mortality in severe and critical patients, especially among those individuals with type 2 diabetes. The aim of our study was to assess associations between severe COVID-19 pneumonia and clinical and biological characteristics of patients with type 2 diabetes.
Methods
This was a retrospective and descriptive study including 40 Tunisians patients hospitalized for severe form of covid 19. The study was conducted the Military Hospital of Tunis during a period of 3 months (April -June 2021). The diagnosis was retained by a positive RT-PCR test and by the radiological aspect on the chest scanner. Statistics were performed using SPSS 20.
Results
The averge age was 71 ± 8.57 years [58-85 years]. A male predominance was noted (71.4%). The averge BMI was 28.8 ± 5.6 kg/m^2. Two thirds of the patients were overweight and 35.7% were obese. The average duration of diabetes was 11.4 ± 4.3 years. Hypertension and dyslipidemia were noted in 71.4%, 28.6% of cases. Two thirds of our population (78.6%) were treated with oral antidiabetics et 21.4% with insulin. The mean CRP was 94.7 ± 42.3 mg/l. Dimer tests were positive in 43% of patients and 7.1% had cytolysis. Patients had severe COVID-19 pneumonia (> 50%) in 21.4% of cases. The average length of hospital stay was 12.4 ± 7.6 days. Patients with severe pneumonia had a longer length of hospital stay ($P < 0.001$) and a tendency to have a longer duration of diabetes ($P = 0.06$). Furthermore, we did not noted an association between age, BMI, insulin treatement and CRP level, and severe COVID-19 pneumonia ($P = 0.4$, $P = 0.6$, $P = 0.7$ and $P = 0.5$ respectively).
Conclusion
Our study showed that severe COVID-19 pneumonia was associated with length of hospital stay in patients with type 2 diabetes. Further studies need to be done, to understand the relationship between severe COVID-19 pneumonia and characteristics of patients with type 2 diabetes, to provide special treatment for this high-risk population.

Sulphonylureas induced hypoglycemia: a negleted cause of focal encephalopathy

Leonor Lopes, Carlos Bello, Maria Clotilde Limbert & João Sequeira Duarte
Hospital Egas Moniz, Endocrinology, Portugal

Introduction
Sulphonylureas (SU) are an effective therapy for type 2 diabetes (T2DM). As insulin secretagogues, hypoglycemia is a potencial adverse effect. Hypoglycemia may cause neuroglycopenic brain injury, which can mimetize stroke and infections of the central nervous system.
Case Report
The authors report the case of an autonomous 71 year-old woman, with medical history of hypertension and T2DM, treated with enalapril and gliclazide, that was admitted in the Emergency Room after being found unresponsive at home. The first medical evaluation revealed: GCS 14, hypertension (172/85mmHg) and capillary blood glucose of 28 mg/dl. Complete neurological exam showed left hemiparesis and aphasia, being stroke the most probable diagnosis.Patient was admitted to the Neurology floor. No ischemic lesion or hemorrhage were found in two separate cerebral MRIs. All other exams were normal, including: holter, cardiac ultrasound, carotid doppler, EEG and lumbar puncture. Blood workup was unremarkable, without signs of infection or inflammatory disease. A1C hemoglobin was 5.7%. All symptoms and deficits remitted after SU discontinuation. After excluding differential diagnosis, it was assumed the diagnosis of neuroglycopenia with focal neurological deficits caused by treatment with SU.
Conclusion
Nowadays, with the development of new antidiabetic drugs, the use of SU has been reduced. The risk of SU induced hypoglycemia is relevant, mainly in the elderly. Cognitive and mental impairment are the most frequent symptoms of hypoglycemia. In rare cases, hypoglycemic encephalopathy with focal deficts may occur. Being a reversible cause of injury, its peremptory diagnosis is relevant.

Diabetic muscle infarction: a case study

Ons Maaoui[1], Sabrine Mekni[1], Senda Ben Rebai[1], Imen Rojbi[1], Youssef Lakhoua[1], Nadia Mchirgui[1], sahar agerbi[2], Soumaya Chargui[2], Nada Sallemi[2], Ibtissem Ben Nacef[1] & Karima Khiari[1]
[1]Hospital of charles Nicolle, Endocrinology, Tunisia; [2]Hospital of Charles Nicolle, Nephrology, Tunisia

Introduction
Diabetic muscle infarction (DMI) is a rare complication of long-standing, poorly controlled diabetes, and it's more common in patients with micro-vascular complications. Herein, we present a case of DMI occurring in patient on hemodialysis.
Case presentation
A 44-year-old man on maintenance hemodialysis presented with an acutely painful and swelling in his left calf. He had a 21-year history of poorly controlled type one diabetes, with micro-vascular complications (nephropathy and retinopathy). On physical examination: his skin was pale, his temperature was 37°c, his heart rate was 80 beats per minute and his blood pressure was 150/80 mmHg. His left calf was swollen and tender with no edema or inflammatory signs. Biochemical findings showed: C-reactive protein (CRP) 42 mg/l, CPK 179 U/l (39-308) and LDH 382 U/l (140-280). A Doppler ultrasound showed no sign of deep vein thrombosis, but demonstrated edema of the superficial tissues which prompted the practice of an MRI showing thickening of the lateral gastrocnemius muscle with edema. It is the seat of a lack of enhancement extending over 3 cm with the interposition of a few fibers of marked enhancement. The thickening and muscle edema was more important in the posterior compartment of the leg. It also showed edematous infiltration of fascia and subcutaneous cellulitis without significant enhancement and minimal fatty degeneration of the different muscle compartments of the leg. The patient was put on analgesics and activity restriction in the acute phase followed by gradual mobilization.
Conclusion
Diabetic muscle infarction is a rare and under-reported condition that should be suspected in any diabetic dialysis patient who develops a painful, swollen muscle.

Quality improvement project; Recognition and management of Hyperosmolar Hyperglycemic State (HHS)

Adnan Adnan, Tahir Omer & Abaid-Ur Rehman
Northampton General Hospital, United Kingdom

Introduction
Hyperosmolar Hyperglycemic State (HHS) is an uncommon and potentially fatal complication of diabetes. HHS is a medical emergency with high mortality. Therefore, it needs to be managed promptly and carefully utilising nationally agreed guidance. Delays in recognition and challenges in management may lead to poor outcome.
Aim and Targets
The primary objective is to improve the recognition and management of HHS. The project was set to the standards of the HHS guideline produced by the Joint British Diabetes Societies (JBDS) in August 2012. Our target is to improve adherence with this national guidance by at least 50% by May 2022.
The Project
A retrospective audit was undertaken initially to understand the current local care of patients admitted with HHS. this was conducted in a single district general hospital. Data were collected from the medical notes of patients with a diagnosis coded as "Hyperosmolar Hyperglycemic State/HHS" in the proceeding 12 months. The data clearly demonstrated that the current local practice falls short of the JBDS recommendation for HHS. This spanned from identification to management (rehydration, insulin therapy and monitoring) of HHS.
Intervention
A number of interventions to increase awareness and improve the management of patients admitted with HHS were applied simultaneously. In addition to teaching sessions for clinicians working in acute medical admission wards, an HHS prescription chart was introduced with details about the diagnostic criteria and further management of HHS and possible metabolic complications based on the JBDS guideline. This was structured in an easy step by step approach.
Discussion and conclusion:
HHS is an uncommon medical emergency and sometimes it's the first presentation of Type 2 diabetes. Moreover, it usually co-presents with other medical conditions (infections, vascular events etc) which makes the recognition more challenging. A second audit to gauge the degree of improvement the interventions contributed to the care of patients with HHS is currently being prepared. This will contribute to further interventions to the already established prescription charts and education sessions as deemed required. This project provides a useful learning opportunity for quality improvement and patient safety contributing to better patient care.

Clinical cardiovascular autonomic neuropathy (CAN) and amputations - a sinister combination for the quality of life in diabetes

Daniel Cosma[1], Cristina Alina Silaghi[2] & Horatiu Silaghi[3]
[1]Horezu City Hospital, Diabetes, Nutrition and Metabolic Diseases Outpatient Clinic, Horezu, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Endocrinology Department, Cluj-Napoca, Romania; [3]"Iuliu Hatieganu" University of Medicine and Pharmacy, 5th Department of Surgery, Cluj-Napoca, Romania

Introduction
Diabetic autonomic neuropathy (DAN) and CAN as one of its most common manifestations are serious complication of type 1 and type 2 diabetes mellitus leading to a significant increase in morbidity and mortality.
Case presentation
A 51-year old male, diagnosed with T2DM for 25 years, complicated by stage III diabetic polyneuropathy, proliferative retinopathy and several amputations on both feet, treated with Metformin (2g/day), Glargine (26 IU/day) and Aspart (21 IU/day), was admitted in our center for: neuropathic ulceration on the plantar surface of the 4th metatarsal head, hyperglycemia on self-monitoring, dry mouth, nocturnal enuresis (3 times/night), blurred vision and deep muscle cramps in the calves with insidious onset, lasting for 15-20 minutes and alleviated by Cilostazol administration. One year prior to current admission, he was diagnosed with Monckeberg sclerosis. On admission: altered general status, BP = 120/80 mmHg, Pulse = 88b/min, symptomatic orthostatic hypotension, rhythmic cardiac sounds with stage III holosystolic murmur on the entire cardiac area, diminished peripheral pulses, multiple ecchymosis after insulin injection in the right lumbar region, bilateral plantar hyperkeratosis, interdigital maceration at the level of the 3rd and 4th space of the left foot. Lab exams revealed: inflammatory syndrome,

iron deficiency anemia, hypocalcaemia and poor glycemic control (A<ce:inf>1</ce:inf>c = 10.19%). The foot surgeon removed the affected soft tissue including the 4th metatarsal joint of the left foot. Under antibiotic therapy with Clindamycin (i.v) and Ciprofloxacin, α-lipoic acid, benfotiamine, aspirin, atorvastatin, cilostazol and iron substitution, the clinical evolution was slowly favorable. The plague culture was negative, possible in the context of prior Amoxicillin Clavulanate administration before hospital admission. Given his clinical presentation, a Cardiosys evaluation was performed, which confirmed the CAN diagnosis. In order to decrease the number of the symptomatic orthostatic episodes, 0.1 mg/day of Fludrocortisone was initiated under 24 h BP monitoring. The therapeutic education with emphasis on carbs ingestion, blood glucose self-monitoring and foot care was resumed.

Conclusions

This case illustrates typically the negative impact of peripheral and clinical CAN association on the quality of life (QoL). Unfortunately, the poor prognosis in this case relies mostly in the lack of adherence to the medical therapy and foot care.

EP495

The prevalence of diabetic peripheral neuropathy among the futsal players participating in the DiaEuro 2017 Championship

Daniel Cosma[1], Cristina Alina Silaghi[2] & Horatiu Silaghi[3]
[4]Horezu City Hospital, Diabetes, Nutrition and Metabolic Diseases Outpatient Clinic, Horezu, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Endocrinology Department, Cluj-Napoca, Romania; [3]"Iuliu Hatieganu" University of Medicine and Pharmacy, 5th Department of Surgery, Cluj-Napoca, Romania

Objectives

To assess the prevalence of diabetic peripheral neuropathy (DPN) among futsal players participating in the 2017 edition of the European Futsal Championship for people with diabetes (DiaEuro).

Methods

In this cross-sectional study were included 94 amateur/professional futsal player, from 9 European countries. The evaluation was made based on the data extracted from the standard medical certificate completed by each player's diabetologist. The official participation criteria were: age ≥ 18 years old, a diagnosis of diabetes and no other severe comorbidities that could contraindicate this type of sport.

Results

Of 94 subjects, 90 (95.74%) had type 1 diabetes, 3 (3.19%) had type 2 diabetes, and one player had type 3c diabetes secondary to chronic pancreatitis. 3 players were on oral medication, one was on diet therapy and 90 players (95.74%) were under insulin treatment as follows: 78 (82.97%) on a basal bolus regimen and 12 (12.76%) on insulin pump. Regarding the diabetes microvascular complication, 2 (2.12%) individuals were diagnosed with DPN and 3 (3.19%) with retinopathy and 6 (4.31%). Furthermore, only one subject out of the 2 with DPN received treatment with alpha-lipoic acid for his condition.

Conclusions

In our analysis of 94 amateur/professional futsal players with diabetes, we found a prevalence of 2.12% of DPN.

Parameter	Interval (min-max)	Mean	STDEV
Age (years)	18 - 55	27.74	±8.23
Diabetes duration (years)*	1 – 39	12.21	±7.34
Last A_1c (%)*	5.3 -10.5	7.31	±0.99

The general characteristics of the study population; *Data were available for 91 subjects; STDEV = standard deviation; A1c = glycated hemoglobin

Metabolic complications of obese Tunisian adults

Zeineb Zemni[1], Olfa Lajili[2], Nadia Ben Amor[1], Emna Bornaz[1], Ben Ali Khaoula[3], Eya Safi[3], Ramla Mizouri[1], Ryme Ben Othmen[1], Faten Mahjoub[1], Olfa Berriche[1] & Henda Jamoussi[1]
[1]National Institute of Nutrition of Tunis, Unit of Obesity Research, Tunis, Tunisia; [2]Military Hospital of Instruction of Tunis, Department of Hygiene, Tunis, Tunisia; [3]Military Hospital of Instruction of Tunis, Endocrinology Department, Tunis, Tunisia

Introduction

Obesity is a major health problem through its numerous complications especially metabolic complications associated with cardiovascular risk. The aim of our work was to describe the clinico-metabolic profile of obese Tunisian adults.

Methods

This was a descriptive cross-sectional study involved 174 obese patients who consulted between July and December 2020 at the Obesity Unit of the National Institute of Nutrition in Tunis.

Results

The average age was 45.21 ± 13.88 years with a female predominance of 75.3%. All patients were obese with an average BMI of 40.2 ± 7 kg/m^2. Obesity was visceral in 100% of cases with a mean waist circumference of 121.05 ± 14.4 cm (men 123.93 ± 14.01 cm vs women 120.11 ± 14.45 cm).Arterial hypertension was noted in 47.13% of our population of which 15.85% were not known hypertensive. Dyslipidemia was found in 54.6% of cases of which 45.26% were unknown. Carbohydrate tolerance disorders was found in 67.81% of cases devised as follow: 37.36% prediabetes; 24.71% diabetes and 5.17% unknown diabetes. Hyperuricemia was found in 33.3% of cases. No patients were symptomatic. Waist circumference Was significantly correlated with BMI (r = 0,62;P < 0,001)), as was triglycerides (r = 0,16; P = 0,039).

Conclusion

In our study metabolic disorders were of incidental discovery in many patients. Their treatment must be specific, it should not be limited to weight loss, and the early detection of these abnormalities and their management will improve the cardiovascular prognosis of patients.

Metabolic profile of morbid obesity compared to moderate and severe obesity: What particularities?

Soumiya Berrabeh[1], Lamiae Zarraa[1], Achwak Alla[1], Salma Derbel[1], Ouafae Elmehraoui[1], Tahri Abir[1], Dounia Zerrouki[1], Siham Rouf[2,3] & Hanane Latrech[2]
[1]Mohammed VI University Hospital Center Oujda, Faculty of Medicine and Pharmacy Oujda, University Mohammed First Oujda, Endocrinology-Diabetology and Nutrition Department, OUJDA, Morocco; [2]Mohammed VI University Hospital Center Oujda, Faculty of Medicine and Pharmacy Oujda, University Mohammed First Oujda, Morocco, Endocrinology-Diabetology and Nutrition Department, Laboratories of Epidemiology, Clinical Research and Public Health, OUJDA, Morocco; [3]Faculty of Medicine and Pharmacy of Oujda, Mohamed the First University, Laboratory of Epidemiology, Clinical Research and Public Health, Oujda, Morocco

Introduction

The prevalence of obesity is increasing in the world. It constitutes a major risk factor associated with diabetes, hypertension, dyslipidemia and cardiovascular diseases. The aim of our work is to compare the metabolic profile of morbid obesity with that of moderate to severe obesity.

Patients and methods

It is a Retrospective, descriptive and analytical study, including 63 obese patients, followed at the endocrinology, diabetology and nutrition department of the CHU Mohamed VI Oujda. The patients were divided into two groups: Group 1 (G1: moderate to severe obesity): 37cases (BMI:30 to 40 kg/m^2), Group 2 (G2: morbid obesity): 26 cases (BMI ≥ 40 kg/m^2). Collected data were analysed using SPSS V24 software.

Results

The mean age of the patients was 30.5 ± 16.9 years in G1 and 39.8 ± 12.5 years in G2. A female predominance was noted in the 2 groups with a Sex-ratio F/M (G1) :2.7 and (G2):7.6. The mean BMI in G1 was 35 ± 2.9 kg/m^2 and 47.8 ± 5.9 kg/m^2 in G2. The mean waist circumference was higher in G2 (165.6 cm vs 111.2 cm). The prevalence of diabetes and pre-diabetes was 35.2% and 43.3% (G1) vs 30.7% and 38.5% (G2) respectively (P = 0.05). The prevalence of hepatic steatosis was higher in G2 compared to G1 (69.2% vs 48.6%) but without significant difference (P = 0.5).The mean uricemia was 54 ± 14.5 mg/l (G1) and 65.3 ± 12 5 mg/l (G2). In contrast, the prevalence of dyslipidemia was higher in G1 (32.4%) compared to the group having morbid obesity (26.9%) with a highly significant difference (P = 0.008).

Discussion/Conclusion
Obesity is an excess of body fat with harmful consequences for health. It has been defined as a disease by the World Health Organization since 1997 in view of its epidemic dimension and its somatic, psychological and socio-economic repercussions. The main metabolic complications of obesity are associated with the phenomenon of insulin resistance and are included in the metabolic syndrome. Several studies suggest that despite a greater accumulation of fat, morbid obesity is not characterized by a more deleterious metabolic profile than moderate and severe obesity. The results of our study are also in line with those of the literature, which show that the severity of obesity is not significantly correlated with metabolic risk.
Keywords
Morbid obesity, moderate and severe obesity, metabolic profile

How to treat severe obesity due to binge eating in children?
Amalia Ioana Arhire[1,2]
[1]Elias Hospital, Endocrinology, Diabetes and Nutrition Department, Bucharest, Romania; [2]Kilostop Junior Nutrition Clinic, Endocrinology, Diabetes and Nutrition Department, Bucharest, Romania

Introduction
As the incidence of pediatric obesity is gaining pandemic levels, with children and teenagers developing obesity complications similar to the adult population, a rapid evaluation and treatment is necessary. We present such a case.
Case report
A 12-year-old male with a medical history of binge eating, treated by Topiramate, since the age of 11 and 3rd degree obesity, complicated with JNC stage II hypertension, NASH and dyslipidemia was referred to our clinic for nutritional assessment and treatment. He was referred by a colleague endocrinologist that evaluated his obesity for endocrinological causes, which were excluded. The clinical examination:Showed normal pubertal Tanner stage (P1G2), BMI 37.3 kg/m^2, height of 155 cm (75th centile), 51.4%fat, 205% obesity degree from the 95th centile, normal muscle mass of 23.7 kg, BP 150/90 mmHg and a waist circumference of 120 cm.
Laboratory
Dyslipidemia with HDL= 30 mg/dl, TG= 133 mg/dl:, insulin resistance HOMA-IR: 6, blood glucose= 82.5 mg/dl, an inflammatory status with a VSH=21, fibrinogen = 357, 25-OH vitamin D of 17 ng/ml, TSH of 2,71, normal salivary cortisol, IGF1, FSH, LH < 0.3, testosterone of 0.16 nmol/l and a prolactin of 293 mcUI/ml. The abdominal ultrasound showed liver steatosis. The basal metabolic rate (indirect calorimetry) - low of 1600 kcal (85%), correlated with the low muscle mass. The cardiology consult found normal ECG, JNC stage II hypertension, septal left ventricular hypertrophy and indicated treatment with Lisinopril 10 mg per day. We began a hypocaloric Mediterranean diet (400 calories daily deficit), moderate physical activity (45-60 minutes), low sodium intake, but the patient didn't lose weight for the first month of nutritional monitoring, so Liraglutide was introduced, with a 0.6 mg /day regimen, with dose titration every 2 weeks to avoid adverse effects, to a dose of 2.4 mg per day. He received Omega 3(2000 mg) and 2000 UI vitamin D per day. After 1 month of diet and Liraglutide, the binge eating improved, he lost 2% of body fat and the BP normalized. Also, the eating disorder improved.
Conclusion
The metabolic syndrome that complicates obesity is a frequent condition in adults with increasing incidence in children. As more and more children develop severe complicated obesity, before the age for bariatric surgery, more pharmacological treatment is needed and clear and standardized cut-offs for the metabolic syndrome definition is necessary.

Lipid profile of the obese: about 100 cases
Rym Ben Othman[1], Ramla Mizouri[2], Amany Amorri[3], Nadia Ben Amor[1], El Amri Abir[3], Berriche Olfa[2], Faten Mahjoub[1] & Jamoussi Henda[3]
[1]Faculty Of Medicine of Tunis, Tunisia; [2]Institut National de Nutrition de Tunis, Tunisia; [3]University of Tunis El Manar, Tunisia

Obesity is a major public health problem. It is a privileged provider of a constellation of metabolic abnormalities, particularly lipids, increasing the risk of morbidity and mortality and hampering the quality of life of the obese.
Material and methods
We conducted a prospective study on 100 obese patients recruited at the Human Obesity Research Unit at the National Institute of Nutrition in Tunis. Our patients benefited from an assay of fasting insulinemia and a complete lipid profile including the assay of cholesterol, triglycerides, HDL-cholesterol with calculation of LDL-cholesterol and non-HDL-cholesterol.
Results and Statistical Analysis
The average age of our population is 37 $\pm$ 10.8 years. The average BMI is 38 $\pm$ 6.7 kg/m^2 with extremes of 30 and 67 kg/m^2. Mean fasting insulinemia is 24.7 $\pm$ 20.1 µU/ml with extremes of 5.3 and 146 µU/ml. One-third of obese people have high fasting insulin levels. Hypertriglyceridaemia is noted in 19% of obese patients. 29% of obese people have hypercholesterolemia. More than a quarter of obese people (27%) have low HDL-cholesterol levels below 1.03 mmol/l (0.4 g/l). On the other hand, 14% of patients have an HDL-cholesterol level greater than or equal to 1.55 mmol/l (0.6 g/l). The average non-HDL cholesterol is 3.35 $\pm$ 0.9 mmol/l (1.3 $\pm$ 0.36 g/l). The average LDL-cholesterol of 2.81 $\pm$ 0.85 mmol/l (1.09 $\pm$ 0.33 g/l) with extremes of 1 and 6 mmol/l (0.39 and 2.32 g/l). Hyper LDLemia was discovered in 29.3% of obese patients. The duration of evolution of obesity is positively and significantly correlated with the elevation of cholesterolemia ($P = 0.001$), LDL-cholesterol ($P = 0.002$) and non-HDL-cholesterol ($P = 0.001$). The rise in fasting insulinemia is positively and statistically correlated with the rise in cholesterolemia ($P = 0.001$), LDL-cholesterol ($P < 10-3$), non-HDL-cholesterol ($P < 10-3$). A negative and statistically significant correlation was also noted between fasting insulinemia and HDL-cholesterol ($P = 0.02$).
Conclusion
The lipid profile of the obese is highly atherogenic. It is distinguished by a variety of lipid abnormalities dominated by elevated LDL-cholesterol, total cholesterol and triglycerides with hypo-HDLemia justifying their early management in order to improve their cardiovascular prognosis.

Comparative study of epidemiological, clinical and paraclinical characteristics between a group of complicated obese versus uncomplicated obese: about 400 cases
Fatma Mnif, Mariem Souissi, Dhoha Ben Salah, Khouloud Boujelben, Kawthar El Arbi, Mouna Mnif, Nabila Rekik Majdoub, Mouna Elleuch, Nadia Charfi & Mohamed Abid
Hedi Chaker Hospital, Sfax, Tunisia

Introduction
Obesity, through its complications, influences the functional and vital prognosis. The search for these complications constitutes a major axis of the management of the obese patient, independently of the weight loss. The objective of this work is to focus on the different complications of obesity and to identify, through a comparative study between two groups of obese patients, complicated versus uncomplicated, the different predictive factors of the occurrence of these different complications, especially arterial hypertension and cardiovascular complications.
Patients and methods
This is a retrospective comparative study of 400 obese patients, hospitalized and followed in the endocrinology and diabetology department of the Hedi Chaker Hospital in Sfax. These patients were subdivided into 2 groups: G1: 264 patients with at least one complication of obesity and G2: 136 uncomplicated obese patients.
Results
The mean age of our complicated patients was significantly higher than that of the uncomplicated ones (46.29$\pm$17.377 years versus 33.97$\pm$12.08 years), ($P = 0.0001$). A significant female predominance was noted in our complicated and uncomplicated obese groups ($P = 0.0001$). 78.7% of group 1 and 86% of group 2 had a family history of obesity ($P = 0.05$). Anthropometric parameters (weight, BMI, waist circumference (WC) waist circumference/hip circumference (WC/TH) and systolic and diastolic blood pressure values were significantly higher in the complicated obese group. It was noted that high BMI positively influences the occurrence of hypertension, cardiovascular, respiratory and osteoarticular complications. In addition, high waist circumference was significantly involved in the development of hypertension, hyperlipidaemia and cardiovascular, respiratory, skin and osteoarticular complications. Lean body mass and fat mass are significantly higher in our complicated obese than in our uncomplicated obese. The saturated fatty acid (SFA) intake in% is significantly higher in uncomplicated obese patients. The comparison between G1 and G2 regarding metabolic parameters shows that these are higher in G1 than in G2. Only alanine aminotransferase (ALT or SGPT) was higher in G2 than in G1.
Conclusion
The knowledge of the factors influencing the occurrence of these complications could help us to better treat them but especially to better prevent them. The treatment of obesity and its complications is certainly a challenge for all health care providers today, but prevention is still the best way to fight against this burden.

Assessment of depression in diabetics with erectile dysfunction (ED): 37 cases

Kolsi Boulbaba[1], Rihab Ben Abdallah Kolsi[2], Mohamed Dammak[3], Khouloud Boujilbéne[3], Kawthar Elarbi[3], Asma Zargni[3], Faten Hadj Kacem[3] & Mohamed Abid[3]
[1]CHU Hedi Chaker Sfax Tunisia, Endocrinology and Diabetology, Sfax, Tunisia; [2]Faculty of Sciences of Sfax, FSS Tunisia, Biology, Tunisia; [1]CHU Hedi Chaker Sfax Tunisia, Endocrinology and Diabetology, Sfax, Tunisia

Introduction
Diabetes is a disease that can slowly be. Among its complications, erectile dysfunction can appear. Be careful, these problems can be warning signs. These problems can be warning signs, especially cardiovascular, but they also have significant psychological retention.
Materials and methods
Prospective study on 37 diabetic patients collegiate in the department of Endocrinology CHU Hedi Chaker Sfax Tunisia. All patients are assessed for erectile function by the International Index (IIEF 5) and screened for depression using the Beck Scale (BDI).
Results
The majority of our hospitalized patients (80.5%) were between 45 and 70 years old. As well as 60.25% of diabetics had diabetes evolving for more than 16 years. The mean blood glucose at young was 18 mmol/l with HbA1c at 9%. Only 20% had a normal sex life. Erectile dysfunction is found in 72% of cases; it is severe in 8% of patients, moderate in 12% of cases, mild to moderate in 22% of cases and mild in 30% of cases. Concerns are all the more frequent as the diabetic disease is old, and especially poorly controlled, 77% of poorly controlled diabetics are subject to erectile disorders against 64% for those whose pathology is under control. According to the Beck Scale (BDI), 54% of our patients had experienced a feeling of sadness, of which 14% were unable to cope.
Conclusion
When the chronic complications of diabetes are already present, almost 75% of patients also have erectile dysfunction. A consequence that alters the quality of life. Only 25% of nurses are interested in the psychological side of diabetics with erectile dysfunction, of which 70% encourage them to consult a psychiatric hospital.

Obesity and lifestyles related to diabetes during COVID-19 pandemic

Virgínia Regufe
Faculty of Medicine of the University of Porto, Porto, Portugal

Diabetes is mainly a consequence of the lifestyle of the current population, characterized by an increase in obesity, sedentarism and a highly caloric diet, added to which is an ageing population. Prevention and its treatment consist in following an adequate diet, practising physical exercise regularly and maintaining normal weight, factors which are achieved through the adoption of healthy lifestyles. However, weight loss remains a problematic issue among diabetics, mainly due to the fact that the diabetic individual neither understands nor incorporates the need for significant alterations in his lifestyle. The current COVID-19 pandemic has drawn, once again, our attention to the problem of obesity. This study depicts the analysis of residents in a neighbourhood in greater Porto, Portugal. The data collection derived from the answers of a questionnaire highlighted the existence of various factors that contribute to the development of obesity over a long period of time, being behavioural patterns one of the most impactful causes as they are related to our lifestyle. Repeated lockdowns were responsible for a decrease in the practice of physical activity and changes in the eating habits of the Portuguese population in general, resulting in an increase in the consumption of fizzy drinks, fried and fast food, processed meals, frequent intake of food and, consequently, weight gain. The present pandemic has also contributed to a rise in a sedentary behaviour exemplified by prolonged periods of time spent watching TV or on other technological gadgets (cell phone, laptop, etc.), attending online classes and working from home, aspects which increase the risk of obesity and diabetes. Smoking, the lack of physical activity and a poor diet also add to the increase in weight and poor glycemic control. There are, however, lifestyle alteration programs which include a variety of procedures to overcome obstacles regarding weight loss. In fact, significant changes in lifestyle appear to be associated with a greater weight loss e better glycaemic control.

Inadequate iodine intake in lactating women in the inland area of norway

Tonje Eiane Aarsland[1, 2], Siri Kaldenbach[3, 4], Beate Stokke Solvik[1, 2], Kjersti S. Bakken[1, 2] & Tor Arne Strand[2, 5]
[1]Innlandet Hospital Trust, Lillehammer, Norway, Women's Clinic, Lillehammer, Norway; [2]University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway; [3]Innlandet Hospital Trust, Lillehammer, Norway, Department of Paediatric and Adolescent Medicine, Lillehammer, Norway; [4]University of Oslo, Clinical Medicine, Oslo, Norway; [5]Innlandet Hospital Trust, Lillehammer, Norway, Research Department, Lillehammer, Norway

Background
Many studies in Norway have found inadequate iodine status in pregnant and lactating women, but no studies have been undertaken in a random, population-based sample. Globally, the main strategy to eliminate iodine deficiency is iodization of salt. However, this is not compulsory in Norway, where the current legislation only permits iodization up to 5 µg per gram of salt. To reach the Nordic Nutrition Recommendation (NNR) of 200 µg/day iodine, supplements are recommended to lactating women who do not cover their needs through food sources. In Norway, the main iodine sources in the diet are milk and lean seafood. A study in 130 lactating women in 2018 revealed that mild-to-moderate iodine deficiency was common in the inland area of Norway. Considering the importance of iodine for infant development, more information on iodine status in lactating women is needed.
Objective
This study aimed to evaluate iodine status and intake in a random sample of lactating women and their infants in the inland area of Norway.
Methods
From April 2020 to October 2021, 366 mother-infant pairs were recruited in a cross-sectional study through public health care centers. Urine samples from the mothers and children and breast milk samples were collected for analysis of iodine concentration. Data on habitual and recent iodine intake was collected using food frequency questionnaire (FFQ) and 2 x 24-h dietary recall (24HR), respectively.
Results
Urinary iodine concentration (UIC), breast milk iodine concentration (BMIC) and data from FFQ are pending analyses. Recent use of iodine-containing supplements was reported by 30.1 % of the women. Including supplements, the estimated 24 h median (IQR) iodine intake was 125 (70.8, 233.45) µg/day. Excluding supplements, the 24 h median (IQR) iodine intake was 100.1 (65.05, 161.5) µg/day. According to the 24 HR, the food sources that contributed the most to the iodine intake were milk and dairy products, carbonated mineral water from a specific water source in Larvik (Norway), lean fish, whey cheese and eggs. More than two-thirds of the 24HR (68.2 %) had an estimated iodine amount below the NNR recommendation for lactating women.
Conclusion
We found inadequate iodine intake in lactating women in the inland area of Norway. Milk, lean fish, eggs, and a specific type of carbonated mineral water were important iodine sources in the diet. The study indicates that a large proportion of lactating women in Norway may need iodine-containing supplements due to a low dietary iodine intake.

Metabolic burden in mediterranean patients with schizophrenia and psychotic disorders

AbdelMouhaymen Missaoui[1], Salem Jdira[2], Oumeyma Trimeche[1], Houda Hsine[2], Wafa Abbes[2] & Ines Khochtali[1]
[1]Fattouma Bourguiba University Hospital, Endocrinology Departement, Monastir, Tunisia; [2]Gabes Regional Hospital, Department of Psychiatry, Gabes, Tunisia

Introduction
Mortality among patients with schizophrenia and psychotic disorders(SAPD) is two to threefold higher than in the general population and is widely attributed to cardiovascular and metabolic morbidity.
Objectives
We aim to highlight the metabolic profile of Mediterranean patients diagnosed with SAPD.
Methods
We conducted a descriptive and analytical cross-sectional study involving 55 patients who attended the psychiatry department at Gabes regional hospital, Tunisia, from 2019 to 2020. SAPD were diagnosed according to the DSM-5. MetS was defined based on the 2005-IDF criteria.

Results
The mean age was 46.8±11.1 years with a male predominance(74.5%). The majority were single(54.5%), from rural areas(52.7%), low-educational backgrounds(65.5%), and low-socioeconomic status households(74.5%). Addictive behaviors were reported in 49.1% mainly tobacco(45.5%). Suicidal behavior was noticed in 9.1%. Schizophrenia and schizoaffective disorder were the leading diseases in 72.8% and 16.4%, respectively. Obesity was the most common metabolic comorbidity in 30.9%. Dyslipidemia, diabetes, and hypertension were recorded in 20.0%, 14.5%, and 1.8%, respectively. The prevalence of MetS was 29.1%. MetS was significantly associated with female gender ($P=0.046$) and atypical antipsychotics prescription ($P=0.018$).
Conclusions
Patients with SAPD are five times more prone to develop MetS than healthy patients. Increased insulin resistance was substantiated in antipsychotic-naive patients. Besides common genetic predispositions to both MetS and schizophrenia suggested by some researchers, this population often has a poor lifestyle, little physical activity, and an unhealthy diet. That could be partially related to negative symptoms of psychotic disorders and drug-induced sedation. Second-generation antipsychotics seem to increase the risk of insulin resistance, obesity, and diabetes by the antagonism at serotonin 5-HT2c receptors.

Hepatic steatosis and cardiovascular risk in type 2 diabetes

Ines Bani, Zohra Hadj Ali, Meriam Dalhoum, Yosra Htira & Feika Ben Mami
National Institute of Nutrition of Tunisia, Department C, Tunis, Tunisia

Introduction
Non-alcoholic fatty liver disease (NAFLD), is a frequent cause of chronic liver disease and is widely associated with metabolic syndrome. When associated with diabetes, it can increase the risk of cardiovascular events. The aim of this study is to evaluate the relationship between hepatic steatosis and the occurrence of cardiovascular events in patients with type 2 diabetes.
Method
It is a retrospective study, including 184 type 2 diabetic patients, conducted in the department C of the National Institute of Nutrition of Tunis during the year 2021. The diagnosis of hepatic steatosis was retained by an abdominal ultrasound.
Results
Our population was composed of 66 men and 118 women. The mean age of the patients was 61 +/- 10 years, and the average duration of diabetes was 13 +/- 8 years. The prevalence of NAFLD was 29.3%. A clear female predominance was noted in patients with NAFLD(77.8%). Diabetic patients with NAFLD had dyslipidemia in 88.9%. The majority of patients had poorly controlled diabetes with a mean HB1AC of 10.4 +/- 2%. The average body mass index of these patients was 35+/- 5 kg/m^2. Hepatic steatosis is positively correlated with coronary artery disease ($P=0.016$) and high blood pressure ($P=0.000$). Morever a significant association was noted with hyper uricemia ($P=0.021$) and obesity ($P=0.000$).
Conclusion
The coexistence of type 2 diabetes and NAFLD increases the occurrence of cardiovascular events and disturbs the glycemic balance of diabetic patients, which underlines the importance of screening for this hepathopathy.

Clinical and biochemical outcomes of sodium-glucose co-transporter-2 (SGLT2) inhibitors in type 2 diabetes mellitus patients as a fourth oral anti diabetic medicine

Muhammad Saleem, Nanik Ram & Sajjad Ali Khan
Aga Khan University Hospital, Section of Diabetes, Endocrinology and Metabolism and Department of Medicine, Aga Khan University Hospital, Karachi, Pakistan. , Karachi, Pakistan

Objectives
to evaluate the clinical and biochemical effects of (SGLT2) inhibitors as a fourth oral anti-diabetic drug in patients with type 2 diabetes mellitus (T2DM).
Patients (Materials) and Methods
In a tertiary hospital in Karachi, Pakistan, a retrospective assessment of patient medical records was conducted from January 1, 2017 to December 31, 2020.A total of 100 patients (mean age [Standard Deviation]: 53.8 [9.63] years) with poorly controlled T2DM were included. Data was collected before the SGLT-2 inhibitor was added, as well as three and six months after the medicine was started. Weight, Body Mass Index, blood pressure (BP), HbA1c, SGPT, and Creatinine were measured at the start and during the study
Results
There was a significant reduction in HbA1c (P-value < 0.001) with (Mean Reduction [Standard Deviation]) 0.81[1.02] % at 3 months and 1.07[1.11] % at 6 months, Weight (P-value < 0.001) with (MR [SD]) 1.83[2.32] kg at 3 and 4.02[6.04] kg at 6 months, BMI with 0.69[0.95] kgm-2 at 3 months and 2.13[3.41] kgm-2 at 6 months of follow up. Systolic Blood Pressure showed significant reduction (P-value < 0.05) of 5.9[15.76] mmHg at 3 months and 6.37[18.33] mmHg at 6 months. Mild variation in creatinine and SGPT was also noted.
Conclusions
SGLT-2 is a safe and effective oral anti-diabetic medicine that can help individuals with diabetes who are currently using glucose-lowering or anti-diabetic medications. These medications can be used as an alternative to injectable insulin for people who do not want to use it, and they can help diabetic patients stick to their regimen.

Verapamil can be used as a type 2 diabetes mellitus saviour and stopping the need for insulin in uncontrolled type 2 diabetes mellitus

Mahmoud Younis
Egypt Ministry Of Health, Endocrinology, Kafr Elsheikh, Egypt

Introduction
Diabetes mellitus is not just a disease as it is already known, the matter is more complicated, and it is considered as an assembly of metabolic defects with end result of hyperglycemia. verapamil can decrease the expression of thioredoxin-interacting protein (TXNIP), which is recognized as an important factor in pancreatic beta cells. verapamil could enhance beta cell mass and function.
Materials and methods
160 type 2 diabetes mellitus and hypertensive patients into 2 parallel groups. Each group had 80 patients, 50 males and 30 females. All patients were monitored in a private clinic. All the patients Lied between 30-60 years old. All patients are on maximum doses of glimepiride, sitagliptin, metformin and empagliflozin but are uncontrolled on this combination with hba1c more than 8. The first group received verapamil 240 mg as substitute or added to the present hypertension therapy for 6 months. The second group was still on hypertensive therapy but received lantus 20 units added to the oral therapy. We measured hba1c and c-peptide levels in the 2 groups at the start of the trial and after 6 months of the trial.
Results
The results show a statistically significant difference in hba1c in group 1 patients before and after 6 months of treatment with verapamil With P value less than 0.0001. The results show statistically significant difference in hba1c in group 2 patients with P value less than 0.0001. The results show significant differences in c-peptide levels in group 1 patients before and after 6 months of treatment of verapamil. The results show non-significant differences in c-peptide levels in group 2 patients before and after 6 months treatment of basal insulin with b value 0.9822. The results show significant difference in hba1c after 6 months of treatment of verapamil vs. basal insulin with b value less than 0.0001. Results also show that verapamil can increase c-peptide levels after 6 months of treatment.
Conclusion
Verapamil could be used as a type 2 diabetes saviour by increasing beta cell mass and function.
Key words: type 2 diabetes mellitus, verapamil, (TXNIP), beta cells

Therapeutic optimization of type 2 diabetes: what role of the pharmacist?

Asmaâ Memou[1], Derouicha Matmour[2], Habiba Fetati[1], Nadjet Fatima Zohra Mekaouche[1], Fatma Boudia[1] & Houari Toumi[1]
[1]Faculte De Medicine D'Oran, Pharmacie, Oran, Algeria; [2]College of Medicine Taleb Murad, Pharmacie, Sidi Bel Abbès, Algeria

Introduction
Type 2 diabetes is a chronic disease whose management is characterized by the complexity of its therapeutic axes (methods of taking, storage of drugs, adverse effects, compliance with treatment, etc.), which requires the patient to be well informed to avoid the onset of complications. Faced with this issue, the pharmacist could make a real contribution.
Goal
The objective of this work was to assess what role the pharmacist could play in the therapeutic optimization of type 2 diabetes.
Matherials and methods
We conducted a descriptive study in patients with type 2 diabetes over a period of 03 months. We used a questionnaire comprising 04 parts: knowledge of antidiabetic drugs, assessment of compliance (Morisky's questionnaire), drug iatrogenism and treatment monitoring.
Results
The study was carried out on 60 patients. Analysis of the results showed that 36.6% of patients on insulin did not master the injection technique, 51.7% did not know how to store the drugs and 40% were poor observers.
In addition, 66.7% exhibited adverse effects, 25% exhibited at least one drug interaction and 26.7% did not master the technique of self-monitoring of blood glucose.
Discussion
Our study revealed the existence of several gaps in these patients in terms of knowledge and proper use of their treatment and monitoring of their disease. This emphasizes the need for pharmacist involvement in therapeutic education programs for these patients in order to optimize their therapeutic management.
Keywords
type 2 diabetes, anti-diabetic drugs, pharmacist, compliance, therapeutic education.

Is Semaglutide superior than Liraglutide in patients with type 2 diabetes on insulin therapy? - case presentation

Ivana Mickovski, Daniela Buklioska-Ilievska, Radmila Milosheska & Taner Hasan
City General Hospital 8 September, Skopje, North Macedonia

Type 2 diabetes (T2DM) is a chronic and progressive disease associated with microvascular and macrovascular complications leading to increased morbidity and mortality. Insulin remains the cornerstone therapy for longer-duration T2DM and b-cell failure. Glucagon-like peptide-1 receptor agonists are a class of multifactorial T2DM medications that have been shown to improve numerous risk factors for diabetes-related complications, including glycemic control, reduction in body weight and a low risk of hypoglycaemia. Improvements in glycaemic control confer a reduced risk of long-term diabetes-related complications. We reported here a case that provides the efficacy and safety of once-weekly semaglutide vs once daily GLP-1 RAs in obese patient with T2DM inadequately controlled on insulin therapy (Insulin Aspart + OADs). Improvements in glycaemic control were greater with once-weekly semaglutide 1 mg than with once-daily liraglutide 1.8 mg, resulting in a longer time to treatment intensification with insulin therapy. Together with lifestyle modifications and physical activity we achieved better glycemic control without severe or blood glucose-confirmed symptomatic hypoglycemia (plasma glucose level below 3.1 mmol/l), HbA1c, FPG, and body weight in patient who is receiving insulin therapy. Also with this therapy we achieved reduction in his lipoprotein metabolism because he could not tolerate any statins. Overall, the case presented here summarized the benefit of once-weekly semaglutide 1.0 mg as an add-on to insulin therapy as the most efficacious GLP-1 RA in terms of further reductions in HbA1c, body weight, BMI in patient with T2DM, insulin therapy and GLP-1RA injections. The reasons for switching to semaglutide from liraglutide included a need to reduce HbA1c or weight further, decreased frequency of administration and cardiovascular protection.
Keywords: Type 2 diabetes, obesity insulin therapy, GLP 1 RAs, lifestyle modifications

EP510

A weight loss of 20 kg on liraglutide

Mohamed Hamid Abdillahi, Mohamed Ali Boutheina, Aicha Ahmed Mohamed, Kaoutar Rifai & Mh Gharbi
Chu Ibn Sina, Rabat, Morocco

Introduction
Liraglutide is a glucagon-like peptide 1 (GLP-1) receptor agonist, approved for the treatment of adult patients with type 2 diabetes mellitus of a particular interest in the significant improvement of glycaemic, systolic blood pressure and lipid control with their impact on weight, making it possible to avoid this infernal spiral of weight gain-increased insulin resistance.
Observation
55-year-old female patient, known diabetic for 10 years, put on metformin 2 g. Before liraglutide: the patient had grade 2 obesity (Weight = 102 kg, BMI = 37.5 kg/m^2). HbA1c = 8.4%, Total cholesterol = 2 g/l, LDL = 1.4 g/l, HDL = 0,36 g/l. After 18 months of liraglutide 1.8 mg/j and metformin 2 g : weight loss of 20 kg (weight = 82 kg, BMI = 29 kg/m^2). HbA1c = 6.5%, Total cholesterol = 1,5 g/l, LDL = 0.8 g/l, HDL = 0,42 g/l
Discussion
Incretins are digestive tract hormones secreted in response to oral carbohydrate intake. They stimulate the secretion of insulin, inhibit that of glucagon, slow down gastric emptying and increase satiety, thus allowing weight loss. These molecules have pleiotropic effects enriching current therapy, with associated weight loss, allowing better control of diabetes. We report in this case a significant weight loss with an improvement of glycaemic and lipid control without any episode of hypoglycemia.
Conclusion
At a time of epidemics of chronic diseases such as obesity associated with type 2 diabetes, recent therapeutic options focusing on several targets are emerging, such as GLP-1 analogues.

Association between cortisol/DHEA-S ratio and inflammatory indicators in patients with non-functioning adrenal incidentalomas

Joanna Kowalska[1], Iwona Zielen-Zynek[1], Justyna Nowak[1], Aleksander Włodarczyk[2], Bartosz Hudzik[1, 3] & Barbara Zubelewicz-Szkodzińska[1,2]
[1]Department of Metabolic Diseases Prevention; School of Public Health in Bytom, Bytom, Poland; [2]Department of Endocrinology, Piekary Medical Center, St. Luke's Local Hospital in Piekary Śląskie, Poland; [3]3rd Department of Cardiology, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia in Katowice, Silesian Center for Heart Diseas, Zabrze, Poland

Introduction
It is well known that DHEA and DHEA-S has and impact on lipid metabolism, cardiovascular system and others. De Castro et al. showed that cortisol/DHEA-S ratio was an independent predictor of long-term mortality in patients with sepsis. Chronic inflammation is an important factor in cardiovascular diseases development that reduce quality and life expectancy. CVDs are more common in patients with adrenal incidentaloma than in general population. Literature data on the cortisol/DHEA-S ratio are contradictory, there are no scientific studies in the group of patients with endocrinopathies, including adrenal incidentalomas.

Aim
The aim of the study was to evaluate inflammation indicators – old one: insulin, CRP and new one: PLR (*platelet-lymphocyte ratio*), MPVLR (*MPV-to-lymphocyte ratio*), NLR (*neutrophil-lymphocyte ratio*), SII (*systemic immune-inflammation index*) in group of patients with non-functioning adrenal incidentalomas.
Material and methods
The study included 150 patients with non-functioning adrenal incidentalomas hospitalized in Endocrinology City Hospital in Piekary in 2016-2019. The exclusion criteria were mainly: other adrenal disorders (e.g. secreting adrenal adenomas, overactive adrenal cortex), decompensated diabetes defined as HBA1C% > 7, kidney failure as eGFR < 60 ml/min/1,73 m^2 liver failure as bilirubin > 2 mg/dl, INR > 1,5 and albumins < 3,5 g/dl, severe inflammation, treated cancer disease. Morphology parameters, cortisol and DHEA-S concentration (taken from the patient's medical record) were used to calculate inflammatory indicators and cortisol/DHEA-S ratio, CRP and insulin concentration was also taken from medical record.
Results
Most of the respondents (n = 150) were women (72.67%). The median age was 62 years in women, 66 years in men (P = 0.00), cortisol concentration at 8 a.m. was 278.62 nmol/l in women, 320 nmol/l in men (P = 0,00), DHEA-S was 78,8 μg/dl in women, 102,5 μg/dl in men (P < 0,05), CRP was 1,69 in women, 1,5 in men (P > 0,05), MPVLR 5,33 in women, 5,32 in men (P = 0,00). There was negative correlation observed (P < 0,05) between cortisol/DHEA-S ratio and: CRP (r = -0,21), insulin (r = -0,18). There was no signifficant correlation (P > 0,05) demonstrated between analyzed cortisol/DHEA-S ratio and new inflammation indicators: MPVLR, SII, PLR, NLR.
Conclusion
There is association between cortisol/DHEA-S ratio and old inflammation indicators but not between cortisol/DHEA-S ratio and new ones in studied group of patients with non-functioning adrenal incidentalomas. There is a necessity to enlarge the studied group to confirm obtained results.

Omega 6 and 3 intake in depressive patients

Rym Ben Othman[1], Amel Gamoudi[2], Ramla Mizouri[3], Nadia Ben Amor[1], Insaf Loukil[1], Cyrin Souissi[1], Olfa Berriche[1], Feten Mahjoub[1] & Henda Jamoussi[1]
[1]INNTA, A, Tunis, Tunisia; [2]Faculty of Medicine Of Tunis, A, Tunis, Tunisia; [3]University of Tunis El Manar, Nutrition, Tunis, Tunisia

Background
several studies show a ralation between the lack of omega 6 and 3 and the developpement of depression. in other hand, there is a modification in the food behaviors in case of depression which can lead to the persistance of symptoms so the intake of omega 6 and 3 should be assessed for every depressive patient
Methods
50 patients whith depression were involved in our study. They were recruited from outpatient department in a psychiatric hospital Razi. The severity of depressive symptoms were assessed by HAD and PHQ9. A food history coupled with the frequency of consumption of foods rich in alphalinolenic acid, alphalinoleic acid, eicosapentaenoic acid, docosahexaenoic acid were carried out in order to assess the typical eating habits of patients. Food quantity was estimated using a photographic manual in order to assess food portions and quantification of intakes. The estimate of the daily intakes of EPA (eicosapentaenoic acid), DHA (docosahexaenoic acid) and alpha linolenic acid (GA C18: 3) was made manually based on data from the table of food composition (CIQUAL 2016). We compared the intakes of our poulation compared to the ANCs of the general adult population.
Results
The mea nage of the population is 45 year old. There were 34 women for 16 men. The average BMI was 28.2 Kg/m^2. The study of consumption shows lipids intake about 36% of total energy intake (TEI). The monounsatured fatty acid about 15.62% of TEI and poly unsatured fatty acid 11.62 % TEI. The intake was unsuffisient for 46% of population for linolenic acid, 86% for EPA, 76% for DHA, 38% for omega 3 and 16% for omega 6. According to HAD more is the intake in omega 3 and linoleic acid less are the severity of symptoms (P = 0.03 and 0.002) and according to PHG9 score the depression was more severe if the intake of linoleic acids was low (P = 0.04).
Conclusions
the omega 3 and 6 intake are important to assess to improve patient symptoms and ensure faster healing.

Nutritional status in patients with heart failure and its relation with cardiac function

Carlos Manuel Alzás Teomiro[1], Ana maría moyano sánchez[1], Concepción Muñoz Jiménez[1], Soraya Leó n Idougourram[1], José Ló pez Aguilera[2], Manuel Crespín[2], María José Molina Puerta[1], María Ángeles Gá lvez Moreno[1] & Aura Herrera Martínez[1]
[1]Reina Sofía University Hospital, Endocrinology and Nutrition, Córdoba, Spain; [2]Reina Sofía University Hospital, Cardiology, Córdoba, Spain

Background
Heart failure (HF) has a rising incidence and is one of the most prevalent diseases worldwide. Serum NT-proBNP and systolic ejection fraction correlate with the severity and prognosis of this condition. The nutritional evaluation of patients with HF, who usually have normal weight, overweight or obesity, has acquired a novel approach due to the incorporation of novel techniques (bioelectrical impedance, nutritional ultrasonography), and functional tests.
Objective
To evaluate the relation between nutritional parameters (bioimpedance, adipose and muscle ultrasound) and clinical outcomes. in patients with HF
Methods
Patients with at least one hospital admission during the previous year were included. Anthropometric, biochemical, ultrasound, cardiac and functional tests were collected. Statistical analysis was performed with SSPS v.24.
Results
Thirty-eight patients (72.2% males; 44.4% with type 2 diabetes) were included; 36.2% presented at least one episode of acute myocardial infarction; mean systolic ejection fraction measured by echocardiogram was 37.35%. During the previous 12 months, 39.5% of patients required more than one admission due to HF, with a mean length of stay in hospital of 5 days. In our cohort, the incidence of overweight/obesity and malnutrition reached 75% and 58.3% respectively. Decreased phase angle (< 5.5) was observed in 60% or the patients. Fat and lean mass measured by bioelectrical impedance correlated with systolic ejection fraction (P < 0.05). This cardiac biomarker also showed a positive correlation with the adipose tissue measured in rectus femoris nutritional ultrasonography (Spearman's rho + 0.384; p < 0.05). Serum NT-proBNP levels correlated with body cell mass (BCMe) measured by bioelectrical impedance, calf circumference, albumin, prealbumin and LDL cholesterol levels (p < 0.05).
Conclusions
Nutritional and cardiac parameters are correlated in patients with HF. Routine nutritional evaluation and early nutrition intervention, if required, should be implemented in order to improve the clinical outcome in these patients. Prospective, interventional studies should be performed.

25(OH)D vitamin D status and anthropometric parameters among patients hospitalized in geriatric department

Justyna Nowak[1], Marzena Jabczyk[1], Bartosz Hudzik[1, 2] & Barbara Zubelewicz-Szkodzińska[1,3]
[1]Department of Metabolic Disease Prevention; Faculty of Health Sciences in Bytom, Medical University of Silesia, Bytom, Poland; [2]3rd Department of Cardiology, Faculty om Medical Science in Zabrze, Medical University of Silesia, Silesian Center for Heart Diseases, Poland; [3]Department of Endocrinology, Piekary Medical Center, St. Luke's Local Hospital in Piekary Slaskie, Poland

Introduction
Vitamin D deficiency is observed across all age groups and both sexes. Moreover vitamin D deficiency is common in elderly especially along elderly patients. Elderly people are prone to develop of vitamin D deficiency caused by various factors such as deceased dietary intake, impaired intestinal absorption, reduced sunlight exposure, impaired skin synthesis as well as impaired hydroxylation in the liver and kidneys. Vitamin D deficiency may leads to rickets, osteoporosis,

osteomalacia and furthermore increase the risk of cardiovascular diseases, type 2 diabetes, mental illness and many others.
Aim
We have set out to investigate status of vitamin D among patients over 60 years hospitalized at the geriatric department.
Material and methods
The study was carried out with 422 patients. From the study was excluded patients with marked physical and/or mental impairment, liver disorders, decompensated thyroid disorders, cancer, as well as people using medications such as glucocorticosteroids or/and using of vitamin D supplement. Finally to the study was included 242 patients (172 females, 70 males). All patients provided consent before included to the study. Venous blood samples were collected after overnight fasting. The serum level of 25-hydroxyvitamin D (ng/ml) was measured by enzyme-linked immunosorbent assay (ELISA). Anthropometric parameters and body impedance analysis were measure on the morning.
Results
The mean serum 25(OH) vitamin D concentration among total patients was 14.88 ± 5.95 ng/ml, among women group was 14.41 ± 6.19 ng/ml, among men group was 16.06 ± 5.16 ng/ml. The mean serum 25(OH) vitamin D concentration was higher among patients aged 60-74 years in comparison to patients aged 75 years and over (16.24 ± 6.18 ng/ml vs 14.22 ± 5.73 ng/ml), $P = 0120$. Most of elderly patients 79.8% ($n = 193$) had vitamin D deficiency defined as 25(OH)D $\leq$ 20.0 ng/ml. Suboptimal vitamin D concentration ($>$20.0-30.0 ng/ml) was observed in 19.0% ($n = 46$) study group and adequate of vitamin D concentration ($>$ 30.0 ng/ml) had 1.2% ($n = 3$) patients. The mean value of BMI was 28.15 ± 5.50 kg/m^2 (men 27.52 ± 4.76 kg/m^2; women 28.41 ± 5.77 kg/m^2), mean of body fat in % was 33.56 ± 9.59 (man 26.93 ± 7.80; women 36.26 ± 8.93) mean of muscle mass in kg was 43.30 ± 8.25 (men 52.47 ± 6.63; women 39.57 ± 5.45). Vitamin D concentration was 14.84 ± 5.50 ng/ml among obese patients (BMI $\geq$30.0 kg/m^2), 15.32 ± 6.00 ng/ml among overweigh patients (BMI 25.0-29.0 kg/m^2) and 4.00 ± 6.00 ng/ml among patients with normal weight (18.5-24.9 kg/m^2), $P = 3480$.
Conclusion
Vitamin D was observed in geriatric patients irrespective of age, gender and body mass. Proper vitamin D supplementation should be recommended in this group of people.

Diplopia, a sign of diabetes: A case report

Ramla Mizouri, Rym Ben Othman, Nadia Ben Amor, Faten Mahjoub, Abir El Amri[1], Amany Amorri, Berriche Olfa & Jamoussi Henda
Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia

Introduction
Diabetes mellitus is the leading cause of neuropathy worldwide. Non-retinal diabetic complications including oculomotor damage represent 1 to 3% of ocular manifestations of diabetes. The affected oculomotor nerves are essentially the external oculomotor nerve (VI), the common oculomotor nerve (III), and more rarely, the pathetic nerve (IV).
Observation
We report the case of a patient referred to our department for additional management of recently discovered diabetes. This is a 44-year-old patient with a history of Buerger's disease with amputation of both right toes. The clinical examination showed binocular diplopia with left horizontal nystagmus and damage to the external oculomotor nerve VI on the left. As part of the exploration of this diplopia, a CT scanner and an angioscanner were performed. They were normal and showed no signs of an ischemic stroke. A cerebral MRI and a lumbar puncture were strictly normal. On biology, we found a fasting blood sugar at 7 mmol/l and a glycated hemoglobin at 8.9%. The patient started diet and metformin. The evolution was marked by the progressive remission of diplopia after glycemic control after six weeks.
Conclusions
Our observation illustrates the interest of screening for diabetes in the face of damage to the oculomotor nerves. The evolution is favorable spontaneously after few weeks, but the recurrence on the same side or on the contralateral side is possible.

Treatment Induced Neuropathy in Diabetes: Case Report

Chin Voon Tong & Poh Shean Wong
Melaka Hospital, Medicine, Melaka, Malaysia

Introduction
Treatment-induced neuropathy of diabetes (TIND) is a small fibre neuropathy precipitated by rapid correction of chronic hyperglycemia.
Methods
We report two patients who developed TIND after rapid improvement of glycaemic control.
Results
21-year-old gentleman, underlying type 2 DM diagnosed since 2017. He was not compliant to insulin therapy and defaulted follow up. His Hba1c ranged from 16.6%-19%. In July 2020, he was admitted for diabetic ketoacidosis and dengue fever. He was discharged with basal bolus insulin. Within a month after discharge, he experienced severe lower limb pain. The pain worsened at night and affected his sleep. On examination, he had increased pinprick sensation over bilateral lower limb dermatomes. Hba1c was reduced markedly to 8.9%. His urine biochemistry revealed proteinuria. He was started on Gabapentin and Vitamin B1, B6 and B12. His insulin dose was reduced. A month later, his neuropathic symptoms had much improved. His subsequent neurological examination revealed reduced pinprick sensation at gloves and stocking distribution. Nerve conduction study (NCS) revealed symmetrical length dependent sensory motor predominantly axonal polyneuropathy, suggestive of diabetic neuropathy. 36-year-old lady, diagnosed with type 2 DM since 2016 and was started on Sitagliptin/Metformin. Nevertheless, she defaulted her follow up and medication. In September 2020, she was admitted for diabetic ketoacidosis with Hba1c $>$ 14%. She was discharged with basal bolus insulin. During follow up, she complained of severe lower limb pain since discharge, with pin and needle sensation, worsened at night. Her neurological examinations were unremarkable. Hba1c had been reduced substantially to 8.7%. She was commenced on Gabapentin and Amitriptyline. One month later, her neuropathic symptoms improved markedly. NCS showed symmetrical length dependent sensory motor axonal polyneuropathy, suggestive of diabetic neuropathy.
Conclusion
These 2 cases highlight the importance of early detection and timely management of this distressing and potentially debilitating condition. The condition may be prevented by gradual titration of glycaemic control treatment, especially in long standing poorly controlled diabetic patients.

Trigger finger complicating diabetes: a case report

Kamel Farah, Khaoula Gorgi, Manal Azriouil, Kaoutar Rifai, Hind Iraqi & Mohamed Hassan El Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Trigger finger is a stenosing tenosynovitis in which constriction of the tendon sheath is associated with the presence of a nodule on the flexor tendon of the finger. This is an often unrecognised complication in the diabetic patient. We report the case of a diabetic patient with a complication of trigger finger.
Observation
A 55 year old female patient, known to be diabetic for 10 years and treated with a basal-bolus insulin therapy regimen. Her evolutionary profile is marked by several episodes of ketoacidosis decompensation. Her diabetes is complicated by chronic renal disease at the stage of proteinuria, and proliferating diabetic retinopathy. The clinical examination found limited mobility in flexion and extension of the fourth finger of the right hand, with a palpable nodule on the flexor tendon of the finger. Biological findings: HbA1c: 9%, renal function and lipid profile were correct. The patient had unbalanced diabetes complicated by microangiopathy and a trigger finger. The therapeutic management is based first on glycemic control and therapeutic education then we proposed corticosteroid injections, with a good evolution.
Discussion
Trigger finger is an often unrecognised tenosynovitis in the diabetic patient. It can occur during flexion or extension. The nodule is palpable on the flexor tendon of the affected finger. In diabetes, trigger finger occur in 4-10% of cases, and their occurrence is correlated with the length of time the patient has had diabetes, but not with its control. In a study of young insulin-dependent diabetic patients, this symptom was noted in 5% of patients and no controls.Treatment is based on

corticosteroid injections in the first instance. If this fails, percutaneous needle lung resection may be performed. A recent meta-analysis has shown that patients treated with percutaneous methods have fewer failures and are more satisfied than those treated with corticosteroid injections.Finally, surgical treatment should only be proposed in case of failure of medical treatment and in case of significant impact but with 45% of side effect.
Conclusion
Our clinical case illustrates one of the osteoarticular complications linked to diabetes, which is frequent but often unrecognized; it is the 'trigger finger'; it is however at the origin of an important functional handicap. A multidisciplinary management should be proposed to these patients while remembering that the first treatment of these manifestations is generally a better glycemic balance.

Correlation between pulse wave velocity and nephropathy in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
Nephropathy is a kidney complication that affects up to 50% of people with diabetes during their lifetime. Diabetes is the first cause of kidney failure. The aim of this study was to examine the relationship between diabetic nephropathy (DN) and arterial stiffness.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications , between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 $\pm$ 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years. Diabetic nephropathy (DN) was found in 34.5 % of the patients. The mean microalbuminuria was 48.58 $\pm$ 86.67 mg/g of creatinuria. CfPWV $>$ 10 m/s was found in 96.5 % of the patients with DN. And the mean microalbuminuria in patients with cfPWV $>$ 10 m/s was 52.36 $\pm$ 90.17 mg/g of creatinuria. In this group, cfPWV was at 14.38 $\pm$ 2.70 m/s VS 13.25 $\pm$ 2.81 m/s in patients without DN ($P = 0.002$). We did not find a correlation between cfPWV and the stage of the nephropathy. Moreover, the presence of arterial stiffness multiples by 5 the risk of diabetic nephropathy (Odds Ratio $= 5$).
Conclusion
This study shows that arterial stiffness is higher in type 2 diabetic patients with diabetic nephropathy than in those without diabetic nephropathy. Indeed, an elevated microalbuminuria is a marker of arterial stiffness in the general population and in the diabetic and hypertensive population. Several studies have investigated the relationship between arterial stiffness in type 2 diabetics, but there is little information regarding the relationship between cfPWV and microalbuminuria.

'Relationship between of the quality of life indicators and neuromarker S100 in patients with type 2 diabetes mellitus on program hemodialysis'

Alisher Kholikov[1] & Urmanova Yulduz[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya. Kh. Turakulov, Department of Hemodyalisis, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Department of Endocrinology, Tashkent, Uzbekistan

The purpose of the study
is to assess the quality of life of patients with type 2 diabetes before treatment with hemodialysis using the WHO Brief Questionnaire for the Assessment of Quality of Life (WHOQOL-BREF) and the Hamilton Depression Scale, taking into account the degree of neuromarker S100.
Material and methods
We examined in total for the period from January 1, 2018 to January 1, 2021 - 90 patients suffering from type 2 diabetes mellitus with chronic renal failure (CRF) on programmed hemodialysis.
Results
We analyzed 90 cases of grade 5 diabetic nephropathy who were on programmed hemodialysis. Of these, women -43, men -47. The obtained results also confirm the literature data that patients with type 2 diabetes mellitus have low quality of life indicators before programmed hemodialysis. According to the degree of chronic brain ischemia (CBI), patients were divided into 3 groups: 1 gr. - 36 (40.0%) patients with diabetic nephropathy (DN) 5 stage with CBI 1 degree; 2 gr. - 32 (35.5%) patients with DN 5 stage with CBI 2 degree; 3 gr. - 22 (24.4%) patients with DN 5 stage with CBI 3 degrees. A reliable difference between the mean values of S100 in the blood in patients 2 and 3 groups compared with the rate indicators was detected. In addition, in 2 and 3 groups of patients revealed direct correlation with the quality of life in 3 questionnaires - WHOQOL-BREF), MMSE test and Hamilton depression scales.
Conclusions
Assessing the quality of life using the WHOQOL-BREF scale, determining the level of anxiety and depression, as well as the MMSE test must act as the criteria for the clinical and functional severity of the state and the effectiveness of the treatment of therapy in patients with CRF in the conditions of therapy with various methods.

Obesity and diabetes mellitus as predictors of adverse course of COVID-19 infection

Yuliya Dydyshka[1,2], Alla Shepelkevich[1], Mariya Efremava[1], Veranika Lobashova[2] & Elena Brutskaya-Stempkovskaya[1]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Republic Center of Endocrinology and Medical Rehabilitation, Endocrinology Department, Minsk, Belarus;

According to WHO epidemiological data, there are more than 650 million obese people in the world, the medical and social significance of which is determined by the development and aggravation of insulin resistance. Accumulation of experience in the treatment of patients with COVID-19 infection has demonstrated that obesity and diabetes mellitus are important risk factors affecting the clinical severity of inflammatory disease - for impaired function of β-cells along with a cytokine storm and the release of contrainsular hormones.
The aim of the study was to identify phenotypic parameters that affect the prognosis of the course of COVID-19 infection by analyzing data on the features of the manifestation and course of the disease in patients with endocrine and metabolic risks.
Materials and methods
The main group consisted of 15 patients with confirmed COVID-19 infection, a history of type 1 or type 2 diabetes mellitus, or increased fasting glycemia (more than 5.5 mmol/l in capillary blood and 6.1 mmol/l in venous blood) and/or any hyperglycemia (more than 11.1 mmol/l). Comparison group - patients with confirmed COVID-19 infection without dysglycemia. All patients had a severe course of the disease, requiring transfer to the intensive care unit and resuscitation.
Results and discussion
The main group consisted of 7 (47%) men and 8 (53%) women. It was found that in the main group BMI (31.6 (29.0–33.8) vs. 26.0 (24.0–31.0), $U = 60$, $P = 0.045$) and the number of days of hospitalization (17, 6 (14.0–21.1) vs. 14.4 (10.0–18.0), $U = 67$, $P = 0.033$) is significantly higher than in the control group, which confirms overweight and obesity as risk factor for adverse course of COVID-19. Patients with DM have a low percentage of lymphocytes (18.48 (19.0–27.0) vs. 29.0 (16.2–37)%, $U = 51$, $P = 0.042$) and a level of leukocytes (4.6 (3.4–7.9) vs. 5.9 (4.2–9.0) $*10^9$/l, $U = 68$, $P = 0.035$), increased levels of C-reactive protein (62.5 (27,0–120.0) vs. 41.0 (22.5–50.9) mg/l, $U = 69$, $P = 0.045$), procalcitonin (0.14 (0.1–0.2) vs. 0.1 (0.08–0.11) ng/ml, $U = 65$, $P = 0.05$) and IL-6 (38.4 (19.0–70.0) vs. 15.0 (9.0–39.0) pg/ml, $U = 53$, $P = 0.04$) compared with patients without diabetes. In the main group of patients, hyperglycemia was first detected in 61.1% of patients, which may indicate COVID-19 as a significant risk factor for the manifestation of DM.
Conclusions
Patients with diabetes have a worse prognosis for COVID-19 due to a complex of associated conditions that increase the risk

India epidemiological mapping study- attempt at early screening - early intervention

Bharat Saboo[1], Abhishek Shrivastav[2], Aniket Inamdar[3], J Jayaprakash Sai[4], Ajoy Tewari[5], Dhruvi Hasnani[6], Vipul Chavda[6], Dr S S Dariya[7] & Rupam Choudhary[8]
[1]Prayas Diabetes Center, Indore, India; [2]R R Hormone Clinic, Jabalpur, India; [3]Samarpan Clinic, OmerGa, India; [4]Apollo Sugar Clinic, Hyderabad, India; [5]Jai Clinic and Diabetes Care Centre, Lucknow, India; [6]Rudraksha Institute of Medical Sciences, Ahmedabad, India; [7]SMS Hospital, Jaipur, India; [8]Apollo Diabetes Clinic, Dispur, India

Background
Hypertension is the most important chronic condition leading to cardiovascular complications in India. Lack of awareness and epidemiological data is the reason for inertia for primordial, primary and secondary prevention. Education, region epidemiological mapping and early screening and intervention can help benefit the population in terms of cardiovascular morbidity and mortality.
Aims & Objectives
To gather, analyze and intervene a large population for early screening, primary and secondary prevention for hypertension.
Patients/Materials & Methods
A team of doctors, nurse, educator and MSW gathered together to understand the prevalence and the incidence of diabetes and Hypertension at rural and sub-urban areas under 9 consultants at different geographical areas of India. Collection of anthropometric data and medical history along with education of the population was done. Further analysis and follow up with Lab parameters was advised to those with newly detected hypertension. They consulted those with preexisting and uncontrolled hypertension and the therapy was up titrated at the consultant's discretion. Screened population was from 30 to 88 years of age
Results
No. of sites: 9 Population screened: 346 Male- 189; Female: 157. Median Age: 46 Newly detected Hypertensive: 66 Pre-existing Hypertensive: 142 Undetected HTN is more common in females, Rural area and those with T2DM.
Discussion & Conclusion
Hypertension is Far More prevalent than what it seems in Indian Population, the need is to emphasize screening amongst those found at more risk of having undetected hypertension, Also healthcare workers should focus more emphasis on educating those with undetected HTN so that they can get themselves screened early and get treated. As this subset of patient often go undetected and suffer long-term consequences

Gut microbiota genera regarding carbohydrate metabolism status and GLP-1 treatment

Jana Caudet-Esteban[1], María Trelis-Villanueva[2,3], Matilde Rubio-Almanza[1], Rosa Cámara-Gómez[1] & Juan Francisco Merino-Torres[1,2]
[1]La Fe University and Polytechnic Hospital, Endocrinology , València, Spain; [2]University of Valencia-Health Research Institute La Fe, Joint Research Unit on Endocrinology, Nutrition and Clinical Dietetics, València, Spain; [3]University of Valencia, Aea of Parasitology, Department of Pharmacy and Pharmaceutical Technology and Parasitology, Valencia, Spain

Introduction and Objetive
The composition of human gut microbiota is an emerging field of research and is currently regarded as pathophysiologically linked to obesity. However, we still lack a thorough understanding of what constitutes health and disease in this subject. We present herein a descriptive study of the gut microbiota composition among Spanish morbidly obese subjects, clustered regarding the carbohydrate metabolism status (CHMS) displayed.
Methods
Stool samples were collected from type II-III obese subjects to perform metagenomic analysis of the intestinal bacterial community. This analysis was realized by the Sequencing and Bioinformatics Service of the Foundation for the Promotion of Health and Biomedical Research of Valencia Region, according to their own protocol. To compare the differences in the relative abundance (RA) of taxa between groups, we employed SPSS v22 and performed the Wilcoxon rank sum test.
Results
Stool samples were obtained from 56 obese subjects (64% women) of 48.1($\pm$9.8) years old and BMI 45.6($\pm$6.6) kg/m^2. 22 subjects presented a normal CHMS, 15 had prediabetes and 19 suffered diabetes mellitus (DM). When comparing the microbiota composition regarding the CHMS, no differences were found in the Shannon nor Chao1 alpha-diversity indexes. At phylum level, no differences were detected either in the RA of *Firmicutes, Bacteroidetes, Proteobacteria, Actinobacteria* nor *Verrrucomicrobia*. At genus level, subjects with a normal CHMS presented higher RA of *Faecalibacterium* ($p=0.032$) and *Clostridium* ($p=0.026$) and lower of *Escherichia* ($p=0.038$), with no differences in *Akkermansia*. Among DM patients, 15 were treated with a GLP-1 agonist (GLP-1A): compared to the rest of the participants, these subjects displayed higher RA of the phylum *Proteobacteria* ($p=0.044$), higher RA of the genera *Parabacteroides* ($p=0.034$) and *Escherichia* ($p=0.002$), and lower RA of *Clostridium*($p=0.007$). In the DM subgroup, patients treated with GLP-1A displayed higher RA of *Bacteroides* spp. ($p=0.027$) and lower of *Prevotella* spp. ($p=0.009$) than the rest of diabetic subjects.
Conclusions
In this small study performed in severely obese subjects, significant differences were found in the RA of the genera *Faecalibacterium*, *Clostridium*, *Escherichia, Bacteroides* and *Prevotella* in regards of the CHMS and the use of GLP-1A. Further research is needed to ascertain whether a pathophysiological relationship between these phenomena exists.

EP523

HbA1c evaluation predicting hyperglycaemia and avoiding morbidity in steroid initiation

Philip Maher[1] & Maeve Durkan[2]
[1]University College Cork, Cork, Ireland; [2]Bon Secours Hospital Cork, Endocrinology and Internal Medicine, Cork, Ireland

Introduction
Steroids can precipitate significant hyperglycemia and Diabetes Mellitus in vulnerable populations including DM, pre-DM and the elderly. Steroid risks include deterioration in DM, glucose toxicity, HONK and HHS. This may be avoided by a simple screening HbA1c, which could prompt a 'safeguard algorithm' for the patients including instruction in glucose monitoring. The 'at risk' cohort is identified, and a surveillance regime is implemented.
Methods
We conducted a pilot study, assessing the prevalence of HbA1c screening pre-steroids commencement. This was a prospective study, identifying all patients (medical, surgical and oncological admissions/inpatients) in the BSH Cork, commencing oral steroids from July 19 – August 1, 2021. We reviewed if any had HbA1c screening within the preceding three months.
Results
Of all inpatients, 49 were commenced on steroids. 8/49 (16%) patients had an HbA1c measurement pre-treatment, ranging from 45-134 mmol/mol.
Discussion
The results highlight low level HbA1c testing pre steroids. 94% of steroid induced hyperglycemia develops within 48 hours of initiation (1), when most patients are still inpatients. 41/49 patients were not tested and are at risk for steroid induced hyperglycemia. Of those tested, all were in 'at-risk category' (HbA1c $\geq$ 42mmol/mol). This may suggest a limitation in our study, in so far as, all those tested may have been known to be hyperglycaemic and the true screening value may be lower. Nonetheless, a simple HbA1c will identify those 'at-risk' for targeted glucose monitoring on steroids, ideally in hospital. This may minimize the risk of readmission and morbidity with HONK/HHS.

Insulin resistance: in type 1 diabetes

M'ballou Camara[1], Fatiha Ettalibi[1], Sana Rafi[1], Ghizlane EL MGHARI[1] & Nawal EL Ansari[1]
[1]CHU Mohammed VI, Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Insulin resistance is one of the characteristic abnormalities of type 2 diabetes. Recently it has been recognized that type 1 diabetes may also present with insulin

resistance of varying intensity. We report a case of insulin resistance in a patient with type 1 diabetes.
Observation
The patient was 23 years old, with a history of type 1 diabetes since the age of 20, with positive antibodies against GAD (glutamate acid decarboxylase), revealed by a cardinal syndrome with inaugural ketosis on discovery under high dose insulin: mixtar30 (70IU at 08:00 - 30IU at 12:00 - 64IU at 20:00) and Actrapid: (5IU at 08:00 - 38IU at 12:00 - 34IU at 20:00), no diabetic heredity. The admission examination revealed a stable conscious patient with hyperglycemia between 2.53 and 3.23 g/l, systolic pressure at 132 mmhg, body mass index (BMI) at 22 kg/m^2 with a waist circumference (WC) of 77 cm. Biology showed normal transaminases: ALT 38U/l, ASAT 33U/l, GGT 12UI/l, total cholesterol 1.67 g/l, LDL 1.28 g/l, HDL 0.61g/l, Triglycerides 1.36 g/l, management consisted of the introduction of oral antidiabetic drugs: metformin 2 g, empagliflozin 10 mg/d, in combination with insulin. The evolution was marked by the improvement of the glycemic figures with reduction of the doses of insulin, currently under: mixtard30: (24UI at 08 h-00-24UI at 20 h) metformine 2g/d and jardiance 10 mg/d.
Discussion
Insulin resistance is mainly related to type 2 diabetes. Recently it has been recognized that type 1 diabetes may also present insulin resistance of variable intensity. The pathophysiology of this insulin resistance is not known. Hypotheses have been put forward, notably a deficit in muscle oxidative phosphorylation. In our case, the high doses of insulin and the chronic imbalance despite the respect of the injections and the dietary rules pushed us to evoke insulin resistance. The improvement of the glycemic figures after the setting on ADO in particular metformin and the recourse to lesser doses of insulin reinforced our diagnosis. Insulin resistance remains rare in type 1 diabetics and the pathophysiological mechanisms have not yet been elucidated, but it should be considered when faced with profiles of type 1 diabetics who remain in chronic imbalance under very high doses of insulin.

Neurognic osteoarthropathy: place of Biphosphonates (one case report)
Lionel Stève Kamgain Simeu, Mjabber Amal, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Teaching Hospital, Endocrinology, Diabetology, Metabolic Dieases and Nutrition, Casablanca, Morocco

Introduction
Charcot's foot is a rare and extremely serious complication of diabetic neuropathy resulting in foot deformities through the non-infectious destruction of bones and joints. Its diagnosis is very difficult, it is often evoked in front of the persistence of inflammatory signs in spite of a well conducted antibiotic therapy.
Case report
59-year-old patient, T2DM for 3 years on Metformin, active smoker for 20 years. Reports for 1 week the progressive installation of a red and painful swelling of the dorsal surface of the right foot without any notion of obvious trauma or signs of infection.
Clinical examination
Overweight patient with a BMI of 26 kg/m^2. On the right foot, hot and painful red tumefaction on the dorsal side of the foot, without ulceration, without pus or serum. Disturbed monofilament test without other neurological signs, on mixed feet with neuropathic predominance classified as stage 2-IWGDF and stage 0A-TEXAS, with perceived and symmetrical pulses, an SPI at 0.9.
Paraclinical findings
Glycemia: 1.43 g/l
Urine dipstick: Negative
CRP: 213 mg/l (<6)
Procalcitonin: 0.19 ng/ml (0.5)
Uricemia: 67 (35-72) mg/l
GFR $=$ 78 ml/min
HbA1c: 7.8%
X-rays of the right foot (F/P): No osteitis.
MRI of the right foot: osteoarthropathy without bone lysis associated with tendinosynovitis.
The patient benefited from a total discharge by removable boot and alendronic acid at a rate of 70 mg/week for 6 months and diabetes balance with a good evolution.
Conclusion
The management of Charcot's foot remains complex and often requires multidisciplinary management. The use of bisphosphonates in the control of inflammation during the acute phase has been reported in the literature. It remains a promising therapeutic alternative and has its place in the control of inflammatory signs.

Does the initial daily insuline dose vary with the amount of glycated hemoglobin
Zeineb Zemni, Wissal Ghamgui, Daii Raja, Rihab Yamoun, Amal Salem, Salma Abadlia, Imen Hedfi, Chaima Jemaii, Yosra Htira & Faika Ben Mami
National Institute of Nutrition of Tunis, Department C, Tunis, Tunisia

Introduction
Insulin therapy remains a treatment of last resort for type 2 diabetic patients with uncontrolled diabetes with oral antidiabetic. The aim of this study was to find a correlation between the initial dose of insulin and the glycated hemoglobin (A1c) level.
Methods
We conducted a cross sectional study. We included 63 patients with type 2 diabetes hospitalized for a switching to insulin in the C department of diabetology and nutrition at the National Nutrition Institute in Tunis, during 3 months. We correlate the initial daily insuline dose and the A1c level using the Spearman test.
Results
The mean age of patients was 58.75$\pm$ 12 years ,43% were men and 57% were women. The average duration of diabetes was 9,27$\pm$ 6 years. We found a statistically significant correlation between the initial daily insuline dose and the A1c level ($r = 0{,}66$; $P = 0.000$).
Conclusion
Our results showed a positive correlation between A1c level and initial insulin dose, which encourages us to consider insulin treatment in time to avoid the need for high doses and to minimize side effects.

Effective treatment of allergy to the insulin excipient meta-cresol with desensitization therapy in type 1 diabetes mellitus: a case report.
Ameni Terzi, Meriem Yazidi, Anis Grassa, Nadia Khessairi, Wafa Grira, Ibtissem Oueslati & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunisia

Introduction
Insulin allergy is a clinical challenge in the management of type 1 diabetes mellitus since there is no other therapeutic alternative. The specific cause of insulin allergy can be related to insulin itself or to additives including zinc, protamine and meta-cresol. The manifestations range from localized reactions to systemic severe anaphylaxis. We here present the case of a generalized allergy to insulin excipient meta-cresol, in a type 1 diabetic patient successfully handled by desensitization therapy.
Case-presentation
A 35 years old female with a medical history of seasonal allergic sinusitis and type 1 diabetes mellitus for 4 years on insulin glargine and insulin aspart, presented to our department for the development of generalized urticaria, erythema and pruritus. Symptoms started since diabetes diagnosis, but the intensity and frequency of these reactions increased recently. Symptoms occur 10-30 minutes after insulin injection. Antihistamine treatment improves partially the condition. The allergic reaction persisted with the other types of insulin (regular human insulin, NPH-insulin, detemir, glulisine). Immunological evaluations revealed negative results for specific immunoglobulin E to latex and protamine. Anti-human insulin IgE antibodies (CAP) were inferior to 0,1 kU/l. Skin prick testing revealed a hypersensitivity to the all types of insulins stated above. Because the patient had an allergic reaction to all available insulin and meta-cresol was the only excipient common to all tested insulin types, a presumed allergy to the excipient meta-cresol was diagnosed. We started desensitization therapy to glargine following Joselyn Rojas's protocol using subcutaneous insulin injection with simultaneous intravenous regular insulin infusion associated to premedication with corticosteroid and H1 antagonist. Subsequently, we conducted desensitization to aspart insulin adopting Füsun

Erdenen's protocol. Seen 1 month later, the patient didn't require antihistamines anymore with tremendous allergic symptoms relief.
Conclusion
Allergy to insulin excipient meta-cresol in a type 1 diabetic is unusual and represents a substantial challenge warranting a stepwise approach to be diagnosed and managed. Specific immunotherapy should be considered as a key treatment option.

Should the Fracture Risk Assessment tool be used without Bone Mineral Density in elderly patients having type 2 diabetes mellitus ?

Malak Belkhiri[1], Boubaker Fadia[1], Houda Ben Salem[1], Mouna Brahem[2], Houcem Mrabet[1], Alaya Wafa[1], Zantour Baha[1], Mohamed Younes[2] & Sfar Mohamed Habib[1]
[1]Taher Sfar University Hospital, Internal Medicine and Endocrinology Department , Tunisia; [2]Taher Sfar University Hospital, Rheumatology, Tunisia

Introduction
Osteoporosis and diabetes are two chronic diseases with increasing prevalences, particularly among elderly. Their coexistence results in socio-economic burdens. Clinical and paraclinical assessment for fracture risk among diabetic eldery patients are necessary to implement in clinical practice. Appropriate tools shoud to be determined and tested.
Objective
To assess comorbidities and fracture risk in elderly patients having type 2 diabetes mellitus (T2DM).
Methods
A cross-sectional study was conducted between December 2020 and January 2021 among 31 patients having type 2 diabetes and aged over 65 years in the department of Endocrinology at the UHC Taher Sfar in Mahdia, Tunisia. Patients with risk factors for secondary osteoporosis weren't included. Fracture risk of the population study patients was assessed using the FRAX tool
Results
Our population study included 16 women and 15 men having T2DM. The mean age was calculated at 69.5 $\pm$ 4.5 years. The most frequent comorbidities encountered were : overweight (26 patients), dyslipidemia (23 patients), hypertension (20 patients), osteoarthritis (21 patients), and history of (a)previous fracture(s) (8 patients). The median of A1c was situated at 9,73%. The median duration of diabetes was of 14,7 years (1–30 years). Twenty seven patients were treated with antidiabetics presenting a potential hypoglycemic risk. Chronic complications of T2DM were found among 28 patients. Bone Mineral Density (BMD) results showed osteopenia in 13 cases (41,9 %) and osteoporosis in 3 (9,7 %). Without including BMD, the Fracture risk of the population study patients assessed using the FRAX was estimated at 11.09% $\pm$ 6.28, whereas FRAX including results of the BMD estimated it at 9.91% $\pm$ 4.26. The risk of fracture using FRAX was higher in our population study without considering the results of the BMD. The BMD therefore underestimated the fracture risk in our diabetic elderly population.
Conclusion
Osteoporosis should probably be considered as a complication of diabetes rather than a comorbidity to encourage clinicians to prevent bone demineralisation and risk of falls leading to fracture specially among eldery patients. Appropriate tools should be used to detect osteopenia, osteoporosis and fracture risk among diabetic 2 patients, since having usually an associated metabolic syndrome. BMD was reported by studies underestimating osteoporosis among T2DM. FRAX tool should probably be used without including BMD to better estimate the risk of fractures the elderly diabetic population. Other contolled essays are needed and testing of new appropriate tools seems relevant.

Risk factors associated with symptomatic hypoglycemia in type 2 diabetes mellitus patients

Aniket Inamdar
Samarpan Clinic, Internal Medicine, Omerga, India

Background
Diabetes mellitus is an emerging global epidemic and is the main illness threatening human health in 21st century. The target clinical outcomes in patients with type 2 diabetes mellitus (T2DM) is good control of HbA1C less than 7 %. However, aggressive treatment is needed to achieve this target in some patients. But this aggressive treatment predisposes patients to a higher risk of hypoglycemia that become a major hurdle in achieving glycemic goal in these patients. Hypoglycemia is one of most feared complication of diabetes treatment and the very important barrier in achieving tight glycemic control in diabetes patients.
Objective
To describe characteristics of the patients with T2DM presenting with hypoglycemia and identify the predisposing factors of hypoglycemia in them.
Materials and Methods
This cross-sectional study was conducted in a hospital in rural India from January 2021 to November 2021. Venous plasma glucose was measured in all patients with T2DM presented with signs-symptoms of hypoglycemia, patients having biochemically confirmed hypoglycemia (venous plasma glucose $<$70 mg/dl) were selected for the study. Proper history was taken from patients and their relatives to obtain the demographic and clinical data including hypoglycemic symptoms.
Results
Fourty three with T2DM were included in the study among whom 60% were female, 56% aged $\geq$60 years, 90% lived in rural and sub-urban areas, 52% had diabetes for $\geq$10 years, and 25% took insulin. Hypertension was the most common (55%) co-morbid condition followed by ischemic heart disease (23%) and CKD (13%).28% patients presented in unconscious state. Their mean plasma glucose at presentation was 51 mg/dl. Skipped meal was the most common precipitating factor followed by drug overdose and other medical illness such as CKD. More than half had (51%) hypoglycemic episodes in the preceding 12 months. Self-monitoring of blood glucose (SMBG) was done in only 7% patients.
Conclusions
Hypoglycemia is the most common and often treatment-limiting serious adverse effect of diabetes therapy. Despite being potentially preventable, hypoglycemia in type 2 diabetes incurs substantial personal and societal burden. Awareness of hypoglycemia and its timely management at home needs to be emphasized. Patient education regarding hypoglycemic signs and symptoms, regular meal timings, proper exercise, regular follow ups and self-monitoring of blood glucose (SMBG) and sick days care are of utmost importance to prevent hypoglycemia.

Degenerative complications of diabetes during the switch to insulin

Amal Mehrzi, El Amri Abir, Amorri Amani, Berriche Olfa, Mahjoub Faten, Ben Amor Nadia, Ben Othmen Rim, Mizouri Ramla & Jamoussi Henda
Tunisian Institute of Nutrition, The A Department of Diabetology and Nutrition, Tunis, Tunisia

Introduction
Type 2 diabetes is a chronic, silent disease. Patients with diabetes could experience complications during the evolution of their disease. We studied the presence of degenerative complications during the initiation of insulin.
Methods
Cross-sectional study including a group of patients with type 2 diabetes requiring a switch to insulin, hospitalized at the A department of Diabetology and Nutrition in the National Institute of Nutrition of Tunis between July 2021 and December 2021. The data was collected by consulting medical records.
Results
We included 50 patients with type 2 diabetes hospitalized for a switch to insulin, 44% were men, 56% were women, with an average age of 51 years, the averge duration of diabetes was 6 years, 10% had diabetes for less than a year. We found that 32% of the patients had diabetic retinopathy, 18% had diabetic nephropathy, 40% had diabetic neuropathy, 10% had a history of stroke, 2% had a history of transient ischemic attack, 20% had a coronary diseace, 4% suffered from chronic obliterative arterial disease of the lower limbs.
Conclusion
In our study degenerative complications were present during the initiation of insulin. This could be explained by the therapeutic inertia in type 2 diabetes. The switch to insulin when indicated is necessary to prevent degenerative complications of diabetes.

Type 1 diabetes, metabolic syndrome and cardiovascular risk

Mohamed Abdellahi Mohamed Ahmed, Dhoha Ben Salah, Siddiqa Soomauroo, Mouna Elleuch, Mouna Mnif, Nabila Mejdoub, Faten Haj Kacem Akid & Mohamed Abid
CHU Hedi Chaker Sfax, Department of Endocrinology and Diabetology, Tunisia

Introduction
Metabolic syndrome (MS) is responsible for the increased cardiovascular risk in type 2 diabetics, but few studies have looked at the metabolic syndrome in type 1 diabetics. The aim of This study is to evaluate the prevalence of microvascular and macrovascular complications and evaluate the cardiovascular risk among patients with T1DM associated with metabolic syndrome.
Materials and Methods
Retrospective study which included 36 type 1 diabetics, hospitalized in the diabetology endocrinology department CHU Hedi Chaker in Sfax, with a metabolic syndrome from 1997 to 2018, MetS was defined according to the NCEP-ATP III criteria.
Results
The average age of our patients was 53 years (extremes: 26-80). a female predominant is noted (21 men vs 15 women) with a sex ratio of H/F to 1,4. Diabetes duration average was 15 years. Metabolic syndrome occurred after an average duration of diabetes of 13.7 years (E: 1-35). HTA was present in 21 patients (58.3%). The mean BMI was 26 kg/m^2, 19.7% of patients were obese. The average waist circumference was 95.5 cm. an android distribution of fat was present in 3 women. The mean total cholesterol level was 7 mmol/l, that of triglycerides was 3.3 mmol/l. hypertriglyceridaemia was present in 17 cases. The average HDL cholesterol level was 0.6 g/l. hypoHDLemia was present in 20 cases. The DM consisted of 3 criteria in 22 cases, 4 criteria in 11 cases and 5 criteria in 3 cases. In the majority of cases, it was the combination of dyslipidemia, HTA plus diabetes (80%). Therapeutically, the average dose of insulin used was 0.8 IU/kg/day (0.2-1.4). The combination of an insulin sensitizer was required in 3 cases. Hepatic steatosis was present in 8 cases. Microvascular complications were present in all patients with retinopathy (74%) and nephropathy (86%). Macrovascular complications, such as coronary insufficiency, were present in 20% of cases. The Cardiovascular risk is very high in all patients.
Conclusion
The prevalence of metabolic syndrome during type 1 diabetes is increasing. Its presence indicates an increased risk for micro- and macrovascular complications. A comprehensive management including lifestyle modification might reduce their risk of micro and macrovascular complications in adults with T1DM and MetS.

A case of idiopathic postprandial syndrome in a middle-aged nigerian woman

Damilola Jesuyajolu[1], Abdulhafeez Mohammed[2], Charles Okeke[3] & Armstrong Nicholas[4]
[1]First Graceland Hospitals, Ajah, Nigeria; [2]Top Medics Hospital, Kwara State,, Nigeria; [3]EYN Primary Healthcare Center, Adamawa State, Nigeria; [4]Umaru Shehu UltraModern Hospital, Maiduguri, Borno State, Nigeria

Introduction
Not much has been reported about Idiopathic Postprandial syndrome, especially in Africa. Many cases are often wrongly diagnosed as reactive hypoglycemia. Idiopathic postprandial syndrome refers to signs and symptoms of hypoglycemia in the absence of low blood sugar occurring after meals and is of unknown cause.
Clinical case
We report a case of Idiopathic Postprandial Syndrome in a 44-year old woman living in Nigeria. We present a 44-year-old woman who had been having recurrent hypoglycemic symptoms, which included dizziness, body weakness, lightheadedness, restlessness, headaches, and fatigue after she eats a meal (Postprandial) for a year. Blood glucose is normal during episodes, and extensive examinations and investigations yielded no other cause.
Discussion
Idiopathic postprandial syndrome (IPS) is a condition in which an individual experiences symptoms of hypoglycemia without having biochemical evidence. The major difference between idiopathic postprandial syndrome (IPS) and hypoglycemia is that IPS may present with only symptoms of low blood sugar without the other components of Whipple's triad. These symptoms usually occur within a few hours of eating and the exact cause is not known. Managing the possible identified triggers, dietary modification and the use of alpha-glucosidase inhibitors have been seen to improve the condition. Much work still needs to be done to identify the exact etiology of the syndrome.
Keywords: Postprandial syndrome, hypoglycemia, idiopathic postprandial, adrenergic symptoms, Whipple's triad

Effect of a high calorie diet on the ileum histology of Psammomys Obesus

Asma GUEZIL[1], Zineb Bellahreche[2], Benmessaoud- Mesbah Ouahiba[1] & Koceir El hadj Ahmed[1]
[1]University Of Science And Technology Houari Boumediene, Bioenergetics and Intermediary Metabolism Team, Laboratory of Biology and Organism Physiology,, Bab Ezzouar, Algeria; [2]University Of Science And Technology Houari Boumediene, Nutrition & Metabolism, Department of Biology and Physiology of Organisms, Bab Ezzouar, Algeria

Obesity is associated with low-grade systemic inflammation, indeed the production of pro-inflammatory cytokines by mesenteric adipose tissue has been implicated in the pathogenesis of inflammatory diseases of the small intestine: duodenum, jejunum and ileum. This is the main site of intestinal inflammation. The objective of this work is to study the effect of a high calorie diet on the histology of the ileum in *Psammomys obesus*. The animals were captured in the area of Beni Abbes, in the Algerian Sahara .11 *Psammomys obesus* were divided into two groups, a control group ($n=5$) fed with the halophile plant containing (0.4 Kcal/g), and the second group ($n=6$) subjected to a high calorie diet (3.85kcal/g) for 12 weeks. A part of the ileum was fixed in bruin's solution and was sliced at 3 mm thickness then stained with masson trichrome. Our results show that the high calorie diet induced significant increase on body weight gain compared to control group. Histological analysis shows an increase in muscularisis thickness in high calorie diet group compared to the control one. Furthmore in the submucosa we observed the presence of fat cells and lymphoid infiltration in high calorie diet group, we also observed fibrosis in conjonctive tissue. These results show that our animal could be a model of inflammation and nutrient-induced fibrosis of the ileum. We conclude that a high calorie diet induces inflammatory lesions in ileum that may affect enteroendocrine cells involved in the control of feeding and metabolic pathways related to obesity.

Esophagogastroduodenoscopy Findings in a group of morbidly obese patients undergoing bariatric surgery

Rahma Khalaf, Faten Mahjoub, Nadia Ben Amor, Olfa Berriche & Henda Jamoussi
National Institute of Nutrition, A, Tunisia

Background
Studies of morbid obese patients undergoing bariatric surgery (BS) have revealed that obesity is related with an increased prevalence of endoscopic and histologic gastritis. Performing esophagogastroduodenoscopy (EGD) prior to BS allows the detection and treatment of Helicobacter pylori (H.pylori) infection which is considered to be limiting access to bariatric surgery.
Aim
The aim of this study was to determine the prevalence of gastric lesions and Helicobacter pylori (Hp) infection in a group of morbidly obese patients referred for endoscopy prior to bariatric surgery.
Methods
This is a monocentric prospective descriptive study including 40 morbidly obese patients undergoing EGD before BS. Preoperative data included Age, gender, BMI, comorbidities, upper digestive symptoms, EGD findings and H.pylori infection assessed during a histopathological examination.
Results
EGD was performed in 40 patients. Only 30 patients underwent bariatric surgery:79.3% had sleeve gastrectomy and 21.4% had bypass surgery. The mean age was 39.49 $\pm$ 8.41 years, 35(85.7%) were females, with a mean body mass index of 48.39 $\pm$7.03 kg/m^2. Of the study population,42.9% had hypertension,

20% had type 2 diabetes, 28.6% had dyslipidemia, 8.6% had hypothyroisidm, 65.7% had obstructive sleep apnea syndrome, 14.3% had hypochromic microcytic anemia and 28.6% had vitamin D deficiency. The overall upper digestive symptoms prevalence was 48.5%, with the most frequent being gastroesophageal reflux disease (37.1%), followed by constipation (11.4%). Regarding endoscopic findings, 45.5% presented no endoscopic lesions. Pathological findings were detected in 61.11% of asymptomatic patients. Of the study population, 35.5% presented hyperemic gastropathy, 18.5% erosive gastropathy, 15.6% had hiatus hernia, 21.9% had peptic oesophagitis and 16.1% had cardial beance. No patient had duodenal or gastric ulcer. On histopathological examination, 40.7% presented no lesions, 59.3% ($n=24$) had chronic non atrophic gastritis and no patient had intestinal metaplasia or dysplasia. H.pylori was present in 20 (50%) patients. All patients with H. pylori infection had chronic gastritis of variable severity. There was no significant association between H.pylori infection and age ($P=0.8$), gender ($P=0.6$), BMI ($P=0.38$), hypochromic microcytic anemia ($P=0.1$), vitamin D deficiency ($P=0.67$).
Conclusion
EGD with histological analysis plays an important role in the pre-surgical evaluation in BS, with a high rate of pathological findings in asymptomatic patients.

Prevalence of metabolic syndrome in obese children and adolescents

Eya Safi, Berriche Olfa, Ben Ali Khaoula, Rim Rachdi, Olfa Lajili, Imen Ouderni, Nadia Ben Amor, Faten Mahjoub & Jamoussi Henda
National Nutrition Institute, A, Tunis, Tunisia

Introduction
The metabolic syndrome is a major public health problem. Its prevalence is constantly increasing, especially in children and adolescents. Our objective was to determine the prevalence of metabolic syndrome in a population of obese children and adolescents.
Method
This is a descriptive cross-sectional study including 47 children and adolescents recruited at the obesity unit of the National Institute of Nutrition in Tunis. Each patient underwent anthropometric measurements, clinical examination, metabolic and hormonal assessment.
Results
The mean age of the population was 14.04 $\pm$ 2.55 years. Females were predominant in 57.4% of cases. The mean body mass index (BMI) was 34.34 [26.27-46.28] kg/m^2. All patients had abdominal obesity with a mean waist circumference of 111.93 $\pm$ 12.47 cm. The mean HOMA index was 9.03 $\pm$ 4.97. Type 2 diabetes and hypertension were present in 2.1% and 8.5% of obese patients respectively. Hypertriglyceridemia was found in 13.3% of cases. Almost two thirds of the patients (64.4%) had hypoHDLemia and more than one third had impaired glucose tolerance (40.4%). Hyperuricemia was noted in 18 patients (35.6%). Almost half of our sample (48.9%) had a metabolic syndrome. This syndrome was found in 15 girls (57.7%) and 7 boys (36.8%) but without significant difference ($P=0.17$). It was positively correlated with age and BMI but not significantly ($P=0.26$ and $P=0.44$ respectively). Metabolic syndrome was independent of uricemia ($P=0.7$). It was positively and significantly correlated with the HOMA index ($P=0.015$).
Conclusion
The metabolic syndrome was frequent in our population justifying prevention, screening and early and adequate management of obesity, from childhood, in order to decrease the risk of metabolic and cardiovascular complications.

EP536

The role of hypothalamus mediators in energy imbalance.

Feruza Khaydarova[1] & Maftunakhon Latipova[1]
[1]Republican Specialized Scientific-and-Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan

Obesity is considered a chronic metabolic disease that occurs at any age. Regulation of body weight in the body is carried out through complex interaction of a complex of interrelated systems that control the body's energy system. Energy imbalance is the cause of obesity and overweight, in which the supply of energy from food exceeds the energy needs of the body. Obesity is closely related to impaired appetite regulation, and hypothalamus is a key place of neural regulation of food consumption. The nucleus of the hypothalamus is connected and interdependent on receiving, integrating and sending hunger signals to regulate appetite.
Purpose of The Study
To identify markers of food behaviour.
Materials and Methods
The screening was carried out to identify eating disorders in 200 men and women aged 18 to 35 years with overweight and obesity and to check the effects of Orexin A and Neuropeptide Y markers. A questionnaire and questionnaires were conducted with over 200 people aged 18 to 35 years. Questionnaires were for abnormal eating habits and hidden depression (Zung Anxiety Rating Scale-ZARS). Anthropometry is measured by waist circumference, hip circumference, body mass index, weight, height. Based on the results of the collected data, were divided three groups: People with obesity; People with overweight; Control group of healthy people.
Results
Of the 200 analysed persons, 86% had eating disorders. Of these, 60% of eating disorders were associated with childhood. According to the result ZARS: Normal condition was about 37%, mild depressive disorder 20%, moderate depressive disorder 25% and 18% of people suffered from severe depressive disorder without knowing it. First group of people with obesity had eating disorders, moderate and severe depressive disorder, second group was overweight with mild depressive disorder. According to laboratory data, the first group had the lowest concentration of Orexin A and Neuropeptide Y in blood serum.
Conclusion
Overweight and obesity are the first signal of many diseases. Prevention and detection of these problems will avert various illness, including type 2 diabetes. Obesity aetiology is associated with eating disorders wich leads to anxiety conditions and signal transmission of the orexinorghetic system of the hypothalamus.
Keywords: obesity, energy imbalance, hypothalamus, orexin A, neuropeptide Y.

Biochemical parameters in laboratory diagnostics of metabolic syndrome

Olga Moskalenko & Edward Kasparov
Federal Research Center «Krasnoyarsk Science Center» of the Siberian Branch of the Russian Academy of Sciences, Russian Federation

MS, is defined by a combination of abnormalities, such as obesity, arterial hypertension, elevated blood sugar and cholesterol levels, type 2 diabetes mellitus and is not a disease, but represents a group of risk factors that often occur together, increasing the likelihood of severe disease. It is well known that the main reasons for the increase in the incidence of MS is a decrease in physical activity with a high-calorie diet.
The aim of the study
Assessment of biochemical parameters in the pathogenesis of MS.
Materials and methods
70 MS patients and 45 practically healthy volunteers were examined at the clinic of the Research Institute of MPS. The glucose level was determined by the glucose oxidant method, lipid profile assessment, the use of standard test systems. Insulin was determined by enzyme immunoassay using the DRG test system. All study participants signed an informed consent approved by the ethics committee of the Federal Research Center. Statistical data processing was carried out using the application packages 'Statistica for Windows 8.0'.
Results
The main diagnostic criterion for MS is abdominal obesity, it is important to find out the cause of obesity, which may be associated, for example, with diseases of the endocrine system, in combination with a number of additional symptoms confirmed by tests. It is known that insulin resistance is one of the most important links in the pathogenesis of MS, and the calculated coefficient HOMA-IR was used to assess it. This coefficient is of the greatest diagnostic value and has received wide practical application at the present time. The calculation of HOMA-IR revealed an almost 2-fold increase in this indicator in patients with MS ($P<0.05$), which is a predictor of the risk of developing vascular and diabetic complications. The level of NEFA in patients with MS was increased in 97% of cases and was almost 2 times higher than the normal values. Also, in patients with

MS, there was an increase in the content of insulin and glucose in the blood in comparison with the control group ($P<0.05$).
Conclusion
The study shows that early diagnosis of MS is important for providing timely medical care and lifestyle correction and preventing the development of severe vascular and diabetic complications.

Vologdàs Regional Diabetes Center - equal care for everyone

Nina Kholmskaia[1] & Valentina Victorovna Kalugina[2]
[1]Vologdàs Regional Diabetes Center, Vologda, Russian Federation; [2]North-Western State Medical University named afterv I.I. Mechnikov, Endocrinology named after academician V.G. Baranov, Saint Petersburg, Russian Federation

Vologda is situated in the North-Western region of Russian Federation. It is mostly rural – about 30% of population lives in remoted villages. One can compare Vologdàs region with Greece – same amount of land area (approximately 140000 m2), but the population density is 10 times less (8 per km2 and 85 per km2 respectively). The Vologdàs region population is approximately 1151000, the amount of Diabetes patients is 42 000 (3,7% of overall population). The territory is divided into 28 subregions with endocrine care available in 5 subregions. That is why there is an issue of equal access to specialized care for people with diabetes. Vologdàs Regional Diabetes Center was established in 2016. Diabetes center is armed with Diamobile on which multidisciplinary team (consisted of Endocrinologist, Cardiologist, Neurologist, Ophthalmologist, Podiatrist and nurse-educator) reaches every part of the region. 50000 consultations were made by multidisciplinary team. During the consultation patienès treatment plan, diet and physical activity are revised. Special attention is paid to the detection of Diabetes complications. Center specialists are cooperating with the main Vologdàs, Moscoẁs and Saint Petersburġs hospitals. The Diabetes registry is maintained by general practitioners and endocrinologists. Before the Center opening the data about Diabetes patients in the region was scarce and inconsistent. Thanks to the multidisciplinary team every bit of data acquired is included into Diabetes registry now, which led to better understanding of prevalence, morbidity and mortality, complications and Diabetes druġs distribution throughout the region. The results of data processing are clearly indicating the improvement of medical care quality. There is a great improvement in Diabetes compensation – 15% of patients have 1% reduction in HbA1c level per 1 year. Type 2 Diabetes Mellitus patienès life expectancy has increased from 72 to 74 years (Vologda region total population average –70,7 years). The percentage of patients treated with insulin is about 23%, the proportion of insulin analogues – 90%. 78% of type 2 Diabetes Mellitus patients have metformin as monotherapy or as a part of combination therapy. Consistent with current guidelines the main emphasis is on life quality improvement and avoiding cardiovascular mortality using SGLT2 inhibitors and GLP-1 agonists.
In the COVID-19 era there is an urgent need for switching to online visits. The most important future direction for Center is partial shift to online consultations. In order to achieve this goal a special application is being developed.

EP539

High prevalence of pre-diabetes and diabetes in asymptomatic patients attending an endocrine clinic in a tertiary care institute in Colombo.

Ishara Ranathunga, J P Naveenkumar, T G Athukorala, Manilka Sumanatilleke & Noel Somasundaram
NHSL, Colombo, Sri Lanka

Background and Objectives
The prevalence of pre-diabetes and diabetes has risen exponentially in the recent past. Though the symptomatic patients frequently undergo testing for the diagnosis of the disease, asymptomatic individuals are not routinely subjected to diagnostic testing. Thus, data on asymptomatic people are still lacking. We have studied the prevalence of pre-diabetes and diabetes in asymptomatic subjects attending the Endocrinology clinic in a tertiary care institute in Sri Lanka.
Methods
A descriptive cross sectional study was conducted from January to August 2020 at the Endocrinology Unit of the National Hospital of Sri Lanka. Systematic sampling was done recruiting non diabetic patients aged more than 40 years, attending the clinic for other endocrine diseases. After obtaining informed written consent, the data was collected using an interviewer administered questionnaire. Pre-diabetes or diabetes was diagnosed according to the ADA-2020 diagnostic criteria.
Results
The study enrolled hundred and nine patients. The mean age was 53.9 years (range 40-76) and 90.8% were females. The mean weight was 62.1 (SD = 11.3) kg and BMI was 26.6 (SD = 4.6) kg/m^{-2}. Forty six percent had a family history of first degree relative being affected with type 2 diabetes. All the patients were asymptomatic of classic symptoms of hyperglycemia. Patients were evaluated with fasting blood glucose levels and HbA1c values. Forty nine patients (45%) were diagnosed with diabetes or pre-diabetes with either one or both values being impaired range. Out of that, six patients (5.5%) were diagnosed with type 2 diabetes and 43 patients (39.4%) were diagnosed with pre-diabetes. Out of the patients diagnosed with pre-diabetes and diabetes ($n=49$), sixty four percent did not had a family history of first degree relative being affected with type 2 diabetes. Out of the pre-diabetes and diabetes patients 32% had their BMI < 25 kgm^{-2}.
Conclusions
The prevalence of pre-diabetes and diabetes are much higher than expected in asymptomatic individuals. Hence, the likely patients should be regularly screened to diagnose asymptomatic phase of the disease. This is important as the prevalence has escalated in the immediate past, and diagnosing and treating early will improve long term outcome of the disease. Further large scale studies including community studies are needed to recognize the current prevalence and the rising trend both in urban and rural regions.

The Evaluation of the quality of life questionnaire of patients with autoimmune polyglandular type 2 syndrome

Zamira Khalimova[1] & Gulzoda Negmatova[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov,, department of neurendocrinology, Tashkent, Uzbekistan; [2]Samarkand State Medical Institute, Department of Endocrinology, Samarkand, Uzbekistan

The purpose of the study is to assess the quality of life of patients with autoimmune polyglandular type 2 syndrome using the questionnaire.
Material and research methods
Under our observation there were the following 2 groups of patients: 1 gr. - patients with PAI with AIT (primary adrenal insufficiency and autoimmune thyroid) - 25 patients, 2 gr. - PAI with DM 1 (type 1 diabetes mellitus type 1 - 30 patients, as well as 20 healthy persons of the appropriate age and gender. The study used generally crystal and clinical and biochemical methods of research, hormonal blood tests (TSH, free thyroxine, antibodies to TPO, cortisol), immunological studies (antibodies to thyroid gland, to the pancreas, to adrenal glands), and instrumental research methods (ECG, ultrasound of internal organs, thyroid gland, genital organs, neurophthalmologic, radiographic - MSCT of adrenal glands, statistical techniques, as well as the quality of life of patients with ADDIQOL. AddoQol consists of 30 questions with the estimate of each question in 6 points. At the same time, the patient must be selected in each question 1 answer: 'Yes' or 'no'. If the patient is gaining more than 15 points with the answer 'Yes', then this indicates a low quality of life [1].
Research results
The assessment of the quality of life (QoL) on the AddOQOL questionnaire showed that the middle score of patients 1 of the group was 18 $\pm$ 0.95, and in healthy - 2.35 $\pm$ 0.54 ($P<0.05$). The average score in patients 2 groups amounted to 19.6 $\pm$ 1.06 ($P<0.05$).
Conclusions
QoL patients in patients with APS 2 type of both groups has significantly lagging behind QoL in healthy faces.

Rickettsiosis in diabetics: a Case Report

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco

Introduction
Rickettsia diseases are infectious, re-emerging, polymorphic, potentially fatal diseases that are widespread worldwide. These are diseases caused by strict intracellular bacteria with a Gram-negative stain associated with arthropods, mainly ticks, but also lice, fleas and other mites. In diabetics, adequate and early management is essential given the risk of developing malignant Mediterranean spotted fever.
Observation
We report the case of a 69-year-old patient, known to be type 2 diabetic for 13 years, well balanced on 1 g/d of metformin (HBA1C at 6.9%) and who consulted for a fever associated with a generalized rash evolving since 1 week with intense myalgia and asthenia. Clinical examination revealed a maculopapular rash and a pressure ulcer spot. Laboratory workup demonstrated thrombocytopenia, lymphopenia, inflammatory syndrome with elevated CRP, hepatic cytolysis and glycemic imbalance. The treatment consisted of antibiotic therapy and insulin therapy with good clinical and biological progress.
Discussion and conclusion
The diabetic subject can present a polymorphic clinical picture of rickettsioses associating an infectious syndrome which is sometimes severe, a skin rash and a disturbance of the biological assessment with thrombocytopenia and hepatic cytolysis as the case of our patient. This observation underscores the value of early and adequate management in diabetics in order to avoid multisystem involvement that can be life-threatening.

Leo-Bueger's disease: a rare cause of gangrene in diabetics

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco

Introduction
Leo Burger's thromboangiitis obliterans 'TALB' is a rare inflammatory, segmental and occlusive disease affecting small and medium-sized arteries and the veins of the extremities of the limbs. It is more common in males and its major aggravating factor is smoking.
Observation
We present the case of a 66-year-old patient with a history of chronic smoking at a rate of 25 packs per year, known type 2 diabetic for 10 years, well balanced under hygieno-dietetic measures alone (HBA1C = 6.5 %) without degenerative complications and who consults for necrosis of the right big toe associated with plantar claudication and right plantar erythema. Clinical examination revealed acute distal ischemia of the right lower limb with abolition of the distal pulses on the right and gangrene in the right big toe. The inflammatory, lipid and hemostasis assessment as well as the immunological assessment and viral serologies (HIV, HCV, and HVB) are negative. Vascular imaging shows an occlusion of the right superior popliteal artery. The patient underwent a femoropopliteal bypass with strict discharge and local care combining cleanings and excision of necrotic tumor tissue. Amputation of the right big toe is indicated. Psychological and medical support is in place to obtain smoking cessation.
Discussion and conclusion
The diagnosis of TALB is a diagnosis of elimination evoked in the absence of specific markers and identified etiological factors and which must be considered in the well-balanced diabetic patient with chronic smoking hence the interest of a overall burden of diabetics aimed both at balancing diabetes but also at correcting other cardiovascular risk factors, in particular smoking cessation, as is the case for our patient.

Type 1 diabetes in autoimmune polyendocrinopathy

Sanaa Bammou, Severin N'Koua, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakech, Morocco

Introduction
Type 1 diabetes is accompanied by a high frequency of autoimmune diseases.
The aim
of this study is to determine the different epidemiological, clinical, immunological and therapeutic aspects of Type 1 Diabetes in Autoimmune Polyendocrinopathy and to analyze the results obtained.
Patients and methods
This is a retrospective study of 44 patients with type 1 diabetes, suffering from Autoimmune Polyendocrinopathy and followed in the Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition the CHU Mohammed VI or in the consultation dedicated to type 1 diabetes.
Results
A total of 44 patients were included in the study. Of these patients, 32 females and 12 males. The average age at the discovery of type 1 diabetes was 12.77 ± 6.26 years. Only one patient had type 1 APS associating chronic mucocutaneous candidiasis, hypoparathyroidism, adrenal insufficiency, exocrine pancreatic insufficiency and type 1 diabetes. A APS type II was found in 14 patients, 2 of whom had Schmidt syndrome. 17 patients had APS type 3: 15 patients had Hashimoto's disease and type 1 diabetes, 1 patient had Hashimoto's disease, celiac disease and type 1 diabetes, only one patient had Graves-Basedow disease associated with diabetes type 1. 12 patients had a APS type 4 associating type 1 diabetes and celiac disease. Therapeutic management is based on replacement therapy, synthetic antithyroid drugs, gluten-free diet with education and monitoring of patients and their family members.
Discussion
APS-1, or APECED syndrome, is the rarest of the autoimmune polyendocrinopathy. The discovery of the syndrome dates back to 1929, when Torpe and Handley described the association of hypoparathyroidism and chronic candidiasis. Type 2 autoimmune polyendocrinopathy is the most frequent: i It mainly affects the adrenal cortex, the endocrine pancreas, the thyroid, the ovary, the anterior pituitary, possibly associated with digestive disorders (Biermer's disease, celiac disease), cutaneous (vitiligo, alopecia areata), rheumatological (rheumatoid arthritis). PAI 3 is a rare disease defined by the association of autoimmune dysthyroidism with type 1 diabetes, celiac disease, vitiligo or other autoimmune disease, in the absence of adrenocortical involvement and hypoparathyroidism according to the Neufeld classification. Autoimmune polyendocrinopathy type 4 is a diagnosis of elimination, which associates at least two of the organ-specific autoimmune endocrine syndromes that cannot be attributed to APS2 or APS 3 .
Conclusion
In any patient with autoimmune disease, regular follow-up is indicated in order to detect the outbreak of possible Autoimmune Polyendocrinopathy Syndrome.

Hospitalization in a diabetes unit

Chaima Sdiri, Yosra Htira, Skander Msolly, Maryam Cheikhrouhou, Zohra Hadj Ali, Chaima Jemai, Hedfi Imene & Feika Ben Mami
Institut De Nutrition, Tunis, Tunisia

Introduction
Diabetes is a chronic disease. Its management may require frequent hospitalization. The aim of our study was to determine hospitalization reasons in the diabetic department of The National Institute of Nutrition of Tunis.
Method
It was a prospective study conducted in the department of diabetology in the National Institute of Nutrition in Tunis for three months. The study was carried out on the medical records of hospitalized patients.
Results
We included 90 patients with diabetes with a sex ratio (M/F) of 0.7 and a mean age of 51.7 ± 17.7 years. The majority were type 2 diabetics (72%). The mean age of diabetes was 12.7 ± 8.8 years [0;34]. Smoking concerned 11% of patients. A history of hospitalization in the department was found in 36% of the cases. Chronic diabetic imbalance was the most frequent reason of hospitalization (72%): the initiation of insulin therapy was necessary in 35% of the cases. Emergency hospitalization was indicated in 22% of patients with diabetes and it was correlated significantly with type 1 diabetes ($P = 0.004$) among whom 11% were hospitalized for diabetic ketosis and 11% for severe hypoglycemia. Among hospitalized women with diabetes, 6% were pregnant. The average length of hospital stay was 5.2 ± 2.4 days [2;15]. Hypertension, dyslipidemia, dysthyroid, obesity and coronary artery

disease were found in 52%, 53%, 11%, 40% and 11% of the cases, respectively.
Conclusion
Our study showed a high rate of hospitalization among patients with diabetes outside of a genuine emergency. Therapeutic and dietary education is an essential pillar in the management of all diabetic patients to achieve a good glycemic control while keeping a regular ambulatory follow-up.

Pegylated Interferon induced Latent Autoimmune Diabetes Mellitus of Adults(LADA) in acute setting is not uncommon

Gideon Mlawa[1,2], Chrisopher Smith[1, 3], Janessa Bell[3], Hassan Rehmani[3], Mahamud Bashir[1], Shrini Patel[3], Haythum Elsayed[3], Muhammad Saleem[3] & Musarat Hussain[3]
[1]Queen's Hospital, London, United Kingdom; [2]Queen's Hospital, Diabetes and Endocrinology/Acute Medicine, London, United Kingdom; [3]Queen's Hospital, Acute Medicine, London, United Kingdom

Background
Pegylated interferon-alpha (IFN-α) is licensed as an antiviral, immunomodulatory and anti-proliferative therapy, but may induce autoimmune conditions including Type 1 diabetes Mellitus/latent Autoimmune Diabetes of Adults (LADA).
Case Report
A 50-year-old male presented with a 3-week history of polyuria, polydipsia and weight loss. Following review by his General Practitioner he was found to have an elevated serum glucose (55.4 mmol/l). Inpatient treatment with intravenous fluids was given alongside initiation of Metformin and Gliclazide. Further investigations revealed HbA1c 170 mmol/l and positive Anti-GAD antibody titer, confirming a diagnosis of LADA, therefore, Insulin detemir was commenced and Gliclazide was stopped. He has polycythemia Vera being treated with peginterferon alfa-2a 135 mg fortnightly, and a history of ischemic heart disease, stroke and an implantable cardioverter-defibrillator. He was taking peginterferon alpha-2a for 4 years prior to diagnosis of LADA.
Discussion
Polycythaemia Vera is a myeloproliferative disorder with Pegylated interferon-alpha as possible treatment option. Pegylated interferon-alpha therapy may be associated with onset of Diabetes mellitus, which can be acute, slow or fulminant. In our case, LADA presented 4 years after initiation of treatment. The pathogenesis of pegylated induced autoimmune diabetes is unclear. It has been proposed that pegylated interferon may shift the Th1/Th2 balance to a Th1-predominant state, resulting in an induction of Th1-type cytokines which leads to an accelerated destruction of β-cells within the pancreas as demonstrated by Murine models. Additional studies have reported high levels of anti-GAD antibodies in patients a few months after initiation of pegylated interferon treatment.
Conclusion
This case highlights causal relationship between Pegylated interferon-alpha and Type 1 autoimmune diabetes/lADA. It's recommended that pre-treatment HbA1c is measured alongside regular serum glucose and GAD antibodies during the course of treatment with Pegylated Interferon-alpha to ensure timely diagnosis and management of diabetes.

Case report: The HAIR-AN syndrome

Sanaa Bammou, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakech, Morocco

Introduction
The HAIR-AN syndrome, which consists of hyperandrogenism (HA), insulin resistance (IR) and acanthosis nigricans (AN), is an underdiagnosed endocrinopathy.
Observation
We report the case of Miss A.M., 24 years old, admitted for exploration of hyperandrogenism. Anamnesis: the patient reported polyuropolydipsic syndrome and the notion of weight gain without eating disorders, making a total of 28 kg in 6 months. This period is also marked by the onset of amenorrhea, increased body and facial hair, increased pigmentation of skin, increased sweating and alopecia. Upon presentation to the Endocrine clinic, examination of the patient revealed
- Severe hirsutism scored at 34 according to the Ferriman and Gallowey score, associated with acne and seborrhea
- Homogeneous obesity without male musculature
- Acanthosis nigricans was positive at the flexor surfaces, neck, axillae, cubital fossae the base of the neck.
- buffalo hump

Investigations showed
follicle stimulating hormone (FSH), luteinizing hormone (LH), and prolactin (PRL) are within normal limits. She had normal estradiol level, and testosterone level of 0.5 mg/l, 4 androstene-dione and 17 OHP within the standards. low-dose dexamethasone suppression test returned to negative at 0.35 mg/dl, 2 normal 24-hour urinary free cortisol (UFC), UFC the first at 31.85 mg/24 h, the second at 42 mg/24 h and salivary cortisol was normal level of 0.6 ng/ml. Ultrasound of the pelvis revealed that the left ovary measured 18.8 cm^3 with several anechoic cystic formations, number$>$ 10 of infracentimetric size, The right ovary measured 13.7 cm^3 in volume, seat of several anechoic cystic formations number$>$ 10 of infracentimetric size concluding to an aspect in favor of a bilateral ovarian dystrophy. The metabolic impact assessment showed hypertriglyceridemia level of 2.02 g/l and diabetes with an HBA1c 6.8%. From a therapeutic, the patient was started hygiene and dietary measures with metformin for her blood sugar, and to help in enhancing the peripheral insulin action., cyproterone acetate associated with ethinyl estradiol.
Discussion
The HAIR-AN syndrome is one of the most underdiagnosed clinical entities in endocrinology. The reason for this is that women with hyperandrogenism are not usually screened for insulin resistance and acanthosis nigricans. It probably accounts for 1%-3% of women with hyperandrogenism. Barbieri and Ryan have described the salient features of this syndrome.
Conclusion
The HAIR-AN syndrome can cause profound psychological distress manifested by morbidity, depression and a sense of worthlessness which may require long-term psychological support.

Familial hypercholesterolemia: a case report

Gorgi Khaoula, Kamel Farah, Lamya Echchad, Rifai Kaoutar, Iraqi Hinde & Gharbi Mohamed El Hassan
Ibn Sina University Hospital, Endocrinology and Metabolism Disease Department

Introduction
Familial hypercholesterolemia is an autosomal dominant genetic disease linked to a mutation in 3 genes involved in the catabolism of LDL particles. It is characterized by an exclusive increase in low-density lipoproteins (LDL). It is associated with a high risk of premature cardiovascular complications. We report the case of a patient with familial hypercholesterolemia.
Case
44-year-old patient, From a first-degree consanguineous marriage, with a history of: hypertension under treatment, deaths at an early age as well as hypercholesterolemia in the family. Her history of the disease dates back to the age of 7 years with the appearance of cutaneous xanthomas and xanthelasmas. The diagnosis of hypercholesterolemia was retained following family screening at the age of 33 years, treated with Rosuvastatin 40 mg. The evolution was marked by the development of severe coronary artery disease requiring double coronary bypass surgery. Clinical examination found tendon and skin xanthomas and xanthelasma. The biological work-up showed LDL-C: 5.41 g/l, HDL-C: 0.34 g/l, triglycerides (Tg): 0.88 g, total cholesterol (TC): 5.93 g/l, Lipoprotein electrophoresis (LPE) found: clear appearance, LDL: 83.3%, HDL: 12.5%, VLDL: 4.2%, ApoB measuring: 3.14 g/l. The diagnosis of familial

hypercholesterolemia in the patient was retained: in view of the familyhistory of the first-degree relative with early coronary disease, the personal history of early coronarydisease, the presence of tendinous xanthomas, and the LDL-C level above 3.3 g/l according to the Dutch Lipid Clinic Network Score. The workup showed multiple bilateral atheromatous plaques in the carotid arteries and in the arteries of the lower limbs. The management of the patient consisted of a reinforcement of hygienic and dietary measures, with a combination of Rosuvastatin 40 mg per day, Ezetimib 10 mg per day and IPCSK9. The genetic study is essential but not available in Morocco, a cascade screening is proposed in her family.
Discussion & Conclusion
Familial hypercholesterolemia is often underdiagnosed and undertreated. The diagnosis is made according to the Dutch Lipid Clinic Score, which take into account LDL c levels, personal and/or family history of cardiovascular disease and clinical signs of dyslipidemia. Early diagnosis is important to treat the disease as early as possible and prevent cardiovascular complications.

Methods to measure the mitochondrial toxicity in mouse kidney stem cell by toxicant

Minsu Lee, KangMin Kim, Jimin Lee, YongIn Kim & Eui-Bae Jeung
Chungbuk National University, Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Cheongju, Rep. of South Korea

Mitochondria play an important role in generating energy, and they are essential to cell survival. Mitochondria have varieties of functions, such as regulating intracellular calcium concentration and signal transduction, controlling hormone synthesis, inflammatory responses, and free radicals. In particular, this research is interested in the mitochondria in kidney tubular cell. Since mitochondria in tubular cells play an important role in supplying energy, removal of waste and reabsorption of nutrients in the blood, control of blood pressure, and maintenance of homeostasis. Mitochondrial damage may occur by drugs or related chemicals for the treatment of various diseases. Therefore, it may be related to mitochondrial dysfunction. Following experiment was conducted to investigate the relation between kidney and mitochondrial dysfunction. First, five drugs known to be toxic and two non-toxic chemicals to mitochondria were selected. After treatment with mouse kidney stem cells, the specific concentration of cell viability (IC_{50}) was selected for each drug. The results of doxorubicin, a representative mitochondria toxicant, treated on the cell, confirmed that the expression of Mn-SOD increased according to the increasing concentration of doxorubicin. Result of performing an analysis using MitoSOX red staining to confirm the relationship between mitochondrial toxicity and reactive oxygen species (ROS), it was found that the level of ROS according to the concentration of a toxic drug was relatively increased compared to that of a non-toxic drug.

Correlation between the markers of peripheral arterial disease, albuminuria, dyslipidemia with the change in HbA1c in patients with T2DM

Ragini Rohatgi, Pooja Kudkar & Daisy Alfred
Rohit Diabetes Centre, Mumbai, India

Introduction
We explored utility of ankle-brachial index (ABI), toe brachial index (TBI), Albumin Creatinine Ratio (ACR), Low Density Lipoprotein Cholesterol (LDL-C) in context with change in HbA1c
Methods
We conducted an observational study in 25 T2DM on standard care in real world setting
Results
The mean follow up (months) was 19.2 ($\pm$6, range 12). The mean age (years) was 57 ($\pm$12, 95% CI 52 to 63). Initially 36% (9/25) had HbA1c $<$ 7% which increased by 16% with an addition of four patients with HbA1c $<$ 7%, 52% (13/25). Additional four patients achieved LDL-C $<$ 100 mg/dl, 72% (18/25) increase to 88% (22/25). Initially, TBI Left was within range (0.5-0.75) in 8% patients (2/25) which increased to 16% (4/25). ACR was unchanged with $<$ 30 in 80% of patients (20/25). There was a decrease in the number of patients with target range of ABI- right and left from 80% (20/25) to 68% (17/25) and 72% (18/25) to 68% (17/25) patients, respectively. There was no significant corelation between the change in HbA1c and change in LDL (r -0.14, 95% CI -0.51 to 0.26, $P=0.47$ ns), ABI- right (r -0.18, 95% CI -0.54 to 0.22, $P=0.36$ ns), ABI- left (r 0.25, 95% CI -0.15 to 0.59, $P=0.21$ ns), TBI- right (r -0.14, 95% CI -0.15 to 0.26, $P=0.48$ ns), TBI- left (r -0.32, 95% CI -0.63 to 0.08, $P=0.11$ ns), ACR (r 0.06, 95% CI -0.34 to 0.44, $P=0.77$ ns). Table: Change in markers
Conclusion
The change in HbA1c was independent of the change in the markers of peripheral arterial disease and nephropathy. The results need corroboration with larger studies.

Dopplerography and neuromarker BDNF indicators correlation in patients with diabetic neuropathy at the later complications stage'

Telman Kamalov & Olimkhon Alimkhanov
Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

The purpose of the study is to study the correlation bond indicators of ultrasonic doppler and neuromarker BDNF in blood in patients with diabetes mellitus type 2 (DM 2) with diabetic neuropathy at the later complications stage
Material and research methods
A study was conducted 215 patients with DM 2, of which 160 persons suffering from diabetic neuropathy (DNP) in the late complications stage. The following groups of patients were formed: 1 gr. - patients with DM2 type without DNP - 55 patients, 2 gr. - Patients of the DNP in the stage of late complications - 160 patients. In the study, the patients were subjected to clinical and biochemical methods of the study (Glycemia, HBA1C, Alt, Ast, Bilirubin, Urea, Creatine, BDNF, etc.), as well as instrumental examination methods - ECG, Electroneuromyography, Doppler Vessels of the lower extremities, and etc
Research results
Revealed significant correlations of BDNF levels and a number of laboratory and instrumental indicators. A correlation bond with a level of HBA1C and doppler indicators in both groups of patients was detected. In this case, the connection with the glycemia on an empty stomach was unreliable. All the above data indicate the need for timely adequate conservative therapy of chronic wound defects of the lower limbs in patients with DM 2, developing the prevention measures for their recurrence and organizing long-term observation of patients with high risk of development of this complication of diabetes.
Conclusions
The correlation relationship with a level of glycated hemoglobin, blood flow rate in the femoral artery, in the leg, the pulsation index in the tibial artery and the index of resistance in the femoral artery

'The Echocardiography data of patients with type 2 diabetes mellitus complicated by cardio-renal syndrome'

Kamola Alimova
Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Department of Diabetic Nephropathy, Tashkent, Uzbekistan

The purpose of the study is to study the Echocardiography dataof patients with type 2 diabetes mellitus complicated by 4 type cardio-renal syndrome
Material and methods
We examined in total for the period from October 1, 2021 to December 1, 2021 - 25 patients suffering from type 2 diabetes mellitus with chronic renal disease (CRD) and chronic cardial insufficiency (CCR). The research methods included: 1) general clinical (study of endocrine, neurological status, anthropometry 2) instrumental (ECG, roentgen of thorax, ultrasound of internal organs 3) biochemical tests (Hb1AC, glycemic profile, urea, creatinine, lipid spectrum, coagulogram),4) hormonal blood tests (insulin, C-peptide etc.)
Results
We analyzed 25 patients with type 2 diabetes mellitus complicated by chronic renal disease III and chronic heart insufficiency (CHI). Of these, women -13, men -12. Biochemical blood tests have shown that urea and creatinine were reliably elevated in all patients. The Echocardiography investigation showed dysfunction of left ventricle and cardiomyopathy. According to the classification of cardio-renal syndrome, we distributed patients to 2 groups: 1 group – 15 patients with 2 type of cardio-renal syndrome. 2 group with 4 type of cardio-renal syndrome.
Conclusions
In the diagnosis of cardio-renal syndrome, the assessment of the indicators of central hemodynamics plays an important role. Patients with type 2 diabetes mellitus complicated by cardio-renal syndrome have dysfunction of left ventricle and cardiomyopathy

'The results of the Echo-cardiographic investigations in patients with diabetic foot syndrome and chronic heart failure'

Telman Kamalov[1] & Muzaffar Khaydarov[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov of Diabetic Foot Syndrome, Tashkent, Uzbekistan; [2]Andijan State Medical Institute of Surgery Diseases, Andijan, Uzbekistan

The purpose of the study is to study the echo-cardiographic disorders in patients with diabetic foot syndrome (DFS) and chronic heart failure (CHF)
Material and methods
The study was conducted in 62 patients with SDS treated in the department of surgical diseases and civil defense of the Andijan State Medical Institute in 2019 - 2021. The following groups of patients were formed: 1 gr - patients with DM 2Type and the neuroichemic form of DFS and HSN-31 patients, 2 groups - patients with diabetes mellitus type 2 (DM 2Type) and neuroichemic DFS form without CHF -31 patients, 3 gr. - A group of control, 20 healthy persons of the appropriate age and gender. All 50 patients were exposed to surgical treatment. In a study, patients were subjected to clinical and biochemical methods of research, functional tests, as well as instrumental methods of examination, doppler vascular vascular methods, bacteriological analysis of separated from the wound, as well as statistical techniques.
Results
In the 1st group of patients, the average value of the fraction of the left ventricle emissions (LVE) were in the range of 41.5 $\pm$ 2.2 compared with the 2nd group of 56.3 $\pm$ 3%; ($P<0.001$). The indexed finite-systolic volume of LV was reduced only in patients 1 of the group (43 $\pm$ 8 ml/m against 57 $\pm$ 9 in 2 groups; $P<0.05$). The value of the anterograde shock volume was also reliably below in 1 group of patients (39 $\pm$ 9 vs 49 $\pm$ 11 ml in 2 group; $P<0.05$). Cardiac output and the heart rate were also reliably reduced in 1 group (4.4 $\pm$ 0.5 vs 5.7 $\pm$ 0.6 l/min; $P<0.05$ and 1.23 $\pm$ 0.26 vs 1.72 $\pm$ 0.29 l/m 2; $P<0.005$, respectively).
Conclusions
In patients with diabetic foot syndrome and chronic heart failure reliable decrease in echo-cardiographic indicators was revealed.

In a study, patients were subjected to clinical and biochemical methods of research, functional tests, as well as instrumental methods of examination, doppler vascular vascular methods, bacteriological analysis of separated from the wound, as well as statistical techniques.
Results
In the 1st group of patients, the average central systolic pressure was significantly higher (168/96 $\pm$ 7.2 mm hg. in comparison with the 2nd group of 126.3 $\pm$ 3 6; ($P<0.001$). Peripheral blood pressure was increased only in patients 1 groups (162/92 $\pm$ 4.2 mm hg. against 118/66 $\pm$ 3.6 mm hg. in group 2; $P<0.05$). The value of the daily blood pressure was also reliably higher in 1 group of patients (171/98 $\pm$ 4.3 vs 129/82 $\pm$ 11.2 mm. In 2 groups; $P<0.05$).

Conclusions
In patients with the syndrome of the diabetic foot of the neuro-ischemic form with chronic heart failure, reliable deterioration of hemodynamic indicators was revealed.

'Biochemical indicators in patients with type 2 diabetes mellitus in hemodialysis'

Mokhira Teshabekova[1]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

The purpose of the study is to study biochemical indicators in patients with type 2 diabetes in hemodialysis
Material and methods
The study was carried out in 30 patients with type 2 diabetes mellitus (DM 2) treated in the Diabetic Nephropathy Department 2019 - 2021. Healthy volunteers ($n=$ 20) amounted to a control group. The paper included general-clinical, clinical and biochemical, hormonal, immunological methods of blood testing, as well as instrumental methods of I investigation -ultrasound of internal organs, ECG, ECHO-ECG, indicators of the quality of life of patients (questionnaire), as well as statistical techniques.
Results
We analyzed 30 patients with type 2 diabetes mellitus, complicated by chronic kidney disease CKD V degree and receiving hemodialysis. Of these, women -12, men -18. The average age of patients amounted to 56.3/675 years, respectively, among men and women. Biochemical blood tests have shown that urea and creatinin were reliably increased in all patients of the group, while in the control group they were within the normal range ($P<0.05$). The average pulmonary filtration rate in these patients was less than 20 ml/min/1.73 m2, which indicated the need for substantive renal therapy.
Conclusion
In patients with DM 2 associated with the CKD, the average temperature of the glomerular filtration rate in these patients was less than 20 ml/min/1.73 m2, which indicated the need for substitution renal therapy.

'The renal dysfunction indicators of the patients with severe complications of diabetic foot syndrome(ulcer, gangrene, amputation) and chronic kidney disease'

Khamidulla Shokirov & Telman Kamalov
Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, of Diabetic Foot Syndrome, Tashkent, Uzbekistan

The purpose of the study is to study the results of the biochemical investigation of the patients with diabetic foot syndrome and chronic kidney disease (CKD).
Material and research methods
A study was conducted 60 patients with diabetes mellitus type 2 (DM 2) with diabetic foot syndrome (DFS) in the late complications stage accociated with chronic kidney disease. All observed patients will be divided into 3 groups:
1 gr. - 20 patients with DFS, complicated by ulcers, gangrene and amputation and in combination with HBP 4-5 stages on hemodialysis
2 gr. - 20 patients with DFS, complicated by ulcers, gangrene and ammputation in combination with CKD 4-5 stages without hemodialysis
3 gr - 20 patients with DFS, complicated by gangrene and amputation, without CKD.
A group of control will be 20 healthy faces. The investigationn methods included biochemical (bilirubin, lipid spectrum, ALT, AST, blood sugar, HbA1C, urea, creatinine, etc) and instrumental (: ECG, MRI of foots, Dopplerography of the legs vessels, ultrasound of the internal organs, etc)investigation
Results
Patients with 1 and 2 groups have revealed a reliable increase in urea levels and creatinine in the blood. The average of the blood urea in group 1 reached 15.6 mmol/l, in the second 26, 5 mmol l, in group 3 - 3.4 mmol/l (normally 2.1 - 8, 2 mmol/l). The average blood creatinine values were 167, 8 mcmol/l in group 1, 188, 7 mcmol/l in 2 groups and 35.6 mcmol/l in 3 groups in men (normally 77-127 in men and 44-96 мcmol/l in women). The average value of creatinine in women group reached 101, 4 mcmol l, in group 2 - 126.7 mcmol/l and in group 3 - 49 mcmol/l.. The value of the HbA1C achieved in groups of values 9, 2%, 10, 4% and 10, 6%, respectively.
Conclusions
In patients with diabetic foot syndrome and CKD IV-V st. without hemodialysis, reliably worst indicators were revealed in comparison with patients with DFS and CKD IV-V st without hemodialysis and patients with DFS without CKD.

'Anamnestic indicators in patients with severe complications of diabetic foot syndrome (ulcer, gangrene, amputation) with chronic kidney disease of various stages'

Khamidulla Shokirov[1] & Telman Kamalov[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, of Diabetic Foot Syndrome, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov,, Tashkent, Uzbekistan

The purpose of the study is to study the anamnestic indicators in patients with severe complications of diabetic foot syndrome with chronic kidney disease of various stages
Material and research methods
A study was included 85 patients with DM 2 with diabetic foot syndrome (DFS) in the late complications stage accociated with chronic kidney disease (CKD). All observed patients will be divided into 4 groups:
1 gr. - 22 patients with DFS, complicated by ulcers, gangrene and amputation and in combination with CKD 4-5 stages on hemodialysis
2 gr. - 21 patients with DFS, complicated by ulcers, gangrene and amputation in combination with CKD 4-5 stages without hemodialysis
3 gr - 22 patients with DFS, complicated by gangrene and amputation, without CKD.
4 gr - 20 patients with DFS, without severe complications, with the initial stage of CKD.
A group of control will be 20 healthy faces. The investigationn methods included biochemical and instrumental investigation
Results
In group 1, 12 men were observed (average age 56, 5 years) and 10 women (average age 52, 6 years). The duration of the DM 2 was 24/25 years, respectively, on the floor. The duration of HD (hemodialysis) was 25/26 months, respectively. In group 2, 10 men were observed (the average age 59, 5 years) and 12 women (average age 58, 6 years). The duration of the DM 2 was 25/27 years, respectively, by the sex. The duration of the HD was 24/28 months, respectively. In the group 3, 13 men were observed (average age 52, 2 years) and 9 women (average age 53, 6 years). The duration of the DM 2 was 18/16 years, respectively, on the sex. All diabetic polyneuropathy was diagnosed. In the 4th group, 11 men were observed (average age 53, 8 years) and 9 women (average age 58, 6 years). The duration of the DM 2 was 15/12, respectively, on the sex.
Conclusions
1. Patients 1 and 2 groups have noted the worst values of clinical and demographic indicators. 2. It is necessary to conduct further research in groups.

Characteristics of dyslipidemia in a group of patients with diabetes

Amal Mehrzi, Saadi Wiem, Abdesslem Haifa, El Amri Abir, Sebai Imen, Ouneissa Kamilia, Yahyaoui Rim, Ben Brahim Asma & Amrouche Chiraz
[1]Tunisian Institute of Nutrition, The Day Hospital Department, Tunis, Tunisia

Objective
Dyslipidemia represents an added factor of cardiovascular risk for patients with diabetes. The objective of this work was to study the characteristics of dyslipidemia in a group of patients with diabetes.
Methods
Cross-sectional study including a group of patients with diabetes associated with dyslipidemia, during a period of 6 months, admitted in the day hospital unit of the National Institute of Nutrition of Tunis. The data was collected by consulting medical records.
Results
We included 58 patients with an average age of 57 ± 11 years and a female predominance (69%). The average duration of diabetes was 14 ± 7 years. Patients were on insulin therapy in 84% of cases. Mean glycated hemoglobin (HbA1c) was 9.4±1%. Arterial hypertension, dysthyroidism, coronary artery disease and renal failure were found in 62%, 13%, 14% and 4% of cases respectively. Pure hypercholesterolemia was noted in 58% of patients while 42% had mixed dyslipidemia. Mean cholesterolemia was 4.6 ± 1 mmol/l, mean triglyceridemia was 1.5 ± 0.6 mmol/l. The average HDL-cholesterol level was 1± 0.2 mmol/l. Mean LDL-cholesterol was 1.1± 0.3 mmol/l.
Conclusion
Lipid abnormalities are frequent in diabetes, hence the importance of systematic screening and adequate therapeutic management in order to improve cardiovascular prognosis.

Treatment adherence in Type 2 Diabetes: Experimental study research project

Virgínia Regufe
Faculty of Medicine of the University of Porto, Porto, Portugal

Summaries
Treatment adherence in Type 2 Diabetes: Experimental study research project
Diabetes is a metabolic disease brought about by high levels of glicose in the blood over a long period of time. It's a disease which shows an increasing incidence, mainly in developed countries. When untreated, diabetes can cause several acute complications, such as ketoacidosis, hyperglycemic hyperosmolar state or even death. Prevention and treatment consist in maintaining adequate eating habits, doing physical activity regularly and keeping a normal weight. The development of type 2 diabetes prevention projects in the community is regarded as a significant opportunity of promoting health, whereby health professionals play a vital role in its implementation. This project is integrated in "Doctoral Program in Metabolism – Clinic and Experimental" and its aim is to evaluate the efficiency of a Therapeutical Education Program in the treatment adherence in Type 2 diabetes carriers. An experimental, quantitative study is going to be conducted among individuals with Type 2 diabetes, who are being followed by health professionals at a university hospital located in Porto, Portugal. The population will be submitted to randomization and separated into experimental and control groups. Randomization will be done through random number selection per site. The evaluation of results will be carried out by responding to a questionnaire entitled "Treatment adherence in diabetes", both prior and posterior to the implementation of the program. It is expected that the results garnered from the questionnaire will prove that the adoption of Therapeutical Education Programs by the population will improve the rates of treatment adherence in diabetes.

Long-term-high-fat/high-carbohydrate-diet-induced subcutaneous adipose tissue inflammation in gerbil model (Gerbillus tarabuli)

Zineb Bellahreche[1], Asma Guezil[2] & Yasmina Dahmani[1]
[1]University Of Science And Technology Houari Boumediene, LBPO/Nutrition & Metabolism, Department of Biology and Physiology of Organisms, Faculty of Biological Sciences, Algiers, Algeria; [2]University Of Science And Technology Houari Boumediene, Bioenergetics and Intermediary Metabolism team, Laboratory of Biology and Organism Physiology, Algiers, Algeria

Obesity results from an imbalance between energy intake and expenditure. The WHO has considered it as a chronic disease which is associated with many complications, such as insulin resistance, metabolic syndrome, etc. It is defined as an abnormal or excessive accumulation of body fat that can harm health. The distribution of this fat (visceral and subcutaneous), the size of the adipocytes and the inflammatory state of the adipose tissue are of great importance in the progression of this disease. The objective of this work is to study the effect of a long-term high-fat/high-carbohydrate diet (HFHC) on the subcutaneous adipose tissue histology of the gerbil. *Gerbillus tarabuli*, nocturnal desert rodents, is native to North Africa (south western Algeria). Our study involved 12 animal divided into 2 groups. Control group: gerbils received a natural diet (carrots and lettuce) and HFHC group: experimental animals were fed a high-fat/high-carbohydrate diet (barley, dried date and butter). After 20 weeks, gerbils were decapitated, their body weight measured, and subcutaneous adipose tissues were fixed in 10 % formalin solution for 24 h, dehydrated in graded ethanol, embedded in paraffin and stained with hematoxylin-eosin for microscopic observation. Our results show a significant increase in the final body mass induced by the HFHC diet. The histological examination revealed changes in the structure of subcutaneous adipose tissue (expansion, inflammation, and fibrosis) in HFHC group. Indeed HFHC diet increased both the accumulation of macrophages in visceral adipose tissue and in subcutaneous adipose tissue with the presence of significant vascularization and connective tissue deposition in the latter. Thus, we suggest that adipose tissue remodeling can affect all adipose tissues in the gerbil model submitted to long-term HFHC diet.

Source of folic acid in obesity patients in the Odessa region (Ukraine)

Maria Zhygalina-Hritsenyuk & Anatoly Gozhenko
Research Institute for Transport Medicine, Odessa, Ukraine

Introduction
Obesity is known to be a disease of civilization. Both genetic and environmental factors play a role in the development of obesity. In the vast majority of cases, the main factor is eating disorders and hypodynamy. The modern human exceeds daily food demand mainly due to saturated fats and refined carbohydrates, with lack of fibre and vitamin. We decided to test the source of folic acid, because this vitamin is part of the folate cycle as a coenzyme to reduce homocysteine levels. At high levels of homocystein, the risk of cardiovascular disease, stroke, Alzheimer's disease and osteoporosis increases. Cardiovascular diseases are the main cause of death in Ukraine. The goal of the work is to study the source of folic acid depending on the body mass index in the inhabitants of the Odessa region.
Methods
Fifty-six persons (16 men and 40 women) aged from 20 to 65 living in the Odessa region were examined. Height, weight, and BMI were measured. Folic acid was determined with an immunochemical method with electrochemiluminescent detection of the test system Cobas 6000; Roche Diagnostics (Switzerland).
Results
Based on the determination of the level of folic acid in the blood, 19.6% of the surveyed inhabitants of the Odessa region had a deficiency of this vitamin. In the obesity group, the rate was 32 per cent. Folic acid deficiency can be nutritional (insufficient use of deciduous green and/or abuse of coffee) or genetically induced (folate cycle polymorphism), and further research is needed, with the development of deficit correction techniques.

Cardio-metabolic profile of morbid obesity compared to moderate and severe obesity

Zeineb Zemni[1], Emna Bornaz[1], Nadia Alaya[2], Olfa Lajili[1], Rihab Yamoun[2], Eya Safi[3], Ben Ali Khaoula[3], Nadia Ben Amor[1], Ramla Mizouri[1], Ryme Ben Othman[1], olfa Berriche[1], Faten Mahjoub[1] & Henda Jamoussi[1]
[1]National Institute of Nutrition of Tunis, The Unit of Obesity Research, Tunisia; [2]National Institute of Nutrition of Tunis, Outpatient Department and Functional Explorations, Tunis, Tunisia; [3]Military Hospital of Instruction of Tunis, Endocrinology Department, Tunis, Tunisia

Introduction
Obesity is the disease of modern society whose prevalence continues to increase. The aim of this study was to compare the cardio-metabolic profile of morbid obesity with that of moderate to severe obesity.
Methods
It was a retrospective study conducted at the obesity unit of the national institute of nutrition in Tunis including 174 obese patients We divided the population into two groups. Group 1 (G1) with morbid obesity including 83 patients and group 2 (G2) with moderate to severe obesity including 91 patients. Morbid obesity is defined by a BMI $\geq$ 40 kg/m^2 and moderate to severe obesity is defined by a BMI between 30-39.9 kg/m^2. Clinical and biological data were collected from medical observation records.
Results
The mean age of our patients was 42.22 years in G1 and 47.93 years in G2 ($P=0.006$). A female predominance was noted in both groups, sex ratio M/F (G1): 0.18 and (G2): 049. A significant association was found between female gender and morbid obesity ($P=0.008$). The study of the metabolic profile did not find any significant difference in the prevalence of diabetes between the two groups but dyslipidemia was higher in G2 ($P=0.024$). The mean waist circumference was higher in the morbidly obese group (127.7 cm VS 114.99 cm) ($P<0.001$). No significant difference was found between the biological parameters of the two groups. Regarding cardiovascular complications, there was no significant difference between the two groups in the prevalence of heart failure, hypertension, and stroke. Joint complications such as gonalgia and low back pain were higher in G1 ($P=0.015$). Sedentary lifestyle was higher in the morbidly obese group (69.88% vs. 51.65%) with a significant difference between the two groups ($P=0.014$). The prevalence of eating disorders (the presence of at least one disorder) was higher in G1 (89.16% vs 74.73%) ($P=0.014$).
Conclusion
Our study showed that despite higher body fat, morbid obesity is not characterized by a more severe cardio-metabolic profile compared to moderate and severe obesity.

EP563

Diabetic ketoacidosis in pregnant women with type 1 DM and Covid 19

Jesus Manuel Cornejo Dominguez, Almudena Lara Barea, Isabel María Mateo Gavira & Cristina Lopez Tinoco
Hospital Universitario Puerta del Mar, Cádiz, Spain

Introduction
Diabetes is a recognized risk factor for the development of complications in COVID-19 infection, with an increased incidence of ketoacidosis observed in patients admitted to hospital.
Case Reports
We present the case of a patient with type 1 DM complicated by diabetic retinopathy and unplanned pregnancy (pregestational Hba1c 9.1%). In follow-up during pregnancy: progression of retinopathy and fetal renal pyeloectasia in morphological ultrasound at 20 weeks, HbA1c second trimester 6.8%. Consultation in the Obstetrics Emergency Room of a 29+4 week pregnant woman due to emetic symptoms of 3 days of evolution, showing ketoacidosis (fasting plasma glucose 287 mg/dl, pH 7.11 bicarbonate 5.7 mmol/l and ketonuria), and starting intravenous insulin and fluid therapy. In case of suspicion of COVID-19 contact, PCR Sars-CoV-2 is performed, which is positive. Cardiotocographic record (CTG) on admission: pattern according to gestational age and adequate fetal HR, limited variability in some section that recovers spontaneously. No sustained decelerations. Non-dynamic. Free Style Libre (previous 14 days): average glucose 155 mg/dl, GMI 7.0%, CVC 41.7%, time on target 65%, above target 29%. Although the patient did not present respiratory symptoms or vital compromise, it was decided to admit her to the intensive care for treatment and monitoring of ketoacidosis and obstetric control with continuous CTG. At 24 h, uterine dynamics is evident in the CTG, for which she receives tocolytic treatment with atosiban to inhibit contractions, magnesium sulfate and betamethasone for fetal lung maturation and a slight worsening of glycemic control. After intensifying intravenous insulin therapy, optimal fasting plasma glucose levels for pregnancy were achieved, but refractoriness in the control of ketoacidosis and intermittent oral tolerance prevented withdrawal of the insulin perfusion. On the 11th day of admission (current gestation of 31+1 weeks) there was evidence of CTG, loss of fetal well-being and uterine dynamics, deciding to carry out an urgent caesarean section that proceeded without complications. After this, correction of ketoacidosis and improvement of oral tolerance were achieved, with withdrawal of intravenous insulin therapy and transfer to a conventional ward without complications.
Conclusions
We present this case emphasizing the importance of multidisciplinary management of diabetic ketoacidosis during pregnancy and the role that COVID-19 infection may have played.

Clinical features and survival outcomes of patients with ectopic Cushing's syndrome: a single-center study

Olga Golounina[1], Liudmila Rozhinskaya[2], Svetlana Arapova[2], Michael Pikunov[3], Patimat Khandaeva[2], Valentin Fadeyev[1], Evgenia Marova[2] & Zhanna Belaya[2]
[1]I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Moscow, Russian Federation; [2]The National Medical Research Center for Endocrinology of the Ministry of Health of the Russian Federation, Moscow, Russian Federation; [3]The National Medical Research Center of Surgery named after A.V. Vishnevsky of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Objective
To analyze long-term treatment outcomes and to determine prognostic factors affecting the survival of patients with ECS.
Matherials and methods
Retrospective, observational study on 147 patients (88 women, 59 men) with ECS diagnosed between 1990 and 2021. Various imaging studies were performed on all patients to find the source of ACTH producing neuroendocrine tumor (NET). Multivariable analysis was performed using a Cox proportional hazards model to define the independent prognostic factors.
Results
The median age at diagnosis was 40 years [28;54]. 89 patients (60,5%) had bronchopulmonary NET, 15 (10,2%) – thymic carcinoid, 5 – pancreatic NET, 6 – pheochromocytoma, 1– cecum NET, 1– appendix carcinoid tumor, 1 – medullary thyroid cancer and 29 (19,7%) patients had an occult NET. Mean time to diagnosis was 31 months, 11 patients (7,5%) had a cyclic course of disease. The most common complications in the active stage of disease were arterial hypertension (83,7%), osteoporosis with low-energy fractures (60%), type 2 DM (56,5%), cardiovascular disease (52,4%). The median follow-up period of patients was 36 months [11;73] with a maximum follow-up of 379 months. To the present date, the primary tumor was removed in 94 (63,9%) patients. Regional and distant metastases were revealed in 32 (21,8%). At the time of last observation, 62 patients (66%) had achieved stable remission, 12 (12,8%) had relapsed and received treatment with somatostatin analogs ($n=9$) or ketoconazole ($n=1$), and 38 patients (25,9%) had died from multiple organ failure ($n=22$), pulmonary embolism ($n=5$), sudden cardiac death ($n=2$), acute cerebrovascular accident ($n=2$), COVID-19 ($n=3$), complications of surgery ($n=2$), hip fracture ($n=1$), unknown cause ($n=1$). Bilateral adrenalectomy was performed on 45 patients (30,6%): due to occult tumor in 16 patients and incurable stage of disease in 29 patients. Multivariate analysis revealed that negative predictive factors for survival were: age $\geq$51 years at diagnosis, $P<0,001$ (HR 5,513 (2,286–13,293)), localization of NET in the pancreas, $P=0,013$ (HR 5,771 (1,473–23,176)), occult tumors, $P=0,006$ (HR 3,670 (1,461–9,216)) and LNSC $\geq$108,4 nmol/l, $P=0,009$ (HR 4,205 (1,433–12,334)). Bronchial NET, $P=0,006$ (HR 0,272 (0,109–0,684)) was a positive predictor of survival.
Conclusion
The survival rate ofECS is up to 75% over a mean follow-up of 36 months in spite of severe multiple complications associated with hypercortisolism. The severity of hypercortisolism, NET localization and occult tumors are negative factors associated with high mortality. Consequently, more aggressive treatment of

hypercortisolism is potentially beneficial for survival in patients with extremely high LNSC.

EP565

Analysis and prognostic significance of miRNAs in papillary thyroid carcinoma

Romena Laukienė[1] & Laima Ambrozaityte[2]
[1]Vilnius University Hospital Santaros Klinikos, Center of Endocrinology, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Clinics, Department of Human and Medical Genetics, Institute of Biomedical Sciences, Vilnius, Lithuania

Background
Papillary thyroid carcinoma (PTC) is the most frequently occurring endocrine malignancy, with an increasing rate of incidence over the last three decades. Generally, PTC has an excellent prognosis with a relatively low mortality rate, but a small portion of PTC patients suffers from an aggressive form of the disease with tumor invasion and metastasis. Analysis of miRNAs expression data may improve perioperative decision making for patients with PTC.
Aim of the study
To settle the diagnostic utility of specific miRNAs in the preoperative assessment of thyroid nodules.
Methods
One hundred thyroid fine needle aspiration (FNA) samples with suspected thyroid carcinoma were collected in the prospective molecular study at Vilnius University hospital Santaros klinikos. The expression level of the selected five miRNAs (miR125a, miR146b, miR200b, miR221, miR4324) was verified by real-time PCR in 36 non-malignant nodule aspirate samples, 34 PTC without lymph node metastases (LNM) samples and 30 PTC with LNM samples.
Results
The relative expression levels of four miRNAs differed significantly between benign and PTC groups ($P < 0.05$). The relative expression levels of two miRNAs differed significantly between PTC without LNM and PTC with LNM groups ($P < 0.05$). A 16.002-fold increase in the value of miR146 increases the probability (odds ratio) that the disease will be cancerous without metastasis rather than benign (95% CI [4.188; 61.148]). A 4.187-fold increase in the value of miR146 increases the odds (odds ratio) that the disease will be cancerous with metastasis rather than benign (95% CI [1.692; 10.366]). A 31.917-fold increase in miR4324 value increases the odds (odds ratio) that the disease will be cancerous with metastases rather than benign (95% CI [5.966; 170.765]). A one-fold increase in miR4324 value increases the odds (odds ratio) that the disease will be cancerous with metastasis by 8.301 times more than non-metastatic (95% CI [2.155; 31.977]).
Conclusions
Our study showed that the expression analysis of four miRNAs (miR125A, miR221, miR146B and miR4324) could improve the accuracy of fine-needle thyroid node biopsy, which would allow a better differentiation of malignant from benign thyroid nodules. Analysis of miRNA expression levels and detection of miRNAs in FNAB can be used for the pre-operative diagnosis of thyroid cancer. To translate these data into clinical application, large cohort studies are required to examine the prognostic and diagnostic value of miRNAs.

EP566

Immunotherapy induced glycemic dysregulation - characterization and proposed mechanisms beyond beta-cell autoimmunity

Ruth Percik[1,2] & Bernice Oberman[3]
[1]Sheba Medical Center, Division of Endocrinology, Diabetes and Metabolism, RAMAT GAN, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; [3]Gertner Institute for Epidemiology and Health Policy Research, RAMAT GAN, Israel

Aim
Check-point inhibitors have revolutionized cancer treatment while introducing a new spectrum of immune-related adverse effects. Hyperglycemia is frequently observed shortly after initiation of immunotherapy. While immune-mediated type 1 diabetes mellitus is currently the only defined condition associated with post-immunotherapy hyperglycemia, it includes only a small fraction of cases (an estimated prevalence of 0.5%). This study was aimed to determine factors associated with glycemic dysregulation following immunotherapy.
Methods
A retrospective study, using the MD-Clone interface, including data from the electronic medical records of all cancer patients treated with checkpoint inhibitors between January 2015 and January 2021.
Results
Among 3384 patients treated with immunotherapy during the study period, a statistically significant increase in glucose levels was observed after the initiation of immunotherapy [mean of maximum glucose levels during the month before immunotherapy 132.3 $\pm$ 55.8 mg/dl vs 139.8 $\pm$ 64.6 in the month after immunotherapy (P-Value < 0.001)]. Glycemic dysregulation was significant among patients treated with glucocorticoids as part of an anti-emetic regimen in protocols combining chemotherapy and immunotherapy or managing immune-related adverse events ($n = 2168$). Mean of maximal glucose level was 136.4 $\pm$ 59 mg/dl during the month before immunotherapy and 145.6 $\pm$ 68 mg/dl one month after immunotherapy ($P < 0.001$)]. Among patients who were not treated with glucocorticoids ($n = 1216$), glycemic dysregulation was not found to be significant.
Conclusions
Concomitant glucocorticoid therapy is the primary determinant of post-immunotherapy hyperglycemia. Evaluation of the possibility of a distinct, reversible, autoimmune damage to beta cells would require a prospective study with a dynamic assessment of the beta-cell reserve.

Association of tissue miRNA (MiR-146b, -21, -221, -222, -181b) expression and the overall survival of papillary thyroid carcinoma patients

Aistė Kondrotienė[1], Albertas Dauksa[2], Diana Pamedytytė[3], Mintautė Kazokaitė[1], Aurelija Žvirblienė[3], Dalia Daukšienė[1], Vaida Simanavičienė[3], Raimonda Klimaitė[1], Rasa Verkauskienė[1] & Birute Zilaitiene[1]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Institute of Biotechnology, Life Sciences Center, Vilnius University, Vilnius, Lithuania

Introduction
Improper management of papillary thyroid carcinoma (PTC) patients results in potentially higher fatal outcomes due to a lack of relevant prognostic markers, inadequate periodic individualized risk assessments and/or insufficient initial treatment. MiR-146b, -21, -221, -222, -181b are potential biomarkers for risk stratification in PTC.
Aim
The aim of our study was to analyze expression levels of five miRNA molecules (miR-21; miR -221; miR -222; miR -146b; miR -181b) in PTC formaline-fixed paraffin embedded (FFPE) tissue samples and evaluate their relation with the overall survival of PTC patients.
Methods
We analyzed expression of miR-221, miR-222, miR-146b, miR-21, miR-181b in FFPE PTC tissue samples of 312 patients and evaluated their relationship with the overall survival of these patients. To evaluate the association of survival rate after thyroidectomy with miR expression pattern, PTC patients were divided into two groups with high and low PTC tissue miRs expression. Patients with miR expression levels below the median values (miR-146b = 2.59; miR-21 = 1.16; miR-221 = 0.79; miR-222 = 2.04; miR-181b = 0.00048) were assigned as having low expression levels, and patients with miR above or equal to median values were assigned as having high expression levels.
Results
The median follow-up time of PTC patients was 152 (IQR 60) months. 35 deaths were recorded till the end of study. Kaplan–Meier curves estimating the overall survival of PTC patients after thyroidectomy according to high/low tissue expression levels of miR-146b, -21, -221, -222, -181b were compared using the Log rank test, however no statistically significant differences were found ($P = 0.479$; $P = 0.583$; $P = 0.383$; $P = 0.995$; $P = 0.516$). Kaplan–Meier plots for miR-146b paired with miR-221 (median survival 141.7 months (IQR 18)), and miR-146b, miR-221, miR-21 panel (median survival 138 months (IQR 12.75)) compared by the Log-rank test demonstrated significant differences in survival curves for miR-146b, miR-21 and miR-221 panel ($P = 0.019$).

Conclusion
Higher expression of miR-146b, miR-21 and miR-221 is associated with a decreased overall survival of PTC patients.

New insights into armadillo repeat-containing 5 gene: originated in gene mutation, suffering protein property alteration, culminate in function inactivation

Minmin Han[1], Xiaoming Cao[2], Xueming Lin[3], Xiao Lv[2], Ruizhi Xue[2], Chunduo Zhang[2], Bingjun Chen[2], Jian Zhang[1], Mengnan Li[1] & Yunfeng Liu[1]
[1]First Hospital of Shanxi Medical University, Endocrinology, Taiyuan, China; [2]First Hospital of Shanxi Medical University, Urology, Taiyuan, China; [2]First Hospital of Shanxi Medical University, Urology, Taiyuan, China

Introduction
As a tumor-suppressor gene, armadillo repeat-containing 5 (ARMC5) gene regulates steroidogenesis and cell apoptosis in manner of second-hit model. Mutations of ARMC5 gene will disturb its normal function, leading to reduced cortisol synthesis and cell apoptosis, which is acknowledged as a frequent cause of primary bilateral macronodular adrenal hyperplasia (PBMAH). Not until another somatic ARMC5 mutation occur in germline mutation carriers, will they manifest as PBMAH. The underlying pathogenesis has always been of great interest among researchers, however, still remains mystery.
Matherials and methods
This study was conducted in a Chinese family with hereditary PBMAH, including four members from two generations. Gene test was conducted in the blood samples and adrenal tissues. In vitro experiments were introduced to explored gene expression of wild type and mutants at transcription and translation levels. Further investigations were conducted to trace the subcellular location, degradation pathway and stability of wild type and mutant protein.
Results
Gene test discovered one germline (mutant 1: c.337dupG, p.A113Gfs*7) and two somatic (mutant 2: c.1157G>A; p.W386X, mutant 3: c.1900G>T, p.E634X) ARMC5 gene mutation sites. In vitro experiments indicated significantly increased mRNA levels of all the mutants along with significantly increased protein content of mutant 2 and 3 than that of wild type, however, the mutant 1 protein cannot be detected with western blot. Extensive subcellular localization experiment demonstrated that wild type protein was localized in both cytoplasm and nucleus, while, the mutants were accumulated primarily in the nucleus. As regard to protein degradation pathway experiment, it proved that wild type and mutant 1 protein were degraded through ubiquitin-proteasome pathway and lysosomal pathway, respectively. Based on the different degradation rate of wild type, mutant 2, and mutant 3, we inferred that the protein stability of the mutant 2>wild type>mutant3.
Conclusion
This study discovered three novel ARMC5 gene mutation sites which extended the spectrum of the mutation. In vitro experiments demonstrated significant differences at transcription and translation levels between the wild type and mutants. In addition, mutant protein presented different subcellular location, degradation pathway, and stability compared with that of wild type. Taking the lead from these findings, we inferred that these protein property alterations might influence its normal function, leading to PBMAH progression.

Novel pathogenetic mutation of MEN1 gene causing hyperparathyroidism, pancreatic glucagonoma, adrenal adenoma, and collagenomas

Rosa Pitino[1], Davide Vimercati[1], Francesca Pizzolitto[1], Edoardo Luigi Maria Mollero[1], Tommaso Daffara[1], Alice Ferrero[1], Renzo Boldorini[2], Marina Caputo[1, 3] & Flavia Prodam[1,3]
[1]Endocrinology, Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]Pathology Unit, Novara Medical School, Department of Health Sciences, Novara, Italy; [3]Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy

Background
Multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary autosomal dominant tumor syndrome caused by inactivating mutations of the tumor suppressor gene *MEN1* which encodes the protein menin. It is characterized by the occurrence of tumors involving two or more endocrine glands, primarily parathyroid, entero-pancreatic, and anterior pituitary, as well as non-endocrine neoplasms. Glucagonomas occur in fewer than 3% of patients with MEN1, causing hyperglycemia, skin rash (necrolytic migratory erythema), weight loss, anemia, and stomatitis.
Case report
In March 2019 a 35-year-old Pakistani woman underwent surgical removal of 2 overactive parathyroid glands causing primary hyperparathyroidism diagnosed after a pelvic fracture and the identification of brown tumors. After surgery, she was lost at follow-up. In August 2020, she was admitted to Emergency Department for fever, weight loss, and new-onset diabetes mellitus causing polyuria and polydipsia without ketoacidosis. Glucagon was at the upper limits of normal (252 pg/ml) and abdominal MRI revealed a neuroendocrine tumor (10 mm in the pancreatic tail) and left adrenal adenoma, confirmed by a 68Ga-DOTATOC-PET, that showed 4 areas of abnormal uptake in the pancreatic tail, body, and head, and in left adrenal gland. Duodenocephalopancreatectomy and left adrenalectomy were performed; histological examination revealed the presence of multiple well-differentiated G1 neuroendocrine tumors (Ki67<3%) with intensive positive IIC for glucagon, and adrenal adenoma. The post-surgical period was complicated by cava vein thrombosis, typical of glucagonoma, and endocarditis. The study of other endocrine glands showed the persistence of primary hyperparathyroidism due to hyperplasia of the remnant parathyroid glands confirmed by Sesta-MIBI-scintigraphy; pituitary function and MRI were normal. Dermatological investigation showed cutaneous collagenomas. Genetic testing identified a novel missense *MEN1* heterozygous pathogenetic variant c.703T>C-p.(Cys235Arg) in exon 4. The patient was monitored by MRI, 68Ga-DOTATOC-PET, and FDG-PET and no significant abnormal uptakes have been identified until now, however, she developed skin lesions suspected for necrolytic migratory erythema and she is in a close follow-up. Genetic inheritance is under investigation.
Conclusion
The clinical behavior of MEN1 depends on histological features of the tumors, the type, and degree of hormone hypersecretion and the risk of tumor recurrence. Some authors described a potential genotype-phenotype correlation, but this link remains debated. Current clinical guidelines recommend that index case and their relatives should be included in a screening program to reduce morbidity and mortality. Our case of a new pathogenetic mutation associated with glucagonoma underlines the need for a closer follow-up and surveillance with an interdisciplinary approach.

Insulinoma in a patient with a crest syndrome

Jesus Manuel Cornejo Dominguez, Maria Isabel Mateo Gavira, Laura Larrán Escandón, Maria del Mar Roca Rodriguez & Isabel Torres Barea
Hospital Universitario Puerta del Mar, Cádiz, Spain

Introduction
Insulinomas are pancreatic neuroendocrine tumors (PNET), characterized by insulin hypersecretion syndrome with the development of hypoglycemia. The incidence of the tumor is 3-10 cases per million inhabitants. The average age of onset is 40-50 years old, being more frequent in women.
Case Reports
We present a clinical case of a patient with CREST syndrome and difficult-to-control hypoglycemia. Female patient, 81 years old, with a history of CREST syndrome (calcinosis, Raynaud's phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia) with multiple complications (esophagitis with scleroderma, vasculitis, nail ulcers) and hypertension. The patient is transferred to the Emergency Department in February 2020 due to loss of consciousness coincident with fasting plasma glucose 27 mg/dl. She had no history of diabetes, previous episodes of hypoglycemia, or apparent intake of hypoglycemic drugs. She was admitted to the Endocrinology Service for study. Refers to asthenia anorexy and weight loss of about 5 kg in the last two months which attributes to dental intervention., although it recognizes significant intake of fast-absorbing sugars. At baselane, insulin 3.2 mcUi/ml, proinsulin 5.8 pmol/l, HbA1c 3.8%, beta hydroxybutyrate <1, C-peptide 1.92 ng/ml, negative oral antidiabetics and anti-insulin antibodies, coinciding with fasting plasma glucose 35 mg/dl. After analytical confirmation of endogenous hyperinsulinism, we started treatment with fluid therapy, requiring a contribution of 1500 ml of 10% dextrose fluid daily to

keep fasting plasma glucose in range. Abdominal CT with intravenous iodinated contrast in basal phase evidenced a 12x15 mm hypodense lesion in the tail of the pancreas with enhancement in the portal phase suggestive of insulinoma. Given clinical and radiological suspicion of insulinoma and given the impossibility of suspending intravenous glucose fluid, treatment with diazoxide it was considered. Initially presents good tolerance and evolution, with progressive reduction of the requirements of intravenous glucose. However, after 6 days of treatment, he develops picture of pruritic skin lesions that do not disappear on pressure compatible with erythroderma. Evaluated by allergy service confirming allergy to diazoxide, started treatment with steroids. Consequently, the treatment was discontinued., being the evolution of the lesions favorable. In the absence of a medical therapeutic alternative, finally required surgical treatment. Distal pancreatectomy with a pathological result of a low-grade neuroendocrine tumor compatible with insulinoma. After surgery, he maintains excellent glycemic control, without hypoglycemia. Nonetheless, the patient presented a torpid postoperative period (acute renal failure, cavitary pneumonia with therapeutic bronchoscopy, respiratory failure with invasive mechanical ventilation) and she finally died.

Clinical characteristics and survival of a cohort of patients presenting with bone metastases from differentiated thyroid cancer

Ana Piñar Gutiérrez, Ana R. Romero Lluch, Suset Dueñ as Disotuar, Irene De Lara-Rodriguez & Elena Navarro
Virgen del Rocío University Hospital, Sevilla, Spain

Introduction
Bone metastases (BM) are rare in differentiated thyroid cancer (DTC). They determine the quality of life and survival of these patients. Our objective was to evaluate the characteristics, survival and prognostic factors of a cohort of patients with BM from CDT.
Methods
Retrospective descriptive study. Patients with BM from DTC diagnosed between 1980-2021 were included. Qualitative variables are shown as n(%); quantitative variables as median and interquartile range. Survival and prognostic factor analysis was performed using the Kaplan-Meier method and univariate tests.

Table 1

Variable	Result
BM diagnosis at initial evaluation	13(48%)
BM diagnosis during follow-up	14(52%)
Time until BM appearance (months)	*151(78-234)*
Thyroglobulin at diagnosis, after thyroidectomy (ng/ml)	1000(195-7743)
T	
1-2	*8(30%)*
3-4	14(51%)
N1	9(33%)
Multiple BM	22(81,5%)
BM location	
Spine	*20(74%)*
Pelvis	*10(37%)*
Cranial	*5(18%)*
Rib cage	*4(15%)*
Upper limbs	*3(11%)*
Lower limbs	*4(15%)*
Metastases in other locations	19(70,3%)
Skeleton-related events	
Bone fractures	*7(26%)*
Spinal cord compression	*7(26%)*
Pain	*10(37%)*
Treatment with I131	*19(70,4%)*
I131 Uptake in BM	*10(37%)*
Antiresorptive treatment	10(37%)
BM Surgery	4(15%)
Palliative radiation therapy	9(33%)
Treatment with Tyrosine-kinase inhibitors	7(26%)

Results
N = 27. Women = 17(63%). Follicular carcinoma = 13(48%). Follow-up time (months) = 72(34-222). Age at diagnosis = 62(55-73). Exitus = 18(66,7%). Suvival at 1 and 5 years was 68.5% and 43.5% respectively. No independent risk factors for increased risk of death were found.
Conclusions
In our case series, 5-year survival was slightly lower than that reported in the scientific literature. This may be due to the fact that 48% presented with BM in the initial evaluation, although it has not been possible to prove it given the low number of cases. No other prognostic factors were found, possibly for the same reason.

Clinical case of ACTH ectopic syndrome associated with small cell lung cancer (SCLC)

Malika Kozhemzharova[1], Anna Bazarova[1], Zhanar Kamitbekova[2], Natalya Pavlova[2] & Asem Baisalova[3]
[1]Astana Medical University, Nur-Sultan, Kazakhstan; [2]Multidisciplinary city hospital No1, Nur-Sultan, Kazakhstan; [3]National Research Cardiac Surgery Center, Nur-Sultan, Kazakhstan

Introduction
Ectopic Cushing's syndrome (ECS) is a rare disease caused by ACTH secretion by extrapituitary neuroendocrine tumors, characterized by high mortality. Despite the clinical sings of Cushing's syndrome, difficult access to reliable clinical examinations, leads to a delay in diagnosis and the choice of optimal treatment tactics. Small-cell lung cancer patients with ECS have a very poor prognosis.
Case report
A 35-year-old woman was hospitalized in the endocrinology department with complaints of dry mouth, thirst, hypertension (up to 170/100 mmHg). The patient also had signs of heart failure due to concomitant congenital heart disease, diabetes mellitus type 2 (T2DM) and obesity. During the year, she was repeatedly examined due to the presence of clinical manifestations of Cushing's syndrome. Physical examination: centrapetal obesity with fat deposits around the face, neck and upper back, BMI = 41.8 kg/m^2, hyperpigmentation in the neck, axillary and inguinal region, reddish-blue stretch marks on the arms, abdomen, buttocks. Laboratory evaluation revealed high levels of ACTH in the blood – 229,3 pg/ml (reference 7,2-63,3), and cortisol in daily urine 3600.8 μg/24 h (normal 58 - 403), and a decrease in potassium levels to 1.1 mmol/l, fasting glucose - 12 - 21 mmol/l. CT scan of the thoracic segment revealed a dense focus of the X segment of the right lung, metastatic character is not excluded. Abdominal CT revealed hyperplasia of both adrenal glands, multiple liver formations. PET-CT (18F-fluorodeoxyglucose): metabolically inactive formation of the lower lobe of the right lung, multiple metabolically inactive hypodense liver formations, moderately pronounced splenomegaly. The tumor marker Pro Gastrin Releasing Peptide (ProGRP) in blood was significantly increased - up to 5000 pg/ml (reference 0-46), which can increase in small cell lung cancer. Somatostatin analogues and steroidogenesis blockers (Ketoconazole) were used to treat the disease, but cortisol levels did not decrease. The primary tumor during life could not be identified, death occurred due to lung and cardiovascular failure. The histological examination at post-mortem autopsy revealed the lung neuroendocrine tumor with signs of malignancy and multiple metastatic lesions of the liver.
Conclusion
Despite the availability of modern imaging diagnostic methods, the search for the primary focus and the treatment of ACTH-ectopic syndrome present considerable difficulties and often require long-term follow-up and an interdisciplinary approach. Although the prognosis for this type of tumor is unfavorable, timely diagnosis using lung tissue tumor markers and PET could help clarify the diagnosis at an earlier stage of the process.

Postoperative prediction of tumor recurrence in patients with nonfunctional pancreatic neuroendocrine tumors

Helena Olearska[1], Anna Sowa-Staszczak[1], Marta Opalinska[2], Anna Kurzyńska[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland; [2]Nuclear Medicine Unit, Department of

Endocrinology, Oncological Endocrinology and Nuclear Medicine, University Hospital, Kraków, Poland

Introduction
Pancreatic neuroendocrine tumors (pNETs) are a heterogeneous group with various treatment options depending on grading, staging, and presence of symptoms related to hormonal secretion. Their incidence significantly increased over the past decade and nowadays constitutes 30% of all NETs of the gastrointestinal tract. Despite the evidence of a different malignancy potential of PNETs G2, postoperative management is the same in all patients.
Aim
The purpose of the study was to determine possible predictors of postoperative tumor recurrence in patients with nonfunctional pNET G2.
Materials and methods
We identified 165 patients diagnosed with pancreatic neuroendocrine tumors. 47 of them with locally advanced or metastatic pNET G2 were included in the study.
Results
Relapse occurred in 37.93% of patients operated with intention to treat, with the mean time to progression equaling about 2 years. In this group based on preoperative CT examinations, the average largest dimension of the tumor was estimated to be over twice bigger in comparison to patients with no recurrence (46.71 mm vs 22.89 mm), which was confirmed by postoperative histopathological examination (53.83 mm vs 34.36 mm). In over 80% of patients with the disease relapse, the average largest dimension of tumor equaled 25 mm or more, whereas in the group without relapse only 55.65% of patients had lesions of this size. Ki-67 varies significantly (metastatic 8.8% vs disease recurrence 6.78% vs no recurrence 5.15%). Both progression and recurrence were associated with the primary location of the tumor in the pancreatic tail. Interestingly, about 50% of patients were symptomatic in all three groups.
Conclusions
Based on the analyzed material it seems that lesions with the largest dimension equaling 25 mm or more and a higher Ki-67 may be a predictor of the disease recurrence. Patients' complaints, important for the management of disease, seem to be unrelated to the possible PNET G2 relapse. The unequivocal confirmation of these findings requires further observation.

Pregnandiene-structures coupled with anti-inflammatory moieties as inhibitors of the 5α-reductase activity

Marisa Cabeza[1], Juan Soriano[2], Eugene Bratoeff[3] & Yvonne Heuze[1]
[1]Departamento de Sistemas Biológicos y de Producción Agrícola y Animal, Universidad Autónoma Metropolitana-Xochimilco, Mexico; [2]Departamento de Patología del Hospital General de México, Mexico; [3]Departamento de Farmacia, Universidad Nacional Autónoma de México, Mexico

Proliferative inflammatory atrophy and prostatic intraepithelial neoplasia are the first signs of prostate cancer. This inflammatory etiology, together with the infiltration of immune cells, could lead to the binding of the cytokines with cancer cells, forming a population that could initiate tumor growth. [1] Androgens also play an essential role in prostate tumor growth, as is well documented. [2] Androgen deprivation therapy is currently the gold standard for hormone-sensitive metastatic prostate cancer patients.[3] These data have inspired researchers to improve therapy for this disease. Previously, our group prepared a new series of hybrid compounds based on a 5,16-pregnadiene scaffold linked to anti-inflammatory drugs. These derivatives showed important antiproliferative properties. [4] In the present study, we identified the effect of five 5,16-pregnadiene derivatives bound to anti-inflammatory drugs (**M1-5**) as inhibitors of the 5α-reductase enzyme activity. This enzyme has been recognized as responsible for forming intraprostatic dihydrotestosterone from testosterone. Dihydrotestosterone has also been associated with prostate cell proliferation [5], so blocking this enzyme and preventing prostate inflammation could improve therapies for this disease. Derivatives of **M1-5** were tested as inhibitors of 5α-reductase activity by incubating radiolabeled testosterone in the presence or absence of these compounds. A fraction of the human prostate membrane and NADPH were added to this medium. Subsequently, the compounds formed were separated and identified by thin-layer chromatography. Compounds **M1-3** and **M5** inhibited *in vitro* formation of dihydrotestosterone, with the highest activity for **M1-2**, with IC_{50} values of 24.2 and 0.26 nM, respectively. However, **M3** and **M5** showed IC_{50} values too much higher, 15.8 and 6.06 μM, than **M1-2**, respectively, and **M-4** no-displayed activity. Previously, our group demonstrated the inhibitory effect of 5,16-pregnandiene on 5α-reductase activity [6]. This 5, 16 pregnandiene effects was completely diminished by indomethacin moiety attached to this compound, as shown in the **M4** derivative.

Somatostatin analogues in the treatment of metastatic paraganglioma

Joao Roque[1], Catarina Regala[2], Tiago Silva[2, 3] & Valeriano Leite[2,3]
[1]Centro Hospitalar Universitário Lisboa Norte - Hospital de Santa Maria, Endocrinology, Diabetes and Metabolism, Lisbon, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Endocrinology, Diabetes and Metabolism, Lisboa, Portugal; [3]Universidade de Lisboa, Faculty of Medicine, Portugal

Introduction
Paraganglioma (PGL) is a neuroendocrine tumor derived from extra adrenal autonomic paraganglia with a germinal mutation rate of 30%. Metastatic paraganglioma (MPGL) can only be predicted after evidence of secondary lesions and it can occur in up to 50% of cases. Clinical course is remarkably variable, but 5-year overall survival is generally around 50%. Treatment options include surgical resection, chemotherapy, radiotherapy, and ^{123}I-MIBG. Being a neuroendocrine tumor, PGL usually express somatostatin receptors but somatostatin analogues have been seldomly used in metastatic PGL and its efficacy is not well demonstrated.
Clinical case
We present a 45yr female patient with a 1-month history of right thoracic pain associated with homolateral back pain and upper limb paresthesia. Thoracic CT identified a 6 cm lesion on the right lung apex, with extensive invasion of posterior thoracic wall, D1 and D2 vertebral bodies and vertebral canal. Urinary normetanephrine was markedly increased (7719 pg/ml, RR $<$600). Tissue biopsy allowed the diagnosis of aggressive PGL with Ki-67 of 15%. PET ^{68}Ga-DOTANOC was unremarkable except for the previously known lesion. After alfa-blockade, surgery was performed and then followed by ^{123}I-MIBG (200 mCi). Post-treatment scintigraphy and PET ^{68}Ga-DOTANOC identified residual tumor without distant metastasis. After 4 years of loss of follow-up, symptoms returned, and both ^{123}I-MIBG scintigraphy and PET ^{68}Ga-DOTANOC identified a 7 cm thoracic lesion and additional bone lesions on multiple vertebrae and iliac bone. The patient underwent a second surgical procedure but had tumor progression 4 months later. Stereotaxic radiotherapy with 49 gray was then given. However, the following PET ^{68}Ga-DOTANOC showed new metastatic bone lesions and so we decided to start lanreotide 120 mg every 28 days. After 6-months, all previously known lesions were stable but a new slightly increased uptake was seen at the pleura. So that, we increased lanreotide frequency to every 3 weeks. Since then, 18 months have passed with no evidence of disease progression and she is still on this treatment regimen.
Discussion
To date, metastatic PGL can only be cured by surgical resection. Chemotherapy, radiotherapy and ^{123}I-MIBG are used for disease control. Most recently, peptide receptor radionuclide therapy has shown promising results. Somatostatin analogues such as lanreotide are currently used on gastroenteropancreatic neuroendocrine tumors but its role in PGL treatment is still unclear. This case shows an extraordinary response of MPGL to lanreotide, raising interest in this potential therapeutic weapon for a subset of patients who have still few treatment modalities available.

EP576

Panhypopituitarism and diabetes insipidus due to metastatic breast cancer

Diana Cuconu[1], Cristina Stancu[1] & Corin Badiu[2]
[1]National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

We report the case of a 36 years old female, with personal history of breast cancer, treated with neoadjuvant chemotherapy, breast sectorectomy and then chemotherapy and radiation therapy 2 years ago. She was continuously monitored by her oncologist, disease free for over a year, with recent CT scan that showed no particular lessions suggestive for secondary disease. Meanwhile, she got pregnant and delivered at term a healthy baby. She was admitted 3 months postpartum with intense headache, weight loss, fatigability and low blood pressure. She mentioned hydric intake of aproximate 6 l/day and similiar diuresis during pregnancy. No visual field defects were found at the neurological examination. The initial blood tests revealed panhypopituitarism and central diabetes insipidus and adequate substitution was started. Her blood pressure normalized, but headache persisted without response to pain medication. The magnetic resonance imaging was suggestive for pituitary metastasis and cytologic evaluation of CSF obtained by lumbar puncture was inconclusive. Transsphenoidal surgery was performed and histopatologic exam confirmed a metastatic carcinoma.

Discussion

Although rare, metastatic pituitary spread should always be taken into consideration in a patient with personal history of malignancies and signs and symptoms suggestive of pituitary involvement. Breast cancer is the most likely source of pituitary metastasis in women, while in men lung cancer is usually encountered. Hematogenous tumor spread explains why neurohypophysis is first affected, with early development of polyuria-polydipsia syndrome and diabetes insipidus that precedes anterior pituitary deficiencies. Once diagnosis is made, treatment is difficult and implies correct substitution of hypopituitarism, surgical removal of pituitary lesion, systemic chemotherapy and radiation therapy.

Conclusion

Pituitary metastasis is a rare cause of hypopituitarism and diabetes insipidus associated with a poor prognosis and a median survival rate after diagnosis of 10 months.

Novel steroidal derivatives preventing prostate dihydrotestosterone synthesis

Marisa Cabeza[1], Juan Carlos López-Lezama[2], Juan Soriano[3], Norma Valencia-Islas[2] & Yvonne Heuze[1]
[1]Departamento de Sistemas Biológicos y de Producción Agrícola y Animal, Universidad Autónoma Metropolitana-Xochimilco, Mexico; [2]Departamento de Farmacia, Universidad Nacional de Colombia, Colombia; [3]Departamento de Patología del Hospital General de México, Mexico

It is well-known that the increase of intraprostatic levels of 5α-dihydrotestosterone is related to the development of prostatic pathologies such as benign prostatic hyperplasia and prostate cancer. So finasteride and dutasteride-based therapies have been used to improve these diseases. These drugs are potent inhibitors of the enzyme 5α-reductase, which is found in the androgen-dependent tissues. This enzyme is responsible for converting testosterone into dihydrotestosterone in these tissues. This study aimed to identify the effect of new pregnane (**2-8**) analogs as inhibitors of 5α-reductase activity. The action of these steroidal derivatives was compared with that of finasteride. Two different experiments were performed: *in vivo* and *in vitro*. In *in vitro* experiments, we separately incubated derivatives **2-8** in the presence of radiolabeled testosterone, a membrane fraction of the human prostate as a source of 5α-reductase and NADPH. In addition, products **2-8** were also evaluated in testosterone-treated neutered male hamsters. After six days of treatment, the hamsters were sacrificed, and the weight of the prostate was determined. Finasteride was used as a reference compound in both *in vitro* and *in vivo* experiments. The results indicated that steroids **2-8** inhibited 5α-reductase activity showing **6-8** higher potency, with IC_{50} values of: 0.169, 0.105, and 0.155 nM, respectively. These IC_{50} values were lower than those determined for the reference compound finasteride (IC_{50} = 8.5 nM). However, pharmacological experiments demonstrated a non-significant difference between the weight of the prostate in castrated hamsters treated with testosterone to those treated with testosterone plus each of the novel steroids. At the same time, testosterone plus finasteride treatment effectively decreased the weight of this gland. In conclusion, derivatives **6-8** were more potent than finasteride to blockade *in vitro* dihydrotestosterone formation. Nevertheless, their lack of efficacy for decreasing the weight of the prostate could be explained based on the pharmacokinetic processes undergoing these steroids.

Table 1. A series of pregnane derivatives (**2-3**) with a 17-N-cyclohexylcarboxamide residue (**5-8**) were evaluated as blockers of 5α-reductase type 2 (SRDA2) activity. The figure shows the 50% (IC_{50} value) inhibition of enzyme produced by **2-8**. Finasteride was used as the reference compound.

Genetic novelty in MEN1: about a tunisian family

Mnif Fatma[1], Kawthar El ARBI[1], Yosra Lajmi[2], Asma Zargni[1], Faten Haj Kacem Akid[1], Khouloud Boujelben[1], Dhoha Ben Salah[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1], Hassen Kammoun[2], Fatma Abdelhédi[2] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Medical Genetics, Sfax, Tunisia

Introduction

Multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary syndrome that should be considered when different endocrine tumors are associated in an individual or familial context. We report the observation of a Tunisian family, two sisters and a brother.

Observations

Patient1: a 31 years old female, followed for multinodular goiter, was hospitalized for a left maxillary tumefaction associated with headache and blurred vision. Investigations concluded to a maxillary epulis complicating a primary hyperparathyroidism (PHP). A macroprolactinoma was also diagnosed. The epulis completely regressed after parathyroidectomy. Patient2: a 48 years old female, was followed for asymptomatic hypercalcemia due to a PHP. The investigations showed multiple parathyroid adenomas wrongly taken radiologically and macroscopically as nodular thyroid tissue. The screening for further lesions of MEN 1 was negative. Patient3: a 41 years old male was followed for multinodular goiter. PHP was revealed by recurrent bilateral renal lithiasis. He underwent a total thyroidectomy with removal of the hyperfixing adenoma on parathyroid scintigraphy. A persistent hypercalcemia was objectified indicating a reoperation. The screening for further lesions of MEN1 was negative. The genetic

study of this family identified a new missense mutation, not described in the literature, at exon4 of the MEN1 gene in the heterozygous state.
Conclusion
Recent studies have shown that specific clinical manifestations may affect one family more than the other. Intra-familial correlations were shown to be significant only for pituitary, adrenal glands and thymus. For this family, PHP was the constant lesion.

Bilateral localization of Leydig tumor in the testicles: Case Report

Fatima Zahra OUTTALEB[1], Amin Alami[2], Zineb Bouchbika[2], Nadia Benchakroun[2], Hassan Jouhadi[2], Nezha Tawfiq[2], Souha Sahraoui[2], Abdellatif Benider[2] & Hind Dehbi[1,3]
[1]Ibn Rochd University Hospital, Laboratory of Medical Genetics, Casablanca, Morocco; [2]Ibn Rochd University Hospital, Mohamed VI Oncology Center, Casablanca, Morocco; [3]Faculty of Medicine and Pharmacy, Hassan II University, Cellular and Molecular Pathology Laboratory, Casablanca, Morocco

Testicular cancer represents 1% of male tumors. The bilateral testicular tumors are very rare (1 to 2% of cases), with a histological predominance of 90–95% of germ cell tumors. The objectives of this case report are to describe the clinical, paraclinical and the management of a rare neoplasic disease of the testicle; the bilateral Leydig tumor of the testicles. It is a 57-year-old patient with a family history of different neoplasms, including ovarian and breast cancer in siblings, and followed since the age of 51 for a Leydig tumor of the testicle, reveled by an indolor testicular mass of the right testicle, without any clinical signs of endocrine disorders. Ultrasound scrotal found a 30 mm left testicular hypoechoic nodule, testis law without particularity, The tumor markers and hormonal explorations were normal. Extension report without anomaly. A right orchiectomy was performed. 3 years later, he presented a second localization of a Leydig tumor in the left testicle, also treated by orchidectomy. No adjuvant treatment (radio or chemotherapy) was indicated. A hormone replacement therapy was also established. Currently, the patient is followed in the oncogenetic consultation, for the identification a possible hereditary predisposition of neoplasms. The Leydig cell tumors of the testicles are typically characterized by the association of a tumor testicular and clinical and biological endocrine signs. The typical manifestations in adult include a secondary feminization. But in 10% of case, the clinical presentation is limited to the testicular mass and only the histology confirms the diagnostic. The diagnosis of the leydigioma is histological but there is no clear limit between tumor benign and malignant, therefore, orchiectomy is the standard treatment and it is only the absence of long-term metastases that will confirm the benignity, prolonged monitoring is essential.

Solitary fibrous tumors of the pleura with Doege-Potter syndrome: a case report

Sohail Douni, Wafae Elaamadi, Safa Sabur, Mohammed Bouchikh & Achir Abdellah
CHU IBN Sina, Department of Thoracic Surgery, Rabat, Morocco

Background
Solitary fibrous tumor of the pleura is a rare primary intrathoracic tumor that arises from mesenchymal tissue. Hypoglycemia associated Solitary fibrous tumor of the pleura is referred to as the Doege-Potter syndrome and is caused by inappropriate secretion of an insulin-like growth factor II.
Case presentation
We report 70-year-old women with no particular medical history, who present a right chest pain for 1 year with fatigue. The clinical examination revealed diminished breath sounds in right lung fields, and dullness to percussion. the Lab test showed non-insulin mediated hypoglycemia. Hypoglycemia was managed firstly with corticosteroid therapy and frequent programmed nutritional intake. Scanning demonstrated a right large, well-circumscribed, homogeneous pleural mass. A transthoracic puncture was performed which came back inconclusive. Right posterolateral thoracotomy through the five intercostal space was performed for the resection of the tumor. The histopathologic examination confirmed the presence of malignant Solitary fibrous tumor of the pleura with free marginal resection. Removal of the mass solved the hypoglycemia. The patient was discharged on postoperative day 5.

Localisation of insulinomas : the role of different imaging techniques

Wafa Belabed, Fatma Mnif, Siddiqa Soomauroo, Faten Haj Kacem Akid, Dhoha Ben Salah, Mouna Elleuch, Nabila Mejdoub & Mohamed Abid Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
The diagnosis of insulinomas is made biochemically. However, proper localization of insulinomas is essential before surgery. Therefore, we aimed to evaluate the role of different imaging techniques in the localization of insulinomas.
Case series
This case series include 10 patients with biochemically proven insulinomas. The age, gender, results of MRI, CT, EUS, are shown in Table-1. In imaging investigations, abdominal ultrasonography (AU) was normal in the 4 patients it was performed on. Abdominal CT scan was performed in all patients and found a tumor in only 6 cases. Abdominal MRI was performed in 2 patients and found a tumor in 1 case. The tumor confirmed by MRI wasn't found by other imaging means. Endoscopic ultrasound was performed in 6 patients, was normal in 2 cases and found a tumor in 4 cases. 3 tumors were only diagnosed with endoscopic ultrasound. CT scan and endoscopic ultrasound were enough to find the localization of insulinomas in 8 patients. No lesion was identifed in 1 case. All the 9 patients with confirmed pancreatic lesion underwent surgery and a diagnosis of insulinoma was made in all patients by immunohistopathological analysis. All these patients achieved cure after surgery.
Conclusion
The diagnosis of insulinoma is easily confirmed biochemically. The challenge remains in its localization as no imaging procedure was enough on its own to confirm the presence of a pancreatic lesion, confirming therefore the difficulty of pre-operative investigations

Table 1

Patient	Gender/-Age	Presence of tumor on AS	Presence of tumor on CT	Presence of tumor on MRI	Presence of tumor on EUS
1	M/18	No	**Yes**	-	-
2	M/58	-	No	-	**Yes**
3	F/40	-	No	-	No

A personalised approach to tracking circulating cell free tumour derived DNA in a patient with adrenocortical carcinoma

Shailesh Gohil[1,2], Karen Page[2], Rob Hastings[2], Jacqui Shaw[2] & Miles Levy[1,2]
[1]University Hospitals of Leicester NHS Trust, Department of Endocrinology, Leicester, United Kingdom; [2]University of Leicester, Leicester Cancer Research Centre, Leicester, United Kingdom

Introduction
Adrenocortical carcinoma (ACC) is rare, with an incidence of 0.5-2 cases per million. Although generally aggressive, prognosis is highly variable and difficult to predict. Unlike other malignancies, there are no biomarkers routinely available for use in patients with ACC to help guide management. Circulating cell free tumour derived DNA (ctDNA), the proportion of circulating cell free DNA (cfDNA) originating from tumour cells, is a liquid biopsy that is quickly gaining favour as a clinically useful and superior biomarker in oncology but is only in the early stages of being investigated in ACC.
Aims
To identify and track ctDNA in a 60 year old male patient with metastatic ACC using a precision, patient specific approach.
Materials and Methods
Blood samples were collected at 5 time points over 25 months and separated into plasma and leucocytes. Paired whole exome sequencing (WES) was performed on leucocyte extracted DNA and DNA extracted from formalin fixed paraffin embedded ACC tissue. The 2 sequences were then compared to identify tumour specific somatic mutations. These mutations were used in the design of a bespoke Ampliseq™ HD ctDNA assay. cfDNA was extracted from plasma and the bespoke assay used to detect ctDNA through targeted next generation sequencing.
Results
This patient had a 14.5 cm left adrenal mass with lymph node metastases at presentation. WES identified 83 tumour specific somatic mutations including a *TP53* mutation. 22 of these mutations (including *TP53*) were chosen as targets for inclusion in the Ampliseq™ HD ctDNA panel assay. Pre-adrenalectomy, 9/22 variants were detected on ctDNA analysis with variant allele frequencies (VAF) of up to 1.16%. Post-operatively, ctDNA was initially undetectable. He was commenced on mitotane however imaging later demonstrated disease progression. ctDNA analysis at this point detected 3/22 variants with VAF up to 2.72%. He received radiotherapy for bone metastases and subsequent chemotherapy following which ctDNA was not detectable on samples 4 and 5. The *TP53* mutation was not detectable at any time point.
Discussion
We have demonstrated that ctDNA can be detected and tracked in a patient with ACC, with ctDNA dynamics mirroring progression and response. Targeting multiple, personalised variants is methodologically key to successful ctDNA detection. Only targeting mutations common in ACC, for example in *TP53*, runs the risk of missing other variants present in ctDNA. Further development is required in assay design to improve sensitivity however ctDNA is a hopeful future biomarker for patients with ACC.

Novel peptides and cell lines to expand the tools and models to study the potential of the somatostatin system in NETs

Federica Mangili[1,2,3,4], María Trinidad Moreno Montilla[2,3,4], Pilar Salamanca Jimenez[2,3,4], Víctor García Vioque[2,3,4], Ricardo Blázquez Encinas Rey[2,3,4], Emilia Alors-Pérez[2,3,4], Giovanna Mantovani[1, 5], Erika Peverelli[1], Jö rg Schrader[6], Alejandro Ibañez Costa[2,3,4] & Justo P. Castaño[2,3,4,7]
[1]University of Milan, Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Córdoba, Spain; [3]University of Cordoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [4]Reina Sofia University Hospital, Córdoba, Spain; [5]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [6]UKE-University Medical Center Hamburg-Eppendorf, I. Medical Department, Hamburg, Germany; [7]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain

Neuroendocrine tumors (NETs) represent a heterogeneous group of malignancies with increasing incidence worldwide, due in part to enhanced awareness and diagnosis improvements. Surgery is often effective for local disease, whereas disseminated or metastatic disease require pharmacological treatment, which is not always successful. Pancreatic (Pan-NETs) and pulmonary (Lung-NETs) neuroendocrine tumors frequently express somatostatin receptors (SSTs), providing the target for treatment with somatostatin analogs (SSAs), but a number of patients are irresponsive or become resistant to these drugs. In this context, the neuropeptide cortistatin (CST) a natural analogue of somatostatin with comparable affinity to SSTs has been highlighted as a potential endogenous anti-inflammatory player.
The aims of this study were: 1) to determine the effect of CST as compared with classic SSA on different functional parameters in Pan-NETs and in Lung-NETs cells models; 2) to characterize the somatostatin/CST/SSTs phenotype on a set of recently stablished Pan-NETs cell models. To this purpose, we evaluate cell proliferation, apoptosis, migration, colony formation and intracellular signaling on Lung-NETs (UMC-11 and NCI-H727), classical (BON-1, QGP-1), and new Pan-NETs (NT-3, NT-18 LM) and Pancreatic Neuroendocrine Carcinoma (NT-38) cell lines. We tested different concentrations (1nM-1μM) of SSAs and CST and we observed a dose-dependent effect on cell proliferation and migration, in UMC-11 and NCI-H727 cell lines. A similar result was detected in BON-1 and QGP-1, but NT-3, NT-38, NT-18LM cell lines were less responsive. Each cell model displays a unique SST expression profile, which may underlie the differential functional responses observed. Thus, we are currently exploring the particular signaling pathways involved. Altogether, this study opens original avenues to explore novel therapeutical strategies with CST in NETs and to establish and characterize new Pan-NET cell models more precisely resembling human tumors.

Genes involved in chromatin-remodeling complex could alter the regulation of alternative splicing in lungNENs

Antonio Agraz-Doblas[1,2,3], Ricardo Blázquez-Encinas[1,2,3], Víctor García Vioque[1,2,3], Nicolás Alcalá[4], Alexandra Sexton[4], María Trinidad Moreno Montilla[1,2,3], Emilia Alors-Perez[1,2,3], pilar salamanca jimenez[1,2,3], Matthieu Foll[4], Lynnette Ferná nez Cuesta[4], Alejandro Ibañez Costa[1,2,3] & Justo P. Castaño[1,2,3,5]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Córdoba, Spain; [3]Reina Sofia University Hospital, Córdoba, Spain; [4]Rare Cancers Genomics Team, Genomics Epidemiology Brand, International Agency for Research on Cancer (IARC/WHO), Lyon, France; [5]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Spain

Lung neuroendocrine neoplasms (LungNENs) comprise a diverse group of rare tumors with a commonly difficult and late diagnosis, which often require complex management and treatment. The most frequently mutated genes in LungNENs have recently been identified, including known components of the chromatin-regulating pathways such as *MEN1*, *PSIP1* and *ARID1A*, which are the subject of ongoing detailed studies. In contrast, other key regulatory mechanisms, particularly posttranscriptional processes linked to RNA regulation and downstream mechanisms involving RNA regulation, remain largely unexplored. Therefore, the main objective of this study was to gain further insight into the role of chromatin-remodeling genes in LungNENs by focusing not only on their mutations but also in their potential interactions with RNA biology. To this end, we used RNAseq data from two distinct cohorts, the first one included 20 lung atypical carcinoids (EGAS00001003699) and the second cohort included 30 typical and atypical carcinoids (SRP156394). To investigate the potential impact of dysregulation of the selected genes we used a biocomputational approach, which enabled to explore the putative connections between the altered genes and other factors contributing to RNA processing, splicing and maturation. Interestingly, initial results already indicated that patients harboring mutations in genes of the chromatin-remodeling pathway also displayed a dramatic dysregulation in the expression levels of these same genes. Furthermore, a detailed examination of the association between the altered genes and particular changes in functional and gene enrichment categories revealed that the chromatin-remodeling machinery could likely modulate transcriptional activity, hence affecting crucial peripheral regulatory systems. Interestingly, samples presenting mutations in chromatin-remodeling pathway genes also showed different patterns in splicing-related genes, which may suggest a dysfunctional RNA processing. Altogether, our study supports the use of biocomputational approaches to discover new alterations in and relationships among regulatory systems, which could lead to the discovery of new biomarkers and therapeutic tools in LungNENs. Ongoing efforts are aimed at using functional assays with LungNEN cell models to better delineate these biocomputational outcomes.

Nonpathogenic variants in genes involved in signalling pathways differ between MEN1 patients with different outcome of pancreatic tumours

Anna Skalniak, Agata Jabrocka-Hybel, Malgorzata Trofimiuk-Muldner & Alicja Hubalewska-Dydejczyk
Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Background
Although it is well-known that single pathogenic variants in the gene *MEN1* are responsible for the development of multiple endocrine neoplasia type 1 (MEN1), the outcome of the disease in individual patients cannot be deduced from known genetic factors, the clinical picture of other family members, nor environmental data. Encouraged by publications suggesting a possible role of the genetic background in MEN1 outcome, we performed a study that aimed at searching for pathways or biological processes in which genetic variants are identified, that might clarify the different phenotypes in MEN1 patients.
Matherials and methods
The exomes of MEN1 patients with confirmed pathogenic genetic variants in *MEN1* were sequenced on an Illumna HiSeq platform. The results served for two analyses: (1) lack or presence of pancreatic tumour, and (2) insulinoma or non-insulinoma pancreatic tumour. For each analysis, three patient pairs were available. Genetic analyses were based on genes with nonsynonymous exonic, splice-site, 5'UTR and 3'UTR variants identified in patients with the given clinical phenotype under investigation. The identified genes were interpreted for their function, gene ontology annotations, interactions, and pathways.
Results
(1) The genes identified in MEN1 patients with vs those without pancreatic tumours were annotated primarily to be involved in metabolic processes, cellular component organization or biogenesis, and biological regulation. Annotations of the individual genes included pancreas development, enteroendocrine cell differentiation, cellular detoxification, lipid metabolic process, and vitamin metabolic process. After adding interactions, the most significantly enriched pathways were BMP signalling and regulation and TGF-beta signalling pathway. (2) In insulinoma- vs non-insulinoma-patients, biological process annotations primarily indicated genes involved in metabolic processes and cellular response to stimulus. Individual gene annotations included lipid metabolic process, response to chemical, regulation of hormone levels, insulin signalling, and secretion. Together with close interaction partners, the following pathways were enriched, among others: metabolism of lipids; oxidation by cytochrome P450; synthesis of IP2, IP, and Ins in the cytosol; transcription factor regulation in adipogenesis; vitamin D receptor pathway; cytoplasmic ribosomal proteins; and selenoamino acid metabolism.
Conclusions
Although the genetic background of MEN1 is well established, we identified inherited genetic variations that differed depending on the clinical outcomes and seemed to be logically linked to the analysed symptoms. Our results give a better insight in the different clinical presentation of MEN1 patients. Analyses on other MEN1 characteristics are currently under investigation.
The project has been funded by the National Science Centre, Poland, grant no. 2015/17/N/NZ5/00129

Papillary thyroid carcinoma and cervical cancer: what is the link?

Ihssane Abidi, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
University Mohammed 5 Rabat, Endocrinologie, Rabat, Morocco

Introduction
Papillary thyroid carcinoma is the most common form of thyroid cancer. It is differentiated, slow growing and usually has a good prognosis. Its risk factors are not all identified; we note exposure to radiation, particularly ionising radiation, and certain genetic mutations which are currently being explored. The aim of our work is to study the relationship between papillary thyroid carcinoma and cervical cancer.
Observation
We report the case of a 65-year-old female patient, type two diabetic and hypertensive, followed since 2016 for FIGO stage 1A2 cervical cancer revealed by a screening cervico-vaginal smear. The patient underwent a conization of the cervix with clinical, biological and radiological monitoring. The evolution was marked, 2 years later, by the appearance of a clinically suspicious thyroid nodule. Ultrasound showed a 6 mm nodule classified as tirads 5. She underwent total thyroidectomy and the result of the anatomopathological examination was in favour of a papillary microcarcinoma classified as Pt1a NxMx with low risk of recurrence. The outcome was good on L-thyroxine.
Discussion
Papillary thyroid carcinoma is often revealed by a thyroid nodule or cervical adenopathy. However, in cancer patients, it is usually revealed by a radiological image at the time of extension or follow-up. A French cohort from the hospital in Rennes showed that women with a history of uterine fibroid and/or hysterectomy are at higher risk of differentiated thyroid carcinoma. The hyperestrogenic environment could be one of the underlying pathophysiological mechanisms. (1) In our case, it is rather the papillomavirus that can possibly be incriminated.
Conclusion
Uterine pathologies are increasingly associated with the risk of incidence of differentiated thyroid carcinoma. In the light of our observation, it will be interesting to carry out a prospective study of patients followed up for cervical cancer in search of papillary thyroid carcinoma; in order to establish the link with papillomavirus.

Poor outcome of systemic therapy in secondary high-grade pancreatic neuroendocrine tumors

Kazhan Mollazadegan[1], Britt Skogseid[1], Johan Botling[2], Tobias Åkerström[3], Barbro Eriksson[1], Staffan Welin[1], Sundin Anders[3] & Joakim Crona[1]
[1]Uppsala University, Department of Medical Sciences, Uppsala, Sweden; [2]Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; [3]Uppsala University, Department of Surgical Sciences, Uppsala, Sweden

Introduction
Longitudinal changes in pancreatic neuroendocrine tumor (panNET) cell proliferation correlate with fast disease progression and poor prognosis. The optimal treatment strategy for secondary panNET grade (G)3, that has progressed from a previous low- or intermediate-grade to high-grade panNET G3 is currently unknown.
Methods
This was a single center retrospective cohort study, aimed to characterize treatment patterns and outcomes among patients with secondary panNET-G3. Radiological responses were assessed utilizing the Response Evaluation Criteria in Solid Tumors version 1.1.
Results
A total of 22 patients were included and received a median of 2 (range 1-4) treatment lines in 14 different combinations. Median overall survival (OS) was 9 months (interquartile range (IQR): 4.25-17.5). For the 15 patients who received platinum-etoposide chemotherapy, median OS was 7.5 months (IQR: 3.75-10) and median progression-free survival (PFS) was 4 months (IQR: 2.5-5.5). The 15 patients who received conventional panNET therapies achieved a median OS of 8 months (IQR:5-16.75) and median PFS was 5.5 months (IQR:2.75-8.25). We observed one partial response on ^{177}Lu DOTA-TATE therapy.
Conclusion
In conclusion, this hypothesis-generating study failed to identify any promising treatment alternatives for patients with secondary panNET-G3. This demonstrates the need for both improved biological understanding of this particular NET entity and for designing prospective studies to further assess its treatment in larger patient cohorts

EP588

Severe refractory nonislet cell tumor hypoglycemia and paraneoplastic hypercalcemia in a patient with pancreatic adenocarcinoma with neuroendocrine differentiation: a case report.

