All 42 participants underwent both tests. The median (IQR) age of all participants was 27 years (23; 32), 59% were female. In healthy participants, glucagon injection stimulated copeptin with a median (IQR) increase of 7.56 (2.38; 28.03) pmol/l, while placebo had no effect (0.10 pmol/l (-0.70; 0.68); treatment difference: 7.67 (1.98, 27.09) pmol/l, $P < 0.001$). In patients with central diabetes insipidus, copeptin showed no relevant increase after glucagon injection, with an increase of 0.55 pmol/l (0.21; 1.65), whereas copeptin was stimulated in patients with primary polydipsia with an increase of 15.70 (5.99; 24.39) pmol/l. Using a copeptin cutoff level of $>$ 4.6 pmol/l had a 100% sensitivity (95%CI 100-100) and 90% specificity (95%CI 70-100) to discriminate between diabetes insipidus and primary polydipsia. The test was safe and well tolerated with a median (IQR) test burden according to VAS of 1.5 (1; 4) in healthy participants, 3 (1.5; 4.5) in central diabetes insipidus, and 3 (2; 4.5) in primary polydipsia.
Conclusion
In conclusion, glucagon stimulates the neurohypophysis, and glucagon-stimulated plasma copeptin has the potential to be used for a safe, novel, and precise test in the differential diagnosis of polyuria-polydipsia syndrome.

Sexual brain processing is enhanced by melanocortin-4 receptor agonism

Layla Thurston[1], Tia Hunjan[1], Edouard Mills[1], Matt B Wall[1,2], Natalie Ertl[1,2], Maria Phylactou[1], Beatrice Muzi[1], Bijal Patel[1], Emma Alexander[1], Sofiya Suladze[1], Manish Modi[1], Pei Eng[1], Paul Bassett[3], Ali Abbara[1], David Goldmeier[4], Alexander Comninos[1,5] & Waljit Dhillo[1,5]
[1]Imperial College London, Endocrinology and Investigative Medicine, London, United Kingdom; [2]Invicro, London, United Kingdom; [3]Statsconsultancy Ltd, Amersham, United Kingdom; [4]Imperial College Healthcare NHS Trust, Sexual Medicine, London, United Kingdom; [5]Imperial College Healthcare NHS Trust, Endocrinology, London, United Kingdom

Introduction
Hypoactive sexual desire disorder (HSDD) is characterized by a persistent deficiency of sexual fantasies and desire for sexual activity, causing marked distress or interpersonal difficulty. It is the most prevalent female sexual health problem worldwide, affecting approximately 1 in 10 women, but has limited treatment options despite its substantial health, social, and economic burden. Melanocortin-4 receptor (MC4R) agonists have emerged as a promising therapy for women with HSDD, although, to date, their mechanism of action is unknown. This study aims to use functional MRI to uncover the reproductive neuroendocrine pathways involved and elucidate how MC4R agonists treat HSDD in women.
Methods
We conducted a randomized, double-blinded, placebo-controlled, crossover clinical study in 31 premenopausal women with HSDD. A combination of psychometric, functional neuroimaging and hormonal analyses were used to investigate the effect of MC4R agonism on sexual brain processing. Participants attended twice, receiving either a subcutaneous injection of an MC4R agonist (Bremelanotide 1.75 mg) or placebo at each study visit, thereby acting as their own controls.
Results
MC4R agonism significantly increased self-reported sexual desire for up to 24-h post administration, compared to placebo ($P = 0.007$). During functional MRI, MC4R agonism enhanced cerebellar and supplementary motor area activity, as well as deactivating the secondary somatosensory cortex, specifically in response to visual erotic videos, compared to placebo ($Z = 2.3$, $P < 0.05$). In addition, MC4R agonism enhanced functional connectivity between the amygdala-insula and amygdala-thalamus during prolonged visual erotic stimuli, compared to placebo ($P = 0.025$). MC4R agonism resulted in a mean increase in LH of 1.1 iU/l (F [1.58] = 13.38, $P = 0.0005$), and FSH of 0.35 iU/l (F [1.60] = 10.97, $P = 0.0016$) across the 300-minute duration of the study, with no effect observed on circulating estradiol or progesterone levels.
Discussion
We demonstrate that MC4R agonism deactivates the secondary somatosensory cortex which can reduce the detrimental self-monitoring process often observed in HSDD, thereby increasing sexual desire. Furthermore, cerebellar and supplementary motor area activation by MC4R agonism are associated with increased sexual arousal and sexual motor imagery respectively. Finally, MC4R agonism enhanced functional connectivity between key limbic structures which can be disrupted in HSDD. In conclusion, these data identify the previously undescribed neural substrates and connections through which MC4R agonism modulates sexual brain processing to increase sexual desire. These findings provide mechanistic insight for the action of MC4R agonism in sexual behaviour and are relevant to ongoing therapeutic development for HSDD and for MC4R agonist development more widely.

Up to one third of the children with attention deficit with hyperactivity disorder (ADHD) may have an isolated and increased free-T3 level

Hervé Caci[1] & Philippe Caron[2]
[1]Hôpitaux Pédiatriques de Nice, CHU Lenval, Nice, France; [2]CHU Larrey, Endocrinology, Toulouse, France

Introduction
Thyroid hormones are involved in the development of the fœtus and the child, and abnormal thyroid function is expected to play a role in neurodevelopmental disorders such as Attention Deficit with Hyperactivity Disorder (ADHD). The high prevalence of ADHD in patients with resistance to thyroid hormone syndrome is well documented but, surprisingly, the reported literature showed ambiguous results mostly suggesting that the thyroid function tests are normal in the majority of patients with ADHD. However, it is possible to pinpoint a number of methodological and analytical limits in the thyroid evaluation of patients in the studies. Here we report on the prevalence of isolated and increased free-T3 level in the presence of normal free-T4 and TSH levels in children with ADHD.
Methods
Serum free-T3, free-T4 and TSH levels were measured in children referred to the first author (HC) in the last two decades and diagnosed with ADHD. No control was possible on the analytic methods as thyroid function tests were performed in town laboratories.
Results
Out of 1.967 patients, 701 children with ADHD (boys $n = 562$, girls $n = 139$) between 6 and 18 years old had complete thyroid function tests (free-T3, free-T4 and TSH levels). According to the reference intervals noted in laboratory reports, a TSH level was abnormal in 16 patients (2.28%): 2 decreased TSH level with normal free-T3 and free-T4 level, 14 increased TSH level with either normal or elevated free-T3 and/or free-T4. Out of the 685 normal-TSH remaining patients, 435 (63.50%) had a normal thyroid profile, and 217 (31.68%): 180 boys (32.67%) and 37 girls (27.61%) showed an isolated and increased free-T3 level. There was no effect of gender: χ^2 (1) = 0.677 ($P > .4$).
Discussion
In children with ADHD, an isolated and increased free-T3 level is frequent and unrelated with gender. This result should be further confirmed and documented. If so, this abnormal thyroid profile may constitute an endophenotype for a significant proportion of children with ADHD, and yield to new pathophysiological hypotheses in the neurodevelopment disorders.
Conclusion
Abnormal thyroid function tests are not rare in children with ADHD, more specifically we highlighted an isolated and increased free-T3 level with normal free-T4 and TSH levels in up to one third of children with ADHD. These results warrant confirmation; this is the main objective of the on-going prospective "ThyrADHD" study (NCT05080491).

Subtype-specific pattern of white blood cell differential in endogenous Cushing's syndrome

Mario Detomas[1], Barbara Altieri[1], Irina Chifu[1], Hanna Remde[1], Laura-Sophie Landwehr[1], Silviu Sbiera[1], Matthias Kroiss[1,2], Martin Fassnacht[1] & Timo Deutschbein[1,3]
[1]University Hospital Würzburg, Würzburg, Germany; [2]Klinikum der Universität München, München, Germany; [3]Medicover Oldenburg MVZ, Oldenburg, Germany

Objective
Glucocorticoid excess impairs immune function, thereby predisposing patients with endogenous Cushing's syndrome (CS) to infections. However, it is still not clear whether there is a CS-subtype specific pattern in white blood cell (WBC) and WBC differential (WBCD) count.
Methods
Retrospective monocentric cohort study in patients with either overt endogenous CS or adrenal adenomas with autonomous cortisol secretion (ACS), with WBC and WBCD analysis at initial diagnosis and after remission.
Results
270 patients (Cushing's disease (CD), $n=88$; ectopic CS (ECS), $n=31$, cortisol-producing adrenal adenoma (CPA), $n=39$; ACS, $n=63$; adrenocortical carcinoma (ACC), $n=49$; were analyzed. Total leukocytes and neutrophils correlated positively with serum cortisol after 1-mg dexamethasone (1 mg-DST) ($r=0.346$ and $r=0.471$, respectively, $P<0.0001$), while a negative correlation was observed for lymphocytes and eosinophils ($r=$-0.399 and $r=$-0.519, each $P<0.0001$). Correlations were confirmed with the 24h-urinary free cortisol (24h-UFC). CD and ECS differed in numbers of neutrophils and lymphocytes ($P<0.0001$). A cut-off of 6.1 for the neutrophil/lymphocyte ratio (NLR) allowed reliable differentiation between CD and ECS (sensitivity 90.0%, specificity 89.4%, AUC 0.918). NLR allowed a better differentiation between CD and ECS than 1 mg-DST and 24h-UFC (AUC respectively 0.83 and 0.74). Regarding CPA and ACC, a difference in platelet/lymphocyte ratio (PLR) was observed (sensitivity 59.6%, specificity 80.6%, and AUC 0.713 with a cut-off of 187.9). Already 3 months after biochemical remission, neutrophils decreased (delta change -47.0%, -29.7%, and -26.2%) and lymphocytes increased (+123.2%, +78.1%, and +17.7%) substantially (always ECS, CPA, and CD).
Conclsion
Most immune cells correlate with the degree of hypercortisolism but differ also among CS subtypes. WBCD and NLR could allow a first differentiation of ACTH-dependent CS. Normalization of WBCD is observed already after 3 months from CS remission.

Role of apparent strong ion difference in the differential diagnosis of thiazide associated hyponatremia

Laura Potasso[1,2], Julie Refardt[1], Sophie Monnerat[1,2], Bettina Winzeler[1] & Mirjam Christ-Crain[1,2]
[1]University Hospital of Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Basel, Switzerland

Background
Differential diagnosis of hyponatremia is challenging, particularly for thiazide associated hyponatremia (TAH), as patients might have either volume depletion in need for fluid substitution or syndrome of inappropriate antidiuresis (SIAD)-like presentation requiring fluid restriction. Urine indices are of little utility, because they are influenced by thiazide therapy. Apparent strong ion difference (aSID) describes the relation between sodium, potassium and chloride in serum and is used in evaluation of acid-base disorders according to Stewart model. aSID could help in the differential diagnosis of TAH because a value >40 identifies patients with contraction alkalosis due to relative hypochloremia, and hypochloremic alkalosis is a well-known possible adverse effect of thiazide diuretics.
Material and Methods
This was a post-hoc analysis of prospectively collected data of hospitalized patients with hypotonic hyponatremia <125 mmol/l. TAH patients were divided according to treatment response in patients needing intravenous fluid substitution or fluid restriction. Treatment response was defined as a sodium increase of at least 4 mmol/l/die or >130 mmol/l based on chart review. aSID at baseline was calculated with the formula serum sodium plus potassium minus chloride and a value >40 was used to identify volume-depleted TAH patients. Descriptive analysis was carried out to find differences between volume-depleted and SIAD-like TAH patients, and patients with SIAD without thiazide use. Logistic regression and ROC curves were computed to investigate the role of aSID >40 for differential diagnosis of hyponatremia in TAH patients, in addition to known factors for identifying SIAD patients as body mass index (BMI) and fractioned uric acid excretion (FUA) with the previous described cut-off of 12%.
Results
Out of 303 hyponatremia patients, 131 (43.2%) had a TAH and 75 (24.8%) SIAD without thiazide use. Among TAH patients, 81 (61.8%) were successfully treated with fluid substitution and 31 (23.7%) with fluid restriction. 19 patients (14.5%) were excluded as they received no treatment, or needed to switch treatment during hospitalization. No differences in baseline characteristics were seen between patients with SIAD and SIAD-like TAH patients, except for BMI, lower in SIAD patients (mean(SD) 23.5(5.1) vs 27.0(5.7) kg/m2, $P=0.003$). A higher BMI and a FUA <12% had a sensitivity of 84% with a specificity of 60% in identifying volume-depleted TAH patients. Adding aSID >40 improved the specificity to 74% maintaining a sensitivity to 82%.
Conclusion
In hospitalized patients with TAH, calculation of aSID may help differentiating patients with volume depletion in need of fluid substitution from SIAD-like manifestation requiring fluid restriction.

Genetic subtype differences in relation to health problems among adults with Prader-Willi syndrome

Anna Rosenberg[1], Karlijn Pellikaan[1], Charlotte Wellink[1], Juan Tellez Garcia[1], Denise van Abswoude[1], Laura van Zutven[2], Hennie Brüggenwirth[2], James Resnick[3], Aart Jan Van der Lely[1] & Laura De Graaff[1]
[1]Erasmus MC, University Medical Center Rotterdam, Division of Endocrinology, Rotterdam, Netherlands; [2]Erasmus MC, University Medical Center Rotterdam, Department of Clinical Genetics, Rotterdam, Netherlands; [3]College of Medicine, University of Florida, Department of Molecular Genetics and Microbiology, Gainesville, United States

Background
Prader-Willi syndrome (PWS) is a complex rare genetic disorder associated with hypothalamic dysfunction, pituitary hormone deficiencies, hyperphagia and (morbid) obesity. PWS is caused by loss of expression of paternally expressed genes on chromosome 15q11.2-q13. The most common genetic mechanisms leading to PWS are paternal deletion (DEL) and maternal uniparental disomy (mUPD). DELs can be subdivided in type 1 and (smaller) type 2 deletions (DEL-1, DEL-2). Most research has focused on behavioral, cognitive and psychological differences between patients with a DEL-1, DEL-2 or mUPD. However, little is known about the genetic subtype differences in relation to physical health problems.
Methods
We reviewed the medical files of all adults with genetically confirmed PWS who visited the outpatient clinic of the Center for Adults with Complex Rare Genetic Syndromes at the Erasmus University Medical Center, Rotterdam, the Netherlands, between January 2015 and June 2021. All patients underwent a systematic health screening, including a structured interview, a medical questionnaire, a complete physical examination, biochemical measurements, and a review of the medical records. Health problems, physical complaints, symptoms of disease and behavioral challenges were compared between adults with an mUPD and DEL and between adults with a DEL-1 and DEL-2.
Results
Twenty-eight adults had an mUPD and 65 a DEL (13 DEL-1, 27 DEL-2, 25 unspecified). Gender, age and BMI did not differ between the genetic subgroups. Although psychiatric problems (psychotic episodes) were significantly more often present in adults with an mUPD ($P<0.001$) and scoliosis was more prevalent among patients with DEL ($P=0.04$), there was only a slight difference in prevalence of other medical problems like hypertension, cold intolerance, edema, hyperphagia, skin picking, abdominal pain and fatigue. There were no significant differences between DEL-1 and DEL-2. However, fatigue, cold intolerance, edema and hyperphagia were slightly more prevalent among adults with a DEL-1, whereas osteopenia, constipation and skin picking were more prevalent among adults with a DEL-2.
Conclusion
The differences in health problems between PWS adults with DEL-1, DEL-2 and mUPD are mostly present in the psychological domain. Especially psychotic episodes were more frequent in adults with an mUPD. Apart from scoliosis, there were no significant differences in physical health outcomes between the genetic subtypes.

Prevalence of comorbidities in a US adult population with growth hormone deficiency

Alden Smith[1], Janna Manjelievskaia[2], Allison Komirenko[3] & Cynthia Morrow[2]
[1]Ascendis Pharma Inc, Health Economic Outcomes Research, Palo Alto, United States; [2]IBM Watson Health, Cambridge, United States; [3]Ascendis Pharma Inc, Clinical Development, Palo Alto, United States

Background
Adults with growth hormone deficiency (GHD) have increased central fat deposits, hypertriglyceridemia, and hyperglycaemia, with an increased risk of developing metabolic syndrome and cardiovascular disease, conditions that can lead to a diminished quality of life. This study analyzed comorbidities among adults with GHD in the US who had Medicaid or commercial health insurance.
Methods
In this retrospective cohort study using IBM Marketscan Medicaid and Commercial Research Database data, adults (aged $\geq$18 years) diagnosed with GHD between Jan. 1, 2008, and Dec. 31, 2017, were matched (1:3) to controls without GHD (or other short stature-related disorders) on age, gender, plan type (commercial vs Medicaid), region, and race (Medicaid only). Baseline comorbidities and medications were measured during the 12 months pre-index. All-cause and GHD-related healthcare utilization and somatropin use were measured during the variable follow-up period.
Results
A total of 24.373 commercial and 2.579 Medicaid patients with GHD met the study inclusion criteria and were matched to 73.119 commercial and 7.728 Medicaid controls, respectively. Demographic makeup of patients with and without GHD was similar, demonstrating effective matching. About half the patients were male. Median age at index was 48 years for commercial patients and 37 years for Medicaid patients. Mean follow-up time was 35 and 37 months for commercial patients and controls, and 41 and 31 months for Medicaid patients and controls, respectively. GHD patients were disproportionately affected by comorbidities compared to controls: endocrine conditions ($>$68% in GHD cases vs. $\leq$10% in controls), metabolic conditions ($>$93% in GHD cases vs. $\leq$39% in controls), hepatic and renal function conditions (18-23% in GHD cases vs. $<$10% in controls), and cardiovascular disease (41-53% in GHD cases vs. $<$29% in controls), and were disproportionately treated with concomitant medications.
Conclusions
Adults with GHD experience a substantial comorbidity burden compared to non-GHD controls.

Inverse relationship between il-6 and sodium levels in patients with COVID-19 and other respiratory tract infections

Sophie Monnerat[1], Cihan Atila[1], Roland Bingisser[2], Martin Siegemund[3], Maurin Lampart[4,4], Marco Rüegg[2], Núria Zellweger[3], Stefan Osswald[4], Katharina Rentsch[5], Mirjam Christ-Crain[1] & Raphael Twerenbold[4,6]
[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Emergency Department, University Hospital Basel, Basel, Switzerland; [3]Department of Intensive Care, University Hospital Basel, Basel, Switzerland; [4]Department of Cardiology and Cardiovascular Research Institute Basel (CRIB), University Hospital Basel, University of Basel, Basel, Switzerland; [5]Department of Laboratory Medicine, University Hospital Basel, Basel, Switzerland; [6]University Center of Cardiovascular Science & Department of Cardiology, University Heart and Vascular Center Hamburg, Hamburg, Germany

Background
Hyponatremia is highly prevalent in patients with COVID-19. One of the most common causes of hyponatremia in these patients is the syndrome of inadequate antidiuresis (SIAD). Interleukin 6 (IL-6) is a key mediator of inflammation in COVID-19. We hypothesized that hyponatremia in COVID-19 is due to IL-6 mediated non-osmotic arginine vasopressin (AVP) secretion, and that the inverse association between IL-6 and plasma sodium concentration is stronger in COVID-19 compared to other respiratory infections.
Methods
This is a secondary analysis of a prospective, observational, cohort study including patients with COVID-19 suspicion admitted to the Emergency Department, University Hospital of Basel, Switzerland, between March and July 2020. We included patients with PCR-confirmed COVID-19 and patients without COVID-19 but similar symptoms, further subclassified in bacterial and other viral respiratory infections. The primary objective was to investigate the association between plasma sodium levels and IL-6 levels.
Results
500 patients were included, of whom 184 (37%) with COVID-19, 92 (18%) with bacterial respiratory infections, 224 (45%) with other viral respiratory infections. Hyponatremia prevalence was higher in patients with COVID-19 compared to patients with other viral respiratory infections (28% vs 12%, $P<0.01$), and similar to patients with bacterial respiratory infections (28% vs 30%, $P<0.41$). In all three groups, median [IQR] IL-6 levels were significantly higher in hyponatremic compared to normonatremic patients (COVID-19: 43.4 [28.4, 59.8] vs 9.2 [2.8, 32.7] pg/ml, $P<0.0001$; bacterial: 122.1 [63.0, 282.0] vs 67.1 [24.9, 252.0] pg/ml, $P<0.05$; viral: 14.1 [6.9, 84.7] vs 4.3 [2.1, 14.4] pg/ml, $P<0.05$). IL-6 levels were negatively correlated with plasma sodium levels in COVID-19, whereas the correlation in bacterial and other viral infections was weaker (COVID-19: $\rho=-0.52$, $P<0.001$; bacterial: $\rho=-0.24$, $P=0.056$, viral: $\rho=-0.24$, $P<0.001$).
Conclusion
IL-6 levels were inversely correlated with plasma sodium levels, with a stronger correlation in patients with COVID-19 compared to patients with bacterial and other viral infections. IL-6 might stimulate AVP secretion and lead to higher rates of hyponatremia due to the syndrome of inadequate antidiuresis in these patients.