Giovanni Rossini, Alfonso Maria Di Tommaso, Donatella Rausa, Andrea Palermo, Dario Tuccinardi, Paolo Pozzilli, Nicola Napoli & Silvia Manfrini
University Campus Bio-Medico of Rome, Rome, Italy

Nonislet cell tumor hypoglycemia (NICTH) is a rare complication of malignancy characterized by overproduction of incompletely processed IGF-2 and subsequent stimulation of insulin receptors and increased glucose utilization. We report a patient with pancreatic adenocarcinoma with neuroendocrine differentiation who presented with NICTH and paraneoplastic hypercalcemia. A 51 year-old male was admitted to the ER for altered mental status and confusion. His blood glucose was 27 mg/dl and serum potassium was 3.1 mmol/l; other investigations showed increased transaminase levels and normal thyroid function. His vital signs were normal and he was taking no medication. He was treated with a 30 ml bolus of 33% dextrose solution, intravenous KCl and continuous infusion of 10% dextrose solution at 100 ml/h, achieving normoglycemia. After stopping the dextrose infusion for 2 hours, his blood glucose levels dropped again to 22 mg/dl and blood samples were taken; insulin and c-peptide levels were undetectable, cortisol was 18.5 mcg/dl and IGF-1 was 48 ng/ml (53-201). A 1 mg glucagon stimulation test was performed and blood glucose raised to 63 mg/dl at 20 minutes. Whole body CT scan revealed a pancreatic mass measuring 14x12 cm with cystic component, pathological abdominal lymphnodes and numerous liver metastases; tumor biopsy revealed a poorly differentiated adenocarcinoma with neuroendocrine differentiation (synaptophysin +, CD56 -). A diagnosis of NICTH was made and he was started on 30 mg methylprednisolone BID, hyperglucidic diet and 10% dextrose infusion was continued. Despite these therapeutic measures, other severe hypoglycemic episodes occurred and he was started on 8 mg dexamethasone BID, because of its longer duration of action, with discrete benefit. On the fourth day, he experienced a hypercalcemic crisis (blood calcium levels 14.9 mg/dl); other exams showed phosphorus 1.8 mg/dl, normal 25 (OH)vitamin D and magnesium with suppressed PTHi 15.3 pg/ml (14-65). Treatment of paraneoplastic hypercalcemia consisted of i.v. bisphosphonate infusion (zoledronic acid 4 mg) in addition to saline rehydration. In the next three days, calcium levels normalized and remained stable. A trial of octreotide was started in attempt to further reduce hypoglycemic events with no benefit. Unfortunately, the patient was not eligible for tumor debulking or chemotherapy and after seven days, he died due to multiorgan failure. This case report has shown that hypoglycemia in the setting of NICTH is difficult to manage and can be accompanied by other hormone secretory syndromes; longer acting glucocorticoids and increased carbohydrate intake may help reducing severity and frequency of hypoglycemic episodes.

Hyperandrogenism due to ovarian stromal hyperthecosis in a woman known with PCOS

Andreea Rosu[1], Ioana Ambăruş - Popovici[1], Bianca Chiriac[1], Ilona - Beatrice Blesneac[1], Mădălina Proţop[1], Ana-Maria Patraşcu[2], Viorel Scripcariu[2, 3] & Cristina Preda[1,3]
[1]"Sf. Spiridon" Clinical Emergency Hospital, Endocrinology Department, Iasi, Romania; [2]Regional Institute of Oncology, Iasi, Romania; [3]"Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Romania

Introduction
Ovarian hyperthecosis (OH) is a rare condition, reported only in case reports and small case series and is characterized by severe hyperandrogenism leading to virilisation and insulin resistance. The term hyperthecosis refers to the presence of luteinized thecal cells within a hyperplastic ovarian stroma and the pathophysiology of this remains poorly understood. Despite the fact that hyperandrogenism is a relatively common clinical problem, severe hyperandrogenism causing virilisation is rare.
Case report
a 40 year-old Caucasian woman with a prior history of PCOS presented to our department with clinical signs of hyperandrogenism (hirsutism – Ferriman-Gallwey score = 28, androgenic alopecia with temporal and anterior baldness, clitoromegaly and deepening of the voice). Menarche occurred at 14 years old with irregular menses and she reported secondary amenorrhea at the age of 30. She was known to have type 2 diabetes and hypertension. Clinical examination revealed acanthosis nigricans on armpits and groin, purple stretch marks on breasts and she was obese with body mass index of 34 kg/m^2 with moon face and buffalo hump. Hormonal profile demonstrated elevated total testosterone 4.11 nmol/l (0.29-1.67), with dehydroepiandrosterone sulfate 134.5 (60-337), 17-hydroxyprogesterone 1.82 ng/ml, low follicular stimulating hormone (FSH) 8.03 mIU/ml and luteinizing hormone (LH) 6.79 mIU/ml and a serum estradiol in the premenopausal range 53.9 pgI/ml. The results of further diagnostic test were as follows: elevated urinary free cortisol 604.8 mg/24 h (9.5-148) but with normal cortisol in overnight dexamethasone suppression test (1.32 mg/dl). Thyroid function tests and prolactin were normal. Abdominal and pelvic CT scan indicated bilateral ovarian enlargement (right ovary: 36/60/55 mm and left ovary: 38/41/57 mm) with hypodense structure on unenhanced imaging showing mild contrast uptake. She underwent laparoscopic surgery with total hysterectomy and bilateral salpingooophorectomy. Anatomopathological examination confirmed diagnosis of OH describing ovarian cortex bilaterally expanded, with multiple follicular cysts in the superficial layer and scattered luteinized cells isolated or organized in small clusters.
Discussions
Even if is a considerable overlap between hyperthecosis and PCOS making difficult to distinguish between these two conditions, testosterone levels are higher than the levels observed in PCOS and since this modified parameter is the single most important laboratory finding, imaging of the adrenal glands and ovaries must be performed. A complete medical history and full physical examination for virilisation are important hallmarks of diagnosis. Effective and timely treatment can reverse the cardio-metabolic consequences of hyperandrogenemia as well as clinical and biochemical outcomes.

Pheochromocytomas and paragangliomas-real world data in a tertiary Greek center

Foteini Thanasoula[1], Anna Angelousi[1], Georgios Kyriakopoulos[2], Maria Yavropoulou[3], Evanthia Kassi[3, 4] & Gregory Kaltsas[2,3]
[1]National and Kapodistrian University of Athens, First Department of Internal Medicine, Unit of Endocrinology, Athens, Greece; [2]National and Kapodistrian University of Athens, Athens, Greece; [3]Laiko Hospital, First Department of Propaedeutic Clinic, Unit of Endocrinology, Athina, Greece; [4]National and Kapodistrian University of Athens, Department of Biochemistry, Athens, Greece

Purpose
Pheochromocytomas (PCs) and paragangliomas (PGLs) are rare neuroendocrine tumors arising from chromaffin cells of the adrenal medulla and the sympathetic/parasympathetic neural ganglia, respectively. Metastatic PCs/PGLs occur in about 5-26% of cases. Their management and diagnosis still remain a challenge due to their heterogeneity, the absence of guidelines and the few prognostic tools.
Aim
The aim of this study was to describe clinical and genetic characteristics of a series of PCs/PGLs patients in a tertiary center as well as to evaluate their diagnostic and therapeutic approach.
Methods
Clinical data of 50 (30 females) patients (25 with PCs and 25 with PGLs) referred to the University Hospital of Laikon were retrospectively collected and analysed.
Results
Patients' follow-up ranged from 12 to 93 months (median: 31). The 84% of PCs and 36% of PGLs were functional. Genetic analysis was performed in 50% of the total included patients ($n = 12/25$ patients with PCs and n = 15/25 with PGLs) and was found positive in both blood and tissue analysis in 12 patients (9 with SDHD/B, 2 with RET and 1 with NF-1 mutation). Genetic mutations were twice as common in PGLs (15%) compared with PCs (7%). Median PASS was 5 (min-max:4-7) for PCs and GAPP 5 (min-max:2-11) for PGLs. Median Ki-67% index levels was 3(min-max:1-18). In 96% of PCs surgery was the treatment of choice compared to 72% of PGLs. Metastatic disease ($n = 9$) or local recurrence ($n = 5$)

were found in 14/50 (28%) of patients; 25% of them with PCs and 26% with PGLs. Surgery was more often chosen (2nd line treatment) for PCs' recurrence or metastasis (37%) compared to PGLs (16%) in which systemic treatments including chemotherapy (temozolomide), radiopeptides, targeted treatment, radiotherapy or follow-up (watch and wait strategy) were applied. MSI/PDL1 expression was negative in 10 tested samples (all metastatic or progressive) and thus immunotherapy was not considered. Survival rate was 98% during the follow-up. Median progression free survival was 36 months for patients with metastatic disease, and median overall survival 96 and 48 months in patients with PCs and PGLs respectively.
Conclusion
In our series, 44.4% of patients with PCs and PGLs were diagnosed with genetic mutations confirmed in both bood and tissue analysis whereas the frequency of patients with PGLs diagnosed with pathological mutations was double compared to patients with PCs. The 28% of our cases presented local recurrence or distant metastases; however MSI/PDL1 analysis was negative and thus immunotherapy was not applicable.

Atypical presentation of recurrence following previous resected Primary Parathyroid Carcinoma- dilemmas in follow up of this rare malignancy

Haris Khan[1], Maimoona Nawaz[2] & Isha Malik[1]
[1]North Manchester General Hospital, Crumpsall, United Kingdom; [2]Fairfield General Hospital, United Kingdom

Introduction
Parathyroid cancer is a rare endocrine malignancy and constitutes 0.005% of all cancers. It can recur in 50% of cases. The first recurrence commonly occurs within 3 years of the original diagnosis. Hypercalcaemia is the main cause of morbidity and mortality. We present a case of a 62-year-old male patient who had an atypical lung nodule recurrence with normal calcium and PTH levels, six years following resection of a functioning parathyroid cancer.
Case Report
A 62-year-old male patient was referred to endocrinology due to hypercalcaemia post resection of adenocarcinoma of the rectum. Post-bowel surgery, his serum calcium levels ranged from 3.07 to 3.71 mmol/litre (2.10-2.60), serum PTH 16.1 pmol/litre (1.2-6.9), and vitamin D3 43.6 nmol/litre (>50). A parathyroid sestamibi scan revealed right superior parathyroid adenoma and an intrathyroidal mass suspicious of parathyroid tissue. He underwent a right hemi-thyroidectomy and bilateral superior parathyroidectomy. Histology confirmed a parathyroid carcinoma in the intrathyroidal tissue with normal superior parathyroid glands. He was monitored annually by endocrinologists and surgeons. This was done by checking his serum calcium, PTH, and ultrasound neck which all remained normal. Six years following the parathyroid surgery, he was found to have an enlarging lung nodule on surveillance imaging for his rectal cancer. A CT-guided lung biopsy confirmed a parathyroid cancer metastasis. A PET CT scan and ultrasound of the neck did not reveal any evidence of local recurrence. The lung nodule was resected which confirmed a parathyroid cancer metastasis.
Discussion/Conclusions
Long-term survival is possible with recurrence of parathyroid cancer and routine surveillance can identify early recurrence. However, there is no clear consensus guidance on the follow-up of patients with parathyroid cancer. The existing guidelines recommend regular surveillance of functioning parathyroid cancer by performing serum calcium, PTH, and ultrasound neck. Our case is atypical in that the patient did not have hypercalcaemia at the time of recurrence despite the originally resected functional parathyroid cancer. If surveillance imaging for rectal cancer had not been done, the lung nodule may not have been picked up in a timely manner. This case highlights the need for lifelong follow-up for parathyroid cancer patients. Current guidelines should be reviewed to include whole-body imaging modalities to pick up early distant recurrence. Our case also highlights that recurrence of functional parathyroid cancer might not present with hypercalcaemia.

Pheochromocytoma associated with type 1 neurofibromatosis

Chtioui Sara, Ahmed Boukhalfa, Rafi Sanaa, Ghizlane EL Mghari & Nawal EL Ansari
Med VI University Hospital Center, Endocrinology, Diabetology and Metabolic Diseases Department, Marrakech, Morocco

Introduction
Compared to normal population, patients with neurofibromatosis are at higher risk for the development of benign and malignant tumors. Pheochromocytomas are relatively rare in neurofibromatosis type 1 (NF1), and malignant ones are even rarer.
Aim of the presentation
Our aim was to report a malignant pheochromocytoma with multiple metastases in a patient with NF1.
Case report
A male patient aged 23 years old, with laparoscopically resected pheochromocytoma. He was investigated for headaches, flushing and palpitations. The diagnosis of pheochromocytoma was confirmed by elevated 24-hour urine levels of metanephrines and catecholamines. Computed Tomography Scan revealed a mass measuring 10 x 8, 2x 9,4 cm in the left adrenal gland and pulmonary metastases. The patient presented with classic clinical features of NF-1, *café-au-lait* spots and skin nodules. He was operated on and histological examination confirmed the diagnosis of pheochromocytoma with a Pass score of 9. After surgery, urinary catecholamines were high and there were diffuse pulmonary and liver metastases with Octreotide scan uptake. Somatostatin analogues and MIBG therapy are being considered.
Conclusion
The association of a malignant pheochromocytoma with neurofibromatosis type 1 although very rare should be known as pheochromocytoma and its metastases may be totally asymptomatic as in the presented case.
Key-Words : Pheochromocytoma-neurofibromatosis-malignant-catecholamines

An analysis of blood parameter changes in cushing's syndrome - a population-based study

Jessica Mangion[1,2], Miriam Giordano Imbroll[1, 2], Sarah Craus[1, 2], Josanne Vassallo[1, 2] & Mark Gruppetta[1,2]
[1]University of Malta Medical School, Mater Dei Hospital, Department of Medicine, Msida, Malta; [2]Mater Dei Hospital, Neuroendocrine Clinic, Msida, Malta

Aim
Glucocorticoids play a significant role in inflammation and immune system disruption. Our study aimed to analyse different biochemical and blood count indices and serum inflammation-based scores in patients with all different causes of endogenous Cushing's Syndrome (CS) in a well-defined population.
Methods
Clinical records of 35 patients diagnosed with CS between 2008 and 2020 at the only central national health service hospital in Malta, were retrospectively analysed. Detailed clinical and biochemical data were obtained for each patient. Correlation and receiver operator characteristics (ROC) curve analyses were used to establish a threshold value for different variables to predict malignant CS.
Results
Malignant cause of CS (ectopic CS and adrenocortical carcinoma) had statistically significant higher cortisol, size of the tumour and lower potassium at diagnosis ($P<0.001$). Additionally, malignant causes had a lower lymphocyte count ($P=0.001$) and eosinophil count ($P=0.008$), and a higher neutrophil-to-lymphocyte ratio (NLR) ($P=0.001$), systemic immune inflammation index ($P=0.005$) and a lower lymphocyte-to-monocyte ratio (LMR) ($P<0.001$). Using Spearman's correlation, a positive correlation was noted between cortisol levels (baseline, post-ODST cortisol and 24-hour urinary cortisol) and pre-operative NLR whilst a negative correlation was observed with pre-operative LMR. Using ROC curve analysis to predict malignant cause of CS, a potassium level of < 3.05

was 75% sensitive and 100% specific (ROC-AUC 0.907, $P = 0.001$), a post-ODST cortisol level of > 841 nmol/l was 100% sensitive and 91% specific (ROC-AUC 0.981, $P < 0.001$), while a NLR ratio > 3.9 was 100% sensitive and 57.7% specific (ROC-AUC 0.885, $P = 0.001$).
Conclusion
Biochemical and blood count indices and serum inflammatory-based scores remarkably differ between benign and malignant causes of endogenous CS. Such indices can help predict the severity of disease and thus prognosis.

New CDKN1b mutation in multiple endocrine neoplasia type 4 and brief literature review on clinical management.

Alessandro Brunetti[1], Elisabetta Lavezzi[1], Alexia Bertuzzi[2], Gennaro Nappo[3], Alice Laffi[2], Vittorio Pedicini[4], Eleonora Vitali[5], Giampaolo Trivellin[5], Gherardo Mazziotti[1] & Andrea Lania[1]
[1]Humanitas Clinical and Research Center - IRCCS, Endocrinology, Diabetology and Andrology Unit, Rozzano, Italy; [2]Humanitas Clinical and Research Center - IRCCS, Unit of Medical Oncology and Hematology,, Rozzano, Italy; [3]Humanitas Clinical and Research Center - IRCCS, Pancreatic Surgery Unit, Rozzano, Italy; [4]Humanitas Clinical and Research Center - IRCCS, Radiology Unit, Rozzano, Italy; [5]Humanitas Clinical and Research Center - IRCCS, Endocrinology Unit and Laboratory of Cellular and Molecular Endocrinology, Italy

Background
The fourth type of Multiple Endocrine Neoplasia (MEN) is a rare variant of MEN presenting a MEN1-like phenotype and originating from a germline mutation in CDKN1B. However, due to the small number of cases documented in literature, the peculiar clinical features of MEN4 are still largely unknown, and clear indications about the clinical management of these patients are currently lacking. In order to enlarge our knowledge on MEN4 and to better typify the clinical features of this syndrome, we present two more patients with a germline CDKN1B mutation developing MEN features and perform a review of the current literature about MEN4.
Case presentation
The first case is a man who was diagnosed with a metastatic ileal G2-NET at the age of 34. Genetic analysis revealed the mutation p.I119T (c.356T>C) of CDKN1B. This variant is classified as of uncertain significance according to 2015 ACMG guidelines and has been previously reported in association to early-onset pituitary adenoma. The patient was screened for pituitary and parathyroid disease without any pathological findings. The second report is a 76-year-old woman with a multifocal pancreatic G1-NET. Genetic analysis identified the CDKN1B mutation c.482C>G (p.S161C). The variant is of first description in literature in association to MEN4. It is located into the C-terminal RhoA binding domain, potentially affecting cell motility. However, in silico analysis supports that this missense variant does not alter protein structure/function and it has been currently classified as a variant of uncertain significance. Pituitary and parathyroid function resulted normal as well.
Review of literature
To date, twenty-three different mutations of CDKN1B have been described in literature in association to MEN4, including fifty-seven carriers. Forty-two of these subjects developed at least one endocrine neoplasm, while involvement of multiple endocrine organs was detected in seventeen of them. Primary hyperparathyroidism results the most frequent endocrine neoplasm (75%), followed by pituitary adenoma (≈40%) and neuroendocrine tumors (≈20%). In general, MEN 4 seems a variant with later onset, less penetrance, and milder clinical features than MEN1.
Conclusions
MEN4 patients might need a different and personalized approach in clinical management. For hyperparathyroidism, since recurrence and/or multiple parathyroids involvement appears to be rare, a less aggressive surgical approach than in MEN1 could be justified. Therefore, MEN4 carriers should be screened for neuroendocrine tumors and pituitary adenomas. Larger case series are still necessary to clarify the peculiar features of MEN4 and to establish a specific diagnostic and therapeutic standard.

EP595

Severe psychosis: think of adrenocortical carcinoma

Kaoutar Rifai, Loubna Guissi, Wahiba Ghaffour, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Adrenocortical carcinoma (AC) is a rare malignant endocrine tumor of the adrenal cortex. The psychiatric manifestations observed in AC are associated with a delayed diagnosis.
Case presentation
A 27-year-old women with medical history of severe psychosis resistant to antipsychotic medications, was hospitalized in our unit for Cushing's syndrome (CS). The physical examination revealed classical signs of CS. The Laboratory results showed 24-hour urinary free cortisol values higher than 4 times the upper limit of normal, elevated midnight serum cortisol at 86 ng/ml and no suppression of cortisol during a low-dose dexamethasone suppression. The presence of a plasma ACTH level < 3 pg/ml suggests ACTH-independent CS. Adrenal CT scan showed a 35*23 mm mass located in the left adrenal gland with an absolute washout of 28%. The patient underwent unilateral adrenalectomy. Histopathological analysis revealed adrenocortical carcinoma with a Weiss score of 4. The evolution was characterized by the improvement of psychiatric symptoms, hence the discontinuation of antipsychotic medications.
Discussion
AC is a rare malignant tumor. Its incidence is approximately 1 to 2 new cases per million per year. It occurs most often in adults between 40 and 50 years of age, with a female predominance. The prognosis is poor (five-year survival rate of less than 50%). The glucocorticoid hypersecretion observed in CS is accompanied by sleep disorders, thymic manifestations, especially depression, and cognitive disorders, but psychotic states are rare. Hypercortisolemia modulates the response of the central nervous system through the activation of membrane channels, synaptic transmission of neurotransmitters (such as serotonin, glutamate and GABA), gene transcription, synaptic plasticity, neurogenesis and apoptosis. Excessive activation of the dopaminergic system is at the basis of the pathophysiology of manic symptoms, psychotic disorders and also some forms of depression.
Conclusion
Our case illustrates the importance of a good interrogation and a careful clinical examination in all patients presenting with a psychiatric illness, in order to eliminate an organic cause which can engage the vital prognosis.

EP596

A case of asymptomatic Pheochromocytoma with high risk of malignancy

Renata Marecek[1], Baleanu Felicia[1], Taujan Georgiana[1], Papadopoulou Blerta[1], Kosmopoulou Olga[1], Rosu Mihaela[1], Dobos Sebastian[2] & Iconaru Laura[1]
[1]Chu Brugmann Site Horta, Endocrinology, Brussels, Belgium; [2]Chu Brugmann Site Horta, General Surgery, Brussels, Belgium

Introduction
The classical triad of pheochromocytoma comprises paroxystic headache, palpitation, and diaphoresis. It is a common cause of secondary hypertension. Glycemic abnormalities are not rare. Hyperglycemia and diabetes can be the presenting features of pheochromocytoma. However, cases of hypoglycemia are also described. Malignant tumors account for about 10% of cases.
Case description
In this report, we present a case of a 41-year-old man referred to the endocrinology department for asymptomatic hypoglycemia as an incidental finding on routine laboratory screening. There was no personal or family medical

history, and patient was not taking any medication. An insulinoma was initially suspected, and patient underwent abdominal magnetic resonance imaging. The latter revealed right 24 mm hypervascular adrenal mass and normal pancreatic parenchyma. The blood pressure was normal (110/60 mmHg). The laboratory showed an elevated level of chromogranin A (322 mg/l, (N): $<$100 mg/l) and elevated urinary metanephrines (814 mg/24 h, (N): 74-297) and normetanephrines (755 mg/24 h, (N): 105-354). The fasting insulin, glucose, and c-peptides were in normal range. PET CT showed a strong surexpression of the somatostatin receptors in right adrenal mass. On a non-contrast-enhanced computed tomographic (CT) scan, density of the lesion was 35 HU. On a contrast-enhanced CT, the value was 100 HU. At this stage, a pheochromocytoma was suspected. Surgical resection was performed. The pathology confirmed a pheochromocytoma. It was described as having a high risk of malignancy because of capsular invasion, presence of nuclear atypia, up to eight mitotic figures in 10 high-power fields (hpf), presence of atypical mitoses, and confluent nodules. There was no invasion of peri-adrenal fat, vascular, lymphatic, or peri-neural tissues. The genetic tests showed no mutation in the SDH, RET, VHL, and NF1 genes. The urinary metanephrines and normetanephrines were in the normal range 2 months after the surgery.

Discussion

In conclusion, we present a case of pheochromocytoma in a patient with incidental asymptomatic hypoglycemia. Our case emphasizes that eight percent of patients with pheochromocytoma are completely asymptomatic. Histopathology results demonstrated a tumor with a high risk of malignancy because of the extensive capsular invasion. Nevertheless in literature, the only indicator of malignancy is the presence of distant metastases. Our case also highlights absence of reliable histopathologic methods to distinguish between benign and malignant tumors. However, certain histologic features are more common in malignancy, including extensive capsular invasion (as present in our patient), tumor necrosis, and vascular invasion.

Levels to designate progressive increase in aggressiveness of medullary thyroid cancer depending on the identified mutations in the Republic of Belarus

Yuliya Dydyshka[1,2], Alla Shepelkevich[1], Victor Kondratovich[3], Tatiana Leonova[3], Alena Subach[4], Anna Portyanko[4], Andrey Gradusha[3] & Alexandra Sosedkova[3]

[1]Belarusian State Medical University, Minsk, Belarus; [2]Republic Center of Endocrinology and Medical Rehabilitation, Endocrinology Department, Minsk, Belarus; [3]Public Health Institution Minsk City Clinical Oncologic Dispensary, Minsk, Belarus; [4]N.N. Alexandrov National Cancer Centre of Belarus, Minsk, Belarus

Background

The recommended method of initial testing for MEN2A is either a single or multi-tiered analysis to detect RET mutations in exon 8, 10, 11, 13, 14, 15, and 16.

The aim of the study was to determine the relationship between the aggressiveness of the clinical course of MTC and identified mutations.

Materials and methods

The research is carried out of the program 'To develop and implement effective technologies for the diagnostic detection and observation of patients with MEN2A.' 32 patients with established medullary thyroid cancer (MTC), who underwent genetic testing, with the presence of pathogenic mutations of the RET proto-oncogene, were selected. The patients were divided into 3 groups depending on whether the mutation of the RET gene belongs to the highest, high, and medium risk levels.

Results

The number of carriers of the mutation of the highest risk level (16 exon M918T) was 2 people, which is 6.25% of the total. The median age at diagnosis is 18 years. At the time of diagnosis, the metastatic form of the disease was not detected in this group of patients. After the treatment, no recurrence of the disease was recorded in patients. In 1 of 2 patients, the presence of pheochromocytoma was established. The number of carriers of high-risk mutations was 11 people, which is 34.38%. All mutations are localized in exon 11. The average age of diagnosis is 28.7 years. At the time of diagnosis, the metastatic form of the disease was detected in 1 patient, which is 9.1%. After the treatment, remote recurrence of the disease was registered in 1 patient (9.1%), and local recurrence - in 2 patients, which is 18.2%. In 4 people (36.4%) pheochromocytoma was found. In 19 people, pathogenic mutations of the RET gene were identified, which are related to the level of moderate risk, which accounted for 59.37% of the total. Mutations in these patients are localized in exon 10 In this group of patients, MTC was diagnosed on average at the age of 41.1 years. The metastatic form of the disease at the time of diagnosis was not detected in this group. Local recurrence after the treatment was registered in 4 patients (21.05%), remote relapses in this group of patients were not registered. Pheochromocytoma was not detected in this group.

Conclusions

High-risk mutations are characterized by the earliest onset of the disease, as well as the most frequent presence of pheochromocytoma.

EP598

Choroidal metastasis from follicular thyroid carcinoma: a case report

Sofien Affes, Ben Amor Saloua, Rekik Mona, Mariem Sehli, Kammoun Sonda & Trigui Amira

Habib Bourguiba University Hospital, Ophthalmology, SFAX, Tunisia

Introduction

Choroidal metastases are among the most common malignant ocular tumors. In the majority of cases, their origin is pulmonary in men and mammary in women. We present a rare case of choroidal metastasis from a vesicular thyroid carcinoma.

Case presentation

A 35-year-old woman presented to our department complaining of progressive vision reduction in the right eye. Six years previously, she was operated for vesicular carcinoma of the thyroid with pulmonary metastases, she was under iratherapy. The ocular examination of the right eye revealed best visual acuity to be 1/20. Intraocular pressure was 12 mmHg. Fundus examination showeda retinal detachment with the presence of an underlying yellow-orange mass. The left eye examination was normal. Ultrasonography B-scans, optical coherence tomography, fluorescein angiography and magnetic resonance imaging made the diagnosis of choroidal metastasis from thyroid carcinoma. Chest X-ray and abdominal ultrasonography were normal. Bone scintigraphy with iodine 131 showed increased uptake in the humerus and the femur, with no ocular or cerebral uptake. External radiotherapy in addition to iratherapy was proposed but refused by the patient. Then, she was lost of view. Five months later, she came back with red and sore right eye. The examination noted the increase in the size of the metastasis with extension of the retinal detachment and appearance of neovascular glaucoma. Iodine 131 scintigraphy showed ocular uptake of iodine, thus confirming the diagnosis. The iratherapy was resumed but the patient quickly died due to deterioration in her general condition.

Conclusion

Choroidal metastases secondary to vesicular thyroid carcinoma are very rare. There are few cases reported in the literature. This work describes an additional case. In all reported cases, there are bone and/or pulmonary metastases in association with choroidal metastases. Indeed, thyroid carcinomas most often metastasize to the lungs and bones. Other metastatic sites are rare and are seen in advanced stages of the disease with poor prognosis. Vesicular carcinomas of the thyroid are known to metastasize to unusual sites and are more aggressive than papillary carcinomas. The appearance of the choroidal metastasis in our patient constituted a severe evolutionary turning point of the disease.

EP599

Co-secretory ACTH & Calcitonin tumor presented with refractory hypokalemia

Bhavna Sharma, Pratichi Joshi, Anees Fatima, Meena Lakha, Shahir Hamdulay & Elaine Hui

Northwick Park Hospital, United Kingdom

81-year-old ex-smoker presented to emergency with transient facial droop, slurring of speech and generalized weakness. He had a background of ischemic

heart disease, hypertension, and previous bladder cancer (treated 5 years ago). Examination revealed clinical signs of hypocalcaemia with no cushingoid features. Bloods revealed refractory severe hypokalemia, severe hypocalcaemia with normal phosphate, and metabolic alkalosis requiring High dependency Unit. Random cortisol done to exclude Cushing's was greater than 1750 nmol/l (unrecordable upper limit). 24-hour urinary cortisol was 18282 nmol/24 hr (normal 1-124 nmol/24 hours) with no suppression on low dose dexamethasone suppression test (>1750 nmol/l). ACTH was 352 ng/l (normal 0-50 ng/l). PTH was 19.9 pmol/l (normal 1.6-6.9 pmol/l). Vitamin D levels were sufficient. Calcitonin done due to refractory hypocalcaemia was 130 ng/l (normal <10 pg/ml). Renal MRI revealed bilateral adrenal hyperplasia and normal kidneys. Renin: aldosterone ratio done on a sample when potassium was 3.1 mmols/l revealed renin levels of 0.1 nmol/l/hr and aldosterone less than 50 pmol/l. Gut hormone profile was normal except elevated glucagon of 80 pmol/l (normal 0-50 pmol/l). CT Chest/Abdomen revealed a right sided lung 20*14 mm nodule and multiple liver lesions. MRI Pituitary was normal. PET scan did not reveal any further areas of abnormal uptake. Biopsy and immunohistochemical studies of liver lesions showed small cells with nuclear pleomorphism positive for CD56, synaptophysin and chromogranin suggestive of small cell cancer of lung origin. Refractory hypokalemia with a very high ACTH and metabolic alkalosis, is characteristic of ectopic ACTH syndrome. Refractory severe hypocalcemia was further suggestive of rare calcitonin co-secretion. He was planned for inpatient chemotherapy with dexamethasone 4 mg BD. He was stepped down to oral alfacalcidiol 500 ng once a day, calcium lactate gluconate (2.263 g + calcium carbonate 1.75 g), two tablets BD, potassium chloride 600 mg/potassium bicarbonate 400 mg (total potassium 12 mmol) tablets, two tablets TDS with magnesium aspartate (magnesium 10 mmol) BD. Unfortunately, the patient succumbed to COVID/Sepsis. Early initial medical management of ectopic ACTH and early recognition of co-secretory tumors in cases of multiple electrolyte derangements may be helpful in achieving a more positive outcome in future. A multidisciplinary management in liaison with critical care, oncology and endocrine is paramount

Sporadic metastatic pancreatic neuroendocrine tumor in a young patient

Marius-Lucian Mitrache[1], Carmen Sorina Martin[1], Cornelia Nitipir[2] & Simona Fica[1]
[1]Spitalul Universitar de Urgenţă Elias, Endocrinology, Bucureşti, Romania; [2]Spitalul Universitar de Urgenţă Elias, Medical Oncology, Bucureşti, Romania

Background
Pancreatic neuroendocrine neoplasms (NENs) are rare tumors which can sometimes be diagnosed based on symptoms of hormone excess, but, more often, they are asymptomatic, and patients frequently present with metastatic disease. While they can occur in hereditary cancer syndromes such as multiple endocrine neoplasia type 1 (MEN1), von Hippel-Lindau (VHL), or neurofibromatosis (NF1), the majority of pancreatic NENs are sporadic
Case report
We report the case of a 37-year-old male referred to a gastroenterology clinic for nonspecific gastrointestinal symptoms. Abdominal ultrasound reported a large hepatic mass, which was confirmed with an abdominal CT scan. This prompted an ultrasound-guided hepatic biopsy, which raised the suspicion of metastatic liver disease arising from a primary pancreatic NEN. The diagnosis was confirmed with immunohistochemistry, which graded the tumor as a NET G2 based on a ki-67 of 5%, and thus the patient was referred to our department. Considering the patient's young age, biochemical screening for MEN1 was performed, but serum calcium, PTH, gastrin, insulin, IGF-1, and prolactin were normal, as were NEN-specific tumor markers. The patient also had no symptoms of hormone hypersecretion, no clinical features of VHL or NF1, and no remarkable family history. Somatostatin receptor SPECT/CT was performed, reporting a primary pancreatic NEN, with multiple metastases to the liver, abdominal lymph nodes and left adrenal gland, and portal vein invasion. The patient received monthly intramuscular lanreotide injections, in combination with a systemic chemotherapy regimen. However, owing to the unsatisfactory response of the treatment and the significant adverse reactions, the patient was recommended for Peptide Receptor Radionuclide Therapy (PRRT). Following five Lu-177-DOTATATE PRRT cycles, partial response was observed, and debulking surgery is being considered as the next therapeutic step.
Conclusions
Widespread metastatic disease is often reported in pancreatic NENs, frequently requiring multiple lines of treatment. As such, multidisciplinary teams play a pivotal role in the management of such complex cases, carefully balancing risks, benefits, the biology of the tumor, and patients' wishes.

Hypercalcaemia in a woman with systemic lupus erythematosus: don't miss the diagnosis of gastric neuroendocrine tumor!

Selma Massanou, Asma Kefi, Khaoula Ben Abdelghani, Mounira El Euch, Syrine Sassi, Sami Turki & Ezzedine Abderahim
Service de Médecine Interne A, Hôpital Charles Nicolle, Tunis, Tunisia

Introduction
Systemic lupus erythematosus (SLE) is a chronic multisystem autoimmune disease with heterogeneous presentation. SLE can be associated with autoimmune diseases or other entities sush as neuroendocrine tumors (NET). The occurrence of gastric NET in SLE is very rare and has been described few times in the literature. Herein we report the case of SLE woman, in whom we discovered a gastric neuroendocrine tumor.
Observation
A 68-year-old woman, with a history of treated arterial hypertension and SLE, presented a hypercalcemia (2.72 mmol/l) in a routine check-up. SLE was diagnosed, 12 years before, according to the American College of Rheumatology (ACR) SLE criteria with oral ulcers, non-scarring alopecia, discoid lupus, leukopenia, thrombocytopenia, autoimmune hemolytic anemia, positive antinuclear antibodies (ANA), and low complements. She had no kidney, heart, joint, or neuropsychiatric impairment. The investigations (thyroid test, celiac serology, and digestive endoscopies) for the search of autoimmune conditions associated with her disease were initially negative or normal. She was treated with antimalarials and corticosteroids. The evolution was good and she did not present any relapses of her SLE. Given the hypercalcemia presented by our patient, after eliminating the emergencies, we began an exhaustive etiological investigation. There were no functional complaints. Our patient denied drug or toxic intake. Laboratory tests revealed normal level of phosphatemia, parathyroid hormone and vitamin D. A body scanner didn't reveal any abnormalities. A gastroscopy showed multiple millimetric fundal elevations with ulceration in the center. On histological examination, it was a well-differentiated grade 1 NET, with, on immunohistochemical study, intense and diffuse cytoplasmic staining of the tumor cells after the use of chromogranin-A. Furthermore, the fundic mucosa was atrophic with reduced glandular volume, suggesting Biermer's disease. Vitamin B12 was low (115 pg/ml), antiparietal cell antibody was positive, and anti-intrinsic factor antibody was negative. Beside, blood chromogranin-A was high (681 ng/ml). After confirming the diagnosis of Biermer's disease, NET was classified as type I. Therefore, according to The National Comprehensive Cancer Network (NCCN) guidelines, we opted for annual monitoring by fibroscopy, with monthly vitamin B12 injections in addition to endoscopic resection. The current follow-up is 2 years with a good evolution.
Conclusion
NET-SLE is a scarce association. In our observation, it occurred on a Biermer's disease, which can be part of an autoimmune manifestation associated with SLE. NET was revealed by hypercalcemia in our case, therefore we highlight the importance of an exhaustive etiological investigation of hypercalcemia especially in SLE patients.

Ectopic Cushing's syndrome due to metastatic lung carcinoid presenting on a background of DIPNECH

Telma Moreno[1,2], Sara Ribeiro[1, 2], Ana Varela[1, 2], Paula Freitas[1,2,3] & Davide Carvalho[1,2,3]
[1]São João Universitary Hospital Center, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto - FMUP, Porto, Portugal; [3]i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal

Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia (DIPNECH) is a relatively recent and rare disease, frequently misdiagnosed. It is characterized as a generalized proliferation of pulmonary neuroendocrine cells and is recognized as a precursor lesion for pulmonary neuroendocrine tumors, although the risk of progression to malignancy is considered low. Here we report a patient with ectopic ACTH-dependent Cushing's syndrome due to metastatic lung carcinoid tumors arising on a background of DIPNECH. A 73-year-old woman presented to the emergency department with 4 weeks of progressive lower limb edema, sudden onset of hypokalemia, refractory hypertension and de novo diabetes. She had basilar crackles on auscultation and hepatomegaly on examination. Past medical history included controlled hypertension, obesity, dyslipidemia. She was being followed in Pulmonology for chronic cough and radiological findings suggestive of DIPNECH. A thoracic CT showed diffuse mosaic attenuation with multiple bilateral lung nodules, with the largest nodules measuring 8 mm. Biopsy of the pulmonary nodules demonstrated tumorlet/typical carcinoid tumor, with evidence of DIPNECH. Severely elevated GGT prompted a cholangio-MRI that showed heterogeneous/micronodular liver parenchyma suggestive of chronic liver disease. Liver biopsy demonstrated hepatic involvement by a well differentiated neuroendocrine neoplasia expressing chromogranin and synaptophysin with a proliferative index Ki67 $< 2\%$, compatible with metastasis. The patient became increasingly confused and disoriented over the first days of hospitalization. In view of clinical suspicion of endogenous hypercortisolism, screening for Cushing's syndrome was performed. She had elevated elevated morning and midnight plasma cortisol levels (58.0 and 83.4 µg/dl, respectively) markedly increased 24-hour urinary free cortisol (3648.0 µg/day) and morning serum ACTH (167.1 ng/l). High-dose dexamethasone suppression test revealed no suppression of urinary free cortisol. A PET-Ga-68-DOTATOC was obtained showing multiple tumor lesions located at the cervical, thoracic and abdominal ganglia, lung (identified as the primary source), bone and liver with over-expression of somatostatin receptors. A PET-FDG-F18 excluded the presence of concomitant dedifferentiated/high grade metabolic lesions. Therapy with octreotide and metyrapone was initiated with a prompt and sustained decrease in serum and urinary cortisol levels. At hospital discharge, the patient was fully oriented, with controlled cortisol and potassium levels. Her vital signs were normal and peripheral edema was mild and limited to the ankles. Six months after discharge she remained clinically and imagiological stable under somatostatin analogs and metyrapone. This case describes disease progression from DIPNECH to metastatic carcinoid tumours presenting with ectopic Cushing's, highlighting the importance of long term clinical surveillance in patients with DIPNECH.

Multiple endocrine neoplasia type 1: A case report

Meriem Adel[1], Ibtissem Ben Nacef[1], Chayma Besrour[1], Sabrine Mekni[1], Houaida Smadhi[2], Youssef Lakhoua[1], Nadia Mchirgui[1], Imen Rojbi[1] & Karima Khiari[1]
[1]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia; [2]Beja Hospital, Endocrinology, Beja, Tunisia

Introduction
Multiple endocrine neoplasia (MEN1) is a rare underdiagnosed inherited multi-tumor syndrome, affecting neuroendocrine and non-endocrine tissues. Its aspects are extremely variable with no genotype-phenotype correlation.
Case report
A 57 year old woman with a history of hypertension, presented five months before her admission with asthenia, headache and vomiting, initial biological exams revealed a central hypothyroidism. A pituitary MRI showed a sellar and suprasellar mass (3 cm of diameter) with an upper deviation of the pituitary stalk, the optic chiasma, and apparent invasion into the left cavernous sinus (knosp 2 at right; knosp1 at left) consistent with a pituitary macroadenoma. Laboratory evaluations concluded to a non-functioning pituitary adenomas with disconnection hyperprolactinemia and hypopituitarism. Ophthalmological examination revealed bitemporal hemianopsia. The patient's serum investigations revealed a primary hyperparathyroidism. Both parathyroid ultrasound and Technetium Tc-99 m sestamibi parathyroid scintigraphy were negative. The patient did not present any clinical, biological, imaging manifestations of gastro-entero-pancreatic neuroendocrine tumors. The diagnosis of MEN 1 was made and few days after, the patient had a transphenoidal adenomectomy. The surgery was complicated with a transient insipidius diabetes. 3 months after surgery, the evaluation revealed the persistence of hypopituitarism (corticotropic insufficiency, and central hypothyroidism) but a normal prolactin serum level. Pituitary MRI showed a tumor remnant. Visual field was normal.
Discussion
MEN 1, a rare endocrine syndrome, is defined by the presence of 2 or more primary endocrine tumors mainly located at parathyroid glands, anterior pituitary and gastro-enteropancreatic (GEP). Mutations of the MEN1 gene are identified as responsible for the development of this syndrome. Primary hyperparathyroidism, the most common manifestation of MEN1, presents usually in the second to the fourth decade of life. Multiple glandular disease is typical of MEN1. The most common type of pituitary adenoma in MEN1 is a prolactinoma. Conversly, non functioning adenoma are rare (5%). GEP, which are asymptomatic in 70% of cases, are the primary life-threatening manifestation of MEN1 due to their malignant potential.
Conclusion
The peculiarty of our case stems from the fact that MEN1 was revealed at an advanced age by a nonfunctionnig macroadenoma. That's why it should not be overlooked in diagnosis. In addition early recognition, multidisciplinary management and life long follow up are crucial.

Metachronous germ cells and sex cords ovarian tumors in an adolescent girl : Hormone replacement therapy at what cost ?

Mnif Fatma, Asma Zargni, Kawthar El Arbi, Dhoha Ben Salah, Mouna Elleuch, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Diabetology and Endocrinology Department, Sfax, Tunisia

Introduction
Gonadal tumors are rare in children. Because surgery is the primary treatment for ovarian tumors, ovarian salvage with fertility preservation and use of a minimally invasive surgical technique are important in children and adolescents. We report the case of an adolescent girl who was referred after bilateral annexectomy.
Observation
This is a 14-year-old girl who just had her first menses. She has been followed the last year for an ovarian tumor. She initially had a right annexectomy. The pathology examination concluded to a moderately differentiated Sertoli tumor of 11*13 mm. Two months later, she developed large ascites. Radiological explorations showed a mass of the remaining left ovary of 9*7 mm with peritoneal carcinosis classified as high risk stage IIIc. After a multidisciplinary discussion about fertility, cryopreservation of the ovarian cortex and all other preservation techniques have been discussed but they are impossible due to the high risk of recurrence upon reintroduction of the ovarian tissue. The child received 2 lines of chemotherapy followed by a left annexectomy. The surgery was considered complete and the pathology examination concluded to an ovarian teratoma. Currently, the 16-year-old patient is castrated with complete remission and no tumor recurrence. Her major complaint was the regression of secondary sexual characteristics.
Discussion-Conclusion
In the absence of high-level evidence literature, the Expert Consensus regarding hormone replacement therapy was consulted (1). Overall, the options for hormonal treatment depend on possible hormone dependence and the risk of recurrence. For germline tumors, these treatments can be used. On the other hand, a certain caution has been adopted for tumors of the sexual cords.

The combination of medullary thyroid carcinoma and sporadic clear cell renal cell carcinoma: coincidence or new syndrome?

Ihssane Abidi, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
University Mohammed 5 Rabat, Endocrinologie, Rabat, Morocco

Introduction
COVID-19 is a pandemic related to SARS-COV-2 virus infection. It is most often manifested by an influenza-like syndrome with other symptoms that are more specific such as loss of smell and taste. Its severity is highly variable, ranging from asymptomatic to severe or prolonged forms. We report the case of a 47-year-old female patient, who is being followed for hypoparathyroidism, who developed severe and persistent cramps after the COVID-19 vaccine.
Observation
This is a 47-year-old female patient with a history of high-risk papillary thyroid carcinoma since 2018, operated and irradiated. Her surgery was complicated by supplementary hypoparathyroidism. Her blood calcium was well controlled and she was asymptomatic since her supplementation with Alfacalcidol and calcium. She received the first dose of astrazeneca in July 2021, after 4 hours she developed persistent painful cramps in her extremities. Her clinical examination did not reveal any signs of hypocalcaemia and the biological dosage was 84 mg/l. As the cramps persisted, we started her on calcium and magnesium. The clinical evolution was good after 6 hours and there was no recurrence.
Discussion
COVID-19 vaccines are as well tolerated in neuromuscular patients as in the general population (1). Hypoparathyroidism is not a neuromuscular disease, but it can be caused by hypocalcaemia, which is the cause of the neuromuscular manifestations. Campesium can be seen with COVID-19 vaccines, and is generally benign and transient. The particularity of our observation is that the cramps were severe and incapacitating with the need for intravenous calcium treatment and monitoring, adding the hypoparathyroid terrain which posed a problem of differential diagnosis.
Conclusion
The vaccine against COVID-19 has become an unavoidable necessity in the face of the pandemic population. It certainly has short and long term side effects. Fragile patients must be monitored to avoid complications, particularly neuromuscular ones.

Multiple endocrine neoplasia type 2: About two Tunisian patients

Mnif Fatma, Kawthar El Arbi, Abdelmouhaymen Missaoui, Faten Haj Kacem Akid, Wafa Belabed, Dhoha Ben Salah, Nadia Charfi, Mouna Mnif[1], Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Multiple endocrine neoplasia type 2 (MEN2) is a rare inherited disease characterized by the occurrence of medullary thyroid cancer (MTC) either isolated or associated with pheochromocytoma, primary hyperparathyroidism (PHP), or typical morphological features. Thus, we report two cases.
Patient(1)
A 27-year-old female patient with a marfanoid appearance, had a histologically confirmed conjunctival and mucosal ganglioneuromatosis, bilateral composite pheochromocytoma (pheochromocytoma and ganglioneuroma) with multifocal and metastatic MTC. MEN2b was strongly suspected. A genetic study showed the presence of a mutation in the exon 16 (codon, M918T), in the heterozygous state, which is the most frequently associated with the MEN2b phenotype.
Patient(2)
A 46-year-old female patient presented with a complete MEN2a panel: multifocal CMT, PHP and bilateral pheochromocytoma. In addition, she had hyperpigmented indurated lesions on the upper back following intense pruritus. These lesions are reminiscent of cutaneous amyloid lichen (CAL), a rare clinical variant of 2A. The genetic study is ongoing.
Conclusion
As distinct from MEN1, each variant of MEN2 corresponds to a specific genetic mutation. It is possible to predict the patient's phenotype from the genetic study. For example, CAL occurs almost exclusively in a proportion of individuals with the codon 634 mutation. Thus clinical examination plays a crucial role in guiding the biomolecular investigation.

Multiple endocrine neoplasia type 1: A puzzle that builds over the years

Mnif Fatma[1], Kawthar El Arbi[1], Yosra Lajmi[2], Asma Zargni[1], Faten Haj Kacem Akid[1], Hamdi Frikha[1], Dhoha Ben Salah[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1], Hassen Kammoun[2], Fatma Abdelhédi[2] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Medical Genetics, Sfax, Tunisia

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a genetic disease that predisposes to the development of both hyperplastic and tumorous lesions of the endocrine glands, in particular parathyroid, pancreatic and pituitary. Thus we report our case.
Observation
An 18-year-old male patient was hospitalized for severe hypoglycemia mistakenly treated as epileptic seizures. The etiological investigation concluded to a benign multiple insulinoma, confirmed by the anatomopathological study. The patient was lost to follow-up and was re-hospitalized 11 years later for an intracranial hypertension related to a macro-prolactinoma of 7 cm of diameter. Prolactin level was 11300µg/l. A MEN1 was suspected. The investigation of additional associated lesions revealed a primary hyperparathyroidism. The evolution was fatal with the death of the patient in a cerebral herniation. The genetic study was not performed.
Discussion
Parathyroid tumors are the first manifestation of MEN1 in over 85% of cases. Less than 15%, the first manifestation may be an insulinoma or prolactinoma, likewise our patient. The chronology of lesion onset could differ from patient to another. The clinical presentation is usually completed over time. Thus a continuous screening of the different lesions is necessary. For our patient, the discovery of a primary hyperparathyroidism as well as a prolactinoma 11 years later make it particular.

Clinical case: MEN1 syndrome

Ieva Meskinyte[1], Saule Cyrolyte[1], Igne Strazdiene[1], Egle Urbonaviciute[1], Raimonda Klimaite[1,2,3] & Neli Jakuboniené[1,3]
[1]Lithuanian University of Health Sciences, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Lithuania; [3]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Department of Endocrinology, Lithuania

Introduction
Multiple Endocrine Neoplasia Type 1 (MEN1) is a rare, autosomal dominantly inherited syndrome that causes tumors of the endocrine glands [1]. This syndrome is most commonly associated with neuroendocrine tumors of the parathyroid glands, pituitary gland and pancreas [2].
Case
A 30-year-old woman was admitted to the Hospital of Lithuanian University of Health Sciences, Kaunas Clinics for unconsciousness and significant hypoglycaemia: 1.0 - 3.04 mmol/l.
Anamnesis
In 2016, the patient was examined for infertility. Hyperprolactinemia was diagnosed. Head MRI was performed to detect pituitary microadenoma, treatment with Cabergoline 0.25 mg/week was started. In 2017, an episode of the hypoglycaemic coma was observed. Due to recurrent unspecified hypoglycaemia, the patient was admitted to the Endocrinology Department.
Laboratory tests were performed (Table 1). GTT results were within the normal range. Thyroid US: hypoechoic masses: dorsal from the left lobe, 1.6x0.5 cm and dorsal from the right lobe 2x0.4 cm - possibly parathyroid adenomas. DXA scan: T value - 2.5; Z value -2.5. Conclusion: osteoporosis.

After evaluating multiple endocrine pathologies (prolactinoma, hyperparathyroidism, hypoglycaemia), MEN1 syndrome was diagnosed with the following outcomes:

1) Microadenoma hypophysis – prolactinoma. Secondary infertility
2) Parathyroid adenomas. Primary hyperparathyroidism. Secondary osteoporosis.
3) Insulinoma. Hypoglycaemia.

Parathyroid Scintigraphy Tc-MIBI + SPECT/CT: right and left parathyroid adenomas. Head MRI: 0.6x0.6 cm hypo-enhanced area on the left side of the adenohypophysis - pituitary microadenoma, without negative dynamics. Abdominal MRI: a possible neuroendocrine tumor - insulinoma in the body and tail of the pancreas. Genetic test: sequencing of 2-4 exons of the transcript encoded by the MEN1 gene was performed. A pathogenic change in the c.446-2A> T sequence was identified, and the diagnosis of MEN1 syndrome was confirmed. The patient underwent parathyroidadenomectomia subtotal, laparoscopic surgery to remove insulinoma. An abdominal MRI was performed 6 months later and two new neuroendocrine tumors were identified in the pancreas. Confirmed during scintigraphy. The patient underwent reoperation. After 1 year, there were no signs of recurrence of insulinoma and hyperparathyroidism, test results were in normal ranges.

Conclusion

This clinical case reflects the classic manifestation of MEN1 syndrome with the typical target organs: the parathyroid glands, pancreas, and pituitary gland. In addition, secondary symptoms of these diseases were hyperparathyroidism, infertility, hypoglycaemia and osteoporosis. Multiple endocrine disorders should lead to a suspicion of a diagnosis of MEN1. Therefore, precise laboratory, imaging tests of the target organs and genetic tests should be performed.

Diagnostic and evolutionary profiles of adrenocortical tumor, about 30 cases

Fadila Chabour & Safia Mimouni
University of Algiers, Medical, Algiers, Algeria

Adrenocortical tumor is a rare malignant tumor of adrenal location. With a poor prognosis that can be improved by rapid diagnosis and adequate early management, hence the importance to evoke this etiology in front of any atypical adrenal mass or any suggestive clinical or biological context. The objective of our modest work is to report through a retrospective study the profile of adrenocortical tumors treated in our service over a period of 13 years from 2007 to 2020. Thirty (30) patients were collected with a middle age of 45 years (27 to 74 years) with a slight female predominance of 60%. A family history of neoplasia was noted in 5 patients (16.66%) and breast neoplasia in a single patient. The most frequent mode of revelation is represented by abdominal pain observed in 56.66% of cases. Hypercortisolemia is found in 40% of cases. Morphologically, the size of the tumor varies from 66 to 180 cm with an average of 110 cm. At least one metastasis was found in 10 patients (33.33%), dominated by hepatic location. 50% of our patients benefited from surgical excision of the tumor and 6.66% underwent a biopsy only. 77% of our patients received adjuvant treatment with mitotane supplemented by chemotherapy in 30% of cases. Only two patients received adjuvant radiotherapy (6.66%). The evolution was marked by remission in 33.33% of cases with an average survival of 5 years and death noted in 50% of patients. In conclusion : Adrenal carcinoma can be seen at any age with a peak frequency in the fifties, affects both men and women with a slight female predominance. Large tumors whose treatment is surgical associated with neoadjuvant treatment in the majority of cases. Unfavorable prognosis, but optimized management can improve survival.

Insulinoma with confusing imaging : a case report

Wafa Belabed, Fatma Mnif, Abdelmouhaymen Missaoui, Dhoha Ben Salah, Faten Haj Kacem Akid, Elleuch Mouna, Mouna Mnif, Nadia Charfi, Nabila Mejdoub & Mohamed Abid
Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction

Insulinoma is a rare pancreatic tumor. It is the most frequent cause of organic hypoglycemia due to endogenous hyperinsulinism.

Case report

A 55-year-old woman was admitted in our department for the management of a recurrent hypoglycemic coma. Endogenous hyperinsulinic hypoglycemia was confirmed with a spontaneous hypoglycemia. Plasma blood glucose was 0.25 g/l concomitant to a high insulinemia of 31.5 µUI/ml ($\geq$ 3) and C-peptide level of 3.16 ng/ml ($\geq$ 0.6) In imaging investigations, abdominal CT scan and endoscopic ultrasound were both normal. A complementary nuclear imaging by Octreoscan was performed and detected the presence of 2 pancreatic lesions: one in the uncinate process and the other in the tail. Abdominal MRI was performed and concluded to the presence of a unique lesion of the pancreas tail. Our patient was then proposed for surgery of the two insulinomas. Per-operative exploration concluded to the presence of a single corporal tumor mass of the pancreas of 1.5 cm. A left pancreatectomy was then performed. Our patient had resolution of symptoms after surgery. The follow-up is 6 months to date.

Conclusion

This case highlights the difficulty of the radiological identification of small pancreatic lesions leading to a multitude of imaging investigations. Our experience also highlighted that the ^{111}In-DTPA-octreotide uptake in pancreatic uncinate process may be physiological and its interpretation must, therefore, be cautious.

Insulinoma : a single-center retrospective analysis of 10 cases

Wafa Belabed, Fatma Mnif, Abdelmouhaymen MISSAOUI, Dhoha Ben Salah, Mouna Elleuch, Faten Haj Kacem Akid, Nabila Mejdoub & Mohamed Abid
Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction

Insulinoma is a rare neuroendocrine tumor with an incidence of 1 to 4 per million person-years. It is the most frequent endocrine tumor of the pancreas and is revealed by a spontaneous hypoglycemia. This study aimed to determine the clinical characteristics, diagnostic workup, and outcome of patients with insulinoma.

Methods

This is a descriptive, retrospective study including patients with confirmed insulinoma collected over a 32-year period. We collected imaging results, medical treatment, surgical management and histologic findings.

Results

A total of 10 patients were included in this study, with a sex ratio of 1,5. The mean age was 46 $\pm$ 15,5 years. Neuroglycopenic and neurogenic symptoms were present respectively in 9 and all cases. The median duration of symptoms was 47 months (3—360). All patients fulfilled Whipple's triad. On biochemical testing, hypoglycemia occurred at a mean glucose level of 1,8 $\pm$ 0,62 mmol/l and at a mean insulin level of 18,9 $\pm$ 6,4 mUI/l. The pancreatic lesion was identified on cross-sectional imaging in 6 cases and on endoscopic ultrasound in 3 cases. No lesion was identified in 1 case. The median tumor size was 1,9 $\pm$ 1,1 cm. Insulinoma was found in the pancreatic uncinate process in 2 cases; in the pancreas body in 4 cases and in the tail in 2 cases. Multiple insulinoma were found in 1 case and was associated to multiple endocrine neoplasia type 1. Surgical procedures included 2 enucleations and 7 pancreatic resections. Histologic findings concluded to benign endocrine tumors in all cases.

All patients had resolution of symptoms after surgery. The median follow-up is 6 years to date.

Conclusion

The diagnosis of insulinoma can be difficult. The average time between start of symptoms and diagnosis is estimated to be 3 years which is consistent with our case series as well. Our experience also highlighted that in cases where cross-sectional imaging failed to localize the pancreatic lesion, Endoscopic ultrasound could be useful.

Renal cell carcinoma revealed by acute adrenal insufficiency

Salma Abadlia, Bchir Najla, Zouaoui Chadia, Sarra Raddadi & Haroun Ouertani
Military Hospital, Endocrinology, Tunis, Tunisia

Introduction
Renal cell carcinoma (RCC) is the most common type of malignant renal tumors in adults. It is often difficult to detect it precociously since early-stage renal tumors are usually asymptomatic and non-palpable. We report a case of RCC revealed by acute adrenal insufficiency (AAI).
Case report
Mr. A.B, 46 years old, 30 pack-year smoker, with a medical history of gout treated with Allopurinol, was admitted to our department for acute adrenal insufficiency. The anamnesis revealed a significant weight loss, asthenia and melanoderma. The evolution was marked by acute abdominal pain with vomiting, leading the patient to consult our emergency department. A baseline blood sample revealed hyponatremia (127 mmol/l), hyperkalemia (6.4 mmol/l) and functional renal failure. The patient immediately received intravenous hydrocortisone hemi-succinate with hyperhydration. The diagnosis of primary AAI was confirmed by a low plasma cortisol level (99 nmol/l) in the face of high adrenocorticotropin hormone (ACTH) level (>2000 pg/ml). Adrenal computed tomography (CT) showed hypotrophic adrenal glands and a right corticomedullary renal mass (38*47*48 mm). Renal magnetic resonance imaging (MRI), performed for a better characterization of this mass, showed a right medio-renal tumor with a central necrotic zone and exophytic development, without signs of locoregional extension. A tumorectomy was performed. Anatomopathological examination revealed RCC.
Discussion
An AAI revealing a RCC has been reported in a few publications. In those cases, the adrenal insufficiency was related to bilateral adrenal metastases. However, in the present study medical imaging showed hypotrophic adrenal glands suggesting an auto-immune mecanism. Indeed, the increasing use of ultrasound, abdominal CT and more recently MRI has increased the diagnosis of renal cancers at a presymptomatic stage to nearly 70%.

Clinical and pathological features and phenotype-genotype correlation of pheochromocytoma and paraganglioma in a highly consanguineous population

Balgees Alghamdi, Meshael Alswailem & Ali Alzahrani
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Context
Pheochromocytoma and Paragangliomas (PPGL) are rare neuroendocrine tumors with a strong genetic background. In this report, our objectives are to understand the molecular genetics and the genotype/phenotype correlation of these tumors in the highly consanguineous population of Saudi Arabia.
Patients and methods
We studied 88 patients with PPGL and no known family history of these tumors. We extracted DNA from peripheral leucocytes and performed PCR-based Sanger sequencing of *RET, SDHA, SDHB, SDHC, SDHD, SDHAF2, VHL, MAX* and/or *TMEM127.* The order in which these genes were selected was based on the clinical phenotype following the Endocrine Society guidelines. When no genetic alteration was found, whole exome sequencing was performed. The clinical phenotype was correlated with the underlying mutations.
Results
Of the 88 patients included in this report, 30 (34%) were males, 58 (66%) were females with a median age of 43.5 years (interquartile range 26-53.7). No mutation was found in 42 patients (47.7%). The other 46 patients (52.3%) had an underlying PPGL-predisposing genetic mutations. The most commonly mutated gene was *SDHB* (11/88), followed by *SDHD* (8/88), *RET* (6/88) and *SDHC* (3/88). There was a tendency for more locally invasive and metastatic PPGL in the patients with underlying genetic alterations, especially SDHB mutations, but this did not reach statistical significance. Although the majority of patients achieved cure (60.5%), 26 patients (29.5%) had persistent/recurrent disease. There was no difference in the final outcome between those with underlying genetic mutations and those without mutations.
Conclusions
In this study, 52.6% of PPGL carry underlying genetic mutations. *SDHB* is the most commonly mutated and associated with higher risk of locally invasive and distant metastases. There is tendency towards locally invasive and distant metastases in those carrying underling mutations but the final outcome was similar between those with and those without underlying mutations.

Frequency of CYP1B1 gene polymorphism in obese and non-obese women with hormone-dependent endometrial cancer

Dusan Ilic[1], Sanja Ognjanovic[1], Bojana Popovic[1], Valentina Elezovic[1], Milica Opalic[2], Lena Radic[1] & Djuro P. Macut[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia

Aim
There is a significant link between the increased activity of estrogen and its metabolites in endometrial carcinogenesis. Polymorphisms of the gene involved in metabolism of estrogen can modulate risk for the development of endometrial cancer. CYP1B1 plays an important role in estrogen metabolism. In our study, the frequency of three *CYP1B1* gene polymorphisms (4326 C> G, 4390 A> G and 355 G> T) were studied in obese and non-obese women with endometrioid endometrial carcinoma and healthy controls.
Methods
Genotype were determined in DNA from peripheral blood lymphocytes of 44 women with endometrial cancer and 47 healthy age-matched controls by restriction fragment length polymorphism polymerase chain reaction (RFLP-PCR).
Results
Polymorphism 4326 C>G was verified in 70.5% of women with endometrial carcinoma and 59.6% of healthy controls ($P=0.277$). In the group of women with endometrial cancer, polymorphism 4326 C>G was verified in 72.2% obese and 69.2% of non-obese women ($P=0.831$). Polymorphism 4390 A>G was verified in 38.6% of women with endometrial carcinoma and 34.0% of healthy controls ($P=0.649$). In the group of women with endometrial cancer, polymorphism 4390 A>G was verified in 27.8% obese and 46.2% of non-obese women ($P=0.218$). Polymorphism 355 G>T was verified in 43.2% of women with endometrial carcinoma and 59.6% of healthy controls ($P=0.118$). In the group of women with endometrial cancer, polymorphism 355 G>T was verified in 44.4% obese and 42.3% of non-obese women ($P=0.888$).
Conclusion
There was no statistically significant difference in the frequency of the *CYP1B1* gene polymorphism in our group of women with endometrial carcinoma and healthy controls and in women with endometrial carcinoma irrespectively of their body mass index.

Ectopic parathyroid adenoma of the recurrent laryngeal nerve (RLN) chain lymph node

Loubna Guissi, Mohamed Hamid Abdillahi, Manal Azriouil, Kaoutar Rifai, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Parathyroid adenoma can be localized in an ectopic situation, especially at the mediastinal level. The localization at the level of the RLN chain lymph node has not been reported yet.
Case presentation
A 67-year-old woman without clinical signs of hyperparathyroidism, having undergone a left isthmolobectomy for a thyroid nodule suspected of being malignant, with intraoperative discovery of lymphadenopathy of the left RLN chain lymph node. The anatomo-histopathological analysis revealed a follicular adenoma and for the lymphadenopathy a morphological appearance in favor of a parathyroid adenoma which was confirmed by immunohistochemistry.The preoperative work-up was unremarkable with a calcium level of 98 mg/l (84-102) and albuminemia at 44g/l (32-46) and phosphoremia at 37 mg/l (23-47). The diagnosis of non-functional ectopic parathyroid adenoma of the RLN chain lymph node was discovered incidentally on histological study.
Conclusion
This case illustrates an unusual location of a non-functional ectopic parathyroid adenoma of the RLN chain lymph node.

Metastatic medullary thyroid carcinoma with diagnostic and therapeutic challenges: a case report

Hind Asbar, Hind Ouakrim, Sana Rafi, Ghizlane EL MGHARI & Nawal EL Ansari
Chu Mohamed Vi Marrakesh - Drh, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Medullary thyroid carcinoma (MTC) is a neuroendocrine tumor that arises from the parafollicular C-cells of the thyroid gland with a tendency to regional and distant metastases. It is a rare tumor, making up about 3% of all thyroid malignancies. MTC occurs in both heritable and sporadic forms, early diagnosis is important as it can improve treatment outcomes. We report a case of metastatic medullary thyroid cancer with both diagnostic and therapeutic challenges.
Case presentation
37-year-old man presented with anterior cervical mass. CT scan showed a cervico-mediastinal mass measuring 29 x 56 x 66 mm, with calcitonin level at 1890 ng/l. The patient underwent total thyroidectomy, with removal of the mediastinal mass and cervical lymph nodes. The pathology revelated initially a poorly differentiated malignant tumor proliferation of thymic origin. Immuno-histochemistry was in favor of a neuroendocrine carcinoma. An anatomical-pathological re-reading revealed a medullary thyroid carcinoma aspect with secondary mediastinal location. One year later, the cervico-thoracic CT scan showed a retro clavicular mass of 31.3 mm x 26 mm x 20 mm, with intimate contact with the left common carotid artery, end intra-parenchymal micronodules measuring 4.4 mm and 4.2 mm, in favor of metastasis. The patient underwent an exeresis of the mass with surgical difficulty due to the intimate contact of the tumor with the cervical vascular axis. The patient was thereafter referred to medical oncology for systemic treatment.
Discussion
Distant metastases in MTC are observed at presentation in 7–23% of patients, they often affect multiple organs including lungs, bones and liver, and they are frequently associated with persistent disease in the neck. Calcitonin and carcinoembryonic antigen (CEA) with conventional radiographic modalities are widely used for the diagnosis, prognosis, and follow-up of MTC patients. In our case, the metastatic MTC was diagnosed with difficulty in the anatomo-pathological reading, with a loco-regional recurrence presenting a difficulty in the surgical management.
Conclusion
MTC is a rare disease with a high risk of not being cured by the initial treatment. In cases of metastasis, the approach depends on the severity and rate of progression of disease. Metastatic MTC can be treated with limited surgical resection, or medical management with tyrosine kinase inhibitors (TKIs) or another agent.

Pro-inflammatory biomarkers in Papillary thyroid cancer

Ramesh Bangaraiahgari[1], RAmakanth Bhargav Panchangam[2], Rajesh Bangaraiahgari[3], Udaya Kumar U[4] & Sabaretnam Mayilvaganan[5]
[1]Arundathi Institute of Medical Sciences, Biochemistry, India; [2]Bhargav Endocrine Hospitals, Vijayawada, India; [3]Arundathi Institute of Medical Sciences, Anatomy; [4]Arundathi Institute of Medical Sciences, Pediatrics, India; [5]SGPGIMS, Endocrine and Metabolic Surgery, India

Introduction
Papillary thyroid carcinoma (PTC) is the most frequent endocrine malignancy. Apart from genetics, autoimmunity has been implicated in its pathogenesis. In this context, we set out study the role of Pro- inflammatory cytokines in PTC in South Indian population.
Material and methods
This prospective case-control study was conducted on surgically managed PTC patients. Institutional ethical committee approval was obtained. Diagnosis of PTC was based on imaging, fine needle aspiration cytology and later confirmed by histopathology. Exclusion criteria were subjects with any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 66 PTC subjects and 64 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in PTC and controls were 18.4 $\pm$ 3.1 mg/ml and 5.5 $\pm$ 1.2 mg/ml respectively. The mean TNF-α level, IL-6 level and Leptin levels were 294 $\pm$ 30 pg/ml, 12.8 $\pm$ 4.5 pg/ml and 1.97 $\pm$ 0.7 ng/ml respectively. Serum leptin level in controls was 3.4 $\pm$1.6 ng/ml. There was statistically significant difference of all the pro-inflammatory cytokines compared to controls (P value $<$ 0.05) with negative correlation for leptin levels.
Conclusions
Our study shows raised titers of pro-inflammatory markers – IL-6, TNF-α and hsCRP, while reduced leptin levels correlated with PTC suggesting a contributory role. But, the exact immuno-modulatory role and pathogenetic mechanism needs more research.
Key words: Papillary thyroid cancer; Tumour necrosis factor; Interleukin-6; Auto-immunity; Leptin

The different faces of a long-lasting metastasized pancreatic neuroendocrine tumor with calcitonin paraneoplastic secretion and cardiac carcinoid

Rucsandra Ilinca Diculescu[1], Iulia Florentina Burcea[1, 2], Anda Simona Dumitrascu[3], Cosmin Boldeanu[4], Madalina- Elena Iftimie[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary Pathology, Bucureşti, Romania; [2]"Carol Davila" University of Medicine and Pharmacy Bucharest, Department of Endocrinology, Bucharest, Romania; [3]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [4]County Hospital, Brăila, Romania

Introduction
Besides medullary thyroid carcinoma (MTC), increased calcitonin serum concentrations may be due, rarely, to neuroendocrine tumour (NET) ectopic secretion, especially those of the foregut (pancreatic/lung). Patients with NETs and right-sided heart failure due to cardiac carcinoid have a worse prognosis than those presenting without.

Case presentation
We present the case of a 72-year-old female with a history of an initially considered well-differentiated non-functional pancreatic NET who underwent three surgical interventions (2008 – body and tail pancreatic excision and splenectomy, 2012 - portal vein invasion and thrombosis, 2015- removal of liver metastases). Immunohistochemistry (IHC) showed positive reactions for CK19, CK7, vimentin, chromogranin A, synaptophysin and NSE in the primary tumour, with positive chromogranin A, synaptophysin and Ki-67 of 10% in the portal vein tumour. Since the first manifestations of the carcinoid syndrome (2015) she has been treated with Octreotide LAR (maximum dose 60 mg/day). She also received chemotherapy: FOLFOX in 2015, and after a voluntary drug holiday, Irinotecan was administered between 2017-2018 and 2020-2021. After the first course of Irinotecan, radiological regression of the hepatic hilum lymph nodes and VI segment nodules (abdominal CT scan, 2016) was noted, whereas without any chemotherapy treatment (2018-2020), abdominal MRI showed progression of the hilum and hepatic nodules. In 2021, under the second Irinotecan course, tumoral growth was noticed, so chemotherapy was stopped and targeted therapy with Sunitinib was introduced. The patient developed cardiac carcinoid (elevated NT-proBNP, 239.4 pg/ml in March 2021), associating a mild tricuspid regurgitation. All neuroendocrine tumour serum markers were within the normal range from diagnosis until now, except for calcitonin serum levels, reaching levels as high as 2452 pg/ml in 2021, currently with decreasing values. The patient also associates secondary diabetes under insulin therapy, permanent levothyroxine substitutive treatment for postoperative hypothyroidism (2009, microfollicular adenoma) and secondary hyperparathyroidism due to vitamin D deficiency.
Conclusion
We presented a complex case of a patient with pancreatic NET who underwent multimodal treatment, associated with paraneoplastic calcitonin hypersecretion and cardiac carcinoid. Calcitonin-secreting NETs are rare, studies reporting that gastroenteropancreatic-NETs with high serum calcitonin have a worse prognosis that those with normal calcitonin. High calcitonin in NETs is associated with high-grade tumours, our case being of intermediate grade, further studies being needed to confirm the link between calcitonin and the clinical outcome of patients with NETs. Nozières C et al, Neuroendocrine tumors producing calcitonin: characteristics, prognosis and potential interest of calcitonin monitoring during follow-up. EJE. 2016 Mar;174(3):335-41.

A NEM 2A with mutation in a gene outside panel ROTERC

Mohamed Abdellahi Mohamed Ahmed[1], Nabila Mejdoub[1], Guidara Souhir[2], Dhoha Ben Salah[1], Mouna Mnif[1], Faten Haj Kacem Akid[1] & Mohamed Abid[1]
[1]Department of Endocrinology and Diabetology CHU Hedi Chaker Sfax, Tunisia; [2]Faculty of Science, Sfax

Introduction
Multiple endocrine neoplasia type 2 is an inherited syndrome characterized by the characteristic combination of medullary thyroid cancer, pheochromocytoma and primary hyperparathyroidism. We report one case with phenotype-genotype mismatch.
Observation
Patient A. T is 45 years of age with a family history of thyroid bone marrow cancer (CMT) and sister brain cancer, father colon cancer, with no personal history of disease. A 60 mm long-axis left adrenaloma during a nephretic colic test with 4* normal urinary metanephrins. The diagnosis of primary hyperparathyroidism was raised in the presence of hypercalcemia: 2.9 mmol/l, Phosphoremia: 0.7 mmol/l and confirmed by normal PTH *. The topographic assessment concluded a parathyroid adenoma and a multinodular goiter. The absence of medullary thyroid cancer (CMT) decreased the probability of NEM2A but this is still possible. The patient received a left adrenalectomy. A The genetic study did not reveal any pathogenic variant or VSI.
Discussion-Conclusion
The association of pheochromocytoma, hyperparathyroidism and multinodular goiter, as well as the family history of CMT and cerebral cancer in the sister and colon cancer in the father, suggested a mutation that does not belong to the ROTERCC panel. Our observation attested to the value of conducting a genetic study for personalized medical care of patients and for establishing genetic counseling for patients and their families.

Medullary thyroid Cancer, an experience from a tertiary care hospital of a developing country

Sajjad Ali Khan, Abdul Aziz, Umer Arif Esbhani & Muhammad Qamar Masood
Aga Khan University Hospital (AKUH), Department of Medicine and Section of Endocrinology, Karachi, Pakistan

Background
Medullary thyroid carcinoma is a rare type of thyroid cancer that is either sporadic or familial. It occasionally occurs alongside parathyroid hyperplasia and pheochromocytoma as part of MEN2A. Our aim was to study the presence and patterns of above mentioned characteristics of medullary thyroid carcinoma in our population.
Methodology
This is a retrospective study conducted in a tertiary care hospital of Pakistan in which data of medullary thyroid cancer over past 20 years was reviewed. Data from 32 patients was analyzed after fulfillment of the inclusion criteria. Their clinical, pathological, biochemical and treatment outcomes were recorded through retrospective review of their medical record files.
Results
The mean age of patients with medullary thyroid carcinoma (MTC) was 42.88 + 2.67 in our study, with male to female ratio of 2:1. 68.8% of MTC patients were sporadic and 31.2% were familial in our study. 81.3% of patients presented with neck swelling, lymph nodes were palpable in 43.8% of patients and distant metastasis were present in 25% of the patients. The rates of metastasis were highest in bones followed by lungs and liver (12.5%, 9.4%, and 3.1% respectively). Histologically, the mean tumor size was 7.62 + 3.64 with 8 (25%) having distant metastasis. Lymph node metastasis was present in 19 (59.3%) of the patients, out of which 16 had bilateral involvement. Over 50% of carcinomas in our study were unifocal, followed by bifocal (21.9%) and multifocal 3 (9.4%). Mean pre-surgery calcitonin was 11225.7 + 4043.57 which then decreased to a mean of 244.43 + 113.48 post surgery. Mean pre-surgery CEA level was 25.08 + 7.23 which then decreased to 0.0645 + 0.044 post surgery. Hyperparathyroidism was found in two patients while pheochromocytoma was found in one patient only. Two patient were positive for RET gene mutations. Total thyroidectomy was done in 26 (81.2%) of the patients while one patient had subtotal thyroidectomy followed by complete thyroidectomy as initial FNAC was Bethesda category 3. Surgery was not performed in 5 patients due to distant metastasis or palliative intent. Chemotherapy was given to only one patient while XRT was performed in two patients.
Conclusion
Medullary thyroid carcinoma usually presents in fourth decade of life with male predominance and mostly sporadic occurrence. Total thyroidectomy with subsequent serial calcitonin and CEA levels thereafter are the mainstay of treatment and follow-up.

Refractory papillary thyroid carcinoma treated with sorafenib: an Algerian experience

Amira Bouchenna[1], Abdelghani Tibouk[1], Ghennam Brahim[2] & Ould Kablia Samia[3]
[1]Central Hospital Of Army, Anatomopathology, Algeria; [2]Central Hospital Of Army, Nucleary, Algeria; [3]Central Hospital Of Army, Endocrinology, Algeria

Introduction
5-10% of papillary thyroid carcinoma develop metastatic disease, of which about 60-70% will become refractory to radioactive iodine. Significant negative impact on the prognosis and an average life expectancy of 3 to 5 years.
Material and method
Since 2018, patients with refractory thyroid carcinoma and considered to be progressive according to the RECIST criteria have been treated with anti tyrosine Kinase type sorafenib.
9 patients treated: an anaplastic carcinoma, a medullary carcinoma and 7 differentiated carcinomas. 3 women/6 men, average age: 56 years old. Tumor regression was observed in 3 patients but stopped in 2 due to the onset of a serious side effect, with rebound phenomenon in one of them; lesion stability in 3 patients; disease progression leading to discontinuate the treatment in 3 patients.

Discussion
Refractory thyroid cancers are rare but responsible for the majority of cancer-related deaths. The use of kinase inhibitors has improved the outcome of these patients.
On the other hand, in addition to their high cost, they have a notable toxicity, responsible of major side effects impairing the quality of life, for an uncertain response. Due to the complexity of these treatments, these patients are at best managed by multidisciplinary groups.

Hungry bone syndrome in the post-operative management of severe primary hyperparathyroidism: a case report

Loubna Guissi, Manale Azriouil, Khawla Gorgi, Kaoutar Rifai, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Hungry bone syndrome (HBS) is a rare complication of parathyroidectomy for primary hyperparathyroidism. We report a case of HBS after parathyroid surgery for severe primary hyperparathyroidism.
Case presentation
A 46-year-old woman was admitted with generalized weakness and difficulty walking due to progressive worsening of low-back pain. Clinical examination revealed tachycardia at 110 bpm and chest deformity. Laboratory results revealed hypercalcemia at 185 mg/l and hypophosphatemia at 19 mg/l. The parathyroid hormone (PTH) concentration was at 4936 pg/ml (normal 15–65) and the alkaline phosphatase concentration reached478 U/l (normal 40–150). Medical treatment was initiated with rehydration, forced diuresis and intravenous infusion of biphosphonates. Ultrasound of the neck and Sestamibi scan showed a localized adenoma. The parathyroidectomy was performed and anatomopathological examination confirmed parathyroid adenoma, weighing 4 g and measuring 3*2*0.6 cm. The postoperative period was characterized by prolonged hypocalcemia, hypophosphatemia and normal PTH levels, which was consistent with the diagnosis of HBS. The patient was discharged on high doses of calcium carbonate and alfacalcidol.
Discussion
HBS refers to the rapid, profound, and prolonged hypocalcaemia associated with hypophosphatemia and hypomagnesaemia, and is exacerbated by suppressed PTH levels, which follows parathyroidectomy in patients with severe primary hyperparathyroidism and preoperative high bone turnover. Although HBS does not have a consensus definition, most resources define it as profound hypocalcemia of less than 8.4 mg/dl that persists for more than four days post-operatively. The severe hypocalcaemia is believed to be due to the greatly increased skeletal usage of calcium, thought to occur as a result of removal of the effect of high circulating parathyroid hormone (PTH) levels on bone, with immediate arrest of bone resorption in the face of continuing and enhanced bone formation. The duration of the HBS is the time taken to remineralise the skeleton, which is also mirrored by normalisation of bone turnover markers, by healing of radiological features of osteitis fibrosa cystica and brown tumours and by significant gains in bone mass. Treatment is aimed at replenishing the severe calcium deficit and at restoring normal bone turnover with the use of high doses of calcium and active metabolites or analogues of vitamin D.
Conclusion
HBS is relatively uncommon, but a serious side effect of parathyroidectomy. It can bring significant morbidity related to the consequences of hypocalcaemia in the case of patients in whom it is not recognized and corrected promptly.

A rare case of gonadotropin independent precocious puberty in young child

Lakshman Kumar Ega[1], Rakesh Sahay[2] & Neelaveni Kudugunti[3]
[4]Osmania Medical College, Endocrinology, Hyderabad, India; [2]Osmania Medical College, Endocrinology, Hyderabad, India; [1]Osmania Medical College, Endocrinology, Hyderabad, India

Introduction
Adrenocortical carcicnoma (ACC) is a rare malignancy with overall incidence of 0.7–2.0 cases/million. It's a rare & aggressive childhood cancer with a reported incidence of 0.2– 0.3 new cases per 1 million. It has Bimodal distribution - at first decade - 85% functional & 5-6th decade of life 15-30% functional. Paediatric virilising adrenal tumours have a better prognosis after complete resection than in adults. Surgery is the mainstay of treatment. Even after complete resection, a high risk of recurrence of ACC remains. 2yrs 3months – 1st born male child brought by parents with complaints of appearance of pubic & axillary hair, enlargement of both breasts, accelerated height gain, increase in penile length without any increase in testicular size. On examination a palpable mass was noticed in right hypochondrium which was firm in consistency. A provisional diagnosis of Gonadotropin independent precocity (GIPP) due to adrenal mass lesion was made. Biochemical and Radiological evaluation was suggestive of Adrenocortical cancer. Subsequently child underwent Right adrenalectomy. Postop was uneventful and he was discharged on Day 6.
Discussion
Here is a male child with Premature development of axillary, pubic hair with features of androgenisation, Increase in penile length without Increase in testes size, with B/l Gynaecomastia, accelerated Ht gain, with palpable mass in RUQ which Implies -Precocious Puberty of Peripheral origin (Gonadotropin Independent) due to Adrenal neoplasm.
Conclusion
Though ACC is a rare cause of GIPP in paediatric age group, this entity should be considered in differential diagnosis.

The development of a GLP protocol for the measurement of 17β-estradiol and testosterone in the H295R steroidogenesis assay, Test No 456

Carol Murray[1], Angela McIntyre[1], Connor McKeever[1], Rebecca White[1], Rachel McBrinn[1], Victoria Light[2], Susan Brown[1], Aron Robinson[1], Graeme Clark[1] & Tilly Bingham[3]
[1]Concept Life Sciences, Dundee, United Kingdom; [2]Concept Life Sciences, Bradford, United Kingdom; [3]Concept Life Sciences, Chapel-en-le-Frith, United Kingdom

Regulators are concerned about the potential for environmental chemicals such as agrochemicals and their metabolites to perturb hormone systems. This has led to recommendations for the testing of potential endocrine disrupting chemicals[1]. The Steroidogenesis H295R assay is an *in vitro* cell model used to investigate compound effects on steroid hormone biosynthesis, specifically 17β-estradiol (E2) and testosterone (T). The human H295R adreno-carcinoma cell line expresses genes that encode for all the key enzymes for steroidogenesis and thus forms one of the required OECD *in vitro* tests (TG456) for the assessment of potential endocrine disrupting chemicals[2]. Although it is possible to assess hormone levels with ELISA we elected to perform the TG456 assay with LC-MS/MS hormone detection, avoiding the test item interference issues reported for immunoassay-based readouts. We describe herein the implementation of a robust GLP bioanalytical method for the detection of testosterone and 17β-estradiol in the steroidogenesis assay, to LLOQ levels of 10 pg/ml for each hormone. This method has been used to correctly identify inducers and inhibitors of T and E2 production while remaining unresponsive to a negative chemical. We present the impact this has on assay performance with respect to the proficiency items and discuss the benefits of the optimised bioanalytical protocol on Test No 456 performance.

Clinical and demographic analysis of the structure of telemedicine "doctor-patient" consultations of the Endocrinology Research Centre

Anna Gorbacheva, Oksana Logvinova, Anna Eremkina & Natalia Mokrysheva
Endocrinology Research Center, Moscow, Russian Federation

Rationale
The COVID-19 pandemic has accelerated the development of telemedicine technologies. Today there is evidence of the successful use of telemedicine in various areas of healthcare, particularly in endocrinology. At the same time, there is not enough information for efficient integration of telemedicine into the routine management of patients.
Aim
The aim of this work was a clinical and demographic analysis of "doctor-patient" telemedicine consultations (TMC) conducted at the Endocrinology Research Centre (Moscow, Russian Federation) in 2020-2021.
Materials and Methods
A cross-sectional, single-centre, retrospective study was conducted. The study included all patients who received at least one TMC at the Endocrinology Research Centre in 2020-2021. Clinical and demographic information was analyzed (gender, age, region of residence, disease code according to ICD-10). All patients signed an informed consent for the telemedicine consultation. The received data were processed using the Microsoft Office software.
Results
In 2020, 1548 TMC were held, in 2021 - 4180 TMC. Among adults, women predominated in the structure of TMC (83-86%), among children there is a tendency towards equivalent appeals for boys and girls (in 2021 - 45% and 55%, respectively). The median age of adult patients in 2021 was 38 years [31;53], among children - 11 years [7;14]. In 2020, residents of 74 regions of the Russian Federation applied for TMC, in 2021 - of 82 regions. There is a tendency for patients from the Central, Volga, Southern and North Caucasian federal districts to predominate in the structure of TMC. In the nosological structure of TMC among adults diseases of the thyroid gland (35.2%), parathyroid glands (6.8%), diabetes mellitus types 1 and 2 (5.8%), ovarian dysfunction (5.6%) and obesity (4.7%) predominated. In children, TMC the most frequent nosologies were type 1 diabetes mellitus (49.8%), thyroid diseases (13.9%), adrenogenital disorders (5%), and polyglandular dysfunction (4.3%).
Conclusion
TMC proved to be in demand in patients with a variety of endocrinopathies. It is important to analyze both the TMC market and the effectiveness of remote counseling for various nosologies in order to determine the place of telemedicine in the modern healthcare structure and introduce TMC into the system of clinical recommendations.

Exposure to the endocrine disruptor cadmium alters human aortic endothelial cells homeostasis

Giuseppina Catanzaro[1], Claudia Sabato[1], Viviana Maria Bimonte[2], Zaira Spinello[1], Agnese Po[3], Zein Mersini Besharat[1], Alessandra Vacca[1], Silvia Migliaccio[2] & Elisabetta Ferretti[1]
[1]Sapienza University, Experimental Medicine, Rome, Italy; [2]Foro Italico University, Movement, Human & Health Sciences, Rome, Italy; [3]Sapienza University, Molecular Medicine, Rome, Italy

Cardiovascular diseases (CVDs) represent a complex and multifactorial issue that results from a combination of behavioural, genetic and environmental factors. Toxic metal contaminants, many of which act as endocrine disruptors (EDs), have been identified as potential risk factors for CVDs. Among EDs Cadmium (Cd), present both in cigarettes and in food, has been suggested to be cytotoxic on vascular endothelium, likely leading to blood pressure increase and vascular inflammation. We previously demonstrated that Cd exposure increased TNF-α, IL-6 and IL-8 mRNA in HUVEC endothelial cells. The aim of this study was to further evaluate and characterize the potentially detrimental effect of Cd exposure on Endothelial cells. The effect of Cd exposure on the vascular system was evaluated by using a human *in-vitro* model for vascular endothelial cells, the human Aortic Endothelial Cells (HAEC). Firstly, we evaluated HAEC morphology after 24 h exposure to increasing Cd concentrations, ranging from 1 to 10 μM. Cd induced a collapse of cytoskeleton, with a toxic effect already evident upon treatment with 1 μM. The effect on cellular morphology was accompanied by a reduction of cell proliferation and an increase in cell death. In addition, the Bax/Bcl2 ratio increased. Moreover, Cd affected the expression of pro-inflammatory cytokines, showing an increase of both IL-6 and IL-8 upon 5 and 10 μM Cd exposure, confirming our previous results obtained in HUVEC. Accordingly, a decrease of endothelial adhesion molecules, such as V-CAM and I-CAM, was observed. In conclusion, our results suggest that Cd exposure affects HAEC morphology and behaviour inducing cytotoxicity and apoptosis. In addition, already at low concentration, Cd exposure induces a pro-inflammatory state with production of pro-inflammatory cytokines and reduction of endothelial adhesion molecules, strongly suggesting that this heavy metal is able to alter endothelium homeostasis.

Epidemiological characteristics and psychological distress of well-controlled endocrine outpatients from Crete, Greece during the COVID-19 Pandemic: preliminary results of the EPITOME study.

Panagiotis-Nikolaos Tsakalomatis[1], VASILIKI DARAKI[1], Theano Roumeliotaki[2], Grigoria Betsi[1], Maria Chrysoulaki[1], Maria Sfakiotaki[1], Eleni- Konstantina Syntzanaki[1], Rodanthi Vamvoukaki[1], Kalliopi Kontolaimaki[1], Vasiliki Venetsanaki[1], Kyriakos Nicolaou[1], Polyxeni Anomerianaki[1], George Mavrakis[1], Katerina Bouki[1], Panagiota Goulia[3] & Paraskevi Xekouki[1]
[1]University General Hospital of Heraklion, Endocrinology & Diabetes Clinic, Heraklion, Greece; [2]University of Crete, Department of Social Medicine, Heraklion, Greece; [3]Fulbourn Hospital, Cambridgeshire and Peterborough NHS Foundation, Cambridge, United Kingdom

Aim
To explore the epidemiological characteristics and symptoms of psychological distress of well-controlled endocrine patients without a diagnosis of a psychiatric disorder attending the Endocrine outpatient clinic of the University Hospital, Heraklion, Crete, Greece during the COVID-19 pandemic. **Methods**: Eighty-four patients participated by completing questionnaires about demographics, endocrine diagnosis, covid infection, preventive measures, vaccination status, source of support and lifestyle changes. Psychological distress was assessed by means of the Greek version of the DASS 21 questionnaire. Ethical approval was obtained by Institutional Review Board and all participants provided written informed consent.
Results
Participants' mean age was 50.8 years; 76.2% were female, 68.7% married and 57.8% employed. Most common endocrinopathies were thyroid diseases, diabetes mellitus and pituitary disorders. Only two patients had been infected with COVID-19 and 31% were a close contact to a COVID-19 patient. The level of adherence to COVID-19 preventive measures was 96.4%, whereas 21.7% hesitated to visit a healthcare professional due to the fear of becoming infected. Sixty-four (77.1%) had at least one dose of the COVID-19 vaccine. The majority cited family as their supportive network (84.3%) followed by friends and neighbors (16.9%) and only 2.4% the social services. Forty-one reported changes at eating habits and thirty one had gained weight; twenty-three had decreased their physical activity and thirty-one dropped hobbies due to the pandemic. Approximately one in four reported sleep difficulties. The majority did not present symptoms of stress (71.43%), anxiety (80.52%) or depression (80.3%). Patients with chronic endocrine disease reported stress symptoms less frequently. **Conclusions**: This is the first study in Crete, Greece regarding social parameters and psychological distress due to the COVID-19 pandemic in endocrine patients.

Our participants follow the recommended preventive measures and are mostly vaccinated. They would seek help from family and friends if required and do not rely on state-provided sources for support. Contrary to numerous studies indicating that depression and anxiety increased during the present pandemic, we found that our sample had low rates of moderate/severe anxiety/depression. We hypothesize that this is related to the well-controlled endocrine problems, and to protective factors such as marital status, employment, family support, as well as the vaccination status and compliance with preventive measures. This is an ongoing study with an aim to define whether different demographics and social parameters may influence levels of distress in this patient group and to develop strategies which may improve well-being during severe crises in endocrine patients.

Comparison of perceived sufficiency of information, sources of information, worries about the pandemic and psychological distress between endocrinology patients and staff at the outpatient department of the university hospital, heraklion, crete greece: preliminary results of the EPITOME study

Vasiliki Daraki[1], Panagiotis- Nikolaos Tsakalomatis[1], Theano Roumeliotaki[2], Grigoria Betsi[1], Maria Chrysoulaki[1], Maria Sfakiotaki[1], Eleni- Konstantina Syntzanaki[1], Vasiliki Venetsanaki[1], Rodanthi Vamvoukaki[1], Kalliopi Kontolaimaki[1], Kyriakos Nicolaou[1], George Mavrakis[1], Polyxeni Anomerianaki[1], Katerina Bouki[1], Panagiota Goulia[3] & PARASKEVI XEKOUKI[1]

[1]University General Hospital of Heraklion, Endocrinology & Diabetes Clinic, Heraklion, Greece; [2]University of Crete School of Medicine, Department of Social Medicine, Heraklion, Greece; [3]Fulbourn Hospital, Cambridgeshire and Peterborough NHS Foundation, Cambridge, United Kingdom

Background
Psychological distress is elevated during pandemics such as the COVID-19 outbreak both in health care professionals and patients.
Aim
To compare worries about the COVID-19 pandemic, need and sources of information, and psychological distress between endocrinology patients and staff at an outpatient department of the University Hospital, Heraklion, Crete, Greece
Methods
One hundred and four patients and sixty members of staff completed questionnaires about demographics, need for information, sources of information, worries about the COVID-19 pandemic and the Greek version of the DASS-21 for psychological distress. Ethical approval was obtained by Institutional Review Board and all participants provided informed consent.
Results
Mean age of staff was 41.2 years and patients 50.6 years (<0.001), with predominance of women in both groups. The majority of both groups stated that they worried about the pandemic reporting a moderate degree of worry. Main worry was the risk of contagion and infection of their family, and this was more prevalent for staff ($P=0.036$). Regarding the need for information on a 5-item Likert scale (1: prefer having no more information than needed; 5: prefer as much information as possible) both groups reported moderate degrees of information needs. Regarding specific aspects of COVID-19 infection, staff was better informed about symptoms, prognosis, infection route, preventive measures (p, 0.001, 0.032, 0.001, 0.047 respectively) with no differences about information on treatment and the COVID-19 vaccine, compared to patients. Both groups preferred formal sources of information. Staff relayed mainly on information by health professionals ($P=0.006$) whilst patients showed an additional preference for informal sources ($P=0.022$). There were no differences in stress and anxiety symptoms between the two groups, which showed low rates of both; few participants displayed moderate/high symptoms of depression, and these were mostly in the staff group ($P=0.040$).
Conclusions
The current study highlights differences between endocrine patients and staff regarding their main worry about the pandemic with staff being more worried about the safety of family/relatives likely due to their higher chance of exposure. Although both groups were informed by formal sources, staff was more informed on most aspects of COVID-19, but this did not include treatment and the COVID-19 vaccine, perhaps due to the scarcity of studies. Among participants, staff reported more often moderate/severe symptoms of depression. These results are relevant when designing policies on information on pandemics and supportive measures for patients and staff in General Hospitals.

Perception of training and job perspectives of the specialty of Endocrinology and Nutrition among final-year residents.

Joaquin de Carlos[1], Luci Zabalza[1], Ana Zugasti Murillo[1] & María Dolores Ballesteros-Pomar[2]

[1]Hospital Universitario de Navarra, Pamplona, Spain; [2]Complejo Asistencial Universitario de León, León, Spain

Introduction
Medical specialization model in Spain is carried out through specialized health training, through the residency program. Residents are a key element for the proper functioning of today's National Health System. The aim of the study is to analyze, by an anonymous survey, the opinion of three aspects among final-year residents in Endocrinology and Nutrition (E&N): self-assessment of the knowledge acquired, working prospects, care and training consequences arising from the pandemic COVID-19.
Materials and methods
Cross-sectional observational study using a voluntary and anonymous online survey, shared among final-year national interns in the last year of the E&N program, carried out between June-July 2021. The survey consisted of 20 questions. The results were analyzed with the SPSS version 25 statistical program.
Results
Fifty-one responses were obtained, 66% of the residents, most of them from the central region of the country. Fifty-nine percent of the respondents were trained in tertiary hospitals with more than 800 beds compared to 41% who were trained in centers with between 200-800 beds. Overall perception of their knowledge was 7.8 out of 10, being diabetes and thyroid the best rated sections, followed by nutrition, pituitary, adrenal and finally lipids. Most external rotations were in thyroid and nutrition areas. A total of 96.1% residents, carried out some activity associated with COVID-19, with a training deterioration of 6.9 out of 10. 88.2% have cancelled their rotations and 74.5% have extended their working schedule. The average negative emotional impact was 7.3 out of 10. Most of them carry out research work, spending time out of their working day to do so. 80.4% would like to continue in their training hospital, remaining 45.1%. 56.7% have an employment contract of less than 6 months, most of them practicing Endocrinology.
Conclusion
The perception of the knowledge acquired during the training period is a 'B'. Residents consider that the pandemic has led to a worsening of their training, generating a negative emotional impact. Employment outlook after completing the residency can be summarized as: temporality, practice of Endocrinology and hospital mobility.

Bisphenol-A and Pentocholorophenol Sodium Levels in Patients with Acne Rosacea

Deniz Demircioglu[1], Nese Cinar[2], Suzan Demir Pektas[3], Tuba Edgunlu[4], Mustafa Unal[5] & Duygu Yazgan Aksoy[6]

[1]Acıbadem University Faculty of Medicine, Department of Dermatology, Istanbul, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolism, Mugla, Turkey; [3]Mugla Sitki Kocman University Faculty of Medicine, Department of Dermatology,

Mugla, Turkey; [4]Mugla Sitki Kocman University Faculty of Medicine, Department of Medical Biology, Mugla, Turkey; [5]Istanbul Haseki State Hospital, Department of Endocrinology and Metabolism, Istanbul, Turkey; [6]Acıbadem University Faculty of Medicine, Department of Endocrinology and Metabolism, Mugla, Turkey

Objective
Rosacea is an inflammatory dermatosis. Telangiectasias, edema, erythema, and acneiform eruptions are the main symptoms. Several genetic and environmental factors have been linked to rosacea; however, the etiology of the disease is still not known. It is considered a systemic disease rather than a skin disorder. Endocrine-disrupting chemicals are substances people are exposed to through water, food, self-care products, and the environment. They interfere with normal hormonal functions and can also enter the body through the skin. Bisphenol A (BPA) and pentachlorophenol sodium (PCS) are two substances associated with different diseases. The possible association of these substances with rosacea is not known. We aimed to determine BPA and PCS levels in patients with rosacea.
Methods
We conducted a prospective study in a training hospital. Thirty-four patients with Rosacea (18F/16M; mean age 48.5 ± 11) and 34 age and sex-matched healthy controls (20 F/14 M; mean age 48.2 ± 10.2) were included. Main anthropometric measures, plasma glucose (FPG), insulin, lipids, TSH, BPA, and PCS levels were measured.
Results
Age, weight, BMI, FPG, and TSH were similar between the two groups. CRP levels were higher in patients with rosacea (9.6 ± 3.4 and 3.7 ± 1.6 for patients and healthy controls, respectively, $P < 0.001$). Serum BPA levels were 55.8 ± 14.4 and 51.9 ± 19.2, and PCS levels 63.3 ± 45.9 and 68.6 ± 40.8 for patients and healthy controls, respectively. There was no significant difference between BPA and PCS levels ($P > 0.05$).
Conclusions
CRP levels were higher with patients with rosacea compared to healthy controls; however, BPA and PCS levels were not different from healthy controls.

Histology of the diffuse endocrine system of the lungs in ontogenesis and in pathological conditions in uzbekistan

Madina Adkhamova[1], Gulnoza Goyibova[1] & Dilfuza Karimova[2]
[1]Tashkent Medical Academy, Department of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Medical Academy, Tashkent, Uzbekistan

Background
The study of fundamental questions related to the analysis of recent advances in the field of cellular and molecular pathways involved in lung organogenesis provides a basis for understanding the pathogenesis of acute and chronic diseases of this organ. Cells of the diffuse endocrine system - apudocytes (APUD) absorb the precursors of biogenic amines introduced from the outside and subject them to decarboxylation with further formation of biogenic amines and peptide hormones. The APUD system also includes innervated clusters of endocrinocytes - neuroepithelial bodies (NETs).
Purpose
Identification in a comparative aspect of the features of the structure of the endocrine apparatus of the APUD-system of the lungs during embryogenesis, as well as in the pathology of the organ caused by inflammatory processes. Material and methods. We studied histological preparations of the lungs in human fetuses at 9-28 weeks of fetal development and full-term newborns.
Results
By the 11th week of their embryonic development, intralobular bronchi appear, the same picture is observed in fetuses of 12 and 13 weeks. Cartilaginous plates are found only in the walls of the lobar and segmental bronchi. In the lungs of fetuses of 9-10 weeks of development, endocrine cells in the epithelium of the bronchi and in the epithelial tubules are not found. Starting from 11 weeks, argyrophilic apudocytes and NET are detected in the large bronchi. In the tubular and alveolar stages of histogenesis, the number of endocrine structures increases, and it is especially significant in the distal parts of the bronchial tree. It should be noted that the branching of the bronchial tree is ahead of the development of the endocrine apparatus in it. Open-type cells are found in the proximal sections of the bronchial tree, while closed-type cells are found in the distal ones. Apudocytes and NETs are found in all children with inflammatory lung disease. Their number is much greater than in the lungs of children who died from diseases not related to the respiratory organs. Closed-type apudocytes are often found in the bronchial epithelium.
Conclusions
We found that open-type apudocytes appear in large bronchi during the development of the lungs, i.e., earlier generations of branching of the airways. Closed-type apudocytes are more characteristic of newly formed bronchial tubes. NETs during lung development appear later than apudocytes and are also more numerous in the developing small bronchi and respiratory region.

Effect of nighttime melatonin intake on vitamin D levels

Sana Fendri[1,2], Naifar Manel[1, 2], Kamel Ichrak[3], Hammouda Omar[2, 3], Bouzid Imen[1], Turki Mouna[1, 2] & Ayadi Fatma[1,2]
[1]Habib Bourguiba Hospital, Laboratory of Biochemistry, Sfax, Tunisia; [2]Faculty of MedIcine, Research Laboratory 19 es 13, Sfax, Tunisia; [3]Higher Institute of Sport and Physical Education of Sfax, Tunisia

Introduction
Melatonin is involved in many physiological processes, including the regulation of circadian rhythms, sleep, antioxidant effect, aging, tumor growth, reproduction and bone formation. The latter function is also regulated by the metabolism of vitamin D. Our goal during this study is to detect a possible increase in vitamin D levels under the effect of exogenous melatonin.
Participants and methods
Different anthropometric parameters were collected (weight, height, body mass index, percentage of fat). The experimental protocol is carried out in a randomized clinical trial between an overnight intake (around 9 p.m.) of melatonin and double-blind placebo, once in the middle of the follicular phase and once in the middle of the luteal phase. The dose is determined at around 9 a.m. the next day, using an immuno-electro-chemiluminescence method on the Cobas 6000 analyser from Roche.
Results
Ten healthy young women between the ages of 20 and 23 were included in our study after obtaining their consent. The mean age of the participants was 21.63 ± 0.94 years. The average height of our patients was 165.72 ± 3.38 m. the average weight of our patients was 59.45 ± 3.5 kg. Vitamin D levels were significantly higher after taking melatonin (mean 13.6 ± 7.9 ng/ml) than after taking placebo (mean 12.68 ± 5.7 ng/ml) during the follicular phase ($P = 0.001$). Whereas, the increase in vitamin D with the intake of melatonin (mean of 15.8 ± 7.8 ng/ml) compared to the taking of placebo (mean of 14.6 ± 5.7 ng/ml) was not significant during the luteal phase ($P = 0.7$). In addition, there was no significant variation in vitamin D levels between the luteal phase and the follicular phase when taking placebo ($P = 0.07$) and when taking melatonin ($P = 0.25$).
Conclusion
Melatonin can regulate the metabolism of vitamin D. indeed the vitamin D receptor can act as a nuclear receptor for melatonin. Further studies are essential to better explain the relationship between melatonin and vitamin D according to menstrual cycles.

Recurrent hypoglycemia : looking for an unsual cause

Chtioui Sara, Ijdda Sara, Rafi Sanaa, Ghizlane EL Mghari & Nawal EL Ansari
Med VI University Hospital Center, Endocrinology, Diabetology and Metabolic Diseases Department, Marrakech, Morocco

Hypoglycemia in non-diabetic patients is a rare event, and autoimmune hypoglycemia with the presence of positive anti-insulin antibodies is even rarer. We report the case of a 15 years old non diabetic female patient, she was referred to our hospital for recurrent hypoglycemia for 2 weeks before admission to hospital, these are severe hypoglycemia with impaired consciousness. The first step was to eliminate the general causes and factitious hypoglycemia. Adrenal insufficiency was also ruled out. A 72-hour fasting test was performed and the peptide C assay (<0.15 ng/ml), and Insulinemia (<1 mUi/l) were not in favor of endogenous insulin secretion. Autoimmune origin was suspected. The dosage of anti-insulin antibodies was realized with a positive result of 0.7 (Normal: 0.4). The patient was put on corticosteroid therapy with a regression of hypoglycemic episodes, pending the results of the anti-insulin antibodies after 2 months of corticosteroid therapy. The case of our patient illustrates the importance of an exhaustive exploration in the face of hypoglycemia and of thinking about the autoimmune cause, which remains rare, especially in non-diabetic patients.
Keywords Hypoglycemia-non-diabetic-autoimmune-insulin.

Di-Butyl-Phthalate (DBP) exposure impact on human masculine reproductive hormones. A review of literature

Tiberiu Nita[1,2,3], Ariane Paoloni-Giacobino[3,4,5], Ludwig Stenz[3, 4], David Vernez[1,2,3] & Nancy Hopf[1,2,3]
[1]University of Lausanne, Faculty of Biology and Medicine, Lausanne, Switzerland; [2]Center for Primary Care and Public Health, Unisanté, Department DSTE, Epalignes, Switzerland; [3]University of Basel, Swiss Centre for Applied Human Toxicology (SCAHT), Basel, Switzerland; [4]University of Geneva, Department of Genetic Medicine and Development, Geneva, Switzerland; [5]University Hospital of Geneva, Department of Genetic Medicine, Geneva, Switzerland

Background
Phthalates are currently used in medical devices, adhesives as plasticizers. Masculine reproductive toxicity is the greatest concern associated with exposure, known as the "phthalate syndrome". The European Chemicals Agency has recognized di-butyl-phthalate (DBP, CAS 84-74-2) as an endocrine disruptor with deleterious effects on reproductive hormones, with an estimated human intake of 0.84-5.22 µg/kg/day. Effects reported include the disruption of Sertoli and Leydig cells with decreased testicular production of androgens, known as the "testicular dysgenesis syndrome". However, a quantitative relationship between DBP exposure and hormone levels is not available in the literature.
Objective
Review the scientific literature on DBP exposure measured as urinary metabolites, and corresponding reproductive hormone effects such as testosterone, in human adult men.
Methods
Four online scientific databases [PubMed, ISI Web of Science, Embase, Cochrane library] were searched in January 2022. The search criteria included English-language full text publications, human, adult men, serum testosterone total (TT) and testosterone free (fT) concentrations, urinary DBP metabolites concentrations (creatinine-adjusted values). Studies with $n>100$ participants were selected. Studies with a low score on qualitative assessment were excluded.
Results
Of the 329 search results, 11 toxicological studies met the inclusion criteria. Nine were cross-sectional studies conducted in East-Asia (4), Europe (4), North America (2), and Middle-East (1), and were conducted in the general population, occupational-exposed and fertility clinic population. The urinary DBP metabolites generally evaluated were mono-n-butyl-phthalate (MnBP) and mono-iso-butyl-phthalate (MiBP). The phthalates are often used in mixtures depending on the product specifications. Therefore, all the included studies provided urinary metabolites concentration of other phthalates. Phthalates may have a common metabolic pathway and consequently, the cumulative effect could alter the testosterone in serum but this was seldom discussed. All included studies used the same chemical analysis for quantifying urinary DBP metabolites (enzymatic hydrolysis, high-performance liquid chromatography with mass-spectrometry detection), while not all studies reported TT and fT. Preliminary results show that there is no significant correlation between urinary concentration of DBP metabolites and testosterone levels, although, several studies report a slight evidence for a reduction of TT and fT with increasing DBP exposure.
Conclusions
The review showed that the studies were incongruent and therefore, a significant correlation could not be established. However, the data suggest that adult men exposed to DBP are more likely to have altered testosterone levels. Future studies should explore possible relationships with luteinizing hormone, follicle-stimulating hormone, sex hormone binding globulin, estradiol and inhibin B in the current context.

EP637

Vitamin D status in patients with adrenal tumors and previous COVID-19 infection

Maria - Alexandra Mohora[1], Raluca Trifanescu[1, 2], Iustin- Daniel Toma[1], Roxana Dusceac[1, 2], Cristina Capatina[1, 2], Dan Alexandru Niculescu[1, 2], Sorina Schipor[3], SUZANA VILMA VLADOIU[3] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuro-endocrine Disorders, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania; [3]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania

Context
The current pandemic showed a great handling of the resources and research in order to find not only a way to cure but also to prevent and improve the course of the Covid-19 infection. Optimal vitamin D (VD) levels and treatment was seen as a potential aid due, in principal, to its immunomodulatory effect. The ACE-2 receptor is the key the virus uses for entering the body, but its location is not restricted to the lungs, it's also found in the adrenal cortex. At that same level, we can find the vitamin D receptor. Romania, with its temperate climate, has a significant number of people with suboptimal levels of VD, especially during the winter season.
Objectives
To assess vitamin D status in patients with adrenal tumors who recovered from SARS-CoV-2 virus infection as compared with those without infection.
Matherials and methods
Notes of205 patients with adrenal tumors - inpatients in an Endocrine Clinic between August 2020 and August 2021 - were retrospectively reviewed. 48 patients (6M/42F) had had the COVID-19 infection - group 1, aged 57 ± 14 years, and 157 patients (30M/127F) without the infection - group 2, aged 54 ± 14 years. 25-OH-VD status, full adrenal workup and abdominal imaging were noted. Regarding tumor secretion, 82.4% were non-functioning adrenal tumors. 25-OH-VD levels were measured by electrochemiluminescence and were classified as follows: optimal 30 ng/ml, insufficiency 10-30 ng/ml, deficiency <10 ng/ml.
Results
The mean value of 25-OH-VD was 27.1 ± 7.8 ng/ml for group 1 and 25.5 ± 10 ng/ml for group 2 (P-value = ns). Regarding VD supplementation, group 1 had 41.6%(20) patients without and 58.3%(28) with treatment and group 2 had 52.8%(83) patients without and 47.2%(74) patients with treatment. In group 1, 77% (36) had VD insufficiency and 26% (12) had optimal VD status, whereas in group 2, 67.6%(106) had insufficiency or deficiency and 32.4%(51) had optimal VD status. Evaluating group 1, 30 patients had VD levels measured before and after the infection, and in the latter case the VD levels were lower for 10 patients, higher for 11 patients and remained almost the same (less than 10% modification) for 9 patients. Regarding COVID-19 risk factors, the prevalence of obesity (44% in group 1 vs 38.8% in group 2) and metabolic syndrome was similar between the 2 groups (Chi-square test = ns).
Conclusion
Patients with adrenal tumors and Covid-19 infection do not have lower levels of vitamin D compared to patients who didn't go through infection.

DOI: 10.1530/endoabs.81.EP637

Contaminación del aire ambiente y función tiroidea en adultos españoles. Un estudio de base poblacional de ámbito nacional (estudio Di@bet.es)

Viyey Kishore Doulatram Gamgaram, Sergio Valdés Hernández, Cristina Maldonado Araque, Natalia Colomo Rodríguez & Gemma Rojo Martínez
Hospital Regional Universitario de Málaga, Endocrinology and Nutrition

Objective
Recent reports have suggested that air pollution may impact thyroid function, although the evidence is still scarce and inconclusive. In this study we evaluated the association of exposure to air pollutants to thyroid function parameters in a nationwide sample representative of the adult population of Spain.
Methods
The Di@bet.es study is a national, cross-sectional, population-based survey which was conducted in 2008-2010 using a random cluster sampling of the Spanish population. The present analyses included 3846 individuals, free of thyroid disease, with negative thyroid peroxidase antibodies (TPO Abs) and TSH levels 0.1-20 mIU/l. Participants were assigned air pollution concentrations for particulate matter $<2.5\mu m$ (PM2.5) and Nitrogen Dioxide (NO2), corresponding to the health examination year, obtained by means of modeling combined with measurements taken at air quality stations (CHIMERE chemistry-transport model). TSH, FT4, FT3 and TPO Abs concentrations were analyzed using an electrochemiluminescence immunoassay (Modular Analytics E170 Roche).
Results
There was a significant association between PM2.5 concentrations and the odds of presenting lower FT4 [OR 1.30 (1.08-1.57) $P=0.006$] and FT3 levels [OR 1.34 (1.11-1.62) $P=0.002$] per each IQR increase in PM2.5 (4.86 µg/m3). The association remained after the multivariate adjustment of the data. There was no association between NO2 concentrations and thyroid hormone levels. No significant heterogeneity was seen in the results between groups of men, pre-menopausal and post-menopausal women.
Conclusions
Exposures to PM2.5 in the general population were associated with a mild thyroid dysfunction consisting of lowered levels of FT4 and FT3 without any significant changes in TSH. The nature of this association remains unknown. Additional studies are warranted to expand the data in this field.

'Evaluation of the quality of life using patient questionnaire with autoimmune polyglandular type syndrome 2'

Gulzoda Negmatova[1] & Zamira Khalimova[2]
[1]Samarkand State Medical Institute, Department of Endocrinology, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

The purpose of the study is to assess the quality of life of patients with autoimmune polyglandular type 2 syndrome using the questionnaire.
Material and research methods
Under our observation there were the following 2 groups of patients: 1 gr. - patients with APS with AIT (primary adrenal insufficiency and autoimmune thyroiditis) - 25 patients, 2 gr. - APS with DM 1 (type 1 diabetes mellitus type 1 - 30 patients, as well as 20 healthy persons of the appropriate age and gender. The study used generally crystal and clinical and biochemical methods of research, hormonal blood tests (TSH, free thyroxine, antibodies to TPO, cortisol), immunological studies (antibodies to thyroid gland, to the pancreas, to adrenal glands), and instrumental research methods (ECG, ultrasound of internal organs, thyroid gland, genital organs, neurophthalmologic, radiographic - MSCT of adrenal glands, statistical techniques, as well as the quality of life of patients with ADDIQOL. AddoQol consists of 30 questions with the estimate of each question in 6 points. At the same time, the patient must be selected in each question 1 answer: 'Yes' or 'no'. If the patient is gaining more than 15 points with the answer 'Yes', then this indicates a low quality of life [1].
Research results
The assessment of the quality of life (QoL) on the AddOQOL questionnaire showed that the middle score of patients 1 of the group was 18 ± 0.95, and in healthy - 2.35 ± 0.54 ($P<0.05$). The average score in patients 2 groups amounted to 19.6 ± 1.06 ($P<0.05$).
Conclusions
QoL patients in patients with APS 2 type of both groups has significantly lagging behind QoL in healthy faces.

A method for evaluating the results of brain 18F-FDG PET/CT in the diagnosis of MRI-negative ACTH-producing pituitary adenomas.

Uliana Tsoy[1], Natalia Kuritsyna[1], Alexander Savello[2], Vladislav Cherebillo[1], Anton Ryzhkov[2], Elena Grineva[1] & Daria Ryzhkova[2]
[1]Almazov National Medical Research Center, Institute of Endocrinology, St-Petersburg, Russian Federation; [1]Almazov National Medical Research Center, Institute of Endocrinology, St-Petersburg, Russian Federation

Background
Detection of MRI-negative ACTH-producing pituitary adenomas is a challenge in the management of patients with Cushing's disease. There are some data on the ability of pituitary adenomas to accumulate 18F-fluorodeoxyglucose during the 18F-FDG positron emission tomography and computer tomography (18F-FDG PET/CT).
Aim
To study the potential of using a standardized uptake value (SUV) and a tumor – background ratio (TBR) when evaluating the results of PET/CT 18F-FDG of the brain for localization ofMRI-negative ACTH-producing pituitary adenomas.
Materials and methods
40 patients were enrolled. 32 patients had Cushing's disease, pituitary MRI scans were negative in all these patients. In all patients the pituitary source of ACTH hyperproduction was confirmed by bilateral cavernous and inferiorpetrosal sinuses sampling. Eight patients had neuroendocrine tumors with ACTH-ectopic production (NETs). Control group consisted of 19 persons without hypercortisolism. Brain 18F-fluorodeoxyglucose PET/CT was performed in all patients. Tumor –background ratio (TBR) was calculated as the ratio of the SUVmax in the pituitary gland to SUVmax in the reference zone of interest, drown above the fat tissue of the cheek. SUVmax in the pituitary gland and TBR were compared between patients with Cushing's disease and control group; patients with NETs and control group; patients with Cushing's disease and control group plus patients with NETs. The optimal threshold value of TBR for detection of MRI-negative ACTH-producing pituitary adenoma was calculated with ROC-analysis.
Results
All 32 patients with Cushing's disease patients had focal increased 18F-FDG uptake on pituitary 18F-FDG PET/CT scans. In control group and in patients with NETs there was no focus of increased accumulation of 18F-FDG. SUVmax in the pituitary gland did not differ in patients with Cushing's disease and control group ($P=0.208$); patients with Cushing's disease and patients with NETs ($P=0.63$); patients with Cushing's disease and control group plus patients with NETs ($P=0.23$). On the contrary TBR in the pituitary gland differ in patients with Cushing's disease and control group ($P=0.000$); patients with Cushing's disease and patients with NETs ($P=0.000095$); patients with Cushing's disease and control group plus patients with NETs ($P=0.000$). The optimal threshold value of TBR for detection of MRI-negative ACTH-producing pituitary adenoma calculated with ROC-analysis was 6.55. The sensitivity and specificity of the method were 90.6% and 89.5%, respectively ($p<0.001$, AUC = 0.961, 95% CI = 0.914-1.000).
Conclusion
Brain 18F-fluorodeoxyglucose PET/CT may be useful for localization of MRI-negative ACTH-producing pituitary adenomas. Application of the TBR, but not of the SUVmax is optimal for evaluating it's results.

Patient with pregnancy and possible MEN 2b syndrome: case report

Veranika Lobashova[1,2], Elena Kuzmenkova[1], Yuliya Dydyshka[3] & Alla Shepelkevich[3]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, Endocrinologic, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Therapy, Minsk, Belarus; [3]Belarusian State Medical University, Endocrinologic, Minsk, Belarus

Background
MEN 2b is a highly penetrant disease with an autosomal dominant pattern of inheritance. It includes medullary thyroid carcinoma, pheochromocytomas, and multiple mucosal neuromata. The common feature of all of these tumors is a

neuroectodermal origin. Although the clinical phenotype is present in all patients, individual manifestations have a variable presentation and are age dependent.
Aim.
We report a case of a patient with possible MEN 2b syndrome anв pregnancy.
A 30-year-old Caucasian woman was admitted to the cardiologic department of the hospital in October 2017 for resistant hypertension unresponsive to medical therapy. The patient had a history of hypertension for 5 years without any treatment or etiological diagnosis. On arrival indicated blood pressure was 240/120 mmHg. She denied family history of premature coronary artery disease and special personal history, such as smoking and drinking. But her mother died in young age (36 yers old) because of adrenal tumor.Contrast-enhanced computed tomography demonstrated an inhomogeneous left adrenal mass (5.5 × 4.1 cm HU +13-+88). Her plasma epinephrine and norepinephrine and levels were elevated (118 (0-65) pg/ml and 7069,5 (0-200) pg/mlm accordingly). Preoperative stabilization with alpha-adrenergic blocking agent (doxazosin) was started a month before surgery. The patient underwent laparoscopic left adrenalectomy after premedication. Histopathology confirmed adrenal pheochromocytoma with residual necrosis. The patient was diagnosed with pheochromocytoma. During the 2-year follow-up, the patient was asymptomatic, and her blood pressure remained normal without medication. Her plasma epinephrine and norepinephrine and levels normalized (15,3 (0-65)pg/ml and 114 (0-200)pg/ml). After the operation she become pregnant, there were no problems during pregnancy, her labour were in December 2018 without any complications.
She visited our center because of the second pregnancy. On examination she had several neurofibromas on her skin. She mentioned that her sister also has neurofibromatosis on her skin. Thyroid sonography demonstrated solide isooechogenic nodule 4,7*3.8 mm at the left thyroid lobe. Serum calcitonin as biochemical marker for the presence of medullar thyroid cancer was elevated - 20,4 (0-10) pg/ml. Her TSH, epinephrine and norepinephrine were normal. Just now her gestation period is 38 weeks and she is waiting for delivery. In the future, we plan to continue examination of the patient and her sister.
Conclusion
Women with MEN 2 should be screened for pheochromocytoma prior to a planned pregnancy. Family history is an important part of diagnostic algorithm of MEN 2b. Genetic tests could help to identify RET mutation.

Circulating plasma microRNA in patients with ACTH-dependent cushing's syndrome.

Anastasia Malygina[1], Zhanna Belaya[1], Alexander Solodovnikov[2], Alexey Nikitin[3], Philipp Koshkin[4], Ivan Sitkin[1], Michael Pikunov[5], Patimat Khandaeva[1], Alexander Lutsenko[1], Diana Trukhina[1], Anastasia Lapshina[1], Andrey Grigoriev[1], Galina Melnichenko[1] & Ivan Dedov[1]
[1]The National Medical Research Centre for Endocrinology, neuroendocrinology and bone disease, Moscow, Russian Federation; [2]Ural State Medical University, Department of Preventive and Family Medicine, Moscow, Russian Federation; [3]Pulmonology Scientific Research Institute under FMBA of Russia, Moscow, Russian Federation; [4]Laboratory of Molecular Pathology, Center of Medical Genetics (Genomed), Moscow, Russian Federation; [5]National Medical Research Center of Surgery Named After A.V. Vishnevsky, Moscow, Russian Federation

Introduction
Recent studies have shown that microRNA could serve as biomarkers in various types of cancer and other diseases.
Aim
To reveal microRNA that differ in patients with Cushing's diseases (CD) and Ectopic ACTH-syndrome (EAS) to form a specific panel for differential diagnosis of ACTH-dependent Cushing's syndrome (CS).
Materials and Methods
Plasma samples from both sinuses and cubital vein were drained during inferior petrosal sinus sampling and stored at -80 C. MiRNA isolation from plasma samples was carried out by an Rneasy Plasma/Serum Kit (Qiagen, Germany) on the automatic QIAcube station. MiR expression was then analyzed by sequencing on Illumina NextSeq 500 (Illumina, USA). The libraries were prepared by the QIAseq miRNA Library Kit. Sequencing was performed on a total of 36 samples. Data analysis and interpretation was conducted on Qiagen GeneGlobe Data Analysis were Center. qRT-PCR was performed using a TaqMan Advanced miRNA cDNA Synthesis Kit (Thermo Fisher, Scientific) and TaqMan® Advanced miR Assays (Thermo Fisher Scientific), in a 96-well format on the StepOnePlus instrument (Applied Biosystems). Data analyses were performed using SDS software (version 2.3, Applied Biosystems), to obtain cycle treshold (Ct) data. We used value Ct <35 as a cutoff of detection. All samples were normalized to spike-in control, cel-miR-39-3p.
Results
Among 36 enrolled patients (mean age 47,5 years (minimum 23, maximum 69 years; M:7, F:29) 24 subjects were confirmed as CD and 12 as EAS. There were 1167 miRNA differently detected ($P<0,05$) in inferior petrosal sinus samples of patients with CD vs EAS. These miRNAs were divided into 3 groups based on the significance of the results. The first group consisted of samples with the highest levels of detected miR in both groups. 108 microRNA were included. For the verification phase 10 microRNA were chosen (miR-383-3p, miR-4290, miR-6717-5p, miR-1203, miR-1229-3p, miR-639, miR-302c-3p, miR-7g-5p, miR-145-5p, miR-16-5p) according to the discovery phase results and data from the previous pilot study. We enrolled 82 patients (mean age 44,5 years (minimum 19, maximum 70 years; M:18, F:64) for validation phase of the study. Among them 64 were confirmed as CD, 18 as EAS. RT-qPCR showed, that four microRNA differ between patients with CD and EAS: miR-383-3p ($p_{adjusted}=0,003$), miR-302c-3p ($p_{adjusted}=0,02$), miR-4290 ($p_{adjusted}=0,02$), miR-6717-5p ($p_{adjusted}=0,02$).
Conclusion
miR-383-3p, miR-302c-3p, miR-4290, miR-6717-5p differed between patients with CD and EAS in peripheral plasma samples as measured by both NGS and qRT-PCR and could form a specific panel for differential diagnosis of ACTH-dependent CS.

Primary hyperparathyroidism response to the somatostatin analogue therapy in a patient with MEN1 syndrome: A case report

Kseniia Yakovenko[1], Karina Pogosian[1], Daria Ryzhkova[2], Lidiia Belousova[1], Tatiana Karonova[1], Elena Grineva[1] & Uliana Tsoy[1]
[1]Almazov National Medical Research Center, Endocrinology, St. Petersburg, Russian Federation; [2]Almazov National Medical Research Center, Nuclear Medicine and Theranostics, St. Petersburg, Russian Federation

Background
Management of primary hyperparathyroidism (PHPT) in Multiple Endocrine Neoplasia type 1 syndrome (MEN 1) is still a challenge. PHPT developing in MEN 1 is characterized by the involvement of all parathyroid glands. Therefore, by modern guidelines, total or subtotal removal of the parathyroid glands is recommended. But this approach often leads to the development of hypoparathyroidism, adequate correction of which is not always possible. Drug therapy of recurrent PHPT in MEN 1 patients may be the alternative to radical surgery. We present a clinical case of MEN 1 patient in whom somatostatin analogue therapy resulted in normalization of serum calcium level.
Clinical case
40 years old Caucasian woman, with a history of insulinoma, that was operated on at the age of 10 and prolactin-secreting pituitary macroadenoma diagnosed at the age 19. In 2015 the patient was tested for PHPT, iPTH level was 28 pmol/l (1.3-9.3), serum Ca^{++} level - 1.47 mmol/l (1.13 – 1.29), CT scans revealed two lesions suspicious for parathyroid adenomas. Subtotal parathyroidectomy of both right and left lower parathyroids glands was performed. Postoperative iPTH was 5.2 pmol/l. All removed lesions were confirmed to be parathyroid adenomas by the pathology examination. Genetic testing was done and variant in MEN1 gene was found. In 2020 PHPT recurrence was confirmed (iPTH 200.10 pg/ml (15.0 – 68.3)), serum Ca^{++} level 1.57 mmol/l (1.11 – 1.29), serum total Ca 2.78 mmol/l (2.15 – 2.65)). 68Ga-DOTA-TATE PET/CT was carried out, it revealed three lesions in the pancreas head and body which intensively accumulated radiopharmaceutical, also 68Ga-DOTA-TATE positive foci was found in the projection of the left upper parathyroid. Subsequently endosonography was performed; it showed multiple lesions in pancreas and submucosal lesions in duodenum. Fine needle aspiration biopsy of pancreatic and duodenal formations confirmed neuroendocrine tumors in all of them. Preoperative short-acting somatostatin analogue (Octreotide) was started. Subtotal pancreatectomy, 2/3 stomach resection, duodenectomy were performed. After surgery octreotide therapy was continued. After 6 weeks of octreotide therapy calcium and parathyroid hormone levels were assessed. Decrease of iPTH and calcium levels was found: iPTH from 172,5 to 122 pg/ml (15.0 – 68.3), serum total Ca from 2,73 to 2.59 mmol/l (2.15 – 2.65).

Conclusion
Our clinical case demonstrated the ability of octreotide to reduce iPTH and normalize calcium levels in a patient with MEN 1 syndrome. It is necessary to further study the potential of somatostatin analogues in the treatment of recurrent PHPT in MEN 1 syndrome.

Dynamics copeptin and apelin in patients before and after transnasal adenomectomy and their relationship with the development of post-operative hyponatremia

Khava Fargieva, Nino Katamadze, Larisa Dzeranova, Ekaterina Pigarova, Elena Przhiyalkovskaya, Andrey Grigoriev & Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Transnasal adenomectomy is the main treatment for various pituitary adenomas. The hypothalamic-pituitary region is the site of synthesis and secretion of several hormones that have a direct effect on sodium-water metabolism, which leads to its frequent violation with the development of central diabetes insipidus and severe transient hyponatremia, the latter of which is the second most important cause of rehospitalization in the postoperative period. Currently, the causes and factors predisposing to the development of this complication have not been identified.
Objective
To study the perioperative dynamics of apelin and copeptin neuropeptides after transnasal transsphenoidal adenomectomy for pituitary adenomas.
Materials and methods
The study included 22 patients who underwent transnasal adenomectomy for pituitary adenoma (inactive pituitary adenoma - 8 patients, acromegaly - 8 patients, Cushing's disease - 6 patients, 6 men and 16 women, median age 52 years [Q25 39; Q75 62]), 10 of whom developed hyponatremia (group 1) with a median serum sodium of 125 mmol/l and 12 did not have any fluid and electrolyte disturbances (group 2). All patients were tested for serum Na, plasma apelin 12 (ELISA, Phoenix) and copeptin (ELISA, Phoenix) at 24 hours before surgery, 24 hours, days 2-3, 5 and 7 after surgery.
Results
The debut of hyponatremia was observed in the period 5-7 days after the operation. In both groups, there was a change in the level of copeptin with a decrease on days 2–3 after surgery and a further increase in group 1 and a decrease in group 2 by day 5 after surgery and returning to baseline values on day 7 after surgery. The level of apelin had different dynamics in the groups: in group 1, it decreased on the first day with a further increase with a maximum on day 5 and a return to the original values on day 7; in group 2, no statistically significant changes were recorded.
Conclusions
Transnasal adenomectomy is the cause of severe hyponatremia in the genesis of which, apparently, the hypothalamic neuropeptides copeptin and apelin play the leading role. The secretion dynamics of these neuropeptides changes reciprocally in groups with and without the development of hyponatremia, which makes them potential hormonal markers of this severe complication.

Hyponatremia, central diabetes insipidus after transnasal adenomectomy and its' risk factors

Darya Mikhaylova[1], Larisa Dzeranova[2], Olga Yu. Rebrova[3], Ekaterina Pigarova[2], Ludmila Rozhinskaya[2], Andrey Grigoriev[4], Oksana Ivashenko[4] & Vilen Azizyan[4]
[1]Moscow Regional Research and Clinical Institute, Neuroendocrine Unit, Department of Endocrinology, Moscow, Russian Federation; [2]Endocrinology Research Centre, Neuroendocrinology, Moscow, Russian Federation; [3]Endocrinology Research Centre, Education, Moscow, Russian Federation; [4]Endocrinology Research Centre, Neurosurgery, Moscow, Russian Federation

Objectives
To assess the frequencies of hyponatremia and central diabetes insipidus (CDI) after transnasal adenomectomy and to identify its risk factors.

Patients and methods
The study included 152 patients aged 18 to 65 years (median [Q1; Q3] 40 [31; 52]) who underwent endoscopic endonasal transsphenoidal surgery due to Cushing's disease, acromegaly, prolactinoma, non-functioning pituitary adenoma, thyreotropinoma or Nelson's syndrome at Endocrinology Research Centre in 2010-2011 years. All patients underwent clinical and laboratory examinations and were discharged on 10-14 days after surgery.
Results
Severe hyponatremia (116 mmol/l) developed in 2 patient (1.3%), moderate (127 mmol/l) in 1 patient (0.7%) on the 1^{st}-7^{th} day after surgery and in all cases it was reversed by fluid restriction. Mild transient hyponatremia (131-134 mmol/l) occurred in 8 patients (5.3%). Persistent CDI (pCDI) has developed in 34 patients (22.4%) with 3 cases of three-phase CDI (including 2 cases of three-phase CDI with mild hyponatremia), transient CDI (tCDI) occured in 25 (16.4%), 82 patients did not have any disturbances (53.9%) by discharge. Postoperative pCI and tDI were promoted by Cushing's disease (odds ratio (OR) 2.5, 95% CI (1.1-5.6) for pDI, 3.6 (1.4-9.2) for tDI), whereas acromegaly decreased the risk (OR 0.3 (0.1-0.6) for pDI, 0.3 (0.1-0.8) for tDI)). Secondary adrenal insufficiency (OR 2.6 (1.2-5.9) for pDI, 3.1 (1.3-7.6) for tDI), microadenoma (OR 4.1 (1.6-10.6) for pDI, 5.2 (1.9-14.6) for tDI), MRI tumor's volume $<0{,}75$ cm^3 (OR 4.8 (1.8-12.6) for pDI, 7.5 (2.1-26.8) for tDI) and surgery pituitary injury (OR 4.1 (1.6-10.6) for pDI, 5.2 (1.9-14.6) for tDI) provoked pDI and tDI. Postoperative DI was also more common at trend level in patients with adrenocorticotropic hormone levels of $<$ 16,5 pg/ml and cortisol level of <228 nmol/l and pDI was more often associated with secondary hypothyroidism at trend level as well.
Conclusions
The proportion of hyponatremia was 7.3%, persistent postoperative CDI – 22.4%, and that of the transient form 16.4% by discharge. Cushing's disease, secondary adrenal insufficiency, microadenoma, MRI tumor's volume $<0{,}75$ cm3 and surgery pituitary injury increase the odds of postoperative CDI, whereas acromegaly does decrease these odds.

A clinical case of hypogonadism and anosmia associated with a new mutation of the KAL1/ANOS1 gene: a preliminary report

Michela Del Prete[1], Gianleone Di Sacco[1], Marco Bonomi[2, 3], Federico Vignati[4], Fabrizio Muratori[1] & Luca Persani[3,4]
[1]Ospedale Sant'Anna, Endocrinology and Diabetology, San Fermo della Battaglia, Italy; [2]Italian Auxological Institute San Luca Hospital, Medical Biotechnologies and Translational Medicine, Milano, Italy; [3]University of Milan, Medical Biotechnologies and Translational Medicine, Milano, Italy; [4]Italian Auxological Institute San Luca Hospital, Endocrine and Metabolic Diseases, Milano, Italy

Introduction
Kallmann syndrome (KS) is a genetic condition characterized by the association of anosmia or hyposmia and GnRH deficiency resulting in congenital hypogonadotropic hypogonadism (CHH). Different genes can be implicated in KS, and the most frequent allelic variant occurs in the KAL1/ANOS1 gene in the X-linked form. Differential diagnosis is often made with other rare genetic diseases as CHARGE syndrome (CS) that includes hypogonadism, hyposmia and several organ defects including eyes and heart defects. Here we report a clinical case of a patient with a clinical diagnosis of KS and in which a new genetic gene variant was found.
Methods
Patient history was collected through questionnaires and physical examination at our outpatient clinic. Blood sample for genetic evaluation of the patient was collected after obtaining informed consents. Gene variants were amplified and verified by Sanger direct sequencing after the next generation sequencing (NGS) of related genes.
Results
A 48-year-old male patient was referred to our endocrinology service for evaluation of hypogonadism. The medical history of patient started when he was 17-year-old. At that time patient was diagnosed with hypogonadism and anosmia wherefore placed on testosterone replacement therapy. No genetic tests had been conducted until our visit on suspicion of KS. Patient had no other further suspected signs or symptoms of genetic disease or CS. NGS sequencing revealed the presence of two different gene allelic variants: a heterozygous variant in the region 8 q12.2 of the CHD gene (p.L2806V: c.84716C$>$G) and a hemizygous X-linked variant in the Xp22.31 region of the KAL1/ANOS1 gene (p.R46H: c.137G$>$A). This latest is a newly identified variant and has never been described so far. Laboratory examination confirmed hypogonadotropic hypogonadism without other pituitary hormonal alterations. Magnetic resonance imaging of the

olfactory bulb and of the pituitary gland and the smell test have been requested and are ongoing.
Conclusion
Both KAL1/ANOS1 and CHD7 genes are known to be important causal gene in the development of KS. Differential diagnosis between KS and CS should be considered in patients with anosmia and hypogonadism. Until now p.R46H variant in KAL1/ANOS1 gene has never been reported, while p.L2806V variant was described in the literature to be associated with benign forms of CS with CHH/KS. A possible oligogenic form of KS might be considered in this specific case.
Keywords Kallmann syndrome; KAL1/ANOS1 mutations; CHD7 mutations; CHARGE syndrome; congenital hypogonadotropic hypogonadism; anosmia.

Sellar plasmacytoma revealing a multiple myeloma.
Samia Hamoudi, Safia Achir & Safia Mimouni
CPMC, Service d'Endocrinologie et Maladies d'Endocrinologie, Alger, Algeria

Introduction
The sellar plasmacytoma, an exceptional localization that can be solitary or associated with a multiple myeloma. We report the case of a sellar mass wrongly diagnosed as an invasive non-functional pituitary adenoma, the diagnosis was rectified postoperatively by the anatomopathological study.
Case description
A 44 year old female patient, with history of cholecystectomy and megaloblastic anemia, was referred to our center for management of a sellar mass initillay diagnosed as a pituitary adenoma. The patient had galactorrhea for 3 years and than she developped severe hedeache with worsening visual impairement. The physical examination revealed bilateral blindness, with galactorrhea, without neurological abnormalities. Magnetic resonance imaging (MRI) of the brain revealed an Iso intense mass in T1 and T2 sequences with intra and supra sellar development strongly enhanced after injection of gadolinium. The tumor compressed the optic chiasma and the right optic nerve in its intracranial portion, invading the cavernous cavity bilaterally (KNOSP 3), measuring **44X36X37 mm** suggesting an invasive macroadenoma; however the endocrine assessment did not show any abnormalities. She underwent an emergency transphenoidal surgery. Immunophenotypic analysis of tissues showed that all tumor cells were positive for CD1389 and confirmed the diagnosis of plasmacytoma. The hematological examination revealed a medullar plasmacytosis of 32% without blood desemination in favor of a multiple myeloma. She underwent radiation therapy centered on the sella turcica, followed by chemotherapy. There was a slight regression of the osteolytic tumor process, which currently measures 38.5 X 32.6 X 27.5 mm.
Conclusion
Plasmacytomas of the skull base revealing multiple myeloma represent a rare entity. However, solitary or multiple, plasmacytoma should be considered in the differential diagnosis of any invasive lesion of the sphenoidal sinus. The clinical presentation is aspecific, histological certainty must be obtained.

Medical treatment of active acromegaly - the results from the Croatian Acromegaly Registry
Lana Sambula[1], Mirsala Solak[2], Ivana Kraljevic[2], Hrvoje Popovac[2], Tanja Skoric Polovina[2], Karin Zibar Tomšić[2], Tina Dusek[2], Annemarie Balasko[2] & Darko Kastelan[2]
[1]General Hospital Koprivnica, Department of Internal Medicine, Koprivnica, Croatia; [2]University Hospital Centre Zagreb, Department of Endocrinology, Zagreb, Croatia

Background
The aim of this study was to evaluate the outcomes of medical treatment in patients with active acromegaly.
Material and Methods
We performed a retrospective analysis of 163 patients (101 female, age at diagnosis 47.2 ± 13.4 years) treated between 1990 and 2020., of which 53 were on medical treatment (32.5%). Remission rate after pituitary surgery was 66.5% (n = 105/158; 5 patients refused surgery). Patients who did not achieve remission and with relapse (n = 2) underwent another surgery (n = 18/60, 30%) and/or radiotherapy (n = 33/60, 55%) and/or medical treatment (n = 53/60, 88.3%). One patient refused further treatment after failed first pituitary surgery. The duration of follow-up was 115.8 ± 304.4 months.
Results
Out of 53 patients on medical treatment, during follow-up monotherapy was used in 34 (64.2%) and combination therapy in 19 (35.8%) patients. Remission (IGF-1 < 1.2 ULN) was achieved in 51 patients (96.2%); in 21/53 (39.6%) with first generation somatostatin analogue (SSA-1) monotherapy, in 10/53 (18.9%) with dopamine agonist (DA) monotherapy, in one (1.9%) with pegvisomant monotherapy, in 13/53 (24.4%) with combination of SSA-1 and DA, in three (5.7%) with combination of SSA-1, DA and pegvisomant, in two (3.8%) patients with combination of SSA-2, DA and pegvisomant and in one (1.9%) after adding temozolomide on top of SSA-1 and DA. Two patients currently have active disease, both on SSA-1 monotherapy, of whom one is non-adherent to the tratment.
Conclusion
Our results indicate that medical treatment, when combined appropriately, can lead to biochemical remission in almost all patients with acromegaly.

Lipid accumulation product (LAP) as surrogate marker of fatty liver in patients with Cushing's disease (CD)
Dragana Miljic[1,2], Sandra Pekic Djurdjevic[1, 2], Mirjana Doknic[1, 2], Marko Stojanovic[1, 2], Marina Nikolic Djurovic[1, 2], Zvezdana Jemuovic[1], Sara Radovic[2], Nevena Radić[2] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Centre of Serbia, Belgrade, Serbia; [2]University of Belgrade - Faculty of Medicine, Belgrade, Serbia

Introduction
The most common etiology of endogenous Cushing's syndrome (CS) is Cushing's disease (CD). Patients with CS also represent a model of patients with metabolic syndrome (MetS) with associated increased cardiovascular morbidity and mortality. Insulin resistance and obesity, two major characteristics of CS, lead to the accumulation of triglycerides within hepatocytes and formation of fatty liver in these patients.
Aim
To evaluate the prevalence of metabolic syndrome and fatty liver and the importance of using lipid accumulation product (LAP) and fatty liver index (FLI) in patients with CD.
Material and methods
We conducted a cross-sectional study analyzing electronic medical histories of 52 patients (41 women, 11 men) diagnosed with CD (33 microadenomas and 19 macroadenomas) treated from 2009 to 2019. Mean age 50.5 ± 13.5 years and body mass index (BMI) 29.3 ± 5.8 kg/m^2.
Results
MetS defined by NCEP ATP III was present in 63.5% (n = 33) of patients with CD. Ultrasound findings of fatty liver in a cohort of our patients with CD were present in 40.4% (n = 21) patients, while only 11.5% (n = 6) had elevated transaminases**.** Patients with CD and MetS were significantly older from patients with CD alone (52.6 ± 13.2 vs. 44.3 ± 12.8 years). Obesity was present in 41.3% while diabetes and glucose intolerance were present in 60% of patients. Prevalence of obesity was even higher in patients with diabetes (72.2% vs. 27.8%; P = 0.007). Obese patients had significantly higher values of LAP (174.7 ± 79.4 vs. 54.4 ± 24.3 P < 0.05) and FLI (29.3 ± 29.5 vs. 1.5 ± 1, P < 0.05). Patients with CD and ultrasonographic features of fatty liver had statistically significant higher values of LAP than those with CD alone (142.6 ± 9.6 vs 61.1 ± 21.2, P = 0.045), while their FLI values were not statistically different. Arterial hypertension was observed in as many as 82.4% of patients. In 96% of patients, some form of dyslipidemia was present.
Conclusion
Cushing's disease is characterized by an unfavorable metabolic profile and grouping of cardiovascular risk factors in the large percentage of patients. Fatty lever extends this unfavorable metabolic phenotype. LAP but not FLI is a good surrogate marker of fatty liver in CD.

Hypopituitarism in patients with pituitary macroadenomas - the prevalence and prognostic factors

Yulya Krivosheeva & Irena Ilovayskaya
Moscow Regional Research and Clinical Institute (MONIKI), Neuroendocrinology, Moscow, Russian Federation

Hypopituitarism due to pituitary lesions may have unclear clinical manifestations, and for its diagnosis it is necessary to conduct a hormonal examination. There are clinical recommendations to conduct a hormonal investigation in all cases of pituitary tumors > 6 mm that seems to be uncertain.
The objective to evaluate the frequency of hypopituitarism in patients with pituitary macroadenomas with different hormonal activity and to identify its possible prognostic factors.
The materials and methods
We have analyzed medical records of 293 newly diagnosed patients with pituitary macroadenomas before any treatment: 121 non-functioning adenomas (NFAs), 59 prolactinomas, 113 somatotropinomas. Median patients' age was 59 [50;64.5] y.o., 32 [27;48.5] y.o. and 53 [41;60] y.o., accordingly.
The results
The hypopituitarism was diagnosed in 59/148 (39.9%) NFAs, in 18/66 (27.3%) prolactinomas and 19/136 (14%) somatotropinomas ($p<0.001$). The proportion of men with hypopituitarism was higher in NFAs but not in prolactinomas and somatotropinomas. The relative risk (RR) of hypopituitarism in male patients with NFAs was 1.575 (95% confidence interval (CI) 1.212–2.047, $P=0.001$). MR-signs of chiasm compression, as well as the presence of chiasmal syndrome, were significantly more common in patients with hypopituitarism compared to patients without hypopituitarism in all subgroups. The RR of hypopituitarism in patients with MR-signs of chiasm compression was for NFAs 2.10 (95% CI 1.50 – 2.95, $p=0.003$), for prolactinomas 1.667 (95% CI 1.29 – 2.18 $p=0.005$), for somatotropinomas 1.45 (95% CI 1.56 – 2.48, $p=0.001$). The RR of hypopituitarism in patients with chiasmal syndrome was for NFAs 1.66 (95% CI 1.26 – 2.18, $p=0.009$), for prolactinomas 2.08 (95% CI 1.60 – 2.69, $p=0.001$) , for somatotropinomas 1.97 (95% CI 1.56 – 2.48, $p=0.005$). The vertical size and volume of tumor were significantly larger in patients with than without hypopituitarism. Vertical tumor size over 22.5 mm (area under the ROC curve (AUC-ROC) 0.7209, sensitivity 55.91% and specificity 73.44%, $P<0.001$) and tumor volume over 4472 mm3 (AUC ROC 0.7066, sensitivity 62.77% and specificity 70.16%, $P<0.001$) were statistically significant cut-off points for the presence of hypopituitarism.
The conclusions
Hypopituitarism should be excluded in patients with pituitary macroadenomas in the presence of the following factors: in non-functioning adenomas – male sex; regardless of hormonal activity – signs of chiasm compression, chiasmal syndrome, vertical tumor size more than 22.5 mm, tumor volume more than 4472 mm3.

Unusual evolution of a non-functionning pituitary adenoma

Yosra Hasni[1, 2], Marwa El Arem[1], Hamza Elfekih[1,2], wiem saafi[1], Abdelhafidh Slimane[3], Amel Maaroufi[1, 2], Maha Kacem[1, 2], Molka Chadli Chaieb[1, 2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia; [3]National Institute of Neurology, Department of Neurosurgery, Tunis, Tunisia

Introduction
Pituitary neuroendocrine tumors (PitNET) represent 15.5% of primary brain tumors and they can be clinically functioning or non-functioning. Although they are mostly benign, PitNET may be invasive in 30-45% of cases and aggressive in at least 15%. Here, we report the case of a patient who presented a multiple and rapid recurrence of a non-functional pituitary macroadenoma.
Observation
A 42-year-old man was admitted initially for headaches, monocular blindness and Knosp grade 3A macrodenoma on MRI. Biochemial analysis didn't reveal hormones deficiencies nor hypersecretions. He underwent a transphenoidal resection with a visual improvement. Histologic diagnosis was a null cell adenoma with Ki67 index = 4% and a positive p53. Based on the new classification of PitNET, it was proliferative and invasive tumor, classsified garde 2b. Six months later, he deveolpped a tumor regrowth with visual impairment (diplopia), for which he underwent a partiel resection and an adjuvant radiotherapy was planned. Before starting the radiotherapy, he was readmitted 6 months later for a complete ptosis of the right eye and an increase in size of his non-functionning pituitary macroadenoma.
Discussion
This case showed that invasive and proliferative non-functionning pituitary adenomas can have an unpredictable rapid recurence and an agressive behaviour than usual. Null cell adenoma are known to be more aggressive than the other types of tumors with a mean time to recurrence of 15.9 months. In our case, the time to recurrence was 6 months only between the first and second surgeries. Selecting the high risk of recurrence tumors is essential to avoid their impacts and to improve the quality of life of patients.

Isolated ACTH deficiency with unusual clinical presentation and normal morning cortisol levels

Hassan Ibrahim, Natalie Fox, Heba Bashir & Ali Rathore
Southend University Hospital, Mid and South Essex NHS Foundation Trust, Diabetes & Endocrinology Department-Carlingford Building, Southend-on-Sea, United Kingdom

A 74-year-old male presented to hospital following an episode of brief loss of consciousness and several hours of post ictal confusion. There was no witnessed seizure activity, tongue biting, or incontinence. His past medical history included SCC right scalp, TIA and primary hypothyroidism. He had been commenced on Cemiplimab (immunotherapy) for metastatic SCC seven months before. On assessment, he appeared well and general examination including neurological examination was normal. However, he was found to have a postural blood pressure drop of 40 mmHg. ECG and Blood tests were unremarkable, except his random cortisol was 163 nmol/l. Repeat 9 am cortisol was 183 nmol/l. Hydrocortisone was commenced as primary adrenal insufficiency could not be ruled out. A differential diagnosis of ictal syncope was also considered but later ruled out after normal MRI and EEG. Subsequently, Synacthen test showed baseline cortisol of 155 nmol/l, rising to 449 nmol/l at 30 minutes and 521 nmol/l at 60 minutes. ACTH was 16 ng/l. He was advised to stop hydrocortisone as primary adrenal insufficiency was ruled out. However, within a few days of stopping hydrocortisone, he felt symptomatic again with dizziness and pre-syncope, and was readmitted to hospital. Oral Hydrocortisone, at a dose of 20 mg daily, was restarted and his symptoms settled. A glucagon stimulation test was performed to investigate possible secondary adrenal insufficiency. Surprising, his morning cortisol came back as <11 nmol/l and remained undetectable (<11 nmol/l) throughout the test, whilst growth hormone levels peaked to 19.6 mg/l confirming severe ACTH deficiency. FSH, LH, testosterone, prolactin and TFTs were all normal. MRI pituitary showed no abnormality. He was treated as isolated ACTH deficiency, secondary to Cemiplimab. He remains well on hydrocortisone replacement. Secondary adrenal insufficiency due to Isolated ACTH deficiency is being increasingly reported to be associated with immune checkpoint inhibitors including Cemiplimab. In our case, clinical presentation was unusual as postural hypotension and syncope are not common with secondary adrenal insufficiency due to preservation of renin-aldosterone axis. Initial investigations were misleading with relatively preserved morning cortisol and good response to Synacthen. However, Cortisol levels became undetectable subsequently with no response to glucagon stimulation confirming diagnosis of severe ACTH deficiency. This case highlights that ACTH deficiency can present with postural syncope and normal morning cortisol levels in the early stages. High index of suspicion and repeated investigations may be required to confirm diagnosis.

The impact of Sheehan Syndrome on bone mineral density

Ameni Salah, Amel Maaroufi, Rihab Ajili, Ghada Saad, Yosra Hasni & Koussay Ach
University Hospital Center Farhat Hached, Endocrinology Department, Sousse, Tunisia

Introduction
Sheehan syndrome (SS), or postpartum pituitary necrosis, is a complete or dissociated adeno-pituitary insufficiency due to hypovolemia secondary to excessive blood loss during or after delivery. Although few studies have investigated osteoporosis in isolated hormone deficiencies, the relationship between SS and osteoporosis has not been investigated in large series of SS. In this study, we aimed to evaluate bone mineral density (BMD) in patients with SS.
Patients and methods
This is a descriptive cross-sectional study, involving 65 patients. It was carried out in the Endocrinology-Diabetology department of University Hospital Farhat Hached in Sousse, Tunisia, over a period of nine months, from July 2019 to March 2020. Patients were evaluated by Dual Energy X-ray absorptiometry to determine bone mineral density (BMD), T-score and Z-score.
Results
The mean age at diagnosis of SS was 48.2 $\pm$ 12.4 years. The incidence of SS in our study was 2.8 cases/year. A causal hemorrhagic delivery was found in all of our patients. Thyrotropic and corticotropic insufficiency were present in 86.2% of our patients, followed by gonadotropic and lactotroph insufficiency in 72.3% and 38.5% of patients, respectively. Somatotropic insufficiency was explored by a dynamic test in only 8 patients, concluding with somatotropic deficiency in 10.8% of cases. Hormone replacement therapy was initiated in all patients based on the affected anterior pituitary axis. In no case has the somatotropic sector been substituted in our series. Bone densitometry was performed in 21 patients, on average 5 years after the diagnosis of SS. Bone mineralization disorders were found in 18 patients: 10 patients had osteoporosis and 8 patients had osteopenia. The lumbar spine was more frequently involved than the femoral neck. Two patients had femoral neck fractures associated with low energy falls, on average 33 years after the diagnosis of SS. In univariate analysis, bone mineral loss was correlated with age, body mass index, vitamin D level, duration of SS and estrogen progesterone Hormone replacement. However, in multivariate analysis no factor was significantly correlated with an elevated risk of bone mineral loss.
Discussion-Conclusion
Anterior pituitary insufficiency, especially in sex and growth hormones, as well as an overdose of thyroid hormones and glucocorticoids could increase bone mineral loss. In fact, bone loss is increased in SS compared to other causes of anterior pituitary insufficiency since patients with SS had an earlier disease onset and more severe hormonal deficits.

Drug-induced galactorrhea and gynecomastia: a case report

Erika Jurkutė[1], Tomas Masilionis[1], Aistė Kondrotienė[1,2], Birutė Žilaitienė[1,2] & Rasa Verkauskienė[1,2]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Finding the cause of gynecomastia and galactorrhea can be challenging, hence one of the most important cornerstones is detailed case history. Hereby we present gynecomastia and galactorrhea case, caused by drug abuse.
Case
A 24-year-old male, 3 years suffering from gynecomastia and galactorrhea, came for an endocrinologist consultation in 2020. As known from documentation laboratory blood results, lungs X-ray and abdominal ultrasound did not reveal any pathological changes. Chest ultrasound confirmed gynecomastia without any lymph nodes changes, although repeated prolactin concentration (165,26 mU/l) stayed in the normal range (89-365 mU/l). Unfortunately, due to the pandemic of Covid-19, further investigation stopped. The patient was referred for the consultation of an endocrinologist in 2021 summer since heavy galactorrhea and gynecomastia remained. The patient denied any diseases, medication use, allergies, family history of endocrine diseases. Objective examination showed normal body mass (BMI 24,9 kg/m^2), heavy whitish secretion from both nipples, normal volume testes (20 ml). Laboratory blood tests were done in July 2021- moderate hyperprolactinemia was observed (419,44 mU/l). The patient was referred for the head MRI, no pathological findings were identified in the hypothalamus-pituitary region. The case was discussed in the multidisciplinary meeting and it was suggested to abstain from the medical treatment, to repeat testicular and abdominal ultrasound, lungs Xray for ruling out an active oncology process, to perform a cytological examination of secretion, to review the history of the case including possible drug abuse. While planning further investigations during the next consultation, the patient unwillingly confirmed regular cocaine abuse and discontinued further testing.
Conclusion
after taking cocaine, the levels of prolactin in the blood fall to baseline. However, hyperprolactinemia develops within 4 days of dosing (in the absence of repeated administration) [1]. These prolactin fluctuations, as well as unwillingness to reveal drug abuse, makes gynecomastia and galactorrhea causes identification challenging in drug users.

Somatostatin analogues in the treatment of a patient with acromegaly - possible positive effects on concomitant epilepsy (a clinical case)

Sergey Seferyan, Polina Zakharova & Irena Ilovayskaya
Moscow Regional Research and Clinical Institute (MONIKI), Neuroendocrinology, Moscow, Russian Federation

Somatostatin may act as a neurotransmitter in the neural network. Ìts associated with a possible long-term effect on calcium channels and, as a result, on the membrane potential of the cell. Bradycardia due to somatostatin analogues' use could be a clinical demonstration of such effect. We would like to present a clinical case of a female patient with acromegaly and possible positive effect of octreotide treatment on concomitant epilepsy. From 2000 (age 40) a woman noted swelling of the face, a slow increase in the size of the hands and feet, hyperhidrosis, but she did not pay much attention to these signs. In 2011 (age 51) she noted episodes of loss of consciousness and convulsive seizures that why she referred for medical help. Endocrinologists recognized clinical signs of acromegaly. According to brain MRI pituitary macroadenoma (4.5x3.0x6.0 cm, V 38.7 cm3) with latero-suprasellar extension and the frontal lobe of the right hemisphere invasion was revealed. IGF-1 levels were 829 ng/ml (56-261) so active acromegaly was diagnosed, epilepsy was considered as secondary condition due to giant adenoma. Debulking surgery with consequent radiosurgery (Novalis) of the residual tumor was performed. Then she received octreotide prolonged release 30 mg monthly and achieved biochemical control. At the same time with acromegaly treatment, she started anticonvulsant therapy with valproic acid (1200 mg daily) and convulsive symptoms disappeared. Till February 2021 (age 61) she was stable, and octreotide was withdrawn, IGF-1 without treatment 118-159 ng/ml (43-220). Since April 2021 she noticed convulsive syndrome again despite the continuous use of valproic acid. Neurologist recommended to continue valproic acid at the same dose, however, convulsive symptoms occurred. In this case, we suggested that treatment with somatostatin analogues was associated with absence of convulsive symptoms in acromegaly patient with lesion-induced epilepsy. We cannot exclude that withdraw of possible positive effect of somatostatin analogues on ion channels disorders resulted in epilepsy relapse, which requires further study of additional therapeutic properties of drugs in this group.

Delayed diagnosis of pituitary stalk interruption syndrome in a 26-years-old patient

Yosra Abderrahim, Boubaker Fadia, Hana Charfi, Arige Abid, Houcem Mrabet, Zantour Baha, Najoua Lassoued, Alaya Wafa & Sfar Mohamed Habib
University Hospital Tahar Sfar Mahdia, Endocrinology-Diabetology and Internal Medicine Department, Mahdia, Tunisia

Introduction
Pituitary stalk interruption syndrome (PSIS) is a rare congenital pituitary defect with an estimated incidence of 0.5 per 100,00 births. This syndrome has

heterogeneous clinical presentations with varying degrees of pituitary hormones deficiencies. PSIS is commonly diagnosed during neonatal period and infancy. However, when symptoms are not evident or overlooked, the diagnosis could be delayed exposing the patient to acute, such as acute adrenal insufficiency, and chronic complications.
Case report
We report a case of a 26 year-old male patient who was referred to our endocrinology department with complaints of short stature and impuberism. The patient had a history of prematurity, poor statural growth, learning and attention difficulties resulting in an early school dropout. On physical examination, the patient's weight and height were 47 kg and 140 cm respectively, both under the 5th percentile. He had a micropenis and a reduced testicular volume with absence of pilosity (Tanner stage 1). A blood test assessing pituitary hormones was performed showing an anterior hypopituitarism with undetectable testosterone level. Magnetic resonance imaging exhibited the diagnostic triad of PSIS associating hypoplasia of the anterior pituitary gland, absence of the posterior pituitary and a thin and interrupted pituitary stalk. Further investigations revealed metabolic and bone complications manifesting in Hypercholesterolemia (Total cholesterol = 8 mmol/l) and a pre-diabetic status (HbA1c= 6%). DEXA scan showed a femoral neck osteopenia and a spinal osteoporosis. The patient started immediately hormonal replacement therapy with a close clinical and biological follow-up.
Conclusion
Growth retardation is the most common presentation of PSIS. Hence the importance of early detection and investigation of short stature as any delay in diagnosis may lead to severe complications and heavy psychosocial consequences.

Pathomorphological markers of somatotroph neuroendocrine tumors predicting the treatment outcome in acromegaly

Agnieszka Tomasik[1], Maria Stelmachowska-Banaś[2], Maria Maksymowicz[3], Izabella Czajka-Oraniec[2], Dorota Raczkiewicz[4], Grzegorz Zieliński[5], Jacek Kunicki[6] & Wojciech Zgliczyński[2]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Department of Endocrinology, Poland; [3]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Cancer Pathomorphology, Warsaw, Poland; [4]School of Public Health, Centre of Postgraduate Medical Education, Department of Medical Statistics, Warsaw, Poland; [5]Military Institute of Medicine, Department of Neurosurgery, Warsaw, Poland; [6]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Neurosurgery, Warsaw, Poland

Background
Transsphenoidal adenomectomy of GH-secreting pituitary tumour is a first-line treatment of acromegaly. Pharmacological treatment is recommended if surgery did not lead to disease remission. Pathological assessment of postoperative tissue provides clinicians with valuable information on the disease course.
Aim
The aim of this study was to assess whether clinical, imaging, and pathological characteristics can predict surgical remission and response to first-generation somatostatin analogs (SRLs) and pasireotide LAR in acromegaly patients.
Patients and methods
A retrospective analysis of a study cohort of 120 patients with acromegaly, treated in one endocrinology centre was performed. Data on demographics, hormonal and imaging results, pathological evaluation (immunostaining for pituitary hormones, Ki-67 index and granulation pattern) and treatment outcome was extracted from the Polish Acromegaly Registry and analyzed.
Results
Patients who achieved surgical remission were older at diagnosis (50 *vs.* 37 years on average, $P<0.001$), had lower fasting GH, IGF-1 and PRL concentrations at diagnosis (4.68 *vs.* 18.9μg/l on average, $P<0.001$; 2.99 *vs.* 3.53xULN on average, $P=0.004$, 11.1 *vs.* 22.4 ng/ml on average, $P=0.015$, respectively) and had smaller tumours (12 *vs.* 24 mm on average, $P<0.001$) which were less invasive than in patients with active acromegaly after surgery. The pathology results showed that patients with surgical remission more often had densely granulated tumours (73.17% *vs.* 40.00%, $P=0.001$) with positive staining for α-subunit (58.33% *vs.* 35.48%, $P=0.021$) and lower Ki-67 index (87.50% *vs.* 65.57% with Ki-67 index $<1\%$, $P=0.002$) compared to patients without surgical remission. Patients, who responded well to first-generation SRLs, presented less common extrasellar expansion and compression of the optic chiasm at diagnosis of acromegaly (58.62% *vs.* 90.00%, $P=0.006$ and 13.79% *vs.* 56.67%, $P=0.001$, respectively) compared to patients with poor response to SRLs. They also had more common densely granulated tumours (62.96% *vs.* 14.29%, $P<0.001$). However, no significant differences between patients with good and poor response to pasireotide LAR were found. In multivariate logistic regression analysis, independent predictors of post-surgical remission were normoprolactinaemia at diagnosis (OR=5.87, $P=0.023$), densely granulated tumour in electron microscopy (OR=5.92, $P=0.012$) and lower fasting GH concentration at diagnosis (OR=0.88, $P=0.001$).
Conclusions
Patients with densely granulated somatotroph tumours are more likely to achieve surgical remission and to respond well to first-generation SRLs. Positive staining for α-subunit and lower Ki-67 index increase the likelihood of surgical remission in acromegaly. The pathological assessment of tumour tissue is an important part of acromegaly patient's evaluation providing valuable information on tumour's characteristics. Together with clinical and imaging parameters it can help to predict the treatment outcome.

Two cases: hemorrhagic rathke cleft cysts mimicking a hemorrhagic adenoma

Hatice Sebile Dökmetaş[1], Ayberk Bayramgil[2], Meriç Dökmetaş[2], Fatih Kılıçlı[1], Güneş Dorukhan Çavuşoğlu[2], Kü bra Karaipek[2] & Ayşe Gül YILDIRIM KIZILKAYA[2]
[1]Medipol Mega University Hospital, Endocrinology, Istanbul, Turkey; [2]Medipol Mega University Hospital, Internal Medicine, Istanbul, Turkey

Introduction
Rathke Cleft Cysts(RCCs) are benign cysts arising from the remnants of Rathke's pouch. The most common symptoms are visual field disorders, headache, and pituitary dysfunction.
Case 1
A 26-year-old male was admitted with headache that started 4 days ago. Cranial MRI revealed an appearance mimicking a hemorrhagic adenoma in pituitary. Pituitary hormones were found as normally. Pituitary MRI showed a 12x10x10 mm hemorrhagic RCCs located in the midline. The patient's headache disappeared spontaneously within 3 days without the use of any medication. One month and six months later, MRI showed a progressive shrinkage of hemorrhagic RCCs diameters as 4.5x5x7.5 mm and 3 mm, respectively. In the pituitary MRI taken at the last follow-up 15 months later, it was observed that sequelae remained as a millimetric-thick slit-shaped microcyst in the central gland.
Case 2
A 24-year-old female was admitted with a complaint of headache that started one month ago. The patient, who had a throbbing headache on the right side of her head, was relieved with analgesics. Pituitary MRI revealed a hemorrhagic RCCs with diffusely expanding pituitary gland with a size of 18x13x8 mm and leveling inside. The patient's pituitary hormones were checked and no pathological values were found. In the control pituitary MRI one month later, the size of the hemorrhagic RCCs decreased to 8x13x8 mm.
Conclusion
Patients with hemorrhagic RCCs whose symptoms decreased during close follow-ups and who did not have hormonal disorders were not operated on. The sizes of the masses of the patients who did not develop any complaints or hormonal disorders during their follow-ups decreased.

Central precocious puberty on pituitary adenoma : about a case report

Kaoutar Rifai, Kamel Farah, Hind Iraqi & Mohamed Hassan El Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Central precocious puberty (CPP) is a frequent reason for consultation in pediatrics. It is defined as the development of sexual characteristics before the age

of 8 years in girls and 9 years in boys. Pediatric pituitary adenomas are rare. We report the case of a patient who presented with central precocious puberty on pituitary adenoma.
Observation
This is a patient aged 7 years and 6 months, without any particular history, having consulted initially for a premature thelarche. Her history of the disease goes back to the age of 7 years by the development of mammary glands, appearance of pubic and axillary hair without metrorrhagia, with an acceleration of the statural growth rate. Moreover, she did not report any pituitary tumor syndrome, and she had a significant psychological impact. The clinical examination found: a weight: 38 kg (+3DS), a height: 1,42 m (+3DS), BMI: 18,8 kg/m^2, blood pressure: 120/60 mmhg, estimation of the pubertal stage: S3P3 and a dry vulva. The rest of the clinical examination was unremarkable. Pelvic ultrasound objectives a thin and median vacuity line, ovarian length $\geq$ 25 mm, body to neck ratio $>$1. Estradiol level :20 pg/ml. Bone age is 9 and ½ years (advanced by 2 years/chronological age). For etiological orientation : Inhibin B : 85 pg/ml, LH : 2.6 IU/l, FSH :6 IU/l, LHRH TEST : peak LH : 50 IU /l, LH/FSH ratio : 6. The diagnosis of central precocious puberty is confirmed. Hypothalamic-pituitary MRI shows a pituitary adenoma of 10*9 mm far from the optic chiasm. The fundus and the visual field did not show any abnormalities. The evaluation of the various endocrine axes is without particularity. Therapeutically, she was treated with GnRh agonists with a good clinical and biological evolution.
Discussion and conclusion
Central precocious puberty is frequent, the search for a tumoral etiology remains a priority. Pediatric pituitary adenomas are rare, representing 3% of all pediatric intracranial tumors and 5% of all pituitary adenomas. They are mainly functional tumors, more frequently secreting prolactin, ACTH, and growth hormone, while gonadotropin hypersecretion is very rare. 4 cases of PPC on pituitary adenoma have been reported in the literature: 2 cases secreting FSH alone and 2 cases secreting FSH and TSH. Treatment with GnRH analogues is indicated in the case of clinically, biologically and radiologically progressive PP, with an impact on adult height, and on the psychological level.

Automated data extraction of structured clinical correspondence with SNOMED coding to assess regional epidemiology of common pituitary conditions

Shao Hao Alan Yap[1], Alex Graveling[2], Prakash Abraham[2] & Sam Philip[2]
[1]University of Aberdeen, Medical Student, Aberdeen, United Kingdom; [2]JJR Macleod Centre for Diabetes & Endocrinology (David Anderson Building), Aberdeen Royal Infirmary, Diabetes & Endocrinology, Aberdeen, United Kingdom

Introduction
Pituitary disorders are associated with increased mortality and morbidity. Data on the prevalence of pituitary disorders is scarce. Formal routine coding of diagnoses in outpatient endocrine practice lags behind medical coding of inpatients. Standardised coding could improve our understanding of disease burden and highlight areas of increasing need within our services.
Objective
Automatically extract and assign SNOMED codes for endocrine diagnoses from structured outpatient correspondence. The coded information was used to ascertain the prevalence of pituitary disorders in patients attending endocrine outpatient clinics at Aberdeen Royal Infirmary, Aberdeen, Scotland.
Method
Retrospective study conducted in a tertiary outpatient endocrine clinic. Patients from postcodes within 2 regional areas of NHS Grampian were included (Aberdeen City and Aberdeenshire), who attended clinics between 1st January 2018 to 31st December 2019. Based on the mid population estimates from the National Records of Scotland, the total study population was 489,880 inhabitants. After each clinical consultation, which may be face to face or remote, a structured letter was created, containing a detailed problem list. Structured correspondence was introduced to provide more uniform output from clinic appointments and ensure key information was captured (despite clinics being conducted by several different healthcare professionals). An automated script was developed to extract each problem statement and update a database. Unique problem list entries were manually coded using the 'disorder' concepts from SNOMED CT (UK edition).
Results
A total of 1870 patients attended the outpatient services (1251 of them were female with a male to female ratio of 1:2); age ranged from 16-96 years. 464 (21.2%) had pituitary disorders. Pituitary disorders have a prevalence of 94.7 per 100,000 inhabitants, with a mean age of 51yrs (SD $\pm$ 18) and male to female ratio at 1: 1.5. The most common diagnosis was pituitary adenoma with a prevalence rate of 65.3 per 100,000 inhabitants. The prevalence per 100,000 for the subcategories were functionless pituitary adenoma (22), acromegaly (7.1) and pituitary-dependent Cushing's disease (3.1). The prevalence is consistent with previous studies.
Conclusion
Automated text parsing of structured endocrine correspondence allowed the creation of a database of endocrine problems. SNOMED coding enabled us to create a common endocrine reference set. Standardised coding helped assess the prevalence of pituitary disorders in this population. A similar automated approach to allow medical coding of routine medical correspondence could help improve understanding of the epidemiology of conditions managed predominately in outpatient settings, as well as facilitate quality improvement projects.

Acromegaly-related cardiovascular morbidity In Tunisian Patients: Prevalence and clinical peculiarities

Faten Haj Kacem Akid[2], Wafa Belabed[2], Mohamed Abdellahi Ahmed[2], Mouna Elleuch[2], Dhoha Ben Salah[2], Fatma Mnif[2], Nabila Mejdoub[2] & Mohamed Abid[2]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background and Aims
Cardiometabolic comorbidity is a well-established complication related to GH hypersecretion. Several studies have highlighted an increased cardiovascular risk in this population. The objective of the current work was to investigate the cardiovascular complications in Tunisian patients diagnosed with acromegaly.
Patients and Method
We conducted a retrospective study that included all patients diagnosed with acromegaly who have been followed up, from 1997 to 2021, at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia. The review of medical charts provided a detailed cardiovascular evaluation in the investigated population.
Results
Our sample included 29 with a mean age at diagnosis of 45.8 $\pm$ 12.4 years old (extremes: 23-72 years) and slight male predominance (52.0%). The overall prevalence of arterial hypertension in the studied population was 20.7% with a mean duration of the evolution of 9.3 years (extremes: 2– 20 years). Hypertension was newly diagnosed in 6.9% of patients. Arrhythmia and cardiac conduction disorders were observed in 10.3%. The cardiac ultrasound assessment revealed a concentric left ventricular hypertrophy in 15.4% of patients. Severe complicated hypertrophic cardiomyopathy with left heart insufficiency was reported in 3.4%. Aortic valvulopathy was found in 3.4% of cases. Ischemic heart disease affected 6.9% of patients.
Conclusion
Cardiovascular complications represent the leading cause of mortality in patients with acromegaly [1]. A various spectrum of cardiovascular manifestations can occur due to GH exaggerated secretion. Hypertension, ischemic heart disease, and arrhythmia are the most common ones. Other acromegaly-specific cardiac conditions can be found such as acromegalic cardiomyopathy [2]. The GH and IGF-1 excess affects the heart morphology and may impair its performances leading to insidious alterations of heart tissue and functions, independently of additional cardiovascular factors. The optimal surgical and medical management of acromegaly is associated with an improvement of cardiovascular risk in this population [3].

The frequency of water and electrolyte disorders after transnasal surgery for adenomas of the hypothalamic-pituitary region: what does active control of blood sodium level give?

Khava Fargieva, Daria Mikhailova, Oksana Ivashenko, Vilen Azizyan, Andrey Grigoriev, Arkadiy Sergeev, Elena Przhiyalkovskaya, Pigarova Ekaterina, Larisa Dzeranova & Natalya Mokrysheva
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Water-electrolyte disorders are serious complications after transnasal adenomectomy for formations of the hypothalamic-pituitary region. The purpose of this work was to evaluate the incidence of postoperative hyponatremia in the tactics of active control of sodium levels in the blood.
Materials and methods
The study included the results of a dynamic study of blood sodium levels in 53 patients (mean age 46.6 years [min 19; max 68]) with pituitary adenomas (GH-secreting - 31 patients, ACTH-secreting - 14 patients, hormonally inactive - 6 patients, TSH-secreting - 1 patient), who underwent endoscopic transnasal transsphenoidal adenomectomy. Sodium control was carried out initially before surgery, after 12-24 hours, on days 2-3, 4-5 and 6-7 after surgery. Comparison of the frequency of hyponatremia was carried out with data on the lack of alertness about the possibility of developing postoperative hyponatremia and the lack of blood sodium control in 2008 (0.7%), the absence of alertness, but periodic monitoring of blood sodium but without mandatory monitoring of blood sodium levels in 2017 (7.2%).
Results
Initially, before surgery, only one patient with a TSH-secreting pituitary tumor had a decrease in the sodium concentration in the blood to 135 mmol/l (reference values 136-145 mmol/l) - 1/53 (1.8%). During the first 12-24 hours and on days 2-3 after surgery, hyponatremia of 135 mmol/l was also detected in 1 case in different patients with ACTH-secreting pituitary adenomas (1.8%), as well as 1 case of low sodium blood to 130 mmol/l in the period of 2-3 days after the operation, which was of a long-term nature and a tendency to reduce the level of sodium in the blood to 125 mmol/l. On days 4-5, a total of 5 hyponatremias (4 newly emerged), 3 of which were of moderate severity 129-125 mmol/l (7.5%), were detected, on days 6-7, 12 hyponatremias were recorded (8 newly emerged), of of which 4 were of moderate severity, and 8 of mild severity (22.6%). The overall incidence of postoperative hyponatremia was 28.3%.
Conclusions
Transient hyponatremia of the early postoperative period up to the 3rd day after surgery does not appear to be clinically significant. An increase in the frequency and severity of hyponatremia was noted from the 4th post-operative intervention, which necessitates mandatory monitoring of blood sodium levels. The approach of active monitoring of the blood sodium level allowed to increase the detection of hyponatremia by 3.9-32.6 times

Hypothalamic syndrome secondary to systemic sarcoidosis

José Vicente Gil Boix, Guillermo Serra Soler, Mercedes Noval Font, Javier Bodoque Cubas, Meritxell Viñes Raczkowski, Alicia Sanmartín Sánchez, Santiago Tofé Povedano, Elena Mena Ribas, Mercedes Codina Marcet, Josefina Olivares Alcolea, Francisca Caimari Palou, Vicente Pereg Macazaga & Iñaki ArgüElles Iménez
Hospital Universitari Son Espases, Endocrinology and Nutrition, Palma, Spain

Introduction
Sarcoidosis is a rare systemic disease where clusters of immune cells form granulomas in various organs of the body. Its prevalence ranges from 1-40 per 100,000 people in Europe. Neurological involvement of the disease occurs in 5-10% of cases, with the hypothalamus-pituitary gland being one of the most commonly affected structures.
Clinical Case
A 36-year-old male with a history of hypertension, obesity, asthma and OSAS. He went to the emergency department due to symptoms of 4 months of evolution of asthenia, hypersomnia, compulsive food intake with a weight gain of 30 kg and behavioral disorders, being admitted to the Internal Medicine department. Physical examination revealed a weight of 157 kg, height 177 cm (BMI 50.1) and white striae on the abdomen. Cardiopulmonary auscultation was normal. Neurologically, there was evidence of decreased strength and painful stiffness on extension in the upper limbs.
Cranial CT scan showed two intracranial lesions, at hypothalamic and right parietal level, with associated perilesional oedema. These lesions were confirmed by MRI, suggesting an inflammatory-granulomatous aetiology. Fine-needle aspiration with Endo Bronchial Ultra Sound of a mediastinal lymph node revealed non-necrotising granulomatous lymphadenitis and a diagnosis of systemic neurosarcoidosis was made. Treatment with corticosteroids, rituximab and mycophenolate mofetil was started. After discharge, he was admitted to the intensive care unit a few days later due to disturbance of consciousness consciousness secondary to hypernatraemia. Ionogram showed a serum sodium of 172 mEq/l with a plasma osmolality of 380 mOs/Kg and a urinary osmolality of 843 mOsm/kg. The endocrinology department, after ruling out diabetes insipidus and assessing the hormone analysis, diagnosed it of hypothalamic syndrome secondary to neurosarcoidosis, presenting with hypernatraemia due to hypodipsia/adipsia, morbid obesity, type 2 diabetes mellitus, hypogonadotropic hypogonadism and hyperprolactinaemia. At discharge, treatment for diabetes was started with metformin and weekly dulaglutide, hormone replacement therapy was started with testosterone gel and a controlled water intake of 2.5-3 litres per day was indicated, depending on physical activity and the season of the year.
Conclusions
- Hypothalamic syndrome as a consequence of neurosarcoidosis can affect a number of vital endocrine and non-endocrine functions that are difficult to control.
- Hypothalamic adipsic hypernatremia can present with severe symptoms and these patients should be educated in controlled fluid intake.

Peak cortisol level on synacthen stimulation test in cushing's disease

Razan Ali Rashid, Christopher S Boot, Andy James & Yaasir Mamoojee
The Newcastle upon Tyne Hospitals, Endocrinology and Metabolic medicine, Newcastle upon Tyne, United Kingdom

Background
Diagnostic work-up for Cushing 's syndrome (CS) can be challenging, with variable performance characteristics on screening tests. We were recently referred a young female patient with Cushing's disease (CD) due to a microadenoma. She presented with a seizure and initial biochemical work-up included a Synacthen stimulation test (SST). Her peak cortisol rose to over 1,000 nmol/l. Exaggerated response during SST is expected in hyperestrogenic states due to elevation in cortisol-binding globulin concentrations, for e.g. pregnancy and those taking estrogen-containing pills. However, overstimulation of the adrenal cortex by increased ACTH, as in ACTH-driven CS, is physiologically expected to result in hypertrophy of the zona fasciculata and therefore produce a heightened cortisol response during SST.
Aim
We retrospectively compared the difference in peak cortisol concentrations, after 250 µg tetracosactide administration during SST, in patients with active CD and those without CS but intact steroid axis.
Methods
In our unit, all patients with CD undergoing Transphenoidal Sugery (TSS) are started on steroid replacement post-operatively. SST is performed, after a standard steroid weaning, at 6-8 weeks post-operatively and if normal, standard biochemical work-up for steroid excess takes place again. We included all patients who were not in biochemical remission after TSS. Our comparator cohort includes all patients with a normal SST result after pituitary surgery for non-Cushing tumours. Roche I and Roche II Cortisol assays were used, with a normal SST response defined as peak serum cortisol level of >550 nmol/l or >420 nmol/l, respectively. Conversion of peak cortisol level from Roche I to Roche II equivalent concentration was done using validated regression equation. Mann-Whitney U test and Fisher's exact test were used for statistical analysis for continuous and categorical variables respectively. Results are expressed as mean ($\pm$SD).
Results
13 patients with active CD and 210 patients with normal SST results were included in our CD and control cohort. Mean peak cortisol in our CD cohort was higher at 1020 ($\pm$305) nmol/l compared to 677 ($\pm$144) nmol/l ($P<0.01$). 62% of SSTs in the CD cohort had a peak cortisol of >850 nmol/l compared to 9% in the control cohort ($P<0.01$).
Conclusion
Patients with active CD demonstrate a higher than average cortisol response during SST. Clinicians should keep a high index of suspicion for ACTH-driven

CS in patients with an exaggerated cortisol response on SST, especially in the context of initial biochemical work-up for pituitary incidentalomas.

Giant prolactinomas: a descriptive study and prognostic analysis

Mouna Elleuch, Hamdi Frikha, Loukil Fatma, Dhoha Ben Salah, Maalej Souhir, Mouna Mnif, Fatma Mnif, Nadia Charfi, NABILA REKIK MAJDOUB, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Giant prolactinomas (GP), defined as prolactinomas ≥4 cm in maximum dimension, are uncommon, with reported prevalence of 2 to 3% of all prolactinomas.
Aim
The aim of this study is to describe clinical and paraclinical characteristics of GP and to identify predictors of therapeutic response.
Matherials and methods
A retrospective, single-center, descriptive study including 18 patients with GP followed at the endocrinology department of Hedi Chaker University Hospital of Sfax, Tunisia.
Results
Mean age was 42.9 ±16.9 years. Patients were predominantly male (77.8%). Mean tumor size was 50.4 ±9.3 mm with a maximum of 70 mm. Prolactinemia at diagnosis was 10569.1 ±19667 ng/ml on average [56-81940]. Clinically, main symptoms included signs of intracranial hypertension (78%) and visual field defects (72.2%). Galactorrhea was reported in 25% of patients only. Pituitary insufficiency included thyrotropic, corticotroph and gonadotropic axes in 33%, 11% and 50% of cases respectively. Sixteen patients were treated with dopamin agonists (bromocriptin 75% and cabergolin 25%), 3 of them showed resistance to medical treatment. Surgery was indicated in 7 cases during follow-up: optic chiasm compression (4 cases) and resistance to medical treatment (3 cases). Mean prolactinemia at 1 year of follow-up was 726.3 ±1315.2 ng/ml. A strong correlation was found between initial prolactinemia and six-month decrease of prolactin level ($r=0.68$; $P=0.04$). However, therapeutic response did not correlate with age or initial tumor size. There was no reported case of complete remission.
Conclusion
GP is a rare form of prolactinomas. It mainly affects men and its symptoms are due to mass-effect. GP respond generally well to dopamin agonists. Initial prolactinemia could be a good marker of therapeutic response.

DOI: 10.1530/endoabs.81.EP665

Pharmacokinetic profile of cabergoline in patients with dopamine agonist resistant prolactinomas: a pilot study

Aleksandra Shutova[1], Natalia Fedorova[1], Svetlana Vorotnikova[1], Vitalii Ioutsi[1], Juriy Panov[2], Ekaterina Pigarova[1], Larisa Dzeranova[1] & Ekaterina Troshina[2]
[1]Federal state Budgetary Institution 'National Medical Research Centre of Endocrinology' Ministry of Health of the Russian Federation, Department of neuroendocrinology, Moscow, Russian Federation; [2]Federal State Budgetary Institution 'National Medical Research Centre of Endocrinology' Ministry of Health of the Russian Federation, Moscow, Russian Federation

Introduction
Approximately 20% of patients with prolactinomas do not respond satisfactory (resistant) even to high dose dopamine agonist treatment. Worth noticing that there are no clear prognostic signs of treatment's resistance as well as its etiology is a subject of discussion.
Aim
The aim of our study was to assessabsorption and metabolism of cabergoline in patients with dopamine agonist-resistant prolactinomas.
Materials and methods
In patients ($n=4$) with resistant prolactinomas (no normalization of PRL, no menses with max tolerated dose of cabergoline more than 3 mg a week) and one with normal effect of the drug we conducted a pharmacokinetic test: 1) cabergoline was preliminary withdrawn 4 days before the test; 2) at 9:00 the blood was taken before and 30-, 60-, 90-, 120-minutes and 4 hours after taking the cabergoline in a fixed doze of 0.5 mg. The concentration of cabergoline substance in the serum was measured using LC-MS/MS.
Results
It is shown that the serum cabergoline concentration curve in 3 patients with resistance to treatment doesn't represent expected pharmacokinetic peaks (the growth rate less than + 1-50%). The pharmacokinetic curve of 1 resistant patient represented a cabergoline concentration peak at 30 min point (the growth rate +175%) with subsequent decline to baseline levels. The serum cabergoline concentration curve of drug-sensitive patient is characterized by an already significant baseline concentration that becomes progressively higher reaching an outstanding peak (the growth rate +112%) at the end of the test period.
Conclusion
Our pilot results show that the patients with dopamine-resistant prolactinomas may have a defect in forming (absorption or metabolic abnormalities) an adequate blood concentrations of the drug. Understanding the underlying mechanisms will allow us to develop personalized treatment strategy.

Male pituitary-gonadal axis function in obstructive sleep apnoea syndrome: the effect of continuous positive airway pressure

Richard Leigh[1,2], Siobhá n Hamon[3], Michael McWeeney[4], Aonghus O'Loughlin[5] & Paula O'Shea[5]
[1]Galway Clinic, Biochemistry Laboratory, Galway, Ireland; [2]Trinity College Dublin, Dublin, Ireland; [3]Ryan Institute, National University of Ireland, Galway, Galway, Ireland; [4]Galway Clinic, Galway, Ireland; [5]University Hospital Galway, Ireland

Background
Obstructive sleep apnoea syndrome (OSAS) is common; disproportionately affecting the overweight and obese. Continuous positive airway pressure (CPAP) is the first-line treatment for moderate to severe OSAS. Clinical equipoise exists as to whether CPAP treatment directly affects pituitary-gonadal hormone synthesis.
Study Aim
This study aimed to determine the effect of CPAP treatment on gonadotropins, prolactin, sex-hormone binding-globulin (SHBG), total testosterone (TT) and calculated free testosterone (cFT) in newly diagnosed male OSAS patients. 2018 European Health Research Compliance. Ethical approval was sought from the Bon Secours Health System Clinical Ethics Committee (CEC) and granted on the 08/03/2019. All participants in the research gave informed consent, obtained in accordance with guidelines provided by the CEC, Trinity College Dublin and the Royal College of Surgeons Ireland.
Methods
OSAS was diagnosed via gold standard in-house polysomnography studies. Participants provided venous blood samples before and twice after (first night CPAP, n = 25 and 3 months CPAP, n = 13) commencing CPAP treatment. At each time-point, concentrations of TT, SHBG, prolactin and gonadotropins were measured. In total, 53 males with a diagnosis of OSAS confirmed by polysomnography were prospectively enrolled to this study.
Results
Hypogonadism in the cohort was low ($n=2$). Hyperprolactinaemia was prevalent ($n=25$). TT and cFT were significantly negatively correlated with obesity. cFT was correlated with OSAS severity, but not TT. Significant reductions were observed in TT (pre 16.6 nmol/l, post 13.5 nmol/l, $P=0.003$), cFT (pre 332 pmol/l, post 250 pmol/l, $P=0.001$) and prolactin (pre 360 mIU/l, post 225 mIU/l, $P=0.006$) after 3-months of CPAP ($n=13$). No significant change was observed in other pituitary hormones or SHBG.
Conclusions
The prevalence of hypogonadism is low in this cohort. CPAP treatment reduced testosterone and prolactin in eugonadal males with OSAS. The benefits of CPAP treatment for OSAS may be independent to change in serum testosterone levels. Hypogonadal OSAS patients should be managed via strategies other than CPAP alone.

San Camillo Forlanini, Endocrinology Unit, Department of Oncology and Medical Specialities, Rome, Italy; [7]Humanitas Gavazzeni, Endocrinologia, Bergamo, Italy; [8]Istituto Auxologico Italiano IRCCS, Division of Endocrine and Metabolic Diseases, Milan, Italy; [9]Niguarda Hospital, Division of Endocrinology, Milan, Italy

Background

primary empty sella (ES) represents a frequent finding (up to 35% of the general population). According to the literature, the prevalence of hypopituitarism in ES ranges between 19-52%. Data on the natural history of ES over a long time, especially in incidental ES, are still lacking and the management can be challenging.

Objective

our primary aim was to assess in a large cohort of patients with ES the prevalence and determinants of hypopituitarism. Our secondary aim was to explore the hormonal and neuroradiological evolution after at least 6-months of follow-up.

Design and methods

retrospective and multicenter study based on medical records of all patients with ES attending four Pituitary Units between 1984-2020. The availability of the neuroimaing and hormonal assessment at diagnosis represented the inclusion criteria. Data collected at diagnosis and at the last available follow-up were analysed.

Results

402 patients (63% females, mean age 51.5 ± 15.5 years) were enrolled. Dynamic evaluations of pituitary function were available in 326 (81%). Longitudinal data were available in 166/402 with a median follow-up of 58 months.

Diagnosis

ES was incidentally discovered in 72% patients whereas in 28% it was diagnosed because of a suspected endocrinopathy (hypopituitarism or hyperprolactinemia). ES was partial in 66.4%, total in 13.4%, and not defined in 20.2%. Traumatic brain injury (TBI) was reported in 23% cases evaluated for this issue. In the overall group, at least one pituitary hormonal deficiency was present in 40.5% (hypogonadism = 20.4%, hypoadrenalism = 14.7%, GHD = 14.7%, hypothyroidism = 10.2%, DI = 1.5%; multiple deficiencies = 11%) and hyperprolactinemia in 6.5%. Hypopituitarism resulted significantly associated with male sex ($P = 0.03$), symptoms/signs suggestive of pituitary disease ($P < 0.001$), and TBI ($P = 0.004$), without significant associations with age, BMI, number of pregnancies and entity of ES. Interestingly, hypopituitarism was present in 29.1% patients with incidental ES (hypoadrenalism = 13.5%, GHD = 12.5%, hypogonadism = 8.7%, hypothyroidism = 2.8%, DI = 1.7%).

Follow-up

at the last evaluation, 5/166 (3%) patients, displayed new hormonal deficiencies and 6.1% showed a neuroradiological progression from partial to total ES. Most patients with hormonal deterioration were already hypopituitaric at diagnosis (80%). The development of new deficiencies was only associated with the increasing grade of ES ($P = 0.004$).

Conclusions

we described one of the largest cohort of patients with primary ES. Patients with ES need to be carefully evaluated at diagnosis, even if ES is incidentally discovered. We suggest completing the assessment with dynamic tests (screening for GHD and adrenal insufficiency). Hypopituitarism is frequent (40%) but a deterioration in pituitary function seems uncommon (3%).

DOI: 10.1530/endoabs.81.EP668

EP669

Predictors of surgical outcome and early criteria of remission in acromegaly

Ludmila Astafyeva[1], Alexsey Shkarubo[1, 2], Ibrahim Sameh R.A.[2], Inna Badmaeva[1], Yuliya Sidneva[1], Julia Strunina[1], Maxim Kutin[1], Dmitrii Fomicev[1], Oleg Sharipov[1], Dmitrii Andreev[1], Ilya Chernov[1] & Pavel Kalinin[1]

[1]N.N. Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation; [2]Peoples' Friendship University of Russia, Russian Federation

Objective

To analyze the remission factors of surgical treatment of acromegaly

Methods

A retrospective study involving 227 patients with acromegaly: 143 (63%) women and 84 (37%) men were operated via trassphenoidal endoscopic approach for pituitary adenoma removal between the periods of 2018-2021. The average age was 45 years [36.00, 56.00]. 118 patients had 6 months follow-up period (3-40 months). The IGF-1 index used for the evaluation, which was calculated using the formula: IGF-1 index = IGF-1 patient (ng/ml) /upper reference interval IGF-1 for this age (ng/ml). The remission for acromegaly was considered as decrease of the IGF-1 index less than 1.0 not later than 3 months following surgery. Intrasellar adenomas were observed in 99 (44%) cases, 128 (56%) tumors had different directions of extrasellar growth (suprasellar in 81, infrasellar in 28 and laterosellar in 64 cases). The tumor size were classified into microadenomas – 20 (8,8%) ($\leq$10 mm in diameter), small and medium (10-35 mm)-164(72,2%), large (36-59 mm)-38(16,7%), giant ($\geq$60 mm)-5(2,0%).

Results

Remission after the surgical procedure was achieved in 65 (55%) of 118 cases with a long follow-up period. The average [IQR] age of patients in the group with remission - 46 years [37,56], and those without remission - 39.00 [31, 50] years ($P = 0.044$). Median [IQR] GH before surgery in the group with remission was 10,77 ng/ml [5.84, 21.23], without remission – 28,00 [9.02, 65.75] ($P = 0.001$). Following the removal of microadenomas or macroadenomas of smaller and medium sizes, remission was achieved in 8(88,9%) and 50(58,8%) cases respectively, during the removal of tumors of large and giant sizes remission was achieved only in 7(29,2%) cases ($P = 0,004$). Considering the intrasellar localization of the tumor, remission was achieved at 36(75%) cases, whereas with adenoma with extrasellar growth in 29(41,4%) cases ($P = 0,001$). The risk of surgical treatment of acromegaly was low: postoperative transient diabetes insipidus was noted in 16,7% of cases, hyponatremia - in 4,8%, rhinorrhea - in 1,3%, meningitis - in 0,88%, epistaxis in one (0,4%) and visual impairment in one (0,4%) case. There were no deaths.

Conclusion

Significantly predictors affecting the remission of acromegaly were recorded in average aged, the absence of visual disturbances, low GH level before surgery, the presence of microadenoma or small and medium-sized pituitary macroadenoma, the absence of extrasellar tumor growth, a decrease in GH $<$2,06 ng/ml and IGF-1 index $<$1,9 in the early postoperative period, the absence of residual tumor tissue after surgery.

Xantho-granulomatous hypophysitis: analysis of clinical, biochemical, radiological and etiological characteristics

Dragana Miljic[1,2], Sandra Pekic Djurdjevic[1, 2], Mirjana Doknic[1, 2], Marko Stojanovic[1, 2], Marina Nikolic Djurovic[1, 2], Zvezdana Jemuovic[1], Toplica Milojevic[3], Mihailo Milicevic[2, 3], Emilija Manojlovic Gacic[2, 4], Jovan Jovanovic[2], Sanja Medenica[5] & Milan Petakov[1,2]

[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center Belgrade, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinic of Neurosurgery, University Clinical Center Belgrade, Belgrade, Serbia; [4]Institute of Pathology, University Clinical Center Belgrade, Belgrade, Serbia; [5]Department of Endocrinology, Internal Medicine Clinic, Clinical Center of Montenegro, School of Medicine, University of Montenegro, Podgorica, Montenegro

Introduction

Xanthomatous hypophysitis (XH) is characterized by inflammatory infiltration of the pituitary gland in which lipid laden macrophages predominate. It can be primary (3% of all primary hypophysitis) and secondary arising in the setting of other lesions: craniopharyngioma, Rathke's cleft cyst (*RCC*), adenomas (with subclinical apoplexy). It is more common in women and younger people. The clinical presentation is similar to pituitary tumors and may present with headaches, visual disturbances, hypopituitarism, and diabetes insipidus.

Aim

The aim of this study was to analyze a cohort of patients in whom the existence of xantho-granulomatous hypophysitis (XGH) was confirmed pathohistologically

(PH): their clinical, biochemical, radiological, etiological and pathohistological characteristics.
Material and methods
The study analyzed retrospectively collected data from electronic medical histories of patients with PH finding of XGH or XH diagnosed from 2015. to 2020. All patients were hospitalized at the Clinic for Endocrinology, Diabetes and Diseases of Metabolism, and the Clinic of Neurosurgery, University Clinical Center of Serbia.
Results
Cohort included three pediatric and nine adult patients, with an average age of 14.6 $\pm$ 4.7 and 54.9 $\pm$ 14.4 years (8 male and 4 female). Panhypopituitarism was diagnosed in 5 patients, exclusively men. Compression symptoms were present: headache in 8 patients (66%) and neuro-ophthalmic disorders in 4 patients (33%). Pituitary tumor, as a secondary cause, was found in 5 patients, three women and two men. One patient had a xanthomatous form of hypophysitis, others XGH. Cystic form were present in 3 (25%) patients, and solid in the remaining 9 (75%) patients. Primary, isolated forms were found in five cases (41%) while secondary ones were associated with RCC (2 patients, 16%) and pituitary tumors (5 patients, 41%).
Conclusion
In conclusion, we presented and analyzed a group of 12 patients with a rare form of XGH that differs from previously published studies in terms of sex dimorphism, lower prevalence of xanthomatous form and predominance of solid comparing to cystic forms on magnetic resonance imaging findings. Primary forms were, as expected, less frequent than secondary ones.

The many faces of Granulomatosis with Polyangitis(GPA) presenting with Diabetes Inspidus, visual disturbances, epistaxis and haematuria

Gideon Mlawa[1], Noha Meneissy[2], Shrini Patel[2], Muhammad Saleem[2], Zahid Khan[2], Saiful Islam[2], Rachel Gunnell[2], Hassan Rehmani[3], Barney Low[3] & Mahamud Bashir[2]
[1]Queen's Hospital, Diabetes and Endocrinology/Acute Medicine, London, United Kingdom; [2]Queen's Hospital, London, United Kingdom; [3]Queen's Hospital, Acute Medicine, London, United Kingdom

Introduction
Granulomatosis with polyangiitis (GPA) is an anti-neutrophil cytoplasmic antibody (ANCA)-associated systemic vasculitis of both small and medium-sized vessels. Pituitary involvement in GPA is uncommon and few cases have been previously reported. Isolated pituitary involvement in GPA is rare and 96% of cases are associated with other organ involvement. GPA commonly affects the upper respiratory tract (93%), lungs (73%) and kidneys (67%).
Case
A 46-year-old male was admitted for investigation of vision changes. He had a 2–3-month history of blurred vision, headaches (retro-orbital discomfort), left eye redness, arthralgia, and epistaxis. His visual acuity was 6/60 with a central scotoma. A pituitary MRI revealed a likely inflammatory mass, involving the hypothalamus and infundibulum, suggestive of hypophysitis. Whilst an inpatient, he was diagnosed with diabetes insipidus and hypopituitarism. His blood test showed FSH 1.0 iu/l, LH $<$0.2 iu/l, Testosterone $<$0.4 nmol/l, TSH 0.03 mu/l, FT4 7.4 pmol/l, Prolactin 83 miU/l, random Cortisol 323 nmol/l and a normal short Synacthen test. An ear, nose, and throat opinion was sought due to the recurrent epistaxis. A nasal biopsy was taken with histology diagnostic of GPA. This was backed by positive ANCA and an elevated ESR (79 mm/hr). He was treated with high-dose steroids and cyclophosphamide. This rapidly and remarkably relieved his symptoms. His visual acuity, central scotoma, and red eye improved. His ESR normalised and a repeat pituitary MRI revealed substantial resolution of the mass. He was commenced on hormonal replacement (thyroxine and testosterone).
Discussion
GPA is a multi-system disorder characterised by necrotising granulomatous small-vessel vasculitis. GPA mainly affects a combination of the ear, nose, and throat. However, it may also affect the joints, skin, eyes, and other organs. GPA occurs in equal proportions between men and women. Although, in the few previously reported cases with pituitary involvement, there were more female patients. The time of pituitary symptom onset in 13(56%) of previous reported cases occurred between 2 months and 15 years after receiving a diagnosis of GPA. The prevalence of central nervous system involvement ranges from 15% to 54%. The most common neurological manifestation is peripheral neuropathy due to small vessel vasculitis (10-28%).
Conclusion
GPA is a rare cause of pituitary failure and should be considered in the differential diagnosis of hypophysitis. Multisystemic presenting symptoms, such as those demonstrated in this case, should alert clinicians to the possibility of pituitary involvement. This is likely to be as part of a multisystemic disease process since isolated pituitary involvement is rare.

Service evaluation of endocrine and surgical outcomes post-pituitary surgery for non-functioning pituitary macroadenomas (NFPAs) in a subset of patients

Rosemary Ikegwu[1,2], Nijaguna Mathad[2, 3], Jonathan Hempenstall[2, 3], Alicja Knysak[2, 3] & Ma'en Al-Mrayat[1,2]
[1]University of Southampton, Faculty of Medicine, Southampton, United Kingdom; [2]Southampton General Hospital, Department of Endocrinology and Metabolism, Southampton, United Kingdom; [3]Wessex Neurological Centre, Southampton, United Kingdom

Background
Non-functioning pituitary adenomas (NFPAs) are the most common pituitary macroadenomas with a prevalence of 7-22 per 100,000 population. As they are non-secretory, they tend to present late with visual disturbances, headaches or hormonal deficiencies. Surgery is the main treatment for NFPAs, particularly endoscopic transsphenoidal surgery which can be associated with surgical and endocrine complications.
Aims
To compare pre- and post-operative endocrine outcomes and surgical complications and benchmark the findings with similar published cohorts
Methods
The clinical and laboratory records of 71 NFPA patients who underwent endoscopic pituitary surgery between 2017-2018 at Southampton General Hospital/UK were reviewed to note their pre-and post-operative endocrine and surgical outcomes. This included assessing of thyroid, adrenal, growth hormone and gonadotrophin axes, clinical hormone deficiencies and post-surgical complications. The data was tabulated for each individual patient and statistically analysed using SPSS for both quantitative and descriptive parameters.
Results
In our cohort, there was little increase in the proportion of patients with hypocortisolism and hypogonadism post-operatively compared with pre-operatively increasing from 31.0% (22/71) to 38.0% (27/71) and from 19.7% (14/71) to 21.1% (15/71) respectively. There was no post-operative increase in the 31% (22/71) of patients with hypothyroidism pre-operatively.11.3% (8/71) of the patients developed diabetes insipidus post-operatively. The most common surgical complication was intra-operative CSF leak affecting 19.7% (14/71) of the patients with 1.4% (1/71) of the cohort having post-operative CSF leaks. Post-surgically, epistaxis affected 7.0% (5/71), deterioration of vision affected 5.6% (4/71). The Wilcoxon Signed Rank Test demonstrated the increase on the number of hormone deficiencies per patient post-operatively was not statistically significant ($P=0.751$). Only 44 patients had their post-operative visual status recorded, 56.8% (25/44) of these had improved vision post-op, 34.1% (15/44) remained stable while 9.1% (4/44) worsened.
Conclusion
Visual status is mostly improved by transsphenoidal surgery. Additionally, endocrine function is only slightly worse following pituitary surgery. Our cohort's endocrine and surgical outcomes are comparable to the findings in previously published studies.

Growth hormone (GH) replacement therapy (GHRT) in patients with adult GH deficiency (AGHD) aged $\geq$60 years: data from NordiNet® IOS and the ANSWER Program

Matthias M. Weber[1], Murray B. Gordon[2], Charlotte Höybye[3], Anne H. Olsen[4], Nicky Kelepouris[5], Navid Nedjatian[6] & Beverly M.K. Biller[7]
[1]University Hospital, Universitätsmedizin Mainz, der Johannes Gutenberg-Universität, Unit of Endocrinology, Medical Department, Mainz, Germany;

[2]Allegheny General Hospital, Allegheny Neuroendocrinology Center, Division of Endocrinology, Pittsburgh, United States; [3]Karolinska University Hospital and Karolinska Institute, Department of Endocrinology and Department of Molecular Medicine and Surgery, Stockholm, Sweden; [4]Novo Nordisk A/S, Epidemiology, Søborg, Denmark; [5]Novo Nordisk Inc, US Medical Affairs – Rare Endocrine Disorders, Plainsboro, United States; [6]Novo Nordisk Health Care AG, Global Medical Affairs – Rare Endocrine Disorders, Zurich, Switzerland; [7]Massachusetts General Hospital, Neuroendocrine Unit, Boston, United States

Introduction
There are limited data on the effectiveness and safety of GHRT in older patients with AGHD. We compared real-world GHRT outcomes in older (aged ≥60 years) vs middle-aged (35–<60 years) adults.
Methods
NordiNet® IOS (NCT00960128) and ANSWER (NCT01009905) were non-interventional studies investigating long-term effectiveness and safety of GHRT with Norditropin® (somatropin, Novo Nordisk). Safety was assessed in the full analysis set (FAS) from both studies (non-GH-naïve patients included). The effectiveness analysis set (EAS) was from NordiNet® IOS only (GH-naïve patients; ANSWER-EAS included patients previously treated for ≤6 months). Serious adverse reactions (SARs) and non-serious adverse reactions (NSARs) with a suspected causal relationship to GHRT, and serious adverse events (SAEs) not considered related to GHRT, are presented as incidence rates per 1000 patient-years and as incidence rate ratios (IRRs) for older vs middle-aged adults.
Results
Baseline characteristics are shown (table). Mean GH exposure was greater in women than men, and in middle-aged than older women (FAS); it increased slightly over time in all groups. Baseline IGF-I SDS was slightly higher in older vs middle-aged women, but not men (EAS). Mean IGF-I SDS increased from below 0 to values ≤1.24 with GHRT. Mean changes in BMI (EAS) and HbA_{1c} (EAS and FAS) were small and similar between age groups in both sexes. No statistically significant differences were observed between older and middle-aged adults regarding incidence rates for NSARs (5.66 vs 5.38; IRR [mean, 95%CI] 1.051 [0.604;1.831]) and SARs (1.00 vs 2.52; IRR 0.396 [0.119;1.324]). As expected, SAE incidence rate (considered unrelated to GHRT) was higher in the older group (16.64 vs 9.04, IRR 1.840 [1.291;2.622]). Similarly, the IRRs of patients ≥75 years ($n=59$) vs the middle-aged group were only significant for SAEs (23.09 vs 9.04; IRR 2.553 [1.113;5.855]).
Conclusion
These data suggest similar clinical outcomes with GHRT in patients with AGHD aged ≥60 compared with 35–<60 years without additional risk of adverse drug reactions in older patients. Baseline characteristics (mean [SD] except for sex).

Cushing's disease and health-related quality of life: a cure for all dimensions?

Diana Borges Duarte[1], Francisca Puga[1], Isabel Ribeiro[2] & Cláudia Amaral[1]
[1]Centro Hospitalar e Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar e Universitário do Porto, Department of Neurosurgery, Porto, Portugal
-Diana Borges Duarte and Francisca Puga are joint first authors and contributed equally

Background
As therapeutic options improve for Cushing's disease (CD), most patients can now achieve control or cure of hypercortisolism. However, persistent complaints are often reported. Evaluation of health-related quality of life (HR-QoL) can highlight impairments beyond the stricter clinical aspects. Our aim was to evaluate HR-QoL with a specific focus on mental and emotional health subscales and to compare reported outcomes between patients with cure and persistent hypercortisolism under medical treatment.
Methods
Consecutive CD patients diagnosed between 2006 and 2020, with a minimum follow-up of 1 year, were invited, between June and August 2021, to complete a QoL evaluation. *CushingQoL* questionnaire was employed to assess disease-related quality of life. When analysing specific subscales on the questionnaire, the scores are based on Likert scales with five response categories (1-5 point-scale): the lower the score, the greater impact on HR-QoL. Clinical, anatomopathological and demographic data were retrieved from clinical records.
Results
Thirty-seven patients (86.5% females) agreed to complete the QoL assessment. Mean age at diagnosis was 42.2 ± 14.7 years and median time of onset of hypercortisolism symptoms was 2.0 (interquartile range 1.0-3.0) years. At the time of QoL evaluation, mean age was 48.0 ± 15.4 years and the median follow-up time was 4.1 (2.5-7.7) years. Concerning CD clinical status, 51.4% ($n=19$) were considered cured and 48.6% ($n=18$) had persistent CD (all patients were on medical therapy: n=6 on cabergoline monotherapy, n=4 on ketoconazole monotherapy, n= 3 on metyrapone monotherapy, the remainder in combination therapy). Median *CushingQoL* score was significantly higher in cured CD patients [68.8 (43.8-77.1) % in cured CD patients vs 35.4 (16.7-42.7) % in persistent CD patients, $P=0.002$]. Concerning the specific *CushingQoL* subscales, Mental Health [3.0 (2.0-3.0) points in cured CD patients vs 3.0 (2.0-3.0) points in persistent CD patients, $P=0.73$] and Emotional Health [3.0 (3.0-4.0) points in cured CD patients vs 3.0 (2.0-4.3) points in persistent CD patients, $P=0.98$] scores did not differ from the persistent hypercortisolism status.
Conclusion
In our cohort, clinical cure of CD was associated with higher health-related QoL score. However, equal scores on Mental and Emotional Health subscales were found. Either the impairment of these specific QoL domains persist beyond long-term control of hypercortisolism or medical treatment is associated with a surgical cure-comparable improvement of these domains while not achieving equal QoL scores on *CushingQoL*.

Association between acromegaly and papillary thyroid cancer: A case series

Andreea Anne-Marie Stefan[1], Dumitriu Roxana Ioana[1, 2], Burcea Iulia-Florentina[1,2], Trifănescu Raluca[1,2], Dan Alexandru Niculescu[1, 2] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Departament of Pituitary and Neuroendocrine Disorders, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Background
Acromegaly is a rare disorder caused by hypersecretion of growth-hormone (GH) and insulin-like growth factor (IGF-1), the underlying lesion being most frequently a pituitary adenoma. This disease is associated with a higher risk of malignancy. We describe the clinical and biochemical particularities in a series of patients with acromegaly and papillary thyroid carcinoma (PTC).
Case study
Out of 311 acromegalic patients, five cases that associated subsequent PTC were included, resulting in a prevalence of 1.6%. Acromegaly diagnosis was sustained by clinical characteristics, hormonal assays and imaging data. The median age at diagnosis was 42 years with only female patients. One patient had GH and prolactin co-secretion. Transsphenoidal intervention was performed, with postoperative tumor remnant in all cases requiring subsequent medical treatment. Two patients also underwent Gamma knife radiosurgery. Following multimodal treatment, one patient was cured and four had controlled disease. Thyroid cancer was diagnosed at a median of 7.5 years after the diagnosis of acromegaly. All

cases presented with the papillary variant. At the time of the cancer diagnosis, 2 out of 5 patients had controlled acromegaly. All five underwent total thyroidectomy and three of them received radioactive iodine. The histopathological analysis revealed four papillary thyroid microcarcinomas (PTMC). One patient had a focus of sclerosing subtype of PTC of over 10 mm, lymph node metastases, and extrathyroidal extension – this patient had co-secretion of prolactin and was the only case with poor oncological outcome. The other patients were cured.