Effect of growth hormone deficiency on serum high-sensitivity C-reactive protein levels in adult patients with non-functioning pituitary tumors

Yasufumi Seki, Noriyoshi Takano, Kaoru Yamashita, Kanako Bokuda, Nobukazu Sasaki, Toru Ishikawa, Miwa Kimura, Satoshi Watanabe, Daisuke Watanabe, Satoshi Morimoto & Atsuhiro Ichihara
Tokyo Women's Medical University, Department of Endocrinology and Hypertension, Tokyo, Japan

Background
Growth hormone (GH) deficiency causes visceral obesity and fatty liver and increases cardiovascular event risks. Because serum high-sensitivity C-reactive protein (hs-CRP) levels, which has been used to estimate those risks, was reported to be decreased by GH supplementation therapy in GH deficient patients, it has been suggested that inflammatory processes might be activated in GH deficient state. However, the clinical factors associated with increased hs-CRP levels in patients with GH deficiency have been still unknown.
Patients and Methods
We retrospectively reviewed charts of 134 patients with non-functioning pituitary adenoma (NFPA) and Rathke's cysts who underwent preoperative GH-releasing peptide-2 (GHRP-2) tests and investigated the association between GH secretion and background characteristics. Patients who had a history of pituitary surgery, severe renal insufficiency or active inflammatory diseases or received GH supplementation therapy were excluded. GH secretion was determined by GHRP-2 tests.
Results
Among 134 patients (94 NFPAs and 40 Rathke's cysts), 46 (34%) presented severe GH deficiency, as diagnosed using GHRP-2 tests. Serum hs-CRP levels were significantly higher in the patients with severe GH deficiency than in those without severe GH deficiency (723 [299-1285] vs 278 [124-561] ng/ml, $P<0.001$). Serum hs-CRP levels were significantly higher in men ($P=0.003$) and in patients with diabetes mellitus ($P=0.040$) and were significantly correlated with age ($r_s=0.19$, $P=0.039$), body mass index ($r_s=0.37$, $P<0.001$), serum levels of gamma-glutamyl transpeptidase ($r_s=0.28$, $P=0.001$), creatinine ($r_s=0.30$, $P<0.001$), low-density lipoprotein cholesterol ($r_s=0.21$, $P=0.013$), triglyceride ($r_s=0.38$, $P<0.001$) and free thyroxine ($r_s=-0.30$, $P=0.001$), blood hemoglobin A1c levels ($r_s=0.20$, $P=0.018$), peak GH response to GHRP-2 ($r_s=-0.47$, $P<0.001$) and IGF-1 SD score ($r_s=-0.18$, $P=0.040$). In the multiple regression analysis, peak GH response to GHRP-2 was a significant variable for determining serum hs-CRP levels ($\alpha=-0.340$, $P=0.003$) after adjustment with age, sex, BMI, smoking, alcohol consumption, hypertension, diabetes mellitus, serum levels of gamma-glutamyl transpeptidase, creatinine, triglyceride and free thyroxine and adrenal function.
Conclusion
GH deficiency was significantly associated with increased serum hs-CRP levels independent to obesity and liver dysfunction in adult patients with non-functioning pituitary tumors. GH deficient state might cause inflammation independent to development of visceral obesity and fatty liver.

What is the relevance of he systematic use of gadolinium (Gd) during the MRI follow-up of non-functioning pituitary adenomas (NFPAs)?

Axel Villemaire[1], Celine Mouly[2], Grunenwald Solange[3], Gilles Adam[4], Jean Darcourt[5], Sofia Patsoura[5], Margaux Roques[5], Isabelle Catalaa[5], Helio Fayolle[6], Christophe Cognard[5], Jean-Christophe Sol[7], Philippe Caron[8] & Bonneville Fabrice[9]

[1]CHU Purpan, Neuroradiology, Toulouse, France; [2]CHU Larrey, Endocrinology, Toulouse, France; [2]CHU Larrey, Endocrinology, Toulouse, France; [4]CHU Purpan, Neuroradiology, Toulouse, France; [4]CHU Purpan, Neuroradiology, Toulouse, France; [6]CHU Purpan, Nuclear médecine, Toulouse, France; [7]CHU Purpan, Neurosurgery, Toulouse, France; [2]CHU Larrey, Endocrinology, Toulouse, France; [9]CHU Purpan, Neuroradiology, Topulouse, France

Objective
To compare the performances of the coronal contrast-enhanced T1-weighted (ceT1-w) and T2-weighted (T2-w) sequences, for the diagnosis of progression during the MRI follow-up of NFPAs.
Materials and methods
106 patients who had at least two MRIs for the follow-up of NFPA were retrospectively included. The largest diameter of the adenomas was measured on coronal ceT1-w and separately on T2-w sequences for all the MRIs of the follow-up, and by 2 independent neuroradiologists on a sample of 100 examinations to assess interobserver variability. Progression was defined by an increase $\geq$ 2 mm of this diameter between 2 MRIs. Progress thresholds of 3 and 4 mm were also tested. The concordance was analyzed between the results of ceT1-w and T2-w sequences.
Results
On 580 follow-up MRIs, there was 93.1% concordance between ceT1-w and T2-w coronal sequences. In case of a possible progression, there was 64.4% concordance for a threshold of 2 mm, 87.7% for 3 mm and 97.1% for 4 mm. The discordance was mainly observed on the first postoperative MRI and in case of multiple recurrences. Kappa was better for the diagnosis of progression on T2-w than on ceT1-w sequences (0.67 vs 0.54). Of note, an agreement of 100% was noted between the 2 sequences on the 82 follow-up MRIs of patients with complete surgical resection.
Conclusion
The coronal ceT1-w and T2-w sequences were concordant in 93.1% during the MRI follow-up of NFPAs, meaning that the systematic injection of Gadolinium should be questioned. If first-line examination without gadolinium injection could be proposed, our results indicate that ceT1-w sequences should be kept for the first postoperative MRI and for the follow-up of aggressive and recurrent NFPAs.

Differences in pituitary apoplexy

Betina Biagetti[1], Silvana Isabel Sarria Estrada[2], Cordero-Asanza Esteban[3], Anas Chaachou-Charradi[4], Karelis Ng-Won[2], Marta Cicuendez Lopez Ocana[3], Irene Hernández-Hernández[1], Alba Rojano Toimil[1], M Pilar Costa Forner[1], Martinez-Saez Elena[4], Anna Casteras[1] & Rafael Simo Canonge[1]

[1]Hospital Vall d'Hebron, Endocrinology, Barcelona, Spain; [2]Hospital Vall d'Hebron, Neuroradiology Section, Radiology Department, Barcelona, Spain; [3]Hospital Vall d'Hebron, Neurosurgery and Neurotraumatology, Barcelona,; [4]Hospital Vall d'Hebron, Pathology Department, Barcelona, Spain

Objective
Pituitary apoplexy (PA) is a rare, sometimes life-threatening clinical syndrome. However, some cases are subclinical (SPA), just revealed by MR performed during the follow-up of known pituitary adenomas or due to other conditions. Our aims were to describe the clinical characteristics and evolution of the patients with SPA compared with patients with acute PA (APA). We also compare the results of surgery vs conservative management in the APA group.
Design
Retrospective longitudinal study.
Methods
We retrospectively analysed a database of a tertiary reference centre searching for patients diagnosed with pituitary apoplexy between January 2010 and August 2021. We analysed the risk factors that differentiate SPA to APA and compared the clinical course between patients who received conservative vs surgical treatment. Statistical analysis was done using Fisher's exact, Mann–Whitney test or Kruskal-Wallis with Bonferroni correction if required.
Results
Thirty-seven patients were identified (17 men, 20 women; age range 18.3–80.8 years, median age 47.7 years). Out of 37 patients, 29 (78.4%) had APA [of which 17 underwent surgery and 12 were conservatively managed] and 8 (21.6%) had SPA. T2DM (11 vs 0; $P < 0.05$), dyslipidemia (10 vs 0$P = 0.05$) and bigger tumours (5589 $\pm$ 8562 mm vs 650 $\pm$ 879 mm; $P < 0.05$) with chiasmatic compression and sinus invasion were more frequent in APA vs SPA and in patients requiring surgery. During follow-up (23.0 $\pm$ 42.0 months), 13/37 (35.1%) patients developed hypopituitarism without differences between groups. Pituitary adenomas' volumes shrunk spontaneously in 13/20 (65%) of non-surgical patients with a median of volume reduction at 1 year MRI of (40.0% vs 23.7%) in conservatively APA vs SPA group respectively. 2 patients had a new apoplexy episode and 4 patients died, 1 related to PA.
Conclusions
These data suggest that bigger tumours in T2DM patients have higher risk of APA and could require surgery. In non-surgical group, the pituitary tumor shrinkage is clinically relevant after one year of PA. Hypopituitarism is quite frequent independently of PA type even in patients with SPA.

The prevalence of metabolic syndrome in patients with hyperprolactinemia

Eunheui Kim, Myungsoo Im, Soree Ryang, Wook Yi & Injoo Kim
Pusan National University Hospital, Busan, Rep. of South Korea

Objective
Hyperprolactinemia might be related to weight gain, metabolic syndrome, and insulin resistance. The aim of this study was to evaluate that patients with hyperprolactinemia were higher prevalence of metabolic syndrome than civilian population.
Methods
From 1st Jan. 1998 to 17th Nov. 2017, 950 patients newly diagnosed hyperprolactinemia in Pusan National University Hospital, Pusan, South Korea, were selected to enroll in a study conducted on hyperprolactinemia and metabolic syndrome. We analyzed the metabolic components measured value within 3 months of the highest plasma prolactin value recorded. Information of waist circumference, serum triglyceride, serum HDL cholesterol, blood pressure, fasting plasma glucose, and medication for dyslipidemia or hypertension or diabetes mellitus were collected. Moreover, we also collected the measured value of BMI, LDL cholesterol, total cholesterol. We compare the metabolic component value of our hyperprolactinemia patients with KNHANES 2010-2015 data.
Results
In 20s~50s fasting blood glucose and in 20s and 30s LDL cholesterol of hyperprolactinemia patients were higher than Korean population, but there was no significance. In 20s total cholesterol ($P = 0.008$) and in 30s systolic blood pressure ($P = 0.00$) of hyperprolactinemia patients was significantly higher than Korean population. The prevalence of metabolic components were higher in patients with hyperprolactinemia than Korean population at triglyceride and blood pressure in 20s, 30s, but there was no significance. But, at fasting blood glucose in 20s, the prevalence of metabolic components were significantly higher in patients with hyperprolactinemia than Korean population ($P = 0.006$). Incidence of obesity of patients with hyperprolactinemia was higher than Korean population over 30s, but there was no significance.
Conclusion
This study suggests the necessity of evaluation of metabolic syndrome for patients with hyperprolactinemia. In the future, larger epidemiological studies on prevalence of metabolic syndrome in patients with hyperprolactinemia should be performed.

Pituitary apoplexy: a retrospective study in a pituitary reference unit

Giselle Giron[1], Rosa Camara-Gómez[1], Lorena Hernandez[1], Regina Lopez[1], Elena Vera[1] & Juan Francisco Merino Torres[1,2]

[1]La Fe University and Polytechnic Hospital, València, Spain; [2]University of Valencia, València, Spain

Pituitary apoplexy (PA) is a rare syndrome that requires urgent assistance. It is due to ischemia or hemorrhage of pituitary tissue, almost always inside a pituitary tumor. PA may be the first manifestation of a neuroendocrine tumor or occur during follow up.
Objective
To describe the characteristics of patients with PA treated in the Department of Endocrinology and Nutrition in the last 10 years and study the presence of possible risk factors for it.
Patients and method
Descriptive, single-center, retrospective study. We selected from electronic records 48 patients with the diagnosis of PA treated in the Endocrinology and Nutrition Department from 2010 to 2020. Demographic, clinical, biochemical, radiological and anatomopathological data were collected. The results are expressed as mean and standard deviation (SD) in the case of quantitative variables or percentage in the case of qualitative variables (SPSS 25.0).
Results
67% of the patients were men with a median age at diagnosis of 58.5 years (SD 13.9). As vascular risk factors they presented: hypertension (50%), diabetes (9.5%), and dyslipidemia (42.9%). Other coexisting clinical situations were: pregnancy (1), rheumatoid arthritis (1), Wegener's disease (1) and postoperative coronary bypass (1). The diagnosis was established with an average of 3 days from the onset of symptoms. The most frequent symptoms were: headache (79.1%), visual alterations (69.8%), nausea/vomiting (51.2%) and fluid and electrolyte disorders (20.9%), especially hyponatremia (50%). 40.5% of the patients had a known pituitary neuroendocrine tumor: pituitary macroadenomas (82%), pituitary macroadenomas with invasion of the cavernous sinus (45.2%), non-functioning tumors (52.9%) and prolactinoma treated with cabergoline (17.9%). Most patients (90.4%) presented some hormonal deficit: LH/FSH (76.3%), TSH (50%), GH (44.7%), ACTH (42.8%), ADH (2.3%). Panhypopituitarism was present in 26.2%. No patient passed away in the acute moment. 71.4% of the cases were treated with endoscopic transsphenoidal surgery for persistent headache and/or visual alterations. 76.2% of the patients continued with hormonal replacement treatment after surgery, of which 7 patients (21.9%) recovered total pituitary function, with an average of 4.6 months (SD 2.6) after the event.
Conclsions
- Pituitary apoplexy is more frequent in males and in pituitary neuroendocrine tumors bigger than 1 cm especially in cases with cavernous sinus invasion.
- Hypertension and dyslipidemia are very prevalent in patients with pituitary apoplexy.
- Despite being a condition that requires urgent assistance, the diagnosis is delayed for days from the onset of symptoms even with patients with known pituitary tumors.

Clinical applicability of using SAGIT instrument and AcroQol in the management of patients with acromegaly

Rok Herman[1], Katja Goricar[2], Andrej Janez[1] & Mojca Jensterle[1]
[1]University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Pharmacogenetics Laboratory, Institute of Biochemistry and Molecular Genetics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Objective
We aimed to evaluate the ability of SAGIT Instrument and AcroQoL questionnaire to discriminate acromegaly control status and to correlate SAGIT scores to AcroQoL results in a cohort of the national referral centre.
Methods
Cross-sectional study included 72 patients followed between 2000 and 2020. We retrospectively determined SAGIT score at the diagnosis. Based on the data from the most recent follow up and additional telephone interviews, we determined the patients' current SAGIT score and assess quality of life by AcroQoL.
Results
At follow up (median duration of 8 (5-12) years), 55 (76.4%) patients were classified as cured or controlled on pharmacotherapy based on biochemical criteria (median IGF-1 0.97 times ULN), while17 patients (23.6%) had uncontrolled disease (median IGF-1 2.65 times ULN). All 5 SAGIT categories significantly lowered from baseline to follow up, with the global score decreasing from 14 (12-15) to 4 (3-6) ($P<0.001$). The duration of diagnostic delay significantly correlated with subscores S, A, G and global score at diagnosis. SAGIT at baseline did not discriminate the current disease status, whereas the follow up global score and its G and I components discriminated between the current disease activity status, with the global score 4 (3-5) in cured/controlled group vs 6 (4.5-8) in uncontrolled group ($P=0.007$). At follow up, the median global AcroQoL score for our cohort was 69.3% (50-84.1), with the highest median score in the Personal relationship subscale and the most affected Physical Performance subscale. AcroQoL was not able to discriminate disease activity status. From the examined variables (BMI, IGF-1 levels, time to remission, disease duration, diagnostic delay, age, gender, adenoma size, and the presence of diabetes mellitus and hypopituitarism), only BMI had significant negative correlations with the global AcroQoL score. At baseline and follow up, there were statistically significant negative correlations between SAGIT subscores S and A and all AcroQoL subscales. The presence of swelling at baseline had a significant effect on the global AcroQoL score ($P=0.035$). At follow up, the significant elements that correlated with the global AcroQol score were joint symptoms ($P=0.002$), headaches ($P<0.001$), sleep apnea ($P=0.006$) and hypertension ($P=0.002$).
Conclusions
Our results emphasise the complementary nature of Patient- and Clinician-reported outcome tools in assessing acromegaly control status. The data identifies the critical role of signs, symptoms, and associated comorbidities as important patient-oriented treatment targets, beyond SAGIT sub-scores G, I and T, by which clinicians could further increase the impaired QoL in this population.

Links between posterior pituitary activity, other endocrine abnormalities and psychometric profile in anorexia nervosa: a multimodal evaluation

Bogdan Galusca[1,2], Doua Singoh Sandra Emmanuelle[1,2], Natacha Germain[1,2], Merabet Mannel[1,2,3], Redouté Jérôme[1,3], Claire Boutet[1,4] & Massoubre Catherine[1,5]
[1]TAPE Reaserch Unit, EA 7423, Jean Monnet University, Saint Etienne, France, Saint-Étienne, France; [2]CHU Nord Saint-Étienne, Saint-Priest-en-Jarez, France; [3]Cermep - Imagery Du Vivant, Bron, France; [4]CHU Nord Saint-Étienne, Radiology, Saint-Priest-en-Jarez, France; [5]Psychiatry Department, CHU Saint Etienne Saint Etienne, France, France

Introduction
Opioid system activity was found disturbed in several reward circuit areas in restrictive anorexia nervosa (AN) patients but also surprisingly at the pituitary level. However, the potential role of this specific abnormality of pituitary in AN physiopathology remains unclear or unknown.
Objectives
The first aim was to find the exact pituitary location (posterior and/or anterior) of this disturbed opioid activity and then to study the link between this disturbed opioid activity and pituitary hormone activity.
Methods
In vivo [^{11} C] diprenorphin cerebral non-displaceable binding potential (BP_{ND}) was assessed by PET imaging. Volumes and intensities were also extracted from MRI scans and processed for each pituitary region and compared in three groups of young women: 12 undernourished (AN), 11 recovered AN patients (ANrec), and 12 Controls (C). A lower BP_{ND} may account for an increased opioid tone and vice versa. Plasma hormones from anterior pituitary and neurohypophysis (NH) twelve points circadian profile including copeptin and oxytocin, endogenous opioids levels and psychological scores eating-related, were evaluated in these subjects as well as in 13 bulimic (BN) patients.
Results
[^{11} C] diprenorphin pituitary binding was found to be fully localized in NH. Only AN patients' NH present lower [^{11} C] diprenorphin BP_{ND} than Controls, interpreted as a higher opioid tone. AN had lower anterior pituitary volume than controls and ANrec while ANrec still had a smaller anterior pituitary volume than controls. Concerning posterior pituitary volume, only AN had significant lower volume than controls. NH [^{11} C] diprenorphin BP_{ND} correlated directly with the anterior pituitary volume. Both AN and ANrec show lower copeptin/24h than in Controls but no difference in oxytocin. BN patients showed an increase in copeptin and a decrease in oxytocin levels compared to Control group. In AN patients copeptin inversely correlate with Restrained Eating while oxytocin correlate with the External Eating score. NH [^{11} C] diprenorphin BP_{ND} correlated among others things with leptin, BMI, pituitary BP, hypothalamus BP, Amygdal IBP, but not with copeptin or oxytocin.
Conclusion
The disruption of opioid activity observed in the previous study appears to be mainly localized in the neurohypophysis. Neurohypopysis opioid tone in AN seem not to impact the vasopressin or oxytocin release but still may interfere in gonadal axis regulation. Copeptin seems to be a good indicator of hydration state and may be a good tool to detect hidden restrictive or purging behaviors. Specific

correlations with the psychological characteristics of anorexia nervosa still suggest a pathophysiological involvement.

Effects of the SGLT2-inhibitor empagliflozin in patients with chronic syndrome of inadequate antidiuresis (SIAD) - results of a double-blind, randomized, placebo-controlled, crossover trial

Julie Refardt[1], Cornelia Imber[2], Rianne Nobbenhuis[3], Sailer Clara Odilia[3], Aaron Haslbauer[3], Deborah Vogt[3], Manfred Berres[4], Bettina Winzeler[3], Stephanie Bridenbaugh[3] & Christ-Crain Mirjam[3]
[1]University Hospital Basel, Endocrinology, Switzerland; [2]University Hospital Basel, Switzerland; [3]University Hospital Basel; [4]University Koblenz

Introduction
Hyponatremia is the most common electrolyte disorder and the syndrome of inappropriate antidiuresis (SIAD) is one of its main causes. However, treatment options for chronic SIAD-induced hyponatremia are inadequate. This is problematic because hyponatremia has been associated with neurocognitive deficits, although there is little data on its reversibility. We previously showed that the sodium-glucose cotransporter 2 (SGLT2) inhibitor empagliflozin is a promising short-term treatment option for hospitalized patients with SIAD-induced hyponatremia, promoting osmotic diuresis via urinary glucose excretion. However, there are no data on long-term treatment in outpatients nor its effect on neurocognitive function.
Material and Methods
In this double-blind, randomized, placebo-controlled, crossover trial we compared 4-week treatment with empagliflozin 25 mg/day to placebo in addition to fluid restriction of $\leq$1.5L/24h in outpatients with chronic SIAD-induced hyponatremia (serum sodium $<$135 mmol/l). At baseline and after both treatment cycles, patients underwent neurocognitive testing (Montreal Cognitive Assessment (MoCA) test). There was a 2-week wash-out period between the two treatment cycles, and a follow-up visit was scheduled 30 days after completion of the treatment phase. The primary endpoint was the difference in serum sodium levels (mmol/l) after 4 weeks of treatment with empagliflozin or placebo, calculated using a linear mixed-effects model.
Results
14 patients, 50% female, with a median (IQR) age of 72 years (65-77) completed the trial. Median (IQR) serum sodium level at baseline was 131 mmol/l (130-132). Under treatment with empagliflozin, median (IQR) serum sodium level increased to 134 mmol/l (132-136), while no notable change was seen under placebo (130 mmol/l (128-132)). This resulted in a 4.1 mmol/l (95% CI 1.7-6.5) higher serum sodium level after 4 weeks of empagliflozin treatment compared to placebo ($P=0.004$). This effect was independent of severity of SIAD. In addition, treatment with empagliflozin led to improved neurocognitive function, as shown by an increase of 1.2 points (SE 0.5) in the MoCA test ($P=0.042$). Treatment with empagliflozin was generally well tolerated, no serious adverse events occurred during the observation period.
Conclsion
This trial shows that the SGLT-2 inhibitor empagliflozin is a promising new treatment option for outpatients with chronic SIAD-induced hyponatremia. Furthermore, hyponatremia treatment led to an improvement of neurocognitive function.