Conclusions

Several studies indicate that a prolonged excess of IGF-1 levels has proliferative and anti-apoptotic effects on follicular thyroid cells, with a prevalence of thyroid cancer in acromegaly of 1.2-10.6% [1]. In our series, all patients were diagnosed with PTC after prolonged and persistent high levels of IGF-1 due to uncontrolled disease. Furthermore, prolactin has a potential tumorigenic role on thyroid follicles [2], the patient with GH and prolactin co-secretion being the one with an aggressive evolution of the PTC. Four patients had PTMC which is acknowledged as a very-low risk neoplasm. In conclusion, although at this point thyroid malignancies are not considered more aggressive in acromegalic patients, periodic thyroid examination is useful in identifying complications in earlier stages.

Idiopathic isolated adrenocorticotropic hormone deficiency

Paraskevi Komzia, Apostolos Gogakos, Fanny Kalograni, Georgios Tsoutsas, Marina Kita & Zoi Efstathiadou

'Hippokration' General Hospital of Thessaloniki, Endocrinology, Thessaloniki, Greece

Introduction

Idiopathic Isolated Adrenocorticotropic hormone (ACTH) deficiency (IIAD) is a rare cause of secondary adrenal insufficiency. It can present with a variety of clinical symptoms, mainly chronic fatigue and euvolemic hyponatraemia, and may coexist with autoimmune disease, most commonly Hashimoto's thyroiditis. Radiographically, an empty sella turcica image can be seen. We present 3 cases of isolated ACTH deficiency.

Case 1

A 47-year-old woman was referred for investigation of adrenal insufficiency due to low morning cortisol levels in a laboratory test performed in the context of investigation of hypertension. Hormone lab tests showed morning Cortisol $<$ 1μg/dl, ACTH 6.8 pg/ml (NL 7-64). The rest of pituitary axes were intact. Tetracosactrin (250μg) stimulation test showed a maximum cortisol response of 8.56μg/dl. Pituitary on imaging was normal. The patient was set on hydrocortisone replacement therapy while continuing to receive her antihypertensive treatment.

Case 2

A 45-year-old man, with no previous history, had an episode of confusion during febrile diarrheal syndrome. During his hospitalization he also presented episodes of hypoglycemia. The initial hormonal test showed very low basal serum cortisol levels (morning $<$0.2μg/dl) and ACTH (1 pg/ml), while in the glucagon test there was no cortisol response (maximum value $=$ 0.2μg/dl). The rest of hypothalamic-pituitary axes were intact. Pituitary imaging test was negative. At the same time, the patient was also diagnosed with autoimmune primary hypothyroidism and treated with thyroxine one week after the initiation of hydrocortisone replacement.

Case 3

A 74-year-old man with hyperthyroidism due to Graves' disease treated with methimazole was hospitalized for fever and hyponatremia (Na $=$ 124). The hormonal tests revealed low levels of cortisol (morning $<$0.7μg/dl) and ACTH (4 pg/ml), as well as thyrotoxicosis [TSH 0.017, FT4 1.74 (FT 0.80-1.28 mg/dl)]. Corticosteroid deficiency was confirmed by a subsequent stimulation test with 250μg tetracosactrin (maximum cortisol response 5.56μg/dl) and a glucagon test (maximum cortisol response 1μg/dl). The rest of pituitary axes were intact and pituitary MRI showed no anatomical damage. The patient was treated with hydrocortisone.

Conclusion

- The diagnosis of IIAD is often missed and becomes apparent after a triggering event such as fever or thyrotoxicosis.
- The presence of hyponatraemia or hypoglycaemia should raise the suspicion of adrenocortical insufficiency
- The etiology of IIAD remains unclear, although the coexistence of autoimmune thyroid disease is common.

Role of new peptide biomarkers in metabolic profiling of adult growth hormone deficiency patients: preliminary data on neudesin and its relationship with LEAP-2

Edoardo Vergani[1], Carmine Bruno[1], Cesare Gavotti[1], Alessandro Oliva[1], Diego Currò[2] & Antonio Mancini[1]

[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Catholic University of the Sacred Heart, Department of Medicine and Translational Surgery, Rome, Italy; [2]Catholic University of the Sacred Heart, Department of Safety and Bioethics, Section of Pharmacology, Rome, Italy

Patients affected by adult growth hormone deficiency (aGHD) show worse metabolic profile, with insulin-resistance, increased total cholesterol, LDL, triglycerides, reduced HDL, and higher risk of developing type 2 diabetes mellitus and cardiovascular complications. Adult GHD and metabolic syndrome (MetS) are closely related to each other, since they share the previous depicted clinical features, while obese MetS patients display lower IGF-1 levels due to a functional reduction of GH secretion. Neudesin is a newly discovered peptide mainly secreted in brain and adipose tissue, under evaluation for its possible activity as negative regulator of energy expenditure, as it decreases food intake in mice models. Liver expressed antimicrobial peptide (LEAP)-2 is involved in ghrelin physiological regulation as it acts as a competitive antagonist with slow dissociation from the GSH receptor-1a, blunting the magnitude of ghrelin activities. We have already demonstrated higher LEAP-2 levels and significantly lower ghrelin/lEAP-2 ratio in aGHD. To better characterize the metabolic profile of aGHD patients we performed an observational cross-sectional study testing the hypothesis that neudesin may be affected in this clinical setting. Given the role in energy balance of the two peptides, we also evaluated any eventual relationship between neudesin, LEAP-2 and metabolic and anthropometric parameters. 39 patients were included in the study. Group A: 18 aGHD patients, 7 females and 11 males. Mean $\pm$ SEM age of the group was 59.7 $\pm$ 2.7 years, while BMI was 30.2 $\pm$ 2.2 kg/m^2. Group B: 21 healthy controls (13 females and 8 males). Mean $\pm$ SEM age of the group was 47.1 $\pm$ 2.5 years, while BMI was 24.5 $\pm$ 0.9 kg/m^2. They were evaluated for glucose and insulin, HOMA and QUICKI index, total/lDL/HDL cholesterol, triglycerides, uric acid and IGF-1. Neudesin, LEAP-2 and ghrelin were measured by ELISA, according to manufacturers' protocols. As expected, aGHD patients showed higher HOMA index, triglycerides and lower HDL than controls. Neudesin is significantly higher in aGHD than controls (2.83 $\pm$ 0.37 vs 1.55 $\pm$ 0.12 ng/ml). We confirmed significantly lower ghrelin levels and significantly higher LEAP-2 (5.19 $\pm$ 0.42 vs 3.69 $\pm$ 0.49 nM) in aGHD, leading to lower ghrelin/lEAP-2 ratio. A significant and strong direct correlation between neudesin and LEAP-2 was found both in aGHD ($r^2 = 0.76$) and in all the analyzed population. While LEAP-2 directly correlated significantly with BMI, neudesin did not. These results, although preliminary, may suggest a possible adaptation to a worse metabolic scenario in aGHD. The presence of two distinct pathways related to food intake and the relative scarce knowledge on neudesin suggest future developments in this field.

Incipient adrenal crisis following ChAdOx1 SARS-CoV-2 vaccination in a patient with undiagnosed isolated adrenocorticotropic hormone deficiency

Yotsapon Thewjitcharoen, Natthakan Saiwaew, Hussamon Prasartkaew, Soontaree Nakasatien & Thep Himathongkam

Theptarin Hospital, Diabetes and Thyroid Center, BANGKOK, Thailand

Background

Isolated adrenocorticotropic hormone (ACTH) deficiency is a rare entity defined by secondary adrenal insufficiency and normal secretion of all other pituitary hormones. Delays in adrenal insufficiency (AI) diagnosis frequently encounter

among older patients because of non-specific symptoms. The occurrences of actual or incipient adrenal crises following coronavirus disease 2019 (COVID-19) vaccine administration are increasingly reported over the last year after vaccine rollout program. Here, we present an interesting case of incipient adrenal crisis following ChAdOx1 SARS-CoV-2 vaccination in a patient with undiagnosed isolated ACTH deficiency.
Clinical case
A 73-year-old Thai woman with underlying uncontrolled type 2 diabetes mellitus and unclear etiology of AI presented with a 2-week history of general malaise, dizziness, nausea, and weight loss of 4 kilograms following the first dose of AstraZeneca (ChAdOx1 SARS-CoV-2) vaccination. She had a past history of AI diagnosed at age of 52 from the previous hospital and had taken prednisolone 2.5 mg per day thereafter. Patient denied history of postpartum hemorrhage and was able to lactate after pregnancy and never had serious traumatic head injury. She also denied the use of other exogenous glucocorticoids and other medications except her current prescribed oral prednisolone. When seen in our hospital 2 weeks after immunization, physical examination and vital signs were unremarkable. Re-evalutation of AI after prednisolone discontinuation for 3 days was performed with the standard 250-microgram ACTH stimulation test. The diagnosis of secondary AI was confirmed. Brain MRI showed normal pituitary gland and evaluation of other anterior pituitary hormones revealed normal results. Isolated ACTH deficiency was diagnosed and the patient had been instructed to increase the dose of prednisolone to 15 mg per day. Insulin treatment was also up-titrated to tightly control glycemic control. Her symptoms considerably improved over a week and backed to the usual weight over a few months. With increasing the dose of prednisolone on the day of vaccination, the patient was uneventful following the second dose of AstraZeneca vaccination.
Conclusions
Late-onset isolated ACTH deficiency is a rare entity but has emerged as a cause of AI. Healthcare professionals should be vigilant about the possible diagnosis or worsening of AI especially in elderly patients who receive COVID-19 vaccine administration. Ongoing educations of sick day management should be emphasized in all AI patients.

ACTH-GH pituitary adenoma in an adolescent: a Case Report

Sahar Abidi, Grira Wafa, Nadia Khessairi, Ibtissem Oueslati, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
RABTA Hospital – Endocrinology Department, Tunis, Tunisia

Plurihormonal pituitary adenomas represent 10-15% of all functioning pituitary adenomas. Functioning ACTH-GH pituitary adenomas constitute an extremely rare entity. Most patients present a clinically manifested acromegaly and subclinical Cushing's disease. We present the case of a 14 years old female who referred to the endocrinology department for inaugural diabetic ketosis. She had a six-month history of amenorrhea and headaches. On examination, she had facial dysmporphia suggestive of acromegaly. Weight was 93 kg, height was 1.77 m . The body mass index was 29,3 kg/m^2. Blood pressure was normal; she had purple abdominal stretch marks. Polysomnography revealed a mild sleep apnea. The hormonal assessment confirmed acromegaly by a nadir of GH of 39 mUI/l in glucose tolerance test. A none suppressive cortisol secretion of 8.9 mg/dl and a high ACTH of 29.14 ng/l. Thyrotropic and lactotropic axis were normal, The gonadotropic axis was deficient. MRI showed a macroadenoma of 18*14*20 mm that extends into the cavernous sinus and compresses the optic chiasm. The patient received basal-bolus insulin therapy. She underwent transsphenoidal surgery. Postoperatively presented with clinical and biochemical adrenal insufficiency and had a transient insipidus diabetes. The MRI documented an empty sella. At a one-year follow-up she was clinically well with no clinical or radiological evidence of pituitary tumor recurrence. She remained on replacement hydrocortisone and necessitated low doses of insulin for her diabetes. ACTH-GH plurihormonal pituitary adenomas are a rare entity. This is a case that illustrates an ACTH-GH pituitary adenoma revealed by diabetic ketosis in an adolescent.

Pituitary adenoma associated with intracavernous meningioma: Case report

Aicha Lachkhem[1], Abdelkader Yahi[2], Haffaf Lounes[1], Benabdelatif Katia[1], Ahcen Staifi[3], Hakim Derradji[4], Elmountassir Ourrad[5] & Ould Kablia Samia[1]
[1]Central Army Hospital, Endocrinology, Algeria; [2]Central Army Hospital, Endocrinology, Algiers, Algeria; [3]Central Hospital Army, Ophtalmology, Algeria; [4]Central Hospital Army, Neurosurgery, Algeria; [5]Central Army Hospital, Radiology, Algeria

Introduction
Pituitary adenoma and meningioma are the most benign tumors in the central nervous system (meningioma 35,9%, pituitary tumor: 15,5%). Pituitary adenoma associated with meningioma without a history of radiotherapy is extremely rare.
Case
A 70 years old man operated for post-traumatic subdural hematoma in whom the brain MRI (magnetic resonance imaging) had also shown a macroadenoma, completed with an MRI of the sellar region which were confirmed in the coronal section in T1 weighted image, an iso-intense adenoma taking up gadolinium poorly measuring 16 x 8,5 mm. This adenoma is associated with a right intra-cavernous lesion measuring 11,8 x 8,8 mm presenting intimate contact with the intravenous portion of the internal carotid artery, iso-intense in T1 weighted images and hyper-intense in T2 weighted images which is intensely and homogenously enhanced after injection of gadolinium salts, corresponding to meningioma. Hormonal work-up revealed a serum prolactin level of 1300 ng/ml and a central hypothyroidism. The patient was then started on dopamine agonist (cabergoline 03 mg/week). The response to treatment was excellent, on his MRI follow-up one year after, the adenoma has disappread leaving an arachnoidocele while the meningioma has remained stable. The patient is being followed by Endocrinolgy and Neurosurgery.
Conclusion
The association of meningiomas and pituitary tumors is very rare. If patients who have under- gone previous radiation therapy are excluded from consideration, the presence of these two types of tumors in the same patient becomes even rarer. To our knowledge, the association of an intracavernous meningioma and a prolactinoma in a patient without previous radiation therapy had never been reported.

Severe hyponatremia after coronary angiogram - the link between ischemic cardiac disease and hypopituitarism

Cristina Ene[1], Angelica Nour-Dinca[2], Dorin Bica[3] & Mihaly Enyedi[4]
[1,2]'Dr Victor Babes' Foundation, Endocrinology, Bucharest, Romania; [2]'Dr Victor Babes' Foundation, Cardiology, Bucharest, Romania; [3]Neurohope, Neurosurgery, Bucharest, Romania; [4]'Dr Victor Babes' Foundation, Radiology, Bucharest, Romania

Background
Hyponatremia in not uncommon in elderly. Common causes include medication, heart, kidney and liver diseases, digestive loses, syndrome of inappropriate anti-diuretic hormone. Hormonal imbalances are sometimes overlooked. Sudden onset after a recently invasive procedure could challenge the diagnostic.
Methods
We present a case report of a severe hyponatremia diagnosed after a coronary angiogram. It is a rare case of hypopituitarism secondary to a pituitary macroadenoma.
Case reports
The patient is a 69 years old man that presented in December 2019 in cardiology department for a coronary angiogram. 48 h after angiography the patient was admitted in ICU for severe hyponatremia and rhabdomyolysis – interpreted at the time as side effect to the contrast agent. At that moment he had normal TSH (T4 or T3 were not analysed) and SIADH was infirmed. The adrenal insufficiency was not rule out. Progressively, in the next 6 month the patient presented asthenic syndrome and significant weight loss, which is why he came to our clinic for second opinion. He had a cardiological check-up and an endocrinological exam. The biological evaluation reveals mild hyponatremia, still elevated creatine kinase and also mild anemia. The hormonal profile established the panhypopituitarism and we started substitutive treatment, with rapidly normalisation of biological disturbance. The MRI exam revealed a pituitary macroadenoma, with of the optic chiasm compression, confirmed by visual field.

The patient needed to repeat coronary angiogram for unstable angina and revealed multiple coronary stenosis and 3 active stents were fitted. This time the procedure was performed after Cortisone dose supplementation, without electrolyte imbalance. Considering double antiplatelet therapy after coronary stenting and cardiac risk, the surgical treatment of macroadenoma was scheduled after 6 months, with closely ophthalmologic follow. Transsphenoidal hypophysectomy was successfully performed, and immunohistochemistry diagnosed a non-functional adenoma.
Conclusion
Hormonal imbalance should be suspected in a sudden-onset of life-threatening hyponatremia. Hypopituitarism is a rare cause of hyponatremia and in this case was overlooked, TSH value being normal, without initial testing of T4 and cortisol value. The acute illness and the iodine agent used for angiography revealed long-term hypocortisolemia. A noncardiac surgery could be very challenging in a recently stented patient, due to the risk of bleeding secondary to antiplatelet therapy and treatment discontinuation may lead to perioperative thrombotic cardiac events. In this case the multidisciplinary team was essential for ensuring an excellent outcome.

A 29 year old woman with aggressive acromegaly as a single manifestation of multiple endocrine neoplasia type 1

María Dolores Moure[1,†,1], Gregorio Catalán[2], Iñigo Pomposo[2], Miren Badiola[1], Iker Miret[1], Luis Castaño[3] & Sonia Gaztambide[1]
[1]Cruces University Hospital, Endocrinology and Nutrition, Bilbao, Spain; [2]Cruces University Hospital, Neurosurgery, Bilbao, Spain; [3]Biocruces, Bilbao, Spain

Introduction
Parathyroid tumors are the most common (90%) and usually the first manifestation feature of *MEN1* syndrome. The occurrence of anterior pituitary tumors in *MEN1* syndrome may range between 10% and 60%. Pituitary involvement includes the initial manifestation of *MEN1* syndrome in 10% to 25% of individuals and usually show more aggressive behavior; 20% secrete prolactin, fewer than 10% secrete GH, 5% secrete ACTH, and the remainder appear to be nonfunctioning.
Objective
Description of a 29-year-old female diagnosed of aggressive acromegaly as single manifestation of MEN1 syndrome.
Case
The patient was referred to endocrinology due to oligomenorrea. Elevated prolactin 69 (3-30 ng/ml) and IGF1 854 ng/ml (117-329) were detected. GH after oral glucose tolerance test (OGTT) (12 ng/ml) confirmed the acromegaly. Magnetic resonance showed a 7.5 x 6 x 8 mm adenoma without cavernous sinus invasion. Transsphenoidal surgery was performed. Histopathological exam described an atypical adenoma with Ki 9% and GH positivity. After surgery, the patient became pregnant and the evaluation of the disease was carried out after delivery. A 3 mm tumor rest was observed. IGF 1 levels 399 ng/ml (71-234) and GH after OGTT (1.2 ng/ml) indicated persistent acromegaly. In a second intervention the rest can not be removed and Octreotide Lar (20 mg/month) was initiated. Despite the increase in medical therapy, IGF 1 remained elevated and the patient was referred to Radiation oncology. *MEN 1* (c.512G > A;p.Arg171Gln) and *SDHD* (c149A>G; p.His50Arg) heterozygous mutations were detected. Calcium metabolism exam and radiological screening were normal. Fathers patient carried the same mutation in both genes (*MEN 1 and SDHD*). He referred a single episode of nephritic colic and myocardial infarction at the age of 38. Calcio and PTH were normal. Radiological image showed a 1 cm nonfunctioning pancreatic mass. No other first-degree relatives showed mutations.
Conclusions
An aggressive acromegaly could be the first manifestation of a MEN1 syndrome.

Pituitary Coma? Discordant pituitary biochemistry after consumption of a commercially available 'Sleep Activator'.

Benjamin Phillips & Mohit Kumar
Wrightington, Wigan & Leigh NHS Foundation Trust, Department of Endocrinology and Diabetes Mellitus, Wigan, United Kingdom

We present a case of discordant pituitary biochemistry which resolved after discontinuing a commercially available combination vitamin supplement. A 35 year-old man presented following an episode of headache and dizziness, preceding collapse and possible seizure activity. Investigations revealed deranged pituitary function: TSH 0.02 mU/l (0.35-5.50), fT4 3.6 pmol/l (10.0-20.0), 9 am cortisol 18 nmol/l (200-500), testosterone >52 nmol/l (8.4-28.7), FSH <0.3 U/l (1.0-18.0), LH <0.1 U/l (2.0-9.0), oestradiol 611 pmol/l (0-146), prolactin 452 mU/l (45-375) IGF-1 207 ng/ml (71.0-234.0). He reported weight gain, low mood, sweats, and reduced libido. 7 months prior he had sustained a head injury from a concrete block. He was commenced on hydrocortisone and levothyroxine. MRI found normal pituitary gland and surrounding structures. On further questioning at follow-up he admitted taking a combined nutritional supplement called 'Kodiak Coma'. Based on clinical suspicion that the supplement was contributing to the derangement in pituitary function tests the patient was asked to stop taking it. Subsequent pituitary function tests returned to normal, with normal short synacthen test (0 min 249, 30 min 659 nmol/l). He was able to discontinue hydrocortisone and remained well. He continued to take levothyroxine replacement for primary hypothyroidism. None of the listed ingredients in 'Kodiak Coma' are known to affect pituitary function or related hormonal axes and the discordant biochemical picture did not correlate to this patient's clinical presentation. Rather we hypothesise that a component or components of the supplement caused assay interference. Biotin is commonly included in nutritional supplement preparations; it is well known to interfere with certain assays of thyroid function, and rarely has been reported to interfere with other pituitary hormone assays. However, a different pattern of interference would have been expected if biotin was the culprit. The manufacturer of Kodiak Coma was contacted for information about its ingredients, but no reply was forthcoming. Nutritional supplements are often marketed towards individuals with no underlying deficiency, illness, or disease. Such products are readily available in high street shops and online. However, it is well documented that active ingredients in products of this kind can lead to negative health outcomes, either by drug interaction, by unintended effect upon clinical investigations, or by a direct effect to cause disease. This patient was subjected to a 4-day hospital admission, medical therapy, and several months of clinical and biochemical follow-up as a result. This case illustrates the unintended risks of nutritional supplements and highlights a potential cause for discordant pituitary biochemistry.

Two case: hemorrhagic rathke cleft cysts mimicking a hemorrhagic adenoma

H. Sebile Dokmetas[1], Ayberk Bayramgil[2], Meriç Dökmetaş[2], Fatih Kılıçlı[1], Güneş Dorukhan Çavuşoğlu[2], Kü bra Karaipek[2] & Ayşe Gül Yildirim Kizilkaya[2]
[1]Medipol Mega University Hospital, Endocrinology; [2]Medipol Mega University Hospital, Internal Medicine, İstanbul, Turkey

Introduction
Rathke Cleft Cysts(RCCs) are benign cysts arising from the remnants of Rathke's pouch. The most common symptoms are visual field disorders, headache, and pituitary dysfunction.
Case 1
A 26-year-old male was admitted with headache that started 4 days ago. Cranial MRI revealed an appearance mimicking a hemorrhagic adenoma in pituitary. Pituitary hormones were found as normally. Pituitary MRI showed a 12 x 10 x 10 mm hemorrhagic RCCs located in the midline. The patient's headache disappeared spontaneously within 3 days without the use of any medication. One month and six months later, MRI showed a progressive shrinkage of hemorrhagic RCCs diameters as 4.5 x 5 x 7.5 mm and 3 mm, respectively. In the pituitary MRI taken at the last follow-up 15 months later, it was observed that sequelae remained as a millimetric-thick slit-shaped microcyst in the central gland.

Case 2
A 24-year-old female was admitted with a complaint of headache that started one month ago. The patient, who had a throbbing headache on the right side of her head, was relieved with analgesics. Pituitary MRI revealed a hemorrhagic RCCs with diffusely expanding pituitary gland with a size of 18 x 13 x 8 mm and leveling inside. The patient's pituitary hormones were checked and no pathological values were found. In the control pituitary MRI one month later, the size of the hemorrhagic RCCs decreased to 8 x 13 x 8 mm.
Conclusion
Patients with hemorrhagic RCCs whose symptoms decreased during close follow-ups and who did not have hormonal disorders were not operated on. The sizes of the masses of the patients who did not develop any complaints or hormonal disorders during their follow-ups decreased.

Ectopic Neurohypophysis
Hatice Sebile Dökmetaş[1], Güneş Dorukhan Çavuşoğlu[2], Meriç Dökmetaş[2], Fatih Kılıçlı[1], Ayberk Bayramgil[2] & Kübra Karaipek[2]
[1]Medipol Mega University Hospital, Endocrinology, Istanbul, Turkey; [2]Medipol Mega University Hospital, Internal Medicine, Istanbul, Turkey

Introduction
Ectopic neurohypophysis is a congenital abnormality related to faulty embryogenesis resulting in incomplete caudal extension of the infundibulum**.** It may present itself with symptoms of growth hormone deficiency or panhypopituitarism and patients require replacement treatment for panhypopituitarism.
Case Presentation
Our female patient was shorter (138 cm) than her peers and did not menstruate at the age of 19 when she first applied to our hospital with this complaint. Her tests were found to be compatible with panhypopituitarism. Her bone age was found to be 15. On pelvic USG, uterus and ovaries were hypoplasic/atrophic. Breast development: Tanner 1-2. Pituitary MRI revealed total loss of stalk and ectopic neurohypophysis. With the diagnosis of pituitary insufficiency, she took prednisone, levothyroxine and growth hormone for 5 years. Oral contraceptive was not started and final height increase was awaited. Her height increased from 138 cm to 165 cm. Oral contraceptive was added later. After two years, breast development and menstrual order were established and significant improvement was seen in bone mineral density.
Conclusion
Ectopic neurohypophysis might show itself with hypopituitarism like in our patient. Replacement of missing hormones is generally required. If the bone age is lower than the chronological age, it was possible to achieve sufficient height growth with GH treatment before starting oral contraceptives.

Case report: pituitary macroadenoma with thyroid stimulating hormone (TSH) and growth hormone (GH) co-secretion
Chin Voon Tong, Yen Nee Low, Eng Hui Ooi & Azliana binti Alias
Melaka Hospital, Medicine, BANDAR MELAKA, Malaysia

Introduction
The prevalence of pituitary adenoma is estimated to be 17% and about half secrete a distinct hormone. Prolactin secretion is the commonest, followed by GH or adrenocorticotropic hormone (ACTH). TSH producing pituitary adenoma is rare and occurs in less than 1% of pituitary adenomas. We report a challenging case of a 30-year-old man who presented with TSH and GH secreting pituitary macroadenoma with mass effect.
Case Report
A 30-year-old man presented with typical symptoms of thyrotoxicosis (palpitation, tremor and weight loss of 20 kg) over four months associated with headache. There were no symptoms suggestive of GH excess or hypogonadism. On examination, he was normotensive. He had a small goitre and fine tremor. He was started on Carbimazole and propranolol by his primary care doctor and referred to the Endocrine Clinic for discordant thyroid function. His Free Thyroxine (Free T4) was elevated at 69.6 pmol/l (11.5-22.7) with a normal TSH of 4.06 mIU/l (0.55-4.78). This was confirmed with sample sent to a second laboratory. A high alpha subunit of 12 ng/ml ($\leq$0.5) and absent TSH response to Thyrotropin Releasing Hormone (TRH) stimulation test support the diagnosis of TSH secreting tumour. Other anterior hormones were assessed and showed elevated Insulin Growth Factor -1 (IGF-1) of 401.8 ng/ml (74-258) and prolactin, 1167.6 mIU/l (45-375). Oral glucose tolerance test confirmed GH excess. Testosterone level was 2.5 nmol/l (5.72-026.14) with Follicle stimulating (FSH) 7.3 IU/l (1.4-18.1) and Luteinizing Hormone (LH) 3.6 IU/l (1.5-9.3). ACTH level was 1.8 pmol/l (1.8-13.9) and there was appropriate adrenal response to tetracosactrin test. Magnetic Resonance Imaging (MRI) showed a sellar-suprasellar mass measuring 3.8 x 3.3 x 3.5 cm which displaced the optic chiasm and compressed it antero-superiorly. Pituitary stalk was not visualized. Therefore, the elevated prolactin was attributed to stalk effect. Visual field assessment showed bitemporal hemianopia. In preparation for surgery, he was given Carbimazole, Propanolol and Lugol's iodine. Pre surgery Free T4 was 20.98 pmol/l, TSH 21.04 mIU/l and GH 4.29 ng/ml ($<$2.47). He underwent Endoscopic Transsphenoidal Surgery with tumour excision successfully. Free T4 post-surgery was 20.66 pmol/l with normalization of TSH at 2.2 mIU/l and GH at 1.26 ng/ml. Preliminary histopathology examination revealed features of pituitary adenoma.
Conclusion
We present here, a rare case of pituitary macroadenoma with TSH and GH co-secretion. This case illustrates the importance of careful evaluation of discordant thyroid function test and the following pre-surgery management of such cases.

Primary Empty Sella Syndrome revealed by a growth retardation : about 14 cases
Khadra Faraoun & Mohammedi Fatiha
Oran University Hospital, Endocrinology, Oran, Algeria

Background
Empty sella turcica (EST) is characterized by the passage of cerebrospinal fluid (CSF) into the sella turcica through the sellar diaphragm. The aim of our work is to study the clinical and hormonal characteristics of patients with EST discovered due to height delay.
Patients and methods
Descriptive study on 14 patient files. Data studied : history, anthropometry, endocrine deficits and associated pathologies.
Results/Discussion
6 boys, 8 girls; average age at first consultation: 8.2 years (range: 2 and 15 years); main reason for consultation: height delay (HD). No cases of fetal distress, neonatal hypoglycemia, peri natal trauma, pituitary surgery or radiotherapy. 5 cases of intrauterine growth retardation, 1 case of mental retardation, 5 cases of celiac disease, 2 cases of autoimmune hypothyroidism. HD on average at -3.8 SD (range: -6 and -2 SD), average weight deficit at -2.8 SD (range: -4.5 and - 2 SD); 1 case of total anterior pituitary insufficiency, 6 cases of dissociated anterior pituitary insufficiency; Partial GH deficiency in 4 cases and complete in 10 cases. 2 cases of partially empty sella turcica and 12 cases of EST. 10 children substituted for the different deficits. One child referred for Neurosurgery for hydrocephalus. There is a delay in the diagnosis of stature delay. Primary EST does not preferentially affect one sex, the congenital origin is most likely. Lifelong monitoring is necessary in order to detect possible endocrine, neurological and ophthalmological complications.

Rupture of the pituitary stalk : clinical, para-clinical and evolutionary aspects of 9 patients followed in the Endocrinology department, Oran University Hospital.
Khadra Faraoun[1] & Mohammedi Fatiha[2]
[1]Oran University Hospital, Endocrinology, Oran, Algeria

Background
The non-traumatic pituitary stalk interruption syndrome described after the advent of MRI is a congenital pituitary abnormality, often responsible for

pituitary insufficiency revealed during the neonatal period. We note 9 cases of late diagnostic during the exploration of growth retardation.
Patients and methods
Descriptive cross-sectional study on files of 9 patients, 5 boys and 4 girls with an average age of 10.5 years (range 3 and 18 years). The diagnosis was made by MRI, the deficit in GH was sought by 2 stimulation tests: insulin hypoglycemia and glucagon test.
Results
Circumstances of discovery : growth retardation including one case with primary amenorrhea. All patients had a severe delay in height of -4DS to -2DS. All 5 boys had a micropenis. On MRI: 4 cases of pituitary stem interruption with ectopia of the post pituitary and pituitary hypoplasia, 3 cases with ectopia of the post pituitary, 1 case with hypoplasia and 1 case of pituitary stem interruption only. Familial history : 3 cases of consanguinity, 2 cases of hydrocephalus and cleft palate and 1 case of trisomy 21 in the siblings. Personal history : 1 case of fetal distress, 3 cases of celiac disease, 1 case of congenital primary hypothyroidism, 1 case of mental retardation. The somatotropic deficit is complete in all patients, gonadal deficit in all patients of puberty, 5 cases of thyrotropic deficit, 3 corticotropic deficits, the latter 2 appearing 1 to 6 years after the diagnosis of the somatotropic deficit. The outcome was favorable with a significant gain in height in children replaced early by growth hormone, the current height delay is at -2DS. The other deficits were replaced as and when they appeared.
Discussion
The presence of midline abnormality in the family and association with malformation syndromes reinforces the genetic origin. Growth retardation may indicate pituitary stem disruption syndrome; this form of late revelation should no longer be underestimated.

Hypopituitarism caused by intravascular large B cell lymphoma (IVLBCL)

Natia Vashakmadze[1,2]
[1]Israeli-Georgian Medical Research Centre 'Helthycore', Department of Endocrinology, Tbilisi, Georgia; [2]David Tvildiani Medical University, Department of Biochemistry and Molecular Biology, Tbilisi, Georgia

Intravascular Large B-Cell lymphoma (IVLBCL) is an extremely rare type of non-Hodgkin lymphoma involving the growth of lymphoma cells within the vessel lumen without lymphadenopathy. As disease has various modes of presentation and is exceptionally rare, IVLBCL is often diagnosed postmortem. Herein, we report a case of IVLBCL with hypopituitarism, an extremely rare complication, that was successfully treated with chemotherapy. 60 years old woman noticed redness of the abdomen, fatigue, and fever. As she was diagnosed with recurrent erysipelas in the past, it was considered as recurrence of the known infection. Despite antibiotics, disease progressed, redness involved whole abdomen and thighs, fever worsened and swelling of the face and limbs as well as tingling and numbness of the lower extremities, difficulty to walk and acute kidney failure has developed. It was clear that patient did not have an ordinary infection but something else. During next few weeks patient developed severe anasarca (+20 liter), general fatigue, telangiectasis of the trunk, severe polyneuropathy, weight loss and marked panniculitis, she was unable to eat or move independently, mental changes were also notable. As all the possible causes (infections, systemic diseases, etc) were excluded, deep skin biopsy was performed from the abdominal part of the body and IVLBCL was diagnosed. IVLBCL can cause damage of virtually any organ, including endocrine glands, as patient had severe fatigue, anasarca, weight loss and mental changes, pituitary function was carefully evaluated. She was found to have hypopituitarism with central hypothyroidism, central hypogonadism, central adrenal insufficiency, and hyperprolactinemia. IGF-1 was not measured due to technical issues. Brain MRI with contrast showed no tumor or mass in the seller region. It was unclear hypopituitarism was due to intravascular spread of the lymphoma cells in hypophysial portal system and microvascular damage of the pituitary cells, or due to disease severity per se, that is sometimes accompanied with idiopathic hypopituitarism. Patient was started on replacement of hydrocortisone first and only after that levothyroxine was added to treatment regimen. Whole body CT/MRI showed no MTS or lymphadenopathy at all. Chemotherapy with R-CHOP scheme was started with dramatic improvement of patient's clinical and laboratory parameters. Hypopituitarism was resolved after 3 months. After 8 course of chemotherapy patient progressed with new skin nodules all over the body, however before starting the second line Chemotherapy, patient started to go into spontaneous remission, nodules disappeared without any treatment at all and she is in remission until now.

Complete remision of nelsońs syndrome with cabergoline treatment

Nerea Egaña Zunzunegui, Cristina Elias Ortega, Inmaculada Venegas Nebreda, Ane Amilibia Achucarro, Ismene Bilbao Garay, Maite Aramburu Calafell, Cristina García Delgado & Alfredo Yoldi Arrieta Donostia Unibertsitate Ospitalea, Donostia, Spain

Introduction
Nelsońs Syndrome is defined as the presence of an enlarging pituitary tumor associated with elevated fasting plasma ACTH levels and hyperpigmentation in patients submitted to bilateral adrenalectomy for the treatment of Cushińgs disease.
Case Report
We present a case of a 48 y/o woman who in 2015, was diagnosed of Cushing's disease and underwent transsphenoidal adenomectomy but remission was not achieved, so the patient was then treated with ketoconazole. However, after a 2-month period bilateral adrenalectomy was performed due to persistent hypercortisolism, and the development of severe hepatitis and simultaneously she was referred to radiotherapy. Subsequently, few months after adrenalectomy, the patient developed Nelson's syndrome with intense skin hyperpigmentation, headaches, and elevated ACTH levels (> 1000 pg/ml). The magnetic resonance imaging demonstrated slight increase in size of adenoma. The patient was initially treated with cabergoline (1 mg/week) observing only a short and transient decline of ACTH so the dose was adjusted. After increasing dose of cabergoline (2 mg/week) ACTH levels decreased and the headaches and hyperpigmentation improved significantly. Four years later, plasma ACTH levels were normalized (33 pg/ml) and MRI showed the disappearance of the pituitary adenoma. In order to investigate on the direct effect played by cabergoline treatment on the remission of Nelson's syndrome, the treatment was withdrawn. ACTH levels are normalized (50 pg/ml) since nowadays.
Discussion
This case demonstrated that cabergoline treatment is able to induce the remission of Nelson's syndrome and may be a valid therapeutic alternative in this syndrome. The peculiar expression pattern of D2 receptors in some non functional and corticotroph tumors could explain the favorable clinical response to cabergoline in the setting.

Genomic and epigenomic aspects of Aspirin antitumoral effect in pituitary adenoma

Borbála Szabó[1], Lilla Krokker[1], Katalin Mészáros[2], Éva Saskői[3], Krisztina Németh[4], Pál Szabó[4], Nikolette Szücs[5], Sándor Czirják[6], Attila Patócs[2] & Henriett Butz[1,2,3]
[1]Semmelweis University, Budapest, Hungary, Department of Laboratory Medicine,, Budapest, Hungary; [2]Hungarian Academy of Sciences - Semmelweis University, Hereditary Tumours Research Group, Budapest, Hungary; [3]National Institute of Oncology, Department of Molecular Genetics, Budapest, Hungary; [4]Research Centre for Natural Sciences, Hungarian Academy of Sciences, MS Metabolomics Laboratory, Budapest, Hungary; [5]Faculty of Medicine, Semmelweis University, Department of Endocrinology, Internal Medicine and Oncology, Budapest, Hungary; [6]National Institute of Clinical Neurosciences, Budapest, Hungary

Background
In our previous works the interdependence of DNA demethylation with proliferation and differentiation of pituitary neuroendocrine tumours (PitNET) and the inhibitory effect of Aspirin on pituitary cell proliferation were demonstrated. Although the role of Aspirin in epigenetic regulation was

described in other malignancies, its correlation with pituitary tumorigenesis is currently unknown.
Our objective
was to investigate the genomic and epigenomic effects of Aspirin in PitNET.
Materials and Methods
DNA methylome by HPLC-MS/MS, and whole transcriptome profile were evaluated by next-generation sequencing in RC4-B/C and GH3 pituitary cell lines upon Aspirin treatment. Effects of Aspirin and demethylation agent, decitabine were further tested *in vitro* by RT-qPCR, western blot and functional (proliferation, viability, migration, luciferase promoter reporter) assays. DNA methylome was also correlated with *PTTG1* expression in 41 human PitNET samples. Gene and protein expression data of 77 PitNET with 35 control samples were obtained from Gene Expression Omnibus and literature mining.
Results
Aspirin induced global DNA demethylation and consequential transcriptome changes *in vitro* including decreased global histone expression. Overexpression of *Tet* enzymes and their cofactor *Uhrf2* was identified behind the increase of 5-hydroxymethylcytosine (5 hmC). Transcription factor regulatory relationships assessed by gene set enrichment analysis showed that Aspirin increased p53 and decreased E2f1 activities. The increased p53 activity was due to its acetylation at the K382 residue. Among p53 controlled genes, *Pttg1* was also identified as downregulated upon Aspirin treatment. Aspirin reduced the expression of *Pttg1* together with its interacting partners by inhibiting *Pttg1* promoter activity. 5 hmC positively correlated with *Tet1-3* and *Tp53* expression, and negatively correlated with *Pttg1* expression that was also reinforced by the effect of decitabine on *Pttg1* expression. Both transcriptome data and *in vitro* assays proved that Aspirin inhibited the cell viability, cell proliferation and migration. Additionally, high overlap (20.15%) was found between Aspirin regulated genes and dysregulated genes in PitNET tissue samples. The 757 common genes were implicated mostly in cell proliferation, cell cycle – including p53 activity and function –, while cellular migration and genome stability were also detected.
Conclusion
We described a regulatory network where Aspirin regulated global demethylation, *Tp53* activity and *Pttg1* expression in pituitary cells along with decreased cell proliferation and migration. These data may suggest the potential beneficial effect of Aspirin in PitNET.

Soluble alpha klotho in blood is a new and highly stable biomarker

Junia Ribeiro de Oliveira Longo Schweizer, Michael Haenelt, Katharina Schilbach, Sylvere Störmann, Jochen Schopohl & Martin Bidlingmaier
LMU Klinikum; Med. Klinik und Poliklinik IV/Endokrinologie, Munich, Germany

Background
Soluble alpha klotho (sαKL) is a circulating protein that has been linked to the growth hormone (GH) axis. We previously showed its association to disease activity in patients with acromegaly, with considerable robustness towards biological confounders. However, there is scarce data in literature regarding the analytical performance of the assay, and pre-analytical stability of sαKL in blood samples.
Objective
We aimed to evaluate analytical performance and pre-analytical stability of sαKL in blood samples, following the guidelines from the Clinical & Laboratory Standards Institute.
Methods
SαKL concentrations were measured by an ELISA (Immuno-Biological Laboratories, Hamburg, Germany). We compared different incubation times (1 h vs. overnight), analyzed precision by 10 repeated measurements within a plate and linearity by serial dilutions (no dilution, 1:2, 1:4, 1:8 and 1:16). We also tested stability of sαKL under different storage conditions: 1) room temperature before (whole blood, 1, 24, 48 or 120 h) or after centrifugation (serum, 15 min, 24, 48 or 72 h); 2) freeze/thaw cycles (0-4 cycles); 3) long-term storage at -20°C (baseline compared to 20 and 31 months). Finally, we compared sαKL concentrations in serum and EDTA samples collected in parallel from the same individuals ($n=18$).
Results
Short incubation times were associated with a significant drift of concentrations obtained over the plate (>25%), an effect not seen after extending the first incubation to overnight (<5%). sαKL measurements by this assay presented with low intra- and inter-assay coefficients of variation (%CV) (<10% for both). Dilution linearity was good at concentrations below 3,000 pg/ml (recovery rate (RR) (%mean (range)): 96 (92-107). Measured sαKL concentrations were not significantly affected by storage for up to 120 hours at room temperature (CV (%mean (range)) (whole blood, before centrifugation: 2.9 (1.5-5.1) or serum, after centrifugation: 8.9 (1.8-18.9)), or by up to 4 freeze/thaw cycles (CV: 4.9 (1.4-10.1), RR: 99.1 (87.3-105.8)). Serum sαKL also exhibits excellent long-term storage stability for more than 2 years at -20°C (CV: 8.6 (2.7-17.5), RR: 89.1 (76.5-111.7)). Furthermore, sαKL concentrations (pg/ml) (median (interquartile range) in serum did not differ from those seen in EDTA (404.4 (341.8-462.6) vs. 428.6 (384.8-514.8), $P=0.27$).
Conclusion
After extending incubation times to overnight, the sαKL assay exhibits good performance characteristics. We suggest to dilute samples at least 1:4, especially in patients with GH excess. sαKL is a biomarker with considerable preanalytical stability at different storage conditions. This facilitates its use as a GH responsive biomarker in studies and clinical practice.

EP693

Influence of Desmopressin treatment in patients undergoing surgery for cushing's disease

Paloma Moreno-Moreno, Ángel Rebollo-Román, Soraya León-Idougourram, Carlos Manuel Alzá s Teomiro & María Ángeles Gálvez-Moreno
Reina Sofia University Hospital, Endocrinology and Nutrition, Córdoba, Spain

Objective
ACTH-secreting pituitary tumors (ACTHomas) express vasopressin (AVP) receptors. AVP receptors are also present in other types of cancer, exerting different effects on tumor growth depending on the receptor subtype. AVP type 1 receptors (V1a and V1b) are associated with stimulation of cell proliferation, AVP receptor type 2 (V2r) is associated with antiproliferative effects. Desmopressin (DAVP) is a synthetic analog of AVP that acts as a selective agonist for V2r, which has shown antitumor properties in models of breast and colorectal cancer. In addition, DAVP stimulation the release of ACTH in ACTHomas. Remission of Cushing's disease (CD) in the postoperative vary between 55-85%, recurrence of up to 25%. Objective: describe the influence of DAVP treatment in patients undergoing surgery for cushing's disease (CD) who develop insipidus diabetes (ID).
Patients and methods
Retrospective analysis of patients who underwent as transsphenoidal surgery (TSS) for CD. Statistical analysis: t-student for comparison of means and Chi squared for comparison of proportions.
Results
60 patients with CD treated with TSS. Age 41,72 ± 14,85 years. Women: 88.3%. Remission 75%. Postsurgical complications: 20% (3 meningitis, 9 transient DI). Of the patients in remission, 15.6% had transient ID. 26.7% had recurrence of CD. Of patients who presented transient ID: 28,57% had recurrence of CD vs 71,42% ($P=0,901$).

Table 1

	Transient ID	No transient ID	p
Age (years)	32.43 ± 8.97	42.50 ± 15.60	0.11
Tumor size (mm)	8.24 ± 11.33	9.53 ± 7.37	0.71
Postsurgical basal cortisol (μg/dl)	8.59 ± 10.64	6.46 ± 4.91	0.64
Midnight salivary cortisol (μg/dl)	0.13 ± 0.10	0.23 ± 0.15	0.31
24-hour urinary cortisol (μg/24 h)	62.45 ± 111.28	64.07 ± 74.98	0.95
Postsurgical ACTH (pg/ml)	42.28 ± 55.95	15.81 ± 16.37	0.35

Conclusions
Transient ID is the most frequent complication in the postoperative period of CD. Patients with ID presented higher postsurgical ACTH and postsurgical basal cortisol levels without being statistically significant. CD recurrence does not differ from patients who did not present ID. Treatment with DAVP does not associated with increased risk of recurrence CD.

Evaluation of the effectiveness of patients with acromegaly treatment (according to the moscow register)

Mikhail Antsiferov, Tatiana Alekseeva, Evgenii Pronin, Olga Ionova, Elena Goldman, Ekaterina Orlova & Karina Matosyan
Endocrinological Dispensary, Moscow Health Care Department, Moscow, Russian Federation

The aim
To determine the prognostic parameters affecting the course of acromegaly (A.) and the effectiveness of drug therapy (MT).
Matherials and methods
779 patients of A. [218 men (28%)] aged 60 (48/69) years, [Me(25%/75%)] were included in the Moscow register. The prevalence of A. in Moscow is 61.6; the incidence is 4.0 cases/million inhabitants. The treatment algorithm included surgical aid (495 patients), primary (I) or secondary (II) MT (584) and radiation treatment (115). Radical adenomectomy was performed in 31% of patients. 69% of patients with pituitary macroadenomas were prescribed II MT. The effectiveness of treatment was assessed by the dynamics of the GH, IGF-1, IGF-1 index (IGF-1/ULN).
Results
An inverse correlation was revealed between the age of diagnosis, the content of GH, IGF-1 and the volume of the pituitary tumor [(r=-0.24; -0.13; -0.41, respectively, (P<0.001)], which indicates a more active course of the disease with its early manifestation. I MT was received by 295 (69 m), II MT – 289 (106 m) patients. Somatostatin analogs of the first-generation (SA1) (lanreotide and octreotide) and cabergoline were used. A retrospective analysis of the effectiveness of MT was carried out between non-selective and selective groups. The selective groups for I and II MT included patients (72 and 50 patients) with a decrease in the level of IGF-1 of more than 70% of the baseline level after 3 months of taking SA1. Control A. at I/II MT in nonselective groups was achieved in 48 and 58% of cases, whereas in selective groups in 72 and 80% of patients [IGF-1 index was 0.9(0.4) and 0.8(0.3), respectively, P<0.001]. The duration of effective MT in selective groups with I MT was 49 (49) vs. 29 (29), with II MT – 53 (48) vs. 30 (37) months (P=0.0001). In both I and II MT, a moderate correlation was found between a decrease in the level of IGF-1 after 3 months of treatment, levels of IGF-1 after 12 months of treatment and at the last visit, as well as the duration of disease control [r=-0.57 (-0.51); r=-0.61 (-0.43); r=-0.58 (-0.4); r=0.52 (0.43), respectively, (P<0.001)].
Conclusion
1. Independent signs associated with the effectiveness of SA1 are: the level of IGF-1 after 3 months of treatment, the initial value of the IGF-1 index and the age of diagnosis. 2. Predictors of low sensitivity to SA1 treatment are: young age of diagnosis; male gender; large size of adenoma; the value of the IGF-1 index > 2.7.

Epidemiological description of 20 years of experience in the management of insulinomas in a third level hospital

Alejandra Maricel Rivas Montenegro[1], Roberto José Añ ez Ramos[1], Sergio Santos Belinchon[2], Laura González Fernández[1], Diego Muñ oz Moreno[1], Elisa Fernández Fernández[1], Marcel Sambo Salas[1], Juan Carlos Percovich Hualpa[1], Olga González Albarrán[1] & Rogelio García Centeno[1]
[1]Hospital Gregorio Marañón, Endocrinología y Nutrición, Madrid, Spain; [2]Hospital Gregorio Marañón, Medicina Interna, Madrid, Spain

Introduction
Insulinoma, despite its low incidence of 0.4%, it is the most common functioning pancreatic neuroendocrine tumor. Most are benign, solitary and sporadic. Around 10% can be malignant and 5-10% are part of MEN-1. On certain occasions, the differential diagnosis is difficult when there is a history of Diabetes Mellitus (DM). Our objective was to describe clinical-epidemiological data and its diagnostic-therapeutic management.
Materials and Methods
Retrospective study that used electronic records of 21 patients with a diagnosis of insulinoma confirmed by pathological anatomy treated at our Hospital from 2000-2020. Qualitative variables were described in frequencies. Shapiro-Wilk test was used to determine the normality of the variables. Data were represented according to median and interquartile range(p25-p75).
Results
76.2% were women. The median age was 57 years(50-74). A median prior to diagnosis was 12 months(5-24). Of note, 3 patients had a previous history of DM2 and 16.7% had MEN-1. Within the laboratory parameters at diagnosis: basal insulin 18 mui/ml(11-37.9), basal C-peptide 1.61 ng/dl(1.1-2.3) and basal glucose 47 mg/dl(37-63). The most used functional test was the 72-hour fasting test; positive in all cases and in the first 24 hours(75%) and the rest in 24-48 hours (25%). Regarding non-invasive preoperative localization studies: the most application and with the best rate of correct localization was computed tomography (TC) (88.9% and 93.8% respectively), followed by magnetic resonance (RM) (42.9%) and abdominal ultrasound(19%). With a registered median size of 1.50 cm(1.3-2.1). The most frequent invasive preoperative localization study was ultrasound endoscopy(9.5%) and the most used intraoperative study was ultrasound(28.6%), which identified the tumor in all the patients. The treatment of choice was surgery in 90.4%; the majority surgical method was open approach(60%). The most frequent surgical complication was pancreatic fistula(17.6%). Four cases(20%) of malignant insulinomas were reported, all were multicentric and metastatic, predominant localization was liver. In relation to the pathological anatomy report, most were unicentric, most prevalence positive immunohistochemical markers were synaptophysin, chromogranin A and insulin. Ki67% had a median of 2%(1.5-5). The most common location was head and body(50%). Cure rates of 94.11% in benign cases and 25% in malignant cases were reported. No recurrences were recorded.
Conclusions
Insulinoma is a rare pancreatic tumor. CT or MRI are preferred non-invasive localization tests. The choice of treatment is pancreas-preserving surgery with a high cure rate. However, its morbidity and mortality increases when it is a malignant insulinoma.

AQP2 gene mutation C.450T>A in a Tunisian family

Fatma Mnif[1], Hana Charfi[1], Fatma Abdelhédi[2], Malek Bouassida[2], Faten Haj Kacem Akid[1], Dhoha Ben Salah[1], Mouna Mnif[1], Nadia Charfi[1], NABILA REKIK MAJDOUB[1], Mouna Elleuch[1], Hassen Kammoun[2] & Mohamed Abid[1]
[1]Hedi Cheker University Hospital, Endocrinology, Tunisia; [2]Hedi Cheker University Hospital, Genetics, Tunisia

Introduction
The nephrogenic diabetes insipidus (DI) is an entity to be known. It is essential to know its etiologies and especially its therapeutic modalities which are different from those of the central DI. The familial nature of the disease should suggest a genetic origin. In our paper, we are presenting the case of a Tunisian family with genetic nephrogenic DI.
Case reports
Our family had a history of neglected polyuro-polydipsic syndrome (PPS), delayed growth, deafness, death at an early age and urinary malformations. Our first patient was a 35 years old female. She had a personal history of delayed growth and chronic renal failure. She was suffering from PPS for several years but neglected. A biological workup ruled out simple causes of DI and the water restriction test confirmed its nephrogenic origin. The patient was put on indomethacin with improvement of her symptoms. Her brother, 25-year-old, with a history of deafness and delayed growth, developed a post-traumatic polyuro-polydipsic syndrome evoking the diagnosis of central DI but refuted by the non-improvement of the symptoms after ddVAP. It was the use of the medical records of the sister already known to be a nephrogenic DI carrier that allowed us to correct the diagnosis of central DI. This allowed us to combine indomethacin and thiazide diuretics with improvement of the symptoms. Radiological exploration of the hypothalamic-pituitary region was without abnormality and pituitary hormonal exploration showed hyper gonadotropic hypogonadism and hyperprolactinemia at 39.55 ng/ml. A CT scan with urinary tract revealed a bilateral

dilatation of the pyelo-caliceal cavities with no detectable obstruction and a neurologic bladder. The genetic study of the AQP2 and AVPR2 genes was carried out by PCR-sequencing for our patients as well as some relatives. This analysis showed the presence of a homozygous missense mutation in exon 2 of the AQP2 gene in our female patient and in another affected sibling. It is a substitution of a thymine (T) by an adenine (A) at positon 450 of the cDNA: C.450T > A. This mutation was present in the heterozygous state in the mother.
Conclusion
Currently, the use of molecular biology facilitates the management of familial DI with genetic counselling and early detection of the different anomalies before their clinical exacerbation. In our case, the study of this family will incite us to do genetic counseling in its different members and to follow them closely to detect other affected members in time.

Endocrine dysfunction secondary to pituitary tuberculoma: a case report

Fatma Mnif, Hana Charfi, Dhoha Ben Salah, Faten Haj Kacem Akid, Nadia Charfi, Nabila Rekik Majdoub, Mouna Mnif, Mouna Elleuch & Mohamed Abid
Hedi Cheker University Hospital, Endocrinology, Tunisia

Introduction
Tuberculosis is an infectious disease that involves any organ. However, the primary pituitary tuberculosis is an extremely rare disease. Intracranial tuberculomas account for 0,15-5% of intracranial space-occupying lesions, of which pituitary as the primary site, and easily misdiagnosed as pituitary adenoma. In this setting, the late diagnosis can result in permanent endocrine dysfunction. We hereby report the case of a patient with pituitary tuberculoma discovered following the onset of diabetes insipidus.
Case report
The patient was a 36-year-old woman. She presented with polyuro-polydipsic syndrome (PPS) associated with holocranial headaches and secondary amenorrhea. Hormonal exploration identified corticotropic insufficiency with hyperprolactinemia. Central DI was retained in view of the hypothalamo-pituitary MRI aspect showing the disappearance of the spontaneous T1 hypersignal and the presence of a thickening of the pituitary stem. The tubercular origin of this thickening was oriented by the presence of a history of erythema nodosum with a positive intradermal reaction to tuberculin. It was confirmed by the presence of Mycobacterium Tuberculosis in the sputum, urine and bronchial fluid. Anti-tubercular drugs were combined with hormone replacement therapy: Hydrocortisone at a dose of 20 mg/d, ddVAP at a dose of 0.3 ml/d and dopamine agonist at a dose of 5 mg/d. After 3 months of treatment, the patient showed a clear improvement of her symptoms with a weight gain of 8 kg, disappearance of headaches, PPS and galactorrhea. But she still had amenorrhea despite normoprolactinemia (PRL < 0.4 ng/ml) with a normal LH level at 3.5 mUI/ml and an elevated FSH level at 11.6 mUI/ml. MRI control after 8 months of anti-tuberculosis treatment also showed a clear improvement with a fine pituitary stalk taking contrast correctly and a normal looking pituitary gland. The total duration of treatment was extended to 24 months. At the last MRI check-up after 24 months of treatment, the tubercular pituitary abscess had completely disappeared and clinically, the patient no longer had PPS or galactorrhea. However, the amenorrhea persisted, with a negative progestin test. The diagnosis of a physiological menopause was retained in view of an explosive gonadotropin response under LHRH.
Conclusion
The non-specific radiological findings challenge the diagnosis of primary pituitary tuberculomas. However, a high clinical suspicion, especially in endemic regions, can minimize unnecessary invasive procedures and surgical interventions. The early clinical suspicion and prompt use of anti-tubercular drugs help to prevent irreversible endocrine dysfunction.

Age and puberty based IGF-1 normative data in healthy children from North India.

Bhanu Malhotra[1], Kv Ravi Teja[1], Sanjay Bhadada[1], Ashu Rastogi[1], Anil Bhansali[1], Naresh Sachdeva[1], Ranjana Walker Minz[1], Rama Walia[1], Mahesh Prakash[1], Arun Kumar Aggarwal[1], Gajinder Dewan[2], Liza Das[1], Philip Monaghan[3], Peter Trainer[3], Marta Korbonits[4], Raman Kumar Marwaha[5] & Pinaki Dutta[1]
[1]PGIMER, Endocrinology, Chandigarh, India; [2]GMSH-16, Chandigarh, India; [3]Christie NHS Foundation Trust, Manchester, United Kingdom; [4]William Harvey Research Institute at Barts and the London School of Medicine, Queen Mary University of London, Endocrinology, London, United Kingdom; [5]SEHEAC, New Delhi, India

Context
Serum IGF-1 levels are of paramount importance for diagnosis and management of growth related disorders. The reference range of IGF- 1 should be ethnicity and Tanner specific. Indian data on the same is scarce and there is a need to develop the same.
Objective
To develop age, sex and Tanner based normative reference range of serum IGF-1 level for Indian children and correlate the same with peri-pubertal hormonal parameters.
Setting and participants
After excluding children with short stature, anemia, chronic systemic illnesses, underlying endocrinopathies and celiac disease; 1929 children (916 girls, 1013 boys) were eligible for participation out of 2191 children screened. They were stratified as per chronological age and pubertal stage (Marshall and Tanner).
Outcome measures
Serum IGF-1 was measured by in house electrochemiluminescence immunoassay by Roche Diagnostics (cobas e 801) Mannheim, Germany; at PGIMER, Chandigarh. External validation of assay was done by robust immunodiagnostics method (iSYS) at Manchester, UK. Normative reference range and correlation were obtained based on Roche method.
Result
Serum IGF-1 levels peaked at chronological age of 13 years (median 50thcentile 397.38 ng/ml) [Greulich Pyle BA 14 years(389 ng/ml)] in girls and at 15 years in boys (327 ng/ml) [BA 16 years (370 ng/ml)], followed by a decline to nadir at 18 years in both. Girls had an early peaking of IGF-1 as compared to boys. The median IGF-1 levels in girls increased from Tanner stage 1 to stage 4, with peak value of 345 ng/ml at stage 4 and declining sharply thereafter. For boys, levels increased from Tanner stage 1 to stage 3, peaked at 308 ng/ml at stage 3, after which the levels were stable and fluctuated around the peak from stage 3 to 5. IGF-1 also correlated significantly with hormonal parameters of puberty (girls: LH (r =0.52), estradiol (r=0.40), DHEAS (r = 0.44); boys: LH (r= 0.57), testosterone (r=0.56), DHEAS (r=0.47); with LH showing the best correlation. This early peaking of IGF- 1 levels in the present study vis-a vis Caucasians (14-16 years) has also been reported in other studies from Asia (11-13 years).
Conclusion
Along with chronological age, Tanner based reference range will further improve the diagnostic utility of IGF-1 normative data in school going children.

Pituitary adenomas characteristics in patients with multiple endocrine neoplasia type 1, its phenocopies and sporadic acromegaly

Diana Trukhina[1], Elizaveta Mamedova[1], Anastasia Lapshina[1], Alexey Nikitin[2], Philipp Koshkin[3], Vilen Azizyan[1], Andrey Grigoriev[1], Zhanna Belaya[1] & Galina Melnichenko[1]

Multiple endocrine neoplasia type 1(MEN1) is a hereditary condition caused by mutations in the *MEN1* gene, which encodes menin protein. The syndrome predisposes to the development of tumors in both endocrine and non-endocrine systems. In patients with MEN1, pituitary adenomas (PA) occur in approximately 40% of all cases. If patient has MEN1 phenotype with no mutations in *MEN1* gene, the condition is regarded as a phenocopy. The reason of several endocrine MEN1-associated tumors combination in these patients remains unknown. Knowing menin expression in groups and if there are any somatic mutations in

PA can provide insight into the oncogenesis of PA. Formalin-fixed paraffin-embedded PA tissues were obtained after transnasal transsphenoidal adenomectomy(TTA). We have used following immunohistochemistry (IHC) markers: Pit-1;T-box;CAM5.2; EK-alpha; GH, ACTH, PRL, TSH, FSH, LH, menin(ab-Menin-ChIP Grade, Abcam, UK). *MEN1* mutations were assessed either by Sanger sequencing or by NGS(NextSeq550, Illumina, USA). Automated bioinformatic analysis was carried out to search for somatic mutations(annotation with SnpEff, ANNOVAR, AlamutBatch). A total of 47 samples were included in the study; *MEN1* gene somatic mutations were determined in 30 samples. Menin expression was assessed in 47 PAs: 11 genetically confirmed MEN1(gMEN1), 13 phenocopies of MEN1(phMEN1) — a combination of acromegaly and primary hyperparathyroidism, 23 – sporadic acromegaly(SAm). The distribution of PA according to the type of secretion in the gMEN group was: 5-ACTH, 1-PRL, 4-adenomas with mixed secretion (2-GH + PRL; 1-TSH + PRL; 1-ACTH + PRL) 1-silent gonadotroph adenoma. All 13 samples phMEN1 and 23 samples SAm were secreting GH. The median age at the time of TTA in gMEN1 was 33 years[16;47], in phMEN1 — 59[56;64], in SAm — 57[52;62]. The groups were similar in terms of sex($P > 0.05$). The results of menin staining (negative staining/positive cytoplasmic staining/positive nuclear staining): gMEN1-5/6/0; phMEN1-0/12/1; SAm-2/14/7. The phMEN1 showed significantly greater cytoplasmic expression of menin than gMEN1 ($P = 0.011$). The gMEN1 differed from SAm: nuclear staining was not detected in any case ($P = 0.011$). There were no statistically significant differences between the phMEN1 and SAm groups ($P = 0.141$). Although there were no differences, in phMEN1 only one case showed weak menin nuclear expression, while in SAm 7 cases had nuclear expression. No somatic mutations of *MEN1* gene in phMEN1 and SAm groups were identified. Menin expression is generally preserved in PA in phMEN1 and SAm groups, though with different pattern of nuclear and cytoplasmic expression, while its expression varies in PA in MEN1. No detection of somatic mutations in phMEN1 and SAm groups leads to investigate other responsible genes or epigenetic causes of different menin expression.

A Delphi panel of Italian endocrinologists to define the unmet needs on the current management of Cushing's Syndrome

Rosario Pivonello[1], Scaroni Carla[2], Barbara Polistena[3], Antonio Migliore[3] & Andrea Giustina[4]
[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgica, Naples, Italy; [2]Università degli Studi di Padova, Dipartimento di Medicina Clinica U.O.C. Endocrinologia, Padova, Italy; [3]C.R.E.A. Sanità - Centro per la Ricerca Economica Applicata in Sanità, Rome, Italy; [4]San Raffaele Vita-Salute University and IRCCS Hospital, Institute of Endocrine and Metabolic Sciences, Milan, Italy

Introduction
Cushing's Syndrome (CS) requires an accurate diagnosis, patient-tailored treatments and long-term management. To define the unmet needs of patients with CS, a consensus among a panel of Italian endocrinologists was promoted. The panel involved 57 specialists with expertise in CS management.
Methods
The endocrinologists were identified by convenience sampling. The survey was built around a set of statements formulated after literature review and discussion with an experts' advisory board. A total of 24 statements were finally included in the survey. The Delphi method was used to reach consensus on the statements using scores on a 1-to-9 scale (with 1 indicating disagreement with the statement and 9 indicating full agreement). A 70% threshold was set to define consensus, meaning that strong agreement was believed reached if at least 70% of participants had assigned scores in the range 1-3 or 7-9, respectively.
Results
Twenty-three endocrinologists (40% of the sample) working in 10 Italian regions took part into the survey. Among them, 52% reported to follow between 5 and 10 Cushing patients per year, 22% between 10 and 20 patients, 17% more than 20 patients, and 9% less than 5 patients. The Delphi process was concluded in 2 rounds. Agreement was reached on 18 of the 24 proposed statements (75%). The statements for which consensus was not reached ($n = 6$; 25%) were mainly related to the definition of a standard pharmacological therapy for CS, the response time to the available pharmacological therapies, the achievement of a complete control of the clinical condition, the evidence base needed for CS pharmacological therapies, and the satisfaction with the safety and effectiveness profiles of the current pharmacological therapies. Some statements in particular accounted for extremely high level of agreement (values over 90%) and they were related to the need of a constant and periodic follow-up of the patients, given the possibility of mid-long term relapse; to the relevance of the escape, which can have a strong impact on the overall management of the condition; to the need to promote the development of management pathways which are specific for CS; to the need that a newer pharmacological option, with improved safety and effectiveness profile, could radically change the current management of the CS.
Conclusions
The survey revealed that the experts involved perceive some relevant unmet needs in the management of CS, mainly related to the lack of a pharmacological treatment with more favourable safety and effectiveness profile.

Age at the diagnosis or age at the onset of symptoms- which should be taken into consideration in patients with early-onset acromegaly- pilot study

Magdalena Godlewska, Anna Bogusławska, Łukasz Kluczyński, Ewelina Rzepka, Alicja Hubalewska-Dydejczyk & Aleksandra Gilis-Januszewska
Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland

Introduction
The group of young adults with acromegaly, despite initial reports about their aggressive course of disease, has not been thoroughly characterized.
Aim
Our aim was to investigate the differences between the patients with early-onset acromegaly and with onset in older age.
Material and methods
Consecutive patients diagnosed with acromegaly between 01.2014 and 12.2021 were included in this retrospective study, approved by the local Bioethics Committee. Firstly, the arbitrary division (Group A: with patients ≤ 30 and Group B: with patients > 30 y.o. upon diagnosis) was used. Secondly, retrospective estimation of age upon symptoms onset divided the patients into Group C and D (≤ 30 and > 30 y.o. at the onset, respectively). We statistically compared Groups A and B and subsequently Groups C and D in terms of clinical, biochemical and radiological parameters, using IBM SPSS Statistics, ver. 27.
Results
Out of 72 consecutive patients with acromegaly, 64 were included in the study. Group A consisted of 11 patients, 54.5% males, Group B had 53 patients, 41.5% males. Retrospective estimation of the age at diagnosis was available in 50 patients: there were 18 patients in Group C (44.4% males) and 32 patients in group D (34.4% males). There were no statistically significant differences between group A and B as well as between C and D in terms of: gender, median diagnostic delay, frequency of accidental diagnosis, hypopituitarism, hyperprolactinemia and, radiologically, occurrence of macroadenomas, median maximal tumor diameter, pituitary apoplexy, cavernous sinus invasion, compression of the optic chiasm. Median growth hormone (GH) nadir concentration was higher in Group A than in Group B: 38.4 uIU/ml(24.1; IQR 65.7) vs. 20.8 uIU/ml(10.45; IQR 34.5), respectively ($P = 0.046$). GH was higher in Group C(37.7 uIU/ml, IQR 67.2) than in Group D(15.3 uIU/ml, IQR 27.7) ($P = 0.046$). No differences in IGF-1 concentration related to upper normal limit were discovered between the groups in both steps of the analysis. Biochemical control was after surgery was similarly frequent in groups A and B; and groups C and D.
Conclusions
In our study, patients with early-onset acromegaly did not statistically differ from typical-onset patients, even when considering two division criteria: arbitrary and based on the estimated symptoms onset. Our main limitation is the small number of patients enrolled, even though all of the newly diagnosed patients in a tertiary endocrinology center over 8 years were included. Further, prospective studies are needed to identify and assess the differences between age groups of acromegaly patients.

Giant pituitary adenomas in children and adolescents: clinical presentation, management and long-term outcome

Giuseppe Giuffrida[1], salvatore giovinazzo[1], Ylenia Alessi[2], Marta Ragonese[1], Oana Ruxandra Cotta[2], Filippo Flavio Angileri[3], Francesco Ferraù[1,2] & Salvatore Cannavò[1,2]
[1]Department of Human Pathology "G. Barresi", University of Messina, Italy; [2]Endocrine Unit, University Hospital "G. Martino", Messina, Italy; [3]Department of Biomedical and Dental Sciences, and Morpho-Functional Imaging, University of Messina, Italy

Background
Pituitary adenomas in children/adolescents represent around 3% of all intracranial neoplasms. They are more frequently hormone-secreting lesions, usually diagnosed in early childhood and late adolescence. Female gender is generally prevalent, because of most evident symptoms (i.e., irregular periods, galactorrhea, etc.). Giant pituitary adenomas (GA) very rarely occur in pediatric age, posing frequent challenges in their management.
Patients and methods
We retrospectively evaluated the records of 7 teenager patients (5 males, median age 16.7 $\pm$ 1.6 yrs) with GA, referred to the Endocrine Unit of the University Hospital of Messina (Italy) from 1990 to 2020. All patients underwent biochemical, clinical and neuroradiological workup. The median follow-up was 16.1 $\pm$ 9.9 years.
Results
GAs were clinically characterized as follows: five functioning PAs (4 PRL-secreting, 1 ACTH-secreting) and two non-functioning pituitary adenomas (NFPAs). Median pituitary tumor diameter was 43 $\pm$ 2.2 mm. Genetic analysis revealed only 1 carrier of MEN1 mutation (a patient with PRL-secreting tumor), while no changes of AIP gene were detected. At diagnosis, main presenting symptoms were headache (n.5), visual disturbances (n.4), menstrual irregularities (n.2), and growth delay (n.1). In terms of pituitary function, 1 patient presented with panhypopituitarism, 2 with multiple pituitary deficits. One patient with NFPA was lost to follow-up, of the remaining 6 patients: 3 (1 PRL, 1 ACTH, 1 NFPA) were referred to first-line surgery by endoscopic trans-nose-sphenoidal approach, 3 PRL-omas were treated with medical therapy (cabergoline) exclusively or prior to surgery. After first-line treatment, stable remission (no tumor remnant and/or no hormone hypersecretion) was observed in 3 subjects, progression (growing tumor remnant and/or persistent hormonal hypersecretion) in 3 cases. In these last cases, second-line treatment was radiotherapy. At last follow-up visit: 5 patients were in remission while 1 patient with PRL secreting tumor was still under effective cabergoline treatment; 2 patients had panhypopituitarism, 3 single/multiple pituitary deficits, while pituitary function was preserved in one subject. GH deficiency (GHD), isolated as well in association with other deficits, was the most frequent pituitary hormone deficit (n.5/7 patients). During follow-up, the following comorbidities were diagnosed: metabolic syndrome (n.3), osteoporosis (n.2), second tumors (n.1).
Conclusions
Giant pituitary adenomas management in children/adolescents is challenging and require a multidisciplinary approach.

The clinical implication of macroprolactinemia detection using PEG 6000 in a group of women of childbearing-age with hyperprolactinemia in sub-Saharan Africa: experience of a tertiary hospital

Anne Ongmeb Boli[1], Mendane Ekobena Francine[2], Etoa Etoga Martine[1,2], Charly FEUTSEU[3], Mbono Samba Esther Aristide[1,2], Falmata Amazia[4], Djahmeni Éric Noël[1], Ndi Manga Arnaud[1], Katte Jean Claude[1], Dehayem Mesmin[1,2], Ama Moor Vicky Jocelyne[5] & Sobngwi Eugène[1,2]
[1]Yaounde Central Hospital, National Obesity Centre, Endocrinology and Metabolic Disease Unit, Yaoundé, Cameroon; [2]University of Yaoundé 1, Faculty of Medicine and Biomedical Sciences, Department of Internal Medicine and Specialities, Yaoundé, Cameroon; [3]University of Yaoundé 1, Biotechnology Centre, Yaoundé, Cameroon; [4]University of Yaoundé 1, Faculty of Medicine and Biomedical Sciences, Doctoral School of life, Health and Environnemental Sciences, Yaoundé, Cameroon; [5]University of Yaoundé 1, Faculty of Medicine and Biomedical Sciences, Department of Biochemistry, Yaoundé, Cameroon

Introduction
Macroprolactin (MacroPRL), a variant of human prolactin may interfere with hormonal assay and falsely increase serum prolactin levels. Therefore, failure to identify macroprolactinemia can lead to inappropriate investigations and treatment in women who are already susceptible to anxiety and stress. We aimed to identify macroprolactinemia among women of childbearing age with hyperprolactinemia.
Materials and methods
We conducted a cross-sectional study at the endocrine unit of one of the tertiary hospitals in Cameroon. Study participants were recruited from both endocrine and gynecological outpatient consultations services. They were women of child-bearing age (18 to 49 years) consulting for signs and symptoms of gonadal dysfunction or hyperprolactinemia (PRL $>$25 ng/ml). Total prolactin was measured using a Human direct ELISA method. Polyethylene glycol 6000 (PEG 6000) precipitation was used to detect macroprolactinemia.
Results
We enrolled 33 women with a mean age of 31 $\pm$ 7 years (range 21-48). Twenty-seven (81.8%) participants were symptomatic with the majority 23/27 (69.7%) reporting galactorrhea and 21 (63.4%) women reported having an irregular menstrual cycle. The median pre-precipitation prolactinemia reduced significantly after PEG precipitation from 61.2 (IQR: 33.2-115.9) ng/ml to 33.8 (IQR: 17.9-70.5) ng/ml, $P < 0.001$. After PEG precipitation, 5 participants had a serum prolactin recovery rate below 60%, and therefore a prevalence of macroprolactinemia at 15.2%. Four (80%) women with macroprolactinemia presented with symptoms, and there was no association between macroprolactinemia and symptoms of hyperprolactinemia among these participants.
Conclusion
Macroprolactinemia was detected in 5/33 (15.2%) of the study population. There was no association between macroprolactinemia and symptoms of hyperprolactinemia. Oligomenorrhoea, amenorrhoea, and galactorrhea were present in the majority of patients with macroprolactinemia hence routine screening for macroprolactinemia is recommended or advised in order to reduce the use of dopamine agonist treatment and imaging.

Cessation of GH secretion in acromegaly without medical or surgical intervetion; Covid-postponed surgery was escaped

Annamária Erdei[1], Eszter Dániel[1], Annamaria Gazdag[1], Mihá ly Griger[2], Edit B Nagy[3] & Endre V Nagy[1]
[1]Division of Endocrinology, Department of Internal Medicine, Debrecen, Hungary; [2]Department of Internal Medicine, Debrecen, Hungary; [3]Division of Radiology and Imaging Science, Department of Medical Imaging, Debrecen, Hungary

Introduction
Acromegaly is usually caused by pituitary macroadenoma producing excess growth hormone. Treatment options include surgery to remove the tumor, medications, and radiation therapy.
Case report
A 39-year-old woman has been referred to the endocrine clinic with suspected acromegaly in December 2019. Surgery for benign ovarian cyst, endometriosis, amenorrhoea, unsuccessful in vitro fertilisations were present in her medical history. She complained about thickening of fingers, facial bloating, dry skin and vision impairment. Laboratory examinations proved acromegaly, central hypothyroidism, hypogonadism and mild hyperprolactinaemia. ACTH and cortisol levels were in the normal range. Sella MR showed pituitary macroadenoma in size 17 x 12 x 14 mm. There was no abnormal finding detected by ophthalmological examination. After the diagnosis was established, levothyroxine was started and pituitary surgery was scheduled for March of 2020. Restrictions due to the coronavirus pandemic prevented the operation; this was postponed to an uncertain date in the future. We decided to start long-acting somatostatin analogue treatment. Before treatment could be started, something unexpected happened. In April 2020, severe headache, nausea, vomiting, weakness, hypotension occurred. Urgent MR showed substantial decrease in the size of the macroadenoma and haemorrhage in the tumor. Laboratory findings confirmed hypadrenia and decrease in growth hormone and insulin-like growth factor 1 levels. On follow-up, hypopituitarism was treated effectively with hormone replacement therapy. Growth hormone and insulin-like growth factor 1 levels were further reduced, the size of the pituitary adenoma decreased below 1 cm on repeated MR, the clinical features of acromegaly disappeared and no special treatment for acromegaly was required.
Conclusions
Pituitary apoplexy is a rare condition, occurs in 2-12 % in pituitary adenomas and in 0.05-4.8% in acromegaly. Typical symptoms are headache, vomiting, visual

disturbances. Pituitary apoplexy might cause remission in acromegaly as seen in the case presented here.

When we count Ki67 in a gonadotropinoma- matters- case report

Mariana Costache Outas
Coltea Clinical Hospital, Endocrinology, Bucharest, Romania

We report the case of a 49 y.o male with an incidental sphenoidal-sellar tumour discovered during a cerebral CT scan during the workup of a medium to severe SARS COV 2 infection. The cerebral MRI describes an invasive tumour located in the sellar region and sphenoidal sinus – extended around the right optic nerve and into both cavernous sinuses. An emergency biopsy from the sphenoidal extension of the tumour revealed a neuroendocrine tumour. The reported diagnostic was olfactory neuroblastoma grade I Hyams (positive stains for synaptophysin, NSE, Ki67 index of 8%). The patient was referred to a mixt expertise surgical team (ENT- neurosurgery). He undergoes removal of the sphenoidal- sellar tumour – 5 weeks from the diagnostic. His first endocrine evaluation was following surgery due to the development of central hypocortisolism, and replacement therapy was started. He undergoes radiotherapy for residual tumour two months after surgery. The initial anatomopathological report from the surgical sample described an olfactory neuroblastoma grade I Hyams (Ki67 index 1%). Reconsideration of immunohistochemistry from the tumour sample stains positive for SF1, GATA3, LH and FSH with a Ki67 index of 1%, and a diagnostic of invasive gonadotropinoma was concluded. We assume the systemic inflammatory status during SAR COV2 infection is responsible for the difference in the Ki67 index counted five weeks apart from the biopsy sample and the tumour sample during surgery.

The septo-optic dysplasia associated with adipsic hypernatremia

Mouna Mezoued[1], Habouchi Amine[2], Bessaid Khadidja[1] & Malha Azzouz[1]
[1]Bologhine Hospital, Endocrinology, Alger, Algeria; [2]Mustapha Hospital, Radiology, Alger, Algeria

Introduction
SOD is a rare congenital anomaly, with an incidence of 1 in 10 000 live births, the adipsic hypernatremia is a rare osmoregulation Disorder observed in SOD.
Case report
We report a case of a 28 months infant, the eldest of a sibling group of 2 children, referred by the pediatrician for exploration of a staturo-ponderal delay. At clinical examination we found a harmonious staturo-ponderal delay and a median line anomaly of development as a single central incisor, ogival palate and a convergent squint. GH deficiency was confirmed in laboratory. Cerebral MRI showed a pituitary stem interruption syndrome with pituitary hypoplasia, an absence of the pituitary stem, an ectopic pituitary gland with infundibular location and an agenesis of the septum pellucidum. At 8 years she presented an important headache associated with vomiting asoociated to a hypernatremia at 185 meq/l, having required rehydration. The diagnostic of adipsic hypernatremia was retained due to the absence of thirst (adipsia) a very high osmolality and a normal urine osmolality concluding to a normal production of AVP. The management is based on the obligation of a daily intake (1,5-2 l/day) of water, an adjustements of these intakes in case of climatic variations or acute illness and regular serum sodium monitoring

Hyperprolactinemia and connective tissue diseases: which significance of such exceptional association?

Arij Ezzouhour Yahyaoui, Asma Kefi, Khaoula Ben Abdelghani, Mounira El Euch, Syrine Sassi, Sami Turki & Ezzeddine Abderrahim
Charles Nicolle, Tunis, Tunisia

Introduction
Dermatomyositis is a chronic, idiopathic inflammatory myopathy that can overlap with rheumatoid arthritis. The immunostimulatory effect of prolactin is suggested by many authors. Herein we report an original association of hyperprolactinemia with a scarce condition: dermatomyositis-rheumatoid arthritis overlap in a young woman.
Case description
A 26-year-old woman with no significant medical history was referred to our department to investigate deterioration of physical condition with myalgia. She was apyrectic and had clinical features of dermatomyositis including Gottron's papules, heliotrope rash, proximal nail fold erythema, symmetric weakness affecting predominantly the proximal muscles of the legs and arms. Serum creatinin kinase was elevated at 395 UI/l and lactate deshydrogenase levels were at 546 UI/l. The muscle biopsy and the electromyogram confirmed dermatomyositis diagnosis. Respiratory function tests and CT chest were normal. There were no symptoms of infection. Given possible association with neoplasms, exhaustive investigation was performed and showed no underlying neoplastic disease. Since the patient had polyarthralgia and a biological inflammatory syndrome, we suspected the presence of another connective tissue disease. An overlap of dermatomyositis and rheumatoid arthritis was diagnosed as the patient presented symmetric swelling of small joints, morning stiffness, and a boutonniere deformity in the 4th and 5th right fingers. Rheumatoid factor was at 80 UI/l and anti-CCP levels were at 15. Menstrual irregularities were reported, therefore hormone tests were performed. They highlighted a hyperprolactinemia at 1136 UI/l and normal levels of FSH, LH and estrogen. Gynecological examination and pelvic sonography showed no abnormalities. The patient was commenced on prednisone 50 mg/day (1 mg/kg), with satisfying clinical and biological evolution. No prolactin inhibitors were prescribed. Prolactin levels were normalized in follow-up and menstrual cycles of our patient became more regular. Pituitary MRI was not performed as the patient lost to follow up.
Conclusion
The effect of hormones on the immune system has been widely described. Many research reported hyperprolactinemia in patients with autoimmune diseases; it might promote the development of autoimmune diseases, leading some authors to suggest some role of dopamine agonists in the therapy of those diseases. More large-scale studies are needed to establish the exact relationship between hyperprolactinemia and autoimmune diseases and effeciency of dopamine agonists in such conditions.

A Rare Case of Isolated ACTH deficiency, Possible cause: long-term use of opioid analgesics for severe Migraine management/Opioid-induced adrenal insufficiency (OIAI) (?)

Nino Zavrashvili[1], Ketevan Chanturishvili[1,2], Ketevan Gvazava[1], Natia Margvelashvili[1] & Natia Shonia[1]
[1]Tbilisi Institute of Medicine, Endocrinology, Tbilisi, Georgia; [2]David Tvildiani Medical University, Endocrinology, Tbilisi, Georgia

Context
Hypothalamic-pituitary-adrenal axis (HPA) may be disrupted by drugs, including opioids. Opioids are widely used for treatment of acute and chronic pain, but they also carry a wide range of adverse effects. Opioid receptors are present in the pituitary gland and hypothalamus and chronic use of opioids may lead to adrenal insufficiency because of central suppression of the hypothalamic-pituitary-adrenal axis (HPA).
Case Presentation
We report a 26-year-old female with a history of severe Migraines and autoimmune primary hypothyroidism who presented with decreased energy, weakness, fatigue, myalgia, arthralgia, nausea, vomiting, diarrhea and urinary frequency. She is checking blood pressure, which is little higher than 130/90 mmHg. Since 2013 the patient had 5 hospitalizations (twice in Germany) in connection with status migranosus. To manage her symptoms during hospitalizations multiple medications would be tried for pain without any success. The patient describes that fentanyl, propofol, morphine and tramadol

would have to be ultimately used. Given the patient's symptoms Cortisol deficiency was suspected. Cortisol was measured and was found to be very low, repeated several times. ACTH at the same time was very low suggestive of secondary adrenal insufficiency. To investigate the reason for secondary adrenal insufficiency, patient had MRI of pituitary gland which was normal, revealing no pituitary tumors or pituitary stalk lesions/other lesions. Additional pituitary hormonal workup was performed. Overall, the biochemical picture was consistent with idiopathic ACTH deficiency. Hydrocortisone therapy was initiated 30 mg QD, lead to significant improvement of symptoms. Hyperglycemia and secondary hyperaldosteronism was incidentally found during workup for above symptoms. Hemoglobin A1c was above normal ranges-5.9 %, but GAD antibodies and C-peptide were not indicative of autoimmune type 1 diabetes. Blood pressure measurements were high and aldosterone and renin plasma activity was elevated. Patient continuous levothyroxine supplementation therapy. However, after 3 years of hydrocortisone therapy patient suddenly started gaining weight and developed Cushing's symptoms so we performed trial with slow down titration of hydrocortisone which lead to improvement of symptoms. We checked morning cortisol and ACTH which were normal. For migraines she is using NSAID'S and is aware of overuse headaches and is trying to be mindful of that.
Conclusion
We should bear in mind the possibility of adrenocorticotropic hormone deficiency even when patients with history pain syndromes and opioid use.

A rare association of Neurofibromatosis type 2 and hypopituitarism

Lina Ghram, Radhouen Gharbi, Sawsen Essayeh, Hajer KANDARA, Manel Jemel & Ines KAMMOUN
Institut De Nutrition, Tunis, Tunisia

Introduction
Neurofibromatosis type 2 (NF2) is an autosomal dominant genetic disorder that cause a growth of noncancerous tumors in the nervous system, it associates cranial schwannomas, meningiomas, and skin and ophthalmologic lesions. It is a rare condition and its association with an intrasellar arachnoidocele has not been reported yet. We report the case of a patient who presents a NF2 associated with hypopituitarism related to an intrasellar arachnoidocele.
Case presentation
It was a 37-year-old, patient referred for symptoms of hypopituitarism. She reported galactorrhea, menses return, constipation, weight loss, asthenia and frequent hypoglycaemia. On physical examination, she presented café-au-lait spots, dry skin with neurofibromas, body hair loss and hypoactive deep tendon reflexes. Biologically, cortisol and FT4 levels were very low at <2 ng/ml (reference : 50 - 180 ng/ml) and 1.38 pmol/l (reference: 9-22 pmol/l) respectively. TSH was 5.86 uUI/ml (reference: 0.27-4.2). The patient received hydrocortisone and L-thyroxine. A hypothalamic-pituitary MRI showed complete atrophy of the pituitary parenchyma with intrasellar arachnoidocele, a meningioma of the foramen magnum and an acoustic neurinoma. The association of a unilateral acoustic neuroma and café au lait spots with skin neurofibromas and a meningioma led to the diagnosis of NF2.
Conclusion
NF2 can cause fluid buildup in the brain, but its association with intra sellar arachnoidocele and hypopituitarism has never been reported .
The prognosis of the disease is reserved and its management requires a multidisciplinary team.

DOI: 10.1530/endoabs.81.EP709

Langerhans cell histiocytosis revealed by an isolated central diabetes insipidus in an adult

Halladja Chaima, Safia Achir, Zina Belheddad & SAFIA MIMOUNI
CPMC Centre Pierre Et Marie-Curie, Endocrinology and metabolic diseases department, Algiers, Algeria

Introduction
Langerhans cell histiocytosis (LCH) is a systemic disorder characterized by clonal proliferation of immature dendritic cells observed mainly in children. The affection of the sellar region in adults with central diabetes insipidus as the first manifestation of the disease is extremely rare creating a problem of etiological diagnosis especially when central diabetes insipidus (CDI) is apparently isolated.
Case description
A 21-year-old man was referred for evaluation of recent polyuria and polydipsia with a history of headache for the past 03 years. Initial biochemistry and hormonal evaluation were normal. Magnetic resonance imaging(MRI) of the brain showed a loss of spontaneous T1 hyperintensity of the posterior pituitary, a globular anterior hypophysis and a thickened *pituitary stalk measured at 07 mm, filling the opto-chiasmatic cistern and exerting a mass effect on the optic chiasma In addition,* the patient had a type II Chiari malformation with intramedullary cyst and a malformation of the colobomatous eyeballs. Notably, The MRI showed a non-expansive osteolytic lesion of the frontal *bone*. Additional investigations were performed in order to establish etiological diagnosis but were non contributory. A bone biopsy of the frontal bone was then performed, and the pathologic examination concluded to LCH diagnosis. Desmopressin therapy was therefore initiated. The patient was referred to the hematology department where he received chemotherapy (vinblastine, Etoposide) with corticosteroid therapy
During follow-up: the patient developed GH deficiency, TSH deficiency, and FSH and LH deficiencies, corticotropic axis has not been evaluated because the patient was on corticosteroid therapy. There was no reduction of desmopressin doses. The frontal lesion was not present on the follow-up MRI. On the other hand, it showed a new lesion in the left frontal sinus suggesting an osteoma; a CT scan remains necessary for a better evaluation of the bony structures
Conclusion
In this patient LCH was revealed by central diabetes insipidus as the first manifestation, associated with solitary bone lesion. Treatment included desmopressin replacement and chemotherapy. During follow-up, the patient developed a panhypopituitarism with no improvement in diabetes insipidus with the appearance of a second bone lesion in the left frontal sinus

Pituitary adenoma in the young adult

Lamiae Zarraa, Abdellaoui Wahiba, Imane Assarrar, Siham ROUF & Hanane Latrech
Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Endocrinology-Diabetology and Nutrition Department CHU MOHAMED VI, Oujda, Morocco

Introduction & Background
Pituitary adenomas represent 10-25% of all intracranial tumors. Their incidence is higher between the ages of 40-60 years and less frequent in young adults. The objective of this work was to evaluate the prevalence as well as the clinical and etiological profile of pituitary adenomas in young adults.
Key words : pituitary adenoma- yount adult.
Material and methods
Retrospective descriptive study of 21 patients followed-up for pituitary adenoma whose age was less than 30 years. Data were collected from medical records and analyzed by SPSS-V21 software.
Results
Pituitary adenoma in young adults under the age of 30 represented 23% of all cases of pituitary adenoma in our series ($n=21/91$). The mean age at diagnosis was 24 ± 4.9 years with a clear female predominance (61.9%). The clinical presentation was dominated by pituitary secretion syndrome in 66% of cases ($n=15$) followed by pituitary tumor syndrome in 23.8% of cases ($n=5$). Hypothalamohypophyseal MRI showed a pituitary macroadenoma in 71.1% of cases, 72% of which had an extrasellar extension associated with invasiveness in 4 patients (19% of cases), and a pituitary microadenoma was noted in 38.9% of cases. Corticotropic adenomas were reported in 42.8%, followed by prolactin adenomas in 33.3% and somatotropic adenomas in 14.3% of cases. A non-secreting pituitary adenoma was reported in only one patient, i.e. 4.7% of our series. The evaluation of the anteropituitary insufficiency showed a gonadotropic insufficiency in 28% of the cases, 30% of which was secondary to hyperprolactinemia, followed by thyroid and corticotropic insufficiency in 14.3% of the cases respectively and somatotropic insufficiency in one patient.57% of the patients benefited from a surgical treatment with the necessity of a surgical revision in only one patient presenting with a non-secreting pituitary macroadenoma invading the optic chiasma.

Discussion-Conclusion
Pituitary adenomas of the young adult is an uncommon clinical entity of pituitary adenomas. The results of our study are consistent with those of the literature which show a lower prevalence of adenomas in young adults. Mostly, they present as secreting adenomas such as the results found in our series where the most prevalent type was corticotropic adenoma.

Evolution from recurrent cushing's disease to pituitary carcinoma

Miruna Anisia[1], Teodora Dumitru[1], Alexandra Stoica[1, 2], Maria Christina Ungureanu[1, 2], Cristina Preda[1,2], Daniel Rotariu[2, 3] & Letitia Leustean[1,2]
[1]'Sf.Spiridon' Clinical Emergency Hospital, Endocrinology, Iasi, Romania; [2]"Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Romania; [3]"Prof. Dr. Nicolae Oblu" Emergency Clinical Hospital, Neurosurgery, Iasi, Romania

Introduction
ACTH-secreting pituitary adenomas occasionally present as aggressive pituitary tumors (APT), with invasion of surrounding structures, rapid growth, resistance to conventional therapies and multiple recurrences. In rare cases they can progress to pituitary carcinomas (PC) in several years, diagnosis being made upon the documentation of systemic or central nervous system (CNS) metastatic spread. Among pituitary carcinomas, the most common malignant subtypes are lactotroph and corticotroph carcinomas.
Case report
We present the case of a 66 years-old female diagnosed with an invasive ACTH-secreting pituitary macroadenoma in 2015. She underwent transsphenoidal surgery followed by Gamma-knife radiation due to recurrent disease. Pasireotide was initiated but discontinued after only two months due to serious side effects, including corticotroph insufficiency. After 2 years of remission, hypercortisolism reappeared but in the absence of approachable residual tumor Cabergoline treatment was initiated, to which she responded well, developing adrenal insufficiency. One year later, considering the increase in tumor size, the second course of Gamma-knife radiosurgery was performed with no efficacy, and in 2020 she underwent transcranial adenomectomy. The immunohistochemistry revealed high agressiveness of the tumor - Ki67 5% and mitotic index was greater than 10 mitoses per 10HPF. The last MRI showed a 9 mm tumor at the vermis and the immunohistopathology report described a pituitary carcinoma metastasis (ACTH intense positive, p53 expression in 40% of the cells and Ki67 5%). External radiotherapy was performed; Temozolomide therapy was contraindicated due to poor clinical condition of the patient. She ultimately died just 2 months following the diagnosis of carcinoma.
Conclusion
The evolution of APTs may have periods of radiological and hormonal quiescence. Morbidity and mortality are increased, even in the absence of progression to PC, especially in functioning corticotroph APTs, where they exacerbate in relation to cortisol excess. So far, no pathological marker has been shown yet to reliably predict pituitary tumor behavior. Early diagnosis would offer the chance for prompt intensive treatment in an attempt to reduce overall morbidity and possible progression to carcinomas.

Bronchial carcinoma as debut in MEN-1 Syndrome

Alicia Justel Enriquez, Carolina Knott Torcal, Sara Jimé nez Blanco, Victor Navas Moreno & Mónica Marazuela
Universitary Hospital La Princesa, Endocrinology and Nutrition Department, Madrid, Spain

Background
Neuroendocrine tumors present in the MEN-1 syndrome are usually located in pancreatic islets and more than 10% appear de novo, affecting any age group. The debut of a carcinoid tumor is rare, with a prevalence of 2% of bronchial carcinoid tumors.
Materials and methods
We present the case of a 49-year-old woman referred from the Oncology clinic for the assessment of thyroid incidentalomas found in a follow-up CT scan of multifocal bronchial carcinoid tumor (typical carcinoid tumorlet), operated in 2015 with persistently increased chromogranin A (CrgA). Pathology results showed a non-infiltrating, low-grade neuroendocrine neoplasm (carcinoid tumor), within the surgical margins, and < 2 mitoses/mm^2. (2 in the mediastinal face of the left lobe and another in the right lobe)
Results
Thyroid ultrasound showed a multinodular goiter with a dominant 28-mm nodule classified as Bethesda category II. Laboratory tests revealed a pituitary profile, thyroid hormones, catecholamines, 5-HIA, and CEA within normal ranges, elevated ChromograninA levels and undetectable calcitonin. Increased levels of calcium and phosphorus are displayed in table 1. Octeoscan, bone densitometry and calciuria were requested, which didn't show any abnormalities. Parathyroid scintigraphy was performed due to elevated calcaemia >1 gr/dl, with possible adenoma in the upper pole of the right thyroid lobe. Patient was referred for surgery in February 2020, although it was delayed due to the pandemic until June 2021. A total thyroidectomy and a parathyroidectomy were performed, and a parathyroid adenoma was found. Afterwards, the patient temporarily presented phosphocalcic metabolism values within a normal range, followed by a subsequent increase (Table 1). MEN-1 genetic study was requested. A pathogenic variant in the MEN-1 sequence was detected: c.1252G$>$A, *P* (Asp418Asn) in Heterozygosis (rs104894264).
Discussion
Following the suspicion of MEN-1, even in patients with an atypical condition, a genetic study should be requested early, prior to the indication of parathyroidectomy. This is due to the possible implication in the surgical technique, given the great recurrence of hyperparathyroidism in these cases and to avoid the appearance of early complications derived from it.

patient with multiple comorbidities, including chronic leg ulcers, which are related to increased morbidity and health costs.
Case report
In October 2019, a 67-year-old patient presented with intense headache, left temporal visual impairment and pituitary macroadenoma (3.4 cm). He was diagnosed with Cushing's disease (serum cortisol = 17.55 mcg/dl after 2 mg/day x48h Dexamethasone, ACTH = 197 pg/ml), optic chiasm syndrome and thyrotropin and gonadotropin insufficiency. The patient had significant comorbidities: secondary hypertension and diabetes, episodes of tachyarrhythmia and femoral artery stenosis. After transsphenoidal surgery, despite 3 months remission of hypercortisolism (basal serum cortisol = 0.14 mcg/dl), a 2.1 cm remnant progressive tumor along with biochimical hypercortisolism-serum cortisol = 14 mg/dl after 1 mg Dexamethasone, led to a 6 months dopamine agonist treatment. In 2020, progressive chronic ulceration appeared in the lower limbs. Despite the January 2021 second transsphenoidal operation, in June 2021, the hypercortisolism worsened: severe hypokaliemia (2.5 mmol/l despite potassium replacement), uncontrolled diabetes (HbA1c = 11%), BP = 220 mmHg despite triple therapy, so a steroidogenesis inhibitor and glucocorticoid receptor blocker therapy were initiated. Afterwards, right opthalmoplegia and severe headaches appeared. Pituitary apoplexy and stroke were ruled out by MRI showing a tumoral remnant, invasive in both cavernous sinuses. The treatment was continued only with Metyrapone 500 mg/day. In August 2021, the patient developed adrenal insufficiency while using Metyrapone (BP = 110/70 mmHg, serum glucose = 69 mg/dl, serum cortisol = 1.57 mcg/dl), so Prednisone 5 mg/day was prescribed, thus receiving block and replace regimen. The patient was treated with gamma knife radiosurgery in September 2021. Afterwards, the infected leg ulcers with Grame negative bacteriae forced him to become wheelchair-bound, requiring repeated hospital admissions, with two episodes of acute renal injury. In January 2022, laboratory tests found persistent hypercortisolism (serum cortisol = 20 mcg/ml after 1 mg Dexamethasone without any treatment). Block and replace regimen was restarted. The cardiovascular examination established the need for bilateral thigh amputation, for now, only one having being performed.
Conclusions
This case highlights how the multiple and aggressive complications of Cushing's disease can significantly affect the quality of a patient's life. The chronic leg ulcers, the risks of hospitalisation and the drug toxicity eventually led to amputation. Furthermore, achieving eucortisolism is a constant challenge in the management of recurrent Cushing's disease. Consequently, rigorous and repeated long-term follow-up evaluations of this condition are mandatory.

Growth hormone leading to faster recovery in pure motor Guillain-Barre syndrome: report of the first off-label use in one patient

Felix Amereller[1], Schopohl Jochen[1], Störmann Sylvère[1], Bidlingmaier Martin[1], Rieckmann Peter[2] & Gulde Philipp[2]
[1]LMU Klinikum, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Medical Park Loipl, Center for clinical Neuroplasticity, Bischofswiesen, Germany

Background
Although the prognosis inGuillain-Barré syndrome (GBS) is generally good, the protracted and sometimes incomplete recovery is a heavy burden for patients. Animal studies suggest that treatment with growth hormone (GH) could stimulate myelin repair and thus accelerate functional recovery in acute polyneuropathy. We report on the first use of GH in GBS.
Objective
To monitor safety and tolerability as well as to evaluate the effect of off-label GH therapy during recovery from GBS in one patient.
Patient and methods
A 28-year old male with flaccid tetraparesis caused by pure motor GBS was treated with GH (1 mg/day) for 10 weeks. Muscle strength was measured regularly before, during and after the treatment (total time span 330 d). Strength gain was used as the main parameter of efficacy. A polynomial regression was calculated for strength measurements prior to treatment, and a second one for strength measurements during GH treatment. Using these functions, alterations in strength gain were examined. α was set to 0.05. Effect-sizes are given in R^2 and Glass' Δ. Pearson cross-correlation was computed for IGF-1 and relative strength gains.
Results
No side effects of GH treatment were observed. Serum IGF-1 increased from 177 ng/ml at baseline (50^{th} percentile of age- and sex-adjusted reference interval) to a mean value of 342 ng/ml during GH treatment ($>97.5^{th}$ percentile). Prior to GH administration, body mass ($R^2 = 0.85$, $P < 0.01$) and relative strength ($R^2 = 0.99$, $P < 0.01$) were significantly associated with time, representing the natural course of recovery. During GH treatment, the slope of strength gain was increased ($R^2 = 0.95$, $P = 0.025$). There were three significant alterations of strength gains: both inpatient stays at a neurorehabilitation facility and the GH application (Glass' $\Delta_{Rehab1} = -1.50$, $P < 0.01$, Glass' $\Delta_{Rehab2} = 0.57$, $P < 0.04$, Glass' $\Delta_{GH} = 1.08$, $P < 0.01$). Alterations of strength gain correlated with IGF-1 serum levels ($R^2 = 0.36$, $P = 0.09$). Body mass gain was not increased during GH treatment.
Conclusion
In this single case, GH treatment seemingly led to an acceleration of strength recovery in GBS. Controlled studies should be discussed in order to establish GH as a therapeutic approach in GBS recovery.

Pituitary Hyperplasia secondary to Severe Primary Hypothyroidism

Harriet Esdaile, Majid Alameri, Abdulla Alnuaimi, Niamh Martin & Karim Meeran
Charing Cross Hospital, Department of Diabetes and Endocrinology, London, United Kingdom

Introduction
Thyrotroph pituitary hyperplasia in context of severe primary hypothyroidism is rare and usually occurs due to loss of thyroxine feedback inhibition and overproduction of thyrotropin-releasing hormone, leading to pituitary gland enlargement. Pituitary hyperplasia caused by primary hypothyroidism responds well to thyroid hormone replacement therapy and rarely requires surgical intervention.
Case presentation
A 42-year-old female with background history of type 2 diabetes, hypothyroidism, transient ischaemic attack (TIA) glaucoma and epilepsy presented initially with light-headedness. Systemic examination was unremarkable. Biochemical assessment revealed severe primary hypothyroidism with TSH of 442 milliunit/l (NR 0.30- 4.20 milliunit/l), free T4 5.2 pmol/l (NR 9-23 pmol/l) and mild hyperprolactinaemia. Magnetic resonance imaging (MRI) revealed a large pituitary macroadenoma with extension into the suprasellar compartment, without compression of the optic chiasm. The patient required escalating doses of levothyroxine, maximally 300 mg daily due to variable compliance (levothyroxine absorption test normal). Imaging was repeated when the patient's TSH had fallen to 0.37 milliunit/l. The repeat MRI pituitary showed marked reduction in the size of the pituitary enlargement, making the diagnosis of thyrotroph pituitary hyperplasia.
Conclusion
Pituitary hyperplasia caused by primary hypothyroidism usually has a good response to thyroid hormone replacement therapy. Surgical intervention is not usually required.

An aggressive macroprolactinoma in young boy about a case.

Charlene Ludwine Bifoume Ndong, Fatima Zahra El Jaafari, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Chu Mohammed VI, Marrakech, Marrakech, Morocco

Introduction
Pituitary adenomas are a rare condition in children and young people. The prolactinoma represents the most frequent of them. We report a case of an atypically evolution of aggressive macroprolactinoma in young patient.
Case
It's about a boy of 14 years old with previous history of headache from 5 years without visual disturbance. He was admitted for intracranial hypertension syndrome. In clinical examination no dysmorphic syndrome, a growth retardation

and a bilateral gynecomastia. MRI showed a macroadenoma with lateral extension to the cavernous sinuses with envelopment of carotid arteries. The hormonal test showed a hyperprolactinemia of 470 ng/ml with a secondary gonadal, corticotropic and thyrotropic deficiency. Partial transsphenoidal adenomectomy was performed and the histological assessment confirmed a macroprolactinoma with upper Ki67 at 7%. Cabergoline was started at 1 mg/week to 2 mg/week. The evolution done by the progressive normalization of blood prolactin and reduction of the size of the residual tumor.

Discussion

Pituitary adenomas in young people are frequently hormonally active. These patients typically presented with endocrine symptoms related to their adenoma type, in our case he presented gynecomastia and tumoral syndrome. Prolactinoma is a more common one.

The radiological caracteristics and the Hight Ki67 proliferation index gave an idea of aggressive tumor. Taking in account the young age it can be part of AIP mutation or another type of genetic predisposition syndrome. These two conditions tend to predict recurrence and resistance to conventional therapy. The good evolution by dopaminergic agonist was atypical. Long-term follow-up will make it possible to report on the recurrence or otherwise of the process.

Conclusion

The management of pituitary adenoma in young patients must take in account the progress on histopathology and molecular fields. The specific medical treatment of prolactinoma may be try as part of complex management.

FSH- secreting pituitary microadenoma and ovarian hyperstimulation

Marian Andrei[1], Luminita Nicoleta Cima[1, 2], Mihaela Tarna[1], Marina Iliescu[1] & Fica Simona[1,2]

[1]Elias University Emergency Hospital, Endocrinology Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction

The prevalence of functioning gonadotropinoma is difficult to assess since most of reports are case reports. Gonadotropinomas rarely lead to a noticeable clinical syndrome. They usually produce symptoms associated with mass effect such as headaches, visual field impairment and hormonal deficiencies.

Case report

We present the case of a 38 years old women diagnosed in 2017 with microprolactinoma. She had elevated prolactin level (108 ng/ml) and a small pituitary adenoma with 9/8 mm in diameter. She was treated with dopamine agonist for 3 weeks after the diagnosis, treatment stopped afterwards due to side effects. In follow-up examinations prolactin level normalized with no treatment, IRM exam revealed 2 pituitary microadenomas (4/3/6 mm and 3.7/2.5/3.5 mm respectively) and she developed bilateral ovarian cysts. She underwent surgical intervention and the cysts were evacuated, but after 1 month, at next follow-up the cysts reappeared. In our department she presented with headache, amenorrhea and recurrent bilateral ovarian cysts. Serum prolactin was normal but she had a high serum estradiol level (963.2 pg/ml) with a FSH and LH of 2.01 mUI/ml and 2.36 mUI/ml respectively. This was enough to raise the suspicion of a functional gonadotropinoma, unfortunately we could not measure serum gonadotropin hormone alpha-subunit to confirm the diagnosis.

Conclusion

The patient initially presented with a prolactin producing pituitary microadenoma and later developed a second pituitary adenoma. The elevated estradiol level and recurrent bilateral ovarian cysts raised the suspicion of a functional gonadotropinoma. The patient needs further evaluation to confirm the diagnosis.

Clinical and laboratory features and management of pituitary apoplexy: Case series

Özge Özer, Medine Nur Kebapci, Aysen Akalın, Belgin Efe & Goknur Yorulmaz

Eskisehir Osmangazi University, Department of Endocrinology and Metabolism, Eskisehir, Turkey

Introduction

Pituitary apoplexy (PA) is a clinical emergency resulting from acute ischemia or bleeding of the pituitary gland. Complaints of patients are usuallay headache and vision problems. We tried to discuss the reasons for presentation, pituitary imaging and hormones of patients.

Patients and Methods

10 patients (5 men and 5 women), median age 53 years at diagnosis were retrospectively reviewed. FSH, LH, estradiol/testosterone, GH, IGF1, TSH, FT4, cortisol, ACTH, PRL were measured. Pituitary MRI were performed.

Results

When we look at the reasons for the patients' admission; headache, nausea and vision problems in 4 patients; weakness, fatigue, nausea in 3 patients; confusion in 1 patient; abdominal pain in 1 patient;polyuria, polydipsia, weight loss in 1 patient. Only one patient had a previous history of pituitary adenoma. Panhypopituitarism was present in all patients. One patient had diabetes insipidus too. Macrodenoma was detected in 6 patients (median tumor diameter 31.8 mm). 4 patients were referred to the operation. The pathology result of all of them was seen as nonfunctioning pituitary adenoma(NFA). In one other patient, the mass involved the pituitary and hypothalamus. The operation was not considered due to the general condition of that patient. This patient died in the follow-up. Another operated patient died despite post-operative replacement therapy. The other patient with PA had been operated for NFA about a month ago. The management of this patient was performed with medical therapy. One of the 4 patients with pituitary apoplexy detected on MRI presented at the 24th week of pregnancy with severe headache that did not go away with analgesics. Her treatment was with medical therapy. No complications were observed in the follow-up and she was discharged. Another patient developed PA while receiving radiotherapy for acromegaly. The other one of these 4 patients had complaint with fatigue. The other patient developed PA after coronary bypass procedure. It was thought that this might cause lost a lot of blood during the bypass procedure. Empty sella developed in the follow-up of these patients. Management of these patients was performed with hormone replacement therapies.

Conclusion

Although PA often presents with headache, there are also different forms of presentation. Patients should always be evaluated from this point of view. PA is a condition that can develop very quickly. It can have very serious consequences. In our case series, it was observed that two patients died. Treatment consists of sellar decompression with steroid replacement and, in severe cases, transsphenoidal surgery

A case of pituitary hyperplasia in a patient with neurofibromatosis type 1.

Faten Cherchir, Ibtissem Oueslati, Meriem Yazidi & Melika Chihaoui

La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction

Neurofibromatosis type 1 (NF1) is an autosomal dominant disorder with diverse manifestations. Patients with NF1 are particularly prone to developing tumors of the central nervous system (CNS) and endocrine disorders. Herein we report a case of pituitary hyperplasia in a woman with NF1.

Observation
A 55-year-old woman was referred to our department for the exploration of recurrent hypoglycemia. Her past medical history included NF1, asthma treated with inhaled glucocorticoids, and ischemic stroke. On physical examination she had a body weight of 46 Kg, a body height of 1m40, corresponding to a body mass index of 23.5 kg/m^2 blood pressure of 120/80 mmHg, a heart rate of 90 bpm, a normal thyroid gland, multiple cutaneous neurofibromas, mainly in the chest and abdomen, café-au-lait spots, and thoracic scoliosis. No dysmorphic syndrome was observed. Biological investigations revealed a morning cortisol level of 11 ng/ml (nr: 40-200), an ACTH level of 4.9 pg/ml (nr: 10-48), a TSH level of 0.68 mUI/l, a FT4 level of 1.13 ng/dl, a prolactin level of 25 ng/ml, a FSH level of 68.7U/l, and a LH level of 18.5 U/l. The diagnosis of isolated corticotroph deficiency was established. A steroid-induced adrenal insufficiency was evoked. The first pituitary magnetic resonance imaging (MRI) scan showed an enlarged sella measuring 7.8 mm in height with superior convexity and homogeneous contrast enhancement. No focal lesion was detected. The patient was treated with hydrocortisone. A follow-up pituitary MRI scan performed at seven months showed the same aspect.
Conclusion
NF1 is a tumor predisposition syndrome, frequently associated with CNS tumors, especially optic gliomas. Few cases of pituitary adenomas have also been reported. To the best of our knowledge, this is the first report of pituitary hyperplasia with no evidence of prolactin and GH hypersecretion diagnosed in the context of NF1. The mechanisms inducing pituitary abnormalities remain misunderstood.

Assessment of the thyroid status in acromegaly patients
Bahar Gokce Sezgin Yuksel[1], Goknur Yorulmaz[2], Ahmet Toygar Kalkan[2], Medine Nur Kebapci[2], Aysen Akalin[2] & Belgin Efe[2]
[1]Eskişehir Osmangazi University, Internal Medicine, Eskisehir, Turkey; [2]Eskişehir Osmangazi University, Endocrinology, Eskisehir, Turkey

Acromegaly is a rare disease associated with hypersecretion of growth hormone due to adenoma of somatotroph cells in the pituitary gland, with elevated morbidity and mortality. Acromegaly and thyroid diseases show high co-occurrence. In our study; we aimed to determine the relationship between disease activity at the time of admission and after treatment with the presence of goiter, presence of nodules, and possible accompanying thyroid malignancy in 119 patients with acromegaly that we followed in our clinic. Material Method: Patients age, gender, body mass index, age at diagnosis, pituitary adenoma size, thyroid gland volume, thyroid nodule dimensions, GH (Growth hormone), IGF-1 (Insulin-like growth factor-1) values, thyroid function tests, fasting glucose, insulin, HbA1c, thyroid autoantibody levels, frequency of thyroid malignancy, whether or not pituitary insufficiency developed after pituitary surgery and medical treatments were recorded.
Results
58% ($n=69$) of the patients had at least one thyroid nodule. MNG (Multinodular goiter) was present in 47.9% ($n=57$) of the patients. Patients dominant nodule mean size with thyroid ultrasonography was 13.6 ± 9.8 mm. In the follow-up of the patients, thyroid malignancy was detected in 4.2% ($n=5$) of the patients. Histopathology was compatible with papillary thyroid carcinoma in all of these patients. A statistically significant correlation was observed between last admission IGF-1 levels and insulin resistance ($P=0.019$). In addition, a positive correlation was found between HbA1c levels and thyroid nodule size in our study ($P=0.025$). It was observed that 26.1% of the operated patients developed hypopituitarism. Postoperatively, 59.1% of the patients were treated with a long-acting somatostatin analog, 27.3% with cabergoline, and only 1 patient with pegvisomant.
Conclusion
Nodular thyroid disease is a common condition in patients with acromegaly. For this reason, clinicians should pay attention to the thyroid examination in the physical examination of patients with acromegaly.

Digestive complications of acromegaly : about 40 cases
Ajili Rihab[1], Salah Ameni[2], Hasni Yosra[2], Zantour Baha[1], Sfar Habib[1] & Ach Koussay[2]
[1]University Hospital Tahar Sfar Mahdia, Endocrinology, Mahdia, Tunisia; [2]University Hospital Farhat Hached Sousse, Endocrinology, Sousse, Tunisia

Introduction
Acromegaly is a rare hormonal condition that results from an excess amount of growth hormone (GH) in the body. A variety of complications have been reported in patients with acromegaly including cardiovascular diseases, diabetes mellitus or respiratory disorders. In addition, Acromegaly is associated with gastrointestinal complications. The aim of this study was to evaluate gastrointestinal complications and their impact on the quality of life among patients suffered from acromegaly.
Methods
We conducted a cross-sectional study including patients admitted for acromegaly in the endocrinology departments of Sousse and Mahdia (Tunisia), over a period of 20 years. The QOL was assessed with ACROQOL questionnaire.
Results
A total of 40 patients were included with a mean age of 38.9 years [13-77]. The sex ratio (M/F) was 0.74. The mean IGF1 level was 937 ng/ml [367-1700]. Anterior pituitary insufficiency was present in 32.5% of cases. The most common functional gastrointestinal symptom was constipation (32%). Among our patients, abdominal ultrasound performed in 20 patients showed splenomegaly and hepatomegaly in 2 cases each. Colonoscopy realized in 9 cases showed dolichocolon in 4 cases and colonic polyps in 2 cases. In our population, acromegaly complicated by dolico-colon was associated with impaired QOL, especially for socio-relational life ($P=0.04$).
Discussion and conclusion
Upper and lower functional gastrointestinal tract disorders are significantly more prevalent in patients with acromegaly. Gastrointestinal complications make the QOL altered. Furthermore, poorer QOL may in part be attributable to the increased prevalence of abdominal symptoms.

Short-term and long-term surgical remission of acromegaly in a tertiary medical center
Alexander Lutsenko, Zhanna Belaya, Elena Przhiyalkovskaya, Liudmila Rozhinskaya, Andrey Grigoriev, Vilen Azizyan & Galina Melnichenko
Endocrinology Research Centre, Moscow, Russian Federation

Background
Surgical outcomes in patients with acromegaly are highly dependent on a surgeon's level of expertise, as the majority of patients present with macroadenomas at diagnosis.
Aim
To assess remission rates in patients with acromegaly admitted to a tertiary medical center.
Materials and methods
We included patients admitted to the neuroendocrinology and bone disease department with no previous radiation therapy or current medical therapy with SSA or pegvisomant. Suppression of GH levels less than 1.0 ng/ml was a criterion for short-term remission. Normalization of IGF-1 levels according to an age-specific reference range was a long-term remission criterion.
Results
44 patients were included in the study: gender (32.8% m, 68.2% f), median age 47.0 [34.0;55.0], IGF-1 744.75 ng/ml [548.83;889.85], GH 9.5 ng/ml [4.94;17.07], tumor volume 832 mm3 [419,25;2532,38]. Microadenomas were identified in 8 patients (18.2%), 36 patients had macroadenomas at diagnosis (81.8%). Early postoperative remission was achieved in 35 patients (79.5%). For microadenomas the remission rate was 87.5% ($n=7$) and for macroadenomas it was 77.7% ($n=28$). Surprisingly, we did not observe differences between patients with and without early remission in age, tumor volume, histological variants and SSTR2, SSTR5 expression – this could be explained by the small sample size. Patients who achieved short-term remission had higher IGF-1 and basal GH levels: IGF-1 935,60 ng/ml [649.60;1186.00] vs 737.60 ng/ml [532.10;876.20], $P=0.047$, GH 36.40 ng/ml [9.61;63.30] vs 8.90 ng/ml [3.74;15.20]. Patients with no remission after surgery were prescribed with SSA. All patients were followed-up, median 19.0 months [12.5;29.0]. Long-term remission was achieved in 61.4% (27 patients), 9

patients had no remission (20.5%), 2 patients had recurrence (4.5%), 6 patients were lost to follow-up (13.6%). In line with short-term remission, patients with long-term remission had lower basal GH 8,9 ng/ml [3,76;11,9] vs 28,0 ng/ml [6,75;47,2], $P=0.006$ and IGF-1 674,80 ng/ml [482,5;876,2] vs 771,0 ng/ml [649,6;992,0], $P=0.030$. We assessed the predictive value of basal GH for long-term remission: AUC 0.811 (95%CI:0.649; 0.973). A cut-off value of 15.55 ng/ml yielded the following results: sensitivity 70.0% (34.8%;93.3%) specificity 85.7% (67.3%;96.0%), accuracy 81.6% (65.7%;92.3%), positive predictive value 63.6% (39.3%;82.5%), negative predictive value 88.9% (75.4%;95.4%). This model demonstrates poor PPV, however, good NPV shows the potential predictive use.
Conclusion
Our study demonstrates short-term and long-term remission rates comparable with literature-reported rates for experienced pituitary centers. Basal GH shows potential for prediction of long-term remission of acromegaly in the Russian population, however cohorts should be substantially increased for more accurate results.

Decreased quality of life in adult patients with sheehan syndrome

Ameni Salah, Amel Maaroufi, Rihab Ajili, Ghada Saad, Yosra Hasni & Koussay Ach
University Hospital Center Farhat Hached, Endocrinology Department, Sousse, Tunisia

Introduction
Sheehan Syndrome (SS) is the oldest known cause of non-tumor acquired anterior pituitary insufficiency in women. The incidence of SS would probably have decreased in recent decades in developed countries thanks to the development of obstetric care. However, it still remains a public health problem in developing countries. In addition, it constitutes a chronic disabling pathology and is strongly linked to an alteration of the quality of life. In this study we aimed to evaluate the impact on quality of life of SS.
Patients and methods
This is a descriptive cross-sectional study. It was carried out in the Endocrinology department of the University Hospital Farhat Hached, Sousse, Tunisia, over a period of nine months, from July 2019 to March 2020. The assessment of quality of life was based on the specific questionnaire "Quality of Life Assessment of Growth Hormone Deficiency in Adults (QoL-AGHDA)". It is composed of 25 items. The answer choice of the 25 "yes/no" items is scored 1/0. The total score is calculated as the sum of the item scores, ranging from 0 to 25, with a higher score indicating a lower quality of life.
Results
Sixty five patients were included to the study. The mean age at diagnosis of SS was 48.2 $\pm$ 12.4 years. Thyrotropic and corticotropic insufficiency were present in 86.2% of our patients, followed by gonadotropic and lactotroph insufficiency in 72.3% and 38.5% of patients, respectively. Somatotropic insufficiency was explored by a dynamic test in only 8 patients, concluding with somatotropic deficiency in 10.8% of cases. Quality of life was assessed in 15 patients, with a mean QoL-AGHDA quality of life questionnaire score of 12.8 $\pm$ 5.5. Eight patients had a total score of the QoL-AGHDA questionnaire greater than or equal to 11. Seven patients, including three with a total QoL-AGHDA quality of life score of more than 18, were followed for an anxiety-depressive disorder. A 66-year-old patient presented cognitive disorders such as memory and concentration disorders after 26 years of evolution of SS. We did not note any significant correlation between the quality of life score and the SS dependent factors (duration of the SS, the existence or not of corticotropic or gonadotropic insufficiency, the dose of hydrocortisone...).
Discussion-Conclusion
SS is a chronic disease strongly associated with impaired quality of life, mainly due to GH deficiency and glucocorticoid overdose.

Predictive factors of biological remission in patients with prolactinoma treated with dopamine agonists

Mouna Elleuch, Hamdi Frikha, Loukil Fatma, Dhoha Ben Salah, Matiem Souissi, Fatma Mnif, Mouna Mnif, Nadia Charfi, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction and aim
Dopamine agonists (DA) are prescribed as first-line treatment for prolactinomas and are generally effective and well tolerated. However, the degree and quickness of therapeutic response is variable among patients. The aim of this work is to study the predictive factors of biological remission in patients with prolactinoma treated with DA.
Methods
A single-center, retrospective and analytical study of patients with prolactinoma followed in the endocrinology department of Hedi Chaker University Hospital of Sfax, Tunisia between 2000 and 2020. Biological remission was defined as prolactinemia <25 ng/ml.
Results
We enrolled 69 patients. Patients were predominantly female (69%), aged 38.1 $\pm$ 14.5 years at diagnosis. One third of patients were obese. Mean initial prolactinemia was 2790.4 $\pm$10780 ng/ml. Adenomas were classified as follows: 24 microprolactinomas, 29 macroprolacinomas and 16 giant prolactinomas. Bromocriptine was prescribed in 46 cases while the remaining were treated with cabergoline. Biological remission was obtained in 24 patients at 6 months of treatment (34.8%) and reached 65.2% at 12 months. Univariate analysis shoewed that the use of cabergoline was significantly associated with remission at 6 months and 12 months ($P<0.001$). The effect of age reached statistical significance at 12 months ($P=0.05$). Using multivariate analysis, factors associated with remission at 6 months were cabergoline use only ($P=0.04$, OR$=6$) while those that significantly influenced remission at 12 months were cabergoline use ($P=0.005$, OR$=11$) and tumor size at diagnosis ($P=0.028$, OR$=1.2$, IC[1.02;1.35]). In this series sex and BMI were not significant markers of remission both in univariate and multivariate models.
Conclusion
Cabergoline has proven to be a safe and effective treatment for prolactinomas. Cost and affordability remain major barriers in developing countries.

Challenging management of giant prolactinomas in men: from efficient small dose of cabergoline to SSA, neurosurgery and Temozolomide

Aleksandra Gilis-Januszewska, Anna Bogusławska, Magdalena Godlewska, Łukasz Kluczyński & Alicja Hubalewska-Dydejczyk
Chair and Department of Endocrinology, Jagiellonian University, Medical College, Cracow, Poland

Giant prolactinomas are very rare and constitute 2-3% of all lactotroph PitNETs with male preponderance. We present a case series of five male patients with giant prolactinomas with various clinical presentation.
Case 1
A 66-year-old male hospitalized due to left peripheral facial palsy. In computer tomography (CT) pituitary mass (41 x 43 x 64 mm) invading cavernous/sphenoid sinuses/carotid arteries/optic chiasm was visualized. Bitemporal hemianopia/-headaches/decreased libido were observed. Prolactin level was 22083 uIU/ml (N: 86-324 uIU/ml). Cabergoline up to 1 mg/week was implemented. After 3 months, regression of pituitary tumor by 14 mm and normal range prolactin level were observed. Milder headaches and improvement of visual field were reported.
Case 2
A 62-year-old male presented with life-threatening panhypopituitarism/diabetes insipidus at the age of 52. In MRI pituitary tumor 36 x 62 x 35 mm with extrasellar extension/optic chiasm compression/invading third ventricle was found. Prolactin level was 223549 uIU/ml. Despite dopamine agonist treatment (bromocriptine 22.5 mg/day and cabergoline 1.5 mg/week) progression of pituitary tumor/high prolactin level were observed. In 2016 patient did not consent to neurosurgery. Short-acting somatostatin analogues was introduced. In 2019, significant visual filed deterioration was observed- patient consent to craniotomy. Histopathology revealed lactotroph-PitNET with Ki67>3%. After 6 months, tumor progression was noted. Patient was disqualified from radiotherapy. Temozolomide (200 mg/m^2 per 5 days every 28 days) was introduced. After 9 cycles, regression of pituitary tumor was observed and decrease of prolactin level by 2600%.
Case 3
A 56-year-old male was hospitalized due to syncope. In CT pituitary tumor 40 x 30 mm was diagnosed with bitemporal hemianopsia. Prolactin level was 10446 uIU/ml. Cabergoline(1 mg/week) was implemented. After 3 months, regression of pituitary tumor (21 x 26 x 19 mm)/normal prolactin level/improvement of vision were noted.
Case 4

A 23-year-old male presented with severe headaches and visual impairment at the age of 21. In MRI pituitary mass 52 x 52 x 41 mm with extrasellar extension was found. Prolactin level was 21522uIU/ml. Insufficiency of thyroid and gonadal axis was diagnosed. Cabergoline was implemented (4 mg/week) with regression of the tumor (25 x 13 x 23 mm), decrease of prolactin level (8400uIU/ml) and complete remission of headaches. Cabergoline was decreased to 2 mg/week.
Case 5
A 67-year-old male diagnosed with a pituitary tumor (65 x 35 x 40 mm) at the age of 50 years. Due to hyperprolactinemia, cabergoline was implemented (7 mg/week). After few weeks, pituitary apoplexy occurred. Patient underwent emergency neurosurgery. Insufficiency of thyroid, adrenal and gonadal-axis appeared. MRI over next 20 years demonstrated stable residual tumor(22 x 28 x 11 mm). Patient is now treated with 0.25 mg of cabergoline/week. The management of giant prolactionomas in men is challenging. Studies on prognostic factors of the efficient treatment in prolactinomas are needed.

The incidence of hyperprolactinemia in patients with breast cancer.

Zamira Khalimova[1] & Aliya Gumarova[2]
[1]Republican Scpecialized Scientific Medical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan; [2]Republican Scpecialized Scientific Medical Center of Endocrinology Neuroendocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Objectives
To study the relationship between hyperprolactinemia and various forms of breast cancer in women of fertile age.
Methods and materials
The study included 100 breast cancer patients, aged 25 to 43 years (mean age 34.5 $\pm$ 1.4 years). The patients were divided into 2 groups: Group I 33 patients with hyperprolactinemia, which corresponded to 33%. Group II 67 patients with breast cancer without hyperprolactinemia, which corresponded to 67%. Clinical (examination of somatic, endocrine and mammological status), hormonal, immunohistochemical, histological, and instrumental studies (ultrasound of the mammary glands, MRI of the brain with a pituitary gland, mammography) were used in the work. The studies were carried out in patients on outpatient and inpatient treatment.in 3 (9.0%) tubular carcinoma, in 2 (6%) medullary cancer, and in 1 case (3%) colloid and papillary breast cancer. In group II, in 67 patients, the distribution of the corresponding forms of breast cancer occurred in 19.4%, 16.4%, 7.5%, 10.4%, 7.5%, 6%, respectively. And also in 25 patients there were other forms of breast cancer (apocrine cancer, cystic hypersecretory carcinoma, adenoid cystic cancer. In 3 (9.0%) tubularcarcinoma, in 2 (6%) medullarycancer, andin 1 case (3%) colloidandpapillarybreastcancer. In group II, in 67 patients, the distribution of the corresponding forms of breast cancer occurred in 19.4%, 16.4%, 7.5%, 10.4%, 7.5%, 6%, respectively. And also in 25 patients there were other forms of breast cancer (apocrine cancer, cystic hypersecretory carcinoma, adenoid cystic cancer.
Conclusion
1. The association of hyperprolactinemia due to formations of the pituitary gland is the main problem that deserves methods of their diagnosis and management.
2. Hyperprolactinemia may increase the incidence of such forms of breast cancer as ductal and lobular breast cancer *in situ* (63.4% vs 19.4%) and tubular carcinoma (9% vs 7.5%) in patients with breast cancer and normoprolactinemia.

Case report: a challenging gastrinoma in a patient with renal cell carcinoma

Alina Ioana Paduraru[1], Iulia Florentina Burcea[1, 2] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Introduction
Gastrinomas are rare neuroendocrine tumours (NETs) that arise from enterochromaffin-like cells and produce gastrin. Most are discovered in the duodenum and pancreas. The clear cell type of renal cell carcinoma (RCC) is known for the expression of gastrin-releasing peptide receptor (GRP-R) and some studies have shown GRP can stimulate tumor cell proliferation and neoangiogenesis. Therefore, we present a case with metachronous development of renal cell carcinoma and gastrinoma.
Case presentation
A 55-year-old obese, hypertensive female patient with a history of renal cell carcinoma (histopathology: Grawitz tumour grade 2) treated with surgery, radiotherapy and interferon at the age of 36 years old, presents with the suspicion of a neuroendorine tumour. SPECT/CT scan identified a possibly neuroendocrine tumour localised in the ileum and the blood tests revealed a gastrin level of 30 times x upper limit of normal (ULN) and chromogranin A 2.11 times x ULN. All other neuroendocrine markers were in the normal range. Treatment with Octreotide LAR 30 mg/28 days was initiated and gastrin level dropped to 5 x ULN. One year later, another SPECT/CT scan revealed radiotracer accumulation in the gastric antral region and first part of duodenum, associated with increased gastrin level (10 x ULN), which led to the increase of Octreotide LAR to 40 mg/28 days and after 2 months, the gastrin level dropped to 2.4 x ULN. Imaging evaluation showed no metastases. Abdominal surgery was performed, but the primary lesion could not be identified during laparotomy. In the meantime, the patient suffered a severe form of COVID-19 infection with 80% of the lungs being affected. The patient stopped treatment for gastrinoma for almost 2 months and gastrin raised again to 7 x ULN. Morever, the pacient was diagnosed with type 2 diabetes and started treatment with Metformin. Currently, gastrin level is 2.8 x ULN, with mild cholestasis syndrome and normochromic normocytic anemia.
Conclusion
Despite the high gastrin levels, the patient has no metastatatic lesions. One particularity of this case is that even though surgery is thought to be the only curative treatment, the surgical intervention could not find any gastrointestinal tumour. Another particular aspect is the unusual association between RCC and gastrinoma, considering that GRP and its receptor can play an important role in carcinogenesis, this being a future path for novel targeted therapy.
Keywords. gastrinoma, neuroendocrine tumours, carcinoid syndrome, renal cell carcinoma

Hypogonatropic hypogonadism with craniopharyngioma in adults before and after surgery.

Irina Klockova, Ludmila Astafieva, Pavel Kalinin, Maksim Kutin & Aleksandr Konovalov
Burdenko Neurosurgical Institute, Neyroonkologiya, Moscow, Russian Federation

Craniopharyngiomas (CF) - a benign tumor of the embryologic origin. The surgical method of treatment is the basic.
Objective
to estimate incidence of hypogonatropic hypogonadism before and after surgical treatment of CF at different topographical variations, and after the preservation of the pituitary stalk.
Methods
The research involved 79 patients older than 18 years (41 women and 38 men) with a mean age - 40 [17; 69] with a verified diagnosis of CF. All patients were operated, in 12 cases the pituitary stalk was saved. Before and 7 days, 3 and 6 months after the surgery all patients were examined by means of hormonal blood tests (LH, FSH, estradiol, testosterone, TSH, free T4, cortisol, prolactin, IGF-1). By localizing tumor patients were divided into 3 groups: 1 – intra-suprasellar (9), 2 – at location of the pituitary stalk (48), 3 –intra-ventricular (22).
Results
hypogonatropic hypogonadism was confirmed. In group 1 : before the surgery - 9 (100%). 3 patients have subtotal ablation. After the surgery the nature of disturbance has not changed. In group 2: hypogonatropic hypogonadism before the surgery - 38 (80%). In 12 cases the pituitary stalk was saved. After the surgery – 46 (96 %). Two women with saved the pituitary stalk had high levels of gonadotropins, respectively postmenopausal period. In group 3: hypogonatropic hypogonadism – 19 (86%, after the surgery - 17 (90 %). Reproductive function recovered in two patients (one woman has a natural pregnancy).
Conclusion
The high incidence of hypogonatropic hypogonadism is caused by the localization of the CF. Preservation of the pituitary stalk does not lead to restoration of the pituitary-gonadal axis in 83 % of cases. Non-radical ablation of ventricular CF can maintain fertility.

EP731

Antioxidant and protective effect of estradiol in liver functions of aged female rats

Pardeep Kumar & Najma Baquer
Jawaharlal Nehru University, Life Sciences, New Delhi, India

Background
The objective of this study was to observe the changes in activity of antioxidant enzymes, hepatic glucose homeostasis, lipogenic enzymes and lipid metabolism, serum lipid profile and liver function occurring in livers of female rats of 3, 12 and 24 months age groups, and to see whether these changes are restored to 3 months control levels rats after exogenous administration of steroid hormone estrogens (17-β-estradiol, E2).
Methods
The aged rats (12 and 24 months old) ($n=$ 8 for each group) were given subcutaneous injection of 17 beta estradiol (0.1 mg/g body weight) daily for one month. After 30 days of hormone treatment, experimental animals of all the groups were sacrificed and livers were isolated for further study. A detailed study was carried on non-enzymatic glutathione (GSH) and enzymatic antioxidants [superoxide dismutase (SOD), glutathione peroxidase (GPX) and catalase (CAT)], hepatic glucose homeostasis, lipogenic enzymes, lipid metabolism, serum aspartate aminotransferase (GOT), alanine aminotransferase (GPT), alkaline phosphatase (ALP), gamma-glutamyl transferase (GGT), phosphatase alkalin (PAL) as well as bilirubin level.
Results
The results obtained in the present work revealed that normal aging was associated with significant decrease in the activities of antioxidant enzymes, serum expression and an increase in hepatic glucose homeostasis, lipogenic enzymes and lipid profile and GGT, PAL, GOT, GPT, ALP as well as bilirubin level increased significantly in livers of aging female rats. Our data showed that exogenous administration of E2 brought these changes to near normalcy in aging female rats.
Conclusions
The present study showed that E2 treatment reversed the changes to normal levels. E2 treatment may be beneficial in preventing some of the age related changes in the liver by increasing antioxidant defences and decrease oxidative stress. E2 plays important role in the progression of chronic hepatic diseases.

Rare case of cushing with papillary thyroid cancer

Marwa Fathy[1,2], Farouk Hassan[2, 3] & Randa Salam[1,2]
[1]Faculty of Medicine-Cairo University, Internal Medicine-Endocrinology Unit, Cairo, Egypt; [2]Cairo University, Clinical Endocrinology, Faculty of Medicine, Cairo, Egypt; [3]Faculty of Medicine-Cairo University, Interventional Radiology, Cairo, Egypt

Introduction
Papillary thyroid carcinoma is the most common type of thyroid cancer (70-80% of all thyroid cancer). It is a differentiated type of carcinoma, it affects women between 30-60 years old, 3 times more often than males. Clinical outcome in patients with differentiated thyroid carcinoma is often favorable. Glucocorticoids (GC) play major role in the physiologic stress response. However chronic exposure to glucocorticoids as seen in Cushing's disease (CD) has detrimental effects on multiple systems: cardiovascular, metabolic, immune, psychological. CD, caused by a pituitary adrenocorticotropic hormone (ACTH)-secreting tumor, is probably underestimated at 1.2-.2.4 per million per year and it affects mostly women). Association of Cushing's disease and papillary thyroid carcinoma is very rare and it appears that ACTH secretion is insufficient to cause typical cushingoid feature
Case report
36 year old female, known to be hypertensive 4 years ago on BB, diuretics and ACEI. In 3/2018, she underwent thyroidectomy and was pathologically proved to have follicular variant of low grade papillary carcinoma. Thyroidectomy was followed by radioactive iodine ended at 2019 and she is on regular follow up with department of Radiotherapy and Nuclear Medicine, she is maintained on Thyroxine 300 mcg/day. Over the last 4 months, she noticed weight gain especially in upper chest and abdomen. She also noticed swelling of both hands and feet associated with generalized weakness.
Examination
Bp: 110/70, Pulse: 90/min, w: 95 kg, Height: 1.57 m. BMI: 38 kg/m^2. Acanthosis Nigerians, Fat accumulation has a central distribution (face, trunk, abdomen more than extremities).
Investigations
Urinary free cortisol (UFC) was (530.6 µg/24 h, N: 20.9- 292.3µg/24 h), Cortisol (am): 19.6 Mg/dl(6.2- 19.4), Low dose dexamethasone suppression test revealed autonomous hypercortisolemia, suggesting cushing disease. MRI of the pituitary revealed a microadenoma of 5 mm on the left side, IPSS on LF side ACTH 517.5 pg. At this point the patient was diagnosed with CD and referred for trans sphenoidal pituitary surgery that removed the tumor. After operation ACTH <10 pg, BMI droped to 32 kg/m^2, regular cycles she stopped antihypertensive medication
Conclusion
Association between papillary thyroid carcinoma and Cushing's disease is very rare and so far there is no known genetic mutation to link the two neoplastic conditions, and no clear relationship between neoplastic thyroid and hypercortisolemia has been established in the current endocrine literature

EP733

Analysis of the causes and frequency of discrepancies between GH and IGF-1 levels in patients with acromegaly based on the polish register of acromegaly patients

Magdalena Ostrowska, Agnieszka Tomasik, Wojciech Zgliczyński & Piotr Glinicki
Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Introduction
Acromegaly is a rare disease of the pituitary gland. Both GH and IGF-1 levels are of key importance for monitoring of treatment effects in patients with acromegaly. In some patients, divergent results of measurements of these hormones are observed.
Purpose
The purpose of the study was to estimate frequency of GH and IGF-1 inconsistencies in the population of patients with acromegaly included in the Polish Register of Acromegaly Patients, and to investigate whether selected biochemical parameters can predict the possibility of GH/IGF-1 incompatibility.
Material and methods
143 patients with acromegaly were included in the analysis.
- G1 ($n=43$) GH <1 µg/l and IGF-1 within the reference range for sex and age,
- G2 ($n=51$) GH $>$ 1 µg/l and IGF-1 above the reference range for sex and age,
- G3 ($n=15$) GH $>$ 1 µg/ml and IGF-1 within the reference values for sex and age,
- G4 ($n=34$) GH <1 µg/ml and IGF-1 above the reference range.

Results
The discrepancy of results of GH and IGF-1 hormonal tests in the studied population was found in 49 patients (34%). There were no statistical differences between the study groups in terms of age, disease duration, time since surgery, GH and IGF-1 levels at diagnosis, fasting glucose and HBA1C. Based on unidimensional logistic regression models, it was found that the GH/IGF-1 discrepancy was significantly associated with GH level at the time of diagnosis of acromegaly (OR $=$ 0.98 CI95 [0.96; 0.99], $P=$ 0.039) and with creatinine level (OR $=$ 10.94 CI95 [1.75; 82.77], $P=$ 0.014). The multivariate regression model showed that parameters studied: surgery, IGF-1 concentration at diagnosis, and creatinine levels, turned out to be the best combination of factors predicting the possibility of GH/IGF-1 incompatibility. The surgery to remove the pituitary adenoma and increasing concentration of creatinine increased the possibility of discrepancy (OR $=$ 15.45 CI95 [2.24; 358.92], $P=$ 0.023 and OR $=$ 15.71 CI95 [1.87; 160.48], $P=$ 0.014, respectively), while the increase in IGF-1 concentration at diagnosis reduced the possibility of GH/IGF-1 discrepancy (OR $=$ 0.998 CI95 [0.997; 0.999], $P=$ 0.008).
Conclusions
1. On the basis of obtained results, the discrepancy between GH and IGF-1 hormonal determinations among the studied patients was 34%. 2. An increase in IGF-1 concentration at the time of diagnosis decreased the possibility of GH/IGF-

1 discrepancy, while adenoma resection and the observed increase in creatinine level increased the risk of GH/IGF-1 discrepancy.

Metabolic and inflammatory parameters for baseline characterization and treatment outcome of prolactinoma patients

Susanna Hofbauer[1,2], Matthias Ernst[1, 2], Laura Horka[1, 2], Samuel Seidenberg[1, 2], Lucas Regli[2, 3], Carlo Serra[2, 3], Felix Beuschlein[1, 2] & Zoran Erlic[1,2]
[1]University Hospital Zurich, Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland; [2]University of Zurich, Zurich, Switzerland; [3]University Hospital Zurich, Neurosurgery, Clinical Neuroscience Center, Zurich, Switzerland

Background
Prolactinomas (PRL) are pituitary adenomas mainly characterized by hyperprolactinemia. In addition to the endocrine effects of prolactin, metabolic alterations have been described in PRL patients. Changes in inflammatory parameters have recently been identified in pituitary adenoma patients. Since both, metabolic (MM) and inflammatory markers (IM) showed promising results in characterization/prognosis of tumor patients, it is tempting to speculate whether those might be useful also in PRL patients.
Patients, methods, results
In this retrospective analysis of medically treated PRL, 23 patients with microprolactinoma (56% women, mean age 34.5) and 30 patients with macroprolactinoma (37% women, mean age 40.7) were included. No difference between micro- and macroprolactinoma patients were evident regarding age, sex, and rate of obesity, hypertension and prediabetes/diabetes mellitus. At baseline, macroprolactinoma patients presented with higher heart rate (HR) ($P=0.005$) and higher likelihood of thyrotropic- ($P=0.007$) and gonadotropic-insufficiency ($P=0.006$). We found a significant correlation between prolactin and BMI (rs=0.364; $P=0.007$) as well as PRL-size with HbA1c (rs=0.413; $P=0.032$), BMI (rs=0.316; $P=0.021$) and HR (rs=0.284; $P=0.050$). Considering prolactin or PRL-size separately in a multivariate analysis with BMI, HbA1c and HR a significant positive association persisted between prolactin and HbA1c ($P=0.009$), whilst HR and BMI were positively associated with each other and independent from prolactin or PRL-size. HbA1c had also a negative correlation with testosterone (rs=-0.478; $P=0.038$), which was not persistent after including prolactin in the multivariate analysis. No correlation could be identified at baseline between prolactin/PRL-size with the studied IM (Glasgow Prognostic Score, Neutrophil-Platelet-Score, Neutrophile-to-Lymphocyte-Ratio [NLR], Platelet-to-Lymphozyte-Ratio [PLR], Prognostic Nutrition Index, Systemic Immune Inflammation Index) and other studied MM (LDL- and HDL-cholesterol, triglyceride, blood pressure [BP]). An association between NLR and fT4 (rs=0.329; $P=0.038$) as well as LDL (rs=-0.617; $P=0.014$) was identified, which did not persist in a multivariate analysis considering both variables together and PRL-size. A correlation between fT4 and PLR (rs=0.351; $P=0.026$) could not be confirmed in the multivariate analyses with prolactin level and PRL-size, separately. In 47 patients complete follow-up data (median follow-up time 17 months, interval 2–141 months) were available. Cabergoline dosage required to achieve normoprolactinemia correlated with baseline LDL (rs=0.493, $P=0.052$), systolic (rs=0.341; $P=0.024$) and diastolic (rs=0.324; $P=0.032$) BP as well as baseline testosterone (rs=-0.447; $P=0.019$). Tumor shrinkage correlated with LDL at baseline (rs=0.570; $P=0.033$). Only systolic and diastolic BP remained predictive for Cabergoline dosage required to achieve normoprolactinemia in the regression analysis.
Conclusion
Metabolic but not inflammatory markers might be related with initial presentation and outcome in PRL.

Endocrine treatment of anabolic-androgenic steroid induced hypogonadism in males: A pilot study

Hans Christian Bordado Henriksen[1,2], Anders Palmstrøm Jørgensen[3], Astrid Bjørnebekk[4], Sudan Prasad Neupane[4] & Ingrid A. Havnes[5,6]
[1]Anabolic Androgenic Steroid Research Group, Section for Clinical Addiction Research, Division of Mental Health and Addiction, Oslo University Hospital, Oslo, Norway; [2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [3]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital, Oslo, Norway; [4]National Centre for Suicide Research and Prevention, Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [5]Division of Mental Health and Addiction, Oslo University Hospital, Oslo, Norway; [6]Adult Psychiatry Unit, Institute of Clinical Medicine, University of Oslo, Oslo, Norway

Background and aims
Non-prescribed use of anabolic-androgenic steroids (AAS) is associated with a wide range of health risks including AAS-induced hypogonadism (ASIH) caused by negative feedback suppression on the hypothalamic-pituitary-gonadal (HPG) axis. Testicular function might be reduced for months up to years after AAS-cessation, increasing the risk of developing fatigue, decreased libido, erectile dysfunction, infertility, sleep disorder, depression and anxiety. There is no consensus on whether endocrine therapy should be used in the treatment of ASIH. In our study, a group of AAS-dependent men will receive endocrine therapy consisting of clomiphene citrate, a selective oestrogen receptor modulator. According to the theory, clomiphene citrate might stimulate endogenous testosterone production by blocking the negative feedback mechanism on the HPG-axis. The primary aim is to explore whether use of clomiphene citrate is safe and effective for AAS-withdrawal. The secondary aims are to detect health risks during ongoing AAS use and assess whether physical and mental health risks are reversed 12 months after cessation.
Methods
This one-site open off-label longitudinal pilot study at Oslo University Hospital in Norway will include 25-30 AAS-dependent men referred to outpatient addiction treatment with a desire to end AAS use permanently. The intervention group will be given endocrine therapy consisting of clomiphene citrate for 16 weeks including exogenous testosterone replacement for the first four weeks following AAS-cessation to ensure that the testosterone level is within normal range before reaching a HPG response. They will be compared to male participants in an already ongoing study of men who end AAS use temporarily without endocrine treatment. Participants from both studies will self-report withdrawal symptoms and other health measures every 2 weeks for 6 months and have visits at inclusion and after 6 months. The intervention group will be monitored using within-subjects repeated measures design on physical and mental health before, during 16 weeks of intervention, and at follow-up 6 and 12 months after AAS-cessation. Physical health parameters are obtained via clinical examinations, investigation of cardiovascular status, blood and fat tissue sampling, dual-energy x-ray absorptiometry (DXA), testicular ultrasound and semen analysis.
Results
Study inclusion started in December 2021. The study protocol and preliminary results will be presented at the conference.
Conclusion
This pilot is the first intervention study to test safety and efficacy of off-label use of clomiphene citrate among withdrawing AAS-dependent men. If this therapeutic approach works, full-fledged clinical trials need to be conducted.

MRI intensity and pituitary volume predict adult-onset growth hormone deficiency in patients with obesity and overweight: a new potential tool guiding subsequent diagnostic testing

Davide Masi[1], Renata Risi[1], Angela Balena[1], Alessandra Caputi[1], Maria Elena Spoltore[1], Rebecca Rossetti[1], Mikiko Watanabe[1], Rossella Tozzi[2], Elena Gangitano[1], Mariaignazia Curreli[1], Stefania Mariani[1], Andrea Lenzi[1], Lucio Gnessi[1] & Carla Lubrano[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Roma, Italy; [2]Sapienza University of Rome, Department of Molecular Medicine, Roma, Italy

Background
Reduced growth hormone (GH) secretory capacity is common in patients with obesity and metabolic derangements. The prevalence of GH deficiency (GHD) in this population is difficult to establish. Magnetic Resonance Imaging (MRI) pituitary findings may reflect specific endocrine alterations, as for GHD which is associated with lower pituitary height and volume (PV).
Purpose
Our aim was to identify the pituitary morphological alterations predicting GHD in subjects with obesity or overweight.
Methods
We conducted a retrospective evaluation of 152 patients undergoing pituitary-MRI and a dynamic test (GHRH + arginine) for suspected adult-onset GHD admitted to our institution from 2015 to 2022. Clinical history and anthropometric parameters were collected. Mean and standard deviation (SD) of pituitary signal intensity was quantified (Horos, Nimble Co, Annapolis, MD USA). Gray matter signal intensity was used as a normalizer. PV was calculated by adopting the ellipsoid formula.
Results
Of 152 patients, 126 had obesity (BMI: 39 ± 6 Kg/m^2) and 26 were overweight (BMI: 28 ± 1 Kg/m^2). An inverse correlation between BMI and PV was observed ($r = -.2844$, $P < 0.0001$). Of note, after normalization with grey matter intensity, T2-weighted-scan derived pituitary intensity and PV showed an inverse correlation ($r = -.2761$, $P = 0.008$). As far as GH secretory capacity is concerned, we found a direct correlation between the area under the curve of the dynamic test and pituitary volume (PV) ($r = .41488$, $P < 0.0001$). Finally, a receiver operating characteristic curve allowed to identify a PV < 75.8 ml and a pituitary height < 3.7 mm as predictors of GHD with a sensitivity of 86.1% and 72.2% and a specificity of 63.6% and 64.5%, respectively.
Conclusion
Our work demonstrates that patients with obesity exhibit a GH-IGF1 axis impairment associated with a reduced PV. Furthermore, we found an inverse correlation between PV, pituitary intensity and GH secretion capacity. The increase in pituitary intensity may reflect the presence of an inflammatory infiltrate possibly leading to pituitary damage and subsequent shrinkage, although this hypothesis needs to be confirmed with *ad hoc* studies. When subjects suffering from overweight/obesity undergo a head MRI for other reasons, those not reaching the identified cut off values of PV and pituitary coronal height predicting GHD in our cohort, might benefit from undergoing dynamic testing in order to assess for eventual GHD.

Pituitary autoimmunity and hormonal changes in patients with severe obesity

Carla Carbone[1,2], Graziella Botta[2], Paolo Cirillo[3], Miriam Longo[1, 3], Raffaela Carotenuto[1, 3], Daniela Forestiere[1, 3], Salvatore Tolone[4], Ludovico Docimo[4], Maria Ida Maiorino[1, 3], Giuseppe Bellastella[1, 3] & Katherine Esposito[1,3]
[1]University of Campania 'Luigi Vanvitelli', Division of Endocrinology and Metabolic Diseases, Naples, Italy; [2]University of Campania 'Luigi Vanvitelli', Department of Experimental Medicine; [3]University of Campania 'Luigi Vanvitelli', Department of Advanced Medical and Surgical Sciences, Naples, Italy; [4]University of Campania 'Luigi Vanvitelli', Division of General, Mininvasive and Bariatric Surgery, Naples, Italy

Background and aim
Obesity is associated with a dysregulation of the immune system which can result in a predisposition to the development of autoimmune diseases. The aim of this cross-sectional study was to evaluate anti-pituitary antibodies (APA) in severe obese patients, in order to identify a possible role of the immune system in obesity and to correlate these antibodies with pituitary hormone changes found in obese patients.
Matherials and methods
36 obese patients from the Bariatric Surgery Unit and 50 non-obese subjects as control group were recruited. Weight, body mass index, blood pressure, heart rate, glycemic and lipid profile and insulinemia were measured in all subjects participating in the study. Basal levels of pituitary hormones (FSH, LH, TSH, GH, ACTH) and peripheral glands hormones (cortisol, testosterone, estradiol, free T4, free T3, IGF-1) were evaluated in all patients. APA were evaluated by indirect immunofluorescence method on cryostatized sections of the pituitary gland of a young baboon.
Results
10 patients (28%) resulted APA positive while no APA positive subject was found in the control group. Therefore, the obese patients were divided into two groups, based on the presence or absence of APA (APA +, APA-); we compared the clinical characteristics and we found a significant lower cortisol level in obese APA + subjects than in obese APA- subjects ($P = 0.045$). The anti-pituitary antibodies titer was inversely correlated with cortisol and growth hormone (GH) levels.
Conclusion
we found a higher prevalence of APA in obese patients than in control group and this result is in line with studies that suggested a higher risk and prevalence of autoimmune diseases in obese patients.

Visual impairment in the empty sella syndrome

Mnif Fatma, Asma Zargni, Kawthar El Arbi, Faten Haj Kacem Akid, Dhoha Ben Salah, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Diabetology and Endocrinology Department, Sfax, Tunisia

Introduction
Empty sella syndrome (ESS) is a rare condition in which the sella turcica is partially or completely filled with cerebrospinal fluid. It can be primary or secondary. Ophthalmologic involvement is rare in primary empty sella Syndrome. It is described in only 1.6 to 16% of cases.
Patients and methods
We report a retrospective study of 46 cases of ESS collected in the endocrinology department over the period from 1991 to 2020. The clinical and biochemical profile of ESS patients were analyzed.
Results
We included 46 patients, with a mean age of 50.4 years (with extremes from 21 to 81 years), with a female predominance (75%). The average parity was 9.5 children per woman. The circumstances of discovery were dominated by headaches (66.67%). Obesity was noted in 19.45% of cases. The hormonal assessment showed a corticotropic deficiency (53.6%), a thyrotropic deficiency (36.11%), a gonadotropic deficiency (22.8%) and diabetes insipidus in 2 patients. Hyperprolactinemia was noted in 13.88% of cases. Visual impairment was noted in 30.56% of cases (11 patients). two patients had diplopia. A decline in visual acuity was present in 2 cases. Visual blur was described in 7 cases. Hormone deficiency replacement was prescribed. The evolution was marked by the persistence of visual disorders in 8 patients.
Discussion
ESS is a benign pathology provided that antehypophyseal insufficiency is detected. We underline the interest of a systematic ophthalmologic examination in patients with ESS in order to detect visual disorders which can be serious and threaten the visual prognosis.

Giant pituitary adenomas: about 15 cases

Lamiae Zarraa, Soumiya Berrabeh, Imane Assarrar, Siham ROUF & Hanane Latrech
Endocrinology-Diabetology and Nutrition Department CHU MOHAMED VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Oujda, Morocco;

Key Words : Giant – pituitary adenoma

Introduction & Background

Giant pituitary adenomas are uncommon tumors defined by a tumor diameter ≥ 4 cm. Their prevalence estimated at 6-10% of all pituitary adenomas, whose clinical characteristics and prognosis are not well known. The purpose of this work was to evaluate the prevalence as well as the clinical and evolutionary characteristics of giant pituitary adenomas in our series.

Material and methods

Retrospective descriptive study including 15 patients followed-up for giant pituitary adenoma which tumor diameter was greater than or equal to 4 cm. Data were collected from medical records and analyzed by SPSS-V21 software.

Results

Giant pituitary adenomas represent 16.6% of our series of pituitary adenomas ($n=15/90$) with a mean age of 44.8 ± 16.5 years (extremes of age of 22 and 69 years), with a clear male predominance and a sex ratio of 4. The clinical presentation was dominated by a decrease in visual acuity associated with headaches in 73.3% of cases, associated with cranial nerve damage (III, VI) in 20% and pituitary apoplexy in 13.3% followed by acrogigantism in one case. The hypothalamohypophyseal MRI showed a giant pituitary macroadenoma with a mean diameter of 5.34 cm (with extremes of 4 and 8.2 cm) and a mean volume of 47.9 $\pm$45.5 cm 3. Invasion of the cavernous sinus was observed in 46.6% of the cases and reaching the contact of the internal carotid artery in 40% of the cases, with invasion of the chiasma and optic pathways in 93%. It was a pituitary prolactin adenoma in the most of cases (53,3%) cases followed by non functional pituitary adenoma. Twenty-four percent of the patients benefited from transphenoidal surgical treatment with an indication for revision surgery in 46% of cases. 13.4% of the cases benefited from radiotherapy as a complement to pituitary surgery and 60% were put on dopaminergic analogues and 13.3% on somatostatin analogue. The Ki67 of the operated patients was 4% in one patient with somatotropic adenoma, 2% in one case with prolactin adenoma and 1% in 4 cases.

Discussion-Conclusion

Giant pituitary adenomas, although uncommon, represent a challenge in clinical endocrinology because their prognosis is uncertain requiring multidisciplinary management in diagnosis, therapeutic management and long-term follow-up.

The changing features of a corticotroph PITNET: from silent to Cushing's disease - case report

Radu Andrei Emilescu[1], Iulia Florentina Burcea[1, 2], Roxana Ioana Dumitriu[1, 2], Valeria Nicoleta Năstase[1], Gheorghe Vasile Ciubotaru[3], Liga Gabriela Tătăranu[2,3] & Cătalina Poiană[1,2]

[1]C. I. Parhon National Institute of Endocrinology, Department of Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Emergency Hospital Bagdasar-Arseni, III, Bucharest, Romania

Introduction

The spectrum of corticotroph cell pituitary adenomas is very wide, silent corticotroph adenomas (SCAs) being a rare subtype with positive immunohistochemistry for adrenocorticotropic hormone (ACTH), without causing Cushing's disease. SCAs may exhibit a more aggressive behavior, and the changing of the clinical phenotype towards Cushing's disease is described.

Case report

We present the case of a 74 years old, ex-smoker, hypertensive, male patient who was admitted to our clinic after sudden unilateral hearing loss, with no signs of hypercortisolism. Magnetic resonance imaging (MRI) of the pituitary showed a large mass of 14.3/15/12.3 mm. There was no opto-chiasmatic involvement and the hormonal profile revealed normal pituitary function with normal serum cortisol, suppressed after a 2 mg x 2 days dexamethasone suppression test (LDDST). The patient underwent transsphenoidal pituitary surgery. Postoperatively he did not have any pituitary deficiencies. Subsequently, 7 years after surgery, the patient is readmitted to our department, with central obesity, hypertension, dyslipidemia, and low bone mass. The hormonal profile showed an elevated ACTH (148.9 pg/ml), with elevated 8.00 a.m. serum cortisol, unsuppressed after a LDDST (14.74 µg/dl). Brain imaging showed a pituitary tumor of 17.9/18.8 mm with suprasellar extension, associated with bilateral adrenal hyperplasia on abdominal computed tomography (CT). Morphological and retroactive immunohistochemical (IHC) analysis of the pituitary tumor revealed strong positive staining for ACTH and weak immunostaining for TPIT; Ki-67 labelling index had a value of $>3\%$. After neurosurgical evaluation found reintervention to be unfeasible, gamma knife radiosurgery was performed and therapy with dopaminergic agonists was initiated. The morning serum cortisol normalized, but remained unsuppressed after LDDST 2 years after radiosurgery, with ACTH values in regression under cabergoline 4 mg/week.

Conclusion

Bidirectional transformation of the clinical phenotype between Cushing's disease and SCA is described, the time interval varying from 1 to 7 years. The silent phenotype is related to TPIT, the dysfunction of its expression being an early change in differentiation of this tumor type. SCAs are more biologically aggressive tumors than NFAs, therefore, close neuroimaging and clinical follow-up are mandatory. Also, patients with SCAs who present with postoperative residual disease should be considered for early adjuvant radiosurgery or long acting pasireotide.

Growth hormone deficiency due to a rare central nervous system tumor

Simona Gabriela Duta[1], Sebastian Pavel[2], Sergiu Stoica[2] & Simona Fica[1,3]

[1]Elias Emergency University Hospital, Endocrinology Department, Bucureşti, Romania; [2]Monza Metropolitan Hospital, Neurosurgery Department, Bucureşti, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Introduction

Short stature is a common reason for pediatric endocrine evaluation and it can have a variety of causes, including constitutional, genetic short stature, dysmorphic syndromes, chronic illnesses and also endocrine disorders. Growth hormone deficiency accounts for 8% of the cases and it can be isolated or associated with other pituitary hormones deficiencies, congenital or acquired, such as in central nervous system tumors.

Case report

A 15-year-old female patient presented to our department for growth deficit and primary amenorrhea. The mother reports normal psychomotor development and no significant medical history. The clinical examination revealed an underweight patient (percentile under 1%) with short stature (- 3.38 SD) and a prepubertal Tanner stage. A complete hormonal assay showed low GH and IGF-1 levels, with no GH response at the clonidine stimulation test. FSH, LF, estradiol and prolactin levels were also low. Cerebral MRI showed a solid, lobulated suprasellar mass of 2.8/2.7/4 cm, with well-defined outline and microcalcifications, hyperintense T2 signal and hypointense T1 signal, predominantly located in the third ventricle, in close contact with the circle of Willis. Tumoral markers and a lumbar spine punction were recommended to rule out a germ-cell tumor. The patient was referred to a neurosurgeon and underwent surgery with complete resection of the tumor, and histopathology and immunohistochemistry evaluation supporting the diagnosis of rosette-forming glioneuronal tumor. Postoperatively, the patient developed diabetes insipidus and central adrenal and thyroid insufficiency, with favorable evolution and recovery under substitution treatment.

Conclusions

Rosette-forming glioneuronal tumor is a very rare tumor, with about 100 cases reported in literature. It is a grade I neoplasm, with indolent evolution and a low recurrence rate following total resection. In our case, it presented with hormonal disturbances due to its size and unusual location. A multidisciplinary approach from an experienced team is absolutely necessary for an appropriate diagnosis, an effective treatment and long-term follow-up for this type of cases.

Hypophysitis and reversible hypopituitarism developed after COVID-19 infection - a clinical case report.

Natalia Gorbova, Liudmila Rozhinskaya, Viktoria Vladimirova & Zhanna Belaya

The National Medical Research Centre for Endocrinology, Neuroendocrinology and Bone Disease Department, Russian Federation

Aim
To present a clinical case of reversible hypopituitarism due to hypophysitis developed after COVID-19 infection.
Materials and methods
A patient with residual clinical manifestations of hypopituitarism underwent clinical evaluation at the time of symptoms of hypopituitarism and in follow-up. Morning serum cortisol (171-536 nmol/l) was measured by electrochemiluminescence immunoassay. Morning ACTH (7.2-63.3 pg/ml), prolactin (66-436 mU/l), TSH (0.25-3.5 mIU/l), fT4 (9-19 pmol/l) and fT3 (2.6-5.7 pmol/l) were measured by chemiluminescence immunoassay. General Electric 3T MRI scanner was used to do an MRI of the brain with standard contrast. Data were analyzed throughout the course of the disease.
Results
A 35-year-old female developed clinical symptoms of hypopituitarism two months after recovery from a confirmed COVID-19 infection. Laboratory investigation confirmed hypocorticism, hypothyroidism, hypogonadism and the patient was prescribed appropriate hormonal therapy in January 2021. Four months later the symptoms were alleviated (April 2021) and there were signs of recovery shown by imaging and hormonal profile (hormonal treatment was stopped for evaluation): morning serum cortisol 227 nmol/l, morning ACTH 33.96 pg/ml, prolactin 68.3 mU/l, TSH 2.626 mIU/l, fT4 10.75 pmol/l, fT3 3.96 pmol/l. Thyroid hormone was discontinued, but hypogonadism and hypocorticism persisted with estradiol - 51.48 pmol/l, 24 h urine cortisol levels - 41.8 nmol/day. Secondary adrenal insufficiency was confirmed during a test with insulin hypoglycemia (serum glucose reached 0.7 mmol/l), the maximum release of cortisol was 410.8 nmol /l. MRI results showed that the signs of hypophysitis were alleviated in comparison with MRI from January 2021. Full recovery of pituitary axis was reported in October 2021, with recovery of normal menstrual cycle. Furthermore, hormonal profile was likewise normal: morning serum cortisol 14,7 µg/dl (6,2-19,4), ACTH 33,2 pg/ml, T4 0,88 ng/dl (0,8-2,1), TSH 2.17 mIU/l.
Conclusions
This report provides evidence of delayed damage to the pituitary gland after infection with the COVID-19, with recovery of its function and structure. To date, the mechanisms of such an impact are not entirely clear; further collection of data on such cases and analysis is required.

EP743

Pituitary apoplexy and Staphylococcus infection in a previously undiagnosed macroadenoma

Iulia Alexandra Pirga
Filantropia Hospital, Endocrinology, Craiova, Romania

Background
Pituitary apoplexy is a rare clinical syndrome, caused by hemorrhagic or ischemic necrosis of the pituitary gland. It is often associated with an existing pituitary adenoma, especially nonfunctioning tumors. Pituitary apoplexy may mimic the clinical findings of an infectious meningoencephalitis.
Case report
A 57-year-old man was admitted to the emergency department following sudden onset of severe headaches, fever, chills, and signs of meningeal syndrome, associated with unilateral ptosis, mydriasis and diplopia. His medical history included arterial hypertension, diabetes mellitus and epilepsy. Blood test revealed a high CRP at 403 mg/l with a white blood count of 11600/mm3. A lumbar puncture was performed, revealing a hyperleukocytosis with a polymorphonuclear predominance at 87%, proteinorachy of 0.93 g/dl, without glycorachy, raising the suspicion of meningitis. The MRI scan demonstrated a 24 x 20 x 27 mm pituitary mass, extending upwards into the suprasellar cistern and compressing the optic chiasm, images consistent with haemorrhage into a pre-existing pituitary macroadenoma. The patient underwent transsphenoidal surgery. Histopathology examination confirmed the diagnosis of pituitary adenoma with apoplexy and inflammation, and microbiologic examination was positive for Staphylococcus Aureus and Staphylococcus Capitis. The post-surgery endocrine workup showed a deficiency of the thyrotropic and gonadotropic axes, a partial deficiency of the corticotrope axis and a moderate increase in prolactin level.
Conclusion
We hypothesize that either there was an underlying inflammatory pathology due to Staphylococcus infection that contributed to the development of pituitary apoplexy, or the presence of necrosis and haemorrhage at that level represented the departure point for the infection. Surgical intervention should urgently be performed when there is a compression of the optic chiasm.
Key words: pituitary apoplexy, infection, macroadenoma

Vanishing Pituitary tumour in a postpartum patient - a diagnostic dilemma

Noha Meneissy[1, 2], Moustafa Hosni[2, 3], Belayet Hossain[4], Barney Low[3], Janessa Bell[3], Writaja Halder[3], Debbie Falconer[3], Shrini Patel[3], Muhammad Saleem[3], Saiful Islam[3], Musarat Hussain[3], Jessica Howes[3], Hassan Rehmani[3], Gideon Mlawa[3,5] & Catherine Qin[1]
[1]Queen's Hospital, London, United Kingdom; [2]Queen's Hospital, Acute Medicine, London, United Kingdom; [3]Barking, Havering and Redbridge University Hospital NHS Trust (BHRUT), Acute Medicine, London, United Kingdom; [4]Barking, Havering and Redbridge University Hospital NHS Trust (BHRUT), Diabetes and Endocrinology, London, United Kingdom; [5]Queens Hospital, Diabetes and Endocrinology/Acute Medicine, London, United Kingdom;

Introduction
Resolution of pituitary tumour without surgical intervention is rare. The mechanism of spontaneous resolution of pituitary adenoma is unclear but may be explained by either pituitary apoplexy or hypophysitis responding to steroids. Bray BP, et al(2021) reported the case of vanishing pituitary mass due pituitary apoplexy. Park SM, et al (2014) reported 22 cases of pituitary mass due hypophysititis which improved mostly with medical therapy.
Case
29-year-old lady presented to hospital in January 2014 with vomiting, abdomen pain, headaches and profound hyponatraemia of 112. She had undectable LH < 0.2), FSH(1), SST normal, Prolactin 407. IGF-1 normal. She was treated with iv fluids. She had MRI pituitary which showed homogenous enhancing pituary macroadenoma measuring (1.0 x 1.5 x 1.8 cm). She was 1 year postpartum. Second baby was born 2012 and stopped breast feeding in 10/2013 and her periods were regular She was seen initially by neurosurgeons for surgical intervention. She was started on hydrocortisone 10 mg then reduced to 5 mg twice a day then stopped in July 2014 as 9 am cortisol was normal at 300. She required no hormonal replacement therapy. Repeat MRI after10 months reported as normal appearance of pituitary gland and surgery was not required.
Discussion
Pitutary adenomas can be divided into functioning and non-functioning. The causes of non-functioning tumours include neoplastic, inflammatory and vascular. Non-functioning pituitary macroadenoma are usually managed surgically if patients are symptomatic unless contra-indicated. Spontaneous resolution of pituitary tumours is rare. The mechanism of spontantoeus resolution of pituitary adenoma is unclear but may be explained by either pituitary apoplexy or hypophysitis responding to steroids. Patient with pituitary apoplexy may present with headaches, vomiting and visual distrubances. The time of onset of spontaneous regression of pituitary adenoma following pituitary apoplexy is unclear, some cases were previously reported to be as early as 1 week. Hypophysitis as an inflammatory process which may response to steroids. It can be postulated that giving steroids facilitates regression of pituitary adenoma. Is unclear whether the patient being on steroid contributed to spontaneous regression of pituitary tumour or not.
Conclusion
Spontaneous regression of pituitary adenoma is uncommon and possible causes discussed above should be considered. Is unclear whether patients with spontaneous pituitary adenoma are at risk of recurrence and they need for long term follow up. The case raises a question of how long can non function pituitary adenoma can be monitored before when to intervening surgically in non functioning pituitary adenomas.

Cardio-metabolic and articular complications of somatotropic adenomas in a single-center study

Khadra Faraoun & Mohammedi Fatiha
Oran University Hospital, Endocrinology, Oran, Algeria

Introduction/Objective
Chronic exposure to hypersomatotropism exposes to multiple co-morbidities, rarely reversible, which can worsen both functional and vital prognosis and impair quality of life. The aim of our work is to list the different complications of acromegaly at the time of diagnosis.
Patients and methods
Descriptive cross-sectional study concerning 81 patients with somatotropic adenomas followed in the Endocrinology department of the Oran University Hospital.
Results
Sex ratio M/F at 1.4, pituitary macroadenomas are involved in 81% of cases, the mean age at diagnosis at 40.2 $\pm$ 15.5 years, the mean consultation time at 23.8 $\pm$ 31.3 months, the mean BMI at 26.4 $\pm$ 4.9 kg/m^2. At diagnosis, we identified hypertension in 41% of cases with a mean duration of 4.5 $\pm$ 5.9 years, congestive valvular heart disease with or without arrhythmia in 31% of cases, sleep apnnea syndrome (SAS) in 50% of cases explored ($n=$ 20), diabetes mellitus in 35% of cases with a mean duration of 5.2 $\pm$ 6.5 years, intolerance to carbohydrates in 15.3% of cases with a mean duration of 2.0 $\pm$ 3.1 years, dyslipidemia in 28%, axial arthropathy in 39% of cases including 3 Erdheim spondylosis and carpal tunnel syndrome in 40% of cases.
Discussion
Our results are similar to those in the literature which vary from 18-60% for hypertension, from 19 to 56% for diabetes mellitus and carbohydrate intolerance, from 33 to 47% for dyslipidemia and from 20 to 80% for SAS; They reflect the need for early diagnosis of acromegaly and for hormonal control to improve prognosis.

EP746

Hormonal profile of pituitary adenomas

Khadra Faraoun & Mohammedi Fatiha
Oran University Hospital, Endocrinology, Oran, Algeria

Background
Pituitary adenomas (PA) or endocrine pituitary tumors are the most common pituitary tumors. Our goal is to assess their hormonal profile.
Patients and methods
Our study is observational, multicenter, with prospective and retrospective data collection. Data entry and analysis was performed by CDC (USA) EPI Info version 6, SPSS20, Statistica10, Medcalc12.
Results
Concerning the hormonal profile of the 475 PA collected, 77.5% were secreting against 22.5% not or apparently non-secreting. Macroadenomas were predominant (66.5%, *P* 0.001). Prolactin was elevated in 62.7%. It was either a functional or disconnected hyperprolactinemia, or of tumor origin. The mean prolactinemia was significantly ($P=0.006$) higher in men: 578.2 Vs 189.1 ng/ml. Hypopituitarism ($\geq$2 axes) calculated as for macroadenomas was noted in 35%. Gonadal deficit, functional in microlesions and organic and/or functional in macroadenomas, was the most common (56.5%) compared to the other deficits. Impaired gonadal function is followed by the thyrotropic deficit noted in 32%. Corticotropic and somatotropic deficits come last, 27% and 6.5%, respectively. Somatotropic function was not systematically explored in our retrospective study. Multiple deficits affecting more than 3 axes were noted in 17.0%. Post-pituitary function impairment was present in 4.7%.
Conclusion
Our results can of course be explained by the frequency of macrolysis but also by the delay in the diagnosis of these tumors.
Key words: pituitary adenomas, hormonal profile, hyperprolactinemia, pituitary deficits.

Delayed Diagnosis of Cushing's Disease Manifested in Adolescence

Irina A. Vaychulis
South-Ural State Medical University, Internal Medicine Department, Chelyabinsk, Russian Federation

Diagnosis of Cushing's syndrome (CS) can be challenging, particularly in mild cases or in cyclic disease, because of the variable, non-specific clinical manifestations and the overlap with more common medical problems. Female patient was referred to our clinic in Dec 2015, at the age of 18 years, presented with headaches, arterial hypertension (AH), excessive body hair growth, irregular menstrual periods, sleep disturbances and mood fluctuations. She smoked, but denied use of alcohol or any drugs. Menarche occured at 10 years of age and her menstrual cycle (MC) was regular. At the age of 14 years she had noticed excessive body hair growth, alopecia, weight gain (15 kg), purple striae and menstrual irregularities. At examination in pediatric clinic AH, normal morning cortisol, TSH, prolactin, electrolites, elevated testosterone and DHEA-s levels were detected. Her brain's MRI and CT of adrenal glands were unremarkable. US showed multifollicular ovaries. She was followed by pediatricians with the diagnosis of PCOS, obesity. Oral contraceptives were not effective to control her MC and were discontinued. In 2015 she lost weight (15-20 kg) with striae discoloration and her MC was temporarily restored without specific treatment. In a few months the described symptoms had returned and she was referred to endocrinologist. At examination in Dec 2015 plethoric rounded face, hyperstenic constitution, normal BMI (23 kg/m^2), hirsutism (lower abdomen, hips, lumbal area), acne, pale striae, AH were found. 24-h urine free cortisol within the normal range, slightly elevated testosterone, androstendione and ACTH (48 ng/ml, ULN 46) levels, normal TSH, prolactin, OGTT, electrolytes and liver function tests were revealed. Further investigation demonstrated ACTH at the upper border of normal range (46 ng/ml), but inadequate suppression of plasma cortisol (350 nmol/l) and ACTH (44 ng/ml) after overnight 1-mg DST. At the same time 6 x 3 mm microadenoma on pituitary MRI had been detected. The diagnosis of ACTH-dependent endogenous hypercortisolism - Cushing's disease (CD) was established and confirmed by subsequent deterioration of laboratory parameters accompanied by weight regain. Symptoms of hypercortisolism have completely disappeared after repeated transsphenoidal adenomectomy in 2016-2017. This case demonstrates the delayed diagnosis of CD with first clinical presentation at the age of 14 years, resembling PCOS. Fluctuating signs of cortisol excess and inconsistent laboratory results raise suspicion about cyclic CD. As no single diagnostic test is 100% accurate in the diagnosis of CS/CD, repeated monitoring is needed. Education of pediatricians and gynecologists to maintain awareness about CS/CD is required.

Clinical, paraclinical and genetic features of diabetes insipidus

Fatma Mnif[1], Hana Charfi[1], Fatma Abdelhédi[2], Malek Bouassida[2], Mouna Elleuch[1], Dhoha Ben Salah[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Nadia Charfi[1], Faten Haj Kacem Akid[1], Hassen Kammoun[2] & Mohamed Abid[1]
[1]Hedi Cheker University Hospital, Endocrinology, Tunisia; [2]Hedi Cheker University Hospital, Genetics, Tunisia

Introduction
Diabetes insipidus (DI) is a rare pathology. The advent of hypothalamic-pituitary MRI has made it possible to make a positive diagnosis by avoiding the water restriction test (WRT). The etiological diagnosis is still a challenge in view of the diversity of diseases involved, which influences the therapeutic management and prognosis.
Work Objectives
The objectives of our work were to describe the clinical, paraclinical and genetic features of DI.

Patients and Methods
We conducted a retrospective and descriptive study of all cases of DI collected in the endocrinology department of Hèdi Chaker University Hospital, Sfax Tunisia during a 21-year period (2000-2021).
Results
We collected 44 patients, with a mean age of 53.2±16.05 years and a sex ratio M/F of 0.7. The most frequent reason for consultation was SPUPD in 70.5% of cases. The severity of SPUPD was variable: polyuria > 5l/24 h in 75% and polydipsia > 10l/24 h in 38%. There were no adverse effects of SPUPD described in our study. The positive diagnosis was made by WRT in 13 patients, and bases on hypothalamic-pituitary MRI in the other cases: an abnormal spontaneous T1 hyper signal was present in 70.4% of patients. Three patients had a nephrogenic DI, one of which was drug-induced (lithium intoxication) and the other two of genetic origin (AQP2 mutations). CDI was identified in 41 patients, 2 of whom had partial diabetes and 5 had transient diabetes. The most frequent etiologies were: post neurosurgical interventions (24.4%), pituitary tumors (17%) and lymphocytic hypophysitis (14.6%). An idiopathic origin was present in 12.2% of cases. Minirin treatment was initiated in all patients suffering from CDI with a clear clinical improvement. For NDI, an association with indomethacin or thiazide diuretic was necessary.
Conclusions
At the end of this work, we insist on the necessity of a better knowledge of this pathology, allowing an early diagnosis and a management, only guaranteeing a better prognosis.

EP749

Hypopituitarism revealing small cell pulmonary carcinoma: an original case report

Asma Tekaya, Asma Kefi, Khaoula Ben Abdelghani, Cyrine Sassi, Sami Turki, Mounira El Euch & Ezzedine Abderrahim
Charles Nicolle Hospital, Department of Internal Medicine A, Tunis, Tunisia

Background
Anterior pituitary insufficiency or anterior hypopituitarism is a defect in the secretion of one or more of the pituitary hormones (ACTH, TSH, FSH and LH, GHand prolactin). It is a rare condition. A variety of diseases may be the cause, the most common being adenoma. In rare cases, it can be a clinical presentation of metastatic disease. Herein, we describe a case of a pituitary metastasis revealing a lung carcinoma in a 61-year old man.
Case report
A 61-year old man, with a history of heavy smoking and type 2 diabetes, was admitted with deterioration of general state. He reported constipation, anorexia, weight loss and decreased libido for 2 years and has stopped taking his insulin for 2 months because of hypoglycemic episodes. Examination showed psychomotor retardation, blood pressure (BP)at 106/62 mmHg, heart rate at 62 bpm, normal blood glucose and BMI of 32 kg/m^2. Ganglionic node palpation revealed several cervical, axillary and inguinal adenopathies. Laboratory tests found hyponatremia, lymphocytosis and elevated inflammatory markers. Colonoscopy was normal. Endocrine investigations revealed central hypothyroidism (TSH: 0.107 microUI/ml, FT4: 0.63 ng/dl) and hypocorticism (cortisol: 35 nmol/l), low testosteronemia at 0.081 ng/ml and hyperprolactinemia at 862 mUI/l. The patient was therefore started on hormonal replacement therapy (hydrocortisone and levothyroxine). Cerebral MRI found 4 metastases: right frontal, left parietal, sellar and suprasellar mass lesions isointense on precontrast T1 weighted, hyperintense T2 weighted and demonstrated predominately rim enhancement on FLAIR. Body scan was concordant with the diagnosis of pulmonary neoplasm with multiple secondary lesions (lymph node, bone, adrenal, cerebral, hepatic, pleural and peritoneal metastases), therefore classified T4N3M1c. Cervical ganglions biopsy confirmed the diagnosis of small cell pulmonary carcinoma. The patient was started on radiotherapy and was addressed to a specialized oncology center for follow up.
Discussion
Our report depicts an original and challenging diagnosis approach of small cell lung carcinoma revealed by pituitary metastasis with hypopituitarism. Pituitary metastases are uncommon. They represent 0.14 to 3.6% of all intracranial metastasis, and are rarely symptomatic (1% to 6%). In scarce cases, pituitary metastasis is the first manifestation of the cancer. Breast and lung cancer are the most frequent cause of pituitary metastasis. The association of infundibular metastasis and elevated serum prolactin has been reported.
Conclusion
Pituitary metastases may be the initial presentation of neoplasms or may occur during therapy. Physicians must be cautious, and must suspect the diagnosis when confronted with any sign that may suggest pituitary damage (hypothyroidism, adrenal insufficiency, etc.)

Neurosarcoidosis and pituitary metastasis of a small cell carcinoma: an unusual association

Fatma Mnif, Hana Charfi, Mouna Elleuch, Dhoha Ben Salah, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Cheker University Hospital, Endocrinology, Tunisia

Introduction
Pituitary stalk thickening (PST) is often identified on magnetic resonance imaging (MRI), either incidentally or during diagnostic workup of hypopituitarism. Currently, there is no unified standard for the definition of PST. As a reference, a pituitary stalk with width over 3 mm has been used as the diagnostic criterion for PST in recent years. The disease spectrum of PST is quite diverse and can be grouped into three broad categories: neoplastic, inflammatory and congenital diseases. Here, we report a rare case of PST secondary to Neurosarcoidosis and pituitary metastasis of a small cell carcinoma.
Case report
We report the case of a 49 years old man with no personal medical history. The diagnosis of neuro-sarcoidosis was suspected in view of the presence of pituitary tumor syndrome, central diabetes insipidus, hypopituitarism and the presence of nodular thickening of the stalk at hypothalamic-pituitary MRI. Biological explorations had shown an increase in 1-25 OH vitamin D, a decrease in 25 OH vitamin D and a slight increase in the tumor marker NSE estimated at 42 ng/l. Chest X-ray and thoracic-abdominal CT scan were in favor of pulmonary, hepatic and adrenal involvement. Labial biopsy and bone scan were negative. To confirm the diagnosis, bronchial biopsies were performed 3 times under fibroscopic control but returned negative. Then they were redone under CT scan to conclude to a small cell lung carcinoma, but the liver biopsy was in favor of a sarcoidosis. The patient was put on replacement therapy (ddAVP at a dose of 0.1 ml*2/d, hydrocortisone at a dose of 30 mg/d and L-thyroxine at a progressive dose up to 100µg/d) with clinical and radiological monitoring. The thoracic CT scan showed an aggravation of the lesions, an increase in the tumor mass and a small pleural involvement. The diagnosis retained was that of a pituitary metastasis of a small cell carcinoma associated with sarcoidosis. Given the deterioration of the general condition and the worsening of the radiological lesions, the patient was referred to the carcinologists for vinblastine and prednisone16 - cisplatin chemotherapy. He received 3 courses of chemotherapy with a good clinical and biological evolution. Since then, the patient was regularly followed up in carcinology.

Immunohistochemichal expression of ephrin receptor (EPH)-A4, -A5, -B2 and -B5 in pituitary lesions

Eirini Papadimitriou[1], Georgios Kyriakopoulos[2], Konstantinos Barkas[3], Ioannis Gkalonakis[3], Panagiota Pantoula[4], Stamatios Theocharis[5], Gregory Kaltsas[1] & Krystallenia Alexandraki[1]
[1]National and Kapodistrian University of Athens, Endocrine Unit, 1st Department of Propaedeutic Medicine, Athens, Greece; [2]Evangelismos General Hospital, Department of Pathology, Athina, Greece; [3]General Hospital of Nikea, Neurosurgery Department, Nikea, Greece; [4]General Hospital of Nikea, Department of Pathology, Nikea, Greece; [5]National and Kapodistrian University of Athens, First Department of Pathology, Athens, Greece

Introduction
Ephrin receptors (EPHs) compose the largest known subfamily of receptors tyrosine kinases and are bound and interact with EPHs-interacting proteins (Ephrins). They have a role in tumor growth, invasion, angiogenesis and metastasis of several neoplasms. Aim of the study was to investigate the expression of EPH-A4, -A5, -B2 and -B5 in pituitary lesions.
Material and Methods
Our study group consisted of 18 patients (9 males with median age 54 and females with median age 59) with pituitary lesions (7 somatotropic and 2 corticotropic adenomas, 8 non-functioning macro-adenomas and 1 resistant prolactionoma) .Formalin fixed-paraffin embedded (FFPE) tissue sections from the lesions were assessed immunohistochemically for EPH-A4, -A5, -B2 and -B5 expression. Positivity is defined when $>4\%$ of pituitary cells have positive staining, after observation of at least 1000 cells. An immunoreactive score (IRS) was created according to the sum of percentage of EPH-A4, -A5, -B2 and -B5 positivity (0/negative staining: 0–4% of pituitary cells positive; 1: 5–30% of pituitary cells positive; 2: 31-60% of pituitary cells positive; 3: 61–100% of pituitary cells positive) and the intensity of staining (0: negative staining, 1: mild staining; 2: intermediate staining; 3: intense staining). A case was characterized to present low, medium or high EPH expression if the total score was 0-2, 3-4 and 5-6, respectively. The H-score is determined by adding the results of multiplication of the percentage of cells with staining intensity ordinal value (scored from 0 for "no signal" to 3 for "strong signal") with 300 possible values.
Results
Cytoplasmic and nuclear for EPH-A4 and cytoplasmic for EPH-A5, -B2 and -B4 pattern of immunostaining was noted. Positivity for EPH-A4 was seen in 17/18 (94%) of the specimens (17/18 with cytoplasmic and 13/18 with nuclear pattern). All corticotropic and somatotropic adenomas found positive for EPH-A4 with both patterns. Positivity for EPH-A5 and EPH-β2 was seen in 4/18 (22%) specimens and for EPH-β4 in 1/18 (5.5%), all non-functioning adenomas with cytoplasmic pattern. EPH-A4 IRS was mild for 4, intermediate for 6 and intense for 3 cases. H-score for EPH-A4 expression ranging from 30-255, whereas for EPH-A5,-B2 and -B4 was lower (10-65).
Conclusion
Our data indicate for the first time the increased expression of mainly EPH-A4 and to a lesser extent of EPH-A5, -B2 and -B4 in pituitary lesions. Their involvement in the pathophysiology of pituitary lesions requires further investigation to clarify their role and their possible potential prognostic value.

Clinical presentation of non-functioning pituitary tumors: the experience at a tertiary care hospital in Portugal

Maria Inês Alexandre[1], Ana Gomes[1, 2], Ema Lacerda Nobre[1, 2], Pedro Marques[1, 2] & Maria Joao Bugalho[1, 2]
[1]Hospital Santa Maria, Endocrinology, Diabetes and Metabolism Department, Lisboa, Portugal; [2]Faculty of Medicine, University of Lisbon, Lisboa, Portugal

Introduction
Clinically non-functioning pituitary tumors (NFPTs) lack clinical or biochemical evidence of pituitary hormone excess. Their clinical presentation is heterogeneous, including mass effect-related symptoms and/or hypopituitarism, or even no symptoms in incidentally-detected NFPTs. We aimed to evaluate the clinical presentation spectrum of NFPTs in a cohort of patients managed at our hospital.
Methods
Clinical, demographic, biochemical and imaging data from 227 patients was retrieved and retrospectively analyzed using SPSS®.
Results
Our cohort included 115 women (50.7%) and the median age of the study population was 58 ± 15 years. Most patients had NFPT-related symptoms at presentation (75.3%), predominantly visual disturbances (56.8%) and headache (35.7%). In contrast, 56 patients (24.7%) had an incidental diagnosis on neuroimaging performed for other reasons, largely trauma (21.4%). Patients with incidentally-discovered NFPTs were significantly older than those with clinically-presenting NFPTs (62.8 ± 14.2 vs 54.8 ± 14.7; $P=0.001$). Regarding the entire group of patients, at diagnosis, the majority had one or more pituitary hormone deficiencies (55.9%), which occurred more frequently in men than women (66.1 vs 46.1%; $P<0.001$), in older patients and in patients with larger tumors ($P<0.001$). Of the 227 NFPTs, 210 (92.5%) were macroadenomas, and 180 (79.3%) had extrasellar extension. The mean diameter at diagnosis was 2.41 ± 1.15 cm. Clinically-presenting patients had larger tumors (2.60 vs 1.97 cm; $P=0.006$). A total of 140 patients (61.7%) underwent surgery, 75.7% of these within the first 12 months since the NFPT diagnosis. The subgroup of incidentally-discovered NFPTs required less often an operation than the clinically-presenting counterparts (41.1 vs 68.4%; $P<0.001$).
Conclusion
Our NFPT cohort included patients who mostly presented with large tumors associated with compressive symptoms and hormonal deficiencies. However, a quarter of cases were incidentally-discovered NFPTs, typically found in older patients, and despite their smaller size still more than one third needed surgery.

Acromegaly: a rare disease with multiple, complex complications

Andra Cristiana Istrate, Letitia Leustean, Maria- Christina Ungureanu, Laura Teodoriu, Stefana Bilha, Alexandru Florescu & Cristina Preda
'Grigore T. Popa' University of Medicine and Pharmacy of Iaşi, Department of Endocrinology, Iaşi, Romania

Introduction
Acromegaly is a rare, challenging disease that if not appropriately treated can lead to numerous complications. Some of the most frequent complications are cardiovascular (hypertension, secondary cardiomyopathy, arrhythmias, valvulopathies, heart failure) and metabolic (secondary diabetes, various alterations of the lipid metabolisms).
Aim
The aim is to asses the impact of long-term acromegaly on the cardiovascular system and glucide and lipid metabolisms.
Patients and method
In this retrospective study the records of 107 patients with previously diagnosed acromegaly, who have been assessed at least once in our tertiary referral centre (Department of Endocrinology, University Hospital "Sfântul Spiridon", Iaşi) over a period of 6 years have been reviewed.
Results
Out of the 107 patients with mean age 51.96 ± 12.14 years, 34 (31.78%) were male and 73 (68.22%) were female. From the total of 107 patients 93 (86.92%) had cardio-metabolic complications. Out of the assessed cardiovascular comorbidities, hypertension was present in 46 patients (42.99%), rhythm disorders were found in 8 patients (20%), cardiomyopathy in 5 patients (12.5%), valvulopathies in 3 cases (7.5%), 6 cases of heart failure (15%), chronic venous insufficiency in 2 patients (5%), cardiac ischemic events were found in 11 patients (27.5%), 2 cases of stroke (5%) and 3 cases (7.5%) of other cardiovascular diseases were also noted. Alterations of the glucide metabolism were determined in 36 patients (33.64%): type 2 diabetes mellitus was found in 21 cases (58.33%), impaired fasting glucose in 6 cases (16.67%) and impared glucose tolerance in 9 patients (25%). Dyslipidemia was found in 44 patients (41.12%), while an increased body mass index was determined in 46 patients (57.01%).
Conclusions
The design of the present research has offered a chance for thorough investigation of cardiovascular and metabolic alterations in acromegaly patients, thus revealing a significant number of complications. Although acromegaly is an orphan disease, the multi-organ severe complications rise complex issues in relation with the diagnosis and treatment approach. This aspect could justify the use of a personalised multi-modal treatment for each patient.
Key words: acromegaly, cardiovascular disease, metabolic complications

Early diagnostic tools in milder forms of central hypothyroidism in patients harbouring a pituitary adenoma: cross-sectional study on 142 patients from a single tertiary center

Elena Galazzi[1], Federico Nicoli[1], Silvia Carrara[1], Chiara Milan[2], Letizia Maria Fatti[1], Mirella Moro[1] & Luca Persani[2]
[1]Istituto Auxologico Italinao, San Luca Hospital, Endocrine and Metabolic Diseases Unit, Milano, Italy; [2]University of Milan, Department of Medical Biotechnology and Traslational Medicine (BIOMETRA), Italy

Introduction
Milder forms of central hypothyroidism (CeH) are still challenging to diagnose due to absence of gold standards, wide variability of fT4 values and aspecificity of symptoms. We aimed to find diagnostic clues at diagnosis (pituitary lesion dimensions, other hormonal deficit) and during long-term follow-up, guiding the clinician to a precocious diagnosis of CeH.
Study
142 patients harbouring a pituitary adenoma with complete pituitary assessment at diagnosis (hormonal/imaging) were studied between 2000 and 2020. Median age was 47.5 years (SD 16.5). Lesions were 45% microadenomas (55% macroadenomas)., 62% were functioning and 30% incidentalomas. At diagnosis, 67% of patients with CeH suffered from at least another hormonal deficit, especially gonadotropins failure (OR 6.9, $P=$ 0.0001) and corticotrope failure (OR 7.6, $P=$ 0.001). No correlation was found between CeH and having a functional adenoma ($P=$ NS). Radiological measures were available in 102/142 patients. Patients with CeH at diagnosis had bigger adenomas ($P=0.054$). Given a maximum adenoma diameter $>$ 12 mm, the probability of carrying CeH was statistically significant (OR 3.53, $P=$ 0.03, sensitivity 68.7%, specificity 61.6%). Mean follow-up was 7.64 years (2-53-9.73) and follow-up data were available for 69 patients, with at least one evaluation of paired TSH and fT4 per year. Only 4/69 developed overt CeH defined by inappropriately normal or low TSH with fT4 values beyond the lower limit of normal. In those patients mean fT4 variability (defined by the difference between the median value of fT4 and the lowest fT4 value detected over follow-up) was -18% (SD $\pm$ 10) and median TSH index (TSH_i) was $+1.7$ (IQR 0.36-2.18) with a mean decrease of -47% (SD $\pm$ 50). Among the other 65/69 patients with a normal thyrotrope reserve, mean ft4 variability was -2% (SD $\pm$ 9) displaying a -2 SD as low as -20% and mean TSH_i was $+2.51$ (SD $\pm$ 0.522) with a median decrease of – 7% (IQR -16; -3) displaying a 2.5° percentile as low as -38%. The difference in intra-individual ft4 variations and TSH_i decrease was statistically different in these two cohorts ($P=0.04$, $P=0.048$ respectively).
Conclusions
In patients carrying pituitary adenomas, the presence of mild CeH could we inferred at diagnosis if adenoma diameter is $>$ 12 mm and gonadotropin or corticotrope deficiency coexist. During follow-up, if intra-individual variation of fT4 from baseline exceed -20% and TSH index decreases by more than -38%, the development of CeH could be suspected.

Pituitary adenomas and pregnancy: descriptive observational study

Miriam Veleno, Sara Menotti, Antonella Giampietro, Sabrina Chiloiro, Alfredo Pontecorvi, Laura De Marinis & Antonio Bianchi
Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Università Cattolica del Sacro Cuore, Pituitary Unit, division of Endocrinology and Diabetes, Rome, Italy

Introduction
Pregnancy results in a significant change in pituitary gland size and function. Due to this physiological adaptation, management of pituitary adenomas during pregnancy represents a particularly complex challenge. Aim of this study was to focus on a single referral institution experience with special attention to this subgroup of patients: pregnant woman affected by pituitary adenoma.
Materials and methods
This is a descriptive observational study, all patients with macroadenoma and who had at least one pregnancy were included. We studied 10 women who got pregnant during their endocrinological follow-up. They were divided as follows: 4 GH and PRL secreting tumors, 2 Cushing diseases, 2 acromegaly, 1 PRL secreting tumor and 1 non functioning macroadenoma. In order to describe the outcome of the adenoma during pregnancy, we considered the previous surgical and medical therapy, hormonal serum levels, imaging data and medical therapy during and after pregnancy. We also analyzed the obstetrical outcomes of their pregnancies.
Results
The median age of the patients was 35. They all had a previous transphenoidal surgery of the pitutitary adenoma. The two patients affected by Cushing disease also had bilateral surrenectomy, due to lack of disease control and due to hyposurrenalism undergone therapy with hydrocortisone. After surgery, because of residual disease, a patient affected by GH and PRL secreting tumors, one affected by acromegaly and the patient affected by non functioning macroadenoma were treated with somatostatin analogs and the other one affected by acromegaly started dopamine agonists. When the patients showed desire for pregnancy, medical therapy was discontinued evaluating hormonal tests and MR imaging. The residual disease at MRI was stable during and after pregnancy and did not affect the optic chiasma, without visual field alterations or reduced vision. Obstetrical outcomes showed no malformation, one twin pregnancy, two caesarean-sections. The patients already undergoing medical treatment before pregnancy, restarted it after pregnancy.
Conclusions
Studies on pituitary adenoma management during pregnancy are limited. In our study, no complication was reported in patients with or without residual tumour on the preconception MRI, regardless of the initial size and of the discontinuation of medical therapy. Patients did not need any kind of therapy during pregnancy and did not show any symptomatic progression of adenomas, without ophthalmological abnormalities or apoplexy. Because of the potential risk that these conditions represents for the mother and the fetus, it is essential to keep patients under close follow-up and treat them quickly and successfully.

Clinical & Epidemiological characteristics of patients undergoing pituitary-related surgeries in a tertiary care centre in Sri Lanka

Piyumi Wijewickrama[1,2], Sathyajith Ambawatte[1, 3], Manilka Sumanatilleke[1], Chaminda Garusinghe[1], Sanjeewa Garusinghe[1], Deepal Attanayake[1], H.K. de. S Kularatne[1], Wadanambi Saman[1] & Noel P Somasundaram[1]
[1]NHSL, Colombo, Sri Lanka; [2]University College Hospital, United Kingdom; [3]St George's Hospital, United Kingdom

Introduction
For clinically relevant sellar masses, early identification and effective endocrine & surgical management is the key. National Hospital of Sri Lanka (NHSL), which is the largest tertiary care centre in Sri Lanka, manages a wide variety of patients with sellar/supra-sellar pathologies, regularly conducting pituitary related surgeries. The aim of the current study was to determine epidemiological and clinical characteristics as well as immediate post-operative course of the patients undergoing pituitary surgeries.
Methods
Prospective, cross-sectional study of demographics, clinical & biochemical characteristics & post-operative course of all adult patients (above 15 years) undergoing pituitary related surgeries in NHSL over 18 months from February 2019.
Results
During this period, 139 persons underwent pituitary related surgeries, with a mean age of 44 years (+/- 15) and a female to male ratio of 3:2. 25% had re-operations while the rest were first surgeries. The majority (68.3%) presented with pressure symptoms while 10.1% & 20.1% presented with hypopituitarism & hormone hypersecretion respectively. Sixty-seven (48.2%) were on pre-operative Levothyroxine, with 12 of them having long standing primary hypothyroidism. Forty-seven (33.8%) patients were on pre-operative long term hydrocortisone replacement. Pituitary adenoma in 111 (79.9%), craniopharyngioma in 22 (15.8%), and supra-sellar meningioma in 6 (4.3%) were observed. MRI of sellar masses demonstrated cavernous sinus invasion in 49 (35.3%), while 80 (57.6%) had optic chiasm compression. Out of pituitary adenomas, the majority 81 (72%) had non-functioning adenoma, 20 (18%) had Acromegaly, 9 (8.1%) had Cushing's and 1 patient with resistant prolactinoma underwent surgery. The majority, 108 (77.7%) were trans-sphenoidal surgeries, while 31 (22.3%) underwent craniotomy. Post-operative complications observed were CSF rhinorrhoea in 25 (18%), bleeding in 8 (5.8%), progressive deterioration of vision in 21(15%) and ischemic stroke in 2 persons. No significant difference was

observed with the type and attempt of surgery with these complications. Fifty-two developed post-operative transient or permanent cranial Diabetes Insipidus while 12 (8.6%) had Syndrome-of-inappropriate-ADH secretion. 137 (99%) were discharged on hydrocortisone. Post-operative Levothyroxine was required in 74(53%) with a significant difference in the re-operation group compared to first surgery ($P=0.02$).
Conclusion
This study identifies baseline characteristics of patients undergoing pituitary-related surgeries in a south Asian developing country, along with immediate post-operative complications. These findings have a national & a regional relevance in improving patient care. This will also have a global relevance due to the rising ethnic diversity all over the world.

Fluid and sodium disorders in patients undergoing pituitary related surgeries in a tertiary care centre in Sri Lanka, with associations and risk factors; a prospective, observational study

Piyumi Wijewickrama[1,2], Sathyajith Ambawatte[1, 3], Manilka Sumanatilleke[1], Chaminda Garusinghe[1], Kasun Kamaladasa[1] & Noel P Somasundaram[1]
[1]NHSL, Colombo, Sri Lanka; [2]University College Hospital, United Kingdom; [3]St George's Hospital, United Kingdom

Introduction
Fluid and sodium disorders are a relatively frequent occurrence after sellar/supra-sellar surgeries. National Hospital of Sri Lanka (NHSL) is the main tertiary care centre in Sri Lanka, conducting regular pituitary surgeries.
Methods
A prospective cross-sectional study was conducted in all adults (above 15-years) undergoing pituitary-related surgeries in NHSL over 18 months from September 2019. The relationship between demographic factors, clinical, biochemical & tumour characteristics, diagnosis and indication for surgery, type and attempt of surgery with the post-operative fluid and sodium outcomes [syndrome-of-inappropriate-anti-diuretic-hormone (SIADH), polyuria, Cranial Diabetes Insipidus (CDI)] were analysed.
Results
There were 139 patients with a mean age of 44 years (+/- 15), 60% females, undergoing Trans-sphenoidal-surgery(TSS) or craniotomy for varying indications related to sellar/supra-sellar pathologies. Mean baseline pre-operative sodium was 138.9 (+/-3.2). Post-operatively, 76(54.6%) developed polyuria (>3l/24-h) with peak median urine output on day 2. Out of them, 52 (68.5%) were diagnosed with CDI (80.7% having only transient CDI) and the rest had transient polyuria without confirmed Cranial-Diabetes-Insipidus (TPWCDI). Out of all polyuric patients, 71 received at least a single dose of Desmopressin at some point. Twenty-eight (20.1%) developed post-operative hyponatremia (sodium<135), with only 12(8.6%) having confirmed SIADH. All SIADH patients were managed with fluid restriction, with only 2 requiring hypertonic saline. Five demonstrated triple phase response. Patients undergoing re-operation had a significant association with confirmed CDI & TPWCDI, compared to first surgery ($P<0.0001$ & $P=0.03$ respectively). However, none developed SIADH. Risk of CDI was higher in patients with a tumour size of >2 cm (OR-1.37;95%CI-1.08-1.726; $P=0.018$). Craniopharyngioma demonstrated a higher risk of post-operative CDI compared to other diagnoses (OR-6.8;95%CI 2.7-17;$P<0.0001$). Acromegaly patients had a higher risk of post-operative TPWCDI (OR-1.46; 95%CI 1.04-2.06; $P<0.0001$) and none developed CDI. Post-operative SIADH was more likely in patients undergoing craniotomy, than TSS ($P=0.001$). Patients with tumour size>3 cm (OR1.6; 95%CI 1.2-2;$P<0.0001$), and craniopharyngioma (OR 2.9; 95%CI 1.1- 7.2; $P=0.02$) were more at risk of SIADH. SIADH was not seen with acromegaly or Cushing's.
Conclusions
Transient fluid & sodium disorders occurred in majority of the patients undergoing pituitary-related surgeries. Polyuria & CDI were more common than SIADH. Re-operation, tumour size and the type of tumour could be predictors of post-operative fluid and sodium disorders. The findings of this real-world study add to the existing global literature and is the first such study conducted in Sri Lanka.

Severe growth retardation due to pituitary stalk agenesis: a case report

Kaoutar Rifai, Manale Azriouil, Farah Kamel, Kaoutar Elmoatamid, Loubna Guissi, Hinde Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Growth retardation is considered severe when the height of the child is -3 standard deviation (SD) below the average height in reference to the growth curves of children of the same sex and age. Pituitary stalk interruption syndrome (PSIS) is one of the most common conditions in children with short stature.
Case report
We report the case of a 12-years old boy with no clinical history of perinatal injury or traumatic birth, who was admitted for short stature. Physical examination showed that his height was 105 cm (-4 SD), his weight was 15 kg (-4 SD), and Tanner stage was 1. A complete pituitary hormone profile was performed, which showed picture of hypopituitarism with low T4: 0,46 ng/ml, and low morning baseline cortisol: 28 ng/ml. His IGF1 level was under 10 ng/ml. His bone age was 2 years according to the Greulich and Pyle. Magnetic resonance imaging (MRI) examination showed an agenesis of the pituitary stalk which was not visualized; however; anterior pituitary and posterior pituitary were normally identified.
Discussion
PSIS is characterized by the presence of a thin or absent pituitary stalk, associated to hypoplastic anterior pituitary and ectopic posterior pituitary on MRI. However, there are variations in MRI appearances of this syndrome that includes the form of the pituitary stalk (interrupted, thin, or absent), the height of the anterior pituitary (from absence to normal) and the appearance of the posterior pituitary (ectopic, absent, or normal) The clinical presentation of PSIS varies with the age of diagnosis; manifestations may include neonatal hypoglycemia, prolonged neonatal jaundice, or short stature in older children. The clinical findings are related to isolated growth hormone deficiency; or combined multiple pituitary hormone deficiency.
Conclusion
PSIS is a rare syndrome of congenital abnormalities involving hypothalamic-pituitary structures. It should be considered in the differential diagnosis of a child presenting with short stature or delayed puberty.

About two cases of adipsic hypernatremia in adults, one with proven blood antibodies against subfornical organ (SFOAb).

Lilia Charfi[1], Hippolyte Dupuis[1], Szuwarski Lucile[1], Gillot Christine[2], Utsunomiya Akari[3] & Marie-Christine Vantyghem[1,4,5]
[1]Chu De Lille, Lille, France; [2]Hospital Center De Béthune Beuvry, Beuvry, France; [3]Hiroshima Prefectural Hospital, Hiroshima, Japan; [4]Inserm, Lille, France; [5]CHRU Lille, France

Adipsic hypernatremia, a rare hypothalamic disorder characterized by a loss of thirst in response to hypernatremia is more often reported in children. An autoimmune mechanism has been recently demonstrated. We report two cases.
Case1
A lean 67-year-old female, with a history of multilocular sclerosis, was admitted, for severe hypernatremia (162 mmol/l) with low ADH level (0.5 pmol/l; N: 0.5-2). She did not complain of thirst, despite ideomotor slowing and a skinfold. Diuresis was 1.40 l/24 h. Pituitary assessment showed mild hyperprolactinemia, a Nugent test at 11.5 mg/dl (n <1.8 mg/dl) with low TSH level (0.08 uU/ml (n 0.4-3.6)). MRI showed pituitary stalk nodular thickening. Etiological research only showed SFOAb. Treatment with desmopressin allowed improvement of ideo-motor slowing and natremia (145 mmol/l). The pituitary stalk thickening had partially regressed one year later.
Case2
An overweighed 38-year-old lady, was referred for a first hypernatremia episode (160 mmol/l) in 2013 after an acute pancreatitis complicated with cardiovascular collapse. She had no polyuria-polydipsia, did not feel thirst, and was irregularly menstruated. Initial pituitary assessment showed gonado-somatotropic insufficiency, mild hyperprolactinemia, normal thyroid and adrenal function. Keeping diagnosis was possible pituitary ischemia. The patient was advised to drink at least 2 liters/day and remained asymptomatic except for infertility. Three other episodes of pancreatitis occurred, the only identified cause being heterozygosity for a *CFTR*

variant. In 2021, a new work-up showed similar pituitary profile as in 2013, hypernatremia (150 mEq/l), negative autoimmune panel, and normal CRP, IgG4 and pituitary MRI. A month later, a 5th pancreatitis with severe bradycardia (30-35/bpm) , hypothermia, low blood pressure and severe hypernatremia 170 mmol/l (ADH: 0.8 pmol/l) required ICU admission. Cortisol and thyreotrope deficit were present, with persistent hyperprolactinemia and somato-gonadotropic insufficiency. She initially improved with rehydration, hydrocortisone 200 mg/day and levothyroxine. Polyuria or thirst were absent. Hypernatremia worsened as soon as rehydration/hydrocortisone were tapered. Desmopressin allowed clinical improvement with a 10 mmol/day natremia decrease. On day 3, a seizure revealed brain hematoma and CT signs of vasculitis. Vasogenic edema finally leds to death.
Conclusion
These two cases of adipsic hypernatremia in adult female patients are possibly related to an autoimmune neurohypophysitis in the context of MS in case1 and systemic inflammatory/autoimmune disease explaining both the hypothalamic and pancreatic involvement in case2 Despite the lack of polyuria-polydipsia syndrome, desmopressin treatment improved clinical status and natremia, but should perhaps be used more cautiously than usually recommended. Autoimmune causes can today be proven and may help to adjust the treatment.

Features of the incidence of postoperative complications in patients with transsphenoidal pituitary adenectomy

Gulmira Inomova[1], Zamira Halimova[2] & Yayrahon Kuldasheva[3]
[1]223 Bog'ishamol Ko'chasi, Endocrinology with Pediatric Endocrinology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician Ya.Kh.Turakulov, Neuroendocrinology, Tashkent, Uzbekistan; [3]Andijan State Medical Institute, Endocrinology with Hospital Therapy, Tashkent, Uzbekistan

Target.
To study the incidence of postoperative complications in patients with transsphenoidal pituitary adenoectomy.
Materials and research methods
180 cases of PA subjected to TPA for the period from 2018 to 2020 were analyzed. Of these, 102 (56.6) women, 78 (43.3) men, patients were divided into two alternative groups: the first group - 93 (51.6%) patients with macroadenomas - 42 (45.2%) men, women 51 (54.8%), the second (comparison group) - 87 (48.4%) with microadenomas of men - 35 (40%), women - 52 (60%) of the pituitary gland. The age of the patients ranged from 30 to 59 years. The levels of hormones STH, IGF-1, ACTH, cortisol, prolactin, TSH, fT4, LH, FSH, estradiol, progesterone according to indications, MRT/CT of the chiasmal-sellar area and the state of the organ of vision were studied.
Results
Patients were distributed as follows: depending on the hormonal activity of patients with adrenocorticotropic hormone secreting Cushing's syndrome-60, acromegaly-60, inactive pituitary adenoma-60; depending on the size of the formation: 93 (51.6%) were with macroadenomas, 87 (48.3%) with pituitary microadenomas. An analysis of the incidence of postoperative complications in the short term (1 month) revealed that in 81 (45%) patients with hypopituitarism; hypothyroidism in (70)39%; hypogonadism in 50(28%); diabetes insipidus in 7(4%); transient diabetes insipidus in 11(6%); visual acuity deterioration in 2 (1.2%) patients and liquorrhea in 3 (5.4%) patients. At the same time, there was a normalization of elevated hormone levels in 133 (74%) patients; 30% improvement in vision; lack of disease dynamics in 47 (26%). Despite the persistent phenomena of hypopituitarism 47(26%) and diabetes insipidus 11(6%), which were mainly observed in 165(92%) patients with macroadenomas and did not depend on the organ activity of the formation (against 54(30%) cases with microadenomas). In the long-term follow-up of patients after TPA (t 3 months to 1 year), an improvement in pituitary function was noted in the form of restoration of gonadotropic insufficiency, phenomena of transient diabetes insipidus and improvement in hypertensive cephalgia.
Conclusion
The frequency of immediate and long-term complications in most cases is observed in pituitary macroadenomas and does not depend on the hormonal activity of the adenoma.