Background
T2-weighted magnetic resonance imaging (MRI) signal has been recently linked with a better tumor response to pasireotide treatment in patients with acromegaly (ACRO). Our aim was to evaluate the prevalence of this radiological feature and its association to therapeutic outcomes in a large cohort of ACRO patients treated with pasireotide.
Methods
A retrospective multicentre study was performed in 15 Spanish tertiary university hospitals including patients with active ACRO who have been taking pasireotide as a second-line treatment according to current clinical guidelines. Pituitary tumor T2-weighted MRI signal was classified as "iso-hyperintense" or "hypointense" by local neuro-radiologists. Insulin-like growth factor 1 (IGF-1) levels and tumor volume reduction ($\geq$25% from baseline) were assessed after 6 and 12 months of pasireotide treatment and results analysed according to MRI pre-treatment signal. Response to pasireotide was defined as "complete" when normalization of IGF-I levels was achieved or "partial" when a decreased of $\geq$50% in IGF-I was obtained. "No response" was defined as $<$50% decrease in IGF-I from baseline.
Results
Sixty-nine patients were included (50.7% females, age 48.3$\pm$13.3), of whom 55 (79.7%) had previously undergone surgery and 63 (92.6%) treatment with first-generation somatostatin analogues, remaining with active disease before initiation of pasireotide. MRI signal was hypointense in 20 (29%) and hyperintense in 49 (71%) of the patients. Hyperintense group showed larger initial tumor compared to hypointense (7900$\pm$2000 mm^3 vs 679$\pm$1500 mm^3 $P=0.001$). Complete response to pasireotide treatment at 6 months was observed in 40 (58.8%), partial response in 1 (1.5%), and no response in 27 (39.7%) patients, while at 12 months, 40 (69%), 1 (1.7%) and 17 (29.3%) were under the aforementioned control categories, respectively, and it was not related to MRI signal category. A $\geq$25% reduction from basal tumor volume was observed in 18 (43.9%) patients after 12 months of pasireotide treatment, in the hyperintense signal group (15 out of 49 patients) (mean reduction -2064$\pm$2638 mm^3 $P=0.04$) while in the hypointense signal group in only 3 patients a decrease $\geq$25% was observed, while in the rest the tumor volume did not changed or increased. There was no correlation of volume decrease and normalization of IGF-1.
Conclusion
Almost 70% of acromegaly patients who had not responded to first-generation somatostatin analogues showed a complete hormonal response to pasireotide, regardless of the T2-weighted MRI signal, at one year of follow-up. Compared to hypointense, hyperintense T2-weighted MRI signal is associated to a better tumor shrinkage response over time.

Patient-reported outcomes (PRO) in adult growth hormone deficiency (aghd) for an improved patients' management: results from the management of AGHD(MAGHD) study

Maria Laura Monzani[1,2], Simone Pederzoli[1,2], Alessio Bellelli[1,2], Elisa Magnani[3], Chiara Diazzi[1], Caterina Golinelli[2], Marco Pacchioni[4], Mirko Orsini[4] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]Endocrinology Unit, AUSL-IRCCS of Reggio Emilia, Reggio Emilia, Italy; [4]DataRiver Srl, Modena, Italy

Background
AGHD is a recognized clinical entity, but symptoms are quite nonspecific; the lack of objective tools able to measure patients' health status remains the main barrier in clinical monitoring and treatment.
Aim
The MAGHD Study aims improving AGHD patients' management through a Smartphone app (MAGHDApp) and a fit-watch integrated with a software

framework able to merge daily data of patients' well-being and physical activity with clinical data collected in institutional databases, giving feedbacks to both patients and clinicians.
Methods
Eighty-three AGHD patients (31 Females, 52 Males, mean age 56.27 + 14.68 years) referring to a single endocrinological center entered the 24-months study. During the first year, AGHD patients performed biannual clinical visits with clinical, biochemical and multidimensional assessment through validated questionnaires (QoL-AGHDA, QLS-H, IIEF-15, FSFI, WEMWBS, IPAQ, PSQI). In parallel, MAGHDApp was developed to daily collect patient reported outcomes (PRO) derived from answers to questionnaires; moreover, a web-platform was exploited to collect data from fit-watch (number of steps, calories burned and hours of sleep). During the second year, patients were invited to use MAGHD technologies recording data, independently from patients' biannual visits. Up-to-now, only data from MAGHDApp have been analyzed.
Results
Fifty-eight patients (70%, mean age 59.9 ± 13.3) entered the second phase using MAGHD technology (MAGHDGroup), the other 25 (30%, mean age 64.4 ± 14.8) were monitored in the second phase as well as in the first. Patients of MAGHDGroup were younger than the others ($P < 0.05$), with no differences in gender distribution between the two groups ($P = 0.09$). During the second year, each questionnaire was sent to patients 6 times and MAGHDplatform collected about 12.000 PRO. Globally, the mean response rate was 60%, no differences were registered according to the type of questionnaire addressed (QoL-AGHDA = 62%, QLS-H = 62%, IIEF-15 = 58%, FSFI = 60%, WEMWBS = 61%, IPAQ = 58% and PSQI = 57%). 66% of questions were answered within 3 h from sending.
Conclusions
This real-life study suggests innovative and technological solutions for management of AGHD patients. These preliminary data document the feasibility of this kind of monitoring, especially in young AGHD patients, and a fair patients' adherence. PRO from MAGHDApp seems to guarantee a reliable, daily monitoring of patients' well-being. This information, coupled with physical activity data, could make patients directly involved in the healthcare process and help clinicians in AGHD management and follow-up.
Acknowledgment
This clinical study is conducted thanks to the competitive assignment of an Independent Grant for Learning & Change, Dissemination & Implementation by Pfizer Inc.

Somatic mutations in the ubiquitin specific peptidase 8 (USP8) gene have been associated with higher levels of somatostatin (SS) receptor subtype 5 (SSTR5) in adrenocorticotroph hormone (ACTH)-secreting pituitary neuroendocrine tumors (PitNETs). However, a correlation between the USP8 mutational status and favorable responses to pasireotide, the somatostatin multi-receptor ligand acting especially on SSTR5, has not been investigated yet. Here, we studied the impact of USP8 mutations on pasireotide responsiveness in human and murine corticotroph tumor cells. SSTR5 upregulation was observed in USP8-mutated tumors and in USP8 wild-type primary tumor cells transfected with S718del USP8 mutant. However, cell transfection with S718del USP8 and C40-USP8 mutants in *in vitro* sensitive cultures from USP8 wild-type tumors abolished their ability to respond to pasireotide and did not confer pasireotide responsiveness to the *in vitro* resistant culture. Pasireotide failed to reduce ACTH secretion in primary cells from one S718P USP8-mutated tumor but exerted a strong antisecretory effect in primary cells from one P720R USP8-mutated tumor. In agreement, AtT-20 cells transfection with USP8 mutants led to SSTR5 expression increase but pasireotide could reduce ACTH production and cyclin E expression in P720R USP8 overexpressing cells, only. *In situ* Proximity Ligation Assay and immunoflurescence experiments revealed that P720R USP8 mutant is still able to bind 14-3-3 proteins in AtT-20 cells without affecting SSTR5 localization. In conclusion, P720R USP8 mutation might be considered as a molecular predictor of favorable response to pasireotide in corticotroph tumor cells.

Spallanzani", Pavia, Italy

Non-functioning pituitary adenomas (NFPAs), mainly gonadotroph pituitary adenomas (GPAs), are the second most common type of PAs. Given the lack of symptoms secondary to hormone hypersecretion, NFPAs are often diagnosed when they cause mass effects. At this stage they are invasive (50% of cases), they cannot be completely resected and often recur. Despite their frequency, no standard of care drug treatment currently exists for these tumors. SSAs (somatostatin agonists) like octreotide and lanreotide, binding to somatostatin receptor (SSTR) 2 and to a lesser extent to SSTR5 and SSTR3, are poorly efficacious in NFPAs. Similarly, the pan-agonist pasireotide, binding to SSTR 1,2,3,5, showed only modest efficacy in a recent phase II clinical trial of NFPA patients. SSTR3 was found to be frequently and strongly expressed in NFPAs, while SSTR2 only in few patients and SSTR5 only exceptionally. We here report the characterization of ITF2984, a novel cyclic hexapeptide pan-SSTR agonist with high SSTR3 specificity. While structurally analogous to other pan-agonists, ITF2984 shows higher affinity for SSTR3 vs known molecules. Molecular modeling revealed that higher α-II' turn probability in ITF2984 correlated with higher SSTR3 affinity, thus providing a rationale for its unique selectivity. ITF2984 inhibited GH release from GHRH-stimulated rat anterior pituitary primary cells similarly to pasireotide. To functionally characterize ITF2984 mode of action, the following assays were performed:

- Receptor internalization in HEK293 and U2OS cell lines overexpressing human SSTRs.
- SSA-mediated activation of human SSTRs by western blotting using phosphosite-specific antibodies.
- Agonist-mediated G protein-signaling of SSTR3 (GIRK activation) in SSTR3 overexpressing HEK293 and AtT20 cells.

Unlike pasireotide and octreotide, ITF2984 induced SSTR3 internalization and phosphorylation, as well as GIRK activation in a pharmacologically relevant concentration range. Thus, ITF2984 behaved as a full SSTR3 agonist. The *in vivo* activity of ITF2984 was tested in the MENX NFPA rat model. Adenomas developing in this model have a gender-specific SSTR3 expression pattern, with higher expression levels in females. Consistent with its receptor affinity profile and the in vitro data, ITF2984 showed selective antitumor activity in female rats, accompanied by a decrease in proliferation (KI67 positivity). In addition, ITF2984 selectively induced SSTR3 mRNA expression in female rat tumors, suggesting a compensatory gene upregulation. These data are in line with an *in*

vivo engagement of SSTR3 and a predominantly SSTR3-driven antitumor activity of ITF2984 and provide an *in vivo* proof-of-concept for the potential clinical use of ITF2984 in NFPAs and other SSTR3-driven diseases.

Safety comparison of 40- vs 60- mg/day doses of oral octreotide capsules for treatment of acromegaly in the chiasma optimal trial

Susan L. Samson[1], Lisa B. Nachtigall[2], Maria Fleseriu[3], Mark E. Molitch[4], Andrea Giustina[5], Asi Haviv[6], Nienke Biermasz[7], Laurence Kennedy[8], Mojca Jensterle[9], Patrick Manning[10], Atanaska Elenkova[11], Shlomo Melmed[12] & Christian J. Strasburger[13]
[1]Mayo Clinic, Department of Medicine and Neurological Surgery, Jacksonville, United States; [2]Massachusetts General Hospital and Department of Medicine, Harvard Medical School, Neuroendocrine Unit, Boston, United States; [3]Oregon Health & Science University, Pituitary Center, Portland, United States; [4]Northwestern University Feinberg School of Medicine, Chicago, United States; [5]San Raffaele Vita-Salute University, Institute of Endocrine and Metabolic Sciences, Milan, Italy; [6]Amryt Pharmaceuticals DAC, Dublin, Ireland; [7]Leiden University Medical Center (LUMC), Leiden, Netherlands; [8]Cleveland Clinic Foundation, Cleveland, United States; [9]University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Slovenia; [10]Dunedin Hospital, Dunedin, New Zealand; [11]Medical University Sofia, USHATE "Acad. Ivan Penchev", Department of Endocrinology, Sofia, Bulgaria; [12]Cedars-Sinai Medical Center, Los Angeles, United States; [13]Charite-Universitätsmedizin, Campus Mitte, Department of Clinical Endocrinology, Berlin, Germany

Background
Oral octreotide capsules (OOC) are a treatment option for patients with acromegaly in the United States who have previously responded to injectable somatostatin receptor ligands (iSRLs, octreotide or lanreotide). In previous phase 3 studies, the safety of OOC was shown to be consistent with iSRLs, without dose-dependent adverse reactions. In the double-blind, placebo-controlled period (DPC) of the CHIASMA OPTIMAL trial (NCT03252353), patients were randomized to twice-daily OOC at 40- mg/day, with the option for up-titration to 80- mg/day. In contrast, patients entered the open-label extension (OLE) at a 60- mg/day dose.
Objective
Examine the safety of 40- mg/day vs 60- mg/day OOC doses.
Methods
Eligible patients had the option to enroll in the OLE following the core trial. All patients received OOC 60- mg/day upon entering the OLE regardless of prior treatment in the DPC, including patients who received placebo in the DPC. OOC doses were up- or down-titrated based on insulin-like growth factor I (IGF-I) level and/or acromegaly signs or symptoms. The current analysis compared the incidence of treatment-emergent adverse events (TEAEs), serious adverse events (SAEs), TEAE-related study drug discontinuation, and acromegaly-related TEAEs (defined as new or worsening signs or symptoms of acromegaly).
Results
Twenty-eight patients randomized to OOC in the DPC (40- mg/day dose) and 19 who were originally randomized to placebo and continued into the OLE (60- mg/day dose) were included in the analysis. Biochemical control was similar in both groups as demonstrated by mean IGF-I levels over the respective periods. Ninety-six percent of patients on 40- mg/day and 57.9% on 60- mg/day experienced $\geq$1 TEAEs. Two patients on 60- mg/day reported a total of 2 SAEs, both deemed unrelated to study drug. Two patients on 40- mg/day experienced TEAEs leading to study drug discontinuation (headache and gastrointestinal symptoms). The incidence of acromegaly-related TEAEs was generally lower in those on 60- mg/day vs 40- mg/day.
Conclsions
This is the first analysis exploring differences in OOC doses. The nature and incidence of TEAEs occurring with a starting OOC dose of 60- mg/day vs 40- mg/day were similar, though this analysis was limited by differences in TEAE reporting across sequential phases of a lengthy trial. A trend was observed for decreased incidence of acromegaly-related TEAEs with the 60- mg/day dose. This finding is in line with previous analyses showing no dose-related TEAEs with OOC.

Efficacy of pasireotide LAR for acromegaly: a long-term real-world monocentric study

Benedetta Zampetti[1], Emanuela Isabella Carioni[1], Paolo Dalino Ciaramella[1], Erika Grossrubatscher[1], Daniela Dallabonzana[1], Roberto Attanasio[2] & Renato Cozzi[1]
[1]Grande Ospedale Metropolitano Niguarda, Endocrine Unit, Milano, Italy; [2]Scientific Committee Associazione Medici Endocrinologi, International Chapter of Clinical Endocrinology, Italy

Patients
Nineteen acromegalic patients (8 females, 21-69 years-old, with macroadenoma, microadenoma or no evidence of pituitary tumor in 15, 2, 2, respectively) resistant to first generation somatostatin analogs (FG-SA) at high doses and/or intolerant to pegvisomant were switched to pasireotide LAR (PasLAR). Eleven had persistent disease after neurosurgery and two had also undergone radiosurgery (12 and 24 months before starting PasLAR). Six complained of acromegalic headache (symptomatic score was 3/3 in 5 and 2/3 in the other). On FG-SA IGF-1, GH and HbA1c were (mean, range) 193% upper limit normal age-matched range (ULNR) (120-303), 5.2 ng/ml (0.6-25), and 40.6 mmol/mol (29-54), respectively. No patient was taking antidiabetic drugs.
Protocol
PasLAR was injected every 28 days, starting with 40 mg for 3 months, uptitrated to 60 mg if IGF-1 persisted pathologic or downtitrated to 20 mg if IGF-1 was $<$ 50% ULNR. GH, IGF-1, HbA1c were assessed at 28, 84 and 168 days after starting protocol. Treatment was withdrawn if IGF-1 remained pathologic after 3 months on 60 mg q 28 days.
Results
PasLAR normalized **IGF-1** in 10/19 patients after the first injection and was withdrawn in 5 unresponsive patients at 6 months. After 12 months, IGF-1 was 74% ULNR (29-133, normal in 9/14) and GH 1.2 ng/ml (0.2-3.9). At the last follow-up (mean 26 months, range 6-60, ongoing dose 20 mg in 3, 40 mg in 7 patients, and 60 mg in 4) IGF-1 was 74% ULNR (22-195, normal in 11/14) and GH 0.7 ng/ml (0.1-2.5). **Headache** quite disappeared in all patients (in 5/6 after the first injection) and reappeared with pathologic IGF levels after PasLAR withdrawal in one irradiated patient. **Tumor shrinkage** (20-35% of basal volume) was observed in 6/7 evaluated patients without previous irradiation at 6-36 months after the start of PasLAR. **HbA1c** was 43.9 mmol/mol (32-66) at 12 months and 43.3 mmol/mol (29-66) at the last follow-up. Glucose metabolism derangement was observed in 6 patients (until DKA in one). Metformin was started in 4 patients and GLP-1 RA in two (in one coupled with insulin). In two patients PasLAR was withdrawn at 36 and 60 months due to poor compliance in the first and QTc lengthening in the second, who had started amiodarone treatment.
Conclusion
Pas-LAR should be considered a second option in patients resistant to FG-SA for its high efficacy and safety. Its quick action allows early identification of responsive patients. Efficacy on severe headache is outstanding.

Towards a pituitary apoplexy classification based on clinical presentation and patient journey

Mathijs Guijt[1], Amir Zamanipoor Najafabadi[1], Irene Notting[2], Alberto M Pereira[1], Marco Verstegen[3], Nienke Biermasz[1], Wouter van Furth[3] & Kim Claessen[1]
[1]Leiden University Medical Center (LUMC), Department. of Medicine, Division of Endocrinology, and Centre for Endocrine Tumors Leiden, Leiden, Netherlands; [2]Leiden University Medical Center (LUMC), Department. of Ophthalmology, Leiden, Netherlands; [3]Leiden University Medical Center (LUMC), University Neurosurgical Center Holland, Leiden, Netherlands

Purpose
The condition of pituitary apoplexy contains the clinical spectre from life-threatening emergency to a condition with chronic symptoms and self-limiting course, which partly determines diagnostic delay and management. Outcome evaluation of course and management of pituitary apoplexy is hampered by the diverse presentation of this condition and requires appraisal. This study aimed to describe the patient journey, clinical presentation and management of various types of pituitary apoplexy in a new classification to facilitate future outcome evaluation and identify unmet needs in the current care process.

Methods
A single-center retrospective patient chart study was conducted between 2005-2021 ($n=98$). Outcome measures were clinical symptoms at first presentation in hospital, being headache, consciousness, visual acuity, visual field defects (VFD), ophthalmoplegia, nausea, vomiting, fever and hypopituitarism and care process characteristics. We described their patient journey and identified three different types, differing in clinical presentation, in-hospital route and final treatment.
Results
Mean age was 47.6 ± 16.6 years, and 51.0% was male. Most patients belonged to the acute apoplexy subtype (type A, 52%), followed by the subacute (type B, 22.5%) and non-acute subtype (type C, 25.5%). Type A generally presents with acute onset headaches, VFD or ophthalmoplegia emergency setting, with lowest mean visual acuity of both eyes and frequent hypocortisolism. Type B presents both with acute onset and chronic headaches, with VFD or ophthalmoplegia that sometimes require acute surgery. Type C usually presents with chronic headaches without acute onset and no urgent ophthalmologic complaints that require acute surgery. Next to differences in clinical presentation at hospital entry, we also showed that patients of different apoplexy subtypes go through a different type of care process with different initial working diagnosis, different attending medical specialties, and eventually different treatments.
Conclusion
Pituitary apoplexy can be approached as a spectrum of disease with 3 main subtypes, being acute, subacute and non-acute, with a different initial presentation, different in-hospital route resulting in different management. The most important unmet needs in the care process of pituitary apoplexy patients are: 1) delay in referral to a Pituitary Tumors Center of Excellence (PTCOE), 2) underdiagnosis of apoplexy subtypes B and C, since subacute and non-acute complaints are not recognized as pituitary apoplexy; 3) lack of long-term outcome evaluation of different treatment modalities within subtypes. Acknowledging subtypes will serve improvements in patient care, and outcome evaluations.