Skeletal complications in Cushing's disease (CD)

Dragana Miljic[1,2], Sandra Pekic Djurdjevic[1, 2], Mirjana Doknic[1, 2], Marko Stojanovic[1, 2], Marina Nikolic Djurovic[1, 2], Zvezdana Jemuovic[1], Nevena Radić[2], Sara Radovic[2] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Centre of Serbia, Belgrade, Serbia; [2]University of Belgrade - Faculty of Medicine, Belgrade, Serbia

Introduction
Structural and functional damage of the skeletal system resulting in fractures is a common complication of CD. Due to major effect of glucocorticoids on the trabecular bone, vertebral fractures are a common and severe complication which can lead to disability.
Goal
To investigate the prevalence of skeletal complications (osteoporosis, osteopenia, presence of fragility fractures) in patients with Cushing's disease, as well as gain insight into the potential risk factors for their development.
Material and methods
Cross-sectional study was carried out analyzing electronic medical histories of 52 patients (41 female, 11 male), diagnosed with CD treated between 2009 and 2019.
Results
The study shows that bone demineralization is present in 52% of patients, 32% of whom were diagnosed with osteoporosis, 20% with osteopenia. A correlation between bone demineralization and age or age of CD diagnosis is shown. Bone fractures were present in 17.3% of the patients, of which 77.8% were vertebral and 22.2% peripheral. Patients who had bone fractures were more prone to bone demineralization ($P=0.02$), and more specifically, there was a significant association between osteoporosis and skeletal fragility fractures ($P=0.003$).
Conclusion
Patients with CD have high prevalence of bone demineralization and osteoporosis. Patients with reduced bone mineralization are at higher risk of fracutres, most commonly vertebral fractures, which is why early diagnosis and treatment are necessary.

Feasibility and effectiveness of switching patients with acromegaly receiving long-acting octreotide to lanreotide (Somatulin Autogel)

Olga Zanozina
Privolzhsky Research Medical University, Regional Clinical Hospital named after N. A. Semashko, Endcrinology, Nizhny Novgorod, Russian Federation

Medical therapy of patients with acromegaly is an important addition to surgical treatment or an alternative to it when it is impossible to use the latter. Long-acting synthetic analogues of somatostatin (octreotide and lanreotide) act on the same subtypes of somatostatin receptors, but the drugs have been shown to differ in efficacy and tolerability.
Objective
to achieve complete clinical and laboratory remission in patients with acromegaly, which did not reach it when using prolonged octreotide.
Materials and methods
12 patients with acromegaly who did not have clinical and laboratory remission during treatment with octreotide Depo (Long), while only 3 patients had incomplete clinical and laboratory remission. Of these, surgical treatment was performed in 9 patients. The mean age of the patient is 52.3 years. The patients were switched from octreotide Depo (Long) 30 mg (5 people) and octreotide Depo (Long) 40 mg (7 people) to Somatulin Autogel 120 mg somatulin. The interval between injections was 28 days. Controlled the level of growth hormone (GH) and insulin-like growth factor 1 (IGF-1)
Results
During 6 months of therapy, 10 patients showed a significant decrease in growth hormone ($P=0.024$) and IGF-1 ($P=0.041$), while the level of IGF-1 was completely normalized in 3 people, and growth hormone - in 3 people. After 12 months, complete clinical and laboratory remission was observed in 4 patients, partial - in 4 patients. Thus, after a year of observation, 8 out of 12 patients achieved remission.
Conclusions
Patients who have not achieved remission on long-acting octreotide should be switched to long-acting lanreotide (Somatulin Autogel)

Clinical characteristics, treatment and outcomes of well-differentiated gastroenteropancreatic G3 NET

Marta Opalinska[1], Anna Sowa Staszczak[2], Anna Kurzyńska[2], Karolina Morawiec-Sławek[2], Agnieszka Stefańska[1] & Alicja Hubalewska-Dydejczyk[2]
[1]University Hospital in Krakow, Department of Endocrinology, Oncological Endocrinology and Nuclear Medicine, Kraków, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland

Background
Although gastroenteropancreatic neuroendocrine tumors G3 (GEP-NET G3) and neuroendocrine cancers (GEP-NEC G3) are characterized in histopathological examination by Ki67 > 20% or > 20 mitoses/10HPF their management and prognosis is substantially different. Despite the WHO introduces the novel well-differentiated neuroendocrine tumour of high grade (NET G3) classification in 2017 the clinical management of them is still challenging due to high NET G3 heterogeneity and limited data in regards to best therapeutic strategies.
Material and Methods
We review clinical characteristics, treatment options, and outcomes in cohort of patients with gastroenteropancreatic NET G3 (GEP-NET) managed at our centre since implementation of the new WHO classification (2017 – 2021).
Results
There were 9 cases of GEP-NET G3 (4 women and 5 men, mean age at diagnosis 62,6 years, range 47-80 years). 8 of them had disease stage IV at diagnosis (with liver, lymph nodes, bone, adrenal, brain and peritoneal metastases) and 1 stage IIB with loco-regional lymph node metastasis. The tumours originate from: pancreas (3 cases), stomach (2 cases), small intestine (2 cases), large intestine (1 case) and in 1 case the primary site was unknown. Mean Ki67 was 35% (range 25-70%). In 4 cases there was good or very good somatostatin receptor expression (SSTR) (Kenning score 3 and 4) in somatostatin receptor imaging. Treatment options included combination of surgery, somatostatin analogues (SSA), Peptide Receptor Radionuclide Therapy (PRRT) or chemotherapy (temozolomide/capecitabine or platinum-based regimens). Mean overall survival was 17,2 months (range 3,0 - 46,6 months).
Conclusion
NET G3 management is challenging due to the their heterogeneity and relatively poor prognosis. Further research is needed to optimize/personalize NET G3 therapy with regard to differences in their organ of origin, stage, grading and SSTR expression status.

Head and neck paragangliomas: the belfast trust experience

Milad Darrat[1], Neil Bailie[2], Susie Hampton[2], Stephen Cooke[3], Philip Weir[3], Louis Lau[4], Brian Herron[5], Patrick J Morrison[6] & Philip Johnston[1,1]
[1]Royal Victoria Hospital, Belfast, Regional Centre for Endocrinology and Diabetes, Belfast, United Kingdom; [2]Royal Victoria Hospital, Belfast, Department of Otolaryngology, Belfast, United Kingdom; [3]Royal Victoria Hospital, Belfast, Department of Neurosurgery, Belfast, United Kingdom; [4]Royal Victoria Hospital, Belfast, Department of Vascular Surgery, Belfast, United Kingdom; [5]Royal Victoria Hospital, Belfast, Department of Pathology, Belfast, United Kingdom; [6]Belfast City Hospital, Department of Clinical Genetics, Belfast, United Kingdom

Background
Head and neck paragangliomas (HNPGL) are rare, usually benign slow-growing tumours arising from neural crest-derived tissue. Definitive treatment strategies for HNPGL have not been clearly defined.
Aims
To provide a comprehensive review of our institutional experience of the clinical features, investigations, management and follow up of this cohort.
Methods
Baseline clinical information was taken from a prospectively maintained HNPGL database between January 2017 to January 2022. Further clinical, radiological and laboratory data as well as outcomes were obtained from electronic medical records (NIECR).
Results
There were 21 patients; 10 M; 11F with a mean age of 54 years (range 17-76). Seven (33.3%) patients had glomus jugulare tumour, six (28.5%) had carotid body tumour, four (19%) had glomus tympanicum, four (19%) were in other locations. Tumour size ranged from 20 mm to 5 cm. Thirteen (61.9%) patients had a pre-operative scans, six of which had octreotide avid scans. To date five (23%) patients had SDHD gene mutation and three (14%) patients had SDHB gene mutation identified. All tumours were non-functioning with normal urine metanephrines. Ten (47%) patients underwent surgical resection with five subsequently receiving adjuvant radiotherapy. Recurrence was present in three patients who had surgery for jugulare tumours. Four (19%) patients were deemed not suitable candidates for surgery either due to their extensive disease burden, tumour location or the presence of multiple co-morbidities. Three (14%) patients received monthly sandostatin/Octreotide-therapy. Two of these three patients had stable tumour size without any significant growth since they started on Octreotide-therapy. The remaining four patients (19%) were managed conservatively with serial imaging and observation.
Conclusion
Management of patients with HNPGL requires a multidisciplinary approach and should be individualized and tailored to each patient. Consideration for primary surgical treatment should consider performance status, tumour location and size. Initial surgery still provides excellent outcomes for patients, with adjunctive radiotherapy as second line treatment. The role of Octreotide therapy should be studied in a larger cohort to determine longer term outcomes.

A paradox in clinical practice: the case of a hidden tubercoloma

Matteo Parolin[1], Matteo Parisotto[1, 2], ambra uliana[1], Paola Sartorato[1] & Ernesto De Menis[1]
[1]ULSS 2 Treviso, Dipartimento di Medicina, Treviso, Italy; [2]University of Padua, Dipartimento di Medicina, Padova, Italy

Introduction
A potential cause of panhypopituitarism could be cerebral tubercular lesions, that are often misdiagnosed. Hormonal effects could be related directly to primary tubercular lesions, or after starting antitubercular therapy. Paradoxical reaction (PR) in tuberculosis is defined as clinical or radiological worsening of pre-existing tuberculous lesions or development of new lesions after beginning an appropriate antitubercular therapy (ATT). It has been suggested that the mechanism underlying a PR is an excessive immune response.
Case Report
A 26-year-old man presented to the Emergency Department with a two-week history of fever, headache, visual impairment and fatigue. He was known to have a *Mycobacterium tuberculosis* axillary adenopathy treated with ATT consisting of rifampicin, isoniazid, ethambutol and pyrazinamide, shifted to a maintenance therapy with Isoniazide and Rifampicine three months before. The patient was taking his medication regularly. On examination all clinical parameters were normal; general physical evaluation was unremarkable except for visual loss. Initial laboratory investigations revealed anterior hypopituitarism, (secondary adrenal, gonadal and thyroid failure) without central diabetes insipidus. Cerebrospinal fluid analysis did not show abnormal findings (in particular acid fast bacilli stains on liquor, cultures, PCR for M. tuberculosis and cryptococcal antigens were negative). A chest x-ray was negative. An MRI of the brain with gadolinium enhancement showed a polylobate cystic suprasellar lesion with thickening of pituitary peduncle. The lesion showed ring enhancement with gadolinium, compatible with a flogistic lesion. Visual perimetry examination showed bilateral temporal deficit. Due to the clinical worsening while on ATT and the absence of secondary infection, a paradoxical reaction to ATT was suspected and the patients was managed with high dose dexamethasone (8 mg daily) added to standard therapy for hypopituitarism showing gradual response to the treatment. There was a complete regression of visual deficit and a partial reduction of the intracranial lesion (an MRI was repeated). The patient was

discharged after ten days in good general conditions, with the indication to continue corticosteroids for two months.
Conclusions
Our patient's neurological finding after the beginning of ATT may have been a new development or a progression of intracranial tuberculoma. A paradoxical reaction to ATT should be suspected in any patient in ATT who present with neurological findings and hypopituitarism. Paradoxical tuberculomas are observed in approximately 1% of all active tuberculosis cases. Corticosteroids are the only anti-inflammatory drug that can be used in the management of PR.

'The efficiency of the treatment by Sandostatin-Lar in patients with non-functional pituitary macroadenomas'

Malika Mirtukhtaeva[1], Ashley Grossman[2], Nitin Leekha[3], Alisher Akbutaev[4] & Urmanova Yulduz[5]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan; [2]University of Oxford Senior Research Fellow, Green Templeton College, United Kingdom; [3]Jaypee Hospital, Sector 128, Noida, India, Oncology Department, Noida, India; [4]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Department of Neurosurgery, Tashkent, Uzbekistan; [5]Tashkent Pediatric Medical Institute, Department of Endocrinology, Tashkent, Uzbekistan

The purpose of the study
Is to study the efficiency of the treatment by Sandostatin-Lar in patients with non-functional pituitary macroadenomas (NFPA)
Material and methods.
Under our observation there were 20 patients with NFPA, of whom women were 8, men - 12. The average age of patients was 29,2/36.4 years. All patients were subjected to transnasal adenomectomy of pituitary gland (TAG) in our clinic. The whole patients were performed by research complex, which included Chemilyuminiscent hormonal (STH, IGF-1, Prolactin, LH, FSH, TSG, ACTH, Cortizol, etc.), ophthalmological (Eye bottom, field of view) and X-ray studies (CT, MRI of the Turkish saddle).
Results
According to our data, In all 20 patients, the average sizes of the pituitary tumor before TAG were in range 3.1 x 3.4 x 3.0 cm. Patients were divided into 2 groups: patients of 1 st group received after TAG the treatment by Sandostatin-Lar during 3 months, patients of 2 nd group not received Sandostatin-Lar.. The Sandostatin-Lar was prescribed 20 mg every 4 weeks for 3 months. The preliminary results showed the stabilization of the tumor residue in 7 of 10 patients (70%) in the group of combined treatment compared to 10 patients from 2 nd group who did not received Sandostatin-Lar.
Conclusions
It is necessary further continuation of research, taking into account immuno-cytochemical studies and biomarkers.

Clinical, paraclinical, therapeutic and evolution profile of pituitary adenomas: about 92 cases

Wahiba Abdellaoui[1], Imane Assarrar[2], Lamiae Zarraa[1], Soumiya Berrabeh[1], Siham Rouf[1, 2] & Hanane Latrech[1,2]
[1]Mohammed VI University Hospital, Medical School, Mohammed the First University, Department of Endocrinology-Diabetology-Nutrition, OUJDA, Morocco; [2]Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy of Oujda, Mohammed the First University, Oujda, Morocco

Introduction
Pituitary adenomas represent about 10 to 20% of all intracranial tumors. They are usually classified according to their size into pico-adenomas, micro-adenomas and macro-adenomas, but can also be classified according to their secretory properties into secreting or nonfunctional adenomas. In this study, we describe the clinica, paraclinica, therapeutic and evolution features of pituitary adenomas in our center.
Material and methods
A retrospective and descriptive study, over a period of 6 years, including 92 patients with pituitary adenoma, followed-up in the Endocrinology-Diabetology and Nutrition department of Mohammed VI University Hospital Center of Oujda, Morocco.
Results
The mean age of the patients was 44 years with a sex ratio (F/M) of 1.6. The clinical features were dominated by headaches and/or visual changes and were reported in 59.8% of patients. Radiologically, macroadenomas were by far the most frequent (70.7%). Hypopituitarism was found in 28.3% of cases. In our study, non-functional adenomas were the most frequent etiology (26.1%), followed by Cushing's disease (22.8%) and prolactinomas (20.6%). Somatotropic adenomas were found in 17.4% of cases. Fifty-eight percent of the patients underwent transphenoïdal surgery, of which 9.8% received radiotherapy. Medical treatment was considered in 63% of patients.
Conclusion
The management of pituitary adenomas must be multidisciplinary engaging neurosurgeons, endocrinologists, radiologists and ophthalmologists. The decision of the therapeutic choice is taken according to several criteria including: size, secreting or functional character, invasive character and response to medical treatment... [1]. All the files of our patients were discussed in a multidisciplinary meeting entitled 'Staff of the pituitary gland'.

A challenging case of sheehan syndrome

Ana Rita Elvas[1], Inê s Vieira[2], Miguel Melo[2], Dí rcea Rodrigues[2], Maria Leonor Gomes[2] & Isabel Paiva[2]
[1]Portuguese Oncology Institute of Coimbra, Endocrinology, Coimbra, Portugal; [2]Coimbra Hospital and University Center, Department of Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
Sheehan Syndrome (SS) is a cause of hypopituitarism resulting from postpartum pituitary infarction. Its frequency is decreasing worldwide, particularly in developed countries due to advances in obstetric care.
Case report
A 50-year-old female patient was admitted to the emergency department with complains of progressive pain in the lower hemithorax and abdomen. She also referred constipation, weight gain and asthenia. The initial laboratory tests showed raised creatinine kinase (4661 U/l [<145]) and aminotransferases (AST 86 U/l [<31]; ALT 36 U/l [<36]). Thyroid function was assessed revealing thyroid stimulating hormone (TSH) of 0.27 uIU/ml [0.4-4.0] and free thyroxine <0.40 ng/dl [0.7-1.5]). Assessment of anterior pituitary function was carried out indicating pan-hypopituitarism: FSH 3.8 mIU/ml; LH 0.6 mIU/ml; Prolactin <0.8 ng/ml [5.2-26.5]; ACTH 16 pg/ml [9-52]; Cortisol 2.1 mg/dl [5-25]; GH <0.1 µg/l [<1]. A brain magnetic resonance imaging (MRI) was performed, revealing the presence of an intrasellar arachnoidocele. She was started on replacement therapy with hydrocortisone and later levothyroxine with symptomatic improvement. The patient had a past medical history of a stillbirth at 28 years old, in Guinea-Bissau, due to postpartum haemorrhage requiring transfusion support. Afterwards a combined oral contraceptive was started, which she maintained for 11 years. After discontinuing the drug at the age of 39, she remained amenorrhoeic.
Discussion
This case fulfils the classic criteria of Sheehan's syndrome with severe postpartum haemorrhage requiring transfusion; postpartum oligomenorrhea; hypopituitarism and the presence of arachnoidocele at brain MRI. Stillbirth in an underdeveloped country is also frequently described and related to a diagnostic latency. The diagnosis was obtained 26 years after the incident, with unspecific symptomatology. The fact that the corticotropic axis tends to be affected later in these cases, may explain the absence of significant consequences. This illustrates a difficulty in diagnosing Sheehan's syndrome outside the acute context and highlights the need to be alert for this entity.

A case with primary autoimmune hypothyroidism causing pituitary enlargement mimicking pituitary macroadenoma and secondary adrenal insufficiency

Mustafa Burak Yaşar[1], Zehra Yagmur Sahin Alak[2], Pinar Uzgec Guller[1], Metin Guclu[1], Fatih Aydemir[3] & Sinem KIYICI[1]
[1]Health Sciences University, Yuksek Ihtisas Research and Training Hospital, Endocrinology and Metabolism, Bursa, Turkey; [1]Health Sciences University, Yuksek Ihtisas Research and Training Hospital, Endocrinology and Metabolism, Bursa, Turkey; [3]Health Sciences University, Bursa Sehir Hospital, Neurosurgery, Bursa, Turkey

Introduction
In primary hypothyroidism, the increase in TRH may cause hyperplasia in the pituitary gland. It has been reported that long-standing hypothyroidism might also cause irreversible pituitary damage, which may lead to a deficiency in one or more pituitary hormones. Herein, we report a case with primary autoimmune hypothyroidism causing pituitary enlargement mimicking pituitary macroadenoma and secondary adrenal insufficiency.
Case
A 17-year-old female patient was diagnosed with primary hypothyroidism when she was 12 years old and levothyroxine-sodium treatment was started. Three years ago, she applied to a tertiary medical center with headache. A solid mass lesion in pituitary gland measuring approximately 15 mm diameter was reported at magnetic resonance imaging (MRI). After hormonal evaluation the mass was considered as a non-functioning macroadenoma and follow-up was recommended. Secondary adrenal insufficiency was observed in follow-up and hydrocortisone treatment was added. She referred to neurosurgery for the operation. Repeated MRI of the sella reported that there was a 10 x 10 mm nodular lesion suspicious for macroadenoma, and pituitary hyperplasia and hypophysitis should be considered in the differential diagnosis. Serum TSH was found suppressed while ft4 and ft3 were in normal range. The patient referred to our center for a differential diagnosis. The patient had fatigue and hair loss complaints. She had regular menstrual cycle and no galactorrhea. The visual field examination was normal. She was using levothyroxine-sodium and hydrocortisone. Macroadenoma wasn't considered when the serial MRI of sella was reevaluated. Pituitary hyperplasia or hypophysitis was suspected as a primary diagnosis. No signs of systemic disease were found clinically in terms of hypophysitis. Serum acute phase reactants and IGG4 levels were normal, and the anti-PIT 1 antibody was negative. Thyroid autoantibodies were positive. Serum TSH level was found increased (>100 uIU/ml) while serum fT4 was low. The hypothalamic-pituitary-adrenal axis couldn't be evaluated due to long-term steroid usage. Other pituitary hormones were normal. We found out that she didn't use levothyroxine-sodium regularly. Previous TSH measurements were occasionally >300 uIU/ml. Pituitary hyperplasia due to irregular replacement was considered. She was warned about regular usage. It was planned to taper and discontinue hydrocortisone during follow-up and reevaluate the pituitary-adrenal-axis.
Discussion
Despite the recent advances in MRI examinations, it might be still difficult to differentiate pituitary adenoma, hyperplasia and hypophysitis. Therefore, the patient's medical history, clinic and laboratory results should be evaluated together carefully. Accurate identification of such patients is important for avoiding unnecessary surgery and costly MRI follow-up.

The management of hypophysitis in Covid-19

Sara Menotti, Miriam Veleno, Antonella Giampietro, Sabrina Chiloiro, Pier Paolo Mattogno, Quintino Giorgio D'Alessandris, Liverana Lauretti, Simona Gaudino, Francesco Doglietto, Alfredo Pontecorvi, Laura De Marinis & Antonio Bianchi
Agostino Gemelli University Policlinic, Endocrinology, Roma, Italy

Introduction
Literature has already described some cases of hypophysitis related to acute respiratory syndrome coronavirus 2 (SARS-Cov2). The pituitary is indeed target for the virus due to the angiotensin-converting-enzyme-2 expression. Hypophysitis patients present with mass effect and pituitary dysfunction related symptoms. ACTH and TSH deficiencies are the most reported, along with central diabetes insipidus (CDI). The best way to manage these hypophysitis is still undefined. However, it must be considered that the prompt correction of Glucocorticoid (GC) therapy in Adrenal insufficiency (AI) is aimed at saving the life of the patients. We describe our experience in the management of hypophisitis in patients who tested positive for SarsCov2, focusing on its two most challenging presentations: adrenal insufficiency and diabetes insipidus.
Discussion
If COVID-19 infection was mild and without fever, we chose to conservatively treat AI patients, with surveillance of symptoms of the onset of adrenal crisis, as nausea, vomiting, abdominal pain and hypotension. Furthermore, we suggested to the patients to monitor their body temperature and to take a careful water balance. If COVID-19 infection was moderate and in any patients at risk of adrenal crisis, we immediately increased the dose of Hydrocortisone to 100 mg (i.m. or i.v) and hospitalized the patients. We raised the GC dose up to Hydrocortisone 300 mg/day for those patients whose clinical condition worsened into acute respiratory distress syndrome (ARDS). In severe COVID-19, the patients who developed central DI may be vulnerable to life-threatening hypernatremia. Patients with severe dehydration were treated with hypotonic fluids, either enterally (using water) or intravenously (using 5% Glucose solution). Desmopressin was administered as occurred, according to the evaluation of the fluid balance, the dosage of natriemia and of plasmatic and urine osmolality. We measured the plasma sodium at frequent intervals (every 12 hours). We accepted mild hypernatraemia (<155 mmol/l) as the price of preventing pulmonary oedema. No patient developed secondary consequences linked to both corticosteroid insufficiency and fatal hypernatremia/hyponatriemia. In hospitalized patients thyroid function was tested at least weekly or more frequently when clinically indicated.
Conclusion
Because of the AI, hypophysitis patients present an increased risk of worsening of COVID-19 infection and developing ARDS. When associated with the central diabetes insipidus, this increases the risk of mortality in these patients. According to our experience, in order to avoid the deterioration of their clinical conditions, it is necessary to keep these patients under strict endocrinological control even when they are hospitalized.

Case of a giant prolactinoma presenting as a clival mass

Pinar Uzgec Guller[1], Mustafa Burak Yaşar[1], Zehra Yagmur Sahin Alak[1], Metin Guclu[1], Fatih Aydemir[2] & Sinem Kiyici[1]
[1]University of Health Sciences, Bursa Yuksek Ihtisas Research and Training Hospital, Endocrinology and Metabolism, Turkey; [2]University of Health Sciences, Bursa Sehir Hospital, Neurosurgery, Turkey

Introduction
Giant prolactinomas are rare tumors accounting for 2–16% of all prolactinomas. They may be aggressive and invasive. Rarely, they might not have a suprasellar component and grow downward. Such extension can make it difficult to distinguish pituitary adenoma from other skull base tumors. We present a case that was considered to be chordoma based on clinical and radiological imaging features, but was diagnosed as prolactinoma by pituitary biopsy.
Case
A 67-year-old male patient with headache, dizziness admitted to the emergency department. There was no pathological finding in his physical examination. Cranial MRI demonstrated a large mass (5 x 3 x 3.5 cm) which destroyed the clivus, extending anteriorly towards the sphenoid sinus, and surrounding both cavernous sinuse. He was referred to neurosurgery department and underwent transsphenoidal biopsy for the differential diagnosis of clival tumors such as chordoma. The histopathological examination revealed it to be pituitary adenoma and immunohistochemical study showed a strong positive staining for the prolactin. He was diagnosed with giant prolactinoma and referred to our outpatient clinic. He reported reduced libido and difficulties in erection. Visual field examination was normal. Hormonal evaluation revealed that serum prolactin level was significantly increased (6290 ng/ml) and serum IGF-1 level was compatible with age and sex. Serum total testosterone level was decreased (115 ng/dl) while FSH and LH levels were within the reference ranges. The pituitary-adrenal and pituitary-thyroid axis were intact. He was started a dose of cabergoline 500 micrograms once weekly. Then the dose increased to 500 micrograms twice weekly as tolerated. He responded well to the medical treatment. Serum prolactin levels dramatically decreased. Pituitary MRI in 12 weeks intervals showed a remarkable reduction in mass.
Conclusion
This case highlights the importance of including invasive pituitary macroadenomas with infrasellar extension in the differential diagnosis of skull base

tumors. Initially, evaluation of clinical signs and hormonal tests in patients with sellar-parasellar masses, can prevent unnecessary invasive procedures.

EP773

Clinical and paraclinical features of pituitary metastases: Report of five cases

Cyrine Chehaider, Ibtissem Oueslati, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
The sellar region is known as a low-risk brain metastasis area. The prevalence of pituitary metastasis represents 1% of all surgical tumors of the pituitary gland. In most cases, pituitary metastasis is identified in patients with a prior history of cancer. In a few cases, it can reveal the primary tumor. The aim of this study was to assess clinical and paraclinical features of pituitary metastasis.
Methods
This was a retrospective and descriptive study including patients with pituitary metastasis admitted to our department. Clinical, hormonal, and radiological data were collected.
Results
Five patients (four women and a man) with a mean age of 51.4 years [extremes: 32-68] were enrolled in this study. Three women had a history of metastatic ductal breast carcinoma. Two women presented with polyuria-polydipsia syndrome and the third one presented with headaches, blurred vision, and decreased visual acuity. Hormonal investigations revealed disconnection hyperprolactinemia ($n=2$), central diabetes insipidus ($n=2$), and hypopituitarism ($n=3$). Pituitary magnetic resonance imaging (MRI) revealed, in both women with polyuria-polydipsia syndrome, a heterogeneous thickening of the pituitary stalk. The third patient presented a large heterogeneous pituitary mass of 27 mm with supra-sellar extension and infiltration of the optic chiasm. In two patients, the primary cancer was revealed by the pituitary metastasis. The first was a 50-year-old woman who presented with headaches, visual disorders, weakness, nausea, vomiting, and hypoglycemia. Pituitary MRI showed a large mass extending from the sella turcica to the sphenoid sinus, optic chiasm, and nasopharynx. Endoscopic biopsy confirmed the diagnosis of undifferentiated nasopharyngeal carcinoma with intracranial extension. Biological investigations revealed hypopituitarism and disconnection hyperprolactinemia. The patient was put on hormone replacement therapy. After corticosteroid treatment initiation, a diabetes insipidus was revealed. The second patient was a 68-year-old man, who presented with polyuria-polydipsia syndrome. The diagnosis of central diabetes insipidus with disconnection hyperprolactinemia and hypopituitarism was established. Pituitary MRI showed a tumor of a 12 mm involving the pituitary stalk and infundibulum. The patient was diagnosed with metastatic small-cell lung cancer.
Conclusion
The hypothalamic-pituitary area is a rare site of metastasis. Clinical presentation and pituitary MRI are the key in guiding the diagnosis. Signs of dysfunction of both the anterior and the posterior pituitary gland are often present. Diabetes insipidus is the most frequent symptom.

Cushing's syndrome due to adrenocorticotropic hormone-secreting metastatic neuroendocrine pancreatic tumor: diagnostic workup and management

Giada Cosentino[1], Luca Manetti[1], Giulia Marconcini[1], Ugo Boggi[2], Riccardo Marconcini[3], Isabella Lupi[1], Daniele Cappellani[1], Claudio Urbani[1] & Fausto Bogazzi[1]
[1]Clinical and Experimental Medicine University of Pisa, Endocrinology, Pisa, Italy; [2]Division of General and Transplant Surgery, University of Pisa, Pisa, Italy; [3]Unit of Medical Oncology 2, Azienda Ospedaliera-Universitaria Pisana, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Italy

We report the clinical history of a 21-years old young female who, in February 2021, presented abdominal pain and biliary vomiting that lasted for two months. An esophagus-gastroduodenoscopy revealed a duodenal ulcerative lesion and proton pump inhibitory therapy was started with clinical benefit. One month later, the patient presented a facial acneiform rush with hirsutism for which she was referred to our attention. An abdominal MRI documented a well-circumscribed hyper-vascular round mass in the pancreatic head with a maximum diameter of 3.5 cm. The fine needle aspiration of the lesion revealed a well-differentiated neuroendocrine tumor, grade 2 (MIB1: 10%). Immunohistochemistry was positive for CK-CAM 5.2, chromogranin, sinaptofisin and a diffuse staining for ACTH in more than 50% of neoplastic elements was detected. Laboratory examination revealed high serum cortisol and ACTH concentrations, respectively 41,1 mcg/dl and 262 ng/l, associated with hyperglycemia and hypokalemia. Futhermore, the 68 Ga DOTA(0)-Phe(1)-Tyr(3)-octreotide (DOTATOC) positron emission tomography (PET) computed tomography demonstrated radiotracer activity within the pancreatic mass with high somatostatin receptor 2 and 5 (SSTR2-5) expression. The hormonal work up was conclusive for ectopic Cushing syndrome (EAS). Hence, the patient was discharged on Ketoconazole (KTZ) 200 mg PO twice a day with clinical and biochemical benefits. In June, the patient underwent duodenocefalopancreasectomy robot assisted surgery with resection of the pancreatic mass, peripancreatic lymph nodes and gallbladder. Histopathological exams confirmed the neuroendocrine origin of the tumor with a Ki67 of 15% and diffuse ACTH staining (pT3 N1 G2 R1). Three months after surgery, the CT scan revealed multiple hepatic metastases while the hormonal exams showed the hypercortisolism relapse. Hence, a double therapeutic approach was planned: oral therapy with osilodrostat (4 mg increased to 10 mg per day) and lanreotide (120 mg monthly). Urinary free cortisol (UFC) declined progressively and clinical signs of CS regressed during therapy. Unfortunately, the subsequent morphologic evaluation with CT, revealed a progression of the hepatic disease. According to the mild hepatic uptake of ^{68}Ga and the extension of the hepatic disease, a radioreceptor therapy or a novel surgery approach were excluded. In December, capecitabine combined with temozolomide (CAPTEM) was started with no adverse events. The second cycle was stopped because of Sars-Cov2 infection of the young patient. In conclusion, EAS is a severe condition that requires rapid management of hypercortisolism; the choice of treatments must be performed in a multidisciplinary team, individualized for each patient, using a shared decision-making approach.

Distribution of E- and N-cadherin in subgroups of non-functioning pituitary neuroendocrine tumours

Kristin Astrid Berland Øystese[1,2], Olivera Casar-Borota[3,4], Jon Berg-Johnsen[5], Jens Petter Berg[2] & Jens Bollerslev[1,2]
[1]Oslo University Hospital, Oslo, Norway; [2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [3]Uppsala University Hospital, Department of Clinical Pathology, Uppsala, Sweden; [4]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [5]Oslo University Hospital, Department of Neurosurgery, Oslo, Norway

Purpose
Clinically Non-Functioning Pituitary Neuroendocrine Tumours (NF-PitNETs) present a varying degree of aggressiveness, and reliable prognostic markers are lacking. We aimed to characterize the distribution of E- and N-cadherin in corticotroph, PIT1 and null-cell NF-PitNETs, and link it to the clinical course of the tumours.
Methods
We investigated the distribution of E- and N-cadherin by immunohistochemistry in a retrospective cohort of thirty tumours of the less common NF-PitNETs (corticotroph ($n=18$), PIT1 ($n=8$) and null-cell PitNETs ($n=4$)). Immunoreactive scores were compared to previously presented cohorts of gonadotroph NF-PitNETs and corticotroph functioning PitNETs.
Results
We found a low immunoreactive score (IRS) for the extracellular domain of E-cadherin, a medium to high IRS for the intracellular domain of E-cadherin and a high IRS for N-cadherin throughout the cohort. The corticotroph NF-PitNETs presented a higher IRS for the extracellular (median 0 (IQR 0-2) and the intracellular (median 9 (IQR 6-12) domain of E-cadherin, and a lower proportion of tumours presenting nuclear E-cadherin (17%) compared to the previous presented gonadotroph NF-PitNETs (P-value < 0.001 for all three comparisons). Presence of nuclear E-cadherin was associated with a weaker staining for the intracellular domain of E-cadherin by the cell membrane (median 4 (IQR 0.5-6) and 9 (IQR 9-12) for tumours with and without nuclear E-cadherin respectively,

P-value <0.001). None of the eight patients presenting tumours with nuclear E-cadherin went through reintervention, while 9 out of 21 without nuclear E-cadherin went through reintervention (*P*-value 0.03).
Conclusion
The immunohistochemical staining for N-cadherin was high throughout the presented cohort. The IRS for E-cadherin varied between subtypes of NF-PitNETs. Nuclear E-cadherin was associated with a lower IRS of the intracellular domain of E-cadherin by the membrane, and with a low rate of reintervention. Considering our results and the benign course of NF-PitNETs, we suggest that a high N-cadherin and downregulation of membranous E-cadherin are not associated with an aggressive clinical course in NF-PitNETs.

Primary cilia in Pituitary neuroendocrine tumours and their association with aggressiveness

Rebeca Martínez-Hernández[1], Ana Serrano-Somavilla[1], Miguel Sampedro-Nuñez[2], María Calatayud[3], Almudena Vicente[4], Gonzalo García-de-Casasola[5], Ancor Sanz-Garcia[6], Manel Puig-Domingo[7] & Monica Marazuela[1]
[1]IIS Princesa, Universidad Autónoma de Madrid, Endocrinology, Madrid, Spain; [2]Hospital La Princesa, Endocrinology, Madrid,; [3]Hospital Universitario 12 de Octubre, Endocrinology, Madrid, Spain; [4]Hospital Virgen de la Salud, Endocrinology, Toledo, Spain; [5]Hospital Universitario Infanta Cristina, Pathology, Parla, Spain; [6]IIS Princesa, Methodology Unit, Madrid, Spain; [7]Germans Trias i Pujol Research Institute and Hospital, Endocrinology, Barcelona, Spain

Purpose
Although growing evidence supports the role of primary cilia (PC) in the regulation of cancer development, their possible role has not yet been studied in pituitary neuroendocrine tumours (PitNETs). The study of cilia could serve as a diagnostic tool providing new insights into the mechanisms of tumorigenesis and aggressiveness of PitNETs.
Methods
A total of 86 patients with PitNETs (28 functioning and 58 non-functioning [NF-PitNETs]) and 12 controls were evaluated by immunofluorescence and immunohistochemistry in tissue microarrays (TMA) and by western blot in PitNETs protein extracts. The frequency of ciliated cells was estimated using a cilia index score based on the length of cilia and the percentage of ciliated area in the tissue. The distribution of PC and its correlation with several clinical parameters and aggressiveness was analysed.
Results
PC were present only in scattered cells of control pituitary tissues, whereas PitNET cells showed robust staining for ciliary markers. Interestingly, the number and /or length of ciliated cells was significantly higher in non-functioning PitNETs, including null cell adenomas and gonadrotropinomas, when compared to functional tumours. Remarkably, PC were significantly increased in non-functioning-PitNETs. In addition, the presence of cilia was associated with tumour invasion, aggressiveness and recurrence in PitNETs.
Conclusions
PC are present in PitNETs, especially in non-functioning PitNETs and may represent an important contributor to aggressiveness. PC may serve as a novel diagnostic marker for predicting tumour behaviour and as a potential target for drug therapy.

Cushing's disease in MEN 4 syndrome

Dina Rebrova[1], Ekaterina Zgoda[1], Leonid Krasnov[1], Vladimir Rusakov[1], Ilya Sleptsov[1], Roman Chernikov[1], Arseny Semenov[1, 2], Elisey Fedorov[1], Igor Chinchuk[1], Ilya Sablin[1], Shamil Shihmagomedov[1] & Ilya Shcherbakov[1]
[1]Saint Petersburg State University, Saint Petersburg State University Hospital, St. Petersburg, Russian Federation; [2]Saint Petersburg State University, Medical Faculty, Saint-Petersburg, Russian Federation

In 2000 female, 28 y.o., admitted endocrinologist with headache, high blood pressure, dark skin and muscle weakness. Lab data showed high levels of ACTH and cortisol, low potassium level. According to MRI scans, pituitary gland seemed normal. On CT in right adrenal was found 32 mm mass with the native density of 20 HU. Diagnosed ACTH-dependent Cushing syndrome (CS). As Mitotane was not available in Russia at that time, she received ketokonazole due to progression of CS but it was canceled later due to intolerance. So, right adrenalectomy was performed. Histology: adrenal adenoma with adrenal hyperplasia. The cortisol level decreased and symptoms diminished. In 2002 pituitary adenoma of 6 mm appeared on MRI. It was resected endoscopically by transsphenoidal approach. Histology: chromophobe adenoma. However, the hypercortisolism and high level of ACTH remained. Later in 2002 she underwent the proton beam surgery with following disease remission. At 2012 the patient had noticed the deterioration of health: skin darkening, high levels of blood pressure, hyperglycaemia. In 2015 the relapse of hypercortisolism was confirmed. According to MRI there were signs of pituitary adenoma relapse (partial empty sella). CT scan showed two adrenal masses up to 23 mm and 10 mm in the left adrenal. Second transsphenoidal partial removal of pituitary adenoma was performed, complicated by liquorrhea, purulent meningitis, secondary hypothyroidism. Second relapse of hypercortisolism with high level of ACTH with no signs of pituitary regrowth on MRI scan occurred in 2018. Ketoconazole therapy was tried once again with bad tolerance and no effect. Right adrenalectomy was performed. The patient is prescribed with adrenal replacement therapy (hydrocortisone 45 mg and fludrocortisone 0,1 mg daily), levothyroxine 100 mkg daily. Levels of ACTH are still persistently high. In 2020 the patient was diagnosed with papillary thyroid cancer and primary hyperparathyroidism. She received right hemithyroidectomy with central neck lymph node dissection, selective parathyroidectomy (lower right and higher left glands). No mutations in MEN1 gene were found. It is known that patient's mother was operated on thyroid gland due to papillary cancer. MEN4 syndrome was described in 2010. We present the patient with 3 MEN4 tumors in absence of MEN1 gene mutations, burdened family history.

Acromegaly with negative pituitary magnetic resonance imaging: a case report

Anis Grassa, Ibtissem Oueslati, Meriem Yazidi, Elyes Kamoun & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Acromegaly is a rare endocrine disorder. In 95% of cases, it is caused by a GH-secreting pituitary adenoma. Rarely, acromegaly is due to ectopic production of GH or growth hormone-releasing hormone (GHRH). Herein, we report a case of acromegaly with negative pituitary magnetic resonance imaging (MRI) and discuss its possible etiology and management.
Observation
A 75-year-old woman was referred to our department for the exploration of acquired acrofacial dysmorphic syndrome. Her past medical history included type 2 diabetes mellitus and hypertension. She presented with paraesthesia of the left hand, arthralgia, and nocturnal snoring. Neither headache nor visual impairment was reported. On physical examination, she had a body weight of 69 kg, a body height of 1 m 68, corresponding to a body mass index of 24.4 kg/m^2, an enlargement of facial features and hands, and a loss of dental articulation. Hormonal investigations revealed an IGF1 level of 424 ng/ml (nr = 55-212), a nadir of GH under oral glucose tolerance test of 7.1 ng/ml (> 1 ng/ml), a TSH level of 1.3 mIU/l (nr:0.35-4,95), a FT4 level of 0.97 ng/dl (nr: 0,7-1,5), a FSH level of 43.9 IU/l, a LH level of 14.64 IU/l, and a prolactin level of 7 µg/l. The peak of cortisol level in response to the insulin-induced hypoglycemia test was 19.7µg/l. Further explorations showed carpal tunnel syndrome, thyroid nodule, and a mild obstructive sleep apnoea syndrome. The chest x-ray and the abdominal ultrasound were normal. Initial and repeat pituitary MRI showed a normal-sized pituitary gland with no evidence of an adenoma. Work-up for ectopic GH-secreting tumor was planned (cervical-thoraco-abdominal computed tomography scan and octreotide scintigraphy).
Conclusion
Acromegaly may be a curable cause when a pituitary adenoma is evident. However, its extra-pituitary origin remains a real challenge as to its localization and management.

TSH-secreting pituitary neuroendocrine tumor revealed after total thyroidectomy, a case study

Bessaid Khadidja[1] & Mouna Mezoued[1,2]
[1]Public Hospital Establishment of Bologhine, Algiers, Algeria; [2]Bologhine Hospital, Endocrinology, Algiers, Algeria

Introduction
TSH-secreting pituitary neuroendocrine tumor (TSH-PitNET) is the rarest pituitary tumors. Most TSH-PitNETs are secreting, with a biological profile of inappropriate TSH secretion (moderately elevated TSH, elevated FT3 and FT4).
Observation
We report the case of a 69-year-old patient, with a history of total thyroidectomy in 2014 for multinodular goiter, hospitalized for suspected levothyroxine pseudo-malabsorption. Despite doses above 2 µg of levothyrox, the TSH always remains high above 10 mIU/l with high FT4. Clinically the patient presents some signs of hyperthyroidism.
Discussion
The diagnosis of pseudo malabsorption is unlikely, despite constantly elevated peripheral hormones the TSH remains elevated. Faced with a biological profile associating elevated peripheral hormones with an unrestrained TSH, the main differential diagnoses are thyroid hormone resistance syndrome and TSH PitNET. The age, sex and level of clinical thyroid functional tests are similar in the two pathologies. Thyroid hormone resistance syndrome is eliminated by a normal preoperative assessment. Hypothalamic pituitary MRI showed a 7.5 mm right pituitary microadenoma. A somatostatin analog braking test at 90 mg/28day was performed, after 2 months of treatment, TSH decreased to 1 mIU/l with reduced doses of levothyrox. The diagnosis of TSH-PitNET is retained in our patient despite the normality of the preoperative assessment which can be explained by a cyclic secretion, or a lifting of inhibition already described in the literature.

Null cell adenoma with low Ki-67 presenting as recurrent pituitary mass

Leo Tiu & Carolyn Montano
Makati Medical Center, Section of Endocrinology, Diabetes and Metabolism, Makati City, Philippines

Background
Approximately one-third of pituitary adenomas are identified as nonfunctioning pituitary adenomas (NFPA) which have a heterogenous profile and an increased potential for relapse one to five years after pituitary surgery. In a retrospective analysis by Almeida et al, multiple surgical resections, elevated ki-67 and cavernous sinus invasion were predictive of recurrence. They typically present with symptoms of mass effect and most are macroadenomas at time of diagnosis.
Clinical Case
A 65-year-old female initially presented with bitemporal hemianopsia, galactorrhea and amenorrhea 28 years prior. She subsequently underwent transsphenoidal hypophysectomy with resolution of symptoms postoperatively. She was clinically stable until 12 years after whenshe had peripheral visual field loss. Upon reevaluation, she was diagnosed with non-functioning pituitary macroadenoma for which she underwent a repeat transsphenoidal pituitary surgery. Her vision improved and she remained asymptomatic thereafter. Sixteen years after her second surgery, she developed blurried vision. Cranial MRI was done which showed lobulated, heterogeneous hyperdense sellar-suprasellar mass measuring 55 x 36 x 47 mm extending to the bilateral sphenoid and ethmoid sinuses, left pterygopalatine fossa, left superior orbital fissure, probably the left foramen lacerum, and left cavernous sinus with encasement of the left internal carotid artery and associated erosion of the adjacent osseous structures. Visual field testing showed mild reduction in field sensitivity with consideration of media opacity and/or uncorrected error of refraction. Baseline hormonal work up was unremarkable. Hence, endoscopic endonasal transphenoidal, transethmoidal parasellar excision of sellar mass, with reconstruction via Hadad Flap was done. There were no intraoperative nor postoperative complications. The specimen was sent for histopathology with provisional anatomic diagnosis of pituitary adenoma. Immunohistochemistry stained negative for chromogranin and any of the pituitary hormones which was consistent with null cell adenoma. The Ki-67, an independent marker of tumor progression and recurrence, was low at less than 1%. However, after 1 month, repeat MRI showed no significant change in the heterogeneously enhancing mass centered in the sellar-suprasellar region. Thus, she received adjuvant radiotherapy with total dose of 5040 cGy divided in 28 fractions and was advised close monitoring of pituitary MRI and development of any new symptoms.
Conclusion
In this case, although with low Ki-67, the presence of multiple surgery and high Knosp grade were recognized as risk factors for its recurrence. Treatment of recurrent NFPAs is multimodal which includes re-operation, radiosurgery and radiation therapy. A multidisciplinary team approach is required for its comprehensive management and long-term follow-up.

Discordant GH and IGF-1 values in a surgically treated acromegaly patient: a management conundrum

Theodor Mustata[1,2], Carmen Sorina Martin[1, 2], Ovidiu Parfeni[2], Bianca Dumea[2], Florina Andrada Predescu[2] & Fica Simona[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania; [2]Elias University Emergency Hospital, Endocrinology Department, Bucharest, Romania

Introduction
Remission after transsphenoidal surgery in patients with acromegaly is confirmed by biochemical assays of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). Although their levels are usually closely correlated, discordant results of these tests have been noted, making the follow-up of acromegaly patients particularly challenging.
Case report
We present the case of a 35 year old female diagnosed with acromegaly at the age of 32 years. At the time of diagnosis a 20.9 x 17 x 16 mm macroadenoma was found on pituitary MRI. IGF-1 was 408 ng/ml (normal age and sex-matched values 115-307), serum nadir GH during a 75 g oral glucose tolerance test (OGTT) was 5.61 ng/ml and prolactin levels were 51.92 ng/ml (normal values < 26.53). She underwent endoscopic transsphenoidal surgery, with immunohistochemistry analysis revealing a mixed somatotroph-lactotroph pituitary adenoma, with a Ki 67 index of 6%. Analysis of GPR101 and AIP genes mutations was negative. She developed transient postoperative SIADH with hyponatermia (sodium values of 118 mEq/l). Postoperative evaluation 3 months after surgery showed no tumor remnant on pituitary MRI, normal IGF-1 [257 pg/ml (normal age and sex-matched values 115-307)], but a lack of inhibition of GH after OGTT (nadir values of 0.733 ng/ml). At this moment the chosen approach was biochemical evaluation every 6 months and annual pituitary MRI. For the next two and a half years the patient had the same biochemical profile of normal IGF-1 but unsuppressed GH during OGTT and no tumor remnant visible on MRI. However, at the last evaluation in January 2022 we found elevated levels of IGF-1 (341.3 ng/ml, 1.23 x upper limit of normal), serum nadir GH during OGTT of 2.55 ng/ml and no changes on pituitary MRI. Taking into account the marginally elevated IGF-1 and the patient's desire to undergo an in-vitro fertilization procedure in the near future, we opted for initiation of therapy with cabergoline until pregnancy is obtained and we are considering referring the patient for a ^{11}C-methionine PET/CT for accurate localization of a potential residual/recurrent pituitary adenoma.
Conclusions
Management of surgically treated acromegaly patients with discordant GH and IGF-1 values is a challenge. Close biochemical evaluation is needed and an individualized approach is warranted, but further studies are needed to asses the risk of disease recurrence and the impact on the patient's quality of life.

Screening of IGF-1 level in patients with Prolactinomas

Yulia Ukhanova & Irena Ilovayskaya
Moscow Regional Research and Clinical Institute named by M.F. Vladimirsky, Neuroendocrine Unit, Department of Endocrinology, Russian Federation

Objective
to determine the need for screening for IGF-1 levels in patients with prolactinomas and without obvious symptoms of acromegaly.
Matherials and methods
A pilot cross-sectional study, based on the analysis of medical records of patients with confirmed prolactinoma, who applied to the Moscow Regional Research and Clinical Institute named by M.F. Vladimirsky. A total of 88 patients were included in the study. The frequency of studying the level of IGF-1, and the frequency of detecting cases of acromegaly were evaluated in patients with prolactinoma. The level of IGF-1 was determined in 60/88 patients with prolactinoma. Among patients with prolactinoma, women with microadenoma (Fmi) - 17, women with macroadenoma (Fma)- 16, men with microadenoma (Mmi) - 7, men with macroadenoma (Mma) - 20. The median level of prolactin at the onset of the disease was 2330 mU/l (1010; 4389) in Fmi, 10006.5 mU/l in Fma (1917.6;95106.3), in Mmi 2017.52 mU/l (1626;4382), in Mma 6080 mU/l (14000;104700).
Results
Among patients with a known level of IGF-1, its increase was recorded in 6/60 patients with prolactinomas. An oral glucose load (OGL) was performed in all 6 patients. The diagnosis of acromegaly was confirmed in 2 Fmi. The percentage of excess of the IGF-1 levels above the upper limit of the normal in patients with a negative test – 20.1%, 45.58%, 46.09% and 115.1%, in patients with diagnosed acromegaly – 70.8% and 217.6%.
Conclusions
In real clinical practice, the level of IGF-1 was determined in 68.2% of patients with prolactinomas. At the same time, the proportion of identified patients with acromegaly among the examined patients with prolactinomas but without obvious clinical signs of acromegaly, was 3.33%. Considering the obtained results, the question of the necessity of screening the level of IGF-1 in patients with prolactinomas requires further study.

Polyuria-polydipsia in an athletic teenager

Mihaela Rosu[1], Felicia Baleanu[1], Taujan Georgiana[1], Olga Kosmopoulou[1], Blerta Papadopoulou[1], Luiza Gambini[2] & Iconaru Laura[1]
[1]CHU Brugmann, Department of Endocrinology, Brussels, Belgium; [2]Kanton Spital Aarau, Department of Endocrinology, Aarau, Switzerland

Introduction
Central diabetes insipidus is characterized by partial or total ADH deficit of various origins. The clinical picture is dominated by massive polyuria with diluted urine, increased thirst and daily water consumption reaching impressive quantities.
Case report
We report the case of a 16 year-old male teenager presenting with excessive thirst and water intake of 8 -10 l/day and voiding large quantities of diluted urine. Symptoms started gradually over the past 3 years. He attributes his increased thirst to increased transpiration during his recently restarted judo-training and he states he can abstain from drinking water if he has to, especially during school-time. He denies headaches and troubled vision. Physical examination was unremarkable, except for a grade 1 obesity (BMI 32 kg/m^2) of recent onset (interruption of regular training during first COVID lock-down). Personal history is devoid of chronic diseases and head trauma and he denies consumption of medication or recreational drugs. Family history is positive for type 2 diabetes in all his four grandparents. Lab tests including electrolytes and pituitary axis returned normal. A thirst test was undertaken, starting at 23.00 h and conducted until 12 p.m. next day. Sodium concentration increased from 140 to 143 mEq/l, serum osmolality increased from 284 to 294 mOsm/l, while urine osmolality raised slightly from 602 to 679 mOsm/kg. No signs of dehydration and no hypotension occurred during the test. At the final blood draw copeptine was measured at an external laboratory. Patient was discharged with no treatment awaiting the results of hypophysis IRM and copeptine. At the follow-up, he still reports a water intake of 3 to 7 l per day. The IRM of the hypophysis and IgG4 level were normal. Copeptine measured at 1.7 pmol/l for a osmolality of 294 mOsm/l (normal range 2.3-24.5 pmol/l for osmolality between 291 and 295 mOsm/kg) thus showing insufficient increase and suggesting a partial deficit of ADH. Arginin- vasopressin was initiated at a dose of 25 microg/day sublingual in the morning. At one–week follow-up water consumption decreased to 1.5-2 l/day, urine output normalized, while maintaining normal sodium and serum osmolality.
Conclusion
The copeptine value and the response to the therapeutic trial of arginine-vasopressin helped diagnosing a central partial ADH deficit which we considered idiopathic, however repeated minor head trauma during his years-long judo-training may have also played a role in the onset of the disease.

A novel population of activated cytotoxic T cells infiltrate pituitary neuroendocrine tumour subytpes

Oriana Mazzitelli[1], Jean Paul Ebejer[2, 3], Nikolai Paul Pace[4], Mark Gruppetta[4, 5], Josanne Vassallo[4, 5] & David Saliba[1]
[1]University of Malta, Faculty of Health Sciences, Msida, Malta; [2]University of Malta, Centre for Molecular Medicine and Biobanking, Msida, Malta; [3]University of Malta, Faculty of Information & Communication Technology, Msida, Malta; [4]University of Malta, Faculty of Medicine and Surgery, Msida, Malta; [5]Mater Dei Hospital, Neuroendocrine Clinic, Msida, Malta

Non-functional pituitary adenomas (NFPA) are non-hormone secreting pituitary tumours while growth hormone-secreting pituitary adenomas (GHPA) are active pituitary tumours causing acromegaly. Since immunotherapy is becoming the preferred therapeutic strategy in cancers, understanding the diversity of immune cells infiltrating the tumour microenvironment is warranted. However, little is known about the immune landscape of pituitary tumours. We validated an acoustic-assisted hydrodynamic focusing cytometer based method (Attune, Thermofisher) to identify rare immune cell populations in NFPA ($n=6$) and GHPA ($n=3$) obtained from patients undergoing transphenoidal surgery. We unravelled key cellular populations of myeloid (macrophages and monocytes) and lymphocytic (CD4 and CD8 T cells) origin using a multi-colour panel of antibodies against cell surface (CD45, CD163, CD64, CD11b, CD3, CD56, CD19, CD4 and CD8) and intracellular (CD68, T-bet, GATA-3 and FOXP3) antigens and assessed the degree of T-cell activation using the CD44 marker. We also checked for the expression of immune checkpoint and exhaustion markers PD1 and TIM-3 respectively. In all samples, lymphocytic infiltrates were detected. In all except 1 NFPA and in all GHPA the CD8:CD4 ratio was greater than 1 ranging from 1.88 - 5.74 in NFPA and 1.35 - 5.21 in GHPA with no statistical difference between NFPA and GHPA. This method also revealed novel populations of activated, cytotoxic T cells in all pituitary adenomas analysed. We are currently characterising the function of these cells in such tumours and how their presence correlates with the patients' clinical data and tumour characteristics.

Clinical case of syndrome of inappropriate secretion of antidiuretic hormone (SIADH) with uncertain localization

Ekaterina Pigarova, Larisa Dzeranova, Nino Katamadze, Khava Fargieva, Natalya Malysheva, Larisa Nikankina & Elena Przhiyalkovskaya
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
The syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is characterized by hypotonic and euvolemic hyponatremia along with urinary hyperosmolarity, resulting from antidiuretic hormone (ADH) release in the absence of adequate stimuli.
Case report
A 59-year-old woman, presented with complaints of constant thirst, general weakness, memory loss, episodes accompanied by headaches, leg cramps,

increased blood pressure. From the anamnesis-for the first time hyponatremia 114-123 mmol/l (135-145), was revealed during hospitalization for fainting 5 years ago, this episodes repeated several times a year. At the same time, a pituitary non-active macroadenoma of 22*12*9 mm (Knosp 2) was found, without indications for surgical treatment during yearly observation by MRI. All diagnostic criteria for SIADH were met in the form of repeatedly confirmed hypotonic hyponatremia with urine osmolality exceeding the blood plasma osmolality (412-520 mOsm/kg), and normal urinary sodium excretion of 92-162 mmol/l and GFR > 60 ml/min. Hypothyroidism and adrenal insufficiency were excluded. Cardiac, hepatic and renal functions were normal. Medications included azilsartan 40 mg and amlodipine 5 mg. To search for the source of a possible ADH-secreting tumor, an oncological search was performed with ultrasound of the thyroid gland, abdominal cavity, CT of the lungs with contrast, gastro- and colonoscopy. She also underwent PET/CT 'whole body' with 68Ga-DOTATATE, according to which no pathological formations were detected. According to the results of which, a node of the right lobe of the thyroid gland 11 x 10 mm was revealed, with a fine-needle aspiration biopsy - Bethesda II. Drinks about 2000 ml (of which 300-400 ml is 0.9% saline), releases 1700-1800 ml of urine per day. Copeptin (Phoenix) -1.659 ng/ml (0.178-2.578 ng/ml), Oxytocin (BMA Biomedicals) -2.668 ng/ml (0-12.821 ng/ml), Apelin-12 (Phoenix) -2.026 ng/ml (0.620-2.095 ng/ml), BNP (RayBiotech)-981.63 pg/ml (646.3-2033.4 pg/ml). Since the synthesis of ADH occurs in the nuclei of the hypothalamus, and the hormone is only stored and secreted in the posterior lobe of the pituitary gland, then the pituitary adenoma per se presumably cannot be a source of ADH (the patient refused the proposed adenectomy).
Conclusions
The modern diagnostic arsenal is not sufficient to identify the source of inadequate secretion of ADH. Fluid restriction and oral saline administration are effective and well tolerated long-term therapeutic interventions.

Epidemiological data of prolactinomas in the Republic of Uzbekistan

Zamira Khalimova & Mijgona Safarova
[1]Republican Specialized Scientific Medical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Objective
To create a national register of prolactin-secreting pituitary adenomas to assess the prevalence of various forms and the effectiveness of therapy.
Material and research methods
National register of patients with pituitary prolactinomas in the Republic of Uzbekistan, includes 172 cases with pituitary prolactinomas, of which 61% (105 women) and 37.2% (64 men), aged 17-74 years, mean age 38.5 ± 12.6 years and 3 (1.7%) children and adolescents. All 172 patients underwent studies of somatic, endocrine, gynecological status, the levels of prolactin, LH, FSH, TSH, free T4, progesterone, estradiol, testosterone, IHLA method, MRI of the chiasmatic - selar region were studied.
Results
Prolactinomas were more common in women (62.7%) than in men (37.2%), with a predominance of their frequency in women aged 21-30 years (66.7%), in men aged 41-50 years (59, 3%). Depending on the size, the patients were distributed as follows: microadenomas 98 (5.7%), macroadenomas -53 (30.8%), giant adenomas with aggressive growth 21 (12.2%). Prolactin levels varied from 7.8 to 530 ng/ml on average in men 94 ± 3.7 in women - 162 ± 9.4 ng/ml. According to the applied methods of treatment: 128 patients (74.4%) are on drug therapy with modern drugs of dopamine agonists, transsphenoidal adenomectomy in 44 patients (25.6%), including 21 with giant (12.2%), 12 with macroadenoma (7%)) and 10 with resistant prolactinomas (5.8%). Treatment outcomes were euprolactinemia in 142 (82.5%), persistent hyperprolactinemia against the background of SPTS in 31 (18%), panhypopituitarism in 28 (16.3%), remission was not achieved in 8 (4.6%)), fertility disorders in 57 (33.1%), including 8 men and 49 women, continue to occur.
Conclusion
Pituitary prolactinoma affects young women and men, predooming them to long-term medication and are a serious cause of infertility in both sexes.

The Nelson's Syndrom (about 3 cases)

Lionel Stève Kamgain Simeu, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Teaching Hospital, Endocrinology, Diabetology, Metabolic Disease and Nutrition, Casablanca, Morocco

Introduction
The Nelson's syndrom (NS) is defined by the development of an ACTH pituitary adenoma. Complication of bilateral adrenalectomy performed in some cases of Cushing's disease.
We report the observation of three patients.
Case1
34-year-old patient, followed for Cushing's disease with pituitary microadenoma, having undergone pituitary surgery, then bilateral adrenalectomy due to surgical failure. Presented two years later an SN associating skin hyperpigmentation, high level of plasmatic ACTH and a pituitary adenoma measuring 10 mm. Having undergone a pituitary adenomectomy. Because of surgical failure and given the difficulty of surgical revision, a treatment associating Cabergoline with stereotactic radiotherapy was instituted.
Case2
21-year-old patient, followed for ACTH-dependent Cushing's syndrome with bilateral thickening of the adrenal glands on CT scan. Patient having benefited from a bilateral adrenalectomy, complicated Nine months later by an NS associating skin hyperpigmentation, high level of plasmatic ACTH and a pituitary microadenoma. In failure after two surgical revisions, he benefited from stereotactic radiotherapy.
Case3
48-year-old female patient, followed for Cushing's disease with pituitary microadenoma, having undergone pituitary surgery, then bilateral adrenalectomy due to surgical failure. Present Ten years after an NS, associating skin hyperpigmentation, high level of plasmatic ACTH, and a pituitary adenoma measuring 20 mm. She underwent a pituitary adenomectomy. Faced with the persistence of the NS after surgery, a treatment associating Cabergoline with stereotactic radiotherapy was instituted.
Conclusion
The management of the NS despite the therapeutic advance, remains heavy and associated with significant morbidity, hence the interest of early detection.

Case report in a patient with insulinoma

Katerina Cheshlaroska Markushoska[1], Biljana Todorova[2], Hristina Cheshlaroska[3] & Belma Bilaloglu Jovanoska[2]
[1]General Hospital Borka Taleski, Internal Medicine, Prilep, Macedonia; [2]University Clinic of Endocrinology, Diabetes and Metabolic Disorders, University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia; [3]Faculty of Medicine, Internal Medicine, Skopje, Macedonia

Introduction
An insulinoma is a neuroendocrine tumor, deriving mainly from pancreatic islet cells, that constantly produces insulin even when blood sugar is very low. Insulinomas are the most common cause of hypoglycemia resulting from endogenous hyperinsulinism. Biochemical diagnosis of insulinoma is established during prolonged fasting test (up to 72 hours) in 95 % of patients, 90-95% of insulinomas can be diagnosed during 48 hours of prolonged fasting. After biochemical confirmation of the existence of insulinoma, imaging studies are used to localize the tumor.
Material and methods
A female patient aged 54 years, mother of two children, no smoker. In menopause from 3 years ago. She has arterial hypertension from the past disease, regulated by an angiotensin receptor blocker. The patient consults the ambulant of Endocrinology Clinic due to symptoms of malaise, fatigue and tingling in the mouth, which occurred episodically and improved after ingestion of carbo-hydrates. During one such episode, glycaemia was measured at 2 mmol/l. She gives information that she does not remember events from the recent past. On one occasion she lost consciousness. These symptoms were started a year ago, so the patient was examined by a neurologist and the existence of neurological disease

has not been established. From the outpatient analysis fasting plasma glucose 3.1 mmol/l, HbA1C: 4.4 %, OGTT: O min: 4.6 mmol/l, 120 min: 1.5 mmol/l, due to suspicion of insulinoma the patient is hospitalized for additional examination.
The diagnosis is made by a prolonged fasting test and a computed tomography scan with contrast to localize the insulinoma. Multiple endocrine neoplasia type 1 is excluded due to other laboratory analyses – parathyroid hormones, the hormones of the hypophysis, ionized Calcium which are in the referent values. The patient was referred for surgery and the histopathological examination confirmed the diagnosis of insulinoma. Postoperative patient without symptoms, with glycaemia in reference values.
Conclusion
When we have a case of insulinoma we need to determine whether it is an isolated case or is part of multiple endocrine neoplasia type 1 (MEN 1). In the case of the patient we are treating we concluded that it is an isolated case of insulinoma.
Because 90 % of insulinomas are benign and long-term cure with a total resolution of preoperative symptoms is expected after complete resection.

GH provocative tests stimulate the growth in children without GH deficiency

Anna Tortora[1], Vincenzo Marotta[2], Giulia Izzo[2], Domenico Rocco[3], Gennaro Clemente[4] & Mario Vitale[3]
[1]Clinica Endocrinologica e Diabetologica, Salerno, Italy; [1]Clinica Endocrinologica e Diabetologica, Salerno, Italy; [3]Dipartimento di Medicina e Chirurgia, Salerno, Italy; [4]IRPPS Consiglio Nazionale delle Ricerche, Penta di Fisciano, Italy

Introduction
GH deficiency (GHD) is a clinical disorder characterized by pathological short stature in the child, altered body composition, impaired psychological well-being and reduced quality of life. These alterations are almost always reversible after recombinant human GH (rhGH) administration, which is currently the only accepted treatment for the subjects with GHD. Secretory dysfunction is confirmed when GH peak does not reach the established cut-off in at least two different stimulus tests performed in two different days. When tests response is considered adequate, the short stature is considered idiopathic and no GH replacement therapy is advised.
Objective
To determine the effect of GH provocative tests on growth rate in children without GH deficiency.
Design and Methods
Children of both gender with pathological short stature (h< 3°percentile) and/or annual growth rate <-2 SDS but with normal response to two GH provocative tests, were selected. Diagnosed endocrinopathies, other organ dysfunction, autoimmune diseases, genetic syndrome or current drug therapies were excluded. Height, mid-parental height, body weight, and body mass index were registered. The height and annual growth rate were converted to percentiles and Standard Deviation Score using reference ranges standardized for age and sex and were recorded pre and post stimulus tests and during subsequent follow-up over time. GH provocative tests employed arginine or clonidine as secretagogues.
Results
Twenty-one children of both genders were enrolled. Heights were measured at test time and at a mean time prior and after the tests of 209 days and 192 days respectively. Children displayed a 5-fold increase of their annual growth rate. The mean growth rate of children pre- and post-tests were -4.3 SDS and +2.0 respectively ($P<0.0001$). In 9 children the height was measured two times after the tests at an average time of 228 days and 887 days. All children displayed a stimulated growth also in the second time interval after the tests, with a decremental in some.
Conclusions
Two sequential somatotropic axis provocative tests increase the growth rate in non-GHD children with pathological short stature and that this effect persists for several months.

Sarcopenia and frailty in acromegalic patients

Kader Ugur[1], Hasan Eryeşil[2], Ramazan Fazıl Akkoç[3] & Ahmet Karatas[4]
[1]Faculty of Medicine, Firat University, Department of Internal Medicine (Endocrinology and Metabolism Diseases), Elazığ, Turkey; [2]Faculty of Medicine, Firat University, Department of Radiology, Elazığ, Turkey; [3]Faculty of Medicine, Firat University, Department of Anatomy, Elazığ, Turkey; [4]Faculty of Medicine, Firat University, Department of Rheumatology, Elazığ, Turkey

Introduction
Acromegaly is a clinical syndrome associated with excess growth hormone. The present study aimed to investigate sarcopenia and frailty, which could affect mortality and morbidity, in patients with acromegaly.
Method
Twenty outpatients diagnosed with acromegaly were included in the study. The hand muscle strength of the patients was measured by electronic hand dynamometer (Model EH101, Zhongshan Camry Electronic Co. Ltd. China). Computed tomography, imaging at the L3 level was used to measure the abdominal muscle mass area (cm2). Measurements for the skeletal muscle mass index abdominal muscle mass area were expressed in (cm2)/height (m2). Normal values for men and women were considered >52.4 cm2/m2 and >38.5 cm2/m2, respectively. The Tilburg Frailty Indicator was used to determine the frailty of the patients. The Social Sciences Version 26.0 software was used to perform analyses in line with appropriate statistical methods.
Results
Thirteen patients were female and 7 were male. The mean age and time of diagnosis were 45.65±9.7, 10.4±6.4 years respectively. Sixteen patients received medical treatment, while 4 did not. Eighteen patients underwent surgical treatment. While 17 patients were in remission 3 patients had active disease under treatment. The mean body mass index of the patients was 29.95±5.1 kg/m^2. The mean hand muscle strength of the patients was 37.36±13.8 kg. 14 of all patients had frailty. Hand muscle strength in patients with and without frailty was 37.2±14.6 kg and 37.6±13 kg, respectively ($P=0.953$). Furthermore, there was no statistical difference in frailty between the patients by the remission status ($P=0.891$). Mean cross-sectional skeletal muscle area was 145.8±33.7 cm^2. The mean skeletal muscle index (SMI) was 53.1±9.7 cm^2/m^2. While sarcopenia was detected in 1 female patient, there was no difference in SMI levels between the groups in terms of SMI by the remission status ($P=0.794$).
Conclusion
The risks associated with sarcopenia and frailty increase as a result of increased intra-muscle fat storage due to increased insulin resistance, extended duration of the disease, accompanying hormonal changes, and decreased mobility due to joint pain. In the present study, patients with acromegaly had higher levels of frailty. In conclusion, it is important to carry out routine assessments for frailty and sarcopenia, which are associated with multifactorial causes, and to take timely measures based on a multidisciplinary approach in order to improve the quality of life and prevent the comorbidities of the aging population with acromegaly, which may induce high mortality and morbidity.

A mini case series of hypophysitis with atypical presentation

Rukiye Dilara Tekin Uzman[1], Ş eyma Aksoy[1], Sebnem Burhan[1], Mutlu Niyazoğlu[1] & Esra Şüheda Hatipoğlu[1]
[1]Başakşehir Çam ve Sakura Şehir Hastanesi, Endocrinology and Metabolism Diseases, Istanbul, Turkey

Introduction
Hypophysitis is a rare condition characterized by inflamation of the pituitary gland, causing mass effect and hypopituitarism. The incidence is estimated to be 1in9 million/year. The diagnosis of hypophysitis is based on clinical and laboratory findings, imaging methods and histopathology in selected cases. The aim of the treatment is to eliminate the compression effects of the mass and to treat hypopituitarsim. The first choice in medical treatment is immunsupressive drugs. Surgical treatment can be considered for patients with progressive visual defects unresponsive to medications. Certain cases may be followed without immunesupression or surgical intervention. Here in we present cases with hipophysitis of atypical presentation.

Clinical Cases

Case 1:

A 20-year female presented with headache, blurred vision, oligomenorrhea and galactorrhea. Basal cortisol was 1.89μg/dl, other anterior pituitary hormones were in referance ranges. A 22 x 17 mm hemorrhagic atypical macroadenoma was present on the pituitary MRI. The stalk thickness was not increased. The patient underwent transsphenoidal surgery; pathologic specimen showed infiltration with lymphocytes, plasmacells and CD68(+) histiocytes; which were evaluated as xantamatous hypopysitis. After the operation the patient's complaints regressed. However glucocorticoid replacement was continued.

Case 2:

A 55-year male presented with headache, vomiting, fever, diplopia, polyuria and polydipsia for 10 days. Laboratory findings at first presentation showed hypocortisolemia, partial central diabetes inspidus, central hypothyroidism and lymphopenia. On the pituitary MRI, a 22 x 17 mm macroadenoma was observed. Initially an adenoma was suspected based on imaging, however hypophysitis was considered in the differantial diagnosis due to a spontaneous decrease in dimensions to 17 x 9 mm (>50%) and increased stalk thickness in control imaging. Lymphopenia improved spontaneously. For the differantial diagnosis laboratory invesitgations including inflammatory markers, IgG4, Covid-PCR and antibodies and, investigations for other infectious and inflammatory/infiltrative diseases showed only increased Covid antibody (IgG>250 U/ml). Patient was evaluated as a secondary hypophysitis after an unrecognised Covid infection.

Case 3

A 35-year male with acute onset headache, double vision and 6th cranial nerve palsy had 16 x 18 x 21 mm cystic lesion (macroadenoma) with increased stalk thickness on pituitary MRI. Pituitary hormones and other laboratory findings were within normal levels. Hipophysitis was considered, however with the acute presentation of mass effects transsphenodial surgery was performed. The intraoperative mass had a purulent apperance, and the pathology was evaluated as abscess and lymphocytic hypophysitis. The microbiologic evaluation confirmed a sterile abscess. Postoperatively the patients complains regressed completely and there was no need for any hormonreplacement therapy.

Conclusion

Hypophysitis is a rare condition with variable presentations. Diagnostic and treatment modalities may vary for each case. Not all cases require immunesupressive treatment and, a case based specific approach is necessary.

The natural course of hypopituitarism at diagnosis and following therapy in non-functioning pituitary macroadenomas

Ziad HUSSEIN[1,2,3], Hani J Marcus[4], Joan Grieve[4], Neil Dorward[4], Peirre Bouloux[3] & Stephanie Baldeweg[3,5]

[1]University College London Hospitals NHS Foundation Trust, London, United Kingdom; [2]Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom; [3]University College London, United Kingdom; [4]National Hospital for Neurology and Neurosurgery, United Kingdom; [5]University College Hospital, United Kingdom

Background

Non-functioning pituitary macroadenomas (NFPMs) may present with hypopituitarism. Pituitary surgery and radiotherapy pose an additional risk to pituitary function.

Aims

The aim of this study was to assess the incidence of hypopituitarism preoperatively and the impact of surgery and radiotherapy on pituitary function.

Methods

All patients treated with surgery and radiotherapy for NFPMs between 1987 and 2018 with more than 6 months follow-up were identified. A retrospective case note review was performed.

Results

Overall, 383 patients were identified, 256 patients (256/383; 67%) were men. The median age was 57 years (IQR 48-67) with median follow-up of 5 years (IQR 2-9). 58 patients (58/377, 15%) presented with pituitary insufficiency, however, on endocrine evaluation, 235 patients (235/377; 62%) had evidence of pituitary impairment. Growth hormone deficiency occurred in 115 patients (115/273; 31%), hypogonadotropic hypogonadism in 161 patients (161/375; 43%), 132 patients (132/375; 36%) recorded to have adrenal insufficiency and 157 patients (157/375; 42%) developed secondary hypothyroidism. Anterior hypopituitarism was reported in 100 patients (100/377; 26%). With regards to treatment modality; 318 patients (318/383; 83%) were treated with surgery alone and 65 patients (65/383; 17%) were treated with surgery and radiotherapy. Histological analysis showed gonadotroph adenomas in 271 patients (371/383; 97%) and plurihormonal adenomas in 12 patients (12/383; 3%). At latest follow-up, 105 patients (105/383; 27%) had no evidence of pituitary impairment post therapy while 278 patients (278/383; 73%) suffered endocrine dysfunction. Patients who were treated with surgery and radiotherapy had a greater degree of partial and complete adenohypophysial hormone deficit than those treated with surgery alone as demonstrated in the table:

Conclusion

Non-functioning pituitary macroadenomas are associated with significant degree of hypopituitarism at time of diagnosis as well as post therapy. The combination of surgery and radiotherapy are associated with higher risk of pituitary dysfunction. Regular endocrine evaluation and lifelong follow-up is required following NFPMs treatment to screen for hormone deficiency and provide appropriate replacement therapy.

Table 1

	Total	Surgery	Surgery and radiotherapy	P value
GH	165/383 (43%)	118/318 (37%)	47/65 (72%)	<0.0001
FSH/lH	178/383 (46%)	136/318 (43%)	42/65 (65%)	0.001
ACTH	156/383 (41%)	111/318 (35%)	45/65 (69%)	<0.0001
TSH	206/383 (54%)	151/318 (47%)	55/65 (85%)	<0.0001
Anterior hypopituitarism	133/383 (35%)	90/318 (28%)	43/65 (62%)	0.0001

Importance of neurosurgical expertise and multidisciplinary approach in pituitary patients

Simone Pederzoli[1,2], Maria Laura Monzani[1, 2], Sara De Vincentis[21, 2], Bruno Madeo[4], Chiara Diazzi[1] & Vincenzo Rochira[1,2]

[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background

Multidisciplinary approach to pituitary disease is highly recommended; it requires a close relationship between expert pituitary surgeons and endocrinologists together with several specialists (e.g. neuroradiologists) in order to provide a high-level standard of care. Although there is evidence that neurosurgeons' expertise is a key element to achieve better outcomes, also endocrinologists' role is fundamental but it may sometimes encounter real-life barriers.

Aim of the study

To explore from a real-life database the impact of neurosurgical centre expertise on post-surgical outcomes in pituitary patients attending a tertiary academic medical centre.

Methods

A retrospective, observational, single-centre study was carried out including all patients attending the Endocrinology Unit of Modena (Italy) that underwent pituitary surgery from January 1995 to December 2020. For each patient, preoperative features of the pituitary lesion, surgery information and post-surgical outcomes (i.e. residual neoplasia, surgery-related complications and pituitary function) were collected from record charts. Patients were grouped according to the expertise degree of the centre where they underwent surgery: Group1 included patients treated in neurosurgical centres with high expertise in pituitary surgery (defined as ≥50 transsphenoidal pituitary surgeries per year); Group2 included patients treated in neurosurgical centre performing <50 transsphenoidal pituitary surgeries per year.

Results
A total of 132 patients (67 men, 65 women; mean age at surgery 50.4 ± 16.8 years) were included. Considering the histological diagnosis, 114 patients (86.4%) had a pituitary adenoma, 11 patients (8.3%) had a craniopharyngioma, and 7 patients (5.3%) had other rarer diagnoses. Group1 included 63 patients (47.7%) and Group2 included 69 patients (52.3%). A pre-surgical endocrinological evaluation was performed in almost all patients with adenoma (89.3%), and just only in 37.5% of patients with craniopharyngioma ($P < 0.001$). Interestingly, patients without a pre-operative endocrinological evaluation were significantly more frequent in Group2 (26.3%) than Group1 (1.9%) ($P < 0.001$). We analysed post-surgical outcomes focusing on pituitary adenoma patients. Patients in Group2 had an almost eight-fold increased likelihood to have residual neoplasia (OR: 8.53; 95% CI: 3.45-21.09) and five-fold increased likelihood to have hypopituitarism (OR: 5.53; 95% CI: 2.41-12.73), while no difference was found for post-surgical complications (9.6% in Group1 vs 22.4% in Group2; $P = 0.070$).
Conclusions
This study confirms that high pituitary neurosurgical expertise is essential to achieve better post-surgical outcomes. The lack of pre-operative endocrinological evaluation is significantly associated to surgery performed in a not-experienced centre. A close multidisciplinary cooperation between experienced endocrinologists and neurosurgeons is required both before and after surgical procedures.

EP794

Pituitary deficiencies after brain injury: a practical approach to evaluation and management

Tamara Wexler[1,2]
[1]NYU Langone, New York,; [2]University of Pennsylvania, Philadelphia,

While increasing attention is being paid to the health effects of brain injury, the role that neuroendocrine dysfunction may play in patients' health after traumatic brain injury (TBI) remains underappreciated. Pituitary deficiencies are seen at a high rate in patients who have sustained TBI, with reports of chronic pituitary dysfunction in 15-60% of adults after TBI, and up to 42% of children and adolescents. Deficiencies may resolve over time, or develop years after injury, and may occur after mild or severe injury. While there is a large and growing body of literature on the risk of pituitary dysfunction after brain injury, differences in assays and definitions account in part for the broad range of reported prevalence, and highlight the importance of a rigorous review of the evidence. Given the large number of people with a history of TBI, there has been much investigation into features that may predict neuroendocrine dysfunction. Studies have investigated biomarkers, imaging characteristics, and types of injury, but no consistent clinically useful association has been described**.** Thus, we rely on signs and symptoms to determine whom to screen**.** The overlap in symptoms seen in pituitary deficiencies and following TBI, and the potential clinical benefit of identifying hypopituitarism, make it particularly important to be aware of patterns that suggest pituitary dysfunction. Symptoms from hypopituitarism include cognitive, physical, and emotional effects, and overlap with symptoms from other etiologies including TBI itself. Clinical symptoms may include difficulties with executive function, increased anxiety and irritability, irregular menses, sexual side effects, and fatigue, and delay physical and neurorehabilitation efforts. It is particularly important to be aware of patterns that suggest pituitary dysfunction in patients with persistent symptoms after TBI, as replacement of deficient hormones can ameliorate or reverse the effects of hypopituitarism. In addition, there are indications that the cognitive issues and fatigue that may be seen as part of "Long Hauler" syndrome after COVID-19/SARS-CoV- infection may be related to pituitary deficiencies. This presentation will review the current understanding of pituitary dysfunction following TBI and the clinical relevance of pituitary axes, and offer a practical approach to evaluation and treatment; emerging information regarding other forms of brain injury will be included, and specific populations (military, children, women) will be highlighted.

Response to classic dynamic tests of a corticotropinoma due to Nelson's syndrome

Foteini Adamidou, Paraskevi Komzia, Efstathios Divaris, Athanasios Panagiotou & Marina Kita
Ippokration General Hospital, Department of Endocrinology, Thessaloniki, Greece

Introduction
Nelson's syndrome is a rare complication of Cushing's disease treated with bilateral adrenalectomy. There is no effective medical treatment yet. Nelson's patients respond to hypothalamic stimuli distinctly from patients with Cushing's disease and those with Addison's disease. We describe the responses to standard ACTH stimulation tests in a patient with Nelson's syndrome.
Case report
A 42-year-old woman presented with ACTH dependent Cushing's syndrome. Pituitary MRI was suggestive of a lesion on the left side, measuring 4 x 3 mm and an ectopic source of ACTH was excluded. Following an unsuccessful transphenoidal surgery in 2013, she was placed on pasireotide 0.6 mg twice daily for one year. Partial response was seen on pasireotide, but she developed severe hyperglycemia. Fluconazole 200 mg daily was tried for 6 months, in conjunction with cabergoline 1 mg twice weekly, with little benefit. The patient finally had a bilateral adrenalectomy in3/2016 and was replaced with hydrocortisone 20 mg am-10 mg pm and fludrocortisone 0.1 mg/d, while maintaining all other pituitary axes intact. Two years later (2/2018), a pituitary tumor was visible on the right lateral pituitary, which grew further in the next 32 months to 10 mm (10/2020). Gradual skin hyperpigmentation was noticeable since 2018. The patient remained hyperglycemic but managed well with GLP-1R agonist and metformin. Her ACTH levels gradually increased since 2016, reaching am levels of 1886 pg/ml (7-64) and late evening levels of 1235 pg/ml (5-30) in late 2021. The patient had an exaggerated response to desmopressin stimulation with ACTH > 2000 pg/ml (dilutions were not performed) to x3 above baseline at 15', remaining at this level beyond 120'. An exaggerated response was noted following CRH stimulation, with ACTH rising from 1741 pg/ml to > 2000 pg/ml at 15', returning to baseline at 120'. ACTH decreased to 134 pg/ml following overnight suppression with 8 mg dexamethasone.
Conclusions
Abnormal and distinct hypothalamic-pituitary dynamics underlie the pathophysiology of Nelson's syndrome, which cannot be explained solely on lack of adrenal negative feedback. In patients with otherwise intact pituitary function repeat neurosurgery or radiotherapy are not desirable options and pasireotide use is similarly limited. A case for blockade of CRH receptor blockade can be a rational therapeutic option in this clinical situation.

Incidental discovery of pituitary insufficiency after non-pituitary surgery

Tamari Khutsishvili[1], Irine Lomtadze[2] & Miranda Baratashvili[3,4]
[1]Todua Clinic, Endocrinology, Tbilisi, Georgia; [2]Aversi Clinic, Endocrinology, Tbilisi, Georgia; [3]Endocrinology, Tbilisi, Georgia; [4]Helsicore, Endocrinology, Tbilisi, Georgia

Introduction
Pituitary Insufficiency is life threatening condition, that can lead or manifest by any stressful situation (surgery, infections, intoxication and etc)
Case report
A 70-year-old man diagnosed with Bladder Cancer had underwent surgery - Cystoplasty. The operation was performed without complications, but, after the intervention, the general condition of the patient sharply declined. There appeared strong general weakness, blurred consciousness, frequent abdominal pains, bradycardia, lowering of T/A(< 80/50 mmHg), fever. His condition required intensive care.
Laboratorial tests:
Na – 133-135 (130-152)mmol/l, K – 3.7 (3.6-5.2)mmol/l, CRP – 173 (< 5)mg/l, creatinine – 132 μmol/l, CBC - Leukocytosis, Urine total - bacteria – 205 cell/ul (< 11.4), Consultations with a Neurologist, Infectionist, Endocrinologist were conducted. TSH, FT4 tests were prescribed, we got a remarkable results – TSH - 1.25 (0.4-3.7) mIU/l, FT4-4.72 (12-22) pmol/l. Besides that, based on the recommendation of a Neurologist, the patient underwent MRT examination of the

brain. An introspectively revealed changes (adenoma?) was seen as the result of examination that is more likely to be Pituitary apoplexy (P/A). According to the findings, there was a doubt that it could be Central Hypothyroidism. The following studies have been scheduled: Cortisol, ACTH in Blood. So we have got worrisome results again: Cortisol – 3,9 (4,3-22,4) mg/dl, ACTH -3.36 (1.6-10.21) pmol/l.According to lab tests (Low Ft4, normal TSH, low cortisol, MRT results) patient was likely to have pituitary hypofunction, that causes central hypothyroidism and central hypocorticism. The patient was diagnosed with the following: Pituitary Hypofunction (E27) Pituitary damage, unspecified (E27.3) Other hypothesized hypothyroidism (E03.8), Malignant tumor of the bladder, unspecified (Ch 67.9)
Prescription
-Hydrocortisone 20 mg/day, In two days - Euthyrox 37 mcg/day 2-3 days after the medication administration patient's condition improved dramatically, T/A, pulse, temperature had been normalized (Antibiotic therapy due to urine infection was going). Patient got active, started adequate speech, movement and communication. We have checked Patient's lab tests in 10 days – TSH -1.8 (0.4-3.7) mIU/l, FT4- 8(12-22) pmol/l, Cortisol –13 (4,3-22,4) mg/dl, he was discharged home. Repeated examination of MRT of the brain, monitoring Pituitary, thyroid hormones, electrolytes is planned. Patient should be under constant supervision of an Oncologist and Endocrinologist.

Severe heart failure in a young male with unrecognized hypopituitarism

Bojana Caric[1,2], Marko Stojanovic[3, 4], Gabrijela Malesevic[1, 2], Siniša Nikolić[5], Aleksandra Grbic[1, 2] & Dragana Miljić[6,7]
[1]University Clinical Centre of the Republic Srpska, Clinic of Internal Diseases, Department of Endocrinology, Banja Luka, Bosnia and Herzegovina; [2]School of Medicine, University of Banja Luka, Banja Luka, Bosnia and Herzegovina; [3]Clinic of Endocrinology, Diabetes and Metabolic diseases, Clinical Centre Serbia, Department of Neuroendocrinology, Belgrade, Serbia; [4]Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia; [5]Department of Physical Medicine and Rehabilitation 'Dr Miroslav Zotović', Banja Luka, Bosnia and Herzegovina; [6]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre Serbia, Department of Neuroendocrinology, Belgrade, Serbia; [7]Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia

Background
The partial or complete hypopituitarism is described as late complication of hemorrhagic fever with renal syndrome (HFRS). Imaging methods of pituitary gland examination in the chronic phase showed pituitary atrophy, but a precise pathogenic mechanism that causes pituitary damage in HRFS remains unclear. While hypopituitarism in HFRS is rarely described, cardiac failure as a known complication of hypopituitarism is even more rarely described. We present a case of severe heart failure in a young male patient with unrecognized hypopituitarism consequent to HFRS and undiagnosed hemochromatosis.
Case Presentaton
42-year-old male patient was admitted at the Department of Endocrinology of University Clinical Centre of Republic of Srpska with suspected hypopituitarism. He managed to walk with the help of another person, and his speech was incoherent and with difficulties. The patient was pale, facial and body hairless with adynamia, myxedema, hypotension, and bilateral gynecomastia with decreased libido and impotency. Echocardiography verified a global reduction in myocardial contractility, dilated left atrium and ventricle, with low ejection fraction (10-15%). Results of hormone tests confirmed diagnosis of panhypopituitarism, and replacement therapy (hydrocortisone, levothyroxine and testostreone) was started. MRI of the pituitary gland was performed and it showed an "empty sella". On the third day after the therapy was introduced, the patient started to speak clearly and mental status was stabilized. The patient was independently mobile after seven days. Echocardiography performed a month after the replacement therapy was introduced showed an improvement in myocardial contractility with normal dimensions of the atrium and ventricle and estimated EF of 40%. Additionally, the diagnose of chemochromatosis was confirmed by genetic analysis of the HFE gene and presence of homozygosity for mutation pH63D (c 187 >G), but the specific therapy was not initiated. At follow-up visit, 6 months after introduction of replacement therapy, the patient felt well, performed usual physical activities, male type of facial and body hair distribution recovered, his sexual function normalized, and he had a normal mental status. Echocardiography was completely normal 6 months after introduction of replacement therapy (the left ventricle with normal dimensions, EF 58%).
Conclusion
The heart failure is extremely rare complication of hypopituitarism, but it is usually reversible when hormonal therapy is replaced. According to significant relationship and a high prevalence of hypopituitarism as a consequence of HFRS, endocrinological investigation should be considered in patients with HFRS and clinical signs and symptoms suggestive of hypopituitarism.

Silent somatropic adenoma in young girl about a case

Charlene Ludwine Bifoume Ndong[1,2], Fatima Zahra El Jaafari[1,2], Sana Rafi[2], Ghizlane EL Mghari[2] & Nawal EL Ansari[2]
[1]Department Of Endocrinology, Metabolic Diseases and Diabetology, University Hospital Of Mohammed VI, Marrakech, Morocco

Introduction
Clinically non-secreting pituitary adenomas are rare in children We report a case of a silent somatotropic adenoma revealed by anatomopathology.
Case
A 13 year-old patient with no prior history of sudden onset intracranial hypertension syndrome. Clinical examination showed no dysmorphic Syndrome, no galactorrhea, no delay or statutory advance, Tanner P1S3. The MRI reveals a heterogeneous tumor process intra and suprasellar of 30 mm *15 mm of large axes, containing pockets of necrosis exerting a mass effect on neighboring structures and in particular on the optic nerves and quiasma evoking a priori craniopharyngioma. Initial hormonal balance: T4: 17,1 pmol/l;Cortisol:8,85 g/dl Prolactina:10,25 ng/ml, FSH: 2,2 UI/l; LH:0,1 UI/l; Eostradiol:8,2 ng/l and visual fields bitemporal hemianopsia. Partial transsphenoidal pituitary surgery performed in emergency with simple surgical follow-up and supplemented thyreocorticotropic deficit. The anatomopatho-immunohistochimical study concludes to a tumor proliferation with round cells whose morphological aspect first evokes pituitary adenoma secreting GH with Ki67 to1%. Before this and the normal initial IGF-1 at 360.1 ng/ml (90-581) a GH braking test under HGPO is performed with a GHnadir at 2.03 ng/ml confirming hypersecretion ofGH. Patient scheduled for surgery.
Discussion
Pituitary adenomas are rare tumors in children and adolescents whose most common type is prolactinoma followed by somatotropic as our case. The clinical expression of somatotropic adenoma is correlated with the early age of GH hypersecretion in relation to the welding or not of the epiphyses giving way to acromegalogigantism or gigantism. None of these dysmorphia have been found in our case thus signing the silent character of this somatotropic. The initial hormonal balance doesn't direct to any pituitary hypersecretion especially with a normal IGF-1 for age. Our presentation by ICHT syndrome, radiological elements as well as age were all in favor of craniopharyngioma which remains the most common tumor at this age. Only anatomopathological examination with positive immuno-labeling for GH supplemented by a GH braking test under HGPO initially not performed allowed to retain the diagnosis. The treatment is surgery with possible treatment by somatostatin analogous in case of no cure hence the surgical resumption planned for our case.
Conclusion
Before any sellar tumour any clinico-radiological presentation in children the anatomopathological study is the sole guarantaor of specific treatment.

Endocrine dysfunction in hemochromatosis

Ben Salem Maram, Wafa Grira, Nadia Khessairi, Meriem Yazidi & Melika Chihaoui
Hospital La Rabta, Departement Of Endocrinology, Tunis, Tunisia

Introduction
Hemochromatosis is associated with iron overload that is responsible of iron deposit causing multiple organ dysfunctions which affects especially endocrine glands.

Methods
We report four cases of pituitary hemochromatosis responsible of endocrine dysfunction.
Results
Three women and one man were included, aged respectively 28, 19, 26 and 35 years old. These patients were suffering from ß-thalassemia and treated with multiple blood transfusions. All patients had delayed puberty with primary amenorrhea and erectile dysfunction. Hormonal screening showed hypogonadotropic hypogonadism with all the patients. They were treated with hormonal substitution. Two patients presented inaugural diabetic ketosis and were treated with insulin for the diabetes mellitus. One patient was diagnosed with corticotroph deficiency and was treated with hydrocortisone. Thyrotropic and somatotropic axis were normal with all patients. No cardiac or hepatic dysfunction was found with these patients.
Discussion and conclusion
Secondary hemochromatosis is responsible of multiple endocrine dysfunctions. The most endocrine dysfunction in hemochromatosis is diabetes mellitus and hypogonadotropic hypogonadism. The other endocrine dysfunctions are rare. Screening for endocrine dysfunction must be systematic and so a regular follow-up for all patients with hemochromatosis.

Hyperprolactinemia, thyrotropic and corticotropic insufficiency in a patient with end-stage renal failure

Yasmine Mouelhi, Nadia Khessairi, Ameni Terzi, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis

Introduction
Hyperprolactinemia is a condition of elevated prolactin levels in blood which could be physiological, pathological, or idiopathic in origin. Some cases of hyperprolactinemia have been reported in patients with renal failure. We present a case of hyperprolactinemia, thyrotropic and corticotropic insufficiency in a patient with end-stage renal failure.
Case presentation
The patient was 27 years old, with a history of hypertension, renal insufficiency at the stage of haemodialysis, tertiary hyperparathyroidism and thyrotropic insufficiency. She was admitted to our endocrinology's department, in October 2021, for further exploration of the other pituitary axes. She had no functional complaints. The physical examination showed a weight of 49 kg with a body mass index of 20.3 kg/m^2. BP was 150/80 mmHg and there were galactorrhea on breast examination .
The biological investigations showed :
- Thyrotropic insufficiency : TSH : 0.099 mUI/l [usual values : 0.35-4.95]; FT4 : 0.69 ng/dl; FT3 :2,39 pg/ml [usual values:1.71-3.71];
- FSH :4.8 UI/l, LH :45.31 UI/l;
- Hyperprolactinemia was confirmed PRL : 229.66 and 255.03 mg/l
- Testosterone : 2.04 mmol/l;
- PTH : 1877.8 ng/dl [15-68]; Calcemia : 2.46 mmol/l
- A corticotropic insufficiency had been confirmed by a hypoglycemia test, and a treatment by hydrocortisone was started.
A Hypothalamic pituitary MRI was performed and showed no abnormalities.
Conclusion
This case confirmed that pituitary function is abnormal in patients receiving haemodialysis. Hyperprolactinemia is common and may be a factor in the infertility and sexual dysfunction in patients with end-stage renal disease.

Title
Pulmonary Embolism in Surgically Treated Cushing's Disease: A Case Report
Authors
Qetevan Gvazava1, Nino Zavrashvili1, Natia Margvelashvili2, Natia Shonia2, Ketevan Chanturishvili2 Endocrinology Department, Tbilisi Institute of Medicine
Background
Cushing's disease is the most common cause of Cushing's syndrome but can be very difficult to diagnose and to treat. as we know it has numerous health effects on patients and long-term health and quality of life in these patients often remains suboptimal, despite treatment. patients with CS have about ten times the risk for VTE. 2019 meta-analysis encompassed 7142 patients with endogenous CS (including Cushing's disease) undergoing transsphenoidal surgery or adrenalectomy, and their risk of unprovoked VTE was almost 18 times higher in comparison with a healthy population. The aim of this case report is to underline the clinical significance of increased VTE in endogenous Cushing's syndrome and to keep high clinical suspicion after undergoing transsphenoidal surgery.
Case Description
We report 57 years old women, who was hospitalized in our hospital with declining health for 6 months. Patient complained of weight gain, discomfort in chest area, face and neck edema, muscle weakness and overall low energy. Upon physical examination and appropriate laboratory work-up, this patient was diagnosed with ACTH dependent Cushing's syndrome. Head MRI later confirmed Cushing's disease and patient was set up for transsphenoidal surgery for removal of pituitary adenoma. Few weeks post-op patient presented in ER with tachycardia, shortness of breath, chest pain. PE was diagnosed and patient was started on anticoagulative therapy, oxygen therapy and close monitoring. It also needs to be mentioned that the patient had a history of hypertension and valve replacement, as well as Covid-19 disease.
Conclusion
In conclusion we want to highlight that CS is a risk factor for VTE/PE, which is often overlooked. It is important to keep high clinical suspicion and continue close monitoring of CS patients even after transsphenoidal surgery treatment. Physicians who treat VTE/PE cases should also be aware of increased risk associated with Cushing's disease.

Hypothalamic neuropeptides as biomarkers for water-electrolyte disturbances

Nino Katamadze, Aleksandra Shutova, Ekaterina Pigarova, Larisa Dzeranova & Khava Fargieva
Endocrinology Research Centre, Moscow, Russian Federation

Hypothalamic neuropeptides as biomarkers for water-electrolyte disturbances. Introduction Diabetes insipidus is a rare condition characterized by excretion of large amounts of dilute urine and increased thirst. Nephrogenic diabetes insipidus (NDI) is caused by the inability of the kidneys to concentrate urine in response to vasopressin.
Aim
The aim of our case report is to present the patient with NDI and to report the data on physiological changes in hypothalamic neuropeptides such as copeptin, oxytocin, apelin, brain natriuretic peptide (BNP) in patient with NDI.
Material and methods
21-year-old male patient was admitted to the hospital with chief complaint of increased thirst and urinary frequency.
Results
In accordance with the results of indirect water-deprivation test NDI was diagnosed in our patient due to maximum urine osmolality of less than 76 mOsm/kg, plasma osmolality 302 mOsm/kg, maximum plasma sodium was 148 mmol/l, and no change in urine osmolality after administration of 2 mg of s.c. desmopressin. Copeptin, oxytocin, apelin, BNP after 8-h fluid restriction accounted for: 0.844 ng/ml (0.178-2.578 ng/ml), 5.694 ng/ml (0-12.821 ng/ml), 1.476 ng/ml, (0.620-2.095 ng/ml),1225.86 pg/ml (646.3-2033.4 pg/ml) and at the peak of dehydration (for 16 h) accounted for: 1.058 ng/ml, 6.176 ng/ml, 1.346 ng/ml, 973.93 pg/ml.
Conclusion
Our data confirm a commensurate increase in the levels of copeptin and oxytocin with a reciprocal decrease in the concentrations of apelin and BNP against the background of additional dehydration, which can later be used for differential diagnostic procedures for the syndrome of polydipsia-polyuria.

Hashimoto's encephalopathy : a case report

Zineb Mhamdi, Kaoutar Rifai, Hinde Iraqi & Mohamed Hassan Gharbi
Ibn Sina University Hospital, Department of Endocrinology and Diabetology, Rabat, Morocco

Introduction
Hashimoto's encephalopathy or SREAT (steroid-responsive encephalopathy associated with auto-immune thyroiditis) is a rare autoimmune disorder that is particularly corticosensitive and whose pathogenesis remains poorly understood. It is associated with high levels of antithyroid antibodies in plasma and/or CSF. Clinical manifestations are deceptive and may include cognitive and behavioral disturbances, seizures or abnormal movements.
Case report
We report the case of a 54-year-old female patient who presented with progressive abnormal movements with balance disorders. The clinical examination revealed a cerebellar syndrome, a cerebellar dysarthria with an abolition of the osteotendinous reflexes. Brain MRI was without abnormalities. The electroencephalogram showed a diffuse slowing of the background rhythm without paroxysmal figure. Lumbar puncture revealed a clear cerebrospinal fluid without pleocytosis with hyperproteinorachy at 1.01 g/l. Antithyroglobulin and antithyroperoxidase antibodies were positive (anti-TPO antibody: 493 IU/ml and anti-TG antibody: 20 IU/ml) with a normal TSH. The diagnosis of Hashimoto's encephalopathy was retained after ruling out other causes, including metabolic, vascular, toxic, infectious and neoplastic. Intravenous corticosteroid therapy at a dose of 1 g of methylprednisolone per day was started for 3 days, followed by oral corticosteroid therapy at a dose of 1 mg/kg for one month and then gradually tapered off over 2 months. The patient was controlled with prednisone 2.5 mg per day with good improvement of her neurological symptomatology.
Discussion and conclusion
Hashimoto's encephalopathy is often underdiagnosed. The revealing neurological signs are polymorphic. Its pathophysiology is controversial, an autoimmune cerebral vasculitis is evoked. It should be systematically investigated in cases of unexplained encephalopathy, by looking for anti-TPO antibodies in the CSF even in cases of euthyroidism. This case highlights the different and often confusing clinical presentations of Hashimoto's encephalopathy but also its particular corticosensitivity.

Gestational diabetes insipidus: about a case

Amal Elkhomri, Bensbaa Salma, Nassim Essabah Haraj, Siham El aziz & Asma CHADLI
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Diabetes insipidus during pregnancy is rare (4/100,000 pregnancies) generally occurring in the last two trimesters. It can be a previous diabetes insipidus, revealed by pregnancy, or a gestational diabetes insipidus. It would be secondary to the plasma degradation of antidiuretic hormone by placental vasopressinase.
Observation
We report the case of a 34-year-old patient, with no history of head trauma, radiation, infiltrative or autoimmune disease. who presents for a polyuro-polydipsic syndrome evolving since the second trimester of her pregnancy, with inputs at 5 liters per day and outputs at 7 liters. At the paraclinical level: Natremia at 134 mmol/l, with normal serum potassium at 4.4 mmol/l, low natriuresis at 20 mmol/24 h, plasma osmolarity at 285 mOsmo/l, and low urinary osmolarity at 160 mOsmo/l, Hypothalamo-pituitary MRI was without abnormalities, the patient was started on desmopressin nasally, the pregnancy was carried to term, with a cesarean delivery without insidents, giving birth to a new born female of 3500 g the postpartum evolution was marked by the disappearance of the polyuro-polydipsic syndrome after the second week
Conclusion
Gestational diabetes insipidus is therefore a polyuro-polydipsic syndrome which appears in pregnant women due to a deficiency in antidiuretic hormone. Rather rare, it usually disappears within three weeks after delivery.

Endocrinopathy behind the facemask

Sandhi Nyunt[1], Parizad Avari[1], Giridhar Tarigopula[1], Niamh Martin[2], Catherine Mitchell[1] & Yong Yong Ling[1]
[1]Hillingdon Hospital, Diabetes and Endocrine, London, United Kingdom; [2]Charing Cross Hospital, Diabetes and Endocrine, United Kingdom

A 44-year-old gentleman presented to the Emergency Department with a 2-week history of fevers and rigors. Past medical history was unremarkable other than an earlier diagnosis of hypertension. He was noted to have new onset atrial fibrillation with rapid ventricular response, and a new diagnosis of hypertrophic obstructive cardiomyopathy (HOCM) was made on echocardiography. In addition, a vegetation was identified on the mitral valve. Treatment for infective endocarditis (Streptococcus oralis) was initiated and he was subsequently transferred to a specialist centre for mitral valve replacement surgery. During the admission, a history of chronic headaches was investigated. MRI pituitary revealed a 3.8 x1.9 cm pituitary macroadenoma with suprasellar extension. There was no cavernous sinus invasion. He was further evaluated in the outpatient endocrine clinic. On removal of his facemask, examination revealed typical acromegalic features with supraorbital ridge prominence, significant underbite and macroglossia. Visual fields were normal to confrontation testing and no organomegaly was present on bedside examination. Urgent endocrine investigations including baseline pituitary function testing were performed. IGF-1 was significantly elevated at 140.3 nmol/l (range 8.5-31.0), 9am cortisol was 352 nmol/l (range 200-750), prolactin 1119 mU/l (range 60-300), TSH 1.98 mU/l (range 0.34-5.60), FSH $<$0.U/l (range 1.7-8.0) and testosterone 8.7 (range 10.0-30.0). Acromegaly was confirmed with an oral glucose tolerance test showing a paradoxical rise in growth hormone. Glucose levels remained normal throughout the OGTT. The patient was commenced on monthly Lanreotide injections and referred to the specialist neuro-endocrine clinic to determine the best course of further management. Unfortunately, this gentleman's endocrine management was further complicated by a second hospital admission with persistent bacteraemia. Further redo of his mitral valve replacement is being considered, and safety of pituitary surgery at this stage remains a concern. In this case, radiotherapy could be a more suitable treatment option for acromegaly. This case highlights the requirement for early diagnosis and treatment to prevent further complications, as well as the need for individualisation of complex treatment decisions within a multidisciplinary setting. Cardiovascular complications including HOCM, arrhythmias, arterial hypertension and valvulopathy, as well as colonic benign neoplasms such as polysis, are common complications of acromegaly. For people presenting with 'idiopathic' HOCM, a IGF-1 may be considered to screen for acromegaly. Finally, the requirements for facemasks and virtual telephone consultations during the Covid-19 pandemic have likely compounded potential delays in diagnosis.

Pituitary hypertrophy secondary to primary hypothyroidism (one case report)

Lionel Stève Kamgain Simeu, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Teaching hospital, Endocrinology, Diabetology, Metabolic Disease and Nutrition, Casablanca, Morocco

Introduction
There are several causes of sellar and suprasellar mass, and pituitary hyperplasia secondary to primary hypothyroidism has been reported in the literature.
Case report
20-year-old patient, born from a consanguineous marriage, presenting with failure to thrive. Patient reporting no tumor syndrom. Clinical examination: Height at 88 cm ($<$-4 SD), weight at 18 kg ($<$3rd percentile), BMI at 23 kg/m2. TANNER at G2P0, micropenis length of 5 cm ($<$-2.5 DS), infantile voice, elf-like features,

with periorbital puffiness, flat nasal bridge, short upturned nose with bulbous tips, large mouth with everted and broad lower lips. Patient with friendly behaviour. Thyroid not palpable, no clinical signs of pituitary hypersecretion. Paraclinical findings: TSHus >500 mIU/l (0.35-4.94) >100 times normal T4L: 2.81 pmol/l (10.6-19.4). IGF-1: 19.26 ng/ml (27-114). Cortisolemia before 10 hrs: 8.5 ng/dl (3.7-19.4) Prolactinemia: 118 ng/ml (3.6-19.4). Cervical ultrasound: heterogeneous thyroid gland without detectable nodules. Bone age: 1 year 6 months RISSER test: 0 Pituitary MRI: pituitary hypertrophy, without clearly detectable nodule. The patient benefited from a substitution by Levothyroxine and Somatostatin analogue with a good evolution.
Conclusion
Pituitary enlargement secondary to primary hypothyroidism should be considered as a differential diagnosis of solid pituitary masses, especially when associated with growth and pubertal retardation. Adequate care helps to avoid no need surgeries.

EP807

Giant prolactinoma in an adolescent girl revealed by visual impairment

Hind Asbar, Hind Ouakrim, Sana Rafi, Ghizlane EL MGHARI & Nawal EL ANSARI
Chu Mohamed Vi Marrakesh - Drh, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Pituitary adenomas are rare in infants and adolescents. Prolactinomas account for 50% of these pituitary adenomas. In adolescent girls, it is usually a microprolactinoma revealed by puberty delay or amenorrhea. We report a rare case of a macroprolactinoma in an adolescent girl revealed by visual impairment.
Case presentation
A 15-year-old adolescent girl presented with loss of vision over a long period of time. Magnetic resonance imaging revealed an expansive sellar and suprasellar mass measuring 48x47x37 mm consisting of cystic and solid components in favor of craniopharyngioma. Patient underwent transsphenoidal surgery for tumor resection. Post operative labroratory findings were in favor of a hyperprolactinemia with prolactine of 600 ng/ml and a thyrotrope deficiency. Histological assessment confirmed diagnosis of prolactinoma. Pituitary MRI control revealed a 20x9x17mm residual macroadenoma. Patient was started on cabergoline resulting in lowering prolactin levels and tumor shrinkage.
Discussion
Prolactinomas are rarely found in adolescents. Tumoral syndrome with visual impairment can be seen in large tumors in males. In girls, the most frequent presentation is a microprolactinoma revealed by amenorrhea. Less frequently, it can be revealed by pubertal delay or short stature. In our case, the patient presented with a macroprolactinoma revealed by visual impairment that was initially accounted for a craniopharyngioma. Medical treatment by dopamine agonists like in adults is the first line therapy as it's effective in up to three quarters of cases.
Conclusion
Prolactin levels should be measured in every child or adolescent with visual impairment and a large suprasellar tumor to rule out a prolactinoma that can be successfully managed by medical therapy.

Inappropriate antidiuretic hormone secretion syndrome associated with covid 19 pneumonia

Amani Mezzi, Najla Bchir, Zouaoui Chedia, abderrahim yosra, chhida anaam & Ouertani Haroun
The Principal Military Hospital of Instruction of Tunis, Tunisia

Introduction
Hyponatremia is a commonly associated with atypical pneumonia. One of its pathophysiological mechanisms is inappropriate antidiuretic hormone secretion(-SIADH). We describe the case of a patient presenting an SIADH caused by COVID19 infection.
Observation
We report a case of a 70-year-old man, known to have well-controlled hypertension, with a medical history of cavum's neoplasia treated with radiotherapy and hypothyroidism post thyroidectomy for multinodular goiter. He was admitted in the intensive care unit for 'status epilepticus' caused by severe hyponatremia (120 mmol/l). The hormonal investigation showed a normal thyroid function test (TSH:2.06 uU/ml FT4 11.4 pmol/l) and a normal stimulated cortisol at 524 nmol/l. Therefore, the diagnosis of SIADH was retained. It was based on euvolemic hyponatremia with concurrent low serum and high urine osmolality (265 mosm/l and 338 osmol/24h, respectively) and high urine sodium (75 mmol/24h). Concerning the etiological investigation, we evoked the disorders of the central nervous system caused by cerebral radiotherapy but it goes back to 6 years during which the natremia was normal. Negative tumor markers, absence of tumoral process on the CT-scan and the normal bronchial fibroscopy infirmed paraneoplasic syndromes. Nasopharyngeal RT-PCR and abnormal chest CT-scan depicting bilateral infiltrates and bilateral pleural effusion confirmed COVID-19 infection. The course was marked by pneumonia's healing at the expense of SIADH's persistence. Currently, the patient is on fluid restriction, his natremia varies between 120 and 137 mmol/l.
Discussion
SIADH may be the only presentation of covid19. This association has been reported in the literature, but the course of the hyponatremia after pneumonia's healing was not mentioned. The pathophysiology is unknown. Several theories were suggested: hypoxemia, stress, nausea, IL6 secretion. However, none of those theories explains the persistence of SIADH after recovering from pneumonia.

Association between uncontrolled acromegaly and nasopharyngeal tumor-case presentation

Valeria Nicoleta Nastase[1], Burcea Iulia-Florentina[1,2], Amalia Raluca Ceausu[3], Anca Maria Cimpean[3], Marius Raica[3] & Catalina Poiana[1,2]
[1]'C.I. Parhon' National Institute of Endocrinology, Pituitary and Neuroendocrine Pathology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania; [3]Victor Babeş University of Medicine and Pharmacy, Department of Microscopic Morphology/Histology and Angiogenesis Research Center, Timişoara, Romania

Introduction
Acromegaly is characterized by elevated levels of growth hormone (GH) and insulin-like growth factor 1 (IGF-1), most often due to a pituitary tumor. Persistent high levels of these hormones lead to a constellation of signs and symptoms and systemic complications associated with increased mortality. A potential association between acromegaly and cancer has been hypothesized regarding colorectal, thyroid, and prostate cancers, but there are few or no descriptions for other kinds of tumors.
Case presentation
Male, 49 years old, presented with headache, multiple episodes of loss of consciousness, joint pain, profuse sweating. Clinical examination revealed acral enlargement, generalized thickening of the skin, prominent supraorbital ridges, nose enlargement, prognathism. Hormonal assessment showed increased levels of IGF-1 (2.8 x upper limit of normal, ULN) and high levels of nadir GH in the oral glucose tolerance test (OGTT, 10.3 ng/ml). All others anterior pituitary hormones were within normal range. Pituitary MRI revealed a hypophyseal mass with heterogenous signal (23/14 mm). The patient underwent surgical removal of the pituitary macroadenoma using transsphenoidal resection. The immunohistochemical (IHC) examination showed positivity for GH and prolactin (PRL). Three months after surgery, the patient presented active disease (IGF-1 = 1.8 x ULN, nadir GH in OGTT = 3.24 ng/ml), with a small pituitary remnant (9/7 mm). The disease persisted uncontrolled after two years of treatment with Octreotide LAR up to 40 mg/28 days, Cabergoline up to 3 mg/week and Pegvisomant up to 40 mg/week (associated in the last three months, with good control of GH secretion). The patient developed severe obstructive sleep apnea documented using polysomnography. Fibroscopy reported a glossy, smooth tumor occupying completely the choanal quadrant and pegvisomant was withdrawn. Surgical intervention was performed, and the histopathological examination described a sessile polyp on the background of a chronic erosive rhinopharyngitis. IHC analysis revealed a positive cytoplasmic reaction for GH in tumoral cells. Two months after the nasopharyngeal tumor resection, IGF 1 was within normal range on somatostatin analogue and dopamine agonist.
Conclusion
Active acromegaly defined by GH excess and increased levels of IGF-1 contributes to mitogenesis, delayed apoptosis and malignant proliferation. In the current case, uncontrolled acromegaly was associated with a nasopharyngeal

tumor presenting IHC positive expression for GH. This aspect could partially explain the decreased IGF-1 levels after surgical intervention and a better therapeutical response to standard medical treatment and could raise the hypothesis of a tumor invasion.

Hypopituitarism in adults - the importance of clinical suspicion

Ana Rita Elvas[1], Mariana Lavrador[2], Miguel Melo[2], Luí sa Barros[2], Maria Leonor Gomes[2] & Isabel Paiva[2]
[1]Portuguese Oncology Institute of Coimbra, Endocrinology, Coimbra, Portugal; [2]Coimbra Hospital and University Center, Department of Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
Hypopituitarism is a rare entity that can have different aetiologies. Symptoms are usually progressive and non-specific; therefore, many patients are under-diagnosed and untreated. We present a clinical case of a patient presenting septic shock, hyponatremia and central hypothyroidism.
Case report
A 46-year-old man was admitted in ICU for septic shock of unknown origin and multiorgan failure. Hormonal profile showed central hypothyroidism, prolactin and gonadotropins deficiency. The integrity of corticotropic axis could not be assessed due to the immediate introduction of glucocorticoids, with a significant improvement in clinical status. An MRI was performed, which revealed increased dimensions of the sella turcica, with an apparent bone discontinuity of the sella turcica floor; it was not possible to visualize the right lobe of the adenohypophysis and the remaining pituitary gland had reduced dimensions. He was discharged home medicated with hydrocortisone and levothyroxine and was referred to Endocrinology outpatient clinic. He presented an history of previous traumatic brain injury (TBI) eighteen years earlier, requiring medical observation and an episode of intense headache with associated vomiting, eight years before when he started his complaints of asthenia, reduced libido, pale skin and decreased body hair began. Its fertility was unknown as he had no wish for procreation. Laboratory study control revealed panhypopituitarism: FSH 2.3 mIU/ml [< 15]; LH 0.7 mIU/ml [< 9.0]; 1.2 ng/ml prolactin [3.5-19.4]; Total Testosterone 0.1 ng/ml [2.7 - 11.0]; TSH 1.0 uUI/ml [0.4 - 4.0] Free T4 0.60 ng/dl [0.7 - 1.5]; ACTH 14 pg/ml [9-52]; Cortisol 0.4 mg/dl [5-25]; IGF1 22 ng/ml [53-215]. He was medicated with hydrocortisone 15 mg daily, levothyroxine 75µg/day and testosterone 250 mg IM every four weeks. At the time of the last observation, he reported a significant improvement in his general condition, normalized sexual activity and body hair growth.
Discussion
Discovering the cause of hypopituitarism can be a challenging. TBI can caused hypopituitarism several years after the event, and can even occur after minor trauma. The onset of symptoms of hypopituitarism after the episode of severe headache and vomiting also raises the possibility of another concomitant event, namely pituitary ischemia/haemorrhage. The hospitalization with septic shock, the detailed clinical evaluation and follow-up of the patient were crucial to detect the occurrence of this condition, associated with high morbidity and whose hormone replacement significantly improved the prognosis and quality of life.

Non-functional pituitary adenomas: clinical and paraclinical aspects

Anis Grassa[1], Cyrine Chehaider[2], Nadia Khessairi[1, 2], Meriem Yazidi[2], Ibtissem Oueslati[2] & Melika Chihaoui[1]
[1]Hopital La Rabta, Endocrinology, Tunis, Tunisia; [2]Hopital La Rabta, Tunis, Tunisia;

Introduction
Non-functional pituitary adenomas (NFPAs) represent 30% of all pituitary adenomas and not associated with clinical evidence of hormonal hypersecretion. The aim of our study was to describe the clinical and paraclinical aspects of NFPAs.
Methods
This is a retrospective descriptive study concerning 40 patients who were hospitalized in the endocrinology department of Rabta hospital in Tunis between January 2014 and December 2020. Clinical and paraclinical data were taken from medical records.
Results
Our population had a mean age of 51.8 ± 15.9 [21-80] years. Patients were 40% male and 60% female, sex ratio was 0.66. The circumstances of discovery were mainly: pituitary incidentaloma (12,5%), headache (50%), visual impairment (45%), endocrine manifestations (10%) and epilepsy (2,5%). Five had a pituitary apoplexy at the time of diagnosis (12.5%). On pituitary imaging, the mean size of the adenomas was 23 mm (4mm-52mm) and were classified: 4 microadenomas and 36 macroadenomas. The optic chiasm and pituitary stalk were invaded in 29 cases (72.5%), the cavernous sinus in 15 cases (37.5%) and the sphenoidal sinus in 6 cases (15%). The main symptoms were headache, visual impairment, asthenia, weight loss, psychomotor retardation and hypoglycaemic discomfort found in 27 (67.5%), 24 (60%), 21 (52.5%), 8 (20%), 7 (17.5%), 4 (10%) cases respectively. Decreased libido was found in 12 patients (30%). Seven women had secondary amenorrhea and 10 men had erectile dysfunction. Axillary-pubic depilation was noted in 5 persons. For the visual impact, an alteration of the visual field was found in 24 (60%) cases, a pathological fundus in 7 cases (17.5%), papilledema in 4 cases and optic atrophy for the rest. A decrease in visual acuity was observed in half of the subjects (50%). Hormonal deficiencies were corticotropic, thyrotropic, gonadotropic insufficiency, disconnection hyperprolactinemia and central diabetes insipidus in 80%, 32.5%, 42.5% and 15% respectively.
Conclusion
NFPAs in addition to their incidental discovery, are usually diagnosed lately as macroadenoma which commonly present with symptoms related to the mass effect on surrunding structures. They put at risk the vital and visual prognosis.

Hypopituitarism induced Radiotherapy for nasopharyngeal carcinoma: a case report

Meriem Adel[1], Ibtissem Ben Nacef[2], Elyes Kamoun[2], Sabrine Mekni[2], Youssef Lakhoua[2], Nadia Mchirgui[2], Imen Rojbi[2] & Karima Khiari[2]
[1]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia;

Introduction
Since the hypothalamic-puituitary axis (HPA) is a radiosensitive region, cranial radiotherapy for head and neck malignancies represents a major risk factor for the development of endocrine complications particularly hypopituitarism.
Case report
A 22 years old girl with a history of a undifferentiated carcinoma of nasopharyngeal type UCNT at the age of 09 years old treated with radiotherapy and chemotherapy was referred to the endocrinology department for investigation of short stature and primary amenorrhea. The patient presented with short stature, height of 146 cm (–3 standard deviations), with normal weight (body mass index 24 kg/m2), Breast Development Scale stage 4 and Pubic Hair Scale stage 4. Radiography of the left hand revealed a bone age of 15 years. Dynamic growth hormone evaluation showed unstimulated levels. The Endocrine investigation was consistent with hypopituitarism (corticotropic insufficiancy, gonadotrop insufficiancy, central hypothyroidism and GH deficiency). However, Prolactin levels were normal. Pituitary MRI showed hypotrophic pituitary gland with partial intrasellar arachnoidocele, and a bilateral postradic demyelination of temporal white matter. Pelvic MRI revealed an uterine and ovarian atrophy. Hormonal substitution therapy with glucocorticoids levoT4 and sex steroids was started.
Discussion
RIH (radiotherapy induced hypopituitarism) is a slow-developing process. Its development dependens on RT per fraction dose, post-RT interval radiation dose, age, the volume of the HPA irradiated. In addition, the incidence of RIH increases with the total dose. However, it should be noted that this incidence does not have a specific threshold dose since cases with doses as low as 20 gy were documented. This further highlights the importance of early detection. Some studies have suggested that the growth hormone deficiency is the first manifestation of RIH followed by deficiencies in gonadotropin, ACTH, and TSH. Moreover, the dysfunction of the hypothalamus leads to the reduction of dopamine release. Hence, hyperprolactinemia, which contributes to gonadal dysfunction, can be present on a case by case basis. Despite the fact childhood cancer survival rates

have improved across all measures, survivors are still at risk of developping endocrine disorders, even years removed from therapy. This accentuates the importance of lifelong surveilance.
Conclusion
RIH worsens the quality of life and reduces the life span of patients. Thus, successefull management depends greately on early detection and hormone replacement therapy.

Cushing Disease with COVID-19: Protective or Dangerous?

Zehra Yagmur Sahin Alak[1], Pinar Uzgec Guller[1], Mustafa Burak Yaşar[1], Metin Guclu[1], Fatih Aydemir[2] & Sinem KIYICI[1]
[1]Health Sciences University, Bursa Yuksek Ihtisas Research and Training Hospital, Endocrinology and Metabolism, Bursa, Turkey; [2]Health Sciences University, Bursa Sehir Hospital, Neurosurgery, Bursa, Turkey

Introduction
Coronavirus disease-19 (COVID-19) pandemic renders high morbidity and mortality. Glucocorticoid excess is characterized by increased susceptibility to infections due to impairment of the innate and adaptive immune system. Manifestations of Cushing disease (CD) including diabetes mellitus (DM), hypertension, and obesity are risk factors for severe COVID-19 disease. We present three CD patients with different clinical courses of COVID-19. The patients' general characteristics are summarized in table 1.
Case-1
The patient was a 27-year-old woman with recurrent CD after transsphenoidal surgery. She had DM, hypertension, and obesity. She tested positive for SARS-CoV-2 with dyspnea, cough, chest pain, and fever. She hospitalized at intensive care unit (ICU). A CT scan showed bilateral diffuse ground-lass opacities of both lungs. Significant clinical improvement was achieved on the 13th day of ICU. She discharged from the hospital on 17th day.
Case-2
A 23-year-old woman was diagnosed with CD recently. She had obesity. The COVID-19 nasopharyngeal PCR was positive during preoperative evaluation. Lung involvement wasn't observed. She survived the COVID-19 disease without symptoms.
Case-3
A 55-year-old woman with CD had a transsphenoidal surgery 2 months ago. She had DM and obesity. She was admitted to our clinic with adrenal insufficiency. She tested positive for SARS-CoV-2 with cough and shortness of the breath. A CT scan showed bilateral pleural effusion and bilateral diffuse ground-glass opacities. She died on the 18th day while treated in ICU.
Conclusions
Cushing disease-associated glucocorticoid excess, immunosuppression and co-morbidities may alter the severity and the course of COVID-19. In contrast, glucocorticoids have shown improve COVID-19 associated mortality in randomized controlled trials. It was also reported that COVID-19 disease infection can be worsened by concomitant hypocortisolism. Herein we report three cases with different prognosis. Thus, patients with CD should be followed more carefully during COVID-19 disease.

Exploring a new entity of monotherapy pembrolizumab-associated hypophysitis

Eric Balti[1], Sarah Verhaeghe[1], Vibeke Kruse[2], Stijn Roels[3] & Peter Coremans[1]
[1]VITAZ Hospital, Department of Endocrinology and Diabetes, Sint-Niklaas, Belgium; [2]VITAZ Hospital, Department of Onco-Hematology, Sint-Niklaas, Belgium; [3]VITAZ Hospital, Department of Radiology, Sint-Niklaas, Belgium

Background
There are increasing number of reports on immune checkpoint inhibitors induced adverse events including hypophysitis. Hypophysitis tends to occur more with CytotoxicT-lymphocyte-associated protein 4 inhibitors (12-15% of cases) which is a different entity compared to those associated to anti-program death 1 (anti-PD1) inhibitors.
Aim
We describe a case of pembrolizumab-associated hypophysitis and conduct a discussion based on a systematic review of the literature.
Case presentation
A 55-year-old woman presented with headache, nausea and fatigue 3.5 months (5 cycles) after initiation of adjuvant pembrolizumab for a stage 3b (TNM) melanoma. Endocrine profile was consistent with secondary adrenal failure, thyrotropic insufficiency and defective gonadotrophin secretion. Progressive decline of thyroid stimulating hormone and free tetraiodothyronine occurred three months prior to diagnosis. Imaging study showed an enlarged pituitary gland with homogeneous enhancement of the gland and pituitary stalk. After interruption of anti-PD1 therapy and administration of adrenal and thyroid hormonal substitutions improvement was observed. Magnetic resonance study showed declining pituitary mass three months later.
Discussion
Systematic search of literature identified 16 studies reporting 19 patients with single use pembrolizumab-associated hypophysitis. Most patients were treated for melanoma (n=7, 35%) and urogenital or breast neoplasia (n=7, 35%). Time to onset of pituitary insufficiency was most frequently 6 months (range 1.5 to 39.0 months) after treatment initiation. The most prevalent hormonal defect was isolated adrenocorticotropic hormone deficiency. Two studies reported multiple central hormonal defects. In those patients and in our case, increased pituitary mass was observed.
Conclusion
In contrast with the majority of other cases of pembrolizumab monotherapy associated hypophysitis, our case has distinct features. These include early disease onset, after pembrolizumab initiation, panhypopituitarism and increased pituitary mass. Whether or not this is a new clinical entity warrants further investigation. Until then, clinicians should be aware that pembrolizumab monotherapy associated hypophysitis might cover a heterogeneous clinical spectrum.

The impact of adenoma size on the clinical course of acromegaly : a comparative study

Faten Haj Kacem Akid, Wafa Belabed, Abdelmouhaymen Missaoui, Dhoha Ben Salah, Mouna Elleuch, Fatma Mnif, Nabila Mejdoub & Mohamed Abid Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Acromegaly is a chronic, slowly progressing disease caused in most cases by growth hormone (GH)- producing pituitary adenoma. This rare disorder is associated with a spectrum of various clinical manifestations and treatment outcomes differ between patients. The aim of this study was to evaluate the impact of adenoma size on comorbidities and biochemical status at the diagnosis of disease.
Methods
This is a one-centre cohort study conducted among adult patients with confirmed acromegaly. Baseline data regarding biochemical and radiological status were collected retrospectively. We performed a comparative analytical analysis between two subgroups:
• G1: patients with pituitary adenoma larger than 20mm ($n = 17$)
• G2: patients with pituitary adenoma smaller than 20mm ($n = 12$)
Results
29 adult patients were included with a mean age at diagnosis of 45,8 $\pm$ 12,4 years. Both genders and age did not differ between the two subgroups. Adenoma size greater than 20 mm (G2) was significantly associated with a higher GH level. Furthermore, there was a positive and significant ($P < 0.05$) correlation between baseline GH level and adenoma size. All patients in G2 had an intact gonadotropic axis, whereas more than half of those in G1 had gonadotropic insufficiency ($P <$ 0,05). The differences in the occurrence of hyperprolactinemia, of corticotropic and thyrotropic insufficiencies were not statistically significant between the two subgroups.
Conclusion
According to our results, the clinical course of acromegaly is influenced by adenoma size at the onset of symptoms. This difference should be considered when treating patients with acromegaly.

Clinical and demographic features of acromegaly in tunisian patients: a monocentric retrospective study

Faten Haj Kacem Akid, Wafa Belabed, Dhoha Ben Salah, Abdelmouhaymen MISSAOUI, Fatma Mnif, Mouna Elleuch, Nabila Mejdoub & Mohamed Abid
Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background and Aims
Acromegaly is a rare condition caused by an excessive secretion of growth hormone (GH) and insulin-like growth factor1 (IGF-1), which are responsible for exaggerated somatic growth and distorted proportions. The objective of the current work was to investigate the clinical and demographic features of acromegaly in Mediterranean patients.
Patients and Method
From 1997 to 2021, 29 patients with acromegaly were diagnosed and followed up at the Endocrinology Department of Hedi Chaker University Center, Sfax, Tunisia. We retrospectively reviewed the medical charts of all patients to assess their clinical and demographic characteristics.
Results
We noted a slight male predominance with a sex-ration of 1.07. The mean age at diagnosis was 45.8 $\pm$ 12.4 years old. The diagnosis of acromegaly was more delayed in females (male: 44.1 $\pm$ 11.2 vs female: 47.7 $\pm$ 13.7 years old). Symptoms related to tumoral mass effects such as headache and visual impairment were the leading causes of consultation in 31.0%. Changes in appearance brought only 17.2% of patients who had acromegaly to seek medical care. In 27.6% of cases, patients with dysmorphic features were referred by their physicians to the Endocrinology department for further hormonal assessment. The worsening of some nonspecific symptoms such as snoring (10.3%), glycemic imbalance (6.9%), and secondary amenorrhea (6.9%) led to the diagnosis of acromegaly. The mean weight was 82.5 $\pm$ 13.0 kg. The average height was 167.3 $\pm$ 11.2 cm (extremes:146-191). The mean BMI was 28.0 $\pm$ 7.2 kg/m^2. Obesity was found in 40.7%. Dysmorphic features were observed in all patients with variable degrees. The dermatologic examination noticed frequently thickening skin (69.0%) and hyperhidrosis (65.5%). A horsely voice was found in 48.3%. Patients with acromegaly reported asthenia, lower back pain, and arthromyalgia in 41.4%, 20.7%, and 10.3%, respectively. The principal general comorbidities associated with this condition were diabetes (34.4%), hypertension (13.7%), and dyslipidemia (10.3%).
Conclusion
Acromegaly is an insidious disease that impacts equally both genders with a prevalence ranging between 2.8 and 13.7 cases per 100,000 people. Clinical manifestations include skeletal and soft tissue deformities, along with cardiorespiratory, neuromuscular, and metabolic disturbances. Most patients are diagnosed at an advanced stage after the onset of tumoral mass effect signs. Better recognition of the clinical landscape of acromegaly by first-line physicians may help in its precocious diagnosis and thus improve its therapeutic outcomes.

EP817

Pituitary Stalk Interruption Syndrome in a 22-year old Filipino Male : A case report

Irene Kei Bariuad-Garcia & Cecille Dela Paz
East Avenue Medical Center, Internal Medicine, Section of Endocrinology, Quezon City, Philippines

Background
Pituitary Stalk Interruption Syndrome (PSIS) is a rare congenital anomaly affecting the pituitary gland with characteristic MRI findings of small or absent anterior pituitary gland, misplaced or absent posterior pituitary gland and very thin or interrupted pituitary stalk (1). Patients with PSIS often presents with signs and symptoms of either isolated growth hormone deficiency or multiple anterior pituitary hormone deficiency and symptoms differ according to age at diagnosis (2). We report a case of pituitary stalk interruption syndrome in a 22-year old Filipino male presenting with micropenis.
Case
A 22-year old Filipino male was referred to endocrinology service for evaluation of micropenis. His birth history was unremarkable. Developmental milestones were at par with age. Both parents and 3 siblings were healthy. On examination, his BP was 90/60 mmHg with a height of 139.7 cm, weight of 32 kg, with a eunuchoid proportion. Facial, axillary and pubic hair were absent. His testes were 1 ml in size, with a 1.5 cm-at-stretch penis. Laboratory findings showed: Total testosterone 0.11 ng/ml (NV: 2.80-8 ng/ml), FSH 0.18 mIU/ml (NV: 1.5-12.40 mIU/ml), LH $<$ 0.100 mIU/ml (NV: 1.70-8.60 mIU/ml), FT4 8.63 pmol/l (12-22 pmol/l), TSH 6.17 uIU/ml (NV: 0.27-4.20 uIU/ml), IGF 1 13.23 ng/ml (120-388 ng/ml), Prolactin 191.40 mIU/l (NV: 86-324 mIU/l), Estradiol $<$ 5 pg/ml (NV: 25.80-60.70 pg/ml), DHEAS 0.07 umol/l (NV: 6.50-14.60 umol/l). ACTH stimulation test was done, baseline cortisol was 78. 27 nmol/l (NV: 172-497 nmol/l), 30 minutes and 60 minutes post ACTH cortisol levels were 290 nmol/l and 60 minutes cortisol: 343. 20 nmol/l respectively indicating intact adrenal gland. His bone age was 14 years. Pituitary MRI results were consistent with pituitary stalk interruption syndrome.
Conclusion
Despite being a rare syndrome, pituitary stalk interruption syndrome should be one of the differential diagnosis in patients presenting with micropenis and short stature. Importance of early recognition of the disease is important because it associated with permanent hormonal deficiencies leading to significant morbidity and mortality.

Hypopituitarism in tropical countries

Lakshman kumar Ega[1], rakesh sahay[2] & neelaveni kudugunti[3]
[1]Osmania Medical College, Endocrinology, Hyderabad, India; [2]Osmania Medical College, Endocrinology, Hyderabad, India; [3]Osmania Medical College, Hyderabad, India

Background
Etiology of hypopituitarism differs in tropical countries compared to the West and includes pituitary abscess, snake bite, HIV infection, Sheehan syndrome, road traffic accidents, iron overload states etc.
Aims and Objectives
The present case series highlights the spectrum of hypopituitarism in tropical countries.

Case Details
1. C1: 23 y/o female presented with loss of consciousness, unrecordable BP and hypoglycemia. H/O spontaneous pre term delivery at home with significant PPH with lactational failure. 2. C2: 21 y/o male came with c/o poor height and weight gain and poor development of secondary sexual characteristics. Examination revealed a large healed scar over foot which developed after snake bite in past. 3. C3: 41 y/o female with h/o recurrent episodes of altered sensorium. H/o PPH, lactational failure, amenorrhea following home delivery. 4. C4: 30 y/o female presented with h/o delivery with PPH, followed by amenorrhea, lactation failure with sparse axillary, pubic hair. MRI pituitary was normal in C1 and showed empty sella for C2, C3 and C4
Conclusion
The etiology and clinical features of hypopituitarism are variable. Awareness and early recognition in these cases is necessary for optimal management of the patient.

Demonstration of the effects of asprosin on the sense of smell in female rats with hidden cookie test

Zeynep Dila Öz[1], Gö khan Zorlu[2], Fatih Tan[1], Gaye Gö ksu Avcu[1], Emine Kacar[1], Abdullah Yasar[3], Ihsan Serhatlioglu[2], Haluk Kelestimur[1] & Bayram Yilmaz[4]
[1]Firat University Faculty of Medicine, Physiology, Elazig, Turkey; [2]Firat University Faculty of Medicine, Biophysics, Turkey; [3]Fırat University, Vocational School of Health Services, Turkey; [4]Yeditepe university, School of Medicine, Turkey

Purpose
Asprosin is a novel glucogenic adipokine produced by the fibrillin 1 (FBN1) gene that is generated and released by white adipose tissue during fasting. Asprosin hormone has been shown to improve the sense of smell in wild-type mice by activating the OLFR734 receptor and decreasing the time it takes for them to discover hidden food. The purpose of this study was to determine the effects of asprosin on the sense of smell in female rats through the use of a hidden cookie test.
Materials and methods
Twenty-four female Sprague-Dawley rats were randomly divided into 2 groups ($n=12$) as control and asprosin. Asprosin and saline were intraperitoneally given at a dose of 500 ng/kg and 1 ml/kg to asprosin and control groups, respectively at 14.00 every day for eight weeks. The hidden cookie test was performed four times a day during ad libitum feeding, and the final experiment was repeated 24 h after fasting when all animals were in the estrous phase. Cookies (Chocapic, Nestle) were buried at a depth of 3 cm. They were recorded from 4 angles for 10 minutes. The finding time of the cookie was scored in seconds. T-test was used for the evaluation of the data. In all analyses, $P<0.05$ was considered statistically significant.
Results
In the hidden cookie test, the meantime of the control group was 445.29 ± 64.58 seconds while it was 450.45 ± 63.46 seconds in the asprosin group ($P>0.05$). Twenty-four hours after fasting, the average time in the asprosin group was 379.58 ± 55.04 while it was 208.83 ± 58.28 seconds in the control group ($P<0.05$).
Conclusion
It was found that there was no significant difference in the hidden cookie test performed when female rats were fed. However, asprosin hormone significantly increased the sense of smell due to the test performed after 24 h after fasting. Key words: Asprosin, adipokine, smell, hidden cookie test

Pre-validation study of alternative developmental neurotoxicity test using Sox1-GFP cell.

YongIn Kim, Sunhwa Jeong, Jimin Lee, KangMin Kim, Minsu Lee & Eui-Bae Jeung
Chungbuk National University, Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Cheongju-si, Chungcheongbuk-do, Rep. of South Korea

The chemically induced disturbance during the neurodevelopment stage could cause a serious disease. *In vivo* study is useful to discriminate against neurotoxic substances but is time-consuming and ethically problematic. So, we have previously established, developmental neurotoxicity test (DNT) *in vitro* method using Sox1-GFP. In this study we aimed to increase the predictability of discriminant function. The equation was statistically improved using thirty additional chemicals. Concomitantly, we conduct reproducibility assessment; inter- and intra- studies were carried out for fifteen chemicals by three experimenter and three independent laboratories. In this study, we correlated our prediction model with wider range of chemicals; 20 toxicants and 10 non-toxicants data was newly added to secure analytical accuracy. To establish a discriminant function, two factors, half inhibition concentration for cell viability (IC50) and half inhibition concentration for neuro-sphere area (ID50), were used. IC50 value was obtained by performing CCK-8 assay after chemical treatment on undifferentiated cells for 2 days. ID50 value was obtained by measuring both GFP intensity and neuro-sphere areas of differentiated cells as neural form which cell was exposed to chemical for 4 days. From the inter result obtained using the stated discriminant function gave 100% accuracy and from intra test it gave 96% accuracy. Inter- and intra- experiments were able to classify chemicals as toxic or non-toxic very equally. Conclusively we have established animal alternative DNT and showed that this test is a transferable, reproducible and accurate method. Therefore, we suggest that this method will be able to be a standardizing method as animal alternative.
Keyword: Developmental neurotoxicity test, *in vitro*, Sox1-GFP cell

Preference of acromegaly patients for treatment attributes in Spain

Carmen Fajardo-Montañana[1], Cristina Álvarez Escolá[2], Betina Biagetti[3], Rogelio Garcí a Centeno[4], Raquel Ciriza[5], Laura Sanchez[6] & Marcos Díaz[6]
[1]Hospital Universitario de La Ribera, Endocrinology Department, Alzira (Valencia), Spain; [2]'La Paz' University Hospital, Endocrinology Department, Madrid, Spain; [3]Vall d'Hebron University Hospital and Vall d'Hebron Research Institute (VHIR), Universidad Autónoma de Barcelona, Diabetes and Metabolism Research Unit, Barcelona, Spain; [4]Gregorio Marañon Hospital, Endocrinoloy Department, Madrid, Spain; [5]Spanish Acromegaly Patient Association (Asociación de pacientes Afectados por Acromegalia), Huesca, Spain; [6]Pfizer S.L.U, Medical Affairs Department, Alcobendas (Madrid), Spain

Background
Acromegaly is a slowly progressive rare disease caused by an increase in growth hormone secretion that causes a subsequent rise in insulin-like growth factor (IGF-1), both contributing to the excessive growth of the extremities, soft tissues and organs, in addition to other comorbidities directly interfering with patient's quality of life. Acromegaly patients are concerned about their disease and their treatments, however, publications about patient's opinion towards their disease and treatments are scarce.
Objective
The aim of this study was to gain further insight into the Spanish acromegaly patients' perspective on their disease, unmet needs and treatment preferences.
Methods
A qualitative study was carried out to determine the attributes and levels of the quantitative. Two-hour-group interviews, comprising 4 and 5 adult patients each, took place in Madrid and Barcelona (September 2019). The group dynamics were conducted by an experienced moderator. The quantitative study was designed as a discrete choice experiment.142 patients were initially invited to complete the online survey; however, only 67 patients completed the questionnaire. Choice-based conjoint analyses were used to estimate the utilities and values for treatment attributes. Subject preferences were estimated at aggregated levels. Using a Bayesian hierarchical modelling, the percentage of levels and attributes were transformed in utilities.
Results
QoL stood out as the most important attribute for respondents (37%), and IGF-1 together with glucose blood level and tumour size control (Table. 1), were the most important attributes according to participants. The pain associated to the treatment administration method was a secondary attribute. Diarrhoea, administration methods and storage conditions were the less important attributes according to participants and were only relevant for the treatment choice.
Conclusion
Despite acromegaly patients showing a high degree of awareness about the importance of IGF1 levels and tumour size control, our results point out the great relevance that patients award to Health-Related Quality of Life. Notably, patients showed great concern about glycemic level alteration, as well as the

Table 1 Utilities summary

Importance of the choice	Attribute	Choice (%)
Key Attribute	Quality of life	37%
	IGF-1 level control	20%
Main attributes	Glucose levels control in blood	17%
	Tumour control	13%
Secondary attributes	Pain associated to the administration method	7%
	Adverse events: diarrhea	2%
	Administration methods	2%
	Storage conditions	2%

levels of IGF-1 and the tumor size. Patients' opinion should be taken in consideration when prescribing a treatment, as these patients show high knowledge and awareness about the management of their condition.

Sheehan Syndrome effects on cardiovascular risk

Ameni Salah, Amel Maaroufi, Rihab Ajili, Asma Benabdelkarim, Maha Kacem Njah, Yosra Hasni & Koussay Ach
University Hospital Center Farhat Hached, Endocrinology Department, Sousse, Tunisia

Introduction
Sheehan syndrome has been for a long time the most frequent cause of hypopituitarism among women in developing countries, including Tunisia. Apart from hormonal deficits caused by SS, young women with SS are exposed to an increased risk of cardiovascular mortality. In this study, we aimed to evaluate the cardiovascular risk in patients with SS.
Patients and methods
This is a descriptive cross-sectional study. It was carried out in the Endocrinology department of the University Hospital Farhat Hached in Sousse, Tunisia, over a period of nine months, from July 2019 to March 2020. The estimation of the cardiovascular risk was made in patients who had no proven cardiovascular disease at the time of the diagnosis of SS, based on the Framingham score.
Results
Sixty five patients were included to the study. The mean age at diagnosis of SS was 48.2 $\pm$ 12.4 years. Thyrotropic and corticotropic insufficiency were present in 86.2% of our patients, followed by gonadotropic and lactotroph insufficiency in 72.3% and 38.5% of patients, respectively. Somatotropic insufficiency was explored by a dynamic test in only 8 patients, concluding with somatotropic deficiency in 10.8% of cases. A cardiovascular accident among first-degree relatives was noted in 10.7% of cases (5 cases of cerebrovascular accidents and 2 cases of myocardial infarction). Four patients had already proven cardiovascular disease at the time of SS diagnosis. The estimation of cardiovascular risk, using the Framingham equation, involved 39 patients. A very low, low or moderate cardiovascular risk was noted in 26.2%, 16.9% and 10.8% of patients, respectively. However a high cardiovascular was noted in 6,2% of patients. Four patients presented with coronary heart disease during follow-up. Three of the four patients, whose cardiovascular risk was considered moderate or high, presented with proven cardiovascular disease during follow-up. Furthermore, none of the patients whose cardiovascular risk was considered very low or low presented with subsequent cardiovascular disease. The difference between the two groups estimated using Fisher's exact test was statistically significant ($P=0.01$).
Discussion-Conclusion
Cardiovascular mortality is markedly increased in adults with hypopituitarism, and women are more affected than men. A number of factors contribute to the excess cardiovascular mortality including GH deficiency and untreated gonadotropin deficiency.

Prevalence of benign and malignant tumors in patients with acromegaly

Iulia-Ştefania Plotuna[1,2], Daniela-Georgiana Amzar[1,2], Melania Balas[1,2], Ioana Golu[1,2] & Mihaela Vlad[1,2]
[1]Victor Babeş University of Medicine and Pharmacy, Timişoara, Romania; [2]Timiş County Emergency Clinical Hospital, Timişoara, Romania

Introduction
Acromegaly is an endocrine disease associated with an abnormal growth-hormone (GH) and insulin-like growth factor 1 (IGF-1) excess. Multiple studies demonstrated an association between these factors and pathways that play a major role in tumor proliferation, survival and resistance to anti-cancer therapies in many human malignancies.
Objectives
We wanted to study the incidence and types of tumors which are associated with Acromegaly.
Material and Method
We analyzed the data from all the patients who were diagnosed with Acromegaly between 2001 and 2021 in our Department of Endocrinology. Patient's data was collected retrospectively and included personal history, clinical examination, laboratory assessment and magnetic resonance imaging results. The study-group included 32 patients, aged between 20 and 64 years, 9 men (28,12 %) and 23 women (71,87 %). The mean age at Acromegaly diagnosis was 50+/-5,41 years old and mean age when the first tumor was diagnosed: 46+/-10 years old. GH and IGF-1 mean levels at diagnosis were 21,31 ng/ml and 639 ng/ml respectively. Acromegaly was controlled in 50 % of the patients after therapy.
Results:
Twenty-three(75 %) acromegalic patients were diagnosed with different forms of tumors and 15% of these were malignant. Four (44 %) men were diagnosed with tumors and all were benign. The most frequent tumors were multinodular goiter and benign prostatic hyperplasia. Eighteen (75 %) women were diagnosed with tumors, from which 20% (5 cases) were malignant. The most common benign tumor was multinodular goiter and the most frequent malignant tumor was papillary thyroid carcinoma. Acromegaly and diagnosis of tumors coincided in 52 % of the patients, most likely because screening for thyroid pathology was implemented. Among women diagnosed with cancer, one patient died as a result of this pathology.
Conclusions
Both women and men diagnosed with Acromegaly suffered more frequently form benign nodular goiter and only among women there were cases of malignant tumors.

What factors predict a favorable response to hormonal therapy in congenital growth hormone deficiency?

Nabila Rekik Majdoub, Kawthar El ARBI, Asma Zargni, Dhoha Ben Salah, Wafa Benothman, Mouna Elleuch, Mnif Fatma, Nadia Charfi, Mouna Mnif, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Growth hormone (GH) treatment in congenital growth hormone deficiency (CGHD) is indicated to improve the prognosis of the statural prognosis. The aim of this study is to identify the predictive factors of a favorable response to GH therapy.
Patients & Methods
This is a retrospective study, conducted over a period of 27 years, including 30 patients with CGHD treated with hormonal therapy.
Results
The CGHD was diagnosed at a mean age of 8.8 $\pm$ 3.6 years with a male predominance. Only 2/22 patients reached the target height. The mean stature gain in standard derivations (SD) was 1.8 $\pm$ 1.07 SD. Severe growth retardation (86.7%) was positively correlated with stature response (2 vs 0.75 SD; $P=0.049$). The gain under hormonal treatment did not depend on the GH peak during stimulation tests, nor on the combined (33.3%) or total (73.3%) character of CGHD. The radiological assessment showed a significant association between pituitary stem abnormalities and a better response to GH (2.6 vs. 1.6 SD; $P=0.019$). The dose and duration of treatment as well as the target size did not influence the evolution under treatment. Only chronological age and delayed bone age at treatment initiation were positively correlated with a good response ($P=0.022$ and 0.042 respectively).

Conclusion
The results of GH treatment were more satisfactory on final height than on target height. Large-scale prospective studies are needed to validate the factors that seem to be involved in the statural response.

Binasal hemianopsia with pituitary adenoma in a 15-year-old girl

Elyes Kamoun[1, 2], Imen Rojbi[1, 2], Sabrine Mekni[1, 2], Houaida Smadhi[3], Youssef Lakhoua[1], Ibtissem Ben Nacef[1, 2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia; [3]Hopital Regional de Beja, Beja, Tunisia

Introduction
Pituitary adenomas represent 10 to 20% of intracranial tumors. In children, craniopharyngioma are the most common tumor of the sellar region. The symptoms can include headache, vomiting, pituitary deficiency and in pituitary adenomas, hormonal excess. The visual examination can find a visual field defect such as a bitemporal hemianopsia. We present a rare case of a pituitary adenoma in a 15-year-old girl with binasal hemianopsia.
Observation
A 15-year-old girl presented frontal headaches and vomiting occurring for a year before her referral to our department. At physical examination, she had a normal blood pressure, and clinical visual field assessment suggested an inferior and right nasal quadrianopsia. Firstline imaging investigations with cerebral tomography discovered a pituitary adenoma. A biopsy with immunohistochemistry was performed confirming the diagnosis of a plurihormonal LH and prolactin sparsely granulated pituitary adenoma. The magnetic resonance imaging confirmed intra and suprasellar adenoma measuring 26.4*20*21mm abutting optic chiasma and the third ventricule. On hormonal investigations, she had a corticotropin deficiency with a peak cortisol after insulin tolerance test at 300 nmol/l and ACTH levels at 26 pg/ml. She didn't have thyrotropin deficiency nor diabetes insipidus. Her menses were irregular, with a secondary amenorrhea of one year at three years after menarche. There wasn't any sign of hormonal excess, the prolactin levels were at 33µg/l, probably secondary to the pituitary stalk compression. A type 1 multiple endocrine neoplasia was excluded as there were no family history of endocrine disease and parathormone levels were normal. The visual field assessment concluded to bilateral defects with a pattern of an incomplete binasal hemianopsia. She was put on 15 mg of hydrocortisone and was referred to surgery.
Conclusion
The suprasellar extension of pituitary adenoma abutting the optic chiasma is responsible of a bitemporal hemianopsia as the optic nerves in the chiasma are responsible for the vision in those fields. A binasal defect can be seen in ophthalmologic pathology, but is extremely rare in pituitary adenoma. Pituitary adenoma prevalence in children and adolescents is less than 5%. This case represents an unusual clinical presentation of a pituitary tumor confirmed to be a pituitary adenoma in a 15-year-old girl with an exceptional optic defect.

Looking for a safe and effective drug: the troubled journey of a Cushing's Disease patient

Angelo Milioto[1], Francesco Cocchiara[2], Giuliana Corica[2], Keyvan Khorrami[1], Federica Nista[1], Diego Criminelli[3], Gianluigi Zona[3], Diego Ferone[1] & Federico Gatto[2]
[1]University of Genoa, Department of Internal Medicine and Medical Specialties, Endocrinology Unit, Genova, Italy; [2]IRCCS Ospedale Policlinico San Martino, Endocrinology Unit, Genova, Italy; [3]IRCCS Ospedale Policlinico San Martino, Neurosurgery Unit, Genova, Italy

Cushing's Disease (CD) is severe clinical condition due to an ACTH-secreting pituitary tumor. Here we present the case of a 25-years old male who came to our attention for hypertension, moon face, acanthosis nigricans, abdominal purple striae and central obesity. The diagnosis of CD was based on the presence of high plasma cortisol after dexamethasone suppression test and elevated urinary free cortisol levels (UFC, 6-fold higher the upper limit of normality (ULN)). The pituitary MRI revealed a small lesion (5.5 mm), which was removed by transsphenoidal surgery, and it was later on confirmed as a corticotroph tumor at the pathology report. Surgery led to a slight improvement of symptoms. However, two months after the intervention, the patient experienced a worsening of the clinical picture, and the following biochemical assessment was suggestive of an early disease relapse. First, pasireotide was administered, although with low efficacy in reducing cortisol secretion. Then, a novel steroidogenesis-inhibitor, available only for investigational use in the context of a clinical trial, was started, but the patient withdrawn due to safety concerns. Therefore, low dose metyrapone was prescribed. However, severe gastrointestinal side effects occurred, and the drug was discontinued after few months. Furthermore, during imaging follow-up, the suspicion for a recurrent pituitary lesion was raised. Following a multi-disciplinary discussion, inferior petrosal sinus sampling was performed, confirming the disease recurrence. Based on the expected low success rate, the team avoided a second surgery. Ketoconazole (600 mg/day) was then administered, leading for the first time to UFC normalization. Unfortunately, the patient developed severe nausea, headache and fatigue, and the dosage was reduced (400 mg/day). As expected, cortisol levels raised and cabergoline (1 mg/week) was then added. Combination therapy led to partial disease control, but a further disease relapse was observed. Therefore, radiosurgery was performed, and the newly available steroidogenesis-inhibitor, osilodrostat, was started as bridge therapy due to persistent hypercortisolism. Osilodrostat was titrated up to 5 mg/day, leading to biochemical control (UFC normalization) with no side effects. At 7-months follow-up, the patient is currently proceeding with this latter treatment schedule, with no safety issues. Our case report highlights the difficulties encountered during the management of CD. The patient underwent surgery, radiotherapy and six different types of drugs before achieving disease control without adverse events. Therefore, clinical predictors of drug safety and efficacy are strongly needed in a challenging disease such as CD.

Management of SIADH in patients with acute admissions to hospital: a single centre experience

Vinit Shah, Francesca Neale, Dorina Condurache, Saranya Baleswaran, Amy Price & Ian Seetho
London North West University Healthcare NHS Trust, United Kingdom

Background
Hyponatraemia is a common electrolyte abnormality that is associated with significant morbidity and mortality in patients admitted to hospital. Fluid restriction is the recommended treatment option for syndrome of inappropriate antidiuretic hormone secretion (SIADH), a common cause of hyponatraemia with limited evidence for alternative treatment options. The aim of our study was to share the experience of our hospital in the successful management of SIADH where we also use oral sodium chloride and urea salts in addition to fluid restriction.
Methods
We collected data for patients with severe hyponatraemia (Serum $Na^+ < 125$ mmol/l) identified by our biochemistry lab from all samples they received. Suitable patients were identified over a two-week period. We included all those patients who were admitted to our hospital for any diagnosis and excluded those who were discharged from the emergency department or for tests completed as out-patients. Relevant data was collected from medical paper notes and drug charts with laboratory data available from patients' electronic patient records. The treatment protocol for SIADH is set out by the hospital guidelines with fluid restriction as first line followed by addition of oral sodium chloride and/or urea salts as second line treatment options. Successful treatment is defined as improvement in serum sodium to >125 mmol/l.
Results
Thirty-eight patients with a mean age of 77 years were identified. The most common reason for admission was confusion and falls (24% and 18% respectively). Approximately one-third of the cases of hyponatraemia was due to SIADH ($n=14$). For patients with SIADH, successful treatment with fluid restriction alone was required in 43% of cases, combined with oral sodium chloride in another 43% of cases and only 7% required triple treatment combination of fluid restriction, oral sodium chloride and urea salts.
Conclusion
SIADH is a common cause of hyponatraemia in patients with acute hospital admissions. Fluid restriction alone is an effective treatment strategy in many of these patients. Additional solute intake is thought to increase renal free water

clearance and increase electrolyte diuresis. The study demonstrates that additional solute intake in the form of oral sodium chloride or urea salts are potential additional treatment options in those resistant to fluid restriction alone to correct hyponatraemia and their potential role in management of complex cases where strict fluid restriction is contraindicated.

The third case report of pituitary apoplexy complicated by a subarachnoid hemorrhage and ventricular extension

Carlien De Herdt[1], Kamerling Niels[2] & Christophe De Block[1]
[1]Universitary Hospital of Antwerp, Endocrinology-Diabetology-Metabolism, Edegem, Belgium; [2]Universitary Hospital of Antwerp, Neuro-Endocrinology, Edegem, Belgium

Introduction
Pituitary apoplexy is a rare endocrine emergency due to hemorrhage of the pituitary gland. The clinical presentation depends on the extent of bleeding and can deteriorate into a life-threatening condition if complicated by a subarachnoid hemorrhage, as previously described in 2 cases.
Case Description
A 60-year-old woman presented herself at the emergency department because of confusion for several hours. Clinical examination revealed anisocoria with mydriasis of the right pupil in an agitated woman able to move her four limbs but unable to execute commands. Seven months earlier, a macroprolactinoma with a craniocaudal diameter of 28 mm and compression of the optic chiasma was diagnosed, resistant to treatment with cabergoline and complicated by panhypopituitarism. CT scan of the brain was urgently performed and revealed an extensive suprasellar hemorrhagic mass and a subarachnoidal bleeding with extension to the lateral, third and fourth ventricles. The patient was sedated to enable placement of an external ventricular drain. CT angiography excluded an arterial aneurysm. The day after admission the patient awakened and executed commands. Visual field examination revealed bitemporal hemianopsia. MRI of the pituitary one month after admission showed a heterogenous suprasellar mass with a craniocaudal diameter of 28 mm. Endoscopic transsphenoidal resection of the pituitary mass was performed and anatomopathological examination showed necrotic tissue. Pituitary MRI 3 months postoperative revealed an important resorption of the hemorrhagic zone with a residual collection at the bottom of the sella turcica. Whether this collection is residual hematoma or adenoma could not be differentiated. Visual field examination 3 months postoperatively showed improvement, but was not normal with a bitemporal quadrantanopia. Panhypopituitarism persisted.
Conclusion
This case report described a woman with a pre-existing macroprolactinoma and a life-threatening presentation of pituitary apoplexy complicated by a subarachnoid bleeding with ventricular extension. Besides having a macroprolactinoma, this patient had no predisposing factors for apoplexy since it has shown that dopamine agonists are not associated with an increased incidence of apoplexy. Pituitary apoplexy has to be considered in an angiographically negative subarachnoid hemorrhage. However in every patient presenting with a subarachnoid bleeding, even if a medical history of a pituitary adenoma, a cerebral aneurysm always have to be excluded since this is much more frequent. The endocrine prognosis is poor because of frequently irreversible pituitary damage. This is the third case of a pituitary apoplexy complicated by a subarachnoid hemorrhage and ventricular extension with a cerebral aneurysm being excluded.

Hormonal and regional complications of craniopharyngomas

Khadra Faraoun[1] & Chentli Farida[2]
[1]Université Oran 1, Endocrinology, Oran, Algeria; [2]Algier University, Oran, Algeria

Background
The craniopharyngioma is a non-endocrine tumor, developed along the infundibulo-pituitary axis, from the 3rd ventricle to sphenoid, histologically benign but locally invasive. It is a tumor with serious complications because of its location, its considerable potential for extension, its tendency to recur, and its adhesions to neighbouring structures. Our aim is to assess hormonal, neuro-ophthalmological and metabolic complications at the diagnosis of craniopharyngiomas.
Patients and methods
It is a multicentre Cross-sectional descriptive study in the town of Oran, with prospective and retrospective data collection. MRI, hormonal, biochemical and ocular tests, made the diagnosis. Data entry and analysis were performed with CDC Epi Info version 6 (USA), SPSS 20, Statistica10.
Results
In our study, we collected 86 non-adenomatous tumours, among them 26 craniopharyngiomas (35%), sex ratio men/women at 1.3. Average age at 17.3 ± 13.5 years (2-56). Mean consultation time 20.5 ± 25.3 (1-96) months (range). Circumstances of discovery: headaches - visual disturbances (79.8%), growth retardation (15.4%) and hypogonadism in adults (20.4%). Average dimensions (mm ± SD): average height 39.1 ± 17.4, transverse diameter 32.2 ± 14.9, antero-post diameter 36.0 ± 17.5, extremes 15-95 mm. Extensions (percentage): Supra sellar (88.5), Infra sellar (46.2), posterior (23.1), Multidirectional extensions (38.5). Anterior pituitary insufficiency 96.1%, multiple anterior pituitary deficiencies 77.5%, hypothalamic syndrome 30.8%, epilepsy 11.5%, diabetes insipidus 23%. Neuropsychiatric complications (55.1%), ophthalmological (79.8%), blindness 23%, hydrocephalus 68.7%.
Discussion
Craniopharyngiomas are accompanied by significant pituitary, hypothalamic and neuro-visual morbidity. The consequences of a delay in diagnosis increases the frequency and severity of complications, hence the need for early diagnosis in order to control this morbidity, the burden of which is considerable on the health system.

'Features of cardiovascular complications in patients with cushing syndrome in the republic of uzbekistan (register data)'

Gavhar Jabborova[1] & Zamira Khalimova[1]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

The purpose of the study
Is to study features of cardiovascular complications in patients with Cushing syndrome in the Republic of Uzbekistan (RUz).
Material and research methods
In the period of 2002 to 2021, 317 patients were installed with the following clinical forms of Cushing syndrome (CS): 1) ACTH-dependent CS (ACTH-DCS) - 258 (81.3%) patients, of which women -174 (54.8%), men - 84 (26.4%), 2) ACTH independent CS (ACTH-iCS) -51 patients (16.08%) of women - 41 (12.9%), men - 10 (3.15%). 3) Ectopic CS (ACTH-ECS) -8 patients (2.5%) of women-5 (1.5%), men-3 (0.94%). The average age during the manifestation of men amounted to 26.38 ± 3.4 years, women - 27.58 ± 3.4 years. The illness of the disease ranged from 4 months to 25 years. 10 patients amounted to a control group. The study used clinical and biochemical, hormonal studies (serum, urine), functional tests, as well as instrumental (neurophthalmological, radiological - MRI pituitary gland, MSCT of adrenal glands, X-ray absorption densitometry and statistical techniques.
Results
The most frequent complications of the CS were cardiovascular complications (CVC), which developed in 113 (48.9%) patients with a predominance of female 74 (61.3%).. Among them, malignant arterial hypertension, acute vascular disasters in the form of myocardial infarction took place more often. In the 1st group of patients with ACTH- DCS total in men, the CVC frequency was 45 (53.5%), and among women - 80 (45.9%), only 125 cases out of 258 (48.4%). In the 2 group of patients with ACTH-iCS among men the CVC frequency was 2 (20.0%), and among women - 13 (31.7%), only 15 cases out of 51 (29.4%). And, finally, in a 3group of patients with ACTH- ECS in men, the CVC frequency was 1 (33.3%), and among women - 1 (31.7%), only 2 cases of 8 (20%).
Conclusions
Of 317 patients with CS in 142 (44.8%) cardio-vascular complications were recorded and more often in the 1 st group of patients.

Acromegaly in the elderly patients

Dayssem Khelifi, Nadia Khessairi, Ameni Terzi, Wafa Grira & Melika Chihaoui
Rabta's University Hospital, Endocrinology's Department, Tunis, Tunisia

Introduction
Pituitary adenomas in people over 65 represent less than 10% of all pituitary adenomas, 80% of which are non-functional. Somatotropic adenomas remain very rare. The interest of our study is to describe the clinical, paraclinical and therapeutic profile of cases of senile acromegaly.
Patients and methods
This is a retrospective study of four senile acromegaly patients followed in our endocrinology's department.
Results
We report four cases of acromegalic patients, one woman and three men, respectively aged 75, 68, 65 and 69 at the time of diagnosis. Two had been diabetic and hypertensive for 05 years. The circumstances of discovery were a tumor syndrome in two patients, a dysmorphic syndrome in one patient and digestive symptoms secondary to a tumor process in another patient. The diagnosis was confirmed by elevated IGF1, a paradoxical GH response on OGTT and a disturbed GH cycle (two diabetics). Radiological exploration by pituitary MRI showed that it was a macroadenoma in 100% of cases with invasion of the cavernous sinuses and compression of the optic chiasm in two cases. The impact assessment revealed: corticotropic insufficiency (2 cases), bilateral visual field impairment (2 cases), moderate to severe sleep apnea syndrome (4 cases), hypertrophic heart disease (2 cases), arthropathy peripheral (2 cases), hypertriglyceridemia (1 case), a stenotic tumoral process inaugurating the disease in one patient and polyposis colon in two other patients, a multinodular goiter (1 case) and a TIRADS 2 nodule (2 cases). Therapeutically, the patient was treated surgically via the transphenoidal approach with simple post-operative follow-up. Given the operative risk and the non-motivation of the two other patients for surgery, they were put on a somatostatin analogue with a favorable outcome. The fourth patient was lost to sight.
Conclusion
Somatotropic adenomas in the elderly patients are rare, characterized by a diagnostic delay. Surgery, if possible, remains the treatment of choice for acromegaly in the elderly, but somatostatin analogues have also shown their effectiveness in the treatment of these patients.

Features of the incidence of postoperative complications in patients with transsphenoidal pituitary adenectomy

Gulmira Inomova & Zamira Khalimova
TashPMI, Tashkent, Uzbekistan

Target
To study the incidence of postoperative complications in patients with transsphenoidal pituitary adenoectomy.
Materials and research methods
180 cases of PA subjected to TPA for the period from 2018 to 2020 were analyzed. Of these, 102 (56.6) women, 78 (43.3) men, patients were divided into two alternative groups: the first group - 93 (51.6%) patients with macroadenomas - 42 (45.2%) men, women 51 (54.8%), the second (comparison group) - 87 (48.4%) with microadenomas of men - 35 (40%), women - 52 (60%) of the pituitary gland. The age of the patients ranged from 30 to 59 years. The levels of hormones STH, IGF-1, ACTH, cortisol, prolactin, TSH, fT4, LH, FSH, estradiol, progesterone according to indications, MRT/CT of the chiasmal-sellar area and the state of the organ of vision were studied.
Results
Patients were distributed as follows: depending on the hormonal activity of patients with adrenocorticotropic hormone secreting Cushing's syndrome-60, acromegaly-60, inactive pituitary adenoma-60; depending on the size of the formation: 93 (51.6%) were with macroadenomas, 87 (48.3%) with pituitary microadenomas. An analysis of the incidence of postoperative complications in the short term (1 month) revealed that in 81 (45%) patients with hypopituitarism; hypothyroidism in (70)39%; hypogonadism in 50(28%); diabetes insipidus in 7(4%); transient diabetes insipidus in 11(6%); visual acuity deterioration in 2 (1.2%) patients and liquorrhea in 3 (5.4%) patients. At the same time, there was a normalization of elevated hormone levels in 133 (74%) patients; 30% improvement in vision; lack of disease dynamics in 47 (26%). Despite the persistent phenomena of hypopituitarism 47(26%) and diabetes insipidus 11(6%), which were mainly observed in 165(92%) patients with macroadenomas and did not depend on the organ activity of the formation (against 54(30%) cases with microadenomas). In the long-term follow-up of patients after TPA (t 3 months to 1 year), an improvement in pituitary function was noted in the form of restoration of gonadotropic insufficiency, phenomena of transient diabetes insipidus and improvement in hypertensive cephalgia.
Conclusion
The frequency of immediate and long-term complications in most cases is observed in pituitary macroadenomas and does not depend on the hormonal activity of the adenoma.

'The frequency of postoperative hypopituitarism in patients with non-functional pituitary adenomas (NFPA) after transnasal hypophysectomy'

Malika Mirtukhtaeva[1] & Urmanova Yulduz[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

The purpose of the study
is to study the frequency of postoperative hypopituitarism after transnasal hypophysectomy (THE) in patients with pituitary adenomas.
Material and methods
Under our observation there were 24 patients with NFPA, of whom women were 14, men - 10. The average age of patients was 36.4 years. Total of 24 patients were performed for the period from 2016 to 2021 33 surgery in the neurosurgery department., of which THE - 32, 1 - bifrontal craniotomy. At the same time, 3 patients were 2 THE, in 3 - 3 THE, 4 patients with TGE also received radiation therapy. The whole patients were performed by research complex, which included radioimmune hormonal (STH, IGF-1, Prolactin, LH, FSH, TSG, ACTH, Cortizol, etc.), ophthalmological (Eye bottom, field of view) and X-ray studies (CT, MRI of the Turkish saddle).
Results
According to our data, postoperative panhibitionituitarism (deficiency of STH, LH, FSH, ACTH + Diabetes insipidus) developed in 6 patients (25%), postoperative partial hypopituitarism (deficiency of STH, LH, FSH) developed in 11 (45.8%) and 7 - STH deficiency (29.1%) developed. Thus, the most pronounced neuroendocrine disorders after THE were detected in 6 (25%) patients.
Conclusions
1) In patients with adenomas of pituitary gland subjected to THE, it is recommended to monitor the levels of all tropic and peripheral hormones of pituitary glands both in the early and later postoperative periods. 2) patients with pituitary adenomas after THE need substitution hormone therapy with appropriate drugs depending on the level of hormones (desmopressin, sex and thyroid hormones, corticosteroid preparations, growth hormone).

'Case of re-growth of aggressive giant non-functional pituitary adenoma with panhypopituitarysm in 28-years old woman'

Urmanova Yulduz[1] & Malika Mirtukhtaeva[2]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

The purpose of the study
Is to research case of re-growth of non-functional giant pituitary adenoma (NFPA) with panhypopituitarysm in 28-years old woman
Material and research methods
Patient Karimova N, was born in 1994 in Namangan region. Clinical diagnosis: Non-functional giant pituitary adenoma with total variant of growth. Status after transnasal selective adenomphysisectomy (12.04.16). Re-growth of tumor. Second transnasal selective adenomphysisectomy (26.11.2021). Complications. Panhypopituitarysm. Secondary hypogonadism, hypocorticism, hypothyroidism. Growth hormone deficiency. Bitemporal hemianopsia. Functional

hyperprolactinemia. Primary infertility. Secondary amenorrhoea. The patient considers himself to be ill from 2015 year after marriage. She was operated on the occasion of pituitary adenoma with supra-infra-latero-sellar growth. Micro-cellular chromophobe adenoma was histologically determined. In early post-operative period the improvement of vision was marked. In late postoperative period neuroendocrine disorders were left without dynamics. As the patient wasn't observed regularly, she received Kabergolin 5 mg twice in week during 6 months. The patient refused from radiotherapy. The worsening of state was marked for the last 6 months, when the above mentioned complaints increased.
Results of the study
Height is 156 sm, weight is 55 kg. BMI = 24, 4 kg/m2. The skin coverings are pale, dry, clean. A/*P* = 110/70 mm.mer.e. Puls rate = 72 beats per min. In blood plasma GH – 0,13 ng/ml (norma 2-5 ng/ml), IGF-1 - 88 nmol/l (norma 300 nmol/l), FSH-0,94 Med/l, LH – 0, 46 MEd/l (norma 3-8 mME/l), cortisol in the morning – 55,1 nmol/l (norma 260-720 нмоль/л,), prolactin – 307 ng/ml (norma 7-8 ng/mi), estradiol – 17, 4 pg/ml. Ophthalmologist. Bitemporal hemianopsia on white color, absence of visual fields on green and red colors from both eyes. MRI : Pituitary macroadenoma with the size 5,6 sm x 4,3 sm x 5,4 sm The patient was operated again in our clinic. In the early postoperative period the patient was marked improving of visual fields.
Conclusions
1. For NFPA with small cellular chromofobe cells in patients of reproductive age it is typical aggressive re-growth of tumor. 2. For prevention of re-growth of giant pituitary tumor after surgery it is necessary to conduct for patient radiotherapy.

Cushing syndrome and disease: A doctor of philosophy study conducted by a patient

Margaret McBride
Lancaster University, School of Medicine & Health Sciences, Bailrigg, United Kingdom

Introduction
Prior to and since the onset of my Doctorate study in 2019, a plethora of on-going research including my own has been conducted into the diagnosis, treatment, and management of Cushing syndrome (CS), and disease (CD). These conditions continue to challenge physicians not only in the diagnosis but how to treat their patients. The wide clinical spectrum of CS and CD produces a medical dilemma as patients' symptoms, can vary. The typical Cushingoid features which are referred to as the classic symptoms are not always obvious when a patient presents. There are population groups which have increased incidence of CS which includes obesity, diabetes, and osteoporosis. The diagnostic approach is a 3-step investigative process and includes *a)* a physician's knowledge of the signs and symptoms, which is crucial to make *b)* a definitive diagnosis of CS. The third step of this process is *c)* to identify the reason for excess cortisol.
Learning Process
The learning process during this study has been exponential and led to a clearer understanding as to why it took so long for my physicians to make a definitive diagnosis of initially CS and then CD. This personal Cushing's journey of study revealed the reasons for the twists and turns on the 'bumpy,' road to diagnosis, treatment and then remission. Comparing other patients experiences during my study with my own, provided an understanding why we experience pain, changes in our personality, fatigue, a reduction in quality of life (QoL), and in most cases, irreversible comorbidities, my own being osteoporosis. During the process of study, I endeavoured to use my knowledge and skills as a Health Professional, promoting awareness through conference presentations and publications. On the long road to remission, I discovered the importance for Health Professionals, particularly General Practitioners and the public, to recognise patients' unmet needs.
Study Conclusions
By taking a more patient-centred approach including time to listen to their patients, in parallel with the well-established biochemical and imaging tests would increase early diagnosis and treatment.
Recommendations
Recommendations included identifying target audiences, examples women's clinics, and methods of screening obese and diabetic patients. Increase in using advanced technologies such as artificial intelligence in identifying early signs, example osteoporosis. Virtual learning platforms for educating Health Professions, extensive use of thematic analysis in QoL questionnaires and media coverage to raise awareness.

Metabolic abnormalities profile of non-functioning pituitary adenomas

Wahiba ABDELLAOUI[1], Imane Assarrar[1], lamiae zarraa[1], soumiya berrabeh[1], Siham ROUF[1, 2] & Hanane Latrech[1,2]
[1]Mohammed VI University Hospital, Medical School, Mohammed the First University, Department of Endocrinology-Diabetology-Nutrition, OUJDA, Morocco; [2]Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy of Oujda, Mohammed the First University, Oujda, Morocco

Introduction
Metabolic abnormalities are common in pituitary adenomas and metabolic targeting is becoming a new therapeutic approach to the management of most tumor pathologies, especially pituitary tumors. The objective of this work was to assess the metabolic profile of non-functioning pituitary adenomas.
Material and methods
A retrospective and descriptive study, over a period of 6 years, conducted in the Endocrinology-Diabetology and Nutrition department of Oujda in the eastern of Morocco. The study included 24 patients with histologically confirmed non-functional pituitary adenoma.
Results
The mean age was 50 ± 11.2 years, with a female predominance (58.3% of cases). The average duration of the disease was 1.9 ± 3.6 years. The clinical examination found 50% of the patients to be overweight and 20.8% were obese. The metabolic work-up showed type 2 diabetes in 20.8% of cases and pre-diabetes in 33.3%. Hyperuricemia was found in 16.6% of patients. On the lipid panel, mixed dyslipidemia was revealed in 20.8% of the patients, hypertriglyceridemia and hypoHDLemia < 0.35 g/l were confirmed respectively in 25% of cases and hypercholesterolemia in 12.5% of patients.
Conclusion
Metabolic abnormalities associated with non-functioning pituitary adenomas are correlated with disease progression and prognosis. The evaluation of metabolic status should be emphasized during treatment of pituitary adenoma and control of metabolic abnormalities should be added to their current therapies.

Kallmann's Syndrome: case report

Rokya Abdel Aziz, Heba Moustafa, Soad Sultan, Randa Salam, Ola El Garhi, Iman Tohamy, Aya Taraby & Amira Nashat
Cairo University, Internal Medicine, Endocrinology, Cairo, Egypt

Introduction
Kallmann syndrome, a rare genetic disorder, refers to the association between hypogonadotropic hypogonadism and anosmia or hyposmia due to abnormal migration of olfactory axons and gonadotropin-releasing hormone producing neurons It can be autosomal dominant, autosomal recessive, or X-linked inheritance.
Case report
A 16-year-old male student, presented to endocrinology unit with delayed puberty. He was born to consanguineous parents and had normal delivery. He had normal developmental mile stones. Bilateral cryptorchidism was discovered at age six, associated with hyposomia but no hearing defect or oral cavity abnormalities. He was diagnosed with anosmia. Skull magnetic resonance imaging (MRI) revealed hypo plastic olfactory bulbs and shallow olfactory grooves, along with a normal pituitary gland and a normal pituitary stalk. No history of deepening of voice or morning erection Physical examination: Height : 164 cm, arm span was 169 cm, BMI: 17, no gynecomastia Genital examination showed Tanner stage 1 (penis 3 cm, empty scrotum at time of examination with no corrugation & absent axillary & pubic hair) Neurologic examination was otherwise unremarkable except for decreased sense of smell.
Investigations
ACTH:12 pg/ml(10-60), TSH:3 mIu/l(0.4-5), PRL was 13 ng/dL(N: < 20 ng/dl), FSH : 0.71 IU/ml (1.4-18), LH :0.1 IU/ml (Adult:1.7-8.6, prepubertal up to 6), Total Testosterone:1.79 ng/ml (> 2.5 ng/ml) Scrotal ultrasound revealed: both testes are ectopic in location rt :at the RT inguinal canal, LF seen in left scrotal neck, both tests are small in size for patient age RT 13x5.8x13.6 mm/lF 10x5x11.3 mm Chromosome analysis showed 46, XY He was prescribed human chorionic gonadotropin 5000 IU weekly for 6 weeks and testosterone cream daily, with a 25 mg of intramuscular testosterone injection and were then increased by

25 mg every two weeks Regular follow-up showed a change in voice and appearance of coarse pubic hair. Morning erections was reported, the testes and penis increased in size respectively (testes = 2 cc, phallus = 4 cm). Serum testosterone increased to 1.5 ng/ml
Conclusion
Clinical abnormalities during childhood such as cryptorchidism, anosmia or pubertal delay should be considered warning signs to start diagnosing Kallmann's syndrome. Early diagnosis triggers the initiation of multidisciplinary care in Pediatrics and adolescent medicine Timely treatment is relevant to restore metabolic, bone, sexual balance and psychosocial effects. Gonadotropin and pulsatile GnRH therapy are the treatment of choice to induce fertility Spermatogenesis can be induced in the majority of these patients and fertility rates are above 50%.

DOI: 10.1530/endoabs.81.EP837

'The functional status of pituitary-gonads-cortex axis in women on fertile age with ACTH-depended Cushing syndrome'

Zamira Khalimova[1] & Oydin Irgasheva[1]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

Aim
– to study the functional status of pituitary-gonades-cortex (PGC) axis in women with Cushing syndrome (CS)
Materials and methods
Weevaluated 25 women with ACTH-depended CS without other associated pathology. Mean age of patients was 28,3 years-old.. All patients have complaints to amenorrhea and primary infertility. Control group constituted by 20 healthy women with same age All patients underwent clinical and biochemical evaluations including endocrine check, lipids profile, hormonal profile in 14 day of menstrual cycle (LH, FSH, prolactin, free testosterone, estradiol, progesterone, etc), genitalia ultrasonography, electroencephalography (EEG), height, weight, BMI, waist circumference (WC), hip circumference (HC), waist-hip ratio, questioning and other studies.
Results
The investigation ofhormonal profileshowed anovulation in 19 patients (76%) (mean LH ranged 3,7 ± 1, 2 mIU/l, FSH 4,4 ± 1,5 mIU/l) in 14 day of the menstrual cycle and high range of free testosterone levels (mean 3,6 ± 0,3 ng/ml). Besides that, all patients have hypercortisolemia. ($P < 0{,}05$). The investigation of levels of estradiol and progesterone in 7,14, 21 days of menstrual cycle showed of their partial decrease. Most of the patients had central obesity with BMI > 35 kg/m^2. WC was in normal range 104,3 ± 7, 4 cm, HC = 85, 6 ± 5,3 cm, whereas waist-hip ratio > 1, 22. Blood tests showed dyslipidemia in all patients (100%).
Conclusions
Mostfertilewomen with ACTH-DCS (76%) have anovulation with high range of free testosterone in all patients with partial decrease of estradiolum, progesterone (secondary hypogonadism).

Diagnosis of Kallmann syndrome in adulthood

Elyes Kamoun[1, 2], Sabrine Mekni[1, 2], Meriem Adel[1], Imen Rojbi[1, 2], Ibtissem Ben Nacef[1, 2], Nadia Mchirgui[1, 2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia

Introduction
Kallmann syndrome is a rare genetic condition characterized by the association of a hypogonadotropic hypogonadism and anosmia. It results from the failure of GnRH cells to migrate to the hypothalamus and lack of development of the olfactory bulb. The main symptom of Kallmann syndrome is delayed or incomplete puberty usually associated with an impaired sense of smell. We herein describe a case of Kallmann syndrome discovered at the age of 57 years old.
Observation
We report the case of a 57 years old man, with a history of a pathologic fracture, referred to our department for exploration of gynecomastia. The patient didn't reveal any symptoms such as erectile dysfunction or reduced sex drive, only an anosmia lasting since his youth. Physical examination revealed a grade 2 bilateral gynecomastia, a blood pressure of 150mmHg over 90mmHg. Examination of the external genital organs showed normal pubic hair, a micropenis measuring 5 cm and hypotrophic testis. On hormonal investigations, his testosterone levels were at 0,442 ng/ml, his LH levels were at 0,05 mUI/ml and his oestradiol levels were at 20,55 pg/ml (< 62 pg/ml in male). His prolactin levels were normal at 2,68µg/l. Corticotropin and thyrotropin deficiency were excluded. On imaging investigations, he had an osteoporosis with a T-score at -5,2 and hypotrophic non nodular testis. The magnetic resonance imaging of the brain couldn't be performed as the patient has metallic orthopedic devices. He was put under calcium, vitamin D, bisphosphonates and testosterone therapy after eliminating contraindication.
Conclusion
This case highlights a non-classical presentation of a Kallmann Syndrome discovered during the investigations of gynecomastia. The delay of diagnosis was due to the reluctance of the patient, explaining with the spontaneous onset of puberty, the late diagnosis at this age. The psychological impact of this disease could have been prevented with an early treatment.

Evaluation of neuroendocrine dysfunction in the diagnosis of depressive and non-depressive alcohol-dependent persons

Shaibal Guha[1], Anand Shankar[2], Amit Kr Das[3] & Subhash Kumar[4]
[1]Positive Health Care Center, Diabetes, Patna, India; [2]Shankar Diabetes Care and Research, Diabetes, Patna, India; [3]SHMC Muzaffarpur, Diabetes, Muzaffarpur, India; [4]Diabetes and Obesity Care Center, Patna, India

Introduction
Acute and chronic alcohol intake and alcohol withdrawal induce dysfunction of neuroendocrine and other regulatory systems. The expression 'neuroendocrine dysfunction' alludes to an assortment of conditions brought about by imbalances in the body's chemical creation straightforwardly connected with the pituitary, nerve center, and their tomahawks following TBI.
Aims
This study aimed to assess a possible hypothalamo-pituitary-adrenal (HPA) axis dysfunction in a population of alcoholics, using a dexamethasone suppression test (DST).
Methods
For this study, 90 participants had been selected, among whom 65% of participants were depressive and 35% of are non-depressive alcoholics.
Discussion
The serum and urinary cortisol were compared between the groups of 89 male patients (65% depressive and 36% non-depressive alcoholics) (Hamilton test), before and after DST. In non-depressive patients, 49% was non-suppressive in DST. In depressive patients, 47% was suppressive in the DST test (serum cortisol). Twenty-four hours urinary excretion in a group of non-depressive patients was suppressed in 79% of cases; depressive patients showed 50.9% non-suppressors. Basal serum cortisol secretion was significantly lower in a group of non-depressive than depressive patients. Also, serum concentrations at 16 h were significantly higher in a group of depressive non-suppressive patients. Basal urinary cortisol excretion was in the normal range in all patients, but after dividing the patients into suppressible and non-suppressible groups, significantly higher ($P < 0.002$) basal urinary cortisol concentrations were found in the latter.
Conclusion
Based on the DST test and the basal cortisol measurement, the findings reveal that the neuroendocrine dysfunction of alcoholic patients could be present even if the depression is pronounced.

Descriptive study of the acromegaly disease activity according to ACRODAT® in a tertiary Hospital in Spain

Juan Carlos Percovich Hualpa[1], Roberto Añez[1], Rogelio Garcí a Centeno[1], Laura Gonzalez Fernandez[1], Diego Munoz[1], ALEJANDRA MARICEL RIVAS MONTENEGRO[1], Elisa Fernández Fernández[1], Crystal Guerrero[2] & Olga González Albarrán[1]

[1]Hospital General Universitario Gregorio Marañón, Endocrinology and Nutrition, Madrid, Spain; [2]University of Virginia, Charlottesville, United States

Background
The goals of acromegaly treatment are to achieve long-term biochemical control, control tumor size and decrease the risk of developing systemic comorbidities. Moreover, from the patient's perspective, symptoms and QoL are critical parameters of disease control and should be assessed routinely. To aid in the global clinical management of acromegaly, a holistic clinical decision support tool, the Acromegaly Disease Activity Tool (ACRODAT®) was developed.
Objectives
To describe and analyze the acromegaly disease activity according to ACRODAT®.
Methods
Observational, cross-sectional study conducted in a Spanish tertiary hospital (Hospital General Universitario Gregorio Marañón). The ACRODAT® tool was used to assess disease activity entering the data collected in the study.
Results
In total, 42 acromegaly patients were enrolled. 26 patients were female (61.9%). The average age was 59.66 years (SD 15.22), the BMI was 31.85 Kg/m^2 (SD 20.53), % body fat mass was 36.93 (7.52), % truncal fat mass was 36.93 (7.52). IGF-1 levels were within normal limits in 64,3% of patients, between ULN and 1.2xULN in 21.4% of patients and $>$1.2 ULN in the 14.3% of patients. 100% of patients showed a stable tumor size. The most frequent comorbidity was cardiac disease (57.14%), followed by sleep apnea (40.48%) and diabetes (35.71%). According to ACRODAT®, 61.9% ($n=26$) of patients were classified as stable (S), 23.8% ($n=10$) as having mild disease activity (M-DA) and 14.3% ($n=6$) as having significant disease activity (S-DA). 100% of S-DA patients showed IGF-1 levels $>$1.2ULN, 83.3% suffered from cardiac disease ($n=5$), 50% from diabetes ($n=3$) and 16.7% from sleep apnea ($n=1$). 66.7% ($n=4$) of S-DA patients showed not-controlled comorbidities, 50% ($n=3$) poor controlled of the symptomatology and 16.7% ($n=1$) poor QoL. In the total cohort of patients, in terms of comorbidities, patients were classified as controlled in 33.3% of patients, partially controlled in 33.33% of patients ($n=14$) and not controlled in 30.2% ($n=13$). Symptomatology was classified as stable in 31% of cases ($n=14$), 55.8% of cases ($n=24$) as mild activity and 9.3% of the patients ($n=4$) as significant disease. 58.1% of patients showed minimal or no impairment of QoL, mild impairment in 25.6% of patients and 14% with significant impairment.
Conclusions
ACRODAT® is a validated tool to monitor acromegaly disease activity that incorporates patient-centric parameters such as QoL and symptomatology.

DOI: 10.1530/endoabs.81.EP841

EP842

Central precocious puberty in a young boy associated with bilateral optic pathway glioma in neurofibromatosis Type 1: a case report

Muhammad Saleem[1], Saad Farooq[1] & Imran Ulhaq[2]
[1]Aga Khan University Hospital, Department of Medicine, Section of Diabetes, Endocrinology and Metabolism, Karachi, Pakistan; [1]Aga Khan University Hospital, Department of Medicine, Section of Diabetes, Endocrinology and Metabolism, Karachi, Pakistan

Background and Importance
Precocious puberty refers to sexual characteristics development before the normal age for its development. Neurofibromatosis Type 1 is an autosomal dominant condition with wide spectrum of clinical phenotype of which precocious puberty is common. This case report highlights the importance of recognizing this disease in patient presenting with precocious puberty and screening for optic pathway gliomas should be done and treat it to prevent the future chances of permanent blindness, neurological disability and gonadotropin deficiency.
Clinical Presentation
9 years old male came with chief complains of decreased/blurring of vision from the age of 3 to 4 years, increased pubic hair growth and multiple regions of skin lesions noticeable for the last 1 year. Clinical examination of the patient revealed classic features of precocious puberty. Hormonal workup showed significantly raised testosterone levels and mildly raised FSH levels. MRI brain was done which showed abnormally thickened bilateral optic nerves and optic chiasma, suggestive of optic nerve glioma. Final diagnosis of Neurofibromatosis Type 1 manifesting as Central Precocious Puberty in association with bilateral optic pathway Glioma was made.
Conclusion
By this case report, physician's attention is directed towards the importance of recognizing this disease with precocious puberty and screening for optic pathway glioma should be done, even when patient don't have any visual symptoms and treat it early which will help in preventing the complications of optic pathway glioma in long term and ultimately shall benefit patients in part of their increased survival, satisfaction and decreasing morbidity.

DOI: 10.1530/endoabs.81.EP842

Acromegaly-related dysmorphic syndrome In Mediterranean Patients: A monocentric retrospective Survey

Faten Haj Kacem Akid[3], Wafa Belabed[3], Elleuch Mouna[3], Cyrine Chehaïdar[3], Dhoha Ben Salah[3], Fatma Mnif[3], Nabila Mejdoub[3] & Mohamed Abid[3]
[1]Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [3]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background and Aims
Acromegaly is an insidious disease related to hypersecretion of growth hormone (GH) that leads to several cardiovascular, respiratory, and metabolic comorbidities. The onset of dysmorphic body changes is one of the earliest signs of this condition. The objective of the current work was to describe the clinical manifestations of dysmorphic modifications characterizing Mediterranean patients diagnosed with acromegaly.
Patients and Method
We conducted a retrospective study that included all patients diagnosed with acromegaly who have been followed up, from 1997 to 2021, at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia. The review of medical charts provided a detailed description of dysmorphic features in the investigated population.
Results
Our sample included 29 with a mean age at diagnosis of 45.8 $\pm$ 12.4 years old (extremes: 23-72). No significant gender differences was reported (sex-ratio = 1.07). Dysmorphic features were observed in all patients with variable degrees. Patients diagnosed with acromegaly presented with facial changes in 96.5% of cases. Cranial ridges (41.1%), frontal skull bossing (48.3%), and enlarged nose (75.9%) were frequently recorded. Similarly, jaw and oral deformities were very common among the studies population such as prognathism (72.4%), enlarged lips (55.2%), and mandibular overgrowth with maxillary widening and teeth separation (37.9%). Macroglossia was found in 48.3% of cases. Acral modifications occurred in more than 80% with swelling thin-skinned hands in 51.7% and enlarged shoe size in 82.8% of cases. Skeletal axial involvement was present in 24.1% including kyphoscoliosis and diffuse skeletal hyperostosis.
Conclusion
Comorbidity and mortality rates in acromegaly are significantly higher compared with healthy subjects due to its delayed diagnosis and therapeutic difficulties [1]. Unlike North America and Northern Europe, acromegaly remains largely underdiagnosed, especially in the southern Mediterranean countries. Dysmorphic modifications are one of the earliest symptoms of this disease [2]. Raising awareness about acromegaly and its dysmorphic syndrome in the general population and among physicians in the Mediterranean region could aid in the early detection of undiagnosed cases.

Cushing's disease in a 14 year old child: A real diagnostic and therapeutic challenge

Trigui Souleima, Lassoued Najoua, Mrabet Houcem, Boubaker Fedia, Alaya Wafa & Sfar Mohamed Hbib
Mahdia, Endocrinology, Sfax, Tunisia

Introduction
Cushing's disease (CD) is a rare but serious pathology in children and adolescents. It differs from adult pathology by the mode of presentation and

management. We report a case of CD in a 14-year-old child whose diagnosis was confirmed only after 2 years.
Observation
This was a 14-year-old female patient with a family history of consanguineous marriage and personal history of nephrotic syndrome who presented with delayed stature, delayed puberty and obesity. On initial examination, she had Cushing's syndrome with facio-truncular obesity, buffalo hump, spontaneous bruising, and purple stretch marks. Her Weight was +2SD, her height was -4SD, with BMI of 33.5 kg/m2.Tanner score was A2P2S2R0. The diagnosis of ACTH-dependent Cushing's syndrome was made in view of an abolished cortisol cycle, an elevated CLU of 182 mg/24h and a low post-braking cortisol level of 140 ng/ml with an elevated ACTH of 97 pg/ml. Investigations to decide between a central origin and ectopic ACTH secretion were initially discordant. In favor of CD: Positive desmopressin test, elevation of Cortisolaemia of 30% higher, and ACTH of 20%higher, no carcinoid tumor on thoracic CT scan and no pathological fixation on Octreoscan. Negative strong braking (Cortisol level at 170 ng/ml) andHypothalamic-pituitary MRI without abnormalities were in favor of ectopic ACTH secretion. A second hypothalamic-pituitary MRI was performed 6 months after the diagnosis of CS, showing a right anterolateral microadenoma of 3. 4 *5 mm with a small dehiscence of the sellar floor, There was no evidence of multiple endocrine neoplasia. Thoracoabdomino-pelvic CT scan showed bilateral adrenal hypertrophy predominantly on the left. The patient received a preparation with ketoconazole and then was operated: A complete excision of the friable microadenoma and all the surrounding parenchyma was passed without incidents. Immediately postoperatively, the patient presented with central diabetes insipidus and recurrent bacterial meningitis. An osteomeningeal breach was surgically repaired in a second stage. She presented panhypopituitarism and was substituted with Lthyroxine and hydrcortisone.Currently, at one and a half years post-operatively, the patient retains signs of hypercorticism with faciotruncal obesity. The 8-h cortisol level is less than 2 ng/ml confirming corticotropic insufficiency, a key biological marker of remission. Discussion/Conclusion: Our case illustrates the diagnostic and therapeutic difficulty of CD in an adolescent girl. Since the cure rate is lower than in adults with a higher risk of recurrence and a shorter median recurrence time, a long term follow-up and a cardiovascular, metabolic and bone assessment in our patient is crucial.

Clinical, biological and radiological particularities of acromegaly: Experience of the Endocrinology Department of the EPH Bologhine of West Algiers

Aicha Bouzid, Hanane Kherrab, Meskine Djamila & Malha Azzouz
Medical University of Algiers, Endocrinology & Metabolism Laboratory Algiers 1, Endocrinology Department of the EPH Bologhine, Algiers, Algeria

Introduction
Acromegaly is caused by chronic hypersecretion of GH and IGF-1. Chronically elevated GH and IGF-1 levels lead to a complex spectrum of signs.
Objectives
To describe the clinical, hormonal and radiological profile of acromegaly at the time of diagnosis.
Materials and methods
Retrospective study including 67 patients hospitalized in the Endocrinology Department of the EPH Bologhine
Results
There were 40 men and 27 women (Sex ratio M/F:1,48), the average age at the time of diagnosis of the patients was 43years, a partial or total anteropituitary insufficiency was found in 38,8% of the cases. This was global in 10.4% and partial in 28.35%. 7.4% of the patients had intestinal polyps, 2 of the 67 acromegalic patients had a thyroid cancer neoplasia and a colonic adenocarcinoma. Metabolically, 15% of the patients had diabetes mellitus Radiologically, a macroadenoma was found in 83.5% of cases, a microadenoma in 13.43% of cases. Hyperplasia was noted in one patient. In one case the pituitary gland was normal and the etiological investigation in search of an ectopic secretion was negative.
Conclusion
Our results agree with the data described in the literature, although acromegaly is more frequent in women. An early diagnosis is necessary in these acromegalic patients.

Case report: Kallmann syndrome associated with a non-functional pituitary microadenoma

Sanaa Bammou, Sana Rafi, Ghizlane EL MGHARI & Nawal EL ANSARI
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakech, Morocco

Introduction
Kallmann syndrome (KS) is a rare disorder. It is now designated as olfactogenital dysplasia with an association between agenesis of the olfactory bulbs and hypogonadism. The association of KS with a pituitary microadenoma has not been well described in the literature.
Case report
It's a 16-year-old and 6 months, admitted for evaluation of a micropenis, he has as ATCDs an orchidopexy performed at the age of 3 years, infertility in the maternal uncle. During the interrogation a growth retardation was noticed from childhood, anosmia since the age of 7 years. The clinical examination revealed a a eunuchoid body proportion Body mass index (BMI) of 24.52 kg/m^2, gynecomastia without galactorrhea. Tanner scale: G1P2. He had micropenis (stretched phallus length 3.5 cm). Hormonal assays identified a hypogonadotropic hypogonadism profile with total testosterone 0,58 ng/ml, luteinizing hormone 0.1 IU/ml and follicle-stimulating hormone 1 IU/ml. prolactin (PRL) and the cortisol blood test are within normal limits. She had normal Thyroid function Karyotyping showed 46XY pattern. MRI of the brain showed hypoplasia of the olfactory bulb, especially on the left. MRI also revealed a 4 mm pituitary microadenoma. Androgen replacement is planned for patient
Discussion
We report a case of a rare association of KS with a non-functional pituitary microadenoma. KS is an isolated form of hypogonadotropic hypogonadism in combination with a defect in sense of smell. It is due to defects in olfactory structures (bulbs, grooves, tracts) and altered migration of GnRH-secreting neurons into the preoptic and hypothalamic regions. The patient's clinical presentation seems to be concordant in the literature, with the classical association of hypogonadotropic hypogonadism and anosmia. MRI is highly valuable in evaluating suspected KS. Data suggest that, in hypogonadotropic hypogonadism, MRI being a non-irradiating technique, should be the first radiological step for investigating the pituitary gland as well as abnormalities of the ethmoid, olfactory bulb and tracts. The central finding in the present case is the MRI finding of a non-functioning pituitary microadenoma in association with KS. This association has been previously reported by Bolu *et al*. in their MRI assessment of 120 male patients with idiopathic hypogonadotropic hypogonadism.
Conclusion
Olfactory MRI imaging may aid in the diagnosis of KS in patients with suggestive clinical findings. Pituitary adenoma is a rare association with the KS. This emphasizes the need to image the pituitary region in KS patients to assess for hypoplastic pituitary malformations or adenomas incidentaloma.

Acromegaly revealed by pituitary apoplexy : a case report About 2 cases

Aicha Bouzid, Hanane Kherrab, Meskine Djamila & Malha Azzouz
Medical University of Algiers, Endocrinology & Metabolism Laboratory Algiers 1, Endocrinology Department of the EPH Bologhine, Algiers, Algeria

Introduction
Pituitary apoplexy is a rare endocrine emergency that can occur due to pituitary infarction or hemorrhage. There are conflicting data regarding the type of pituitary adenoma prone to apoplexy. Prolactinomas seem to have the highest risk. We report 2 cases of apoplexy of a somatotropic adenoma not medically treated
Case 1
Patient aged 45 years, with a history of chronic headaches, hospitalized in the emergency room for management of a meningeal syndrome with violent headaches associated with vomiting, a significant decrease in visual acuity, exophthalmos and ptosis of the left eye. The patient was treated with antibiotics and underwent a brain scan which returned normal. In front of the observation of a dysmorphic syndrome typical of acromegaly, she was referred to the endocrinology department where the diagnosis of acromegaly was confirmed biologically, the pituitary imaging revealed a necrotic pituitary adenoma. The evolution was marked by a recurrence of the macroadenoma 6 years later.

Case 2
A 57-year-old patient was admitted to a neurology emergency room for intense headaches that were resistant to analgesics, with decreased visual acuity and diplopia. The pituitary CT scan showed a macroadenoma of 2 x 1.6 cm with erosion of the sellar floor. The evolution is marked by the spontaneous appearance of an empty sella turcica with progressive installation of an antehypophyseal insufficiency with therapeutic normalization of GH levels under medical treatment (somatuline and cabergoline) and substitution of hormonal deficits.
Conclusion
Pituitary apoplexy is a rare complication of pituitary adenomas, it must be suspected in front of brutal headaches with ophthalmologic disorders. Its management must be multidisciplinary.

Chronic diarrhea: the diagnostic process

Paraskevi Floroskoufi[1], Eirini Vourlioaki[1], Papazoglou George[2], Stergos Koukias[2] & Aikaterini Stamataki[1]
[1]Venizeleio General Hospital of Heraklio, Endocrinology Department, Greece; [2]Venizeleio General Hospital of Heraklio, Pathology Department, Greece

Introduction
Neuroendocrine tumors (NETs) are a heterogeneous group of rare neoplasms that originate from endocrine cells with the ability to secrete amines and hormonal polypeptides. Pancreatic neuroendocrine tumors (PNETs) can be functional or non-functional. Functional PNETs secrete common hormones such as gastrin, insulin and glucagon and much less frequent hormones such as vasoactive intestinal peptide (VIP). Their clinical characteristics depend on the peptide secreted. It is estimated that up to 10% of all pNETs being associated with MEN1.
Case report
We present the case of a 45-year-old woman who came to the emergency department with diarrhea, dehydration and electrolyte disorders (severe hypokalemia and hypercalcemia). The patient reported ~5 daily episodes of diarrhea without mucus or blood for 7 months while the last month she mentioned an increase to ~15 daily episodes of diarrhea with fatigue, polydipsia and polyuria. Due to the hypercalcemia, further testing was compatible with the diagnosis of primary hyperparathyroidism. 99 Tc-sestamibi scanning for parathyroid gland evaluation revealed features suggestive of parathyroid adenoma. Contrast-enhanced computed tomography of the abdomen, as part of the workup for the chronic diarrhea, showed 3 masses in the pancreatic body and tail. Biopsy guided by ultrasound was performed and the cytological examination revealed a neuroendocrine carcinoma of the pancreas. Given this history and imaging findings, a workup for MEN1 was initiated. Magnetic resonance imaging (MRI) of pituitary gland showed a pituitary macroadenoma measuring 16 × 17 x 13 mm while the laboratory investigation was compatible with the diagnosis of acromegaly. The genetic test was positive for MEN 1 syndrome both for the patient and her three children.
Conclusion
Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal dominant hereditary tumor syndrome with a high degree of penetrance, that is caused by inactivating mutations of the tumor suppressor gene *MEN1*, and is characterized by a predisposition to a multitude of endocrine and nonendocrine tumors Our patient demonstrates a classic example of MEN1 syndrome with tumors in all 3 defining endocrine organs, including pituitary macroadenoma, parathyroid adenoma, and pancreatic neuroendocrine tumors. When the diagnosis of the syndrome is done, genetic testing of first-degree relatives is considered necessary

EP849

Features of a clinical flow and diagnostics of patients with the family anamnesis of inactive adenomas of hypophysis (IAH)

Dilorom Xolova[1]
[1]Republican Scepialized Scientific Medical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Objective was to study features of clinical semiology, their value for differential diagnostics in population of patients with the sporadic and family IAH anamnesis.
Materials and methods.
71 IAH patients with intracellar adenoma of a hypophysis. Patients with IAH were divided into two alternative groups: the 1st group - 50 (70,4 %) patients with environmental factors without the burdened family anamnesis and 2nd - 21 (29,6 %) with the burdened family anamnesis, including with a panmiksiya - 9 (2,7 %) and an inbriding - 12 (16,9 %) patients. Average patients age was 18-70 years (44,5±3,85 years). At the same time the greatest number of the arrived IAH patients to fall on age from 35 (23,9 %) to 40 (25,4 %) years and to a lesser extent be elderly to 30 (18,3 %) and 55 (5,6 %) and is more than years that will be coordinated with literary data. It should be noted that at patients of 2-group with hereditary IAH signs is more often than patients of 1-group - without hereditary signs prevail frequency of clinical signs, such as sexual violations - 26,5 %, decrease in sight - for 40,2 %, headaches - for 26,5 %, doubling in eyes - for 15,0 %, visual discomfort - for 12,5 %, olfactory violations - for 19,8 %, vegetative crises - for 12,3 %, duration of a disease among women 5-20 years - for 12,3 and 24,6 %, but to a lesser extent till 20 and more than 21 years - for 23,2 and 15,2 %, and among men of such difference it is not revealed. Frequency of complaints in 1-group on visual violations it is revealed, decrease in visual acuity at IAH patients with a tumor to 10 mm at 10 % surveyed, to 20 mm - 70,0 %, with huge - 100 %, at patients of 2-groups - 50,0 %, 87,5 % and 72,7 %. At patients with the family it is IAH the main clinical symptoms of a disease associate: - visual, sexual, headaches, vegetative crises, climax come aged till 20-25 years, and time of establishment of the diagnosis - 10-20 years; - adenomas > 10 мм which progress quicker, in huge adenomas, with the heavy course of a disease more often come to light, than at patients from the single is IAH; - the IAH family form and development of clinical symptoms at early age should be object of diagnostic screening.

Polyuro-polydipsia syndrome revealing a craniopharyngioma in a 60-year-old female patient following a surgery

Zineb Mhamdi, Ikram Amira, Kaoutar Rifai, Hinde Iraqi & Mohamed El Hassan Gharbi
Ibn Sina University Hospital, Department of Endocrinology and Diabetology, Rabat, Morocco

Introduction
Craniopharyngioma is a benign, slow-growing epithelial tumor of embryonic origin, originating in the pituitary stem or pituitary gland and developing in the sellar and/or suprasellar region. It is characterized by its considerable potential for extension, its tendency to recur, and its adhesions to surrounding structures.
Case report
We report the case of a 60-year-old female patient with secondary amenorrhea at the age of 38 years, neglected and never explored, and who installed after surgery for intestinal obstruction on colonic tumor, a polyuria with polydipsia with 4 nocturnal awakenings and estimated input-output of 4 liters per day. The first-line workup was without abnormalities. The hypothalamo-hypophyseal MRI showed a 17 x 13 mm tumor that corresponds to a craniopharyngioma. This craniopharyngioma was complicated by a panhypopituitarism with 8 o'clock cortisol : 15 ng/ml, FT4 : 0.63 mUI/ml and hypogonadotropic hypogonadism profile with low FSH, LH and estradiol. The patient was put on Desmopressin with a good improvement of the polyuro-polydipsic syndrome. She was also put on Hydrocortisone and Levothyroxine.
Discussion and conclusion
Craniopharyngioma is a rare and benign epithelial tumor of the central nervous system, affecting mostly children. It is rarely observed in adults. Its diagnosis remains late despite the development of imaging techniques resulting in significant morbidity and poor survival. This is why it is essential to take each symptom seriously.

Eunuchoid skeletal proportions in male hypogonadism: a comparative analysis of anthropometric measures between men with congenital hypogonadotropic hypogonadism (CHH) and Klinefelter Syndrome (KS)

Sara De Vincentis[1,2,3], Rossella Corleto[1, 2], Alessio Bellelli[1, 2], Lucia Zirilli[2], Emanuele Santamaria[1], Antonio Granata[2] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Modena, Italy; [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria Policlinico of Modena, Modena, Italy; [3]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Modena, Italy

Background
Patients with CHH and KS have eunuchoid body proportions of the skeleton compared to normal male subjects, characterized by tall stature, and reduced upper-to-lower segment ratio (U/l). *Vice versa*, steroids exposure deeply differs between CHH and KS at puberty, with both testosterone and estradiol being very low only in CHH. At present, body skeletal proportions comparison between CHH and KS is not available.
Aim
To compare anthropometric measurements of adult male CHH patients to adult KS patients.
Methods
A prospective, cross-sectional, observational study was carried out. CHH patients were subdivided into 2 subgroups according to the timing of treatment start (testosterone replacement therapy [TRT] or gonadotropins): CHH1) CHH patients who started treatment late after 18 years; CHH2) CHH patients who started treatment on time before 18. All KS patients did not start TRT before 18 since KS do not usually delay puberty. The following anthropometric measurements were collected by using a digital scale and stadiometer (Seca gmbh&co®): height, weight, sitting height, total arm span. Legs length was obtained by subtracting sitting height from stature; U/l was calculated dividing sitting height for legs length.
Results
A total of 70 CHH and 45 KS age-matched patients were enrolled (mean age 33.7 ± 13.7 and 35.3 ± 13.7 years, respectively). CHH1 showed a longer arm span compared to CHH2 ($P=0.001$) and KS ($P=0.003$), and a shorter sitting height compared to KS ($P=0.008$). On the contrary, legs length was shorter in CHH2 compared to CHH1 ($P<0.001$) and KS ($P=0.011$). Accordingly, U/l and upper-to-height ratios were lower in CHH1 compared to CHH2 ($P<0.001$) and KS ($P=0.001$). Furthermore, the arm span-to-height ratio was higher in CHH1 compared to CHH2 ($P<0.001$) and KS ($P=0.008$).
Conclusions
Under the same definition of eunuchoid body proportions, the traditional hallmark of male hypogonadism, more fine differences are observed comparing adult CHH to KS patients. CHH patients who delayed treatment showed longer arm length and lower U/l in comparison to CHH patients receiving treatment on time at pubertal age and KS. This suggests a different mechanism involved in the eunuchoid skeleton development between CHH and KS confirming a major role for estrogen/androgen deficiency in the former (leading to disproportional growth of both legs and arms due to delay in epiphyseal closure that could benefit from on time replacement treatment) and a possible role of genetic supernumerary X in the latter, displaying a disproportional growth only at the legs site since infancy.

Investigating the prevalence of hypogonadism and associated cardio-vascular risk of males presenting with infertility: Results from a diverse and multi-ethnic UK patient cohort

Vina Soran[1], Abigail Knell[1], Tharu Tharakan[2], Axel Cayetano-Alcaraz[2], Channa Jayasena[3] & Suks Minhas[2]
[1]Imperial College London, United Kingdom; [2]Imperial Healthcare NHS Trust, Charing Cross Hospital, Urology, London, United Kingdom; [3]Imperial College London, Section of Endocrinology and Investigative Medicine, London, United Kingdom

Background
Hypogonadism is estimated to account for over 10% of male-factor infertility. However, due to conflicting data regarding the relationship between testosterone levels and sperm quality, hormone evaluation is not consistently requested during initial assessment of the infertile male. Hypogonadism is associated with cardiovascular disease (CVD) and has been linked to an increased risk of mortality The aim of this study was to investigate the prevalence of hypogonadism and cardiovascular risk in a cohort of infertile men.
Methods
This was a single-centre retrospective analysis of all patients presenting with male-factor infertility between January 2015 and December 2020. Biochemical hypogonadism was defined as a morning serum testosterone level <10 nmol/l according to local reference range. Semen analyses were compared between hypogonadal and eugonadal males. Lipid-profiles were compared between both cohorts. Patient demographic and clinical data were used to calculate the Charlson Comorbidity Index (CCI) and QRISK®3 scores.
Results
Of 855 patients, hypogonadism was present in 284 (33.22%) of patients. The median (IQR) testosterone level in eugonadal males was 15.5 (12.7-20.68), compared to 7.3 (5.25-8.60) in hypogonadal males ($P<0.0001$). A significantly greater proportion of hypogonadal males were found to be azoospermic compared to eugonadal males (57.6% vs. 42.2%, $P<0.0001$). Moreover, eugonadism was more prevalent amongst patients from a White-Background (30.8%, vs 20.1%, <0.0001). Whereas hypogonadism was more common amongst patients from an Asian-Background (22.5% vs. 12.6%, $P<0.0001$). Accordingly, median testosterone levels were significantly lower in Asian males compared to white males (10.3 vs. 13.5, $P=0.000162$). A higher BMI was observed in hypogonadal males compared to eugonadal males (28.9 vs. 26.4, $P<0.0001$) and had significantly higher serum cholesterol (5.00 vs. 4.7, $P=0.031$), triglycerides (1.73 vs. 1.09, $P<0.0001$) and non-HDL cholesterol (3.90 vs. 3.49, $P=0.001$) compared with eugonadal males., However, HDL-Cholesterol levels were higher in males with normal testosterone (1.06 vs. 1.25, $P<0.0001$). Median QRISK®3 scores were significantly higher in hypogonadal males than eugonadal males (1.40% vs. 1.10%, $P=0.0004$). A significantly greater proportion of hypogonadal males had a CCI score of 1 compared to eugonadal males (15.1% vs. 7.2%, $P=0.0002$).
Discussion and Conclusions
This study demonstrated a high prevalence of hypogonadism within a cohort of infertile males compared to existing literature. Whilst an association between testosterone and sperm quality was not established, hypogonadism was shown to be associated with raised lipid parameters and an increased risk of CVD. All infertile men should undergo endocrinological evaluation and follow-up to mitigate the risks of dyslipidaemia and CVD.