The immune microenvironment landscape in pituitary tumors, genes and cells

Sandra Vela Patiño[1,2], Ma. Isabel Salazar[2], Ilan Remba-Shapiroa[1], Eduardo Peña-Martínez[1], Gloria Silva-Roman[1,2], Sergio Andoneui-Elguera[1], Keiko Taniguchi-Ponciano[1], Laura Bonifaz[3], Cristina Aguilar-Flores[3], Moises Mercado[1] & Daniel Marrero-Rodríguez[1]
[1]Hospital de Especialidades, Centro Medico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Unidad de Investigación Medica en Enfermedades Endocrinas, Mexico; [2]Escuela Nacional de Ciencias Biologicas, Laboratorio de virología e inmunovirología, Departamento de Microbiología, Mexico; [3]Hospital de Especialidades, Centro Medico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Unidad de Investigación Medica en Inmunoquimica, Mexico

The tumor immune microenvironment is essential, it could influence a favorable or negative response against the tumor cells, and it has been related to therapy response and prognostic factors. Tumor infiltrating lymphocytes (TILs) plays an important role in the development, progression, and tumor control, thus presence of TILs could be related to disease-specific traits. The aim of the present work is to evaluate the expression of immune-related genes in forty-two pituitary adenomas (PA) distributed in the three major lineages, NR5A1- (Clinically non-functioning PA), TBX19- (ACTH adenoma) and POU1F1- (GH, TSH, PRL adenoma) through whole transcriptome analysis and RT-qPCR, and to identify the microenvironment immune cells infiltrating the tumor through transcriptome deconvolution and immunofluorescence. We found characteristic expression profiles of immune-related genes including interleukins and chemokines for each tumor lineage. Genes such as IL4I1, IL36A, TIRAP, IL17REL and CCL5 were upregulated in all PA whereas IL-34, IL20RA and IL2RB characterize the NR5A1-, TBX19- and POU1F1-derived tumors, respectively. Transcriptome deconvolution showed that macrophages, CD4+ T cells, CD8+ T cells, NK cells, and neutrophils could be infiltrating the PA. CD4+ and CD8+ T cells and NK cells infiltration predicted was corroborated by immunofluorescence in pituitary adenomas. In conclusion, we found characteristic immune response gene expression profiles for each pituitary tumor lineage, that explain partially, the immune response CD8+, CD4+ T cells, NK cells and macrophages infiltration. Our results suggest a crosstalk between the tumor cells and its microenvironment.

The positive feedback exerted by mtor inhibitor everolimus in pituitary neuroendocrine tumoral cells is reverted by cabergoline co-treatment

Federica Mangili[1], Emanuela Esposito[1], Donatella Treppiedi[1], Rosa Catalano[1], Giusy Marra[1], Genesio Di Muro[1], Anna Maria Barbieri[1], Marco Locatelli[2], Andrea Gerardo Lania[3], Anna Spada[1], Maura Arosio[4], Giovanna Mantovani[4] & Erika Peverelli[1]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Neurosurgery Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [3]Endocrine Unit, IRCCS Humanitas Clinical Institute, Humanitas University, Rozzano, Rozzano, Italy; [4]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

The mTOR inhibitor everolimus has been shown to display antimitotic effects on diverse neoplasms, including pituitary neuroendocrine tumors (PitNETs); however, its effect is reduced by an escape mechanism that increases AKT phosphorylation (*P*-AKT) leading to survival pathway activation. Dopamine receptor type 2 (DRD2) reduces p-AKT in some non-functioning PitNETs (NF-PitNETs) and in lactotrophs MMQ cells, through a α-arrestin 2-dependent mechanism. This study aims to analyze the efficacy of everolimus combined with DRD2 agonist cabergoline in reducing proliferation in primary cultured NF-PitNETs and MMQ cells, to analyze AKT phosphorylation and α-arrestin 2 activity. We found that 9 out of 14 NF-PitNETs were resistant to everolimus 1 nM, but the combined treatment with cabergoline inhibited cell proliferation in 7 out of 9 tumors (-31.4 ± 9.9%, $P<0.001$ vs basal), accordingly increased p27 and reduced cyclin D3 expression. In everolimus unresponsive NF-PitNETs group, 3 h everolimus treatment determined a significant increase of p-AKT/total-AKT ratio (2.1-fold, $P<0.01$, vs basal), and this effect was significantly reverted by cabergoline cotreatment. To investigate the molecular mechanism involved, we used MMQ cells as a model of everolimus escape mechanism. Indeed, 1 nM everolimus did not affect MMQ cells proliferation and increased p-AKT/total-AKT ratio (+1.53 ± 0.24-fold, $P<0.001$ vs basal), whereas cabergoline significantly reduced cell proliferation (-22.8 ± 6.8%, $P<0.001$ vs basal) and AKT activity. The combined treatment of everolimus and cabergoline induced a significant reduction of both cell proliferation (-34.8 ± 18%, $P<0.001$ vs basal and $P<0.05$ vs cabergoline alone) and p-AKT/total-AKT ratio (-34.5 ± 14%, $P<0.001$ vs basal and $P<0.05$ vs cabergoline alone). Moreover, to test a possible involvement of α-arrestin 2, silencing experiments were performed in MMQ cells. Our data showed that the lack of α-arrestin 2 prevented everolimus and cabergoline co-treatment inhibitory effects on both AKT activation and cells proliferation. These results unveiled that cabergoline overcomes the everolimus escape mechanism in primary NF-PitNETs cultured and MMQ cells inhibiting AKT phosphorylation, paving the way for a potential role of β-arrestin 2 as a biomarker predicting PitNETs responsiveness to combined therapy with dopamine agonists.

Low post-operative cortisol after TSS for pituitary surgery predicts short term but not long term remission

Vanitha Karunakaran[1], Mohamed Okasha[2], Nick W Thomas[2], Sinan Barazi[2], Eleni Maratos[2], Benjamin C Whitelaw[1], Jackie Gilbert[1], Paul V Carroll[3], Jonathan Shapey[2] & Simon J B Aylwin[1]
[1]King's College Hospital, Department of Endocrinology, London, United Kingdom; [2]King's College Hospital, Department of Neurosurgery, London,

United Kingdom; [3]Guy's and St Thomas' NHS Foundation Trust, Department of Endocrinology, London, United Kingdom

Background
It is generally accepted that a post-operative cortisol of <50 nmol/l is a good predictor of long-term remission following trans-sphenoidal surgery (TSS).
Aim
We wished to determine the rate of late recurrence and need for consequent intervention in patients who had initial biochemical remission after TSS for pituitary dependent Cushing's.
Methods
We performed a retrospective analysis of our patients who underwent TSS for pituitary Cushing's between 2004 and 2019. Remission was defined as post-operative 0900 cortisol of <50 nmol/l within 3 months following TSS including patients who had surgical re-exploration during the initial admission due to a high day 2 post-operative cortisol. Those with post-operative basal cortisol greater than or equal to 50 nmol/l were considered to have 'persistent disease'. Late recurrence was defined as the emergence of biochemical cortisol excess during the follow-up period (non-suppressible cortisol, and/or elevated urine free cortisol). Kaplan-Meier curves were plotted to determine the rates of recurrence and need for second intervention in patients initially in remission and re-intervention rates were compared to those with persistent disease.
Results
86 patients (mean age 47years; 65 females, 21 males) underwent TSS for pituitary Cushing's; 28/86 had macro- and 58/86 micro-adenomas. Median follow-up time was 9 years (range 1-16). 52/86 (60%) patients were in remission (39% of macro- and 71% of microadenoma) after TSS including 5/9 patients who had immediate re-exploration. 12/52 (23%) relapsed during follow-up. Using a Kaplan Meier analysis, the 5 year remission rate was 68% and 10 year remission rate was 53% in those with immediate post-op cortisol <50 nmol/L. In total, of the 52 patients in remission post-operatively, 23% relapsed and all had a further intervention (2^{nd} TSS $n=6$; radiotherapy $n=6$). Early relapse requiring intervention was uncommon in the remission group; only 1/52 patients had a second intervention within 1 year and 3/52 within 3 years. In contrast, 30/86 patients had persistent cortisol excess and of these 83% (25/30) had a repeat intervention in the first year after surgery.
Conclsions
Our data demonstrate a significant recurrence rate (32% at 5yrs) in patients considered by the most stringent criteria to be in remission following TSS leading to further intervention. Our data also demonstrate that those with persistent disease are likely to require a second intervention shortly after initial surgery. A post-operative cortisol of <50 nmol/l is a predictor of short-term remission but is not necessarily a confident long-term predictor of remission.

Antagonist of growth hormone-releasing hormone (GHRH) inhibits SARS-CoV-2 Spike protein-induced inflammation in macrophages and PBMCs

Giuseppina Granato[1], Iacopo Gesmundo[1], Tatiana Lopatina[1], Maria Felice Brizzi[1], Andrew Victor Schally[2] & Riccarda Granata[1]
[1]Division of Endocrinology, Diabetes and Metabolism, Department of Medical Science, University of Turin, Turin, Italy; [2]Department of Medicine, Miller School of Medicine, University of Miami, Miami, United States

Macrophages play essential roles in the immune defence and their hyperactivation has been implicated in epithelial damage in acute respiratory distress syndrome (ARDS), commonly observed in severe COVID-19 patients. In these cells, SARS-CoV-2 spike (S) protein triggers aberrant production of pro-inflammatory cytokines like interleukin-1 beta (IL-1β), interleukin-6 (IL-6) and tumor necrosis factor-alpha (TNF-α), as well as reactive oxygen species (ROS) and matrix metalloproteinases (MMPs), which contribute to viral pathogenesis. Thus, one of the therapeutic strategies to reduce acute lung injury and multi-organ dysfunction in COVID-19 would be to blunt macrophage-mediated inflammatory response. Interestingly, it has been recently shown that the interaction between S protein and lipopolysaccharide (LPS) leads to aggravated inflammation in monocytes and peripheral blood mononuclear cells (PBMCs). The hypothalamic hormone growth hormone-releasing hormone (GHRH), in addition to promoting pituitary GH release, exerts many peripheral functions, including the regulation of inflammatory responses. GHRH antagonists, in turn, display potent anticancer and antinflammatory activities, also on in vitro and *in vivo* models of LPS-induced inflammation and lung diseases. However, the role of GHRH antagonists in models of COVID-19 remains to be explored. Thus, we aimed to assess the potential antinflammatory role of GHRH antagonist MIA-602 in human THP-1 macrophages and PBMCs stimulated with LPS, either alone or in combination with S protein. Human monocytic THP-1 cells were differentiated into macrophages with phytohemagglutinin (PMA); PBMCs were obtained from buffy coats of healthy donors by density-gradient separation. Both THP-1 cells and PBMCs were pretreated for 2 h with LPS, then incubated for 24 h with MIA-602, alone or in combination with S protein. The mRNA and protein levels of cytokines were analyzed by real-time PCR and ELISA, respectively. We found that the combination of S protein and LPS potently enhanced the levels of inflammatory cytokines, when compared with each compound alone. Importantly, MIA-602 completely blocked the inflammatory response to LPS + S protein and reduced by over 50% the increase in both gene expression and secretion of TNF-α, IL-1β and IL-6. Moreover, in support of its antinflammatory role, MIA-602 reduced ROS and MMP-9 levels, by 10% and over 30% respectively, as assessed by Muse cell analyzer and gelatin zymography. Overall, these results suggest that GHRH antagonists may be potential therapeutic candidates for attenuating the inflammatory cascade in patients with COVID19.

Use of corrected SUVmax as a prognostic indicator of response to PRRT

Marta Opalinska[1], Anna Sowa-Staszczak[2], Adrian Kania-Kuc[1], Ibraheem Al Maraih[1], Aleksandra Gilis-Januszewska[2] & Alicja Hubalewska-Dydejczyk[2]
[1]University Hospital in Kraków, Nuclear Medicine Unit, Department of Endocrinology, Oncological Endocrinology and Nuclear Medicine, Krakow, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland

Background
PRRT is an effective treatment option (especially for controlling disease progression)for disseminated neuroendocrine tumors (NETs), with good expression of the somatostatin receptors. Despite significant progress in NET personalized management, searching for novel predictive and prognostic factors of response to PRRT is crucial for more effective follow-up, better treatment choices leading to more favorable final outcome. Some recent studies indicate that the response to PRRT assessed on the basis of imaging of somatostatin receptors may be a potentially useful tool for prediction of overall PRRT effect.
Methods
10 patients with disseminated NET lesions who underwent [68Ga]Ga-DOTA-TATE-PET/CTs before and after PRRT were eligible to the analysis. 5 patients received 177Lu-DOTA-TATE whereas 5 tandem (mix 1:1 of 177Lu- and 90Y-DOTA-TATE)therapy. PET/CTs examinations were performed on average 3.2 months before and 4.6 months after treatment. For all measurable metastatic lesions in both PET/CTs(before and after PRRT) the corrected SUVmax was calculated as the ratio of SUVmax of lesion to SUVmax of normal liver tissue. The next step was to evaluate the change of corrected SUVmax between PET/CTs done before and after PRRT, compared to the first PET/CT. Finally, those results were complied with the result of PRRT assessed after mean follow-up time 20.3 months as: 1. Partial response (PR) 2. Stabilization(SD) 3. Progression(PD) of the disease.
Aim
Assessment if corrected SUVs change in 68Ga-somatostatin analogue PET/CT in response to PRRT may have a predictive value in patients with NET and if it differ in between PRRT with 177Lu-DOTA-TATE alone or tandem therapy.
Results
During follow-up the PR was confirmed in 1 patient, 4 had stabilization and 5 progression of the disease. Among the whole group of lesions there was a mean 27.3% reduction in corrected SUVmax in comparison between PET/CTs done before and after PRRT, and 27.4% and 27.2% reduction in Lu-177 group and tandem group, respectively. The decrease of lesion's corrected SUVmax for patient with PR was 56.4%for tandem therapy, in none of patients treated with 177Lu-DOTA-TATE regression was observed. In the SD group the average decrease od SUVmax was 42.9%for Lu-177 and 8.7%for a tandem PRRT. In patients with PD the increase in corrected SUVmax was observed, 3.6%for Lu-177 and 14.6%for tandem therapy.

Conclsion
A decrease of the mean value of corrected SUVmax in metastatic NET lesions after PRRT may have a predictive value in estimation of progression risk. There were no statistically significant differences in SUVmax changes between 177Lu-DOTA-TATE and tandem therapy.

Metastatic pheochromocythoma and paragangliomas: clinical and follow-up characteristics in a reference unit

Giselle Giron[1], Maria Isabel Del Olmo Garcia[1], Angel Segura[1], Stephan Prado[1], Pilar Bello[1], Rosana Palasi[1], Jose Luis Ponce[1], Susana Lopez Agullo[1], Lidia Gómez-Elegido Tenés[2] & Juan Francisco Merino Torres[1,2]
[1]La Fe University and Polytechnic Hospital, València, Spain; [2]University of Valencia, València, Spain

Introduction
Pheochromocytomas(PCC) and paragangliomas(PGGLs) are rare neuroendocrine tumors. Management is very complex, this is why physicians involved in the management of these patients need to take into account not only clinical aspects but also genetics of these tumors. We present a group of patients diagnosed of metastatic PGG or PCC, their characteristics and long term follow-up.
Methods and design
Descriptive and unicentric study that includes 23 patients diagnosed with metastatic PCC/PGGLs, assessed at *Hospital Universitari i Politècnic La Fe* in Valencia, Spain between 2011 and 2022. Demographic, surgical, anatomopathological, clinical, imaging tests and treatments variables are included. Results are expressed as mean and standard deviation (SD) in the case of quantitative variables or percentage in the case of qualitative variables (SPSS 25.0).
Results
55% of the patients were women. Mean age at diagnosis of the primary tumor was 39 years, and at diagnosis of the first metastasis was 45 years (SD 19). 86% where carriers of a mutation, 54.5% germinal mutation: SDHB 66.7%, SDHD 16.7%, AF2 8.3%, SDHA 8.3%. The 28% remaining had somatic line mutations: CSDE1 29%, NF1, EPAS1, FH, HRAS and VHL in 14.3% each. All of the cases underwent surgery. On the pathological study of the primary tumor all of the patients had at least one value of bad prognosis, with high risk of malignization potential in 8 cases (PASS and GAP scores more than 3 points). For follow up and treatment decision we utilized different imaging techniques: 68GalioPET-CT (100%) with positive uptake in 72.2% of cases, 123-MIBG (77.3%), 18FDG PET-CT (86.4%). The mean of treatment lines used in each patient was 2.7. Regarding systemic treatment: Somatostatin analogues were the most used (72.7%), followed by QT CVD (45.5%), Lu-DOTA-TATE (30%), MIBG (22%). Treatment with Lu-DOTA-TATE manages to stabilize the disease in more than 50% of cases (57.1%) with an average PFS of 21 months, with a partial response on hormonal secretion (PR) in more than 50%. Chemotherapy with CVD: 50% have a PR, 10% a CR in 10% of cases continues an ED. 50% of the metastatic PCC/PGGs treated with CVD were carriers of the SDHB mutation.
Conclsion
- Germline and somatic genetic studies are essential to guide the management of these patients.
- Treatment with Lu-DOTA-TATE seems effective in patients with positive uptake in Ga68-PET-CT with considerable PFS.
- Patients should be assessed within a multidisciplinary committee and framed in Reference Units, given their therapeutic complexity.

Role of beta arrestins and G proteins in mediating DRD2 signaling in pituitary tumors

Emanuela Esposito[1], Federica Mangili[1], Genesio Di Muro[1], Anna Maria Barbieri[1], Donatella Treppiedi[1], federico arlati[1], Rosa Catalano[1], Giusy Marra[1], emma nozza[1], Maura Arosio[1,2], Giovanna Mantovani[1,2] & Erika Peverelli[1]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy

Dopamine receptor type 2 (DRD2) agonists (DA) are the first-choice treatment for prolactin (PRL)-secreting pituitary tumors, but poorly effective in non-functioning (NF)-PitNETs. Along with G protein-dependent signaling, DRD2 also mediates non-canonical beta-arrestin-dependent pathways, where reduction of AKT phosphorylation plays a leading role for the antiproliferative effect of DRD2 in pituitary tumors. Through UNC9994 and MLS1547, a beta-arrestin 2-biased and a G protein-biased agonist, respectively, the present study aimed to clarify the role of G proteins and beta-arrestin 2 in mediating DRD2 signaling in rat tumoral lactotroph cells MMQ and in human primary cultured NF-PitNET cells. In MMQ cells, treatment with UNC9994 reduced cell proliferation (-41.4 ± 20% at 100 nM, $P<0.01$ *vs* bas) with a greater efficacy compared to cabergoline (-22.2 at 100 nM ± 10.9%, $P<0.01$ *vs* bas), while MLS1547 treatment resulted into a slight lowering of cell proliferation (-10.8 ± 7.4% at 100 nM, $P<0.05$ *vs* bas). Accordingly, UNC9994 was more efficient in reducing AKT phosphorylation (-45.5 ± 16%, $P<0.01$ *vs* bas) than cabergoline, whereas an increased AKT phosphorylation was detected after MLS1547 treatment. Consistently, cabergoline and UNC9994 treatments determined a significant reduction of cyclin D3 (-14.7 ± 5.8%, $P<0.01$ *vs* bas and -18.8 ± 9%, $P<0.05$ *vs* bas, respectively), together with an upregulation of p27/Kip1 (+35 ± 20%, $P<0.05$ *vs* bas and +41.6 ± 20.5%, $P<0.05$ *vs* bas, respectively). Beta-arrestin 2 silencing reverted either UNC9994 and cabergoline anti-proliferative effects, as well as their effects on AKT phosphorylation. Pretreatment with pertussis toxin (PTX) maintained the antiproliferative effects of cabergoline (-16.6 ± 3.6%, $P<0.001$ *vs* bas) and UNC9994 (-31 ± 1.9%, $P<0.001$ *vs* bas), while it abolished the ability of MLS1547 in reducing cell proliferation. After 6 h treatment with MLS1547, cell migration showed a considerable reduction (-44 ± 10% at 1μM, $P<0.001$ *vs* bas), to a greater extent than cells treated with UNC9994 (-31 ± 19% at 1μM, $P<0.01$ *vs* bas). 5 out of 8 human primary cultured NF-PitNET cells *in vitro* responsive to cabergoline antiproliferative effects (-31 ± 9.4%, $P<0.001$ *vs* bas) showed a significant reduction of cell proliferation after UNC9994 and MLS1457 treatments (-27.4 ± 7.5%, $P<0.001$ *vs* bas, and -21.7 ± 9.3%, $P<0.01$ *vs* bas, respectively). On the other hand, 3 out of 8 NF-PitNETs that did not respond to cabergoline appeared to be unresponsive also to UNC9994 and MLS1547. In conclusion, our data demonstrated a relevant role for the beta-arrestin 2-dependent pathway in regulating DRD2 inhibitory effects on tumoral growth, whereas the canonical G protein-mediated signaling seemed to be key in controlling cell migration.

Martino, University of Messina, Endocrine Unit, Department of Human Pathology of Adulthood and Childhood G. Barresi, Messina, Italy; [8]General Hospital, Montebelluna, Department of Internal

Medicine, Treviso, Italy; [9]University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Ferrara, Italy

Introduction
First-generation SRL (fg-SRL) represent the treatment of choice in acromegaly patients with post-neurosurgical adenomatous remnant and GH-hypersecretion. Anyway, approximately 60% of patients do not achieve adequate disease control. The main predictors of resistance include male sex, young age, invasiveness of the lesion and its hyperintensity on T2-weighted MRI scans; but also, SSTR2 expression, the cytokeratin pattern, Ki-67 and the presence of AIP gene mutation.
Aim
To identify the most relevant predictors of fg-SRL resistance among the most used clinical and histological parameters, specific to the Italian acromegaly population.
Methods
The MISS was an Italian multicenter, retrospective, case-control study, involving the Centers of Turin, Rome, Milan, Messina, Treviso and Ferrara (study duration 5/2018-12/2020). Non-response was defined after six months of full-dose fg-SRL treatment by the presence of both uncontrolled age-adjusted IGF-I, random GH levels and a tumor shrinkage $<20\%$. Controls were collected in a ratio of 1 to 2 compared to resistant cases.
Results
Ninety-six patients were enrolled (63 resistant cases and 33 controls). Age at diagnosis was associated with the condition of fg-SRL resistance, even when corrected for IGF-I values (coefficient -0.04, OR 0.96, AUC 0.62, $P=0.035$). An iso/hyperintense signal in T2-weighted MRI scans resulted the strongest radiological predictor (coefficient 1.19, OR 3.3, AUC 0.64, $P=0.027$), even if corrected for the maximal tumor diameter at diagnosis. Both a low grade SSTR2 expression and a sparsely granulated (SG)/intermediate cytokeratin pattern proved to be predictors of the resistant condition (coefficient 1.52, OR 4.58, AUC 0.7, $P=0.013$; coefficient 0.97, OR 2.65, $P=0.047$, respectively); the latter resulting also to be superior to the T2-wheighted intensity on MRI (coefficient 1.71, OR 5.56, AUC 0.76, $P=0.003$). Among those patients undergone neurosurgery without any neoadjuvant treatment, the absence of an appreciable tumor remnant led to a negligible probability of non-response to medical treatment, even considering random GH at three months after surgery for the inclusion in the model (coefficient -3.09, OR 0.04, AUC 0.82, $P=0.003$).
Conclusions
A T2-iso/hyperintense MRI pattern was associated with a 3.3-fold greater probability of resistance to fg-SRL. Moreover, both a SG/intermediate granulation pattern and a low grade SSTR2 expression led to a 5 times greater probability of being resistant. Finally, the absence of an appreciable post-surgical remnant suggested a better response to fg-SRL. These factors deserve to be evaluated before setting up medical treatment with fg-SRL. Future guidelines should take this emerging evidence into account when making recommendations on therapeutic choice.

The cut-off limits of GH response to GHRH + arginine test related to body mass index for the diagnosis of adult GH deficiency: do we need to review our diagnostic criteria?

Daniela Cuboni, Emanuele Varaldo, Fabio Bioletto, Alessandro Maria Berton, Chiara Bona, Nunzia Prencipe, Ezio Ghigo, Mauro Maccario, Silvia Grottoli & Valentina Gasco
University of Turin, Department of Medical Science, Division of Endocrinology, Diabetes and Metabolism, Turin, Italy

Introduction
The diagnosis of GH deficiency (GHD) in adults is based on a reduced GH response to provocative tests. The proportion of patients with low GH response to provocative tests increases with the number of other pituitary hormone deficiencies and several studies involving panhypopituitary patients have shown that under certain circumstances GH stimulation tests may be unnecessary to diagnose GHD.
Objective
Aim of this study was to re-evaluate the diagnostic cut-offs of GH response to GHRH + arginine (ARG) test in function of BMI. To this aim the patients' pituitary function was considered as the gold standard for the diagnosis or exclusion of GHD; in particular GHD was defined by the presence of at least 3 others pituitary deficits, while a preserved somatotropic function was defined by the lack of others pituitary deficits.
Methods
The GH responses to GHRH + ARG were studied in 349 patients with history of hypothalamic-pituitary disease [age (mean ± SD): 43.8 ± 16.5 years; BMI: 27.4 ± 9.2 kg/m^2]. Patients were divided into lean (143), overweight (107) and obese (99) subjects according to BMI. The best GH cut-off to GHRH + ARG, defined as the one with the best sensitivity (SE) and specificity (SP), was identified using the receiver-operating characteristic curve (ROC) analysis.
Results
The best GH cut-off to GHRH + ARG was 5.5 μg/l in lean subjects (SE 89.2%, SP 79.7%), 4.2 μg/l in overweight subjects (SE 94.0%, SP 62.5%) and 2.8 μg/l in obese subjects (SE 85.7%, SP 83.3%). The diagnostic accuracy was 85.3, 82.2 and 84.8% respectively.
Conclusions
To our knowledge this is the first study that evaluate the diagnostic cut-offs of GH response to GHRH + ARG in function of BMI using a clinical definition of GHD as gold standard. Our results suggest that with this new approach, the GHRH + ARG cut-offs should be revised.

SARS-CoV-2 infection in acromegaly patients: case series

Stefana Bilha, Anca Matei, Andra Cristiana Istrate, Letitia Leustean, Maria Christina Ungureanu, Dumitru D. Branisteanu & Cristina Preda
"Grigore T. Popa" University of Medicine and Pharmacy Iasi, Endocrinology, Iasi, Romania

Introduction
SARS-Cov-2 infection challenged the appropriate management of acromegaly, because of delayed or limited admissions and treatment. Despite lack of data regarding SARS-Cov-2 infection in acromegalic patients (only one case reported to date), increased susceptibility to infection and poor prognosis might be triggered by the associated metabolic, cardiovascular and respiratory comorbidities. We report a series of acromegaly patients with a positive PCR test at their admission in our Endocrinology Department and their COVID-19 disease evolution.
Methods
All inpatient admissions in our unit undergo RT-PCT testing for SARS-CoV-2 infection from the debut of the pandemic according to the local protocol. Inpatient admisssions for acromegaly diagnosis and monitoring during the first 4 waves of the COVID-19 pandemic (March 1st 2020 to November 30th 2021 – 21 months) were reviewed and compared to the acromegaly inpatient admissions during the same period of time before the pandemic (June 1st 2018 to February 29th 2020).
Results
The number of inhospital admission for acromegaly dropped by aproximately 50% during the first 4 waves of the pandemic compared to the same length of time prior to the pandemic (155 vs 359 inpatient admissions for acromegaly). Among the 86 patients admitted for acromegaly diagnosis or monitoring during the pandemic (approximately 2 admission per patient), 4 patients (aged between 39 and 61 years(y) old) had a positive RT-PCR test for SARS-CoV-2 infection. All were overweight or obese (BMI range 28-34 kg/m^2) and 3 out of 4 had ongoing active disease and were under lanreotide treatament (IGF1 serum concentrations: 180 to 334 ng/ml (<2 ULN); basal GH: 1.59 to 3.19 ng/ml); SAGIT overall score between 2 and 8. Two out of 4 patients had a mild case of COVID-19 (First: 61 y old, active disease, heart failure, severe sleep apnea, restrictive respiratory dysfunction, vaccinated against SARS-CoV-2; second: 39 y old, active disease, type 2 diabetes mellitus, unvaccinated), while the other 2 were completely asymptomatic (Third: 46 y old, active disease, unvaccinated; Fourth: 61 y old, biochemical control, unvaccinated). Patients were managed according to local protocol for SARS-CoV-2 infection.
Conclusions
Although SARS-CoV-2 infection occurs is thought to have a worse prognosis in acromegaly patients due to the coexistence of cardiometabolic complications and

impaired respiratory function, all patients in our series developed only mild or asymptomatic COVID-19 cases, despite being rather obese and having biochemically active disease with one exception.

Familial neurohypophyseal diabetes insipidus: an extremely rare report of a family with a nonsense mutation in the arginine vasopressin gene

Diogo Ramalho[1], Joana Serra-Caetano[2], Rita Cardoso[2], Patrícia Rosinha[3], Bárbara Filipa Araújo[4], Inês Rua[5], Orlando Rodrigues[6], Isabel Dinis[2] & Alice Mirante[2]
[1]Centro Hospitalar de Vila Nova de Gaia/Espinho, Endocrinology, Vila Nova de Gaia, Portugal; [2]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Pediatric Endocrinology, Coimbra, Portugal; [3]Centro Hospitalar do Baixo Vouga, Endocrinology, Aveiro, Portugal; [4]Centro Hospitalar e Universitário de Coimbra, Endocrinology, Coimbra, Portugal; [5]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Pediatrics, Coimbra, Portugal; [6]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Medical Genetics, Coimbra, Portugal

Introduction
Familial neurohypophyseal diabetes insipidus (FNDI) is a rare form of central diabetes insipidus (CDI) characterized by childhood-onset progressive polydipsia and polyuria due to mutations in the *arginine vasopressin-neurophysin II* (*AVP-NPII*) gene.
Case description
Two male siblings were referred at 1 month of age to exclude CDI owing to a family history of CDI in the father and paternal grandfather. The proband was the father diagnosed at 3 months old. The grandparent was diagnosed later, in his early twenties, when diuresis was about 15 L daily. His symptoms had apparently not been recognised since childhood. At 6 months of age, the older sibling (1) drank 500 ml of water/night and 1.5 L of water/daily and the younger sibling (2), at 11 months old, drank 800 ml of water/night and had 2 diaper changes/night, in a total of 2500 ml water intake and 8 diaper changes/day. No growth deceleration was observed in both. Physical examination and past medical history were unremarkable. Random urine specific gravity was lower than 1.005. Glycemia, thyroid function, serum osmolality, 8 am. cortisol, creatinine, sodium, potassium and calcium were within normal range. The sibling 1 was admitted for elective water deprivation test that confirmed CDI (basal serum and urinary osmolality: 278 mOsm/Kg and 292 mOsm/kg; serum and urinary osmolality at the end: 289 mOsm/kg and 281 mOsm/kg; urinary osmolality after 10 mg of desmopressin [DDAVP]: urinary osmolality of 574 mOsm/kg [increased by 102%]). He promptly initiated DDAVP (0.025 mg, twice daily) with clinical improvement. Pituitary magnetic resonance imaging confirmed a small and hypointense neurohypophysis. CDI was presumptively assumed in the sibling 2, and symptoms improved under DDAVP (0.025 mg, twice daily). Sequencing analysis of the *AVP-NPII* gene revealed the same mutation in the four family members, a heterozygous nonsense mutation in the NPII coding region (c.343G>T, p.Glu115Ter) of the *AVP-NPII* gene. Currently, the four patients are asymptomatic under DDAVP.
Discussion and conclusions
To our knowledge, there is only another family with this autosomal dominant mutation described worldwide. Genetic counselling should be offered to ensure an early and adequate diagnosis and treatment. It should also provide the family with accurate information on preimplantation genetic testing (PGT) in order to obtain genetically healthy descendants. In Portugal, FNDI requires prior authorization from the "National Council for Medically Assisted Procreation" for couples who intend to perform a PGT cycle.

Introduction
The European Registries for Rare Endocrine Conditions (EuRRECa) was created in collaboration with the European Reference Network on Rare Endocrine Conditions (Endo-ERN), the European Society for Paediatric Endocrinology and the European Society of Endocrinology to support the needs of the endocrine community. The Core Registry, one of its platforms, enables the collection of longitudinal patient and clinician reported outcomes. A module collecting aspects of the care and outcomes of the patients with pituitary tumours has been active since November 2021.
Aim
To describe the population registered in the EuRRECa Core Registry between June 2019 and December 2021 in the Hypothalamic and Pituitary group of conditions.
Methods
Core Registry clinical contributors are invited to register new and existing cases of endocrine conditions seen in their centres. Diseases are mapped according to the Orphanet nomenclature. A core data set and a condition-specific data set collect information regarding demographics, diagnosis and outcomes.
Results
A total of 159 cases have been registered by 5 centres from 4 countries. Of 159 cases, 5(3%) were between 0-9 years of age, 6(4%) between 10-17 years and 148 (93%) over 18 years. In the latter, the commonly reported conditions include pituitary adenoma 91/148 (62%) and acquired hypopituitarism 45/148 (30%) followed by suprasellar tumours 6/148 (4%) and other sellar and parasellar tumours 3/148 (2%). Of 91, 38(41%) were non-functioning pituitary adenoma, 20 were prolactinoma (22%), 16 (18%) were unspecified functioning pituitary adenoma, 12(13%) were unspecified pituitary adenoma, 3 (3%) were somatomammotropinomas and 2 (2%) were corticotroph adenomas. Diagnosis was reported by the combination of clinical assessment, biochemistry and MRI in 84/159 cases (53%), histology was added in 10 cases (6%) and genetic testing in 3(2%). Of 159 cases, 154(97%) were under active follow-up. Participation in a different detailed disease registry was reported in 15/159 cases. Biobank samples were available in 12/159 (8%). Twenty-one patients (13%) had expressed an interest in using the patient platform, 16(76%) had been sent an invitation to join and of these, 4(25%) activated their account. Of 159, 67 cases have been entered into the pituitary tumour module.
Conclusion
Pituitary adenoma is the most reported condition in the Hypothalamic and Pituitary group with most patients being over 18 years. These results support the creation of a pituitary adenoma detailed module which provides clinicians the opportunity of sharing aspects of the condition and care of their patients with health care professionals and the research community.

Prevalence, type and evolution of autoimmune diseases with respect to hormone control in patients with cortisol, GH and prolactin hypersecretion

Federica Guaraldi[1], Matteo Zoli[1,2], Emanuela Arvat[3], Martina De Martin[4], Francesca Pecori Giraldi[4], Scaroni Carla[5], Davide Gori[2], Roberta GIORDANO[3], Silvia Grottoli[3], Ezio Ghigo[3], Sofia Asioli[2] & Diego Mazzatenta[1,2]
[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Pituitary Unit, Bologna, Italy; [2]Alma Mater Studiorum - Bologna University, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy; [3]University of Turin, Department of Medical Sciences, Turin, Italy; [4]Istituto Auxologico Italiano, Department of Clinical Sciences and Community Health, Milan, Italy; [5]Azienda Ospedaliero Universitaria of Padua, Department of Medicine DIMED, Padua, Italy

Background
In vitro and animal experiments have clearly demonstrated that excessive cortisol, GH and prolactin secretion, as well as dopamine agonists (D2As) and somatostatin analogs (SSAs), often prescribed for their treatment, affect the immune response and the onset/evolution of autoimmune diseases (AIDs) through direct and indirect complex mechanisms. Data from clinical studies are very scanty.
Study aim
To assess the 1) distribution of AIDs according to patient age and gender, adenoma and AID type; and 2) evolution of AID(s) with respect to hormonal activity and eventual DA/SSA treatment, in patients with Cushing's disease (CD), acromegaly and prolactinoma with respect to patients with non-functioning adenoma (NFPA; controls).
Patients and methods
Clinical data of interest were collected retrospectively and prospectively from patient records and a purposely designed questionnaire.
Results
715 patients. 144 with CD (118 F; previous treatment:144 endoscopic surgery (ES), 12 radiation therapy (RT), 18 adrenalectomy, 42 medical therapy (MT); 120 under remission, 24 active disease under treatment); 124 with acromegaly (75 F; previous treatment: 100 ES, 25 RT, 60 medical therapy; 81 remission, 43 active disease under treatment); 260 with prolactinoma (162 F; previous treatment: 29 ES, 4 RT, 251 medical therapy; 177 remission, 83 active disease under treatment) and 187 NFPA (101 F; previous treatment: 170 ES and 17 RT). Age at evaluation was similar among groups. Patients with AID were 39 (27.1%) in CD, 23 (18.5%) in acromegaly, 52 (21%) in prolactinoma, and 17 (9%) in NFPA group. CD was associated with the highest risk of developing AIDs ($\chi2=8.42$, $P<0.0001$); prevalence in acromegaly and prolactinoma was similar and higher than in NFPAs ($P<0.0001$). In all groups, females were typically affected ($P=0.001$). AID type, gender and age distribution were similar to the general population. Almost all patients presented a single AID. Hashimoto's thyroiditis was the most common ($P<0.001$), followed by psoriasis and rheumatoid arthritis. AIDs diagnosed before CD ($n=24$) typically improved during overt hypercortisolism and recurred after CD remission, except for Hashimoto's thyroiditis (independent evolution). New onset/recrudescence of AIDs ($n=13$) occurred from some weeks to some years after CD remission (median 1 year). AIDs similarly occurred before and after prolactinoma diagnosis; in acromegaly they mainly occurred during active disease ($P>0.01$); for both groups AID evolution was independent from hormone control and SSA/D2A treatment.
Conclusions
Patients with pituitary adenomas, especially females with CD, deserve careful and repeated evaluation of AIP during follow-up, independently from adenoma size and treatment.

Central pontine myelinolysis: Case report

Paloma González Lázaro[1], Cristina Contreras Pascual[2], Cristina Montalban Méndez[1], Antonio Moreno Tirado[1], Maria Zhao Montero Benítez[1] & Pedro Jimenez Torrecilla[1]
[1]Hospital General La Mancha Centro, Alcázar de San Juan, Spain; [2]Hospital Santa Barbara, Soria, Spain

Introduction
Central pontine myelinolysis (CPM) is a rare and potentially life-threatening complication of a sudden rise in serum osmolality. Along with extrapontine myelinolysis, it is part of the osmotic demyelination syndrome (ODS). Known risk factors include severe hyponatremia, alcoholism, thiazide use, hypokalemia, and malnourishment.
Case report
We report the case of a 31-year-old-male with history of alcohol and cannabis dependence, who had attended a private clinic two weeks earlier for gastric balloon placement, he was admitted to the emergency-department reporting nausea and vomiting with oral intolerance, nervousness, and agitation. He was initially detected to have hypo-osmolar hyponatremia (osmolality: 261 mmol/l, sodium: 114 mmol/l), and hypokalemia. His urine analysis revealed a urine osmolality of 279 mmol/l with a sodium level of 13 mmol/l supposedly because of hypovolemia due to inadequate fluid intake. The patient received intravenous potassium and was to be given 2000 ml of NaCl 0.9% in the first 24 h; Also, thiamine was prophylactically started to prevent Wernicke encephalopathy. Approximately 16 h after admission, the sodium levels increased to 123 mmol/l. The patient received glucose 5% infusion when sodium levels increased to 125 mmol/l within the first 24 h. In the following week the sodium levels normalized with a daily increase of 1-3 mmol/l. The potassium levels normalized quickly as well. During this period, the patient developed ataxia and resting tremors. Vitamin doses were switched to therapeutic because Wernicke encephalopathy was suspected. In the following days the patient's neurological status deteriorated leading to a 'locked in' state when he was only able to open and move his eyes. An MRI of the brain showed a hyperintense signal in the central pontine region. Following the diagnosis of CPM, he was rehabilitated with occupational and physiotherapy.
Discussion
Our case, a patient with history of alcohol and cannabis dependence syndrome, complicated by central pontine myelinolysis probably due to an overly rapid correction of plasma osmolality. Given the fact that our patient had multiple risk factors and severe hyponatremia (<120 mmol/l) he would have benefited from a more intensively controlled rise in serum sodium levels or more aggressive lowering of sodium levels when overcorrection became apparent.
Conclusion
CPM is a rare complication of a rapid correction of serum osmolality, and we should always be aware of this complication. In patients with multiple risk factors, CPM might be prevented by frequent control of electrolytes and osmolality in combination with volume status and urinary output.

GH/IGF-I impact hepatic lipid accumulation in non-acromegalic individuals with and without non-alcoholic fatty liver disease

Paul Fellinger[1], Hannes Beiglboeck[1], Lorenz Pfleger[1], Sabina Smajis[1], Martin Gajdosik[1], Rodrig Marculescu[2], Greisa Vila[1], Yvonne Winhofer[1], Alexandra Kautzky-Willer[3], Michael Krebs[1], Martin Krssak[1] & Peter Wolf[1]
[1]Division of Endocrinology and Metabolism, Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Wien, Austria; [3]Medical University of Vienna, Department of Medicine III, Division of Endocrinology & Metabolism, Vienna, Austria

Background
Growth hormone (GH) plays an important role in modifying body composition. In acromegaly, a state of chronic GH/IGF-I excess, visceral and ectopic fat mass, especially in the liver, are significantly reduced. The aim of this study was to investigate the impact of GH/IGF-I on hepatocellular lipid content (HCL) and energy metabolism in a non-acromegalic cohort of patients with and without non-alcoholic fatty liver disease (NAFLD).
Methods
We performed a cross-sectional study in 76 non-acromegalic individuals (36 females). Concentrations of glucose, insulin, c-peptide and GH were measured every 30 minutes during a standardized 2-h-75g oral glucose tolerance test (OGTT). Insulin sensitivity was estimated by the oral glucose insulin sensitivity index (OGIS). IGF-I was measured prior to the OGTT and was given as the percentage of the sex-, age-, and assay specific upper limit of normal (IGF-I ULN). Liver parameters, like HCL and ATP synthesis rate (*k*ATP), as well as high energy phosphorous metabolites were analysed using 1H- as well as 31P-magnetic resonance spectroscopy (MRS) at 7 Tesla. NAFLD was defined as HCL $>5.5\%$.
Results
In the whole cohort (age: 43.4+-15.3y; BMI: 25.7+-4.3 kg/m^2; IGFI-ULN: 65.7+-17.2% [IQR 33.6-102.6%]) the median HCL was 2.79% [IQR 1.35-9.5%] with 27 patients presenting with a HCL higher than 5.5% indicating NAFLD. Fasting GH (0.21 [0.1; 0.6] ng/ml vs 0.67 [0.2; 2.5] ng/ml;$P=0.0055$), as well as dynamic GH levels during OGTT (AUC_{GH}: 15.30 [7.2; 25.6] ng/ml/min vs 48.8 [25.7; 143.2] ng/ml/min;$P=0.0002$). IGF1-ULN correlated significantly with

high-energy phosphorous metabolites but did not correlate with *k*ATP in the whole cohort. In the multiple logistic regression analysis IGF1-ULN as well as fasting glucose were next to BMI and OGIS a significant, independent predictor for NAFLD.

Conclsion

In summary, here we show that increased HCL is associated with lower fasting and post-glucose-load GH concentrations in otherwise healthy individuals with or without NAFLD, while both GH and IGF-I independently relate to the presence of NAFLD. The relationship between GH/IGF-I metabolism and HCL could be further investigated as a potential therapeutical target in patients with NAFLD.