Hereditary syndromes in children with short stature

Olga Gumeniuk & Yuriy Chernenkov
Saratov State Medical University, Saratov, Russian Federation

Short stature is a clinical sign noted in genetic syndrome.
Purpose
Molecular genetic characterization of children with short stature.
Objects and methods
The study involved 7 patients 3-15 yrs (3 boys and 4 girls) with short stature. Full clinical and molecular genetic research (Whole Exome or Genome Sequencing) was conducted.
Results
SDS height was from -2 to -4. All patients had multiple stigmas of dysembriogenesis, autistic behavior disorders, mental and speech development delay. In boys KBG syndrome (heterozygous mutation in the ANKRD11 gene on chromosome 16q24), Wiedemann-Steiner syndrome (mutation in the KMT2A gene on chromosome 11q23.3), Coffin–Siris Syndrome, type VI (mutation in the ARID*A* gene on chromosome 12q12) were diagnosed. In girls De Grouchy syndrome, Yunis–Varon syndrome (mutation in the FIG4 gene on chromosome 6q21) was diagnosed. Two children with pronounced skeletal deformities and growth retardation were diagnosed with Brooke's syndrome.
Conclusion
Short stature in children combined with stigmas of dysembriogenesis, autistic behavior disorders, mental and speech development delay is it is an indication for molecular genetic examination in order to diagnose rare genetic syndrome.

The kiss of metabolism and reproduction: is kisspeptin the key?

Mihaela Poterasu[1] & Simona Fica[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Elias Emergency Hospital, Bucharest, Romania

Background
The relationship between energy balance and reproduction is U-shaped, meaning that both a negative and a positive energy balance have a detrimental effect on reproductive function. In a world increasingly burdened by the growing prevalence of obesity, we turned our attention to the negative extremity of weight, by exploring anorexia nervosa (AN) and constitutional thinness (CT) metabolic and reproductive features. Kisspeptin (kiss-1) is a relatively recently discovered neurohormone with implications in the onset of puberty, sex steroid feedback and brain sexualization. More recent data show a possible involvement of kisspeptin in the metabolic processes, with a role in regulating the homeostasis of blood glucose, insulinemia and appetite, as well as regulating fat deposits, but these still need confirmation in further studies.
Objectives
The aim of this study was to evaluate the particularities of the indicators of reproductive function and look for possible implications in this regard of the neurohormone kiss-1 in normal and underweight patients, with or without eating disorders such as AN. In particular, the study focuses on the role of kisspeptin in amenorrhea induced by dietary restriction in patients with AN.
Material and Methods
We included in this cross-sectional and observational study a cohort of 34 young female patients gathered in 4 similar-sized groups, as it follows: AN and underweight, AN and normal weight, CT, and healthy, normal weight patients. Anamnestic, anthropometric and biological data were recorded, as well as the total fat percentage (TFP) data from the whole-body DXA scan.
RESULTS
Kiss-1 was significantly higher in patients with atypical AN subjects than in underweighted, typical AN patients (1.24 ± 0.15 vs 0.96 ± 0.17 ng/ml, $P=0.03$). No significant associations were found between kiss-1 levels and clinical-biological factors of reproduction, even though kiss-1 was significantly correlated with TFP throughout the cohort ($P=0.03$, $r=0.365$). Menses are significantly associated with the diagnosis of AN ($r=0.625$, $P<0.001$), weight ($r=0.448$, $P=0.005$), TFP ($r=0.457$, $P=0.007$) as well as with gonadotropins and thyroid hormones levels (FSH $r=0.353$, $P=0.007$, LH $r=0.474$, $P=0.005$, TT3 $r=0.472$, $P=0.006$, fT4 $r=0.625$, $P<0.01$).
Conclusions
Kiss-1 increases in atypical AN patients, who, despite their psychiatric diagnosis, have a normal weight and are not in such deteriorating physical health condition, probably in an attempt to maintain viable reproductive function for as long as possible. This result, together with the correlation of this neurohormone with TFP, sheds light on the involvement of kiss-1 in both reproductive and metabolic regulation of the study population.

Maternal prolactin-levels in pregnancy and offspring body composition at 7 years. Odense Child Cohort

Freja Pelck Hansen[1], Anders Grøntved[2], Richard C Jensen[1], Frederik D Højsager[2], Ivan Brandslund[3], Henriette Boye[4], Tina Kold Jensen[4, 4], Marianne Andersen[1] & Dorte Glintborg[1]
[1]Odense University Hospital, Endocrinology, Odense, Denmark; [2]University of Southern Denmark, Odense, Denmark; [3]Vejle Hospital, Hospital Lillebælt, Vejle, Denmark; [4]Odense University Hospital, Odense, Denmark

Background
Prolactin is associated with metabolic risk inside and outside of pregnancy. Maternal prolactin levels could be associated with offspring body composition.
Aim
To investigate if maternal prolactin-levels were linked to offspring body composition at seven years of age.
Design
Prospective observational cohort study (the Odense Child Cohort).
Methods
Maternal fasting blood samples were assessed during 1st (prolactin) and 3rd trimester (prolactin and glucose). Prolactin ratio was defined as 3rd trimester/1st trimester prolactin. Offspring body composition at seven years of age was assessed by Dual-Energy X-ray Absorptiometry (DXA)-scan, BMI and waist circumference. A total of 854 mother-child-pairs were included. Gestational diabetes mellitus (GDM) was defined by WHO13-criteria (fasting glucose ≥ 5.1 mmol/l). Oral glucose tolerance test (OGTT) was performed around gestation week 28 in 180 women with risk factors for GDM and in 168 randomly included women. Multiple regression analyses investigated associations between maternal prolactin (continuous and quartiles) and offspring body composition stratified by offspring sex and models were adjusted for maternal age, parity and BMI.
Results
Median (quartiles) maternal age was 30 (27–33) years and pre-gestational BMI 24.5 (21.3; 26.5) kg/m^2. In boys ($n=301$), maternal prolactin-ratio (4th quartile) was positively associated with fat percentage (Adjusted $\beta=0.09$, $P=0.02$, and gynoid fat percentage (Adjusted $\beta=0.08$, $P=0.04$). In boys born of mothers with risk of GDM ($n=135$), the association between maternal prolactin-ratio (4th quartile) and fat percentage (Adjusted $\beta=0.13$, $P=0.026$) and android fat percentage (Adjusted $\beta=0.22$, $P=0.032$) was attenuated. Maternal prolactin was not associated with body composition in girls.
Conclusions
Maternal prolactin-ratio was positively associated with fat percentage and android fat percentages in boys born of mothers at risk for GDM.

Nijmegen breakage syndrome with unusual presentation: a case report

Teodora Dumitru[1], Miruna Anisia[1], Diana-Cristina Andrei[1], Cristina Preda[1,2], Caba Lavinia[3] & Maria Christina Ungureanu[1, 2]
[1]Emergency University Hospital "Saint Spiridon", Endocrinology, Iasi, Romania; [2]'Gr. T. Popa' University of Medicine and Pharmacy, Endocrinology, Iasi, Romania; [3]'Gr. T. Popa' University of Medicine and Pharmacy, Medical Genetics, Iasi, Romania

Introduction
Nijmegen breakage syndrome(NBS) represents a rare autosomal recesive disorder, characterized by severe chromosomal instability. It is caused by mutations in the NBN gene, which product, nibrin, belongs to the hMre11/hRad50 protein complex, critical for processing DNA double-strand breaks during mitotic and meiotic recombination. The hallmarks of NBS are growth retardation, microcephaly, premature ovarian failure(POI) in females, immunodeficiency and predisposition for malignancy.
Case report
A 9-year-old girl presented in the Department of Endocrinology Iasi with a history of two vaginal bleeding episodes and recurrent respiratory infections. Her clinical features were short stature (G=23 kg, T=127 cm, -1.78 SD->Pascanu), craniofacial dysmorphia with microcephaly, up-slanting palpebral fissures, long nose, sloping forehead, micrognathia and Sutton's nevi, no clinical signs for secondary sexual characteristics development, borderline intellectual ability. Biological tests were normal, but the hormonal assessment showed hypergonadotrophic hypogonadism (increased FSH=69,9 mUI/ml and LH=13,3 mIU/ml and low estradiol< 20 pg/ml). The pelvic ultrasonographic (US) examination reveals small uterus and ovarian sizes, regardless of age, without ovarian follicles. The karyotype and MLPA for SHOX gene deletion were normal. The two episodes of vaginal bleeding were interpreted in a mild pelvic traumatic injury context (falling from the bicycle). Six months later, she developed extensive vitiligo lesions on her lower body. The suspicion for Nijmegen Breakage Syndrome was confirmed by the Sanger sequencing, which identified the mutation of the Nibrin gene (NBN) in exon 6: c.657_661delACAAA, in a homozygous state. When she was 12 years old, we started the treatment for pubertal induction with low doses of transdermic estradiol.
Discussions
NBS is caused by mutations in the NBN gene, which product, nibrin, belongs to the hMre11/hRad50 protein complex, critical for processing DNA double-strand breaks during mitotic and meiotic recombination. The hallmarks of NBS are growth retardation, microcephaly, premature ovarian insufficiency (POI) in females, immunodeficiency and predisposition for malignancy. Our case is an unusual presentation for the NBS – suspicion of precocious puberty with vaginal bleeding. In the literature, NBS is associated with premature ovarian failure. The pathomechanism of hypoplastic ovaries or streaks gonadal is explained by genome instability.

Clinical and biochemical markers of premature ageing in young hypopituitary women with untreated hypogonadism

Irena Ilovayskaya & Anna Loktionova
Moscow Regional Research and Clinical Institute, Neuroendocrinology, Moscow, Russian Federation

Hypogonadotropic hypogonadism as a part of hypopituitarism can be a cause of persistent amenorrhea and hypoestrogenemia in women of reproductive age as it is observed in postmenopause. We know that premature and early menopause leads to accelerated aging with such markers as decreased quality of life, phyco-emotional deprivation, dyslipidemia, bone mineral density and others. We hypothesized that untreated hypogonadism in young women with hypopituitarism could cause premature aging. Clinical symptoms, hormonal levels, lipid and mineral metabolism, BMI, BMD and quality of life (GHQ-28) were evaluated in young women with hypopituitarism ($n=49$, 25[22;31] y.o.), healthy age-matched young women (YW $n = 53$, 24[23;28] y.o.) and middle-aged women with natural postmenopause (PM $n = 50$, 56[53;59] y.o.) were compared. Duration of amenorrhea and postmenopause was similar (median 5 and 6 years, $P=0.9$). Hypopituitarism group included patients with organic pituitary lesions, hypothyroidism and hypocortisolism were compensated. The prevalence of general, neurovegetative and psychoemotional symptoms was significantly higher in women with hypopituitarism than in YW though it was similar to PM. In contrast, common to the postmenopause vasomotor symptoms were observed less frequently in hypopituitarism. Concentrations of E2, T and DHEAS, total cholesterol, triglycerides, calcium and alkaline phosphatase as well as quality of life in women with hypopituitarism were not typical of YW but were comparable to PM. Frequency of increased BMI was higher in women with hypopituitarism (51%) than in YM (11%) and comparable to PM (48%). BMD in lumbar spine and femur was even lower in young patients with hypopituitarism than in postmenopausal women. Thus, clinical and biochemical abnormalities revealed in women with untreated hypogonadism at young age were similar in many aspects to those in postmenopausal women at middle/old age in spite of the age difference and various reasons for hypoestrogenemia. These findings could be considered as markers of premature ageing because the biological changes attributable to postmenopause occurred well in advance.

Perceptions and experiences of women with polycystic ovary syndrome-a systematic review

Gar Mun Lau[1], Mirna Elghobashy[1], Mansi Thanki[2], Shirley Ibegbulam[2], Helena Gleeson[3], Lynne Robinson[4], Pallavi Latthe[4], Caroline D. T Gillett[5], Wiebke Arlt[3, 5], Antje Lindenmeyer[6], Punith Kempegowda[3, 5] & PCOS SEva Working Group[5]
[1]College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [2]School of Pharmacy, University of Birmingham, Birmingham, United Kingdom; [3]Department of Endocrinology, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [4]Birmingham Women's Hospital, Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [5]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, United Kingdom; [6]Institute of Clinical Sciences, University of Birmingham, Birmingham, United Kingdom

Introduction
With a global prevalence of around 10%, polycystic ovary syndrome (PCOS) is a common endocrine condition affecting women. Despite its prevalence, limited evidence exists around the condition and its impact on patients. Qualitative research provides insights into symptoms and experiences faced by women with PCOS that can affect management and compliance.
Aim
A systematic review was undertaken to evaluate the current literature on the experiences, perceptions and opinions of women with PCOS, with an aim to highlight key areas for improvement in the standard of care and education on PCOS.
Methods
A comprehensive search of seven electronic databases was conducted between July 2021 and October 2021. Studies focusing on both adolescent and adult patients with PCOS were considered for inclusion. The quality of individual studies was assessed by adaptation to the Critical Appraisal Skills Program (CASP) quality assessment tool. 1615 articles were screened and 34 full-text articles were used in the systematic review and subsequently coded using NVivo 12 software.
Results
Thematic analysis revealed 5 domains: *Signs/Symptoms of PCOS, Diagnosis, Management, Improving Outcomes, Perceptions of women with PCOS regarding their care.*Common themes included poor mental health (25/34 studies), subfertility (16/34 studies), and frustration or dissatisfaction with their diagnostic journey (16/34 studies). There were a number of concerns regarding the symptoms experienced by women, particularly difficulty losing weight and irregular menstruation. The majority of the literature reported negative experiences towards the standard of care. Issues surrounding diagnosis, such as a delay and under-diagnosis, led to cynicism towards healthcare providers and poor health outcomes. Only four studies suggested that a diagnosis of PCOS was a relief for patients. The main barrier perceived by patients was a lack of knowledge amongst healthcare professionals. Additionally, uptake of management advice was poor for most patients, as they experienced personal, educational and healthcare professional related barriers. Research indicated that empowering women with information helped with professional interactions and subsequent reduction of symptoms as women take a more patient-centered role in their management.
Conclusion
Despite its prevalence, women with PCOS feel under-supported by healthcare professionals and society in general. Prompt diagnosis and provision of appropriate information about the condition and its long term impact are required. Enhancing educational opportunities and access may empower women with PCOS and lead to improved clinical outcomes and reduced morbidity.

Therapeutic management in transsexual women infected by VIH: about a case

Daniel Medina Rivero[1, 2], Isabel Mateo Gavira[2] & Laura Larrán Escandón[2]
[1]Hospital San Carlos San Fernando, San Fernando, Spain; [2]Hospital Universitario Puerta del Mar, Cádiz, Spain

A 38-year-old transsexual woman, with no known drug allergies, active tobacco smoker, ICAT 2. As diseases of interest, stage A2 human immunodeficiency virus (HIV) infection with current negative viral load. Lúes in 2012 treated. In treatment with Stribild (elvitegravir 150 mg/ cobicistat 150 mg/ emtricitabine 200 mg/ tenofovir disoproxil fumarate 245 mg). She went to the Transsexual Persons Care Unit due to gender inconsistency since childhood with the adoption of the female role for years. She now expresses her desire to start hormonal and surgical treatment to try to accommodate her secondary sexual characteristics to the desired sex. After the directed anamnesis and carrying out of complementary tests according to the recommendations of the Assistance Process of Attention to Transsexual People in Andalusia, cross-hormonal therapy is started. Antiandrogenic treatment was prescribed with cyproterone acetate 50 mg/day and estrogenic treatment with estradiol valerate at progressive doses up to a final dose of 6 mg/day (maximum recommended dose). However, despite adequate adherence to treatment and the high doses of estrogen used, plasma levels of estradiol remained low. Given the suspicion of possible interaction between antiretroviral treatment and estradiol valerate, Internal Medicine was consulted, deciding to change treatment to Triumeq (dolutegravir 50 mg/abacavir 600 mg/lamivudine 300 mg). Six months after the change in treatment, the target plasma estradiol levels were reached, even allowing the dose of estradiol valerate to be reduced to 4 mg/day. A prevalence of 19.1% of HIV-infected transsexual women is estimated. Several studies have associated the use of ritonavir-boosted protease inhibitors or cobicistat with a decrease in exogenous estrogen levels. The use of non-analog reverse transcriptase inhibitors (nevirapine, efavirenz) with decreased estrogen levels has also been described. Therefore, based on current evidence, the best option as antiretroviral treatment in transsexual women with cross-hormonal therapy could be a nucleoside reverse transcriptase inhibitor (such as abacavir, lamivudine) together with an integrase inhibitor (dolutegravir, raltegravir) without booster.

A 20-steroid LC-MS/MS panel to investigate classical and backdoor pathways of androgen biosynthesis in the Leydig cells

Matteo Magagnoli[1], Marco Mezzullo[1], Silvia Limoncella[2], Alessia Tommasini[1], Daniele Santi[2], Carla Pelusi[1], Manuela Simoni[2], Uberto Pagotto[1], Livio Casarini[2] & Flaminia Fanelli[1]
[1]Alma Mater University of Bologna, Unit of Endocrinology and Prevention and Care of Diabetes - Center for Applied Biomedical Research - Department of Medical and Surgical Sciences, Bologna, Italy; [2]University of Modena and Reggio Emilia - Baggiovara Hospital, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences - Center for Genomic Research, Modena, Italy

Background
The classical steroidogenic route to the synthesis of dihydrotestosterone in Leydig cells involves delta-5 and delta-4 precursors. Besides, the "backdoor pathway", encompassing progesterone metabolites, is gaining increasing interest in fetal development and men pathophysiology. Nowadays, liquid chromatography/tandem mass spectrometry (LC-MS/MS) is the ideal technique to simultaneously quantify large panels of steroids with elevated sensitivity and specificity.
Aim
We developed and validated a LC-MS/MS method measuring 20 among androgens, precursors and metabolites pertaining to both the classical and the backdoor pathways in the steroidogenic mouse Leydig tumor cell line 1 (mLTC1).
Methods
Steroidogenesis of serum-starved mLTC1 cells was induced by 100μM choriogonadotropin (hCG). Steroids released in 500μL cell medium were extracted with 2mL N-hexane:ethyl-acetate (8:2) spiked with 100μL internal standards in methanol. The organic phase was dried and samples were reconstituted with 100μL of 75% methanol before 10μL were analyzed. The platform included the Serie200 HPLC (Perkin Elmer) and the API-4000 QTrap (Sciex) operated in multiple reaction monitoring mode. 16OH-progesterone, 11-deoxycortisol, androstenedione, 11-deoxycorticosterone (21OH-progesterone), testosterone, androstenediol, 17OH-progesterone, 17OH-pregnenolone, dehydroepiandrosterone, androstanedione, epitestosterone, dihydrotestosterone, 17OH-dihydroprogesterone, progesterone, androstanediol, androsterone, pregnenolone, 5α-dihydroprogesterone, 17OH-allopregnanolone and allopregnanolone were separated in 13-min gradient operated on a Luna C8 100x3 mm, 3 μm column, equipped with 4x2.0 mm guard column (Phenomenex), termostated at 45°C, using 100μM ammonium fluoride and methanol as mobile phases. Analytes were revealed by quantitative and qualitative transitions and quantified by isotopic dilution.
Results
Isobaric compounds were separated to ensure selectivity. The dynamic range was between 3 and 5 orders of magnitude. Functional sensitivity was between 0.012 and 38 nmol/l. Intra-assay and inter-assay imprecision and trueness, valued at low, medium and high levels, were below 9.1 and 10.0%, and within 93.4-122.0%, respectively. Recovery and matrix factor were within 55.6-104.1% and 76.4-106.3%, respectively. Levels (nmol/l) of 16OH-progesterone (20.7 ± 4.2), 11-deoxycortisol (0.924 ± 0.115), androstenedione (727 ± 89), 11-deoxycorticosterone (3.69 ± 0.40), testosterone (52.8 ± 10.1), 17OH-progesterone (6.58 ± 0.75), androstanedione (774 ± 164), epitestosterone (26.1 ± 4.4), dihydrotestosterone (9.61 ± 2.51), progesterone (4.79 ± 0.60), androsterone (379 ± 80) and 17OH-allopregnanolone (4.30 ± 0.58) were within the measurement range. Levels of 17OH-dihydroprogesterone (0.844 ± 0.107), androstanediol (21.5 ± 5.9) and dihydroprogesterone (0.791 ± 0.136) were slightly above the limit of detection, whereas other compounds were undetectable.
Conclusions
We validated a LC-MS/MS method including a broad number of androgens, precursors and metabolites. Medium secretion levels from mLTC1 cells were measured effectively for most of the steroids, however, levels of some neutral and delta-5 steroids were below method's sensitivity. Nonetheless, we provided a powerful tool to simultaneously characterize the gonadal classical and backdoor steroidogenic pathways.

Associations of serum AMH levels and hormonal, metabolic and cardiovascular parameters in adult men

Veronika Tandl[1], Caterina Colantonio[2], Christoph W Haudum[1], Barbara Hutz[1], Ewald Kolesnik[2], Albrecht Schmidt[2], Andreas Zirlik[2], Nicolas Verheyen[2], Thomas R Pieber[1] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Division of Endocrinology and Diabetology, Graz, Austria; [2]Medical University of Graz, Division of Cardiology, Graz, Austria

Background
Anti-Müllerian hormone (AMH) is well known for its association with ovarian follicular count and ovarian reserve in general as well as for its recruitment of primordial follicles in women. With an explicit decrease in menopause, it is mainly used for clinical questions from in-vitro-fertilisation to polycystic ovary syndrome. Interestingly, AMH levels in men are quite high during lifetime, but there is only few data about its relevance and potential effects in adult men. The aim of our study was to investigate and describe AMH levels in men in association with a number of hormonal, metabolic and cardiovascular parameters and whether there are links to physiological or pathophysiological functions.
Methods
We analysed data from the BioPersMed cohort (Biomarkers for Personalized Medicine), a prospective cohort of asymptomatic subjects at cardiovascular risk. Clinical parameters, past medical history, AMH, hormonal profiles including androgens, fasting glucose and insulin values as well as oral glucose tolerance tests, lipid measurements including high- (HDL) and low-density (LDL) lipoproteins, inflammation markers such as C-reactive protein (CRP) and others were analysed as well as anthropometric parameters, DXA(dual energy X-ray absorptiometry)-derived body composition.
Results
Out of $n = 1022$ healthy volunteers, we identified 389 men (38% of the cohort) with a mean age 58 +/- 9 years. While AMH was BMI-dependent ($P = 0.0113$), and decreased slightly with age ($P = 0.03$), it was inversely associated with pituitary hormones LH (luteotropic hormone, $P = 4.5e\text{-}5$) and FSH (follicle stimulating hormone, $P = 1.6e\text{-}10$). The highest AMH quartiles showed an inverse association with C-peptide, but also HDL, while androgens or SHBG were not significantly different between groups, in contrast to pronounced differences of these parameters according to BMI categories.
Conclusion
AMH in men is an interesting, however neglected biomarker with a number of potential associations with hormonal, but also metabolic and potentially cardiovascular risk profiles. Its clinical value has to be determined in follow-up studies, but AMH in men might become an important health marker and needs further investigation.

Hormonal profile in idiopathic male infertility

Dinu Draganescu Daniela[1], Anca Botezatu[2], SUZANA VILMA VLADOIU[1], Fudulu Alina[2], Albulescu Adrian[2], Oana-Monica Popa[1], Andrei Muresan[1], Plesa Adriana[2], Iancu Iulia Virginia[2], Dinu Draganescu Daria[3], Cristina Stancu[1], Velicu Alexandru[1], Purice Mariana[1], Padure Adriana[1], Udrea Luminita[1], Kremer Andreea[1], Dumitrica Alina Elena[1] & Corin Badiu[1]
[1]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [2]Ştefan S. Nicolau Institute of Virology, Molecular virology, Bucharest, Romania; [3]University Medical Center Groningen, Groningen, Netherlands

Male infertility arises as a global public health in the context of the dramatic decrease in birth rates, within a complex picture of hormonal, genetic and epigenetic factors. However, the underlying causes of male infertility remain unknown in many cases. Our study included samples ($n = 82$, median: 34 years, range 20–55 years) obtained from men investigating couple infertility and from a normal control group ($n = 11$, median: 29 years, range 21–55 years). Blood and seminal fluid were harvested after 3–5 days of sexual abstinence. Hormonal profile was evaluated, including FSH, LH, testosterone, estradiol, inhibin B and prolactin. Exclusion criteria: Radiotherapy and/or pelvic chemotherapy (over the last 6 months), known genetic aberrations, endocrine diseases, urogenital infections, bilateral orchiectomy, vasectomy and occupational exposure to harmful organophosphorus hydrocarbons, ionizing radiation, heavy metals. Inclusion criteria: spermatic parameters according to WHO 2010 Standards (Word Health Organization, 2010). The infertile group was divided in three subgroups: azoospermia (AZO $n = 23$), oligoasthenozoospermia/severe oligoasthenozoospermia (OAS/OASS $n = 14$), oligoasthenoteratozoospermia/-severe, oligoasthenoteratozoospermia (OATS/OATSS $n = 41$). The analysis of hormonal profile displayed statistically significant differences for FSH ($P = 0.0003$), LH ($P = 0.0092$), prolactin ($P = 0.043$), and inhibin B (0.0003). Moreover, a significant difference between azoospermia and control group was noted regarding FSH/E2 ratio (median: 0.4532 vs 0.152; $P = 0.00163$). A similar

pattern was displayed by the FSH/E2 ratio between subjects with <1 million spermatozoa/ml and control group (median: 0.420 vs 0.152; $P=0.00174$). The motility/E2 ratio was significantly lower in the azoospermia group compared to the control group (median: 0.000 vs 2.064; $P=0.034$). Sperm concentration/E2 ratio displayed a significant difference between the selected groups vs the control group (median: AZO-0; OAS/OASS-63328; OATS-70998; control-1453000). Investigating the LH/T and T/LH ratio, it was observed a significant difference between azoospermia and control group (median:2.207 vs 1.097, $P=0.0094$; respectively median:0.373 vs 0.912; $P=0.0388$). Subtle imbalances of reproductive hormones levels, revealed by disturbed evaluated ratios might be one of the causes of inappropriate sperm production mechanism. It appears that estrogen activity as reflected in the investigated ratios, is important with regards to proper fertility in males, since the spermatogenesis is modulated by estrogen at the level of HPG axis. In conclusion, investigated ratios could serve as a potential instrument in the diagnosis and management of male infertility, since these hormones cooperate to maintain the semen quality, stability and feedback control of the system.

Does iron homeostasis influence gonadal axis in men with obstructive sleep apnea ?

Barbara Bromińska[1], Nadia Sawicka-Gutaj[1], Aleksandra Hernik[1], Ewelina Szczepanek-Parulska[1], Halina Batura-Gabryel[2] & Marek Ruchala[1]
[1]University of Medical Sciences in Poznań, Department of Endocrinology, Metabolism and Internal Disease, Poznań, Poland; [2]University of Medical Sciences, Department of Pulmonology, Allergology and Respiratory Oncology, Poznań, Poland

Introduction
Obstructive sleep apnea syndrome (OSAS) is characterized by chronic inflammation. Hepcidin is an acute-phase protein involved in iron metabolism. Increase in hepcidin has been shown in OSAS. Testosterone probably exerts inhibitory effect on hepcidin levels and even trump iron and inflammation-mediated mechanism in chronic inflammatory state. On the other hand iron balance may influence gonadal axis. The aim of this study was to assess whether hypogonadism in OSAS could be associated with iron metabolism.
Material and Methods
We recruited 92 males. Mean age was 61 years old. Sixty nine were diagnosed with OSAS, based on polysomnography. This group was divided into two subgroups. First comprised of 45 eugonadal men (g1), while the second included 24 hypogonadal patients (g2). Control group consisted of 23 patients with normal testosterone levels and normal sleep pattern (g3). We measured multiple parameters, among them: serum testosterone, LH, CRP, insulin levels and irone balance parameters.
Results
We have found significant differences in testosterone ($g1>g2$, $g3>g2$; $P<0.0000$), iron ($g3>g1$, $g3>g2$; $P=0.0378$), CRP ($g2>g3$; $P=0.0389$), BMI ($g1>g3$, $g2>g3$; $P=0.0065$), insulin ($g2>g1$; $g2>g3$; $P=0.0153$) and hemoglobin ($g3>g1$, $g3>g2$, $P<0.0000$) between groups. There was a tendency toward statistically significant difference in hepcidin levels ($g1>g2$, $g1>g3$; $P=0.0513$). On linear regression in a whole group testosterone level was inversely associated with hepcidin ($P=0.0152$; $\beta=$ -0,1804), insulin ($P=0.0024$; $\beta=$ -0,1409) and BMI ($P=0.0042$; $\beta=$ -0,3589). On multiple regression BMI and hepcidin were independent factors negatively influencing testosterone levels ($P=0.0009$).
Conclusion
Changes in testosterone in males with OSAS might be at least partially attributed to hepcidin concentration. Metabolic factors such as insulin and BMI negatively influence gonadal axis. The exact mechanism of potential mutual relationship between iron homeostasis and gonadal status in men with OSAS remains to be elucidated.

Is there seasonal variation in testosterone levels? Data from a large cohort of men

Taiba Zornitzki[1], Sagi Tshori[1], Galit Shefer[1], Shira Mingelgrin[1], Carmit Levy[2] & Hilla Knobler[1]
[1]Hebrew University of Jerusalem, The Faculty of Medicine, Diabetes, Endocrinology and Metabolic Disease Institute, Rehovot, Israel; [2]Department of Human Genetics and Biochemistry, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Context
Several previous studeis suggested seasonal variation in testosterone levels. However, these studies were limited by either their small sample size or by variability in baseline characteristics and confounders such as: differences in age and weight distribution, co-existent illness, time in the day in which testosterone was measured and by differences in geographic location and climate conditions. Ultraviolet (UV) exposure is one of the main environmental stimuli. In a recent study (Parikh R, *et al*, Cell Rep. 2021, 36(8): 109579), we explored a novel skin-brain-gonad axis triggered by UV and mediated by skin p53. Through the use of various mouse models, we found that UV exposure led in male and female mice to increased hypothalamus-pituitary-gonadal axis hormone levels and to increased sexual responsiveness and attractiveness. These data provide for the first time an underlying mechanism for seasonal variability in testosterone levels.
Objectives
To evaluate in a large cohort of males with a wide-range of age, metabolic status and co-existent morbidities, whether month of blood test performance was associated with total and bioavailable testosterone levels independent of age, body-mass index (BMI), existing cardiovascular disease (CVD) and CVD risk factors.
Methods
Cross-sectional study including data from computerized medical records of 27,328 men aged 20-70, treated by the largest health care organization in Israel, who underwent testosterone measurement. In 7,940 subjects with available sex-hormone-binding globulin levels, bioavailable testosterone was calculated.
Results
Total and bioavailable testosterone levels gradually decreased with age and BMI ($P<0.001$) and were significantly lower in men with diabetes, hypertension, hyperlipidemia and known CVD ($P<0.001$). Intrigungly, testosterone levels were higher in current smokers compared with non-smokers ($P<0.001$). We stratified total and bioavailable testosterone levels according to the month in which the test was performed and observed a peak of total and bioavailable testosterone levels during August to October. After October, total testosterone and bioavailable testosterone started to decline reaching a nadir in March. Overall, total and bioavailable testosterone levels were significantly lower in March compared to August-October ($P<0.001$). In a linear regression analysis, age, BMI, current smoking, and month of testing were independently associated with both total ($P<0.001$) and bioavailable testosterone levels ($P=0.002$).
Conclusion
In a large cohort of men with a wide-range of age, BMI and co-morbidities, month of testing was independently associated with total and bioavailable testosterone levels. These data provide compelling evidence that seasonal variation has to be considered in clinical practice.

A new, accurate and time-saving, two-step intracavernosal injection procedure to diagnose psychological erectile dysfunction

Giorgia Spaggiari[1], Antonio Raffaele Michele Granata[1], Manuela Simoni[1, 2] & Daniele Santi[1,2]
[1]Azienda Ospedaliero-Universitaria of Modena, Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy

Background
The recognition of the erectile dysfunction (ED) pathogenesis is essential to identify the appropriate ED management. Since vascular ED (vED) could be a manifestation of a systemic arterial damage, the watershed in the ED diagnostic framework is the discrimination between psychological (pED) and vED. However, reliable tools to directly diagnose pED are currently lacking.
Aim of the study
To identify which parameters could predict pED. Moreover, we suggest a new intracavernosal injection (ICI) procedure to optimize the ED diagnostic work-up.
Methods
A retrospective, real-world analysis was carried out including all men who underwent ICI procedure at the Andrology Unit of Modena (Italy) from 2018 to 2021. Data about previous medical history and ED characteristics were collected. A first ICI procedure with 5 μg of prostaglandin E-1 (PGE-1) was performed. In

the absence of a full drug-induced erection (immediate or delayed), an echo-color doppler penile evaluation after administration of PGE-1 10 μg was conducted, measuring intracavernosal blood flows, to document a possible vascular etiology. Hormonal measurements, including testosterone, luteinizing hormone, follicle-stimulating hormone, estradiol, prostate-specific antigen, prolactin and thyroid-stimulating hormone serum levels, were performed to rule out a possible hormonal DE etiology.
Results
Out of 179 enrolled patients, 70.4% showed pED, 21.7% vED and 7.8% hormonal genesis. Multinomial logistic regression analysis identified absence of cardio-vascular disease ($P=0.017$), presence of spontaneous morning erections ($P=0.018$) and normal penile erections with masturbation ($P=0.035$) as predictors of pED. Clinically, normal ICI test response was detected in 86 patients and abnormal response in 93 subjects. Among the latter, 54 patients experienced a delayed response. The combination of ICI test with late penile erections evaluation was able to diagnose pED (sensitivity 97%, specificity 100%), avoiding unnecessary retesting.
Discussion
We propose a two-steps ICI procedure that allows to recognize pED with a high sensitivity/specificity, saving costs and time and limiting adverse events. Moreover, the presence of spontaneous morning erections and valid penile erections after masturbation could guide the diagnostic work-up, indirectly identifying those patients deserving of a deeper evaluation of vascular health.

Effect of testosterone on body composition - randomised placebo-controlled study in hypogonadal men with uncontrolled type-2 diabetes - STRIDE STRUDY

Preethi Mohan Rao[1, 2], Alifyah Najefy[1] & T. Hugh Jones[1,2]
[1]Barnsley Hospital NHS Foundation Trust, Robert Hague Centre for Diabetes and Endocrinology, Barnsley, United Kingdom; [2]University of Sheffield, Human Metabolism and Oncology, Sheffield, United Kingdom

Objective
The objective of the study was to assess the effect of intra-muscular testosterone on body composition in men with hypogonadism and poorly controlled type 2 diabetes.
Research design and methods
This is a randomised double-blinded placebo-controlled add-on trial of intramuscular testosterone undecanoate administered every 12 weeks in 65 hypogonadal men with poorly-controlled diabetes. Phase 1 patients were randomly assigned to either treatment or placebo arm for 6 months of TRT. Phase 2 was an open-labelled phase for 6 months and patients on placebo moved on to the treatment group wherein patients in the treatment group continued. Body composition was measured by dual energy X-ray absorptiometry (DEXA scan). Outcomes were assessed at baseline and every 3 months.
Results
Mean age of the cohort was 59 years. Baseline characteristics were comparable between active/placebo groups. Only 48 patients had DEXA scans both at baseline and at 6 months. Limb fat mass and percentage fat significantly correlated strongly and inversely with total testosterone(TT), calculated free testosterone (cFT) and bioavailable testosterone(cBT) and there was no correlation with limb lean mass. There was strong inverse correlation between total fat mass, total fat percentage and truncal fat percentage with TT, cFT and cBT($P<0.05$). Truncal fat mass correlated inversely with TT and cBT but did not correlate significantly with cFT. There was no significant correlation between lean mass and TT, cFT or cBT. These correlations remained significant after correcting for age, BMI and SHBG in linear regression model. There was a significant reduction in Left leg fat mass in the active group compared to placebo group. ($P=0.03$) after 6 months of TRT. There was no significant difference in either the fat mass or lean mass between the active and placebo group elsewhere including truncal area. There were no significant changes in either fat or lean mass before and after 12 months of treatment with testosterone in the active group
Conclusions
Testosterone levels strongly and inversely correlates with fat mass and has no correlation with the lean mass. There was significant reduction in left leg fat mass after 6 months of TRT. There were no significant changes in any other body composition at 6 or 12 months and it suggests that these changes may take more than a year to show positive changes.

Real-world evidence of follicle stimulating hormone effectiveness in male idiophatic infertility

Marilina Romeo[1,2], Giorgia Spaggiari[1], Federico Nuzzo[1], Antonio R.M. Granata[1], Manuela Simoni[1, 2] & Daniele Santi[1,2]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Modena, Italy; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Modena, Italy

Introduction
Male idiopathic infertility represents a therapeutic challenge for physicians, since a targeted aetiological treatment does not exist. Several hormonal and non-hormonal therapies have been proposed so far to increase pregnancy rates. Among hormonal therapies, exogenous follicle-stimulating hormone (FSH) administration shows the most convincing physiological rationale in the face of a clinical efficacy below expectations. Indeed, from evidences available in the literature, it was calculated that 10 to 18 men have to be treated to achieve one only pregnancy. This result comes from the published controlled clinical trials, but only few data are currently available on the real FSH effectiveness in clinical practice.
Aim
To assess the effectiveness of FSH administration in male idiopathic infertility in a clinical setting.
Methods
An interim analysis of a retrospective, observational, monocentric, real-world study was performed. All consecutive male outpatients attending the Andrology Unit of Modena (Italy) for couple infertility were enrolled. According to the reimbursement rules of the Italian Health System, FSH could be prescribed to men with idiopathic infertility and FSH serum levels <8 UI/l. Collected data included medical history, physical and andrological examinations, sex steroid hormones, conventional semen analysis and therapeutic choice.
Results
201 infertilemen were enrolled (mean age 37.6 ± 6.2 years), presenting mostly (91.2% of cases) for primary couple infertility. At baseline, 17 patients (12.4%) showed normozoospermia, 25 subjects resulted azoospermic (12.5%), while a variable degree of semen parameters impairment was recorded in 159 men (75.1%). Among 161 patients potentially eligible for exogenous FSH administration, 54 patients (33.1%) received hormonal therapy. FSH-treated patients showed significantly lower baseline FSH levels (3.5 ± 1.8 vs 8.9 ± 10.9 IU/l), sperm concentration (8.2 ± 8.4 vs 29.7 ± 26.5 millions/ml) and sperm motility (5.1 ± 8.6 vs $25.7\pm18.9\%$) compared to FSH-untreated men. Comprehensively, nine pregnancies were obtained in FSH-treated patients (16.7%), one spontaneous and eight after assisted reproduction procedures.
Conclusion
From our single centre experience on FSH treatment in male idiopathic infertility, it emerged that FSH is currently administered to men with low baseline FSH levels and impaired semen parameters. Our experience suggests that FSH empirically administered leads to pregnancy in 1 on 6 patients treated. Despite this study lacks a control group in a real world setting, the number of patients required to achieve a pregnancy seems to be lower than what calculated on published data.

The FSH administration to men with idiopathic infertility improves sperm DNA fragmentation index together with testosterone serum levels increase

Daniele Santi[1,2], Giorgia Spaggiari[1], Monica Lispi[3, 4], Drakopoulos Panagiotis[3] & Manuela Simoni[1,2]
[1]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda Ospedaliero-Universitaria di Modena, Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [3]Merck KGaA, Global Medical Affairs Fertility, Research and Development, Darmstadt, Germany; [4]University of Modena and Reggio Emilia, Clinical and Experimental Medicine PhD Program, Modena, Italy

Background
Testicular overstimulation is the pursued therapeutic goal when exogenous follicle-stimulating hormone (FSH) is empirically administered to men with idiopathic infertility. Although a robust physiological rationale theoretically supports the FSH use in male idiopathic infertility, useful markers to evaluate its

efficacy are still far from being detected. While pregnancy rate remains the strong outcome in couple infertility management, the identification of reliable, and possibly early, markers of therapeutic response to FSH in males is mandatory. Randomized controlled clinical trials (RCTs) on the topic focused, on the seminiferous component, not considering the potential involvement of the testosterone-secreting compartment.
Aim of the study
The evaluation of the potential relationship between testosterone serum levels and semen quality measured through sperm DNA fragmentation (sDF) index before and after FSH administration in male idiopathic infertility.
Methods
A retrospective post-hoc re-analysis was performed on raw data of RCTs in which idiopathic infertile men were treated with FSH and both testosterone serum levels and sDF were reported among primary and/or secondary endpoints. Additional data regarding couple infertility history, age, anthropometric variables, FSH treatment scheme and semen variables were included in a single dataset.
Results
Two RCTs (Colacurci *et al*. 2012 and Simoni *et al*. 2016) were included accounting for 148 patients (median age 37, 25-52 years). After three months of FSH administration, a significant increase was observed in FSH levels ($P<0.001$), inhibin B ($P=0.012$), sperm concentration ($P=0.003$), total sperm number ($P=0.021$), progressive motility ($P<0.001$) and normal sperm morphology ($P<0.001$). Moreover, an overall sDF index reduction was confirmed after treatment ($P=0.002$). SDF resulted significantly inversely related to sperm concentration both at baseline and after FSH treatment (Rho -0.325, $P<0.001$ and Rho -0.316, $P=0.001$, respectively). Interestingly, sDF index after treatment showed a significant inverse correlation with testosterone serum levels (Rho -0.327, $P=0.002$). Multivariate stepwise linear regression analyses using sDF index as dependent variable identified testosterone as a predictor for sDF index change ($P=0.005$). Similarly, logistic regression analysis highlighted testosterone and SHBG levels as predictive of sDF reduction after FSH administration ($P=0.043$ and $P=0.005$, respectively).
Conclusion
Combining raw data of published RCTs investigating FSH administration to idiopathic infertile men, a significative improvement of conventional semen parameters together with a reduction in sDF were confirmed. Intriguingly, a potential correlation between testosterone serum levels and sDF was highlighted for the first time, opening a completely unexplored way in the identification of potential early predictors of FSH therapy response in male idiopathic infertility.

Introduction
The effects of testosterone on coagulation have not yet been clarified. In particular, it is still controversial whether male hypogonadism, or testosterone replacement therapy (TRT), may slightly increase the risk of venous thromboembolism, in particular during the first months of therapy. This study aimed to assess the hemostatic balance in hypogonadal men before and after short-term TRT, compared to healthy controls.
Methods
Thrombin generation assay (TGA) was performed in 38 hypogonadal men (10 primary hypogonadism, 19 organic central hypogonadism, 9 functional hypogonadism) before and 6 months after the initiation of TRT (transdermal testosterone gel, $n = 36$; long-acting i.m. testosterone undecanoate, $n = 2$), and in 38 age-matched healthy controls (median age 55.1 and 54.7 years respectively, $P=0.91$). Thrombophilia, Klinefelter syndrome, uncontrolled diabetes mellitus, anti-coagulant or anti-platelet therapy were exclusion criteria. TGA is based on the continuous registration of thrombin generation (mediated by procoagulants) and decay (mediated by anticoagulants) in platelet-poor-plasma. To make the procedure sensitive to imbalances in Factor (F)VIII–protein (P)C activities, thrombomodulin is added to the TGA assays. The following parameters are recorded: *thrombin peak* concentration; *endogenous thrombin potential (ETP*, the total amount of thrombin generated during the test); the *ETP-ratio*(ETP with/ETP without thrombomodulin) which accounts for FVIII-PC balance.
Results
Larger amounts of thrombin were generated in hypogonadal men at baseline (ETP 2173 ± 288 nMxmin) and during TRT (2166 ± 301) compared to controls (1947 ± 273, $P<0.001$ and $P=0.001$), with no significant change over 6 months in hypogonadal patients ($P=0.82$). Similar results were observed when thrombomodulin was added to TGA. The ETP-ratio was comparable in hypogonadal patients before (0.68 ± 0.23) and after TRT (0.68 ± 0.20, $P=0.73$), and in controls (0.61 ± 0.20, $P=0.17$ and $P=0.13$). Thrombin peak did not change from baseline to six months ($P=0.29$); however, it was significantly higher than controls only at baseline ($P=0.03$). ETP was inversely associated with total testosterone concentrations at baseline ($r=-0.44$, $P=0.008$) but not when on TRT.
Conclusion
A procoagulant imbalance is observed in hypogonadal men. This does not appear to involve the FVIII-PC axis and is not modified by short term testosterone therapy. Further studies are needed to clarify which coagulation factors drive the procoagulant imbalance, whether longer TRT can normalize it, and if platelets or endothelial cells are affected as well.

Combined omic analysis revealed autism-linked NLGN3as new candidate gene associated to GnRH neuron development and disease

Roberto Oleari[1], Antonella Lettieri[2], Alyssa J.J. Paganoni[1], Federica Amoruso[1], Peter Scheiffele[3], Sasha Howard[4] & Anna Cariboni[1]
[1]Department of Pharmacological and Biomolecular Sciences, Milano, Italy; [2]University of Milan, Department of Health Sciences; [3]University of Basel, Biozentrum, Basel, Switzerland; [4]William Harvey Research Center, London, United Kingdom

During development, gonadotropin releasing hormone (GnRH) neurons are born in the nasal placode and migrate to the hypothalamus, where they position to regulate sexual reproduction by the pulsatile release of GnRH. Defective GnRH neuron development or action may lead to GnRH deficiency (GD) which is characterized by absent or delayed puberty (1). GD can also be present as a trait shared by several complex neurodevelopmental disorders (NDDs), such as cerebellar ataxia, developmental delay and autism spectrum disorder (ASD) (2). Interestingly, a recent register-based population study showed for the first time that patients with GD have increased risk for being diagnosed with ASD or other NDDs, but the underlying genetic correlation is unknown (3). Although more than 20 genes have been associated to GD pathogenesis (4), half of the cases are still idiopathic, suggesting the need of novel experimental approaches to identify the elusive genes. Here, we combined the transcriptomic analysis of primary and immortalized GnRH neurons with exome sequencing data from GD patients to identify novel candidate genes. As a proof-of-principle, we identified pathogenic variants in the autism-linked Neuroligin 3 (*NLGN3*) gene in two unrelated patients sharing GD and ASD. We demonstrated that NLGN3 is enriched in GnRH neurons at late developmental stages and its overexpression in a model of immortalized GnRH neurons (GN11 cells) promoted neurite extension. Further, the two identified NLGN3 mutations, which are both loss-of-function, formed prematurely truncated proteins that were retained in the endoplasmic reticulum thus preventing cell protrusion formation in GN11 cells. Overall, our results highlighted how the combination of gene expression and exome sequencing data is a reliable approach to identify novel candidate gene for GD such a NLGN3, an autism-linked gene that we found for the first time associated to GD.

Endometrial cell-type-specific disease signatures and endometrial organoids in polycystic ovary syndrome

Gustaw Eriksson[1], Congru Li[1, 2], Han-Pin Pui[1], Sanjiv Risal[1], Angelica Lindé n Hirschberg[3], Sophie Petropoulos[4,5,6], Qiaolin Deng[1] & Elisabet Stener-Victorin[1]
[1]Karolinska Institutet, Department of Physiology and Pharmacology, Solna, Sweden; [2]Peking University Third Hospital, Department of Obstetrics and Gynecology, Beijing, China; [3]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden; [4]Karolinska Institutet, Department of Clinical Science, Huddinge, Sweden; [5]Centre de Recherche du Centre hospitalier de l'Université de Montréal (CRCHUM), Immunopathology Axis, Montréal, Canada; [6]Université de Montréal, Department of Medicine, Montreal, Canada

Introduction
Polycystic ovary syndrome (PCOS) is the leading cause of female infertility and is associated with high degree of comorbidities including type 2 diabetes and endometrial cancer. Hyperandrogenemia is a hallmark of PCOS and contributes to endometrial-related dysfunctions, including implantation failure and miscarriage. Whether cellular heterogeneity contributes to the functioning of the endometrium is not previously studied. Therefore, the aim is to reveal cell-type-specific disease signatures in the endometrium in women with PCOS at the single-cell level and to validate the role of molecular targets in endometrial organoids (EOs).
Method
Single nuclei were extracted from frozen endometrial biopsies collected from women with PCOS ($n=12$) and healthy controls ($n=5$) at cycle day 7-10. The nuclei RNA libraries were prepared following the 10x genomics protocol allowing us to sequence ~10,000 cells per sample and ~20,000 reads per cell. Sequencing data is processed using Cellranger count for further data integration, quality control and analysis with the Seurat package. In parallel, 3-dimensional (3D) EOs are established from fresh endometrial biopsies that are enzymatically dissociated and collected at cycle day 7-10. The cells are resuspended in Matrigel droplet and organoids are generated and maintained in a defined medium. Following several passages, EOs are cryopreserved to create a biobank to be used for future functional analyses of identified molecular targets by single-cell RNA-sequencing, immunofluorescence microscopy and Seahorse metabolic analysis.
Results
Single-nuclei were extracted from 17 endometrial samples, 12 from women with PCOS and 5 from healthy controls for 10x snRNA-sequencing. Our initial bioinformatic analyses show that the endometrial tissue of women with PCOS has a distinct single-cell transcriptomic profile, with cell-type specific differentially expressed genes that differ from the healthy controls. The EO protocol has been established and EOs from four women with PCOS have been cryopreserved with EOs successfully reestablished after thawing. Validation with immunofluorescent staining shows that the 3D EOs consist of an intact proliferative epithelial membrane with a consistent polarity across the whole EO.
Conclusion
This rigorous mapping of endometrial tissue samples will increase the understanding of the cellular complexity and dysfunction and will be linked to phenotypic features in women with PCOS. By successive formation of 3D PCOS-EOs, we can further study cellular and molecular mechanisms causing PCOS-specific endometrial dysfunction.

Assessment of early vascular changes in adult females with polycystic ovary syndrome in correlation with insulin resistance

Marwa Fathy[1], Mona Mansour[1], Aasem Saif[1], Alaa Mahmoud Abd Elhamid[2], Adel Mohamed[3], Mai Galal[2], Shrouk Moussa[1] & Samar Saad[4]
[1]Faculty of Medicine-Cairo University, Internal Medicine-Endocrinology Unit, Cairo, Egypt; [2]Faculty of Medicine-Cairo University, Internal Medicine-Vascular Unit, Cairo, Egypt; [3]Faculty of Medicine-Cairo University, Gynaecology and Obstetrics Department, Cairo, Egypt; [4]Faculty of Medicine-Cairo University, Clinical Pathology, Cairo, Egypt

Background
Polycystic ovary syndrome is a long lasting, complex, hormonal condition associated with microvascular endothelial dysfunction and strongly related to CIMT changes at an early age. ED represents an initial reversible step in atherogenesis development, so early clinical identification of ED may play a pivotal in the prevention or reversal of progression to atherosclerosis. Also, CIMT is considered as an early marker of atherosclerosis
Objective
to assess the early vascular changes in Egyptian women with PCOS marked functionally by measurement of endothelial dysfunction using brachial artery flow–mediated dilatation (FMD) andstructurally via CIMT using high resolution Doppler ultrasonography with correlation of such early vascular changes with HOMA-IR index. Also, to assess independent determinants of CIMT in PCOS patients for optimal control of all modifiable CV risk factors and targeted treatment protocols.
Material and Methods
In this study, Seventy Egyptian females were included and they were divided into **50** diagnosed to have PCOS using Rotterdam Criteria (PCOS group) and **20** in control group. Patients were recruited from General Gynecology Clinics and Endocrinology &Metabolic Diseases Outpatient Clinic at Cairo university hospitals during the period from 2019 to 2020. fasting insulin, fasting blood glucose, HbA1C, lipid profile, TSH, free testosterone, HOMA-IR, CIMT and endothelial function were assessed in all patients.
Results
HOMA-IR correlates positively with (BMI, waist circumference, SBP, DBP, TG, T. Cholesterol) and negatively with HDL in PCOS patients. We also found that CIMT was significantly higher in PCOS group (0.06 ± 0.01) than control group (0.05 ± 0.01) with $P < 0.001$. A more intense vasodilatation was observed in controls than in polycystic ovary syndrome (PCOS) patients ($P < 0.001$). The diagnosis of PCOS per se is a strong independent predictor of CIMT and endothelial dysfunction.
Conclusion
polycystic ovary syndrome is a condition associated with increased vascular risk as it is associated with microvascular endothelial dysfunction and strongly related to CIMT changes. For optimal control of all modifiable CV risk factors and targeted treatment protocols, we recommend screening of early stages of atherosclerotic diseases in PCOS women which may be possible causes of morbidity and mortality as PCOS is also associated with increased risk of different metabolic complications including HTN, insulin resistance, DM, CV diseases

Gender affirming hormonal treatment in Danish transgender persons. A nationwide register-based study

Dorte Glintborg[1], Katrine Hass Rubin[1], Simon Bang Kristensen[1], Øjvind Lidegaard[2], Guy T'Sjoen[3], Malene Hilden[2] & Marianne Skovsager Andersen[1]
[1]Odense University Hospital, Odense, Denmark; [2]Copenhagen University, København, Denmark; [3]Ghent University Hospital, Gent, Belgium

Background
Gender affirming hormonal treatment (GAHT) is for many a cornerstone of transgender care. National data regarding use of hormonal treatment by transgender persons are limited.
Aim
To assess use of GAHT in transgender persons.
Design
National register-based cohort study in Danish transgender persons followed from 2000 until 2018. The main outcome measure was redemption of GAHT. Persons with an ICD-10 diagnosis code of "gender identity disorder" (CGI-cohort) and persons with legal sex change but without diagnosis (CPR-cohort) were included. In the CGI-cohort, transgender women were defined by prescription of estrogen and/or antiandrogens and transgender men were defined by prescription of testosterone after study inclusion. Discontinuation of GAHT was defined as no

redemption of GAHT ≥ 13 months or shift from feminizing to masculinizing hormone treatment, or vice versa.
Results
The cohort included 2770 transgender persons ($n=1700$, CGI-cohort and $n=1070$, CPR-cohort). The median age (interquartile range) at study inclusion was 26.0 (17.3) years for persons assigned male at birth ($n=1437$) and 22.5 (10.4) years for persons assigned female at birth ($n=1333$). In the CGI-cohort, the redemption rate for GAHT in transgender women increased from 4.0 (95% CI: [3.1; 5.2]) events per 100 person in year 2000-2005 to 20.5 [17.7; 23.6] between 2014 -2018. In transgender men, the event rate of GAHT increased from 4.2 [2.8; 6.2] to 18.9 [16.4; 21.7]. The rate of discontinuation of GAHT was 0.06 (95% CI 0.048; 0.071) per person year.
Conclusions
The event rate of GAHT increased during 2000-2018. Our data suggested high adherence to GAHT.

Have we ignored red cell parameters in Turner Syndrome? Results from a single specialist centre

Katharina Beck[1], M d s a Dilrukshi[2], Matilde Calanchini[2], Noémi B A Roy[3] & Helen E Turner[2]
[1]University of Oxford, Medical Sciences Division, Oxford, United Kingdom; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, Department of Endocrinology, Oxford, United Kingdom; [3]Oxford University Hospitals, Department of Haematology, Oxford, United Kingdom

Introduction
Anaemia and other haematological disorders have been reported in Turner Syndrome (TS). TS-related comorbidities (premature ovarian insufficiency, autoimmune hypothyroidism, coeliac disease and liver diseases) and treatments (hormone replacement [HRT] and growth hormone) are possible explanations. We aim to investigate the prevalence of abnormal full blood count (FBC) in adult TS and assess associated clinical characteristics.
Methods
FBC parameters and clinical characteristics were retrospectively collected from the electronic patient records of 120 adult TS women attending a dedicated TS clinic.
Results
Median age was 34 years (IQR 27.25-49) and 45, X was the commonest karyotype ($n=46$, 38%). The most frequent abnormality in the most recent FBC was an elevated red blood cell (RBC) count in 25% ($n=30$), elevated mean cell haemoglobin (Hb) concentration in 19% ($n=23$) and/or elevated Hb in 9% ($n=11$). While some results were isolated when compared to previous FBCs, seven patients (6%) had elevated Hb and RBC count on more than one occasion. Associated conditions included primary hypothyroidism on treatment in 2, structural renal abnormalities in 2, and non-alcoholic fatty liver disease without significant liver impairment in 5. None were smokers or had a diagnosis of obstructive sleep apnoea. Six were of premenopausal age and on HRT (progestogens; medroxyprogesterone, levonorgestrel, or norethisterone; none received testosterone analogues) with 4 having regular withdrawal bleeding, while 1 patient was of postmenopausal age and no longer on HRT. Amongst TS patients on HRT, 51% had elevated Hb, haematocrit, RBC count, mean cell Hb and/or mean cell Hb concentration, compared to 45% not on HRT. Amongst TS patients who had NAFLD, 70% had elevated Hb, haematocrit, RBC count, mean cell Hb and/or mean cell Hb concentration compared to 44% amongst those without any liver disease. Six patients (5%) had recurrent anaemia (microcytic in 2, normocytic in 4). Half had a 45, X karyotype, 1/6 was on HRT, 4/6 had regular periods or withdrawal bleeds. Three women had been diagnosed with iron deficiency, associated with gastro-oesophageal reflux disease in 2.
Discussion
While our cohort shows a similar prevalence of anaemia in TS to a recent large observational study, the finding of elevated red cell parameters in the context of TS is novel and deserves further analysis in larger studies. Exploring the association between the abnormal red cell parameters and levels of sex hormones, EPO levels, Jak2 status as well as TS-associated conditions is warranted in the future.

Multiple prolactinomas in a young man with Kallman syndrome and familial hypocalciuric hypercalcemia

Mojca Jensterle[1], Andrej Janez[1], Tina Vipotnik Vesnaver[2], Maruša Debeljak[3] & Magdalena Avbelj Stefanija[4]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Clinical Institute of Radiology, University Medical Centre Ljubljana, Ljubljana, Slovenia; [3]Clinical Institute for Special Laboratory Diagnostics, University Children's Hospital, University Medical Centre Ljubljana, Ljubljana, Slovenia; [4]Department of Paediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, University Medical Centre Ljubljana, Ljubljana, Slovenia

Introduction
Kallmann syndrome (KS) is a rare congenital form of hypogonadotropic hypogonadism (HH) associated with anosmia, that occurs with an incidence of 1:48,000 (1:30,000 males). Multiple separate pituitary adenomas are also rare, identified in only 0.7 % of pituitary adenoma cases.
Case Presentation
A male Caucasian patient presented with absent puberty, small testicles (1 ml), microphalus, osteopenia and anosmia at age 15. Endocrine assessment confirmed HH. Based on concomitant olfaction dysfunction, he was diagnosed with Kallmann syndrome (KS). Hormonal replacement treatment was initiated for puberty induction with testosterone enanthate and then continued with testosterone undecanoate following local monitoring protocol. At age 26 the patient presented with mild headache. MRI revealed two separate pituitary adenomas along with the absence of the olfactory bulbs. Given the presence hyperprolactinemia (17x upper limit of the reference range) the diagnosis prolactinoma was made and treatment with cabergoline was started which resulted in complete biochemical response and in marked reduction of both adenomas in size. Hypogonadism persisted and testosterone replacement therapy was continued. Targeted genetic testing of genes associated with neuroendocrine tumors (AIP, *MEN1*, *NF1*, *PRKAR1A, RET, TSC1, TSC2, VHL*), and of 49 genes associated with HH and *TSHZ1*gene associated with isolated congenital anosmia using a next generation sequencing platform was negative. Mild concomitant hypercalcemia in accordance with familial hypocalciuric hypercalcemia (FHH) prompted mutation analysis of the *CASR* gene which yielded a pathogenic inactivating variant.
Discussion
Double separate prolactinoma in a patient with KS has not yet been reported in the literature. The effect of sex hormone treatment of KS patients on the possible development of prolactinoma is unknown at present. The relevance of the *CASR* gene mutation in our patient for the KS phenotype also needs further insights since CaSR is expressed in GnRH neurons in mouse brain and CaSR deficient mice have a reduced hypothalamic GnRH neuronal population. This would possibly point to a role for the CaSR pathogenic variant in the development of KS in our patient. On the other hand, no delayed puberty, infertility or central hypogonadism have been reported in FHH patients.
Conclusion
We are unaware of earlier reports of an ultra rare co-occurrence of KS and multiple prolactinomas and FHH. The role of an inactivating variant in *CASR* gene as well as the effect of sex hormone treatment on the patient's phenotype are uncertain at this stage.

Reproductive endocrinology characteristics in young women with osteoporosis

Clara Kühner[1], Veronika Koeppen-Ursic[1,2] & Vanadin Seifert-Klauss[1]
[1]Klinikum rechts der Isar der Technischen Universität München : Frauenklinik der Technischen Universität München, Interdisciplinary Osteoporosis Center (IOZ) of the Technical University Munich (TUM), München, Germany; [2]Klinikum Freising GmbH, Orthopedics, Freising, Germany

Introduction
Premenopausal women that suffer from osteoporosis are under-diagnosed and many anti-osteoporotic medications are neither licensed for young women, nor

have they been established as safe or effective. Current guidelines on osteoporosis only address postmenopausal women, resulting in uncertainty and insufficient treatment for premenopausal women. To prevent bone fragility in young women, more knowledge and education about possible risk factors for osteoporosis in young age is needed.
Methods
Women under the age of 50 were recruited to fill out a questionnaire, if their T-values were osteoporotic, or if they presented with one or more fractures with a T-value of -2,0. They answered 42 questions on potential risk factors for bone fragility. Frequencies of risk factors were compared with published prevalences for the normal premenopausal population.
Results
Data of 104 women was analysed. The average age at first diagnosis of osteoporosis/osteopenia was 37 years *(range: 19-49)*, 78% had already sustained a fracture. 40% had been pregnant at least once, but only 74% of them had given birth. 16% of the patients had involuntary infertility, of these 82% had never been pregnant. Female infertility is estimated to affect 7,5% in the general population. 75% of the women had used or were on hormonal contraception, which is less than in the German population (87%). 14% had started hormonal contraception prior to 16 years of age. Hypermenorrhoea was more common amongst young osteoporosis patients than in the general female population (22% vs. 10%). Nearly half of the participants (45%) reported secondary amenorrhoea of more than 6 months at least once in their lifetime, much more than women without osteoporosis (1,5-3%). 22% of our patients stated having had an eating disorder for longer than one year. The lifetime prevalence for eating disorders in Germany ranges from 1,7-3,6% for anorexia nervosa and 2,6% for bulimia nervosa. 74% of the participants with an eating disorder also had amenorrhoea. Depression was more prevalent in young osteoporotic women (13%) than in the average population (8,2%), as was hypothyroidism (18% vs. 1-2%). 30% of the participants worked shifts or admitted to a chronic sleep disorder.
Discussion and conclusion
Compared to the normal population, some reproductive endocrine characteristics are more frequent in young women with osteoporosis, such as hyper- and amenorrhoea, eating disorders, hypothyroidism and depression.

The endocrine disruptor Benzo[a]Pyrene inhibits gonadotropin-mediated steroidogenesis in a mouse Leydig tumor cell line

Samantha Sperduti[1,2], Neena Roy[1], Clara Lazzaretti[1], Elia Paradiso[1], Sara D'Alessandro[1,3], Elisa Mascolo[1], Lara Baschieri[1, 3], Daniele Santi[1, 4], Manuela Simoni[1,2,4] & Livio Casarini[1,2]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]University of Modena and Reggio Emilia, Center for Genomic Research, Modena, Italy; [3]University of Modena and Reggio Emilia, International PhD School in Clinical and Experimental Medicine (CEM), Modena, Italy; [4]Azienda Ospedaliero-Universitaria di Modena, Department of Medical Specialties, Modena, Italy

Introduction
Benzo[a]Pyrene (BaP) is an endocrine-disrupting chemical, which may impact reproduction. It is a polycyclic aromatic hydrocarbon generated by the incomplete combustion of organic compounds. BaP may be accumulated in the environment, achieving effective concentrations in the nanomolar range and exerting genotoxic effects in long-term exposed humans.
Aim
We evaluated the short-term impact of BaP on luteinizing-hormone (LH) /choriogonadotropin (hCG)-mediated functions in the steroidogenic mouse Leydig tumor cell line (mLTC1), *in vitro*.
Methods
mLTC-1 cells were treated with increasing BaP doses (range fM-μM), over 0-40 h, in the presence or in the absence of the maximal, non-saturating effective LH and hCG concentration (1500 and 300 pM, respectively). The maximal, non-cytotoxic BaP dose was evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyl tetrazolium bromide (MTT) assay. 3-h intracellular cyclic adenosine monophosphate (cAMP) production was assessed by bioluminescence resonance energy transfer (BRET), in transfected cells overexpressing the specific biosensor. 10, 50 and 100 μM forskolin-treated cells served as controls. 15-min cAMP-response element binding protein (CREB), extracellularly-regulated kinases 1 and 2 (ERK1/2) and p38 mitogen-activated protein kinase (p38-MAPK) phosphorylation was evaluated by Western blotting. 8- and 24-h progesterone and testosterone levels were measured by immunoassay. Results were compared with those from gonadotropin- and BaP-untreated samples by Kruskal-Wallis test followed by Dunn's post-hoc test ($P<0.05$; $n = 6$).
Results
1 μM BaP was determined as the maximal, non-cytotoxic dose ($P\geq0.5$) and was used for cell treatments, as well as the environmentally available dose of 1 nM. LH/hCG-induced intracellular cAMP accumulation was dampened by 1 μM BaP (2.0-fold compared to BaP-untreated; $P<0.05$), with no gonadotropin-specific differences, while 1 nM BaP did not produce any effect. 1 μM BaP failed in inhibiting 10-100 μM forskolin-induced cAMP ($P\geq0.5$), excluding that the compound modulates adenylyl cyclase enzyme functioning. Consistently, BaP interfered with most of the downstream intracellular cAMP-dependent events. 1 μM BaP decreased LH/hCG-induced CREB phosphorylation ($P<0.05$) and increased basal ERK1/2 phosphorylation ($P<0.05$), while no perturbation of p38-MAPK phosphorylation was detected ($P\geq0.05$). The modulation of signal transduction is linked to interfering effects on steroidogenesis. LH/hCG-mediated, 24-h progesterone synthesis (1.5-fold BaP-untreated; $P<0.05$), as well as 8-h testosterone production (2.0-fold BaP-untreated; $P<0.05$), decreased significantly in the presence of 1 μM BaP.
Conclusions
These results demonstrated that a micromolar BaP concentration inhibits short-term steroidogenic signals in a mammal Leydig cell line, through an unknown molecular mechanism. These data suggest that BaP may potentially interfere with endocrine signals, dysregulating male gonadal and reproductive functions.

Characteristics of male idiopathic hypogonadotropic hypogonadism (IHH) patients

Muhammad Saleem[1], Nanik Ram[1], Sajjad Ali Khan[1] & Muhammad Mustansir Mehdi Khan[2]
[1]Aga Khan University Hospital, Section of Diabetes, Endocrinology and Metabolism and Department of Medicine, Aga Khan University Hospital, Karachi, Pakistan, Karachi, Pakistan; [2]Aga Khan University, Pakistan

Background
Idiopathic Hypogonadotropic Hypogonadism (IHH) is a condition caused by deficiency or insensitivity to gonadotropin-releasing hormone where the pathology behind the mechanism is unknown and no secondary causes of hypogonadotropic hypogonadism are present. The condition not only effect sexual characteristic but can affect the physical and psychosocial development of a patient therefore making its prompt diagnoses and treatment necessary. The purpose of this study was to determine the sign, symptoms and laboratory parameters of the male IHH patients presenting in a tertiary setting.
Materials and Methods
This cross-sectional study was carried in Aga Khan University on male patients presenting with IHH to the Endocrinology clinic from December 2000 to December 2020. The patients presenting with signs or symptoms of hypogonadism, associated low sex steroid hormone and inappropriately low or normal gonadotropins with absent expansive hypothalamic or pituitary lesions or multiple pituitary hormone defects were included in the study. Quantitative variable was shown as Mean ± Standard Deviation while qualitative variables were shown as frequency and percentages.
Results
Data of 79 IHH patients was reviewed with Mean Age ± SD being 24.2 ± 7.5 years. Clinically 64 (81.0%) presented with small genitalia, 50 (63.6%) had absent secondary sexual characteristics, 53 (67.1%) presented with infertility, 44 (55.7%) had not attained puberty, 52 (65.8%) had erectile dysfunction, 46 (58.2%) with loss of libido, 11(13.9%) had a positive family history, 24 (30.3%) had gynecomastia, 9 (11.4%) had undescended testes and 6 (7.6%) had hyposmia or anosmia. The mean serum testosterone level of the patients was 26.3 ± 60 ηg/dl while mean FSH and LH level were 2.7 ± 5.0 and 1.3 ± 2.4 respectively.
Conclusion
It was observed that the primary complains of patients presenting with IHH were small genitalia, infertility, and absence of secondary sexual characteristics with a low serum testosterone level.

Daytime salivary androgen rhythm by LC-MS/MS in women affected by Polycystic Ovary Syndrome (PCOS) fulfilling the three Rotterdam diagnostic criteria

Flaminia Fanelli[1], James M Hawley[2], Marco Mezzullo[1], Alessia Fazzini[1], Laura Zanotti[1], Matteo Magagnoli[1], Uberto Pagotto[1], Brian Keevil[2] & Alessandra Gambineri[1]
[1]Alma Mater University of Bologna, Unit of Endocrinology and Prevention and Care of Diabetes - Center for Applied Biomedical Research - Department of Medical and Surgical Sciences, Bologna, Italy; [2]University Hospital South Manchester, Manchester NHS Foundation Trust, Department of Clinical Biochemistry, Manchester, United Kingdom

Background
Excess testosterone in PCOS is accompanied by increased levels of other ovarian and adrenal androgens and precursors. Recently, 11-oxygenated adrenal androgens have been postulated as major components of the circulating androgen pool in PCOS. Obesity is strictly connected with androgen excess and with the derangement of hormone circadian rhythmicity. To date, it has not been clarified whether hyperandrogenism in PCOS, either complicated by obesity or not, is accompanied by the dysregulation of androgen biorhythm.
Objective
To investigate the daytime rhythmicity of androgens and precursors in saliva of women with PCOS fulfilling the three Rotterdam diagnostic criteria, according to their BMI status.
Methods
PCOS patients (age 15-34y) showed oligo-amenorrhea, polycystic ovarian morphology and either clinical (hirsutism) or biochemical (elevated serum testosterone) hyperandrogenism. These were subdivided in overweight/obese (OB-PCOS; BMI $\geq$ 27 kg/m^2 $n = 8$) and non obese PCOS (NO-PCOS; BMI $<$ 27 kg/m^2 $n = 8$) and compared with age-matched non obese healthy women (NO-CTR; age: 23-32y; BMI $<$ 27 kg/m^2 $n = 16$). All were in follicular phase, had standardized meals and self-collected saliva every hour from 7 until 23am. Testosterone, androstenedione, 17OH-progesterone, dehydroepiandrosterone, 11OH-androstenedione and 11keto-testosterone were measured by LC-MS/MS.
Results
BMI was higher in OB-PCOS (31.1 (29.1-34.4)) compared to NO-PCOS (22.5 (20.2-27.2)) and NO-CTR (21.3 (20.7-22.9) kg/m^2) ($P<0.001$), but similar between NO-PCOS and NO-CTR. All women showed higher androgen and precursor levels at awakening, which decreased until bedtime (all $P<0.001$). Testosterone and androstenedione, at each time point, and 17OH-progesterone, at most time points, were higher in OB-PCOS and NO-PCOS vs NO-CTR women (all $P<0.050$). Testosterone was higher in OB-PCOS vs NO-PCOS at 8, 10, 11, 16 and 17am (all $P<0.050$). Dehydroepiandrosterone was higher in OB-PCOS compared to both NO-PCOS and NO-CTR at 9-13 and 16-17am (all $P<0.050$). PCOS women showed a trend for high 11-oxygenated androgens at mid-morning and afternoon, but lower at late night, only achieving significance at 10am, with 11OH-androstenedione higher in OB-PCOS vs NO-CTR; at 17am, with 11-ketotestosterone higher in OB-PCOS and NO-PCOS vs NO-CTR; and at 23am, with 11OH-androstenedione lower in OB-PCOS vs NO-CTR (all $P<0.050$).
Conclusion
Androgen biorhythm was preserved in PCOS. Excess secretion of androgens originating from both ovary and adrenal was maintained throughout the day in both PCOS groups. The overweight/obese PCOS phenotype is featured by a partial rhythm derangement with a more severe testosterone excess and enhanced adrenal tone, as featured by dehydroepiandrosterone, at mid-morning and afternoon. Interestingly, 11-oxygenated androgens did not show a specific alteration in the examined PCOS phenotypes.

Cardiopulmonary capacity and muscle strength in transgender women in long-term gender-affirming hormone therapy: a cross-sectional study

Leonardo Alvares[1,2], Marcelo Rodrigues dos Santos[3], Francis Ribeiro de Souza[3], Lívia Marcela Santos[1], Elaine Maria Frade Costa[2], Berenice Bilharinho de Mendonça[2], Maria Janieire de Nazaré Nunes Alves[3] & Sorahia Domenice[2]
[1]Centro Universitário São Camilo, Brazil; [2]Faculdade de Medicina da Universidade de São Paulo, Unidade de Endocrinologia do Desenvolvimento, São Paulo, Brazil; [3]InCor - Instituto do Coração do Hospital das Clínicas da FMUSP, São Paulo, Brazil

Introduction
Effects of prior exposure to testosterone (T) during puberty on the performance of transgender women (TW) in estrogen therapy undergoing physical effort are not known, mainly about cardiopulmonary capacity (CPC). Objectives: To evaluate CPC and muscle strength in TW undergoing long-term gender-affirming hormone therapy (GAHT). Methods: A cross-sectional study was carried out with 15 TW (34.2 $\pm$ 5.2 yo), 13 cisgender men (CM) and 14 cisgender women (CW). TW were in hormone therapy for 14.4 $\pm$ 3.5 years. Bioimpedanciometry, handgrip test and CP exercise on a treadmill with an incremental effort were done. Results: The medium strength (kg) was 35.3 $\pm$ 5.4 in TW, 29.7 $\pm$ 3.6 in CW, and 48.4 $\pm$ 6.7 in CM (TWvsCW $P=0.0250$;TWxCM $P<0.0001$). About Median Strength/FFM (Free Fat Mass), a mean of 0.6 was observed in TW group and 0.7 in both others (TWvsCW $P=0.1432$; TWvsCM $P=0.0301$). Mean VO2peak (L/min) of TW was 2606 $\pm$ 416.9, of CW 2167 $\pm$ 408.8 and of CM 3358 $\pm$ 436.3 (TWvsCW $P=0.0238$; TWvsCM <0.0001; CWvsCM $P<0.0001$). Analysis of VO2 max/FFM (L/min/kg), TẂs rate was 47.7 $\pm$ 5.1, CẂs was 53.3 $\pm$ 8.3 and CḾs was 52.4 $\pm$ 5.8 (TWvsCW $P=0.0704$;TWvsCM $P=0.1357$). O2pulse of TW was intermediate between CW and CM (TWvsCW $P=0.0131$, TWvsCM $P<0.0001$) . There was high correlation of VO2peak and FFM/height2 (FFM/Hgt2) of TW ($r=0.7388$;$P=0.0017$) not seen in the other groups. Percentage predicted Heart Rate at effort was higher in TW (103.1) than in CW (96.5) ($P=0.0065$) and CM (99.2) ($P=0.1373$). Discussion: By integrating the data set we may conjecture that TW undergoing long-term GAHT could have an exacerbated ergoreflex and a decreased functionality of the muscular unit. Conclusion: Cardiopulmonary capacity, mainly peak VO2, is blunted in TW after long-term hormone therapy. However, TW still present slightly higher exercise performance when compared with CW.

Noonan Syndrome, Dandy-Walker variant and delayed puberty- a rare association

Mariana Lavrador, Lú cia Fadiga, Mafalda Martins Ferreira, Luí sa Barros & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Introduction
The Dandy-Walker complex (DW) comprises a rare intracranial malformation of the posterior fossa and multiple organ anomalies. The association with endocrine pathology is rare - described in isolated cases (Kallman syndrome, primary hypothyroidism (PH) and central precocious puberty). Noonan syndrome (NS) is a genetic disease usually diagnosed at birth, with variable phenotype. Most cases have AD transmission, with the PTPN11 gene mutation responsible for 50%.
Case report
Male patient referred for consultation at 16 years due to short stature and delayed puberty. At 1st evaluation: height 148.5cm (-3.1 SD), weight 41 Kg, pubertal stage P3, testicular volume 10mL; facial dimorphisms (hypertelorism, bulbous nose, triangular face), and 5th finger's brachydactyly. Past medical history of congenital diaphragmatic hernia, intestinal occlusion at 11 months, strabismus, delayed developmental milestones and unilateral cryptorchidism (surgically corrected at 12y). Family target height of 165 cm. He denied olfactory dysfunction. Of the complementary diagnostic exams: bone age of 13y1month; FSH <0.3 mIU/ml; LH <0.1 mIU/ml; total and free testosterone (TT/FT) 2.2 ng/ml (2,7-11) and 3.3 pg/ml (13-40); LHRH stimulation test with FSH 15.7 mIU/ml and LH 14.5 mIU/ml post stimulation; primary hypothyroidism (TSH 5.7 uIU/ml; T4L 0.7 ng/dl – started LT4 25 mg); 46XY karyotype; brain MRI showed "patency of the olfactory bulbs, identifying both olfactory sulci, without hypothalamic-pituitary alterations; increase in fourth ventricle dimensions, focal increase in retrocerebellar extra-axial space - DW variant". Genetic study (CGH-array) without alterations. He started induction of puberty with testosterone enanthate 125 mg monthly, until 20y, with a final height of 162.1 cm (-2 SD), P5 Tanner stage, and testicular volume of 25mL. Lost of follow up until 30y. At 30y: FSH 11 mUI/ml, LH 4.5 mUI/ml, and TT 5,3 ng/ml; new genetic study by total exomic sequencing, with identification of the variant c.1472C $>$ T p.(Pro491Leu), in heterozygosity, in the PTPN11 gene, classified as pathogenic – Noonan Syndrome type 1.
Conclusion
This case illustrates the rare association of a patient with NS, DW variant and delayed puberty. The diagnosis of NS only at adulthood shows how genetic testing has improved over the years. The DW variant explains diaphragmatic

hernia, intestinal obstruction, hypertelorism, and eventually the PH. NS explains facial dimorphism, cryptorchidism and learning difficulties, as well as short stature and delayed puberty. Diagnosis of NS is of particular importance for surveillance of comorbidities and genetic counseling.

Anti-müllerian hormone analysis as a predictor of the polycystic ovary syndrome diagnosis in romanian women

Nicoleta Baculescu[1,2], Laura Leonte[2], Serban Radian[1, 2], Monica Gheorghiu[1, 2], Andra Caragheorgheopol[1], Bianca Biban[1], Cristina Serban[1], Florin Grigorescu[2, 3] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Institut du Cancer de Montpellier, Montpellier, France

Background
Higher anti-Müllerian hormone (AMH) values are associated with polycystic ovary syndrome (PCOS) and AMH is proposed as a marker of PCOS, however, the optimal diagnostic threshold is not yet defined.
Aim
To study the significant correlations of AMH in PCOS and the accuracy and threshold of AMH for the PCOS diagnosis in Romania.
Subjects and methods
Serum AMH, TT, LH, FSH, fasting glucose and insulin (Ins), HOMA-IR and BMI were analyzed in a cohort of 157 patients with PCOS selected by Rotterdam 2003 criteria and 166 controls, aged 18-35 years, recruited at the National Institute of Endocrinology, Bucharest, Romania. Receiver operator characteristic (ROC) curves were constructed to determine the diagnostic utility of different parameters.
Results
Serum AMH was positively correlated with oligo/amenorrhea ($P=0.0034$), TT ($P=0.0178$), LH ($P=0.0123$), LH/FSH ($P=0.0015$) and number of antral follicles per ovary ($P=0.0011$) in PCOS, while BMI ($P<$ -0.0001), fasting-Ins (P= -0.0209) and HOMA-IR (P= -0.0138) were negatively correlated with AMH in these patients. In stepwise linear regressions including as effects LH/FSH, TT, BMI, fasting-Ins or HOMA-IR and age, LH/FSH and BMI remained significant independent predictors of AMH values in PCOS ($P=0.0002$ and $P<$ -0.0001 respectively). In ROC curve analysis using all population of the study (PCOS and controls), the area under the curve (AUC) for AMH in the diagnosis of PCOS was 0.893 [95% confidence interval (CI): 0.834-0.953; $P<$ 0.0001], with the best compromise between sensitivity and specificity at a cut-off of 32.41 pmol/l (*i.e.*4.53 ng/ml) (Se=85.06%, Spe=80.65%). The AUCs for TT, LH, LH/FSH, fasting-Ins, HOMA-IR and BMI were 0.773 [95% CI: 0.717-0.830; $P<$ 0.001], 0.736[95% CI: 0.664-0.809; $P<$ 0.0001], 0.788 [95% CI: 0.715-0.862; $P<$ 0.001], 0.669 [95% CI: 0.598-0.741; $P=0.0004$], 0.615 [95% CI: 0.537-0.694; $P=0.005$] and 0.612 [95% CI: 0.546-0.678; $P=0.001$] respectively.
Conclusions
AMH values reflect both reproductive and metabolic dysfunction in PCOS. The optimal AMH threshold for PCOS diagnosis was 32.41 pmol/l (4.53 ng/ml) in the Romanian population of this study. The accuracy of serum AMH in PCOS diagnosis is greater than that of TT, gonadotropins or isulin-resistance quantified by HOMA-IR.

Health related quality of life and symptoms of anxiety and depression in women with polycystic ovary syndrome in different weight categories

Josefin Kataoka[1], Marie Olsson[2], Ingrid Larsson[3], Johanna Schmidt[4] & Elisabet Stener-Victorin[2]
[1]Institute of Neuroscience and Physiology, Department of Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Institute of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden; [3]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [4]Institute of Clinical Sciences, Department of Obstetrics and Gynaecology, Sahlgrenska academy, University of Gothenburg, Gothenburg, Sweden

Background
Women with polycystic ovary syndrome (PCOS) have lower health related quality of life (HRQL) and more symptoms of anxiety and depression than women without PCOS, where a higher BMI is positively correlated to both lower HRQL and more symptoms of anxiety and depression. Studies on women with PCOS and severe obesity regarding symptoms of anxiety and depression are lacking.
Aims
To examine if women with severe obesity and PCOS have lower HRQL and more symptoms of anxiety and depression than women with severe obesity without PCOS, and evaluate the effect of a structured weight reduction program. Further, to compare HRQL and symptoms of anxiety and depression in women with and without PCOS in different weight categories.
Patients and methods
In total, 407 women from four studies were included (PCOS $n = 179$, non-PCOS $n = 228$). The main study included 246 women with severe obesity (BMI ≥ 35) (PCOS $n = 63$, non-PCOS $n = 183$). To compare weight categories, data from earlier studies were added, including 134 women with BMI < 35 (PCOS $n = 63$ non-PCOS $n = 51$). Questionnaires Short form (SF)-36 and Self-rating Scale for Affective Syndromes (CPRS-SA) were used to assess HRQL and symptoms of anxiety and depression. Women in the main study entered a weight reduction program, with a very low energy diet (VLED), and 73 women were left to follow-up (PCOS $n = 16$, non-PCOS $n = 57$).
Results
In women with severe obesity, HRQL and symptoms of anxiety and depression did not differ between women with and without PCOS. In women with normal- and overweight, women with PCOS had lower mental HRQL ($P=0.001$ resp. $P=0.004$) and more symptoms of anxiety ($P=0.001$ resp. $P=0.001$) and depression ($P=0.002$ resp. $P=0.012$) compared to women without PCOS. In women with severe obesity, significant weight reduction was achieved in both women with and without PCOS, and led to improved physical HRQL in both groups (PCOS: $P=0.011$, non-PCOS: $P=0.001$).
Conclusions
The difference in HRQL and symptoms of anxiety and depression seen between women with and without PCOS with normal- or overweight is not seen in women with severe obesity. Women with severe obesity benefits from losing weight to improve their physical HRQL. Keywords: Polycystic ovary syndrome, severe obesity, health related quality of life, anxiety, depression

Obese patients with PCOS and prediabetes: two years follow up of the effects of metformin, pioglitazone and empagliflozin treatment on metabolic control, hormonal imbalance and ovulations

Nevena Ilic[1], Corrado Pasquali[2], Violeta Culafic-Vojinovic[3], Tatjana Eror[4] & Stanislava Zivkovic[5]
[1]Euromedik hospital, Endocrinology, Belgrade, Serbia; [2]Sant'Eugenio hospital, ICU, Rome, Italy; [3]Euromedik hospital, Belgrade, Serbia; [1]Euromedik hospital, Endocrinology, Belgrade, Serbia; [1]Euromedik hospital, Endocrinology, Belgrade, Serbia

Introduction
The role of metformin in PCOS is very well known and several studies reported effects of thiazolidinediones and SGLT2 inhibitors on metabolic parametars in these patients.
Objective
The aim of this study was to compare the effects of metformin, pioglitazone and empagliflozin treatment on metabolic control, hormonal imbalance, weight loss and ovulations in obese patients with PCOS and prediabetes.
Methods
BMI, waist circumference, HOMA index, leptin/adiponectin, LH/FSH, androstendione, testosterone, DHEAS, triglycerides, cholesterol, HDL, LDL and presense of ovulation were tested at the admission and 24 months after therapy.
Patients
146 overweight/obese patients (mean age $25 \pm 2,6$) with PCOS and prediabetes were divided in 3 groups based on medication they were treated with.
Results
Empagliflozin was superior to metformin in weight loss and metformin was superior than pioglitazone ($P<0,05$). Empagliflozin was superior to metformin and pioglitazone in reducing waist circumferences ($P<0.01$). Metformin was

superior to empagliflozin and pioglitazone in lowering LH/FSH and testosterone ($P<0,001$). Metformin and empagliflozin were superior in reducing androstendione than pioglitazone ($P<0,01$). Empagliflozin and pioglitazone were superior to metformin in raising SHBG and HDL ($P<0,01$) and lowering L/A ($P<0,05$), trilgycerides ($P<0,001$) and HOMA index ($P<0,01$). There was no difference between groups in ovulatory menstrual cycles regulation.
Conclusions
Empagliflozin and pioglitazone were superior to metformin in metabolic control while metformin was superior in resolving hyperandrogenism. Metformin, pioglitazone and empagliflozin were equally efficient in regulating menstrual cycles in patients with PCOS Pioglitazone and empagliflozin can be a second therapy of choice in patients with PCOS.

Perrault syndrome in three Tunisian women

Faten Haj Kacem Akid, Wafa Belabed, Mouna Elleuch, Abdelmouhaymen MISSAOUI, Dhoha Ben Salah, Fatma Mnif, Nabila Mejdoub & Mohamed Abid
Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Perrault syndrome (PS) is a rare disease characterized by the association of a premature ovarian failure (with primary or secondary amenorrhea) and a sensorineural deafness. In this context we report the case of three patients presenting the association of these two anomalies.
Cases
We report the cases of three females, including two sisters from a consanguineous marriage, aged 21, 16 and 23 years, respectively. The two cardinal signs of this syndrome made of premature ovarian failure and sensorineural deafness were present in the three patients, associated with a Parkinsonian syndrome in the third case. The examination did not show any dysmorphic syndrome or mental retardation. The audiometric exploration of the two sisters concluded to a deafness whose endocochlear nature was confirmed by the auditory evoked potentials. Hormonal exploration confirmed the presence of hypergonadotropic hypogonadism in all three patients. All three patients had a 46XX caryotype, thus eliminating Turner syndrome. The immunological investigation was negative. Pelvic ultrasound in all three patients showed hypoplastic ovaries and uterus. The brain MRI of the two sisters showed an aspect in favor of a leukodystrophy, never described in the literature. The family investigation revealed an isolated congenital deafness in a nephew of both sisters, also from a consanguineous marriage. Biomolecular study in search of genes involved in gonadal and endocochlear differentiation is in progress.
Conclusion
Ovarian dysgenesis associated with sensorineural hearing loss are the cardinal features of Perrault syndrome. A range of associated neurological and neuroradiological disorders are increasingly reported in the literature. Certainly, advances in molecular biology will be able to support the etiopathogenic link between gonadal, auditory and neurological involvement in this syndrome.

EP886

Delayed puberty with a novel mutation in the p450 oxido reductase gene

Neelaveni Kudugunti[1], Dr Datta Reddy Aakiti[2] & Rakesh Sahay[1]
[1]Osmania Medical College, Hyderabad, India; [2]Yashoda Hospitals - Malakpet, Hyderabad, India

P450 Oxidoreductase (POR) deficiency is a rare autosomal recessive disorder of steroidogenesis with varied clinical presentation. POR is the electron donor for all microsomal enzymes involved in steroidogenesis namely P450c 17(17 hydroxylase/17,20 lyase), P450c 21 (21 –hydroxylase), and P450 aro(aromatase). POR deficiency can cause genital ambiguity in both sexes, impaired steroidogenesis and skeletal malformations. Here we present a patient with ovarian cysts and delayed puberty with a novel mutation in the POR gene. A 14 year old girl born of 3rd degree consanguineous marriage presented with acute abdominal pain, on evaluation found to have torsion of large right hemorrhagic ovarian cyst requiring surgical intervention with oophorectomy. 3 to 4 months later patient presented with recurrence of abdominal pain, investigation revealed large cyst in left ovary for which cystectomy was done, subsequent serial ultrasonography evaluation for the next 6months revealed increase in size of ovarian cysts. At this point endocrinology consultation was sought for not attaining menarche. History of acne eruption in the mother during pregnancy but no hirsutism. Her height was 164 cm (75-90th centile), weights 69 kg (90-97th centile), arm span – 171 cms, US/LS ratio-0.85:1. Sexual maturation is A1 P3 B1. No facial dysmorphism, no features of androgen excess, normotensive. Short 4th metatarsal left foot, no other skeletal deformities. Normal external genitalia. Karyotype is 46, XX. Prolactin is 12.8 ng/ml, FSH 13.8, LH 33.7, T3- 1.66, T4-10.5, TSH -1.10, Estradiol 24.22 pg/ml, AMH-0.45 ng/ml and testosterone 14.40 ng/dl. 8 AM serum cortisol is 12.62 mg/dl, 17 hydroxy progesterone 21.7 ng/ml, post ACTH stimulation serum 17 OHP is 22.8 ng/ml, serum cortisol 9.74 mgldl. Bone age-14 years. USG pelvis uterus 30x20x15 mm, ET 4.5mm, bulky left ovary with multiple cysts. Genetic testing showed homozygous mutation in POR (NM_000941.2), (Chr7:75615521); Exon 15; c.1860G>T (p.Trp620Cys). She was advised estrogen replacement and hydrocortisone cover during stress. In conclusion our case presented with normal genitalia, no skeletal abnormalities, no hyper androgenic features with large ovarian cysts and delayed puberty(suggestive of aromatase deficiency) with high 17(OH) progesterone and subnormal rise in cortisol and 17(OH) progesterone post ACTH stimulation consistent with POR deficiency. The wide range of phenotypic presentation may be explained by the differential inhibition of POR dependent enzymes. Given the varied clinical presentation and the risk of hypocortisolism, clinicians should be aware and alert to this diagnosis.

Assessment of a new marker of polycystic ovary syndrome in morbidly obese women

Ibtissem Oueslati[1], Amani Terzi[1], Bassem Hammami[2], Hana Belhadj Hassen[1], Seif Boukriba[3], Habiba Mizouni[3], Moncef Feki[2] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Laboratory of Biochemistry, Tunis, Tunisia; [3]La Rabta University Hospital, Department of Radiology, Tunis, Tunisia

Introduction
Polycystic ovary syndrome is the most common cause of anovulatory infertility in women. Anti-Mullerian Hormone (AMH) was considered a reliable marker for the diagnosis of polycystic ovary syndrome (PCOS). However, AMH level is influenced by age and body mass index. The aim of this study was to analyze the performance of the (LH x AMH)/FSH ratio in the diagnosis of PCOS in women with morbid obesity.
Methods
This was a cross-sectional study including 50 women of reproductive age with morbid obesity (body mass index $\geq$ 40 kg/m2). Each patient underwent a clinical examination, biological and hormonal assays, and an ovarian ultrasound between the third and fifth day of the menstrual cycle. PCOS was diagnosed according to the Rotterdam criteria. (LH x AMH)/FSH ratio was calculated.
Results
Participants had an average age of 34.2 $\pm$ 7.5 years. PCOS was diagnosed in 20 women (40%). The (LH x AMH)/FSH ratio was positively correlated with Ferriman and Gallwey score ($r=0.602$, $P=0.002$), testosterone level ($r=0.586$, $P<10\text{-}3$), delta 4-androstenedione level ($r=0.343$, $P=0.01$), and ovarian volume ($r=0.442$, $P=0.004$). However, this ratio was not correlated with age, body weight, body mass index, and waist circumference. Its mean value was 3.34 in women with PCOS and 0.84 in those without PCOS ($P< 10^{-3}$). The area under the ROC curve for the diagnosis of PCOS was 0.807 for the (LH x AMH)/FSH ratio, 0.714 for the AMH level, and 0.788 for the LH/FSH ratio. A (LH x AMH) /FSH ratio $\geq$ 1 was positively associated with PCOS (Odds ratio= 10.2, $P=0.001$, 95%-CI: 2.39-43.5) with a sensibility of 85%.
Conclusion
Our results showed a significant association between (LH x AMH)/FSH ratio and PCOS. This new ratio was not influenced by age and obesity. Therefore, it may be a good screening tool for PCOS in women with morbid obesity.

Significance of thyroid dysfunction on metabolism and pregnancy in women with polycystic ovary syndrome

Milena Brkic[1], Svetlana Vujovic[2], Radoslav Gajanin[3], Valentina Soldat Stankovic[4] & Gabrijela Malesevic[5]
[1]School of Medicine, University of Banja Luka, BanjaLuka, Bosnia and Herzegovina; [2]School of Medicine, University of Belgrade, Belgrade, Serbia, Department of Endocrinology, Clinical Center of Serbia, Beograd, Serbia; [3]School of Medicine, University of Banja Luka, Department of Clinical Pathology, University Clinical Center of the Republic of Srpska Banja Luka, BanjaLuka, Bosnia and Herzegovina; [4]School of Medicine, University of Banja Luka, Department of Endocrinology with General Internal Medicine, Banja Luka, BanjaLuka, Bosnia and Herzegovina; [5]School of Medicine, University of Banja Luka, University Clinical Centre of the Republic Srpska, internal medicine, Banja Luka, BanjaLuka, Bosnia and Herzegovina

Introduction
There is a significant overlap of symptoms between polycystic ovary syndrome (PCOS) and thyroid disease, despite the fact that they are two different diseases. Both diseases individually affect a woman's metabolic parameters and fertility, and their association makes them much more difficult to manage.
Objective
To investigate the effect of elevated thyroid stimulating hormone (TSH) concentrations on metabolic and endocrine parameters in women with PCOS. Analysis of the correction of TSH values and insulin resistance (IR) on pregnancy using levothyroxine with myo-inositol and d- hiro- inositol.
Methods
Examines between 25 and 35 years of age, diagnosed with PCOS were divided into 2 groups: women ($n=50$) with Hashimoto's thyroiditis, with TSH $\leq$6 mIU/l and regular thyroid hormone levels who did not conceive and women ($n=50$) without elevated serum TSH. Each exminee underwent hormonal analyses during the early follicular phase, glucose and insulin on an empty stomach for 30,60 and 120 minutes during an oral load test with 75 g glucose, body mass index, transvaginal ovarian ultrasound. The lipid profile was checked and homeostatic model assessment (HOMA). Women with PCOS and elevated TSH were divided into two groups ($n = 25$). One group took levothyroxine 0.25 g and myoinositol plus d chiro inositol for 6 months, and the other group ($n=25$) levothyroxine 0.25 mg. Both groups adhered to the same diet with exercise 3 times a week for 30 minutes. After 6 months, the same hormonal, biochemical analyses were checked.
Results
In women with elevated TSH and PCOS, the lipid profile and HOMA were significantly impaired compared to the control group ($P<0,01$)There was no statistical difference in androgen and prolactin concentrations between examines. In women with PCOS and elevated TSH after taking levothyroxine and myo-inositol, d-chiro -inositol combination therapy, there was a statistically significant correction of TSH, anti TPO, HOMA and pregnancy in relation (44:24%) in correlation with women who used only levothyroxine. In both groups of patients, there was a statistically significant correction of the lipid profile.
Conclusion
Hashimoto's disease in the range of subclinical hypothyroidism in combination with PCOS has a negative impact on the metabolic profile. Combination therapy of myo-inositol, D-chiro-inositol and levothyroxine has shown a significant effect on fertility rate and pregnancy by promoting insulin sensitivity and improving thyroid function. In women diagnosed with PCOS, especially those who want to become pregnant, it is necessary to examine the function of the thyroid gland at the first visit to the endocrinologist. Keywords:polycystic ovary syndrome, Hashimoto's thyroiditis

Association of SPISE and HOMA-IR indexes with metabolic characteristics of different age groups of women with polycystic ovary syndrome

Milica Opalic[1], Sanja Ognjanovic[1], Bojana Popovic[1], Dusan Ilic[1], Jelica Bjekic - Macut[2], Valentina Elezovic[1], Lena Radic[1], Danijela Vojnovic Milutinovic[3], Olivera Stanojlovic[4] & Djuro P. Macut[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]CHC Bezanijska Kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Introduction
Polycystic ovary syndrome (PCOS) is the most prevalent endocrinopathy among women during reproductive age. PCOS cardinal manifestations include hyperandrogenism, oligo/anovulation, and/or polycystic ovarian morphology, and is closely linked to metabolic disorders such as obesity and insulin resistance (IR). It was observed that single-point insulin sensitivity estimator (SPISE) index is associated with metabolic abnormalities and could predict glucose regulation during life. The aim of this study was to analyze metabolic and hormonal characteristics among two age groups of women with PCOS and their association with SPISE index and homeostatic model assessment of insulin resistance (HOMA-IR) index.
Subjects and methods
We analyzed 150 women with PCOS diagnosed using ESHRE/ASRM. Patients were divided into two age groups, younger/equal to 30 years (PCOS-A, $n = 74$, age: 23.3$\pm$3.1 years, BMI: 23.1$\pm$ 4.5 kg/m2), and older than 30 years (PCOS-B, $n = 74$, age: 35.7$\pm$4.9 years, BMI: 25.3$\pm$ 6.4 kg/m2). We measured lipids indices, glucose and insulin during oral glucose tolerance test (OGTT), while HOMA-IR and SPISE index were calculated. Statistical analysis was performed by SPSS software.
Results
Both groups had similar body mass index ($P=0.071$) and waist circumference (77.0$\pm$12.9 cm vs. 82.0$\pm$15.3 cm, $P=0.07$), but the incidence of obesity was higher in PCOS-B group (PCOS-A 5.9% vs. PCOS-B 23.5%, $P=0.004$). Women in PCOS-B in comparison to PCOS-A had higher total cholesterol ($P<0.001$), LDL cholesterol ($P=0.022$) and triglycerides ($P=0.012$). Incidence of impaired glucose tolerance was same in both groups, and no patient had diabetes. Although fasting glucose was statistically higher in PCOS-B group ($P<0.001$), there was no between-groups differences in levels of fasting insulin ($P=0.12$) and HOMA-IR ($P=0.151$). SPISE index was statistically lower in PCOS-B ($P=0.022$), showed negative correlation with HOMA-IR, baseline glucose and glucose in 120 minute of OGTT in PCOS-B (r=-0.483, $P=0.004$, r=-0.360, $P=0.007$, r=-0.337, $P=0.004$, respectively) and negative correlation with only fasting insulin in PCOS-A (r=-0.284, $P=0.024$).
Conclusion
PCOS is characterized by the existence of risk factors including obesity, elevated glucose and lipid concentrations all leading to an increased risk of cardiometabolic vascular disorders. The assessment of different indicators during time-line of PCOS could be used for prediction of long-term metabolic outcomes.

Klinefelter syndrome associated with intellectual deficit, short stature and cardiac anomalies

YOSRA HASNI[1, 2], Hayfa Farid[1], Hamza Elfekih[1,2], Oumayma Zarrouk[1], Amel MAAROUFI[1, 2], Maha KACEM[1, 2], Molka CHADLI CHAIEB[1, 2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia

Introduction
Klinefelter syndrome is the most prevalent male chromosomal disorder, characterized by the presence of additional X chromosomes. Most males with Klinefelter syndrome have 47, XXY and normal intelligence. Intellectual disability occurs in males with Klinefelter syndrome variants, who have a higher number of X chromosomes. Here we report a rare case of a 49, XXXXY syndrome revealed by intellectual deficit and pubertal delay.
Observation
An 18-year-old male patient was presented in our department for pubertal delay associated with intellectual deficit. He showed dry mouth, polydipsia, and polyuria. On examination, he had short stature: height = 166 cm, weight = 67 Kg, BMI = 24.3 Kg/m^2, hypertelorism, gynecomastia, atrophic testes and micropenis. Biological examination showed diabetes mellitus and hypertriglyceridemia. Hormonal analysis confirmed a hypergonadotropic hypogonadism (Testosterone = 20 ng/dl, LH=29 IU/l, FSH= 55 IU/l). Thyroid function was normal and his IGF-1 level was low (170 [224-255 ng/ml]). Imaging examination showed a bone age of 16 years and cardiac anomalies: mitral and aortic *insufficiencies.* Genetic analysis exhibited a 49, XXXXY karyotype and the patient underwent testosterone therapy.
Conclusion
49, XXXXY syndrome is a rare variant of Klinefelter syndrome with an incidence of 1/85,000 male births. Its diagnosis is usually made postnatally because of growth deficiency and dysmorphism which wasn't the case for our patient.

Malformations and intellectual deficit are other characteristics of this syndrome that requires performing a karyotype.

Effects of antiandrogen therapy of cyproteron acetate on androgen effects on the skin including androgenetic alopecia in menopausal women - case report: 10 years follow up -

Dragan Tesic, Milena Mitrovic, Tijana Icin, Dragica Andric & Mirjana Tomic
Clinics of Internal Diseases, Clinic of Endocrinology, Diabetes and Metabolic Disorders, Novi Sad, Serbia

Introduction
The term female pattern hair loss (FPHL) is commonly used synonymously with female androgenetic alopecia. While the the role of androgens and androgen receptor genes is well-defined in male androgenetic alopecia (AGA-M), its role in in the pathogenesis of FPHL is stil uncertain. More diffuse involvement, resulting in an oval-shaped alopecia surrounded by a rim of normal hair density (Ludwig's classification) might be a clinical challenge. The aim of case report is to present the menopausal patient with full blown signs of androgen excess such as acne, seborrhea, hirsutism (SAHA: seborrhea, acne, hirsutism, and alopecia), obesity and pronounced psychological consequences.
Case description
female, born in 1952y. Since 2000y. (menopausis in 2004y) she gained 35 kgs (85.1 kg), BH 158 cm and since 2010y. she started to notice increased hairiness (hirsutismus) and weakening and hair loss (FPHL), in 2016 Grade 3. At that time on adrenal CT it was detected adenoma on one gland. Cushing syndroma and Chon syndroma excluded, but among laboratory finding significant was LH 18 U/l, FSH 44.4 U/l, testosteron 13.8 nmol/l, insulin (fasting) 27.1 mU/l, post prandial 281.6 mU/l. Fasting triglycerides 0.95 mmol/l, HDL-cholesterol 1.8 mmol/l, total holesterol 5.56 mmol/l. In two years period (206-2018) she managed to reduce her body weight to 75 kg, insulinemia to 11.9 mU/l, testosteronemia to 5.8 nmol/l. Alopecia and hirsutisms had been without change, so we decided to introduce cyproteron acetate tbl. 2x50 mg. First drop in T was noticed 1 year later (2019y.), but even before that after a year on that therapy patient noticed changes in reduced alopecia and hirsutismus. After 2 ys od therapy in 2021y. we noticed futher drop in T between 1.44 and 3.04. Clinical improvement was manifested in alopecia removal of Grade 3 in to Grade 1. In these time DHT (Barts) has been 10.1-21.7 (reference -23) ng/dl.
Discussion
The aim of this case report is to emphasize the need of normalisation the testosteron level (refrence 2.6 nmol/l) for obtaining the effect of reducion of androgenization, meaning withdrawal of alopecia and hirsutism. If we consider hyperinsulinemia as a triger hormon change for the cascade of further androgenisation, its reduction seems not not to be enough for beneficial efects. More further, hyperinsulinism was assocociated only with hypertension but not with characteristic lipid consetalation that runs with insulin resistance, high triglycerodes and low HDL cholesterol.

EP892

Effects of letrozole on reproductive organs of young and aged male rats

Alexander Reznikov[1], Olga Sachynska[1], Liubov Polyakova[1] & Oksana Faliush[2]
[1]VP Komisarenko Institute of Endocrinology and Metabolism, National Academy of Medical Sciences of Ukraine, Dept. of Endocrinology of Reproduction and Adaptation, Kyiv, Ukraine; [2]VP Komisarenko Institute of Endocrinology and Metabolism, National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

The aim of this work was to study the condition of the reproductive system after long-term administration of letrozole followed by its withdrawal in young males and against the background of involutive changes in aging males in a comparative aspect. The experiments were carried out on Wistar rats with an initial age of 5 months and 15 months, which have been gavaged by letrozole every other day at a dose of 1 mg/kg body weight for 3 months and then 2 months after its discontinuation. The blood plasma testosterone and estradiol levels were measured by immunoassays. The spermatozoa concentrations in epididymal washes were determined. The testicles and accessory sexual glands were weighed, and morphology of gonads and ventral prostate have been studied. The results of the study were compared with those of control animals of corresponding age. As the result of letrozole treatment, the ratio of testosterone and estradiol levels in blood plasma of aged rats increased. The spermatozoa content in epididymis rose up by 28% at average. The histological study revealed functional activation of Leydig cells, a significant retardation of involutive changes of their number and morphology. Some Leydig cells demonstrated the signs of functional exhaustion. Letrozole caused an increase of relative weights of the coagulation gland by an average of 40%, seminal vesicles by 31%, and ventral prostate by 33% compared with those of control animals. Two months after letrozole withdrawal, there were no any signs of difference between letrozole-treated and control animals. In young rats, the effects of letrozole were almost not detectable. Letrozole administration to male rats with age-related involution of the reproductive system increases testosterone/estradiol ratio in blood plasma, the spermatozoa content in epididymises and the weights of androgen-dependent accessory sexual glands. This is accompanied by slowing down of age-related changes of the gonad and prostate gland morphology. Letrozole-induced reproductive effects are reversible.
Keywords: letrozole, reproductive organs, male, rats.

Mitochondrial uncoupling proteins (UCPs) regulate the mitochondrial activity of human sertoli cells

David F. Carrageta[1], Laís Freire-Brito[1], Bruno S. Monteiro[1], Bárbara Guerra-Carvalho[1,2,3], Raquel L. Bernardino[1], Pedro F. Oliveira[2], Mariana P. Monteiro[1] & Marco G. Alves[1]
[1]UMIB - Unit for Multidisciplinary Research in Biomedicine, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal; [2]QOPNA & LAQV, Department of Chemistry, University of Aveiro, Aveiro, Portugal; [3]Department of Life Sciences, Faculty of Sciences and Technology, University of Coimbra, Coimbra, Portugal

Introduction
Mitochondrial uncoupling proteins (UCPs) are channel proteins present in the mitochondrial inner membrane which are responsible for the transport of protons between the mitochondrial intermembrane space and the matrix. Currently, six UCP homologues had been identified (UCP1-6). UCPs are major regulators of reactive oxygen species (ROS) production, general cellular redox state and metabolism. UCPs also exhibit specific functions, such as UCP1 and thermogenesis or UCP2 and regulation of insulin secretion in beta-pancreatic cells. Altered expression and function of UCPs have been linked with the onset of metabolic diseases, including obesity and diabetes mellitus and increased oxidative stress. Male infertility is an overlooked comorbidity related to metabolic diseases since the testis is susceptible to metabolic alterations and increased oxidative stress. However, the expression and function of UCPs in the human testis remain unknown.
Aim of the study
The main objective of this study was to identify the expression of the different UCPs homologues in human Sertoli cells (hSCs). In addition, the function of UCPs on the mitochondrial activity and metabolism of hSCs was analysed through its inhibition by genipin, a specific UCP inhibitor.
Matherials and methods
Primary cultures of human Sertoli cells from healthy men with conserved spermatogenesis were established ($n=6$). Total RNA was extracted and all UCP homologues (UCP1-6) mRNA expression was analysed by RT-PCR. UCP1-3 were detected by immunofluorescence. Then, UCPs were inhibited in hSCs by genipin, a specific UCP inhibitor, (0.5, 5, 50, and 100 μM). Cellular viability, proliferation, and ROS production were accessed after 24 h treatment. Mitochondria function was accessed by Seahorse XF Cell Mito Stress assay. Culture media were collected and analysed by ^{1}H-NMR.
Results
We were able to identify all UCPs homologues (UCP1-6) in hSCs. The inhibition of UCPs by high concentrations of genipin decreased hSCs proliferation but no cytotoxicity was observed. In addition, UCP inhibition by genipin decreased mitochondrial activity in a dose-dependent manner. Interestingly, no increased ROS production was observed.
Conclusion
We were able to identify, to the best of our knowledge, for the first time the expression of UCPs (UCP1-6) in hSCs. UCPs can regulate the mitochondrial activity and metabolism of hSCs. Our results suggest that UCPs dysfunction could play a central role in the crosstalk between metabolic disorders, high oxidative stress and male infertility.

Mitochondrial uncoupling proteins (UCPs) are key regulators of human spermatozoa motility

Laís Freire-Brito[1], David F. Carrageta[1], Bruno S. Monteiro[1], Bárbara Guerra-Carvalho[1,2,3], Alberto Barros[4,5,6], Pedro F. Oliveira[3] & Marco G. Alves[1]

[1]UMIB - Unit for Multidisciplinary Research in Biomedicine, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal; [2]Department of Life Sciences, University of Coimbra, Coimbra, Portugal; [3]QOPNA & LAQV, Department of Chemistry, University of Aveiro, Aveiro, Portugal; [4]Genetics of Reproduction Center, Porto, Portugal; [5]Department of Genetics, Faculty of Medicine, University of Porto, Porto, Portugal; [6]i3S - Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal

Introduction

Mitochondrial uncoupling proteins (UCPs) are mitochondrial transmembrane channels belonging to the anion carrier family. Six UCP homologues (UCP1-6) had been identified with a ubiquitous distribution throughout the body and many different physiological functions. UCPs are important regulators of several biological processes, including thermogenesis, oxidative phosphorylation, ROS production, as well as cellular metabolism. However, the knowledge concerning the molecular action mechanisms is limited. UCPs' (dys)function is pivotal to the onset of metabolic diseases and consequent increased oxidative stress. Although the molecular mechanisms are poorly understood, there is an interconnection between oxidative stress, male infertility, and metabolic disorders, such as obesity and diabetes mellitus. In addition, the expression and function of UCPs in the human spermatozoa remains to be explored.

Aim of the study

This study aimed to evaluate the expression of UCPs homologues (UCP1-6) in human spermatozoa. In addition, the influence of UCPs in spermatozoa viability, total and progressive motility, mitochondrial activity, and ROS production was evaluated through its inhibition by genipin, a selective UCP inhibitor.

Matherials and methods

Highly motile and viable spermatozoa were isolated from seminal samples of normozoospermic men ($n=10$) by density gradient centrifugation. The mRNA expression of UCPs homologues (UCP1-6) was evaluated by RT-PCR and the protein expression (UCP1-3) by immunofluorescence. Samples were incubated in BWW media supplemented with genipin (0, 0.5, 5, and 50 μM) at 37°C. After 3 h, total motility and viability were analyzed. The mitochondrial activity and total ROS production were accessed by JC-1 dye and CM-H2DCFDA probe, respectively. The culture media were collected and evaluated by 1H-NMR. To further study the observed loss of motility and its reversibility, total and progressive motility were evaluated each 15 min up to a total of 105 min.

Results

We were able to identify the mRNA expression of all UCPs homologues (UCP1-6) in human spermatozoa. Inhibition of UCPs by the highest concentration of genipin (50 μM) led to the irreversible loss of motility. Mitochondrial membrane potential was also found diminished, although no alterations in human spermatozoa viability, metabolic profile, or ROS production were observed.

Conclusion

UCPs are major regulators of human spermatozoa's mitochondrial activity and motility. Our data suggests that the dysfunction of human spermatozoa UCPs is not only potentially interconnected to metabolic diseases, oxidative stress, and male infertility but also a potential novel target for the development of male contraceptives.

Sperm medium supplementation with hyperoside as a potential strategy to counteract spermatozoa dysfunction associated with oxidative stress

Mafalda V. Moreira[1], Sara C. Pereira[1], Soraia Pinto[2], Alberto Barros[2,3,4], Branca M. Silva[5], Marco G. Alves[1] & Pedro F. Oliveira[6]

[1]Institute of Biomedical Sciences Abel Salazar (ICBAS) - School of Medicine and Biomedical Sciences, University of Porto, Department of Anatomy and Unit for Multidisciplinary Research in Biomedicine (UMIB), Porto, Portugal; [2]Centre for Reproductive Genetics Professor Alberto Barros, Porto, Portugal; [3]Faculty of Medicine, University of Porto, Department of Genetics, Porto, Portugal; [4]i3S – Instituto de Investigação e Inovação em Saúde, Porto, Portugal; [5]University of Beira Interior, Covilhã, Portugal; [6]QOPNA & LAQV, University of Aveiro, Department of Chemistry, Aveiro, Portugal

Infertility is a global health problem that affects about 15% of couples and approximately half of infertility cases are associated with male factors. Oxidative Stress (OS) is reported as one of the major causes of male infertility, mainly due to spermatozoa's vulnerability to the attack of reactive oxygen species (ROS). Infertile couples often recur to assisted reproductive technology (ART) to achieve a successful pregnancy. However, ART protocols also increase the exposure of gametes to OS conditions. A strategy often used to overcome this problem is the supplementation of media with antioxidants. Hyperoside (quercetin 3-*O*-galactoside) is a flavonol glycoside that has been shown to possess prominent antioxidant properties, preventing oxidative damage in several cellular systems. Thus, we proposed to investigate the impact of hyperoside supplementation on the protection of sperm against oxidative damage. For this purpose, sperm samples of normozoospermic patients ($n=20$) were supplemented with HYP (100 and 500 μM), for 1 h, in the presence and absence of hydrogen peroxide (300 μM). As a positive control, spermatozoa were supplemented with the well-known antioxidant, vitamin C (VC). After treatment, sperm quality parameters (motility and vitality) were evaluated, according to WHO guidelines. The total antioxidant capacity (TAC) of sperm medium was measured by ferric reducing antioxidant power (FRAP) and OS biomarkers expression was assessed by slot blot technique. Further, DNA fragmentation was measured by TUNEL assay. Our results demonstrated that supplementation with HYP did not induce any deleterious effects to the physiology of the spermatozoa, after 1-h of treatment. Further, under an H_2O_2-induced OS condition, HYP was able to preserve sperm motility and decrease DNA fragmentation. Furthermore, HYP also appears to prevent the increase in lipid peroxidation under OS conditions. Overall, our findings lead us to suggest that sperm medium HYP supplementation can contribute to the improvement of sperm maintenance during ART protocols

Vascular erectile dysfunction as a mirror of general health: focus on patients comorbidities

Barbara Rossi[1,2], Marilina Romeo[1, 2], Antonio Raffaele Michele Granata[1], Vincenzo Rochira[1, 2], Manuela Simoni[1, 2], Giorgia Spaggiari[1] & Daniele Santi[1,2]

[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy.; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background

Erectile dysfunction (ED) represents the most frequent sexual dysfunction. Among several possible ED aetiologies, vascular ED (vED) presents the greatest implications for global individual health, resulting an early hallmark of cardiovascular diseases. Indeed, vED was demonstrated associated with a 1.25 times greater risk of developing major cardiovascular diseases. Alongside cardiovascular aspect, the evaluation of patients health, measured by the comorbidities number, in relation to the ED aetiology has never been investigated so far.

Aim of the study

To explore the potential relationship between the number of comorbidities and ED aetiology and severity.

Material and methods

A large database including all patients longitudinally evaluated for any andrological reason is kept the Andrology Unit of Modena (Italy). The current study is an interim analysis including ED patients evaluated from 2008 to 2010. For each patient, medical history, physical examination, ED characteristics, blood examination for hormonal assays and treatment choice were collected. The ED was graded using the International Index of Erectile Function (IIEF)-15 score and the number of comorbidities with Chronic Disease Score (CDS). Patients were grouped according to the ED aetiology, i.e. psychological, vascular, hormonal and neurological. CDS was compared among groups of patients generated on ED characteristics considering baseline and follow-up visits.

Results

418 men (mean age 43.4 ± 12.8 years) with ED were followed for 10.2 ± 6.5 years. 368 patients (87.6%) showed a psychological aetiology, 29 (6.9%) vED, 14 (3.3%) hormonal genesis and seven (1.7%) a neurological ED. Although CDS did not differ among ED groups ($P=0.226$), it was directly related to patients age (Rho: 0.449, $P<0.001$) and inversely to ED domain at IIEF-15 (Rho: -0.319, $P=0.005$). At logistic regression analysis, CDS resulted not able to predict ED diagnosis, while only smoking habit was correlated to vED (Exp: 0.211: 0.082-0.541, $P=0.001$). As expected, CDS significantly increased during follow-up

with the highest score collected at the last visit compared to baseline (1.8±2.7 vs 1.2±2.1, $P<0.001$). At follow-up visits, CDS was significantly higher in vascular ED (4.2±3.4) compared to psychological (2.2±3.0), hormonal (1.7±3.4) and neurological (1.0±1.1) forms ($P<0.001$).
Conclusions
Here, we demonstrate that the anamnestic evaluation of the comorbidities number is not useful in clinical practice to predict ED aetiology. However, the increase in CDS observed during follow-up resulted particularly evident in vED, confirming the vED role as a mirror of general health.

Lean Polycystic Ovarian Syndrome - An evaluation of diagnostic and clinical outcome differences in relation to obese PCOS in patients attending a tertiary care institute in Colombo

Ishara Ranathunga, T G Athukorala, Manilka Sumanatilleke & Noel Somasundaram
National Hospital of Sri Lanka, Sri Lanka

Background and Objectives
Polycystic ovary syndrome (PCOS) is a common female reproductive endocrine disorder with a prevalence of 15-20%. Although a majority of patients diagnosed with PCOS are overweight/obese, minority can present with normal body mass index of $\leq$25 kg/M^2 which complicate the effective diagnosis and management. We have studied the socio-demographic and clinical characteristics of lean PCOS patients in comparison to obese PCOS patients attending the Endocrinology clinic in a tertiary care institute in Sri Lanka.
Methods
A descriptive cross sectional study was conducted from September 2019 to September 2020 at the Endocrinology Unit of the National Hospital of Sri Lanka. Systematic sampling was done recruiting PCOS patients diagnosed with Rotterdam criteria. After obtaining informed written consent, the data was collected using an interviewer administered questionnaire. HOMA-IR was calculated using the fasting insulin and blood glucose level.
Results
The study enrolled sixty females. Out of that 23 (38.3%) patients were diagnosed to have lean PCOS while the rest (37, 61.6%) had overweight/obesity. The mean age was 25.1 years (range 18-37). The mean weight was 55.0 (SD=6.7) kg and BMI was 22.2 (SD=1.8) kg/m^{-2}. Twenty (83.0%) had irregular menstrual cycles while 11 (47.8%) patients had clinical or biochemical evidence of hyperandrogenism. Only 9 (39.1%) patients had polycystic ovaries on trans-abdominal ultrasound scan. According to the body fat percentage assessed by the whole body DEXA scan 90.9% patents had their body fat in the overweight and obese category in contrast to the BMI category. HOMA-IR detected 37.5% to have high insulin resistance. There was significant difference in the presence of acanthosis nigricans, hirsutism, polycystic ovaries on USS and non-alcoholic fatty liver disease (NAFLD) in the obese PCOS patients while acne was more prevalent in the lean PCOS females ($P<0.05$).
Conclusions
The minority of patents affected with PCOS are falling under the category of lean PCOS. The diagnosis and the therapeutic approach poses a significant clinical challenge due to the absence of typical clinical features such as acanthosis nigricans, hirsutism, and polycystic ovaries on USS in this group of patients. Use of body fat estimation is more sensitive in detecting overweight/obesity in this group rather than using conventional BMI measurement. Nevertheless, the suspicion and awareness among clinicians of the possibility of lean PCOS in this group of females can improve the diagnosis and patient outcomes.

Introduction
National Institute of Health and Care Excellence (NICE) recommends screening for emotional wellbeing as part of consultations for polycystic ovary syndrome (PCOS).
Aim
We evaluated several dimensions of emotional wellbeing in people attending PCOS consultation with specialists in the UK and India.
Methods
All people attending specialist clinics in a tertiary centre in the UK from October 2020 to September 2021 and in India between March 2021 to September 2021 were invited to complete a survey before and after attending the clinic. This survey had questions on demographics, Hospital Anxiety and Depression Scale (score 8-10 borderline; score $\geq$11 cases of anxiety and depression, respectively), Body Image Concern Inventory (BICI; score $\geq$72 suggestive of body dysmorphic disorder, BDD), Beliefs About Obese Persons Scale (BAOP; higher score suggestive of weight bias), and Female Sexual Function Index (FSFI; higher score suggestive of psychosexual dysfunction).
Results
A total of 115 women (36 UK and 79 India) completed the survey. The prevalence of anxiety and depression were 56.5% (50.0% UK vs 59.5% India;Mann-Whitney U- $P=0.483$) and 16.5% (13.9% UK vs 17.7% India, $P=0.529$), respectively. Overall, 29.6% had BDD with higher prevalence in the UK women (36.1% UK vs 26.6% India; $P=0.208$). Participants had higher scores for BAOP (overall: 15.5/48 (13.0-18.0)) with higher scores for UK women (UK: 16 (13.3 - 18.9); vs India: 15 (12.5 - 17.5); $P=0.575$). The overall scores for FSFI were towards the upper end of the scale (20.4/36 (7.5-25.2)) with no significant difference between the two groups (UK: 23.1 (13.2 - 26.2); vs India: 17.7 (6.9-24.5); $P=0.413$). Post-survey results further revealed that a proportion of women felt limited information was provided about anxiety (UK: 6/19 (31.6%);vs India: 17/40 (42.5%)), depressive symptoms (UK: 5/19 (26.3%); vs India: 19/40 (47.5%)) or body image concerns UK: 3/19 (15.8%); vs India: 10/40 (25%)) during consultation.
Conclusion
There is a high prevalence of emotional ill-being associated with PCOS both in the UK and India. While it is challenging to encompass all aspects of clinical care during consultation, future work should explore alternate ways to improve screening and management of emotional wellbeing in women with PCOS.

Perrault syndrome in a Tunsian Girl : a case report

Chayma Bel Hadj Sliman, Fatma Chaker, Anis Grassa, Nadia Khessairi, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Perrault syndrome is a rare autosomal recessive disorder defined by the association of 46XX ovarian dysgenesis and neurosensory deafness. Other manifestations may be present, in particular cerebellar and/or peripheral neuronal degenerative disease. we report the case of Perrault syndrome in a 15-year-old Tunisian girl.
Observation
A 15-year-old girl was referred to our department for pubertal delay. She had a congenital deafness and epilepsy diagnosed at one year old and she was on sodium valproate. Physical examination showed a body weight of 45 kg (between -1 and -2SD), a body height of 1.62 m (between mean and -1 SD), Tanner scale was B1P2. Hormonal investigation showed an hypergonadotrophic hypogonadism (FSH= 153 UI/l (1-17) and LH=34 mUI/l (0,5-41,7)). Pelvic ultrasound showed an infantile uterus. Ovaries were not visible. A complementary pelvic MRI confirmed the absence of ovaries and the hypoplastic uterus. Karyotype was 46XX and the genetic study showed the absence of the GJB2 gene mutation. The diagnosis of Perrault syndrome was confirmed. The electromyography was normal and cerebral MRI showed white matter demyelination. The patient was treated with estrogen and progesterone to induce puberty.

Conclusion
We report this case because of its rarity as few cases have been reported in Tunisia so far in the literature. The prevalence of Perrault syndrome is poorly known, often under diagnosed because of the phenotypical and genetic heterogeneity of this syndrome.

Gynecomastia: clinical, paraclinical and etiological aspects

Bel Hadj Sliman Chayma, Nadia Khessairi, Anis Grassa, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Gynecomastia is an enlargement of male breast glandular tissue caused by an imbalance of the hormones androgens and estrogens. It can be physiological at different stages of life (birth, adolescence, senescence), caused by medication or reveal a serious pathology. The aim of our study was to evaluate the characteristics of presentation, biochemical profile, and etiology of gynecomastia.
Methods
A retrospective study was conducted at the endocrinology department of the Rabta Hospital in Tunis including 100 patients who presented with gynecomastia between January 2015 and December 2020. Clinical and paraclinical data were collected from medical records.
Results
The mean age of our patients was 37.16 years with extremes ranging from 11 years to 88 years. Seven patients (7%) had a history of cryptorchidism and testicular ectopy. Impuberism and late puberty were noted in 17 patients (17%). The mean duration of Gynecomastia before seeking specialized endocrine care was 78 months with an acute onset in 19% of cases. On physical examination, 56 patients (56%) had bilateral and symmetrical gynecomastia, 19 patients (19%) had bilateral and asymmetrical and 25% unilateral gynecomastia. 15 patients had stage I, 33 patients had stage II and 52 patients had stage III gynecomastia. Testosteronemia was measured in 43 patients and was low in 26 patients (26%). Gynecomastia was considered physiological in 25 patients (25%). The etiology of gynecomastia was considered to be drug-induced in 15 patients (15%), including spironolactone in six patients. The other drugs involved were chemotherapy and dopaminergic antagonists. Other causes were non-functioning pituitary adenomas, prolactinomas, isolated hypogonadotropic hypogonadism, testicular diseases, hypothyroidism and hyperthyroidism in 7%, 6%, 8%, 7%, 2% and 1% of the cases respectively. Idiopathic gynecomastia was found in 29% of cases.
Conclusion
Gynecomastia is a frequent and often benign pathology but it can be the expression of a relevant underlying endocrine disease or even tumor pathology. This highlights the importance of an adequate and complete clinical, biochemical, and imaging assessment of every patient presenting with gynecomastia.

Therapeutic aspects of gynecomastia: about 100 cases

Anis Grassa, Bel Hadj Sliman Chayma, Nadia Khessairi, Ibtissem Oueslati & Fatma Chaker
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Gynecomastia is defined as the benign proliferation of the mammary glands in males, which results from an excess of estrogens, androgen deficiency, hormone resistance, or altered ratio of estrogens to androgens. It can be unilateral or bilateral. The aim of our study was to describe the therapeutic aspects and the evolution of gynecomastia.
Methods
This is a retrospective descriptive study of 100 patients who presented with gynecomastia at the endocrinology department of the Rabta hospital between January 2015 and December 2020. Clinical and paraclinical data were collected from medical records.
Results
Our population had a mean age of 37.16 $\pm$ 21.7 years at the time of the first visit. The mean age of puberty was 13.9 $\pm$ 2.7 years. Seven patients (7%) had a past medical history of testicular ectopy and cryptorchidism. Physical examination showed the presence of glandular tissue in all patients and diagnosis was documented by ultrasound and/or mammography in 60 patients. Biological workup revealed hypogonadotropic hypogonadism in 15 patients, including 7 patients with non-functional pituitary adenoma and 8 patients with isolated hypogonadotropic hypogonadism, hyperprolactinemia with prolactinoma in 6 patients, hypothyroidism in 2 patients, and hyperthyroidism in 1 patient. Gynecomastia was secondary to testicular disease in 7 patients. In addition, 15 patients had drug-induced gynecomastia. Finally, gynecomastia was physiological in 25 patients and idiopathic in 29 others. Regarding the management of gynecomastia, 29 patients received treatment for the etiology, 11 patients received testosterone enanthate injections. Nine patients received local treatment with androstanolone and 12 patients underwent cosmetic surgery. The rest of the patients were monitored and did not receive any treatment. The evolution was marked by clinical improvement in 38% of cases.
Conclusion
Each case of gynecomastia should be subjected to a precise etiological workup including at least a testosterone and estradiol dosage. The treatment modalities of gynecomastia depend on the results of the etiological investigation.

Polycystic ovary syndrome : clinical, paraclinical and therapeutic profile

Anis Grassa, Nadia Khessairi, Bel Hadj Sliman Chayma, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders in women and its main symptoms are related to menstrual disorders and hyperandrogenism. The aim of our study was to evaluate the clinical and paraclinical profile of PCOS.
Methods
We conducted a retrospective study that included 50 women, followed at endocrinology department's consultations of Rabta Hospital in Tunis. Each patient underwent a clinical examination, hormone assays and ovarian ultrasound. The diagnosis of PCOS was made according to the Rotterdam 2003 criteria.
Results
The mean age of our patients was 26.9 $\pm$ 7.9 years [15 -45]. The family history of PCOS was found in 24% and type 2 diabetes mellitus's personal medical history in 21.7%. Eight percent of patients were smokers. The mean age of menarche was 12.1 $\pm$ 1.3 years. Sixty-two percent of patients had spaniomenorrhoea and 6% had secondary amenorrhoea. These disorders were post-pubertal in half cases. The average weight was 87.5 $\pm$ 21.9 kg [38-150] for an average body mass index of 33.3 $\pm$ 7.6 kg/m^2 [16-57]. Therefore 65% of patients were obese and 37% presented acanthosis nigricans on clinical examination. Clinical hyperandrogenism signs such as acne and hyperseborrhea were found in 22.7% while major virilizationsigns were noted in 4%. Hirsutism was classified moderate to severe in 60.8%. Biological hyperandrogenism was found in 62% of cases including mean testosterone level of 0.78 $\pm$ 0.4 ng/ml. The average LH/FSH ratio was 1.7 $\pm$ 0.9, and was higher than 2 in 29%. Ovarian ultrasound showed a polycystic aspect in 72% of cases with increased ovaries size in 56%, the rest were strictly normal. Hygienic diet was instituted in 96% associated to metformin in 18% of cases and an Oestrogen -Progestin combination therapy in 60%. An additional laser hair removal treatment was done in 28%. Clinical and biological improvement was noted in half cases.
Conclusion
The etiological investigation of hyperandrogenism with menstrual disorders should remain exhaustive to eliminate potentially serious diagnoses. PCOS remains a benign disease. However, it must be managed effectively, given its impact on the patient's quality of life.

Clinical utility of the Anti-Mullerian Hormone testing for the prediction of PCOS

Valentina Soldat Stankovic[1, 2], Snjezana Popovic Pejicic[2], Aleksandra Grbic[1, 2], Tamara Dojcinovic[1], Gabrijela Malesevic[1, 2], Milena Brkic[2] & Djuro P. Macut[3,4]
[1]University Clinical Centre of the Republic Srpska, Internal Medicine, Banja Luka, Bosnia and Herzegovina; [2]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina; [3]Endocrinology Clinic, Beograd, Serbia; [4]University of Belgrade - Faculty of Medicine, Internal Medicine, Beograd, Serbia

Introduction
The diagnostic criteria of polycystic ovary syndrome (PCOS) are still under discussion and the hormonal parameters, including anti-Mullerian hormone range and hyperandrogenism, are not determined. Serum AMH level has been proposed as a surrogate marker for PCOM and could, therefore, be integrated in the diagnostic classifications for PCOS.. The aim of the present study was to characterize hormonal features of PCOS and to establish the most important hormonal parameters for PCOS diagnosis.
Design
A case-control study.
Methods
The study included 60 women with PCOS according to the complete Rotterdam criteria, aged 18-40 years. The control group consisted of 60 healthy women with a regular menstrual cycle of the same age. Hormonal assays, and ultrasound of the pelvic organs were performed. The diagnostic accuracy of AMH, follicle-stimulating hormone (FSH), luteinizing hormone (LH), estradiol, testosterone (T), dehydroepiandrosterone sulfate (DHEAS), sex hormone-binding globulin (SHBG) and free androgen index (FAI) in predicting PCOS was established using a logistic regression model and calculating area under the receiver operator characteristic (ROC) curve (AUC).
Results
PCOS women had higher levels of serum LH ($p < 0.01$), T ($p < 0.01$), AMH ($p < 0.01$), FAI ($p < 0.01$), DHEAS ($p < 0.01$), estradiol ($P < 0.01$), 17-OH PG ($p < 0.01$) and significantly lower SHBG level ($p < 0.01$) and FSH level ($p < 0.01$) compared to healthy women. Testosterone level > 0.41 ng/ml showed the highest sensitivity (85.0%) and specificity (96.7%) for PCOS diagnosis. The level of AMH > 4.69 ng/ml also showed high sensitivity of 75% and specificity of 75% in PCOS diagnosis in the studied sample. The diagnostic accuracy of PCOS reached 94,2% with the combined use of hormonal indexes, which was significantly higher than the use of each index separately.
Conclusions
The results of the study estimate the threshold for AMH and T which could be suggested for use in the PCOS diagnostics with a high sensitivity and specificity. Moreover, the combination of hormonal indexes improved the diagnostic accuracy for the PCOS detection.

Development of ANA antibodies induced by estrogen treatment.

Daniel Medina Rivero[1], Isabel Mateo Gavira[2] & Laura Larrán Escandón[2]
[1]Hospital San Carlos San Fernando, San Fernando, Spain; [2]Hospital Universitario Puerta del Mar, Cádiz, Spain

A 36-year-old woman in follow-up due to early ovarian failure of idiopathic origin. No family history of interest. History of menarche at 12 years of age with regular menses until 18 years of age, when it begins with amenorrheic spells lasting up to 8 months. Laboratory tests revealed hypergonadotropic hypogonadism with negative ovarian autoantibodies, normal karyotype, and gynecological ultrasound showing a normal-looking uterus with slight bilateral ovarian atrophy. Negative antiadrenal and anti-TPO antibodies. She has undergone treatment with combined contraceptives since the diagnosis, only temporarily interrupted for 9 months to start the insemination protocol with egg donation, which was not completed. After 10 years of hormone replacement therapy, she develops polyarthralgia that worsens in the first days of estrogen treatment. She associates dactylitis of the hands and feet and episodes of joint angioedema. No accompanying fever. He also does not present joint deformities, abdominal pain or edema at the easy or genital level. In the study requested by Rheumatology, the following was observed: X-rays and bone scintigraphy without significant findings, densitometric study within normal limits, and the autoimmunity study revealed positive levels of ANA antibodies with a homogeneous pattern and a titer of 1/320. Other antibodies (anti-histone, anti-dsDNA, anti-nucleosome, anti-ribosome, anti-phospholipid, ENA, anti-adrenal, anti-ovarian, anti-citrullinated peptides, ANCA-MPO, ANCA-PR3 and those associated with polyglandular syndromes autoimmune) are negative. Likewise, angioedema due to hereditary or acquired defects of proteins of the complement system is ruled out. After discontinuation of estrogen treatment, the symptoms disappear. Finally, it is classified as a picture of angioedema and ANA induced by estrogen without criteria for systemic lupus erythematosus. She is currently asymptomatic and without hormone replacement therapy.

Unrecognized premature ovarian failure in adolescents-case report

Milena Brkic[1], Svetlana Vujovic[2] & Branka Cancarevic Djajic[3]
[1]School of Medicine, University of Banja Luka, BanjaLuka, Bosnia and Herzegovina; [2]School of Medicine, University of Belgrade, Belgrade, Serbia, Department of Endocrinology, Clinical Center of Serbia, Beograd, Serbia; [3]School of Medicine, University of Banja Luka, Department of gynecology and obstetrics University Clinical Center of the Republic of Srpska Banja Luka, BanjaLuka, Bosnia and Herzegovina

Introduction
The average age for physiological menopause is 50 years. Menopause before the age of 40 is usually defined as premature ovarian failure (POF). POF in adolescents is an extremely rare event and its occurrence raises important questions about the cause-and-effect relationship, which may signal genetic and systemic disorders.
Design
Case report
The 29-year-old first reported to an endocrinologist for secondary amenorrhea. The anamnesis revealed that the patient got menarche at the age of 10. She had regular menstrual cycles for 4 years and irregular periods for 2 years. After the age of 16 she stopped menstruating. After 6 months, the therapy was excluded and during the next period of 12.5 years until the appearance of the endocrinologist and the desire to have children, she did not take anything from the therapy. From hardship allegations; irritability, insomnia, lack of energy, loss of libido, sweating, headache and weight gain. Menopause in a mother from the age of 30. Hormonal analyses:hypergonadotropic hypogonadism (FSH 200 mIU/l, LH 29.34 mIU/l, estradiol < 7 pg/ml, AMH0.01 ng/ml). Ultrasonography of the pelvis showed a normally located and normally developed uterus with a 4.7mm thin endometrium and both ovaries of reduced dimensions. Chronic autoimmune thyroiditis with elevated antibodies to thyroid peroxidase and thyroglobulin, but euthyroid with thyroid hormones in the normal range, was detected in the patient by ultrasonography. Testing did not detect congenital and acquired trobophilia. Karyotype: 46XX. Genetic analysis of FMMR1 genes normal. Ovarian antibodies negative. Introduced replacement therapy with oral estrogen-progestogens with the addition of estradiol at a dose of 2 mg in the follicular phase of the menstrual cycle, D3 hormone, antioxidants. After 2 years of treatment : FSH 28 mIU/l, LH 19.1 mIU/l, estradiol 22.4 pg/ml). Spontaneous abortion in the 6th week of gestation after *in vitro* fertilization with donated eggs.
Conclusion
Most cases of P0F remain idiopathic with a reduced success rate of assisted reproduction and procreation. The goal of treating adolescents with POF is replacement therapy with higher doses of estrogen than menopausal women to ensure proper replacement and optimal bone health.

Primary Ovarian Insufficiency in RMND1 Mitochondrial Disease

Emese Boros[1], Farel Elilie Mawa Ongoth[2], Claudine Heinrichs[1], Anne Laure Mansbach[3], Sara Seneca[4], Alec Aeby[5], Khalid Ismaili[6] & Cécile Brachet[1]
[1]Hôpital Universitaire des Enfants Reine Fabiola, Université Libre de Bruxelles, Paediatric Endocrinology, Brussels, Belgium; [2]Hôpital Universitaire des Enfants Reine Fabiola, Paediatric Endocrinology, Brussels, Belgium; [3]Hôpital Universitaire des Enfants Reine Fabiola, Université Libre de Bruxelles, Paediatric Ear Nose and Throat Department, Brussels, Belgium; [4]Universitair Ziekenhuis Brussels, Vrije Universiteit Brussels, Center for Medical Genetics/Research Center Reproduction and Genetics,

Brussels, Belgium; [5]Hôpital Universitaire des Enfants Reine Fabiola, Université Libre de Bruxelles, Paediatric Neurology, Brussels, Belgium; [6]Hôpital Universitaire des Enfants Reine Fabiola, Université Libre de Bruxelles, Paediatric Nephrology, Brussels, Belgium

Context
The genes implicated in premature ovarian failure play a role in crucial biologic processes such as DNA repair, meiosis, germ cell recruitment, steroidogenesis and mitochondrial function. Mitochondrial disorders are varied in their onset, inheritance pattern, and clinical presentation, but they often cause dysfunction in organs with high energy demands. Frequent features include hypertrophic cardiomyopathy, heart conduction defects, myopathy, sensorineural deafness, cerebellar ataxia, epilepsy, optic and peripheral neuropathy, among others. In addition, mitochondrial disorders often present with a range of endocrine features, including diabetes mellitus, GH deficiency, hypogonadism, thyroid disease, and ovarian dysfunction. RMND1 (Required for Meiotic Nuclear Division 1 homolog) is a nuclear encoded mitochondrial protein. Biallelic variants in *RMND1* are described in patients with white matter encephalopathy, hearing loss and renal dysfunction. In addition to this phenotype, two independent families (3 patients) have been reported with ovarian failure.
Case Presentation
We report on a 17 year-old girl with *RMND1* related mitochondrial disorder including white matter encephalopathy, hearing loss and renal insufficiency who presented primary ovarian insufficiency. She is homozygous for the already described c.713 A>G (p.Asn238Ser) in *RMND1*.
Conclusions
We report the third patient with *RMND1* biallelic pathogenic variants and primary ovarian insufficiency. Given the two previous reports linking *RMND1* and ovarian insufficiency and the many reports linking mitochondrial diseases with ovarian dysfunction, we believe that the *RMND1* pathogenic variants are indeed responsible for the severe ovarian insufficiency observed in our patient.

Vitamin D binding protein (VDBP) has a critical role in orchestrating optimal vitamin D homeostasis and bioavailability. VDBP has been implicated in modulating the gene expression of amino-transporters within the placenta and might thus control the transfer of amino acids to neonates during *in utero* development. We hypothesize that dyshomeostasis of VDBP could lead to adverse metabolic profiles and low birth weight in neonates. VDBP genetic polymorphisms steer the unique interplay of VDBP biodynamics and pregnancy complications. The aim of this study was to investigate associations of maternal VDBP polymorphisms with neonatal anthropometric profiles at birth, according to different cut-offs of vitamin D status. We included 66 maternal-neonatal dyads recruited from Northern Greece. Serum 25(OH)D concentrations were determined using LC–MS/MS and VDBP was measured by ELISA. We classified maternal and neonatal vitamin D status at birth, according to 25-hydroxyvitamin D (25(OH)D) concentrations as follows: 25(OH)D $\leq$ 25 nmol/l (deficiency), 25–50 nmol/l (insufficiency) and 25(OH)D $\geq$ 50-75 nmol/l (sufficiency). Our results revealed that with maternal 25(OH)D $<$50 nmol/l neonatal anthropometry parameters including abdominal circumference, lower arm radial circumference and lower leg calf circumference were significantly higher in maternal VDBP genetic variants rs2298850 CG+GG and rs4588 CA+AA and rs7041 GT+TT. This relation between birth neonatal anthropometry and maternal VDBP polymorphism, was not significant for birth maternal 25(OH)D $<$ 25 nmol/l. In conclusion, these findings, emphasize a potential role of functional polymorphisms, for maternal VDBP genotypes for rs2298850, rs7041 and rs4588, in conjunction with a maternal cut-off of maternal 25(OH)D in the range of sufficiency on neonatal growth and development. Further investigations are required to decipher the exact dynamic pathways of maternal VDBP and genetic variants on pregnancy complications and offspring body anthropometry.

Evaluation of socio-demographic and clinical characteristics of PCOS patients attending a tertiary care institute in Colombo

Ishara Ranathunga, T G Athukorala, Manilka Sumanatilleke & Noel Somasundaram
NHSL, Colombo, Sri Lanka

Background and Objectives
Polycystic ovary syndrome (PCOS) is a common endocrine disorder with heterogeneous eatiology. It is characterized by irregular menses and or oligo/anovulation, hyper-androgenism, and polycystic ovaries. The prevalence and diagnosis of PCOS changes depending on which clinical criteria are utilized to confirm the diagnosis. The prevalence can be high as 15%–20% when the Rotterdam criteria are used. However, there is significant inter-individual variation in presentation. We have studied the socio-demographic and clinical characteristics of PCOS patients attending the Endocrinology clinic in a tertiary care institute in Sri Lanka.
Methods
A descriptive cross sectional study was conducted from September 2019 to September 2020 at the Endocrinology Unit of the National Hospital of Sri Lanka. Systematic sampling was done recruiting PCOS patients diagnosed with Rotterdam criteria. After obtaining informed written consent, the data was collected using an interviewer administered questionnaire. HOMA-IR was calculated using the fasting insulin and blood glucose level.
Results
The study enrolled sixty females. The mean age was 26.7 years (range 18-44). The mean weight was 64.8 (SD=11.9) kg and BMI was 27.1 (SD=4.8) kg/m^{-2}. According to Asian BMI cut-offs, 1 (1.7%) patient was underweight and 13 (21.7%) had normal weight. Forty six (76.7%) had their weight in the overweight or obese category. Fifty four (90.0%) patients had clinical or biochemical evidence of hyperandrogenism while 24 (40.0%) females had polycystic ovaries on trans-abdominal ultrasound scan and 50 (83.3%) partipants had irregular menstrual cycles. According to the body fat percentage assessed by the whole body DEXA scan 4.1% of the study population had normal body fat, while 50.0% and 45.8% had overweight and obesity respectively. HOMA-IR detected 61.1% patients to have high insulin resistance. Out of the patients who had USS of the abdomen 27.5% had co-existent non-alcoholic fatty liver. Fifty four percent of the patients had sub/infertility.
Conclusions
The majority of the population were overweight or obese and had higher prevalence of insulin resistance and non-alcoholic fatty liver. Out of the clinical characteristics used to make the diagnosis of PCOS, the presence of clinical or biochemical evidence of hyperandrogenism and irregular menstrual cycles are more common than the detection of polycystic ovaries on trans-abdominal USS. The higher prevalence of overweight, obesity, insulin resistance and NAFLD associated with PCOS makes the diagnosis and management of the disease crucial to prevent long term consequences of the disease

PCOS pearls - findings from the qualitative study assessing the lived experience of people with polycystic ovary syndrome

Mirna Elghobashy[1], Gar Mun Lau[1], Maureen Busby[2], Kristine Stacke[3], Pallavi Latthe[4], Helena Gleeson[5], Lynne Robinson[6], Wiebke Arlt[5, 7], Antje Lindenmeyer[8], Caroline D. T Gillett[7], Punith Kempegowda[5, 7] & PCOS Seva Working Group[7]

[1]University of Birmingham Medical School, College of Medical and Dental Sciences, United Kingdom; [2]PCOS Vitality, Belfast, United Kingdom; [3]Verity – The PCOS Self Help Group, London, United Kingdom; [4]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [5]Queen Elizabeth Hospital Birmingham, Department of Endocrinology, United Kingdom; [6]Birmingham Women's Hospital, United Kingdom; [7]University of Birmingham, Institute of Metabolism and Systems Research, United Kingdom; [8]University of Birmingham, Institute of Clinical Sciences, United Kingdom

Introduction
Existing educational resources for polycystic ovary syndrome (PCOS) have limited inclusion of patient perspectives. We invited women with PCOS to share their lived experiences to understand their perception and opinion on the current standard of care.
Methodology
Women with PCOS aged 18-60 years were invited to complete an online survey in April and May 2021. The survey had open questions focused on their lived experiences with PCOS. Participants had the option to share their views either as written text or as voice note audio recording(s) on WhatsApp. The data from audio were transcribed verbatim. Responses were initially coded by two study members independently, using a thematic inductive method with NVivo 12. These codes were then reviewed by two senior study members to identify common themes.
Results
43 of 45 participants had a formal diagnosis of PCOS, the remaining two had suspected PCOS which was under investigation. Four participants opted to share their views as voice note recordings. Overall, five common themes emerged: experience of symptoms (504 references by 42 participants), patient journey (421 references by 42 participants), knowledge (197 references by 40 participants), peer-to-peer advice (162 references by 41 participants), and impact of PCOS on social aspects of life (42 references by 19 participants). Poor mental health was most commonly reported (83.3% of participants), followed by dermatological (81.0%) and menstrual issues (76.2%). Participants were generally dissatisfied with the care they received (88.1%). A lengthy diagnostic journey was reported in 35.7% of cases. 52.6% felt less feminine, particularly with regards to weight gain and infertility. Women with PCOS said that others with the condition should educate themselves and be proactive in their management. 46.3% reported that being more enlightened regarding their condition improved their health outcomes and enabled them to advocate for their own care.
Conclusion
PCOS has wide-ranging consequences for women living with the condition, with many feeling dissatisfied with the clinical support they currently receive. Education is important to improve their understanding of their condition and encourage a proactive approach to their own care. Therefore, we propose involving people with PCOS to co-create educational resources informed by lived experiences which will help those newly diagnosed to gain a more comprehensive and realistic understanding of the condition from fellow sufferers.

Developmental programming by maternal androgen excess is mediated by androgen receptor pathways

Haojiang Lu[1], Congru Li[1], Yu Pei[1], Gustaw Eriksson[1], Han-Pin Pui[1], Sanjiv Risal[1], Sara Torstensson[1], Angelo Ascani[2], Eva Lindgren[1], Claes Ohlsson[3], Anna Benrick[4, 5], Elisabet Stener-Victorin[1] & Qiaolin Deng[1]
[1]Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden; [2]Medizinische Universität Graz, Graz, Austria; [3]University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden; [4]University of Gothenburg, Department of Physiology, Gothenburg, Sweden; [5]University of Skövde, School of Health and Education, Skövde, Sweden

Introduction
The hyperandrogenic *in utero* environment in pregnant women with polycystic ovary syndrome (PCOS) can affect embryo development and impair offspring health at adult age. Moreover, long term hyperandrogenic exposure also leads to unfavored changes to the mothers' reproductive physiology, leading to miscarriage, preterm delivery, and perinatal mortality. The underlying mechanism(s) of pregnancy complications associated with PCOS and the consequence of hyperandrogenic intrauterine environment on the offspring is not well known.
Method
We used a PCOS-like mouse model induced by continuous exposure of dihydrotestosterone from prepuberty that develops obesity, anovulation and dysfunctional ovarian morphology, to study the effects of maternal hyperandrogenism during pregnancy. In addition, slight modifications are applied to the prepubertal PCOS-like mouse model to investigate critical periods in peripubertal life that projects to adverse pregnancy outcomes. To explore molecular mechanisms that contribute to the developmental defects, whole genome bisulfite and RNA sequencing of primordial germ cells and placenta were performed.
Results
Lower pregnancy rate and impaired placenta and embryonic development were found in the androgenised group, which was partially prevented by co-treatment with flutamide, an androgen receptor blocker. Moreover, germ cell specification was greatly compromised at embryonic day 10.5 and 13.5. The results of whole genome bisulfite sequencing and RNA sequencing of the primordial germ cells and placentas are currently under analysis. Furthermore, androgen exposure before the onset of vaginal opening may alter the physiology of uterus and vagina causing difficulty in labour.
Conclusion
Our results so far suggest that hyperandrogenism greatly compromise the PCOS-pregnancy and embryo development due to placenta dysfunction. Such effects are mainly mediated by the androgen receptor pathway as administration of flutamide partially prevents the compromised placenta and fetal development.

The role of level and density of PSA in screening of prostate cancer

Shakhzod Shamsiev & Azamat Umarov
Tashkent Medical Academy, Department of Endocrinology, Tashkent, Uzbekistan

Introduction
It is known from world experience that the common screening method for diagnosing prostate cancer is the level and density of prostate-specific antigen (PSA), but the high sensitivity and low specificity of PSA testing have not been evaluated in Uzbek clinical practice. There are no proper guidelines to investigate suspected prostate cancer in Uzbekistan.
Methods
A total of 101 men were included in our investigation who were examined in the Republican specialized center of urology. All the patients underwent a complete examination, including laboratory(PSA level), ultrasound, transrectal ultrasonography, and prostate biopsy The patients were divided into subgroups by PSA level and PSA density, PSA density was calculated as total PSA (ng/ml) divided by prostate volume (ml).
Results
In patients with lower PSA levels less than 4 ng/ml detected benign processes compared to patients who had higher values of more than 50 nglml. Only two cases that had less than 4 ng/mg were suspicion of malignancy. When the PSA value was more than 100 ng/ml, almost all the cases were malignant. Between PSA values of 4-100 ng/ml, the probability of cancer diagnosis was 54% (54 cancers out of 101 in this range). Limitation of PSA testing has the risk of overdiagnosis and the resultant negative biopsies owing to poor specificity. Whereas the limit for cancer diagnosis remains 4 ng/ml from our study, most of the patients can be assured of benign lesion below this level, and thus morbidity associated with the biopsy can be prevented. PSA density was associated with the risk of finding PCa both with and without adjusting for the additional clinical information age, family history, previous biopsies, total PSA, and free/total PSA.
Conclusion
The PSA level plays important role in diagnosing prostate cancer and can reassure and educate the patients towards the diagnosis of cancer of the prostate in Uzbekistan. It is recommended prostatic biopsy if the level is below 4 ng/ml and a level of 100 ng/ml can be very unfavorable for the patients. Regarding the PSA-density might inform biopsy decisions, and spare some men from the morbidity associated with a prostate biopsy and diagnosis of low-grade prostate cancer.

EP912

Gonadal dysgenesis with mayer-rokitansky in 46, XX female; case report

Heba Moustafa, Hemmat ELhaddad, Rokia Abdel Aziz, Randa Salam, Elham Mohamed, Iman Tohamy & Amira Nashat
Cairo University, Internal Medicine, Endocrinology, Cairo, Egypt

Introduction
The normal development of the female reproductive tract depends on the interaction between genetic, hormonal and environmental factors for the differentiation of the Müller Wolff ducts, and the urogenital sinus
Case report
16-year-old female, single, school student presented to our endocrine department complaining of delayed puberty. The patient was delivered by normal vaginal delivery, no history of anosmia or hearing defects There is no history of headache or blurring of vision or other neurological symptoms No history of chronic diseases, excessive exercise, medications, anorexia, clinical hypothyroidism or hyperandrogenism Family history revealed positive consanguinity Physical examination: Weight: 60 kg Height: 172 cm, BMI: 20 No facial dimorphism, no features suggestive of Turner syndrome Female phenotype, Tanner classification: breasts (3) axillary hair (2), pubic hair (2). Normal external genitalia Laboratory work up showed follicle-stimulating hormone: 98 mIU/ml (N: 0.7-11.1) Luteinizing hormone: 26 mIU/ml (N: 0.8-7.6), Estradiol 10 pg/ml (12.5-166), prolactin 4.4 ng/ml pelvi -abdominal ultrasonography, MRI pelvis : Infantile hypo plastic uterus (body 20 mm, cervix 12 mm) Non visualized both ovaries Normal female karyotyping46, XX Hormonal substitution by estrogen and progesterone was then undertaken.
Conclusion
The Mayer-Rokitansky-Kuster-Hauser Syndrome is a specific type of mullerian duct malformation characterized by congenital absence or hypoplasia of uterus and upper two thirds of the vagina in both phenotypically and karyotypically normal females with functional ovaries. The association of gonadal dysgenesis and Mayer-Rokitansky-Kuster-Hauser syndrome is very rare, hormone substitution therapy remains the only therapeutic option, to trigger the development of secondary sexual characters and prevent osteoporosis.

Color-doppler ultrasound predicts hypothalamic-pituitary-testicular axis function in infertile patients

Giuseppe Grande[1], Pierfrancesco Palego[2], Andrea Canossa[2], Nicola Caretta[2], Andrea Di Nisio[2], Giovanni Corona[3], Alberto Ferlin[2], Carlo Foresta[2] & Andrea Garolla[2]
[1]'San Valentino' Hospital, Endocrinology Unit, Montebelluna, Italy; [2]University of Padova, Department of Medicine, Unit of Andrology and Reproductive Medicine, Padova, Italy; [3]Azienda Usl Maggiore-Bellaria, Endocrinology Unit, Medical Department, Bologna, Italy

Scrotal color-doppler ultrasonography (sCDUS) and transrectal ultrasonography (trCDUS) provide crucial information about the clinical status of testes and male accessory glands. However, the US evaluation of the infertile male is still often considered as a second level diagnostic tool. To analyze the role of ultrasound in male infertility, in order to predict hypothalamic-pituitary-testicular axis function, 1120 records from infertile men were retrospectively evaluated (from January 2016 up to June 2020). Data on physical examination, semen analysis, sperm culture, sCDUS and trCDUS, as well as sex hormones were analyzed. Among them, 238 reports from oligozoospermic/azoospermic infertile patients (P) (mean $\pm$ SD years) fullfilling the inclusion criteria were considered for data analysis. Patients were subdivided into two groups according to FSH values (Pa with FSH $<$ 8 U/l and Pb with FSH $>$ 8 U/l). Sixtythree fertile volunteers (mean $\pm$ SD years) were enrolled as controls (C). Pb group had significantly lower bitesticular volume compared to Pa and to C. A higher prevalence of ultrasound abnormalities was recorded in P compared to C. Pa had a higher prevalence of trCDUS abnormalities than Pb (69.9 vs 38.4% $P<0.005$), while Pb had a higher prevalence of abnormalities at sCDUS (60.0 vs 28.3%, both $P<0.01$). A higher number of US abnormalities was associated with a more severe reduction in total sperm count. Bitesticular volume was inversely proportional to the number of altered seminal parameters and a bitesticular volume $<$17 cc was associated with a higher risk of azoospermia (odds ratio 1.799). Moreover, this parameter was able to predict gonadotropin levels. Finally, intratesticular number of vascular spots was directly correlated with sperm count and inversely correlated with gonadotropin levels. Our data confirm the pivotal role of ultrasound in the diagnostic workflow of male infertility.

Isolated FSH deficiency. A rare cause of male infertility

Evangelia Vogiatzi[1], Stavroula Psachna[1], Dimitrios Ioannidis[1], Dimitrios Lilis[1], Maria Drakou[1], Anastasios G. marathonitis[2], George Marathonitis[3], Vasiliki Koika[4], Neoklis Georgopoulos[4] & Antonis Polymeris[1]
[1]Sismanoglio - Amalia Fleming Attica General Hospital, Department of Endocrinology, Diabetes Mellitus and Metabolism, Melissia, Attica, Greece; [2]Sismanoglio - Amalia Fleming Attica General Hospital, Department of Cardiology, Marousi, Attica, Greece; [3]Sismanoglio - Amalia Fleming Attica General Hospital, Department of Internal Medicine, Melissia, Attica, Greece; [4]University of Patras Medical School, Department of Internal Medicine, Devision of Endocrinology, Unit of Reproductive Endocrinology, Patras, Greece

Background
Follicle stimulating hormone (FSH), a dimeric glycoprotein hormone, stimulates Sertoli cell proliferation and spermatogenesis in males. Azoospermia is defined as the absence of sperm in the ejaculate. The majority of patients with non-obstructive azoospermia have high FSH levels. Isolated FSH deficiency has been reported in a few patients.
Case Presentation
A 22-yr-old, 172-cm-tall male presented with azoospermia. He was born at full term with normal delivery of non-consanguineous parents. He had normal pubertal development with normal erections and potency. Upon physical examination he had normal virilization, normal sense of smell and no gynecomastia. His testes were both palpable in the scrotum measuring 25ml. No sperm was observed in the semen analysis twice. Semen fructose levels were normal. Urine analysis for retrograde ejaculation and testicular ultrasound revealed no abnormalities. His chromosomal karyotype was 46, XY. His testosterone, luteinizing hormone (LH), inhibin B (INHB) and anti-mullerian hormone (AMH) levels were normal, whereas FSH was low. Hypothalamic-pituitary magnetic resonance imaging (MRI) demonstrated no abnormalities. FSH levels remained low after intravenous injection of 100μg of gonadotropin-releasing hormone (GnRH), whereas LH levels rose. Sequencing of the β-subunit of FSH (FSHβ) gene did not reveal any mutation.
Discussion
Reports on isolated FSH deficiency are very rare with a prevalence of 0.89% in a retrospective study. The first observations of isolated FSH deficiency in males were described in 1998. Since then ten more case reports have been published, half of which were caused by an inactivating mutation of FSHβ gene. The patients presented with azoospermia, testicular hypotrophy, but with normal levels of testosterone and virilization. It appears that in cases of no FSHβ gene mutation there is milder phenotype, with oligo-astheno-teratospermia and even normal testicular volume. In cases where testicular biopsy was performed, spermatogenesis arrest, Sertoli cell hypoplasia and Leydig cell hyperplasia were reported. Hypothalamic-pituitary MRI and karyotype were normal. Remarkably, despite low INHB and AMH levels in patients with FSHβ gene mutations, cases without the mutation exhibited normal levels. Exogenous FSH led to an increase in testicular volume, spermatogenesis and in some cases in successful pregnancies.
Conclusion
Isolated FSH deficiency represents a rare form of male infertility which may be restored and therefore carries a high diagnostic value.

Developmental neuro toxicity and cytotoxic mechanism evaluation of endocrine-disrupting chemical butylparaben

KangMin Kim[1], Minsu Lee[1], Jimin Lee[1], YongIn Kim[1] & Eui-Bae Jeung[1]
[1]Chungbuk National University Gaesin Campus, Veterinary Medicine, Cheongju, Rep. of South Korea

Butylparaben is an endocrine disrupting chemical (EDC) which is used as antimicrobial preservative in many cosmetic products. EDCs are structurally diverse class of synthetic and natural compounds. EDCs can cause non-

communicable diseases such as obesity, type 2 diabetes, and neurodevelopmental disease. Present study investigated that whether exposure to butylparaben during maternal pregnancy could cause the offspring's neuronal development disorder. *In vitro* study butyl paraben promoted apoptosis and inhibited proliferation of Sox1-GFP cell. The mRNA expressions for ER stress were evaluated. Furthermore, *in vivo* study for developmental neuro toxicity test battery for butylparaben was carried out. Butylparaben 100 mg/kg, 50 mg/kg was treated for pregnant mouse from E10.5 to weaning period. The result of behavior test shows abnormal cognitive, social and anxiety like behavior in butyl paraben treated mice. *In vitro* study, ER stress genes was evaluated, BiP, CHOP, and AFT6 were significantly up-regulated following treatment with EDC. From these results, butylparaben is a potential neuro developmental toxicant.

Swyer syndrome presenting with clinical features of cushing disease: a case report

Ameni Terzi, Meriem Yazidi, Cyrine Chehaider, Ibtissem Oueslati, Fatma Chaker & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunisia

Introduction
Swyer syndrome is a rare sex development disorder characterized by pure 46 XY gonadal dysgenesis. It is associated with aberrations in testicular determination and differentiation leading to a female morphotype with presence of external and internal female genitalia, undifferentiated fibrous gonads, a male karyotype and hypergonadotropic hypogonadism. We present the case of a 46 XY adolescent female with complete gonadal dysgenesis diagnosed following her hospitalization in the endocrinology department for a suspicion of Cushing syndrome.
Case presentation
A 18-year-old female patient with no medical history was referred to our department for suspicion of Cushing syndrome. She had primary amenorrhea and reported weight gain within 2 years. On physical examination, her body mass index was 34.5 kg/m2 with a height of 156 cm. She had round moon face, red cheeks, a buffalo neck, thin arms and legs, and abdominal purple stretch marks. She had a female morphotype, normal female-type external genitalia with secondary sexual characters rated S4, P3 and A3 according to Tanner's classification. A 4-mg dexamethasone suppression test reduced the serum cortisol level to 0,3µg/dl excluding the diagnosis of Cushing syndrome. Hormonal investigations revealed elevated pituitary gonadotropin levels with FSH at 34.9 UI/l and LH at 15.8 UI/l. The testosterone and prolactin level were normal at 0.92 nmol/l and 9 ng/ml respectively. A pelvic ultrasound confirmed the presence of 2 small non-follicular ovaries with uterine hypoplasia (25X17X8mm). The karyotype was male "46 XY". The diagnosis of pure 46 XY gonadal dysgenesis was made. A hormone replacement therapy was applied and the patient was referred to a gynecologist for bilateral prophylactic gonadectomy.
Conclusion
In light of this case, we wish to draw attention to a serious sex-reversal disorder that affects women in their identity, Swyer syndrome revealed here by an unusual circumstance of discovery. This pathology is associated with a higher risk of malignant degeneration and an elevated incidence of gonadal neoplasia mainly the gonadoblastoma and dysgerminoma highlighting thus the paramount urge of preventive adnexectomy. Similarly, a screening of the siblings with female morphotype is necessary since this disorder is related to mutations or deletions in several genes such as SRY that can be inherited genetically.

Machine learning-based model for gestational diabetes mellitus prediction in the first trimester of pregnancy

Polina Popova[1], Aleksandra Tkachuk[2], Alexandra Klyushina[3], Lyudmila Vasilyeva[3], Elena Vasukova[2], Anna Anopova[1], Evgenii Pustozerov[2], Yana Teplova[1] & Elena Grineva[2]
[1]Almazov National Medical Research Centre, Saint Petersburg, Russia, World-Class Research Center for Personalized Medicine, Saint Petersburg, Russian Federation; [2]Almazov National Medical Research Centre, Saint Petersburg, Russia, Institute of Endocrinology, Saint Petersburg, Russian Federation; [3]Almazov National Medical Research Centre, Saint Petersburg, Russia, Institute of Molecular Biology and Genetics, Saint Petersburg, Russian Federation

Background and aim
Gestational Diabetes Mellitus (GDM) is often diagnosed at 24-28 weeks of pregnancy when the fetal phenotype is already altered. We aimed to develop a machine learning model based on clinical variables, lifestyle features and genetic markers for GDM prediction in the first trimester of pregnancy based on the 2013 World Health Organization (WHO) criteria.
Methods
Using multivariable logistic regression analysis, different models to predict GDM were developed based on clinical variables from early pregnancy (age, pre-pregnancy body mass index (BMI), arterial hypertension, a history of GDM, impaired glucose tolerance, polycystic ovary syndrome, family history of type 2 diabetes, and parity), lifestyle features (food consumption, physical activity and smoking habits assessed through questionnaires), genetic markers (number of risk alleles in rs10830963 of the MTNR1B gene) and their combination. The input data were obtained from 1050 pregnant women participating in prospective studies performed in the Almazov National Medical Research Centre (655 GDM cases and 395 controls). Receiver operating characteristic (AUC) analysis assessed the model's performance with eight-fold cross-validation.
Results
C-statistics for logistic regression models were as follows: clinical covariates alone: 0.690 (95% CI: 0.658 to 0.722) and 0.688 (95% CI: 0.647 to 0.729) for an eight-fold cross-validated assessment of the score; rs10830963 alone: 0.597 (95% CI: 0.565 to 0.629) and 0.546 (95% CI: 0.375 to 0.717) cross-validated; combination of clinical covariates and rs10830963: 0.721 (95% CI 0.690 to 0.752) and 0.715 (95% CI 0.672 to 0.759); combination of clinical covariates and lifestyle features: 0.806 (95% CI 0.779 to 0.833) and 0.802 (95% CI 0.724 to 0.881) cross-validated; combination of clinical covariates (age, pre-pregnancy BMI, a history of GDM), rs10830963 and lifestyle features (the frequency of pre-pregnancy consumption of meat, bread and alcohol): 0.823 (95% CI: 0.797-0.849) and 0.813 (95% CI: 0.734-0.892) cross-validated.
Conclusions
A first trimester machine learning-based model, which incorporates classical risk factors and novel biomarkers, has a high accuracy to predict GDM based on the 2013 WHO criteria.

Partial androgen insensitivity syndrome revealed by a bilateral gynecomastia

Zineb Mhamdi, Imane Alilouch, Kaoutar Rifai, Hinde Iraqi & Mohamed El Hassan Gharbi
Ibn Sina University Hospital, Department of Endocrinology and Diabetology, Rabat, Morocco

Introduction
Partial androgen insensitivity syndrome is a disorder of sexual development, distinct from complete androgen insensitivity syndrome. It is characterized by the presence of abnormal genital development in an individual with a 46, XY karyotype, with normally developed testes and a partial response to androgens at normal levels for age. It is an autosomal recessive X-linked disorder related to molecular abnormalities of the androgen receptor gene.
Case report
We report the case of an 18-year-old patient with a history of hypospadias operated in childhood, who consulted for bilateral gynecomastia. The clinical examination revealed a 3.5 cm Tanner P5 micropenis with absence of facial and axillary hair. His karyotype was 46, XY. Biologically: testosteronemia : 18.84 ng/ml, FSH was normal and LH : 15.6 mIU/ml with a Testosterone/Dehydroepiandrosterone (DHT) ratio of 6. The diagnosis of partial androgen insensitivity was therefore retained. Androstanolone (Andractim* gel) was used for 6 months with therapeutic failure. The patient was referred to plastic surgery for surgical management of his gynecomastia.
Discussion and conclusion
Partial androgen insensitivity is most often diagnosed in a newborn with atypical genital development (hypospadias, cryptorchidism, micropenis, or even very feminine phenotype with clitoral hypertrophy). The diagnosis will be evoked more rarely in front of an isolated micropenis or an isolated gynecomastia as in the case of our patient, or pubertal virilization in a young girl or fertility disorders in a man. It varies according to the degree of insensitivity of the genital tract to androgens.

Complete androgen insensitivity syndrome: about 2 cases

Amal Elkhomri, Nassim Essabah Haraj, Siham El Aziz & Asma CHADLI
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Androgen insensitivities are rare genetic diseases, characterized by a more or less complete defect of tissue sensitivity to testosterone. It ranges from a more or less complete lack of masculinization to isolated infertility in a 46, XY individual. This partial or complete androgen insensitivity is linked to a defect in the function of the androgen receptor. We report the case of two patients with complete androgen resistance syndrome discovered during the exploration of primary amenorrhea
Observation 1
33-year-old patient, operated in 2016 for bilateral intra-abdominal gonadectomy, with an anatomopathological examination of an ectopic testicle on the right without signs of malignancy, and an embryonic carcinoma on the left, the patient underwent chemotherapy sessions, she presents a harmonious and feminine Morphological development, with absence of vaginal orifice, a carotype was done in favor of a 46 XY, pelvic MRI with absence of internal genitalia, and genitography with absence of vaginal orifice, the patient was put on estrogen and progestin, with good clinical evolution
Observation 2
20-year-old patient, who underwent bilateral gonadectomy in 2017 with pathological examination of hypoplastic testicular pulp with hamartomatous nodules and hypoplastic foci of Leydig cells compatible with androgen insensitivity syndrome without malignancy, with a gynecological examination presence of labia majora and labia minora not well formed with an incipient vagina. a carotype was done in favor of a 46 XY, pelvic MRI with absence of internal genitalia, and genitography with absence of vaginal orifice, the patient was put on estrogen and progestin, with good clinical evolution
Conclusion
Androgen insensitivity syndrome, a rare entity, is the most frequent etiology of the anomaly of the XY sex differentiation, gonadectomy is necessary, and hormonal substitution helps maintain female sexual characteristics and prevent osteoporosis.

Safety and monitoring of gender affirming hormone therapy in portugal

Miguel Saraiva[1], Rafael Santos[2], Zé lia Figueiredo[3], Carolina Lemos[4] & Isabel Palma[1]
[1]Centro Hospitalar Universitário do Porto - Hospital de Santo António, Endocrinology, Diabetes and Metabolism, Portugal; [2]Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Portugal; [3]Hospital de Magalhães Lemos, Portugal; [4]i3S-Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Portugal

Introduction
The prevalence of Transgender individuals seeking gender affirming hormone therapy (GAHT) has been increasing. It is important to closely monitor this therapy in order to minimize the risk of adverse effects.
Aim
To evaluate the safety and monitoring of the GAHT in the Portuguese adult transgender population
Methods
Cross-sectional study conducted in March 2021. Data collected through an *online* questionnaire that was delivered to adult transgender people living in Portugal who had been under GAHT for at least one year. To answer some of the items on the questionnaire, an ordinal scale ranging from 0 (worst result) to 6 (best result) was used.
Results
A total of 142 individuals answered the questionnaire: 101 under masculinizing GAHT (Group M) and 41 under feminizing GAHT (Group F), with a median age of 25.0(21.0–33.0) years. 43.3% of the individuals denied having signed an informed consent document and 11.3% denied having done blood sample analysis before starting GAHT. This happened more frequently with individuals of the Group F (24.4% *vs* 5.9%, $P=0.002$). Accordingly, this group also reported having obtained the first prescription of GAHT by an endocrinologist less frequently (58.5% *vs* 79.2%, $P=0.012$). 93.7% of the individuals had regular medical appointments because of the GAHT, although this was less common in Group F (85.4% vs 97.0%, $P=0.010$). 79.6% reported undergoing regular blood sample analysis to monitor the GAHT. Of those, 75.2% did so according to the timings recommend by WPATH. As for adverse effects, 89.7% of the individuals on Group M experienced at least one – more commonly mood swings (56,3%) and acne (52,9%) – and 96.3% of the individuals on Group F experienced at least one – more commonly decreased libido (66.7%) and mood swings (63.0%). The perceived overall safety of the GHAT was classified with a median of 5.0(4.0-6.0) points, although individuals on the Group F scored significantly lower (4.3 vs 5.0 points, $P=0.007$).
Discussion
This study highlights the importance of the involvement of specialized physicians, namely endocrinologists, in the prescription and monitoring of the GAHT. There is still plenty of room to improve Transgender health care in Portugal, mostly in transgender people undergoing feminizing GHAT - a population known to be especially vulnerable to social stigma.

Clinical features of reproductive status in women who underwent Covid-19

Surayyo Mekhmanova[1], Khurshida Nasirova[1] & Zamira Khalimova[2]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after Y.H. Turakulov, Neuroendocrinology, Tashkent, Uzbekistan

Keywords: Reproductive system of women who have had coronavirus, Covid-19, women.
The relevance of the problem. Currently, there are no published evidence-based recommendations for the management of women who have undergone COVID-19. According to statistics, women carry COVID-19 more easily than men, and the likely consequences of this coronavirus infection for reproductive health cannot be ignored. It is necessary not only to carefully monitor the respiratory parameters of patients with COVID-19, but also to assess the potential impact of a new infection on the organs of the reproductive system
Objective
To study the clinical conditions of women and assess their general condition.
Material and methods
100 women aged 18-45 years (average age 32 years) who underwent Covid-19 were examined. These women will be divided into 2 groups depending on the severity of the disease. they underwent a complete clinical hormonal and imaging examination and were divided into I a women with mild form, 60 women aged 18 to 44 years, I b women with severe form in the acute stage, 21 women aged 18 to 40 years, an average of 30 years At the moment, the control group will consist of 10 healthy women of the same age. A survey of complaints about the acute phase of women who had Covid-19 was conducted.
Results
The most frequent and significant changes were complaints of general weakness (p0,000), menstrual cycle changes (p0,002), headaches (p0,000), dry skin (p0,000), hair loss (p0,000), mood loss (p0,000), memory loss (p0,000), anxiety (p0,003) The least complaints were Hirsutism (p0,157), Decreased visual acuity (p0,317), Galactorrhea (p1,000)
Conclusion
In this way, the function of the reproductive system and somatic disease is aggravated in patients who have undergone Covid-19, which requires careful monitoring by an endocrinologist, gynecologist and neurologist.

The clinical and etiological aspects of hirsutism : about 100 cases

Anis Grassa, Bel Hadj Sliman Chayma, Nadia Khessairi, Fatma Chaker & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Hirsutism is often caused by hormonal disorders such as high levels of circulating androgens, hormonal changes related to menopause or disorders of the ovarian or adrenal gland. The aim of our study was to evaluate the clinical and etiological profile of hirsutism.
Methods
A retrospective study was conducted at the endocrinology department of Rabta Hospital in Tunis including 100 patients who presented with hirsutism between January 2009 and December 2020. Clinical and paraclinical data were collected from medical records. Hirsutism was classified according to the Ferriman Galleway score.
Results
The mean age of our patients was 29.5 years $\pm$ 10.7 [15 -73]. Family history of hirsutism, infertility and death in early childhood were found in 27%, 36% and 4% of cases respectively. The average age of menarche was 12.1 years $\pm$ 1.2. Eight women were menopausal. The onset of hirsutism was progressive in 95 cases either peripubertal or post-pubertal respectively 44% versus 56%. Hirsutism was classified as mild, moderate and severe in 32%, 57% and 11% of cases respectively. The clinical features found to be associated with hirsutism included acne (28%), virilism signs (9%) and menstrual irregularities in 60% of patients. The mean of testosterone level was 0.9 ng/ml $\pm$ 0.7 [0.15-4.08]. Additional investigations such as dosage of Dehydroepiandrosterone sulfate, 4-androstenedione, and 17-OH progesterone were done according to etiological orientation and revealed means of 900.1 µg/ml, 354 ng/ml, and 1.86 ng/ml respectively. The etiologic investigation showed ovarian tumor, adrenal tumor with androgen secretion, late-onset congenital adrenal hyperplasia, Cushing's syndrome, polycystic ovary syndrome (PCOS) and idiopathic hirsutism in 3%, 5%, 7%, 2%, 51% and 32% of cases respectively.
Conclusion
Hirsutism is a very frequent and troublesome symptom. However, it can reveal serious underlying pathology, especially in its severe form.

DOI: 10.1530/endoabs.81.EP922

Clinical and metabolic profile of hirsute women

Bel Hadj Sliman Chayma, Nadia Khessairi, Anis Grassa, Ibtissem Oueslati, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Hirsutism is described as excessive development of facial and body hair in women in androgen-dependent areas. Our aim was to determine the clinical and metabolic aspects of hirsutism and its relationship with the metabolic syndrome.
Methods
We conducted a retrospective descriptive study at the endocrinology department of Rabta Hospital in Tunis. We recruited 100 women who presented with hirsutism between January 2009 and December 2020 Clinical and paraclinical data were collected from medical records. The diagnosis of metabolic syndrome was made according to the IDF 2009 criteria.
Results
The mean age of our patients was 29.5 $\pm$ 10.7 years. Our patients were smokers in 8% of cases and diabetics in 19% of cases. The onset of hirsutism was post-pubertal in 56% with menstrual disorders in half cases. Associated clinical signs were skin acne (50%), Acanthosis Nigricans (20%) and signs of virilization (9%). Our population had an average weight of 83.9 $\pm$ 20.9 kg [38-150] with an average body mass index of 32.5 $\pm$ 7.7 kg/m^2 [16-57]. Obesity was noted in 58% and described as grade 1 in 44.2%, grade 2 in 25% and morbid in 30.8% of cases. Mean testosteronemia was 0.9 $\pm$ 0.76 ng/ml. Biological investigations showed mean values for blood fasting glucose = 1.08 $\pm$ 0.44 g/l, glycated haemoglobi*n* = 7.37 $\pm$ 2.42%, total cholesterol = 1.8 $\pm$ 0.5 g/l, HDL-cholesterol = 0.45 $\pm$ 0.1 g/l and LDL-cholesterol = 1.11 $\pm$ 0.3 g/l. A metabolic syndrome was present in 54% of patients. Etiologies were dominated by polycystic ovary syndrome (51%), followed by idiopathic hirsutism (32%), adrenal pathology (15%) and ovarian tumors (3%).
Conclusion
Our results suggest that the increase of androgenic activity favors an android distribution of body fat, which is associated with an impairment of glucose and lipid metabolism.

Recovery of hypothalamic-pituitary-gonadal function with low dose testosterone treatment in a male with idiopathic hypogonadotropic hypogonadism

Fernando Braca[1], Juan Carmelo Betancor Acosta[1], Nuria Perez Martin[1] & Mauro Boronat Cortes[1, 2]
[1]Hospital Insular, Las Palmas de Gran Canaria, Spain; [2]University of Las Palmas de Gran Canaria, University Institute for Biomedical and Health Research, Las Palmas de Gran Canaria, Spain

Idiopathic hypogonadotropic hypogonadism (IHH) is a rare congenital disease caused by deficiency or action of gonadotropin-releasing hormone. While generally considered a long-life condition, IHH can be reversible in about 20-30% of cases, but mechanisms of reversibility are unknown. We report the case of a male with IHH who began treatment with low dose (20 mg/day) transdermal testosterone to induce pubertal development at age 18. Following the start of treatment, he experienced testicular growth and his serum testosterone concentrations increased beyond the expectations in relation to the dose. Treatment was withdrawn, but this led to the reappearance of symptoms of hypogonadism and a drop in testosterone levels. Testosterone was again prescribed at the same dose and, for the subsequent years, he completed full puberty, including attainment of 20 cc testicular volume, mature secondary sexual characteristics, normal levels of testosterone and only partially arrested germinal function, as demonstrated by inhibin B levels and spermogram. Testosterone treatment was withdrawn three more times, but hypogonadism resumed on each occasion. This case suggests that low-dose testosterone treatment can induce reversal of IHH through the activation, albeit non-permanent, of the hypothalamic-pituitary-gonadal axis, and could be a therapeutic option for this condition.

Cardiovascular risk factors among women with polycystic ovary syndrome in an urban Sri Lankan population

Kaveen Weerasinghe
Post Graduate Institute of Medicine, University of Colombo, Sri Lanka, Obstetrics and Gynaecology, Sri Lanka

Introduction
Polycystic ovary syndrome (PCOS) is an endocrine and metabolic disorder that affects 5-10% of women of reproductive age world wide. Women with PCOS are known to have a higher prevalence of metabolic syndrome and cardiovascular risk factors compared to the general population. However data on PCOS and cardiovascular risk factors amomg Sri Lankan women is limited.
Methodology
A case control study was conducted among 172 women from Colombo, Sri Lanka. 86 women aged $<$45 years diagnosed with PCOS according to Rotterdam criteria were compared to 86 age matched controls from the community with no history or evidence of PCOS. Biometric data, biochemical, and endocrine parameters were compared between groups using approprite statistical tests.
Results
Among 86 women with PCOS, 41 (47.7%) were overweignt and 28 (32.6%) were obese. Prevalence of obesity ($P=0.002$) and overweight ($P=0.01$)among women with PCOS were significantly higher compared to the control group. Acanthosis nigricans was present among 59.3% ($n=51$) of women with PCOS. Women with PCOS had significantly higher levels of fasting insulin ($P=0.001$), fasting blood glucose ($P=0.015$), and 2 h blood glucose level following 75g oral glucose load ($P=0.002$). Prevalence of type 2 diabetes mellitus among women with PCOS was 26.7% while prevalence was 12.8% in the control group. Further 24.4% of women with PCOS had prediabetes. Women with PCOS had significantly higher triglyceride levels ($P=0.01$), total cholesterol levels (0.02) and lower HDL levels ($P=0.02$) compared to control group. Systolic ($P=0.05$) and diastolic ($P=0.01$) blood pressures were significantly elevated among women with PCOS compared

to the control group. Prevalence of hypertension among women with PCOS was 11.6%. 34.9% ($n=30$) of women with PCOS fulfilled diagnostic criteria for metabolic syndrome. Women with PCOS had higher odds of obesity, insulin resistance, hyperglycemia, dyslipidemia, hypertension and metabolic syndromeare compared to age matched controlls.
Conclusion
Women with PCOS often have multiple cardiovascular risk factors including obesity, diabetes mellitus, dyslipidemia, and hypertension. Management of cardiovascular risk factors should be prioratized in the long term care of women with PCOS. Further research is required to assess implications of PCOS on longterm cardiovascular morbidity and mortality among Sri Lankan women.

Molecular and comprehensive computational analysis revealed normal LHCGR gene among women with PCOS

Nidal Essa[1], Rashid Abdalla Rashid Abdalla[2] & Mohamed A. Hassan Mohamed Hassan[3]
[1]University of Medical Sciences and Technology, Clinical Chemistry, Sudan; [2]Pharmacy; [3] Department of Bioinformatics, Sudan

Background
Polycystic ovary syndrome (PCOS) is a common disorder, yet not fully understood. Multiple hormonal and metabolic factors influence the pathophysiology of disease; resulting in various phenotypic characteristics among PCOS population. The luteinizing hormone/choriogonadotropin receptor (*LHCGR*, OMIM: 152790) is a G protein- coupled receptor mapped on chromosome 2p16.3; its coding region comprises 10 exons separated by 10 introns which transcript to protein with 699 amino acids.
Objectives
To determine genetic mutations of *LHCGR* gene in Sudanese families affected by PCOS.
Methods
A prospective laboratory based cross-sectional study was implemented to examine genetic mutations in LHCGR that associate with PCOS in families (cases; $n = 35$ families, 90 females and controls; $n = 11$ families, 30 females) in Khartoum State, Sudan. Quantitative Enzyme Linked Immuno-Sorbent Assay (ELISA), enzymatic methods and partial selected exon 11 from in silico analysis data were analyzed by polymerase chain reaction (PCR) for polymorphism detection followed by Sanger sequencing for genotyping among selected families.
Results
From the In silico analysis, we revealed that the most (29) distributed SNPs were located through *LHCGR* coding region. Thereafter, we select exon 11 which contain the most reported SNPs and Sanger sequencing revealed normal sequence of exon 11 of *LHCGR* gene that were statistically correlated with serum LH, Testosterone and insulin levels among PCOS families and characterized by homozygous inheritance mode. The PCOS cases had significantly different biochemical parameters from the controls (LH: $P<0.001$; testosterone: $P<0.001$; fasting glucose: $P=0.02$; insulin: $P=0.01$; triglycerides: $P=0.03$; total cholesterol: $P<0.001$; high density lipoprotein (HDL): $P=0.012$; low density lipoprotein (LDL): $P<0.001$). There were no differences in follicle stimulating hormone (FSH) ($P=0.984$) or prolactin ($P=0.068$).
Conclusion
This is the first molecular family-based study in Sudan exploring the genetics of the *LHCGR* gene in women manifesting PCOS. These novel mutations give further information about the genetic inheritance and may explain some of the altered ovarian function and responses in women with PCOS.

Online education as effective medical training for young endocrinologist

Martina Jambrović[1], Anja Barac Nekic[2], Lana Sambula[3], Iva Petrak[4], Nino Matas[2] & Karin Zibar Tomšić[5]
[1]General Hospital Čakovec, Department of Internal medicine, ČAKOVEC, Croatia; [2]General Hospital Dubrovnik, Department of Internal medicine, Croatia; [3]General Hospital Dr. Tomislav Bardek Koprivnica, Department of Internal medicine, Croatia; [4]General Hospital Nova Gradiška, Department of Internal medicine, Croatia; [5]University Clinical Hospital Centre Zagreb, Department of Endocrinology and Diabetology, Zagreb, Croatia

Background
Learning through various online platforms is very common nowadays and its popularity has increased especially during the pandemic period. Nowadays, medical professionals are turning more than ever to online education through available online books, websites, and various online platforms. The aim of this study was to show that virtual training can improve the knowledge and confidence of young endocrinologists.
Methods
The Croatian Section for Young Endocrinologists organised the 2nd Regional Online Symposium for Young Endocrinologists in November 2021 for the purpose of continuing education and knowledge sharing among young endocrinologists from the region. The theme of the symposium was 'Endocrinopathies in Pregnancy.' The symposium started with an introductory test with 18 questions. At the end of the symposium, we administered the same test to see how much the participants had learned and improved their knowledge. The test also served as feedback for the organisers to see how good each presentation was and if there was room for improvement. The anonymous test consisted of 18 questions from 5 areas of endocrinology (pituitary, adrenal, diabetes and metabolism, calcium and bone metabolism, and thyroid).
Results
A total of 53 subjects participated in the introductory test and 37 subjects in the final test. There was a statistically significant difference in resolution between the introductory and final tests for 8 of the 18 questions. Baseline knowledge, based on the joint median of correct answers from a domain, was 24% in the pituitary area, 29% in the calcium and bone area, 46% in the adrenal area, 49% in the diabetes and metabolism area, and 59% in the thyroid area. There were statistically significant improvements in the final test (from greatest to least improvement) for the area of calcium and bone (all 3 questions achieved statistically significant improvement), then pituitary (2/3 questions achieved statistically significant improvement), thyroid (2/2 questions achieved statistically significant improvement), diabetes, and metabolism (1/4 question achieved statistically significant improvement), whereas there were no statistically significant differences in resolution between the introductory and final tests for the adrenal (0/4) area.
Conclusion
Online education is a very widely used and good learning model to improve and transfer the knowledge of young physicians and scientists. Different models of online learning need to be promoted and implemented in daily practise.

Mild Androgen Insensitivity (MAIS): A challenging clinical and laboratory diagnosis

Tahir Omer[1,2] & Abaid Ur Rehman[1]
[1]Northampton General Hospital, Northampton, United Kingdom; [2]University of South Wales, Cardiff Campus, United Kingdom

Introduction
The androgen receptor (AR) as a steroid hormone receptor is crucial for the embryological male sex differentiation and the maintenance of the phenotypical male characteristics throughout life in addition to spermatogenesis. Mutations in the AR gene can disrupt its function leading to Androgen Insensitivity Syndrome (AIS). AIS has a recessive mode of inheritance and can be broadly classified into 3 phenotypical categories: complete androgen insensitivity syndrome (CAIS), partial (PAIS) and mild (MAIS). CAIS usually presents with female external genitalia and primary amenorrhoea. Karyotyping might be very helpful in these patients. Patients with PAIS syndrome typically have ambiguous genitalia, including partial labio-scrotal fusion and hypospadias. Patients with MAIS, on the other hand, have a mild presentation with subtle secondary sexual characteristics abnormalities that can remain unnoticed for long. Due to its variable presentation, MAIS can prove challenging to diagnose clinically and biochemically.
Case presentation
We describe the case of a young man in his early 20s with normal childhood growth and development. He has been to see the Cardiologist for recurrent palpitations when he was noticed to have some degree of gynaecomastia. He was then referred to our clinic for further work up. Physical examination demonstrated sparse body hair, hypoandrogenic phenotype, gynaecoid habitus, normal penile length and small scrotum. His blood test showed a confusing picture of raised FSH, raised LH, mildly raised Prolactin, high normal Testosterone, normal SHBG and raised Oestradiol. His total HCG was normal. His Karyotype was normal

46XY. U/S scrotum showed very small testes and no masses. MRI pituitary and MRI adrenal were normal. Genomic DNA sequencing of AR gene demonstrated a missense mutation indicating MAIS.
Discussion and Conclusion
Mutations affecting the *AR* gene can lead to either complete, partial or mild androgen insensitivity syndrome. The case reported here is consistent with mild androgen insensitivity. Due to its subtle presentation, this was not diagnosed until early adult life. The high gonadotrophins together with high normal Testosterone raised the possibility of pituitary gonadotroph adenoma initially. Klinefelter's and similar chromosomal disorders were also included in the differential diagnoses. The patient was also investigated for potentially secreting Adrenal and testicular tumours. Nevertheless, none would completely explain the clinical picture with small scrotum and the raised Testosterone and Oestrogen levels. Patients who present with gynaecomastia should always undergo adequate endocrine and genetic testing to reach a conclusive diagnosis.

Genetic coincidence of hypo- and hypergonadotropic hypogonadism

Sava Petrov[1], Hristo Ivanov[2], Ekaterina Babadzhanova[1] & Maria Orbetzova[1]
[1]Medical University - Plovdiv, Endocrinology, Plovdiv, Bulgaria; [2]Medical University - Plovdiv, Department of Pediatrics and Medical Genetics, Plovdiv, Bulgaria

Congenital hypogonadotropic hypogonadism is characterized by delayed or absent puberty and infertility due to abnormally low levels of gonadotropic hormones and sex steroids. The most common reason for its development is Kallmann syndrome - a rare congenital disorder resulting from impaired migration of GnRH-secreting neurons from the olfactory epithelium to the hypothalamus. It is associated with hyposmia and anosmia. In 1942 Klinefelter described 9 men with gynecomastia, sparse facial and body hair, small testes and inability to produce sperm. In 1959 the additional X chromosome was discovered - genotype 47, XXY, characteristic of the complete and most common form of Klinefelter syndrome. The classic phenotype includes low serum testosterone, high LH and FSH levels. We present clinical cases of two adolescents at age of 18th and 19th with history for diminished pubertal spurt, treated with recombinant gonadotropic hormones by the pediatricians by the age of sixteen. 18-years boy was diagnosed with microdeletion of Y-chromosome and the 19-years boy did not have genetic diagnostic determination. Both patients presented with hormonal constellation for hypogonadotropic hypogonadism, low volumes of testicles, diminished spermatogenesis. We performed kariotipazation and found disomy X-47, XXY. Patients were referred to Sequence analysis and deletion/duplication testing of the 46 genes listed in the Genes Analyzed section for hypogonadotropic Hypogonadism Panel and found deletion of ANOS1 gene. That cases present a rare coincidence of two genetic states for both hypo- and hypergonadotropic hypogonadism.
Key words: Hypogonadotropic hypogonadism, Kallmann syndrome, Klinefelter syndrome

Primary amenorrhea revealing testicular regression syndrome in two sisters

Wiem Saafi, Taieb Ach, Asma Ben Abdelkrim, Ghada Saad, Hamza Elfekih, Yosra Hasni, Maha Kacem, Molka Chaieb, Amel Maaroufi & Koussay Ach
Farhat Hached University Hospital, Endocrinolgy, Sousse, Tunisia

Introduction
Disorders of sex development represent a rare group of congenital disorders causing discord between the phenotypical and genotypical sex. We present the case of two female patients in whom we discovered a sex development disorder when they consulted for amenorrhea.
Case report
Two sisters of 21 and 25 years old had an endocrinological consult for primary amenorrhea. They were conceived from a consanguineous marriage and had no particular medical history. We didn't notice any intellectual retardation or dysmorphic syndrome. Physical examination found a high of 1.90 meters for both sisters and normal blood pressure. The Tanner stage was S3P2A2 with normal feminine external genital organs. No signs of hyperandrogenism were noted. Hormonal exploration revealed hypergonadotropic hypogonadism with normal testosterone levels and undetected estradiol levels in both cases. The patients had the same karyotype:46, XY, (SRY+). Pelvic MRI discovered the absence of gonads, uterus, and fallopian tubes. No adrenal or renal abnormalities were found. We retained the diagnosis of testicular regression syndrome. Hormonal replacement by estroprogestative was initiated in both sisters.
Conclusion
Embryonic testicular regression syndrome is a rare disorder of sex differentiation. The phenotype of patients with this disorder is variable with different degrees of masculinization. The phenotype depends on the extent and timing of the intrauterine accident concerning sexual development.

Hyperprolactinaemia in postmenopausal women receiving long-term hormone replacement therapy: a case series

Tahir Omer & Adnan Adnan
Northampton General Hospital, Northampton, United Kingdom

Introduction
A few studies have examined the effect of Hormone replacement therapy (HRT) on serum Prolactin level (PRL) in postmenopausal women. It has been demonstrated that HRT can trigger a stimulatory response on PRL secretion. However, the significance of this is yet to be further evaluated given the great variation in PRL concentration during menopause which has not been fully meticulously examined.
Case reports
We present 3 cases of postmenopausal women who were found to have high PRL while being investigated for a variety of symptoms and other endocrinological conditions and presentations. The patients were on different HRT preparations for a variable length of time. We discuss the implications of high prolactin in this age group, the variability and scarcity in the available literature and the possible treatment strategies. Case 1: A lady in her early 50s with a chronic history of PMR on steroids. She was referred to our clinic to investigate the HPA axis for secondary adrenal insufficiency. Tests revealed raised Prolactin level with no clear cause. MRI pituitary and the anterior pituitary profile were normal. She was not on any other medication. Case 2: A lady in her late 50s who presented to her GP with severe symptoms of menopause and was started on HRT. The dose was gradually increased. She was found to have raised prolactin level and referred to our clinic. MRI pituitary and anterior pituitary profile were normal apart from the raised Prolactin. Case 3: a 60-year-old lady who has been on long term HRT which was only recently discontinued. She continued to suffer from hot flushes and excessive sweating. She was referred to our clinic for further investigation. Pituitary profile, urinary 5HIAA, urinary Metanephrines were normal apart from the raised prolactin. CT CAP and MRI pituitary were all normal.
Discussion and conclusion
PRL can vary significantly during menopause. The incidence of Hyperprolactinaemia decreases with age. The commonest cause for raised PRL in menopause is Macroprolactinomas. Exogenous oestrogen could play a crucial role in Prolactin secretion. High PRL is associated with obesity, dyslipidaemia and insulin resistance. Some studies have also shown adverse effect on bone density. HRT dose adjustment and Dopamine agonists are among the treatment strategies. Some studies, however, argue that as the patient is usually asymptomatic, treatment might not need to be introduced but long-term monitoring is warranted.

Mc Cune ALBRIGHT Syndrome: A rare endocrine disorder with a challenging management: A case report

Maryame Ben Lafqih & Meryam Alahyane, Sana Rafi, Ghizlane EL Mghari, El Ansari Nawal
Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction
McCune-Albright syndrome (MAS) is a rare, Mosaic genetic (Lethal in the homozygous state) but non-hereditary disorder. The diagnosis is most often made

in childhood, the management is multidisciplinary and includes several aspects. We report a case of Mc Cune Albright syndrome and the various difficulties encountered in its management.
Case report
A, H 22 years old, at the age of 6 months presented skin macules. At the age of 3 years he developed gait disorders, a taller stature compared withother children of the same age and gender, then signs of precocious puberty with secondary sexual characteristics at the age of 7 years. In 2015 the diagnosis of Mccune Albright syndrome was retained.
Discussion
Mc Cune Albright syndrome is initially defined by a clinical triad: precocious puberty, polyostotic fibrous dysplasia, skin hyperpigmentation. Currently this definition has been extended to include other endocrinopathies and hepatobiliary disorders. In addition to the classic triad, our patient presented a somatotropic adenoma complicated with a thyrotropic deficit, in association witha left testicular tumor with Leydig cells. The management is multidisciplinary with no approved treatment. The fibrous dysplasia could be managed medically sometimes surgically, but no current treatment stops lesional progression. The surgical management of polyostotic craniofacial fibrous dysplasia is often disappointing with high risk of postoperative regrowth. The thickening of skull induced by fibrous dysplasia and high hemorrhage risk makes the surgical treatment of acromegaly difficult, the reason justifying the choice of medical treatment for our patient.
Conclusion
McCune Albright syndrome is a rare pathology, the diagnosis is sometimes made early in childhood but the treatment is still limited an challenging. Furtherre search is needed to improve its management.

Role of altered estrogen signalling in the pathogenesis of Recurrent Pregnancy Loss (RPL): A cohort based pilot study from Assam, India

Natasha Kashyap[1], Chandana Ray Das[2], Ratul Dutta[3], Anjuma Begum[4], Sujoy Bose[4] & Purabi Deka Bose[1]
[1]Cotton University, Molecular Biology and Biotechnology, Guwahati, India; [2]Gauhati Medical College and Hospital, Guwahati, India; [3]Down Town Hospitals, Guwahati, India; [4]Gauhati University, Biotechnology, Guwahati, India

Context
Recurrent Pregnancy Loss (RPL), defined as two or more consecutive pregnancy losses, is a serious reproductive problem, affecting 1–5 per cent of reproductive-age women. Although a high percentage (7.46%) of RPL cases are reported from India, scanty reports are available on the molecular mechanisms associated with RPL susceptibility in the population of the north-eastern state of Assam. Hormonal imbalances are a major cause of recurrent pregnancy loss. Recent studies indicate that estrogen plays a crucial role throughout pregnancy in fetal development, utero-placental blood flow, and implantation.
Objective
This work proposes to elucidate the role of alterations in the estrogen signalling pathway in the pathogenesis of RPL in the population of Assam. It would have therapeutic significance in atleast a sub-population of idiopathic RPL patients.
Methods
RPL patients who had undergone three or more spontaneous miscarriages ($n=21$) and medically terminated pregnancies (MTP) cases ($n=35$) were enrolled for this study. Biochemical level of estrogen in RPL patients and MTP cases was studied by ELISA. This was followed by transcript level study of differential expression of its receptors, ERα and ERβ by real time PCR method, and further validation at the protein level using immunofluorescence.
Results
The ELISA results indicated a higher level of estrogen in the RPL cases (5.03 $\pm$ 1.52 pg/ml) when compared with the MTP cases (3.6 $\pm$ 2.2 pg/ml) ($P<0.020$). The mRNA expression of the ER isoforms, ERα (0.08 $\pm$ 0.11 fold change) and ERβ (0.07 $\pm$ 0.09 fold change) was found to be downregulated in the RPL cohort compared to MTP. ERα, being the more functionally important receptor for estrogen-mediated signal transduction, its protein expression was also validated through immunofluorescence (IF). The IF results showed sporadic expression of ERα protein in both the MTP as well as RPL cases, with a sharp downregulation or even no expression of the receptors in the RPL product of conception (POC) tissues. However, correlation analysis did not show any significant correlation between these factors ($P>0.05$).
Conclusion
The results indicate the possible role of estrogen receptor expression that may be involved with RPL pathogenesis in the study population. However, the findings of this pilot study require validation in a larger sample size for therapeutic implementation.

The evolution and therapeutic aspects of hirsutism: about 100 cases

Bel Hadj Sliman Chayma, Nadia Khessairi, Anis Grassa, Fatma Chaker & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Hirsutism is defined as excessive hair growth in androgen-dependent areas in women, related to an increased exposure androgen action in pilosebaceous follicles. It may be isolated, or associated to cutaneous manifestations from acne to signs of virilism. The aim of our study was to describe the therapeutic and evolutionary aspects of hirsutism.
Methods
It was a retrospective study at the endocrinology department of Rabta Hospital in Tunis including 100 women who presented hirsutism with over a period of 10 years from January 2009 to December 2020. Clinical and paraclinical data were collected from medical records.
Results
The average age of our patients was 29.5 $\pm$ 10 years old. The mean age at puberty was 12.1 $\pm$ 1.2 years old. The onset of hirsutism was acute in 5% of cases. It was associated with spaniomenorhoea, secondary amenorhoea and infertility in 46%, 4% and 10% of cases respectively. Biological hyperandrogenism was present in 59% of cases with a mean testosterone level of 0.9 $\pm$ 0.7 ng/ml. Biological and radiological investigations led to the diagnosis of ovarian tumour in 3 patients, adrenal tumour in 5 patients, late-onset congenital adrenal hyperplasia in 7 women, Cushing's disease in 3 patients and polycystic ovary syndrome in 51 patients. Hirsutism was idiopathic in 32% of cases. Concerning treatment, all patients were recommended to follow hygienic and dietary rules and metformin was associated in eleven cases. Eighteen patients received etiological treatment, i.e. adrenalectomy, oophorectomy, hydrocortisone replacement therapy in 5%, 3% and 7% respectively. While Thirty-four percent were put under estrogen and progestin combination therapy, only 29% were treated with an antiandrogen. An additional treatment by laser hair removal was further done by 11 patients. Evolution was marked by clinical improvement in 46%.
Conclusion
Not only is hirsutism a source of anxiety and social embarrassment for women, but in some cases it can hide a serious illness requiring urgent treatment. That's why a rigorous etiological investigation is required before the treatment.

Hormonal changes in women with abnormal endometrial bleeding in peri and postmenopause

Ana Kocevska, Bashkim Ismaili, Kristina Skeparovska, Dimitar Georgiev, Ana Marija Spisic & Pranvera Izairi
Skopje, Special Hospital for Gynecology and Obstetrics 'Mother Theresa' Skopje, Skopje, North Macedonia

Objectives
To determine the histopathological changes of the endometrium that occur during the period of perimenopause and postmenopause and to determine their association with the presence of obesity, diabetes, thyroid disorders and the levels of FSH, LH, estradiol, insulin and parathormone.
Material and methods
This study involved 120 patients with fractionated explorative curettage due to abnormal uterine bleeding. The control group consisted of 40 healthy women without fractionated explorative curettage. Anamnestic data were taken from from all respondents. Body height and weight were measured. This laboratory

analyses were performed: Glycemia, HbA1c, Hormonal Status (FSH, LH, Estradiol, Insulin, TSH, Thyroxine and Parathormone).
Results
The most common pathological change of the endometrium was an endometrial polyp. Patients with explorative curettage were older than healthy women and had significantly higher Body Mass Index, higher levels of serum glycemia, triglycerides, serum insulin, FSH, LH, PTH and lower estradiol levels. Patients in the experimental and control group did not differ significantly in TSH and thyroxine levels.
Conclusions
In the period of perimenopause and postmenopause, there are changes in the genital organs, but also there are endocrine disorders. According to our study, some of them are related to the occurrence of changes in the endometrium and the need for fractional explorative curettage as a diagnostic procedure.

Vaginoplasty in the treatment of androgen resistance syndrome: about 2 cases

Amal Elkhomri[1], Nassim Essabah Haraj[1], Siham El aziz[1], Moataz Amine[2], Aboutaeib Rachid[2] & Asma CHADLI[1]
[1]CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco; [2]CHU Ibn Rochd, Urology and Andrology, Casablanca, Morocco

Introduction
Androgen insensitivities are rare genetic diseases, characterized by a more or less complete defect of tissue sensitivity to testosterone. It ranges from a more or less complete lack of masculinization to isolated infertility in a 46, XY individual. Many surgical methods of vaginoplasty have been opted with the aim of reconstructing the anatomy to allow future sexual activity as well as an improvement in the quality of life. We report the case of two patients with complete androgen resistance syndrome discovered during the exploration of primary amenorrhea
Observation 1
33-year-old patient, operated in 2016 for bilateral intra-abdominal gonadectomy, with an anatomopathological examination of an ectopic testicle on the right without signs of malignancy, and an embryonic carcinoma on the left, the patient underwent chemotherapy sessions, she presents a harmonious and feminine Morphological development, with absence of vaginal orifice, a carotype was done in favor of a 46 XY, pelvic MRI with absence of internal genitalia, and genitography with absence of vaginal orifice, the patient was put on estrogen and progestin, with good clinical evolution
Observation 2
20-year-old patient, who underwent bilateral gonadectomy in 2017 with pathological examination of hypoplastic testicular pulp with hamartomatous nodules and hypoplastic foci of Leydig cells compatible with androgen insensitivity syndrome without malignancy, with a gynecological examination presence of labia majora and labia minora not well formed with an incipient vagina. a carotype was done in favor of a 46 XY, pelvic MRI with absence of internal genitalia, and genitography with absence of vaginal orifice, the patient was put on estrogen and progestin, with good clinical evolution The first patient underwent a rectosigmodian vaginoplasty and the second a vaginal enlargement surgery. The result was excellent with the obtaining of a 6 cm deep neovagina. After six months of follow-up, the two patients keep neovaginal cavities with regular digital dilation
Conclusion
The choice of the most appropriate surgical technique is conditioned by the results of the clinical examination, ultrasound, genitography and endoscopic exploration.

Introduction
The biological rhythm pattern is synchronized through circadian oscillation of cortisol and melatonin release. Increased cortisol levels and circadian rhythm disruption act as an oncogenic factor in endometrial cancer through among others-dysregulation of cell proliferation/apoptosis and invasion.
Aim
To investigate, whether there is an oscillatory expression of the clock genes, MT1 and GR expression in human endometrial carcinoma cells. To explore whether glucocorticoids and melatonin can affect the expression of these genes and further to evaluate whether dexamethasone and melatonin affect the viability and invasiveness of Ishikawa cells.
Material and methods
Ishikawa cells were cultured and serum starved for 16h. Following starvation, cells were serum shocked and maintained in DCC-supplemented medium in the presence of dexamethasone (10^{-7}M), melatonin (10^{-7}M,10^{-8}M) and GR antagonist RU486(10^{-5}M), alone or co-incubated with dexamethasone and melatonin for 54h. Cell viability and cell invasion were evaluated by MTS and scratch assay, respectively. The mRNA levels of circadian clock genes: CLOCK, BMAL1, CRY-1, PER-2, ROR-α, REV-ERBb, glucocorticoid receptor-alpha and melatonin receptor were measured by qPCR.
Results
Dexamethasone induced cell invasiveness of Ishikawa cells was inversed by 10% in the presence of melatonin at 10^{-8}M for 54h. Co-incubation of dexamethasone-treated cells with melatonin (10^{-7}M,10^{-8}M) reduced the Ishikawa cell viability as compared to cells incubated with dexamethasone alone(10^{-7}M). For the first time, we showed that following synchronization with serum shock, Ishikawa cells expressed Bmal-1, Clock, Per-2, Cry1 in an oscillatory manner with a peak observed every approximately 36h. Interestingly, MT-1 and GRα also exhibited almost the same oscillaroty expression pattern. Incubation of Ishikawa cells with dexamethasone at concentration 10^{-7}did not affect the oscillatory pattern of Clock, Per-2, Cry, while it decreased the amplitude of Cry-1 expression at 18h of incubation. However, dexamethasone disrupted the pattern of Bmal-1 expression, mainly by increasing the frequency of oscillations; this effect was reversed by co-incubation with RU-486 implying a GR-mediated effect. Notably, melatonin at concentration of 10^{-8}M reversed the disruption of Bmal-1 expression pattern, without changing the GRα expression. Long-term incubation with melatonin alone at both concentrations did not affect significantly the oscillatory pattern, however at the highest concentration appeared to increase the amplitude of the oscillation in Bmal-1, Clock, Per-2, Cry-1 expression (approximately by 27%, 127%,83% and 73% respectively) with more robust effect at 18h of incubation (first peak).
Conclusion
Melatonin ameliorates the glucocorticoid-induced invasiveness of human endometrial cancer cells possibly through reversing the glucocorticoid-induced disruption of circadian clock system. Further studies need to confirm the causal link.

Importance of karyotyping in the evaluation of male hypogonadism

Ei Thuzar Aung[1], Sanjana Srinivas[2], Helmine Kejem[3] & Upendram Srinivas-Shankar[3]
[1]Whiston Hospital, St Helens and Knowsley Teaching Hospitals NHS Trust, Department of Diabetes and Endocrinology, Prescot, United Kingdom; [2]Whiston Hospital, St Helens and Knowsley Teaching Hospitals NHS Trust, Prescot, United Kingdom; [3]Arrowe Park Hospital, Wirral University Teaching Hospital NHS Trust, Department of Diabetes and Endocrinology, United Kingdom

We present the case history of a 48-year-old man with anxiety and depression, who was referred for evaluation of absent libido, long standing erectile dysfunction and reduced body hair. There was no history of orchitis, pituitary problems or low impact fractures. He was always single and did not father children. Clinical examination revealed obesity (BMI 31 kg/m2), absent facial hair, reduced body, axillary and pubic hair. There was bilateral gynaecomastia. The phallus was normal, but the testes were not palpable. He appeared euthyroid and did not have features of cortisol or growth hormone excess. Visual fields were normal to confrontation. He was not diagnosed to have any congenital malformations but had an atrophic right kidney on a routine ultrasound scan of the abdomen. Biochemical profile revealed undetectable testosterone <1.5 nmol/l (nr 10 -28) and raised FSH 49.8 u/l (1.0 – 12) and LH 20.9 u/l (2.0 – 9.0) consistent with primary hypogonadism. Oestradiol, alpha-fetoprotein, beta HCG, prolactin, IGF1 and thyroid function tests were normal. Ultrasound scrotum revealed small testes in the lower inguinal canal. Karyotyping revealed 46XX disorder of sexual differentiation (DSD), SRY positive. Testosterone supplementation was initiated. He was referred to the urologist for orchidectomy given risk of malignant transformation in the undescended testis. He was also referred for genetic counselling and clinical psychologist. Patient chose to remain on testosterone and requested testicular implants. DEXA bone mineral density scan revealed osteoporosis.