Change in androgens and adrenal hormones during long-term osilodrostat treatment in patients with Cushing's disease: Results from the Phase III, prospective LINC 3 study

Rosario Pivonello[1], Beverly M.K. Biller[2], Shimatsu Akira[3], John Newell-Price[4], Antoine Tabarin[5], Greisa Vila[6], Andrea Piacentini[7], Alberto Pedroncelli[8] & Maria Fleseriu[9]

[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Massachusetts General Hospital, Neuroendocrine and Pituitary Tumor Clinical Center, Boston, MA, United States; [3]Omi Medical Center, Kusatsu, Japan; [4]The Medical School, University of Sheffield, Department of Oncology and Metabolism, Sheffield, United Kingdom; [5]CHU de Bordeaux, Bordeaux, France; [6]Medical University of Vienna, Division of Endocrinology and Metabolism, Department of Internal Medicine III, Vienna, Austria; [7]Recordati SpA, Milan, Italy; [8]Recordati AG, Basel, Switzerland; [9]Oregon Health & Science University, Pituitary Center, Departments of Medicine and Neurological Surgery, Portland, OR, United States

Introduction

Osilodrostat decreases cortisol production by inhibiting 11β-hydroxylase, increasing adrenal hormones above the blockade. Here, we describe these effects of osilodrostat and associated adverse events (AEs). The efficacy and safety of osilodrostat in patients with Cushing's disease (CD) were confirmed in the published Phase III, prospective LINC 3 study (NCT02180217).

Methods

137 patients with CD (mUFC >1.5x upper limit of normal) were enrolled in a 48-week (W) core phase including an 8W double-blind, randomised-withdrawal period for eligible patients. 106/113 patients who completed W48 entered an optional extension, ending when all ongoing patients completed $\geq$72W of treatment or discontinued. Testosterone, 11-deoxycortisol, 11-deoxycorticosterone and aldosterone were assessed centrally at baseline and regular intervals by liquid chromatography-tandem mass spectrometry, and dehydroepiandrosterone sulfate (DHEAS) by chemiluminescence immunoassay. Hirsutism (females; rated on a semi-quantitative scale: 0=absent; 1=mild; 2=moderate; 3=severe), blood pressure, oedema and serum potassium were assessed regularly.

Results

Median osilodrostat exposure was 130W (range 1–245); median osilodrostat dose was 7.4 mg/day (range 0.8–46.6). Following an increase during the core phase, mean testosterone levels stabilised in males and decreased towards baseline levels in females during long-term treatment. Of females with baseline, W48 (n=76) and W72 (n=64) assessments, hirsutism score improved from baseline in 26 and 22 patients at W48 and W72, respectively, and remained unchanged in 37 and 33 patients. Mean (SD) DHEAS levels decreased during the core phase to within the normal range, then stabilised during the extension (W48 and W72; females: 1.6 [1.6] and 1.0 [0.9] μmol/l; males: 3.4 [3.3] and 3.0 [3.1] μmol/l). Aldosterone levels also decreased and then stabilised during long-term treatment. Overall, mean potassium levels remained stable throughout the study. AEs related to accumulation of adrenal hormone precursors were reported in 58.4% (n=80/137) of patients, regardless of study drug relationship, and managed with additional therapy in 36.5% (n=50/137) of patients. The most common AEs were hypertension (n=24), peripheral oedema (n=22) and hypokalaemia (n=18), managed with concomitant medication in 17, 6 and 4 patients, respectively. They mostly occurred during the first 26W of treatment (females: 35.5%; males: 49.1%) at different osilodrostat doses (1–60 mg), with no discernable dose-related effect. Few patients discontinued treatment because of these AEs (1.5%; n=2/137).

Conclusions

Adrenal hormone levels frequently change when initiating osilodrostat but stabilise during long-term treatment. AEs associated with these changes are manageable without osilodrostat discontinuation; they should be closely monitored and treatment initiated as needed to achieve optimal patient outcomes.

Impact of urinary and late-night salivary cortisol levels on clinical signs of hypercortisolism and quality of life in patients with Cushing's disease treated with osilodrostat

John Newell-Price[1], Maria Fleseriu[2], Rosario Pivonello[3], Richard Feelders[4], Andre Lacroix[5], Richard Auchus[6], Andrea Piacentini[7], Alberto Pedroncelli[8] & Beverly M.K. Biller[9]

[1]The Medical School, University of Sheffield, Department of Oncology and Metabolism, Sheffield, United Kingdom; [2]Oregon Health & Science University, Pituitary Center, Departments of Medicine and Neurological Surgery, Portland, OR, United States; [3]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [4]Erasmus Medical Center, Department of Internal Medicine, Endocrine Section, Rotterdam, Netherlands; [5]Centre hospitalier de l'Université de Montréal, Montreal, Canada; [6]University of Michigan, Ann Arbor, Division of Metabolism, Endocrinology and Diabetes, Departments of Internal Medicine and Pharmacology, Ann Arbor, MI, United States; [7]Recordati SpA, Milan, Italy; [8]Recordati AG, Basel, Switzerland; [9]Massachusetts General Hospital, Neuroendocrine and Pituitary Tumor Clinical Center, Boston, MA, United States

Background

24-h mean urinary free cortisol (mUFC) and late-night salivary cortisol (LNSC) levels are complementary parameters recommended for screening and monitoring treatment response in patients with Cushing's disease (CD). In the published core period of the Phase III LINC 3 study (NCT02180217), therapy with osilodrostat (potent oral 11β-hydroxylase inhibitor) produced rapid, sustained reductions in mUFC and LNSC alongside improvements in clinical signs of hypercortisolism in patients with CD. Here, we explored these improvements by mUFC and/or LNSC control.

Methods

The core LINC 3 study enrolled 137 adults with CD and mUFC >1.5xULN who received open-label osilodrostat over 48 weeks (W; starting dose: 2 mg twice daily; maximum: 30 mg twice daily); eligible patients were randomised in an 8W placebo-controlled, withdrawal period (W26–34). mUFC (three-sample average; normal 11||138 nmol/24h) and LNSC (single sample; normal $\leq$2.5 nmol/l) were assessed centrally by liquid chromatography-tandem mass spectrometry. Cardiovascular/metabolic-related parameters, physical features (rating: 0=absent; 1=mild; 2=moderate; 3=severe), and CushingQoL and Beck Depression Inventory II (BDI-II) scores were also evaluated. Data were recorded at baseline and regularly until W48. Analyses are presented for patients with both mUFC and LNSC assessments, defined as: both mUFC+LNSC controlled, only mUFC controlled, only LNSC controlled, and both mUFC+LNSC uncontrolled. Control was defined as $\leq$ULN.

Results

Of evaluable patients at baseline (n=87), 74 (85.1%) had both mUFC+LNSC uncontrolled. At W48, 38 patients (54.3%) had both mUFC+LNSC controlled, 21 (30.0%) had only mUFC controlled, 3 (4.3%) had only LNSC controlled, and 8 (11.4%) had both mUFC+LNSC uncontrolled. Mean improvements from baseline to W48 in cardiovascular/metabolic-related parameters were generally greater in patients with both mUFC+LNSC controlled than patients with only mUFC or LNSC controlled or both mUFC+LNSC uncontrolled, respectively: weight, ||5.9, ||3.3, ||2.2, –3.8 kg; systolic blood pressure, ||14.4, ||8.0, ||7.4, ||3.0 mmHg; diastolic blood pressure, –8.6, ||4.8, ||8.2, ||4.0 mmHg; fasting plasma glucose, ||0.9, ||0.3, ||0.8, ||0.6 mmol/l. CushingQoL/BDI-II scores improved from baseline to W48 irrespective of mUFC and/or LNSC control. Patients with both mUFC+LNSC controlled or only mUFC controlled had the greatest proportion with improved physical manifestations of hypercortisolism (facial rubor, striae, fat pads, bruising, hirsutism [females], muscle atrophy).

Discussion

After 48W of osilodrostat treatment, most evaluable patients had both mUFC+LNSC controlled or only mUFC controlled. Improvements in clinical signs of hypercortisolism and health-related quality of life occurred irrespective of mUFC and/or LNSC control; however, improvements were greater in patients with both mUFC+LNSC controlled for some clinical outcomes.

GLP-1 receptor agonists stimulate growth hormone release

Ingrid Reppo[1], Keiu Heinla[2], Tuuli Sedman[2] & Vallo Volke[1]
[1]Tartu University Hospital, Department of Endocrinology, Tartu, Estonia; [2]University of Tartu, Tartu, Estonia

The secretion of growth hormone (GH) is under the feedback control of numerous nutritional and endocrine factors. The most widely used endocrine dynamic tests used to diagnose GH deficiency, insulin hypoglycemia test, and glucagon test, are time-consuming and cumbersome both for patients and medical personnel. There is an unmet need for easier to conduct, shorter, and safer diagnostic tests. We and other groups have previously demonstrated that acute administration of glucagon-like peptide-1 receptor agonist (GLP-1RA) moderately stimulated the hypothalamic-pituitary-adrenal axis in healthy volunteers. As GLP-1RAs possess multiple metabolic effects, we hypothesized that they may also affect the secretion of GH. We report here the results from 2 clinical trials of GLP-1 RAs on GH secretion. In a pilot single-group, open-label clinical trial the effect of a single subcutaneous injection of 10 μg exenatide was tested on healthy volunteers ($n=10$). Exenatide elicited a robust increase of GH levels compared to pre-treatment values ($P<0.05$) with the peak occurring around 60-90 minutes in most subjects. Oral semaglutide is the first oral GLP-1 RA available. We next conducted a randomized, placebo-controlled, crossover clinical trial to test the effect of oral semaglutide on GH release. The study included 10 adult healthy volunteers (age 26-47, 5 females, and 5 males). All participants were tested on two occasions that were at least 1 month apart and received randomly oral semaglutide (7 mg) or placebo. Participants were asked to avoid strenuous physical activity the day before testing. Basal fasting ($\geq$ 8 h) blood samples were taken in the morning (8-9 am) after at least 15 minutes of rest. Study medication was taken with up to 40 ml of water. Post-treatment blood samples were drawn 60, 90, 120, 150, 180, and 240 minutes thereafter. The intensity of nausea according to the visual analog scale (0- no nausea, 10 – vomiting) was also registered. The primary endpoint of the study was the change in growth hormone concentration. The effect of oral semaglutide on GH was variable but did induce a clinically significant GH increase in some study subjects. We conclude that GLP-1 RAs hold a promise for a GH stimulation test and further studies are warranted.

Endoscopic surgery for acromegaly: results and predictors of outcome from a 22-year experience of a referral Pituitary Centre

Federica Guaraldi[1], Matteo Zoli[1,2], Davide Gori[2], Riccardo Cavicchi[3], Ernesto Pasquini[4], Giacomo Sollini[4], Sofia Asioli[2] & Diego Mazzatenta[1,2]
[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Pituitary Unit, Bologna, Italy; [2]Alma Mater Studiorum - Università di Bologna, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy; [3]Alma Mater Studiorum - Università di Bologna, School of Medicine - Neurosurgery Residency Program, Bologna, Italy; [4]Ospedale Bellaria, ENT Division, Bologna, Italy

Background
Endoscopic surgery (ES) performed in Pituitary Centers of Excellence (PCOE) represents the gold standard treatment for GH-secreting adenomas. However, rate of cure greatly varies according to definition criteria, follow-up duration, various patient and adenoma features, and surgeon ability.
Study aim
To assess short- (3 month) and long-term ($\geq$1 year) outcome and identify predictors of ES, in a large and homogeneous cohort of acromegaly patients.
Subjects and methods
Clinical, radiological, and histological data at enrolment and follow-up of consecutive patients with GH-secreting adenoma, treated by ES at an Italian PCOE, from 1998 to 2020, were retrospectively analyzed.
Results
291 patients (167 females; mean age at surgery 46.2 $\pm$12.4 years) were included. 195 (67%) had a macroadenoma with invasion of surrounding structures (Hardy-Wilson-Knosp classification) in 92.3% of the cases. According to Trouillas grading, 183 (62.9%) were grade 1a, 35 (12%) 1b, 48 (16.5%) 2a, and 25 (8.5%) 2b. 269 patients were treated by ES and 22 by combined ES-craniotomy. 134 were naïve for treatment; 35 had been treated with surgery; 107 with medical therapy and 21 with radiation therapy. Histological examination revealed 250 GH- (150 sparsely and 99 densely granulated) and 41 GH-PRL-secreting adenomas. At 3-month follow-up, 217 (74.6%) patients presented disease remission, 74 (25.4%) had residual adenoma. At last follow-up (mean duration 67.8$\pm$50.4 months; range 12-240.8), 197 patients (67.7%) were cured; 94 (32.3%) had residual adenoma, controlled by medical therapy in 63.8% of the cases. During follow-up, 9 (3%) patients underwent second surgery, 90 (30.9%) received medical therapy and 4 (1.4%) radiation therapy. At last follow-up, 16 (5.4%) suffered from hypopituitarism, 11 (3.7%) from central diabetes insipidus. Surgical complications included cerebrospinal fluid leak ($n=35$; 12%) and epistaxis ($n=2$;0.7%) . According to multivariate regression analysis, GH <1 μg/l at 48h post-surgery and dense granulation were positive predictors; age <30 years, male gender, tumor invasiveness, Trouillas grade 2b and previous surgery were negative predictors ($P<0.0001$) of short- and long-term outcome. The chance of developing invasive highly proliferative adenoma (2b) was inversely related to age ($P<0.02$; OR 6.6 for age <30 vs. >60 years old). Moreover, 2b adenomas increased the risk of complications ($P<0.005$), independently from gender and histological features.
Conclusions
Our study, performed on the largest available cohort of acromegaly patients, supports the indications of ES in PCOE as first and second line treatment, independently from patient and tumor features, for the overall high chance of cure and very low risk profile.

Pituitary adenomas in the elderly may be hiding behind age-related comorbidities

Sandra Pekic Djurdjevic[1,2], Marko Stojanovic[1,2], Emilija Manojlovic Gacic[1,3], Mirjana Doknic[1,2], Dragana Miljic[1,2], Toplica Milojevic[4], Mihailo Milicevic[1,4], Aleksandar Stanimirovic[4], Sandra Banjalic[5], Zvezdana Jemuovic[2], Marija Jovanovic[1,5], Marina Nikolic Djurovic[1,2], Danica Grujicic[1,4], Vera Popovic[1] & Milan Petakov[1,2]
[1]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center, Belgrade, Serbia; [3]Institute of Pathology, Belgrade, Serbia; [4]Clinic for Neurosurgery, University Clinical Center, Belgrade, Serbia; [5]Center for Radiology and Magnetic Resonance Imaging, University Clinical Center, Belgrade, Serbia

Background
Extended life expectancy and increase in neuroimaging availability, lead to increase in incidence of pituitary adenomas (PA) diagnosed after the age of 70. Recognition of PA in the elderly may be challenging and delayed due to symptoms overlapping with aging and comorbidities.
Objective
To investigate character and presenting symptoms of PA in patients diagnosed after the age of 70.
Methods
105 patients (7.9%) with PA diagnosed after the age of 70 (58 males, 55.2%) were identified from the PA database ($n=1332$) of the Department of Neuroendocrinology for the past 17 years. Gender, age at diagnosis, tumor size, presenting signs and symptoms, presence of comorbidities and hyponatremia, functional type of PA and treatment modality were analyzed.
Results
Mean age at diagnosis was 74.5$\pm$0.4 years (range: 70-85). Thirteen patients (12.4%) were older than 80 years at diagnosis. Eighty-three patients (79%) had two or more comorbidities. Nonfunctional PA (NFPA) were significantly more prevalent ($n=85$; 81%) than functional PA ($n=20$; 19%; $P<0.01$). Eleven patients (10.5%) had acromegaly, six (5.7%) had prolactinoma, and three patients had corticotropinoma (2.9%). NFPA patients were older than those with functional PA (75.0$\pm$0.5 vs 72.7$\pm$0.6; $P<0.05$). Macroadenomas ($n=97$; 92.4%) were significantly more prevalent than microadenomas ($n=8$; 7.6%; $P<0.01$). Six patients with microadenoma had acromegaly. PA were significantly larger in males (28.6$\pm$1.8 vs 21.8$\pm$1.8 mm, $P<0.01$). Thirteen patients (12.4%) had gigantic adenomas (>4 cm), nine with NFPA. Prolactinomas (35.6$\pm$3.8 mm) were significantly larger than NFPA (25.8$\pm$1.4 mm) and acromegaly (13.1$\pm$2.9 mm), $P<0.01$. Presenting symptoms included: headache ($n=52$, 49.5%), visual impairment (often misinterpreted as cataract) ($n=46$, 43.8%), and cranial nerve palsies ($n=11$, 10.5%). Twelve patients (11.4%) had hyponatremia due to secondary hypocorticism. Dyslipidemia was diagnosed in 58 patients (55.2%). In 60 (57.1%) PA was detected fortuitously by imaging for reasons unrelated to pituitary disease, during investigation for non-specific neurological symptoms (gait, speech impairment, dizziness, falls, memory impairment, dementia, depression, loss of consciousness, deafness), headache, head trauma, cerebrovascular insults or subarachnoid hemorrhage. Hypopituitarism was confirmed as complete in 45 patients (42.9%), and partial in 15 patients (14.3%). Fifty-two patients (49.5%) underwent transphenoidal surgery, with no

severe complications. Six patients (5.7%) with prolactinomas and six patients (5.7%) with acromegaly were medically treated.
Conclusion
The age-incidence for pituitary tumors shows a typical high risk in the elderly. Nonfunctioning macroadenomas are the most prevalent. Age-related comorbidities led to the late diagnosis of pituitary tumors in most elderly patients which accounted for the pituitary tumor size (macroadenomas in most).

Differences of clinical characteristics and treatment of sporadic and MEN-1 related insulinomas

Marta Opalinska[1], Aleksandra Gilis-Januszewska[2], Karolina Morawiec-Sławek[2], Ewelina Rzepka[2], Anna Bogusławska[2], Anna Sowa Staszczak[2] & Alicja Hubalewska-Dydejczyk[2]
[1]University Hospital in Krakow, Department of Endocrinology, Oncological Endocrinology and Nuclear Medicine, Kraków, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Background
Although in most cases insulinomas are small and benign tumors, in about 4% they are malignant, mainly in course of inherited syndromes like MEN1, tubular sclerosis or neurofibromatosis type 1. While in case of benign tumors surgery is usually curative, the metastatic form brings difficulties in managing due to dissemination and the risk of recurring, life-threating, severe hypoglycemias. To elucidate the clinical differences between sporadic and MEN-1 linked insulinoma we review clinical characteristics and treatment in cohort of patients treated in our centre since implementation of electronic database.
Material
Data was reviewed from patients diagnosed with insulinoma managed at our centre from 2015 to 2021 year.
Results
There were 19 cases of insulinomas (9 women and 10 men). In 6 (32%) cases the mutation in menin gene were confirmed. The median age at diagnosis in the whole group was 58 years, (range 16-87 years) in case of sporadic and MEN-1 related insulinoma 69 years (range 29-87 years) and 40 years (range 6-79 years) respectively. In case of MEN-1 related insulinoma at diagnosis 5/6 patients had primary hyperparathyroidism (PHP) in one case it was confirmed 11 years after insulinoma diagnosis. None of patients with negative MEN-1 gene mutations had PHP, 2 out of 13(13%) had dissemination of insulinoma at diagnosis. Median of Ki67 in case of sporadic insulinoma was 2% range (1-12%) and in case of MEN-1 related insulinoma 2% range (1-5%). In 3 cases (50%) of MEN-1 related insulinoma there was more than one lesion of neuroendocrine characteristic in pancreas. In 6 out of 19 cases (32%) insulinoma was disseminated at diagnosis, in 23% cases (3 out of 13) of sporadic and in 50% (3 out of 6) cases of MEN-1 related insulinoma. All patients with disease limited to pancreas were treated radically by surgery (in 3cases by tumor enucleation, in 8 cases with partial or total pancreatodudenectomy). One of MEN-1 patient had recurrence of hypoglycemia after surgery due to appearance of new insulinoma lesion. The patients with dissemination were treated, due to symptomatic hypoglycemia, with combination of diazoxide, somatostatin analogues and PRRT. 5 out of 6 patients with insulinoma in course of MEN-1 mutation are still alive), one died because of coexisting pancreatic cancer.
Conclusion
There are clinical differences between the course of sporadic and MEN-1-associated insulinoma. In the case of disseminated disease, there is often a need for multi-drug treatment to delay progression and prevent episodes of severe hypoglycemia.