Discussion

46XX DSD is a rare disorder occurring in about 1:20,000 males. These patients commonly present in adulthood with infertility and have various phenotypical presentations, ranging from severe impairment of external genitalia to cryptorchidism to a normal male phenotype. Our case history highlights the importance of external genitalia examination in those presenting with hypogonadism. Further karyotyping is important in the evaluation of such patients, especially in those with phenotypical abnormalities.

The frequency of thyroid diseases in adolescents (boys and girls) in Djizakh and Namangan regions of the Republic of Uzbekistan.'

Utkir Mavlonov[1], Urmanova Yulduz[1], Dinara Alieva[2], Guzal Dalimova[2], Dilmar Savchenko[2] & Shokhsanam Safarova[2]

[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, department of neurendocrinology, Tashkent, Uzbekistan

The purpose of the study

Is to study the frequency of thyroid diseases in adolescents (boys and girls) in 2 regions of the Republic of Uzbekistan.

Material and methods.

We have been examined and surveyed in the framework of screening just for the period from January 1, 2021 to April 1, 2021 - 1023 boys and girls in the two regions of RUZ - 523 adolescents were examined in the Djizakh region and 500 adolescents in the Namangan region Aged from 11 to 15 years. The main contingent amounted to students of colleges and schools. All 1023 adolescents were performed by all anthropometric studies based on the international growth and weight map of Tanner-Waithause. The assessment of the puberty stage according to J. Tanner, if necessary, patients were sent to add-on-x-ray (radiograph of brush, CT/MRI of the Turkish saddle), ultrasound of genital organs, consultation of the surgeon, genetics, etc. research.

Results

In total, among 1023 adolescents, 230 (22.4%) patients with iodine deficient diseases of the thyroid gland were identified: diffuse goiter (DG) 1 ST - 135 B (13.3%), diffuse goiter 2 ST - 54 BC (5, 3%), autoimmune thyroiditis - 38 (3.7%). At the same time, in patients with DG, euthyroidism was observed in 106 adolescents (10.3%), and hypothyroidism - in 83 (8.1%). In the Namangan region, 141 (28.2%) patients with iodine deficient diseases of 500 examined, and in Jizzakh - 89 out of 523 examined (17.1%)

Conclusions

In total among 1023 adolescents, 230 (22.4%) patients with iodine deficient diseases of the thyroid gland were revealed. This in turn also indicates that iodine deficiencies are a factor in the risk of developing violations of sexual, physical and general development in adolescents

Disorders of sex development 46XY revealed at adult age : A report of three cases and and literature review

Benabdelatif Katia, MALEK IABBASSEN, Bensalah Meriem & Ould Kablia Samia

Central Military Hospital, Algiers, Algeria

Introduction

Disorders of sex development include a large number of congenital conditions related to unusual chromosomal sex (gonosomal abnormalities), defective testicular development, or abnormal hormone secretion or receptivity, resulting in unusual external and/or internal genitalia development rare.

Patients and methods

we report 3 cases of disorders of sex development 46XY reveled at adult age. clinical, biological and radiological funding are reported in the following table.

Conclusion

Disorders of sex development are rare situations that require a rigorous assessment and early treatment. They often are congenital pathologies that have consequences in terms of self-esteem, sexuality and fertility in the future.

Precocious puberty associated with primary adrenal insufficiency: A case report

Lina Ghram, Bchir Najla, Zouaoui Chadia, Rekaya Zeineb, Fatma Ben Zaied & Haroun Ouertani
Hôpital Militaire Principal d'Instruction de Tunis, Tunis, Tunisia

Introduction
Precocious puberty (PP) is a rare pathology involving approximatively 0.2% of girls and less than 0.05% of boys and is defined as the appearance of secondary sex characteristics before 8 years of age in girls and before 9 years of age in boys. We report an unusual case of a patient who presents a precocious puberty associated to a primary adrenal insufficiency.
Case presentation
We describe a case of a 7-year and 4 months old girl referred for a precocious puberty. In fact, her mother reports breast enlargement since the age of 5 years but she only consulted when she had her menarche 2 months ago. Her medical history was uneventful. Her mother had her own menarche at the age of 11. Physical examination displayed a girl with weight at 33 kg (< -2 [standard derivation] DS), height at 137 cm (> +3 [standard derivation] DS). Her statural age was 10 years and a half. The patient presented an elevated Areola above contour of the breast with development of the overall breast tissue (Tanner stage S4) and her pubic hair was adult in type (Tanner stage P4). Bone Age according to Greulich and Pyle atlas was 11 years. Pelvic ultrasound revealed a uterine long axis of 39 mm, thickness of the uterine endometrium of 6mm, follicular ovaries without ovarian cysts nor pelvic mass. Endocrine analysis showed high estrogen value: 25,5 pg/ml and high basal luteinizing hormone (LH) : 5,98 UI/l (> 5 UI/l), suggesting a central precocious puberty. The pituitary magnetic resonance imaging showed homogeneous hyperplasia of the anterior pituitary gland without sellar ou suprasellar tumor. The evaluation of the other pituitary axes showed a normal thyroid function test (FT4 : 11,3 pmol/l and TSH : 1,75 uUI/ml), and a low cortisol level 66 nmol/l concomitant to an ACTH level: 98 pg/ml. The patient received hydrocortisone. A treatment by GnRH agonist was started and a genetic investigation is now being undertaken.
Conclusion
Central PP is due to a premature activation of the hypothalamic-pituitary-gonadal axis. It can be attributable to cerebral congenital malformations or acquired insults, but the cause in about 90% of cases in girls is idiopathic. Rare cases of PP associated to adrenal insufficiency were reported in the literature. It seems to be related to a stop loss DAX1 variant.

Mayer-rokitansky-küster-hauser syndrome: about two cases

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco

Introduction
Mayer-Rokitansky-Küster-Hauser syndrome (MRKH) is a rare malformation of the birth canal in women. It is defined as agenesis of the uterus and vagina with normal development of secondary sexual characteristics and a normal karyotype (46, XX). This is an entity with a heavy psychological impact requiring multidisciplinary care.
Observation 1
We report the case of a 16-year-old patient with a history of delayed puberty in the sister, who consulted for primary amenorrhea. Clinical examination revealed a height delay of -3 standard deviation, a weight delay of -1 standard deviation and a Tanner stage A1 S1 P1. Hormonal exploration found hypergonadotropic hypogonadism. The karyotype showed a female genetic sex (46 XX). Abdominal pelvic ultrasound and MRI revealed utero-vaginal aplasia. The impact assessment showed a bone age of 13 years compared to a chronological age of 16 years. Hormone therapy treatment is started, associated with psychological care.
Observation 2
A 15-year-old patient with no notable history consulted for delayed height and puberty. Clinical examination revealed a statural delay at -2 standard deviation and Tanner stage S1P1A1. Hormonal workup showed hypergonadotropic hypogonadism with FSH at 133.4 IU/l and LH at 28.85 IU/l with low plasma estradiol levels. The karyotype showed a female genetic sex of 46, XX in the absence of Y chromosomal material. Ultrasound and abdominal pelvic MRI revealed utero-vaginal hypoplasia. The impact assessment showed a bone age of 12 years compared to a chronological age of 15 years. The diagnosis of MRKH was made with the absence of associated malformations. Estrogen therapy was started in our patient.
Discussion and conclusion
MRKH syndrome is a rare congenital malformation characterized by hypergonadotropic hypogonadism and which should be considered in the presence of any utero-vaginal abnormality. MRI is the exam of choice for the diagnosis of this syndrome. Its management is multidisciplinary and is essentially based on hormone replacement therapy.

Polycystic ovary syndrome: diagnosis and treatment

Nisrine Bouichrat[1], Dounia Zerrouki[2], Imane Assarrar[3], Messaoudi Najoua[1], Siham Rouf[4] & Hanane Latrech[4]
[1]Mohammed VI University Hospital, Medical School, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition, Oujda, Morocco; [2]Mohammed VI University Hospital, Medical School, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition, Oujda, Morocco; [3]Mohammed VI University Hospital, Medical School, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition, Oujda, Morocco; [4]Mohammed VI University Hospital, Medical School, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy of Oujda, Mohamed the First University, Oujda, Morocco

Introduction
Polycystic ovary syndrome is a real public health problem and is the most frequent cause of hyperandrogenism in women of childbearing age. The therapeutic management of PCOS depends on the patient's phenotype and associated comorbidities. The aim of our work is to study diagnosis and evolution after treatment of PCOS in our population.
Material and method
This is a retrospective descriptive study of 78 patients followed for PCOS at the Endocrinology Diabetology and Nutrition Department of the Mohammed VI University Hospital of Oujda in the eastern region of Morocco. The diagnosis of PCOS is based on the criteria of the Rotterdam Consensus of 2003. All patients underwent an interrogation, clinical examination, biological assessment and pelvic ultrasound. The collected data were analyzed by SPSS version 21 software.
Results
The average age of patients was 24 years. Hirsutism was the most frequent reason for consultation in 97.2% of cases with severe hirsutism in 12% of cases, followed by cycle disorders (84.3%), and acne in 55.7%. The average BMI was 26.1 $\pm$ 5.8 kg/ m^2 obesity was observed in 20% of patients, with abdominal obesity in half of the cases. Therapeutically, all our patients were put on dietary hygienic measures and metformin, the estrogen-progestogen contraceptive was indicated in 38% of patients and spironolactone in 26%, with a combination of these 2 treatments in 18% of cases. The evolution after at least 6 months of treatment revealed a very satisfactory improvement of the clinical signs with a decrease in the frequency of hair removal and a reduction in the density and darkness of the hairs.
Discussion-Conclusion
PCOS is a real problem in young women, which has psychological and social repercussions as well as metabolic ones. Its treatment should aim to: reduce hyperandrogenism, improve metabolic status and quality of life, and restore fertility. Our results are consistent with those reported in the literature.

Tension-free thyroidectomy (TFT) may reduce the complication rate in thyroid surgery: experience of the first 120 cases

Ilya Sleptsov, Roman Chernikov, Ilya Sablin, Alexander Pushkaruk & Yuri Fedotov
Saint Petersburg State University Hospital, Endocrine Surgery, Saint Petersburg, Russian Federation

Background and aims
The safety of thyroid surgery in terms of recurrent laryngeal nerve palsy and hypoparathyroidism was increasing in the last decade. In this study, we present a

new method of tension-free thyroidectomy (TFT), which could be used to further decrease the complication rate after thyroidectomy.
Patients and Methods
TFT is based on the medial approach to the recurrent laryngeal nerve (RLN) and the parathyroid glands after the division of isthmus and successive total dissection of Berry's ligament with full mobilization of the RLN and the parathyroid glands before the thyroid is pilled out from the neck. One hundred twenty consecutive patients (163 nerves at risk) underwent "tension-free thyroidectomy" (TFT) from August to November 2021 performed by one surgeon. There were 96 females and 24 male patients (ratio 4:1) with a mean age of ninety-two 46,3 (range from 17 to 75). Lobectomy was carried out in 93 (77,5%) patients, total thyroidectomy in 35 (22,5%). In 42 cases patients additionally underwent central or/and lateral neck dissection. Indications for surgery were papillary carcinoma ($n=53$), medullary cancer ($n=2$), follicular neoplasia - Bethesda IV group after fine-needle biopsy ($n=49$), Graves disease ($n=12$), multinodular toxic goiter ($n=3$), multinodular euthyroid goiter ($n=1$). Mean thyroid nodule size was 25,4 mm (ranged 7 - 120 mm). Intraoperative neuromonitoring was used in all the cases (5 mA). Translaryngeal untrasound or direct laryngoscopy were used prior and after surgery to evaluate vocal cords mobility. Calcium and parathormone levels were measured in patients after thyroidectomy on the first, 14^{th} and 30^{th}postoperative days.
Results
No fluctuation of electric activity of laryngeal nerves during surgery was revealed. Intraoperative loss of signal (LOS) due to thermal effect of electrocautery and subsequent transient unilateral RLN palsy occurred in 4 cases (2,5% from the total number of nerves at risk). In all these patients normal vocal fold function was confirmed on the $30\text{-}45^{th}$ days after surgery. No permanent nerve palsy cases revealed. Four patients (out of 35 in the total thyroidectomy group – 11,4%) exhibited a decrease of parathyroid hormone level on the postoperative day 1 which was resolved at day 30^{th} under the substitution therapy with calcium and alfacalcidol. No cases of permanent hypoparathyroidism occurred.
Conclusion
TFT can be considered a safe and feasible operation. Larger and comparative (randomized) studies with conventional dissection technique should be performed to investigate the hypothesis that this approach can provide a lower complication rate.

Radiofrequency ablation for benign thyroid nodules of 650 patients: long-term follow-up

Vyacheslav Solovov & Olga Ablekova
Samara Oncology Center, Interventional Radiology, Samara, Russian Federation

Purpose
The objective of this study was to evaluate the efficacy and safety of ultrasound (US)-guided radiofrequency ablation (RFA) for treating of benign thyroid nodules both autonomously functioning thyroid nodules (AFN) and symptomatic ones.
Material and Methods
The retrospective analysis included the results of treatment of 650 patients with benign tumors of the thyroid gland in the Samara Oncology Center since 2014 year. 182 (28 %) patients had autonomously functioning thyroid nodules and 468 (72 %) had symptomatic ones. The mean volume of nodule was 36.5 ml.
Results
RFA reduced nodular volume by 70.8 % after 6 months, 84.2 % after 60 months and it was an effective method for treating nodule-related clinical problems and hot nodules. 67 (10.1 %) patients with big nodule volume underwent 2-7 sessions of RFA. Cosmetic results were excellent in 96 % of patients. No serious complications such as thyroiditis, voice change, and hematomas were observed in RFA patients. Skin burned observed in 1 patient.
Conclusion
RFA was effective and safe method for outpatient treatment of benign thyroid nodules. RFA might be alternative to surgical treatment.

Decrease the functional activity of adaptive immunity cells one month after radioiodine therapy for Graves' diseaseDecrease the functional activity of adaptive immunity cells one month after radioiodine therapy for Graves' disease

Andrey Savchenko[1], Margarita Dudina[2,3], Sergey A. Dogadin[2, 3], Alexandr Borisov[1], Daria Fomina[2] & Vasiliy Belenyuk[1]
[1]Federal Research Center «Krasnoyarsk Science Center» of the Siberian Branch of the Russian Academy of Sciences, Scientific Research Institute of medical problems of the North, The Cell and Molecular Physiology and Pathology Laboratory, Krasnoyarsk, Russian Federation; [2]Krasnoyarsk State Medical University, Internal disease, Krasnoyarsk, Russian Federation; [3]Krasnoyarsk Regional Clinical Hospital, Endocrinology, Krasnoyarsk, Russian Federation

Introduction
Radioactive iodine (RAI) for Graves' disease (GD) was reported to have specific immune effects. The ability of T and B lymphocytes to cooperatively interaction during the immune response may be impaired in GD patients eligible for RAI therapy. We aimed at investigating cellular subsets involved in functional activity of adaptive immunity cellsone month after RAI therapy in patients with GD.
Materials and methods
Thirty-six women with GD, mean age 42.13 ± 15.35, were included in this study. All patients treated with thiamazole for at 12 months (9 – 14) before RAI therapy. Thiamazole was withdrawal 14 days before RAI therapy. All patients had a fixed 400-700 MBq ^{131}I dose orally. Fifty-six healthy subjects were also studied. The study of the phenotype of T- and B-lymphocytes was carried out by flow cytometry using direct immunofluorescence of whole peripheral blood and monoclonal antibodies labeled with FITC (fluorescein isothiocyanate), PE (phycoerythrin), ECD (phycoerythrin-Texas Red-X), PC5 (phycoerythrin-cyanin 5), PC7 (phycoerythrin-cyanin 7), AA700 (alexa fluor 700) and AA750 (alexa fluor 750) in the following panels: CD8-FITC/CD127-PE/CD25-PC5/CD4-PC7/CD3-AA700/CD45-AA750 и CD5-FITC/CD23-PE/CD19-ECD/CD45-PC5/CD27-PC7. Serum measurement of TSH, fT4, fT3 and TRAb were performed by ELISA and enzyme immunoassay.
Results
The thyroid state of GD patients before RAI treatment corresponded to subclinical hyperthyroidism with a high level of serum TRAb (Me = 28,01 mU/l ($Q_{0,25}$ = 2,81; $Q_{0,75}$ = 35,71, $p<0,001$)). An increase in the percentage of $CD3^+CD25^+$ $CD3^+CD4^+$ $CD3^+CD4^+CD25^+$ and $CD3^+CD8^+CD25^+$ cells but with a decrease in the amount of $CD3^+CD8^+$ lymphocytes relative to the control was found in GD patients before RAI therapy. All patients treated with RAI were euthyroid, while the content of TRAb remained almost at the initial level. One month after RAI therapy in GD patients we observed decreased the percentage of cells with phenotypes $CD3^+CD25^+$ $CD3^+CD4^+CD25^+$ and $CD3^+CD8^+CD25^+$ and an increase number of $CD3^+CD4^+CD127^{Low}CD25$-High lymphocytes. Also, we detected changes in the phenotypic composition of blood B lymphocytes of GD patients before ^{131}I treatment: a decrease the percentage of $CD19^+$ cells and an increase the relative number of $CD19^+CD27^+CD23^+$ lymphocytes. One month after RAI therapy we revealed decreased percentage of $CD19^+CD5^+CD23^+$ lymphocytes and increased relative to the initial values the levels of $CD19^+CD27^-$ and $CD19^+CD5^-$ cells.
Conclusion
One month after RAI therapy in GD patients changes in the phenotype of T and B lymphocytes in the blood reflect a tendency towards a decrease in the functional activity of adaptive immunity cells which can also be realized in the inhibition of autoimmune processes.

Myocardial Ischemia precipitating thyroid storm diagnosed during storm recovery through Wellen's wave: An ECG for an eye

Shinjan Patra[1], Ayan Roy[2], Anu Priya[1] & Atul Kaushik[3]
[1]All India Institute of Medical Sciences (AIIMS) Jodhpur, Endocrinology and Metabolism, Jodhpur, India; [2]All India Institute of Medical Sciences (AIIMS) Kalyani, Endocrinology and Metabolism, Kalyani, India; [3]All India Institute of Medical Sciences (AIIMS) Jodhpur, Cardiology, Jodhpur, India

Introduction
Thyroid storm is a major life-threatening condition in a patient of thyrotoxicosis which can precipitate the cardiovascular morbidity in forms of tachycardia, arrythmia and congestive heart failure. It can be precipitated by acute coronary

syndrome. Most literatures have reported acute coronary syndromes during the presentation itself but we describe an unique case where the diagnosis was possible after the resolution of the thyroid storm.
Clinical case
A 55-year-old graves' disease patient had presented with classical features of thyroid storm which was precipitated by discontinuation of the anti-thyroid drugs. His initial electrocardiogram (ECG) showed sinus tachycardia. He was promptly started on intravenous fluid, 80 mg of daily carbimazole along with lugol's iodine and intravenous dexamethasone. Within 48 h of treatment, his vitals became normal with resolution of the thyroid storm. His thyroid hormone status also showed marked improvement (free T4 falls from 90.31 ng/dl to 2.31 ng/dl) (normal range: 0.7 ng/dl-1.7 ng/dl). Due to his persistent jaw pain, mild chest discomfort and hiccough, ECG recordings were done in regular intervals. Interestingly it showed dynamic changes consisted of biphasic T waves. This ECG changes were seen after the resolution of the thyroid storm features. The cardiac enzymes were within normal limits. Wellen's syndrome was suspected. Coronary angiography revealed left anterior descending artery (LAD) obstruction and patient promptly underwent percutaneous transluminal angioplasty. Patient's angina equivalent symptoms had resolved remarkably. He recovered satisfactorily and was discharged after 5 days.
Clinical lesson
Ischemic heart disease is a well-known co-morbidity in a case of thyroid storm which can be identified at the initial presentation. But here the dynamic changes of ECG appeared after the resolution of the thyroid storm. It was classical of type A wellen's wave which is a harbinger of imminent massive anterior myocardial wall infarction due to near-complete blockage of LAD. Initial sinus tachycardia probably had masked the appearance of typical Wellen's wave in this case. But as soon as the thyroid storm resolved, typical dynamic changes appeared in the form of wellen's wave. Early suspicion due to following serial dynamic ECG changes has prevented a major catastrophe in this case. This case highlights the importance of tracking serial ECG changes in a patient of thyroid storm which can unmask any underlying ischemic cardiac disease even after apparent improvement of the clinical status. This clinical case also reports a unique association of thyroid storm and type A wellen's syndrome.

Immune checkpoint inhibitors induced myxedema coma

Hatice Sebile Dökmetaş[1], Meriç Dökmetaş[2], Ayberk Bayramgil[2], Kübra Karaipek[2], Güneş Dorukhan Çavuşoğlu[2], Cansu Temiz[2], Cem İdrisoğlu[2], Fatih Kılıçlı[1] & Ahmet Bilici[3]
[1]Medipol Mega University Hospital, Endocrinology, Istanbul, Turkey; [2]Medipol Mega University Hospital, Internal Medicine, Istanbul, Turkey; [3]Medipol Mega University Hospital, Oncology, Istanbul, Turkey

Introduction
Myxedema coma is very rare and its mortality is quite high. It is even rarer to occur due to an immune checkpoint inhibitor.
Case
A 69-year-old patient presented with complaints of dyspnea, fatigue, edema, and hypotension. He had diabetes mellitus, hypertension, and metastatic lung cancer diagnosis. Three weeks ago, he had taken the 10th cycle of atezolizumab for lung cancer, which he had been taking for 7 months. The patient's body temperature was 35.80 °C, heart rate was 69/min, and arterial blood pressure was 100/50 mmHg. There was sleepiness, apathetic appearance, enlarged tongue, non-pitting edema, abdominal distension, and decreased bowel sounds. In the blood tests of the patient, serum glucose 100 mg/dl (70-100), sodium 115 mmol/l (136-145), TSH 218 μIU/ml (0,2-4,2), free T4 <0,03 ng/dl (0,9-1,7), and anti-thyroglobulin was 483 IU/ml (0-115). The thyroid gland was small and the parenchyma was heterogeneous in the ultrasonography. Blood gas showed hypoxia and hypercapnia. The patient was diagnosed with myxedema coma due to the PDL-1 inhibitor-atezolizumab, which he had taken. Treatment of myxedema coma, mainly intravenous levothyroxine and hydrocortisone, was initiated. After serum-free T4 level returned to the normal range with iv levothyroxine, his treatment with oral 150 mg/d levothyroxine was continued.
Conclusion
As a result of the increasing use of PD-1, PDL-1, and CTLA-4 inhibitors in recent years, also hypothyroidism is the most common endocrine side effect, but myxedema coma is very rare. When all the literature is examined, it is seen rarely that in patients who develop myxedema coma due to immune checkpoint inhibitor. It develops due to PD-1 inhibitors nivolumab and pembrolizumab and CTLA-4 inhibitor ipilimumab. In our case, myxedema coma developed due to atezolizumab, a PDL-1 inhibitor. It should be kept in mind that hypothyroidism and also rarely hypothyroid coma may develop in patients using these drugs.

Subacute thyroiditis in patients after COVID-19 infections at the outpatient stage

Volha Shyshko[1,2], Darya Malakhava[2] & Alena Yurenia[1]
[1]Minsk City Clinical Endocrinology Center, Endocrinology, Minsk, Belarus; [2]Belarusian State Medical University, Endocrinology, Minsk, Belarus

Introduction
SARS-COV-2 is a new infection with little known consequences. As data accumulated, it became known that the thyroid gland is also affected as a result of infection. During the reconvalescence period, some patients developed severe thyrotoxicosis, which did not have the classic clinical picture of subacute thyroiditis or autoimmune.
Aim
To study the course of subacute thyroiditis in patients after infection with COVID-19.
Materials and methods
The study included 53 cases of subacute thyroiditis during 2020-2021. Group 1 - 13 patients with subacute thyroiditis and Covid-19 within 6 months, group 2 - 40 patients with subacute thyroiditis. The analysis of indicators was carried out: complaints at the first visit, hormonal status (T4, TSH), complete blood count, thyroid volume, nodes.
Results and discussion
Subacute thyroiditis is more often registered in women (69.2% (9) and 92.5% (37) in groups 1 and 2, respectively, compared with men (30.8% (4) and 7.5% (3) in groups 1 and 2, respectively), ($P<0.05$) The most common complaints in group 1: pain in the projection of the thyroid gland 30.4% (7), palpitations 13% (3), sweating 13% (3 cases); in group 2: pain in the projection of the thyroid gland 34.5% (19), fever 16.4% (9x), weakness 12.7% (7), palpitations 9.01% (5 cases), no complaints in 17.5%(7). The change in thyroid function is comparable in 2 groups: TSH in group 1 is lowered in 36.3% (4), normal in 36.3% (4), increased in 27.4% (3); in group 2: TSH decreased in 32.5% (13), normal in 40% (16), increased in 27.5% (11). fT4 in group 1: normal in 50% (3), increased in 33.3% (2), decreased in 16.7% (1); in group 2: decreased by 22.5%(9), normal in 52.5%(21), increased in 25%(10) ($P>0.05$). High ESR was significantly more often registered in group 1 (80% (8), compared with group 2 62.5% (25) ($P<0.05$) Nodular formations in the thyroid gland in group 1 were detected in 38.5% (5), in group 2 -in 100% (40).
Conclusions
1. Subacute thyroiditis is more common in women than in men in both groups. 2. Patients with COVID-19 are not characterized by fever in subacute thyroiditis. 3. The frequency of occurrence of thyroid status deviations is comparable in both groups. 4. In group 1, ESR increased more often than in the second group. 5. Nodular formations were significantly more often registered in patients without a history of COVID-19 infection.

Therapeutic plasmapheresis to induce euthyroidism prior to thyroidectomy

Wee Mee Cheng & YC Kuan
Sarawak General Hospital, Medical, Kuching, Malaysia

Use of therapeutic plasmapheresis in hyperthyroidism is mainly described in thyroid storm when traditional measures fail. Patients with hyperthyroidism who respond poorly or suffer adverse effects to conventional antithyroid therapies, which then need to be stopped, can have persistently high levels of thyroxine and at risk of a full blown thyroid storm. Hence an alternative treatment to achieve euthyroidism followed by thyroidectomy as definitive therapy is vital. We report here a case of a lady who as a result of multiple adverse effects from conventional antithyroid therapies, underwent therapeutic plasmapheresis as a last resort to

achieve euthyroidism prior to thyroidectomy. A 35 year-old lady who was diagnosed with Grave's hyperthyroidism 2 months earlier and treated with carbimazole presented with fever, sore throat and generalized body weakness. Blood investigations revealed leucopenia (total white cell - $1.50x10^3$/uL) and neutropenia (absolute neutrophil count $0.03x10^3$/uL). A diagnosis of carbimazole-induced agranulocytosis with neutropenic sepsis was made. Carbimazole was stopped. Intravenous antibiotics, antifungal prophylaxis and granulocyte colony-stimulating factors (GCSF) were instituted. Her neutropenia was fairly resistant and needed twice daily GCSF for a week to recover. Thus, it was deemed unsafe to challenge with prophylthiouracil. Oral cholestyramine and lithium were started as alternative treatment for her thyrotoxicosis. Two weeks later she developed widespread pruritic maculopapular rash attributed to lithium which was then withheld. She also could not tolerate cholestyramine fully and often vomited on taking the drug. We opted to rechallenge her with lithium at lower doses and administer oral cholestyramine via nasogastric tube in the ward. However, her FT4 remained above 100 pmol/l (12.3-20.2) five days later (Table 1). Eventually we resorted to using therapeutic plasmapheresis one week before her scheduled operation date. She underwent 2 sessions of plasmapheresis uneventfully. Short term Lugol's iodine was started perioperatively along with steroid cover. She successfully underwent total thyroidectomy and is currently well on levothyroxine replacement. This case highlights the use of, plasmapheresis as an effective and safe alternative to achieve rapid restoration of euthyroidism prior to thyroidectomy when conventional measures fail, even before acute deterioration into thyroid storm.

Ocular manifestations of Graves' disease

Kammoun Sonda[1], Rekik Mona[1], Affes Sofien[1], Faten Haj Kacem Akid[2], Ben Amor Saloua[1] & Trigui Amira[1]
[1]Habib Bourguiba Hospital, Tunisia; [2]Hedi Chaker Hospital, Tunisia

Introduction
Graves' ophthalmopathy, also called Graves' orbitopathy, is a potentially sight-threatening ocular disease that has puzzled physicians and scientists for nearly two centuries. Generally occurring in patients with hyperthyroidism or a history of hyperthyroidism due to Graves' disease, Graves' ophthalmopathy is also known as thyroid-associated ophthalmopathy or thyroid eye disease, because it sometimes occurs in patients with euthyroid or hypothyroid chronic autoimmune thyroiditis. We report two cases of Graves' ophthalmopathy and review clinical presentation, diagnosis and management of this condition.
Observation
Observation 1
A 52-year-old patient, with a history of hyperthyroidism since 1 year, referred for evaluation of the activity of his thyroid eye disease. Ophthalmologic examination found bilateral proptosis with right eyelid inocclusion, bilateral conjunctival hyperemia and superficial punctate keratitis. Oculomotricity and the remainder of the ophthalmological examination were without abnormalities in both eyes. The patient was successfully treated with corticosteroids.
Observation 2
A 55-year-old patient presented with complains of right proptosis and orbital pain for the past month. His medical history included diabetes treated with oral hypoglycemic agents. Examination revealed right ophthalmoplegia with exophthalmos. The remainder of the ophthalmological examination was unremarkable. The left eye was without abnormalities. A thyroid assessment carried out showed patent hyperthyroidism. Anti-TSH receptor antibodies were positive. Brain MRI showed bilateral orbital involvement due to dysthyroidism in the context of Graves' disease. The patient received corticosteroid associated with the etiological treatment. Outcome was favorable with regression of ocular symptoms after few days of treatment.
Conclusion
Graves' orbitopathy is the most frequent extrathyroid complication in Graves' disease. Natural history, described by Rundle, features an initial inflammatory or active phase in which acute episodes and spontaneous remissions alternate, then a fibrotic phase, with regression within 12–18 months. Diagnosis is based on symptoms and ocular signs. Clinical examination must therefore be rigorous; in case of doubt, the ophthalmologist's opinion is determining. Various classifications assess clinical signs: most widely used are the EUGOGO (European Group Of Graves' Orbitopathy). MRI imaging is essential to assess the degree of severity, in correlation with clinical involvement. Intravenous glucocorticoids are recommended in moderately severe and active OT. This condition affects the quality of life of patients and requires multidisciplinary care.

Thyroid-associated orbitopathy exacerbation following COVID-19

Wiem Saafi[1], Ghada Saad[1, 2], Hamza Elfekih[1,2], Sinda Allegue[1], Amel Maaroufi[1, 2], Maha Kacem[1, 2], Molka Chadli Chaieb[1, 2], Yosra Hasni[1, 2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, Sousse, Tunisia

Introduction
Thyroid-associated orbitopathy is an autoimmune disease of the retroocular tissues commonly associated with Graves' disease (GD) and rarely reported in Hashimoto's thyroiditis (HT). GD and HT are autoimmune thyroid disease which are sometimes hard to distinguish from one another and their association in one person is rarely described. Here, we report a case of an exacerbation of thyroid-associated orbitopathy in a patient with GD following a SARS-CoV-2 infection and a phase of spontaneous hypothyroidism.
Case report
A 36-year-old smoker male was hospitalized in the endocrinology department for the management of a Graves' orbitopathy. The diagnosis of GD was made two years ago in the presence of unilateral left orbitopathy, goiter, subclinical hyperthyroidism (TSH = 0.003 mUI/l and FT4 =1.36 ng/dl [0.9-1.7]) and positive anti-TSH receptor antibodies (TRAbs) = 5 IU/l (< 2 IU/l). Anti-thyroperoxidase (TPO-Ab) and anti-thyroglobulin (Tg-Ab) antibodies were negative. Thyroid scintigraphy showed intense homogenous hyper fixation of the gland. The patient received a small dose of antithyroid drugs. Euthyroidism was obtained after four months of treatment. After discontinuing medical treatment and follow-up for two years, the patient consulted for aggravation of his orbitopathy. He had a history of COVID-19 infection nine months ago and showed symptoms of hypothyroidism few months later. On examination, he had bilateral asymmetric orbitopathy without signs of activity. Laboratory exams confirmed hypothyroidism (TSH = 95 mUI/l and FT4 = 0.13 ng/dl). Antithyroid antibodies were positive: TPO-Ab = 291.4 IU/ml (< 60 IU/ml), Tg-Ab = 1055 IU/ml (< 100 IU/ml) and TRAbs = 2.37 IU/l.
Discussion
SARS-CoV-2 infection is associated with triggering of GD and HT. In our case, TPO-Ab and Tg-Ab were negative when the diagnosis of GD was first made. However, when the patient developed hypothyroidism, we found positive elevated levels of these antibodies and a concomitant decrease in TRAbs, suggesting a possible association between both diseases. Concerning the aggravation of the patient's orbitopathy, it is most likely related to smoking and the spontaneous shift to hypothyroidism.

DOI: 10.1530/endoabs.81.EP952

Table 1 Serial TFTs of the patient

Time	At diagnosis	After 2 months on carbimazole	After switching to lithium/ cholestyramine	Post 1st session plasma exchange	Post 2nd session plasma exchange	3 days post thyroidectomy
FT4 [12.3 - 20.2 pmol/l]	>100	22.7	>100	49.3	19.2	14.1
TSH [0.3 - 3.9 mIU/l]	<0.005	<0.005	<0.005	<0.005	<0.005	<0.005

Risk of malignancy of indeterminate thyroid nodules: an Italian single-center cohort study

Gianluca Cera[1], Roberto Novizio[1], Andrea Corsello[1], Esther Diana Rossi[2], Pietro Locantore[1] & Alfredo Pontecorvi[1]
[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS - Università Cattolica del Sacro Cuore, Unit of Endocrinology and Diabetes, Rome, Italy; [2]Fondazione Policlinico Universitario Agostino Gemelli IRCCS - Università Cattolica del Sacro Cuore, Division of Anatomic Pathology and Histology, Rome, Italy

Background
In 2014 a new Italian classification system of thyroid cytology divided the indeterminate TIR3 category in two groups, TIR3A and TIR3B, aiming to reduce unnecessary thyroidectomies. The reported risk of malignancy is: TIR3A: $<10\%$, suggesting follow-up and possible FNA repetition after 6 months, and TIR3B: 15-30%, recommending surgery.
Objectives
We aimed to: evaluate the histological prevalence of malignancy in TIR3A and TIR3B nodules in our center; investigate whether oxyphil cells in TIR3B samples correlated with benignity; assess whether cytological ThinPrep versus conventional smear preparation affects the cytological report; estimate the association between clinical and ultrasound (US) features with malignancy.
Methods
We performed a retrospective analysis of patients who received fine needle aspiration (FNA) from 05/2014 to 07/2017 at Fondazione Policlinico Gemelli, Rome. We included 139 TIR3A and 162 TIR3B nodules who underwent surgery, to compare cytology and histology. Samples were obtained with capillarity technique and prepared on conventional smears or ThinPrep slides. Clinical and US data reported to be associated with malignancy were collected. Differences in rates of malignancy were evaluated with Fisher's test. Logistic regression was performed to identify predictors of malignancy.
Results
Malignancy was reported in 12.2% ($n=17$) of TIR3A and 27.1% ($n=44$) of TIR3B nodules, with no significant difference with literature data. In TIR3B subgroup, 83 cytological samples showed oxyphil cells, with a malignancy rate of 10.8% ($n=9$), significantly lower than overall TIR3B ($P<0.01$). 66 TIR3A and 109 TIR3B FNA were prepared with ThinPrep technique, and 73 TIR3A and 53 TIR3B with conventional smears, with no difference in malignancy risks. Logistic analysis showed irregular margins to be predictive of malignancy in both TIR3A (OR 10.75, 95%CI 2.25-51.37) and TIR3B (OR 6.80, 95%CI 1.94-24.01). Other predictors were family history and microcalcifications for TIR3A, and vascularity, hypoechogenicity and, secondarily, microcalcifications for TIR3B ($P<0.05$). The predictive power of the logistic model increased when considering those features concurrently.
Conclusion
In a representative cohort of indeterminate nodules, malignancy rate of TIR3A and TIR3B nodules was overall comparable to the one reported in the Italian classification system. However, TIR3B with oxyphil cells had a malignancy rate comparable to TIR3A, advocating for careful search of this feature. US findings of irregular margins and, to a lesser extent, microcalcifications and hypoechogenicity, proved to be associated with malignancy. Some vascularity patterns were also associated with malignancy but they remained unreliable features because of their dubious interpretation. FNA preparation technique had no effect on malignancy risk.

The level of neutrophil reactive oxygen species in euthyroid and relapse patients with Graves' hyperthyroidism

Margarita Dudina[1,2], Andrey Savchenko[3], Sergey A. Dogadin[1, 2] & Ivan Gvozdev[3]
[1]Krasnoyarsk State Medical University, Internal disease, Krasnoyarsk, Russian Federation; [2]Krasnoyarsk Regional Clinical Hospital, Endocrinology, Krasnoyarsk, Russian Federation; [3]Federal Research Center «Krasnoyarsk Science Center» of the Siberian Branch of the Russian Academy of Sciences, Scientific Research Institute of medical problems of the North, Laboratory of Molecular and Cell physiology and pathology, Krasnoyarsk, Russian Federation

Introduction
Graves' disease (GD) is organ-specific autoimmune-inflammatory disorder characterized by a complex pathogenesis. The inflammatory process is dominated by an imbalance of the antioxidant-oxidant mechanism, increased production of reactive oxygen species (ROS), which can potentiate the cytotoxicity of neutrophils and sustain the autoimmune process and perpetuate the disease. Aim: to study the level of ROS synthesis by peripheral blood neutrophils in patients with Graves' disease depending on hyperthyroidism compensation.
Materials and methods
One hundred and twenty-six women with Graves' disease, aged 18 to 65 years, divided in groups with compensated hyperthyroidism 93 (73.81%) and relapse of hyperthyroidism 33 (26.19%) were studied and compared concerning ROS production. All patients continuously treated with thiamazole about two months. The maintenance dose of thiamazole was 10 mg per day. The synthesis level of ROS in peripheral blood neutrophils was evaluated using a 36-channel chemiluminescence analyzer 'BLM-3607' (MedBioTech, Krasnoyarsk) and was characterized by Tmax – the rate of development of the chemiluminescent reaction, Imax – the maximum ROS synthesis and the area under the chemiluminescence curve (S – total synthesis of ROS for 90 minutes of measurement).
Results
Regardless for hyperthyroidism compensation the indicator S of spontaneous and zymosan-induced lucigenin-dependent chemiluminescence increases significantly relative to the control ($p<0{,}001$), but decreases the Tmax of zymosan-induced chemiluminescence ($p<0{,}01$). In GD relapse patients total synthesis of ROS during zymosan-induced chemiluminescence was higher up to 4,35 compared to euthyroid group ($p<0{,}05$). Antigenic stimulation of neutrophils in GD patients of both groups revealed an increase the Imax during luminol-dependent chemiluminescence ($p<0{,}01$). Samples with zymosan in GD relapse patients, also, demonstrated more than tenfold increase in the total synthesis of ROS relative to the control, but no statistically significant differences with euthyroid patients.
Conclusion
Violation of the ROS production by peripheral blood neutrophils in euthyroid patients mainly affects the production of primary ROS which is associated with hyperthyroidism compensation and the immunosuppressive effect of thiamazole. In patients with relapse of hyperthyroidism, there are more changes in the production of high-energy oxidants not only at initial oxidative reactions stage but also at the level of secondary ROS, indicating the activation of cellular response immunological mechanisms. Cytopathogenic effect of ROS neutrophils generation in patients with Graves' hyperthyroidism determine the intracellular targets of immunotropic treatment of the disease.

Association between hyperthyroidism caused by Graves' disease and subjective sleep disorders

Kazuhisa Matsumoto[1], Shoichiro Izawa[1], Kenji Fukaya[1], Eriko Matsuda[2], Misato Fujiyama[2], Kazuhiko Matsuzawa[1], Tsuyoshi Okura[1], Masahiko Kato[3], Shin-ichi Taniguchi[4] & Kazuhiro Yamamoto[1]
[1]Tottori University Faculty of Medicine, Division of Endocrinology and Metabolism, Yonago, Japan; [2]Tottori University Faculty of Medicine, Head and Neck Surgery Division of Endocrinology and Metabolism, Yonago, Japan; [3]Tottori University Faculty of Medicine, Division of Pathobiological Science and Technology, Yonago, Japan; [4]Tottori University Faculty of Medicine, Department of Regional Medicine, Yonago, Japan

Background and objective
Sleep disorders (SDs) are classified into subjective and objective SDs, and subjective SDs are directly related to quality of life. According to previous studies, Graves' disease (GD) causes SDs, especially insomnia. However, the characteristics of subjective SDs and its clinical course after hyperthyroidism normalization remain unclear. Additionally, the factors involved in subjective SDs with hyperthyroidism in GD remain unclear. Hyperthyroidism is involved in sympathetic activity (SA). SA is likely to correlated with SDs. This study aims to evaluate the characteristics of subjective SDs and its clinical course after GD treatment, and to clarify the factors involved in subjective SDs associated with hyperthyroidism.
Methods
A prospective study with a substudy that involved cross-sectional analysis at baseline to evaluate the relationship thyroid function and the characteristics of SDs was perfomed. 72 participants (22 newly diagnosed with GD with untreated hyperthyroidism, 20 previously diagnosed with GD with normal thyroid function, and 30 normal controls) with no other underlying SD-related diseases were enrolled from November 2017 to October 2020. We compared the groups at enrollment and conducted prospective observations after 12 months of treatment on participants with newly diagnosed GD. Subjective SDs were assessed by

differences and changes in the Pittsburgh Sleep Quality Index (PSQI) global and component sleep quality scores. SA was assessed by pulse rate and urinary metanephrines.
Results
Free thyroxine (FT4) level, pulse rate and urinary metanephrines were significantly higher in untreated hyperthyroidism group compared to other group ($P < 0.05$). FT4 level was significantly positive correlated with pulse rate ($r = 0.643$, $P < 0.001$) and urinary metanephrines ($r = 0.387$, $P < 0.001$). PSQI global sleep quality scores ($P = 0.036$) and sleep disturbance scores ($P = 0.011$) were significantly different among the three groups, and were highest in the untreated hyperthyroidism group. Multiple regression analysis demonstrated that FT4 level was associated with poorer PSQI global sleep quality scores independently of other factors ($P = 0.006$). Prospective observation in 18 untreated hyperthyroidism group showed that FT4 ($P < 0.001$) and SA such as pulse rate ($P = 0.002$) and urinary metanephrines ($P < 0.001$) significantly improved by therapeutic intervention. PSQI global sleep quality scores ($P = 0.047$) and sleep disturbance scores ($P = 0.007$) significantly improved.
Conclusions
Hyperthyroidism in GD caused subjective SDs, especially sleep disturbance. SA due to hyperthyroidism may contribute to subjective SDs. Treatment for hyperthyroidism and SA may improve subjective SDs.

Dosing study of brand vs. generic levothyroxine in well-controlled primary hypothyroidism

Elyes Kamoun[1,2], Manel Jemel[1, 2], Radhouen Gharbi[1, 2], Samir Mkaouer[1], Hajer Kandara[1, 2] & Ines Kammoun[1,2]
[1]Institut De Nutrition, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia

Introduction
Most brand-name drugs do not differ that much from their generic counterparts, so switching between the two is not an issue. Levothyroxine, however, is an exception. The question of generic equivalency of levothyroxine products has remained unanswered for several decades. The purpose of the present study was to learn whether there is a difference of dosage between brand-name and generic levothyroxine in patient with well controlled primary hypothyroidism
Methods
We performed a cross-sectional study in our outpatient consultation, including the patients presenting a well-controlled primary hypothyroidism. The patients were assigned into two groups, those already taking Levothyrox® (G1) and those already taking Berlthyrox® (G2). All patients were taking the same formulation during the three months preceding the study. Pregnant women were excluded. We assessed the duration of treatment, the age and weight, the cause of hypothyroidism, the levothyroxine dose, the adherence to the treatment and the TSH levels (N : 0,27 - 4,2µUI/ml).
Results
We included 46 patients, 16 patients under Levothyrox® and 30 patients under Berlthyrox®. The median age was 52 years, and the median duration of treatment was eight years. The cause of the hypothyroidism was an auto-immune hypothyroidism in 32 cases (70%), thyroidectomy in 5 cases (11%) and iodine therapy in 9 cases (19%). The levothyroxine dosage ranged from 25 to 200µg/day with a median of 100µg/day. TSH levels ranged from 0,29 to 4,27µUI/ml with a median of 2µUI/ml. The median dosage of levothyroxine in the group 1 was 75µg [25-125µg], and the median dosage of levothyroxine in the group 2 was 100µg [50-200µg]. The difference between the two groups was significant ($P = 0,039$). There wasn't a significant difference between the two groups concerning the age ($P = 0,772$), the weight ($P = 0,94$), the duration of treatment ($P = 0,224$), the cause of the hypothyroidism ($P = 0,147$), the adherence to the treatment ($P = 0,576$) and TSH levels ($P = 0,368$).
Conclusion
Generic and brand-name levothyroxine showed a comparative effectiveness to achieve normal TSH levels. But our study showed that the dosage required to obtain normal TSH levels was significantly different between the two groups. Therefore, the switch between formulations should be monitored for the risk of under or over treatment. It causes concerns in our practice with some patients taking the formulation available, as episodes of shortage have been noted for both formulations.

EP957

Did well-controlled hypothyroid patients have necessary good compliance?

Elyes Kamoun[1,2], Manel Jemel[1, 2], Radhouen Gharbi[1, 2], Wafa Ben Hilel[1], Hajer KANDARA[1, 2] & Ines Kammoun[1,2]
[1]Institut De Nutrition, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia

Introduction
Treatment of primary hypothyroidism relies on a daily intake of levothyroxine, which dosage is determined first by the weight then by TSH levels monitoring. The daily dosage can vary with the cause of the hypothyroidism and the weight. The aim of our study was to determine if the adherence was a factor influencing the dosage of levothyroxine in a group of well-controlled hypothyroid patients.
Method
We performed a cross-sectional study including the patients presenting with a well-controlled primary hypothyroidism. We excluded pregnant women. We collected from their file their age, the cause of hypothyroidism, their weight, the TSH level (laboratory norms between 0.27 and 4.2µUI/ml), the duration of treatment and the current dosage of levothyroxine. We assessed for each patient the adherence to the levothyroxine with a Tunisian dialect translated version of the Girerd score. The adherence was defined as good compliance, minor noncompliance and noncompliance.
Results
We included 48 patients treated for primary hypothyroidism, with mean age of 50.4years and age varying from 19 to 37 years old. Mean duration of treatment was 10.5 years with extremes varying from two to 30years. The causes of the hypothyroidism were an auto-immune hypothyroidism in 69% of cases, thyroidectomy in 10% of cases, and iodine therapy in 21% of cases. The levothyroxine dosage ranged from 25µg to 200µg with a median of 100µg per day. TSH levels ranged from 0.29µUI/ml to 4.27µUI/ml with a median of 2µUI/ml. There was a good compliance in 19 patients (40%), a minor noncompliance in 26 patients (54,6%) and a noncompliance in 3 patients (6%). Adherence to treatment wasn't associated with age ($P = 0.731$) nor duration of treatment ($P = 0.262$). By performing an ANOVA test, adherence to treatment wasn't significantly associated with daily dosage ($P = 0,513$) nor dose per body weight ($P = 0,654$).
Conclusion
A lack of adherence to the treatment or to the time between the meal and the treatment is the first suspected cause of an elevation of TSH levels in a treated and well-titrated hypothyroid patient. Our study in a group of well-controlled patients showed that adherence isn't an influencing factor for the dosage when hypothyroidism is well-controlled but should always be advised to avoid TSH rise.

Immunogenetic aspects of polyglandular autoimmune syndrome

Fatma Mnif[1], Siddiqa Soomauroo[1], Wafa Belabed[1], Hajer Fourati[2], Abdelmouhaymen Missaoui[1], Dhoha Ben Salah[1], Mouna Elleuch[1], Nabila Rekik[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Human Genetics, Sfax, Tunisia

Introduction
Polyglandular autoimmune syndrome (PAS) are uncommon constellations of autoimmune diseases characterized by the occurrence of two or more auto-immune endocrine diseases in the same individual.
Patients and methods
It is a case-control study about 108 cases for 120 healthy subjects recruited as the control group. We aimed to study the polymorphism of the HLA class-II genes of patients compared to that of healthy subjects so as to identify the genetic susceptibility to PAS.
Results
Among 108 patients, 2 patients had PAS type I (PAS-I), 39 patients had the type II (PAS-II) and 67 patients had the type III (PAS-III). Thirteen patients with PAS-II against 120 healthy subjects in the control group were included for the genetic testing of HLA class-II allele. DRB1*03 allele was associated with the occurrence of PAS-II whereas DRB1*13 was detected in only one patient but in 40 subjects expressing a negative association of this allele with PAS-II but remains statistically insignificant. We also found the association of DQB1*0302 in our population ($P = 0.004$). DQB1*06 is a protective allele more prevalent in healthy

subjects (22.97%) than in patients (3.8%) ($P=0.023$) but this difference becomes insignificant after Bonferroni correction. Twenty-seven patients with PAS-III were tested for HLA class-II alleles. DRB1*03 allele was found to be associated with PAS-III ($P=0.0001$) whereas no association was noted with DRB1*04 allele ($P=0.22$). DRB1*13 allele was found in 5 patients and 40 subjects in favor of the negative association of this allele in PAS-III ($P=0.11$). A significant association was also observed with DQB1*02 allele in our population ($P=0.0034$). In all, 40 patients with PAS-II/III were tested for HLA class-II alleles and demonstrated the association of PAS-II/III with DRB1*03 allele ($P=0.0021$) but a less significant association was noted with DRB1*04 ($P=0.05$). As far as protective DRB1*13 and DQB1*06 alleles are concerned, we noticed a negative association but insignificant after correction in PAS.

Discussion and Conclusion

The genetics of PAS is based essentially on the association of certain alleles of the human major histocompatibility complex. The presence of susceptibility alleles DRB1*03 and DQB1*0302 is described in literature. However, some studies showed the association of DR4-DQB1*0302 with PAS-II or III is due entirely to the presence of pancreatic auto-antibodies whereas haplotype DR3-DQB1*0201 is associated not only with type-1 diabetes mellitus but also PAS-II/III in the absence of pancreatic autoantibodies. The study of genetics have evolved considerably during the last years, especially due to molecular biology techniques.

Graves' orbitopathy caused by alemtuzumab: a case series

Mariola Méndez Muros[1], Juan Jesús García González[1], Alberto Torres Cuadrado[1] & Antonio Manuel Garrido Hermosilla[2]
[1]Virgen Macarena University Hospital, Endocrinology and Nutrition Department, Seville, Spain; [2]Virgen Macarena University Hospital, Ophthalmology Department, Seville, Spain

Introduction

Alemtuzumab is a monoclonal antibody targeting the CD52 glycoprotein, which is expressed by most mature leucocytes. In early relapsing-remitting multiple sclerosis (MS) alentuzumab effectively decreases relapse rate and disability progression. However, nearly 50% of the pacients treated with alentuzumab develop secondary autoimmune disorders, being Graves' disease the most common. The development of thyroid eye disease is unusual.

Aims and Methods

We performed a retrospective chart review with MS and alemtuzumab-induced autoimmune hyperthyroid disease (AH-IA), who developed thyroid eye disease after alemtuzumab treatment. All patients with MS who had received at least one cycle of treatment with Alemtuzumab between 2014 and 2020 in Virgen Macarena University Hospital (Seville, Spain) were included.

Results

Our hospital is a regional referral center for MS, so approximately 121 MS patients were treated with alemtuzumab. 41 (33,9%) developed Graves' disease and 6 (14,6%) were referred for ophthalmological evaluation. Of these, only one presented as a severe case, while the other five presented a mild course. Five were non-smokers at the time of developing ocular signs and symptoms. Five had significantly raised TRAb ($>$ 10 IU/l) at presentation with eye disease—the sixth presented at a time prior to this test being routinely available. There was a 5:1 ratio of females to males. All patients initially received treatment with antithyroid drugs to control thyroid function. Four of them underwent total thyroidectomy as a definitive treatment. At diagnosis of orbitopathy, all patients had thyroid dysfunction consistent with hyperthyroidism. Four patients underwent conservative management with lubricants and selenium. One patient required treatment with oral corticosteroids. The most severe case was a 30-year-old woman who presented with constant diplopia, palpebral retraction >1.5 mm, severe soft tissue involvement, and exophthalmos. With a clinical activity score (CAS) of 3 she was started on treatment with i.v corticosteroids. Due to poor evolution, and an increase in the clinical activity score to 6, she started treatment with Tocilizumab, a humanized MAB against the interleukin (IL)-6 receptor approved as second-line treatment for moderate to severe and active glucocorticoid-resistant Graves' orbitopathy (GO). At 6 months, she presented great clinical improvement, with a CAS of 2 points (inactive GO).

Conclusions

We report the risk of developing GO in patients with MS treated with alemtuzumab who developed GD. In a novel way not described to date in the literature, we present a case of severe and active GO resistant to glucocorticoids in which Tocilizumab was successfully used.

Euthyroid sick syndrome as a prognostic marker in patients with SARS-CoV-2 infection

Joana Estevens[1], Liliana R. Santos[1,2], Daniel Nunes[3], Carlos Lemos[1,3], Paula Soares[4] & António Pais de Lacerda[1,2]
[1]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal; [2]Centro Hospitalar Universitário Lisboa Norte EPE, Serviço de Medicina II, Lisboa, Portugal; [3]Centro Hospitalar Universitário Lisboa Norte EPE, Serviço de Patologia Clínica, Lisboa, Portugal; [4]IPATIMUP - Instituto de Patologia e Imunologia Molecular da Universidade do Porto, Porto, Portugal

After almost 3 years since SARS-CoV-2infection was detected for the first time, knowledge about its repercussions on the thyroid gland function in the course of acute illness or in the post-COVID-19 are still poorly understood. This gland may be particularly susceptible to SARS-CoV-2 as this coronavirus enters cells through ACE-2 receptors, which are largely expressed in the thyroid gland. Through an observational, longitudinal and retrospective study, we investigated the serum levels of TSH and fT4 in adult patients infected by SARS-CoV-2 admitted to an internal medicine ward of a tertiary hospital. We evaluated the changes in thyroid function during hospitalization of 221 patients and the correlation between these changes and the severity of the disease. In a smaller cohort (n1= 20) we evaluated thyroid function after hospital discharge. We found a high predictive value of serum TSH and fT4 values for severity of COVID-19 (OR = 2.5, p-value = 0.02). We used Pearson Chi-Square p-value and assume severe COVID-19 if PaO2/FiO2 $<$ 300. We have shown that low TSH (mean 0.18 mU/l) and fT4 (mean 0.6 pmol/l) values have a higher prognostic value for mortality (OR = 2.3, p-value = 0.05) than other commonly used input data: hypertension, obesity, diabetes, PCR and IL-6 levels, sex and smoking. In the follow up cohort, thyroid function values tend to return to normal values over time. TSH and fT4 decreased values may be in line with the Euthyroid Sick Syndrome that has been described in acute diseases and as well as in patients with COVID-19.

Use of thyroid hormone in hypothyroid and euthyroid patients. the THESIS questionnaire survey in spain

Juan Carlos Galofré[1], Roberto Attanasio[2], Laszlo Hegedüs[3], Endre V. Nagy[4], Roberto Negro[5], Enrico Papini[6], Petros Perros[7] & Juan Jose Diez[8]
[1]Clínica Universidad de Navarra, Endocrinology, Pamplona, Spain; [2]IRCCS Orthopedic Institute Galeazzi, Endocrine Unit, Milan, Italy; [3]Odense University Hospital, Endocrinology and Metabolism, Odense, Denmark; [4]Department of Medicine, Faculty of Medicine, University of Debrecen, Division of Endocrinology, Debrecen, Hungary; [5]V. Fazzi Hospital, Division of Endocrinology, Lecce, Italy; [6]Regina Apostolorum Hospital, Department of Endocrinology and Metabolism, Rome, Italy; [7]Royal Victoria Infirmary, Department of Endocrinology, Newcastle upon Tyne, United Kingdom; [8]Hospital Universitario Puerta de Hierro, Department of Endocrinology, Madrid, Spain

Background

Hypothyroidism is one of the most frequent conditions in endocrinology. Despite of that fact, indications for treatment differ among specialists in Spain.

Aims

To identify attitudes of Spanish endocrinologists in the use of levothyroxine (LT4) therapy and the management of hypothyroidism.

Methods

The members of the *Sociedad Española de Endocrinología y Nutrición* (Spanish Society of Endocrinology and Nutrition) were requested to participate in a web-based survey. The questionnaire, conducted between September and November 2020, was adapted in accordance with the availability of thyroid hormone formulations in Spain.

Results

A total of 512 of 1956 (25.8%) members (66% female) completed the survey; 97.4% affirmed that LT4 is the initial treatment for hypothyroidism. The indications for LT4 therapy in euthyroidism were infertility in thyroid antibody positive women (48.5%) and simple goitre (21.2%). However, 44.2% of endocrinologists reported that there was no such indication for these patients. Only a minority of interviewees (2.6%) considered combining LT4 with liothyronine as the treatment of choice at diagnosis whereas 49% stated that it should never be used.

Conclusions
The standard of treatment of hypothyroidism in Spain is almost exclusively with LT4 tablets. Availability of other formulations of LT4 or combination therapy for hypothyroidism management remains to be explored specially in patients with persistent symptoms. Remarkably, non-evidence based use of LT4 is extensively practiced in Spain for euthyroid women with autoimmune thyroiditis and fertility problems.

Substitution with combined vitamins and minerals will provide a sufficient level of iodine during pregnancy

Boyana Trifonova[1,2], Anna-Maria Borissova[3,4], Lilia Dakovska[3] & Eugenia Michaylova[5]
[1]University Hospital Sofiamed, Sofia, Bulgaria, Clinic of Endocrinology, Sofia, Bulgaria; [2]Sofia University Saint Kliment Ohridski, Sofia, Bulgaria, Faculty of Medicine, Sofia, Bulgaria; [3]University Hospital Sofiamed, Sofia, Bulgaria, Clinic of Endocrinology, Sofia, Bulgaria; [4]Sofia University Saint Kliment Ohridski, Sofia, Bulgaria, Sofia, Bulgaria; [5]Clinical Laboratory Bodimed, Sofia, Bulgaria

In 2005, the evaluation of an international expert group* placed Bulgaria among those who successfully overcame the problem of 'iodine deficiency'. The aim of the study is to assess the current iodine status in pregnant women in two main regions of Bulgaria - with a known iodine deficiency and other with sufficiency in the past.
Material
A cross-sectional multicenter population-based study was conducted in a total of 84 settlements from the two regions, at 537 pregnant women, mean age of 30.49 $\pm$ 5 years.
Methods
The UIC was determined by certified inductively coupled plasma mass spectrometry. The accepted intervals for assessment of median UIC are: low 1 - 149, normal 150 - 249, over-optimal $>$ 250 µg/l.
Results
The mUIC level for the whole pregnant group was 170 µg/l (11 - 497), (95% CI 161 - 177). The pregnant women only in three regions have a mUIC below the lower reference limit of the norm for pregnant women of 150 µg/l [Gotse Delchev - 144.5 (119 - 208), Gabrovo - 130.5 (108 - 168), Troyan - 113.5 (93 - 185)]. A comparison was made between these three regions and the other seven with normal mUIC levels. According to the questionnaire 271 (50.47%) of all pregnant women take combined vitamins with minerals (including iodine). Pregnant women who do not take any medications from Gabrovo-Troyan-Gotse Delchev are 23.1% v.s. 15.7% of pregnant women in the other seven regions ($P<0.006$).
Conclusion
During pregnancy it is important to substitute with combined vitamins and minerals to ensure sufficient intake of iodine for this period. *Van der Haar F. *Review of Progress towards Sustained Optimal Iodine Nutrition in Bulgaria, MoH, USAID, UNICEF, 2005, P 32*

The relationship between thyroid hormones and different degrees of obesity; a case-control study

Bayar Qasim[1], Ayad Mohammed[1] & Mazyar Ahmed[2]
[1]College Of Medicine, University Of Dohuk, Medicine, Iraq; [2]Kurdistan Board For Medical Specialties, Medicine, Erbil, Iraq

Background
Obesity is a serious health problem worldwide and is caused by a wide variety of etiologies. There are several hormones which have been proved to be associated with increased body weight and has a direct effect on the fat metabolism like thyroid hormones.
Methods
This is a case control study which included 384 adult persons, they were divided into 2 groups according to the thyroid function status, the first group included 204 apparently healthy adults with normal thyroid function as a control group and the other group included 180 patients with decreased thyroid function status as a case group.
Results
The mean age of our patients was 37.12 years, females constituted 53.1%. Most individuals were overweight and obese. There was a very significant correlation between the levels of the TSH and the age, sex, and the BMI (P values 0.000, 0.05, and 0.000) respectively (table 1). Based on FT4 levels, 51.4% had normal level and 48.6% had decreased FT4 levels. The FT4 level had also a very significant correlation with the age, sex, and the BMI (P value 0.000, 0.001, and 0.000) respectively.
Conclusions
Body mass index is directly and positively correlated with both the TSH and the FT4 level. Overt cases of thyroid dysfunction are easier to be detected clinically than subclinical cases, obesity patients can be screened using the thyroid function status and treatment of patients with thyroid dysfunction must be adjusted according the weight.

Therapeutic approach to the diagnosis of Bethesda 5

Ana Barrera-Martín, Mª Rosa Alhambra Expósito, Paloma Moreno-Moreno & María Angeles Galvez Moreno
Reina Sofia Hospital, Córdoba, Spain

Introduction
Thyroid nodules are very common in the general population (20-75% ultrasound). There are clinical management criteria established by international societies and standardized cytological diagnostic criteria (Bethesda). However, there is still uncertainty in the management of category 5.
Objectives
To evaluate the clinical attitude to the cytological diagnosis of Bethesda category 5 (B5) in thyroid fine-needle aspiration cytology (FNA). And study associations between malignancy and other variables.
Material and methods
Retrospective study of thyroid nodules classified as B5 after FNA referred to our hospital between 2020 and 2021. Statistical analysis: SPSS v.22.0 (Student's t-test to compare means and Chi-square/Fisher's test for proportions).
Results
Twenty patients (70% female); mean (SD) age, 49.3 (15.6) years. Sonographic features of included nodules are shown in table 1. Of the nodules, 5% were ACR-TIRADS 3, 25% ACR-TIRADS 4 and 70% TIRADS 5. Application of the ACR TIRADS system's FNA criteria would have reduced the number of biopsies performed by 10%. Of the nodules without indication of FNA, both were papillary

Table 1 Sonographic features of included nodules

Structure/composition		Echogenicity		Shape		Margin		Echogenic foci	
	%		%		%		%		%
Cystic or almost completely cystic	0%	Anechoic	0%	Wider tan tall	85%	Smooth or defined	35%	None or large comet-tal artifacts	50%
Spongiform	0%	Hyperechoic o isoechoic	15%	Taller tan wide	15%	Lobulated or irregular	65%	Macrocalcifi-cations.	0%
Mixed	20%	Hypoechoic	85%			Extra-thyroi-dal exten-sion	0%	Periferical calcifica-tions	0%
Solid	80%	Very hypoe-choic	0%					Punctate echogenic foci	50%

thyroid microcarcinomas. All patients underwent surgery, 80% total thyroidectomy, and 20% hemithyroidectomy. Eighty (80%) lesions met the reference-standard criteria for malignancy: 10 papillary thyroid cancers, 4 papillary thyroid microcarcinoma, 2 Hürthle cells carcinoma. The rest: 10% (2) follicular adenoma, 5% (1) multinodular goiter and 5% (1) non-invasive follicular neoplasm with nuclear alterations of papillary carcinoma. The variable the presence of calcifications on the nodule were directly related to the malignancy/benignity of the nodule (p 0.025). In fact, microcalcifications is only present in malign pathology.

Conclusions

The percentage of patients with malignant processes of our series corresponds to the bibliography. Although the use of this category seems correct, the clinical attitude is erratic and surgical over-treatment occurs.

An unusual pathology in graves' Disease

Sebnem Burhan[1], Rukiye Dilara Tekin Uzman[1], Ş eyma Aksoy[1], Fatih Mert Doğukan[2] & Esra Şüheda Hatipoğlu[1]
[1]Basaksehir Cam and Sakura City Hospital, Endocrinology and Metabolic Diseases, İstanbul, Turkey; [2]Basaksehir Cam and Sakura City Hospital, Pathology, Istanbul, Turkey

Introduction

Graves disease (GD) is an autoimmune disease in which thyrotropin receptor antibodies overactive the thyroid gland. Therefore, antithyroid drugs, radioactive iodine therapy, or surgical interventions are treatment options. In GD, pathology after thyroidectomy may include hypertrophy and hyperplasia in thyrocytes, mononuclear cell infiltration in the stroma, and increased blood supply. We presented a case with areas of necrosis and vasculitis due to GD in the pathological specimen obtained after a patient underwent a total thyroidectomy due to development of hepatotoxicity under antithyroid therapy.

Case

An 18-year-old female patient complained of palpitation, weakness, and fatigue. TSH was suppressed, fT4, fT3 and thyroid stimulating antibody were elevated. thyroid ultrasonography and scintigraphy also confirmed GD. After 2 months of methimazole she could not achieve adequate control and developed hepatotoxicity. Therefore she was switched to propylthiouracil and surgery was planned. On the histopathological examination, diffuse hyperplasia of thyroid follicular epithelial cells with nearly complete loss of colloid material was observed. The typical lobular structure was preserved, whereas the follicular pattern had been lost due to the pronounced lack of colloid. A focus of lymphocytic thyroiditis with accompanying pseudopapillary projections was present. Patchy areas of thyroid parenchyma showing coagulation necrosis were remarkable. In some small intraparenchymal venules, thrombotic vasculopathy was noticed. There was no cytological atypia and increased mitotic activity. Immunohistochemical test results (TTF-1 (+), PAX8 (+), calcitonin (-), GATA-3 (-)) were confirmatory of the thyroid follicular epithelial cell origin. There was no evidence of systemic vasculitis in his physical examination. Sedimentation, CRP, p-ANCA, c-ANCA, ANA, C3, and C4 were within normal ranges. PET CT did not show a systemic vasculitis.

Discussion

Vasculitis in the thyroid is not common. However, there have been few cases with giant cell arteritis or temporal arteritis in the thyroid artery. Antithyroid drug-associated vasculitis is generally ANCA-associated leukocytoclastic vasculitis and presents with skin manifestations. We did not find evidence of systemic manifestations in our case. Autoantibodies were negative. Due to absence of prominent nodular patterns, cytological atypia, increased mitosis, or solid growth pattern in histopathological examination; poorly differentiated thyroid carcinoma was excluded. The existing findings in the thyroidectomy material were evaluated as vasculitis localized to thyroid gland and related to GD.

Radiofrequency thermal ablation (RFA) of Thyroid nodules: our initial experience

Mee Jung Rachele Mattarello[1], Roberto Mingardi[1], Francesca De Santi[1] & Mauro Mazzucco[2]
[1]Casa di Cura Villa Berica, Endocrinology and Diabetology Service, Vicenza, Italy; [2]Casa di Cura Villa Berica, Minimally Invasive Cancer Therapy Center, Vicenza, Italy

In recent years, US-guided thermal ablation techniques have been proposed as a therapeutic alternative to traditional surgery or to metabolic radiotherapy for thyroid nodes. RFA is one of the most used technique and experience in both ultrasound and ultrasound interventional is important for results and minimizing complications. We present our experience after 1 year of activity on the first 33 patients with thyroid nodules treated with RFA. The nodules were evaluated by ultrasound (Samsung RS85) and classified according to the TI-RADS criteria In all patients, 2 ultrasound-guided fine needle aspirations were performed at different points of the nodule according to guidelines. Thermoablation was performed under local anesthesia with Amica-Gen HS Hospital Service RF

Table 1 Characteristics of Thyroid Nodules

Volume Average (cc)	27.7 (4.5 - 80)

Association between selected serum inflammatory parameters, low FT3 and mortality in hospitalized patients with COVID-19 - single center observation

Aleksandra Młodożeniec[1], Renata Orłowska-Florek[1,2], Adrianna Czarnożycka-Wróbel[1], Paulina Szul[1], Krzysztof Gargasz[2] & Agnieszka Gala-Bladzinska[1,2]
[1]St. Queen Jadwiga Clinical District Hospital No.2 Rzeszów, Department of Internal Medicine, Nephrology and Endocrinology, Poland; [2]Medical College of Rzeszów University, Poland

Introduction
The incidence and mortality rate for COVID-19 differ in different regions, but the risk of in-hospital death is high in all countries. It is very important to identify patients at risk of death at the beginning of hospitalization. The disease often leads to NTIS (nonthyroidal illness syndrome), which can be the result of the cytokines storm [1]. The inflammatory parameters and the level of FT3 appear to be obvious leading risk of death.
Objective
The study aimed to investigate the serum levels of thyroid hormones and selected inflammatory biomarkers in adult COVID-19 patients and to determine whether they predict the risk of death.
Methods
We retrospectively analyzed the lab results of patients hospitalized in our clinic from October 2020 to January 2021 with confirmed SARS-CoV-2 infection ($n=393$). Patients with a history of thyroid disease, patients treated with thyroid drugs and those who have recently received iodinated contrast were excluded. All of them were initially in stage II of the course of the disease [2]. The STATISTICA 13.1 statistical program was used to perform the tests and P values < 0.05 were considered statistically significant.
Results
Fifty-three (13,49%) adult patients were enrolled in the study. The median age was $72 \pm 12,2$ years, 26 patients (49%) were men. NTIS was detected in 64% of all patients and low FT3 serum levels showed strong correlation with disease severity and mortality prognosis in COVID-19. The results are shown in Table 1.
Conclusions
1. Low serum FT3 concentrations predict clinical deterioration and higher mortality in COVID-19 patients. 2. The levels of Il-6, WBC, ferritin, neutrophils are prognostic markers of in-hospital mortality in patients with COVID-19.

Thyrotoxicosis and multisystemic inflammatory syndrome in a patient with recent history of COVID-19

Calin Cristiana[1,2], Daniela Ioana Iulia Greere[2,3], Iulia Florentina Burcea[2, 3] & Catalina Poiana[2,3]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Pituitary and Neuroendocrine Disorders Department, Bucharest, Romania; [1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders Department, Bucharest, Romania

Introduction
There is evidence on the association of subacute thyroiditis (SAT) and SARS-CoV-2 infection, the first case report being described in a young woman back in July 2020 (1). Multisystemic inflammatory syndrome in adults (MIS-A) is a rare complication of SARS-CoV-2, usually 2 to 12 weeks after initial infection. The development of Graves disease after SAT is rare, with approximately 31 reported cases, of which only 5 occurring in men (2). We present the case of a young patient with thyrotoxicosis following SARS-CoV-2 infection.
Case Report
A 45-year-old male patient presented to our hospital with weight loss, palpitations and irritability. The medical history revealed SARS-CoV2 infection 3 months prior to presentation and an acute cytomegalovirus hepatitis 2 years ago. The patient was tachycardic, normotensive and afebrile. The laboratory tests revealed markedly elevated acute inflammatory markers: fibrinogen - 1240 mg/dl, CPR - 25.02 mg/dl, cholestasis: GGT - 914 U/l, ALP - 325 U/l and thyrotoxicosis: TSH - 0.0013 microUI/ml, freeT4 - 40.5 pmol/l, with negative thyroid stimulating hormone receptor antibody (TRAb). Screening for obstructive cholestasis and liver infectious disease was negative. Ultrasound examination indicated a diffuse enlargement of thyroid gland with multiple hypoechoic areas in the left thyroid lobe, suggestive for subacute thyroiditis. Treatment with intravenous dexamethasone 24 mg per day for 1 week in combination with methimazole 20 mg per day was started. Within the first week, the patient's condition improved with significant decrease of freeT4 and serum cholestasis markers and normalization of inflammatory markers. The patient was discharged with methylprednisolone 16 mg every two days and methimazole 15 mg per day. At 2-weeks follow-up, the thyroid function was normal under treatment, but TRAb had a positive value.
Conclusion
Our patient's presentation was atypical for SAT with no pain in the anterior surface of the neck and no fever. Given the late positivity of TRAb, we can consider the hypothesis that thyrotoxicosis emerged due to Graves disease and the markedly elevated acute inflammatory markers were explained by a multisystem inflammatory syndrome in adults. Clinicians should be aware of the potential development of MIS-A as a sequela of COVID-19. Also, there is a rare possibility that the subacute thyroiditis triggered the development of Graves disease.

A rare case of symptomatic amyloid goiter diagnosed by tru-cut biopsy

Erhan Hocaoglu, Ensar Aydemir, Coskun Ates, Filiz Mercan Saridas, Soner Cander, Ozen OZ GUL, Canan Ersoy & Erdinc Erturk
Uludag University Medical School, Endocrinology, Bursa, Turkey

Introduction
Amyloid goiter is a rare entity caused by massive amyloid infiltration of the thyroid gland. In some cases, differential diagnosis can be challenging. In this report, we present a patient with amyloid goiter caused by secondary amyloidosis.
Case
A 48-year-old male patient was admitted to our hospital with the complaints of neck swelling, pain, and mild dysphagia that started three weeks after the SARS-Cov-2 infection and continued for one month. The patient had a history of Crohn's disease, ankylosing spondylitis and renal amyloidosis. He was on hemodialysis for 8 years. On physical examination, the thyroid gland was bilaterally palpable and tender. Laboratory tests were as follows: C-reactive protein 55 mg/l, sedimentation 50 mm/hr, TSH 0.02 mU/l, free T4 0.76 ng/dl, free T3 2.17 ng/l. Anti-thyroid peroxidase (TPO) and TSH receptor antibody were negative. Ultrasound showed an enlarged thyroid gland with hyperechogenicity of the parenchyma and normal vascularity. Thyroid scintigraphy revealed low uptake. Subacute thyroiditis was considered in the patient. As the administration of ibuprofen did not ameliorate his symptoms, oral metilprednisolone (32 mg/day) was initiated. Afterwards, low-dose levothyroxine replacement was started for hypothyroidism. Despite using steroid (methylprednisolone at a maximum dose of 64 mg/day) for more than one month, his symptoms did not significantly relieve and the patient was hospitalized. Computed tomography scan of the neck showed diffuse enlargement of the thyroid gland and parenchymal heterogeneity. Fine-needle aspiration of the thyroid gland was performed, but the findings were non-specific. After that, tru-cut biopsy was planned for the patient. Pathological analysis revealed amyloid goiter. Positive staining with Congo red was obtained. Immunohistochemical staining patterns were consistent with amyloid AA. The patient, who was evaluated together with the general surgery department, was discharged with a total thyroidectomy planned for symptomatic amyloid goiter. After a short time, it was learned that the patient died due to myocardial infarction in another center.
Conclusion
In some cases, it can be difficult to distinguish amyloid goiter from subacute thyroiditis and other diseases. Amyloid goiter should be kept in mind in patients present with rapid thyromegaly and have a history of chronic inflammatory disease that may be associated with secondary amyloidosis. Fine-needle aspiration has a limited role in diagnosis. Either a core-needle biopsy or surgical specimen is often necessary.

Autoimmune thyroid disorders and connective tissue disease

Raida Ben Salah[1], Faten Haj Kacem Akid[2], Siddiqa Soomauroo[2], Mohamed Abdellahi Mohamed Ahmed[2], Sarra Chouaib[2], Faten Frikha[1], Nabila Rekik[2], Mohamed Abid[2] & Zouheir Bahloul[1]
[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Mixed connective tissue disease (MCTD), also known as Sharṕs syndrome is a rare autoimmune disease (AD), characterized by the presence of high titers of a distinctive autoantibody: ribonucleoprotein auto-antibody (anti-RNP). It presents with varied overlapping symptoms of different connective tissue disorders which may appear sequentially over time. As other AD, MCTD may be associated with one or more AD, such as autoimmune thyroid disorders (AITD).
Patients and methods
It is a descriptive retrospective single institution study. We collected data from 113 patients diagnosed with an AITD associated with another AD over 18 years. This present study reports the association between AITD and MCTD.
Results
We identified one patient diagnosed with both MCTD and AITD. She was hospitalized in the department of Internal medicine for investigation of joints pain and Raynaud's phenomenon. Antibody testing showed positivity for anti-RNP. She was treated by a prescription of nonsteroidal anti-inflammatory drugs and calcium channel blockers. The evolution was marked by the occurrence of flares of arthralgias. Biochemical assays led to the fortuitous discovery of a hypothyroidism. Hashimoto's thyroiditis (HT) was diagnosed concomitant to the MCTD in the context of other autoimmune diseases associated with the MCTD. Both thyroid antibodies (thyroid peroxydase antibody and thyroglobulin antibody) were positive. The patient was treated by L-thyroxin substitution.
Discussion and Conclusion
MCTD are AD characterized by the involvement of several organs and the presence of various autoantibodies. It can be associated with other AD. The most frequent association are with the Sjogrens' syndrome, Hashimoto's thyroiditis and some authors reported cases of autoimmune hepatitis and MCTD or primary biliary cirrhosis and MCTD. The frequency of thyroid disease, particularly chronic autoimmune thyroiditis (Hashimoto's thyroiditis), may be increased in patients with MCTD and vice versa. In a study conducted by Biro *et al*. including 1517 patients bearing an AD, 159 patients were diagnosed with MCTD. Among them, 21.4% were also diagnosed with HT whereas only 2.5% were diagnosed with Graves' disease. The screening of other autoimmune disorders in the presence of an AD is necessary, especially in patients who remain unwell or who develop new non-specific symptoms despite proper treatment, so as to avoid the delay in diagnosis of other autoimmune disorders and thus avoid treatment delay.

Hypovitaminosis D and Hashimoto's thyroiditis: effects of four-month supplementation therapy with oral cholecalciferol

Alice Villa[1], anna schiavo[1], Maria Gabriella Volpe[1], Andrea Sansone[2] & Francesco Romanelli[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Roma, Italy; [2]Tor Vergata University Polyclinic, Department of Systems Medicine, Endocrinology and Medical Sexology, Roma, Italy

Background
Hypovitaminosis D represents at present a worldwide public health problem. Recent studies have demonstrated the pleiotropic effects of vitamin D, in addition to its known actions on calcium-phosphorus metabolism. Among the several non-skeletal effects, a potential anti-inflammatory and immunomodulatory action has been suggested. Vitamin D deficiency has been reported in several chronic conditions associated with increased inflammation and deregulation of the immune system, such as Hashimoto's thyroiditis, and may act as a cofactor in the etiopathogenesis of these clinical conditions. On this basis, correction of hypovitaminosis D through therapeutic supplementation could have an impact on these pathologies.
Aim
to evaluate, in patients with Hashimoto's thyroiditis and hypovitaminosis D, the impact of cholecalciferol therapy on the parameters of calcium-phosphorus metabolism, antibody titer and indices of thyroid function.
Matherials and methods
a sample of 42 patients (6 men and 36 women) affected by hypovitaminosis D and Hashimoto's thyroiditis was recruited; oral cholecalciferol therapy was administered at a dosage of 100.000 IU, once a month during a meal. Before initiation (T0) and one week after the fourth dose of cholecalciferol (T1), the following parameters were evaluated: TSH, FT3, FT4, 25-OH-cholecalciferol, PTH, Calcium, Phosphorus, Creatinine, AbTg, AbTPO.
Results
a linear mixed-effects analysis was performed using R software (version 4.1.1). No significant changes in antibody titer or thyroid hormones were observed following cholecalciferol treatment. There was a statistically significant increase in serum 25-OH cholecalciferol after supplementation, with no significant changes in the other parameters. There was no significant reduction in PTH, although a downward trend was shown, after 4 months of therapy.
Conclusions
our results show that Vitamin D replacement therapy with cholecalciferol, in Hashimoto thyroiditis patients, does not affect the inflammatory nor the functional thyroid status, despite the fact that supplementation is effective in correcting hypovitaminosis D. No significant change in the antithyroid antibody titer emerged. Further studies are needed to investigate the immunoregulatory functions of vitamin D and its effects on thyroid autoimmunity.

Unilateral graves' disease : a case report

Hager Khiari, Sabrine Mekni, Meriem Adel, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis

Introduction
Graves disease is a frequent etiology of hyperthyroidism. It is defined as a diffuse hyperfunctioning of the thyroid gland caused by an autoimmune disorder. We herein present a rare case of unilateral Graves disease involving the right lobe of the thyroid.
Observation
A 44-year-old woman was referred for investigation of subclinical hyperthyroidism revealed by a routine check-up. On physical examination, she had tremor, eyelid retraction, tachycardia and the thyroid gland was no palpable. She complained of heat intolerance and nervousness for 1 year. On biological investigations, she had a serum TSH level of 0.001 mUI/l (normal range:0.35-4.94) and a serum free thyroxin (FT4) level of 1.48 ng/dl(normal range:0.7-1.48) : confirmed persistent grade 2 subclinical hyperthyroidism. She also had a serum glucose level of 0.96 g/l, a serum total cholesterol level of 1.51 g/l, a serum triglycerides level of 0.86 g/l, HDL-cholesterol level of 0.53 g/l and LDL- cholesterol level of 0.80 g/l. She had a white blood cells of 6680 elements/mm3, neutrophils of 3360/mm3 and lymphocytes of 2290/mm3. The liver and kidney function tests and c-reactive protein (CRP) were normal. The serum TSH receptor antibody level was high 17.54 UI/ml (normal range <2 UI/l) and the level of antithyroperoxidase antibody was within normal range. The bone mineral density was normal. The cervical ultrasonography showed a normal thyroid volume, normovascular gland and a nodule in the lower pole of the right lobe with a long-axis diameter of 14 mm EU-TIRADS 5. The thyroid scintigraphy revealed an increased uptake in the right thyroid lobe with an accompanying suppression in the left lobe. The fine needle aspiration biopsy of the nodule revealed benign appearance on cytological examination. The patient received antithyroid drug: methimazole and propranolol and recovered well.
Conclusion
Graves' disease usually presents with frank clinical signs of hyperthyroidism, bilateral exophthalmos, and a diffuse goiter. This case illustrates a rare case of unilateral involvement of the thyroid and a subclinical hyperthyroidism in a patient with confirmed diagnosis of graves' disease. Clinicians should be aware of this rare presentation of the disease as it affects treatment.

Hyperthyroidism revealing thyroid heterotopia

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology and Metabolic Disease, Rabat, Morocco

Introduction
Thyroid heterotopia is an abnormal location of coexisting normal thyroid tissue with a normal organ and normal location. It is a congenital anomaly due to a defect in the maturation of the thyroid tissues, which is distinguished from ectopic thyroid and from a thyroid cancer metastasis.
Observation
We report the case of a 65-year-old patient, with no notable history, who consulted for clinical signs of thyrotoxicosis associating asthenia, tachycardia, thermophobia and unquantified weight loss. The thyroid hormone balance confirmed hyperthyroidism (TSH at 0 mIU/l and high FT4). Cervical ultrasound showed a normal thyroid appearance. Scintigraphy thyroid test with Technetium 99m revealed a nodule under the left hyper-fixing maxilla extinguishing the thyroid parenchyma. The patient received treatment with iodine 131 iodine therapy at a dose of 20 mcu. The evolution is marked by a disappearance of the clinical signs and a normalization of the thyroid profile. A control thyroid scintigraphy was performed objectifying a disappearance of the nodule under the left maxilla.
Discussion and conclusion
Sub maxillary thyroid heterotopia is rare, the clinical expression can be variable depending on function of neighboring organs, the diagnosis is essentially based on scintigraphy thyroid, which makes it possible to objectify hyper fixation and to obtain a precise etiological diagnosis in front of the discrepancy between the thyroid profile and the cervical ultrasound. Treatment by iodine therapy allows rapid healing.

Cervicomediastinal thymic cyst mimicking thyroid : A case report

El Omri Malika, Amany Mallat & Marwa Ben Njima
University Hospital Farhat Hached Sousse, ENT, Tunisia

Introduction
Cervical thymic cysts are among the rarest congenital neck masses. Thymic migration into the superior mediastinum during organogenesis explains the topography and diversity of clinical presentations of these cysts. Due to the possibility of mediastinal extension, the management of these lesions is different than other congenital neck masses. The aim of our work is to present the clinical, radiological, and therapeutic features of cervicomediastinal thymic cysts.
Case report
A 13-year-old child was referred to our hospital for chronic cervical swelling. Clinical examination revealed a left basicervical mass. This *mass* was firm and *painless*. The rest of examination was without abnormalities. He did not have any neurological symptoms. Ultrasound and cervical Computed Tomography showed thyroid plunging from the lower pole of the left thyroid. On the surgical field, thyroid-independent cystic formation from the upper mediastinum with extension to the cervical region was found. A complete excision was performed after ligature and section of the lower cystic attachments. The anatomopathological examination diagnosed a thymic cyst with thymic parenchyma hyperplasia.
Conclusion
It's very important to recognize a cervicomediastinal thymus cyst as a differential diagnosis of pediatric neck masses, such as cervical lymphadenopathy, branchial anomalies, vascular malformations, inflammatory lesions and neoplasm. Ultrasound and CT scan can help to establish the etiological diagnosis.

Correlation between thyroid nodules cytologies applying the Bethesda System with post-thyroidectomy histopathological diagnosis

Laura Mola Reyes[1], Lorea A. Herraiz Carrasco[2], Cristina Martin-Arriscado Arroba[3], Laura Kanaan Kanaan[2], Teresa De Grado Manchado[2], Rona H. Penso Espinoza[2], Irene Crespo Hernández[2] & Maria Elena Mendoza Sierra[2]
[1]Hospital Central de la Defensa Gómez Ulla, Madrid, Spain; [2]Hospital Central de la Defensa Gómez Ulla, Endocrinology and Nutrition, Madrid, Spain; [3]Hospital Universitario 12 de Octubre, Instituto de Investigación I+12., Madrid, Spain

Introduction
Thyroid nodules represent a common cause of specialist consultation, with a risk of malignancy of 4-15%. The most widely used cytopathological method for diagnosing thyroid cancer is fine-needle aspiration biopsy (FNAB) of thyroid nodules and the use of the Bethesda system (BS) for cytopathological reporting. We conducted the present study to report our experience using the BS, and to compare the results obtained with this system with the final histopathological results of the thyroidectomies performed.
Material and methods
Analytical study was carried out comparing the results of FNAB according to the BS, and the final result of histopathology of patients with thyroid gland lesions who consulted at the Hospital Central de la Defensa Gómez Ulla (Madrid), during the year 2020. The results were expressed as mean $\pm$ standard deviation for quantitative variables and as absolute and relative frequency for qualitative variables. The comparison between the characteristics of the sample and the BS was carried out using the chi-square test and ANOVA, adjusting for the Bonferroni host-post test. Statistical software: Stata InterCooled for Windows version 16. Significance level: 0.05.
Results
Reports of 201 cytologies corresponding to 152 patients were reviewed. Mean age 65.6 $\pm$ 15.1 years. Predominantly female sex 75.0%. Main reason for FNAB request: size of the nodule (40.5%). Mean size of biopsied thyroid nodules: 23.5 ± 10.5 mm. The highest percentage of cytologies corresponded to the Bethesda II category: 152 (75.6%), followed by Bethesda I: 26 (12.9%), III: 11 (5.5%), V: 6 (3, 0%) and IV: 3 (1.5%), VI: 3 (1.5%). 15 patients (9.9%) underwent surgery, corresponding to 25 cytologies performed (12.4%). 7 malignancies were identified. There was a final histopathological result of malignancy in 14.3% of Bethesda II, 33.3% in Bethesda III, 0% in Bethesda IV, 100% in Bethesda V, and 66.7% in Bethesda VI (p-value $= 0.013$). Overall, categories IV, V and VI had a malignant lesion in the final histopathology diagnosis in 66.7% of cases (positive predictive value, PPV). 85.7% of Bethesda II, had a benign lesion (negative predictive value, NPV). Considering only patients with satisfactory samples, the diagnostic accuracy was 73.7%.

Conclusion
The BS for the interpretation of the FNAB of thyroid nodules enhances the diagnostic certainty and assists the medical-surgical team in the therapeutic decision. In our institution, most part of cytologies were reported as benign. Regarding patients who underwent thyroidectomy, FNAB showed a high NPV, with a lower PPV.

Anaplastic thyroid carcinoma: about 7 cases

Ezer Chebil, Jebahi Sameh, Thabet Wadie, Hassnaoui Mahdi & Mighri Khlifa
Taher Sfar University Hospital, ENT, Mahdia, Tunisia

Introduction
Anaplastic thyroid cancers are undifferentiated malignancies accounting for 2% of thyroid cancers.
Objective
To study the clinical, evolutionary and therapeutic characteristics of these carcinomas.
Materials and methods
A retrospective study covering 7 cases collected at our ENT department between 1994 and 2021.
Results
They were 6 women and one man with an average age of 50 (41-78). The reason for consultation was cervical swelling 100% of the time. Dyspnea was noted in 2 cases. The average duration of the symptomatology was 14 weeks. The tumor was plunging into the mediastinum in 2cas. In 4 cases, there was an invasion of the trachea and/or sub-hyoid muscles. Lymph node metastases were noted in all patients, bone in 2 patients and lung in 1 case. Histological confirmation of the diagnosis was made on thyroidectomy in 3 cases, and on a micro-biopsy of the thyroid gland in 4 cases. A tracheotomy was done in 3 cas. Three patients had a total thyroidectomy. The rest of the patients were inoperable. Radiation chemotherapy was indicated in all patients. Six patients died after an average delay of 11 months [8 months to 13 months]. A patient is still alive with a one-month decline.
Conclusion
Anaplastic thyroid carcinoma is a cancer with a dark prognosis. Patients in the localized disease stage can expect better survival. Therapeutic research explores targeted therapies that block the EGF receptor or inhibit neoplastic angiogenesis.

Radiofrequency thermal ablation for a small papillary thyroid carcinoma: a case report

Mee Jung Rachele Mattarello[1], Francesca De Santi[1], Roberto Mingardi[1] & Mauro Mazzucco[2]
[1]Casa di Cura Villa Berica, Endocrinology and Diabetology Service, Vicenza, Italy; [2]Casa di cura Villa Berica, Minimally Invasive Cancer Therapy Center, Vicenza, Italy

Recently ultrasound-guide radiofrequency thermal ablation has been proposed as an effective and safe procedure for treating patients who have low risk papillary thyroid microcarcinomas or are unfit for surgery. We present the case of a 56 years old patient with a small (10 mm) thyroid nodule diagnosed as TIR 4, suspect citology for papillary carcinoma after fine needle aspiration. The nodule was also studied with CEUS (Sonovue US contrast medium) which showed increased vascularization in the arterial phase compared to the remaining parenchymna and late wash out. We proposed the possibility of radiofrequency thermal ablation to our patient. We used 1 cm active tip electrode needle (HS Amica Gen) with moving shot technique: 3 shots at 30W power for 5 minutes and 15 seconds. The Procedure was safely and effectively carried out. Follow examinations with ultrasonography and CEUS conduced after 1,3,6 months demostrated a complete necrosis with avascular area and progressive reduction of size in the treated site. Anyway we repeated the fine needle aspiration 6 month later and the sample detected only very poor cellularity inflammatory cells, amorphous material and no neoplastic cells. Our experience confirmed that the radiofrequency ablation can effectively eliminated small papillary carcinomas with a very low complication rate. We have to consider this alternative strategy for treatment of small indolent papillary thyroid carcinomas alternatively of traditional patients even without surgical contraindication.

When sarcoidosis mimics cervical metastasis of thyroid cancer: a case report

Sara SI AMER[1], Imene Benoumechiara[1] & Nora Soumaya Fedala[1]
[1]University Hospital Center Mohamed Lamine Debaghine, Department of Endocrinology, Diabetology and Metabolic Diseases, Algiers, Algeria

Introduction
Sarcoidosis is a systemic inflammatory disease characterized by noncaseating granulomas. Its pseudo-tumor manifestation in certain organs such as the thyroid can mimic thyroid carcinoma and lead to erroneous therapeutic decisions. We report a case of sarcoidosis with cervical adenopathy initially considered as a cervical metastasis of thyroid cancer.
Observation
A 61-year-old woman, with a history of spontaneous subacute subdural hematoma operated in 2010, Followed at our level in consultation since 1991, for postoperative hypothyroidism, the patient underwent a left lobo-isthmectomy of a thyroid nodule suspect whose pathological study came back benign. She presents suddenly in consultation for a left cervical tumefaction on the bed of thyroid remnant which appeared recently and quickly in two months. It is a left basi-cervical mass of 4 cm, mobile and painless, without inflammatory or compressive signs, without palpable cervical lymphadenopathy, or signs of dysthyroidism,. The initial exploration made of a thyroid ultrasound showed a large mass occupying the suspicious left thyroid compartment with doubtful cervical lymphadenopathy, followed by a fine needle aspiration returned Bethesda IV. Not operated given the disappearance of the mass following a course of corticosteroids for an idiopathic thrombocytopenia discovered in parallel. This event made it possible to rectify the diagnosis thanks to a new exploration. Ultrasound found a free left thyroid compartment with bilateral cervical lymph node formations and a large suspect right supraclavicular lymphadenopathy, a dosage of thyroglobulin in needle aspiration biopsy fine was realized returning negative eliminating the thyroid origin and cytopuncture found granulomatous adenitis without caseous necrosis compatible with sarcoidosis. Biologically, the converting enzyme was twice normal and there was high calciuria. The CT scan shows a diffuse interstitial pneumopathy associated with cervical and mediastino-pulmonary lymphadenopathy concluding in an aspect of stage 3 sarcoidosis. The presumptive diagnosis was confirmed histologically by a bronchial biopsy.
Conclusion
The etiological diagnosis of a cervical mass or cervical lymphadenopathy, can represent a real challenge for the clinician. On a ground of thyroid pathology, the elimination of a neoplastic cause is a priority, sarcoidosis with these systemic and heterogeneous manifestations can constitute a diagnostic trap to be taken into consideration.

Parathyroid carcinoma: about 3 cases and review of literature

Rachida Bouattay, Emna Bergaoui, Maroua Naouar, Mehdi Ferjaoui, Heyfa Belhadjmiled, Amel Elkorbi, Naourez Kolsi, Kaled Harrathi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT, Monastir, Tunisia

Introduction
Parathyroid carcinoma is a very rare tumor. The reported incidence is between 0.5 to 5% of primary hyper parathyroidy in various series. This entity does not present any clinical or biological specificity compared to the parathyroid adenoma which exposes to diagnostic difficulties.
Objective
The aim of our presentation is to study the clinical, therapeutic and evolutionary aspects of parathyroid carcinomas.
Material and methods
This is a retrospective study of 3 cases of parathyroid carcinomas treated in our department over a period of 22 years (2000-2021).

Results
There are two women and one man, with a history of recurrent renal lithiasis in one case and a parathyroidectomy 10 years ago for parathyroid adenoma in one case. The average age was 54 years old. The average consultation time was 6 months. The reason for consultation was diffuse bone pain in two cases and a compressive anterior cervical swelling in one case. Calcium and parathormone levels were elevated in all our patients. Cervical ultrasound done in all cases and cervico-thoracic scan done in one case, did not suggest malignancy in all cases. The scintigraphy showed a fixation at the lower left parathyroid gland in two cases and lower right gland in one case. The treatment consisted of Para-thyroidectomy in all cases, associated with ipsilateral central dissection in two cases and ipsilateral lobo-isthmectomy in one case. Frozen section examination evoked malignancy in two cases. Definitive histology examination confirmed the diagnosis of parathyroid carcinoma with capsular rupture and vascular emboles in two cases. The lower left parathyroid gland was the most affected. The average tumor size was 4 cm (range 2 cm to 7 cm). The evolution was good in all cases with a mean follow-up of 4 years.
Conclusion
Diagnosis of parathyroid carcinoma can be difficult and the management still remains a challenge.

Thyroidectomy in laryngeal squamous cell cacinoma

Masmoudi Mohamed, Chaima Zitouni, Wadii Thabet, Chebil Azer, Hasnaoui Mahdi & Mighri Khalifa
Taher Sfar Hospital, Otorhinolaryngology, Mahdia, Tunisia

Introduction
Intraoperative management of thyroid gland in laryngeal cancer is controversial. In fact, there is no uniform consensus about the need for thyroid surgery in laryngeal cancer.
Objective
Determine the incidence of thyroid gland invasion in patients undergoing surgery for laryngeal squamous cell carcinoma.
Methods
A retrospective study including 62 cases of laryngeal squamous cell carcinoma who underwent a total laryngectomy. A thyroid surgery was performed in case of a subglottic extension $\geqslant$ 1 cm, an anterior extralaryngeal extension (T4a) or evidence of thyroid gland invasion on CT-scan or intraoperatively.
Results
The mean age of our patients was 59 years, predominantly males (98,4%). Eighteen patients had a subglottic extension $\geqslant$1 cm. The tumor was staged T4a in 14 cases. A loboisthmectomy was performed in 16 cases. A total thyroidectomy was done in 2 cases. On histopathological examination, thyroid extension was found in 2 cases (11.11%). No case of hypoparathyroidism nor hypothyroidism was noted among patients treated with thyroidectomy.
Conclusion
Thyroid gland involvement in laryngeal squamous cell carcinoma is rare (0-30%). Furthermore, hemithyroidectomy causes hypothyroidism in 63% of patients, and if combined with radiotherapy, the incidence goes up to 89% of patients. Therefore, thyroidectomy shouldn't be performed systematically for patients treated with total laryngectomy. It should be done in case of a locally advanced disease with thyroid cartilage transfixion, a macroscopic thyroid gland invasion and a signific subglottic extension.

Primary mucinous carcinoma of the thyroid gland: A rare tumour

Sirine Ayedi[1], Wadii Thabet[1], Manel Mallouli[2], Imen Achour[1], Bouthaina Hammami[1] & Ilhem Charfeddine[1]
[1]Habib Bourguiba Hospital, University of Sfax, Otorhinolaryngology, Tunisia; [2]Habib Bourguiba Hospital, University of Sfax, Pathology, Tunisia

Introduction
Primary mucinous carcinoma of the thyroid gland is extremely rare. To the best of our knowledge, only nine cases have been reported in the literature. Our aim is to report a case of primary mucinous carcinoma of the thyroid gland and to describe its diagnostic and prognostic features.

Case Report
A 55-year-old man referred to our department for a 2-month history of an anterior neck mass associated with dysphagia. Physical exam showed a 4-cm and hard, right anterior neck mass, with left cervical lymph nodes (group V). Ultrasonography identified a 3-cm right thyroid nodule: EUTIRADS 5 with bilateral suspicious cervical lymph nodes. CT scan revealed a 3-cm hypodense right thyroid nodule associated with several mediastinal and cervical lymph nodes. TSH level was normal. Fine-needle aspiration (FNA) result was "nondiagnostic." The patient underwent total thyroidectomy with bilateral central (group VI) and lateral neck dissections (groups II, III and IV). The tumour invaded the strap muscles and the left thyroid lobe. Several lymph nodes were noted in the central group, lateral cervical and mediastinal regions. Intraoperative examination was in favour of a poorly differentiated thyroid carcinoma. Postoperative course was uneventful. The histologic exam (with immunohistochemical study) confirmed the diagnosis of a primitive mucinous carcinoma of the thyroid gland. Surgical margins were positive. Lymph node metastases were noted in the central and lateral neck regions. The patient died 15 days after the surgery.
Conclusion
Primary mucinous carcinoma of the thyroid gland is unusual. Differential diagnosis must be discussed with other primary typical thyroid carcinomas or adenomas, metastatic carcinoma of the lung, breast, colon and other organs. Primary mucinous carcinoma has a worse prognosis than common thyroid carcinomas: survival ranging from 1 month to 2 years.

Association between vitamin D serum concentration and development of papillary thyroid cancer

Darko Katalinic[1], Ivan Aleric[1], Aleksandar Vcev[1], Miljenko Solter[2], Irena Ranogajec[3] & Lars Toetome[4]
[1]Faculty of Dental Medicine and Health and Faculty of Medicine, J. J. Strossmayer University, Osijek, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia; [3]Clinical Hospital Sveti Duh, Zagreb, Croatia; [4]Center for Cancer Medicine, Oslo, Norway

Purpose
Papillary thyroid cancer (PTC) is the most common thyroid and endocrine malignancy worldwide. Vitamin D (calciferol or 25-hydroxyvitamin D) (25(OH) D) has been postulated as a key modulator in several cancer-related pathways, although its contribution to PTC still remain controversial. The aim of the study was to analyse the correlation between 25(OH)D serum levels and 25(OH)D insufficiency as well as the risk of development of PTC and its variants: classical type (CV-PTC), tall cell type (TCV-PTC) and follicular variant (FV-PTC).
Methods
The study included 259 patients: 112 patients diagnosed with PTC (CV-PTC, n = 78; TCV-PTC, n = 8; FV-PTC, n = 26), and 147 patients diagnosed with benign thyroid nodules, all aged 43-71 $\pm$ 7 years. Diagnosis of the PTC and its variants was confirmed with cyto/histopathological examination. The serum levels of 25(OH)D were measured by fully automated chemiluminescentmicroparticle immunoassay (CMIA). 25(OH)D insufficiency was defined as a serum 25(OH)D level $<$75 nmol/l.
Results
The prevalence of 25(OH)D insufficiency was 38.2%. Serum 25(OH)D levels and the prevalence of 25(OH)D insufficiency showed no significant differences between both group of patients (P=0.65). Among PTC patients, 25(OH)D insufficiency was not associated with any PTC subtype or other clinical manifestation (P=0.87).
Conclusions
This study shows no association of 25(OH)D insufficiency with the development of PTC, different PTC subvariants or any other clinical characteristic of PTC.

A rare cause of metastasis to the thyroid gland: cervical carcinoma

Erhan Hocaoglu, Ensar Aydemir, Coskun Ates, Filiz Mercan Saridas, Soner Cander, Ozen OZ GUL, Canan Ersoy & Erdinc Erturk
Uludag University Medical School, Endocrinology, Bursa, Turkey

Introduction
Metastasis to the thyroid gland is a rare clinical presentation. The most common sites of primary tumors that metastasize to the thyroid gland are kidney, lung, gastrointestinal system and breast. Primary gynaecological tumors are account for only 3% of secondary thyroid malignancies. Here, we present a case of thyroid metastasis from squamous cell carcinoma (SCC) of the cervix.
Case
A 54-year-old female was consulted to our clinic with the pathology result of subtotal thyroidectomy. Five years ago, she had been diagnosed with cervical SCC treated with total abdominal hysterectomy and bilateral salpingo-oophorectomy and radiotherapy. The patient had no other known comorbidities. She had a history of lung metastasis. Two months ago, in addition to lung, pathological increased activity uptake (SUVmax 5.7) in the right thyroid lobe was reported in PET-CT. A 7.6 mm hypoechoic nodule was detected in the right thyroid lobe on ultrasound, and the result of fine needle aspiration biopsy was reported to be compatible with SCC. She was operated for lung metastasis last month, SCC was found in two regions, and adenocarcinoma in one region, respectively. Afterwards, right subtotal thyroidectomy was performed for suspected thyroid metastasis. The pathology result was reported as metastatic SCC. Tumoral tissue was 18x17x10 mm and tumor cell groups were scattered among the thyroid follicles. When the patient was consulted, thyroid function tests were normal, calcitonin was negative, thyroglobulin level was 22.4 ng/ml and anti-thyroglobulin 1.5 IU/ml. Thyroglobulin and thyroid transcription factor-1 (TTF-1) staining were requested from the pathology of the patient and negative staining was obtained. The patient was accepted as thyroid metastasis of cervical cancer. In addition to chemotherapy, the patient received radiotherapy to the neck and thorax. Six months later, a 23x20 mm soft tissue lesion was detected in the right thyroid lobe on ultrasound. Three months after that, a 45 mm mass (SUVmax 8.9) extending from the right thyroid lobe to the vertebral corpus was detected on PET-CT. Tracheostomy and gastrostomy were performed. The patient died shortly after.
Conclusion
Thyroid metastasis from cervical cancer is very rare and only a few cases have been reported. Patient who present with a thyroid nodule and has a history of a previous malignancy should be evaluated for metastatic disease.

Thyroglobulin is a poor predictor of differentiated thyroid cancer in patients operated for thyroid nodular diseases

Shoham Rigbi[1], Lior Baraf[2, 3], Ben-Zion Joshua[3,4], Uri Yoel[2, 3] & Merav Fraenkel[2,3]
[1]Ben Gurion University of the Negev, Goldman School of Medicine, Be'er Sheva, Israel; [2]Soroka Medical Center, Endocrinology, Be'er Sheva, Israel; [3]Ben Gurion University of the Negev, Faculty of Health, Be'er Sheva, Israel; [4]Barzilai Medical Center, ENT, Ashkelon, Israel

Background
Thyroglobulin, serves as a specific tumor marker following thyroidectomy in differentiated thyroid cancer (DTC) patients. However, its role as DTC predictor in patients with thyroid nodules (TN) is controversial.
Aim
We aimed to assess the potential role of preoperative serum thyroglobulin concentration to predict DTC in patients who were operated for thyroid nodular disease.
Methods
This retrospective study included patients who had partial or total thyroidectomy between January 2014 and May 2019, with preoperative diagnosis of benign multinodular goiter (MNG) or a TN with indeterminate cytology (INC; Bethesda system 3/4 categories). We compared patients for demographic, clinical, imaging, and biochemical data according to their final diagnosis: DTC or benign TN disease. Further statistical analysis included odds ratios calculation and receiver-operator curves (ROC) analysis.
Results
Of 131 patients who met inclusion and exclusion criteria, the indication for surgery was benign MNG in 69, and TN with INC in 62 patients. Final diagnosis of DTC was reported in 18/69 (26%) and 30/62 (48%) of patients with preoperative diagnosis of benign MNG and INC-TN, respectively. Preoperative Median thyroglobulin was 148.5 ng/ml (IQR 67.8-1158.5) vs. 190 ng/ml (IQR 62.4-574), in malignant and benign MNG respectively ($P=$ 0.97), and 160.5 ng/ml (IQR = 82.2-536.7) vs. 205.5 ng/ml (IQR = 65.2-821.5) in malignant and benign INC-TN respectively ($p=$ 0.93). Nodule diameter, TSH level, and thyroglobulin did not differ between patients with final diagnosis of DTC versus those with benign histology.
Conclusion
Preoperative serum thyroglobulin alone is insufficient to differentiate preoperatively between malignant and benign thyroid disease.

An unusual association between medullary thyroid carcinoma and testicular seminoma: Chemotherapy-induced complications, genetic predisposition or random relationship?

Allin Septar[1], Romeo Smarandache[2], Dan Alexandru Niculescu[1], Andrei Goldstein[1], Elena Braha[2], Andrei Muresan[2], Andra Caragheorgheopol[2], Dana Terzea[1], teodor constantin[2], Larisa Buduluca[1] & Madalina Musat[2,3]
[1]Inst. National de Endocrinologie C.I. Parhon, Bucuresti,; [2]Inst. National de Endocrinologie C.I. Parhon, Bucuresti, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Bucharest, Romania

Medullary thyroid carcinoma (MTC) is a rare malignancy arising from parafollicular C cells of the thyroid gland, sometimes due to germline mutations in the RET protooncogene. Testicular cancer is the most common malignancy in men aged 15 - 40 years with survival rates improved by the introduction of cisplatin therapy in the late 1970s. Nonetheless, platinum-based chemotherapy was shown to increase the risk of a solid second cancer with substantially increased site-specific risk of malignancies of thyroid, melanoma, kidney and bladder.
Case report
We present the case of a 42-year-old man diagnosed with MTC during oncological follow-up for testicular seminoma.18FDG PET-CT showed increased uptake in a single thyroid nodule 1 month after completion of chemotherapy (3 cycles of cisplatin, etoposide and bleomycin). The patient had left orchiectomy 8 months before. Thyroid ultrasound revealed an isoechoic nodule on the lower right lobe of 4.7/3.5/3.5 cm and suspicious bilateral lymph nodes. High serum levels of calcitonin (3820 pg/ml), carcinoembryonic antigen (12.2 ng/ml) and fine-needle aspiration citology smears were suggestive of MTC. Screening for other components of multiple endocrine neoplasia 2 syndromes was negative and no germinal mutations in the RET gene were detected either. Total thyroidectomy along with bilateral neck lymph node dissection were performed. Pathology yielded a diagnosis of MTC in the right lobe with metastasis in one ipsilateral lymph node. Immunohistochemistry revealed diffuse staining for Chromogranin A, TTF1 and CEA, weak focal staining for Calcitonin and strong SSTR2 and SSTR5 positive staining. Postoperative follow-up at 6 and 8 weeks revealed high serum calcitonin (338 pg/ml) and cervical ultrasound showed a small tissue remnant in thyroid bed and several suspicious cervical lymph nodes. No other mets were detected on 18FDG PET-CT. Second intervention surgery for neck dissection was performed with several metastatic lymph nodes excision and calcitonin reassessment was scheduled at 6 wks postop follw-up.
Discussion
The relationship between papillary and follicular thyroid cancer along with testicular germ cell tumour has been described as a consequence of cisplatin chemotherapy, however literature review showed no association of MTC and testicular seminoma so far. Screening with Next Generation Sequencing panel for 4813 Genes (TruSight^{TM}) is under consideration.
Conclusion
Association of Ret negative MTC and testicular seminoma diagnosed 8 months apart suggest synchronous association of the two cancers worth of a wider genetic screening with NGS.

Male gender is independent factor of poor prognosis in medullary thyroid cancer

Arseny Semenov[1,2], Roman Chernikov[1], Dmitry Buzanakov[1, 2], Anna Zolotukho[2], Anna Uspenskaya[1], Nataliya Gorskaya[1], Ivan Ziborov[2], Igor Chinchuk[1], Konstantin Novokshonov[1], Yuliya Karelina[1], Fedorov Elisey[1], Viktor Makarin[1], Dina Rebrova[1], Shamil Shihmagomedov[1] & Iliya Sleptsov[1,2]
[1]Saint Petersburg State University, Saint Petersburg State University clinic, Saint-Petersburg, Russian Federation; [2]Saint Petersburg State University, Medical Faculty, Saint-Petersburg, Russian Federation

Background
*The medullary thyroid carcinomas comprise 5-7% of all thyroid carcinomas. At the same time, they are responsible for up to 13% of all deaths of thyroid cancer.*Incidence of sporadic medullary thyroid cancer in population 5-6 time higher in women, probably partially because women are likely to have thyroid nodules and undergo medical examination.
Objective
The aim of the study is to determine how gender affects prognosis in patients with medullary thyroid carcinoma
Materials and methods
A continuous retrospective cohort study of patients who underwent primary surgery for medullary thyroid carcinoma in 2010-2020 at the N.I. Pirogov Clinic for Advanced Medical Technologies, Saint Petersburg University, was conducted. Preoperative ultrasound data, basal serum calcitonin levels preoperatively and postoperatively on the 1st day after surgery, as well as histological examination data of surgical specimens were evaluated. Postoperative observation data for a period of at least 1 year were obtained for 347 patients. Patients were distributed by age to 6 age groups. Data analysis was performed using Tibco Statistica 14
Results
Patients were divided by percentage or by age and compared with each other. Male patients had a larger tumor size and basal calcitonin levels in all groups except over 70 years of age. The difference was significant and did not depend on the RET status of heritability. It is noted that with increasing age, the odds ratio of an aggressive course increased from 3.2 in all patients under 50 years to 9.25 from 50 to 60 years and 49.9 from 60 to 70 years. In the group over 70 years of age, OR is not significant due to the small number of patients and the death of most male patients with aggressive forms at an earlier age. Mostly medullary thyroid cancer even metastatic is indolent and found occasionally so difference caused by higher rate of symptomatic disease in men was found insignificant. The male sex significantly correlated with the risk of invasion into the surrounding tissues 0.715503, necrosis 0.547170, perineural growth 0.550827, the number of affected lymph nodes in the central and lateral tissues of the neck 0.465853 and 0.406780 respectively, with a probability of repeated interventions 0.485560 and a shorter recurrence period 0.444950. With a weak correlation with the node size of 0.255830.
Conclusion
the male gender is associated with a greater risk of aggressive course of medullary thyroid carcinoma, less effective surgical treatment, and greater need for target therapy.

Thyroid Carcinoma in patients with Graves' Disease: about 7 cases

Rachida Bouattay, Maroua Naouar, Emna Bergaoui, Heyfa Belhadjmiled, Mehdi Ferjaoui, Amel Elkorbi, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
[1]Fattouma Bourguiba Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
Graves' disease (GD) is an autoimmune disorder characterized by diffuse hyperplasia and excessive production of thyroid hormone. The association between thyroid carcinoma and GD is controversial. Thyroid nodular lesions in patients with GD should raise a high suspicion of carcinoma. The aim of this study is to focus on the possibility of an association between hyperthyroidism and thyroid Carcinoma.
Materials and Methods
This is a retrospective study about 7 cases of differentiated thyroid cancer out of 52 patients operated for Graves' disease in ENT department of Fattouma Bourguiba Hospital of Monastir during a 20-year period (2000-2020).
Results
All patients were female. The average age was 50 years [17-68]. Preoperative thyroid ultrasound revealed a nodular goiter in all cases, suspicious nodules in 4 cases. Indications for surgery included the following: resistance to medical treatment in 2 cases and nodular goiter with suspicious nodules in 4 cases. Frozen histological examination disclosed the presence of carcinoma in 5 cases. These patients underwent a total thyroidectomy, associated to bilateral central neck lymph node dissection. The histology concluded to the diagnosis of a papillary carcinoma in all cases. Among them, there were 2 cases of microcarcinoma. None of the cases showed lymph node metastasis. Surgical treatment was followed by radioactive iodine therapy in all cases. With a mean follow-up of 4 years, there was no distant metastasis or cancer recurrence.
Conclusion
Thyroid nodular lesions in patients with GD are not uncommon. Thus, careful evaluation of all thyroid nodules in GD patients is essential. It seems reasonable to check GD patients for the development of possible thyroid carcinoma, even if they are nodule free.

Prevalence of differentiated thyroid carcinoma on hyperfunctioning or toxic thyroid nodules

Sandra Amuedo Domínguez[1], Irene De Lara Rodríguez[1], Ana R. Romero Lluch[1], Suset Dueñ as Disotuar[1], Juan L. Tirado Hospital[2] & Elena Navarro[1]
[1]Virgen del Rocío University Hospital, Department of Endocrinology and Nutrition, Seville, Spain; [2]Virgen del Rocío University Hospital, Department of Nuclear Medicine, Seville, Spain

Background
Autonomic hyperfunctioning thyroid nodules account for approximately 5% to 10% of all thyroid nodules. Compared with non-toxic nodules, hot nodules are traditionally believed to have an exceptionally low malignancy rate, and this has led to recommendations not to perform fine-needle aspiration (FNA) on these lesions, regardless of their size. However, recent studies have questioned the presumed low risk of malignancy in hot nodules, suggesting that the incidence of cancer has been underestimated and the need for further studies to provide more evidence in this regard.
Aims
1) To assess the prevalence of differentiated thyroid carcinoma (DTC) in the definitive histological examination in patients who underwent total thyroidectomy or hemithyroidectomy due to unique toxic nodules in a tertiary hospital. 2) To verify the existence of ultrasound predictors of malignancy on toxic nodules.
Methods
Retrospective descriptive study. Inclusion criteria: gammagraphically unique hot nodules from 2006 to 2021. Exclusion criteria: toxic multinodular goiters. Demographic data, performance or not of FNA, ultrasound characteristics of the nodules and thyroid function record at diagnosis were analyzed.
Results
The ultrasound classification by ACR TI-RADS of the remaining 68 benign nodules was: 1.5% TR1, 20.6% TR2, 20.6% TR3, 28% TR4, 1.5% TR5 and 28% unknown.
Conclusions
The prevalence of malignancy on the operated nodules was 4.2% (slightly lower than that described in the literature for non-toxic nodules). Higher scores in the malignancy risk scales on solitary toxic nodules could suggest the need to perform FNA on them.

Table 1 Baseline Demographic Characteristics

Toxic nodules (n)	172
Age (years)	64.4 ± 12.7
Gender (women), % (n)	74.4 (131)
Mena nodule size(mm)	28 ± 7.8
Underwent surgery,% (n)	41.3 (71)
Benign histology % (n)	95.7 (68)
Malignancy histology % (n)	4.2 (3)

Table 2 Sonographic characteristics of malignant interventional toxic nodules

Histologically confirmed DTC (3)	Risk ACR TI-RADS	Risk ATA
Papillary Carcinoma	4	Intermediate
Papillary Carcinoma	5	High
Follicular Carcinoma	3	Low

King of the CASTLE? Immunohistochemistry in diagnosing rare thyroid carcinomas: a case report

Mihaela Stanciu[1,2] & Ruxandra Paula Ristea[2]
[1]"Lucian Blaga" University of Sibiu, Faculty of Medicine, Endocrinology, Sibiu, Romania; [2]Academic Emergency Hospital of Sibiu, Endocrinology, Sibiu, Romania

Introduction
Carcinoma showing thymus-like differentiation (CASTLE) is a rare, low-grade thyroid carcinoma, with indolent clinical course and usually a favorable prognosis. The clinical and imagistic features are not specific for CASTLE but similar to other malignant lesions of the thyroid, making diagnosis difficult and reliant on immunohistochemical examination. The conclusive diagnosis requires pathological examination and positive cluster of differentiation 5 (CD5) immunoreactivity
Case Report
Hence, the present paper aims to present a rare case of CASTLE compressing the trachea in a 50 year-old female patient, after being misdiagnosed in another center with undifferentiated thyroid carcinoma, for which she underwent an unsuccessful surgical procedure followed by postoperative radiotherapy and chemotherapy. The patient sought out a second opinion, for the investigation of an 18 months history of persistent dyspnea, dry cough, weight loss, loss of appetite, and fatigue, associated with dysphagia and dysphonia. The patient underwent a challenging radical surgery, total thyroidectomy and cervical lymphadenectomy being performed. Histopathological analysis of the specimen showed large areas of fibrosis, large, round vesicular nuclei with small nucleoli, low cytoplasm and peritumoral lymphoplasmacytic infiltration. Immunostaining for CD5 was positive. Postoperatively, no adjunctive radiotherapy was recommended, no acute complications were reported, replacement therapy with Levothyroxine was initiated, metastatic follow-up was negative and there was no evidence of loco-regional recurrence after 6 months of follow-up.
Conclusion
The diagnosis of CASTLE is difficult and requires a rigorous histological analysis and positive CD5 immunoreactivity. The improvement of long-term survival is based on the level of tumoral invasion in the adjacent structures, absence of metastasis and successful resection of the tumor and neck dissection. The particularity of this case consists in emphasizing the importance of establishing the accurate diagnosis for obtaining optimized management, with the purpose of reducing unnecesessary procedures.

Thyroid storm in a patient with severe leptospirosis managed with veno-venous extracorporeal membrane oxygenation

Roy Christopher Ang & Yasmin Laura Marie Zuñiga
National Kidney and Transplant Institute, Division of Internal Medicine, Quezon City, Philippines

Background
Leptospirosis is an endemic zoonosis in the Philippines, with complications including jaundice from liver injury and acute kidney injury requiring renal replacement therapy. On the other hand, thyroid storm, most commonly in the setting of Graves's disease, is a rare complication of hyperthyroidism. To date, thyroid storm has not been documented in patients with severe leptospirosis.
Case Presentation
Herein, we present the case of a 52-year-old man, with no known thyroid disease and with prior wading in flood waters, who presented with fever, conjunctival suffusion, icterisia, and oliguria. He arrived on the 7th day of illness with hypotension and atrial fibrillation. Workups revealed low thyroid stimulating hormone (TSH), elevated free T4 (FT4), and elevated free T3 (FT3). There was also elevated serum creatinine, leukocytosis, and thrombocytopenia. He was diagnosed with severe leptospirosis, started on ceftriaxone intravenously, and underwent hemodialysis. He subsequently developed hemoptysis, prompting intubation and veno-venous extracorporeal membrane oxygenation (V-V ECMO) . Thyroid storm was suspected when he had persistent fever in the background of hyperthyroidism and atrial fibrillation. After starting propylthiouracil, super-saturated potassium iodide, and intravenous hydrocortisone, there was lysis of fever and improvement in hemodynamic status. On the 3rd day of V-V ECMO, significant improvement in oxygenation and resolution of pulmonary hemorrhage allowed weaning and decannulation. There was, however, eventual development of ventilator associated pneumonia and agranulocytosis, prompting the discontinuation of propylthiouracil. Despite the addition of broad-spectrum antibiotics, intractable metabolic acidosis and hypotension ensued, which led to the patient's demise. TSH receptor antibody was eventually revealed to be undetectable, while thyroid ultrasound was unremarkable.
Discussion
Overlap of symptoms between thyroid storm and severe leptospirosis, such as fever and jaundice, may delay early diagnosis and management of thyroid storm. Furthermore, the full therapeutic regimen was not maximized due to hypotension and development of agranulocytosis. While there is documented success on the use of V-V ECMO in severe leptospirosis, the utility of ECMO in thyroid storm is limited to Veno-Arterial ECMO for thyrotoxicosis-induced cardiomyopathy. To date, there have been no published reports of leptospirosis occurring simultaneously with thyroid storm.The absence of thyroid nodules or a diffusely enlarged thyroid gland, together with an undetectable thyroid receptor antibody, should prompt consideration of destructive thyroiditis from severe leptospirosis.
Conclusion
The case highlights diagnostic and management challenges in a rare case of thyroid storm in the setting of severe leptospirosis.
Keywords: ECMO, leptospirosis, thyroid storm, Weil's

Thyroid abscess as a complication of post-COVID-19 subacute thyroiditis: a case report

Loubna Guissi, Ikram Amira, Kaoutar Rifai, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Thyroid abscess is a rare pathology, with the incidence of less than 1% of all thyroid diseases. We describe a unique case of thyroid abscess complicating post-covid-19 thyroiditis, which is the first case reported in Morocco to our knowledge.
Case presentation
A 39-year-old man who had recently recovered from a mild episode of COVID-19 infection, consulted for weight loss, palpitations and neck pain. Examination of the neck revealed enlarged, firm, and tender thyroid gland. His electrocardiography revealed sinus tachycardia. Laboratory tests showed elevated erythrocyte sedimentation rate at 40 mm/h and c-reactive protein at 75 mg/l. TSH was low ($<$ 0.05 mU/l), T4 and T3 levels were elevated at 7.72 ng/dl (reference 0.77-2.02) and 11.23 pg/ml (reference 2.2-4.6), respectively. Thyroid peroxidase antibody and TSH-receptor antibody were negative. Ultrasound of the neck showed heterogeneous goiter with areas of thyroiditis, and reduced blood flow on Doppler study. The diagnosis of subacute thyroiditis was made, and the patient was discharged home on oral prednisone (60 mg) and atenolol (40 mg) daily. During the follow-up, the prednisone was gradually tapered off over 7 weeks, and atenolol was discontinued. The thyroid function tests returned to normal at 9 weeks follow up, however the patient developed a cervical swelling with pus discharge. Ultrasonography was consistent with Thyroid abscess. A retroviral screening for Human Immunodeficiency Virus was negative. Culture of the pus from the abscess obtained during the fine needle aspiration grew Staphylococcus aureus. The patient was successfully treated with percutaneous drainage and oral amoxicillin clavulanate.
Discussion
Thyroid abscess is a less seen diagnosis, mostly so as the gland is inherently protected. The encapsulation, rich blood and lymphatic supply, and iodine content inside offer the gland protection from being seeded. Thyroid abscess usually occurs in patients who are immuno-compromised, those with pre-existent thyroid pathologies or anatomic gland anomalies. Some authors have related thyroid abscess to neoplastic causes, thyroid nodule, subacute thyroiditis, Hashimoto's thyroiditis or traumatic causes. In our case, when no immunosuppression or anatomical factors are present, there was sufficient clinical and biological evidence within reasonable limits that failed to yield any other risk factor for thyroid abscess other than subacute thyroiditis that the patient developed after SARS-COV-2 infection.
Conclusion
Thyroid abscess is an unusual complication of post-COVID-19 subacute thyroiditis and can lead to significant morbidity. Therefore, clinicians must be aware of the presenting features and therapeutic options.

Ectopic lingual thyroid presenting as massive bleeding in a high-risk surgical patient treated with radioactive iodine

Joaquin De Carlos, Jose Javier Pineda, Emma Anda, Marta Toni, Maria Dolores Ollero, Patricia Munarriz, Ana Irigaray, Ander Ernaga & Nerea Esparza
Hospital Universitario de Navarra, Pamplona, Spain

Introduction
Lingual thyroid ectopia is a rare congenital abnormality affecting embryogenesis of the gland descent from foregut through pre-tracheal region in the neck. Most cases have an asymptomatic course but may occasionally produce local obstructive symptoms. Diagnostic methods are ^{99m}Tc, ^{131}I or ^{123}I radionuclide scan, computed tomography scan, magnetic resonance, and ultrasound. Surgery is the elective treatment for cases presenting complaints or complications. Radioactive iodine ablation is an alternative for patients who refuse surgical intervention or unfit for anesthesia. We report 49-year-old women with an ectopic lingual thyroid presented as oral hemoptysis with high surgical risk, successfully treated with ^{131}I.
Materials and methods
A case report description conducted with the consent of the patient and with provisions of the Declaration of Helsinki.
Results
49-year women with relevant medical history such as primary hypothyroidism under thyroid hormone replacement, well controlled type 2 diabetes, HTA and morbid obesity (BMI 58). Presented to Emergency department with a 12-h history of upper gastrointestinal bleeding, mild dysphagia, and no respiratory symptoms. Gastroscopic examination demonstrates a jet arterial bleed above the epiglottis at the base of the tongue. Intubation was performed with surgical hemostasis by means of pharyngeal packing containing and resolving the hemorrhage. CT of the neck confirmed a well-defined rounded occupational image at the base of the tongue and floor of the mouth, in the midline, with intense and homogeneous enhancement, measuring 35x37x39mm, compatible with ectopic lingual thyroid that imprints on the oropharyngeal lumen. Thyroid ^{99m}Tc combined with single-photon emission computed tomography/computed tomography confirmed an increased radiotracer homogeneous activity on at this location. Hospitalization was complicated with bilateral pneumonia and bilateral acute pulmonary embolism (PESI 59, class I). Surgical option was denied because of patients' comorbidities and associated complications due to this conventional tongue surgery. She was treated with 16.5 mCi of ^{131}I remaining asymptomatic.
Conclusion
Lingual thyroid ectopia is a rare congenital anomality in population, that warrants treatment when it produces obstructive or compressive symptoms or complication arrives. Scintigraphy methods plays a major role in establishing the diagnosis, even though US and TC or RM may also be helpful in the process of differential diagnosis with other cervical masses. Surgery has been the conventional approach to remove ectopic thyroid gland. However, other strategies such as RAI are safe and efficient strategy for high risk surgical and comorbid patients, remaining them asymptomatic.

Methimazole-induced cholestatic jaundice

Soltani Chayma[1], Rym Belaid[1], Abid Naourez[1], Hamzaoui Lamine[2] & Amri Raja[1]
[1]Mohamed Tahar's Maamouri Hospital, Internal Medicine Department, Nabeul, Tunisia; [2]Mohamed Tahar's Maamouri Hospital, Gastro-Enterology Department, Nabeul, Tunisia

Introduction
Methimazole is a widely prescribed antithyroid drug for the treatment of hyperthyroidism with a few adverse effects generally well-tolerated. However, methimazole-induced cholestatic jaundice (CJ) is a rare but serious adverse reaction. Herein we report a rare case of methimazole-induced CJ in a woman with hyperthyroidism.
Case report
A 57-years-old women presented to our endocrinology department with a 2-week history of asthenia, insomnia, tremulousness, and swollen eyes. On Physical examination she had a body weight of 69 kg, a body mass index of 23 kg/m^2, a blood pressure of 130/70 mm Hg and a pulse rate of 100 beats per minute. The neck examination revealed a homogenic and elastic goiter with a thrill. The eye examination showed bilateral and symmetric upper eyelid retraction, swelling and grade 1 exophtalmos. Laboratory tests showed hyperthyroidism with a low TSH of 0.006 µIU/ml and elevated freeT4 of 52.36 ng/l(9-17). The liver enzymes were normal. The ultrasound of the thyroid revealed a diffuse micronodular and hypervascular thyroid gland. Thyroid scintigraphy showed homogenous increased uptake of the thyroid gland. She was started on methimazole 30 mg a day and propranolol 10 mg three times a day. Six weeks later, she returned with severe jaundice, pruritus, dark urine and light-colored stool. The clinical findings showed a severe icterus. Physical examination of the abdomen, heart, liver, and spleen were unremarkable. She had neither fever nor signs of chronic liver disease. Initial tests were consistent with a CJ: elevated alanine aminotransferase 168 U/l (10-45), aspartate aminotransferase 213 U/l (10-40), gamma glutamyl transferase 129 u/l (7-50) and significantly elevated alkaline phosphatase 952 U/l (35-104), total bilirubin 321 mg/dl (5-17), conjugated bilirubin 319 mg/dl (2-5). The prothrombin time was normal. The hepatobiliary ultrasonography excluded biliary obstruction. The viral hepatitis, autoimmune hepatitis and primary biliary cirrhosis were also ruled out. Cholestatic jaundice due to methimazole was very likely. The medication was discontinued immediately. The patient was started on prednisone 1 mg/kg/day. The recovery was slow but complete after 7 weeks of methimazole withdrawal. She was then referred for iodine radiation treatment.
Conclusion
We discuss this case to study the rare association between methimazole use and cholestatic jaundice. This drug can cause severe but reversible CJ. Thus, physicians and patients should be aware of this adverse effect so that they can discontinue methimazole therapy upon the occurrence.

Auto-immune polyglandular syndrome type IIIa: a case report

Rym Belaid, Soltani Chayma, Garbouj Wafa, Alaya Zeineb & Amri Raja
Mohamed Tahar's Maamouri Hospital, Internal Medicine Department, Nabeul, Tunisia

Introduction
Autoimmune polyglandular syndromes (APS) are rare polyendocrinopathies characterized by the failure of several endocrine glands as well as nonendocrine organs, caused by an immune-mediated destruction of endocrine tissues. The type IIIa APS is the association of thyroid autoimmune diseases, type 1 diabetes mellitus and other autoimmune conditions excluding Addison's disease and hypoparathyroidism. Herein, we report the case of autoimmune hypothyroidism associated to type 1 diabetes, systemic lupus erythematosus (SLE) and primary biliary cirrhosis (PBC) in a young woman.
Case report
A 35 years-old woman with a medical history of type 1 diabetes treated by insulin since the age of 9 years and autoimmune hypothyroidism diagnosed at the age of 25, presented to our internal medicine department with inflammatory polyarthralgia of the hands, wrests, ankles and shoulders accentuated in the last 4 months. The physical examination showed a butterfly shaped rash of the face, red spots on exposed areas that worsen with sun exposure and oral ulcerations. The blood investigations showed an accelerated erythrocyte sedimentation rate (VS) (80 mm/h), a normal blood white count with no lymphopenia and a normal serum calcium level. The X-rays of the aching joints didn't show erosions or pinches. The immunology tests showed positive anti-nuclear antibodies (ANA) (1/400) and anti-double-stranded DNA (anti-DNA). The SLE was diagnosed according to the criteria of the SLICC with a score of 5 points, ACR with a score of 4 points, EULAR/ACR 2019 with 20 points. The patient was started on hydroxychloroquine 400 mg a day and corticosteroids 10 mg a day. Further investigations were pursued showing an immunological profile compatible with PBC that was inactive at the moment of the diagnosis. The diagnosis of APS type IIIa was made after excluding an adrenal insufficiency by a normal 250 µg synacthen test.
Conclusion
We report the case of a female with type 1 diabetes, auto-immune hypothyroidism, SLE and PBC, which is a very rare combination. We present this case as evidence for the coexistence of several different immune-mediated diseases in the clinical context of a APS type IIIa. Thus, a regular follow up of these patients is needed to detect and treat the other auto-immunes disorders at an early stage.

Coexisting grave's disease and coeliac disease in an adolescent with down's syndrome

Anissa Ben Bouzid, Rym Belaid, Nada Ben Abdelaziz, Naourez Abid & Raja Amri
Mohamed Tahar's Maamouri Hospital, Internal Medicine Department, Nabeul, Tunisia

Introduction
Trisomy 21 is the most common chromosomal disorder. It is associated with an increased risk of endocrinopathy particularly thyroid gland disorders. This is frequently a compensated hypothyroidism. Hyperthyroidism is rare. We report the case of an adolescent with Down's syndrome and celiac disease who presented with subclinical hyperthyroidism.
Case report
It was a 15-year-old female from a non-consanguineous marriage with a history of celiac disease on a gluten-free diet. The physical examination showed a stable weight of 48 kg, a height of 146 cm and a body mass index of 22.53 kg/m^2. She had a goiter visible in extension of the neck but no exophthalmos. She had no history of excessive sweating, diarrhea or tremors. Cardiovascular examination was unremarkable. Blood investigations noted a normochromic normocytic anemia of 11.3 g/dl. The thyroid assessment done as a part of an annual biological monitoring showed a TSH of 0.005 mUI/l and a free T4 of 17.21 pmol/ml (12-22). Anti-TSH receptor antibodies were positive. Cervical ultrasound showed a diffuse enlargement of the thyroid. The diagnosis of Grave's disease was retained.
Conclusion
Down's syndrome is a breeding ground for thyroid dysfunction. Celiac disease is common in people with down's syndrome and it is associated to various endocrine autoimmunities such as thyropathies. Hyperthyroidism is extremely rare. The diagnosis is often made through a systematic assessment, hence the interest of a biological control aimed at detecting dysthyroidism early to avoid complications that are potentially serious. The particularity of our observation was the association of celiac disease and grave's disease in an adolescent discovered by an annual thyroid check-up.

Primary thyroid lymphoma: case report

Hatice Sebile Dökmetaş[1], Kü bra Karaipek[2], Meriç Dökmetaş[2], Fatih Kılıçlı[1], Ayberk Bayramgil[2], Güneş Dorukhan Çavuşoğlu[2] & Yaşar Özdenkaya[3]
[1]Medipol Mega University Hospital, Endocrinology, Istanbul, Turkey; [2]Medipol Mega University Hospital, Internal Medicine, Istanbul, Turkey; [3]Medipol Mega University Hospital, General Surgery, Istanbul, Turkey

Introduction
Primary thyroid lymphoma is a rare malignancy. In many series, it is reported that it is seen at a rate of 0.6-5% among thyroid cancers and approximately 2% among extranodal lymphomas. It is often seen as a painless mass in the neck. Almost all of them have underlying Hashimoto's thyroiditis. In many instances, thyroid lymphoma was recognized after thyroid surgery for suspected carcinoma. The most common thyroid lymphomas are B-cell and Hodgkin lymphomas. The distinction between primary and secondary lymphoma is important because of the variables in diagnosis, treatment, and prognosis. Surgery, chemotherapy, radiotherapy, or combinations can be used in the treatment.
Case
A 69-year-old male patient underwent total thyroidectomy and central neck dissection due to a 3.5x2.5 cm nodule in the right thyroid lobe. During the operation, it was observed that the mass lesion in the right lobe had progressed to the lateral carotid and invaded the right internal jugular vein. In addition, partial right internal jugular vein excision was performed. The pathology report was determined as large B-cell lymphoma and lymphocytic thyroiditis findings were observed in the surrounding thyroid tissue. Lymphoma involvement was present in most of the lymph nodes. There was vascular and muscle invasion. In patient blood tests free T3:1.7 pg/ml (N:2.04-4.4), free T4:1.15 pg/ml (N:0.93-1.7) TSH:3.72 mIU/ml (N:0 .27-4.2), and Thyroid autoantibodies negative detected. The patient received 4 cycles of R-CHOP (Adriamycin + Cyclophosphamide + Rituximab + Vincristine) chemotherapy protocol. The before and after treatment PET-CT was reported as: The focus showing pathological 18F-FDG uptake in favor of malignant involvement in the whole body cannot be identified.
Conclusions
Thyroid lymphoma, which is rarely seen in patients presenting with a thyroid mass, should also be considered. While Hashimoto's thyroiditis is seen in most primary thyroid lymphomas, primary thyroid lymphoma develops in only 0.6% of Hashimoto's thyroiditis cases.

Influence of the mother's history during pregnancy on the development of hyperthyroidism in children living in conditions of iodine deficiency

Shakhlo Muratova[1], Anvar Alimov[1] & Shakhnoza Azimova[2]
[1]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician E. Kh. Turakulov of the Ministry of Health of the Republic of Uzbekistan, Thyroidology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician E. Kh. Turakulov of the Ministry of Health of the Republic of Uzbekistan, Pediatric Endocrinology, Tashkent, Uzbekistan

Our goal was to determine the anamnestic characteristics of mothers during pregnancy in children with hyperthyroidism living in conditions of iodine deficiency, which possibly contribute to the development of hyperthyroidism in patients of the pediatric group.
Materials and methods of research
the analysis of the anamnesis of mothers during pregnancy of 146 children and adolescents with hyperthyroidism. The control group consisted of 97 relatively healthy children under 18 whose parents agreed to participate. Statistical processing of the results was carried out using the statistical software packages 'SPSS 23 for Windows' ('IBM Corp. Armonk', NY, USA).
Results
Analysis of the mother's anamnesis during pregnancy of children and adolescents with hyperthyroidism are presented in Table 1. The results obtained indicate that the presence of autoimmune thyroid disease in the mother increases the risk of developing hyperthyroidism in the child by 7.5-8.2 times (OR = 8.2 (95% CI 3.1-21.5), $P<0.001$), while endemic maternal goitre during pregnancy and systemic autoimmune diseases (OR = 2.6 (95%

Table 1 Anamnesis of the mother during pregnancy of the studied children

		n	%	Chi-square	p
Graves' disease	Hyperthyroidism	11	7,5	0	
	Control	0	0

CI 0.7-9.4), $P=0.69$) is not a reliable provoking factor (OR = 1.4 (95% CI 0.5-3.8), $P=0.36$). In addition, overweight and obesity (OR = 3.9 (95% CI 1.1-13.6), $P=0.03$), as well as anemia of varying severity in pregnant women (OR = 5.8 (95% CI 2.2-15.4), $P<0.001$) may increase the risk of developing hyperthyroidism in children. At the same time, vitiligo (0.7%), type 2 diabetes mellitus (2.1%), polycystic ovary syndrome (0.7%) were diagnosed only in mothers whose children had hyperthyroidism.
Conclusion
possible factors that increase the risk of developing hyperthyroidism in children living with iodine deficiency are the following maternal anamnestic indicators during pregnancy: Graves' disease, autoimmune thyroiditis, overweight and obesity, anaemia of pregnancy, type 2 diabetes mellitus, vitiligo and polycystic ovary syndrome.

Thyroid disease in patients with type 1 diabetes

Joaquin De Carlos, Francisco Javier Basterra, Amaya Sainz De Los Terreros, Javier Garcia, Marta Garcia, Ana Iriarte, Miguel Marti & Maria Jose Goñi
Hospital Universitario de Navarra, Pamplona, Spain

Introduction
An increased risk of thyroid disease (TD) has been described in patients with type 1 diabetes (DM1) with respect to the general population. The objective is to establish the incidence and characterize the differences in patients who develop TD in relation to the debut of DM1 (previous, concurrent or a posteriori).
Materials and methods
Retrospective study of 1126 patients followed up in Endocrinology consultations in Navarra. Three types of TD were differentiated: hyperthyroidism (HI), hypothyroidism (HO) and autoimmune thyroid disease with normo function (AT). Clinical and analytical variables were analyzed. Comparison between the medians of the groups was performed using the Mann Whitney U test. Differences between categorical variables were analyzed using the $\chi 2$ test.
Results
The study population included 669 men (59.3%) and 459 women (40.7%), with a mean age at debut of 20 years and a mean follow-up of 11.4 years (7.6 sd). A total of 300 (26.6%) developed thyroid disease. The analysis of the 32 that already had TD before the onset of DM1 (8 HI, 21 HO, 3 AT) revealed thar women, gastric autoimmunity and younger patients had a higher risk of developing TD. 87 patients presented concurrent TD (10 HI, 40 HO, 37 AT) at the onset of DM1. Female gender, debut over 45 years and positive gastric autoimmunity was also more frequent in those 181 patients that developed TD at follow up (16 HI, 102 HO, 63 AT) of the DM1.
Conclusion
In the population studied, the cumulative incidence of TD in the follow-up of patients with DM1 was high, with hypothyroidism predominating. There are different clinical and analytical variables that can predict which risk groups have a greater predisposition to develop TD before, at the onset or after the diagnosis of DM1. The factors to be taken into account that affect a different susceptibility to develop TD are gender, age at DM1 debut, thyroid autoimmunity and gastric autoimmunity. Although confirmation is required in future studies, they may be indicative for closer surveillance.

Serum selenium status in UK Graves' disease patients with and without orbitopathy

Carla Maden, Pei Chia Eng, Dri Choa, Rochan Agha-Jaffar, Jeremy Cox, Michael Yee, Stephen Robinson & Tessa Fayers
Imperial College Healthcare NHS Trust, United Kingdom

Introduction
Selenium supplementation is recommended for all patients with mild Graves' orbitopathy (GO). The thyroid gland contains high levels of selenium, which has an anti-oxidant effect and a role in the metabolism of thyroid hormones. The study on which this recommendation is based was conducted in countries of a selenium-deficient region and did not measure subjects' selenium concentrations. There is therefore no consensus on optimum dose, duration, or safety. Environmental selenium varies extensively between countries and no published studies report measured the baseline selenium status of UK GO patients. We aimed to determine baseline selenium status in a UK population, and compare this to Graves' patients without GO.
Methods
Baseline serum selenium status was measured in UK Graves' disease patients with and without orbitopathy between January – December 2021.
Results
There were 56 patients; 25 had orbitopathy (the mean Clinical Activity Score was 1.9), (20 females and 5 males, average age 48.8yrs) and 31 did not (26 and 5; 47.5). Average serum selenium was 1.13 (range 0.5-1.93, reference range 0.76-1.46 μmol/l); 1.14 in the GO group vs. 1.12 in the non-GO group. There were 12 current or previous smokers in the GO group (48%) vs. 8 in the non-GO group (26%).
Conclusion
These results show that baseline selenium status in GO and non-GO patients is largely within the normal range. This suggests that selenium may have lesser benefit in the UK compared to regions with lower environmental selenium. Patients may also be at risk of iatrogenic overdose. A randomised control trial investigating the clinical effects of selenium supplementation in a UK GO population with concurrent measurement of selenium status is warranted.

Assessment of thyroid function in healthy pregnant women living in iodine deficiency regions

Anastasia Rybakova, Nadezhda Platonova, Larisa Nikankina, Natalia Malysheva & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation

Background
During pregnancy, the physiology of the thyroid gland undergoes important changes. As a result, change levels of thyroid hormones. In the latest clinical guidelines, experts have recommended to perform population-based studies to determine reference intervals for thyroid hormones.
Aim
To evaluate the reference intervals of free thyroxine in different trimesters of pregnancy in women living in regions with mild iodine deficiency.
Materials and methods
We have conducted the observational multicenter cross-sectional study included 2008 healthy pregnant women at different trimesters of pregnancy, from three regions of the Russian Federation (Moscow, Ivanovo and Smolensk). We assessed the level of free thyroxine, antibodies to thyroid peroxidase, antibodies to serum thyroglobulin (Architect, Abbot, reference range 9-20 pmol/l), the level of iodine concentration in the morning portion of urine (cerium arsenic method) and we have conducted a questionnaire (date birth and gestational age). Women with elevated titers of anti-TPO and/or anti-TG antibodies were excluded from the study (245 women).
Results
We have determined the median iodine concentration: Moscow 111 μg/l, Ivanovo 125 μg/l, Smolensk 133 μg/l, which confirms the presence of mild iodine deficiency in the regions areas (median iodine concentration less than 150 μg/l in pregnant women corresponds to mild iodine deficiency). Reference intervals for free thyroxine are presented using the median, 2.5 and 97.5 percentiles with 95% confidence interval (Me [2.5;97.5] CI+-95%). We obtained the following results: 1st trimester ($n=386$): Me 11.7 [9.03;16.1] CI+1.96; -1.74; 2nd trimester ($n=478$): Me 10.7 [8.35; 13.8] CI+1.43; -1.28; 3rd trimester ($n=899$): Me 9.9 [7.73; 13.0] CI+1.41; -1.30.
Conclusions
Based on the results of our study, we determined the reference intervals of free thyroxine in healthy pregnant women without anti-TPO/TG antibodies living in mild iodine deficiency regions. We revealed a decrease in the level of free thyroxine by the third trimester, which can be physiological isolated hypothyroxinemia.

Impact of age on hypothalamic-pituitary-thyroid axis

Snjezana Popovic Pejicic[1, 2] & Nina Pejicic[2]
[1]Medical Faculty, University of Banja Luka, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina

Background/Aim
Impact of age on hypothalamic –pituitary –thyroid axis, interesting from theoretical and practical aspects, have been studied. Our aim was to find out: correlation between T3 (triiodothyronine) and T4 (thyroxine) hormone level and old age, so as of other, for thyroid function relevant parameters: TSH (thyroid stimulate hormone), TRH (thyreothropin releasing hormone) test, thyroid ultrasonography, thyroid gland scintigraphy with ^{131} J, ^{131}J fixation test, thyroid antibodies and thyroglobulin.
Methods
Study included 125 subjects, divided in four groups, according to the age: control group (from 20 to 40 years); group A (from 41 to 50 years); group B (from 51 to 60 years) and group C (from 61 to 70 years), as well as into subgroups according to the sex. All patients were established total and free hormones T3, T4, TSH and test with TRH; thyroid gland scintigraphy with ^{131} J, ^{131} J fixation tests, thyroid antibodies and thyroglobulin. All hormone analyses, thyroglobulin and thyroid antibodies were determined by radioimmunoassay (RIA). Thyroid scinitgraphy was done with ^{131} J and ^{131} J fixation test was monitored 4, 24 and 48 h after 1.85 MBq test dose applied perorally.
Results
There was a significant decrase in levels with aging of both total and free T4, and, somewhat, minor fall of both total and free T3 in men, in contrast to mild level rise of total T4 and T3 in women, but within the range of eutyroidisam, with no alternations in free hormone levels. A significant fall of thyroglobulin antibodies with aging was observed in the group of males and a considerable increase of thyroglobulin was shown in the group of females. Old age and sex dont' have impact on radio jodine fixation persentage in thyroid gland, thyroid scintigraphy and throid gland echostructure.
Conclusion
Hypothalamic-pituitary –thyroid axis is presereved with aging. The determination of the values of the free T4 should be basic test at older persons. Evident drop in thyroid hormone levels with aging can be considered as adaptation of the organism to reduce requrements for energy, thys representing a significant metabolic parameter of biologic aging process. A normal range of thyroid hormone values shoud be modified for the persons older than 70. These physiological variation should be standardised in the interpretation of the tests of the thyroid function.

Hypothyroidism associated with treatment with immunotherapy: case series

Maria Zhao Montero Benítez, Paloma González Lázaro, Cristina Montalban Mendez, Antonio Moreno Tirado, Pedro Jimenez Torrecilla, Florentino Del Val Zaballos, Amparo Lomas Meneses, Francisco Javier Gó mez Alfonso, Maria Lopez Iglesias & Inés Gómez García
Alcázar de San Juan, Endocrinology Department, La Mancha Centro Hospital Centre, Alcázar de San Juan, Spain

Introduction
The development of immunotherapy has opened up a new approach in the management of different types of tumors that previously had not treatment, and its use is becoming increasingly widespread. Immunotherapy is based on blocking immune checkpoints involved in activating the immune response to malignant neoplasms. Since its introduction into clinical practice, several adverse effects related to the immune system have been reported. Among the endocrinological adverse effects, hypophysitis and thyroid dysfunction are the most frequent. Adrenal insufficiency, DM1 and hypoparathyroidism have also been documented.
Case Series
We present the cases of 5 patients who developed hypothyroidism during immunotherapy treatment at the General La Mancha Centro Hospital and General Hospital in Tomelloso (Ciudad Real, Spain). All patients were male, aged between 56-72 years, and none of them had thyroid disorders prior to the use of immunotherapy. After the diagnosis of advanced oncological disease (melanoma, lung cancer, kidney cancer, and multiple myeloma), it was decided to start immunotherapy treatment, 3 patients with nivolumab (anti PD-1), 1 patient with durvalumab (anti PD-L1), and 1 patient with velcade (proteosomal inhibitor) plus daratumumab (AcMo anti CD38). Several months after starting treatment, patients were diagnosed with hypothyroidism (3 subclinical and 2 central), with asthenia being the main symptom. Antithyroid antibodies were present in 2 patients. In those patients with suspected hypophysitis, an MRI was performed to rule out this pathology, and no cases were observed. After ruling out adrenal insufficiency, which was only documented in the patient treated with velcade plus daratumumab, replacement therapy was initiated, without requiring suspension of immunotherapy in any case.
Discussion
Endocrine disorders related to immunotherapy are increasingly recognized as one of the most common adverse effects. Its diagnosis is sometimes complicated, as symptoms are nonspecific and may overlap with symptoms due to tumor progression. In most cases, the management of these endocrinopathies does not require discontinuation of immunotherapy, although they are usually irreversible and require long-term treatment.
Conclusion
Thyroid dysfunction is a relatively common adverse effect in patients treated with immunotherapy. The risk of developing endocrinopathy is greater at the beginning of treatment, hence the need to monitor thyroid function both at the beginning and during treatment with immunotherapy, in order to carry out an early diagnosis and treatment.

Hyperthyroidism and pregnancy: About 70 patients

Amal Elkhomri, Bensbaa Salma, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
During pregnancy, the thyroid balance of women is altered due to certain hormonal and metabolic changes. It can be all the classic causes of hyperthyroidism, very often in the first trimester it is transient gestational hyperthyroidism.
Objective of the study
The objective of this study is to evaluate the prevalence of hyperthyroidism during pregnancy and the different methods of management.
Materials and methods
Prospective study conducted in the endocrinology and diabetology department, including 70 patients with hyperthyroidism during pregnancy
Results
The results had objectified a mean age of 29 years, with a mean gestational age of 11 SA, with a history of personal thyreopathy in 4 patients, the predominant clinical reason is vomiting in pregnancy, which was present in 98% of patients. On thyroid checkups: The Mean TSHus was 0.05 mIU/l, with mean T4L at 23 ng/l and mean T3L at 7 ng/l, a basedow disease was objectified in 4 patients, and a multi-heteronodular goiter in 5 patients. Therapeutically, 57% of the patients were put on synthetic antithyroid drugs with a betablocker, while for the other patients a simple monitoring was initiated The evolution was marked by the disappearance of the signs of hyperthyroidism in 87% of the patients, with normalization of the thyroid balance after the first trimester.
Conclusion
Hyperthyroidism during pregnancy is a frequent reason for consultation, most often revealed by vomiting during pregnancy, which should not be neglected, requiring adequate management to avoid maternal-fetal complications.

DOI: 10.1530/endoabs.81.EP1003

EP1004

Thyrotoxic hepatitis during pregnancy: about 42 cases

Amal Elkhomri, Bensbaa Salma, Nassim Essabah Haraj, Siham El aziz & Asma Chadli
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Hyperthyroidism in pregnancy is a common condition representing two different conditions: transient hyperthyroidism of pregnancy and true hyperthyroidism. It is

accompanied by liver enzyme disturbances without any other obvious cause.
Objective of the study
To evaluate the prevalence of acute hepatitis associated with hyperthyroidism.
Matherials and methods
Prospective study conducted at the endocrinology and diabetology department of the CHU Casablanca including 42 patients with hyperthyroidism and acute pancreatitis complicated by hyperperemesis gravidarum
Results
The results showed a mean age of 26 years, with a mean gestational age of 11 days after birth, with no personal history of thyroid disease, the predominant clinical reason was vomiting in pregnancy, which was present in all patients. Biologically: The mean TSHus was 0.05 mIU/l, with a mean T4L of 26 ng/l and a mean T3l of 8 ng/l, with a hepatic cytolysis with an average ASAT of 111 IU/l and ALAT of 173 IU/l, a mean lipasemia of 208 IU/l, the abdominal ultrasound was without any particularities and negative hepatic serologies. Therapeutically, the patients were put on synthetic antithyroid drugs with a betablocker and digestive rest with parenteral nutrition. A normalization of the hepatic balance was observed in 87% of the patients after correction of the thyroid balance.
Conclusion
Thyrotoxic hepatitis is retained in front of a disturbed hepatic balance in the context of thyrotoxicosis after having eliminated any other cause in particular viral, autoimmune or drug-induced hepatitis. Hyperthyroidism, whatever its variant, remains a possible cause of hepatitis during pregnancy.

Insulin resistance and insulin-like growth factor-1 in patients with nodular goiter

Oksana Miroshnichenko[1], Iurii Karachentsev[1, 2], Myroslava Mykytyuk[1, 3], Oksana Khyzhnyak[1, 3], Victor Dubovyk[1], Leonid Gerasymenko[1] & Maxim Sazonov[1]
[1]V. Danilevsky' Institute of Endocrine Pathology Problems, Kharkiv,; [2]Kharkiv National Medical University, Department of Endocrinology, Kharkiv,; [3]Kharkiv Medical Academy of Postgraduate Education, Department of Endocrinology, Kharkiv, Ukraine

Introduction
Publications suggesting that thyroid nodules might be associated with insulin resistance (IR) and metabolic syndrome are quite interesting. The **aim** of the work is to analyze the association between anthropometric indicators IR and insulin-like growth factor-1 (IGF-1) in patients with nodular goiter.
Methods
Examined 73 patients with euthyroid single-node ($n=34$) and multinodular goiter ($n=39$), age (51.0 ± 10.6) years; determining WC, WC/HC, BMI, WHtR, ABSI, BFD, BRI, CI, AVI, BAI, IGF-1. Thyroid volume, its structure, number, size, and location of foci were assessed by an ultrasonic complex.
Results
In the total group IGF-1 is associated with BMI ($r=$ -0.30; $P=0.016$), WC ($r=$ -0.26; $P=0.036$), WHtR ($r=$ -0.30); $P=0.020$), AVI ($r=$ -0.27; $P=0.03$), ABSI ($r=$ -0.31; $P=0.015$), BFD ($r=$ 0.27; $P=0.033$)), BRI ($r=$ 0.29; $P=0.02$) and BAI ($r=$ 0.36; $P=0.004$); thyroid volume is associated with age ($r=$ 0.35; $P=0.009$), WC/HC ($r=$ 0.43; $P=0.001$), BFD ($r=$ 0.26; $P=0.06$) and CI ($r=$ 0.31; $P=0.02$). In patients with BMI $\geq$ 35 kg/m^2 thyroid volume is associated with BMI ($r=$ 0.71; $P=0.049$). In patients with IGF-1 above the sex-age norm, thyroid volume is associated with WC/HC ($r=$ 0.71; $P=0.01$), BAI ($r=$ 0.66; $P=0.03$) and BFD ($r=$ -0.52; $P=0.01$). It has been found that BAI explains 82.37% of the variance of IGF-1 in the general group and more than 90% of the variance of its level in groups of patients with nodular goiter with high IGF-1 with/without obesity.
Conclusion
Patients with nodular goiter with IGF-1 above the sex-age norm have significantly higher values of anthropometric indicators IR compared with patients with a normal level of this indicator. In patients with obesity, thyroid volume is significantly associated with BMI. BRI ($R^2=81.14\%$) is a predictor of increased thyroid volume in patients with IGF-1 high levels and obesity.

Quality of life and symptomatology in patients with hypothyroidism post-graves' disease

Miguel Pereira[1], Celestino Neves[2], Juliana Gonçalves[2], João Sé rgio Neves[2] & Davide Carvalho[2]
[1]São João University Hospital Center, Psychology, Porto, Portugal; [2] São João University Hospital Center, Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Quality of life (QoL) and its related physical and psychological symptomatology is an important factor when we treat Graves' disease.
Objective
To analyze the QoL and physical and psychological symptomatology of patients with hypothyroidism after definitive treatment of Graves' disease.
Methods
We evaluated 16 patients with hypothyroidism that previously had Graves' disease. These patients were submitted to total thyroidectomy and/or radioiodine treatment to deal with Graves' disease. Our sample had a mean age of 58.7 ± 15.0 years, 81.3% were female and 68.8% were married. We assessed thyroid function tests, thyroid antibodies, the resistance to thyroid hormone indices (Thyroid Feedback Quantile-Based Index [TFQI], lipid profile, high-sensitivity C-reactive protein, B12 vitamin, folic acid and applied several questionnaires, namely: the Thyroid Dependent Quality of Life questionnaire (ThyDQoL), the Thyroid Symptom Rating Questionnaire (ThyTSQ) and the Brief Symptom Inventory (BSI). Statistical analysis was performed with the One-way ANOVA test and Pearson's correlation test. P values $\leq$ 0.05 were considered as statistically significant.
Results
In this sample we found that patients had a mean BMI of 27.5 ± 4.3 kg/m^2, TSH 1.67 ± 2.11 µUl/ml and FT4 1.21 ± 0.17 ng/dl. Patients reported a mean QoL value of -2.02 points (range from -9 to 1). In regard to the ThySRQ, 56% of patients have noticed at least moderately memory problems, 62.6% of patients reported at least being moderately tired and 68.9% showed some kind of dizziness symptoms. Nearly 80% of patients did not report any weight gain or appetite problems. In terms of correlations, we found significative correlations between TSH and lack of appetite ($r=$ 0.66; $P=0.01$), audition problems ($r=$ -0.65; $P=0.006$) and depression ($r=$ -0.56; $P=0.02$). We observed correlations between TFQI and weight ($r=$ -0.54; $P=0.03$) and depression ($r=$ -0.54; $P=0.02$). We also noticed a negative correlation between FT4 and dizziness symptoms ($r=$ -0.55; $P=0.02$). Results point out that QoL is negatively correlated with FT3 ($r=$ -0.59; $P=0.01$) and FT4 ($r=$ -0.49; $P=0.05$).
Conclusions
In this study we can observe that QoL in general manners seems to be strongly influenced by FT3 and FT4 than by TSH. Our study is in agreement with previous studies suggesting that FT4 has a good sensitivity regarding well-being evaluation. Further studies, with a more robust number of patients are needed to analyze more deeply the nuances of this kind of treatment and its contribution to the QoL.

Rhabdomyolysis revealing a profound hypothyroidism

M'ballou Camara, Fatiha Ettalibi, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
CHU Mohammed VI, Endocrinology, Diabetes, Metabolic diseases and Nutrition, Morocco

Introducing
Hypothyroidism is the most common endocrinopathy causing rhabdomyolysis. Muscle manifestations are common in hypothyroidism, but myopathy is most often limited to discrete clinical signs such as myalgias, stiffness or cramps accompanied by a simple elevation of muscle enzymes. On the other hand, rhabdomyolysis associated with hypothyroidism is a rare diagnosis to our knowledge. We report a case of severe rhabdomyolysis in the setting of profound Hashimoto's hypothyroidism.
Observation
Mr A.I, 32 years old. Hospitalized in psychiatry for an acute psychotic attack, having as antecedent a schizophrenia since 6 years under neuroleptics in stop for 3 years. The interrogation found signs of hypothyroidism. The clinical examination showed a bradycardia, a generalized myxedema with a puffiness of the face and pre tibial myxedema, the osteotendinous reflexes sharp, a reduced mimic, the lower lips everted with a moderate bilateral ptosis, filling of the supra clavicular

hollows. Goitre homogeneous. On workup: Total CPK at 28 times normal, normokalemia, moderate renal failure, deep peripheral hypothyroidism. Thyroid ultrasonography revealed a goiter with significant vascularization, positive anti-TPO antibodies. The diagnosis of Hashimoto's thyroiditis was made. This hypothyroidism is associated with rhabdomyolysis diagnosed on a CPK level (28 times norma), in normo kalemia, as well as moderate renal failure. The patient was put on Levothyroxine with an initiation dose of 1.7 µg/kg/j.
Discussion
Muscle involvement during hypothyroidism is often frequent and early, simulating a pathology of the locomotor system. Moderate elevation of creatinine phosphokinase (CPK) during hypothyroidism is found in 80% of cases, however, cases of major CPK elevation during hypothyroid myopathy remain exceptional. Most patients with hypothyroidism who develop rhabdomyolysis have a clear precipitating factor, in which case intermittent use of neuroleptics can be suggested, although rhabdomyolysis caused by severe hypothyroidism alone has been reported in the literature. Myolysis in hypothyroidism is explained by muscle degeneration with atrophy of type II fibers and compensatory hypertrophy of type I fibers secondary to a defect in mitochondrial metabolism. Glycosaminoglycan deposition, altered contractility of actin-myosin units, and low myosin ATPase activity in skeletal muscle are also involved in the pathophysiology.
Conclusion
Rhabdomyolysis is a rare but fatal complication of hypothyroidism. Hormone replacement therapy, started gradually, allows resolution of muscle signs and normalization of muscle enzymes. A major elevation of CPK should prompt a search for hypothyroidism, although this is a rare cause, and warrants monitoring of thyroid status during any muscle lysis with elevated muscle enzymes, as recommended

Subacute thyroiditis following asymptomatic COVID-19 case report

Iuliana Ilie[1], Madalina Musat[2, 3] & Luciana Oprea[2]
[1]Gral Medical Clinic, Endocrinology, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania, Endocrinology, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Subacute thyroiditis (SAT) is a relatively uncommon and self-limited cause of thyrotoxicosis of viral or post-viral origin. During the COVID-19 pandemic a thyroid impact was also considered due to the potential of SARS-CoV-2 virus to cause multiorgan effects. Several SAT cases associated with SARS-CoV-2 infection or vaccination were recently reported in the literature. We present the case of a 52-year-old female who presented with neck pain, fever, asthenia, and malaise for approx. 2 weeks. On examination she had a moderately asymmetrically enlarged and tender thyroid gland, and was tachycardic, with no respiratory symptoms. From her medical history we retain no SARS-COV2 vaccine or any form of upper respiratory airways infection recently. A prior endocrinology evaluation in 2020 revealed thyroid cysts of max 12mm and a normal thyroid function. Currently she had mildly high serum free T4 and suppressed serum TSH, high ESR of 111 mm/h, mild leukocytosis with neutrophilia. Liver function tests were also abnormal-elevated ALT (138 IU/l), mildly elevated GGT and alkaline phosphatase. The patient did not have any history of liver disease or alcoholic intake. On ultrasonography, the thyroid appeared enlarged with bilateral hypoechogenic areas that had reduced vascularization on Color Doppler. The liver appeared normal on ultrasound. Thoracic X-Ray was also normal. One week prior to presentation the patient had two nasopharyngeal swabs SARS-CoV-2 RT-PCR tests, both negative. However, at SAT diagnosis SARS-CoV-2 IgG antibodies were positive. Other viral serologies that can affect hepatic function were negative, including: anti CMV, anti-Epstein-Barr antibodies, IgM anti-HAV, HBsAg, Anti-HCV antibodies. A diagnosis of SAT post asymptomatic SARS-CoV-2 infection was made and the patient was started on corticosteroids with improvement of both clinical and biological parameters. A benign, short-lived and subclinical hepatic involvement is also common in subacute thyroiditis. The association of SAT with SARS-CoV-2 virus is reported in the literature, mostly following symptomatic SARS-COV 2 infection or vaccine, although the size of the problem is still unclear. In our case, SAT in asymptomatic COVID-19 patient remains a challenge in establishing the certain trigger of thyroiditis, although in a review of 27 patients with COVID-19 related SAT, 4 cases were described after asymptomatic SARS-COV 2 infections. Serum TSH level in hospitalized patients with moderate-to-severe COVID-19

Arina Mikhailova, Daria I. Lagutina, Ksenia Golovatyuk, Alena Chernikova, Anna Bystrova & Tatiana Karonova
National Medical Research Centre named after V.A. Almazov of the Ministry of Healthcare of Russia, Saint-Petersburg, Saint Petersburg, Russian Federation

Background
Recently, clinical evidence of thyroid dysfunction has been observed both in acute and post-COVID period. The aim of this study was to estimate the serum TSH level in hospitalized patients with moderate-to-severe COVID-19.
Methods
It was a single-center study conducted by the Almazov National Medical Research Centre (Russian Federation). Patients hospitalized with detected SARS-CoV-2 infection by RT-PCR test and chest computed tomography (CT) were enrolled. We did not include patients with a medical history of thyroid disease. Clinical data, laboratory tests (TSH at the 1st and at the 9th day of hospitalization; C-reactive protein, lactate dehydrogenase and ferritin levels at the 1st day of hospitalization), CT data and received systemic corticosteroid therapy were analyzed.
Results
A total of 77 patients with an average day of illness at the time of hospitalization 8 $\pm$ 1.2 days were included. The baseline abnormal TSH level ($<$0.4 mIU/l) was found in 4 patients (5.2%), while by the 9th day of hospitalization their number doubled and reached 9 (11.7%). Furthermore, we found that by the 9th day the TSH level more than 4.5 mIU/l was detected in 4 patients (4.2%). Thus, 13 out of 77 (16.9 %) patients had the abnormal serum TSH level by the 9th day. No statistically significant correlations with the TSH level of the C-reactive protein, lactate dehydrogenase and ferritin levels was detected in our study ($P>$ 0.05). Also we did not find any correlations with the TSH level of the CT degree and of the clinical severity ($P>$ 0.05). There was no any difference in average daily glucocorticoid dose among patients with abnormal TSH level and without it.
Conclusions
Abnormal TSH level could be explained by the function alterations of the hypothalamic-pituitary-thyroid axis associated with SARS-CoV-2. Future studies may clarify pathogenic aspects of thyroid dysfunction caused by COVID-19.

Long-term thyroid function in women diagnosed with subclinical hypothyroidism in pregnancy

Rocío Revuelta[1], Ana Castro[1], Belen Martínez[1], Andrea Cruz[1], Maria-Piedad Picazo-Perea[2], Esther Martin-Torres[2], Aurora Lopez-Martos[2] & ALMUDENA VICENTE[1]
[1]Toledo University Hospital, Endocrinology and Nutrition, Toledo, Spain; [2]Toledo University Hospital, Biochemistry, Toledo, Spain

Introduction
Subclinical hypothyroidism (SCHT) in pregnancy has been associated with adverse obstetric and perinatal outcomes. However, few studies have investigated the evolution of postpartum thyroid function in women first diagnosed with SCHT in pregnancy (gestational SCHT).
Objective
To determine the evolution of thyroid function (TF) and the clinical and biochemical factors related to the long-term persistence of hypothyroidism (HT) in women with gestational SCHT.
Methods
Gestational SCHT was defined as the presence of TSH values above the upper limit of the specific range in our population (0.21-3.8 mcU/ml) determined in the first trimester (1T). We reviewed the medical records of women diagnosed with SCHT in our Health Area in 2016. We compared the clinical and biochemical characteristics of pregnant women diagnosed for the first time with SCHT in pregnancy, with TF data at least 6 months postpartum.

Results
Thyroid dysfunction screening was performed in 3821 women. 293 met SCHT biochemical criteria (7.66%). Of 140 women diagnosed with gestational SCHT, 106 had long-term TF data. The mean age was 31.4 ± 5 years, being 61.5% older than 30 years. The prevalence of persistent hypothyroidism (HT) at the end of the follow-up was 48.1%(n= 51), being significantly more frequent in women with positive anti-TPO antibodies (Ab) (61.4% vs 38.6%; $P<0.05$) and TSH greater than 10 in 1T (85.7% vs 45.4%; $P<0.001$).
Conclusions
1. In our study, almost half of the women with gestational HTSC present long-term persistent HT, being more frequent in those with positive anti-TPO and/or TSH higher than 10 in the 1T. 2. It would be advisable to monitor these women, especially when planning subsequent pregnancies.

The interplay between TSH and geriatric syndromes: results from the Moscow centenarians study

Lubov Matchekhina, Ksenia Eruslanova, Ekaterina Dudinskaya & Olga Tkacheva
Pirogov Russian National Medical University, Russian Gerontology Research and Clinical Centre, Moscow, Russian Federation

Aim of the study
to assess the interaction between TSH and the most common geriatric syndromes in the cohort of centenarians
Materials and Methods
It was a longitudinal study, including 82 centenarians (95 years and older), who live in Moscow. Complex geriatric assessment and blood tests were performed. Complex geriatric assessment included past medical history, FRAIL, IADL-C, MNA, GDS-15 and MOCA scores. We analyzed the interactions between TSH, metabolic parameters, functional status and cognitive functions in centenarians. In one year after the investigations we contacted patients' relatives or social workers to find out about patients' status. The statistical analysis was performed using IBM SPSS Statistics Version 26. Statistically significant were differences with p< 0,05.
Results
Mean age of the patients was 98,3 (±1,9) years, while 87,8% of the cohort were women. Analyzing functional status we found out that 34,4% of the patients were frail, and the number of prefrail patients was 56,2%. Cognitive impairments of different severity were presented in 84,4% of the patients. In 59% of the patients HbA1c was below 6%, 33% had concentrations between 6 and 6,4% and only in 8% we found HbA1c higher than 6,5%. The median level of TSH was 2,26 mIU/l [1,8;3,6] with a tendency to higher normal concentrations. TSH was negatively correlated with C-reactive protein (r= -0,4, $P<0.05$) and positively correlated with albumin levels (r= 0,26 P=0,038). The interaction between the TSH and chronic pain severity measured by VAS was negative (r= -0,03, P=0,021). Cognitive status of centenarians assessed by MMSE showed a positive correlation with TSH levels (r= 0,38, P=0,011).
Conclusion
In the cohort of centenarians higher levels of TSH seem to play a protective role in maintaining cognitive functions and nutritional status; lower TSH levels seem to be linked with the higher intensity of chronic pain.

A possible complication of hypothyroidism: ischemic colitis

Shielah Mauntana[1] & Mahesh Gajendran[2]
[1]Paul L. Foster School of Medicine, El Paso, United States; [2]Long School of Medicine, University of Texas Health Center at San Antonio, Division of Gastroenterology, San Antonio, United States

Background
Ischemic colitis (IC) is a disorder characterized by a decrease in blood flow of the large intestine. Many factors can contribute to decreased blood flow in the arteries supplying the large intestine, such as nonocclusive causes like hypertension and atherosclerosis and occlusive causes like embolism from myocardial infarction. With Ischemic colitis's high mortality rate and its association with many cardiovascular diseases, it's important to understand comorbidities that might lead to these events. Thyroid hormone is a hormone that affects not only metabolism and energy expenditure, but also cardiac function. Thus, thyroid dysfunction might play a role in the development of ischemic colitis. This study aims to find and assess comorbidities like thyroid dysfunction associated with admission for ischemic colitis.
Methods
We conducted a cross-sectional study of adults with IC listed as the primary ED diagnosis from 2005 to 2014 using the Nationwide Readmission Database (NRD). The characteristics of the IC-related ED visits were analyzed.
Results
The estimated number of ED visits with a primary diagnosis of IC from 2005-2014 was 541,267 people. Our results showed that the mean age of the cohort was 62 +/- 14 years, suggesting that most patients affected with ischemic colitis are elderly. 88,497 out of 541,267 ischemic colitis patients were found to have hypothyroidism, amounting to 16.35% of the ischemic colitis population.
Conclusions
The results suggest that Hypothyroidism and ischemic colitis may be associated, perhaps through thyroid hormone's effect on cardiovascular homeostasis. Thyroid hormone has a major role in cardiac contraction, angiogenesis, vascular function, structure, as well as mitochondrial function. Dysfunction of the thyroid hormone pathway can lead to cardiac impairment, hypertension, and heart failure. All these events may lead to decreased blood flow in the vasculature, hypoperfusion to the organs, and subsequently ischemic colitis.

Thyroiditis as immune related adverse event to pembrolizumab plus lenvatinib therapy: a case report

Lamya Echchad & Abidi Ihssane
Sud Francilien Hospital Center, Endocrinology and Metabolism Disease Department, France

Introduction
The development of molecular biology and cancer immunology has brought drastic changes in anticancer in recent years. Recently, tyrosine kinase inhibitors (TKI) and immune checkpoint inhibitors (ICPIs) have emerged as new classes of anticancer therapies. Although generally considered less toxic than cytotoxic chemotherapy, these new drugs can cause significant side effects including thyroid dysfunction. We report the case of thyroiditis induced by Pembrolizumab (ICPIs) plus Lenvatinib (TKI) in patient with metastatic renal cell carcinoma.
Observation
A 72 years old male patient with a history of type 2 diabetes mellitus, arterial hypertension, was diagnosed with metastatic renal cell carcinoma and treated by pembrolizumab plus Lenvatinib. Two months after the start of this association, he was presented to the emergency department with a history of vertigo and tachycardia. Thyroid function tests revealed transient hyperthyroidism with negative TRAK, TPO and TG antibodies. The cervical ultrasound had showed a small thyroid with hypoechoic parenchyma, low vascularity consistent with thyroiditis. He was put on 40 mg of Carbimazole per day and 40 mg of Propanolol twice per day. His thyroid function was subsequently monitored until he was found to have overt hypothyroidism and put on under 200 µg of levothyroxine per day.
Discussion & Conclusion
In patients treated with TKIs or ICPIs, the thyroid toxicities are common and pauci-symptomatic at the beginning of their evolution but can lead to prolonged hypothyroidism that should not be ignored. The cumulative clinical experience of recent years and the basic studies have led to a better understanding of the mechanisms of thyroid dysfunction. Schematically, the iatrogenic thyroiditis of TKIs is linked to vascular damage related to their selectivity to block diverse vascular growth factor signaling pathways which may led to a rapid reduction in thyroid vascular flow and as a result the occurrence of ischemic thyroiditis. In the other hand, the iatrogenic thyroiditis of ICPIs is based on an inflammatory mechanism by autoimmune reaction that in many cases is accompanied by hormonal deficiency in the long term. As the use of these antibodies becomes more prelevent, more investigations and research are needed to identify risk factors for these side effects and possibly tailor the treatment of patients accordingly. Finally, thyroid function tests including TSH, FT4 and TPO antibodies screening should be a part of baseline of laboratory testing of all patient undergoing treatment with these drugs.

What is the ideal approach for thyroidectomy in a given patient? Proposal of an algorithm

Ramesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Rajesh Bangaraiahgari[1], Udaya Kumar U[1] & Sabaretnam Mayilvaganan[3]
[1]Arundathi Institute of Medical Sciences, India; [2]Bhargav Endocrine Hospitals, Vijayawada, India; [3]SGPGIMS, India

Introduction
Thyroidectomy can performed by open or wide array of endoscopic techniques. Lack of uniform consensus on specific indications for each technique leads to confusion on ideal thyroidectomy technique. In this context, we analysed our experience with specific emphasis on deducing an algorithm on ideal technique for a given patient.
Material and methods
This is a retrospective study conducted at a tertiary care endocrine surgery department in South India over a period of 10 years from July 2009 to June 2019. Data on our thyroidectomy techniques was analysed with the specific emphasis on choice of technique based on disease related, non disease related and patient choice factors. We categorized all the clinico-investigative, logistic and patient factors influencing the choice of thyroidectomy technique in to four types A, B, C and D. Type A included disease related factors; Type B included logistics related factors; Type C factors based on comorbidities; Type D based on patient and their family. Finally, an algorithm to select an ideal technique of thyroidectomy for a given patient was developed based on the results.
Results
Open thyroidectomy was performed in 1794/2075 (86.5 %) cases. Endoscopic thyroidectomy was employed in 281 subjects. Type A to C factors, bifurcated the choice of technique to OT and ET without the need for Type D factors. Type D factors primarily dictated the choice amongst the available ET techniques. Further, DI, II and VII factors converted some of the ET feasible subjects to OT. DIII, IV, V, VI factors dictated the choice of a particular ET technique.
Conclusions
1) The ideal technique of thyroidectomy for a given patient depended on logistics, expertise and patient choice rather than disease (goiter) related factors and 2) Our proposed algorithm appears to guide in making decision on the ideal choice of thyroidectomy technique.

EP1016

Opportunistic thyroid function screening in older medical patients in Ireland

Lok Yi Joyce Tan & Mary Jane Brassill
Tipperary University Hospital, Department of Medicine, Clonmel, Ireland

Introduction
Thyroid dysfunction is one of the commonest endocrine disorders with hypothyroidism being the most common thyroid dysfunction in the elderly population[1]. An elderly patient with thyroid dysfunction can be asymptomatic, or present with non-specific symptoms, making biochemical testing of thyroid function useful and essential. We reviewed the screening rate and prevalence of thyroid dysfunction in older medical patient patients admitted to an Irish secondary hospital.
Methods
A retrospective cross-sectional analysis was conducted on all hospitalized general medical patients over 70 years of age discharged during October 2020. This was identified using the Integrated Patient Management system. Chart review was carried out to identify those with a known diagnosis of thyroid disorders. Thyroid function test (TFTs) screened during admission and/or within the prior six months were include in the analysis. Data was inputted to a Microsoft excel spreadsheet and analysed. The thyroid stimulating hormone (TSH) level is measured using the Roche assay and its reference range is between 0.27 - 4.2 mIU/l.
Results
202 patients were included in this study with a median age of 80 years (SD 6.3). 51%($n=$ 102) were male. 85% of the entire cohort ($n=$ 171) had TFTs performed. 21%($n=$ 42) had a known thyroid disorder. TFTs were performed in 95 % of those (40/42). 33% (13/40) had abnormal TFTs requiring a medication adjustment. Of those with no known thyroid disorder, 82% (131/160) had TFTs performed. 11%($n=$ 14) had abnormal results. 8%($n=$ 10) had high TSH levels. One had overt hypothyroidism and the remaining 9 had subclinical hypothyroidism, providing a prevalence of 0.8% and 6.9% respectively. The mean age of the patients with subclinical hypothyroidism was 79.9 years (SD 8.1). 3.1% (4/14) had subclinical hyperthyroidism, providing a prevalence of 3.1% with mean age of 83.5 years (SD 3.7).
Discussion
We observed a high prevalence of abnormal TFTs in those with known thyroid disorders, leading to medication adjustment. Screening those without known thyroid disease also yielded abnormal results in 11%. Subclinical hypothyroidism was the most prevalent thyroid disorder among the elderly population in our study. These findings indicate that routine, opportunistic testing of TFTs in medical patients over 70 is beneficial, with medication adjustment required in 33% of those with known thyroid disorder, and 11% of the remainder having abnormal TFTs.

EP1017

Prevalence of thyroid disease among women receiving antenatal care at a tertiary care centre in Sri Lanka

Kaveen Weerasinghe
Post Graduate Institute of Medicine, University of Colombo, Obstetrics and Gynaecology, Colombo, Sri Lanka

Introduction
Sri Lanka is endemic for goiters and recent studies show a high prevalence of thyroid dysfucntion among the population. However, data on thyroid dysfuntion among the general population and pregnant women in Sri Lanka is limited. Thyroid dysfunction is associated with adverse pregnancy outcomes. Furthermore, pregnancy related physiological changes increase the risk of thyroid dysfucntion. However, women in Sri Lanka are not routinely screened during pregnancy for thyroid dysfunction.
Methods
A descriptive cross sectional study was conducted among 872 women who received antenatal care and underwent universal first trimester or early second trimester thyroid status screening at a tertiary care centre in Sri Lanka over a period of one year. Pregnancy records were analyzed to extract data on past medical history, thyroid status, and pregnancy outcomes.
Results
872 women underwent screening with TSH at the booking visit. Pregnancy specific reference ranges were used (0.1-2.5 mIU/ml for first trimester and 0.2-0.3 mIU/ml for second trimester). Among them, 91.4%($n=$ 797) were euthyroid. Two women had been diagnosed with Graves disease prior to pregnancy and were on treatment with with oral antithyroid medications. Remaining 8.6%($n=$ 73) of the population were found to be hypothyroid. Among women with hypothyroidism, 21.9%($n=$ 16) had been diagnosed prior to pregnancy while remaing 80.1%($n=$ 57) were newly diagnosed during antenatal screening. Prevalaence of subclical hypothyroidism among the population was 5.4%($n=$ 47) and prevalence of overt hypotyroidism was 3%($n=$ 26). 57.5%($n=$ 42) of women with hypothyroidism were positive for TPO antibodies. One woman had undergone thyroidectomy due to papillary thyroid carcinoma while 2 women who had undergone thyroidectomy for goiters prior to pregnancy. Prevalence of goiters among the population was 6%($n=$ 52). Women with overt hypothyroidism had a higher risk of foetal graowth restriction ($P=0.04$), and neonatal intensive care admission ($P=0.02$). There were no statistically significant differences between pregnancy outcomes of women with euthyroid status and subclinical hypothyroidism.
Conclusion
Thyroid disease has a high prevalence among the study population which was comparable to findings of previous studies. Overt hypothyroidism was associated with adverse pregnancy outcomes. Further studies are required to assess thyroid status among Sri Lankan women, implications of thyroid status on pregnancy outcomes, plan strategies for screening, and interventions.

Carbimazole-induced hepatocellular injury in patient with Graves' disease - avoid rechallenging

Hassan Ibrahim, Maria Comia, Mustapha Abubakar, Richard Ip & Taofeek Ojewuyi

Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend-on-Sea, United Kingdom

Grave's disease is an auto-immune disorder which responds well to medication and up to half of the patients who take anti-thyroid drugs go into remission. We present a patient with Graves' disease, who developed acute hepatitis associated with Carbimazole and, re-challenged with Carbimazole when she represented with in fast atrial fibrillation (AF) with relapse of hepatitis. A 75 year-old lady admitted with palpitation and chest tightness. She had a background of paroxysmal AF. She was found to be in AF with fast ventricular response and blood tests done during her admission showed abnormal thyroid function tests (TFT) consistent with hyperthyroidism: TSH <0.01 mU/l (0.3-5.0), FT4: 33.5 pmol/l (7.9-16.0), FT3: 11.7 pmol/l (3.8-6.0), TSH receptor antibody 5.5 IU/l (0-0.9). Patient was started on Carbimazole 20 mg once a day and planned for follow up as outpatient with the endocrine team within 2 months. Few weeks after discharge, she presented with chest tightness and blood tests revealed deranged liver function tests (LFT); total bilirubin 29 umol/l (0-21), ALT 295 U/l (<35) and ALP 458 U/l (30-130). Carbimazole was discontinued. She has had a normal liver ultrasound as well as normal autoimmune and viral hepatitis screen. Her LFT improved after stopping Carbimazole. She was followed up by the endocrine team post-discharge and definitive treatment in the form of total thyroidectomy was planned. Patient was re-admitted three weeks post outpatient follow up due to palpitations and fast AF. Patient refused to try Propylthiouracil and hence she was restarted on low dose of carbimazole with strict weekly LFT follow up until thyroidectomy could be arranged. However, while trialed on Carbimazole, LFTs started getting deranged (ALT raised to 64 U/l from 29 U/l) and Carbimazole was again discontinued. Two weeks following discontinuation of Carbimazole LFT returned to normal: total bilirubin 8 umol/l, ALT 24 U/l and ALP 125 U/l. Patient's condition discussed with surgical team and her total thyroidectomy appointment was expedited. She was started on Lugol's iodine 10 days prior to surgery with normalization of TFT. Patient underwent total thyroidectomy which was uneventful. Hepatotoxicity is rare but serious side effect of thyrostatic medications. The drug should be withdrawn immediately and alternative therapy for thyrotoxicosis should be considered. This case strongly supports the need to avoid antithyroid drugs (ATD) rechallenge in patients who develop significant liver dysfunction following ATD use and identifies that Carbimazole may be associated with acute hepatocellular dysfunction and not just Cholestasis.

The hobnail variant of papillary thyroid carcinoma: clinical/molecular characteristics of a large monocentric series and comparison with conventional histotypes

Simona Censi[1], Jacopo Manso[1], Francesco Paganin[1], Federica Vianello[2], Francesca Galuppini[3], Gianmaria Pennelli[4], Maurizio Iacobone[5], Loris Bertazza[1], Susi Barollo[1] & Caterina Mian[1]
[1]Endocrinology Unit, Department of Medicine (DIMED), University of Padua, Padua, Italy; [2]Radiotherapy Unit, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy; [3]Endocrinology Unit and Surgical Pathology and Cytopathology Unit, Department of Medicine (DIMED), University of Padua, Padua, Italy; [4]Endocrinology Unit and Surgical Pathology and Cytopathology Unit, Department of Medicine (DIMED), Padua, Italy; [5]First Surgery Clinic and Endocrine Surgery Unit, Department of Surgery, Oncology, and Gastroenterology, University of Padua, Padua, Italy

Background
Hobnail variant of papillary thyroid carcinoma (HPTC) has been recently identified. Given the rarity of the variant its characteristics have been studied only in little series, limiting the quality of the data available for its better management. The aims of our retrospective study were 1) to define the clinical and molecular characteristics of a series of HPTC in a monocentric and relatively large series; 2) to define the clinical and molecular characteristics able to influence its outcome and 3) to compare them with a series of conventional PTC.
Material and methods
the clinical and molecular (*BRAF*, *TERT* promoter, *TP53*) characteristics of 74 HPTC were compared with a series of 143 conventional PTC. All patients had a total thyroidectomy and radio-iodine (RAI). The median follow-up was 27 months.
Results
HPTC had: median age at diagnosis of 49.2 years, median size of 20.5mm, a T3/T4 in 42%, lymph-node involvement in 58% (38% N1a and 20% N1b), metastatic in 5%, multifocal in 45%, extra-thyroidal invasive in 63%, angio-invasive in 97%. 13.5% had further treatments (after thyroid surgery and RAI), external radio-therapy (RTE) was administered in 7%. HPTC were mutated in *BRAF*, *TERT* promoter and *TP53* in 56%, 9% and 20% of cases, respectively. At the end of the follow-up, 16% had a biochemical/structural persistence or a HPTC-related death. The outcome was influenced by TNM, stage, *TERT*-promoter mutation, lymph node ratio (LNR), but the latter was the only independent outcome determinant (odds radio, OR = 203). A Hobnail morphology $<$ or $\geq 30\%$ was not able to influence the outcome, as well as the other variants considered. Compared to classical PTC, HPTC has a lower female predominance (65% vs 78%, $P<0.01$), larger median size (20.5mm vs 13.00mm, $P<0.0001$), more frequent lymph-node and metastatic involvement and higher stage at diagnosis (all $P<0.01$), higher LNR ($P=0.002$), more frequent further treatments ($P=0.04$), more frequent RTE ($P=0.001$) and a worse outcome (being persistence/PTC-related death:16% vs 4.9%, $P<0.01$). There was no difference in the frequency of *BRAF* (56% vs 62%) and *TERT* promoter mutations (9% vs 5%), while there was a higher frequency of *TP53* mutations in HPTC (20% vs 1%, $P<0.01$).
Conclusions
the clinical characteristics of HPTC suggest a more aggressive treatment, a prompt RAI use and stricter follow-up than in conventional PTC. The LNR revealed the more powerful association with a worse outcome in HPTC. The major limit of our study is the follow-up duration available until now.

Male was not a prognostic risk factor in postoperative DTC patients treated with 131I treatment: a propensity score-matching study

Wei Zheng, Yaqian Zhou, Shen Wang, Xuan Wang & Jian Tan
Tianjin Medical University General Hospital, Nuclear Medicine, Tianjin, China

Objective
Propensity score matching (PSM) was used to study whether male patients with differentiated thyroid cancer (DTC) were the risk factors for prognosis after ^{131}I treatment.
Methods
1677 patients with DTC who underwent total thyroidectomy and received ^{131}I treatment were divided into male group ($n=546$) and female group ($n=1131$). The PSM method was adopted to process all the data to reduce the influence of data bias and confounding variables. Independent sample T test and Mann-Whitney U test were used for all continuous variables, χ^2 test was used for all classified variables. Univariate and multivariate logistic regression were used to analyze the risk factors affecting prognosis, and a receiver operating characteristic (ROC) curve was used to analyze the relationship between sTg level and poor prognosis.
Results
Before PSM, the proportion of male patients with poor prognosis was significantly higher than that of female patients (21.2%(116/546) vs 14.0%(158/1131), $\chi^2 = 17.53$, $P=0.001$). After PSM, there was no difference in the proportion of poor prognosis between male and female groups (19.9%(107/537) vs 15.6%(84/537), $\chi^2 = 5.43$, $P=0.143$). Multivariate logistic regression analysis showed that male (odds radio (OR) = 1.439 (95%CI: 1.016~2.038), $P=0.040$), high T stage (T3, T4 stage)(OR = 1.816 (95%CI: 1.273~2.590), $P=0.001$), N1b stage (OR = 1.766 (95% CI: 1.233~2.530), $P=0.002$), M1 stage (OR = 9.833 (95%CI: 3.190~30.309), $P<0.001$) and sTg level (OR = 1.035 (95%CI: 1.029~1.042), $P<0.001$) were risk factors for poor prognosis before PSM, while high T stage (T3, T4 stage)(OR = 1.870 (95%CI: 1.212~2.886), $P=0.005$), M1 stage (OR = 8.993 (95%CI: 2.434~33.225), $P=0.001$), high sTg level (OR = 1.040 (95%CI: 1.030~1.049), $P<0.001$) were still risk factors, and male (OR = 1.383 (95%CI: 0.912~2.096), $P=0.127$) were no longer risk factors for poor prognosis after PSM. ROC curve analysis showed that the cut-off value of sTg was 10.25 μg/l, with the sensitivity of 81.0%(222/274) and the specificity of 84.2%(1173/1393).
Conclusions
After reduction of selection bias by PSM, males are no longer a risk factor for prognosis after ^{131}I treatment of DTC. In addition, high T stage (T3, T4 stage), M1 stage and sTg $\geq$ 10.25 μg/l were risk factors for poor prognosis.

Clinical experience with tyrosine kinase inhibitors in radioiodine-refractory differentiated thyroid cancer

Andrea Fernández Valero, Miguel Damas-Fuentes, José Ignacio Martínez Montoro, Maria Molina Vega, Isabel Mancha Doblas, Jorge García Alemán, Arantzazu Sebastian Ochoa, Jose Manuel Trigo Pérez & Francisco José Tinahones Madueño
Hospital Universitario Virgen de la Victoria, Málaga, Spain

Introduction
Differentiated thyroid cancer (DTC) represent 85- 90 % of all thyroid cancer cases. Most of these have an excellent prognosis with standard treatment. However, between 7 and 23% will develop distant metastases and, of these, more than 65% will become radioactive iodine-refractory. In some of these patients who are considered to be radioiodine-refractory with rapidly progressive or symptomatic disease, or in patients who are not candidates for other therapies, the use of systemic therapies, such as Tyrosine kinase inhibitors (TKIs), should be considered since they have demonstrated an extension of progression-free survival.
Materials and Methods
Retrospective observational study. Data of 23 patients diagnosed with DTC who received treatment with TKIs between June 2010 and October 2019 were analyzed. Clinical response according to RECIST criteria of response to treatment, toxicities and tolerability of these therapies were evaluated at 3, 6, 12 and 18 months.
Results
There were 23 patients (11 men and 12 women). The overall mean age at diagnosis was 59,17 $\pm$ 14,59 years. 12 patients had a diagnosis of papillar thyroid cancer, 4 of follicular thyroid cancer and 7 of Hurthle cell cancer, being 70% of them stage IV. The mean time from cancer diagnosis to initiation TKIs therapy was 7.6 $\pm$ 8.7 years. Regarding the therapy: 19 were treated with Sorafenib, 3 with Lenvatinb and just 1 with Axitinib. Twelve months after the beginning of the treatment 19 patients were still undergoing TKI therapy: 12 (52.5%) had a stable disease (SD), 1 (4.3%) partial response (PR) and 6 (26.1%) progressive disease (PD). The remaining 4 patients had to withdraw: 1 due to toxicity and 3 due to death as a result of progression of the disease. A group of 15 patients completed 18 months of treatment (6 of them required a shift to second-line treatment with Lenvatinib or Axitinib) 10 had SD, 3 PR and 2 PD. A total of 7 patients (30.4%) died during this time. Adverse events occurred in 100% of the patients, being hand-foot syndrome, diarrhea and fatigue the most frequent. However, they were generally low grade (grade 1 or 2) requiring dose reductions or temporary withdrawals. There was only one definitive withdrawal due to toxicity (with Axitinb)
Conclusions
- Eighteen months after the beginning of the treatment 56.5% of the patients remained without disease progression thanks to treatment with TKIs. Despite their frequent side effects, TKIs are generally well tolerated

EP1022

Patterns of biological behavior of anaplastic thyroid cancer - case reports

Boyan Nonchev[1, 2], Antoaneta Argatska[1], Rosen Dimov[3, 4], Veselin Chonov[5, 6] & Elena Chobankova[2]
[1]Medical University of Plovdiv, Department of Endocrinology, Plovdiv, Bulgaria; [2]Kaspela University Hospital, Clinic of Endocrinology, Plovdiv, Bulgaria; [3]Medical University of Plovdiv, Department of Special Surgery, Plovdiv, Bulgaria; [4]Kaspela University Hospital, Clinic of Surgery, Plovdiv, Bulgaria; [5]Medical University of Plovdiv, Department of General and Clinical Pathology, Plovdiv, Bulgaria; [6]Kaspela University Hospital, Department of Pathology, Plovdiv, Bulgaria

Introduction
Anaplastic carcinoma of the thyroid (ATC) is the rarest and most aggressive thyroid gland cancer accounting for less than 5 % of all thyroid gland neoplasms. There is inconclusive evidence that ATC represents a terminal dedifferentiation of preexisting well-differentiated thyroid carcinoma or it may originate as already aggressive nondifferentiated cancer without any prior thyroid neoplasm.
Case description
Case 1
A 74-year-old woman with history of long-standing nodular goiter presented with rapidly growing, painful neck mass with compressive symptoms including hoarseness, dysphagia and vocal cord paralysis. She underwent debulking thyroid surgery in November 2021 revealing a right lobe 4/3/3 cm mass with histological features of anaplastic carcinoma and extensive infiltration of the surrounding soft tissues and muscles, esophagus, carotic artery, jugular vein, laryngeal nerve. Palliative radiotherapy was initiated together with adjuvant chemotherapy but the residual tumor showed progressive enlargement and lead to life-threatening complications.
Case 2
A 57-year-old man in whom on routine US examination in 2017 a solid hypoechoic nodule 3.6/3.3/4.5 cm with increased intranodular blood flow causing tracheal deviation and local compression was seen. The patient was referred to surgery which was not performed until April 2019 when he presented with significant enlargement of the thyroid mass. After total thyroidectomy the histological result was consistent with anaplastic carcinoma 9/8/7 cm in size with capsular and soft tissue infiltration. However, the patient refused any further treatment. On the last follow-up visit 32 months following the diagnosis the patient was euthyroid on replacement therapy with no clinically evident local recurrence or distant metastases.
Discussion and conclusion
Anaplastic thyroid carcinoma is poorly responsive to current treatment modalities with a 4-month median overall survival from the time of diagnosis. Recent study demonstrated significant improvement in survival over the last 2 decades presumably due the introduction of molecular-based personalized therapies. Among the most significant prognostic factors are considered age, size of the tumor, presence of extrathyroid invasion and distant metastases along with several new factors such as white blood cell and platelet count at presentation. The two stage IV B patients described presented with similar histological findings but completely different course of the disease. Further studies on the molecular characteristics of anaplastic cancers will probably provide valuable data on the individual risk of recurrence and progression and contribute to the improvement of the long-term prognosis.

EP1023

Management and prognosis of anaplastic thyroid cancer

Moncef Sellami, Wadii Thabet, Malek Mnejja, Bouthaina Hammami, Souha Kallel & Ilhem Charfeddine
Habib Bourguiba Hospital, University of Sfax, Tunisia, Otorhinolaryngology, Tunisia

Introduction
Anaplastic thyroid carcinoma (ATC) is rare. This highly aggressive malignant tumor accounts for 2 – 3 % of all thyroid gland neoplasms. ATC continues to be one of the deadliest diseases worldwide and carries a very poor prognosis. The aim of this study was to describe the treatment modalities of ATC and its prognostic features.
Methods
A retrospective study of patients with ATC treated in our department between 2004 and 2021.
Results
Nine patients were included: 4 men and 5 women. The median age was 65 years [44 years – 90 years]. All patients presented with an anterior neck mass lasting for a median duration of 2.5 months [0.5 – 9] with a recent rapid increase in size. Weight loss and compressive symptoms were reported in all cases. Physical examination showed a hard anterior neck mass in all cases, with a median size of 7.8 cm [3 – 15]. Lateral neck lymph nodes were reported in 3 cases. Vocal fold paralysis was found in 4 patients. CT scan, performed in 8 cases, revealed a thyroid lesion pushing the trachea, the esophagus internal jugular vein, and carotid in 7 cases. Fine needle aspiration was performed in 3 patients and revealed a poorly differentiated thyroid carcinoma. Six patients underwent a total thyroidectomy. Central neck dissection was performed in 3 patients and lateral neck dissection in one patient. The diagnosis was made after thyroid biopsy in 2 patients and lymph node biopsy in 1 patient. The tumor invaded the trachea ($n=$ 7), thyroid cartilage ($n=1$), cricoid cartilage ($n=$ 1) esophagus ($n=$ 1), recurrent laryngeal nerve ($n=$ 3), internal jugular vein ($n=$ 1). Three patients had pulmonary metastasis. Two patients had postoperative radiotherapy. Two patients had postoperative radio-chemotherapy. Recurrence was noted in these 4 cases. Palliative radio-chemotherapy was indicated in 1 case. The median survival duration was 4 months [2 days-13 months].
Conclusion
Anaplastic thyroid cancer is a devastating thyroid cancer with the poorest prognosis. As in our study, with conventional treatment including surgery,

radiotherapy, and conventional chemotherapy the overall survival of patients with anaplastic thyroid cancer has been less than 12 months.

Introduction
Papillary thyroid carcinoma (PTC) is the most common type of differentiated thyroid cancer, accounting for about 80% of all cases of thyroid cancer. Generally, PTC is an indolent disease and shows a good prognosis in most patients. However, up to 30% of patients have local tumor renewal or systemic spread. It is crucial to identify patients with a high risk of disease progression. DNA methylation biomarkers may provide clinically valuable information and improve the early non-invasive prognosis of PTC.
Aim of the study
To evaluate DNA methylation level changes of selected genes in peripheral blood plasma samples in PTC patients before and 4-6 weeks after surgery.
Methods
The studyincluded 68 patients with a histologically confirmed diagnosis of PTC with different histological variants: classical ($n=29$), diffuse sclerosing ($n=17$), follicular ($n=18$), and tall cell carcinoma ($n=4$). Peripheral blood samples were collected before surgery and 4-6 weeks after surgery during 2020 – 2021 in Hospital of Lithuanian University of Health Sciences, Kaunas clinics. DNA methylation level changes of *TSHR* gene were analysed by quantitative methylation-sensitive polymerase chain reaction. DNA methylation levels of *TSHR* were compared before and one month after the surgery using both paired and non-paired non-parametrical tests.
Results
Significantly lower *TSHR* promoter methylation levels were found 4-6 weeks after surgery compared to samples collected before surgery ($P=0.034$) in follicular variant of PTC. Paired sample analysis showed a statistically higher *TSHR* methylation level before surgery compared to *TSHR* methylation level after surgery in follicular variant PTC ($P=0.002$).
Conclusion
TSHR promoter methylation level changes may be a promising biomarker in predicting PTC prognosis.
Funding
This study was supported by the Lithuanian Research Council (Grant No. S-SEN-20-14 "The role of epigenetic markers for early detection of papillary thyroid carcinoma and prognostic significance in long-term outcome in elderly patients").

Routine molecular testing of fine needle aspiration biopsies of thyroid nodules

Vlasta Sykorova[1], Jitka Moravcova[1], Eliska Vaclavikova[1], Barbora Pekova[1], Karolina Mastnikova[1], Josef Vcelak[1], Zdenek Novak[2], Petra Pacesova[2], Tereza Grimmichova[2], Jan Jiskra[3] & Bela Bendlova[1]
[1]Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic; [2]Institute of Endocrinology, Department of Clinical Endocrinology, Prague, Czech Republic; [3]General University Hospital in Prague, Department of Endocrinology and Metabolism, 3rd Department of Medicine, Prague, Czech Republic

Objectives
Fine needle aspiration biopsy (FNAB) together with ultrasonography is a necessary tool for diagnosis and follow up of thyroid nodules. Molecular testing is increasingly used mainly for indeterminate categories of the Bethesda System for Reporting Thyroid Cytopathology revised in 2017. Our aim was to introduce a routine molecular analysis of the main genetic causes of thyroid cancer.
Methods
Since 2017 we have analyzed 1171 samples of patients with thyroid nodules. We gradually established testing procedure mainly in samples evaluated as Bethesda categories III and above. First, we analyze DNA for the most common mutation V600E in the *BRAF* gene using allele specific Real Time PCR (LC480, Roche). *BRAF*-positive samples are screened for *TERT* mutations using direct sequencing (CEQ 8000, Beckman Coulter). *BRAF*-negative samples are analyzed by next generation sequencing using the Thyro-ID panel (MiSeq, Illumina) examining other 12 genes. The samples negative in the NGS panel are subjected to detection of 23 fusion genes including *ALK*, *BRAF*, *GLIS, NTRK1*, *NTRK3*, *PPARG*, *RET* genes using Real Time PCR. In samples suspected of MTC, we search for *RET* mutations.
Results
In total, *BRAF* mutation was detected in 146 patients, *RAS* mutations in 72 patients, *RET* mutations in 4 patients, *TERT* mutations in 20 patients and fusion genes in 43 patients. In 21 patients we detected genetic variants in the other genes (*TP53*, *PTEN*, *PIK3CA*, *KIT*, *TSHR)*. From our cohort, in 390 patients post-surgical histopathological evaluation has been known. Positive predictive values of *RET*, *BRAF*, *TERT*, *KRAS*, *HRAS*, *NRAS* mutations and fusion genes were 100%, 98.4%, 93.3%, 75%, 60%, 42.1% and 97.6% respectively, if borderline tumors were not included in malignancy. In the *BRAF*-positive cohort was a case of follicular adenoma with *BRAF* K601E mutation and in the *TERT*-positive cohort one case of follicular tumor of uncertain malignant potential with *TERT* and *NRAS* mutation.
Conclusions
We established molecular testing of thyroid nodules that significantly contributed to clinical management of patients in the Czech Republic. *BRAF*, *RET* and *TERT* mutations and *RET/PTC* and *ETV6/NTRK3* fusion genes are associated with almost 100% risk of malignancy or even worse prognosis, therefore according to ETA guidelines from 2017 and recent publications their carriers are recommended for the total thyroidectomy. The risk of malignancy of *RAS* mutations is lower and rather a lobectomy is recommended. *Supported by AZV NU21-01-00448 and MH CR RVO 00023761.*

Objectives
Papillary thyroid carcinoma (PTC) is the most frequent malignant endocrine disease and the most common genetic cause of the PTC is the substitution c.1799T > A (p.V600E) in the *BRAF* gene (35-70% of PTC) that represents more than 95% of *BRAF* mutations. Other rare mutations in the *BRAF* gene include other substitutions (e.g. p.K601E), small deletions or insertions close to codon 600. The aim was to analyze a large cohort of thyroid nodules for rare genetic variants in the *BRAF* gene.
Methods
A total of 1106 fresh frozen thyroid tissues collected from 2003 to 2021 were screened for exon 15 *BRAF* alterations. The cohort consisted of 851 papillary thyroid carcinomas (PTC), 33 borderline tumors, 28 oncocytic and follicular carcinomas (FTC), 6 poorly differentiated carcinoma (PDTC), 15 anaplastic

carcinomas (ATC), 15 follicular adenomas (FTA) and 122 benign tissues. The exon 15 of the *BRAF* gene was analyzed by next generation sequencing using the Nextera XT Sequencing Kit (Illumina) or Thyro-ID (4 bases). The VarSome software was used to interpret detected variants.
Results
The most common *BRAF* mutation p. V600E was detected in a total of 430 thyroid tissues - in 425 PTC, two borderline tumors (NIFTP and WDT-UMP), one PDTC and two ATC. In total, *BRAF* p.V600E was detected in 51.3% of PTC. The rare somatic *BRAF* alterations were detected in 11 from 851 patients of PTC (1.29%), in one benign thyroid tissue and one FTC. We detected eight various variants - the most common was p.K601E and V600_K601delinsE in four and three patients, respectively, followed by p.V600E + p.Q609E, p.V600_S605delinsEG, VKS600-2DFT, p.T599_V600insEAT, p.A598_T599insI and p.T599dup in one case only.
Conclusions
The rare *BRAF* variants represented 2.9% of *BRAF*-positive thyroid nodules. Except for p.K601E, other rare variants were found exclusively in PTC. However, *BRAF* fusion genes, that seem to be other genetic causes of PTC, were not analyzed in this study. *Supported by AZV NU21-01-00448 and MH CR RVO 00023761.*

[1]National Institute of Endocrinology 'C.I. Parhon', Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Endocrinology, Bucharest, Romania; [3]National Institute of Endocrinology 'C.I. Parhon', Endocrine Surgery, Bucharest, Romania; [4]National Institute of Endocrinology 'C.I. Parhon', Pathology, Bucharest, Romania

Background
During the past decades, the prevalence of both obesity and differentiated thyroid carcinoma increased worldwide. The link between obesity and thyroid cancer is controversial. Some studies found a relationship between obesity and thyroid carcinoma (especially $BRAF^{V600E}$ mutated) and between type 2 diabetes mellitus and thyroid cancer, while other did not.
Aim
To assess the relationship between papillary thyroid carcinoma and increased body mass index (BMI).
Methods
Retrospective study by analyzing the files of patients with thyroid nodules who underwent thyroid surgery within a tertiary endocrine center. 101 patients (aged 54.5 ± 14 years) with thyroid nodules were included. TSH, FT4 were measured by chemiluminescence. Preoperatively, fine needle aspiration and cytology exam were performed in suspicious nodules, according to current guidelines. Bethesda classification was used for reporting the results. After thyroidectomy, according to histology exam, 51 patients had multinodular nontoxic (MNG) and 50 had papillary thyroid carcinoma (PTC).
Results
Globally, normal BMI (18.5-24.99 kg/m^2) was found in 27% of patients, while 47%were overweight and 26% were obese. 43% of patients were residents in iodine-deficient regions without significant differences between patients with MNG and PTC. Cytology exam was performed in 57 patients: Bethesda II was described in 11 patients (19,3%), Bethesda IV in 23 (40,35%), Bethesda V in 13 (22,8%), Bethesda VI in 7(12,28%) and for two patients our results came back inconclusive (Bethesda I – 3,5%) and 1 more patient (1,75%) had cytology exam performed from ganglia which came back positive for malignancy. Age was similar in patients with MNG (55.6 ± 12.3 years) and in patients with PTC (55 ± 15.6 years, P = ns). Mean TSH levels were similar in patients with MNG (1.2 ± 0,81 mIU/l) and in patients with PTC (1.4 ± 0,78 mIU/l, P = ns). Mean diameter of the largest nodule was significantly higher in patients with multinodular goiter (31.3 ± 12.6 mm) than in patients with PTC (26.3 ± 12 mm, P = 0.02). Patients with normal BMI had similar mean diameter of the largest nodule (29.9 ± 15 mm) with overweight and obese patients (31.63 ± 11.2 mm, P = ns, t-test) and also showed a similar prevalence of PTC- 48.2% as compared with 48.6% in overweight and obese patients (P = ns, chi square). Mean TSH levels was slightly higher (1.49 ± 0,80 mIU/l) in overweight and obese patients with PTC, than in patients with normal BMI (TSH = 1.26 ± 0,75 mIU/l, P = ns).
Conclusion
In our retrospective series, there was no link between BMI and papillary thyroid cancer. Larger prospective studies are needed in order to clarify this relationship.

EP1028

Sub acute thyroiditis following COVID infection or vaccine: case reports

Hemmat El Haddad[1], Amr El Meligui[2], Randa Salam[1], Hesham Maged El Din[1], Ahmed Rabie[1], Samar Amin[1], Mona Youssry[1] & Noha Tarek[1]
[1]Cairo University, Internal Medicine, Endocrinology, Cairo, Egypt; [2]Cairo University, Cairo, Egypt

Introduction
The novel severe-acute-respiratory-syndrome-coronavirus-2 virus has led to the ongoing Coronavirus disease 2019 (COVID-19) disease pandemic. There are increasing reports of extra pulmonary clinical features of COVID-19, either as initial presentations or sequelae of disease ((gastrointestinal, hepatobiliary, pancreatic, cardiovascular, ocular, and neurologic) Autoimmune/inflammatory syndrome induced by adjuvants (ASIA syndrome) can be seen as a post-vaccination phenomenon that occurs after exposure to adjuvants in vaccines We report cases of subacute thyroiditis following COVID infection or vaccine
Clinical cases
1-A 47 years old female developed subclinical hypothyroidism 3 weeks after COVID 19 infection TSH was 10.1 IU/ml (0.4-4), FT4 was 0.94 ng/dl ((0.7-1.9), Ant microsomal abs: 945IU/ml (0-9), Ant thyroglobulin abs: 285IU/ml (n: < 116) Thyroid sonar: diffuse heterogeneity & increased vascularity. 2-A 45 years old female developed subclinical hypothyroidism after exposure to COVID 19 infection by one month with TSH 7.74 IU/ml, FT4 1.2 ng/dl, Ant microsomal ab 959 IU/ml, Ant thyroglobulin ab 257 IU/ml Thyroid sonar: diffuse heterogeneity 3-A 35 years old female who had local pain in the neck 2 weeks after COVID infection. Investigations revealed non-uniform echo texture of the thyroid gland in the thyroid sonar TSH: 3.06 IU/ml, FT4 1.06 ng/dl, Ant microsomal ab 33 IU/ml, Ant thyroglobulin ab 955.7 IU/ml Post vaccine cases 1-A 59 years old female under treatment for thyrotoxicosis. She went into remission for 3 months with one tab neomercazole 5 mg 10 days of the first dose of vaccine for COVID 19, the patient developed exacerbation of her thyrotoxicosis with tachycardia, pulse 115, anxiety, insomnia and tremors. Her TSH became 0.009 IU/ml & increase of the dose of Inderal & neomercazole was done. Within 2 months the patient responded in a good way & entered into remission again 2-A 65 years old female who developed hypothyroidism after vaccine TSH: 10.21 IU/ml, FT4 0.82 ng/dl, Ant microsomal ab 600 IU/ml, Ant thyroglobulin ab 206 IU/ml 3-A 36 years old female who developed subclinical hyperthyroidism after vaccine Her thyroid sonar was normal sized sonar with heterogeneity TSH 0.03 IU/ml, FT4 0.93 ng/dl After 3 months her thyroid sonar is completely normal TSH 1.210 IU/ml, FT4 0.84 ng/dl, FT3 2.94 pg/ml (2.3-4.1)
Conclusion
Clinicians must be aware of the possibility of thyroid dysfunction and subacute thyroiditis after COVID-19 infection and after the inactive SARS-CoV-2 vaccine. Early recognition and timely anti-inflammatory therapy can help in successful management of the disease.