P410

Favorable liver safety profile of the selective glucocorticoid receptor modulator relacorilant in healthy and hepatically impaired adults and in patients with cushing syndrome

Andreas G. Moraitis, Joseph Custodio & Iulia Cristina Tudor
Corcept Therapeutics, Menlo Park, United States

Background
Relacorilant is a highly selective glucocorticoid receptor (GR) modulator in development for the treatment of endogenous Cushing syndrome (CS). Unlike the GR antagonist mifepristone, relacorilant lacks affinity for the progesterone and other receptors. In a phase 2 study in patients with CS (Pivonello *et al*, 2021), relacorilant provided clinically meaningful changes in several cortisol-excess-related comorbidities, including hypertension and hyperglycemia, without undesirable antiprogesterone effects or drug-induced hypokalemia. Four clinical studies of relacorilant in patients with CS are ongoing: GRACE (NCT03697109), a phase 3 trial enrolling patients with endogenous CS of all etiologies; GRADIENT (NCT04308590), a phase 3 trial focusing on hypercortisolism due to adrenal adenomas or hyperplasia; a phase 2/3 long-term extension trial (NCT03604198); and a phase 1b trial in patients with adrenocortical carcinoma and glucocorticoid excess (NCT04373265). Here, we report data from open-label phase 1 and 2 studies of relacorilant in healthy and hepatically impaired adults and in adult patients with CS.
Methods
Data from 3 studies are reported: a study including subjects with hepatic impairment in which 9 subjects with moderate hepatic impairment (Child-Pugh Class B) and 9 matched controls with normal hepatic function received relacorilant (300 mg QD) for 10 days; a phase 1 fixed-sequence drug-drug interaction study (NCT03512548) in which 28 healthy subjects received relacorilant (300 mg QD) for 10 days followed by 10 days of relacorilant (300 mg QD) + itraconazole (200 mg QD); and a phase 2 study in which 35 patients with endogenous CS received relacorilant (100–400 mg QD) for up to 16 weeks (NCT02804750).
Results
While relacorilant is eliminated primarily hepatically, no apparent difference in relacorilant pharmacokinetics in subjects with moderate hepatic impairment vs matched controls was observed, with relacorilant exposures largely overlapping across both groups. Reductions in liver function tests (LFTs) were also observed in this study. In healthy adults receiving relacorilant followed by relacorilant + itraconazole (an agent with reported liver toxicity), a similar trend toward reduced LFTs was seen throughout the study. In the phase 2 study in patients with CS, reductions in LFTs were also observed, including normalization of LFTs in some patients with abnormal values at baseline.
Conclusions
These results suggest that relacorilant has a favorable liver safety profile, including a trend toward improved LFTs in volunteers and patients with normal and abnormal liver function. The hepatic impairment study results support relacorilant use without dose adjustment in patients with moderate hepatic impairment.

Independent injection vs healthcare-setting administration of somatostatin analogues: A systematic literature review

Cesar Luiz Boguszewski[1], Marta Korbonits[2], Audrey Artignan[3], Almudena Martín García[4], Aude Houchard[5], Antonio Ribeiro-Oliveira[6] & Wouter W de Herder[7]
[1]Federal University of Parana, Department of Internal Medicine, Curitiba, Brazil; [2]Barts and the London School of Medicine and Dentistry, Department of Endocrinology, London, United Kingdom; [3]Costello Medical, Cambridge, United Kingdom; [4]Patient author; [5]Ipsen, Boulogne-Billancourt, France; [6]Ipsen, Cambridge, United States; [7]Erasmus MC, Department of Internal Medicine, Rotterdam, Netherlands

Background
A systematic literature review (SLR) was conducted to assess the use of independent injections (self/partner/home-administered) as an alternative to healthcare-setting injections for chronic diseases. The primary objective was to identify studies reporting on independent injection of somatostatin analogues (SSAs). Comparative evidence on independent injection of other medications was examined as a secondary objective.
Methods
MEDLINE/Embase/the Cochrane Library were searched for records published between January 2001–September 2021, using terms for independent injection. Congresses (2019–2021) and SLR bibliographies were also hand-searched. Abstracts/full-text publications were reviewed by two independent reviewers. Studies were eligible if they reported on efficacy/effectiveness, adherence, safety, economic or patient-reported outcomes in populations receiving independent injections of SSAs (primary objective) or other monthly subcutaneous treatments (secondary objective). Studies investigated under the secondary objective were required to include a comparator in the healthcare setting.
Results
3.430 unique records were screened, of which 12 studies, comprising
18–3,921 patients, were included, all reporting on SSAs (lanreotide or octreotide).

No studies were identified to support the secondary objective. In four studies reporting comparative efficacy/effectiveness, independent injection was associated with equal/greater disease control in patients with acromegaly and neuroendocrine tumors (NETs) compared with healthcare-setting administration. Treatment adherence, defined as successful injection administration, was shown in 74%–93% of patients with acromegaly receiving independent injections in two studies, both assessing lanreotide. A higher proportion of injection-site reactions was observed in patients self-injecting lanreotide compared with partner injections (19% vs 2%, $P<0.05$). Two studies reported non-serious adverse events, which were rare in both the independent and healthcare-administration settings. Preference for independent injection varied between studies/disease indications, ranging from 4%–100% across five studies, with patients citing increased autonomy and convenience for preference over healthcare-setting administration. Lower anxiety, perceived safety, and the ability to communicate with a healthcare provider (HCP) were factors underlying a preference for healthcare-setting administration. Self- or partner-injection was associated with economic savings compared with the healthcare setting across five studies, including nurse, travel, and administration time.

Conclusions

Independent injection is similar to the healthcare setting regarding efficacy/effectiveness, adherence, and safety outcomes. Patient preferences for administration setting varied and may reflect the need for improved patient education/training, or home care program support for those where independent injection is a preferred/suitable option.

Self- or partner-injection also provided cost savings. Our findings provide a basis to understand outcomes related to independent injection and empower patients to discuss optimal treatment choices with their HCP.

Sodium alterations impair the long-term prognosis of hospitalized patients with COVID-19 pneumonia: hospital readmissions and mortality rates after a 18-month follow-up

Marianna Martino, Nairus Aboud, Michele Perrone, Paolo Falcioni, Giulia Giancola, Alessandro Ciarloni, Gianmaria Salvio, Francesca Silvetti, Augusto Taccaliti & Giorgio Arnaldi

Università Politecnica delle Marche, Division of Endocrinology and Metabolic Diseases AOU Ospedali Riuniti Ancona; Department of Clinical and Molecular Sciences (DISCLIMO) UNIVPM, Ancona, Italy

Background

Dysnatremia is common in hospitalized patients, often worsening the prognosis in pneumopathies and critical illnesses, such as COVID-19. Here, hyponatremia is an indicator of pulmonary involvement, while hypernatremia is associated with worse assistance outcomes, particularly when resulting from an overcorrected hyponatremia. Longer hospitalizations, readmissions after discharge and higher short- and long-term mortality rates have been observed in acute patients experiencing sodium abnormalities.

Objective and methods

117 patients hospitalized for COVID-19 between 1st March and 30th April 2020 and participating the "EPISODICO" study [1] were followed-up for 18 ± 4 months. The proportion of emergency room or hospital readmissions (Ancona University Hospital) for all causes, the mortality rate after recovery from COVID-19 and their association with recurrent sodium alterations were assessed.

Results

Of the 97 discharged patients (70 males, 62 ± 12 years), almost 30% were readmitted to the emergency room or any hospital department at least once. At readmission, 10% patients had hyponatremia, 14% had hypernatremia, whereas 7% patients experienced both disorders ("mixed dysnatremia") by the end of follow-up. Gender, age, clinical and biochemical features of their previous hospitalization for COVID-19 were similar between readmitted and non-readmitted patients, the former having overlapping sodium levels in both hospitalizations. Considering the whole "EPISODICO" cohort, mortality rate at the end of follow-up was 25%, since twenty patients died in the "EPISODICO" study and further nine patients died during follow-up: of them, 4 died as outpatients in 1-11 months after discharge, and 5 as inpatients in 3-17 months after the first discharge. Last available sodium levels were significantly lower in dead patients as compared to survivors (137 ± 11 vs 141 ± 3 mmol/l, $P=0.026$). Death occurred in 2/3 patients having hyponatremia at readmission and in 100% patients encountering mixed dysnatremia. When only "EPISODICO" participants with sodium alterations during their COVID-19 hospitalization were selected, readmission rate was 26% and mortality rate at the end of follow-up was 28%.

Conclusions

Similarly to what happens in other acute medical conditions, COVID-19-related sodium alterations are frequently associated with hospital readmissions and long-term mortality. The worst outcomes involve patients whose sodium abnormalities recur after discharge, particularly hyponatremia at the time of hospital readmission and mixed dysnatremia occurring during hospital stay.

Background

Cushing's disease (CD) is associated with hypercortisolism-induced cardiovascular morbidity and mortality and impaired patient quality of life (QoL). We report long-term effects of osilodrostat (potent 11β-hydroxylase inhibitor) on cardiovascular/metabolic-related risk factors, physical features of hypercortisolism and QoL in CD patients following the core and extension phases of the LINC 4 study (NCT02697734).

Methods

LINC 4 comprised a 12-week (W), randomised, double-blind, placebo-controlled period, 36W of open-label osilodrostat, and an optional extension in adults with CD and (mUFC >1.3x upper normal limit). Dose adjustments were permitted based on efficacy/tolerability (open-label range, 1–30 mg bid). Cardiovascular/metabolic-related parameters, physical features of hypercortisolism (rating: 0 = absent;1 = mild;2 = moderate;3 = severe), and CushingQoL scores were evaluated at core baseline, every 2, 4, 12 or 24W (depending on study phase/parameter) and at extension end-of-treatment (EOT). Change from baseline is provided for patients with assessments at core baseline, W48 and EOT.

Results

Of 65 patients completing W48, 60 entered the extension. Median (range) osilodrostat exposure from core baseline to study end: 87.1 (2–127) W; median (IQR) average dose: 4.6 (3.7–9.2) mg/day. Mean changes (95%CI) in cardiovascular/metabolic-related parameters from core baseline to W48 and EOT, respectively, included decreases in systolic (-9.7 [$-14.9,-4.6$] and -12.4 [$-17.4,-7.4$] mmHg; baseline: 131.5 mmHg) and diastolic (-4.2 [$-7.3,-1.2$] and -5.6 [$-8.9,-2.4$] mmHg; baseline 87.5 mmHg) blood pressure, fasting plasma glucose (-3.1 [$-6.8,0.6$] and -3.5 [$-8.5,1.4$] mg/dl; baseline: 95.3 mg/dl) and cholesterol (-0.5 [$-0.8,-0.2$] and -0.6 [$-0.9,-0.3$] mmol/l; baseline: 5.5 mmol/l). Improvements (mean change [95%CI]) from core baseline to W48 and EOT occurred for weight (||4.3 [||5.9,||2.6] and ||6.8 [||8.8,||4.8] kg; baseline: 78.3 kg) and waist circumference (||4.5 [||6.0,||3.1] and ||7.6 [||9.6,||5.6] cm; baseline: 102.8 cm). Physical features of hypercortisolism improved (severity reduced) or remained stable from core baseline to EOT in most patients (respectively): ecchymosis (21% [$n=10/48$], 79% [$n=38/48$]); striae (26% [$n=12/46$], 72% [$n=33/46$]); hirsutism

(females: 29% [$n=11/38$], 61% [$n=23/38$]); muscle weakness (33% [$n=16/49$], 61% [$n=30/49$]); facial rubor (48% [$n=23/48$], 46% [$n=22/48$]); central obesity (55% [$n=27/49$], 37% [$n=18/49$]); fat pads (dorsal: 58% [$n=28/48$], 31% [$n=15/48$]; supraclavicular: 65% [$n=32/49$], 35% [$n=17/49$]). CushingQoL score improved from core baseline to W48 and EOT (mean change [95%CI]: 12.0 [8.2.15.9] and 17.1 [12.5.21.7]; baseline: 51.8).
Conclusion
Alongside cortisol control, most cardiovascular/metabolic-related parameters continued to improve during long-term osilodrostat treatment. Additionally, most physical features of hypercortisolism, including hirsutism, improved or remained stable, and CushingQoL score improved. Osilodrostat is an effective treatment that may alleviate disease burden for many CD patients.

Predictive factors of somatostatin receptor ligand response in acromegaly – a prospective study

Mirela Diana Ilie[1,2], Antoine Tabarin[3], Alexandre Vasiljevic[4], Bonneville Jean-Francois[5], Lucile Moreau-Grangé[6], Franck Schillo[7], Brigitte Delemer[8], Anne Barlier[9], Dominique Figarella-Branger[10], Ségolène Bisot-Locard[11], Alexandre Santos[11], Philippe Chanson[12] & Gerald Raverot[4]
[1]Claude Bernard University Lyon 1, Villeurbanne, France; [2]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [3]Hospital Center University De Bordeaux, Bordeaux, France; [4]Group Hospital Is - Hcl, Bron, France; [5]Hospital Center Universitaire De Liège, Luik, Belgium; [6]Hospital Center University De Rouen, Rouen, France; [7]Centre Hospitalier Régional Universitaire de Besançon, Besançon, France; [8]CHU of Reims - Maison Blanche Hospital, Reims, France; [9]Conception, Marseille, France; [10]CHU Timone, Marseille, France; [11]Novartis Pharma, Rueil-Malmaison, France; [12]Bicetre Hospital, Le Kremlin-Bicêtre, France

Context
Somatostatin receptor ligands (SRLs) are the cornerstone medical treatment of acromegaly, however many patients remain uncontrolled under SRLs. Well-established predictive markers of response are needed.
Objective
We aimed to explore the relationship between responsiveness to SRLs, on one hand, and somatostatin (SST)2A and 5 receptor expression, adenoma granulation, and T2-weighted MRI signal intensity (T2WSI), on the other hand.
Design
Multicentric, prospective, observational cohort study, conducted in France.
Methods
Forty-nine naive patients with active acromegaly following surgery were treated with octreotide (Group 1; $n=47$), or pasireotide if also uncontrolled under first-generation SRL (Group 2; $n=9$). Data was collected at baseline, month 3 and 6. Biochemical measurements, immunohistochemistry studies, and MRI readings were centralized.
Results
In Group 1, IGF-I decrease from baseline to month 6 positively correlated with SST2A immunoreactive score (IRS), $P=0.01$. Densely granulated/intermediate adenomas had greater IGF-I and GH decrease under octreotide than sparsely granulated adenomas ($P=0.02$ and$P=0.006$, respectively), and expressed greater levels of SST2A ($P<0.001$), coupled with lower levels of SST5 ($P=0.004$). T2WSI changed between the preoperative MRI and month 6-MRI in half of the patients. SST5 IRS was higher in hyperintense than in hypointense adenomas (preoperative MRI), $P=0.04$. Most sparsely granulated and most hyperintense adenomas expressed high SST5 levels.
Conclusion
We prospectively confirm that SST2A and adenoma granularity are good predictors of response to octreotide, and that SST5 is not. We propose the IRS for scoring system harmonization. The MRI sequences must be optimized in order to be able to use the T2WSI as a predictor of response to treatment.

Effects of somapacitan on glucose metabolism in adults with GH deficiency

Gudmundur Johannsson[1], Beverly MK Biller[2], Hidenori Fukuoka[3], Ken Ho[4], Michael Højby Rasmussen[5], Navid Nedjatian[6], Claus Sværke[5], Kevin CJ Yuen[7] & Yutaka Takahashi[8]
[1]University of Göteborg and Sahlgrenska University Hospital, Göteborg, Sweden; [2]Massachusetts General Hospital and Harvard Medical School, Neuroendocrine Unit, Boston, United States; [3]Kobe University Hospital, Division of Diabetes and Endocrinology, Kobe, Japan; [4]Garvan Institute of Medical Research, Darlinghurst, Australia; [5]Novo Nordisk A/S, Global Development, Søborg, Denmark; [6]Novo Nordisk Health Care AG, Global Medical Affairs - Rare Endocrine Disorders, Zurich, Switzerland; [7]Barrow Neurological Institute and St. Joseph's Hospital and Medical Center, University of Arizona College of Medicine and Creighton School of Medicine, Barrow Pituitary Center, Phoenix, United States; [8]Nara Medical University, Department of Diabetes and Endocrinology, Nara, Japan

Somapacitan is a once-weekly, long-acting growth hormone (GH) derivative approved for the treatment of adult GH deficiency (AGHD). Our objective was to evaluate the effects of somapacitan on glucose metabolism compared with daily GH or placebo in patients with AGHD using data from three previously published phase 3 trials: REAL 1 (NCT02229851), REAL 2 (NCT02382939) and REAL Japan (NCT03075644). REAL 1 was a randomised, placebo-controlled (double-blind) and active-controlled (open-label) trial in GH-naïve patients, who received somapacitan ($n=120$), daily GH ($n=119$) or placebo ($n=61$) for 34 weeks (main phase). In a subsequent 52-week extension (86 weeks of treatment in total), patients receiving somapacitan continued with somapacitan ($n=114$), patients receiving daily GH were re-randomised to receive either somapacitan ($n=51$) or daily GH ($n=52$), and patients receiving placebo were switched to somapacitan ($n=55$; not included in this analysis). REAL 2 and REAL Japan were randomised, open-label, active-controlled trials in patients previously treated with daily GH. In REAL 2, patients received somapacitan ($n=61$) or daily GH ($n=31$) for 26 weeks. In REAL Japan, patients received somapacitan ($n=46$) or daily GH ($n=16$) for 52 weeks. In these *post hoc* analyses, the absolute or relative change from baseline between treatments for HbA1c, fasting plasma glucose (FPG), fasting serum insulin and index of insulin resistance (HOMA-IR) was explored. In treatment-naïve patients (REAL 1), there were no statistically significant ($P<0.05$) differences between somapacitan and placebo for any glucose-related endpoints at week 34 (main phase). No statistically significant differences in HbA1c were observed between somapacitan and daily GH at week 34 or week 86 (main phase plus extension). Transient differences were seen at week 34 between somapacitan and daily GH (with higher values reported for daily GH) for FPG (estimated treatment difference [95% CI]: –0.16 mmol/l [–0.30; –0.03]), fasting serum insulin (estimated treatment ratio [ETR] [95% CI]: 0.85 [0.73; 0.99]) and HOMA-IR (ETR [95% CI]: 0.80 [0.69; 0.94]); these differences were not seen at week 86. In previously treated patients (REAL 2, REAL Japan and REAL 1 patients who received daily GH in the main phase and were re-randomised for the extension), no statistically significant differences were seen between treatments for any glucose-related endpoints. No new cases of diabetes were reported in somapacitan-treated patients in these trials. In conclusion, somapacitan was similar to daily GH and had no clinically relevant adverse effects on glucose metabolism in treatment-naïve or previously treated patients with AGHD in these phase 3 trials.

Cabergoline monotherapy in acromegaly – a multicenter, retrospective, cohort study of non-irradiated patients using current criteria for disease control

Sandrine A Urwyler[1,2,3], Irene Samperi[1,2,3], Kirstie Lithgow[1,2,3], Akash Mavilakandy[4], Mike Matheou[5], John Ayuk[1,2,3], Karin Bradley[6], Aparna Pal[5], Narendra Reddy[4] & Niki Karavitaki[1,2,3]
[1]Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, United Kingdom; [3]Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Department of Endocrinology, Birmingham, United Kingdom; [4]Department of Diabetes and Endocrinology, University Hospitals of Leicester NHS Trust, Leicester Royal Infirmary, Leicester, United Kingdom; [5]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [6]Department of Endocrinology, Bristol Royal Infirmary, University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom

Background
Dopamine agonists (DA) are included in the management algorithm of acromegaly. Studies on cabergoline monotherapy report IGF-1 normalisation in

between 0% and 100% of the patients during treatment periods ranging between 2.6 and 24 months. However, in many of these studies, previous radiotherapy is a confounding factor. Furthermore, real world data applying the current disease control criteria (normal IGF-1 and GH < 1 mg/l) are not available. The aim of this study was to investigate the efficacy and safety profile of cabergoline monotherapy in non-irradiated patients with uncontrolled acromegaly.
Patients and methods
In this multicenter, retrospective cohort study, non-irradiated patients offered cabergoline monotherapy for uncontrolled acromegaly were identified from the registries of four UK Pituitary centers (Birmingham, Bristol, Leicester and Oxford). Clinical, laboratory and imaging data were collected and analyzed.
Results
Sixty-nine patients were included. Median age at diagnosis of acromegaly was 50.5 years (range 28-78), 34.7% of the patients were females and 21.7% of the tumours were prolactin-co-secreting. Prior to starting cabergoline, IGF-1 levels were 2.13 (median) times the upper limit of normal (ULN) (range 1.02-8.54). Median duration of cabergoline treatment was 23 months (3-252). Normal IGF-1 was achieved in 31.8% (22/67) of the patients within a reported median interval of 12.5 months (2-84). Median weekly cabergoline dose at most recent review was 2.5 mg (0.25-4) in the responders, and 3 mg (0.25-7) in the non-responders ($P = 0.39$). On univariate regression analysis, IGF-1 normalisation was significantly related with the presence of a prolactin co-secreting adenoma (B 1.38, $P = 0.030$) and lower pre-cabergoline IGF-1 ULN levels (B -0.73, $P = 0.015$). ROC analysis showed that IGF-1 < 1.55 ULN had sensitivity 50% and specificity 85% in predicting achievement of normal IGF-1; sensitivity and specificity for IGF-1 < 1.97 ULN were 75% and 67.5%, respectively (AUC 0.760). GH < 1 mg/l was found in 25% (14/56) the patients, whereas 16.1% (9/56) had achieved both GH and IGF-1 criteria. Side effects were recorded in 5 patients (nausea $n = 2$, nasal congestion $n = 1$, dizziness/blurred vision/-abdominal pain/weakness $n = 1$, hair loss $n = 1$).
Conclusions
In this large cohort of non-irradiated patients with acromegaly, cabergoline normalised IGF-1 in 32% of the cases and dose did not differ between responders and non-responders; efficacy of treatment was associated with the presence of prolactin co-secreting adenoma and pre-cabergoline IGF-1 ULN levels. Achievement of both optimal GH and IGF-1 levels was seen in only 16% of the patients.