DOI: 10.1530/endoabs.81.EP1028

EP1029

Hashimoto's thyroiditis manifested with rhabdomyolysis and cardiac effusion following SARS-CoV-2 vaccination: A case report

Rachid Smaili, Randa Ait Imrane, Ikram Raaidi & Myriem Bourkia
University Hospital of Tangier, Internal Medicine and Clinical Immunology, TANGER, Morocco

Background
Autoimmune inflammatory syndrome induced by adjuvants (ASIA syndrome), include the different conditions linked following exposure to an adjuvant. Autoimmune thyroiditis following vaccination as an auto-immune/inflammatory syndrome is rarely reported. In the era of mass vaccination against SARSCov2, there is limited information about cases of auto-immune thyroid disease as an ASIA syndrome following SARS-CoV-2 vaccination.

Case
A 19years old man, with no medical history was presented five days after second vaccination doses against SARS-CoV-2 with unusual clinical symptoms of hypothyroidism as acute rhabdomyolysis with a pericardial effusion, and a very high level of thyroid stimulating hormone, decreased free thyroxin and higher level of peroxidase and thyroglobulin thyroid autoantibody. One week after L-thyroxin treatment CK was normal and kidney function is normalized with a remarkable improvement of thyroid functions.
Conclusion
Rhabdomyolysis and pericardial effusion can occur as severe symptoms of Hashimoto thyroiditis as an ASIA syndrome after vaccination against SARS-CoV-2.
Key words:ASIA syndrome - SARS-CoV-2 vaccine - Hashimoto's thyroiditis - Acute rhabdomyolysis - pericardial effusion.

Hand and foot skin changes resembling PTU-induced vasculitis in a young male with diffuse toxic goiter- a case report

Martina Tomasovic[1], Marija Sinik[1], Bojan Joksimovic[1], Milena Lackovic[1], Vladimir Samardzic[1], Marina Vujovic[1], Zoran Gluvic[1], Milan Obradovic[2], Sonja Zafirovic[2] & Esma R. Isenovic[2]
[1]Zemun University Clinical Hospital, Department of Endocrinology and Diabetes, Belgrade, Serbia; [2]"VINČA" Institute of Nuclear Sciences – National Institute of the Republic of Serbia, Department of Radiobiology and Molecular Genetics, Belgrade, Serbia

Propylthiouracil (PTU) sometimes induces autoimmune syndromes, such as PTU–induced lupus or vasculitis. Here we present hands and feet vasculitis-like skin changes observed several days after PTU introduction in a patient who suffered from serious diffuse toxic goiter. Because of segmental distribution, normal liver function test, and no signs of clinical deterioration, it was decided to continue PTU management and observe the patient. Primarily maculopapular rash became vesicular shortly after and then scaly. After two weeks, skin changes were entirely restored with no scaring. Taking into account thorough epidemiological survey, clinical course, and performed diagnostics, presented skin changes were diagnosed as Hand, Foot, and Mouth disease (HFMD). Clinicians must be aware of the side effects of used drugs, especially after their introduction. Some clinical presentations could only resemble expected or well-known side-effects, intolerance, or hypersensitivity to the used drug. Every clinical presentation associated with any drug introduction must be thoroughly evaluated. The presented case revealed that skin changes of HFMD mimicked PTU-induced vasculitis.

Frequency of thyroid ultrasound alterations in polycystic ovary syndrome

Sawsen Essayeh[1], Wassim Frikha[2], Radhouan Gharbi[1], Wiem Madhi[1], Manel Jemel[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technology of Tunis, Endocrinology, Tunis, Tunisia; [2]La Rabta Hospital, Radiology, Tunis, Tunisia

Introduction
Polycystic ovary syndrome (PCOS) is a common endocrine disease in women of childbearing age. This condition combines, according to the diagnostic criteria of the Rotterdam consensus 2003, clinical and/or biochemical signs of hyperandrogenism, oligo- and/or anovulation and polycystic ovaries detected by ultrasound. Thyroid diseases are also frequent in the general population. The aim of our study was to determine the prevalence of thyroid ultrasound alterations in a group of patients with PCOS compared to a control group.
Patients and Methods
31 patients with PCOS and 30 age- and body mass index-matched healthy volunteer women were recruited into the study. Thyroid ultrasound was performed in all participants.
Results
The age and the body mass index were comparable between the two groups (29.8 ± 7 vs 29.5 ± 5.5 years, $P = 0.86$; 32 ± 6.6 vs 31.1 ± 8.9 kg/m^2 $P = 0.62$). Cervical ultrasound was more frequently pathological in the group of PCOS women (58% vs 33%, $P = 0.05$). The ultrasound feature of thyroiditis was significantly higher in the PCOS group compared to the control group (39% vs 3%, $P = 0{,}001$). The means of thyroid volume were similar in both groups (9.4 ± 5.5 vs 10 ± 7.2, $P = 1$). The percentages of goiter and thyroid nodules were comparable between the two groups ($P = 1$, $P = 0.7$ respectively).
Conclusion
Our study showed an increased prevalence of thyroiditis on cervical ultrasound in PCOS women but it did not show any difference in the occurrence of thyroid nodules or goiter.

Efficacy of ethanol injection in cystic thyroid nodules

Naween Kumar[1], Rajeev Ranjan[2] & Siddharth Singh[3]
[1]Global Healthcare & Diabetes Research Centre, Diabetes, Darbhanga, India; [2]Chest Clinic, Medicine, Chapra, India; [3]IGIMS, Diabetes, Patna, India

Introduction
Thyroid cystic nodules (TCN) are generally due to degenerative changes within colloid nodules or adenomas. True thyroid cysts are uncommon. But the prevalence of malignancy among TCN is controversial since some authors consider it to be low risk while some others consider it to have the same risks as malignancy as the solid lesions of the thyroid. Percutaneous ethanol injection (PEI) is utilised for treating benign cystic thyroid nodules. It is a protected option for cystic TNs and compelling treatment for lessening strong TNs of various sizes whether or not hyperfunctioning. In this meta-analysis study, the aim is to obtain strong evidence regarding the safety and long-term efficacy of PEI.
Methods
Data reported on compressive symptoms, cosmetic concerns, and volume reduction rate were collected from different well-known databases like PubMed, Web of Science and Scopus. Data collected since 2020 were used for this study. For pooling the data, a random-effects model was also designed.
Results
From the final selected 395 papers, 19 studies that evaluated 1667 nodules were included. Volume reduction rate at 6, 12, 24, 36, 60 and 120 months were 78%, 82%, 73%, 69%, 75% and 70% respectively. Observations were made for significant reductions of cosmetic concerns and compressive symptoms. However, extremely durable inconveniences were not seen in this review.
Conclusions
In this present meta-analysis study, the PEI significantly reduced the volume of harmless cystic thyroid nodules. This reduction was seen as effective at the post-treatment of six months, and stability was seen in the effects over time.

Pregnant patient with a history of methimazole-induced agranulocytosis presenting with hyperthyroidism: a case report

Abdusattar Abduraup & Jerome Barrera
Zamboanga City Medical Center, Internal Medicine, Zamboanga City, Philippines

Background
Pregnancy has a profound impact on the thyroid gland and its function. Severe thyrotoxicosis can lead to many complications and endanger the mother or fetus. Antithyroid drug (ATD), at its lowest possible dose, should be given. However, one of the complications of treatment include agranulocytosis which is a rare but serious allergic event with a prevalence of 0.1 to 0.5 percent. Thus, alternative treatment should be prescribed because a cross-reaction between ATDs was observed in 15.2% of patients in a study. Insufficient data is available regarding the use of these medications in pregnant patients with history of drug-induced adverse reactions. There are alternative treatments but are contraindicated in pregnancy.
Case
We report a 29-year old patient gravida 5 para 4 at 10 weeks age of gestation presenting with palpitations. She is a known case of Graves' disease for 7 years and maintained on Methimazole. She was admitted a year prior as a case of impending thyroid storm; methimazole-induced agranulocytosis. Initially, maintained on Lithium but shifted back to Methimazole without a physician's

advice and later on, discontinued the medication upon knowledge of pregnancy. On her first trimester, noted with palpitations and elevated free thyroxine (T4) at 71.29 pM (normal range: 11-24 pM). She was started on Propylthiouracil 50 mg/tablet 1 tablet thrice a day. On her second trimester, no reported symptoms of hyperthyroidism and/or agranulocytosis such as fever or sore throat. Thyroidectomy was offered but she strongly refused. Free T4 was then maintained at a value slightly above the upper normal limit. Propylthiouracil was shifted to methimazole 5 mg/tablet 1 tablet once daily and revised to 1 tablet every other day on her third trimester. Delivery was uneventful and the newborn was evaluated with unremarkable findings. Four weeks postpartum, no noted symptoms of hyperthyroidism and/or agranulocytosis. Free T4 was within normal at 18.84 pM. Alternative treatment was offered due to the risk of agranulocytosis.
Conclusion
Hyperthyroidism in pregnancy is associated with a variety of complications for the mother and fetus. Effective treatment options include ATD, thyroidectomy or RAI therapy. But, not all are relatively safe for pregnancy. In initiating ATD, cross-reaction between medications should be considered especially for patients with history of adverse reaction, such as agranulocytosis, which can be life-threatening. However, there are limited studies in the management of this specific case. Treating physician and patient should discuss each of the options, including the benefits and drawbacks.

Place of scintigraphy in case of diagnostic doubt in Graves' disease

Severin N'Koua, Jaddi Oussama, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
Department of Endocrinology, Diabetology and Metabolic Diseases, CHU Mohamed VI. Marrakech., Marrakech, Morocco

Graves' disease is a rare and severe disease that most often affects older children and is predominantly female. The diagnosis is made in the presence of a clinical picture very suggestive of thyrotoxicosis, confirmed by biological and radiological tests. We present the case of an 11-year-old female patient who presented with a moderate presented of basedow with an ultrasound appearance of thyroiditis for which scintigraphy was helpful in the diagnosis. Female patient, 11 years old with no history, has been suffering from moderate weight loss for 2 months without any other signs of thyrotoxicosis. On clinical examination: bilateral exophthalmos, normocadic at 78 bpm non palpable thyroid. On clinical examination: bilateral exophthalmos, normocadic at 78 bpm non palpable thyroid. On workup: TSH $<$ 0,05 Mui/l; T4L : 20,8 (N:9-19) pmol/l; Cervical echography : aspect of a thyroiditis. diagnosis doubt and therapeutic necessity, a scintigraphy was performed showing a diffuse and homogeneous fixation. the patient had been put on carbimazol 20 mg/d. The difference between Graves' disease and thyroiditis is not always trivial in view of the clinical manifestations during the Hashi toxicosis phase and the ultrasound appearance, the interpretation of which remains operator dependent. In such conditions, the use of anti-thyroid antibodies or scintigraphy can play a decisive role. Indeed, in Graves' disease the scan image appears diffuse and homogeneous unlike in thyroiditis where the image appears white. Thyroid scintigraphy is one of the definitive diagnostic tools, especially when there is clinical and sonographic confusion between the two conditions.

The effect of l-thyroxine replacement on blood pressure and heart rate in children with hypothyroidism: correlation with free thyroxine and thyrotropin levels

Ahmed Elawwa[1], Ashraf Soliman[2] & Marwa Faraj[1]
[1]Department of Pediatrics, College of Medicine, Alexandria University, Alexandria, Egypt; [2]Hamad Medical Center, Pediatrics, Doha, Qatar

Chronic administration of L thyroxine to children with hypothyroidism may affect cardiovascular dynamics.
Aim of the study
We measured the BP and heart rate (HR) of 25 randomly selected children with hypothyroidism in relation to their serum free T4, and TSH levels and thyroxine dose mg/kg.
Methods
25 randomly selected children with a mean age 9.6 +/- 4.5 years with the diagnosis of congenital or acquired hypothyroidism. They were on L thyroxine therapy to keep serum FT4 and TSH in the normal range for age. Their blood pressure (BP) and HR (average of three readings), weight, height, dose of thyroxine, and their serum level of TSH and Free T4 levels within two weeks before the clinic visit were recorded. The Z scores of the height (HtSDS), BMI (BMISDS), systolic (SBPSDS) and diastolic blood pressure (DBPSDS) were calculated (as per the 2004 guideline report on hypertension from the National Heart and Lung institute) and HR (as per the Monitoring and Diagnosis Group at Oxford (MADOX) systematic review of 2011) were calculated for age and gender.
Results
L thyroxine dose was 2.11 +/- 0.7 mg/kg. Their mean serum free thyroxine levels was 15.1 +/- 2.5 mg/l and TSH level was 3.9 +/- 2.8 mIU/ml. Their HtSDS (-0.57 +/- 1.4) and BMISDS (0.63 +/- 1.63) were within normal. All had normal diastolic blood pressure readings (within 2 standard deviations of the mean for age and sex). Two of the individuals had systolic blood pressures $>$ 2SDS above the mean for age and gender, with normal BMISDS. Both had normal FT4 and TSH levels. One patient had tachycardia (HR = 146/min (z score +3.2 for age). His FT4 and TSH levels were normal. There was a positive correlation between thyroxine dose/kg and serum level of FT4(r=0.52), heart rate (r=0.56), SBPSDS (r= 0.38), and DBPSDS (r=0.24). There was no significant correlation between the HtSDS on the one hand and FT4, TSH or thyroxine dose on the other hand. The BMISDS was negatively correlated with TSH level (r=-0.4)
Conclusion
In this study on hypothyroid children on L thyroxin therapy, 2 had high systolic blood pressure and one had tachycardia. The significant correlation between the thyroxine dose, FT4 level and BP and HR should alert the Pediatrician to monitor BP and HR closely in relation to TSH and FT4 levels these patients.

Diagnosis and management of anaplastic thyroid carcinoma: about 3 cases and review of literrature

Rachida Bouattay, Emna Bergaoui, Maroua Naouar, Mehdi Ferjaoui, Heyfa Belhadjmiled, Amel Elkorbi, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT, Monastir, Tunisia

Introduction
Anaplasic thyroid carcinoma is an extremely aggressive undifferentiated tumor of follicular cell origin. It is uncommon and comprising approximately 1% of all thyroid cancers.
Purpose of the presentation
The objective of this work is to determine the clinical, histological and therapeutic aspects of anaplasic thyroid carcinoma.
Methods
This is a retrospective study about 4 patients treated for an anaplasic thyroid carcinoma, in the ENT department of Fattouma Bourguiba hospital in Monastir over a period of 22 years (2000-2021).
Results
The average age was 68 years. A female predominance was noted. The average consultation time was 2 months. Patients consulted for a rapidly progressive goitre in all cases, associated with dysphagia and dyspnea in 3 cases (75%). Cervical examination showed a painful and indurated anterior cervical swelling with a medium size of 5 cm in all patients. Associated lymph nodes were found in 2 cases (50%). Indirect laryngoscopy showed laryngeal paralysis in 2patients (50%), one of which was bilateral (25%). Cervical ultrasound and cervico-thoracic scan showed a mass pushing back the trachea in three cases (75%). 3 patients (75%) had an emergency tracheostomy with thyroid biopsy. The other patient underwent a lobo-isthmectomy. Radiotherapy was indicated in all cases. The evolution was fatal in all patients with a survival of less than 6months.
Conclusion
Anaplastic thyroid cancer is a very rare case and has a poor prognosis. The important information such as clinical manifestations, physical examination and imaging are necessary to diagnose and administer the proper management.

Hürthle cell tumors of the thyroid gland: diagnostic and therapeutic features

Masmoudi Mohamed, Chaima Zitouni, Wadii Thabet, Chebil Ezer, Hasnaoui Mahdi & Mighri Khalifa
Taher Sfar Hospital, Otorhinolaryngology, mahdia, Tunisia

Introduction
Oncocytic tumors can occur in the thyroid gland and other endocrine tissues, including the parathyroid, pituitary gland, adrenal cortex, pancreas, gut, and lung. Thyroid oncocytic tumors are rare: 3-10% of thyroid epithelial tumors. They are characterized by the presence of oncocytic cells called "Hürthle" cells.
Objective
Describe the clinical, pathological and therapeutic features of oncocytic tumors of the thyroid gland.
Methods
A retrospective study including 35 cases of thyroid oncocytic tumors treated in our department between 1988 and 2021.
Results
The average age of our patients was 48 years. The sex-ratio (F/M) was 10,9. The mean size of the nodules on ultrasonography was 31,3mm. The nodule was unique in 25 cases. The nodules were classified according to the EU-TIRADS classification: EUTIRADS 2 (12 cases), EUTIRADS 3 (22 cases), EUTIRADS 4 (10 cases) and EUTIRADS 5 (10 cases). A lobectomy was performed in 31 cases, a total thyroidectomy was done in 1 case, and an isthmectomy was done in 3 cases. Among our patients, 33 patients had oncocytic adenoma and 2 patients had oncocytic carcinoma. In case of oncocytic carcinoma, a totalization with central lymph node dissection and radioactive iodine therapy were done. Evolution was favorable in these 2 cases.
Conclusion
In general, oncocytic tumors do not have a specific clinical presentation or distinguished features on ultrasonography. Furthermore, distinguishing hyperplasia from neoplasia, and benign from malignant is difficult on cytology. Anatomopathological examination is often needed to make the diagnosis of these tumors. Compared to other differentiated tumors, oncocytic carcinomas tend to be more aggressive, and have less radioactive iodine intake. Overall survival in 5 years is 50-70%.

Type 1 diabetes mellitus and autoimmune thyroid disorders

Faten Haj Kacem Akid[1], Raida Ben Salah[2], Siddiqa Soomauroo[1], AbdelMouhaymen MISSAOUI[1], Sarra Chouaib[1], Sameh Marzouk[2], Nadia Charfi[1], Zouheir Bahloul[2] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia

Introduction
Type 1 diabetes mellitus (T1DM) is the result of the autoimmune destruction of beta-cells of the endocrine pancreas, leading to absolute insulin deficiency. The process of this autoimmune destruction occurs in genetically susceptible individuals with positive relevant autoantibodies. T1DM may be associated with other autoimmune diseases (AD) such as autoimmune thyroid disorders (AITD).
Patients and methods
It is a descriptive retrospective study. We collected data from 113 patients diagnosed with AITD associated with another AD over 18 years. The present study reports the association between T1DM and AITD.
Results
T1DM was diagnosed in 41 patients (31.53%) which consisted of 25 women and 16 men. The mean age upon discovery of the T1DM was 30.49 years. The T1DM was associated with an overt hypothyroidism in 18 patients, a subclinical hypothyroidism in 1 patient, an autoimmune thyropathy in euthyroid phase in 7 patients, an overt hyperthyroidism in 14 patients and a subclinical hyperthyroidism in 1 patient. It was affiliated with Hashimoto's disease in 26 cases (63.4% of cases) and with Graves' disease in 15 cases (36.6% of cases). The T1DM preceded the diagnosis of the thyroid disorder in 24 cases with a mean period of 69 months between and succeeded the latter in 6 cases within a mean period of 40 months. In 11 cases, both diagnoses were concomitant.
Discussion and Conclusion
T1DM is the most frequent AD associated with AITD. Their prevalence is 2 to 3 times higher in the T1DM population than that of the general population. As a matter of fact, 6.6% out of 10% of healthy adults have positive thyroid antibodies compared to 20% out of 40% of T1DM adults. According to Barker, T1DM is associated with Hashimoto's disease in 14-28% of cases. In other studies, it is associated with Graves' disease in 0.5-7% of cases. Several studies demonstrated that AITD was more frequent in diabetic women than men, which could be explained by higher prevalence of AITD in women. Serum TSH assay is recommended upon discovery of diabetes in patients with hypothyroid or hyperthyroid symptoms, then every 1-2 years as follow up. Our results consistent with that of the literature showed the high prevalence of the T1DM in patients with AITD, and thus the necessity of regular screening in these patients.

Predictive factors of malignancy in thyroid nodules: value of ultrasonography

Masmoudi Mohamed, Chaima Zitouni, Wadii Thabet, Chebil Azer, Hasnaoui Mahdi & Mighri Khalifa
Taher Sfar Hospital, Otorhinolaryngology, Mahdia, Tunisia

Introduction
Ultrasound has become an indispensable diagnostic modality in the evaluation of the risk of malignancy of a thyroid nodule.
Objective
Identify the predictive factors of malignancy in thyroid nodules on ultrasound.
Methods
This is a retrospective study including 333 patients diagnosed with thyroid nodules and operated between 2010 and 2020. A significance threshold of 0.05 was adopted for the statistical analysis.
Results
The mean age of the patients was 44 years, predominantly females (88.3%). A thyroid cancer was diagnosed in 43 cases. The most common histological types were papillary carcinoma (83%) and vesicular carcinoma (14%). Predictive factors of malignancy were: solitary nodule ($P = 0,01$), cervical lymph node metastasis ($P = 0,017$), size > 4 cm ($P < 0,001$), solid nodule ($P < 0,001$), hypoechogenic nodule ($P = 0,004$), central vascularization ($P < 0,001$), central and peripheral vascularization ($P = 0,006$), microcalcifications ($P < 0,001$).
Conclusion
Although the vast majority of thyroid nodules are benign, a small proportion are cancers. Several predictive factors can evaluate the risk of malignancy of a thyroid nodule, however, predictive factors on ultrasonography are still the most important. The EU-TIRADS classification, is the most commonly used classification to stratify this risk of cancer in thyroid nodules. In the EUTIRADS classification, markedly hypoechoic, non-oval shape, irregular margins and microcalcifications are the only predictive factors included.

Risk factors for central neck lymph node metastasis in patients with macro and micropapillary thyroid carcinoma

Georgios Boutzios[1], Sofia Chatzi[2], Areti Mina[2], Eleni Koukoulioti[2], Ilias Giovannopoulos[2] & Gerasimos Tsourouflis[3]
[1]School of Medicine, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece; [2]School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [3]School of Medicine, National and Kapodistrian University of Athens, Second department of Propedeutic Surgery, Athens, Greece

Introduction
The prevalence of lymph node metastasis from micropapillary thyroid carcinoma (mPTC) in different studies is up to 33%. Preoperative diagnosis of central lymph node (CLN) metastasis is essential for the surgical management of those patients. Prophylactic CLN dissection for patients with mPTC is controversial. Our study aimed to assess the prevalence and the risk factors of LMN metastasis in patients mPTC

Methods
We retrospectively study the clinicopathological characteristics of 167 patients with PTC operated at the Second Department of Propaedeutic Surgery, University of Athens. Patients before surgery underwent ultrasound thyroid mapping for lymph node invasion assessment. All underwent total thyroidectomy with prophylactic central neck dissection.
Results
A total of 167 patients (73,1% females) were analyzed. The mean age was 51.08 ± 13.38 years, and the mean follow-up was 5.3 years. In 30.2% (55/161) of the patients, the lesion was located in both thyroid lobes, in 29.1% (53/161) and 26.4% (48/161) in the right and left lobe, respectively. Only 2.7% (5/161) of the patients had lesions located in the isthmus. 33% (60/162) of PTC patients had bilateral lesions, and 41.8% (76/165) had more than one lesion. The median number of lesions was 1.0 ± 3.05. 54.5% (91/167) of the patients had macro-PTC. In 34.8% of them, the lesion was located in both thyroid lobes. 45.7% % had multiple lesions. Furthermore, 49.3% had capsule penetration, 39.1% had an extrathyroidal expansion, and 32.8% had lymph node invasion. 45.5% (76/167) had micro-PTC. In 41.8% of the patients, the lesion was located in both thyroid lobes. 48.1 % had multiple lesions. In addition, 47.3% of these patients had capsule penetration, 35.9% had an extrathyroidal expansion, and 30.8% had lymph node invasion.
Conclusion
Our study found an increased risk of lymph node invasion in patients with micro-PTC, compatible with macro-PTC. Thus, an ultrasound thyroid mapping for lymph node invasion assessment before surgery is needed.

Papillary thyroid cancer and its variants - genomic evidence and clinical significance

Darko Katalinic[1], Ivan Aleric[1], Aleksandar Vcev[1], Miljenko Solter[2], Irena Ranogajec[3] & Lars Toetome[4]
[1]Faculty of Dental Medicine and Health and Faculty of Medicine, J. J. Strossmayer University, Osijek, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia; [3]Clinical Hospital Sveti Duh, Zagreb, Croatia; [4]Center for Cancer Medicine, Oslo, Norway

Purpose
Papillary thyroid cancer (PTC) accounts for approximately 80% of all thyroid cancers and is defined by its unique cytologic and histologic features. Mutations of the *RET and BRAF/V600* genes are found in nearly 70% of PTC cases. They are able to trigger the activation of mitogen-activated protein kinase pathways and to promote neoplastic cell proliferation. Genetic events may further lead to numerous different cell variants of PTC which may be identified via the different cyto/histopathologic features. The most common are the classical (CV), tall cell (TCV) and follicular variant (FV). The aim of the study was to perform the genomyc analysis of the *RET* and *BRAF (V600)* mutations in patients with PTC as well as to compare the obtained results with clinical findings.
Methods
The study included 112 patients diagnosed with PTC, aged 41-74 years. Mutations of the *RET* and *BRAF (V600)* genes were detected using Real-time polymerase chain reaction. Diagnosis of the PTC and its variants was confirmed with cyto/histopathological examination.
Results
The most important genomic, cyto/histopathological and prognostic elements regarding all three variants of the PTC are as follows: CV-PTC ($n = 78$): *RET* and *BRAF (V600)* mutations are common findings, with *BRAF (V600)* confirming a worse prognosis. The 65% of these patients have shown stabile disease course, with 25% with metastatic nodes; TCV-PTC ($n = 8$): Aggressive behavior has been attributed to *BRAF (V600)* mutation; FV-PTC ($n = 26$): Absence of *BRAF (V600)* mutation was the most important genetic element.
Conclusions
In most cases, PTC has an excellent prognosis, but certain variants express more aggressive clinical course. CV-PTC: *BRAF (V600)* mutation was negative prognostic element; TCV-PTC presents mostly in older patients, has agreater propensity for locoregional dissemination and has more aggressive course than CV-PTC; The prognosis of FV-PTC has been similar to that of CV-PTC. The patients with CV-PTC and FV-PTC had fovorable clinical course comparing to those with TCV-PTC. Our study suggests that PTC is etiopathogenically complex disease and requires further molecular investigations.

Graves' disease associated with thyroid papillary carcinoma

Mohamed Masmoudi, Marwa Regaeig, Wadii Thabet, Azer Chebil, Mehdi Hasnaoui & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Otorhinolaryngology, Tunisia

Introduction
Thyroid carcinoma in Graves' disease is rare (1 to 2%). Papillary carcinoma is the most common histologic type. It is usually discovered incidentally after histologic exam. Our aim is to report a case of Graves' disease associated with thyroid papillary carcinoma and to describe its therapeutic and prognostic features.
Case report
A 51-year-old woman treated with anti-thyroid drugs and β blockers for Graves' disease. Cervical ultrasound found an enlarged, hypervascular thyroid gland with a 10 mm nodule classified EUTIRADS 5. Indication for surgery was: failed medical therapy after 3 years of treatment and concomitant suspicious thyroid nodule. The patient underwent total thyroidectomy. Intraoperative examination suggested a papillary thyroid carcinoma. So, a central neck dissection was performed. Histologic exam confirmed the diagnosis of papillary thyroid carcinoma associated with Graves' disease. The patient underwent ablative radioiodine therapy. After 7 years of follow-up, she had no recurrence.
Conclusion
Patients with Graves' disease had a higher risk of developing thyroid cancer than the general population. However, studies reported conflicting results about the prognosis of thyroid cancer concomitant with graves' disease.

Lymph node metastasis in adults and young adults with thyroid carcinoma: an algerian observation

Nadjib Kaouache, Bilal Zouraghen, Merabet Samira, Grari Soumaya, Menacer Sami, Boulefkhad Ryma, Habi Chahinez, Azzouz Nassim, Lezzar Al Kassem & Nassim Nouri
University Hospital of Constantine, Endocrinology, Constantine, Algeria

Introduction
Thyroid cancer (TC) in adolescents and adults (AYA) is defined as thyroid cancer diagnosed among those aged between 15-39 years. It is the fifth most common cancer in AYAs, and its incidence is increasing. Compared with older adult patients, the AYA with TC has a higher prevalence of node metastasis which represents a risk factor for recurrence.
Aim
To describe the characteristics of thyroid carcinoma with confirmed nodal metastases at the time of diagnosis in an Algerian cohort of AYA patients. And to compare patient with and without lymph nodes metastases.
Methods
Medical records of patients diagnosed with differentiated thyroid carcinoma and aged 18-40 years at the moment of diagnosis followed in the endocrinology department of The University Hospital of Constantine in Algeria during the period between July 2014 and December 2018 were retrospectively reviewed. Clinical and pathological data were collected. The group with no lymph node metastases (LN0) was compared to the group with lymph node metastases (LN1) and factors associated with LN metastases were evaluated.
Results
101 patients were included, the mean age was 31 (17- 40 years) and 85.1% were females. Total thyroidectomy was done in 88.1% and lymph node dissection in 23.8% which was central in 13.9% and central and lateral in 9.9%. 90.1% of patients had papillary thyroid cancinoma, 7.9% had follicular carcinoma and 2 patients had Noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP). Following the 8th AJCC classification, 64% were T1, 12.9% T2 and 20.8% were T3. 15.8% had lymph node involvement. Multifocality, bilaterality, vascular thyroid invasion, and capsular thyroid invasion were present in 30.7%, 15.8%, 7.9%, and 17.8%. As for risk stratification according to the ATA system, the initial risk was low, intermediate, and high in 41.6%, 35.6%, and 10.9% of patients, and data were insufficient to state this risk in 11.9% of patients. Thyroid cancer LN1 group had greater tumor size (27.5mm and 17.2mm $P = 0.0.38$) and thyroid dysfunction (7.1% and 0% $P = 0.048$) at the moment of diagnosis than the LN0 group. There was no difference between thyroid cancer with LN1 and LN1concerning, mean age, sex, pathology type and variant, vascular and capsular invasion.

Conclusion
In this cohort of AYA Algerian patients with thyroid cancer, greater tumor size and thyroid dysfunctions were more important in patients with lymph node metastasis at the moment of diagnosis.

Introduction
Dyshormonogenetic goiter (DG) is considered as a form of thyroid hyperplasia due to enzymatic defects in hormone synthesis. The architectural polymorphism and cellular atypia may mimic thyroid neoplasms and cause difficulties in differential diagnosis.
Results
We report 3 cases of DG occurring in one females and two males who were aged 20, 9, and 7 years old, respictively. All patients presented with clinically evidence of goiter. Hypothyroidism was documented before the histological diagnosis was made in all patients. The thyroid gland was enlarged and multinodular in all cases. Cervical ultrasound and thyroid scintigraphy were performed for all patients. The ultrasound showed a multinodular goiter in all patients. The scintigraphy showed a global hyperfixation of the thyroid for two patients with a right hypofixing zone for one patient. All patients underwent surgical treatment. A total thyroidectomy for two patients and a right loboishmectomy for one patient. The anatomopathological examination confirmed a DG in all cases. The evolution was favorable for all patients and without recurrence.
Conclusion
DG is a rare entity, representing one of the causes of congenital hypothyroidism. It is morphologically characterized by architectural and cellular pleomorphism that may mimic thyroid malignancy and cause difficulties in differential diagnosis that explains the delema of establishing surgical indications.

Metachronous renal cell carcinoma metastasis to the thyroid

Cristina Cretu[1], Cristina Cristea[1], Ioana- Cristina Barbacariu[1], Paula Dragoman[1], Lucia Flavia Livenschi[1], Diana Nicoleta Florescu[1], Radu Danila[2, 3], Delia Ciobanu[3, 4] & Cristina Preda[1,3]
[1]Saint Spiridon County Hospital, Endocrinology, Iaşi,; [2]Saint Spiridon County Hospital, Surgery, Iaşi, Romania; [3]'Grigore T. Popa' University of Medicine and Pharmacy of Iaşi, Iaşi, Romania; [4]Saint Spiridon County Hospital, Pathology, Iaşi, Romania

Introduction
Metastatic disease into the thyroid is a rare event, despite the gland's rich vascular supply. Renal cell carcinoma (RCC) is an unusual neoplasm that not only has the potential to recur after a latent disease-free interval, but also has the potential to metastasize to rare sites like the thyroid. However, of the clinically significant secondary neoplasms of the thyroid, metastatic RCC is the culprit in most cases.
Case report
We present the case of a patient with metachronous RCC metastasis to the thyroid. A 62-year-old male with a 2-year history of non-toxic multinodular goiter was admitted to our Endocrinology Department. He had a history of multiple malignancies: 5 years earlier he had been diagnosed with clear cell RCC (ccRCC) (for which a left nephrectomy was performed) as well as basal cell carcinoma and 25 years earlier he had been diagnosed with colon cancer. Ultrasound evaluation documented a solid, very hypoechoic right thyroid nodule with significant growth, but fine needle aspiration biopsy couldnt be performed because of the nodule's posterior position. Considering the sonographic features of the lesion, the inability to perform a biopsy and the history of prior malignancies, we recommended surgical treatment. A total thyroidectomy was performed. Immunohistochemistry findings, along with the patient's history, confirmed the diagnosis of thyroid metastasis from ccRCC. The patient was subsequently referred to an oncologist for further evaluation and treatment and he received targeted therapy with Sunitinib.
Conclusions
RCC recurrence after nephrectomy is highly variable, presenting with metastasis ranging from a few months to several years after the initial diagnosis. Metastatic RCC to the thyroid should be considered in any patient presenting with a thyroid mass and a medical history of RCC.

Occult papillary thyroid carcinoma with lymphatic metastasis as first presentation of the disease - A report of two cases

Adela Haxhiraj[1,2,3], Adishah Çerma[2], Violeta Hoxha[2], Dorina Ylli[2] & Agron Ylli[2]
[1]Klinika Neo Style, Tiranë, Albania; [2]Mother Teresa Hospital, Tiranë, Albania; [3]Salus Hospital, Tiranë, Albania

Introduction
Occult papillary carcinomas are small thyroid carcinomas (<1 cm) diagnosed after an initial manifestation of lymph nodes or distant metastasis. We report two cases of patients with this pattern of clinical presentation.
Case description
The first case is a 21-year-old woman, with a one-year history of a growing cervical cyst. Fine needle aspiration of the cyst showed metastasis from papillary thyroid cancer. She had no previous history for thyroid pathologies. A thyroid ultrasound was performed and the gland was described as heterogeneous, with no clear evidence of a primary carcinoma site but with too highly hypoechoic areas in the left lobe. Initial blood tests were as follow: TSH, Thyroglobulin and Calcitonin within the normal range, high levels of anti-TPO and anti-TG confirming the diagnose of Hashimoto thyroiditis. Total thyroidectomy and lymph node resection was recommended to the patient. The post-surgery biopsy confirmed multiple papillary focal lesions of papillary carcinoma with maximal diameter 1 cm. The patient received 131-iodine therapy with 100 mCi and is on regular follow up. The second patient is a 45-year-old man, with no medical history who went to the general practitioner for a neck lump. After initial examination, a biopsy of the lymph node was recommended. The result revealed lymph node metastases probable from thyroid papillary carcinoma. Blood test were within normal range. Thyroglobulin 13.54 ng/ml (3.5-77). The patient underwent total thyroidectomy and bilateral neck dissection. Histopathological exam was consistent with a papillary carcinoma of 3 mm in size. Post-surgery thyroglobulin 8.02 ng/ml. In a couple of weeks, the neck lumps reappeared. A computerised tomography was performed and bilateral neck and axillary lymph nodes were observed. The patient underwent a second surgery and later, radioactive iodine therapy with 100 mCi. The second biopsy confirmed once again metastasis from thyroid papillary cancer. Post-second surgery Thyroglobulin 0.01 ng/ml. The patient is still under strict observation because of the recidivist lymphatic disease.
Conclusion
It is important to consider the diagnosis of papillary thyroid carcinoma in every patient that seeks medical evaluation for lymph node swelling. Despite the improvement of ultrasonography, many cases of occult papillary carcinoma remain undetected, emphasizing the role of pathological examination to confirm the diagnosis. The preferred treatment approach remains total thyroidectomy with ipsilateral cervical lymph node resection, usually followed by 131-iodine therapy.
Key words: occult carcinoma, cervical lymph node, thyroglobulin, thyroidectomy, biopsy

Thyroid incidental uptake at 18F-FDG PET/CT, an alert to malignancy - a case report

Inês Manique[1], Luí sa Cortez[1] & José Silva-Nunes[2]
[1]Centro Hospitalar Universitário Lisboa Central, Endocrinologia, Diabetes e Metabolismo; [2]Centro Hospitalar Universitário Lisboa Central, Endocrinologia, Diabetes e Metabolismo, Portugal

Introduction
Thyroid incidentaloma in 18F-FDG PET-CT is relatively common and the most focal uptake are benign. However, the risk of malignancy of thyroid lesions with focal uptake on 18F-FDG PET-CT is 34.8%. Metastasis to the thyroid is uncommon (less than 0.2% of thyroid fine needle aspiration – FNA - puncture

findings), with renal neoplasms being the most frequently associated (48.1%) and, more rarely, those from the breast (7.8%).
Case report
A 54-year-old female with breast adenocarcinoma (HER2+; pT3pN3M0) diagnosed in 2009, underwent neoadjuvant chemotherapy (CT), left radical mastectomy, adjuvant chemoradiation and immunotherapy. Six years later, she had a recurrence of the disease with pericardial effusion. A new CT treatment was performed, and the patient started goserelin, transtuzumab and pertuzumab (dual blockade anti-HER2). In 2020 a 18F-FDG PET-CT was performed and showed mild thyroid uptake in a left lobe's nodular lesion. At the first Endocrinologist observation she denied cervical compressive symptoms and blood tests revealed euthyroidism. The thyroid ultrasound showed in the left lobe "a nodule with 30x15x25mm, undefined contours, heterogeneous ecostructure, hyperechoic punctate foci … valuable bilateral cervical lymph node expression". Cytological evaluation of the nodule was suggestive of metastatic carcinoma. Given the absence of possible confirmatory immunohistochemistry (IHC) with FNA and this being the only secondary lesion to suggest progression of the disease, in a multidisciplinary discussion, it was decided to perform total thyroidectomy. The anatomopathological examination clarified the diagnosis, revealing "Thyroid tissue with extensive infiltration by adenocarcinoma. Lymphovascular and neural invasions are identified. The neoplasm coincides with the margin (CK7+, focal GCDFP15, ER 100%, Her2 score 3+, CK20-)". In this context, she suspended hormone therapy and double anti-HER2 blockade and started CT. She is awaiting for postoperative imaging revaluation.
Conclusion
The report of thyroid focal uptake on PET-CT with 18F-FDG in patients with breast carcinoma should raise the suspicion for metastasis. There is no consensus on the therapeutic approach in these patients, namely with respect to total thyroidectomy. In the present clinical report, histological confirmation with IHC confirmed the progression of the oncological disease and had an impact on the therapy.

Papillary thyroid cancer with larger-volume lymph node metastases: evaluation of response to surgical treatment for decision making on indication of radioiodine

Hernan Tala[1], Jeannie Slater[2], Jose Ignacio Figueroa[3], Eduardo Brigando[4] & Josefina Razmilic[3]
[1]Clínica alemana de Santiago, Facultad de Medicina Clínica Alemana/Universidad del Desarrollo, Santiago, Chile, Internal Medicine (Endocrinology Unit), Santiago, Chile; [2]Clínica alemana de Santiago, Facultad de Medicina Clínica Alemana/Universidad del desarrollo, Pathology Department, La Pintana, Chile; [3]Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana/Universidad del Desarrollo, Santiago, Chile, Internal Medicine (Endocrinology Unit), Chile; [4]Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana/Universidad del Desarrollo, Santiago, Chile, Chile

Introduction
PTC patients with lymph node (LN) metastases of greater volume (in>5 LN and/or with larger metastases >5mm, hereinafter N1>5) usually receive radioiodine (RAI). Some guidelines suggest carrying out an evaluation of the response to surgical treatment (RST), recommending lower RAI dose (activity) in patients with good RST.
Objectives:
a)To evaluate the RST in patients with PTC and N1>5 b)To evaluate the disease-free-survival (DFS) in patients with PTC and N1>5 who present thyroglobulin (Tg) <1.0 ng/ml, absence of Tg-Antibodies (TgAb (-)) and non-suspicious ultrasound (US) findings in the evaluation of the RST and who are treated with low doses of RAI.
Experimental Design
Prospective Observational Cohort Study
Materials and Methods
Patients with PTC and N1>5, operated between 2016 and 2020 and who had RST evaluation by US, Tg and TgAb (using LT4) and with TSH≤2.0mIU/ml at least 6 weeks after surgery and prior to the administration of RAI were included. Patients were divided into 3 groups according to the RST (Table 2). Low-dose RAI (30-50mCi) was offered to patients who presented RST defined in this study as adequate (Tg ≤1ng/ml, TgAb (-) and non-suspicious US, Group I). In patients with metastases ≥10mm and/or ≥10 involved LN, low-dose RAI was offered when their Tg was ≤0.2ng/ml, AcTg (-) and normal US. Continuous variables are described as median and range, and categorical variables as proportions. Study was approved by local ethics committee.

Table 1 Characteristics at diagnosis

	n=97
Age	37 (14-78)
Female gender.	70%
PTC (Non-agressive histology)	91%
Agressive PTC histology	9%
TNM 8th Edition	
pT1a-pT1b-pT2	89%
pT3a-pT3b	11%
N1a	33%
N1b	67%
n>5 & <10 and size>5 & <10mm	45%
n≥10 or size ≥10mm	55%

Table 2 Post-surgical evaluation (prior to RAI)

I:Tg ≤1 ng/ml, TgAb (-) & non-suspicious US	55.7%
II:Tg >1.0 and/or TgAb (+) & US non-suspicious US	19.9%
III:suspicious US regardless TgAb & Tg levels	14.5%

Results
Of 581 patients with LN metastases, 97 met the inclusion criteria.
In 53.7% of the patients of group I low dose (30-50 mCi) of RAI was given. With a median follow-up of 24months, DFS was 96% (only 1 patient presented a tiny 3 mm suspicious adenopathy).
Conclusions
a)Approximately half of PTC patients with N1>5 have an adequate RST. b)This preliminary data suggests that in this group of patients, the administration of a low dose of RAI would be associated with a very good disease-free survival, appearing to be a safe option in them.

Worsening dysphagia and dysphonia: a case report

Donatella Rausa, Silvia Irina Briganti, Giovanni Rossini, Lavinia Monte, Nicola Napoli & Silvia Manfrini
Campus Biomedico via Alvaro del Portillo 200, Unit of Endocrinology and Diabetes, Department of Medicine, Roma, Italy

Premise
multinodular goiter and compressive symptoms in the neck could not be necessarily associated.
Case-report
A 82-year-old woman diagnosed follicular lymphoma in 2017 reached to the Emergency Department in Agoust 2021 because of a progressive and worsening dysphagia and dysphonia, begun six weeks before. The patient complained a weight loss of about 8 kg due to the inability in feeding. Her medical history was relevant for thyroid goiter, known since the age of 18, undergone partial right lobectomy at the age of 30 and regular follow-up until July 2021 (also FNA with a benign response was performed in 2019). Thyroid function tests showed subclinical hyperthyroidism. Anti-Tg, anti-TPO and TSH-Receptor antibodies resulted negative. ENT consultation and laryngoscopy showed a paralysis of the left vocal. Neck ultrasound and CT were performed, confirming the presence of a substernal goiter with the whole left thyroid lobe filled-up by a multilobate nodule about 3.5 cm-sized, strongly adherent to the trachea and the internal jugular vein. No enlarged cervical lymphnodes were described. Total body CT identified a solid mass 3 cm-sized in the mediastinum at the level of D3, with no evident cleavage plane to oesophagus. Enlarged mediastinal lymphnodes and pulmonary localization were found, suspicious for metastatic localizations. Cerebral MRI described a solid tissue area 1 cm-sized in the left jugular foramen, surrounding IX, X, XI cranial nerves in the intra-foramina tract, suspicious for perineural metastatic disease. Core-biopsy of the left thyroid nodule and of the paravertebral mass was performed identifying a diffuse and aggressive B-cell lymphoma.. Bone marrow aspiration resulted negative. The patient died a few weeks after in consequence of an acute gastrointestinal bleeding.

Discussion
Secondary thyroid lymphoma can be diagnosed in presence of thyroid nodules with cytologic benign result. Metastatic thyroid tumors are very uncommon and occur as goiter, worsening dysphonia and stridor, dysphagia, tightness of the neck. It is clinically important to discriminate between primary and secondary thyroid lymphoma because therapy and prognosis are different: thyroid metastatic lymphoma has a worse prognosis than primary thyroid lymphoma and it requires an accurate clinical and radiological staging because most of the cases have a widely disseminated disease from the diagnosis and a poor prognosis.

Metastatic papillary thyroid carcinoma - a multidisciplinary approach

Tiberiu Manole[1], Ionela Florina Baciu[1, 2], Anda Dumitrascu[3], Liviu Goldstein[4] & Catalina Poiana[1,2]
[1]'C I Parhon' National Institute of Endocrinology, Pituitary and Neuroendocrine Pathology, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Department of Endocrinology, Bucharest, Romania; [3]'C I Parhon' National Institute of Endocrinology, Radiology, Romania; [4]'C I Parhon' National Institute of Endocrinology, Nuclear Medicine, Bucharest, Romania

Introduction
Papillary thyroid carcinoma (PTC) is the most common endocrine malignancy. It represents over 80% of all follicular derived well-differentiated thyroid cancers. Despite the fact that the majority of PTCs are well differentiated and have a low rate of local invasion, recurrences, or metastases, there are complex cases which require a multidisciplinary team for a favourable result.
Methods
Clinical examination, blood tests, scintigraphy, CT scan, radioiodine therapy.
Case
We present the case of a 67-year-old woman who underwent a total thyroidectomy in 2019 for multinodular goitre with Graves' disease, which at the pathological report turned out to be papillary thyroid carcinoma in the right thyroid lobe. She received 1 dose of radioiodine therapy one month after the surgery (100 mCi ^{131}I) and did a whole-body scintigraphy which revealed iodine fixing areas in the right thyroid lodge, both lungs (pulmonary metastases), right parietal dura mater, left iliac bone and left femur (bone metastases). Four days after the iodine therapy, the patient developed a partial seizure and left hemiparesis and hypoesthesia caused by the brain metastasis. She underwent tumoral resection in the Neurosurgery Department but the neurological deficit and hypoesthesia didn't improve, while the pathological report concluded the growth was a PTC metastasis. Six months after the thyroidectomy the patient did another dose of radioiodine therapy (135 mCi) with no spontaneous TSH increase after LT4 withdrawal, so she was administered Thyrogen which secured a good uptake of radioiodine in the tumour. She then did a whole-body scintigraphy which revealed a reduction of the primary and secondary lung lesions and stable bone metastases, with no cerebral uptake. Also, the thyroglobulin (TG) decreased every time she did radioiodine therapy. Eighteen months after the thyroidectomy she underwent a third dose of radioactive iodine (100 mCi) which revealed stable lesions. The patient will therefore return for a fourth dose of radioiodine therapy two years after the thyroidectomy.
Discussions
This patient initially presented with a multinodular goitre and Graves' disease which turned out to be PTC at the pathological report. She has multiple metastases which require a multidisciplinary approach. Also, it is important to note that the TG drops every time she undergoes radioiodine therapy.
Conclusions
PTC is a common endocrine carcinoma which in rare cases can metastasise and severely affect the quality of life of the patients.
Keywords
papillary thyroid carcinoma, metastases, radioiodine therapy.

Rare association of two primary carcinomas: papillary thyroid carcinoma and pulmonary adenocarcinoma (about a case)

Nezha Raki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Uhc Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
the coexistence of pulmonary adenocarcinoma and papillary thyroid carcinoma is a rare event. We report the case of a patient followed in consultation with thyroid carcinoma who was diagnosed with pulmonary adenocarcinoma.
Observation
This is a 67-year-old patient, who had a total thyroidectomy for a multi-heteronodular goitre with dissection of a pretracheal lymph node. Histopathological examination revealed a multifocal grade 1 thyroid papillary carcinoma, 3 cm long, with reactive adenitis on the pretracheal lymph node, classified as pT2N0Mx. Radioactive iodine therapy was performed. The patient presented 2 years after the surgery an episode of pneumonia with deterioration of the general state; a chest scan revealed an 8.8 cm right lower mediastinum-pulmonary tissue process, the diagnosis of mucinous adenocarcinoma was confirmed after lung biopsy. The immunohistochemical study was carried out and showed an expression of CK7 without expression of thyroglobulin. A positron emission tomography (PET scan) performed as part of an extension assessment, objectified a hypermetabolic pulmonary process of the right lower lobe associated with a slightly hypermetabolic micronodular infiltrate perilesional with hypermetabolic microfocus of segment II of the liver.
Conclusion
The coexistence of several neoplasias is rare, and poses major diagnostic and therapeutic problems, worsening the prognosis and requiring multidisciplinary management.

EP1052

Rare presentation of medullary thyroid carcinoma

Viyey Kishore Doulatram Gamgaram[1,1], José Abuín Fernández[2], Araceli Pineda Cantero[3], Sergio Valdes[1] & Francisco José Sanchez Torralvo[1]
[1]Hospital Regional Universitario de Málaga, Endocrinology and Nutrition, Málaga, Spain; [2]Hospital Quirón Salud Málaga, Endocrinology and Nutrition, Málaga, Spain; [3]Hospital Regional Universitario de Málaga, Internal Medicine, Málaga, Spain

Introduction
Medullary thyroid cancer is a rare neoplasm, accounting for approximately 4% of all cases of thyroid cancer. Exceptionally, it can be associated with the hormonal production of ACTH or CRH, causing ectopic Cushing's syndrome.
Clinical Case
We present the case of a 43-year-old man who, as a history of interest, presented a T6-T8 vertebral body fracture 2 years ago and a right hip fracture 1 year ago. Bone densitometry is compatible with osteoporosis. He began daily treatment with Teriparatide 20 mg subcutaneously, calcium carbonate 2.5 g and Cholecalciferol 800 IU. He was admitted to the hospital due to worsening pain. On examination he presented facial plethora, abdominal obesity, and muscular atrophy. Given the suspicion of Cushing, a blood test was performed, highlighting ACTH 114 pg/ml, Cortisol 43.2 µg/dl, Urinary free Cortisol in 24 h 516 mg, and 1 mg Dexametasone supression test 17 µg/dl. An MRI of the spine was performed and showed multiple medullary bone infiltration of the vertebrae and posterior costal arches. A CT scan of the chest showed pathological adenopathies in the upper mediastinum and an increase in the size of the thyroid with a nodular image in the right lobe. Abdominal CT showed both enlarged adrenal glands without observing nodulations. The study was completed with cervical ultrasound, where a 4 cm nodule in the right lobe with lobulated edges, heterogeneous echogenicity, and multiple adenopathies with a pathological appearance were observed. Fine needle aspiration was performed and confirmed the result of medullary carcinoma (Bethesda V). Blood tests showed Calcitonin levels of 8202 pg/ml and urinary Metanephrines were negative. Surgical intervention was performed by means of total thyroidectomy and central and lateral lymph node dissection, with the result in the biopsy of medullary thyroid carcinoma with lymph node involvement and positive immunohistochemistry for ACTH. We arrived at the diagnosis of medullary thyroid carcinoma with bone metastases, ectopic Cushing's due to ACTH production originated in the medullary thyroid carcinoma. Treatment was started with daily Levothyroxine 150 mg on an empty stomach and Vandetanib 300 mg.
Conclusions
Medullary thyroid carcinoma is an uncommon cause of Cushing's syndrome, but it is associated with high morbidity, as described in our patient. Those affected generally have a poor prognosis due to the presence of metastatic disease at the time of diagnosis, and on many occasions they have a large primary tumor mass with little probability of successful resection.

Differentiated thyroid cancer in children and adolescents: about 6 cases

Rachida Bouattay, Maroua Naouar, Emna Bergaoui, Heyfa Belhadjmiled, Mehdi Ferjaoui, Amel Elkorbi, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
Thyroid cancer is rare in the pediatric population, but thyroid carcinomas occurring in children carry a unique set of clinical, pathologic, and molecular characteristics. In comparison to adults, children more often present with aggressive, advanced stage disease. The aim of the study is to determinate the clinical, histological and therapeutic aspects of differentiated thyroid cancer in children and adolescents.
Materials and Methods
This is a retrospective study about 6 cases of pediatric thyroid cancer collected in ENT department of Fattouma Bourguiba Hospital of Monastir during a 20-year period (2000-2020).
Results
The average age was 15 years, gender-ratio was 0,2. No personal history of radiation exposure and family history of thyroid cancer were noted. All of patients presented to our consultation for management of a thyroid nodule, associated, in one case, with middle jugular node measuring 2 cm in diameter. All of patients underwent a total thyroidectomy, associated to bilateral central neck lymph node dissection in 3 cases and ipsilateral central neck lymph node dissection in 2 cases. A lateral lymph node dissection was performed in 2 cases. Histologic examination confirmed the diagnosis of papillary carcinoma in all cases. The mean tumor size was 3 cm. In all cases, papillary thyroid carcinoma was multifocal. We noted a tumor capsular invasion in 2 cases. Lymph node metastasis were along the recurrent nerve chain in all cases and in jugular chain in 2 cases. Surgical treatment was followed by radioactive iodine therapy in all cases. There was no distant metastasis or cancer recurrence after a mean follow-up of 3 years,
Conclusion
Although children with differentiated thyroid cancer typically present with locoregional metastases and a high rate of distant metastatic disease, overall survival is very good. Treatment should be based on their increased risk for recurrence instead of overall mortality, and lifelong follow up is required because recurrence and death may not occur for decades after diagnosis.

EP1054

Differentiated thyroid cancer with tuberculous cervical lymphadenopathymimicking metastasis: a report of 2 cases

Rachida Bouattay, Maroua Naouar, Emna BERGAOUI, Heyfa Belhadjmiled, Mehdi Ferjaoui, Amel Elkorbi, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
Papillary and follicular thyroid carcinoma are the most frequent endocrine malignancy. Lymphatic metastases at the time of diagnosis are common in differentiated thyroid cancer (DTC). In these patients, most authors recommend a thyroidectomy with neck dissection. However, neck dissection can lead to numerous post-operative complications. Thus, careful pre-operative evaluation of cervical lymph node metastasis may be crucial, so that patients do not undergo unnecessary neck dissection for other benign conditions The aim of the study is to determinate the clinical, histological and therapeutic aspects of the coexistence of differentiated thyroid cancer and tuberculous cervical lymphadenopathy.
Materials and Methods
We report three cases of association between differentiated thyroid cancer with tuberculous cervical lymphadenopathy collected in ENT department of Fattouma Bourguiba Hospital of Monastir over a period of 10 years.
Results
Our study investigated three women aged 47, 49 and 56 years old respectively. The first patient had a history of hypertension, diabetes mellitus and hysterectomy for endometrial stromal sarcoma while the second patient didn't have any past medical history. The third case was admitted in the Rheumatology Department for bone pain and worsening of the general state. A bone biopsy was performed during that hospitalization showing follicular thyroid carcinoma metastasis. In all cases, ultrasonography showed thyroid nodules associated to suspicious jugular node. All of patients underwent a total thyroidectomy, associated to central and lateral lymph node dissection. The histology disclosed a papillary carcinoma in two cases and follicular carcinoma in the third one. In all cases, thyroid carcinoma was associated to tuberculosis in the lateral cervical lymph node. In all cases, surgical treatment was followed by radioactive iodine therapy and antituberculosis medication. Follow-up has been negative for any recurrence or distant metastasis during the past 24 months.
Conclusion
Cervical lymphadenitis is the most common clinical presentation of extrapulmonary tuberculosis. The coincident of (DTC) and tuberculous lymphadenitis are not rare. The large lymph nodes with central necrosis recognized at uncommon site of metastasis from DTC might remind us of such coexistence. Preoperative diagnosis for tuberculous infection is important to avoid unnecessary surgical complications and secondary infections.

Cushing's disease and multiple endocrine neoplasia with medullary thyroid carcinoma and bilateral pheochromocytoma : about a case

Amal Elkhomri, Nassim Essabah Haraj, Siham El Aziz & Asma CHADLI
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Multiple endocrine neoplasia (MEN) are inherited conditions of autosomal dominant transmission characterized by the occurrence of various associated endocrine lesions. We report an observation of a patient with a rare association of medullary thyroid carcinoma and bilateral pheochromocytoma with cushing's disease.
Observation
The patient was H.B, 18 years old, followed for a medullary thyroid carcinoma (MTC) since 2018 discovered at the stage of pulmonary and lymph node metastasis, having benefited from a total thyroidectomy with right lymph node curage, classified as T2N1bM1 with the presence of numerous images of emboli (6N+/12N)
Clinically
the patient presents lingual and subconjunctival neuromas, with large purple stretch marks on the flanks, the roots of the lower limbs, and the subaxillary region, associated with signs of hyper androgenism.
Para-clinical
calcitonin at 44600 pg/ml, with metanephrines at 2.53 umol/24h (0.20-1.50), with adrenal CT: two adrenal nodules, measuring 13.5 X 11.5 mm on the left, and 12.5 X 12.5 mm on the right, of spontaneous density, at 40 HU, with enhancement after injection of PDC, Cortisolemia of 8 h after a minute braking test at 14. 5 mg/d, with ACTH: 34 pg/ml (10-50), we completed by a pituitary MRI which objectified a pico adenoma of 2.9 X 2.6 mm. The genetic study did not reveal any mutations in exons 10 and 11, exons 15 and 16 were not studied. The patient underwent bilateral lymph node resection and left adrenalectomy in the first stage, with a control calcitonin level of 3360 pg/ml, a right adrenalectomy is planned.
Conclusion
NEM 2B is an autosomal dominant syndrome characterized by a variable association of pheochromocytoma, CMT, mucosal and subconjunctival neuromas, with a marfanoid and a ganglioneuromatosis, although exceptional, the association with a cushing disease is very rare.

Thyroid oncocytic tumor: about 23 cases

Rachida Bouattay, Maroua Naouar, Emna Bergaoui, Heyfa Belhadjmiled, Mehdi Ferjaoui, Amel Elkorbi, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
Oncocytic tumors (OT) are rare, representing 3 to 10% of epithelial tumors of the thyroid. It is important to individualize these tumors given the relatively high frequency of carcinomas and the aggressiveness of oncocytic carcinoma. The aim

of this study is to determinate the clinical, histological and therapeutic aspects of thyroid oncocytic tumor.
Materials and Methods
This is a retrospective study about 23 cases of oncocytic thyroid tumors collected in ENT department of Fattouma Bourguiba Hospital of Monastir during a 20-year period (2000-2020).
Results
The average age was 41 years, a female predominance was noted (19F/4M). Our study included: 20 oncocyte adenomas and 3 oncocytic carcinomas. The average consultation time was 18 months. Eighteen patients have single thyroid nodule and five patients have a multinodular goiter. The mean ultrasound size of the thyroid nodule was 4 cm. There was no cervical lymphadenopathy in all cases. Fine needle aspiration cytology from the thyroid nodule was performed in two cases showing papillary carcinoma in one case. 19 patients underwent a lobo-isthmectomy. A total thyroidectomy with node dissection were performed in 4 cases. Radioactive iodine therapy was indicated for the 3 patients with oncocytic carcinoma. There was no distant metastasis or cancer recurrence after a mean follow-up of 24 months.
Conclusion
Among well differentiated thyroid tumors, oncocytic tumors feature a distinctive set of clinical, morphologic and biologic characteristics, some of which have been a matter of controversy.

Correlation between body mass index and clinico-pathological features of papillary thyroid carcinoma

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Epidemiological studies have reported that being overweight and being obese are associated with increased incidences of numerous cancers, including thyroid cancer. In addition to cancer risk, obesity has also been demonstrated to be associated with more aggressive pathological characteristics of the tumor and worse prognosis in patients with several cancers.
Purpose of study
Demonstrate the relationships between BMI and the clinico-pathological features of papillary thyroid carcinoma.
Materials and methods
Retrospective study was conducted in the Ibn Rochd University Hospital Endocrinology and Diabetology department of Casablanca, including211 patients followed for papillary thyroid carcinoma between August 2018 and January 2022. The patients were divided into 2 groups: a group with obesity, and a control group, comparing the clinico-pathological characteristics of the two groups. Statistical analysis performed by the software SPSS 25.0
Results
According to the results, 377patients were women (90.8%), mean age was 40.4 years (12-86) and mean BMI was 28.9 kg/m^2(21-45). The mean tumor size was 28.6 mm (1-80). Statistical analysis of the prognostic factors: tumor size, multifocality, presence of vascular emboli and distant metastasis showed no significant differences in the obese group compared to the control group. Only the presence of capsular invasion ($P<0.01$) was strongly associated with obesity.
Conclusion
The association between obesity and carcinoma has been widely elucidated. Our study demonstrated that there is no relationship of BMI and clinico-pathological features of thyroid carcinoma such as multifocality, tumor size, vascular invasion and the presence of lymph node metastases apart from the presence of capsular invasion.

Adenocarcinoma of the colon and papillary thyroid carcinoma: An exceptional association

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
The association of thyroid and colon cancer is rare, it can be observed in the context of Gardner's syndrome and Cowden's syndrome with a prevalence of 0.6%. We report a case of metachronous association of a differentiated thyroid cancer with a colon cancer.
Observation
45-year-old patient, followed for well-differentiated colonic adenocarcinoma without metastasis, having received eight courses of chemotherapy. One year later, the patient underwent a total thyroidectomy for multinodular goiter. Anatomopathologic examination of the surgical specimen showed a papillary carcinoma with vesicular differentiation classified as PT3. The patient received additional treatment with radioactive iodine131 at a dose of 100mci. The extension workup did not reveal any metastasis and the surveillance workup did not reveal any recurrence.
Conclusion
Multiple primary cancers are rare, but their incidence has recently increased. Common genetic and environmental risk factors seem to be involved in many cases. Multiplicity itself is not necessarily a poor prognostic factor. However, early detection will allow prompt management and increase the cure rate of the disease.

Association between breast cancer and thyroid cancer : About 55 cases

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Background
Several studies have demonstrated the relationship between breast cancer and thyroid cancer by the presence of common genetic determinants. The aim of the study was to define the breast cancer prevalence among patients followed for thyroid carcinoma and to determine factors favoring this association.
Matherials and methods
A Cross-sectional study was conducted in the Ibn Rochd University Hospital Endocrinology and Diabetology department of Casablanca, including 55 patients followed for thyroid carcinoma between 1986- 2021 among all the thyroid differentiated carcinomas (793 patients) and presenting breast cancer. Statistical analysis performed by the software SPSS 25.0
Results
Prevalence of patients presenting breast cancer and thyroid cancer was 6.3%. Mean age was 45.5 years (36-70). Family history of neoplasia was found in 49.1% of cases. Breast cancer preceded the discovery of thyroid cancer in 51% of cases. Iratherapy was performed in 98.2% of patients. External radiotherapy was realized in 45.4% of cases for the treatment of breast cancer papillary carcinoma and invasive ductal carcinoma were the predominant histological type in 89.1% of cases. Predictor factors of this association were female patients who had the first neoplasia at a young age ($\leq$45years), family history of neoplasia and prior external radiotherapy.
Conclusion
Our study results support the hypothesis of the presence of a relationship between the breast cancer occurrence in patients followed for thyroid cancer. Close monitoring and vigilance for early detection of thyroid cancer in patients treated for breast cancer is recommended.

Sorafenib for metastatic thyroid carcinoma

Diana Cuconu[1], Chiriac Iulia[2] & Corin Badiu[3]
[1]National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania; [2]National Institute of Endocrinology, Nuclear Medicine, Bucharest, Romania; [3]'Carol Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Differentiated thyroid cancers include papillary, follicular carcinomas and are usually associated with a good prognosis. Up to 10% of patients develop metastatic lessions and radioiodine resistance. Tirosine kinase inhibitors (TKI) represent a strong therapeutic option for patients with advanced metastatic disease

and radioiodine resistance. Sorafenib is the only TKI approved for the treatment of locally advanced or metastatic differentiated radioiodine resistant thyroid carcinoma in Romania. Hereby we aim to evaluate the biochemical and morphological response to different doses of Sorafenib in three patients with radioiodine resistant differentiated thyroid cancer (TC). Case 1- A 54 years old woman with advanced PT3N1bM1 PTC diagnosed in october 2018. She underwent total thyroidectomy with central and lateral compartment neck dissection and radioiodine therapy with rapid onset of radioiodine resistance after a total dose of 260 mCi I131. A second surgery for local recurence was proposed and declined by the patient. She was started on Sorafenib 800 mg/day, but six months after treatment developed biochemical and morphological progression. Case 2- A 39 years old male with follicular TC pT4N1bM1 diagnosed in january 2019. After total thyroidectomy and radioiodine therapy he developed radioiodine resistance and local recurrence. A genetic testing identified TERT C228T mutation, without BRAF mutations. He received Sorafenib 800 mg/day and 6 months after treatment he presents with biochemical and morphological progression. Case 3- This is the case of a 59 years old woman, with a personal history of multinodular goiter without endocrine evaluation and FNAB citology for over a decade, diagnosed in 2013 with FVPTC and spinal metastasis. She developed pain and neurological deficits that were first managed with surgical resection of C5 metastasis followed by total thyroidectomy, then external beam radiotheraphy, multiple surgeries for locally recurent disease and radioiodine therapy with a total dose of 375 mCi. Sorafenib was initiated with an important biochemical response. Due to high blood pressure she continued with 400 mg/day and presents with biochemical and morphological stable disease.
Discussion
We used sorafenib in patients with metastatic TC with a heterogenous response from stable disease to rapid biochemical and morphological progression. Regarding treatment toxicity we observed mild to moderate adverse reactions easily manageable with antihypertensive medication or dose reduction.
Conclusion
While new TKI are being proposed for treatment of metastatic, radioiodine resistant differentiated thyroid carcinoma, there is a need to find genetic markers and histopathological factors that can predict the response to sorafenib therapy.

Horner syndrome as the first manifestation of medullary thyroid cancer

Bianca Dumea[1], Carmen Sorina Martin[1, 2], Ovidiu Parfeni[1], Theodor Mustata[1], Florina Andrada Predescu[1] & Fica Simona[1,2]
[1]Elias Hospital, Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
Medullary thyroid cancer is a rare neuroendocrine tumor arising from the parafollicular C cells of the thyroid gland. Calcitonin production is a characteristic feature of medullary thyroid cancer and preoperative high levels indicate an increased risk of local and distant metastatic disease. Although rare, Horner syndrome could be caused by metastatic medullary thyroid cancer. Horner syndrome usually presents with ptosis, miosis and facial anhidrosis and most of the times is aquired following a lesion anywhere along the sympathetic pathway.
Aim (s)
We report you the case of a 47 year old female reffered for sudden onset of left ptosis and vertical diplopia.
Matherials and methods
MRI of the brain and cervical spine revealed multiple left cervical lymphadenopathy suspicious for malignancy and neurologic evaluation established the diagnosis of Claude Bernard Horner syndrome due to cervical compression. Additional tests were performed and neck ultrasound revealed multiple thyroid nodules with a left dominant nodule of 3.74/2.24/2 cm with a high index of sonographic suspicion for thyroid cancer and multiple left lymphadenopathy. Lab tests revealed a hypercalcitoninemia (2000 pg/ml) and a high level of carcinoembryonic antigen (411 ng/ml) confirming the diagnosis of medullary thyroid cancer. Screening for primary hyperparathyroidism and pheocromocytoma was negative. Considering the high basal level of calcitonin and the ultrasound examination of the neck positive for ipsilateral lymph nodes, an extensive screening for regional and distant metastasis was performed. Constrast enhanced CT revealed multiple regional and distant lymphadenopathy but no distant metastasis to the brain, lungs, abdomen or pelvis region.
Results
Thus, the patient was reffered to the surgery department for total thyroidectomy and central and modified radical neck dissection.
Conclusion
Horner syndrome and medullary thyroid cancer are two rare entities and Horner syndrome is an extremely rare and unusual manifestation of the medullary thyroid cancer. It is important to emphasize the importance of multidisciplinary team approach in order to establish a correct diagnosis and treatment plan in such a challenging case.

Breakfast with liquid levothyroxine (Levotirsol®): a single-center experience

Settimio D'Andrea[1], Antonella Berardicurti[2], Livia Santarelli[1] & Walter Vena[3]
[1]Ospedale SS Annunziata, Diabetology Unit and Endcorinology Service, Sulmona, Italy; [2]Università degli Studi 'Gabriele d'Annunzio' - sede di Chieti, Department of Medicine and Ageing Sciences, Chieti, Italy; [3]Humanitas Research Hospital, Endocrinology, Diabetology and Andrology Unit, Cascina Perseghetto, Italy

Introduction
Levothyroxine (LT4) tablets are the most used treatment for hypothyroidism worldwide. LT4 tablets should be taken in the morning and have a fasting state. Some patients could be unable to adhere to this recommendation resulting in poor therapy compliance and thyrotropin (TSH) concentration above the upper normal limits. A previous double-blind placebo-controlled trial showed that LT4 liquid could be ingested during breakfast without a significant difference in TSH values. Recently, a new LT4 liquid (Levotirsol®, IBSA Farmaceutici S.r.l., Lodi, Italy) was released in Italy improving therapeutic options. Our study aimed to explore the possibility to recommend LT4 liquid directly at breakfast.
Methods
We performed an observational, retrospective, and non-controlled study at the Unit of Diabetology and Endocrinology Service of Hospital "Sant'Annunziata" of Sulmona (Italy). We enrolled hypothyroid patients treated with LT4 tablets that refer poor or unsatisfied compliance to the treatment. All included participants received LT4 liquid at the same dose of LT4 tablets to ingest during breakfast. After at least 40 days, they were contacted by telephone to obtain data on TSH and fT4.
Results
We enrolled 26 hypothyroid patients in therapy with LT4 tablets that express poor compliance and/or unsatisfaction with tablets. Three patients were lost at follow-up and one patient back spontaneously to tablets treatment. Finally, we had data about 22 patients aged 54.3(IQR = 48.6-59.3) years. All selected participants were female and were affected by primary hypothyroidism. The duration of LT4 liquid treatment was 68.5 (IQR = 57.3-73.5) days. Ten enrolled subjects showed TSH serum levels before LT4 liquid above 5 mcUI/ml for poor therapy compliance, the remaining 13 subjects presents a TSH value in the normal range but referred that the tablets adherence was the difficult and impaired quality of life. We reported that TSH serum levels after LT4 liquid treatment during breakfast (3.9, IQR = 2.1-4.4) were significantly lower compared to TSH at the beginning (4.8, IQR = 3.9-6.9; $P = 0.03$). Furthermore, freeT4 serum levels after liquid therapy were higher respect to freeT4 levels before liquid therapy (1.0, IQR = 0.8-1.2 VS 0.9, IQR = 0.7-1.1; $P = 0.0002$). When only patients with TSH above the range were considered for analysis, TSH serum levels decreased significantly after LT4 liquid therapy ($P = 0.02$).
Conclusions
We showed that LT4 liquid in hypothyroid patients with poor therapy compliance improves TSH serum levels. LT4 liquid ingested during breakfast could represent an improving therapeutic choice, especially in patients with poor therapy compliance. Further longitudinal trials are needed to confirm these data and to explore the possibility to recommend LT4 liquid without a fasting state.

EP1063

Therapeutic plasma exchange in amiodarone induced thyrotoxicosis: a case report

Cristina Clausi, Jacopo Manso, Andrea Graziani, Simona Censi, Sofia Carducci, Yi Hang Zhu, Ilaria Piva & Caterina Mian
University of Padua, Endocrinology, Padova, Italy

A 52-year man came to Emergency Department with Atrial Fibrillation with rapid ventricular response due to amiodarone induced thyrotoxicosis (AIT). The patient was found tachi-arrhythmic (153 beats per minute), tachypnoic (27 breaths per

minute) and with intense hyperidrosis. His first blood test documented thyroid stimulating hormone (TSH) <0.01 mUI/l, free triiodothyronine (fT3) 20.0 pmol/l and free thyroxine (fT4) over 100 pmol/l. Thyroid ultrasonography revealed an enlarged hypoechoic and non-homogeneous thyroid gland, in absence of vascular signal. He was initially treated with esmolol 60 mg ev, hydration and hydrocortisone 100 mg ev. Subsequently we began therapy with prednisone 50 mg/die, methimazole 20 mg/die, propranolol 160 mg/die and digitalis 0.0625 mg/die. This first therapy did not improve his clinical condition, thus we substitute methimazole with Propylthiouracil 200 mg/die, prednisone with desametasone 8 mg/die and added potassium iodure 400 mg/die. Nevertheless, blood tests and heart rate still did not improve. We proposed therapeutic plasma exchange (TPE), whom he underwent in the next two following days, as a bridge therapy for surgery. After two runs of TPE with markedly improvement of biohumoral status, the patient underwent urgent thyroidectomy with slowly normalization of TSH and reduction of FT3 and FT4 during the post-surgery days. The man was eventually dismissed by the hospital with desametasone, propranolol, digitalis, oral anticoagulant and calcium carbonate, then introducing replacement therapy with Levothyroxine in the following days. Amiodarone is a drug frequently used in different kinds of arrhythmias. It can induce thyrotoxicosis up to 6-10 % of the patients. There are two types of AIT: AIT1 (iodine-induced in patients with underlying thyroid autonomy) treated by thyrostatic drugs and AIT2 (destructive thyroiditis, results of direct damage or apoptosis in thyrocytes) treated by corticosteroids. Thyroid storm is a rare but potentially fatal endocrinology emergency, with a mortality of 10-30 % due to cardiovascular and multisystemic involvement. AIT can be a cause of thyroid storm. Burch-Wartofsky Point Scale helps physician to determinate the gravity of the condition: a value ≥ 45 requires aggressive therapy. TPE can be used as bridge therapy to thyroidectomy in patients refractory or with contraindications to medical management of thyroid storm. TPE aims to reduce FT3 and FT4, autoantibodies and cytokines and the activity of 5'-monodeiodinasis. Those effects are usually temporary, leading to the risk of rebound-thyrotoxicosis. TPE may be considered also in other pathological endocrinological conditions, such as corticosteroid responsive encephalopathy associated with autoimmune thyroiditis.

Congenital hypothyroidism due to hormone synthesis disorder : the value of early diagnosis

Kamel Farah, Mohamedou Abdouly, Manal Azriouil, Kaoutar Rifai, Hind Iraqi & Mohamed Hassan El Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Primary congenital hypothyroidism is the most common neonatal endocrine disorder, traditionally subdivided into thyroid dysgenesis, referring to a range of abnormalities in thyroid development, and dyshormonogenesis. We report two cases of dyshormonogenesis in a brother and sister followed for congenital hypothyroidism by inactivating mutation of the TSH receptor, illustrating the good evolution in case of an adapted treatment.
Clinical cases
This is a brother and sister aged 21 and 17 years respectively, from a non-consanguineous marriage. The diagnosis of congenital hypothyroidism due to a hormone synthesis disorder was made at the age of 1 month in both of them, in view of : clinical and biological signs of peripheral hypothyroidism, the cervical ultrasound showed a thyroid gland in place, with regular contours and homogeneous echostructure, and the genetic study was in favour of an inactivating mutation of the TSH receptor. Both patients are treated with Levothyroxine, with regular intake of the treatment, and a good clinical and biological evolution with no mental retardation.
Discussion
Congenital hypothyroidism on hormone synthesis disorder is characterized by a defective molecular pathway for thyroid hormoneogenesis resulting in failure of hormone production by a structurally intact gland. Hypothyroidism secondary to TSH resistance is rare. TSH receptor abnormalities have been described first in cases of thyroid hormone resistance and then in cases of congenital hypothyroidism with an established gland in a eutopic but hypoplastic position. Delayed treatment of neonatal hypothyroidism can result in profound neurodevelopmental delay; therefore, congenital hypothyroidism is screened in developed countries to facilitate prompt diagnosis and treatment. Careful evaluation will usually reveal the etiology of congenital hypothyroidism, which can inform treatment and prognosis. Early and adequate treatment with Levothyroxine results in excellent neurodevelopmental outcomes for most patients with congenital hypothyroidism.
Conclusion
Congenital hypothyroidism is common and can result in severe neurodevelopmental morbidity. Neonatal screening is an important tool to detect congenital hypothyroidism. Prompt diagnosis and treatment are essential to optimize long-term outcomes. These two clinical cases illustrate the importance of early diagnosis and treatment for a successful outcome.

EP1065

Betrayed by the lab: a case of facticial thyrotoxicosis

David Veríssimo, Catarina Ivo, Vitó ria Duarte, Ana Clá udia Martins, Joao Silva, Luis Lopes, Dolores Passos, J Já come Castro & Mafalda Marcelino
Portuguese Armed Forces Hospital, Endocrinology Department, Lisboa, Portugal

Introduction
Factitious thyrotoxicosis is caused by intentional and surreptitious ingestion of thyroid hormone and can be a challenge in the differential diagnosis with other pathologies.
Case report
Female, 35 years old, referred to our department for suspected subacute thyroiditis after COVID-19. The patient had previous medical history of hysterectomy, bilateral oophorectomy, 2 galactophorectomies with right breast reconstruction, depressive syndrome and hypothyroidism medicated with levothyroxine 75 mg since 2016. In March 2021, two months after SARS-CoV-2 infection, she noticed increased cervical volume with associated pain and weight loss of 10 kg. Thyrotoxicosis was identified and thyroid scintigraphy showed diffuse low uptake, suggestive of subacute thyroiditis. Levothyroxine was suspended and she was medicated with 20 mg prednisolone. After 4 months she maintained thyrotoxicosis with no response to therapy, and a total thyroidectomy was suggested by her medical team, being referred to our department. Upon observation, she complained of tiredness and drowsiness, had no signs of thyrotoxicosis and thyroid examination was normal and painless. The patient expressed a desire to undergo surgery to control the symptoms. At that time, under prednisolone 20 mg, analytical evaluation showed: TSH <0.005 uU/ml, FT4 6.25 ng/ml (0.97-1.58), FT3 18.8 pg/ml (2.38-4.37), thyroglobulin 2.4 ng/ml, negative TRAB, TG and TPO antibodies, AST 46 IU/l (7-32), ALT 73 IU/l (7-32). Thyroid scintigraphy was repeated and showed diffuse low uptake. Due to suspected factitious thyrotoxicosis, it was decided to admit the patient and without instituting any therapy a clear improvement in thyroid function was observed after 5 days: TSH <0.008, FT4 1.11 (0.97-1.48), FT3 3.70 (1.88-3.18). When confronted with the results and after being evaluated by Psychiatry, the patient denied intentionally taking levothyroxine.
Discussion
In the presented case, the suspicion of factitious thyrotoxicosis was based on the absence of goiter, low level of thyroglobulin, low uptake on thyroid scintigraphy and persistence of thyrotoxicosis six months after the diagnosis of subacute thyroiditis. The suspicion was confirmed by the rapid decrease in the serum value of thyroid hormones (50% FT4 and 41% FT3) without any therapy.
Conclusion
This case reflects the importance of clinical suspicion and timely diagnosis of factitious thyrotoxicosis, avoiding unnecessary and potentially invasive treatments.

EP1066

A case of thromboembolic disease with mild hyperthyroidism

Elaine Soong[1] & Shoib Rehman[1,2]
[1]Norfolk & Norwich University Hospital, Diabetes & Endocrinology, United Kingdom; [2]University of East Anglia, United Kingdom

Background
Hyperthyroidism is a thyroid hormone excess state which usually manifests with various cardiovascular symptoms such as sinus tachycardia, tachyarrhythmia and high output cardiac failure. Pulmonary embolism is not commonly associated with thyrotoxicosis but some studies have shown an increased propensity of

thromboembolic disease with thyrotoxicosis. We report a case of an elderly lady presenting with hyperthyroidism, atrial fibrillation and associated pulmonary embolism.
Case
An 82-year-old lady presented to the emergency department as she felt faint, clammy and short of breath for one day. Her past medical history includes a multinodular goitre with subclinical hyperthyroidism, type 2 diabetes, pulmonary embolism post hernia repair, hysterectomy and gallstones. Bloods on admission showed predominantly T3 thyrotoxicosis, free T3 7.8 pmol/l (3.8-6.0) with suppressed TSH $<$0.10mu/l (0.35-4.94) and free T4 23 pmol/l (7.5-21.1). Her anti-thyroid peroxidase antibody was positive at 108.5 kU/l (0.0-34.0) but her thyroid-stimulating antibody was negative $<$0.10 iu/l ($<$0.56). On clinical examination, her heart rate was 130 bpm and she was hypotensive but responded to fluid resuscitation. ECG showed atrial fibrillation. Her D-dimer was elevated at 4230 mg/l ($<$500). Pulmonary embolism was suspected given mild derangement in thyroid functions with disproportionate hemodynamic instability and CT pulmonary angiogram reported massive bilateral pulmonary embolism with saddle embolus across the bifurcation of the main pulmonary artery with pulmonary hypertension. There was some tracheal narrowing from the multi-nodular retrosternal goitre. The patient was initiated on standard therapy with beta-blockers, antithyroid medications, anticoagulation and planned elective radioactive iodine therapy.
Discussion
Patients with hyperthyroidism have a 10-15% chance of developing atrial fibrillation. Hyperthyroidism also predisposes patients to develop venous thrombosis or pulmonary embolism as they often have endothelial dysfunction, reduced fibrinolytic activity and hypercoagulable state which form the Virchow triad. Pulmonary embolism is a potentially fatal thrombotic disease and hence it is vital to maintain a high level of suspicion even in patients with mild thyrotoxicosis but are hemodynamically unstable.
Conclusion
Hyperthyroidism is associated with an increased risk of atrial fibrillation and pulmonary embolism. These can lead to excess mortality if it is not investigated and managed promptly.

EP1067

A case report of hyperthyroidism which does not warrant antithyroid treatment

Eng Hui Ooi, Chin Voon Tong & Yen Nee Low
Melaka Hospital, Melaka, Malaysia

Introduction
The most common cause of hyperthyroidism in Malaysia is autoimmune cause like Grave disease, or toxic multinodular goitre. Thyroid hormone resistant syndrome is a rare genetic disease which usually presented with mild hyperthyroidism clinically and biochemically it had elevated free T4 and non suppressed TSH. Inexperienced doctor will commonly mistreat patient with antithyroid medication. This is because this genetic disease is extremely rare to encountered in practice.
Case Report
A 24 years old gentleman, he was first presented to Hospital Ipoh for left Anterior Cruciate Ligament tear after sport injury in 2019. Pre-operative assessment noted patient tachycardia. Otherwise, he did not have palpitation, tremors, weight loss, heat or cold intolerance, diarrhea, or anxiety. On the other hand, he had strong family history of hyperthyroidism which were his mother, mother's siblings and his grandmother. On examination, his blood pressure is normotensive, and heart rate was slightly tachycardic. He had no fine tremors, and goiter. Cardiovascular and respiratory system examination was unremarkable His thyroid biochemical profile showed normal thyroid stimulating hormone (TSH), 3.4 mIU/l (0.55 -4.78) with elevated free T4 (FT4), 27.9 pmol/l (11.5-22.7). In view of pendemic covid, his operation was postponed and he request his case transfer to my hospital, Hospital Melaka to continue follow up. Throughout the follow up, serial thyroid function test showed normal TSH, and elevated FT4. He was asymptomatic for hyperthyroidism other than occasionally tachycardic. His magnetic resonance imaging brain demonstrate a pituitary microadenoma. However, thyrotropin releasing hormone (TRH) stimulation test reveal normal TSH response. We presumed that he had thyroid hormone resistance syndrome, with the given history of mild hyperthyroidism features and the investigation mentioned as above. He is otherwise well without any antithyroid treatment. He had undergone left knee Anterior cruciate ligament tear repair in Jan 2022 under general anesthesia. Intraoperative and postoperative were uneventful. We had our limitation to further workup because the genetic test was not available in our country. We had rule out thyrotropin secreting tumor and primary hyperthyroidism before we come to a conclusion of thyroid hormone resistance syndrome. However, we would like to emphasis that not all hyperthyroidism warrant antithyroid treatment. Early recognition and refer to correct team is crucial to avoid unnecessary treatment.

Myo-Inositol Supplementation in autoimmune thyroiditis and subclinical hypothyroidism on the background of vitamin D deficiency.

Nadiya Pasyechko & Veronika Kulchinska
Ternopil State Medical University, Internal Medicine No1, Ternopil, Ukraine

Background
In recent years, thyroid diseases have been occupying the top places in the structure of the endocrine pathology. There exists tight functional relationship between the thyroid and reproductive systems, which leads to a high probability of the development of combined disorders in one of these links of homeostasis. Vitamin D deficiency in the population remains a global problem. The purpose of the study is to investigate the effect of myoinositol on the thyroid status of women with subclinical hypothyroidism on the background of autoimmune thyroiditis and vitamin D deficiency.
Materials and methods
The study included 102 patients, aged 18-42 years, with subclinical hypothyroidism on the background of autoimmune thyroiditis. The patients were randomly subdivided into two groups. Patients of the first group ($n=$ 52) before the main treatment by levothyroxine at a dose 37,5$\pm$12,5, received the myoinositol supplementation at a dose of 2000 mg/day, and cholecalciferol at a dose of 2000 IU/day. Patients of the second group ($n=$ 50) before the main treatment received only cholecalciferol at a dose of 2000 IU/day.
Results
Vitamin D deficiency was observed in 91.68 % of women with subclinical hypothyroidism, and vitamin D insufficienty was observed in 8.32 %. A negative correlation was found between the level of 25 (OH) D and the level of ATPO ($r=$-0.194, $P<$0, 05). The myoinositol supplementation together with vitamin D led to a probable increase in the content of 25 (OH) D in the serum, as well as to a decrease in the titer of ATPO.
Conclusions
The positive effect of myoinositol drugs together with vitamin D on the functional state of the thyroid gland, on the level of antibodies to TPO in women of reproductive age with subclinical hypothyroidism on the background of autoimmune thyroiditis and vitamin D deficiency has been established.

The structure of thyroid dysfunction in children with type 1 diabetes mellitus

Zhanar Nurgaliyeva, Araily Manasbayeva, Zhanerke Amangeldi & Nozima Kholmirzayeva
NJSC 'Kazakh National Medical University named after S.D. Asfendiyarov', Department of Pediatric Diseases with a Course of Neonatology, Almaty, Kazakhstan

Relevance
Type 1 diabetes mellitus (DM) is one of the most common endocrine disorders among chil-dren and accounts for 5-10% of all DM. According to scientists, in patients with type 1 diabetes, the risk of developing thyroid pathology is increased and with their combination, the course of both diseases worsens. There are different opinions among specialists regarding the clinical significance of latent thy-roid dysfunction. The study of the functional state of the thyroid gland in children with type 1 diabetes seems to be very relevant. In Kazakhstan, we have not met studies to assess the function of the thyroid gland in children with type 1 diabetes.
Materials and methods
Cohort retrospective study of data from 1140 medical records of inpatient patients with type 1 diabetes who were on inpatient treatment for the study of thyroid hormones ($n=$ 580): TSH, free T3, free T4, AT-TPO, AT-TG.

Results
For the period from 2014 to 2020, the thyroid profile was studied in 58.9% of children with type 1 diabetes: euthyroidism was detected in 41.0%, hypothyroidism - in 18.0%, hyperthyroidism - in 2.4%, other different variants of thyroid dysfunction in 38.6% of children. When analyzing the distribu-tion of primary hypothyroidism, the frequency of thyroid hypofunction was recorded in 46-52% of cases more often over the last 4 years of follow-up. The frequency of hypothyroidism among all thyroid dys-function is 30.4% of cases. Among the various thyroid dysfunctions, the following variants are regis-tered: isolated increase in free T3 - 66.0%, isolated increase in free T4 - 5.0%, increase in free T3 and free T4 with normal TSH - 13.0%, increase in TSH, free T3 with normal free T4 - 13.0%, decrease in free T3 - 3.0%.
Conclusion
In patients with type 1 diabetes, thyroid dysfunction is detected in almost 60.0%. It should be noted that primary hypothyroidism is registered in every third child with type 1 diabetes among all thyroid dysfunctions. In 39% of patients with type 1 diabetes, there were various fluctuations in the lev-els of hormones TSH, free T4, free T3, which were not included in the diagnostic criteria for thyroid pathologies and required separate study.

Cardiac arrhythmias associated with subclinical primary hypothyroidism: about two cases

Henda Ben Sassi, Boubaker Fadia, Wiem Mkacher, Zohra El Mechri El Mechri, Houcem Mrabet, Alaya Wafa, Zantour Baha & Sfar Mohamed Habib
University Hospital Tahar Sfar Mahdia, Department of Endocrinology

Introduction
Thyroid hormones play an important role in the normal functioning of cardiac and vascular physiology, therefore hypothyroidism results in profound cardiovascular effects. Arrhythmia in patients with hypothyroidism seems rare and not well recognized.
Observation
Our first patient was a non-smoker 61-year-old woman, followed-up in the cardiology department for hypertension and dyslipidemia during the previous 5 years. She was treated with ACE inhibitors and a statin. Her sister had a dysthyroidism. The history was marked by the appearance of palpitations over the past 2years. Physical examination showed a palpable thyroid of normal size. The chest X-ray didn't show any anomaly. Sinus tachycardia was found on ECG. Renal and lipid balance was correct. The thyroid investigation showed a subclinical hypothyroidism with a sensitive thyroid stimulating hormone: (TSH) = 6,05 mU/l and Free T4 = 14,8 pmol/l. One year later, the patient showed symptoms of weight gain and asthenia. A check-up was done: TSH = 7,2 mU/l; FT4 = 14 pmol/l; AntiTPO antibodies were negative (= 4,9), Cholesterol = 6,5mmol, TG = 3mmol inciting to treat her with appropriate thyroxin replacement with a regular follow-up. The patient no longer reported tachycardia. Our second case was about a 57- year-old female patient, with a history of hypertension for 5 years. She was treated with ACE inhibitors. The patient was admitted to the cardiology department for junctional tachycardia and treated with beta blockers and digoxin. There was no infectious syndrome associated during her hospitalization, she was found to have subclinical primary hypothyroidism (TSH = 12.8 mU/l/FT4 = 12.5 pmol/l), her anti TPO antibodies were negative. The initial cervical ultrasound noted a 5.5 mm right lobar nodule classified as TIRADS4B (EU-Tirads5) with an ultrasound aspect of thyroiditis for the rest of the parenchyma. Three months later, the thyroid assessment was checked and was normal (TSH = 3.7 mU/l) and the control cervical ultrasound showed multiple micro cysts in both lobes Eu-TIRADS2. The cardiac rhythm disorder was resolved at that time. The ultrasound follow-up two years later showed a heterogeneous hypo echoic thyroid gland with no thyroid nodule.
Conclusion
Hypothyroidism can result in decreased cardiac output, increased systemic vascular resistance and atherosclerosis with ischemic heart disease risk. Cases of arrhythmia are rarely reported in hypothyroidism and could be due to alteration of myocyte-specific gene expression, interstitial oedema, myofibril swelling with loss of striation, endothelial dysfunction, disturbances of the sympathetic-vagal tone, increased arterial stiffness… Replacement with thyroxin could help and should be initiated cautiously.

Moyamoya disease and Graves' disease in a Tunisian girl

Chayma Bel Hadj Sliman, Fatma Chaker, Anis Grassa, Nadia Khessairi, Ibtissem Oueslati & Melika Chihaoui
Rabta Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
There is an association between Moyamoya syndrome and Graves' disease, described primarily in Asian populations. We report a case of Moyamoya vasculopthy with stroke and hypertension associated with graves' disease in a 15-year-old Tunisian girl.
Observation
A 15-year-old girl diagnosed with Moyamoya vasculopathy was referred to the endocrinology department for hyperthyroidism. The patient had a history of recurrent stroke and hypertension since 2 years-old. She complained of palpitations, weight loss and tremors, bilateral exophthalmia and floppy eyelid syndrome. Physical examination showed bilateral palpebral edema, bilateral exophthalmia and complete eyelid closure. Laboratory investigations showed high level free T4 = 38,8 pmol/l (12-22), low TSH < 0.05 mUI/I (0,4-4) and high level of TSH receptor antibodies: 35 UI/ml (< 5). Thyroid ultrasound revealed an hypoechoic, hypervascular goiter without nodules. Thyroid scintigraphy showed intense and homogeneous uptake. Orbital and brain MRI showed bifrontal anoxic-ischemic lesions with left wallerian degeneration associated with inflammatory myopathy of the right lower oculomotor muscle. The diagnosis of graves' disease was confirmed. The patient was treated with methimazole leading to clinical and biological euthyroidism after 8 months treatment.
Conclusion
This is the first case of Moyamoya disease coexisting with graves' diesease in a tunisian patient. The pathogenesis and the prognosis of hyperthyroidism and specially Graves' ophtalmopathy are still unknown.

EP1072

Impact of Ramadan fasting on patients followed for Hypothyroidism.

Amine Gueddari[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Uhc ibn rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
During Ramadan, Muslims change their eating and sleeping habits. All these changes can cause metabolic and hormonal variations. The main treatment for hypothyroidism is L-thyroxine. It is known that the absorption of L-thyroxine is optimal when taken on an empty stomach. Very few studies have been conducted to examine the best time to administer L-thyroxine during Ramadan.
Objective of the study
To evaluate the impact of Ramadan fasting on hormonal balance and to compare the use of L-thyroxine 30mn before Fotour and at Sohour.
Material and methods
Prospective study including 62 patients followed in consultation for hypothyroidism. A TSH measurement was performed before and after 6 weeks. The evaluation of the therapeutic compliance was evaluated by the MORISKY Medication Adherence Scale.
Results
We recruited 62 patients, 53 of whom were women (85.5% of cases) and 9 men (14.5% of cases). The average age was 50.4 years (29-80). Hypothyroidism of peripheral origin was present in 24 patients (38.7% of cases) while hypothyroidism secondary to total thyroidectomy was present in 38 patients which is 61.3% of cases. Twenty-nine patients preferred to take L-thyroxine at the time of Fotour (46.8% of cases), while 33 patients preferred to take it at the time of Sohour (53.2% of cases). Compliance was good in 87.1% of cases and average in 12.9% of cases. In post-Ramadan, 75.8% of patients remained euthyroid, 17.7% hypothyroid and 6.5% hyperthyroid without significant correlation between the two therapeutic schemes ($P = 0.07$).
Conclusion
Fasting during the month of Ramadan may be responsible for hormonal imbalance in patients on L-thyroxine, hence the interest of educating these patients on the use of medication and of a close follow-up after the month of fasting.

A retrospective study of the medical-surgical approach of a cohort of patients with Graves' orbitopathy

Mariola Méndez Muros[1], Reyes Ravé García[1], Tomás Martín Hernández[1] & Antonio Manuel Garrido Hermosilla[2]
[1]Virgen Macarena University Hospital, Endocrinology and Nutrition Department, Seville, Spain; [2]Virgen Macarena University Hospital, Ophthalmology Department, Seville, Spain

Objective
To study the characteristics of a cohort of patients with Graves' orbitopathy (GO) as a self-audit prior to the creation of a multidisciplinary team for the global approach of these patients.
Material and Methods
Retrospective study of patients with GO treated at the Endocrinology and Ophthalmology Services of a tertiary referral hospital (Virgen Macarena University Hospital, Seville, Andalusia, Spain) between 2018 and 2021. The following variables were evaluated in a cohort of 267 patients: demographic data; date and service of diagnosis; number of visits; thyroid function at diagnosis of GO; highest severity of GO and highest level of anti-TRAb (TSI) reached during follow-up; imaging; treatments for GO and EG; smoking.
Results
The results of the 267 analyzed patients are described in Table 1. The severity of the GO was analyzed according to the EUGOGO classification: 56.93% had mild GO, 41.57% moderate to severe, and 1.50% with visual risk. Highest level of anti-TRAb (TSI) reached during follow-up was recorded in 237 patients of the total, with a mean of 15.93 IU/l $\pm$ 13.49 IU/l SD. Regarding the treatment of GD, 89.98% of the patients were treated with antithyroid drugs, 15.36% received radioactive iodine (the majority without corticosteroid prophylaxis) and 40.82% required total thyroidectomy. With regard to smoking, 41.57% were active smokers, with 81% being offered anti-smoking advice and referring 14.4% of all smokers to the Smoking Cessation Unit of the Pneumology Service.
Conclusions
After analyzing our cohort of patients with GO, we have detected some areas for improvement: A corticosteroid prophylaxis deficit has been observed in the context of radioactive iodine administration for the treatment of GD. Referral to the Smoking Cessation Unit should be performed routinely in all smokers with GD. The analysis of these results will allow us to optimize the multidisciplinary management of our patients with GO.

EP1074

Diagnosis of thyroid adenomas at the outpatient stage

Lubov Timofeeva[1], Elena Yanovskaya[2] & Yuriy Aleksandrov[2]
[1]FSBEI HE «I. N. Ulianov Chuvash State University», Ultrasound, Cheboksary, Russian Federation; [2]Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation

Methods of radiation diagnostics and fine needle aspiration biopsy (FNAB) are the methods of the first stage of diagnosis of thyroid nodules, which is confirmed by a large number of international recommendations. However, these methods do not always give the right answer for thyroid adenomas. The aim of the study was to study the effectiveness of a set of methods: ultrasound, sonoelastography, scintigraphy and FNAB in the diagnosis of thyroid adenomas. The study included 86 patients with a morphologically confirmed diagnosis of thyroid adenomas. The patients underwent ultrasound (86) and FNAB (86), sonoelastography (55) and scintigraphy (37). The results of a multiparametric ultrasound examination showed that the images of the adenomas do not correspond to standard estimates. There are also no ultrasound signs that are the 'key to diagnosis'. Signs of 'border', 'contour', 'height less than width' were characteristic of most benign nodules of various structures. Signs of 'solid structure' and 'increased blood flow' have also been found in thyroid cancer. Discriminant analysis showed that the signs of 'borders', 'contours', 'halo' and the absence of 'calcification' are the 'reference' signs of thyroid adenomas. The estimate according to EU-TIRADS was: EU-TIRADS2 -20.3%, EU-TIRADS3 - 5.3%, EU-TIRADS4 - 72.5%, EU-TIRADS5 - 1.9%. The efficiency parameters of EU-TIRADS were 86.9% sensitivity, 73.5% specificity and 80.2% accuracy. Cytological examination showed results with a significant spread: TBSRTC1 - 8.5%, TBSRTC2-13.1%, TBSRTC3-15.1%, TBSRTC4 -48.5%, TBSRTC5 - 13.5%, TBSRTC6 - 1.3%. According to sonoelastography data, images of thyroid adenomas demonstrated low probability of malignant process: 1 (41.8%) and 2 patterns (54.5%). The Young's modulus index was 23.5$\pm$7.1 kPa, but in some cases the values exceeded 45 kPa. Elastography in thyroid adenomas has a sensitivity of 96.4%, specificity of 57.1% and accuracy of 88.41%. Elastography of thyroid adenomas showed better indicators than in the EU-TIRADS. However, when studying e, it was found that taking into account only e data can lead not only to the absence of thyroid cancer cases, but also to erroneous conclusions in a. In thyroid adenomas scintigraphy, sensitivity was 53.3%, specificity - 42.3%, accuracy - 44.7%. However, the possibilities of this method are mainly limited to hyperfunctional nodules, which is observed in adenomas only in half of cases. Based on the data obtained, the concept of the need for regulation (sequence) of the complex phased application of methods of radiation diagnostics and cytological examination in the examination of patients is formulated.

In COVID-19 patients the occurrence of low T3 serum values is associated with disease severity and death, but hormonal substitutive replacement is still debated. Clinical trials reported so far failed to demonstrate clear beneficial effects of T3, T4 or both treatments. With the aim to analyze the peripheral effects of the acute deficiency of T3 in blood, we analyzed body fluid composition in 74 COVID-19 patients, admitted to our University Hospital during the last pandemic wave. COVID-19 patients were sub divided into those that presented low FT3 serum levels, i.e., $\leq$ 1.7 pg/ml (n. 42), 13 of which showed very low FT3 serum values, i.e., $\leq$ 1.1 pg/ml, and those that showed normal FT3 serum levels, i.e., $>$ 1.7 pg/ml (n. 32). Body fluid composition was analyzed by Bioelectrical Impedance Analysis (BIA). We demonstrated that COVID-19 patients with low FT3 serum values exhibited increased values of the Total Body Water/Free Fat Mass (TBW/FFM) ratio. Patients with the lowest FT3 serum values had also the highest level of TBW/FFM ratio, an indicator of the fraction of FFM as water and one of the best-known body-composition constants in mammals. We found an inverse

GENDER	Year of diagnosis	IMAGING				GO TREATMENT									THYROID FUNCTION AT DIAGNOSIS* (n= 266, 1 patient not evaluated)		
		Patients diagnosticated per year

55 (20,6%)	139 (52%)	-Before 2018: 93 -2018: 26	-Before 2018: 35 -2018: 4							6%							
Female	Before 2018	-2019: 23,7	-2019: 3			18,3%	4,5%				12%	3,4%			85,7%	7,5%	6,4%
212 (79,4%)	128 (47,9%)	-2020: 28 -2021: 36	-2020: 5 -2021: 12	26,9%	18,3%			10,5%	27,34%				1,5%	1,1%			

correlation between FT3 serum values and this constant. Reduced FT3 serum values in COVID-19 patients were correlated with the increase in the total body water (TBW), the extracellular water (ECW) and the sodium/potassium exchangeable ratio (Na_e:K_e), and with the reduction of the intracellular water (ICW). Since the Na+/K+ pump is a well-known T3 target, we measured the mRNA expression levels of the two genes coding for the two major isoforms of this pump. We demonstrated that COVID-19 patients with NTIS had lower levels of mRNA of both genes in the peripheral blood mononuclear cells (PBMC)s obtained from our patients during the acute phase of the disease. In conclusion, we demonstrated that the acute T3 deficit in our COVID-19 patients has marked effects on the hydroelectrolytic equilibrium of their peripheral blood mononuclear cells. The Na+/K+ pump is a possible target of T3 action, involved in the pathogenesis of the anasarcatic condition observed in these patients. Measurement of BIA parameters is a useful method to analyze water and salt retention in COVID-19 patients hospitalized in ICU that develop NTIS and may represent a novel reliable outcome to evaluate the benefit of T3 treatment in future clinical interventional trials.

Autoimmune thyroiditis after 2 years covid pandemic: prevalence, clinical features, significance. Study on 450 patients in a medical center of Bucharest-Romania

Dan Peretianu[1], Mihaela Stanciu[2] & Oprea Cristina Dana[1]
[1]Medical Center Povernei, Endocrinology and Applied Immunology, Bucharest, Romania; [2]Faculty of Medicine, V. Papilian, Endocrinology, Sibiu, Romania

Material-Method
We registered from February 26, 2020 until January 23, 2022 (almost 2 years) patients with chronic autoimmune thyroiditis Hashimoto. Usual parameters for this disease were investigated: age, sex, ATPO, FT4, TSH, ultrasound pattern, antibody evolution, immune associations, lost pregnancies, other clinical associations (alergies, breast cancer). Patients were divided into 2 groups: those who had covid-19 (C-19) vs. those who did not have viral disease (NOC). Statistical analysi: Fisher z test (percentage comparisons), X^2 (discrete data comparisons), T (continuous data comparisons).
Results
I. We registered 456 patients. Of these, 84 had covid-19 (18,24%). The prevalence was extremely high compared to the declared prevalence of covid-19 in Romania: 10,95% (https://worldpopulationreview.com/countries/romania/population, https://www.worldometers.info/coronavirus/country/romania). Z = 5,43, $P << 0{,}0001$. II. No differences between patient groups: **A**. Gender: Female: C-19 = 90,13%, NOC = 89,52%; **B.** Age of onset (mean, years): C-19 = 50,39 years, NOC = 50,94. **C.** Current age: C-19 = 55,86, NOC = 55,6. **D.** ATPO level: C-19 = 749,67 IU/ml, NOC = 837,67. **E.** ATPO evolution: predominantly undulating, 46% vs 67%, X^2 = 2,88, P= 0,24. **F**. Thyroid function at onset: C-19: normothyroidism = 41,7%, hypothyroidism = 44%, hyperthyroidism = 14,3%. NOC = normothyroidism = 41,3%, hypothyroidism = 48,95%, hyper = 9,91%. **G.** Current thyroid function: C-19: normal = 670,8%, hypo = 26,19%, hyper = 3,57%, NOC: normothyroidism = 67,2%, hypothyroidism = 29,84%, hyperthyroidism = 2,96%. **H.** Pregnancy losses: C-19 = 7,69%, NOC = 13,21%. I. Immune associations: C-19 = 45,23%, NOC = 37,09%, P= 0,16. III. Clinical forms of covid-19. Asymptomatic = 4, oligosymptomatic = 4, mild = 27, moderate = 34, severe = 8, very severe = 5, death = 2. Comparison with the evolution of the Romanian general covid population (Pantea-Stoian *et al*, 2020, Sci. Rep, 21613) is NOT different, but seemingly lighter. For example, the lethality in our group was only 2,38%, while in the general population it was 2,95%.
Conclusions
Either 1. Derived from the increased prevalence of immune associations - The genetic structure of the mucosal cells of patients with Hashimoto's thyroiditis allows the attachment of S protein much faster and to lower viral loads (research to be solved for future generations), Either 2. Derived from the lack of difference between groups and set mathematical analysis - the prevalence of covid-19 in Romanian society **was** not 10,95%, **but** 18,24%, as it appears in our group of patients with chronic autoimmune thyroiditis Hashimoto.

Clinical and paraclinical features of ectopic thyroid gland in adult patients.

Anis Grassa, Ibtissem Oueslati, Hajer Yezza, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Ectopic thyroid gland is a rare pathology due to an abnormality in the embryological development and/or migration of the gland. The aim of this study was to assess clinical and paraclinical characteristics of adult patients with ectopic thyroid gland.
Methods
This was a retrospective study including adult patients with ectopic thyroid gland. Clinical, biological, hormonal, radiological and therapeutic data were collected.
Results
Five patients (four women and a man) were enrolled in this study. Their median age was 40 years [extremes: 17-61]. Their past medical history included intellectual disability, stature retardation, and type 2 diabetes mellitus in two cases respectively and vitiligo in one case. All patients were referred to our department for management of hypothyroidism. On physical examination, all patients had non-palpable thyroid gland. The mean TSH level at baseline was 48.7 mIU/l [extremes: 7.6 -100]. Three patients had overt hypothyroidism and two patients had subclinical hypothyroidism. Two patients had a cervical ultrasound showing an empty thyroid compartment. Two other had cervical CT scan, showing sublingual mass in one case and retropharyngeal mass in the other. Thyroid scintigraphy was performed to all patients, showing two sublingual thyroids, one left paramedian, one sub-hyoid and one retropharyngeal. All patients were put on replacement therapy. The doses of levothyroxine to achieve euthyroidism varied from 75 µg to 200 µg/day.
Conclusion:
The diagnosis of ectopic thyroid gland should be suspected in patients with hypothyroidism associated to a non-palpable thyroid gland in normal position even in adults. Its confirmation is radiological based on the scintigraphy.

The relationship between type 2 diabetes mellitus with metabolic syndrome and clinical hypothyroidism

Rim Rachdi, Berriche Olfa, Olfa Lajili, Eya Safi, Nadia Ben Amor, Rym Ben Othman, Ramla Mizouri, Faten Mahjoub & Jamoussi Henda
The National Institute of Nutrition in Tunis, Diabetology Department A, Tunisia

Introduction
Metabolic syndrome is a multifactorial disease with multiple risk factors that arises from insulin resistance accompanying abnormal adipose deposition and function, increasing the risk of type 2 diabetes, one of the most common endocrine pathologies. Abundant evidence suggests an association between TSH levels, insulin resistance and some markers of the metabolic syndrome, without foreseeing the kind of this link. The aim of our study was to search if there was a link between type 2 diabetes with metabolic syndrome and hypothyroidism, and to explore the markers that are specially correlated with thyroid status.
Materials and methods
Retrospective study including 100 patients with type 2 diabetes showing criteria of metabolic syndrome, carried within the diabetology department 'A' of the National Institute of Nutrition in Tunis.
Results
70% of patients had a normal thyroid balance (euthyroid group (G0)) and 30% presented a clinical hypothyroidism (hypothyroid group (G1)). The average age in G0 was 57,8 years compared to 60,8 years in G1 (P=NS). All G1 patients were female (100%) compared to 82% in G0 (P=0,01). Median diabetes duration was 9,78 years in G0 compared to 11,76 years in G1 (P=NS). 51,43% of patients were on insulin in G0 vs 66,66% in G1 (P=NS). The average BMI of G0 patients was 35,9 kg/m^2 compared to 36,48 kg/m^2 in G1 (P=NS). Mean fasting blood glucose was significantly higher in G1 than G0 (12,19 mmol/l vs 10,36 mmol/l; P=0,04). The hypothyroid patients had more often low levels of HDLcholesterol and high levels of triglycerides (respectively 60% vs 57,14% in G0; P=NS and 30% vs 28,57% in G0; P=NS). Hypercholesterolemia was significantly more common in G1 than G0 (63,33% vs 25,71%; P=0,0003). The occurrence of cardiovascular events was observed in 11,43% of patients in G0 compared to 6,66% in G1 (P=NS). Thyroid status didn't have any influence on blood pressure

control (mean systolic and diastolic blood pressures were 137 mmHg and 79 mmHg, respectively in both groups).
Conclusion
The prevalence of hypothyroidism among our patients with type 2 diabetes was much higher than in the common population. Our hypothyroid patients had significantly higher fasting blood glucose levels and were more likely to be treated with insulin and to have low levels of HDLcholesterol and high levels of triglycerides. The recommendation for systematic exploration of thyroid status in patients with type 2 diabetes with metabolic syndrome requires larger-scale studies.

Thyroiditis revealing a congenital anomaly: about an observation

El Omri Malika, Marwa Ben Njima, Amany Mallat, Mouna Bellakhdhar, Meherzi Abir, Jihen Haouas, Ghammmam Monia, Kermani Wassim & Abdelkefi Mohamed
Hospital Farhat Hached, ENT, Sousse, Tunisia

Introduction
Remnants of the fourth branchial arch are extremely rare with less than 100 cases reported in the literature and account for 1–4% of all branchial anomalies. These anomalies typically present as recurrent neck infections and/or abscesses or acute suppurative thyroiditis. We report a case of cyst of the 4th cleft revealed by a thyroiditis treated in our department.
Case report
A 6-year-old boy presented with recurrent neck swellings. During that time, he had a history of drainages, and attempted excisions, with recurrence of signs and symptoms after every intervention. Upon presentation to our clinic, he complained of painful swelling of his neck. Clinical examination revealed swelling of the anterior left neck that was tender to palpation and was approximately 5 cm. Ultrasound showed an irregular oval mass with polylobed contours, measuring 54 x 30mm, multi-loculated, of basi-cervical left location and pushing back the homolateral carotid axis and the left lobe of the thyroid which is of heterogeneous appearance. Computerized tomography scan showed a lobulated and multi-loculated mass of lateral and basi-cervical left location measuring 54x42x57 mm which compressed anteriorly the sternocleido-mastoid muscle as well as the left lobe of the thyroid. In the operating room, direct laryngoscopy revealed a sinus tract originating from the left side of the pyriform sinus apex; surgical exploration of the neck revealed the tract to pass through the hypopharyngeal wall, consistent with a fourth branchial anomaly. All scar from previous surgery, the ipsilateral thyroid gland, and the tract were completely mobilized. Postoperatively, the patient did well, and histopathology confirmed the presence of a sinus tract. The patient had an unremarkable postoperative course and has had no further recurrences.
Conclusions
Fourth branchial arch anomalies are rare and fascinating aberrations of fetal development that may present in many different ways such as thyroiditis. Combining a proper preoperative evaluation with careful surgical planning may result in the proficient eradication of these lesions, offering the patient relief from this source of recurrent infection.

Neutropenia in hyperthyroidism

Cristina Elías Ortega, Nerea Egañ a Zunzunegui, Cristina Garcia Delgado, Maria Teresa Aramburu Calafell, Jorge Rojo Alvaro, Inmaculada Venegas Nebreda, Ane Amilibia Achucarro, Ismene Bilbao Garay & Alfredo Yoldi Arrieta
Donostia Unibertsitate Ospitalea, Donostia, Spain

Introduction
Neutropenia can indicate infectious and hematological pathology but it can also be a sign of hyperthyroidism. For this reason, it has been suggested to perform a complete blood count before starting treatment with antithyroid drugs in case of new-onset hyperthyroidism. Antithyroid drugs can cause severe neutropenia, also called agranulocytosis, when the neutrophil count is less than 500/µl. Therefore, the use of these drugs should be reconsidered if it is less than <1000/µl, and, in the event of symptoms compatible with agranulocytosis, treatment should be interrupted according to the recommendations of the American Thyroid Association (ATA). Agranulocytosis is a rare adverse effect of antithyroid drugs, appearing in 0.1%-0.5% of cases. However, there is no evidence that neutropenia in patients with hyperthyroidism is associated with an increased risk of antithyroid-induced agranulocytes.
Objectives
We studied the prevalence of neutropenia in patients with hyperthyroidism and the variations in the neutrophil count with the use of antithyroid drugs.
Material and Methods
We analyzed 52 cases of hyperthyroidism due to Graves Basedow disease diagnosed between 2014-2020. 8 men and 44 women with a mean age of 46 years (range 22-74). We studied the presence of neutropenia at diagnosis and during treatment with antithyroid drugs (methimazole or carbimazole). We classify neutropenia as mild 1000-1600/µl, moderate 500-1000/µl and severe <500/µL.
Results
5 patients presented neutropenia (9.61%), 2 at diagnosis and 3 during treatment. All the neutropenias found were mild (1000/µL -1600/µL), without clinical repercussions, and resolved during follow-up. Only 1 patient continued to present neutropenia from diagnosis until the 6th month of treatment. There were no cases of agranulocytosis.
Conclusions
Knowledge of the relationship between hyperthyroidism and neutropenia is essential for a correct diagnosis and treatment. Despite the limitations of our study, the cases of neutropenia in the context of hyperthyroidism were mild and the neutropenia was resolved without the development of agranulocytosis. This reinforces the idea that antithyroid treatment is not contraindicated in patients with mild neutropenia.

Thyrotoxic crisis presented as psychiatric decompensation

Mafalda Martins Ferreira, Cátia Araújo, Mariana Lavrador, Joana Reis Guiomar, Patrí cia Oliveira, Carolina Moreno & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal

Introduction
Thyrotoxic crisis is a rare endocrinological emergency with high mortality and it is more frequent in Graves' disease.
Clinical case
A 66-year-old women with schizophrenia was admitted to the Emergency Department due to altered state of consciousness, fatigue, constant moaning interspersed with unusual psychomotor agitation, heteroaggressiveness, diarrhea and anorexia. Lack of compliance with her psychiatric medication, new delusional ideas or use of recreational substances or drugs were excluded. The patient presented with normal blood pressure, peripheral oxygen saturation of 100% but she was sweating, subfebrile (37.6ºC) and tachycardic (154 bpm) and had painful palpation of the left iliac fossa without peritoneal defense. She had bilateral pulmonary stasis and showed permanent restlessness. Abdominal ultrasound excluded intra-abdominal infection and chest X-ray excluded pneumonia but showed Kerley B lines. The electrocardiogram showed persistent sinus tachycardia with poor response to beta-blockers, digoxin, analgesia and antipyretic medication. She had slight elevation of hepatic cytolysis enzymes, normal bilirubinemia, slightly elevated CRP (2.25 mg/dL) without leukocytosis,

Table 1

	Control group					Neutropenia group				
	neutro	%	T4l	T3l	Dose	neutro	%	T4l	T3l	Dose
Baseline	3333	47.79	4.15	13.41		1678	34.85	4.17	15.22	
1-3 months	3753	54.49	1.23	4.77	17.3	1540	32.33	1.03	3.20	15.5
2-6 months	3552	50.93	1.13	3.55	10.9	2056	39.7	1.05	3.15	8.9

normal amylasemia and negative cardiac markers. Due to persistent sinus tachycardia, thyroid function was requested and showed TSH <0.004 uIU/ml (0.4-4.0); free-T4 >5.0 ng/dL (0.7-1.5) and free-T3 >20 pg/mL (1.8-4.2). The diagnosis of thyrotoxic crisis was assumed with Burch-Wartofsky Scale of 60 points. The patient did not have any known thyroid disease. Propitiuracil, corticosteroids, cholestyramine and propranolol were started. She was initially stabilized in an Intermediate Care Unit due to congestive heart failure requiring non-invasive mechanical ventilation. The microbiological study was negative and no precipitating factor was found. TRABS and thyroid stimulating immunoglobulin were both detected: 9.7 U/l (< 1.0) and 1.0 U/l (<0.1) respectively. Thyroid ultrasound showed multinodular goiter with 2 larger nodules measuring 4 and 2 cm. She did not have Graves' orbitopathy. The patient was discharged after clear improvement of thyroid hormones: free-T4 1.60 ng/dL (0.7-1.5); free-T3 3.6 pg/mL (1.8-4.2) and underwent total thyroidectomy a few months later.
Conclusion
Long-term, disabling schizophrenia with a predominance of negative symptoms led to the devaluation of initial complaints - interpreted as psychiatric decompensation. In fact this was the second time the patient went to the emergency department with the same symptoms of restleness and agitation without a obvious cause. The time between the onset of symptoms and diagnosis was 5 days. Fever, persistent tachycardia and the patient's objective state of discomfort in the absence of appreciable analytical or ultrasound alterations led to the diagnosis.

Lipid profile during block replace treatment in Graves disease

Ana-Maria Stancu[1], Ruxandra Dobrescu[2], Stanescu Laura Semonia[3] & Corin Badiu[3]
[1]'Carol Davila' University of Medicine and Pharmacy, Thyroid Related Disorders, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [3]National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania

Introduction
Graves' disease (GD) is an autoimmune disorder causing hyperthyroidism. Variations of functional profile as well as type and titer of thyroid specific antibodies makes the control often difficult. One treatment option is adding levothyroxine to anti-thyroid drugs (ATDs), so-called block-replace therapy (BRT).
Aim
To study the BRT impact on lipid profile, thyroid function tests (TFTs) and TSH receptor antibodies (TRAb).
Materials & Methods
A prospective, observational study which enrolled 108 patients with active Graves' disease, aged >18 years, with new diagnosis or relapse of GD who are receiving medical therapy. Pregnant women, patients treated with radiotherapy or surgery were excluded. We compare the data regarding TFTs, TRAb and lipid profile from diagnosis (visit 0) and during BRT (3 visits). Mean time between visit 1 and 2 was 137.2 days, respectively 105.3 days between visit 2 and 3. Data were analyzed with Microsoft Excel and Minitab v21. Data are presented as mean ± SD.
Results
90 women, aged 45.07 ± 13.73 years and 18 men, aged 54 ± 14.03 years were included. Out of 108 patients, only 95 had measured their lipid profile at diagnosis and 6 of them were on therapy with statin. The mean of total cholesterol at visit 0 was 161.64 mg/dl, significantly lower than during the BRT (194.51 mg/dl at visit 1; 194.61 mg/dl at visit 2 and 202.42 mg/dl at visit 3, $P<0.001$). The mean of low density lipoprotein (LDL-cholesterol) progressively raised from 92.29 mg/dl (N: <100 mg/dl) at diagnosis to 116.45 mg/dl at visit 1 and 122.01 mg/dl at visit 3. No impact was observed on the levels of triglycerides. For 102 patients, the mean of fT4 during BRT was 13.237 pmol/l (N:9-19) on a dose of 46.15 ± 17.48 µg of levothyroxine daily. Mean dose of methimazole at diagnosis was 29.73 ± 15.43 mg/day and 16.70 ± 12.93 mg/day during BRT. Mean levels of T3 decreased from 364.53 ng/dl at diagnosis to 126.86 ng/dl (visit 1). Also, TRAb decreased from a mean of 17.07 UI/l (visit 0) to 8.71 UI/l (visit 3) ($P=0.002$).
Limitations
Small number of patients, limited time for observation, heterogeneous group.
Conclusion
Controlling hyperthyroidism in a block and replace regimen normalized the thyroid function, and worsened the lipid profile. This could be explained by the previously altered lipid profile before developing thyrotoxicosis, masked at the moment of diagnosis. A dynamic risk evaluation of lipid profile is suggested while treating thyrotoxicosis.

Key words: hyperthyroidism, Graves' disease, block-replace therapy, lipid profile.

Basedow disease and Susac syndrome: an exceptional association

Arij Ezzouhour Yahyaoui[1], Asma Kefi[1], Khaoula Ben Abdelghani[1], Syrine Sassi[1], Sami Turki[1], Mounira El Euch[1] & Ezzeddine Abderrahim[1]
[1]Charles Nicolle, Internal Medicine A, Tunis, Tunisia

Introduction
Susac syndrome is a rare endotheliopathy causing micro-ischemic damage to vessels in the brain, ears, and eyes. While the underlying aetiology of this disease remains unknown, it is widely believed that observed clinical manifestations result of an autoimmune endotheliopathy. Herein we report a case of Basedow's disease associated to a scarce condition: Susac syndrome.
Observation
Our patient is a 48-year-old woman, who was admitted for chronic holocranial headache, without blurred vision nor vomiting. Physical examination only revealed a right hemiparesis. The brain MRI highlighted temporal and periventricular oval demyelinating lesions with T2 hypersignal and T1 hyposignal. These lesions were also described in the corpus callosum. An audiogram was performed and showed a bilateral and symmetric perceptive deafness. Ophthalmologic examination described a decreased visual acuity. Retinal fluorescein angiography showed bilateral and diffuse vasculitis. Somatosensory evoked potentials had a slightly decreased amplitude. Visual and auditory evoked potentials were normal. Cerebrospinal fluid testing did not show any abnormality. Therefore, the diagnosis of Susac syndrome was made. Thrombophilia testing and antinuclear antibodies were negative. She had a biological inflammatory syndrome and low levels of TSH. The thyroid scintigraphy was compatible with a Basedow's disease. We started treatment with radioactive iodine. Treatment of Susac syndrome consisted of three boli of methylprednisolone (1g/day for 3 days). Oral corticotherapy was then prescribed, with a good clinical and biological evolution.
Conclusion
Susac syndrome is caused by a microangiopathy that gives the classic clinical triad of subacute encephalopathy, visual loss secondary to retinal branch occlusions, and sensorineural hearing loss. Given autoimmune part of Susac aetiology, association to other autoimmune condition, especially Basedow disease, must be actively sought. Early therapy may reduce sequelae and improve recovery.

The diffuse sclerosing form of papillary carcinoma of the thyroid

Meherzi Abir, Marwa Ben Njima, Mouna Bellakhdhar, El Omri Malika, Jihene Houas, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Tunisia

Objective
Papillary thyroid carcinoma is the most common malignant tumor of the thyroid, the diffuse sclerosing variant is however very rare and represents between 0.7 and 6.7% of all papillary thyroid carcinomas. We propose through this poster to study its clinical, epidemiological, therapeutic and prognostic characteristics.
Matherials and methods
We report two cases of diffuse papillary sclerosing carcinoma of the thyroid, collected at the ENT and CCF service of the Farhat Hached University Hospital of Sousse.
Results
The 2 patients were a man aged 38 years old and a women aged 55 years old with a family history of papillary thyroid carcinoma. The reasons for consultation were

right superclavicular swelling that had been present for 5 months in the man and right jugulocarotid adenopathy that had been present for 4 months in the woman. Cervical ultrasonography revealed a 2 cm right supraclavicular adenopathy containing fine microcalcifications and multiple microcalcifications were noted in the right lobe of the thyroid which contained a 10 mm nodule fully calcified in men and a suspicious nodule classified EUtirads 5 of 33 mm in women. Both patients underwent total thyroidectomy with dissection of the bilateral central lymph node and homolateral lateral one. Extemporaneous examination revealed papillary carcinoma in the female patient, whereas it was in favor of benign in the male patient. The final histological examination showed a papillary carcinoma in its diffuse sclerosing variant with sub-millimetric microscopic foci of epithelial malignant tumor proliferation, disseminated throughout the right lobe of the thyroid in men and infiltrating both thyroid lobes and peri-thyroid fat in women, as well as multiple endolymphatic emboli and lymph node metastases in the mediastinum-recurrent, jugulocarotid and supraclavicular. The postoperative period was dominated by the appearance of transient hypoparathyroidism. Both patients received additional treatment with radio-active iodine. The evolution was good. The decline was 12 months.
Conclusion
The diffuse sclerosing variation of papillary carcinoma is an uncommon histological form distinguished by its locally aggressive nature and deceptive clinical appearance. Its therapy must be complete.

Failure of rhTSH-stimulated FDG PET-CT scan to identify metastases of a papillary thyroid carcinoma

Ricardo de Leon-Durango, Alba Hernandez-Lazaro, Carmen Acosta-Calero, Agnieszka Kuzior, Claudia Arnas-Leon & Francisco Javier Martinez Martin
Hospital Universitario de Gran Canaria Dr. Negrín, Pakistan

Introduction
Recurrences of differenciated thyroid carcinoma are occasionally hard to locate; rhTSH-stimulated FDG PET-CT may offer a higher sensitivity, particularly when thyroglobulin in high, but its utility has not been clearly established.
Methods
Review of the patient's clinical record
Results
A 61 years old woman noticed a right anterior neck lump when she was 47; FNAC was suggestive of a solid papillary thyroid carcinoma and she underwent right thyroid lobectomy. The pathology diagnosis was atypical papillary trabecular carcinoma (5.5 cm maximal diameter) with oncocytic changes, with minimal extracapsular invasion but clean surgical margins. She underwent left lobectomy two months later, with normal pathology, followed by ablation with 125 mCi of 131-I one month later, and substitution therapy with levothyroxin ever since. One year afterwards, the rhTSH test was negative, and follow-up thyroglobulin, antithyroglobulin antibodies and neck ultrasonography were negative for the next 9 years. By the tenth year, thyroglobulin was detectable (1.1 ng/mL) and increased in the 11th and 12th years (2.14 and 2.75 ng/mL) but thyroid gammagraphy scans were negative, and ultrasound only revealed unspecific laterocervical adenopathies, with negative FNAC. A CT scan showed only two well-defined pulmonary nodules of 7.5 mm maximum diameter in the lingula and the apical segment of the left lobe. A new rhTSH test with peak TSH of 87.5 mcU/mL showed little response (baseline and stimulated thyroglobulin 5 and 7.5 ng/ml, respectively) with negative stimulated gammagraphy scan. An FDG PET-CT was ordered (13th year) showing only the two known pulmonary nodules, stable in size (both 7.0 mm), without metabolic criteria of malignancy (SUVmax: 1.7). In order to elucidate if the nodules could be metastatic, a new FDG PET-CT was performed (14th year) after rhTSH stimulation, thyroglobulin showed again a modest response (8.25 to 10.4 ng/mL) and the nodules showed a small increase (10 mm) and an increase in metabolic activity under stimulation (SUVmax 1.3 to 2.3). Ablation with 150 mCi of 131-I was performed, but the gammagraphy scan did not show enhancement of the pulmonary nodules. One month afterwards, the patients's thyroglobulin was not substantially decreased (8.25 to 7.80 ng/mL).
Conclusions
The use of rhTSH-stimulated FDG PET/CT reportedly changes the patients' management only in a minority of the cases. In our patient, the apparent enhancement of two pulmonary nodules with this technique seems to be a false positive, with negative result of the post-treatment gammagraphy and no change in the patient's management.

Autoimmune thyrotoxicosis Post SARS CoV-2 Vaccination

Dorothy Maria Anthony Bernard, Chin Voon Tong & Yen Nee Low
Hospital Melaka, Internal Medicine and Endocrinology, Bandar Melaka, Malaysia

Introduction
Covid-19 vaccination have been introduced to reduce overall severity and mortality of COVID-19 infection. Autoimmune/inflammatory syndrome induced by adjuvants (ASIA) is a syndrome first described in 2011 that triggers autoimmune conditions after exposure to various adjuvants through various mechanisms. We report three cases of autoimmune thyrotoxicosis post mRNA type vaccine for COVID-19 possibly linked to adjuvants present in the vaccine.
Case 1
A 34-year-old patient was newly diagnosed with Grave's disease, within 1 month after her SARS-CoV-2 vaccine (Pfizer-BioNTech) when she presented with symptoms of palpitations, heat intolerance and a painless neck swelling. Physical examination revealed fine tremors with a diffuse goiter. Results of biochemical workup was as follows: TSH (Thyroid stimulating hormone): <0.008 mIU/l (low), FT4(free thyroxine): 123.1 pmol/l (elevated), FT3(free triiodothyronine): 9.10 pmol/l (elevated), anti-TPO (antithyroid peroxidase) : 9.51 IU/ml (normal), anti TG (antithyroglobulin): 11.04 IU/ml (normal), TSHrAb (anti–TSH antibody levels) : 30.03 IU/l (elevated). Ultrasound thyroid revealed increased vascularity in bilateral thyroid lobes with heterogenous appearance. She was started on oral Carbimazole and Propanolol.
Case 2
A 29-year-old healthcare worker with underlying thyrotoxicosis in remission for 7 years presented with symptoms of as heat intolerance, agitation, oligomenorrhea, mood instability, palpitations and diarrhea within 1 month after her 1st dose of SARS-CoV-2 vaccine (Pfizer-BioNTech). Physical examination revealed fine tremors with no thyroid eye signs or goiter present. Results of biochemical workup was as follows: TSH: <0.008 mIU/l (low), FT4: 29.4 pmol/l (elevated), FT3: 8.47 pmol/l (elevated), anti-TPO: 254.8 IU/ml (elevated), anti-TG: 30.13 IU/ml (normal), TSHrAb: <0.8 IU/l (normal). Thyroid ultrasound revealed increased in vascularity. She was started on oral Carbimazole and Bisoprolol.
Case 3
A 30-year-old healthcare worker with underlying thyrotoxicosis in remission for 9 years also presented with lost of weight of 6 kg, heat intolerance and fine tremors, within 1 month after her 1st dose of SARS-CoV-2 vaccine (Pfizer-BioNTech). Physical examination revealed fine tremors with a diffuse goiter present. Results of biochemical workup was as follows: TSH: <0.008 mIU/l (low), FT4: 56.6 pmol/l (elevated), anti-TPO: 375.7 IU/ml (elevated), anti-TG:1691.1 IU/ml (elevated), TSHrAb: <0.8 IU/l (normal). Thyroid ultrasound revealed heterogenicity and increase vascularity in bilateral thyroid lobes. She was started on oral Carbimazole and Propanolol.
Conclusion
This case series reports three cases of autoimmune thyrotoxicosis post vaccination with Pfizer-BioNTech against COVID-19. Any emerging symptoms of thyrotoxicosis post vaccination should prompt clinicians to screen appropriately. However, the benefits of vaccination still outweigh any risks and should be advocated for all patients unless they have other contraindications.

EP1088

Amiodarone-induced thyrotoxicosis refractory to medical therapy: A case report

Zineb Mhamdi, Adil El Mesmoudi, Souad El Moussaoui & Ghislaine Belmejdoub
Military Hospital Mohammed V, Department of Endocrinology and Diabetology, Rabat, Morocco

Introduction
Amiodarone is an anti-arrhythmic drug rich in iodine compounds. One 200 mg tablet corresponds to about 25 times the daily requirement of iodine. One of the major complications of taking Amiodarone is the development of dysthyroidism which is observed in 15% to 20% of cases. Hyperthyroidism occurs in 1 and 13% of these patients.
Case report
We report the case of an 34 year old female patient, followed for complete arrhythmia by atrial fibrillation under Amiodarone 200 mg/d, who presented a thyrotoxicosis with TSH at 0.005 mUI/l, FT3 at 1.5 times normal and FT4 at 2 times normal. Anti-TPO and TSH receptor antibodies were negative. Cervical ultrasound showed an enlarged thyroid. Thyroid scintigraphy was white.

Treatment with Carbimazole 40 mg/d and Prednisolone 60 mg/d was initiated without improvement. In view of the resistance to medical treatment, total thyroidectomy was indicated.
Discussion and conclusion
Amiodarone-induced hyperthyroidism can be explained by two mechanisms: thyroid hyperfunction by iodine overload in the context of a pre-existing nodular pathology (type 1) and must be treated with synthetic antithyroid drugs or thyroiditis with follicular destruction (type 2) and which responds well to glucocorticoids or the mixed form as in our patient's case. Surgery is indicated if there is resistance to medical treatment, to correct thyrotoxicosis rapidly in patients for whom discontinuation of Amiodarone is not possible.

Introduction
Papillary thyroid carcinoma (PTC) is the most common type of differentiated thyroid cancer of all cases of thyroid cancer. Fine-needle biopsy by ultrasonography is still the main diagnostic method of PTC, but there is a technical limitation. That's why, a minimally invasive diagnostic test that can accurately diagnose the onset of the disease is the subject of research.
Our objective
We aimed to explore the concentration levels of *ACTB* in PTC patients, healthy controls (HC) plasma samples and to compare with clinicopathological factors.
Methods
Studyincluded 154 patients treated at Hospital of Lithuanian University of Health Sciences, Kaunas clinics 2020 - 2021: 68 patients with a histologically confirmed diagnosis of PTC and 86 HC. The concentration of *ACTB* was measured by qPCR in plasma samples. Statistical analyses were performed using SPSS 22.0 software (SPSS Inc., Chicago, IL, USA). The results were considered statistically significant at $P < 0.05$.
Results
Average age at diagnosis was 48.19 $\pm$ 14.9 years in PTC group and 45.30 $\pm$ 12.07 years in HC ($P > 0.05$). In the PTC group, there were 8 male patients (11.8%) and 60 female patients (88.2%), while in the HC: 65 (75.6%) female and 21 (24.4 %) male patients ($P > 0.05$). The concentration of *ACTB* was significantly higher in the PTC patients compared to HC (1005.97 vs 623.12 ng/ml, $P = 0.047$). We observed that *ACTB* concentration were significantly higher in PTC with greater tumor size (> 2 cm) compared to lower (≤ 2 cm) tumor size ($P = 0.005$). The total tumor size was calculated as the sum of the diameters of all tumors in PTC multifocal cases. A weak positive correlation between the concentration of *ACTB* with the total size of PTC tumors was found ($P = 0.012$, $r = 0.304$). However, there was no correlation between lymphovascular invasion, lymph node metastasis and other clinicopathological features.
Conclusion
This analysis included comparison of the *ACTB* concentration associations between PTC patients, HC groups and clinicopathologic factors. We found that plasma concentration of *ACTB* was significantly higher in patients with greater tumor size. Our study indicated that *ACTB* concentration changes may be used as parameter in differentiating PTC patients from HC. But further studies are also warranted to expand upon our findings.

EP1090

Thyroid carcinoma and anti-synthetase syndrome: A rare association!

Asma Tekaya, Asma Kefi, Khaoula Ben Abdelghani, Mounira El Euch, Cyrine Sassi, Sami Turki & Ezzedine Abderrahim
Charles Nicolle Hospital, Department of Internal Medicine A, Tunis, Tunisia

Background
Anti-synthetase syndrome (ASS) is an idiopathic inflammatory myopathy (IIM). Clinical features may include myositis, interstitial lung disease (ILD), non-erosive arthritis, Raynaud's phenomenon, and mechanic's hands with the presence of anti-synthetase antibodies. Although ASS-neoplasia association has been reported, it remains scarce and debated association. Herein, we report an original case of thyroid carcinoma in a patient followed for ASS.
Case report
A 40-year-old woman, consults for myalgia and weakness of the 4 limbs since 4 months. She presented with progressive proximal muscle deficit, elevated muscle enzymes, mechanics' hands, ILD and positive anti-JO1 antibodies, thus she was diagnosed with ASS. Treatment was based on corticosteroids and Cyclophosphamide with good evolution. Initial screening for neoplasia was negative. Six years later, during a routine check-up, examination found a centimetric thyroid nodule. Thyroid function test was normal. Cervical ultrasound showed a 7mm right lobar thyroid nodule classified as EU-TIRADS 5. Fine needle aspiration found cytological atypia of undetermined significance. Total thyroidectomy was performed. Pathological examination concluded that a non-encapsulated intrathyroid papillary carcinoma. In addition to the surgical treatment, the patient received radioactive iodine with good outcome. The current follow-up is 2 year.
Discussion
We report the occurrence of thyroid neoplasia in a patient diagnosed with IIM, after 6 years of follow-up. The originality of this case is due to of the type of the IIM and the delay in the onset of the cancer in relation to its diagnosis. Compared to other IIM, ASS' association to neoplasia is still debated: in the cohort of Pinal-Fernández, with 169 ASS patients, the frequency of cancer doesn't seem higher than that of the general population. The Chinese cohort of Shi, with 124 ASS patients, found that 6.5% developed neoplasms, with a mean time of 3 years between neoplasia and SAS, of which, the majority presented with ILD. In the review carried out by Boleto, male gender, age over 60 years, and the presence of anti-SSA/Ro were predictive factors of development of cancer in ASS patients.
Conclusion
Thyroid carcinoma was discovered in our observation during regular screening for ASS-associated neoplasia. Thyroid carcinoma-ASS is an extremely rare but possible association, which will need to be detected and treated. Given the rarity of ASS, recommendations regarding the systematic screening for cancer have yet been established. In the meantime, we must remain vigilant about the possibility of the occurrence of cancer in these patients, and therefore ensure regular screening.

EP1091

Diarrhea as the only symptoms in hyperthyroidism- case report

Rajmonda Tare
Endocrinology, Internal Department, Regional Hospital 'Xhaferr Kongoli', Albania

Introduction
Hyperthyroidism (overactive thyroid) is a condition where thyroid makes and releases high levels of thyroid hormone (thyroxine) in the blood. This condition can speed up our body metabolism. Hyperthyroidism causes an overactivity of the sympathetic system. It also this sympathetic hyperstimulation in the gut leads to increased motility causing diarrhea, malabsorbation and consequently weight loss.
Objective
To describe a patient with hyperfunxional nodular goiter and diarrhea as the only symptoms, for which Unimazole (ATS), was found to be effective therapy for the diarrhea.
Methods
We present the clinical course of a old woman with a prolonged diarrhea which with all diagnostic procedures and medication given did not improve until it was thought to be an endocrine cause. Unimazole control of such cases of hyperthyroidism with diarrhea can be explained by the effect of this drug in reducing intestinal hypermotility as the basis of physiopathology in hyperthyroidism.

Results
A 73-year-old woman, has not previously had gastrointestinal disorders, had prolonged diarrhea, which associated with loss of 3 kg during a 1-month period. Laboratory, ultrasound images, recommended by the infectious disease doctor could not detect the cause of this prolonged diarrhea. Despite antibiotic treatment and antidiarrheal treatment, diarrhea did not stop. Other hyperthyroidism symptoms were not reported, but when hyperthyroidism was identified, the diarrhea was dominated and very well controlled by treatment with unimazole.
Conclusion
Thyroid hormone in excess, among its other possible effects in the organism, affect the gastrointestinal tract through sympathetic intestinal hyperstimulation and increased motility causing diarrhea. Antithyroid therapy act by blocking sympathetic hyperstimulation. Our case leads us to think that hyperthyroidism should be considered in the differential diagnosis of diarrhea of unknown cause.
Keywords diarrhea, unimazole, hyperthyroidism.

Case Report of Hypothyroidism as a Cause of Ataxia
Farah Elgharroudi, Ismail Zahra, Nawal EL Ansari & Ghizlane EL Mghari
Chu Mohammed VI, Endocrinology, Marrakech, Morocco

We present a case of a 56-year-old male who reported to us with history of instability of gait since one year which was acute in onset and progressive, there was also history of hearing impairment and constipation since 3 years without improvement despite several symptomatic treatments. There was no history of weakness in any part of body, headache, vomiting, convulsions or alteration of sensorium. There was no history of trauma to the head, fever or drug intake. On examination, his vitals were normal. Cognitive functions were normal. Neurological examination showed gait ataxia, dysarthria and dysmetria on finger-nose and heel-to-knee tests. The gait was wide-based and there was a tendency to fall to right side. His fundus was normal. His power was normal but had hung up reflexes. Sensory system was normal. His hemogram was normal. Serum electrolytes, blood sugar, renal and liver function tests were normal. Total cholesterol: 191 mg/dl, triglycerides: 345 mg/dl, HDL cholesterol: 45 mg/dl, LDL cholesterol: 77 mg/dl. viral serologies were negative. T3:0,1 (0,3-5 pmol/dl) T4: 1.5 pmol/dl (12-22), TSH: $>$100 uIU/ml (0.27-5.5). The Serum anti-TPO antibody was not available. Cervical ultrasound showed an appearance related to thyroiditis: Reduced thyroid with heterogeneous echo structure size, alternating hypo and hyperechogenic range producing a tabby aspect of the gland and hypervascularization on Doppler. MRI brain was normal (Figures 1 and 2). Electrocardiogram and trans-thoracic ultrasound were normal with left ventricular ejection fraction below 50%.

Successful treatment of Graves' disease with high dose iodine-131, without subsequent hypothyroidism: a case report
Anna Brodovskaia
Ivanovo State Medical Academy, Department of Internal Medicine, Ivanovo, Russian Federation

Background
Radioiodine is an effective treatment for Graves' hyperthyroidism. In most cases this therapy renders the patient completely hypothyroid. As a consequence they will require lifelong thyroid replacement therapy. Now it is controversial whether radioiodine should be given in a sufficient dose to induce hypothyroidism or a lower dose in an attempt to achieve a euthyroid state.
Case Report
A 71-year-old woman with a 30 years history of Graves' disease and frequent recurrences of thyrotoxicosis presented with tremulousness, palpitations, dyspnea, progressive fatigue and weight loss. Examination revealed BMI 28 kg/m^2, Ps 105 bpm, BP 150/80 mmHg. An ECG showed sinus tachycardia. Laboratory analyses showed recurrence of hyperthyroidism: TSH 0,19 mUI/l (N 0,27-4,2), FT4 1,86 ng/dl (N 0,93-1.52), positive TSH receptor antibodies (5,62 IU/l). The thyroid ultrasonography showed diffusely enlarged thyroid (total volume 54 ml). Thyroid scintigraphy showed increased 24-hour radioiodine uptake (90%) with diffuse activity on the scan image. She was treated with methimazole (30 mg/day) and anaprilin (40 mg/daily) and the patient's condition improved. According to medical history she had poor control of the disease by drugs. Surgery was risky for the elderly patient. Therefore radioactive iodine ablation was suggested. Iodine-131 was administered orally at individual dosage of 13 millicuries (based on 200 microCi/g of thyroid tissue). Previous to therapy thyroid laboratory results showed TSH 1,75 mUI/l, FT4 0,68 ng/dl. Methimazole was canceled 3 days before the procedure. The introduction of I-131 was well tolerated. Patient had normalization of thyroid function tests within 4 weeks. Hypothyroidism occured 12 weeks after radioiodine (TSH 46,4 mUI/l, FT4 0,23 ng/dl). Then thyroid replacement therapy (75 mg of levothyroxine) was initiated. However, within the 6 month after treatment the patient presented subclinical hyperthyroidism and the dose of levothyroxine was reduced and then canceled. Ultrasound showed residual thyroid tissue (total volume 18 ml). The patient is currently euthyroid (TSH 0,58 mUI/l) and under follow-up.
Conclusion
For patients with Graves' disease, a high dose of radioiodine is directly related to the cure rate and the incidence of hypothyroidism. The most preferred is to individualize the radioiodine dose based upon the size of the thyroid gland and the 24-hour radioiodine uptake. In this case, a persistent goiter suggests incomplete destruction of the gland and the possibility of persistent autonomous thyroid tissue. After radioiodine, all patients require monitoring for hypothyroidism or persistent hyperthyroidism.

Papillary carcinoma of the thyroid and cervical teratoma: incidental association?
Imane Alilouch, Farah Kamel, Zineb Mhamdi, Kaoutar Rifai, Hinde Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology and Diabetology, Rabat, Morocco

Introduction
Teratomas are complex malformative tumors defined by the presence of tissues derived from the 3 embryonic layers. They can be mature or immature, depending on their degree of differentiation. They are most often found in the sacrococcygeal region and the gonads. Cervical location is exceptional (4%).
Observation
We report the case of a 45-year-old patient who presented with a right cervical swelling that progressively increased in volume. The patient consulted the ORL department and a cervical ultrasound scan was performed, which revealed an ETIRADS 4 nodule, a cytopuncture was done and came back in favor of signs of malignancy, the patient underwent a total thyroidectomy with left recurrent curage, the anathamopathological study showed a papillary tumor of the thyroid classified as pT3a with the presence of 5 reactionary lymph nodes associated with a cystic formation evoking a mature terartoma.
Discussion and conclusion
Cervical teratomas are rare lesions usually diagnosed at birth. Their occurrence in adults is extremely rare and, less than 40 cases have been reported in the literature**.** The association of cervical teratoma and papillary thyroid carcinoma has not been described**,** Is it a genetic link or a simple coincidence or do we need more studies to confirm a link between the two associations?

Retroplacental hematoma : a dreaded complication of hypothyroidism : An observational study
Widad Douali[1], Mennani Fatimaeezzahra[1], Rafi Sana[1], El Mghari Tabib Ghizlane[1] & El Ansari Nawal[1]
[1]Chu Mohamed VI Marrakech, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Hypothyroidism is the most common endocrine dysfunction during pregnancy. In pregnancy, hypothyroidism is most often due to chronic autoimmune thyroiditis (Hashimoto's disease) The consequences of hypothyroidism vary depending on the time of onset of hypothyroidism during pregnancy and the etiology

retroplacental hematoma is a serious complication of hypothyroidism We report the case of a patient with in utero fetal death on retroplacental hematoma complicated by hypothyroidism
Observation
questioning
The patient is 35 years old. History: followed for hypothyroidism on levothyrox 150 mg/d Admitted for heavy metrorrhagia with obstetrical ultrasound has objectified: fetal death in utero with evidence of a retroplacental hematoma **On clinical examination**
Patient Conscious, pale and discolored conjunctivae Blood pressure = 130/80 mmhg; heart rate = 69bpm; Non-palpable thyroid The rest of the exam was unremarkable. On the balance sheet: Blood count: hemoglobin = 6.9; White blood cells = 9110; platelets = 300000 TSH = 77 mui/l; Cervical ultrasound: atrophic thyroid glan
d Therapeutic care
The patient was put on levothyrox: 175 mg/d A cardiovascular evaluation has been requested
Discussion
-Retroplacental hematoma is a polycausal disease with etiological factors (vascular, age, environmental) -Publications suggest that dysthyroidism and more particularly hypothyroidism may be a risk factor for Retroplacental hematoma According to a study published in 2013; RPH in hypothyroidism can be explained by several factors: thyroid hormones play a very important role in Placentation: 11-16 amenorhea week (defined as Invasion of trophoblasts into the maternal decidua and the spiral artery) In Hypothyroidism: insufficient trophoblastic invasion responsible for ischemia and placental abruption hypothyroidism is associated with thrombo-embolic and hemorrhagic phenomena which is explained by the alteration of the coagulation system – fibrinolysis the presence of anti tpo ac is more likely associated with other immune diseases and alteration of the immune system another study published in 2020 did not find a significant link between hypothyroidism and RPH
Conclusion
This observation underlines the importance of determining the place of this risk factor within the various FDRs of RPH already known and the need to set up preventive strategies, in particular when the usually effective treatment of hypothyroidism is lacking.

Cholestatic Hepatitis in Graves' Disease: A case report
Meriem Adel, Sabrine Mekni, Maysam JRIDI, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Thyrotoxicosis is an uncommon cause of cholestasis. It's a diagnostic challenge considering the broad differential diagnosis. Herein we report a case of Grave's disease revealed by severe cholestatic jaundice.
Observation
A 46 old male with a history of Sickle cell disease complained of diarrhea and significant weight loss for eight months, followed the last month by palpitations, heat intolerance, anxiety, insomnia and progressive jaundice. He had no family history of autoimmune disease. He denied hepatotoxic drugs, alcohol use or high-risk sexual behavior. On physical examination his body mass was 21.23 kg/m^2, his blood pressure was 110/50 mm Hg and his heart rate was 93 beats per minute. He had jaundice of sclerae and skin with mild hepatomegaly. His thyroid was symmetrically enlarged. Biochemical findings showed: total bilirubin 183.6 µmol/l (3.4–20), direct bilirubin 135 µmol/l (< 8.6), alkaline phosphatase 143 U/l (40–129), AST 69 U/l (1–38), ALT 23 U/l (1–41), TSH 0.005 µUI/l (0.27-4.2) and FT4 61.07 pmol/l (12-22). Hepatitis A, B, and C testing were negative and autoimmune screen was unremarkable except positive hyroid-stimulating hormone receptor antibodies. Abdominal ultrasound, computed tomography and MRI revealed hydatic cystis in the VI and VII segment without biliary ductual dilatation. Thyroid ultrasound showed a symmetrically diffuse enlarged, hyper vascular, heterogeneous gland without nodules. Regarding the severity of the thyrotoxicosis, methimazol, propranolol and corticoids were administrated before radioiodine treatment with a close monitoring of liver function. By day 40 bilirubin fell by 50% (91.4).
Conclusion
This case highlights the merit of considering thyrotoxicosis as a cause of cholestasis as attaining a euthyroid state is critical for hepatic recovery.

EP1097

A rare localization of lymph node metastasis from papillary thyroid carcinoma
Mohamed Masmoudi, Wadii Thabet, Marwa Regaeig, Ezer Chebil, Mehdi Hasnaoui & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Otorhinolaryngology, Tunisia

Introduction
Lymph node (LN) metastases of papillary thyroid carcinoma (PTC) usually happen in the paratracheal and internal jugular chain and are unusual in the parapharyngeal space (PPS). Our aim is to emphasize on the possibility of parapharyngeal metastatic LNs in PTC and to describe the diagnosis methods, treatment options, and impact on the prognosis.
Case Report
A 62-year-old woman presented with a dysphagia lasting for 2 years. Examination revealed an anterior neck mass. On ultrasound, it was an EU-TIRADS 5 left thyroid nodule. Consequently, the patient underwent a total thyroidectomy with a bilateral central dissection and a left selective neck dissection (II-IV). Histopathologic examination of the thyroid gland confirmed the diagnosis of a PTC of the left lobe with metastasis on central and lateral LN dissections. The tumor was staged as pT2 N1b M0. Postoperatively, she had radioactive iodine ablation therapy. She received a cumulated dose of 200 mCi (2 courses). Ultrasound and thyroid scintigraphy were normal. However, because of a high thyroglobulin (TG) level, a CT scan was performed (3 months postoperatively) and showed a left 3–cm prestyloid mass. The mass was hypodense, with some irregular areas of enhancement: a parapharyngeal metastatic LN was suspected. The patient did not present any symptom related to the mass. On physical examination, there was no evidence of cervical lymphadenopathy, no palpable thyroid lesion, no cranial nerve deficits. The oropharyngeal exam was normal. A surgical resection of the mass was performed with external cervical approach: a mass measuring 3 × 2 cm was found in the left prestyloid space. On histopathologic examination, the mass was a metastatic LN of a PTC. Three months after the surgery, the patient was doing fine, with no evidence of disease.
Conclusion
PPS metastases from thyroid carcinoma are uncommon, and only few cases have been reported in the medical literature. These PPS LNs are not included during nodal dissection. If these areas are left undissected, they might be the cause of a persistent disease or a delayed recurrence. As a result, for patients with PTC, especially those who underwent neck dissection and have an unexplained increase in serum TG levels, CT or MRI should be done for surveillance rather than ultrasound to detect the presence of nodes in this compartment.

Malignant non-Hodgkin lymphoma of the thyroid Gland: About 4 cases
Rachida Bouattay, Emna Bergaoui, Maroua Naouar, Mehdi Ferjaoui, Heyfa Belhadjmiled, Amel Elkorbi, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT, Monastir, Tunisia

Introduction
Cervico-facial non hodgkin lymphomas are rare conditions; they represent 5% of all malignant tumors of the head and neck. Their localizations are essentially lymph nodes but all the organs can be affected.
Purpose of the presentation
The objective of this work is to determine the clinical, histological and therapeutic aspects of malignant non-Hodgkin lymphoma localized in the thyroid gland.
Methods
This is a retrospective study about 4 patients treated for a malignant non-Hodgkin lymphoma of the thyroid gland, in the ENT and hematology departments of Fattouma Bourguiba hospital in Monastir over a period of 20 years (2000-2019).
Results
The average age was 48 years. A female predominance was noted. The average consultation time was 6 months. Patients consulted for a rapidly progressive goitre in all cases, associated with dysphagia and dyspnea in 3 cases (75%). Cervical examination showed a painful, mobile and indurated anterior cervical swelling in all patients. Associated lymph nodes were found in only one case (25%). Cervical ultrasound and cervico-thoracic scan showed a mass pushing back the trachea in two cases (50%). Fine needle aspiration showed an aspect of a

large cell lymphoma of thyroid gland in 2 cases (50%). In the histological examination, it was a diffuse large B-cell lymphoma in the 4 cases. The extension assessment did not objectivize other synchronous locations. Three patients were classified at stage IA, one patient at stage IIA. The treatment consisted on chemotherapy in all patients with no tumor recurrence or relapse in all cases with an average follow-up of 24 months.
Conclusion
Malignant non-Hodgkin's lymphoma of the thyroid gland is a rare disease. The treatment often gives good results and the prognosis depends essentially on the tumor stage and the speed of treatment.

COVID-19 vaccine-associated subacute thyroiditis

Pei Chia Eng[1, 2], Lien Davidson[2], Rochan Agha-Jaffar[2], Jeremy Cox[2], Michael Yee[2], Maura Moriarty[2], Stephen Robinson[2], Tannaz Vakilgilani[2] & Vassiliki Bravis[2]
[1]Imperial College London, London, United Kingdom; [2]St Mary's Hospital, London, United Kingdom

Introduction
Subactue thyroiditis (SAT) is a self-limiting inflammatory condition caused by follicular destruction of the thyroid gland, commonly precipitated by viral upper respiratory tract infection 2 weeks preceding the onset of thyroid symptoms. However, SAT following COVID-19 vaccination is rare. Herein, we report two cases of subacute thyroiditis which presented after administration of COVID-19 vaccine.
Case series
The first patient was a 42 year old man who reported rapid onset of sore throat, neck pain and symptoms of thyrotoxicosis including weight loss, sweating and heat intolerance. The onset of symptoms was two weeks following his second dose of BNT162B2 mRNA (Pfizer-BioNTech) COVID-19 vaccine. There was no significant medical history and or prior use of medications that would precipitate thyrotoxicosis. He recovered well with a course of non-steroid anti-inflammatory agent. The second patient was a 31 year old lady, with no past medical history, who presented with neck pain and fever and symptoms of thyrotoxicosis three weeks after her third dose of BNT162B2 mRNA (Pfizer-BioNTech) COVID-19 vaccine despite having had two Sputik Covid V vaccine previously. She recovered well with a course of steroids. Both patients had negative TSH-receptor antibodies and thyroid peroxidase antibodies (0.20IU/ml, 0.39IU/ml). Imaging studies were consistent with thyroiditis with no obvious uptake noted on Technectium scan.
Discussion
SAT after vaccination, may develop as a result of direct injury by vaccine attributed by molecular mimicry. Due to the similarity between SARS-CoV2 spike protein and thyroid peroxidase, the cross reaction between the coronavirus spike protein with the TPO antibodies induce an autoimmune/inflammatory response to thyroid follicular cells. As with any form of SAT, treatment is symptomatic with non-steroidal agents and corticosteroids including levothyroxine if patient devloped hypothyroidism. In all these cases, association of SAT with the administered vaccines was suggested by temporal relationship between symptom onset and vaccination. Therefore, clinicians are encouraged to be vigilant of autoimmune diseases as possible complications of COVID-19 vaccination, even in patients with mild COVID-19 infections.
Conclusion
SAT can rarely occur following COVID-19 vaccination. Early identification of the possible endocrine side effects of the COVID-19 vaccine can help treat this condition. As SAT is a mild self-limiting illness, its possible association with prior vaccination should not deter people from vaccination.

Autoimmune thyroid disease and autoimmune hepatitis

Raida Ben Salah[1], Faten Haj Kacem Akid[2], Siddiqa Soomauroo[2], Cyrine Chehaider[2], Sarra Chouaib[2], Nabila Rekik[2], Faten Frikha[1], Mohamed Abid[2] & Zouheir Bahloul[1]
[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Autoimmune hepatitis (AIH) is a generally progressive and chronic liver disease that can occur both in children and adults. Although the cause of AIH is unknown, aberrant auto-reactivity is thought to have a role in its pathogenesis. The diagnosis is based on clinical presentation, biological and histological findings. Like other autoimmune diseases (AD), AIH can be associated with one or more AD either organ-specific or non-organ specific AD.
Materials and methods
It is a descriptive retrospective single institution study. We collected data from 113 patients diagnosed with autoimmune thyroid disease (AITD) associated with another AD over 18 years. This present study reports the association between AITD and AIH.
Results
We registered one case of AIH associated with an AITD. The infertility work-up of the patient revealed hypothyroidism: Hashimoto's thyroiditis (HT) discovered at the age of 43. Both thyroid peroxidase antibody and thyroglobulin antibody were positive. She was treated by L-thyroxin with a favorable course of progress. At the age of 48 years, the patient presented with a chronic hepatitic cytolysis and the investigations led to the diagnosis of AIH. Antibody testing showed positivity for the smooth muscle antibodies (SMA) and histological findings from the liver biopsy were compatible with AIH. The patient was treated with glucocorticoid therapy and immunosuppressant drugs such as azathioprine.
Discussion and Conclusion
AIH is a heterogeneous group of chronic liver disease characterized by particular lesions on liver histopathology, elevated serum immunoglobulin, liver autoantibodies: SMA, soluble liver antigen autoantibody, Liver Kidney Microsome autoantibody, elevated serum transaminases and negative serology for viral hepatitis. AIH may affect adults of both sexes but affect mainly young women. Different studies estimated the frequency of the association: AIH and AITD around 10%. In our study, it was found to be around 1% which could be explained by the relatively small pool of patients. In 75% of cases, the AITD was HT. The cross reactions between the thyroid auto-antibodies and the presence of auto-reactive T cells or similar epithelial antigens found in the liver and the thyroid could explain the basis of the physiopathological mechanism behind this frequent association. We need to distinguish AIH from other forms of autoimmune liver diseases as it generally responds to anti-inflammatory and/or immunosuppressive treatment. Appropriate management can prolong survival and subsequently improve quality of life.

Thionamides induced hypoglycemia

Nirit Aviran Barak
Maccabi Health Services, Endocrinology, Netanya, Israel

A 22-year-old female Ashkenazy Jewish previously healthy complaint on weakness In glucometer, her sugar level was 50 mg% and she felt better after ingestion of a small amount of sugar. 3 weeks ago while traveling in Peru, she developed thyrotoxicosis and was started mercaptizol 30 mg a day and deralin. She didn't drink iodine (iodinated preparations for water purification) while traveling and had no pain or fever. In physical examination there where no goiter or exophthalmos While I saw her she was already euthyroid and felt quite good except for tiredness. In literature, we found few case reports of mercaptizol and PTU-induced insulin autoantibodies which cause symptomatic hypoglycaemia. Most cases were described in the Asian population (especially Japanese people) and resolved a few weeks after stopping the drug. In our patient, the hypoglycemia resolved after only one episode and discontinuation of mertcaptizole. We don't have antibodies titer yet. insulin levels (C -peptide) were relatively high My conclusion is that physicians should be aware of Mercaptizol and PTU induced hypoglycemia which can be life-threatening

Differential diagnosis between overt and transient hyperthyroidism in triplet pregnancy

Nino Abesadze
TSU, PhD Candidate, Tbilisi, Georgia

Introduction
Thyroid health in pregnancy is highly important. Best way to evaluate thyroid in pregnancy, is thyroid function assessment via blood tests. But we always have to focus also on clinical manifestations, thyroid ultrasound and other factors, that may influence test results. As we know high HCG can suppress TSH and twin pregnancy may induce subclinical hyperthyroidism. There are many reports of twin pregnancies, but very few about triplet pregnancy. Therefore we decided to report this rare case.
Case report:
34 y/o women presented with triplet pregnancy on 12 weeks of gestation. Routine thyroid tests showed laboratory picture of overt hyperthyroidism: TSH- <0.005 (0.3-2.5); FT3-3.98 (2-4.4); FT4- 1.89 (0.93-1.7). On clinical evaluation she had no signs of GO. HR-98, BP-120/80, BMI-18.6. Patient had hyperemesis gravidatum. She lost 6 kg during pregnancy. In previous 2 pregnancies she had normal thyroid functions. Positive family history of AIT. We ordered Anti-TSHR- N, thyroid ultrasound- N. Considering additional tests and mild clinical symptoms, we choose watchful waiting, to distinguish between overt thyrotoxicosis and transient hyperthyroidism of early pregnancy. After 3 weeks laboratory tests came already normal. TSH-0.22; FT4-0.93. We ordered TSH every month thereafter and it stayed in normal trimester-specific range on every occasion. Patient gave birth on 39 weeks of gestation with 3 healthy babies.
Conclusion
Because of potential harm and evidence of fetal risks, we have to be very careful with initiating of Anti-thyroid medications and avoid overusing them, if we don't have clear diagnosis. As we see in 2-3 weeks thyroid functions may improve by themselves. Also many criteria can help clinicians to distinguish very carefully between real thyrotoxicosis and transient state. Multiple pregnancy is one sign, we must take into account.

Clinical profile and body composition of patients newly diagnosed with hypothyroidism

Olfa Lajili, Zouaoui Chadia, Bchir Najla, Yosra Abderrahim, Annam Benchhida & Haroun Ouertani
The Military Hospital of Tunis, Endocrinology and Nutrition Department, Tunis, Tunisia

Introduction
Patients with hypothyroidism usually gain weight, and those with hyperthyroidism lose weight. Body weight changes related with thyroid dysfunction support the idea that thyroid hormones have an effect on body weight and body composition. The aim of our study was to describe the clinical profile and body composition of Tunisian patients who were newly diagnosed with hypothyroidism.
Methods
This was a cross-sectional and descriptive study includes 25 patients: 14 who were newly diagnosed with overt hypothyroidism (Group1: G1) and 11 who were newly diagnosed with subclinical hypothyroidism (Group 2: G2). The study was conducted in the Endocrinology and Nutrition Department of the Military Hospital of Tunis during a period of 4 months (March-June 2021). Body composition was assessed by impedancemetry. Statistics were performed using SPSS 20.
Results
The mean age was 49 $\pm$ 14 years [20-80 years]. A female predominance was noted (75%). The median TSH level was 20 mUI/l [8-95 mUI/l]. Cervical ultrasound showed that 25% of patients had thyroid nodules. Anti-Thyroid Peroxydase antibodies were positive in 35% of patients. The mean Body Mass Index was 29 $\pm$ 5 kg/m^2. One third of the patients (35%) were obese. The median weight gain at time of diagnosis of the hypothyroidism was 0.6 kg [0,4-4,2 kg]; (G1: 1,5 kg vs G2: 0,5 kg; $P=0,6$). Mean percentages of fat mass (FM), lean mass (LM) and water mass (WM) in both groups were respectively (G1: 30 $\pm$9% vs G2: 35$\pm$8%; $P=0,26$), (G1: 70$\pm$9% vs G2: 65$\pm$8%; $P=0,26$) and (G1:51$\pm$7% vs G2:47$\pm$6%; $P=0,26$). The mean total cholesterol, LDL-cholesterol and triglyceride levels in both groups were respectively (G1:6$\pm$2 mmol/l vs G2: 5$\pm$1 mmol/l, $P=0,2$), (G1 3$\pm$2 mmol/l vs G2: 3 $\pm$0,7 mmol/l; $P=0,75$) and (G1: 1,7$\pm$0,7 mmol/l vs 1,7$\pm$1,1 mmol/l, $P=0,867$). Our study showed that increased TSH levels were associated with increased percentages of LM and WM (respectively $P=0,01$ and $P=0,01$) and decreased percentages of FM ($P=0,02$). However, there was no correlation between TSH level and weight gain at time of diagnosis of the hypothyroidism ($P=0,71$).
Conclusion
Our study showed that patients newly diagnosed with overt or subclinical hypothyroidism gained weight. The percentages of different body compartments were correlated with TSH level. However, there was not an association between gain weight and TSH level at time of diagnosis of the hypothyroidism.

Graves' disease: Particularities in the pediatric population

Dhoha Ben Salah, Kawthar El ARBI, Asma Zargni, Mouna Elleuch, Cyrine Chehaider, Mnif Fatma, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Graves' disease (GD) is the most common cause of hyperthyroidism in pediatric patients, up to 95% in some studies.
Observation
We report the observation of a 6-year-old female who consulted for a behavioral disorder made of agitation and lack of concentration. She had a family history of autoimmune thyroid disease. On examination, an accelerated statural growth rate of +2DS was noted. She had a significant palpebral retraction without exophthalmia. A biological check-up showed a blocked TSH level at 0.01µU/ml associated with a high T4 at 26.4 pmol/l. In addition, TSH receptor antibodies blokers (trab) were positive at 17.8 U/l for a normal value (NV) of less than 1.5. Anti-thyroperoxidase antibodies were positive at 148 U/l (NV $<$ 20U/l). The thyroid ultrasound was normal with a normal volume and homogeneous gland. The diagnosis of Graves' disease was retained and a treatment with methimazole was started at a dose of 0.5 mg/kg/d. The thyroid check-up 3 months later was normal. The treatment is in progress.
Conclusion
GD is a rare condition in children and affects mostly older children with a clear female predominance. Although rare, GD remains the most frequent cause of hyperthyroidism in children. Diagnosis is easier if exophthalmia is present, which is a very specific sign of this condition. However, palpebral disorder is the most common as exophthalmia is less frequent in children. Medical treatment is based on synthetic antithyroid drugs.

Hashimoto's thyroiditis associated with primary biliary cholangitis: a case report

Hind Ouakrim, Charlene Ludwine Bifoume Ndong, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
Chu med 6, Endocrinologue, Marrakech, Morocco

Introduction
The association of multi-organ autoimmune disorders is described. We report a case of Hashimoto's thyroiditis (HT) and primary biliary cholangitis (PBC), both are a chronic autoimmune inflammation, with lymphocytic infiltration and destruction of thyroid cells for (HT) and progressive destruction of intrahepatic bile ducts leading to cirrhosis for (PBC)
Case report
54-year-old female patient, followed for (PBC) at cirrhosis stage admitted for evacuation of refractory ascites. Interrogatory: signs of hypothyroidism: asthenia, constipation, chilliness and hair loss, Physical examination of the patient revealed bradycardia at 55bpm, palpable thyroid, end signs of hepatocellular insufficiency: subicterus and stellate angioma. Blood tests revealed a hypothyroidism (TSH: 26.6µUI/ml; T4: 5.2 pmol/l), end anti-Thyroperoxidase and anti-mitochondria type 2 antibodies are positive.
Discussion
PBC is frequently associated with other autoimmune diseases, the most common of which are Hashimoto's thyroiditis, Gougerot Sjögren's disease, celiac disease, and scleroderma, their screening must be systematic in order to initiate early and adequate treatment. As soon as an autoimmune disease is diagnosed, the search

for other organ damage is necessary in order to initiate treatment in the early stages, which improves the patient's overall prognosis.

Nephrotic lupus revealing a profound hypothyroidism

Severin N'Koua, Sana Rafi, Ghizlane EL Mghari & Nawal EL ANSARI
Department of Endocrinology, Diabetology and Metabolic Diseases, CHU Mohamed VI, Marrakech, Morocco

Abstract
Systemic lupus erythematosus is a serious autoimmune disease characterised by the production of antinuclear antibodies directed particularly against native DNA. Its presence increases the susceptibility to develop other autoimmune diseases including autoimmune dysthyroidism. We present the case of a patient who presented with profound hypothyroidism as part of the work-up for lupus nephropathy. Female patient, 40 years old, reports physical asthenia for 2 months. On clinical examination: normal BMI, discrete bilateral IMO, homogeneous goitre; erythematous lupus lesions on the face. Thyroid assessment: TSH elevated: 100 IU/l; T4l: 1.9 IU/l; T3l: 1, cervical echo: aspect of thyroiditis. Renal check-up: GFR: 20ml/24h; 24h proteinuria: 2.64g/24h; albumin: 30g/l; protein: 69g/l, Immunological check-up: anti TPO + and anti-nuclear and anti-DNA positive; renal biopsy in favour of a membrano-proliferative glomerulonephritis (GNMP). Cardiovascular work-up: normal ECG and TTE without any particularity with LVEF recommended at 65%, normal lipid profile. The patient had been put on levothyrox 25 µg/d with a progressive increase and a corticotherapie for her lupus nephropathy. Most of the studies presented in the literature show a high prevalence and incidence of new cases of hypothyroidism and autoimmune thyroiditis (AIT) in patients with systemic lupus erythematosus (SLE), globally in women. In the presence of lupus, it is advisable to look for thyroid disorders that need to be treated. In the absence of thyroid disorders, long-term monitoring for thyroid disorders is important as thyroid dysfunction has a high probability of occurring later not only because of the autoimmune terrain but also because of glomerulopathy which can be complicated by a nephrotic syndrome with leakage of thyroid hormones.

EP1107

Diarrhea as the only symptoms in hyperthyroidism-case report

Rajmonda Tare
Endocrinology, Internal Department, Regional Hospital 'Xhaferr Kongoli', Albania

Introduction
Hyperthyroidism (overactive thyroid) is a condition where thyroid makes and releases high levels of thyroid hormone (thyroxine) in the blood. This condition can speed up our body metabolism. Hyperthyroidism causes an overactivity of the sympathetic system. It also this sympathetic hyperstimulation in the gut leads to increased motility causing diarrhea, malabsorbation and consequently weight loss.
Objective
To describe a patient with hyperfunxional nodular goiter and diarrhea as the only symptoms, for which Unimazole (ATS), was found to be effective therapy for the diarrhea.
Methods
We present the clinical course of a old woman with a prolonged diarrhea which with all diagnostic procedures and medication given did not improve until it was thought to be an endocrine cause. Unimazole control of such cases of hyperthyroidism with diarrhea can be explained by the effect of this drug in reducing intestinal hypermotility as the basis of physiopathology in hyperthyroidism.
Results
A 73-year-old woman, has not previously had gastrointestinal disorders, had prolonged diarrhea, which associated with loss of 3 kg during a 1-month period. Laboratory, ultrasound images, recommended by the infectious disease doctor could not detect the cause of this prolonged diarrhea. Despite antibiotic treatment and antidiarrheal treatment, diarrhea did not stop. Other hyperthyroidism symptoms were not reported, but when hyperthyroidism was identified, the diarrhea was dominated and very well controlled by treatment with unimazole.
Conclusion
Thyroid hormone in excess, among its other possible effects in the organism, affect the gastrointestinal tract through sympathetic intestinal hyperstimulation and increased motility causing diarrhea. Antithyroid therapy act by blocking sympathetic hyperstimulation. Our case leads us to think that hyperthyroidism should be considered in the differential diagnosis of diarrhea of unknown cause.
Keywords diarrhea, unimazole, hyperthyroidism.

Autoimmune thyroiditis and anemic syndrome

Farida Saidova[1], Leyli Akhmedova[2], Jale Aslanova[1], Oruc Shahsuvarov[1] & Nizami Muradov[3]
[1]Scientific Center of Surgery after M.A.Topchubashov, Endocrine Surgery, Baku, Azerbaijan; [2]Azerbaijan State Advanced Training Institute for Doctors after A.Aliyev, Central Scientific Research Laborator, Baku, Azerbaijan; [3]Scientific Center of Surgery after M.A.Topchubashov, Anaestethiology and Reanimatology, Baku, Azerbaijan

The purpose was to identify the frequency of occurrence of various morphological types and different degrees of severity of anemia in patients with autoimmune thyroiditis (AIT).
Material and methods
Were analyzed 97 case histories of patients operated for AIT in 2012. When assessing hematological parameters, two groups were identified: group 1 – patients with AIT with mild anemia ($n=$ 72), age 45.7 $\pm$ 1.6, men - 5 (6.9%), women - 67 (93, 1%); group 2 - patients with AIT with moderate anemia ($n=$ 25), age 40.0 $\pm$ 2.3, men - 1 (4%), women - 24 (96%). In the clinical analysis of blood, hemoglobin, hematocrit, the number of erythrocytes and erythrocyte indexes of MCV, MCH, MCHC were determined.
Results
In patients with AIT with a mild degree of anemia, microcytic anemia was determined in 55 (76.4%), normocytic - in 17 (23.6%) patients. In moderate anemia, microcytic anemia was detected in 21 (84%) patients, normocytic anemia - in 4 (16%) patients. hypochromic type of anemia in the group 'all patients' was noted in 79 (81.4%), normochromic type in 17 (17.5%) and hyperchromic in 1 (1%) patient. By morphological type in patients with AIT with mild anemia, the hypochromic type was observed in 56 (77.8%) patients, normochromic - in 16 (22.2%) patients. In moderate anemia, this tendency was more pronounced: hypochromic type of anemia was detected in 23 (92%) patients, normochromic type - in 1 (4%) and hyperchromic in 1 (4%). Thus, in patients with AIT, mild anemia was more often determined (in 72.4%), then moderate anemia (in 25.7%). With moderate severity of anemia, microcytic (84%) and hypochromic (92%) types of anemia were more often observed. With mild anemia, the same types of anemias were observed, but with a lower frequency (76.4% and 77.8%, respectively).
Conclusion
The hemogram in patients with AIT was characterized by a more frequent development of mild anemia (72.4%). With mild anemia, hematological disorders were characterized by microcytic (76.4%) and hypochromic (77.8%) types of anemia. Similar, but more pronounced disorders were observed in moderate anemia: microcytic 84% and hypochromic 92%, which is characteristic for iron deficiency anemia.

Subacute thyroiditis associated with COVID-19

Yuriy Aleksandrov[1] & Vasiliy Semikov[2]
[1]Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation; [2]I.M. Sechenov First Moscow State Medical University, Surgery, Moscow, Russian Federation

COVID-19 is a serious problem of modern medicine. The disease has many manifestations, as it affects almost all organs and systems. One of the target organs of the endocrine system is the thyroid gland. The aim of the study was to identify the patterns of development and course of subacute thyroiditis in patients who underwent COVID-19. The study included 9 clinical cases. In all cases, these

were women aged 32 to 54 years. All patients were sick with COVID-19 (4 of them were treated at home, 5 - in a specialized hospital). In two patients, the first symptoms of the disease appeared even with a positive PCR test, in 2 patients, symptoms appeared 2 weeks after receiving an already negative PCR test, in 5 - in the interval of 1.5 - 2 months after receiving a negative PCR test. All patients have subfebrility, deterioration of general well-being, sharp weakness. 5 patients complained of an unexpressed headache with irradiation in the neck. This was regarded by all patients as a consequence of the ongoing or recent COVID-19. 4 patients noted discomfort with head movements and swallowing. The examination revealed moderate leukocytosis ($11,9 \pm 4.7 \times 10^9$/l), elevated ESR (36 ± 11 mm/h). There were no other symptoms indicating the nature of the disease, except for soreness during palpation in the projection of the thyroid gland in all patients. In this regard, all of them underwent ultrasound of the neck organs, in which heterogeneous hypoechoic darkening was detected, occupying from 14 to 85% of the volume of the thyroid gland, an increase in the lymph nodes of the neck was detected in 6 patients. From the moment of the first symptoms to the diagnosis and the start of treatment, it took from 2 to 4 weeks. At that time, 4 patients were treated for COVID-19, and 5 were undergoing rehabilitation treatment. The difficulty of making a correct diagnosis was due to asthenization and nonspecific symptoms of viral infection, as well as the fact that the development of subacute thyroiditis was preceded by the use of antiviral and antibacterial drugs, as well as glucocorticoids. Sonography was the key diagnostic method for all patients.

A case of graves' orbitopathy in a patient sero-negative for TSH receptor autoantibody

Chayma Besrour, Rojbi Imen, Mekni Sabrine, Meriem Adel, Mchirgui Nadia, Ben Nacef Ibtissem & Khiari Karima
Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia

Introduction
The orbit represents the second target after the thyroid gland in autoimmune dysthyroidism. In 80% of cases, endocrine orbitopathy occurs as a result of hyperthyroidism, especially Grave's disease (GD). Males are rarely affected but the damage is more serious.
Observation
We report the case of a 52-year-old patient, an active smoker (35 Pack-Year), transferred from the neurology department for treatment of bilateral malignant exophthalmos with subclinical hyperthyroidism. The examination showed a palpable normal sized thyroid with no vascularity. Orbital MRI showed bilateral grade 2 proptosis with oculomotor muscle hypertrophy consistent with Grave's orbitopathy (GO). The biology showed a subclinical hyperthyroidism, but the assay of the anti-TSH receptor antibodies came back negative twice. A thyroid scintigraphy was performed and it confirmed the Grave's disease. The patient was treated with corticosteroid therapy for his GO and showed a slight improvement. As for his subclinical hyperthyroidism, he was put on a low dose of an anti-thyroid drug, and developed euthyroidism.
Discussion
GO concerns 50% of patients with GD, among them only 3-5% develop severe forms. The responsible pathophysiological mechanism is linked to the presence of TRAKs. But these antibodies are only present in 95% of cases; suggesting are there other mechanisms to this GO?

Graves' disease refractory to a cumulative dose of 72 mci of iodine 131

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco

Introduction
Graves' disease is the most common cause of hyperthyroidism. There are three main therapeutic weapons: synthetic antithyroid drugs, surgery and radioactive iodine. The latter represents an effective treatment without noticeable side effects. We report a case of Graves' disease refractory to iratherapy.
Observation
This is a 38-year-old patient, with no notable history, who consulted for Graves' disease diagnosed with clinical signs of thyrotoxicosis and a biological profile of primary hyperthyroidism (TSH = 0.00 mUi/ml; T3 = 4.23 pg/ml; T4 = 22.13 pg/ml) with positive TRAKs. The morphological assessment objectified a goiter hyper fixing to the thyroid scintigraphy. Iodine-131 treatment is given at an initial dose of 25 mci. The course is marked by a persistence of a suppressed TSH (0.05 mIU/ml) after 6 months leading to the administration of an additional dose of 25 mci. Laboratory evaluation after 6 months objected to hyperthyroidism with TSH low at 0.08 mIU/ml. The patient received an additional 25 mci dose with the onset of hypothyroidism for which the patient was put on hormone replacement therapy with LT4 with good clinical and biological progress.
Discussion and conclusion
Graves' disease is a frequent endocrinopathy with potentially serious complications which can sometimes pose a difficulty in choosing a treatment. Iodine-131 iratherapy is a low-cost, simple treatment that is currently considered the treatment of choice for Graves' disease. However, the course can sometimes be marred by an absence of response to the radioactive treatment requiring a repeat of the doses in order to obtain a clinical and biological resolution as is the case for our patient.

EP1112

Thyroid tuberculosis: a case report

Kadiri Chaimae & lachkar hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco

Introduction
Thyroid tuberculosis is a rare localization that can pose problems of differential diagnosis with thyroid nodules. Its rarity is explained by the good oxygenation of the thyroid parenchyma and the bacteriostatic role of thyroid hormones. The definitive diagnosis is based on the pathological examination of the surgical specimen or after cytopathology or bacteriological examination of the transparietal puncture in complicated cases of collection.
Observation
This is a 30-year-old patient with no notable history who presents with multiherenodular goiter with the presence of satellite lymphadenopathy confirmed by cervical ultrasound without associated general signs. The thyroid workup is normal. A total thyroidectomy is performed with simple operative consequences. Pathological examination revealed a hyperplastic thyroid parenchyma with the presence of epitheliogigantocellular granulomas with local caseous necrosis. Anti-tuberculosis treatment is started for six months as well as LT4 supplementation with a favorable clinical course and normal TSH.
Discussion and conclusion
Thyroid tuberculosis remains a rare condition. It poses a diagnostic problem and sometimes induces inappropriate treatment. Fine-needle aspiration makes it possible to make the diagnosis by looking for an epithelio-gigantocellular granuloma with caseous necrosis and/or a Koch's bacillus and to initiate the anti-tuberculosis treatment which consists of multiple antibiotic therapy. Excisions are exceptional except in cases of diagnostic doubt as is the case for our patient. The prognosis is very favorable.

Coexistence of two different thyroid malignancies: an exceptional phenomenon

Mehdi Ferjaoui, Emna BERGAOUI, Maroua Naouar, Rachida Bouattay, Amel Elkorbi, Naourez Kolsi, Kaled Harrathi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT, Monastir, Tunisia

Introduction
Simultaneous papillary thyroid carcinoma (PTC) and follicular thyroid carcinoma (FTC) of the same thyroid lobe is a very rare pathology.
Purpose of the presentation
The objective of this work is to determine the clinical, histological and therapeutic aspects of an association of papillary thyroid carcinoma (PTC) and follicular thyroid carcinoma (FTC) on the same thyroid lobe.
Methods
We report 2 cases of PTC and FTC on the same thyroid lobe, treated in the ENT department of Fattouma Bourguiba hospital in Monastir over a period of 21 years (2000-2020).

Case1
A 22-year-old woman was referred to our department due to nodules in the right thyroid lobe detected on ultrasonography during a routine health check-up. the thyroid function tests were normal. Ultra sound showed multiples nodules in the right lobe, the biggest one was 20mm and classified as EUTIRADS IV. The patient underwent a right lobo-isthmectomy with an extemporaneous examination that suggest the benignity. Postoperative pathology revealed that the nodule with a size of about 18 mm in the right lobe was a follicular thyroid carcinoma with angio-invasionassociated with another nodule in the same lobe that was a micro papillary carcinoma (6mm) developed on a lymphocytic thyroiditis. The patient underwent a totalisation with central ipsilateral lymph-node dissection 1month later. She was initiated with thyroid hormone replacement therapy and a radioactive iodine treatment. The evolution was judged good, no recurrence or metastasis, with a follow-up of 20 months.
Case2
A 54-year-old women was evaluated at our hospital for a quick installation of a paraplegia. X-ray-imaging revealed a spinal compression. Vertebral biopsy was suggestive of a bone metastasis of a follicular thyroid carcinoma. Cervical ultrasonography showed a 29mm nodule in the right lobe that was suspected of malignancy. The patient underwent a total thyroidectomy with bilateral central lymph node dissection. There were no postoperative complications. Final histological examination revealed the coexistence of a large invasive follicular carcinoma associated with a micro papillary carcinoma in the right lobe of the thyroid. She was initiated on suppressive doses of thyroid hormone replacement therapy, a radioactive iodine treatment and vertebral radiotherapy. During its monitoring, the patient developed skull, femoral and spinal dorsal metastases with the indication of external radiotherapy.
Conclusion
Pathologists and surgeons should be aware of the possibility of the simultaneous presence of PTC and FTC tumours to avoid possible misdiagnoses.

Differentiated thyroid carcinoma in Basedow disease : a series of five cases

Kamel Farah, Khaoula Gorgi, Kaoutar Rifai, Hinde Iraqi & Mohamed Hassan El Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
The occurrence of thyroid cancer in Basedow disease is rare. We report a series of five cases of patients with Basedow disease who were operated on and whose pathological examination showed an association with differentiated thyroid cancer.
Clinical cases
We report a series of five patients with a mean age of 39 years. The diagnosis of Basedow disease was made on the basis of clinical, biological and scintigraphic evidence. Cervical ultrasound showed a benign multiheteronodular goitre in four patients, while thyroiditis with a nodule classified as EU-TIRADS V was present in one patient. All patients underwent total thyroidectomy after medical preparation with synthetic antithyroid drugs. However, one patient underwent central lymph node dissection. Histology was consistent with papillary thyroid carcinoma in four patients and vesicular carcinoma in one patient. Four patients classified as low-risk received 100 mci isotope totalization and TSH- suppressive Levothyroxine therapy, while one patient classified as very low-risk received TSH- suppressive Levothyroxine therapy alone. All clinical cases were in remission.
Discussion
The association of thyroid carcinoma with Basedow disease, once considered antinomian, is now a proven but rare occurrence. The incidence of differentiated thyroid carcinoma in Basedow disease is usually between 2 and 10%. Papillary carcinoma is the most frequently found. Nodularity should suggest Basedow disease -associated carcinomas. The pathogenesis of this association remains poorly understood. Studies have shown that anti-TSH receptor antibodies can stimulate adenyl cyclase activity and induce the formation and growth of thyroid cancer. In addition, the influence of synthetic antithyroid drugs can normalise the level of TSH that is inhibited in hyperthyroidism, with the risk of growth of a previously occult tumour. The most frequent situation is juxtaposed hyperthyroidism, resulting from healthy thyroid tissue adjacent to the cancer. These observations underline the importance of a careful search for malignancy in nodules associated with Basedow disease.
Conclusion
The diagnosis of Basedow disease does not eliminate the possibility of associated thyroid cancer. Thus, the appearance of a nodule within the goitre should raise suspicion of malignancy and indicate radical surgical treatment. Our results suggest a good prognosis for differentiated carcinomas on Basedow disease with isotopic totalisation.

EP1115

Coexistence of chronic lymphocytic thyroiditis with papillary thyroid carcinoma: about 13 cases

Rachida Bouattay, Maroua Naouar, Emna BERGAOUI, Heyfa Belhadjmiled, Mehdi Ferjaoui, Elkorbi Amel, Harrathi Khaled, Kolsi Naourez & Jamel Koubaa
Fattouma Bourguiba University Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
The association between chronic lymphocytic thyroiditis (CLT) and papillary thyroid carcinoma (PTC) has been investigated for several years from different perspectives. In spite of that, there were only few attempts to design a common frame of references to understand the complex mutual interactions between the various pathways of inflammatory response and of thyroid tumor induction and progression. The aim of this study is to investigate the clinical characteristics and outcome of the association between chronic lymphocytic thyroiditis and papillary thyroid carcinoma.
Materials and Methods
Our study was retrospective, realized on 13 cases of simultaneous chronic lymphocytic thyroiditis and papillary thyroid carcinoma collected in ENT department of Fattouma Bourguiba Hospital of Monastir a 20-year period (2000-2020).
Results
Among the 13 patients, there were 2 men and 11 women. Mean age was 41 years [20-56]. 4 patients were under hormone replacement therapy for hypothyroidism. Patients presented to our consultation for management of anterior neck swelling in 10 cases, associated to compression symptoms in one case. We noted 2 cases of an incidental finding of thyroid nodule during an ultrasound (US) examination of neck. Thyroid nodules were highly suspicious for malignancy on US in 4 cases. The mean size of nodule was 4 cm. We noted the presence of antithyroidal antibodies in 2 cases. All of patients underwent a total thyroidectomy, associated to bilateral central neck lymph node dissection in 10 cases. Histologic examination confirmed the diagnosis of papillary carcinoma in all cases. Surgical treatment was followed by radioactive iodine therapy except in one case which was a papillary microcarcinoma measuring 4 mm. In all cases, Thyroglobulin level was undetectable after withdrawal of T4 treatment with an average follow-up of 3 years.
Conclusion
The association between chronic lymphocytic thyroiditis and papillary thyroid carcinoma is not a rare entity. Patients with CLT were younger and predominantly female. The presence of CLT in patients with PTC has been associated with better prognostic outcome, lower recurrence rate and less aggressive disease, which are the most important and well-known prognostic variables for thyroid cancer mortality.

EP1116

Distant metastases from thyroid cancers: About 4 cases

Marwa Ben Njima, El Omri Malika, Mouna Bellakhdhar, Jihen Haouas, Ghammmam Monia, Meherzi Abir, Nihed Abdessayed, Kermani Wassim & Abdelkefi Mohamed
Hospital Farhat Hached, Sousse, Tunisia

Introduction
Metastases of thyroid tumors are rare. Metastatic sites are in order of frequency : pulmonary, bone and brain. Facial bones metastases are exceptional. These metastases are more frequent in vesicular than papillary carcinoma histological.

The aim of our work is to describe the clinical and radiological aspects as well as the therapeutic modalities.
Observation 1 and 2
A 38-year-old woman and 13-year-old boy consulted for a chronic cough with thyroid nodules on examination. The chest X-ray showed a micronodular miliary. The diagnosis of distant metastases was confirmed on an adenectomy specimen for the boy and on a lung biopsy for the woman. A total thyroidectomy with bilateral central and functional lymph node dissection was underwent and radio-iodine ablation for both cases.
Observation 3
A 55-year-old woman consulted for low back pain with neurological deficit due to lumbosacralosteolysis. A bone biopsy showed a metastases of a vesicular carcinoma of the thyroid. Further imaging showed 2 left nodules. The patient underwent decompressive radiotherapy followed by a total thyroidectomy and bilateral central lymph node dissection.
Observation 4
A 43 year old woman consulted for chronic nasal obstruction and decreased visual acuity. Clinical examination showed a median basicervical swelling that measured 9 cm and a tumoral mass filling the right nasal cavity that bleeded on contact. The ophthalmological examination showed the presence of a compressive optic neuropathy. Imaging showed a large tissue mass in the right pterygopalatine fossa extending to the right nasal cavity, the right maxillary sinus, the sphenoidal sinus, the sella turcica and the endocraniumassociatedwith a right thyroid mass with endothoracic extension and secondary pulmonary lesions. Biopsy of these lesions confirmed a poorly differentiated thyroid carcinoma. The therapeutic decision was taken in a multidisciplinary consultation meeting and was palliative chemotherapy. The evolution was marked by death.
Conclusion
Distant metastases of thyroid cancer have no clinical or radiological specificity. The metastatic potential remains independent of the size of the thyroid nodule. These metastases are more common with the vesicular histological type and have more reserved prognosis.

DOI: 10.1530/endoabs.81.EP1116

EP1117

Managing thyroid storm in acute setting: a single centre experience case series

Gloria Elekwa[1, 2], Akunna Elonu[1, 2], Rebecca Volmy[1, 2], Alexanderia Williams[1, 2], Gideon Mlawa[2] & Janessa Bell[2,3]
[1]Ross University School of Medicine; [2]Queens Hospital, Romford, United Kingdom; [3]American University of the Caribbean School of Medicine, Sint Maarten (Dutch Part)

Background
Thyrotoxicosis is one of the commonest endocrine disorders and its severe form can manifest as thyroid storm in acute setting leading to organ dysfunctions including heart failure.
Cases
1: A 58-year-old female with a significant past medical history of MI, paroxysmal AF/atrial flutter, and hyperthyroidism presented with a one-week history of palpitations, plethora, diaphoresis, heat intolerance, loose stools, and a TSH < 0.01; Free T4-33. On physical exam, patient was warm and well perfused, minimal pedal edema. She was in fast AF. She was medically managed carbimazole, b-blockers and steroids 2: A 28-year-old female with past medical history of asthma and a current smoker. Patient presented with palpitations, anxiety, diarrhea, fatigue, and 2 stone weight loss in 6 months. On physical examination the patient had a smooth, painless goiter, carotid bruits and prominent exophthalmos. The patient was tachycardic (HR 163), and febrile (38.1 C) with elevated CRP 42 and T4 58 TSH<0.01 She was medically managed with Propylthiouracil 100 mg tds; Propranolol 40 mg TDS Prednisolone 30 mg OD 3. 39-year-old patient with known hyperthyroidism presents with palpitations, anxiety. She was found to have swollen legs and was tachycardic at 110 bpm. CXR showed bilateral shadowing suggestive of fluid overload. Blood tests: TSH <0.01, T4 >100, TSH receptor positive. 4.64-year-old lady presented with for 4 months of breathlessness. Found to be in thyrotoxicosis, atrial fibrillation (AF) as well as peripheral oedema. Blood test showed FT4 69 pmol, positive TSH – receptor antibodies. Treated with rate controlling medications, propylthiouracil, steroids and diuretics
Discussion
Thyroid storm is on the severe end of the thyrotoxicosis spectrum, and it is usually triggered by a secondary external event such as infection, myocardial infarction, trauma or surgery. The Burch Wartfosky point scale is used to diagnose thyroid storm. In this scale, the following are assessed: Temperature, cardiovascular dysfunction, central nervous system derangements, gastrointestinal symptoms and heart failure. A score greater than or equal to 45 aligns with a clinical diagnosis of thyroid storm, and scores between 25 and 44 suggest thyroid storm as a likely diagnosis. Scores below 25 points make a diagnosis of thyroid storm unlikely.
Conclusion
Thyroid storm is medical and an endocrine emergency and appropriate and timely treatment will ensure better patient care and outcome In an emergency like acute thyrotoxicosis or thyroid storm, higher doses of thionamides, beta blockers as well as glucocorticoids can be used to return the patient to a euthyroid state.

Factitious thyrotoxicosis: A case report

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asma CHADLI
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Although the most common cause of thyrotoxicosis is Graves' disease, identification of other causes is important to establish appropriate management. The diagnosis of factitious thyrotoxicosis often presents a difficult challengebut should not be overlooked. We report a case of a patient with treated thyroid carcinoma who presented with factitious hyperthyroidism.
Observation
50-year-old patient, followed for papillary thyroid microcarcinoma under L-Thyroxin 125µg, halted for 3 months, admitted for hyperthyroidism. The patient was then put on Carbimazol 90 mg/day + corticotherapy for 1 month. As the hyperthyroidism persisted and did not improve, he was given radioactive iodine therapy at a rate of 100mCi. All this evolved in a context of weight loss of 24 kg in 4 months. The clinical examination found a patient in general good condition, BMI: 17 kg/m^2, Burch Wartofsky score at 10, free thyroid compartment, no gynecomastia, testicles in place, not swollen, normal size. On biological test T4L: 3051 pmol/l vs 50 pmol/l (8.5-34.90), T3L: 30.43 ng/l vs 6.22 pg/ml (2-4.40), TSHus:0.05 µIU/ml, Tgus: 0.1 ng/ml, BHCG: < 5IU/l (< 5), CEA: 0.99 ng/ml (< 4.30), AFP:5.5 ng/ml (<8.8), LDH: 144 IU/l (125-220), cervical-thoracic-abdominal-pelvic CT scan objectified an anterosuperior mediastinal mass of thymic appearance with adenolymphitis of the ileo-coecal region, F-FDG PET-CT did not show a hypermetabolic processes at the thyroidectomy lodge, locoregional lymph node, or distant suspicious processes for dedifferentiated recurrence of papillary microcarcinoma. The diagnosis of factitious thyrotoxicosis was retained in view of the degression of thyroid hormones during his hospitalization with clinical improvement of the patient during the hospitalization: degression of symptoms, and weight gain of 3 kg. The diagnosis was confirmed after a psychiatric evaluation.
Conclusion
Thyrotoxicosis has a wide spectrum of etiologies. Patients with factitious thyrotoxicosis are extremely difficult to identify because they do not appear to be different from patients with thyrotoxicosis of other causes.

EP1119

Simultaneous occurrence of medullary and papillary thyroid carcinomas: a report of 2 cases

Mehdi Ferjaoui, Maroua Naouar, Emna BERGAOUI, Rachida Bouattay, Elkorbi Amel, Harrathi Khaled, Kolsi Naourez & Jamel Koubaa
Fattouma Bourguiba University Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
Papillary thyroid carcinoma (PTC) and medullary thyroid carcinoma (MTC) are two different types of thyroid carcinoma with significant different clinical and histological findings. Synchronous occurrence of these two carcinomas is uncommon. The aim of the study is to determinate the clinical, histological and therapeutic aspects of the coexistence of medullary and papillary thyroid carcinomas.

Materials and Methods
We report two rare cases of simultaneous medullary thyroid carcinoma and papillary thyroid carcinoma collected in ENT department of Fattouma Bourguiba Hospital of Monastir over a period of 20 years.
Results
Case one was a 46-year-old woman, with no personal history of radiation exposure and family history of thyroid cancer, presented to our consultation for management of a left thyroid nodule discovered by ultrasound examination of her neck. The patient underwent a total thyroidectomy with node dissection. The histology disclosed a medullary carcinoma in left lobe and a micropapillary carcinoma in the right lobe. Three months postsurgery, the patient's calcitonin levels were less than three ng/l and there was no distant metastasis. The second case was a 49-year-old man, with no apparent family history of endocrine disorders or any previous external radiation therapy, hospitalised in our ENT department for multinodular goiter with compression symptoms. A cervical computed tomography objectified a laryngo-tracheal invasion by an endoluminal tissue lump. Fine needle aspiration cytology from the thyroid nodule was performed showing a medullary carcinoma. A total thyroidectomy and total laryngectomy with node dissection were performed. The histology results showed a medullary carcinoma occupying the majority of the thyroid associated to a papillary carcinoma in the right lobe. Surgical treatment was followed by I-131 100 mCi therapy and external radiotherapy. The extension assessment revealed synchronous renal cell carcinoma associated to bone and lymph node metastases due to MTC.
Conclusion
PTC and MTC are two different types of thyroid carcinoma with significant different histology. Synchronous occurrence of these two carcinomas is uncommon and rare. The prognosis depends essentially on MTC.

Postoperative hypoparathyroidism after total thyroidectomy: prevalence and risk factors

Mehdi Ferjaoui, Maroua Naouar, Emna BERGAOUI, Rachida Bouattay, Elkorbi Amel, Harrathi Khaled, Kolsi Naourez & Jamel Koubaa
Fattouma Bourguiba University Hospital, ENT and Head and Neck Surgery Department, Monastir, Tunisia

Introduction
Total thyroidectomy is the most common surgical procedure for the treatment of thyroid diseases. Postoperative hypoparathyroidism and the resulting hypocalcemia are frequent complications after total thyroidectomy. The aim of this study was to assess the rate of postoperative hypoparathyroidism after total thyroidectomy in order to identify potential risk factors.
Methods
We designed a retrospective study including 387 patients with total thyroidectomy who were operated in our department from January 2016 to January 2019. The prevalence of hypoparathyroidism was evaluated at day 3, 1 month, 6 months and 12 months after surgery.
Results
The average age of our patients was 46.9 years old; 16.7% were males and 83.3 % were females. The total thyroidectomy was done in 210 (54.2 %) of cases for a malignant pathology. A total of 189 patients (48.83%) underwent a neck dissection. 90 (23.2 %) developed postoperative hypoparathyroidism at day 3. Most of them recover parathyroid function over time. Prevalence of hypoparathyroidism at 1 month, 6months and 12 months was 9%, 4% and 2.8 %, respectively. The risk of developing definitive hypoparathyroidism was related to the presence of parathyroid tissue at histology, concomitant central lymph node dissection and incidental para thyroidectomy without auto transplantation.
Conclusion
Although most patients with postsurgical hypoparathyroidism recover parathyroid function, intra-operative preservation of the parathyroid glands is the best prophylaxis to avoid postoperative hypoparathyroidism after total thyroidectomy.

Metastatic medullary carcinoma of the thyroid

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Medullary thyroid carcinoma (MTC) is a rare and silent endocrine tumor representing 5-10% of thyroid cancers. It is the most aggressive form of thyroid carcinoma, usually diagnosed at advanced stages.
Purpose of study
Study the phenotypic and genotypic profiles as well as the anatomical-histological characteristics related to the recurrence of the disease.
Matherials and methods
Descriptive cross-sectional study including patients followed for CMT in the Endocrinology and Diabetology Department of the Ibn ROCHD University Hospital of Casablanca from 2007 to 2021. The statistical analysis was performed by the software SPSS version 25.0.
Results
The study included 24 patients followed up for CMT, the mean age was 47.6 $\pm$ 14.35 years, the majority were women (70.8%), a family history of thyroid carcinoma was found in two patients, clinically the thyroid nodule was the reason for consultation in thirteen patients (54. 2%), all patients underwent total thyroidectomy, lymph node dissection was performed in eighteen patients, CMT was in the context of MEN2 in six patients (25%), the genetic study of RET proto-oncogene mutations was positive in three patients. Fourteen patients had metastatic disease (58.3%). Lymph nodes were the most frequent metastatic site. Calcitonin levels at diagnosis were $>$ 500 pg/ml in 57.1% of patients. Most of them had undergone an incomplete first thyroid surgery. In addition, the tumors were larger, multifocal ($P<0.05$) and with capsular invasion ($P<0.02$). Of these patients three received chemotherapy, radiotherapy was performed in two patients, and two patients were scheduled for treatment with Sorafenib.
Conclusion
The prognosis of CMT is more pejorative than papillary thyroid carcinoma, several factors were correlated with the development of metastasis, which requires adequate management with close monitoring of the disease.

Papillary thyroid carcinoma revealed by hyperthyroidism

Messaoudi Najoua[1], Imane Assarrar[1], Nisrine Bouichrat[1], Marouan Karrou[1], Siham ROUF[2] & Hanane Latrech[3]
[1]Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco; [2]Faculty of Medicine and Pharmacy of Oujda, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition, Oujda, Morocco; [3]Faculty of Medicine and Pharmacy of Oujda, Mohamed the First University, Department of Endocrinology-Diabetology-Nutrition, Laboratory of Epidemiology, Clinical Research and Public Health, Oujda, Morocco

Introduction
Papillary thyroid carcinoma is the most common histological type of differentiated thyroid malignancy. This type of tumor is rarely associated with thyroid hormone hypersecretion. We report the case of a patient with papillary thyroid carcinoma revealed by hyperthyroidism.
Case report
A 35 years old patient was admitted for the management of malignant hypercalcemia discovered incidentally on the biological workup performed preoperatively for a humerus fracture. The biological and radiological assessment revealed a primary hyperparathyroidism secondary to a parathyroid adenoma and hyperthyroidism secondary to a nodular goiter. TSH anti-receptor antibodies and calcitonin were negative. After obtaining normocalcemia and normalization of the thyroid assessment, the patient underwent a total thyroidectomy with a left parathyroid adenectomy. The anatomopathological study confirmed the presence a parathyroid adenoma without signs of malignancy, as for the thyroidectomy specimen, the histological study revealed a vesicular carcinoma with presence of a capsular effraction and vascular emboli, classified pT3aNxMx.
Conclusion
The association of thyroid cancer and hyperthyroidism is a rare event. Its pathogenesis remains poorly elucidated. Hyperthyroidism in these cases may be

secondary to the primary carcinoma, as well as due to metastases, hence the importance of a complete extensive evaluation.

Two types of thyroid cancer in one patient

Emir Muzurovic[1], Sanja Borozan[2] & Snezana Vujosevic[2]
[1]Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro; [2]Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro

A 65–year-old male was referred to endocrinologist due to significantly elevated calcitonin level of 3662 pg/ml. Previously, almost 3 decades before, the patient underwent right thyroid lobectomy for papillary carcinoma. Then, 9 years afterwards, he was reoperated and total thyroidectomy with neck exploration was performed. In pathohistological finding, metastatic papillary carcinoma was proved. Radioactive iodine ablation was used as a post surgical treatment. After completing a proposed therapeutic course, a patient has not been motivated for a regular follow-up. During the hospital examination, CT scan of the neck region revealed a solitary pathological node in front of the trachea, 18 mm in diameter which was surgically removed. Pathohistological finding was suggestive for metastatic medullary thyroid carcinoma. A bone scan and nuclear magnetic resonance demonstrated a 32 mm extramedullary intraspinal solid mass in Th10 region. In further course, a Galium PET/CT scan showed an increased update in right cervical level lymph node, measuring 12x8 mm in diameter, and in left side of the spinal canal at the level of Th9-Th10, consistent with metastasis, without pathological uptake on brain images, thorax, abdomen or pelvis. One month afterwards, a solid mass in spinal region and neck dissection were removed, followed with calcitonin level normalization.

Branchial cyst into the thyroid gland: an usual presentation

Sirine Ayedi[1], Chaabouni Medamin[1], Rim Hammami[1], Moncef Sellami[1], Abid Najla[2] & Ilhem Charfeddine[1]
[1]Habib Bourguiba Hospital - University of Sfax, Ent Department, Sfax, Tunisia; [2]Habib Bourguiba Hospital - University of Sfax, Pathology Department, Sfax, Tunisia

Introduction
Fourth branchial cleft cyst are commonly reported as recurrent low-neck abscesses, acute suppurative thyroiditis, and neck masses. We report an accidental finding of a fourth branchial cleft as a suspected thyroid nodule.
Case presentation
We present a case of a 47-year-old woman who consulted the Ear, Nose, and Throat department of our hospital with a 4-year history of thyroid nodule. The thyroid nodule was discovered incidentally on ultrasonography. She reported no cervical swelling, pain, dysphagia, dysphonia or dyspnea. She did not report any recent infections, neck trauma, or surgery. The patient had no palpable neck mass or *fistulous orifices*, with a strictly normal ENT examination. Several ultrasonographic examinations revealed the thyroid nodule. Its size was a 14*8*7 mm tissular nodule classified EU-Tirads 5 but didn't show a cyst, without significant modification compared to the previous ultrasonographic examinations. The patient underwent lobo-isthmectomy. The patient's postoperative course was satisfactory. Meanwhile, the pathologist confirmed the presence of a 1 cm lateral neck cyst within this thyroid lobe with no other thyroid nodules. After a mean follow-up of 5 years, no superinfection episodes or recurrence were reported.
Conclusion
Fourth branchial anomalies are very rare and can remain asymptomatic for a long time. Its localization and mode of discovery may be unusual. Clinical presentation and imagery can't always help to diagnosis. In our case, it was considered as a suspicious thyroid nodule, but the anatomopathological examination rectified the diagnosis.

Thyroid nodule: an exceptional mode of revelation of extrapulmonary Tuberculosis

Arij Ezzouhour Yahyaoui, Asma Kefi, Ben Abdelghani Khaoula, El Euch Mounira, Sassi Syrine, Turki Sami & Abderrahim Ezzeddine Charles Nicolle, Internal Medicine A, Tunis, Tunisia

Introduction
The incidence of extrapulmonary forms of tuberculosis has increased. Thyroid tuberculosis is an uncommon condition even in developing countries where tuberculosis is endemic. Herein we report an original case of a 62 year-old woman in whom tuberculosis was revealed by thyroid nodule.
Observation
Our patient is a 62-year-old woman with a history of mild asthma for 7 years. She presented with a slight neck swelling and a loss of weight and appetite for three months, with no discomfort on swallowing nor tenderness. There were no specific signs suggestive of dysthyroidism. She denied any history of tuberculosis, night sweats, fever, dyspnea or cough. On examination, she had a slight thyromegaly without tenderness nor bruit. Other systemic and regional examinations did not show any abnormality. The blood routine tests were normal. The thyroid function tests disclosed normal levels of serum thyroid stimulating hormone (TSH) and free thyroxin (FT4). Blood and urine calcium levels were normal. Cervical ultrasound revealed multiple nodules of various sizes in the right lobe associated to lymph nodes in the lower internal jugular chain. Ultrasound (US)-guided fine needle aspiration biopsy of lymphadenopathies demonstrated non-caseating granulomatous lymphadenitis. A CT scan was performed and revealed apical ground glass opacities, symmetric hilar, mediastinal and abdominal adenopathies. Quantiferon test was positive. Tuberculin skin test was positive too with an 18 mm-diameter reaction. Sputum smear microscopy was negative. Bronchoalveolar lavage was normal: there was no alveolitis, CD4/CD8 ratio was normal, mycobacterium tuberculosis PCR was negative. The angiotensin-converting enzyme and beta2-microglobulin were not elevated. The patient was diagnosed with ganglionar and thyroid tuberculosis. The patient is now put on anti-tuberculosis drugs: combination of Rifampicin, Isoniazid, Ethambutol and Pyrazinamide for 2 months, which will be followed by Rifampicin and Isoniazid for 4 months. Now the patient is remaining euthyroid, neck swelling is not progressing and her appetite improved significantly. Follow-up sonography is scheduled in one month.
Conclusion
Thyroid tuberculosis is a scarce condition which should be considered in front of thyroid nodule. Fine-needle aspiration cytology may avoid unnecessary surgical intervention. Treatment options for thyroid tuberculosis are antituberculous drugs and/or surgery.

Multinodular goiters: management

Meherzi Abir, Marwa Ben Njima, Mouna Khalifa, Mouna Bellakhdhar, El Omri Malika, Jihene Houas, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

Background
analysis the epidemiologic and the clinical features of this entity, then to discuss the management
Patients and methods
We report a retrospective study of 120 patients operated on for multi nodular goiter over a period of 5 years between January 2017 and December 2021.
Results
In our study a female predominance was noted with a sex ratio F/H of 8/1. The average age of the patients was 44 years with extremes from 15 to 74 years. A familial thyroid pathology was reported by 42 patients in our study (35%). On clinical examination 82 patients had a single nodule; the consistency of the GMN was firm in 88%, soft in 3% and hard in 9% of cases. 64.4% of the dominant nodules within the MNG were smaller than 4 cm. Cervical adenopathies were palpated in 13 patients (11%). Clinical signs of tracheobronchial axis compression were present in 45 patients or 37.5%. Recurrent paralysis was found at the IL in 3 patients (2.5%). A thyroid workup was performed in all patients. 96.6 of patients were euthyroid, the rest were hypothyroid. Ultrasound was performed in all patients. It revealed nodules larger than 1 cm in all patients. Cytopuncture was performed in 23 patients (19%). It concluded to a benign nodule in 19 cases (76%), a suspicious nodule in 3 cases (12%) and was non-contributory in 3 cases (12%). In 52 patients, surgical treatment consisted of total

thyroidectomy (44%) and loboisthmectomy in 68 patients (56%). The surgical treatment was complicated by 4 unilateral recurrent paralysis of which two were definitive and 5 definitive hypoparathyroidism.
Conclusion
Thyroid goiter is the most frequent endocrine disorder. Clinical testing, thyroid function testing, and imaging studies are all part of the diagnostic process. Additional FNAC testing may be necessary. Depending on the results of the diagnostic examination and related consequences, treatment options include medications, surgery, and radioiodine (I-131).

Graves' disease: surgical management

Meherzi Abir, Habiba Ben Sghaier, Mouna Bellakhdhar, El Omri Malika, Jihene Houas, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

The goal of this study is to examine the role of surgery in the treatment of Graves' disease and to assess the surgical outcomes.
Methods
We present the results of a retrospective analysis of 31 Graves' disease cases operated on in the ENT and cervico-facial surgery departments of Farhat Hached Sousse Hospital during a six-year period [2015-2021]. Our group consisted of 05 males and 26 women. The average age ranged from 12 to 70 years. Between diagnosis and operation, the average period was 35.6 months [06-120 months]. A homogenous goiter (93.5%) and a thyroid of normal volume were discovered during a cervical examination (6.5 percent). TSH and FT4 levels were 14.42 pmol/l and 1.12 mU/l, respectively, at the median. When faced with: resistance to medical therapy (77.4%), existence of compression signals (9.7%), presence of thyroid nodules (6.5%), severe ophthalmopathy (3.2%), and patient desire, surgery was recommended (3.2 percent). In all of the patients, a complete thyroidectomy was performed. Following surgery, one patient experienced brief recurring paralysis. Hypocalcemia was discovered in 38.7% of the patients. In any event, it was only temporary. After surgery, no patient experienced an acute thyrotoxic crisis. A histological investigation revealed Graves' disease, but no evidence of cancer. The average period of follow-up was three years.
Conclusion
Graves' disease is a thyroid autoimmune illness. Because of the disease's evolutionary vagaries, treating it is tough. Medical therapy has been related to repeated recurrences and a variety of side effects, all of which have a negative impact on these patients' quality of life. Surgery based on total thyroidectomy represents a safe alternative with a low rate of complications.

Hypoparathyroidism Post-total thyroidectomy: pathophysiology and management

Meherzi Abir, Safa Jemli, Mouna Bellakhdhar, El Omri Malika, Jihene Houas, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

Thyroid surgery is a frequent procedure that has certain risks. After a complete thyroidectomy, hypocalcemia is the most prevalent consequence. It has a variety of causes, with hypoparathyroidism being the most frequent and dangerous.
Materials and procedures
A retrospective analysis collected 27 cases of patients who had a total thyroidectomy complicated by hypocalcemia among 320 patients who underwent a total thyroidectomy throughout the study period, which spanned nine years (2010–2020). The goal of our research is to identify the characteristics that predict post-total thyroidectomy hypocalcemia, as well as the consequences and various therapy options.
Results
The average age of the participants was 40.5 years [17–78 years]. Females made up 92.6 percent of the patients. On D3, postoperatively, a systematic assessment of serum calcium was performed. In terms of clinical symptoms, 48% of individuals were asymptomatic. On D1 surgical day, 3 patients had symptomatic hypocalcaemia, and on D2 postoperative day, 11 patients had symptomatic hypocalcaemia. In addition, all of the patients' preoperative serum calcium levels were normal. Apart from surgical devascularization of the parathyroid glands, 23 individuals had postoperative hypocalcemia. The primary symptom in symptomatic individuals was paresthesias of the extremities (85.7 percent). In two of the patients, muscle cramps were noted. There were no cardiac arrhythmias or tetany crises in any of the individuals. The mean serum calcium concentration was 1.67 mmol/l (range: 1.4 to 1.9 mmol/l). In 18 individuals, intra-hospital parenteral correction with calcium gluconate was required. On discharge, all patients were given calcium supplements along with vitamin D. The average treatment time was 3.7 months [1–9 months]. In 25 cases, the result was positive (correction of hypocalcaemia). Two patients were misplaced.
Conclusion
Hypocalcemia following thyroid surgery can be severe, but it's usually reversible. The first step in prevention is to carefully dissect the parathyroid glands and preserve their circulation. Despite this, a low preoperative vitamin D level predicts the development of postoperative hypoparathyroidism, which might be asymptomatic prior to surgery. Other prospective trials are needed to clarify the interest in a possible preoperative vitamin D supplementation as well as the mode of supplementation.

Management of refractory Graves' disease

Meherzi Abir[1], Habiba Ben Sghaier[1], Mouna Bellakhdhar[1], El Omri Malika[1], Jihene Houas[1], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

The goal of this paper is to analyze the factors that cause people to flee medical treatment and to put forth management guidelines. Materials and methodes: This is a retrospective analysis of 27 instances with Graves' disease that were resistive to medical treatment after escaping from well-conducted medical treatment in the ENT and cervico-facial surgery departments at Farhat Hached Sousse Hospital over a six-year period [2015-2021]. Results: All of the patients were put on a synthetic antithyroid medication as a first line of treatment (ATS). Carbimazole (thyrozol) was the most commonly used compound in 81.5 percent of instances, followed by propylthiouracil (basdene) in 18.5 percent. In 74 percent of instances, a beta-blocker was used as an adjuvant treatment. Medical treatment lasted an average of 33.7 months. Following an escape from medical treatment, surgical treatment was advised in all of the patients: resistance to medical treatment in 24 patients, 2 of whom had tried IRAtherapy cures but were ineffectual, and the presence of a gigantic goiter with compressive indicators in 3 patients. In all patients who achieved euthyroidism, a total thyroidectomy was performed (mean follow-up of 18 months).
Conclusion
Graves' illness is the most prevalent cause of thyrotoxicosis, which has life-threatening effects. Iodine and surgery are the alternatives to euthyroidism, which must be achieved first.

Graves' disease revealing primary biliary cirrhosis (a case report)

Maryame Ben Lafqih, Meryam Alahyane, Sana Rafi, Ghizlane EL Mghari & El Ansari Nawal
Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction
Liver function abnormalities in hyperthyroidism are common, several abnormalities have been reported: hepatic cytolysis, cholestasis, insufficiency or even non-specific abnormalities. The pathophysiology of hepatic dysfunction secondary to hyperthyroidism is not yet well established. Graves' disease can be associated with various autoimmune diseases. However, association with Primary biliary cirrhosis has been described in few cases in literature. We report a case of Graves' disease revealing primary biliary cirrhosis
Case report
F, I, 47-year-old female patient, with no pathological history, consults for a syndrome of thyrotoxicosis. Physical examination showed: Bulging eyes, homogeneous diffuse goiter, with vascular thrill. Thyroid function tests revealed : low serum TSH <0.05 U/l, and high serum free T4:51.46 pmol/l and free T3: 19.6 pmol/l. An ultrasound exam showed an enlarged thyroid with increased vascularity,

compatible with thyroiditis. Meanwhile, the patient presented a cholestasis and cytolysis syndrom, serology tests for hepatitis were negative; high level of total IGGs, anti-mitochondrial antibodies not made. The abdominal ultrasound: dysmorphic liver. On fibroscann : Elasticity estimated at 11.4 (F3) The patient was put on prednisone and beta blocker, with a normalization of liver and thyroid tests. Then a total thyroidectomy was performed. The anatomopathological study confirmed the diagnosis of Graves' disease.
Discussion
Hepatic involvement in Graves' disease is uncommon, however, abnormal liver function tests are relatively common. Clinical and biological cholestasis syndromes are less common. The pathophysiology of hepatic dysfunction in hyperthyroidism is multifactorial, it may be secondary to hyperthyroidism, to antithyroid drugs, or associated with autoimmune liver disease. Various theories attempt to explain cholestasis in hyperthyroidism. Its association with hyper metabolism, increases hepatic oxygen consumption, without an increase in hepatic blood flow, and therefore a decrease in oxygen in the centrilobular areas. Our patient had a clinical and biological cholestasis syndrome, the etiological assessment was negative, the fibroscann confirmed hepatic cirrhosis. The normalization of liver tests under corticosteroids is in favor of diagnosis of primary biliary cirrhosis.
Conclusion
Primary biliary cirrhosis is another autoimmune disease that should be considered as an association with Grave's disease when other causes of cholestasis syndrome are ruled out. Early identification could help plan disease management and prognosis improvement.

Coronary insufficiency during hyperthyroidism: Report of six cases

Mouna Elleuch, Cyrine Chehaider, Sawssen Ben Teber, Dhoha Ben Salah, Siddiqa Soomauroo, Nadia Charfi, Mouna Mnif, Fatma Mnif, Nabila Rekik, Faten Hadj Kacem & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Cardiothyreosis is the consequence of the effects of excess free thyroid hormones on the vascular wall and myocardium. This complication is the most serious aspect of hyperthyroidism. Rhythm disorders and heart failure are the most frequently noted. The prevalence of coronary insufficiency is lower. The aim of this study is to evaluate the characteristics of coronary insufficiency in patients with hyperthyroidism.
Method
This is a retrospective descriptive study including six patients among a hundred patients who were followed for hyperthyroidism and cardiothyreosis, during a period of 20 years, in the Endocrinology department of Hedi Chaker Hospital in Sfax. These six patients had coronary insufficiency related to cardiothyreosis.
Results
The prevalence of coronary insufficiency in cardiothyreosis was 6%. All six patients were male, with a mean age of 44.16 years [extremes: 25-61]. The majority were aged $\leq$ 35 years (4 cases). They had no personal history of cardiovascular pathology except hypertension for one patient. The etiology of hyperthyroidism was Graves' disease in 2 cases, Hashimoto's thyroiditis in 2 cases, toxic multi-nodular goiter and iodine overload. The mean TSH level was 0.054 µIU/ml [extremes: 0.01 - 0.19 µIU/ml], FT4 was 54.36 pmol/l [extremes: 31.3 - 71.43 pmol/l]. No cases of subclinical hyperthyroidism were reported. The diagnosis of hyperthyroidism was concomitant with the diagnosis of cardiothyreosis in 5 patients and delayed in one patient. Tachycardia was present in all patients with a mean heart rate of 101.2 bpm. The different forms of coronary syndrome were objectified, ranging from unstable angina to myocardial infarction with or without necrosis Q wave. Coronary angiography reports of 4 patients were obtained: they showed arterial occlusion in 2 cases and a healthy coronary network in the other 2 cases. Coronary insufficiency was always associated with one or more of the other types of cardiothyreosis. Rhythm disorders were present in 5 cases (atrial fibrillation in 4 cases and atrial extrasystoles in one case). Systolic ejection fraction was low in all patients with a mean of 35.83% [extremes: 20-55%]. 2 patients had died in major heart failure. The others had not developed new coronary events after obtaining euthyroidism.
Conclusion
The risk of coronary insufficiency during hyperthyroidism is well established. Less common than rhythm disorders and heart failure, it is usually associated with them. Early diagnosis and adequate treatment of hyperthyroidism would prevent this complication.

Long-term disease recurrence in the adipose tissue and striated muscle of a mimally invasive papillary thyroid carcinoma

Antonella Carbone[1], Antonella Verrienti[2], Domenico Savio Cito[3], Marialuisa Sponziello[2], Valeria Pecce[2] & Rocco Bruno[3]
[1]Endocrine Unit, Area Medica, Pisticci, Italy; [2]Department of Translational and Precision Medicine, Sapienza University, Rome, Italy; [1]Endocrine Unit, Area Medica, Pisticci, Italy

Introduction
Differenziated thyroid carcinomas (DTC), particularly papillary thyroid carcinomas (PTCs), usually have an indolent behavior, howewer 10-20% of the patients develop recurrences, following surgery. There are several histological features associated with more frequent recurrences as the hystopathological variants of PTCs, the presence of vascular invasion or lymph node metastases and the presence of extrathyroidal extension (ETE). Case history: a 56yrs old male patient prevously treated for PTC, with excellent response to the first treatment, presented twelve years after a gradual increase of thyroglobulin (Tg) (from 0.3 to 0.76 ng/ml in 6 months) and a neck lump in the left cervical region at ultrasound imaging. Fine needle aspiration cytology of the mass and Tg measurement in the wash out liquid of the needle was 472 mg/l. Cytology revealed polymorphous epithelial cells with atypical nuclei suggesting metastasis of PTC. Surgery was then performed and pathology showed a massive metastasis in the local adipose tissue and striated muscles of the neck. Genetic analysis of the primary tumor and metastatic tissue revelead a BRAF p. V600E in both primary tumor and in metastatic tissue (37% and 48% respectively). Conclusions: Our patient's history suggests the need of a continuous and prolonged follow-up in patients with multiple features that increase the recurrence risk (minimal ETE, size $>$2 cm, BRAF V600E mutation as in our case).

Epidemiological, clinic-pathological, evolutionary profile of noninvasive follicular thyroid neoplasm: About 27 cases

Sofia Ouhessaine, Nassim Essabah Haraj, Siham El Aziz & Asma CHADLI
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) is a newly defined entity accepted as a tumor precursor.
Objective of the study
To describ the epidemiological, clinical characteristics, and the evolutionary profile.
Methods
Retrospective study including 27 patients followed for noninvasive follicular thyroid neoplasm collected at the Endocrinology and Diabetology department of Ibn Rochd Casablanca University Hospital, spread from 2017 to 2021.

Results
The mean age of our patients was 51.3 years, with a clear predominance of women (88.8% of cases). The most frequent symptomatology was cervical swelling in 88.36%, the discovery was fortuitous in 11.63%. In our series 92% patients had multinodular goiter, 14.8% followed for dysthyroidism, 26.7% had no personal history and 2 patient had a familial history of thyroid carcinoma. All patients had clinical and biological euthyroidism except 3 patients who had hyperthyroidism. All patients underwent total thyroidectomy with noninvasive follicular tyroid neoplasm, the average size of 1.07 cm. Multifocality was objectified in 5 patients, without associated malignancy. Their was no indication for Lymph node dissection and Iratherapy ($P=0.000$), with no distant metastasis ($P=0.000$). The remission rate was objectified in 100%.
Conclusion
The diagnosis of NIFTP can only be made after complete resection of the lesion. Patients diagnosed with NIFTP without associated malignancy and without nodules detected can be spared from additional treatment and from the traditional follow-up recommended for differentiated thyroid cancer.

Severe hyperthyreosis

Iva Petrak[1] & Karin Zibar Tomšić[2]
[1]Opća Bolnica Nova Gradiška, Nova Gradiska, Croatia; [2]University Hospital Centre Zagreb, Zagreb, Croatia

A 72-year-old male patient presented to the ER because of general weakness, myalgia, frequent paroxysms of atrial fibrillation, shortness of breath, and hoarseness. The symptoms persisted for two months, gradually worsening and causing him to lose weight. At some point, he noticed redness of the sclera and soreness of the eyeballs. Paroxysms of rapid atrial fibrillation have been known for more than 15 years, so he had amiodarone in therapy. His initial laboratory findings showed markedly elevated fT4 >100 pmol/l, fT3 36 pmol/l, and suppressed TSH <0.01 mIU/l. Thyroid antibodies were normal. Ultrasonography showed a diffusely altered thyroid with normal blood flow, and no nodular changes. Therapy was started with thiamazole 30 mg daily, propranolol 80 mg daily, and methilprednizolone 32 mg daily. Amiodarone was excluded from therapy. Two weeks later, fT4 was still significantly elevated, above 100 pmol/l. The thiamazole dose was increased to 60 mg per day, and two weeks after that, fT4 began to decrease, so the thiamazole dose was reduced to 30 mg per day. Two weeks after the dose reduction, he came to ER due to rapid atrial fibrillation. The fT4 level was again greater than 100 pmol/l, so the thiamazole dose was increased to 60 mg per day and lithium carbonate was added to the therapy, while the dose of methilprednosolone was gradually reduced in the meantime. Because the fT4 level was still extremely high 400 pmol/l after 1 week despite therapy, the patient was hospitalized and therapy was continued with thiamazole at a dose of 90 mg daily, lithium carbonate, parenteral corticosteroid, and supportive therapy. After 7 days, a decrease in fT4 level to 64 pmol/l is observed. As the gradual decline in thyroid hormones continued, the dose of lithium carbonate and parenteral corticosteroids was gradually reduced but continued with high doses of thiamazole of 90 mg per day. As the patienťs recovery was monitored by continued reduction of corticosteroids, lithium, and thiamazole, it was planned to perform thyroidectomy after complete physical recovery and achievement of euthyroidism. The patient was discharged for home treatment. Lithium carbonate was discontinued after 1 week, corticosteroid after 3 weeks, and thiamazole after 6 months of gradual reduction with achievement of euthyroidism. The patient recovered completely, so he refused thyroidectomy.
Conclusion
Thyroid storm due to amiodarone therapy.

When unilateral exophthalmos is the only manifestation of graves' disease: diagnostic and therapeutic issues

Sara Si Amer, Imene Benoumechiara & Nora Soumaya Fedala
University Hospital Henter Mohamed Lamine Debaghine, Department of Endocrinology, Diabetology and Metabolic Diseases, Algiers, Algeria

Introduction
Basedowian exophthalmos is an inflammatory disease of the orbit of autoimmune origin, potentially threatening with severe functional and psychosocial effects. It is usually accompanied by hyperthyroidism. It constitutes a real diagnostic challenge in patients with euthyroidism, as is the case with our patient.
Observation
A 34-year-old young woman with no particular pathological personal or family history. Who initially consults, a year ago, in ophthalmology for a unilateral, right, non-painful, hardly retractile exophthalmos, estimated at 27mm, and associated with ipsilateral palpebral retraction, without other signs, in particular inflammatory. The clinical activity score was 1. Faced with the unilateral character, an orbito-cerebral CT scan was performed, ruling out a tumor cause and confirming unilateral proptosis with slight infiltration of the periorbital muscles. It is oriented at our level for further exploration. The clinical examination does not find any clinical signs of hyperthyroidism or goiter. The thyroid balance was normal, namely TSH: 0.981 mui/ml, FT4: 15.67 pg/ml, TPOAb/TgAb negative, only positive TSH anti-receptors at 3.74. Thyroid ultrasound shows the appearance of lymphocytic thyroiditis. The patient received oral corticosteroid therapy which did not allow the regression of this proptosis, a cure of silicon was prescribed.
Discussion-Conclusion
Unilateral exophthalmos may be the only clinical manifestation of Graves' disease in euthyroidism, thus posing a diagnostic challenge. And although the management of Basedowian exophthalmos is well codified, it still remains problematic in some patients.

Correlation between plasmatic long pentraxin PTX3 and nodular thyroid disease: a preliminary report

Damiano Chiari[1,2], Barbara Bottazzi[3], Roberto Leone[3], Giorgia Amy Rodda[1], Barbara Pirali[2], Luciano Branchini[2] & Walter Zuliani[2]
[1]Humanitas University, Milan, Italy; [2]Humanitas Mater Domini Clincal Institute, Castellanza, Italy; [3]Humanitas Research Hospital, Milan, Italy

Introduction
The long pentraxine-3 (PTX3) is a key component of humoral innate immunity that is expressed in various cell types during stress and tissue injury. PTX3 also acts like an oncosuppressor regulating tumor-promoting inflammation and it is implicated in tissue repair and autoimmunity. Autoimmune disease, tissue remodelling and oncogenesis often coexist in the thyroid. PTX3 role in thyroid disease is still unknown. Aim of the study is to evaluate if plasmatic levels of PTX3 in patients submitted to thyroidectomy for benign or malignant nodular disease are higher than normal.
Materials and methods
After informed consent, patients over 18 years old with nodular disease of the thyroid who were eligible for thyroid surgery were enrolled in this study. All patients underwent total or hemi-thyroidectomy at Humanitas Mater Domini Clinical Institute in Castellanza (VA). A blood sample was taken on the day of surgery and another one was taken 45 days after surgery to evaluate plasmatic PTX3 level. Blood samples were centrifuged and PTX3 levels were evaluated with ELISA test. In this preliminary report, we evaluated the data of the first 53 consecutive patients enrolled in the study.
Results
We found that preoperative plasmatic PTX3 levels were significantly higher than normal in patients with thyroid disease ($P<0.05$). Plasmatic PTX3 mean value was 4.54 ng/ml (range 1.06 – 8.63 ng/ml), when normal value is considered 2 ng/ml with 1 ng/ml of standard deviation. At 45 days follow-up PTX3 mean value was reduce to 3.40 ng/ml (range 0.89 – 9.21 ng/ml); this reduction was statistically significant ($P<0.05$).
Conclusions
For the first time, at the best of our knowledge, we observed a correlation between elevated PTX3 plasmatic levels and nodular disease of the thyroid. We hope to identify if plasmatic PTX3 could be used as a marker for nodular thyroid disease.

Graves' orbitopathy: clinical evaluation and therapeutic aspects

Sofien AFFES[1], Ben Amor Saloua[1], Rekik Mona[1], Nadia Ben Amar[1], Faten Hadj Kacem[2] & Trigui Amira[1]
[1]Habib Bourguiba University Hospital, Ophthalmology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia

Introduction
Graves' disease is a common autoimmune disease that can be complicated by orbital damage sometimes threatening the visual prognosis. We report the case of a patient with Graves' orbitopathy and we discuss the difficulties of clinical evaluation and therapeutic management.
Case report
A 68-year-old woman presented to our department complaining of eye protrusion and progressive vision reduction in both eyes. She has had a history of Graves' disease, treated with synthetic antithyroid drugs for 1 year, then thyroidectomy. The ophthalmological examination revealed in the right eye a visual acuity at 1/10, a proptosis, intraocular pressure (IOP) at 20 mmHg, a limitation of abduction, a dense cataract with a pale optic disc at the fundus. In the left eye, visual acuity was at 3/10; there was a proptosis, IOP at 22 mmHg, a mild cataract with optic disc hyperaemia at the fundus. We completed with an orbital MRI and a thyroid assessment. The patient was put on hypotonic eye drops and received bolus of intravenous corticosteroids. The evolution was marked by an improvement in oculomotricity and a partial regression of proptosis and IOP. Given the persistence of the threat to the visual prognosis, orbital decompression surgery was indicated.
Discussion
The diagnosis of dysthyroid orbitopathy is often obvious. The clinical evaluation must specify the evolutionary stage (clinical activity score) and the gravity or severity according to the classification of the European group EUGOGO. It is important to recognize the 3 major stages of the disease: diagnosis with an ophthalmological and thyroid evaluation, the activity phase which may or not require specific treatment, and the sequelae phase after 6 months of stability and inactivity. Initially, rapid restoration of euthyroidism, smoking cessation and simple ophthalmological symptomatic treatment are proposed. In the event of advanced and active dysthyroid orbitopathy, oral or intravenous corticosteroid therapy associated or not with orbital radiotherapy. The place of emergency decompressive surgery in cases of optic neuropathy is controversial.
Conclusion
Dysthyroid orbitopathy is a complex pathology whose management is often difficult. A multidisciplinary management is recommended in order to allow an adequate biological, clinical and radiological evaluation and to propose an adequate treatment.

Autoimmune thyroiditis and hypothyroidism: a personalized medical approach

Silvia Martina Ferrari[1], Francesca Ragusa[2], Giusy Elia[2], Sabrina Rosaria Paparo[2], Valeria Mazzi[2], Eugenia Balestri[2], Chiara Botrini[2], Armando Patrizio[3], Alessandro Antonelli[2] & Poupak Fallahi[4]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Italy; [2]University of Pisa, Department of Surgical, Medical and Molecular Pathology and Critical Area, Italy; [3]Azienda Ospedaliero-Universitaria Pisana, Department of Emergency Medicine, Italy; [4]University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery, Italy

Autoimmune thyroid diseases (AITD) are organ specific autoimmune disorders with a T-cell-mediated immune attack directed against the thyroid. Hashimoto's thyroiditis and Graves' disease are the two principal AITD clinical presentations, which are characterized by hypothyroidism and thyrotoxicosis, respectively. We review the available data in literature about personalized medicine in patients with autoimmune thyroiditis (AT) and hypothyroidism. The synthetic Levothyroxine (L-T4) (1.5-1.7 μg/kg) is the daily treatment for these patients. L-T4 is available in different formulations, including tablet, liquid solution, or soft gel capsule. The tablets are the most prescribed, while the liquid, or the soft gel capsules formulations, are generally administered in hypothyroid patients who have issues of malabsorption, or who are in treatment with drugs interfering with L-T4 absorption. Furthermore, the administration of myoinositol and selenomethionine in patients with subclinical hypothyroidism and AT showed promising effect; with a significant decline in TSH and antithyroid autoantibodies levels. Actually, myoinositol, which is the precursor of phosphoinositides and takes part into various cellular processes, has also a key role in thyroid autoimmunity and function. Moreover, thyroidectomy can be suggested in patients with AT, owing to a variety of reasons such as: important signs or symptoms of local compression; the presence of thyroid nodules with "suspicious" features; cosmetic reasons for a goiter. Recently, a randomized trial suggested that total thyroidectomy, but not medical therapy, can ameliorate fatigue and quality of life in these patients. Further researches involving larger population will help in the evaluation of the effect of these novel treatments on the quality of life in these patients.

The study of lipidic spectrum in the females with 'subclinical hypothyroidism' living in uzbekistan

Rakhshona Mirzaeva[1] & Dilfuza Karimova[2]
[1]Tashkent Medical Academy, Department of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Medical Academy, Tashkent, Uzbekistan

Introduction
Hypothyroidism - is a clinical syndrome, which occurs owing to the constant insufficiency of thyroid gland hormones in organisms for a long period of time or as a result of reducing their biological effect as a tissue. Now, hypothyroidism occurs in 7-10 % of females and 2-3 % of men. Subclinical hypothyroidism – is characterized by a gradual aggravating chronic condition of the thyroid gland of immune pathologic character, normal level (T4) of free thyroxin, and a large amount of thyroid-stimulating hormone (TSH). It is in the leading place among all pathologies of the thyroid gland according to the prevalence in the population.
Purpose
At present, the mentioned pathology is considered to be the most important. But, nevertheless, its diagnostics and study of concomitant diseases still cause some problems. If not revealed in proper time latent hypothyroidism may produce a number of grave conditions. Our aim is concentrated on estimating the lipid and hormonal profile of women ill with latent hypothyroidism, preventing its transition to manifested hypothyroidism, and stopping the development of various diseases.
Material and methods
We divided according to the degree of the thyroid-stimulating hormone of examined women. In our examination, 100 women took part from 17 years to 66 years. We divided all patients 3 groups according to the amount of thyroid-stimulating hormone:
Result
According to our investigations, the lipid profile of patients ill with subclinical hypothyroidism have been examined. The studies showed that general cholesterol, lipoproteins with low density, triglycerides have been considerably increased in the first and second groups. It consists of 32 patients.
Conclusion
In patients with an amount of TG of more than 4 mU/l the level of general cholesterol, triglycerides, lipoproteins with low density (LLD) have been found in quantities, whereas the level of lipoproteins with high density (LHD) was considerably lower. It has been determined that in patients who haven't reached the age of 66 the risk of acquiring ischemic heart disease is high as a result of subclinical hypothyroidism.

Sonographic features of autoimmune thyroiditis - a clinical perspective

Samantha Anandappa & Anand Velusamy
Guy's and St Thomas' NHS Foundation Trust, Endocrinology, London, United Kingdom

Autoimmune Hypothyroidism is a common clinical condition with a suggested prevalence of up to 12% of the population. The subsequent enlargement of the thyroid gland caused by circulating thyroid antibodies can cause neck discomfort warranting a referral to the thyroid ultrasound (USG) clinic. The USG characteristics of autoimmune hypothyroidism can be challenging to grade and the atypical appearances often makes it difficult to exclude a mitotic lesion. We have set forward few recommendations and clinical perspectives to overcome some of these challenges and minimise misdiagnosis.
Case 1
30 yrs F with established Hashimoto's on Levothyroxine and under the care of Rheumatology for suspected mixed connective tissue disease. Thyroid USG performed for neck discomfort demonstrated markedly hypoechoic 2x2x4 cm nodule with an ill-defined border containing considerable punctate microcalcifications **(U5).** Several bulky lymph nodes were also noted in levels III and IV but with normal morphology. Subsequent FNA was reported to be in keeping with **THY5** and the patient underwent total thyroidectomy. The biopsy was then

reported as benign in keeping with nodular Hashimoto's thyroiditis with oncocytic metaplasia.
Case 2
52 yrs F with previous history of thyroidectomy for Hashimoto's thyroiditis and IgG4 disease on a background of other autoimmune diseases such as Raynauds and fibromyalgia. After presenting with dysphagia underwent USG assessment which identified an incidental hypoechoic vascular lesion (7x5mm) at the left thyroidectomy bed (U3). FNA demonstrated lymphoid cell infiltrate consistent with Hashimoto thyroiditis.
Case 3
33 yrs F presented after noticing a new neck lump. USG assessment demonstrated both the thyroid lobes to be heterogeneous, slightly hypoechoic with fibrous stranding and patchy areas of increased vascularity in keeping with underlying thyroiditis. In the right lobe, 1.5 x 1.5 x 1.3 cm heterogeneous predominantly hypoechoic, ill-defined nodule with areas of macro- as well as micro-calcifications were noted. The nodule seemed to invade into the overlying strap muscle in the anterior aspect. There was profound peripheral and internal vascularity **(U5).** Suspicious looking bulky lymph nodes were noted at levels 3 and 4 with mixed vascularity. Thyroid antibodies were elevated; FNA consistent with lymphocytic thyroiditis and a reactive lymph node. These cases highlight the potential setbacks and misdiagnosis of thyroid pathology if an underlying disease process is not appropriately investigated. We would recommend a clinician's interpretation of the sonographic findings along with the routine measurement of thyroid function and thyroid antibodies and an MDM referral as appropriate.

Evaluation of calcitonin measurment in fine needle aspitaion biopsy in the diagnostic of medullary thyroid carcinoma

Khelil Nour El Houda[1] & Meskine Djamila[2]
[1]Tlemcen Faculty Of Medicine, Departement of Endocrinology - Tlemcen Hospital, Tlemcen, Algeria; [2]Algiers Faculty Of Medicine, Algiers, Algeria

Medullary thyroid carcinoma (MTC) is a rare but relatively serious disease, whose prognosis depends on the stage of the tumor and the quality of the initial surgical treatment. The determination of the plasma calcitonin; cervical ultrasound, and fine needle aspiration biopsy are first line examinations; nevertheless they do not always make it possible to make a certain diagnosis in preoperative; moreover they do not define the MTC nodule in a multi nodular goiter and the metastatic lymph nodes. In this study; fine needle aspiration (FNA) and CT FNA were performed in 45 lesions. By comparing the results to histology; the sensitivity of the FNA for the diagnosis is estimated at 53.12% and the specificity at 92.30% while the sensitivity of the CT FNA is 96.87% and the specificity is 100% and this for a cut off >22.99 pg/ml. These results suggest that CT FNA; a simple; accessible and inexpensive exam; represents an interesting diagnostic approach that provides an additional argument for the positive and topographic diagnosis of MTC.

Application of TI-RADS and BETHESDA classification in the diagnosis of thyroid cancer

Mohina Salimova, Said Ismailov & Zulaykho Shamansurova
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Introduction
Malignant tumors of the thyroid gland are common in the field of endocrinology as an oncological disease. The diagnosis of thyroid cancer (TC) is based on sonographic and cytological methods. The widespread use of TI-RADS classification and the Bethesda System for Reporting Thyroid Cytopathology proposed by the American College of Radiology (ACR) and the U.S. National Cancer Institute (NCI) relatively significantly increases diagnostic accuracy. In this study diagnostic value of TI-RADS and Bethesda System for early detection of TC were assessed.
Material and methods
In 90 patients record cards who were admitted to surgery in Republican Specialized Scientific Practical Medical Centre Endocrinology ($n=$ 60) and Vitamed Clinic ($n=$ 30) with TC diagnosis during 2018-2021 years were analyzed. Patients were divided into two groups: Group 1 – TC were diagnosed by using TI-RADS and Bethesda and Group 2 - TC diagnosis performed based on traditional way. All patients underwent preoperative and postoperative follow-up, with determination of serum level of TSH, free T4, TG, Anti-TG, Anti-TPO, CEA titers. The results of US, fine needle aspiration biopsy (FNAB), express histology, and final histological examination were analyzed and compared between groups.
Results
The mean age of patients were 39.64 ± 1.4 years. TC diagnosed were in 6.5 times frequently in women than in men. The results of clinical and biochemical data of blood count did not differ in TC patients from healthy subject. In group 1, results of the study on modern classifications by the method of US and FNAB were matched in 80% of cases and TC was confirmed. However, in group 2, by traditional method TC confirmed only in 23%. In Group 1 the FNAB results in 83% were matched with after surgery histology. Whereas in group 2, the result was matched in 78.6% of cases. Moreover, In group 1, after surgery histology 100% corresponds to the final histological conclusion. While in group 2, the figure was 95%.
Conclusion
TC is mainly diagnosed in middle-aged patients. and was frequent in women than in men. Using Bethesda classification and TI-RADS were more informative and corresponds with FNAB results in 80% and 100% with after surgery histology, whereas with traditional way FNAB were matched only in 23% of cases and in 95% with final histology.

Hurthle cell carcinoma of the thyroid gland: diagnostic, therapeutic and prognostic features

Mohamed Masmoudi, Wadii Thabet, Chaima Zitouni, Ezer Chebil, Mehdi Hasnaoui & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Otorhinolaryngology, Tunisia

Introduction
Oncocytic tumors of the thyroid gland are rare (3-10 %). They are usually benign. Hurthle cell (oncocytic) carcinoma is uncommon: 5 % of thyroid carcinomas. Our aim is to describe the diagnostic, therapeutic and prognostic features of Hurthle cell carcinomas.
Materials and Methods
We report 3 cases of Hurthle cell carcinoma treated in our department between 1988 and 2021.
Results
Our series included 35 cases of oncocytic tumors. Hurthle cell carcinoma was noted in 3 cases. The mean age was 50 years [35 – 67 years]. All patients consulted for anterior neck mass with compressive symptoms. Ultrasonography showed a unique thyroid nodule in all cases: EUTIRADS 4 in 2 cases and EUTIRADS 5 in one case. The mean size was 4,1 cm. Thyroid-stimulating hormone (TSH) serum level was normal in all cases. Fine needle aspiration (FNA) result was "nondiagnostic" in all cases. Surgical treatment consisted of a thyroid lobectomy in all cases. The intraoperative examination was benign in all cases. The postoperative histological examination confirmed the diagnosis of Hurthle cell carcinoma; it was associated with papillary microcarcinoma in 1 case. All patients underwent totalization of the thyroidectomy with unilateral central neck dissection. No lymph node or distant metastases were noted. A complement by radioactive iodine was indicated in all cases. The evolution was favorable in all cases after a mean follow-up of 6.5 years.
Conclusion
The benignity or malignancy of oncocytic tumors cannot be confirmed by cytology. The diagnosis of malignant oncocytic tumor is usually made on postoperative histological exam. Surgery is the mainstay of treatment of Hurthle cell carcinomas. Responses to treatment with radioactive iodine are much lower when compared to other types of thyroid carcinomas. Hurthle cell carcinomas are more aggressive.

Thyroid cancer arising from thyroglossal duct cyst: What are the therapeutic strategies?

Mohamed Masmoudi, Wadii Thabet, Chaima Zitouni, Ezer Chebil, Mehdi Hasnaoui & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Otorhinolaryngology, Tunisia

Introduction
Thyroglossal duct cysts are the most common congenital cervical anomaly. Malignant transformation is very uncommon: 1-1.5%. However, therapeutic strategy is still not codified. Our aim is to describe the therapeutic features of thyroid cancer arising from thyroglossal duct cyst.
Materials and Methods
We report 3 cases of thyroid cancer arising from thyroglossal duct cyst, treated in our department between 1996 and 2021.
Results
Two men and one woman were included. The mean age was 17 years. The mean size of the cervical swelling was 36 mm. The treatment consisted of excision of the thyroglossal duct according to the Sistrunk procedure in the 3 cases. The diagnosis of malignancy was made on intraoperative examination in one case and on postoperative histologic exam in 2 cases. The histologic type was papillary carcinoma in all cases. Total thyroidectomy and radioactive Iodine were performed in all cases and bilateral central neck dissection was associated in two cases. The evolution was favorable in all 3 cases after a mean follow-up of 30 months.
Conclusion
The therapeutic management of thyroid cancer arising from thyroglossal duct cyst remains a subject of debate regarding the need for thyroidectomy and radioactive iodine. According to several authors, carcinoma can develop de novo within the thyroglossal duct, while others believe that the thyroglossal duct may be a natural route for the spread of carcinoma from the thyroid gland.

DOI: 10.1530/endoabs.81.EP1144

EP1145

Thyroid ultrasound characteristics in malignancy prediction

Valentina Velkoska Nakova
Clinical Hospital, Faculty of Medical Science, University Goce Delcev, Internal Medicine, Stip, Macedonia

Objective
To evaluate the diagnostic accuracy of thyroid ultrasound characteristics of nodules in prediction of malignancy.
Material and methods
Retrospectively were analyzed 102 patients who underwent for FNA biopsy of thyroid nodule. All patients were examined by one ultrasound examiner. Size, taller than wide, echogenicity, borders, halo, calcification, and internal vascularity were recorded in all examined nodules. The Bethesda System for Reporting Thyroid Cytology was used in all cytological diagnoses.
Results
Out of the 102 patients, 88 (86.3%) were females. The mean age was 58.7 ± 14 years. The study included 14 malignant and 88 benign nodules. Size, microcalcification and internal vascularization showed statistically significant positive associations with thyroid malignancy ($P < 0.05$). The highest OR was found for the microcalcification (22.5 95% CI 4,48-112,78). The sensitivity and specificity of ultrasound characteristics in predicting malignancy were: size 66.76% (95% CI 34.89 – 90.08%) and 70.45% (95% CI 59.78 - 79.71%); microcalcification 83.33% (95% CI 51.59 -97.91%) and 81.82 (95% CI 72.16 – 89.24%); and internal vascularization 66.67% (95% CI 34.89 – 90.08%) and 68.18 (95% CI 57.39 – 77.71%), retrospectively. Each ultrasound characteristic had negative predictive value from 93 - 97% in malignant nodules.
Conclusion
The presence of microcalcification was found the most important criteria in prediction of thyroid malignancy.

DOI: 10.1530/endoabs.81.EP1145

Papillary carcinoma of the thyroid associated with Marine-Lenarth syndrome: about a case

Amira Bouchenna[1], Abdelghani Tibouk[2], Ghennam Brahim[3] & Ould Kablia Samia[1]
[1]Central Hospital of Army, Endocrinology, Algeria; [2]Central Hospital of Army, Anatomopathology, Algeria; [3]Central Hospital of Army, Nucleary, Algeria

Introduction
The Marine-Lenhart syndrome (MLS) is commonly defined as a combination of Graves' disease and autonomous functioning thyroid nodule (s). the risk of malignancy of these nodules is less than 1% We report a case.
Observation
27-year-old patient, hospitalized for treatment of a basal disease, cervical ultrasound found a 1.5 cm lower left lobe thyroid nodule classified eutirads 4. the sintigraphy found an aspect of diffuse hypercaptive goiter, TSI rate at 18 ui/l, confirming the SML. fine needle aspiration of the nodule is suspected of malignancy. a total thyroidectomy is performed after preparation with lugol. anatomo-pathological examination found a papillary carcinoma of the thyroid of 1.5 cm classified PT1bNxMx supplemented by iratherapy of 30mci
Discussion
MLS can affect up to 4% of Graves' disease cases. Since the reported incidence of malignancy in all cold nodules is about 1%, it's recommend to practice ultrasound and FNAC before treatments.

EP1147

Papillary thyroid carcinoma in its cystic form: a case report

Kamel Farah, Loubna Guissi, Kaoutar Rifai, Hinde Iraqi & Mohammed Hassane Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
The cystic nodule is an unusual presentation of papillary thyroid carcinoma (PTC), seen in less than 10% of cases. Ultrasound discovery of a thyroid cyst represents less than 5% risk of malignancy. We report the case of a patient followed for papillary thyroid carcinoma in its cystic form.
Observation
A 42-year-old patient with no specific history. The patient underwent a right isthmolobectomy for a thyroid nodule. Anatomopathological examination of the surgical specimen revealed a thyroid cyst with endocystic vegetations of papillary appearance, totally necrotic, in favour of a papillary carcinoma in its cystic variant. Then the patient underwent a left totalization with benign histology. The postoperative course was simple. This tumor is classified as PT1aNxMx with low risk of recurrence. The patient benefited from TSH- suppressive Levothyroxine therapy, with good clinical and biological evolution.
Discussion
The malignant potential of cystic thyroid nodules should never be neglected, even if it carries a low risk of malignancy. The diagnosis of PTC in its cystic form relies primarily on typical nuclear features, however, in case of histologic uncertainty, immunohistochemical stains such as HBME-1 can be used to help classify unusual presentations of PTC. Treatment and monitoring of cystic PTC follows the conventional guideline for solid PTC.
Conclusion
Papillary thyroid carcinoma in its cystic form is rare. Our case illustrates the importance of the management of cystic thyroid nodules with an adapted follow-up in order not to ignore a malignant etiology such as papillary thyroid carcinoma.

Metastasis of breast cancer in the thyroid gland: Report of two cases

Mehdi Ferjaoui, Emna Bergaoui, Maroua Naouar, Amel Elkorbi, Rachida Bouattay, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Hôpital Fattouma Bourguiba, ENT, Monastir, Tunisia

Introduction
Breast cancer is the most frequently diagnosed cancer in women. Common sites of metastatic spread are bone, lungs and liver. Metastases to the thyroid gland are exceptional.
Objectives
The aim of the study is to document two rare cases of thyroid metastasis from breast carcinoma and to specify their clinical, radiological and therapeutic particularities.
Methods
Review of 2 clinical cases of thyroid gland metastasis identified in women with no known breast carcinoma.
Case1
73-year-old patient with a history of chronic renal failure, was referred to our department for an anterior cervical tumefaction evolving for 8 months. The physical examination showed a lower anterior cervical swelling. Cervical ultrasound showed a 3 cm calcified left thyroid nodule. The patient underwent a left lobo-isthmectomy. The final pathology with immunohistochemical studies revealed an intrathyroidal metastasis from an infiltrating ductal carcinoma of the breast. The patient was therefore referred to her gynaecologist and the primary breast origin was confirmed. The evolution was good with a follow-up of 24 months.
Case2
The second case was a 70-year-old woman with no pathologic history, admitted for the management of high dyspnea and progressive dysphonia for 2 months. On examination, she presented a hard lower cervical swelling with a non-palpable lower border, without cervical adenopathy. Laryngoscopy showed a fixity of the left vocal cord. Cervical ultrasound and scan confirmed the thyroid origin of this mass by showing a plunging calcified lower left nodule. Fine needle aspiration, suggested a follicular thyroid carcinoma. The treatment was surgical. The patient underwent a total thyroidectomy with bilateral dissection of sectors VI and a tracheotomy for her dyspnea. The histological examination revealed an intrathyroidal metastasis of a poorly differentiated carcinoma of the breast. The patient was then lost sight of.
Conclusion
Intra thyroid metastases, although rare, should be considered in any patient, especially females. Rarely observed in clinical practice, they often pose a diagnostic and therapeutic challenge.

EP1149

A female patient with diffuse sclerosing variant of papillary thyroid cancer and background autoimmune thyroiditis

Zoi Efstathiadou[1], Athanasia Michou[1], Efstathios Divaris[1], Apostolos Gogakos[1], Athanasios Panagiotou[1], Prodromos Hytiroglou[2] & Marina Kita[1]
[1]"Hippokration" General Hospital of Thessaloniki, Department of Endocrinology, Thessaloniki,; [2]Aristotle University of Thessaloniki School of Medicine, Department of Pathology

Introduction
Diffuse sclerosing variant of papillary thyroid carcinoma (DSPC) represents a rare but rather more aggressive subtype of PTC.
Purpose
Description of a patient with DSPC and background autoimmune thyroiditis.
Case description
A 33-year-old female patient reported extensive neck swelling that had progressed over several months. The patient had been diagnosed with hypothyroidism attributed to autoimmune thyroiditis, 3 years before. At that time, goiter was also found with a reported predominant nodule in the right lobe. On examination, the patient was euthyroid, with a palpable enlargement of the right lobe and isthmus, with particularly hard texture. Ultrasound imaging revealed diffuse enlargement of the thyroid gland particularly of the right lobe, where a formation of a suspicious mass was noted. Linear hyperechogenic foci were dispersed throughout the entire thyroid surface. Hypoechogenic areas with ill-defined borders were noted centrally, possibly representing lymph nodes. A fine-needle aspiration biopsy of the right lobe was positive for papillary thyroid cancer and the patient underwent total thyroidectomy. Histopathology showed a 2.4 cm papillary carcinoma of the right lobe, with psammomatus bodies, squamous metaplasia, and background sclerosis. Vascular infiltration by the tumor cells was present. The remaining thyroid parenchyma exhibited extensive lymphocytic and plasmatocytic infiltrates with abundant lymphoblastic centers. Dispersed foci of the neoplasm were observed in all sections of the entire gland. Metastases were recognized in 3 excised central lymph nodes. A few weeks later the patient underwent a completion surgery with central and right lateral compartment exploration, with metastases found in 13/24 and 4/30 lymph nodes, respectively.
Conclusions
The imaging characteristics and the overlapping presence of Hashimoto's thyroiditis can lead to a delayed diagnosis of DSPC. Considering the more aggressive nature of this variant, raising awareness for early recognition of its particular ultrasonographic characteristics is of paramount importance for effective treatment and improved prognosis.

Ectopic cushing's syndrome : a rare cause

Eirini Vourlioaki, Paraskevi Floroskoufi, Aspasia Kouloukoura, Eleftheria Argyropoulou & Aikaterini Stamataki
Venizeleio General Hospital of Heraklio, Endocrinology Department, Heraklio, Crete, Greece

Introduction
Medullary thyroid carcinoma (MTC) accounts for 1-5% of all thyroid cancers. It is a neuroendocrine tumor arising from the calcitonin-secreting parafollicular cells of the thyroid. In rare cases, the neoplastic cells additionally secrete other substances, such as histamine, serotonin, ACTH, CRF etc, leading to paraneoplastic syndromes.
Case report
An 80 year old male presented to our Department with an already diagnosed metastatic MTC. Three years ago he had undergone a total thyroidectomy together with a right cervical lymph node dissection. His pre- and post-thyroidectomy calcitonin measurements were 2900 and 400pg/ml, respectively.
Past medical history
Rheumatoid arthritis At his present visit, he was in good clinical condition. Calcitonin and CEA were measured 3640pg/ml and 123ng/ml, respectively. Whole body imaging revealed metastatic lymph nodes on the right cervical area and the upper mediastinum, as well as multiple secondary liver lesions, larger than those shown in last imaging. Because of disease progression, the patient was commenced on Vandetanib (Tyrosine Kinase Inhibitor, TKI) 300 mg/d. One month later, he presented with an itchy maculopapular, exanthema, starting from face and upper extremities and extending rapidly to almost the whole body, with local exfoliation and inflamation and was barely tolerated by the patient. Antibiotics, antihistamines and local and systematic corticosteroids were administered, with almost no improvement. Vandetanib had to be discontinued for four months, during which the exanthema subsided to a great extent, while, concomittantly, melanchrosis appeared on the upper extremities and then almost everywhere on the body. In addition, the patient complained about proximal weakness and had oedema on lower extremities. Imaging and blood tests showed disease progression. There was suspicion of hypercortisolism which was confirmed by relevant tests and led to diagnosis of ECS. The patient was then administered Metopyrone 250 mg bid and Cabozatinib 40 mg/, which is a different TKI. Six months later, the patient is in good clinical condition, with almost no symptoms. Imaging and biochemical tests show stabilization of the disease.
Conclusion
At most 0,7% of patients with MTC are reported to develop ECS. MTC represents 2,2-7,5% of all causes of ECS. ECS rises morbidity and mortality of MTC, due to consequences of hypercortisolism. TKIs are considered as the first-line therapy for ECS in the setting of unresectable or progressive MTC.

Papillary thyroglossal duct carcinoma: report of two cases

Mehdi Ferjaoui, Emna Bergaoui, Maroua Naouar, Amel Elkorbi, Rachida Bouattay, Kaled Harrathi, Naourez Kolsi & Jamel Koubaa
Fattouma Bourguiba Hospital, ENT, Monastir, Tunisia

Introduction
The thyroglossal duct cyst is frequently diagnosed in front of an anterior cervical swelling. Its degeneration is possible and observed in 1% to 2% of cases. The clinical feature is not specific, and the diagnosis of malignancy is most often established on final histological examination.
Purpose of review
The purpose of this paper is to review the presentation of thyroglossal duct carcinoma and discuss the clinical and therapeutic particularities.
Methods
Two cases of papillary carcinoma developed on a thyroglossal duct were identified over a period of 12 years (2010-2021).
Results
A man and a woman with no pathological history, aged 44 and 27 years old, consulted for upper cervical swelling evolving for 5 months and 3 years. The physical examination found an add-hyoid swelling of four cm and two cm, mobile on the protraction of the tongue. Cervical ultrasound suggested the degeneration in one case. The Sistrunk operation was performed associated with total thyroidectomy at the same time in a single case where the extemporaneous examination suggested malignancy. The histological study confirmed a papillary carcinoma developed on a thyroglossal duct in both cases. The other patient therefore underwent a thyroidectomy in a second time. Both patients were put on frenetic hormone therapy. Additional Iodine radiation therapy was indicated in both cases. With a follow-up of 12 months no one showed recurrence.
Conclusion
Malignancy on thyroglossal duct cyst is a rare situation. Papillary carcinoma is the most common cancer. The treatment remains a subject of debate, even if, currently, most authors recommend associating a total thyroidectomy with the Sistrunk procedure.

Cholestatic jaundice: think of thyrotoxic hepatitis

Kaoutar Rifai, Loubna Guissi, Salma Ahallat, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Liver dysfunction during hyperthyroidism may be secondary to thyrotoxicosis, to an associated liver pathology, or to the medical treatment of hyperthyroidism posing a problem of etiological diagnosis. In this context, we report a demonstrative observation.
Case presentation
We report the observation of a 23-year-old female patient, followed for Basedow disease under carbimazole since 1 year, not controlled under medical treatment. During her follow-up, she presented cholestatic jaundice, associated with significant cytolysis and biological cholestasis, which persisted despite the discontinuation of synthetic antithyroid drugs. Biliary tract obstruction, viral or autoimmune hepatitis, and primary biliary cirrhosis were excluded. Liver biopsy showed lymphocytic infiltrate with discrete hepatic steatosis without stigma of autoimmune or toxic hepatitis. Our patient was treated only with Iodine 131. The post-iratherapy evolution was marked by the achievement of clinical and biological euthyroidism with normalization of the hepatic balance. This constitutes a major argument in favor of the thyrotoxic origin of this hepatopathy.
Discussion
Jaundice, during uncomplicated thyrotoxicosis, is rare and moderate (5-11%). Its exact etiopathogenesis remains poorly elucidated. An increased hepatic oxygen consumption due to hypermetabolic state not compensated by an increase in hepatic blood flow has been suggested. This imbalance leads to a decrease in oxygen tension in the centrilobular areas, which may lead to hepatocyte dysfunction with cholestasis. On anatomopathological examination, lymphocytic infiltrate in portal spaces, vacuolation and more rarely hepatic steatosis and intrahepatic cholestasis are often described, which was found in our patient.
Conclusion
Hyperthyroidism is an unusual cause of cholestatic jaundice that should be evoked in the absence of underlying liver disease.

Role of plasmapheresis in the management of severe amiodarone-induced hyperthyroidism refractory to conventional medical treatment

Belén García Izquierdo[1], Macarena Contreras Angulo[2], Laura Armengod Grao[2], Carlos García Gómez[2], Álvaro García García[3], Azucena Losa Maroto[3], José Luis Bueno Cabrera[3], Miguel Juan García-Oria Serrano[4], Encarnació n Donoso[5] & Pedro Iglesias[2]
[1]Hospital Universitario Puerta de Hierro Majadahonda, Endocrinology and Nutrition, Majadahonda, Spain; [2]Hospital Universitario Puerta de Hierro Majadahonda, Endocrinology and Nutrition, Madrid, Spain; [3]Hospital Universitario Puerta de Hierro Majadahonda, Hematology, Madrid, Spain; [4]Hospital Universitario Puerta de Hierro Majadahonda, General and Digestive Surgery, Madrid, Spain; [5]Hospital Universitario Puerta de Hierro Majadahonda, Biochemistry, Madrid, Spain

Introduction
Amiodarone is an antiarrhythmic drug whose high iodine content may influence thyroid function. The first line treatment of amiodarone-induced hyperthyroidism (AIH) is mainly medical. Plasmapheresis has been used in cases of antithyroid intolerance or refractory hyperthyroidism, although clinical experience is poor.
Clinical case
We present a case of a patient with structural heart disease and severe AIH refractory to medical treatment who required a high number of plasmapheresis cycles to achieve adequate control of thyroid function before definitive treatment. A 53-year-old man, with atrial fibrillation treated with amiodarone (200 mg/day) for 3 years until 2 months prior to admission, was hospitalized due to chest pain. Echocardiography showed an atrial septal defect, with indication for non-urgent surgical closure. During admission, severe hyperthyroidism was discovered (TSH <0.01 µIU/ml, normal range (NR): 0.35-5.0; free T4 (FT4) 10.03 ng/dl, NR: 0.7-1.98; and free T3 (FT3) 9.3 pg/ml, NR: 2.3-4.2). A grade 2 diffuse goiter was palpable. Thyroid autoimmunity study was negative. Suspecting AIH, medical treatment with antithyroid drugs and corticosteroids was started. The difficulty in controlling thyroid function led to an increase in treatment up to 45 mg/day of methimazole, prednisone (90 mg/day), cholestyramine (16 g/day) and of potassium perchlorate (800 mg/day). After 3 weeks, hyperthyroidism persisted (TSH $<$ 0.01 µIU/ml, FT4 11.92 ng/dl and FT3 9.76 pg/ml), establishing the diagnosis of severe AIH refractory to medical treatment; therefore, total thyroidectomy was considered. In order to reduce the perioperative cardiovascular risk, treatment with plasmapheresis was started. As complications, he presented several episodes of skin rash, a slight tendency to anemization (hemoglobin nadir 11.2 g/dl, NR: 12.0-17.0) and asymptomatic hypocalcemia with a minimum value of 7.6 mg/dl (NR: 8.7-10.3 mg/dl). After 17 sessions of plasmapheresis, a reduction in circulating levels of thyroid hormones was achieved (TSH 0.01 µIU/ml, FT4 4.33 ng/dl and FT3 4.95 pg/ml), which allowed definitive treatment with surgery 40 days after diagnosis.
Conclusion
Plasmapheresis in association with medical treatment is a useful tool in the management of severe AIH refractory to conventional therapy with maximal doses in preparation for definitive treatment with thyroid surgery.

EP1154

Stop oral therapy and start later: This is a new perspective for hypothyroid patients who need lifelong intravenous levothyroxine

Zafer Pekkolay
Dicle University Faculty of Medicine, Endocrinology, Diyarbakir, Turkey

Introduction
Although the replacement route is oral in most hypothyroid patients, euthyroidism cannot be achieved with oral therapy in some patients rarely (1). Although oral levothyroxine is used above the standard dose (1.6-1.9 mg/kg/day), there is resistance to oral therapy if there are laboratory and clinical signs of hypothyroidism (2). Crushing the drug and using it with vitamin C increases the absorption of levothyroxine (3). Rarely, some patients require lifelong intravenous levothyroxine.
Case report
Total thyroidectomy was performed in a 60-year-old female patient in 2014, after thyroid nodule FNAB result was found to have AUS. Its pathology was reported as medullary thyroid cancer. Despite increasing oral doses of levothyroxine after surgery, the patient with severe hypothyroidism had a negative pseudomalabsorption test, a negative celiac panel, and a negative Helicobacter pylori antigen. Although the patient was given high doses of levothyroxine and lioiodotroin, his hypothyroidism did not improve. Combining levothyroxine with vitamin C/acid

drinks and crushing the levothyroxine tablet did not ameliorate hypothyroidism. Euthyroidism was achieved with intravenous levothyroxine 200 mg/session three times a week (Table 1). Due to a change in our healthcare system, the patient could not receive intravenous treatment for about two months. The patient drank 450 micrograms of levothyroxine to overcome this problem by dissolving it in tap water. The patient's thyroid function tests, who came to the outpatient clinic in the first month of this treatment, were euthyroid. Euthyroidism was observed again in the patient who used the treatment he received for one more month (Table 2).

Table 1 Patient's history summary

Age (year), Gender	*60, Female*
Hypothyroidism etiology	*Medullary Thyroid Cancer*
Duration of hypothyroidism (year)	*7*
Levothyroxine dose	*600 mg/week/intravenous*
Pseudomalabsorption	*Negative*
Celiac panel	*Negative*
Helicobacter pylori antigen	*Negative*
LT4 + LT3	*No-response*
LT4 intake with vitamin C/sodas	*No-response*

Table 2 Oral levothyroxine only (450 mcg/day)

	1st month of treatment	2nd month of treatment
TSH (mU/l) (0,27-4,2)	**0,7**	**0,88**
Free T3(ng/dL) (0,93-1,7)	**0,8**	**1,0**
Free T4(pg/mL) (2,0-4,4)	**1,8**	**2,0**

Comment and new perspective:
The patient, who needed a total of 600 mg intravenous per week for seven years, switched to oral therapy because intravenous therapy could not be performed. Clinical response was obtained from the patient. In patients who do not respond to oral therapy in the first period, oral therapy can be tried later. This may indicate that intestinal levothyroxine absorption may increase after oral levothyroxine absorption is not taken for a while.

Refractory hypothyroidism and chronic gastritis

Mohamed Malad, Errahali Yassine, Malak Riznat & Guerboub Ahmed Anas
Mohamed V Military Training Hospital, Endocrinologie, Rabat, Morocco

Introduction
Refractory hypothyroidism is a fairly common situation in the practice of any endocrinologist, being defined by the persistence of hypothyroidism despite adequate doses of replacement therapy with Levothyroxine, generally supraphysiological. We report the case of refractory hypothyroidism under high doses of Levothyroxine.
Observation
she was a 54-year-old woman, diabetic Type2, followed for 06 years for papillary carcinoma of the thyroid gland, for which it was operated and irradiated, currently in clinical, biological and morphological remission. she was already under 325 µg/day of levothyroxine taken orally, or 4 µg/kg/day, for a target of TSH between 0.1 and 0.5, by the way as a TSH suppressant treatment. The patient recognizes having a regular pace of taking his medication without omission or errors related to the schedule of her medication. On examination, she shows symptoms of hypothyroidism, asthenia and pallor, with infiltration of the face and integuments. Biology revealed a TSH = 30 IU/ml, and FT4 at 0.58ng/dL (usual values between 0.7 and 1.5). An oral thyroid hormone absorption test was performed, at a dose of 1000 µg in a single dose on an empty stomach, under strict medical supervision. The FT4 assay was performed at times 0, 1h, 2h, 3h, and at 24h after intake. The results showed the absence of elevation of FT4, which is in favor of malabsorption. After elimination of the obvious causes, a malabsorption assessment was requested and returned without anomalies: the total cholesterol level at 1.8 g/l, ferretinemia at 77 mg/l, calcium phosphorus and vitamins B9 and B12 normal. A serology of celiac disease, anti-parietal antibodies, and digestive fibroscopy were requested. This finally led to the diagnosis of autoimmune gastritis, considered the cause of the malabsorption of levothyroxin. The patient was put under levothyroxine in the form of soft capsules and has marked a good evolution.
Conclusion
Our observation illustrates the interest of the thyroid hormone absorption test, a key examination to distinguish between true malabsorption and pseudo-malabsorption. This load test must lead to an etiological assessment in search of an organic cause for the malabsorption.

Low testosterone: An unexpected journey

Jessica Lee[1], Edel Casey[1], Anna Hawkins[1], Antony Pittathankal[1, 2], Raj Tanday[1], Syed Imran[2], Gideon Mlawa[3] & Khash Nikookam[1,2]
[1]King George Hospital, United Kingdom; [2]Spire London East Hospital (Formerly Spire Roding Hospital), Ilford, United Kingdom; [3]Queen's Hospital, United Kingdom

A 68 year old gentleman referred to endocrinology clinic with a few years history of erectile dysfunction (ED), which manifested as reduced libido and partial erections. Investigations revealed primary hypogonadism with a low morning serum Testosterone of 4.8 (Ref: 7.9-31 nmol/l), raised FSH at 47 (Ref:1.5-12.4 iu/l) LH at 36.8 (Ref: 1.7-8.6iu/l) and normal thyroid function tests (TFTs). The patient declined testosterone replacement therapy following a discussion of pros and cons of the risk vs benefit. Clinical examination revealed a deep seated right thyroid lobe and also a possible right thyroid nodule. Ultrasound (US) thyroid showed a right U3 nodule of 6.3x4.1mm. Subsequent cytology following US guided Fine Needle Aspiration (FNA) of the right U3 nodule revealed Thy3f. According to the Royal College of Pathologists [1] Thy3f suggest follicular neoplasms whose characteristics are difficult to distinguish between benign or malignant nature. The Royal college of pathologists also states that the malignant potential of Thy3f nodules to be approximately 15-30% [1]. The options of surgery vs monitoring by means of US guided FNA of the thyroid nodule were discussed. Patient opted for the latter option, repeat Cytology showed Thy1 (non-diagnostic). In view of all of the above and the recommendation from the British Thyroid Association guidelines, patient elected for right hemithyroidectomy [2]. The histology revealed the presence of variable size thyroid follicles containing colloid material and no evidence of malignancy. Patient had an uneventful post-operative recovery, and subsequent examination showed a well healed post thyroidectomy scar.
Conclusion
While modern clinical practice tends to lean towards investigations and imaging to guide clinical management, a good history, thorough examination and patient engagement should always be at the cornerstone of every consultation. This in turn can lead to improved patient care and outcome.

From benign cytology to papillary thyroid carcinoma

Yasmin Nikookam[1], Bonnie Grant[1], Usman Shah[1], Gideon Mlawa[1], Anna Hawkins[1], Edel Casey[1], Antony Pittathankal[1, 2], Imran Syed[2] & Khash Nikookam[1,2]
[1]Barking, Havering and Redbridge University Hospitals NHS Trust, Greater London, United Kingdom; [2]Spire London East Hospital, Greater London, United Kingdom

Thyroid cancer is the most common endocrine malignancy with an increasing incidence globally predominantly due to the papillary thyroid carcinoma subtype. It is the 17th and 20th most common malignancy in females and males respectively. In 2018, Cancer Research UK reported 3865 new cases and 400 deaths. Mortality rates are predicted to continue to rise in the UK with an estimated rate of 1 per 100,000 deaths in 2035. We present a 42-year-old female

who presented with a 3-year history of lethargy, tiredness, poor concentration and hair loss. She had a history of iron deficiency anaemia previously requiring iron transfusions. On clinical examination and neck palpation rather tender and prominent thyroid isthmus noted. She was biochemically euthyroid with TSH 3.65 mU/l (range 0.27-4.2 mU/l), free T4 13.15 pmol/l (range 12-22 pmol/l) and free T3 4.7 pmol/l (range 3.1-6.8 pmol/l). Other blood tests showed vitamin D deficiency and an iron deficiency anaemia. Thyroid ultrasound (US) identified a large heterogenous exophytic left paracentral isthmus thyroid nodule measuring 2.1 x 1.1 cm with moderate vascularity within the nodule, classified as U3. Fine needle aspiration cytology (FNAC) described a colloid nodule (Thy2) with no malignant features seen. The management options were jointly discussed with the patient; do nothing, surveillance with repeat US and FNAC or referral for surgery. The patient opted for repeat US performed four months later which showed the nodule had slightly increased in size to 2.4 x 1 cm with significant heterogenicity within the solid and cystic components and moderate vascularity, classified again as a U3 nodule. Repeated FNAC was Thy2 with no malignant cells seen The options of doing nothing, repeated radiological surveillance or surgery were discussed further with the patient and she opted to undergo a left hemithyroidectomy. Histology revealed a 1.1mm focus of papillary thyroid carcinoma (pT1a) within the nodule. She recovered well post-operatively and thyroid function showed TSH 6.64 mU/l, FreeT4 11.2 pmol/l and Free T3 4.3 pmol/l for which she has been started on levothyroxine.

Conclusion

UK guidelines recommend an ultrasound (U) graded radiological examination in patients with thyroid nodules which then determines the patients who require fine needle aspiration cytology to aid diagnosis. This case highlights that thyroid nodule size, particularly if there has been an increase, may correlate with malignant potential. This has been emphasised in the American Thyroid Association management guidelines, but does not feature within UK guidelines.

EP1158

The combination of multi-nodular goiter and Thevenard's disease: about 3 familial cases

Ihssane Abidi, Kaoutar Rifai, Iraqi Hinde & Mohamed Elhassan Gharbi
University Mohammed 5 Rabat, Endocrinologie, Rabat, Morocco

Introduction

Thevenard's disease is a sensory neuropathy with a type of ulcerative-mutilating acropathy of progressive course. It has a hereditary character with autosomal dominant inheritance. It is a scarce disease, which usually affects feet but can also affect hands. It causes disorders of thermoalgesic sensitivity, leading to painless ulcerations at the pressure points and then bone deformities with osteoarticular destruction and 'cubic foot' appearance. Repeated superinfections, often with multi-resistant germs, are the cause of frequent amputations. Les surinfections à répétition, à des germes souvent multi-résistants, sont à l'origine des amputations fréquentes. We report the case of the three sisters who suffer from Thevenard's disease with multinodular goiter.

Cases

They are three sisters whose age varies between 30 and 40 years, they are under treatment for Thevenard's disease since the age of 18, with unilateral transtibial amputation in the three and deformities of the third phalanges of the hands in the youngest. They had multi-nodular goiter in euthyroidism (Tirades 2 and 3 nodules) revealed around the age of 30. The autoimmunity record was negative. They were operated on for signs of compression (dysphonia+). Anatom examination opathological was benign with signs of thyroiditis among the three sisters. The clinical and biological course was good under L-thyroxine. Note that there is no notion of goiter in their family or other predisposing factors.

Discussion

Thevenard's disease begins during adolescence or in adult age. Its diagnosis is made in practice, on bundles of clinical, electrophysiological and family arguments. Neuromuscular biopsy has only a differential diagnostic interest, discarding other polyneuropathies responsible for impaired thermoalgic sensitivity, such as diabetic, amyloid, para-amyloid and leprous neuropathies. The diagnosis of certainty requires the detection of a mutation in the SPTLC1 gene. Preventive treatment of skin lesions is the mainstay of the care of these patients because no curative treatment is available. Its association with multinodular goiter has not been reported in the literature. Moreover, this association among three sisters suggests a link between Thevenard's disease and nodular goiter which remains to be defined.

Conclusion

Goiter is most commonly caused by iodine deficiency, autoimmune or nodular diseases. Nevertheless, its appearance outside these circumstances and in association with serious diseases such as Thevenard's disease opens up a perspective for clinical and genetic research.

Role of iratherapy in the treatment of Graves' disease in children: a case report

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco

Introduction

Graves' disease is a rare and severe disease in children with a marked female predominance. The diagnosis is made in front of a very suggestive clinical picture most often grouping together a goiter, an exophthalmos and a picture of thyrotoxicosis, confirmed biologically by the presence of hyperthyroidism with positive anti-TSH receptor antibodies and radiologically by diffuse, homogeneous, hypervascular goiter. There are three essential therapeutic weapons: synthetic antithyroid drugs, radioactive iodine or surgery. We report the observation of an adolescent girl in whom Graves' disease posed management difficulties.

Observation

We report the case of a 12-year-old patient, followed for Graves' disease for 4 years on 40 mg per day of carbimazole with poor adherence to therapy. She currently has a thyrotoxicosis syndrome made up of palpitations and thermophobia. Cervical examination revealed a diffuse and homogeneous goiter. Biological hyperthyroidism is confirmed by suppressed TSH. The thyroid scintigraphy showed hyperfixing goiter. The patient underwent iratherapy treatment at a dose of 20 mci with a good clinical course and obtaining biological hypothyroidism after 6 months. LT4 treatment was started.

Discussion and conclusion

Graves' disease is rare in children. It occurs in 0.02% of children. Its positive diagnosis is often easy, but its disease management remains a subject of controversy in pediatric endocrinology. Medical treatment with synthetic ant thyroid drugs is always attempted as a first-line treatment. Other treatment alternatives are surgery and iratherapy which allows rapid healing while avoiding complications from surgery.

Surgical treatment of Graves' disease

Mohamed Masmoudi, Marwa Regaeig, Wadii Thabet, Azer Chebil, Mehdi Hasnaoui & Khalifa Mighri
Tahar Sfar Hospital, Mahdia, Otorhinolaryngology, Tunisia

Introduction

Graves' disease is an autoimmune disease of the thyroid gland, which represents the most common cause of hyperthyroidism, accounting for 50 - 80% of all cases. Three treatment options are available for Graves' disease: anti-thyroid drugs, radioactive iodine and thyroidectomy. But therapeutic management is still controversial. The aim of our study is to discuss, after a review of the literature, the role of surgery in the treatment of Graves' disease.

Patients and methods

We conducted a retrospective study of medical records of 40 patients who underwent surgery for Graves' disease in our department between 1996 and 2019.

Results

Our series included 30 women and 10 men, aged between 11 years and 63 years. All our patients had hyperthyroidism. Thirty-eight patients had a diffuse goiter whereas the gland was not palpable in 2 patients. A vascular thrill was perceived in 4 patients. Twelve patients had Graves' orbitopathy. All our patients were treated with anti-thyroid drugs and β blockers. The average duration of medical treatment was 18 months. No patient in our series was treated with radioactive iodine. Indications for surgery were: failed medical therapy after 2 years of treatment (29 cases), a compressive goiter (4 cases), concomitant suspicious thyroid nodules (4 cases), second effect of antithyroid drugs (2 cases) and pregnancy (1 case). All our patients had a total thyroidectomy. Seven patients

developed post operative complications: transient hypocalcemia in six cases and recurrent laryngeal nerve palsy in one case. No case of recurrent disease was noted.
Conclusion
Total thyroidectomy is the more efficient radical method for treating patients with Graves' disease. It offers rapid and durable control of hyperthyroidism.

Case report: Amiodarone-induced thyroid dysfunction

Faten Haj Kacem Akid, Oumeyma Trimeche, AbdelMouhaymen Missaoui, Dhoha Ben Salah, Mnif Fatma, Nadia Charfi, Mouna Mnif, NABILA REKIK MAJDOUB, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Amiodarone is considered by many the most potent antiarrhythmic drug. The other side of the coin is that it's associated with many side effects including disturbances in the thyroid function, which can be seen in 14 to 18 % of the cases (1). This case is about a 56-year-old male patient with a history of mitral valve disease who was on Amiodarone for 3 years. His personal history was notable with Epilepsy of unknow etiology for which he was on sodium valproate. During follow-up, the thyroid function was assessed twice at a 1-month interval and results were consisting with a patent hyperthyroidism. One month later, the patient was referred for our endocrine department and lab work revealed this time hypothyroidism. Thus, the patient was treated with levothyroxine. This case highlights the effects of Amiodarone on the thyroid gland and demonstrate the possible spontaneous evolution of amiodarone induced thyrotoxicosis into hypothyroidism.

Hypothyroidism : the interest of thyroid hormone test

Yasmine Mouelhi, Nadia Khessairi, Ameni Terzi, Wafa Grira, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Hypothyroidism is a common endocrine disease with reduced systemic metabolism and its treatment consists on hormonal supplementation. However, despite concurrent replacement therapy with high doses of L-thyroxin, some patients might be seen with clinical and biochemical evidence of hypothyroidism. We report a case of persistent hypothyroidism on high dose of levothyroxin.
Case presentation
It was a 41-year-old female, with a history of recurrent chronic Helicobacter pylori gastritis and total thyroidectomy for a multinodular goitre in 2017, treated with 900 µg per day of L-thyroxin with good compliance and regular intake. She was admitted in our department in December 2021 for exploration. Clinically, she had signs of hypothyroidism: asthenia, puffy face, pudgy fingers and macroglossia. Biology revealed a TSH= 55.32 µUI/ml and a FT4 < 0.42 ng/dl. A levothyroxin absorption test under medical supervision was performed with 600µg of L-thyroxin. TSH and FT4 were measured before the test and at 2h, 4h, 6h and 24h after the test. The FT4 remained low with a peak at 0.48 ng/dl (2h after the start of the test). The test concluded that there was malabsorption of thyroid hormones. Serological markers for celiac disease and a new digestive fibroscopy were requested.
Conclusion
This case illustrates the interest of the thyroid hormone test which allows to distinguish between malabsorption and pseudomalabsorption, non compliance to the treatment. If the diagnosis of malabsorption is retained, further investigations for etiological purposes should be carried out.

Objective
Osteoporosis and osteopenia (OS/OP) are frequent in patients with cortisol-producing adrenal adenomas (CPA) associated with severity of cortisol excess (CE). However, the relationship between OS/OP and CE severity considering sex differences is unknown.
Patients and Methods
This was a retrospective cross-sectional observational study conducted as a part of the Advancing Care and Pathogenesis of Intractable Adrenal Disease in Japan (ACPA-J) study, which was based on a registration system for a cohort of patients with adrenal tumors. A total of 237 patients aged 20 to 90 who were diagnosed with mild autonomous cortisol secretion (MACS) and overt Cushing's sindrome (CS) originated from CPA between January 2006 to December 2015 in 10 referral centerswere included in the study. MACS was defined by 1-mg overnight dexamethasone suppression test (DST) cortisol level >1.8 µg/dL (50 nmol/l). OS was defined by less than -2.5 SD of the bone miniral density (BMD) T-score obtained from the lumbar spine or femoral neck, fragility fractures, and medication for osteoporosis. OP was defined as a value of -2.5 SD $<$ BMD T-score <-1.7 SD, without a history of fragility fracture and medication for osteoporosis.
Results
In total,112 of 237 patients, who were predominantly female ($P<0.001$) and had lower BMI ($P=0.013$), had OS/OP. Patients with OS/OP was significantly affected by CE ($P<0.01$) than those without. The adjusted odds ratio (OR) for predicting OS/OP was obtained in multivariate logistic regression analysis. Clinical measures of CE, 1-mg DST cortisol levels, were positively associated with OS/OP in total cases (OR 1.124, 95% CI: 1.070–1.181, $P<0.001$) and the cases with MACS (OR 1.156, 95%CI: 1.046–1.278, $P=0.005$). A cutoff value of 1-mg DST cortisol level >5.0 µg/dL was associated with OS/OP differently between men and women. OS/OP risk in men with MACS was significantly affected only by 1-mg DST cortisol levels (OR 1.221, 95%CI: 1.027–1.452, $P=0.024$). However, multivariate logistic regression analysis suggested that OS/OP risk in women with MACS was significantly affected by 1-mg DST cortisol levels (OR 1.129, 95% CI: 1.005–1.267, $P=0.041$) and age (OR 1.047, 95% CI: 1.006–1.090, $P=0.024$).
Conclusions
CE severity in CPA is positively associated with OS/OP. However, the associated factors of OS/OP in the patients with MACS are different between men and women.

Fresh pair of eyes for peri-menopausal lady

Yin Yin & Christopher McGettigan
QEQM Hospital, East Kent University Hospital NHS Foundation Trust, Endocrine and DM, Margate, Kent, United Kingdom

A 50-year-old peri-menopausal lady has had a background history of hypertension on single-agent antihypertensive medication (ACEI), chronic headache, recurrent collapses, and panic attacks for the past 14 years. She has been visited by her GP frequently and performed countless blood tests including FSH, LH, and TSH which confirmed that her symptoms were neither related to menopause nor hyperthyroidism. She also presented to the Emergency Department a dozen times and called paramedics 8 times for similar symptoms. She was diagnosed with panic attacks or investigated for meningitis. Her symptoms have never been resolved or getting better after discharge from the hospital. Unfortunately, her chronic catecholamines symptoms were controlled with anti-depressants and analgesics. Subsequently, she was relocated to a new place in 2014 and registered with a new GP for symptom relief medications. The GP reviewed her before issuing a repeat prescription and re-investigated the unresolved symptoms. 24-hour urine catecholamines were markedly elevated which were evident by urine volume of 3.7l, Noradrenaline 54327 nmol/24 h (0-570 nmol/l), Adrenaline 78nmol/24 h (0-100 nmol/l), urine dopamine 1468 nmol/24 h (0-2500 nmol) respectively. Finally, she was referred to the endocrine clinic for further evaluation and management. She was a slim and well-presented lady with a slightly anxious disposition. Her BP was 150/90 with a pulse rate of 100 beats/min. Hypertensive retinopathy grade 1 was detected in fundoscopy. There was no postural drop and no thyroid nodules. MRI adrenals showed 39 mm high intensity right adrenal lesion. Alpha blockade with Phenoxybenzamine was used before surgery. She underwent laparoscopic right adrenalectomy in January 2015 and the histology reported encapsulated tumour without lymphovascular invasion and low risk for malignancy. The adrenergic symptoms were entirely resolved postoperatively. She became normotensive and Urinary catecholamines were dramatically normalized although she required hydrocortisone replacement for a few months due to the suboptimal short synacthen test. It was stopped subsequently as her adrenal response has recovered fully thereafter. She has been followed up in endocrine outpatient clinic from 2015 to 2020 with 6-monthly urinary catecholamine but there is no biochemical as well as clinical features of pheochromocytoma relapse.

Discussion

The diagnosis of a very rare and potentially life-threatening endocrine tumour was made by a General Practitioner instead of an endocrinologist. This case also highlighted that the definitive treatment is not only curative and reducing cardiovascular risks, but also improving her quality of life.

Prevalence of endocrine autoimmune pathology in adult patients with vitiligo

Nurana Nuralieva[1], Marina Yukina[1], Ekaterina Troshina[1], Vitaliy Petrov[2] & Vladimir Volnukhin[2]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Moscow Scientific and Practical Center of Dermatovenereology and Cosmetology, Moscow, Russian Federation

Introduction

In Russia, full-scale studies aimed at assessing the incidence of endocrine autoimmune diseases (eAID) in adult patients with vitiligo have not been conducted.

Objectives

analysis of occurrence of eAID in patients with vitiligo.

Methods

1) The first part of the study included 39 patients aged 19-73 years with endocrine pathology and vitiligo, who were initially examined in Endocrinology Research Centre. 2)The second part of the study included 26 patients aged 19-71 years with vitiligo who were initially examined in Moscow Scientific and Practical Center of Dermatovenereology and Cosmetology.

Results

1) eAID were diagnosed in 85% of cases ($n=$ 33): 38,5% of patients ($n=$ 15) had one eAID, 46,1% of patients ($n=$ 18) had multiple eAID, other participants ($n=$ 6, 15,4%) had antibodies to thyroid or insular apparatus of pancreas without disruption of their functions. Autoimmune leison of thyroid (ALT) was diagnosed in 69% of cases ($n=$ 27, of these n=19 (70%) – primary hypothyroidism and n=8 (30%) – Graves' disease (GD)), Addison's disease was diagnosed in 28% of cases ($n=$ 11), type 1 diabetes mellitus was diagnosed in 21% of cases ($n=$ 8), hypoparathyroidism was diagnosed in 13% of cases ($n=$ 5), hypergonadotropic hypogonadism was diagnosed in 10% of cases ($n=$ 4), endocrine ophthalmopathy was diagnosed in 10% of cases ($n=$ 4). Multiple eAID were presented by autoimmune polyglandular syndrome (APS)-2 in 61% of cases ($n=$ 11) and APS-1 in 22% of cases ($n=$ 4), 3 patients (17%) had GD in combination with endocrine ophthalmopathy. Vitiligo preceded the manifestation of eAID in 30% of cases ($n=$ 10) and developed simultaneously with eAID in 12% of cases ($n=$ 4). 97% of patients ($n=$ 38) had the non-segmental vitiligo. One patient (3%) with APS-2 (Addison's disease, primary hypothyroidism, autoimmune gastritis) had universal vitiligo. 2) ALT was found in 15% of patients ($n=$ 4, of these n=3 (75%) – primary hypothyroidism and n=1 (25%) – GD), other eAID were not detected. Carriage of antibodies to thyroid or insular apparatus of pancreas without disruption of their functions was detected in 19% of patients ($n=$ 5). Vitiligo preceded the manifestation of eAID in 50% of cases ($n=$ 2) and developed simultaneously with eAID in 25% of cases ($n=$ 1). 96% of patients ($n=$ 25) had the non-segmental vitiligo. One patient (4%) without manifest eAID and antibodies carriage had segmental vitiligo.

Conclusion

The non-segmental vitiligo is most often associated with the development of eAID, especially ALT. The development of vitiligo precedes the manifestation of eAID in 30-50% of cases, which necessitates a regular screening examination of these patients.

Does Autonomic cortisol secretion really affect metabolic parameters? preliminary results

Seda Karslı[1], Seda Turgut[1], Didem Acarer Bugün[1], Naim Pamuk[1], Hamide Piskinpasa[1], İlkay Çakir[1], Meral Mert[1] & Sema Ciftci[1]
[1]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, İstanbul, Turkey

Aim

Autonomic cortisol secretion (ACS) is a clinical picture without overt signs of Cushing's Syndrome despite adrenal adenoma and ACTH-independent cortisol secretion. These patients, who currently do not have a standard treatment, are followed up, especially for known comorbidities of hypercortisolemia such as obesity, diabetes mellitus (DM), hypertension, osteoporosis, and hyperlipidemia. However, it remains unclear how long the patients will be followed and when the treatment should be begun. This study aimed to evaluate the parameters to be examined in the clinical follow-up by comparing the metabolic and hormonal parameters of ACS patients with the control group with non-functional adenoma (NFA).

Material and methods

Our study included 54 female patients diagnosed with ACS ($n=$ 30) and age-matched NFA ($n=$ 24) as the control group. 1 mg overnight dexamethasone suppression test cut-off point was accepted as $\geq$1.8 mg/dL in ACS diagnosis. Age, body mass index, waist circumference, fasting blood glucose, HbA1c, AST, ALT, lipid profile, thyroid function tests, basal cortisol, ACTH, DHEAS, maximum mass size of adrenal adenoma, 25-hydroxyvitamin D, HOMA-IR measured, and visceral adiposity index (VAI) were calculated for both groups.

Results

The mean age of ACS was 52.13 $\pm$8.8 years, while the mean age of NFA was 49.04 $\pm$6.8 years ($P>0.05$). The prevalence of hypertension and DM was similar ($P>0.05$). There were significant differences between the two groups in terms of maximum adenoma size ($P=0.007$), DHEAS levels ($P=0.013$), and TSH levels ($P=0.01$). No significant difference was found in other comparisons ($P>0.05$). Maximum adenoma size showed a significant positive correlation with waist circumference ($r=$ 0.331, $P=0.018$), and significant negative correlations with DHEAS and ACTH ($r=$ -0.519, $P<0.001$, $r=$-0.289, $P=0.049$, respectively). There was no significant difference in VAI scores between the two groups ($P>0.05$).

Conclusion

In our study, no significant difference was found between ACS and NFA patients in terms of metabolic disease frequency. While the maximum adenoma size was found to be significantly higher in ACS patients than in NFA patients, DHEAS and TSH levels were shown to be lower in those patients. These results were consistent with the possible effects of mild hypercortisolemia. Our study showed that DHEAS and TSH levels might play a role in patient follow-up, and it was emphasized that the diagnosis of ACS should be considered, especially in patients with larger adenoma sizes. Further studies are needed to eliminate the uncertainties in the diagnosis and follow-up of ACS.

Silent giant pheochromocytoma : about a rare entity

Chtioui Sara, Ahmed Boukhalfa, Rafi Sanaa, El Mghari Ghizlane & El Ansari Nawal
Mohamed VI Hospital University, Endocrinology Department, Marrakesh, Morocco

Introduction
Pheochromocytomas are catecholamine producing tumors which arise from chromaffin cells within the adrenal medulla. Silent pheochromocytomas are rare entities that do not present with the classical symptoms commonly seen in catecholamine-secreting tumors.
Case report
We report a case of 70-year-old-woman patient who presented with left sided abdominal pain and discomfort for 6 months. A preoperative Computed tomography (CT) scan showed a huge left suprarenal tumor 09×112×153mm in size. The right adrenal gland was normal and there were no finding of distant metastatic. The urinary catecholamines were very elevated. The patient underwent a laparoscopic surgical resection without untoward intraoperative and postoperative events. In the pathological evaluation, the mass weighed 1137 g and showed a pheochromocytoma with a PASS score of 8. The patient is on long term follow up. She was well and completely asymptomatic at last review six months after surgery.
Conclusion
This case brings to the attention of clinicians the need to have a high index of suspicion of a giant pheochromocytoma in a patient presenting with vague abdominal symptoms whose CT scan shows a large retroperitoneal tumor, even in the absence of clinical symptoms. Key-words : Pheochromocytoma-silent-giant tumor-surgery

A rare case of hypocortisolism in hypercoagulable state

Htet Htet Aung[1], Amna Zeeshan[1], Dmitriy Chernov[1], Nizar Damani[2], Rahat Tauni[1] & Melina Kostoula[1]
[1]West Hertfordshire NHS Trust, Diabetes and Endocrinology, Watford, United Kingdom; [2]West Hertfordshire NHS Trust, Radiology Department, Watford, United Kingdom

We report a case of 39-year-old woman presenting with sudden severe abdominal pain and vomiting. She had a past medical history of anti-phospholipid antibody syndrome (APLS) diagnosed in the United States (US) 20 years ago. She had multiple episodes of vomiting over the last 10 years and was diagnosed with cyclical vomiting as investigations including CT abdomen and endoscopy did not reveal a structural cause. She was taking warfarin for APLS. She was haemodynamically stable and clinical examination was unremarkable. Investigations showed normal electrolytes, subtherapeutic international normalised ratio (INR), raised cardiolipin antibody and raised activated partial thromboplastin time (APTT). CT abdomen showed enlarged bilateral adrenal glands with heterogenous parenchyma suggestive of adrenal haemorrhage and warfarin was stopped. A morning cortisol level was 171 nmol/l and short synacthen test showed inadequate cortisol response rising from 166 mmol/l only to 179 nmol/l at 30 minutes confirming the diagnosis of primary adrenal insufficiency. She was commenced on oral hydrocortisone. Subsequent MRI adrenals confirmed stable bilateral adrenal haemorrhage with cystic area of peripheral methaemoglobin and central haemosiderin. As the adrenal haemorrhage was non-progressive, anticoagulation was restarted due to high risk of thrombosis in the future. She is being followed up in the endocrine clinic with full adrenal work up including renin and aldosterone awaited. Adrenal infarction or haemorrhage is a rare complication of APLS, and hypercoagulable state may lead to adrenal vein thrombosis with haemorrhagic transformation of adrenal glands. The presenting features of adrenal thrombosis and haemorrhage include localised pain and/or adrenal insufficiency but often such patients do not have any symptoms. Patients with APLS and adrenal insufficiency may not present with hypotension as patients with APLS are commonly hypertensive, therefore masking hypotension. Unless promptly treated with intravenous glucocorticoids, complete adrenal insufficiency associated with vascular phenomenon of APLS can potentially be fatal. Therefore, physicians should have a high index of suspicion in such cases. Decision about anticoagulation should be individualised but most patients need anticoagulation as they remain at high risk of thrombotic phenomenon elsewhere.

Silent primary adrenal insufficiency: a case of treatment-resistent hyponatremia

Deniz Cengiz
Ankara Ataturk Sanatoryum Training and Research Hospital, Internal Medicine, Ankara, Turkey

64 year old male with known hypertension presented with fatigue and mild vertigo to the emergency department. Blood pressure was 110/65 mmHg. Physical examination revealed bilateral inspratory crackles with bilateral pedal oedema. There was not any skin discolourisation or bruises. Patient history indicated a suspected lung malignancy but pathological diagnosis was yet to be concluded. Laboratury test showed that sodium level was 117 mEq/l, potassium level was 5.2 mEq/l, venouse blood gas ph was 7.37, HCO_3 level was 22 mmol/l, $PaCO_2$ was 44 mmHg. Spot urine sodium8 mEq/l, serum osmolarity was 271 mOsm, urine osmolarity was 425 mOsm/l. Other renal, liver, thyroid function tests and lipid levels were within normal laboratory values. He had no obvious hyponatremia sypmtoms other than fatigue and mild nausea without vomitting. Previous medical center initiated hypertonic saline for two days, yet sodium level did not improve. He was transferred with the suspicioun of inappropriate ADH syndrome. Lung imaging showed a right mid-zone opacity with bilateral basal pleural effusion. Further investigations revaled no head injury or cranial pathology, morning serum cortisol level was 26 µd/dl. Patient admitted and started on furosemid and water restriction to 1.5 L for hypervolemia. Due to two days without improvement, PET-CT imaging was requested for evaluation. A 85x60 mm heterogeneous, hypodens mass at left adrenal gland with metabolic activity (suv maks 6.93) was reported. Despite patient's lack of metabolic acidosis, hypotension or confusion, it is suspected to be adrenal function disorder and insufficiency. Serum ACTH, cortisol, renin, aldosterone levels were sent and short synachten test was performed before corticosteroid treatment with 100 mg hydrocortizon four times daily started. Second cortisol level was 11 µd/dL and latter Synachten test was consisted with primary adrenal insufficiency. Patients' sodium level was improved after two days of steroid treatment and increased to 128 mEq/l. Later on, patient was diagnosed with squamous cell lung cancer with adrenal and lymph node metastasis. This case was complicated with mild nonspesific symptoms with initial high basal cortisol levels and absence of hyperpigmentation. It is suggested that patients with low plasma sodium should be carefully evaluated for laboratory errors, differantial diagnosis; and adrenal functions should not be overlooked.

Post-thyroidectomy hypocalcemia: a single-center retrospective study

Paloma Iglesias[1], Ana Laura Salguero[1], Jose Antonio Rosado[1], Maria Merino[2], Guadalupe Guijarro[1], Cristina Navea[1] & Isabel Pavon[1]
[1]Hospital Universitario de Getafe, Endocrinology, Madrid, Spain; [2]Hospital Universitario de Getafe, Endocrinology, Spain

Background
Post surgery hypocalcemia is the most common sequel of thyroidectomy. An accurate prediction of hypocalcemia in the immediate postoperative period would enable the selection of patients for appropriate treatment and facilitate early discharge.
Objective
This study aims to investigate the prevalence of hypocalcemia after thyroidectomy and to identify potential risk factors.
Methods
This is a retrospective cohort study of 91 patients who underwent total thyroidectomy in a tertiary center between 2017 and 2019. Data were extracted from patient medical records. Hypocalcemia was evaluated in relation to risk factors (age, sex, body mass index and type of thyroid disease). Serum parathyroid hormone (iPTH) was measured 24 h (h) after surgery. Serum ionized calcium ($Ca2+$) was analyzed 8h, 24h and 48h post-surgery.
Results
Hypocalcemia was noted in 28 (30%) of 91 patients who underwent thyroidectomy. There was no significant relationship between the occurrence of hypocalcemia and age, sex, body mass index and type of thyroid disease. The best cut-off values of serum iPTH to predict hypocalcemia was found to be 19 pg/ml at 24h post total thyroidectomy with a sensitivity and specificity of 92.45% and 100%, respectively.
Conclusion
Clinical factors are not reliable predictive markers of immediate post-thyroidectomy hypocalcemia. Prediction of hypocalcemia using serum iPTH

seems to be a promising approach. In our cohort, a cut-off value of 19 pg/ml at 24h after surgery showed a good sensitivity and specificity. Serum vitamin D levels were not performed preoperatively. This can be considered a limitation of our study.

EP1171

A case of postgravid osteoporosis

Nodira Alikhanova, Lola Abboskhujaeva, Feruza Takhirova, Gulzoda Akramova & Munavvara Shokirova
Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician Yo.Kh.Turakulov, Tashkent, Uzbekistan, Diabetology, Osteoporosis and Metabolism

Introduction
Of interest are cases of osteoporosis of unknown etiology after a recent delivery.
Matherials and methods
A 33-year-old woman complained of frequent fractures of the bones of both feet (four times in the last year) after the birth of her third child. For the woman, this was the fourth pregnancy, according to her, after the birth of her second child, she had pain in the lower back, which aggravated with physical exertion (at 24 years old).
Results
The patient's calcium level was 2.37 mmol/l, phosphorus 1.25 mmol/l, vitamin D - 20.07 ng/ml, parathyroid hormone - 50.04 pg/ml, NTx - 79.74 nM BCE (normal 17- 94 nM BCE), osteocalcin - 5.28 ng/ml (normal 6-43 ng/ml), alkaline phosphatase - 60.0 U/l. Dual-energy x-ray absorptiometry (DEXA) showed that the Z-score of 1-4 lumbar vertebrae was -3.3, the left hip was -2.2, the neck of the left femur -2.3, the right hip -2.8, the neck right thigh -2.0. The analysis of the obtained results showed that the resorption markers were within the normal range, and the formation markers were below the norm, therefore it was advisable to prescribe teriparatide, but due to the lack of access to teriparatide in our country, we prescribed the patient a calcium preparation 1000 mg per day, osteogenon 6 tablets per day, alendronic acid 70 mg per week and vitamin D at a dose of 300,000 IU. Repeatedly after 2.5 months, all parameters remained unchanged, except for vitamin D (20.07 → 34.89) and NTx (79.74 → 75.60), osteocalcin (5.28 → 2.93), alkaline phosphatase also decreased (60 → 54). The patient was then switched to teriparatide 20 mg subcutaneously once daily. After 6 months, during therapy with teripartide, osteocalcin increased from 2.93 to 13.82, the same situation was observed in relation to alkaline phosphatase (54 → 185). X-ray densitometry parameters also had positive shifts: Z-score of 1-4 lumbar vertebrae increased from -3.3 to -2.6, Z-score of the left hip -3.2 → 2.9, right hip -2.8 → 2, 6. Based on the positive changes in the results of laboratory and functional studies, it was recommended to continue therapy with teriparatide. The patient is being monitored.
Conclusion
Pregnancy and the lactation period are physiological for a woman's body, the development of osteoporosis during pregnancy and lactation, not due to other reasons, requires further research.

Osteoporosis after menopause: interaction between genes related to iron metabolism and estradiol

Laura Aguiar[1,2,3], Joana Ferreira[1,2,3], Raquel Binda Pereira[2], Ana Paula Barbosa[3, 4], Mário Rui Mascarenhas[3,4], Paula Faustino[3, 5], Ângela Inácio[1,2,3] & Manuel Bicho[1,2,3]
[1]Instituto de Investigação Científica Bento da Rocha Cabral, Lisbon, Portugal; [2]Laboratório de Genética, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [3]Instituto de Saúde Ambiental, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [4]Clínica de Endocrinologia, Diabetes e Metabolismo de Lisboa, Lisbon, Portugal; [5]Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal

Introduction
Osteoporosis is a common metabolic bone disease characterized by reduced bone mass and increased risk of fragility fractures. The pathogenesis of this disease is complex and influenced by multiple risk factors, where genetic factors play an important role. Menopause predisposes women to osteoporosis due to declining estrogen levels. Osteoporosis and iron metabolism have an important relationship. Iron overload suppresses osteoblast formation and stimulate osteoclast resorption of bone, suggesting that polymorphisms in genes affecting iron homeostasis can increase the susceptibility for the development of osteoporosis.
Objectives
This study aimed to investigate the potential implication of genetic polymorphisms in genes related to iron metabolism and their interaction with estradiol in the development of osteoporosis in a sample of postmenopausal women.
Material and methods
A case-control study was carried out for a sample of 169 Portuguese postmenopausal women, of which 78 had osteoporosis and 91 had normal bone mass. Polymorphic analyzes on the *HFE* gene (H63D and C282Y) were performed by PCR-RFLP. The haptoglobin (*Hp*) phenotype was determined by polyacrylamide gel electrophoresis. Plasma 17β-estradiol concentration was determined by ELISA. All statistical analyzes were performed using SPSS software, version 24.0.
Results
An association was found between lower levels of 17β-estradiol and osteoporosis [OR (95% CI) = 5,946 (2,199-16,079); $P<0.001$]. When the genes were analyzed separately, no significant differences were found between the two populations in relation to the polymorphisms under study. However, women with the presence of the H allele of the H63D polymorphism of the *HFE* gene and lower levels of estradiol had an increased risk of developing osteoporosis [OR (95% CI) = 22,750 (2,492-207,731); $P=0.001$], as well as the presence of the CC genotype of the C282Y polymorphism of the *HFE* gene and lower levels of estradiol [OR (95% CI) = 11,667 (2,139-63,638); $P=0.002$]. Also women who had the *Hp* 2 allele and lower levels of estradiol had an increased risk of developing osteoporosis [OR (95% CI) = 7,023 (1,813-27,200); $P=0.005$].
Conclusion
Since these genes are related to iron metabolism, the results of this study suggest an action of this metabolism in interaction with estradiol levels in the development of osteoporosis in postmenopausal women.

Primary hyperparathyroidism-induced osteoporosis: lessons from the DENOCINA trial

Valentim Lopes & Adriana Lages
Braga Public Hospital, Braga, Portugal

An 89 years old caucasian female patient with antecedents of hemithyroidectomy in 2016 due to benign nodular disease, and actually suplemented with 0.1 mg/day of levothyroxine, was referred to the Endocrinology consultation because of a primary hyperparathyroidism diagnosed in the sequence of the study of an episode of nephrolitiasis that happened in 2012 and a diagnosis of osteoporosis that was established in 2017. A 99mTc-Sestamibi revealed an augmented right inferior parathyroid gland. Although the patient had surgical indication for paratiroidectomy (symptomatic hyperparathyroidism), it was decided to treat the patient medically, because of her age and functional dependence, with the agreement of the patient and her family. She was initially treated with alendronic acid 70 mg once week during 5 years, but without significant response in terms of bone mineral density, hypercalcemia and osseous pain. The treatment was then switched to denosumab 60 mg twice year in 2020, and, in 2021, because the hypercalcemia didn't ameliorate, inspired by the results of the DENOCINA trial, we decided to introduce, in add-on, cinacalcet, initially in the dose of 30 mg/day. The calcium was 11.5 mg/dL and the PTH was 147 pg/mL (with adequate levels of vitamin D) before the initiation of cinalcalcet. Actually, 4 months after the initiation of cinacalcet, with a dose that was titrated to 60 mg/day, the calcium is in the upper limit of the normality (10.5 mg/dL) and the PTH has fallen to 85 pg/ml. But most important, the patient tolerated well both drugs, did experience an improvement in the osseous pain and gained more autonomy in the accomplishment of her daily activities.

miR-15b mediates the obesity-induced adipocyte insulin resistance by targeting insulin receptor

Xingjing Liu

Zhongda Hospital, Institute of Diabetes, Medical School, Southeast University, Department of Endocrinology, Nanjing, China

Background
In recent years, the morbidity of obesity has been increasing rapidly worldwide, which is a major risk factor for type 2 diabetes mellitus (T2DM). Obesity, mainly characterized by abnormal and excessive white adipose tissue accumulation, is the most common cause of insulin resistance (IR), where the insulin target tissues fail to respond normally to circulating insulin. However, the precise mechanism by which obesity affects insulin resistance in the major insulin sensitive tissues remains unclear. Adipose glucose uptake plays a significant role in systemic insulin sensitivity, therefore clarifying the regulatory factors of adipose insulin sensitivity is of great significance to find effective therapeutic targets of obesity. Obesity causes the increase of hepatic miR-15b, which provokes hepatocyte insulin resistance, but has no effect in skeletal muscle. The upregulation of miR-15b induced by obesity causally resulted in an impairment of hepatocyte insulin signaling and the decrease of the insulin receptor (INSR) expression. However, no studies have explored whether miR-15b is involved in adipose tissue insulin resistance induced by obesity so far.
Aim
To study the role of miR-15b in the adipose tissue of DIO mice and IR 3T3-L1 adipocytes
Method
We fed mice with high-fat diet (HFD) for 10 weeks to construct obese and insulin-resistant (IR) mice models, and treated3T3-L1 adipocytes with chronic hyperinsulinemia to establish IR adipocyte models. Cell transfection was performed using riboFECTTMCP or Lipofectamine2000. Insulin stimulated fluorescence labeled 2-NBDG uptake assay was used to detect the capacity of glucose uptake in adipocytes. The expression levels of miR-15b, the insulin receptor (INSR) and its downstream insulin signaling molecules were detected by real-time PCR and Western blot respectively.
Resluts
We found that expression of miR-15b was increased, while INSR expression was downregulated in adipose tissue of diet-induced-obese (DIO) mice. In IR 3T3-L1 adipocytes, the expression of miR-15b also ascended, accompanied by the decrease of INSR expression. Bioinformatics analysis and luciferase reporter analysis suggested that INSR was a potential target of miR-15b. Overexpression of miR-15b led to decreased INSR expression and impaired insulin signal transduction in adipocytes, and inhibition of endogenous miR-15b can reverse the downregulation of INSR and insulin resistance induced by high insulin. In addition, when miR-15b was overexpressed, the simultaneous overexpression of INSR partially alleviated the insulin resistance in adipocytes.
Conclusion
These results suggested that the impaired insulin signaling in adipocytes caused by obesity was at least partially mediated by the downregulation of INSR induced by elevated miR-15b.

Greece: Study of people's mobility in parks vis-à-vis internet searches for diet or obesity in the Covid-19 era

Ioannis Ilias[1], Charalampos Milionis[1], Athanasios Tselebis[2] & Eftychia Koukkou[1]
[1]Elena Venizelou Hospital, Department of Endocrinology, Diabetes & Metabolism, Athens, Greece; [2]Sotiria Hospital, Department of Psychiatry, Athens, Greece

Introduction
In the Covid-19 era mass media present people worldwide, including in Greece, to transiently flock to green spaces and parks. A study from the Western United States in 2020, indicated that indeed, park visitation may have increased by 20% compared to baseline (the immediate pre-Covid-19 period). The Google mobility index (GMI) is based on location data/visits - from smartphone users - to various areas; among areas of mobility the GMI can focus specifically on visits to parks. Studies have shown that internet searches honed on diets may have fluctuated during the Covid-19 era, while obesity may have increased.
Aim
To assess whether the GMI for parks, as a surrogate of physical activity, is related to Google Trends (GT) searches for diet and obesity.
Methods
We extracted the GMI data for Greece, regarding people's mobility in parks, from March 2020 to February 2022; the data were analyzed by two-way analysis of variance (ANOVA) vis-à-vis season and non-lockdown (NLD)/lockdown (LD) time. For the same time period we also extracted the GT data for internet searches in Greece regarding 'diet' and 'obesity' (in English and Greek). We assessed the autocorrelation of the parameters, to search for periodicity/seasonality, and we performed cross-correlation analysis of the GMI vis-à-vis GT searches. Separate cross-correlation analyses were done for NLD and LD time periods also.
Results
Park visitations' GMI vs baseline had a markedly dimorphic aspect during NLD/lD time periods; in winter, NLD: +16%, LD: -11%, in spring, NLD: +38%, LD: +9%, in summer, NLD only: +150%, in autumn, NLD: +76%, LD: -5% (p were 0.067 for comparisons by season and <0.001 for comparisons by NLD/lD status). The autocorrelations for periodicity/seasonality of the parameters did not reach statistical significance. Mostly negative cross-correlation coefficients for GMI against GT, lagging mainly from to +2 to +11 weeks (with GT trailing GMI) were noted, ranging from - 0.22 to - 0.56 ($P<0.05$). Analyses done separately for NLD and LD periods yielded analogous results.
Discussion
Surprisingly, during LD periods, when stay-at-home mandates were in effect, whereas walking in parks was allowed for exercise, park visitations mostly declined. Moreover, periods of increased mobility in parks during the Covid-19 era were coupled, with a time delay, to a drop in internet searches for 'diet' and 'obesity'. Whether this represents a counterintuitive perception in the community, in Greece, that physical activity in parks renders dieting superfluous remains to be evaluated.

EP1176

The level of biomarkers of early kidney damage in patients with prediabetes

Dilara Isakova[1], Ivan Petrov[2], Irina Troshina[1] & Tatyana Vasilkova[1]
[1]Tyumen State Medical University, Department of Hospital Therapy with courses in Endocrinology and Clinical Pharmacology, Tyumen, Russian Federation; [2]Tyumen State Medical University, Department of Research and Innovation, Tyumen, Russian Federation

Purpose
To assess the level of biomarkers of early kidney damage (urinary and plasma cystatin C) in patients with prediabetes and to characterize their association with risk factors for the development of nephropathy.
Materials and methods
The object of the study were 60 patients (32% men, 68% women) with early disorders of carbohydrate metabolism (impaired fasting glycemia (IFG) and impaired carbohydrate tolerance (IGT), WHO criteria, 2009). The mean age in the group was 44.3 ± 7.8 years. The average level of fasting glycemia diagnosis was 5.7±0.42 mmol/l, the average level of glycated hemoglobin was 5.96±0.36%. The mean BMI was 31.6±5.4 kg/m^2. All participants underwent a morning urine test for microalbuminuria (MAU), assessment of creatinine levels, followed by calculation of GFR (MDRD). Urinary and plasma levels of cystatin C were analyzed by enzyme immunoassay using the Cystatin C-ELISA-Best test system. Statistical processing of the results was carried out using the program Statistica 7.0. using: $\chi 2$ test, Mann-Whitney U-test for two independent samples, Spearman test. Differences were considered significant at $P<0.05$.
Results
The mean urinary cystatin C was 10.3±1.2 mg/l. An elevated urinary level of cystatin C was observed in 54.6% of the subjects. There were significant differences in the level of the analyzed urinary marker in the group of patients with MAU ($P<0.001$). A direct correlation was also established between the concentration of cystatin C in urine with BMI ($r=0.42$, $P<0.01$), SBP ($r=0.59$, $P<0.05$), DBP ($r=0.34$, $P<0.05$), creatinine level ($r=0.68$, $P<0.001$), glycemia during oral glucose tolerance test 2 h after exercise ($r=0.51$, $P<0.01$) and negative correlation relationship with GFR level ($r=0.59$, $P<0.01$). The mean plasma level of cystatin C was 1.02 mg/l. There were significant differences in the level of the analyzed plasma marker in the group of patients with MAU ($P<0.01$). Direct relationship was established between the concentration of cystatin C and blood creatinine ($r=0.61$, $P<0.001$), the severity of MAU ($r=0.61$, $P<0.001$), the age of patients ($r=0.42$, $P<0.05$) and an inverse relationship with the level of GFR ($r=-0.65$, $P<0.01$).
Conclusions
An increase in the level of analyzed markers in patients with prediabetes demonstrates kidney damage at the stage of early carbohydrate metabolism disorders. The revealed changes in the levels of urinary and plasma cystatin C, compared with traditional nephrological markers (MAU, GFR), indicate a higher

diagnostic significance in the light of early detection and enable preventive intervention in terms of prevention.

Prolonged oral glucose tolerance test in the diagnosis of postprandial non-diabetic hypoglycemia

Marina Yukina, Nurana Nuralieva & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
tests alternative to the fasting test are necessary for the diagnosis of numerous causes of non-diabetic hypoglycaemia (NDH), that not provoked by starvation (postprandial hypoglycemia), such as insulin autoimmune syndrome (IAS) and noninsulinoma pancreatogenous hypoglycemia syndrome (NIPHS). However, there is no consensus on the most optimal test (prolonged oral glucose tolerance test (pOGTT) or mixed meal test (MMT)) in this cohort of patients.
Objectives
1)To determine the accuracy of pOGTT and MMT in the diagnosis of postprandial NDH. 2)To compare the glycemic curves during pOGTT in patients with IAS and NIPHS.
Methods
We included152 patients aged 18-74 years: with IAS ($n=$ 14), NIPHS ($n=$ 9), fasting NDH ($n=$ 108) and without NDH ($n=$ 21). All patients underwent pOGTT and MMT. During pOGTT the analysis of venous blood for glucose was performed at baseline, 120 minutes after a 75 g oral dextrose load, and then every 30 minutes until reaching 6 h, if hypoglycemia in venous blood has not been previously recorded. During the MMT the analysis of venous blood for glucose was performed at baseline, and then every 30 minutes after a mixed meal (containing 36.8 g of carbohydrates, 12 g of proteins, 11.6 g of fats (calorie content - 300 kcal)) oral load until reaching 5 h, if hypoglycemia in venous blood has not been previously recorded. During both pOGTT and MMT, analysis of insulin and C-peptide levels was performed once in a blood sample with diagnosed hypoglycemia.
Results
1)Sensitivity, specificity, AUC of the pOGTT were: 100,0% [82,7%; 100,0%]; 61,1% [44,8%; 75,2%]; 80,6% [72,5%; 88,6%], respectively. Sensitivity, specificity, AUC of the MMT were: 22,2% [5,7%; 55,9%]; 77,4% [67,2%; 85,0%]; 49,8% [34,7%; 64,9%], respectively. When comparing the AUCs of pOGTT and MMT the significant difference was found, $P<0.001$. 2)The minimal level of glycemia in patients with IAS and true positive result of pOGTT (2,84 [2,60; 2,93] mmol/l) and in patients with NIPHS and true positive result of pOGTT (2,52 [2,15; 2,63] mmol/l) didn't differ significantly, p=0,130. Patients with IAS developed hypoglycemia at the 180-300 minutes after beginning of the pOGTT, and patients with the NIPHS developed hypoglycemia at the 120-180 minutes after beginning of the pOGTT.
Conclusion
1)Patients with suspected NDH should undergo 5-hour pOGTT for the purpose of postprandial hypoglycemia excluding. 2)Patients with NIPHS develop postprandial hypoglycemia earlier, than patients with IAS.

Dietary education for patients with type 2 diabetes : state of art

Mehrez Achwak, Wafa Alaya, Selma Mohsen, Najoua Lassoued, Fedia Boubaker, Baha Zantour & Mohamed Habib Sfar
Taher Sfar University Hospital, Tunisia

Introduction
Dietary practices are essential in diabetes control and acquiring HbA1c target. The aim of our work is to evaluate the prevalence of dietary education practice in a type 2 diabetes population and its associated factors.
Methods
Cross-sectional study enrolling 84 type 2 diabetes patients followed up in the outpatient endocrinology department. The data was collected through a questionnaire in face-to-face interviews with patients. Age, body mass index (BMI), diabetes duration, glycosylated hemoglobin (HbA1c) and serum lipid profile were assessed.
Results
The mean age was 59 $\pm$ 12 years. Of the study population, 42 % were females. The mean diabetes duration was 9.4 $\pm$ 6.4 years. The mean HbA1c was 9.9% $\pm$ 2.4. The mean BMI was 27.7 $\pm$4.7 kg/m^2. More than two-third (71%) of the patients were overweight/obese. Less than the the half of the participants (45%) were measuring their blood glucose level at their home. Only 33% got nutrition education on diabetes diet from a health professional. The rest of respondents reported getting dietary information from media in 30% and from friends and family in 37%. Recieving nutrition education from a health care professional was associated with following dietary recommendations ($P=10^{-3}$), self monitoring of blood glucose ($P=0.04$) and a better glycemic control ($P<10^{-3}$). Patients who got a dietary education had lower BMI (26.6 $\pm$ 3.1 kg/m^2 vs 28.3 $\pm$ 5.2 kg/m^2 $P=0.06$) and better serum lipid profile including a lower triglycerides levels (1.09 $\pm$0.36 mmol/l vs 1.52$\pm$ 1.1 mmol/l; $P=0.009$). Getting nutrition education was significantly associated with good dietary practices including : getting meals meals based on a diet plan ($P<10^{-3}$), knowing diffrent food groups ($P=0.003$) and reducing sweets and sugary consumption ($P<10^{-3}$). Patients who recieved a nutrition education insisted more on the importance of having a physician nutrition specialist ($P=0.002$)
Conclusion
Among the patients, diabetic dietary awareness and management are still a major challenges faced by healthcare professionals. This study highlights the importance of reinforcement of an active dietary education through health-care providers (physician nutrition specialist, dietitician…) to encourage patient to make changes in their nutritional habits and improve their dietary knowledge and practices.

Differential effect of vitamin D therapy on insulin resistance in vitamin D deficient women

Stavroula Psachna, Evangelia Vogiatzi, Christina Kogia, Dimitrios Ioannidis, Dimitrios Lilis, Maria Drakou, Antonis Polymeris & Peter Papapetrou
Sismanoglio- Amalia Fleming - General Hospital, Department of Endocrinology, Metabolism and Diabetes Mellitus, Greece, Melissia, Greece

Forty-one vitamin D deficient women (aged 26-75 years, mean 56.2, median 57) were treated with Vitamin D3 (50000 IU/week for 1.5 month and 25000 IU/week for another 1.5 month). Before treatment their serum 25(OH)D was 17.3$\pm$6.1 ng/ml (mean$\pm$SD) and after treatment 37.0$\pm$7.5 ($P<0.0001$). Their HOMA-IR was 2.2$\pm$1.1 before and 2.3$\pm$1.1 after ($P=$NS), serum insulin 9.0$\pm$4.2 mIU/l before and 9.6$\pm$4.5 after (NS), glucose 96.2$\pm$8.2 mg/dl before and 97.0$\pm$10.0 after (NS), calcium 9.4$\pm$0.4 mg/dl before and 9.2$\pm$0.5 after (NS), parathyroid hormone (PTH) 82.5$\pm$34.2 pg/ml before and 61.4$\pm$29.4 after ($P<0.0001$), and BMI 26.2$\pm$3.8 before and 26.3$\pm$3.8 (NS) after treatment. The change in HOMA-IR and Insulin after therapy was not uniform in all the women. In 24 women (group I) HOMA-IR increased significantly: from 1.7$\pm$0.7 before to 2.4$\pm$1.2 after treatment ($P<0.0001$), and Insulin from 7.2$\pm$2.7 to 9.9$\pm$5.0 ($P=0.0003$). In 17 women (group D) HOMA-IR decreased significantly: from 2.9$\pm$1.2 to 2.2$\pm$1.0 ($P<0.0001$), and Insulin from 11.7$\pm$4.5 to 9.2$\pm$3.9 ($P<0.0001$). HOMA-IR and Insulin were significantly different before treatment ($P=0.0002$ and $P=0.0003$) between the two groups I and D, but they were not significantly different after treatment. PTH was not significantly different between the two groups either before or after treatment. The values of some parameters before and after treatment were combined and thus for group I the number of cases became n=48 and for group D n=34. There was a negative significant correlation between the combined values of PTH and 25(OH)D in group D but not in group I. The values of 25(OH)D were not significantly correlated with those of HOMA-IR in both groups. However, there was a significant negative correlation between HOMA-IR and PTH in group I ($P=0.04$), but a significant positive correlation between HOMA-HR and PTH in group D ($P=0.04$). Similar were the correlations between 25(OH)D or PTH with Insulin in both groups. Our conclusion is that during vitamin D therapy of vitamin D deficient women there is no direct effect of the serum 25(OH)D level on HOMA-IR or Insulin. The effect of the treatment is mediated by the level of PTH which is significantly correlated with HOMA-IR or Insulin. This conclusion is in keeping with the known from the literature direct effect of PTH on the beta cells of pancreatic islets affecting the secretion of insulin. It seems that the treatment increases the HOMA-IR in women with relatively low baseline values, but it decreases it in those with relatively high baseline HOMA-IR values.

The Global Threat of non-communicable Diseases

Sophie Kiefer[1], Anna Scherdjow[1], Jonas Lüske[2] & Annina Althaus[3]
[1]FOM University of Applied Sciences | Elsenheimerstraße, München, Germany; [2]Charité – Universitätsmedizin Berlin, Berlin, Germany; [3]Berlin International University of Applied Sciences, Berlin, Germany

Background
Since the last decade, the disease pattern has significantly changed around the world. Non-communicable diseases, most commonly diabetes mellitus, have become the main threat to global health. The incidence of diabetes mellitus type 2 (DM2) is rising steadily, accounting for about two-thirds of deaths in Germany. Based on a prevalence of 9 million diabetic patients per year, DM2 constitutes a considerable medical and economic burden in Germany. However, the healthcare spending and its cost drivers are not yet sufficiently known.
Aims of the study
The primary objective of this study was to describe healthcare resource use and cost development of DM2 treatment in Germany, focusing on the most significant cost drivers and opportunities for cost-savings. The secondary objective was to analyse the impact of technical progress on diabetes care.
Methods
A systematic literature search was conducted in PubMed and Embase. Additionally, publications of the national health authorities (Robert Koch Institute RKI), Federal Joint Committee (Gemeinsamer Bundesausschuss G-BA) and the German Diabetes Society (Deutsche Diabetes Gesellschaft DDG) were included. Following the PRISMA guidance, the review identified the study design, epidemiological approach, analytical perspective, and data collection approach in each of the included studies.
Results
From 1.965 records, the final sample was composed of 41 articles. Most of the studies addressed direct costs and were based on calculations by extrapolations. The annual diabetes-specific direct costs of DM2 were between 542 and 6.323 € per patient. The most used method is the incremental or excess cost approach (1.8-fold higher costs compared to individuals without DM2). Confirmed risk factors included physical inactivity, obesity, genetic predispositions, and tobacco use. People with low social and income status had a significantly increased risk of developing DM2. The major cost drivers are demographic change with aging, exponentially increasing obesity, the availability of medications and therapies and the increased use of medical services by patients due to available treatment options of diabetic complications. Increasing prevalence, especially in childhood, is a major cost driver on its own. The preventive measures taken so far have not yet paid off. The potential financial savings from medical-technological progress are eroded by increasing age and use of medical services.
Conclusion
DM2, based on the results of this study, constitutes a considerable medical and economic burden in Germany and has a serious impact on the government health expenditures. To successfully combat diabetes and reduce health care expenditures, preventive efforts must be intensified.

Knockdown of CASK in Pancreatic β Cells Affects Adipocyte Insulin Sensitivity by Reducing Exosome Release

Ting Xiao & Yao Wang
Southeast University, Department Of Clinical Medicine, Nanjing, China

Objective
Previously, we identified that knockdown of calcium/calmodulin-dependent serine protein kinase (*Cask*) in β cells *in vitro* resulted in decreased insulin secretion. We then used the Cre-loxP system to specifically delete the *Cask* gene in β cells of mice, and the mice exhibited impaired glucose tolerance and glucose-stimulated insulin secretion under a normal chow diet. However, under a high-fat diet (HFD), the insulin sensitivity and glucose tolerance of KO mice were significantly improved than wild-type. The insulin-stimulated phosphorylation levels of IRS1 and AKT in adipose tissue of HFD-KO mice increased significantly, but there were no significant changes in insulin sensitivity in liver and skeletal muscle. Study shows that β cells can regulate the function of target organs by secreting miRNAs via exosomes. Therefore, this study mainly discussed whether knockdown of *Cask* in β cells specifically affected the insulin sensitivity of adipocytes by regulating the release of exosomes and their contents.
Methods
Cask-siRNA was used to knockdown the *Cask* gene in MIN6 cells. The secretion of exosomes was detected by NTA and WB. Fluorescent labeling exosomes released by β cells were co-incubated with mature 3T3-L1 adipocytes for observing the uptake of exosomes. Adipocytes were treated with exosomes from the supernatant of MIN6 cells, and the expression of insulin signaling pathway related proteins was detected. The exosomes were sequenced, and differentially expressed miRNAs were screened and analyzed. 3T3-L1 adipocytes were transfected with miR-15b minics/inhibitors to detect the expression of its target gene INSR and the downstream proteins.
Results
We found that knockdown of *Cask* in β cells reduced the secretion of exosomes, and adipocytes could absorb exosomes derived from β cells. The number of exosomes absorbed by adipocytes also decreased after *Cask* deletion. The insulin sensitivity of adipocytes treated with exosomes from *Cask*-knockdown MIN6 cells was significantly higher than control. In addition, it was found that the content of miR-15b in the exosomes of MIN6 cells decreased after knockdown of *Cask*, and miR-15b can inhibit the insulin signaling pathway. Overexpression of miR-15b in 3T3-L1 adipocytes reduced the expression of INSR and the insulin signaling pathway was blocked. While inhibiting miR-15b in insulin-resistant adipocytes rescued the damaged insulin signaling.
Conclusion
Cask participates in the release of exosomes in β cells. Knockdown of *Cask* reduces the release of exosomes, thus reducing the content of miR-15b in them. Adipocytes can absorb the exosomes from β cells, which causes the changes of insulin sensitivity through miR-15b.

Association between lipid profile and diabetic nephropathy in type 1 diabetes mellitus

Patricija Poskaite[1,2], Lina Radzeviciene[2] & Rasa Verkauskiene[2]
[1]Lithuanian University of Health Sciences (LUHS), Department of Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Diabetic nephropathy (DN) is a severe complication of type 1 diabetes mellitus (T1DM) and has become common primary disease leading to end-stage renal disease worldwide. Abnormalities in lipid metabolism is very important in the progression of renal damage in patients with T1DM.
Aim
to assess the relationship between lipid abnormalities and diabetic nephropathy in type 1 diabetes mellitus patients.
Methods
we performed a retrospective analysis of clinical data from Litdiane database from 2013 to 2016. 18-67-year-old 100 patients with type 1 diabetes were enrolled in the study. Participants filled questionnaires about T1DM, disease duration, complications and treatment. Anthropometric parameters height and weight were measured. Laboratory tests including total cholesterol, triglycerides, low-density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol, glycated hemoglobin (HbA_{1c}), creatinine, albumin in 24h urine sample were performed. Study included group 1 of 50 T1DM patients with DN and group 2 of 50 T1DM patients without DN. Patients taking statins and patients with eGFR $<$ 30 ml/min were excluded from the trial.
Results
62 females and 38 males participated in the study. Mean age in DN group was 38.4 ± 11.2 years and in group without DN 30.4 ± 10.3 years. Mean duration of diabetes was 17.7 ± 11.1 years, average body mass index (BMI) was 24.2 ± 3.9 kg/m^2, HbA1c 9 $\pm$ 2.2 %, eGFR 92 ± 30.9 ml/min/1.73m^2. Patients with macroalbuminuria (26%) and microalbuminuria (40%) had significantly increased serum cholesterol ($P < 0.05$). LDL cholesterol was significantly higher (3.3 ± 0.9) in DN group ($P = 0.005$). Cases of hypertriglyceridemia were significantly more frequent between males than females (39.5% vs 9.7% $P < 0.001$). Statistically significant relationship was verified between higher serum cholesterol (5.8 ± 1.5) and DN group ($P = 0.001$).
Conclusion
lipid metabolism is significantly impaired among patients with diabetic nephropathy. Early monitoring, regular screening and appropriate lipid-lowering drug therapy may delay further renal complications in type 1 diabetes mellitus patients.

Weight loss induced by bariatric surgery may improve systemic inflammation: Preliminary results

Naim Pamuk[1], Seda Turgut[1], Hakan Seyit[2], Didem Acarer Bugün[1], Hamide Pişkinpaşa[1], Evin Bozkur[1], Mehmet Karabulut[2] & İlkay Çakır[1]
[1]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, General Surgery, Istanbul, Turkey

Background
Obesity is a widespread disease that causes chronic low-grade inflammation and related chronic diseases such as steatohepatitis, metabolic syndrome, diabetes mellitus (DM), and cancer. It is known that weight loss positively affects life expectancy by reducing obesity-related complications. Therefore, effective management of particularly morbidly obese patients is getting prominent in clinical practice. Bariatric surgery (BS) is the main effective treatment option and weight loss method for morbid obesity. This study aimed to investigate the impact of bariatric surgery on systemic inflammation and metabolic parameters.
Methods
Morbid obesity patients who underwent BS between December 2014 and June 2020 were screened retrospectively. Patients with inadequate data or diagnosed acute or chronic inflammatory disease were excluded. A total of 693 patients between 18 and 65 years were included in the study. The preoperative and postoperative 12th-month data were analyzed. A novel hematologic and immune biomarker systemic inflammation response index (SIRI) was calculated to evaluate inflammation. ΔSIRI computed as the preoperative SIRI (SIRI1) minus the postoperative 12th-month SIRI (SIRI2). The percent of total weight loss (%TWL) was also calculated to classify participants. The patients with %TWL < %40 were defined as Group 1, and patients with %TWL ≥ %40 were defined as Group 2. All parameters were compared between the groups.
Results
The mean age of 693 patients (152 female/541 male) was 39.9 ± 10.3 years. The mean body mass index was 47.7 ± 6 preoperatively and 30.2 ± 5.4 postoperatively at the 12th month. The mean SIRI1 (1.14 ± 0.54) was significantly higher than the mean SIRI2 (0.77 ± 0.45) for all patients ($P < 0.001$). Group 2 had significantly higher ΔSIRI and lower age than Group 1 ($P = 0.001$, $P < 0.001$, respectively). In addition, the frequency of both diabetes and hypertension increased in group 1 ($P < 0.001$ for both). After controlling for age, gender, hypertension, and DM covariates, only ΔSIRI levels sustained the significant difference status ($P = 0.007$). All metabolic parameters significantly improved after bariatric surgery ($P < 0.05$).
Conclusion
The present study showed that regardless of age, DM, and hypertension, increased inflammation recovery is significantly associated with effective weight loss. In the light of this finding, we suggest BS may give an independent contribution to the improvement of chronic inflammation induced by obesity. Further prospective studies in larger populations may improve the management of morbidly obese patients by clarifying the inflammation mechanism and process.

The relevance of managing ketoacidosis in otologic mucomycosis

Meherzi Abir, Safa Jemli, El Omri Malika, Marwa Ben Njima, Habiba Ben Shgaeir, Mouna Bellakhdher, Jihene Houass, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

Background
Uncontrolled diabetes mellitus in ketoacidosis, as well as other kinds of metabolic acidosis, are major risk factors for mucormycosis. As the frequency of diabetes mellitus increase, so does the number of individuals at risk for this lethal infection. However, a lack of symptoms could lead to a delay in diagnosis. The aim of this paper is to study the clical features of otologic mucomycosis and to analysis the impact ketoacidosis the disease's course.
Materials and methods
The zygomycete infection was confirmed by either or both histologically and mycological examination of specimens.
Result
Auricular mucormycosis was diagnosed in 4 patients. Patient ages ranged from 3 to 78 years, with a median age of 58.75 years. There were 3 (75 %) male subjects. The underlying diseases were kidney failure in one patient, cell-mediated immunity defect in another one and diabetes mellitus was noted in one case. No underlying condition was registred in one case. Auricular mucormycosis involved otocerebral (2 patients), chronic otitis media (1 patient) and malignant otitis externa (1 patient). Diagnosis was obtained by positive histology, positive direct microscopy and fungal culture in all patients. The species identified were Lichtemia corymbifere in two cases, Rhizopus arrhizus in one case, and Rhizopodiformis in the latter case. The quasi majority of antifungal-treated patients (3/4cases) received an amphotericin B formulation (amphotericin B deoxycholate in two cases and liposomal amphotericin B (L-AmB) in one case). Two (2/3) of these patients received amphotericin B in combination with other antifungals (fluconazole in one case and itraconazole in the other case). Mucormycosis was considered responsible for death in one patient.
Conclusion
Ketoacidosis is a significant factor in the development and in the control of this lethal infection. thereby it is important to optimalize information for clinicians in charge of diabetic patients.

The role of preoperative thyroid function tests in weight loss after bariatric surgery in morbidly obese patients

Didem Acarer Bugün[1], Seda Turgut[1], Hakan Seyit[2], Naim Pamuk[1], Hamide Pişkinpaşa[1], Evin Bozkur[1], Mehmet Karabulut[2] & Meral Mert[1]
[1]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, General Surgery, Istanbul, Turkey

Background
Obesity is one of the most critical problems nowadays, its frequency and consequences. Since the risk of morbidity and mortality increases in obese individuals, lifestyle changes, pharmacotherapy, and bariatric surgery (BS) methods are used for treatment. BS is generally considered the most effective method to treat morbid obesity. However, it is known that thyroid function has a role in weight regulation, the effect of preoperative thyroid function on weight loss after BS is not fully understood. Therefore, we aim to evaluate the impact of thyroid function tests and metabolic variables on weight loss after BS.
Methods
The patients who underwent bariatric surgery between 01.12.2014 and 01.06.2020 in our hospital were retrospectively screened. Patients with a history of thyroid disease treated with thyroid hormone or antithyroid drugs were excluded from the study. A total of 635 patients between 18 and 65 years were included, preoperative and postop 1st-year data were recorded, and the percent of total weight loss (%TWL) was calculated, in our study. Patients were divided into two groups in terms of %TWL. Those with %TWL < 35 were defined as Group 1, and those with %TWL < 35 were defined as Group 2. All parameters were compared between the groups. Regression analysis was applied to evaluate which factors affected postoperative weight loss contributed more to the outcome.
Results
The mean age of 635 patients (154 male/481 female) was 39.3 ± 10.6 years. Age, pre-and postop fasting plasma glucose (FPG), postop ALT levels were significantly higher in Group 1 than Group 2 ($P < 0.001$, $P = 0.011$, $P < 0.001$, $P = 0.009$, respectively). FT3 level was significantly higher in Group 2 than Group 1 ($P = 0.005$). While there was no significant difference between the two groups regarding gender, DM and HT patients were significantly more frequent in Group 1 ($P = 0.003$, $P = 0.005$, respectively). The regression analysis determined that increasing fT3 levels raised the probability of being in %TWL ≥ 35 group by 1.6-fold (OR = 1.577, $P = 0.027$).
Conclusion
Weight loss after BS varies according to individuals. Therefore, predicting patients who will respond better to surgery is essential for the clinical management and follow-up of patients with obesity. In this regard, the present study showed that increasing fT3 levels, even if in the normal range, raised the probability of losing weight adequately.

Hypobetalipoproteinemia: case report and literature review

Matheus Kowal Rosales[1], Laura Vilas Boas[2], Thielsen Cardoso da Silva[2], Jéssica Maria Telles[1], Gabrielle Andrusko dos Santos[1], Marcela Malinoski Munoz[3] & Mirnaluci Paulino Ribeiro Gama[1]
[1]Hospital Universitário Evangélico Mackenzie, Brazil; [2]Evangelical Mackenzie Faculty of Parana, Brazil; [3]Federal University of Paraná - UFPR, Brazil

Introduction
Primary hypobetalipoproteinemia corresponds to a series of congenital disorders that have a variable incidence from 3.2% to less than 1 in 1 million, depending on the type of genetic mutation. The diseases that comprise it occur due to different types of mutations in genes that will encode important proteins at different stages of lipid metabolism. Individuals with determinant mutations of severe phenotypes, such as Bassen-Kornzweig syndrome, as known as Abetalipoproteinemia (ABL), chylomicron retention disease (CRMD), homozygous familial hypobetalipoproteinemia (FHBL), may present manifestations even during childhood with a picture of malabsorption of fats with vomiting, steatorrhea and weight-height deficit, and later on, they progress with progressive affections resulting from deficiency of fat-soluble vitamins, such as retinal degenerations and neuropathies. Heterozygous individuals are often asymptomatic although they may develop fatty liver disease and eventually some vitamin deficiencies.
Case report
A 20-years-old male patient was referred to endocrinology service due to a lipogram alteration. Asymptomatic, reported having a balanced diet, without being submitted to any type of diet. Maintained a preserved intestinal habit, with no significant history of diarrheal conditions. Laboratory tests showed total cholesterol 61 mg/dl, HDL 30.4 mg/dl, LDL 17.4 mg/dl. VLDL 10.6 mg/dl and triglycerides 53 mg/dl are associated with a deficiency of fat-soluble vitamins (vitamin D, E, and K). Apolipoprotein B dosage was 24 mg/dl (RV: 55 to 155 mg/dl) and also had an abdominal ultrasound with evidence of mild hepatic steatosis.
Conclusion
Hypobetaliproteinemia corresponds to a heterogeneous group of diseases. Most of them do not cause serious manifestations and go unnoticed. However, even these can lead to late repercussions such as liver disease and hypovitaminosis. Therefore, it is important to be attentive to patients with low levels of LDL and total cholesterol, avoiding dismissing these findings as "benign" changes. Despite this, it must be recognized that, possibly, these patients have some cardiovascular protection due to low LDL titers. The severe forms, despite being very rare, lead to evident clinical manifestations in the first years of life, showing the importance of lipids for humans.

Endocrinological and inflammatory markers in individuals with spinal cord injury: A systematic review and meta-analysis

Gabriela Böhl[1], Peter Francis Raguindin[1,2,3], Ezra Valido[1, 4], Alessandro Bertolo[1, 5], Oche Adam Itodo[1,2,3], Beatrice Minder[6], Patricia Lampart[7], Anke Scheel-Sailer[7], Alexander Leichtle[8], Marija Glisic[1, 2] & Jivko Stoyanov[1,2]
[1]Schweizer Paraplegiker-Forschung, SCI Population Biobanking and Translational Medicine Group, Nottwil, Switzerland; [2]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland; [3]University of Bern, Graduate School for Health Sciences, Bern, Switzerland; [4]University of Lucerne, Department of Health Sciences and Medicine, Luzern, Switzerland; [5]Inselspital, Department of Orthopedic Surgery, Bern, Switzerland; [6]University of Bern, Public Health & Primary Care Library, Bern, Switzerland; [7]Schweizer Paraplegiker-Zentrum, Nottwil, Switzerland; [8]Inselspital, University Institute of Clinical Chemistry, Bern, Switzerland

Background
Spinal cord injury (SCI) can lead to dramatic physiological changes which can be a factor in developing secondary health conditions and might be reflected in biomarker changes in this elevated risk group. We focused specifically on the endocrine and inflammation profile differences between SCI and able-bodied individuals (ABI).
Objectives
To determine the differences in inflammatory and endocrine markers profiles between individuals with SCI and ABI.
Methods
We systematically searched 4 electronic databases for relevant studies. Data was extracted and assessed by two independent reviewers. Weighted mean difference between SCI and ABI was calculated using random-effects models. Heterogeneity was computed using I^2 statistic and chi-squared test. Study quality was evaluated through the Newcastle-Ottawa Scale.
Results
The search strategy yielded a total of 2,603 records after duplicates were removed. Titles and abstracts of records were screened, from which 256 articles were selected for full-text assessment. Sixty-two studies were included in the meta-analysis. Most of the studies were conducted only among male SCI individuals (68%), had a sample size of or fewer than 100 participants (74%), and were conducted in North America (40%). The mean age of the study population ranged from 16 to 64 years and the mean injury duration ranged from <1 to 29 years, with the majority of studies containing both individuals with tetraplegia and paraplegia (77%). One-third of the studies (31%) included individuals with complete injury, while 40% of the studies had both complete and incomplete injury. Most of the studies were classified as being of moderate quality (71%). SCI individuals had higher levels of pro-inflammatory C-reactive protein and IL-6 than ABI. Creatinine and Vitamin D levels were lower in SCI than ABI. Total testosterone levels and IGF-1 were also found to be lower, while cortisol and leptin levels were higher in SCI when compared to ABI. However, no significant differences were found regarding glucose and insulin. Accordingly, meta-regression, subgroup analysis, and leave-one-out analysis, were performed, however they were able to only partially explain the high levels of heterogeneity.
Conclusion
Individuals with SCI show higher levels of inflammatory markers and present significant endocrinological changes when compared to ABI. Moreover, higher incidence of obesity, diabetes, osteoporosis and hypogonadism in SCI individuals, together with decreased creatinine levels reflect some of the readily measurable aspects of the phenotype changes in the SCI group. These findings need to be considered in anticipating related medical complications and personalizing SCI medical care.

The relationship between free thyroid hormones and diabetic retinopathy in euthyroid patients with type 2 diabetes mellitus

Leyla Akdoğan[1], Şefika Burç ak Polat[1], Nagihan Uğurlu[2], Ahmet Dirikoç[1], Didem Özdemir[1], Oya Topaloğlu[1], Reyhan Ersoy[1] & Bekir Çakır[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Ophtalmology, Ankara, Turkey

Introduction
The prevalence of diabetes mellitus (DM) continues to increase worldwide. Diabetic retinopathy (DRP) is one of the most common complications of Type 2 DM. Recently, the effect of thyroid hormones on diabetic microvascular complications has gained much attention. This relationship is explained by the important effects of thyroid hormones on endothelial function. There are studies investigating the relationship between TSH and diabetic nephropathy and DRP. There are very few studies evaluating free thyroid hormone levels. In this study, it was aimed to investigate the relationship between free thyroid hormone levels and DRP in euthyroid patients with type 2 DM.
Method
In this study, the biochemical records of patients with Type 2 DM who had euthyroid status and evaluated for retinopathy, applied to the endocrinology and ophtalmology clinics of our hospital between January 2018 and August 2018. Demographic data of the patients and characteristics that may be associated with diabetic retinopathy were evaluated. Whether the patients had DRP and, if any, retinopathy levels were recorded. It was evaluated whether there was a difference in free thyroid hormone levels between the groups with and without DRP.
Results
A total of 171 patients, 106 men and 65 women, were included in the study. Mean age was 57.19 $\pm$10.81 years. DRP was not present in 127 patients (74.2%), nevertheless 36 patients (21%) had nonproliferative DRP and 8 patients (4.6%) had proliferative DRP. There was no difference between the groups in terms of age, gender, hypertension, cardiovascular disease, fasting plasma glucose, serum creatinine, lipid levels and microalbuminuria. The duration of diabetes was longer in the nonproliferative DRP group ($P=0.026$). HbA1c levels were higher in the proliferative DRP group ($P=0.05$). No significant difference was found in terms of TSH levels and free thyroid hormone levels in all three groups.
Conclusion
In our study, the relationship between free thyroid hormone levels and DRP in euthyroid type 2 DM patients was investigated. Diabetes duration and Hba1c levels were found to be risk factors in DRP similar to the literature. When the

groups with and without DRP were compared, no difference was found in TSH and free T4 and free T3 levels.

Diabetes mellitus in the Tashkent region of Uzbekistan

Feruza Takhirova & Nodira Alikhanova
Republican Specialized Scientific And Practical Medical Center Of Endocrinology named after academician Yo.Kh.Turakulov, Diabetology, Tashkent, Uzbekistan

Objective
Studying the prevalence of diabetes mellitus is necessary to assess the epidemiological situation in the region
Aim
To study the prevalence of diabetes mellitus in the Tashkent region.
Methods
The source of information was the data of the statistics office of the endocrine dispensary of the Tashkent region for the period 2018-2020. For the statistical processing of the data, the Microsoft Excel 2010 program was used.
Results
The largest number of patients is observed in Zangiata district of Tashkent region, which is 2.29% of the adult population of the district, the lowest prevalence of diabetes is observed in Bekabad and Bustanlik districts (1.11%); the number of diagnosed patients with diabetes in 2020 in the Tashkent region was 3416 people (0.17%); the highest percentage of type 1 diabetes mellitus type 2 diabetes is observed in the Angren region 26.3% to 73.7%.
Conclusion
Analysis of the situation with diabetes mellitus in the Tashkent region showed that, like throughout the Republic of Uzbekistan, there is late diagnosis of type 2 diabetes mellitus, and not all patients are registered.

NanoLuc® Binary Technology to explore the mechanism of action of a Magmas inhibitor

Patricia Borges de Souza, Irene Gagliardi, Maria Rosaria Ambrosio, Marta Bondanelli & Maria Chiara Zatelli
Unifersity of Ferrara, Department of Medical Sciences Section of Endocrinology, Ferrara, Italy

Introduction
Magmas encodes for an integral constituent of the TIM23 translocase complex located in the mitochondrial inner membrane that drives proteins from the intermembrane space into the mitochondrial matrix by functionally interacting with Tim14. We previously demonstrated that Magmas silencing is able to sensitize ACTH-secreting mouse pituitary adenoma cells to pro-apoptotic stimuli, reduce DNA synthesis, accumulate cells in G0/G1 phase with concomitant decrease in S phase, supporting the hypothesis that Magmas may play a role in tumor development by protecting neoplastic cells from apoptosis and by promoting cell proliferation. We then synthesized a protein Magmas inhibitor, reported herein as "Compound 5", which does not affect viability of cancer cells, but sensitizes them to the pro-apoptotic effects of chemotherapeutic agents such as Staurosporine, Doxorubicin and Cisplatin. These studies provide evidence for a role of Magmas in chemoresistance and indicate that Compound 5 may be useful to restore sensitivity of chemoresistant cancers cells, possibly allowing for a reduction in chemotherapeutic agent effective dose, with consequent decrease in side effects.
Aim
The purpose of this research is to understand whether the mechanism of action of Compound 5 is to disrupt Tim16-Tim14 interaction. This issue is important to explore the key features of Magmas inhibitors, providing information as to the better chemical structure of these compounds which might increase their chemosensitizing effects.
Methods
Tim16 and Tim14 were amplified from pCMV6-Entry vectors and cloned into NanoBiT® Expression Constructs using unique restriction enzyme sites present in the MCS of each vector. The resulting vectors containing Tim16 or Tim14 genes were transformed into One Shot® TOP10 Chemically Competent *E. coli* and the resulting ligation DNA was miniprepped. For each gene of interest, 4 possible ligation combinations may exist considering both -C and -N terminal tags. These constructs were transfected into chemoresistant cells 2 by 2 (Tim16:Tim14). After 48 h Compound 5 was added at a final concentration of 5uM and after 3 h luminescence from living cells was detected by use of furimazine for up to 2 h.
Results
Tim16 and Tim14 interaction was confirmed by measuring luminescence, developing when Tim16 and Tim14 were -C terminal tagged. The addition of Compound 5, on the other hand, decreased by $>65\%$ luciferase emission ($P<0{,}0001$).
Discussion
Compound 5 could be further developed to aid the treatment of chemoresistant cancer. Not only it is devoid of toxic activity, but enhances the pro-apoptotic stimuli of chemotherapy, by specifically targeting Tim16-Tim14 interaction.

Hypoglycemia due to non islet cell tumor in a non-diabetic patient- a case report

Hanaan Ashraf[1] & Idrees Mubarik[2]
[1]Aster DM Healthcare, Internal Medicine, Dubai, United Arab Emirates; [2]Aster DM Healthcare, Endocrinology, Dubai, United Arab Emirates

Background
Non-islet-cell tumor hypoglycemia (NICTH) is a rare but severe complication of malignancy. NICTH has been related to the production of IGF II by tumours of mesenchymal or epithelial origin. It gives rise to frequent episodes of severe hypoglycemia and can have negative impact on quality of life. This case report describes a case of Non Islet cell tumor hypoglycemia due to hepatocellular carcinoma with hypoglycemia as the first presentation.
Clinical presentation
34 years old male patient brought to the ER by ambulance as patient was found unresponsive with blood sugars of 30 mg/dl. Patient was started on dextrose infusion and regained consciousness. On history patient has been having episodes of headache and increased hunger and abdominal discomfort for the past 1 month duration. These episodes occurred thrice a week. He had noticed increase in size of abdomen, fullness and loss of appetite. Patient denied history of Alcohol or Drug use. He had no positive past medical/surgical/family history. On examination patient was cachexic, Abdomen non tender hepatomegaly and ascites. Cardiovascular and Respiratory system examinations were normal. Laboratory investigation of the patient revealed Hb 10.9 mg/dl, WBC-5.8(n- 67.6, l-19.7), PLT-363, LFT: AST-83, ALT-39, GGT-399, Alk phosphatase 278, Insulin-0.20 mIU/ml, C-peptide 0.68 ng/ml, creatinine 0.78, Hba1c-4.5, Insulin antibodies negative, Hepatitis B + ve. USG Abdomen revealed large heterogenous predominantly hyperechoic lesion of right lobe of liver with the possible thrombotic occlusion of right portal vein seen likely suggestive of neoplastic aetiology, ascites present. CT abdomen and pelvis reported hepatomegaly and large mass lesion involving right lobe of liver measuring 18.2 x 14.4 x 13.5 cm in size. The mass had invaded portal vein confluence and right branch of portal vein. Patient was subsequently evaluated for AFP-181500 IU/ml, IGF-1-36.74 ng/ml, CEA-0.50 ng/ml. The diagnosis of Hepatocellular carcinoma was made, Multidisciplinary team was formed, patient was treated for hypoglycemia with dextrose infusion and prednisolone 60 mg/day, planned for PET scan to check for metastasis, debulking/palliative care for relief from hypoglycemia.
Conclusion
NICTH is a rare condition and its incidence is unknown. It is more likely to develop in those with large tumor burden. The diagnosis can be confirmed by a combination of suppressed serum insulin levels and suppressed C peptide and growth hormone concentrations in the setting of hypoglycemia, along with elevated IGF-II levels. Initial treatment aims at maintaining euglycemia, managed with parenteral dextrose infusion. Identification of NICTH and complete tumor resection represents ideal management.

EP1192

Insulin autoimmune syndrome (hirata's disease) -a case report

Hanaan Ashraf[1] & Idrees Mubarik[2]
[1]Aster DM Healthcare, Internal Medicine, Dubai, United Arab Emirates; [2]Aster DM Healthcare, Endocrinology, Dubai, United Arab Emirates

Background
Insulin autoimmune syndrome (IAS) or Hirata disease, is a rare cause of hyperinsulinemic hypoglycemia characterized by autoantibodies to endogenous insulin in individuals without previous exposure to exogenous insulin. IAS has been described as a form of type VII hypersensitivity, characterized by the presence of autoantibodies against a circulating antigen. The cornerstone of the IAS is the appearance of circulating insulin autoantibodies (IAA), which have a pathogenic role in the development of the syndrome. Occasionally It develops when a triggering factor that is a medication or a viral infection acts on an underlying predisposing genetic background. Here, we report a case of Insulin Autoimmune Syndrome.
Clinical presentation
43 years old Asian woman presenting to the ER with diaphoresis and tremors for the past 10 days duration. She had 3-4 episodes/day and were triggered by fasting and exercise. Her blood glucose when checked was noted to be 45 mg/dl. Patient was administered dextrose infusion and evaluated for hypogylcemia. She is non diabetic, no other comorbidities and was not on any medications. General physical examination revealed an obese, alert and healthy female. Her blood pressure 130/82 mmHg and pulse rate was 84/min. She was admitted for 72 hour fast test, patient was kept NPO and closely monioted for symptomatic hypoglycemia. Patient developed diaphoresis and tremors, blood glucose of 50 mg/dl, Samples for insulin, C- peptide, Pro Insulin, serum Beta hydroxy butyrate, and urine ketones were collected, fast terminated and patient was given oral carbohydrates and her condition improved confirming presence of Whipples triad. Her laboratory investigations revealed renal function, liver function tests, thyroid profile and hemogram to be normal. Her 8 am cortisol 12, Hba1c:5.5, Insulin $>$ 1000.0 mIU/ml, Pro insulin 69.70 pmol/l ($<$11), Beta butyric acid $<$60 umol/l.C-peptide 6.29 ng/ml (0.78-5.19), Insulin antibody $>$100 U/ml ($>$10 positive). Usg Abdomen was normal. Contrast enhanced CT abdomen was performed to look for pancreatic pathology and was normal. Diagnosis of Insulin autoimmune syndrome is made. She was adviced frequent small meals and also treated with steroids for a week. On follow up she had resolution of her symtpoms.
Conclusion
The diagnosis of IAS is challenging and should be considered in any patient undergoing evaluation for hypoglycemia. Discrepancies between an unusually high insulin concentration and slightly raised proinsulin and C-peptide levels, with a concurrent insulin to C-peptide molar ratio of $>$ 1, are suggestive of IAS.

Higher blood lead level with menopause and weight recycling in korean women

Kyu Rae Lee
Gachon University Of Medicine And Science, Family Medicine, Incheon, Rep. of South Korea

Background
Previous studies show that lead levels are closely related with obesity, and severe weight reduction in obese women increases skeletal bone mobilization and blood lead levels especially postmenopausal women. However, it is under the curtain if blood lead level is associated with menopause, weight recycling in women until now.
Methods
We assessed weight, height, waist circumferences and obtained past medical histories, blood lead levels as well as socio-demographic, cardio-metabolic variables of 1043 women participated KNHANES (Korea National Health Analysis Nutrition Examination Survey) in 2018. All participants were recategorized into four groups [premenopausal weight loss (-1), premenopausal weight stable (0), postmenopausal weight stable (1), postmenopausal weight gain (2)]. ANCOVA tests were performed using by SPSS for window (Ver. 18, Il, USA) and probabilities less than 0.05 was significant at both sided.
Results
Higher blood lead levels showed significantly associated with higher cardio-metabolic risk variables (hypertension, hyperglycosemia, hypertriglyceridemia, and low HDL cholesterolemia), more obese in postmenopausal weight recycling gain group. ($P<0.01$)
Discussion and Conclusion
Further controlled clinical trial would be considered in the future. We concluded that higher blood lead levels were associated with postmenopausal Korean women with weight recycling.

EP1194

Acromegaly presenting with type 2 diabetes: a case report

Yilmaz Cankurtaran[1] & Zehra Yagmur Sahin Alak[2]
[1]Aydın, Bozdoğan Rasim Menteşe State Hospital, Internal Medicine Department, Aydın, Turkey; [2]Bursa, Health Sciences University, Bursa Yuksek Ihtisas Research and Training Hospital, Endocrinology and Metabolism, Bursa, Turkey

Introduction
Alterations in glucose homeostasis and diabetes mellitus (DM) are the most common metabolic comorbidities in acromegaly. DM has been reported in 16–56% of patients with acromegaly. It is estimated that 20% of patients with acromegaly have developed DM before the formal diagnosis of acromegaly. We report a case of a patient with acromegaly secondary to a pituitary macroadenoma who presented with diabetes.
Case report
A 47- year-old female patient was admitted to our internal medicine clinic for control and assessment of diabetes before tooth extraction due to dental caries. She had suffered from type 2 diabetes for ten years. She had been unable to control the blood glucose level adequately, 1- year history of amenorrhea, generalized fatigue and weight loss for the last one year. She had been on oral antidiabetic therapy (metformin, dapagliflozin, gliclazide, and sitagliptin) for one year with bad glucose values. On examination, her vital signs were within normal. Physical examination revealed acromegalic coarsened facial features but she had no clear-cut cushingoid features and acral enlargement. Anthropometry and laboratory tests were as follows: Height, 150 cm; body weight 55 kg; body mass index (BMI), 24.44 kg/m^2 basal and postprandial glycemia 202, and 280 mg/dL respectively, A1c level of 11.8%. Investigations revealed high IGF-1 levels of 735 mg/l (101–267 mg/l) and growth hormone nadir (1 hour after a 75-g oral glucose load) was 30 ng/mL ($<$1 ng/mL). Complete pituitary hormonal profile revealed prolactin 28.29 ng/mL (4–25 ng/mL), thyroid-stimulating hormone 1.02 uIU/mL (0.35–4.94 uIU/mL), FT3 2.81 pg/mL (2.3–4.2 pg/mL), FT4 1.25 ng/dL (0.89–1.76 ng/dL), follicle-stimulating hormone 57.78 mIU/mL (3.35-21.63 mIU/mL), luteinizing hormone 15.94 mIU/mL (2.39-6.6 mIU/mL), adrenocorticotropic hormone 26.7 pg/mL (7.2-63.3 pg/mL) and cortisol 22.71 mg/dl (5.27-22.45 mg/dl). Magnetic resonance imaging of the sella demonstrated a 17x14 mm pituitary adenoma. The patient was diagnosed with acromegaly, and acromegaly-associated exacerbation of diabetes mellitus. Trans-sphenoidal resection was performed and histopathologic and immunohistochemical findings indicated GH and PRL -producing pituitary adenoma.
Discussion
Acromegaly is often develop insidiously and diagnosis may be delayed as a consequence. The present report outlines a case of missed diagnosis of acromegaly associated with severe hyperglycemia. Clinical suspicion of acromegaly is generally difficult during anamnesis of patients with DM, particularly in the absence of disease-related symptomatology. When treating patients diagnosed with diabetes, secondary causes should not be neglected.

What predictive factors influencing stature gain during the first year GH therapy?

Wahiba Abdellaoui[1], Tahri Abir[1], Nada El Yamani[1], Siham Rouf[1, 2] & Hanane Latrech[1,2]
[1]Mohammed VI University Hospital, Medical School, Mohammed the First University, Department of Endocrinology-Diabetology-Nutrition, Morocco; [2]Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy of Oujda, Mohammed the First University, Morocco

Introduction
Growth Hormone deficiency (GHD) is a rare etiology of short stature. The lack of early diagnosis and adequate treatment have adverse consequences, especially the small final height with the resulting psychological impact. The aim of this study is to identify some of the predictive factors influencing stature gain during the first year of GH therapy.
Matherials and methods
This is a retrospective and analytical study regarding 36 children with GHD, collected in the endocrinology department of Mohammed VI Hospital. The data were collected and processed using SPSS software V21.
Results
The prevalence of patients with GHD is 16.36% among 220 cases with short stature requiring exploration. The mean chronological age (CA) at the start of

treatment was 11,6 years. Mean height Z-score at time of diagnosis was −4,3 SD. The delay of bone age (BA) over the chronological age was of 4,2 years on average. The mean therapeutic dose was 0.025 to 0.035 mg/kg/day. The average stature gain at the end of the first year of GH treatment was 10,5 cm. Correlation analysis showed that a change in height gain in the first year had a significant correlation with the age at the start of treatment ($P<0.001$), the severity of growth hormone deficiency ($P=0,047$) and the presence of multiple pituitary hormone deficiencies ($P=0.18$). No correlation was found between height gain and sex gender, body mass index, and abnormalities on pituitary magnetic resonance imaging.
Conclusion
Despite a very evocative clinical features, the diagnosis of GHD remains difficult and relatively late in some patients. The height gain is more important during the first year of GH therapy. The earlier the treatment is administrated, the better the results will be in case of a severe deficiency.

Permanent central diabetes insipidus after traumatic brain injury

Ludmila Astafyeva[1], Yuliya Sidneva[1], Inna Badmaeva[1], Pavel Kalinin[1], Svetlana Valiullina[2] & Andrey Marshintsev[2]
[1]Burdenko Neurosurgery Center, Moscow, Russian Federation; [2]Clinical and Research Institute of Emergency Pediatric Surgery and Trauma (CRIEPST), Moscow, Russian Federation

The article presents a case of permanent central diabetes insipidus (CDI) in a patient after severe traumatic brain injury (TBI) in traffic accident. A 16-year-old boy entered to a medical facility in the coma (6 points of Glasgow Coma scale (GCS)). Diagnosis: acute TBI; severe cerebral contusion; subarachnoid hemorrhage; depressed comminuted cranial vault fracture; basilar skull fracture; visceral contusion. CDI diagnosed three days after injury when polyuria and hypernatremia (155 mmol/l) developed. Desmopressin therapy started through a feeding tube. Thirst was appeared when patient out of coma on day 21 while desmopressin therapy was continuing. Because of persistent thirst and polyuria desmopressin therapy continued in the spray form. Against this backdrop polyuria reduced to 3-3.5 liters per day while nasal desmopressin therapy was continuing. The symptoms of CDI persisted in the long-term period two years after TBI while the intact adenohypophysis function. This case demonstrates a rare development of permanent diabetes insipidus in a boy after TBI. CDI manifested only as polyuria and hypernatremia in a coma. Thirst joined at rising levels of consciousness. The probable causes of CDI were neurohypophysis and his tract injury as a result of extended basilar skull fracture and/or irreversible secondary hypothalamus injury because of brain diffuse axonal damage after head trauma.

Pilomyxoid astrocytoma revealed by a failure to thrive: An uncommon case report

Salma Ben Yakhlef, Achwak ALLA, Wahiba ABDELLAOUI, Siham ROUF & Hanane Latrech
Mohammed VI University Hospital, Mohammed I University, Oujda, Morocco, Department of Endocrinology- Diabetology, Oujda, Morocco

Introduction
Pilomyxoid astrocytoma (PMA) is a rare entity usually described in the hypothalamic-chiasmatic area. It generally concerns infants and very young children. Clinical presentation is not well-defined. But, the therapists should be aware of diencephalic syndrome as an unconventional cause of failure to thrive during early childhood. We report a case of PMA exhibited by failure to thrive;which is a rare outlined association in the litterature.
Case report
An 11-month-old boy was admitted to our university hospital for further exploration of poor weight gain (<3rd percentile). The physical examination revealed pallid and dry skin besides lack of subcutaneous fat. He had a sunken anterior fontanel, muscle atrophy and left eye's nystagmus. Brain magnetic resonance imaging (MRI) exhibited a suprasellar mass measuring 59*41*40 mm, isointense on T1-weighted MRI and hyperintense on T2-weighted MRI and homogeneously enhanced upon contrast administration. The lesion extended into retro-sellar region, optic chiasm and right hypothalamus. The lesion compressed mainly temporal lobes, cerebral pedicles and the anterior surface of the pons. The patient underwent a right pterional craniotomy besides a subtotal tumor resection (95%). After the surgery, the child's clinical course declin ed with blindness of the left eye and left-sided mild hemiparesis besides focal seizures prevented by Levetiracetam twice a day. Hormonal assessment in post op period showed a panhypopituitarism. Therefore, hormonal replacement medications have been immediately introduced. Histological examination revealed monomorphous bipolar cells with a generous myxoid matrix and an angiocentric disposition of the tumor cells. Immunochemistry showed oligo-dendrocyte lineage transcription factor 2(oligo-2)and S-100 positively stained cells while they seemed negative for IDH1 and P53. The proliferation index of Ki 67 was about 8%. During a 6-month follow-up, MRI showed a residual supra-sellar mass with a sellar component compressing optic chiasm, cerebral pedicles, and pons anterior surface, with cystic component extending to third and lateral ventricles.A chemotherapy was suggested instead of surgical reintervention and the patient died after 2 sessions due to medullary anaplasia.
Conclusion
The non specific clinical aspects of diencephalic syndrome and its fluctuating presentation deeply reflects the lack of understanding of its pathogenesis and should keep in mind the necessity of brain MRI within etiological investigations to make diagnosis as early as possible and plan an adequate therapy.

Spectrum of radiological abnormalities of children with growth hormone deficiency at the endocrinology-diabetology-nutrition department of oujda's university hospital

Wahiba Abdellaoui[1], Nada El Yamani[1], Tahri Abir[1], Siham Rouf[1, 2] & Hanane Latrech[1]
[1]Mohammed VI University Hospital, Medical School, Mohammed the First University, Department of Endocrinology-Diabetology-Nutrition, Morocco; [2]Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy of Oujda, Mohammed the First University, Morocco

Introduction
Growth hormone deficiency (GHD) is a non-exceptional cause of short stature. Hormonal evaluation and hypothalamic-pituitary MRI are essential to establish the etiological diagnostic. The objective of our study is to assess the different pituitary lesions found in a group of children with GHD.
Patients and methods
This is a retrospective longitudinal study of 36 cases of GHD who underwent pituitary MRI examination collected in the Endocrinology-Diabetology Department of Mohammed VI University Hospital.
Results
The mean age at diagnosis was 11.6 years with a sex ratio (M/F) of 1.57. Mean height Z-score at time of diagnosis was −4.3 SD. The mean bone age (BA) at the time of diagnosis was 7.6 years. The delay of BA over the chronological age was of 4.2 years on average. The diagnosis of total GHD was found in 66.7% of patients and partial GHD in 33.3% of patients. The isolated deficiency was noted in 52.8 % of cases and multiple deficiencies in 47.7% of cases. Magnetic resonance imaging of the hypothalamic-pituitary region was normal in 33.3% of cases. Pituitary stalk interruption was observed in 41.7% of patients, pituitary hypoplasia was observed in 11.1% of patients, an empty sella was observed in 8.3% of patients, and agenesis of anterior pituitary in 5.6% of patients.
Conclusion
The multiplanar capability of MR imaging plays an important role in the assessment of the hypothalamic-pituitary area and in determining the underlying cause of various pituitary diseases in GHD.

Aggressive corticotropic pituitary adenoma: when to think about? about a clinical case

Aicha Ahmed[1], Cheibetta Zekeria[1], Mohamed Ali Boutheina[1], Rifai Kaoutar[2], Iraqi Hind[2] & Gharbi Mohamed Hassan[2]
[1]Ibn Sina, Endocrinology, Rabat, Morocco; [2]Chu Ibn Sina, Endocrinology, Rabat, Morocco

Introduction
Most pituitary adenomas are benign. However, there are invasive forms with rapid growth rate and particular histological signs (atypical adenomas), making them considered pituitary carcinomas without metastases.
Observation
A 63-year-old patient was followed for 10 years for Cushing's disease in the pituitary macrodenoma. Clinical evaluation found Cushing syndrome, pituitary tumor syndrome associated with diplopia, and trigeminal neuralgia. At the endocrine level, it presents substituted thyrotropic and gonadotropic insufficiency. Metabolically, severe osteoporosis complicated by vertebral fracture. He was operated on by the transphenoidal route and irradiated three times by gamma-knife radiosurgery without clear remission. Immunohistochemistry expressed only ACTH. Currently, the patient has persistent Cushing's disease with eight times normal urinary free cortisol (UFC). MRI showing an invasive pituitary macrodenoma with extension to the cavernous sinus. Anticortisolic treatment (ketoconazole) was started with an improvement in CLU to 3 times normal. For the treatment of macroadenoma, surgical treatment has been discussed but rejected by surgeons. So, we indicated a somatostatin analogue 'pasireotide', but it is not available in Morocco.
Discussion
Aggressive pituitary adenomas (AHA) are said to be atypical and have suprasellar and parasellar extension with invasion of the cranial nerves, cavernous sinus. Usually, they are resistant to conventional treatments (surgery and radiation therapy). It is important to differentiate them from pituitary carcinomas according to histological criteria. Treatment of these forms of aggressive adenoma consists of a combination of several surgical, pharmacological, and radiotherapy therapies. Pasireotide, which is an analogue of somatostatin, has particularly demonstrated efficacy in corticotropic pituitary adenomas. New therapeutic prospects based on chemotherapy using temozolomide have also been shown to be effective. These pituitary tumors must be recognized and aggressively treated to prevent complications.

EP1200

Change in the size of somatotropin after radiation therapy depending on age

Zamira Khalimova[1], Saodat Issaeva[1] & Mukhlisa Khokimboeva[2]
[1]Republican Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan; [2]General Secondary School, Tashkent, Uzbekistan

Aim
To study the relationship between the age of patients and the dynamics of the size of somatotropinomas after radiation therapy (RT).
Materials and methods
The object of the study is 94 patients with acromegaly who received RT. The average age was 43.8 ± 10.4 years. The patients were divided by age into the following groups: Group I 16-29 years old (9 patients); II group 30-44 years old (44 patients); III group 45-59 years old (34 patients); IV group 60-74 years old (7 patients).
Results
The analysis shows that before RT in group I, macroadenomas were observed in 84.9% of cases, microadenomas in 3.8% and giant adenomas in 11.3% of cases. In group II, microadenomas accounted for 3%, macroadenomas - 82.4%, giant adenomas - 14.7%. In group III, macroadenomas were 85.7%, giant adenomas - 16%. Moreover, giant adenomas tended to increase in parallel with increasing age also if in patients of group I they accounted for 11.3% of cases, increased to 14.7% and 16.3% in groups I and III, respectively. Assessment of the dynamics of the size of education in different age groups against the background of RT also revealed interesting results. After RT in group I, cases of microadenomas increased to 30.2%, macroadenomas decreased 1.3 times and amounted to 67.9%, and giant adenomas 1.89%. In group II, up to the stage of microadenomas decreased in 38.2% of patients (due to a decrease in cases of macroadenomas and giant adenomas), cases of macroadenomas decreased almost 1.5 times, and one patient experienced a recurrence of pituitary adenoma. So, in the long-term periods of post-radiation therapy, a significant decrease in the size of somatotropinoma was observed ($P<0.01$). In group III of patients, 43% of patients had microadenomas, the frequency of macroadenomas decreased by 1.5 times - in 57% of patients, no giant adenomas were detected.
Conclusion
The use of RT leads to a significant decrease in the size of the growth hormone in all age periods. In the age period from 30 to 59 years, a significant improvement in the results was observed in the long term after RT.

EP1201

Impact of COVID-19 outbreak on acromegaly patients management

Elisa Filippi, Silvia Camerini, Marica Spinello, Roberto Vettor, Pietro Maffei & Francesca Dassie
UOC Clinica Medica 3, DIMED, Padova, Italy

Introduction
Acromegaly is a chronic disease that requires continuous follow-up and examinations over time. During the COVID-19 pandemic outbreak many endocrinological scientific societies recommend to reduce pituitary patient access to hospital facilities to decrease risk of infection.
Aim
The aim of our study is to evaluate the impact of restrictions on outpatient access in the clinical management of the patient with acromegaly during COVID19 pandemic outbreak.
Methods
We enrolled 41 patients with acromegaly, who had at least one clinical evaluation during the year 2018 (period before COVID-19) and a re-evaluation in the COVID19 period between 2020-2021. We collected the following data: anthropometric measures, disease activity status, ACROQoL score, comorbidities, previous treatments, ongoing medical treatments, pituitary adenoma characteristics, Sign and Symptoms Score (SSS), SAGIT® and ACRODAT®.
Results
The 41 patients (24 females and 17 males) had a mean age of 53.27 ± 11.43 years at 2018 evaluation, among these patients 6 were infected with SARS-COV-2 during the considered period. In the entire cohort of patients analysed, there was a significant reduction in IGF-1 values (2018 vs 2021: IGF-1 256.61 ± 165.60 mg/l vs 201.44 ± 87.44 mg/l, $P = 0.004$) with a significant increase in patients who had IGF-1 ULN values <1.2 in 2021 (2018 vs 2021 54% vs 76%, $P=0.004$). GH values decreased over time but not significantly (2018 vs 2021: 6.43 ± 23.51 vs 1.37 ± 1.12 mg/l, $P=$NS), while SSS showed a worsening of referred acromegaly related symptoms at the second evaluation (2018 vs 2021: 1.987 ± 0.70 vs 2.32 ± 0.61, $P=0.001$). There was also a trend towards reduced disease activity at ACRODAT assessment (2018 vs 2021: 61.63% ± 38.30 vs 49.29 ± 33.63, $P=0.047$; red 46.34 vs 24.39 yellow 24.39 vs 34.15 green 39.27 vs 41.46, $P=$NS) which was not confirmed by SAGIT (2018 vs 2021: 6.78 ± 3.67 vs 7.08 ± 2.55, $P=$NS). The ACROQoL and the percentage of cardiovascular, osteo-skeletal, respiratory and cancer comorbidities of the patients remain stable over time. These findings were also confirmed in the cohort of patients undergoing medical treatment (excluding patients in remission, first disease diagnosis and immediate post-surgical period).
Conclusions
COVID-19 pandemic status and its consequent limitations do not seem to have affected outpatient access and achievement of good disease control within the analysed sample. Pandemic seems to not affect quality of life even if reported symptoms have worsened.

Mycophenolate mofetil as a treatment for infundibulo-neurohypohysitis related to Gougerot-Sjögren's syndrome revealed by postpartum diabetes insipidus: A case report

Rachid Smaili[1], Ikram Raaidi[1], El Bachiri Soumaya[1], Lahbib Hafsa[2] & Myriem Bourkia[1]
[1]University Hospital of Tangier, Morocco, Internal Medicine and Clinical Immunology, TANGER, Morocco; [2]University Hospital of Tangier, Endocrinology Department, TANGER, Morocco

Infundibulo-neurohypophysitis is an inflammation of the pituitary stalk and posterior gland. It is an autoimmune disease characterized by lymphocytic infiltration of the pituitary gland. It occurs mainly at the end of pregnancy or in the postpartum period, and is related to autoimmune diseases, including autoimmune thyroiditis. But it is rarely related to Gougerot-Sjogren syndrome, which is an autoimmune connective tissue disease with lymphocytic infiltration of the exocrine glands. We report unusual case of a 25-year-old woman with a history of atopic dermatitis who presented in the early postpartum period with central diabetes insipidus and visual hallucination, dry eyes and mouth. Investigation showed a typically imaging of an infundibulo-neurohypophysitis in the pituitary MRI, associated with a primary Gougerot-Sjogren's syndrome confirmed at the salivary gland biopsy. Patient was treated with mycophenolate mofetil at 1 gramme by day, and desmopressin replacement therapy with a good clinical and radiological improvement at one year of follow-up.

Key words: Infundibulo neurohypophysitis- gougerot sjogren's syndrome – postpartum period - mycophenolate mofetil.

Profil of vitamin D in children with growth hormone deficiency at the Endocrinology-Diabetology-Nutrition Department of Oujda's University Hospital

Wahiba Abdellaoui[1], Nada El Yamani[1], Salma Ben Yakhlef[1], Siham Rouf[1,2] & Hanane Latrech[1,2]
[1]Mohammed VI University Hospital, Medical School, Mohammed the First University, Department of Endocrinology-Diabetology-Nutrition, Morocco; [2]Laboratory of epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy of Oujda, Mohammed the First University, Morocco

Introduction
Hypovitaminosis D is prevalent in children with growth hormone deficiency. Infants and young children are special risk groups of vitamin D deficiency due to their rapid growth with high nutritional requirements. The lack of early diagnosis and adequate treatment have adverse outcomes. It impairs particularly bone maturation and increases metabolic risk. The purpose of our study is to assess the vitamin D status of children followed up for GHD in the Endocrinology-Diabetology and Nutrition department of Mohamed VI University Hospital Center.
Matherials and methods
This is a retrospective and analytical study regarding 36 children with GHD who underwent a vitamin D dosing, collected in the endocrinology department of Mohammed VI Hospital. The data were collected and processed using SPSS software V21.
Results
The mean age at diagnosis was 11.6 years with a sex ratio (M/F) of 1.57. The average standard deviation score was 4.3 SD for height and 2.9 SD for weight. The median difference in bone age from chronological age was 4.2 years. The insulin growth factor 1 (IGF1) was low related to pubertal stage in 77,8 % of patients. Bone X-rays were performed in all patients and did not reveal any abnormalities. The diagnosis of total GHD was assessed in 66.7% of patients and partial GHD in 33.3% of the cases. The mean vitamin D value was around 22,3 ng/ml, and ranged between 10–30 ng/ml in 66.7 % of the patients. It was less than 10 ng/ml in 11.1%, and greater than 30 ng/ml in 22.2% of the cases. Patients with total GH deficiency had a significantly lower vitamin D levels ($P=0.036$). The reminder of phosphocalcic laboratory tests was normal in all patients.
Conclusion
Vitamin D deficiency increases metabolic risk and skeletal consequences of growth hormone and IGF1 deficiency. The strong link between vitamin D and IGF1 levels requires vitamin D replacement therapy in order to improve their height growth velocities. The results of our study highlighted the value of vitamin D dosing in children with GHD, in order to detect any deficiency which may affect the growth of children with GHD.

Role and expression of miRNAs (miRNA 548e_5p, miRNA 873_5p, miRNA 378b) in fetal development and incidence of Preeclampsia in pregnancy

Ramesh Bangaraiahgari[1], Rajesh Bangaraiahgari[2], Bhargav Panchangam[3], Udaya Kumar U[4], Vinaya V[5] & Banala Rajkiran[6]
[1]Arundathi Institute of Medical Sciences, Department of Biochemistry, Telangana, India; [2]Arundathi Institute of Medical Sciences, Department of Anatomy, Telangana, India; [3]Endocrine Hospitals, Vijayawada, India; [4]Arundathi Institute of Medical Sciences, Department of Pediatrics, Telangana, India; [5]Apollo Institute of Medical Sciences and Research, Telangana, India; [6]Sunshine Hospital, Telangana, India

Background
Preeclampsia (PE) continues tochallenge both the clinicians and researchers worldwide, as the existing knowledge on its etiopathology does not come up with an efficient and foolproof treatment regime due its progressive nature and uncertain diagnosis and prognosis. In this context, miRNAs represent a potential therapeutic target and a diagnostic tool.
Objectives
Circulating microRNAs present in maternal blood play an important role in the etiopathology of PE. The aim of this study is create the panel of miRNAs and quantify their real time expression in peripheral blood of PE patients (from early-onset PE (EOPE) ($<$ 34 weeks), and late- onset PE (LOPE) ($\geq$34 weeks)) and compare with thecontrols.
Study design
Using real time polymerase chain reaction (RT-PCR) method, we quantify the miRNA's expression (miRNA 548e_5p, miRNA 873_5p, miRNA 378b) in EOPE ($n=$ 50) and LOPE ($n=$ 50) and compare with the controls ($n=$ 50), through this we will find out their association with PE and its onset.
Outcome measures
Expression of the target miRNA in EOPE and LOPE patient samples will be compared to the controls and quantification will help in studying the specific miRNA and role in fetal growth or elevation of blood pressure, etc. Once, the panel of targeted miRNA is preparedand quantified it will help in diagnosis and therapeutics.
Results
Basesd on the rt-pcr analysis the expression of mi-RNA (miRNA 548e_5p, miRNA 873_5p) was significant in EOPE & LOPE where as micro RNA 378b expression was higher in controls samples. miRNA 548e_5p plays to role role down regulate ZEB gene which is involved in epithelial to mesenchymal transition. miRNA 873_5p plays to role down regulate JMJD _8 gene. Jumonji C domain _containing protein which is involved in endothelial differentiation. Micro RNA 378b was found in controls, and not in PE. It down regulates the expression of TGFbeta3.
Conclusion
The expression of miRNA 548e_5p, miRNA 873_5p is only found in patients with PE, Where as miRNA 378b is found only in controls.

Psychological stress levels in men with infertility

Gesthimani Mintziori, Stavroula Veneti, Athanasios Mousiolis & Dimitrios Goulis
Aristotle University of Thessaloniki Medical School, Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Thessaloniki, Greece

Aim
Infertility, defined as the non-achievement of pregnancy by a couple after 12 months of free sexual intercourse, affects 4 - 17% of couples worlwide. In 20% of cases, the cause is found exclusively or mainly in the man. The purpose of this study is to evaluate infertility as a risk factor for increased psychological stress.

Material and Methods
A case – control study was conducted in which the levels of psychological stress of men with infertility and fertile healthy men were assessed. The primary research question was whether male infertility was associated with increased psychological stress. The Greek editions, validated for the Greek population of the Perceived Stress Scale -14 (PSS-14) and Spielberger State-Trait Anxiety Inventory (STAI) questionnaires were used to assess the latter.
Results
The study involved 91 men: 47 infertile men with mean ($\pm$ SD) age 37.5 $\pm$ 0.9 years and mean body mass index (BMI) 24.4 $\pm$ 1.1 kg/m^2 and 44 fertile with mean age 37.9 $\pm$ 0.7 years and BMI 24.1 $\pm$ 1.2 kg/m^2. No differences in stress scales were observed between infertile patients and fertile men (STAI 45.9 $\pm$ 0.4 vs. 44.86 $\pm$ 0.493, $P=$ 0.105 and PSS-14 29.66 $\pm$ 0.75 vs. 28.89 $\pm$ 0, 5, $P=$ 0.436 in infertile and fertile men, respectively).
Conclusion
There was no statistically significant difference in psychological stress levels between infertile and fertile men, although levels were relatively high in both groups. One possible cause is the SARS-CoV-2 pandemic, which by affecting lifestyle can lead to high levels of stress and mitigation of any differences between the groups.

The impact of gh treatment in turner syndrome

Anamaria Hrisca[1], Teodora Dumitru[2], Diana Andrei[2], Alexandru Florescu[1, 2], Letitia Leustean[1, 2], Cristina Rusu[4, 5], Cristina Preda[1, 2] & Maria Christina Ungureanu[1, 2]
[1]University of Medicine and Pharmacy 'Grigore T. Popa', Endocrinology, Iasi, Romania; [2]'St. Spiridon' Clinical and Emergency Hospital, Endocrinology, Iasi, Romania; [4]University of Medicine and Pharmacy 'Grigore T. Popa', Clinical Genetics, Iasi, Romania; [5]'St Mary' Emergency Children Hospital, Clinical Genetics, Iasi, Romania

Introduction
The treatment with growth hormone (GH) plays an essential role in the Turner syndrome (TS) management. This study evaluated its efficacy in improving adult height (AH) and metabolic parameters.
Material and methods
We retrospectively analysed auxological, biochemical, genetic and pharmacological parameters of 56 girls with confirmed TS. They were categorised according to their karyotype as X monosomy (62%), isochromosome (17%), X mosaicism (11%) and ring X chromosome (10%). They were aged 10.85 $\pm$4.008 years at the initiation of the treatment, and the average GH treatment duration was 4.36 $\pm$ 2.82 years with a dose of 0.035-0.05 mg/kg/day.
Results
The GH treatment significantly increased height between the first and the last visit (123.36 $\pm$ 17.78 cm vs 150.45 $\pm$ 7.37 cm). There was a significant correlation between the initial age and the final height. IGF1 serum level was low in 15 patients before treatment and raised to normal values during treatment. Nine patients were overweight and the BMI did not significantly change during treatment. The total cholesterol and triglycerides decreased after the initiation of the treatment (from 173.87 $\pm$ 27.59 mg/dl to 155.69 $\pm$ 31.06 mg/dl and 79.25 $\pm$ 44.07 to 75.6 $\pm$ 34.61). Fasting plasma glucose raised from 87.53 $\pm$ 10.57 to 93.85 $\pm$ 9.35 mg/dl, with only a few isolated cases of hyperglycemia (6 patients). There was no significant change in terms of hepatic enzymes during treatment. Vitamin D deficiency was identified in 17 patients (16.13 $\pm$ 4.3 ng/ml). Eleven girls (19.6%) presented autoimmune thyroiditis, ten girls - cardiac anomalies, 2 - renal malformation and 4 - celiac disease. The treatment had no negative impact on cardiac function.
Conclusion
Our study strengthens the literature findings that GH treatment at an early age effectively improves the final height. GH therapy has additional positive effects on serum lipids, without adverse effects on carbohydrate metabolism, hepatic function or cardiac modifications, confirming treatment safety in TS girls.

Ultrasound EU-TIRADS classification of thyroid nodules and its correlation with fine-needle aspiration results : Experience of the endocrinology, diabetology and nutrition department of the Mohammed VI University Hospital of Oujda

Achwak Alla[1], Salma Ben Yakhlef[1], Siham ROUF[2] & Hanane Latrech[2]
[1]Chu Mohammed VI Oujda, Endocrinology Diabetology and Nutrition Department, Oujda, Morocco; [2]Chu Mohammed VI Oujda, Endocrinology Diabetology and Nutrition Department, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy, Mohamed I University, Oujda, Morocco, Oujda, Morocco

Introduction
Nodular thyroid pathology is very frequent. Its exploration requires a clinico-biological evaluation, a cervical ultrasound to look for the ultrasound criteria of malignancy allowing to classify the thyroid nodules according to the EU-TIRADS classification in order to orientate the diagnosis and to indicate the Fine needle aspiration, to finally allow a targeted management. The aim of our study is to investigate the correlation between the EU-TIRADS classification and the Fine-Needle aspiration outcomes.
Materials and Methods
This is a retrospective study including 85 patients with thyroid nodules. Conducted at the Endocrinology, Diabetology and Nutrition Department of the Mohammed VI University Hospital Center of Oujda in MOROCCO.
Results
The average age of our patients was 45 $\pm$ 14.1 years with a female predominance of 88%. According to the EU-TIRADS 2017 classification, we noted 2.2% of cases classified as EU-TIRADS2, 35.2% of cases classified as EU-TIRADS3, 49.5% of cases classified as EU-TIRADS 4, and 14.1% of cases classified as EU-TIRADS5. Fine-needle aspiration was performed in 86.9% of cases, 13% of cases came back malignant. The calculated risk of malignancy for each score is 0% for EUTIRADS 2, 9% for EUTIRADS 3, 12% for EUTIRADS 4, 60% for EUTIRADS 5. The EU-TIRADS and Bethesda 2017 correlation had a statistically significant relationship ($P=$ 0.004).
Discussion and Conclusion
The EU-TIRADS system has been prospectively validated and its diagnostic value was confirmed by Yoon *et al* (1) in a study of 4696 nodules. Compared with other risk stratification systems, the main objective of EU-TIRADS is to provide easy indications to detect thyroid carcinomas with high sensitivity while maintaining high negative predictive value. This, in turn, should reduce unnecessary cytopunctures. In 2017, Russ *et al* (2) found a correlation between the EU-TIRADS score and the risk of malignancy for each score, and concluded that the risk of malignancy increased with increasing EU-TIRADS score.

Biological profile of patients with Graves' disease after treatment with iodine 131: experience of the nuclear medicine department of Tlemcen hospital

Khelil Nour El Houda[1], Meghelli Sidi Mohammed[2], Benmansour Fatéma Zohra[3] & Bouhadjer Nassima[3]
[1]Faculty of Medicine (Tlemcen), Department of Endocrinology - Tlemcen Hospital, TLEMCEN, Algeria; [2]Faculty of Medicine (Tlemcen), Department of Nuclear Medicine - Tlemcen Hospital, TLEMCEN, Algeria; [3]Faculty of Medicine (Tlemcen), TLEMCEN, Algeria

Hyperthyroidism is a clinical situation characterized by an excess of thyroid hormones in the circulation, the most common etiology of which is Graves' disease. Its treatment is based on ATS, iodine 131 and surgery. The iratherapy, object of our study, is a treatment of current practice. It is a simple and radical treatment whose goal is to switch to euthyroidism or hypothyroidism. In case of failure or recurrence, a 2nd or even a 3rd cure is prescribed. We conducted a retrospective, descriptive study with the aim of clarifying the future of patients followed in the nuclear medicine department of the CHU Tlemcen after metabolic radiotherapy with iodine 131 for Graves' disease. Out of 101 patients, 3 groups were identified: the first with 87 patients having received a single course of iodine 131, the average activity administered is 9.89 mCi, the success rate at 18 months

is 75%. The second group with 13 patients who received 2 courses of iodine 131 whose mean activity administered in the first course was 10.01 mCi, after failure and persistence of hyperthyroidism they received a second course whose mean activity administered is of 10.11 mCi, the success rate at 18 months this time is 77.7%. Finally, a third group consists of a single patient who received 3 courses of iodine 131 with a cumulative activity of 35.08 mCi. The latter found himself in hypothyroidism after the 3rd treatment. Radiation therapy has its place as a therapeutic alternative for Graves' disease after failure or intolerance to medical treatment

Differentiated Thyroid Cancer (DTC) is the most common malignant tumor in endocrinology, being the papillary subtype frequently found. The DTC is usually indolent and with a more favorable clinical prognosis of survival in 10 years, which has been diagnosed more frequently after the development and dissemination of complementary detection methods, according to the world literature. However, access to imaging exams with increasing resolving power makes a large number of low-risk patients suffer unnecessary and aggressive treatment. To overcome this new reality, the current guidelines, such as ATA 2015, have changed the way that this disease is treated and classified, in order to prevent the low-risk patients to be overtreated. The objective of this paper was toidentify if the current treatment guidelines for DTC have impacted the decision to use less iodine therapy after thyroidectomy. We performed a retrospective cross-sectional, quantitative, observational analysis of patients diagnosed with DTC, submitted to thyroidectomy with their respective treatment histories and clinical and laboratory follow-up data. In the sample of 201 patients, of the 54 staged as intermediate risk by ATA 2009, 16 (30%) were stratified to low risk by ATA 2015. A percentage of 26,5%($n=$ 18) of microcarcinomas were diagnosed since 2015, being significantly larger ($n=$ 17 (12,8%) than those treated before the new classification (p-value = 0,019). However, patients who maintained the low-risk classification had a mean ablative dose of 61,92 mCi, while the 16 patients who were reclassified from intermediate to low risk in 2015, has a mean dose of 97,5 mCi. In conclusion, the DTC is being treated in smaller tumors but continues to be treated with high doses of radioiodine associated with total thyroidectomy, when they could have been submitted to cheaper surgery or even active surveillance. Thus, despite a significant change in estranging due to updates in the latest guideline, in medical practice there I still a wide variation in the management of low-risk DTC.

Correlation of ultrasound predictors of malignancy and risk of thyroid cancer in patients with thyroid nodules - about 85 cases -

Achwak Alla[1], Nada Derkaoui[1], Siham ROUF[2] & Hanane Latrech[2]
[1]Chu Mohammed VI Oujda, Endocrinology Diabetology And Nutrition Department, Oujda, Morocco; [2]Chu Mohammed VI Oujda, Endocrinology Diabetology And Nutrition Department, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy, Mohamed I University, Oujda, Morocco

Introduction
Thyroid pathology, particularly nodular, is very frequent. It is in most cases benign, thyroid cancer remains rare (5% of nodules). Thyroid ultrasound is the reference examination and should be performed in all patients with known or suspected thyroid nodules. It will allow the detection, diagnosis, search for signs of malignancy and monitoring of these nodules. The aim of our study is to investigate the correlation between the ultrasound signs of malignancy and the risk of thyroid cancer.

Materials and methods
This is a retrospective study including 85 patients with thyroid nodules. Conducted at the Endocrinology, Diabetology and Nutrition Department of the Mohammed VI University Hospital Center of Oujda in the East of MOROCCO.
Results
The average age of our patients was 45 $\pm$ 14.1 years with a female predominance of 88%. The location of thyroid nodules was variable with no statistically significant relationship with the risk of malignancy ($P=0.348$). The mean size of benign nodules was 35.1 mm, whereas malignant nodules had a mean size of 31.8 mm ($P=0.580$). The nodules were taller than wide in 8.7% of cases with a statistically significant relationship with the risk of malignancy ($P=$ 0.004). We did not find a significant relationship between hypoechoic or isoechoic nodules and malignancy ($P=0.168$). On the other hand, irregularity of the contours was noted in 12% of the cases and had a statistically significant relationship in predicting cancer ($P=0.015$). We had the same finding for microcalcifications ($P=0.017$) and central vascularization ($P=0.021$). We noted 2.2% of cases classified as EU-TIRADS2, 35.2% of cases classified as EU-TIRADS3, 49.5% of cases classified as EU-TIRADS 4 and 14.1% of cases classified as EU-TIRADS5. Fine-needle aspiration was performed in 86.9% of cases, 13% of cases came back malignant. The EU-TIRADS and Bethesda 2017 correlation had a statistically significant relationship ($P=$ 0.004).
Discussion and conclusion
Our results were consistent with the literature, allowing us to conclude that a good diagnostic approach using ultrasound by an experienced clinician, followed by fine-needle aspiration, when indicated, facilitates the therapeutic management of these thyroid nodules, promoting high quality care while minimizing cost and unnecessary surgeries.

Study of Correlation between Serum Osteoprotegerin, TNF-alfa and Biomarkers of Bone Metabolism in Patients with treatment naive Graves' Disease. - A cross sectional study

Kishore Behera[1], Suchanda Sahu[2], Kanhaiyalal Agarwal[3], Girish Kumar Parida[3], Uttam Kumar Soren[1] & Anand Srinivasan[4]
[1]All India Institute of Medical Sciences, Endocrinology & Metabolism, Bhubaneswar, India; [2]All India Institute of Medical Sciences, Biochemistry, Bhubaneswar, India; [3]All India Institute of Medical Sciences, Bhubaneswar, Nuclear Medicine, Bhubaneswar, India; [4]All India Institute of Medical Sciences, Bhubaneswar, Pharmacology, India

Objectives
Primary - Study of Correlation between Serum Osteoprotegerin, and Biomarkers of Bone Metabolism in Patients with treatment-naive Graves' Disease (GD). Secondary- Serum level of Osteoprotegerin, TNF alfa and Biomarkers of Bone Metabolism in Patients 3 months after treatment of GD with methimazole (MMI).
Material and Methods
A total of thirty-five treatment-naive newly diagnosed GD were recruited for the study, most of them were female. All patients were started with MMI for the treatment and various blood parameters were measured at baseline and after 3months of treatment.
Measurements
Serum calcium, phosphorus, and bone-specific alkaline phosphatase (B-ALP), OPG (osteoprotegerin), TNF-alpha and urine deoxypyridinoline (Udpd) along with serum-free T3 and T4, TSH and TR-ab were analysed at baseline and three months after MMI treatment. All the patients were euthyroid at 3months of MMI treatment.
Results
Mean Serum OPG (0.94 ± 1.39 v $0.63\pm.27$ng/ml; $P=0.262$)level at base line and after treatment with MMI did not show any significant change. Mean TSH level (0.207 0.59 vs 1.00 1.95, $P=0.025$) was significanly low at base line than after treatment;FT4 (5.9 ± 5.22 v 1.77 ± 1.89 ng/dl;$P<0.001$), FT3 (12.19 ± 6.91 v 4.99 ± 3.55pg/ml;$P<0.001$), and TNG -alfa values decreased significanly after treatment, however PTH (58.09 ± 28.75 v 75.57 ± 41.50;$P<0.026$) increased significantly after treatment. There is no correlation of OPG with thyroid hormone profile, TSH, thyroid receptor antibody (TR-ab) and bone metabolic parameters such as serum calcium, phosphorus, and bone-specific alkaline phosphatase (B-ALP), TNF-alpha and urine deoxypyridinoline (Udpd) in our study. Mean TNF-alfa decreased significantly (393.43 ± 270.473 v 139.34 ± 101.264pg/ml; $P=0.001$)level after treatment with MMI. TNF-alfa was positively correlated with TR-ab ($r=$ 0.374; $P=0.027$)and B-ALP ($r=$ 0.388;p0.021).
Discussion
The bone turnover marker in GD seems to be mediated other than OPG. We observed increased circulating TNF-alfa in GD with a significant decrease after

treatment. TNF-alfa could be a marker of GD activity as evidenced by a close positive correlation with TR-ab a sensitive marker of GD autoimmunity. TNF-alfa could be the factor associated with the bone turnover marker in GD despite the euthyroid state.

Post COVID 19 subacute thyroiditis -de Quervain

Merita Emini[1], Izet Sadiku[2] & Mimoza Ramadani Piraj[1]
[1]Pristina, Clinic of Endocrinology, University Clinical Center of Kosovo, Pristina, Kosovo; [2]Pristina, Clinic of Infection Diseases, University Clinical Center of Kosovo, Pristina, Kosovo

Introduction
COVID-19 in Kosovo was introduced in March 2020 as a global pandemic started in Wuhan, China in December 2019. The link between COVID-19 and diabetes was seen in the first cases but was if this disease is interfering in other endocrine glands was still unclear. In May 2020 we found the first case of subacute thyroid immediately after COVID-19 which case trigger us for further observation of its spread.
Aim
To investigate the clinical forms and laboratory follow-up of cases with subacute thyroiditis in COVID-19.
Material and methods
In this presentation we report for 7 patients with subacute thyroid de Quervain and positive serology for COVID-19 with demographic, biochemical, clinical and imaging data.
Results
From 7 patients (6 female and 1 male), biochemical data showed increases in C-reactive protein (in some of them triple digits), increased erythrocyte sedimentation rate, increased free fractions of triiodothyronine and thyroxine hormones such as inhibition of thyrotropin, serological tests (IgM and IgG) were positive for infection with COVID-19. All cases presented with neck pain followed with headache in some of them, fatigue and marked laziness as well as fever. Typical changes of subacute thyroiditis have been identified on ultrasound (Fig.1) and scintigraphy (Fig.2). The ways in which they were get infection with COVID 19 differed diametrically. Almost all have been treated with corticosteroids with complete improvement of inflammatory parameters and normalization of thyroid hormones.
Conclusion
The presentation of such cases helps physicians of different profiles to identify complications of COVID-19 and especially such rare cases of subacute thyroiditis which may be underestimated during clinical practice. Keywords: subacute thyroiditis, COVID-19, Kosovo

Refractory graves' disease dramatically responded to adjunctive colestyramine, case report and literature review.

Mohammad Bilal Jajah, Heng Chun Wong & Jayamalee Jayaweera
West Suffolk Hospital, Bury St Edmunds, United Kingdom

Background
Graves' Disease usually responds well to medical treatment with thionamides. However, in some cases, it fails to respond to this treatment, even at maximum doses. A few reported cases have shown that colestyramine helps to restore normal thyroid function when added to the ongoing anti-thyroidal medications in refractory thyrotoxicosis. We reported a case of relapsing refractory Graves' disease, in which colestyramine has helped to restore normal thyroid function tests and allowed for subsequent total thyroidectomy.
Case Presentation
A 21-year-old female presented with relapsing Graves' Disease after 5 years of remission. She was planned for surgery and started on carbimazole in order to restore a euthyroid state before the procedure. This was not achieved despite carbimazole doses being increased to 60 mg over a period of 8 weeks. Colestyramine, 4 mg four times a day, was added as an adjunct, which normalized her thyroid function after 2 weeks of treatment. The patient underwent successful total thyroidectomy subsequently.
Discussion
Bile acid sequestrants (e.g. colestyramine) have been found to reduce thyroid hormone levels in thyrotoxic patients by interfering with enterohepatic circulation and recycling of thyroid hormone. Cholestyramine, given in a dose of 4 g four times daily with thionamides, lowers serum T4 and T3 concentrations more rapidly than thionamides alone and may be useful adjunctive therapy in selected patients who require rapid amelioration of hyperthyroid symptoms. A few case reports have noted that colestyramine, when added to antithyroid drugs in patients with refractory thyrotoxicosis, has successfully achieved a euthyroid state within a few weeks of treatment. This case further supports the growing body of evidence that in medically refractory thyrotoxicosis, colestyramine could be used as an adjunct in reducing thyroid hormone levels to acceptable ranges for surgery to be done. Further studies including randomized control trials could be done to examine the effects of colestyramine in this group of patients.
Conclusion
Colestyramine could be an effective additional treatment in refractory thyrotoxicosis when maximum doses of thionamides fail to restore normal thyroid function.

EBV-associated lymphoepithelioma like carcinoma of thyroid : a case report

Talbi Dounia, Lamia Echchad, Kaoutar Rifai, Hinde Iraqui & Mohamed El Hassan Gharbi
Chu Ibn Sina, Endocrinology, Rabat, Morocco

Introduction
Epstein-Barr virus (EBV) is a well-known human tumor virus with a very high prevalence in the population, this virus is associated with epithelial and lymphoid malignancies, including lymphoepithelioma carcinoma of thyroid. This subtype of thyroid carcinoma is characterized by histologic features similar to those of undifferentiated carcinoma of the thyroid.
Case Report
A 17-year-old male patient, his medical and family histories were non-specific. the physical examination found a large cervical swelling painful on palpation. The neck ultrasonography was performed revealed a left thyroid nodule of 46*26mm classified Tirads5 accompanied by three enlarged neck lymph nodes in the left level II and level III regions. Thyroid functional tests, calcitonin, and thyroid antibodies were within normal limits. A total thyroidectomy was scheduled for the patient ans bilateral neck lymph node dissection. The histologic slides of the thyroid tumor revealed EBV-associated lymphoepithelioma thyroid carcinoma with gonglion metastases. he subsequently benefited from chemotherapy and radiotherapy. and was put on Levothyroxine suppression therapy.
Discussion
EBV has been revealed to be associated with the development of many cancers, such as gastric cancer, nasopharyngeal carcinoma, and Hodgkin's lymphoma. However, the relationship between thyroid tumorigeneses and EBV has not been fully elucidated with conflicting results. The preliminary investigation of EBV in thyroid lymphoma was inspired by EBV persistently infecting B lymphocytes, it can also infect T lymphocytes, myocytes, and epithelial cells, Once EBV infects a host cell, it starts to induce a lytic or latent infection with diverse genes expressed. These genes collaborate to induce tumorigenesis by causing systematic inflammation, suppressing the antitumoral immune system, and preventing anoikis The Chronic inflammation induced by EBV infection may play a significant role in the progression of lymphoepithelioma carcinoma of thyroid.
Conclusion
Lymphoepithelioma-like carcinoma is a rare entity among thyroid tumors, We reported a patient with an EBV-associated thyroid carcinoma. However, whether these rare thyroid malignancies are related to EBV infection requires further investigation.

Aggressive thyroid tumor with difficult histological diagnosis

Malika El Omri[1], Mouna Khalifa[1], Abir Meherzi[1], Safa Jemli[1], Jihen Hwas[1], Moni Ghammem[2], Mouna Bellakhdher[1], Wassim Kermani[1] & Mohamed Abdelkefi[1]
[1]Farhat Hached Hospital, ENT, Sousse, Tunisia; [2]Farhat Hached Hospital, Sousse, Tunisia

Introduction
Oncocytic tumors of the thyroid include adenomas and carcinomas. The distinction between malignancy and benignity represents a major difficulty on the histological level. From this aspect arise constraints in the attitude therapy to adopt.
Material and methods
we present one rare case of an oncocytic carcinoma of the thyroid with laryngotracheal invasion in a 54 male patient operated in ENT department of Farhat Hached hospital of Sousse.
Observation
This is the case of a 54 years old patient who presented with a left basicervical mass evolving for 6 months without other associated signs such as local compression signs or clinical dysthyroidism. There was no history of pain, fever, dysphagia or resiratory difficulties. On examination, there was a large swelling occupying the anterior basicervical region; of 3 centemeters in the right side an of 6 centemeters in the left side; with ferm, nontender, and nonpulsatile consistency. The examination did not find any cervical lymph nodes and nasofibroscopy showed normal vocal cords in aspect and in mobility. Free thyroxine (fT4) and thyroid stimulating hormone (TSH) levels were normal. Thyroid ultrasound confirmed the thyroid origin of the mass and showed no signs of malignancy. A total thyroidectomy was performed. Extemporaneous and definitive histological examination concluded to an oncocytic adenoma. Five years later, the patient came back with an anterior basicervical mass of 5 centemeters, associated with moderate dyspnea. CT scan concluded to thyroid mass of 4 centemeters with a subglottic tissue process with necrotic center of 3 centimeters. Also, pulmonary metastasis was noted. He had a direct laryncoscopy with tracheoscopy showing an infiltration of tracheal wall 2 centimeters from the glottic plane. Histological exaination of the biopsy concluded to an infiltration of the tracheal wall by an oncocytic tumor. We concluded to a recurrence of a misdiagnosed oncocytis thyroid carcinoma as an oncocytic adenoma. The patient had a tumorectomy associated to a sub-isthmic tracheotomy followed by 3 courses of radioactive iodine treatment. The patient was forseen for target therapy but wasunfortunatelylost to follow.
Conclusion
Oncocytic cell carcinoma is commonly retained as an aggressive tumor with low survival rate. Surgery is the mainstay of treatment for carcinoma and planning its appropriate initial surgical management is especially important as curative procedure.

EP1216

T4 + T3 combination therapy of refractory hypothyroidism to levothyroxine treatment, in a subject after ablative radioactive iodine treatment for differentiated thyroid cancer. A case report and review of literature.

Marjeta Kermaj[1], Irsa Zaimi[2], Klotilda Resuli[3], Mariola Kapia[4] & Agron Ylli[1]
[1]UHC 'Mother Tereza', Endocrinology, Tirana, Albania; [2]Fier Regional Hospital, Endocrinology, Fier, Albania; [3]Vlora Regional Hospital, Endocrinology, Vlora, Albania; [4]Health Center 6, Endocrinology, Tirana, Albania

Introduction
Hypothyroidism is considered refractory to oral levothyroxine substitution, when there is biochemical (serum level of TSH (thyroid stimulating hormone) above the upper target level) or clinical evidence of hypothyroidism, despite increasing dosages of oral levothyroxine beyond 2.5 μg/kg daily. In these circumstances, further increments in the dosage of levothyroxine may not always be the most appropriate intervention. In such a situation, physicians need to search for causes of decreased absorption of levothyroxine or increased demand for thyroxin and the solution.
Case report
We present the case of a 55-year-old woman who underwent total thyroidectomy for multinodular goiter, then ablative treatment with 30 mci of radioactive iodine 131, after postoperative biopsy resulted in papillary thyroid cancer. She then started treatment with the levothyroxine replacement dose. In control after 6 weeks of treatment with levothyroxine, TSH level was high and her complaints related to hypothyroidism. We gradually increased the dose of levothyroxine after each periodic TSH test, reaching more than 300 mg of levothyroxine/day, but the TSH level remained high. We searched for the cause of refractory hypothyroidism, but found neither poor compliance nor malabsorption. In our case where it was necessary and urgent to inhibit TSH, following the protocol of differentiated thyroid cancer to control the progression of papillary thyroid cancer, we tried combination therapy with T4 (Thyroxin) and T3(triiodothyronine), and in the next control TSH decreased. We adjusted the T4/T3 doses gradually and after a few checks, the desired TSH levels were reached and the patient felt clinically well.
Conclusion
Whilst current guidelines do not suggest routine use of combination T4/T3 therapy, they do acknowledge a trial in patients with refractory hypothyroidism to levothyroxine treatment, may be appropriate. Our case confirms that.

EP1217

Mantle cell lymphoma in the thyroid gland : clinical features and management case report

Meherzi Abir, Safa Jemli, El Omri Malika, Marwa BEN NJIMA, Mouna Bellakhdher, Jihene Houass, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

Background
Primary thyroid non Hodgkin's lymphoma (PT-NHL), which defined as a lymphoma occurring in the thyroid gland with or without the involvement of regional lymph nodes, is a quite rare pathologic entity, accounting for 1,3-1,5 % of thyroid neoplasm, and 0,5% of lymphoma. there exists insufficient data to describe the incidence of mantle cell lymphoma in the thyroid gland. Due to this rarity and non specific clinical presentation, it seems essentiel to better understand the disease course. Thus we report this case in order tu study its clinical features and discuss management particularities.
Case presentation
A 58-year-old man, without pathological history, complaining from acute progressive dyspnea and dysphagia, associated with an enlarging anterior neck mass that increased rapidly through the last few weeks. On the clinical examination, we found a painless, hard huge goiter which depends mainly on the left lobe, fixed to the musculature, associated with bilateral lymph nodes. The laryngeal fibroscopy showed severe edema of the larynx, without modification of cordal mobility showed diffuse swelling of the thyroid compressing the airway tract. We proceed for diagnosing by a biopsy guided by the ultrasound imaging which confirms the mantle lymphoma of the thyroid; we complete the general evaluation by realizing a full body computed tomography in which we note the absence of other lymph node and a gastroscopy that eliminated the stomach localization. The disease was staging according to the classification proposed by Ann Arbor and modified by Myssof: stage IV. After 5 courses of chemotherapy R-CHOP, A complete remission was achieved. After a follow-up of 3 years, no relapse has occurred.
Conclusion
MCLs are usually diagnosed at an advanced stage, with mostly extranodal involvement, MCLs are classified as an aggressive lymphoma, with median survival of 3–5 years. Treatment options for MCL have been evolving. Chemotherapy and CHOP regimens have usually been used (cyclophosphamide, vincristine, doxorubicin, and prednisone). Immunotherapy (rituximab) and autologous stem cell transplantation have recently been used to treat patients.

Oncocytic carcinoma of the thyroid: Therapeutic and diagnostic challenge

Meherzi Abir, Marwa Ben Njima, Safa Jemli, Habiba Ben Sghaier, Mouna Bellakhdher, Jihene Houass, Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

Background
To study the diagnostic difficulties, the clinical characteristics, as well as the therapeutic modalities of this entity.
Material and method
Report a case of oncocytic carcinoma of the thyroid of aggressive evolution collected in the ENT department and CCF Farhat Hached in Sousse.
Result
This is a 54-year-old patient, with no notable history, who was operated on in 2012 for a large goiter evolving for 3 years previously, having had a total thyroidectomy, with an anatomopathological examination objectifying an oncocytic adenoma on a goiter multi nodular. The patient was lost to follow-up, then reconsulted 5 years later, for the reappearance of a voluminous right anterior cervical swelling and cervical polyadenopathy, associated with dyspnea and hemoptysis. A cervico-thoracic CT showed a tumoral process above and below the glottic laryngeal with signs of locoregional extension, a tumoral process of the thyroid compartment and pulmonary lesions of secondary appearance. A histological re-reading was requested, correcting the diagnosis towards an oncocyte-type vesicular carcinoma. The patient had a lumpectomy with an anapath result confirming tumor recurrence. Additional radiation therapy was performed and the patient was put on L-thyroxine at a restraining dose. He was again lost sight.
Conclusion
Oncocytic carcinoma of the thyroid is a rare, aggressive tumor with metastatic potential posing an anatomopathologic diagnostic and therapeutic problem, requiring careful histological verification and adequate surgical management.

EP1219

Thyrotoxicosis after the cessation of amiodarone treatment
Ivana Bozic-Antic[1,2]
[1]Euromedic Healthcare System, Belgrade, Serbia; [2]Faculty of Dentistry Pancevo, University Business Academy in Novi Sad, Serbia

Introduction
Amiodarone is an effective drug for treating heart arrhythmias. High iodine content and specific metabolism of this drug, in 15-20% of patients lead to thyroid function disorder. Amiodarone induced thyrotoxicosis (AIT type 1 or type 2) usually occurs during the use of the drug, while it is rare after the drug cessation.
The aim
A case report of a patient with type 2 AIT that manifested after the cessation of short-term amiodarone treatment.
Case presentation
A 73-year-old patient was treated for atrial fibrillation with amiodarone for six months. Two months after the drug cessation, clinical manifestations of thyrotoxicosis (weight loss, sweating, tachycardia) occured. Laboratory tests showed overt thyrotoxicosis with normal antithyroid antibodies and high thyroglobuline (TSH 0.01 uIU/ml, fT4 45.4 pmol/l, fT3 10.8 pmol/l, antiTPO 6 IU/ml, antiTg 11 IU/ml, TSH-receptor antibodies 0.9 IU/l, thyroglobuline 232 ng/ml). Blood cell count and sedimentation rate were normal. The thyroid gland was painless, normal size, normoechogenic, with normal vascularisation and without nodal lesions. The patient was succesuflly treated with corticosteroids (at the beginning 60 mg/day with gradual drug suspension). After 10 weeks patient was euthyroid. One month later hypothyreosis occured, and levotyroxine substitution was started.
Conslusion
This case report showes a patient with type 2 AIT which occured two months after the cessation of short-term treatment with amiodarone. The elimination of amiodarone from the body is variable and iodine depot in the body can remain increased for up to 9 months after the drug is stopped. For this reason, it is necessary to monitor patients not only during amiodarone treatment, but also months after the suspension of the therapy.

Iatrogenic agranulocytosis in a woman with hyperthyroidism
Mubina Hodžić[1], Alma Badnjevic-Cengic[2] & Amila Cerim-Aldobasic[2]
[1]Cantonal Hospital, Internal Diseases, Endocrinology Unit, Zenica, Bosnia and Herzegovina; [2]Cantonal Hospital, Zenica, Bosnia and Herzegovina

Hyperthyroidism is a condition with the overproduction of thyroid gland's hormones. One of the treatment option is methimazole, blocking the synthesis named hormones, usually before thyroid surgery or radioactive iodine therapy. I report a 68-year old woman who admitted to hospital in November 2021. after a hematological examination due to leucopoenia and agranulocytosis. She is been treating the hyperthyroidism last 12 years with methimazole. In the beginning she was taking twice daily 10 mg, and later once daily 10 mg of methimazole. Blood counts were normal before as she recalls. She also was treating depression syndrome from the beginning as a hyperthyroidism. Since last year she is been having tonsil problems, difficult swallowing. Last ten days before admitted she had a throat pain, ear pain, no fever and chills. No losing weight. In laboratory findings there were leucopoenia with agranulocytosis leucocyte 1.15/neutrophils 0.33(Absolute number). Her hormones of gland thyroid were in hyperthyroidism range (TSH 0.001 referral range (0.34-5.5), fT3 5.84 ref.r.(2.5-4.5), fT4 2.39 ref.r.(0.58-1.64)). She received a granulocyte grow factor in hematology admission. She had frequent controls of blood count till the leucocyte raised over 1x 10*9 per liter. Her immunology test were negative, other non specific laboratory, ultrasound, radiological chest results. PCR SARS CoV-2 was negative. Palpatory the thyroid gland was large. In ultrasound the lobes were largly, hypoechoic and non homogeneous, roughly echo picture, with several hypoechoic nodule. We consulted the nuclear specialist. The therapy was propylthiouracil 50 mg 1tablet daily with Lugol solution 3 times a day per 2 drops. The control hormones of gland thyroid were: TSH was suppressed, fT3 and fT4 were in referral range. The scintigraphy of thyroid gland was perform with Technetium -99m, where radiopharmaceutical was very weak binding diffuse with some intense binding in one of the nodule in right lobe, and several small ones in left lobes. The therapy option was total thyroidectomy. Her blood count was normal (total recieved 2 ampules of Leucocyte growth factor). She was discharged from hospital. In Decembar she came to check up. No symptoms on her side, blood count with differential blood count were normal. Her TSH was still suppressed, and other hormones of gland thyroid were in referral range. Therapy was the same with recommendations to surgery option
Key words:hyperthyreoidism, methimazole, agranulocytosis, granuloyte growth factor

Case report: Toxic multinodular goiter in pregnant women
Sanaa Bammou, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakech, Morocco

Introduction
-Thyroid disorders can predate or develop during pregnancy.
-The effects on the fetus vary depending on the disease and the drugs used for treatment. But usually, untreated or undertreated hyperthyroidism can lead to harmful complications.
Case report
It's a 26-year-old patient with a history of goiter since childhood, history of goiter in the mother; grandmother and maternal aunt. the patient is 18 weeks pregnant, the pregnancy is unplanned. Anamnesis:the notion of weight loss; palpitation and dyspnea The clinical examination revealed a: goiter Grade 3 with turgidity in the jugular veins. Investigations showed: white blood cell 11440/mm3 Neutrophil : 6115/mm3 Hemoglobin:12.7 g/100ml blood platelets :19400/mm3 ALAT :10 UI/I ASAT:19 UI/I TSH:0.005uUI/ml T4:16;6 pmol/l T3:7,2 pmol/l On cervical ultrasound: nodular goiter classified EU TIRADs 3; the largest measuring on the right 42*32 mm and on the left 23*21mm Patient was started synthetic antithyroid drug and she was sent to surgery after euthyroidism.
Discussion
The association of thyroid disease and pregnancy is relatively common [1-4]. The increase in thyroid volume during pregnancy has been known since antiquity. In fact, pregnancy is favored by the increase in the need for thyroid hormones, and the hormonal variations that accompany it, an increase in the functional activity of the thyroid gland, and the nodular remodeling of goiters, and potentially the growth of possible nodules. cancer [2,3]. Thyroid surgery, in the event of pregnancy, is indicated in cases involving the vital prognosis of the mother and/or fetus (bulky goiters compressing the esophagus or the trachea, a state of hyperthyroidism difficult to balance such as the case of of Basedow) at any time, preferably during the second trimester to avoid first-trimester abortion and third-trimester preterm delivery [1,4]. It is also indicated during pregnancy for medullary carcinoma [4].
Conclusion
Pregnancy is a test for the thyroid gland. The latter has significant adaptive capacities which allow it on the whole to cope with the increase in hormonal needs, the depletion of the iodine load. But imbalances are possible, which is not without consequence on the maternal and fetal situation. All the interest of the preconception and prenatal consultation and its role in detecting pathologies early and treating them in time and by the optimal means.