Terlipressin induced acute severe hyponatremia

Begoña Pla Peris, Icíar Castro de la Vega, Mayet Roxana Padilla Segura, Esther Serisuelo Meneu, Pablo Abellán Galiana, Javier Maravall, Susana Pérez Naranjo, Margarita González Boillos & Agustín Ángel Merchante Alfaro
Hospital General Universitario de Castellón, Spain

Introduction
Terlipressin is a non-selective vasopressin analogue used in patients with decompensated cirrhosis, gastrointestinal haemorrhage or hepatorenal syndrome. It directly binds to V1 receptors improving circulatory volume by causing splanchnic vasoconstriction and portal hypertension inhibition, and has a full V2 receptor agonism in the collecting duct. In consequence, it increases reabsorption of water and can lead to a decrease in plasma osmolality and hyponatremia. Hyponatremia induced by Terlipressin is uncommon (1/1.000 to <1/100, Summary of Product Characteristics). Maximal plasma levels are reached after 1-2h following iv administration and metabolic elimination takes place within a 4-6 h period.
Case Presentation
We present the case of a 46-year-old man admitted to hospital with cirrhosis needing liver resection for liver metastases from colorectal cancer. Patient was treated with 1 mg of terlipressin intravenously every 6 h and isotonic intravenous maintenance fluids (0.9% NaCl) 1000 ml every 24 h. 36 h later he presented with lethargy, confusion, nausea and vomiting. Laboratory findings showed severe hyponatremia (108 mmol/l [134-145]) with low osmolality (231 mOsm/kg [280-305], and normal blood glucose levels (100 mg/dl). He was euvolemic at physical examination. Natremia levels 36 h before the start of terlipressin treatment were 132 mmol/l. Urinary osmolarity and urinary sodium were not available at this moment, given the priority of correcting the symptomatic severe hyponatremia. Treatment with intravenous infusion of hypertonic saline was started and terlipressin was discontinued, sodium levels returning to normal over 48 h (132 mmol/l [134-145]).
Conclusion
Hyponatremia induced by Terlipressin is uncommon and can develop rapidly. It is reversible with cessation of therapy and requires careful consideration. This case is an illustration of this undesirable effect. As endocrinologists, we must be familiar with terlipressin pharmacokinetic properties. Sodium levels and fluid balance should be monitored intensively and immediately after first terlipressin dose.

Is there a difference in clinical skills gained between healthcare professionals of high- and low and middle-income countries with online simulation-based learning?

Anisah Ali[1], Kashish Malhotra[2], Dengyi Zhou[1], Tamzin Ogiliev[3], Carina Synn Cuen Pan[1], Emily Warmington[1], Wentin Chen[1], Harjeet Kaur[1], Jameela Sheikh[1], Pavithra Sakthivel[1], Rachel Nirmal[1], Vina Soran[1], Zakee Abdi[4], Isabel Allison[1], Simran Piya[5], Nia Evans[6], Thia Hanania[1], Dwi Delson[7], Eka Melson[8,9], Meri Davitadze[10], Punith Kempegowda[9,11] & Simba Simulation[9]
[1]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom; [2]Dayanand Medical College and Hospital, Punjab, India; [3]Lancaster University Medical School, Lancaster, United Kingdom; [4]Medical University of Plovdiv, Plovdiv, Bulgaria; [5]University of Edinburgh, College of Medicine and Veterinary Medicine, Edinburgh, United Kingdom; [6]Royal Glamorgan Hospital, Cwm Taf Morgannwg University Health Board, Rhondda Cynon Taff, United Kingdom; [7]University of Dundee, School of Medicine, Dundee, United Kingdom; [8]NHS Tayside, Ninewells Hospital, Dundee, United Kingdom; [9]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, United Kingdom; [10]Georgian-American Family Medicine Clinic, 'Medical House', Tbilisi, United Kingdom; [11]University Hospitals Birmingham NHS Foundation Trust, Queen Elizabeth Hospital, Birmingham, United Kingdom

Background
There is a differential clinical learning opportunity for healthcare professionals in low- and middle-income countries (LMICs) compared to high-income countries (HICs). Barriers to learning include cost, time and accessibility. Simulation via Instant Messaging - Birmingham Advance (SIMBA) is a free virtual simulation-based model aimed at improving clinicians' professional development, without compromising patient safety. The study compared the impact of SIMBA in LMICs and HICs, on participants' professional development and learning.
Methods
Between May 2020 and October 2021, 16 SIMBA sessions were conducted. Participants interacted with moderators over WhatsApp to solve anonymised real-life clinical scenarios. Following simulation, interactive Zoom sessions were led by experts in relevant fields, allowing participants to ask any questions regarding the cases. Participants completed pre- and post-SIMBA surveys as part of their activity on the day of simulation. They were grouped based on their country of residence as HICs and LMICs based on the 2022 World Bank Report to compare their performance, perceptions and improvements in core competencies as defined by the Accreditation Council of Graduate Medical Schools using the Chi-square test. Thematic analysis of open-ended questions was also performed.
Results
In total, 462 participants completed both the pre- and post-SIMBA surveys, of which 29.7% ($n = 137$) were from LMICs. While participants from HICs reported better knowledge on patient management (LMIC: 77.4% vs HIC: 86.5%;$P = 0.01$), those from LMIC reported higher improvement in professionalism (LMIC: 41.6% vs HIC: 31.1%;$P = 0.02$). Both groups reported similar gains in patient care (LMIC: 51.8% vs HIC: 57.2%;$P = 0.28$), systems-based practice (LMIC: 56.9% vs HIC: 47.1%;$P = 0.052$), practice-based learning (LMIC: 72.3% vs HIC: 65.5%;$P = 0.15$), communication skills (LMIC: 31.4% vs HIC: 25.8%;$P = 0.22$), applying simulated topics to their practice ($P = 0.266$), engagement ($P = 0.197$), and overall quality of the teaching session ($P = 0.101$) . In thematic analysis, the major strengths of SIMBA over traditional methods were providing individualised, structured, and engaging sessions.
Conclusion
SIMBA improves healthcare professionals' clinical competencies from both LMICs and HICs demonstrating that SIMBA can provide equivalent teaching experiences irrespective of country of residence. Furthermore, international accessibility due to the virtual nature of SIMBA shows potential for global scalability, especially in LMICs where it can help to provide standardised medical training and steer future global health education policy development.

Obstructive sleep apnea syndrome (OSAS) in acromegaly: does the gender matter?

Giacomo Pio[1], Tiziana Feola[2,3], Liliya Rostomyan[4], Giuseppe Vitrani[2], Patrick Petrossians[4], Albert Beckers[4], Andrea Romigi[2] & Marie-Lise Jaffrain-Rea[2,5]
[1]University of L 'Aquila, Department of Biotechnological and Applied Clinical Sciences; [2]Neuromed IRCCS, Pozzilli, Italy; [3]Sapienza University of Rome, Department of Experimental Medicine; [4]Centre Hospitalier Universitaire de Liège, Department of Endocrinology; [5]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

Obstructive sleep apnea syndrome (OSAS) is a frequent cardiovascular risk factor in acromegaly. We aimed to retrospectively evaluate sex-related differences in OSAS characteristics and indications of non-invasive ventilation.
Patients and Methods
Thirty-nine adult patients (16 F, 23 M) from two European centers were studied by home sleep apnea test (HSAT) or polysomnography (PSG). OSA was defined by an apnea-hypopnea index (AHI) $\geq$5/h and analyzed according to age, gender, disease activity, obesity, diabetes mellitus, hypertension and nocturnal continuous positive airway therapy (CPAP). Categorical variables were considered in all cases, whereas, except for pre/post-ventilation AHI, sleep parameters were used in cases defined according to the last International Classification of Sleep Disorders (ICSD-3, 2014) ($n=33$). Data are expressed as median (range) and statistical analysis based on non-parametric tests.
Results
The median age at diagnosis of acromegaly and at PSG were 48.5 and 52.0 yrs respectively, 25/39 patients (64.1%) had an active disease. OSAS was diagnosed in 36/39 patients (92%) and classified as mild/moderate ($\geq$5 AHI$<$30) in 12/39 (30.8%) and severe (AHI$\geq$30) in 24/39 patients (61.3%). Severe OSAS tended to be more frequent in M (17/23 v*s* 7/16 F, $P=0.057$), who were more frequently advised to start CPAP therapy (21/23 vs 9/15 F, $P=0.037$). Males had a significantly higher BMI (32.6 vs 28.4 kg/m^2 $P=0.017$) and higher prevalence of hypertension (21/23 vs 8/16, $P<0.004$) despite similar age, GH and IGF1 ULN at the time of diagnostic HSAT/PSG. Overall, AHI was significantly correlated with patients age ($\rho=0.36$, $P=0.023$) but not with BMI, and similar in diabetic and non-diabetic patients. By univariate logistic regression, hypertension was the only independent predictor of severe OSAS ($P=0.018$). Nocturnal cardiorespiratory monitoring. Sleep evaluation was also obtained on CPAP therapy in 17 patients (6 F, 11 M), out of which 10 (58.8%) had controlled acromegaly (3 F, 7 M). A significant decrease in AHI (median – 90.4%, $P<0.001$) was observed in all but one patient. OSAS was controlled in 11/17 patients (64.7%; 5/6 F, 6/11 M), including 8/12 with severe OSAS (66.7%), and regardless of hypertension.
Conclusion
OSAS is extremely common in acromegaly, especially using the ICSD-3 criteria, and HSAT may be recommended for routine screening. We found hypertension as a major predictor of severe OSAS, which tended to be more frequent in men. CPAP was found to be effective regardless of OSAS severity and should be encouraged in such patients.

A rare posterior pituitary tumor with thyroid transcription factor-1 positivity

Şeyma Aksoy, sebnem burhan, Rukiye Dilara Tekin Uzman & Esra Şüheda Hatipoğlu
Istanbul Başakşehir Çam and Sakura City Hospital, Endocrinology and Metabolism Diseases, Istanbul, Turkey

Introduction
A pituitary adenoma is directly assumed to originate from anterior pituitary. It is expected that pathologies of posterior hypophysis cause diabates insipitus (DI). However recently posterior pituitary tumors (PPTs) are also declared which are not associated with DI in contrast to what is expected. Rather they have a clinical and radiologic presentation akin to anterior pituitary adenomas. Differentiation of two conditions is mainly based on pathologic immunohystochemical staining of posterior pituitary tumors with Thyroid Transcription Factor-1 (TTF-1), which is universally positive in posterior pituitary tumors but negative in anterior ones. PPTs are believed to originate from pituicytes, which are specialized glia of the posterior pituitary. Incidences of these rare tumors are as low as less than 0.5% of sellar tumors (1). Transsphenoidal surgery (TSS) is the treatment of choice for symptomatic PPT.
Case report
A 44-year-old man presented with headache. Magnetic resonance imaging (MRI) indicated a 22x12.7x13 mm pituitary lesion. Anterior pituitary hormones at presentation were within normal levels. Patient underwent TSS. Patologic evaluation showed a nullcell adenoma with Ki-67 (MIB-1) index of % 5-6. A residual 16x15 mm tumor was detected in the pituitary MRI 3 months after the operation. The patient underwent TSS again at the postoperative 11th month. GH, ACTH, TSH, LH, FSH, pit-1, SF-1 staining was negative in patological examination. TTF-1 was positive. Synaptophysin and S-100 protein were weakly positive. GFAP, EMA and chromogranin were negative. Ki-67 (MIB-1) index was % 15. Due to TTF-1 positivity, PPTs and metastatic neuroendocrine tumors were included in the differential diagnosis. Neuroendocrine tumor metastasis was ruled out as chromogranin, insulinoma-associated protein 1 and cytokeratins were negative. FDG-PET also did not show a primary/metastatic malignancy. On follow-up there was no recurrence or residual tumor and no hormonal deficiency.
Discussion
PPTs generally arise in the region of the sella and present similarly to nonfunctional pituitary adenomas, making it difficult to distinguish them from other common pituitary lesions based on hormonal status and imaging alone. TTF-1 positivity is crucial to diagnosis. Because of the high rate of recurrence, TTF-1 positive tumors should be followed up at close intervals. (1) Shibuya M. Welcoming the new WHO classification of pituitary tumors 2017: revolution in TTF-1-positive posterior pituitary tumors. Brain Tumor Pathol. 2018 Apr;35(2): 62-70.

Efficacy of methotrexate in the treatment of isolated, steroid-resistant sarcoidosis of the hypothalamic-pituitary system

Pawel Kuca[1], Agnieszka Wojciechowska-Luzniak[1], Lukasz Dzalach[1], Anna Migda[1], Grzegorz Zielinski[2], Maria Maksymowicz[3] & Przemyslaw Witek[1]
[1]Medical University of Warsaw, Department of Internal Medicine, Endocrinology and Diabetics, Warsaw, Poland; [2]Military Institute of Medicine, Department of Neurosurgery, Warsaw, Poland; [3]The Maria Sklodowska-Curie National Research Institute of Oncology, Department of Patomorphology, Warsaw, Poland

Isolated sarcoidosis of the hypothalamic-pituitary system is a very rare form of neurosarcoidosis. It usually leads to secondary damage to endocrine function, resulting in hypopituitarism and diabetes insipidus. A 32-year-old male patient with progressive deterioration of his general condition, weakness, polyuria, dizziness and visual field disturbances was admitted to the Department of Endocrinology for the diagnosis of a tumor in the hypothalamic-pituitary region. MRI showed a tumor (19x16x15 mm) with suprasellar extension, and hormonal evaluation revealed multi-hormonal pituitary insufficiency and diabetes insipidus. The patient was referred for pituitary surgery: the lesion initially described in MR as a tumor was sub totally removed from the fronto-parietal access. The histopathological examination revealed a hypothalamic sarcoidosis. Based on the imaging studies performed, the presence of sarcoid lesions in other typical locations (lungs, lymph nodes, heart, eye, skin) was excluded. Isolated sarcoidosis of the pituitary system was diagnosed. Methylprednisolone treatment was initiated at 500 mg/week for 6 weeks, followed by 250 mg/week for 6 weeks. Additionally, the patient required replacement treatment with l-thyroxine, testosterone and desmopressin. Following 12 weeks of methylprednisolone therapy MRI showed a progression of the infiltrative process: the tumor was enlarged (20x19x17 mm) and two satellite foci appeared. Due to the clinically and radiologically identified steroid resistance of the lesions, immunosuppressive treatment with methotrexate was introduced in the 15 mg sc regimen for 7 days for 4 weeks, and then 25 mg sc every 7 days chronically. Subsequent MRI examinations performed 3, 12 and 24 months after the initiation of methotrexate therapy showed a regression of the infiltrative process in the CNS and decompression of the optic chiasm together with clinical improvement and no signs of sarcoid lesions in other locations. At the same time, no complications of the applied treatment were observed. In the control hormonal tests, the features of multi-hormonal anterior pituitary insufficiency were maintained, which required continuation of substitution treatment. In conclusion, an optimal treatment of isolated neurosarcoidosis of the hypothalamic-pituitary system has not been clearly established. Steroid therapy with high doses of methylprednisolone should be considered first, but the possibility of steroid resistance should also be considered. The use of immunosuppressants, such as methotrexate as a second line therapy, may have a positive effect on reducing the extent of the sarcoid

process. Such a treatment is effective and safe, although the time frame and the dosing schedule of methotrexate are still unknown.

Aberrant expression of clock genes in human gastric neuroendocrine tumors type 1

Angeliki Karapanagioti[1,2], Narjes Nasiri-Ansari[1], Kosmas Daskalakis[3], Erasmia Vlachou[4], Georgios Kyriakopoulos[1,5], Harpal Randeva[6,7], Gregory Kaltsas[2] & Eva Kassi[1,2]
[1]National and Kapodistrian University of Athens, Medical School, Department of Biological Chemistry, Athens, Greece; [2]National and Kapodistrian University of Athens, Medical School, 1st Department of Propaedeutic Internal Medicine, Laiko General Hospital, Athens, Greece; [3]Örebro University, Department of Surgery, Faculty of Medicine and Health, Sweden; [4]NIMITS Medical Institution Military Shareholder Fund, Department of Gastroenterology, Athens, Greece; [5]Evangelismos General Hospital, Department of Pathology, Athens, Greece; [6]University Hospital Coventry & Warwickshire, Warwickshire Institute for the Study of Diabetes, Endocrinology and Metabolism (WISDEM), Coventry, United Kingdom; [7]Warwick Medical School, Divisions of Translational and Experimental Medicine-Metabolic and Vascular Health, Coventry, United Kingdom

Introduction
Gastric neuroendocrine tumors (GNET) are rare gastric neoplasms which are developed due to hypergastrinemia and enterochromaffin-like (ECL) cell hyperplasia. Although the effect of the circadian clock system disruption on tumorigenesis has been already studied in various malignancies and autoimmune diseases, the role of the peripheral clock system in the transition from ECL-cell hyperplasia to GNEN1 (Type 1 Gastric Neuroendocrine Neoplasms) remains unexplored.
Aim
We aimed to investigate the expression of clock-related genes in peripheral blood mononuclear cells (PBMCs) and gastric tissues of the same patients with ECL-cell hyperplasia and patients with GNEN1.
Methods
Fresh frozen gastric tissues were collected between (9:00 -11:00 am) from 9 patients diagnosed with GNEN1. The histological reports confirmed the presence of ECL and GNEN1 lesions (in each separate specimen) collected from the same patient. PBMCs were also isolated from the whole blood (8:00-9:00am) of the same patients and 10 patients with confirmed ECL-cell hyperplasia. CLOCK, BMAL1, CRY1, PER2, REV-Erb, ROR-α, GR-α genes expression was evaluated by qPCR in PBMCs, ECL-cell hyperplastic and its paired GNEN1 lesions. Clinical, histological and epidemiological data of patients were also collected.
Results
The mean age of patients was 57.8 ± 12.8 years old. Paired analysis revealed that the expression of BMAL-1 and CLOCK was significantly ($P < 0.01$) increased while the expression of REV-Erb and GR-α was reduced ($P < 0.05$) in GNE1 tissue as compared to adjacent ECL tissue. There was no significant difference in the expression of PER-2 and CRY-1 in GNE1 tissues as compared to adjacent ECL tissues. Interestingly, the expression of CLOCK, PER2 and REV-Erb was significantly increased in PBMCs of GNE1 as compared to patients with ECL-cell hyperplasia.
Conclusion
Our data indicate for the first time that there is aberrant circadian clock gene expression in human gastric neuroendocrine tumors in both gastric lesions and PBMCs. Since CLOCK gene was overexpressed, apart from GNEN1 lesions, in PBMCs of patients with GNEN1 as compared to PBMCs isolated from subject diagnosed with ECL-cell hyperplasia, its potential role as an non-invasive biomarker of transition of ECL-cell hyperplasia to non-invasive GNEN1 could be explored. However, a larger sample size of patients is necessary to evaluate the role of dysregulation of the local circadian clock system in the development and/or evolution of these neoplasms.

The diagnosis of vertebral fractures on routine chest radiography of acromegaly patients: a real-life study

Chiara Sardella[1], Claudio Urbani[2], GIULIA MARCONCINI[3], Daniele Cappellani[3], Luca Manetti[3], Annalisa De Liperi[4], Chiara Romei[5], Riccardo Morganti[6], Claudio Marcocci[7] & Fausto Bogazzi[3]
[1]University Of Pisa, Department of Clinical and Experimental Medicine-Section of Endocrinology, Pisa, Italy; [2]University of Pisa, Department of Clinical and Experimental Medicine-Section of Endocrinology, Pisa, Italy; [2]University of Pisa, Department of Clinical and Experimental Medicine-Section of Endocrinology, Pisa, Italy; [4]Pisa University Hospital, Radiology Department-2 nd Radiology Unit, Pisa, Italy; [5]Pisa University Hospital, Radiology Department-2 nd Radiology Unit, Pisa, Italy; [6]University of Pisa, Section of Statistics, Pisa, Italy; [7]Universa of Pisa, Department of Clinical and Experimental Medicine-Section of Endocrinology, Pisa, Italy

Objectives
The primary objective was to study the prevalence and the risk factors of vertebral fractures (VFs) in acromegaly patients either at diagnosis of acromegaly or during the follow-up. The role of routine chest radiography for detecting VFs in acromegaly was also evaluated.
Design and methods
A retrospective cohort study was performed on 60 consecutive acromegaly patients, in a tertiary referral center. The presence of VFs was firstly evaluated in each patient on lateral radiograph of the thoracolumbar spine (X-spine) performed at the last clinical visit during the follow-up. Secondly, routine chest X-rays (X-chest) performed at the time of diagnosis of acromegaly because part of the general evaluation at admission, were retrospectively reviewed for detecting VFs and compared to X-spine. Data were evaluated using binary logistic regression.
Results
Overall, 27 (45%) out of 60 patients had VFs at X-spine. Among those patients 37% had fractured vertebrae at the time of the diagnosis of acromegaly, although undiagnosed. Patients with VFs at baseline had higher IGF-1 index compared to those who had fractures after the diagnosis of acromegaly ($P = 0.043$). The comparison between the X-spine and the X-chest revealed an incidence of new VFs in 40% of patients, after diagnosis of acromegaly. The determinants of VFs were age (HR 1.05, $P = 0.038$) and hypogonadism (HR 6.14, $P = 0.025$). Conversely, therapy for acromegaly or bone mineral density values did not influence the outcome.
Conclusion
Nearly 40% of patients, who suffer from VFs, had fractured vertebrae undiagnosed on chest radiography at time of diagnosis of acromegaly. At baseline, VFs might correlate to the severity of acromegaly. After diagnosis of acromegaly, patients are at high risk of developing new fractures especially when hypogonadism is associated. On routine chest radiography, acromegaly patients should be also evaluated for the presence of VFs.

Assessment of quality of life in women with Sheehan syndrome

Salma Salhi, Ibtissem Oueslati, Wafa Grira, Fatma Chaker, Nadia Khessairi, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Sheehan syndrome represents a rare cause of hypopituitarism. It results from postpartum ischemic necrosis of the pituitary gland. Data evaluating the quality of life in women with Sheehan syndrome are scarce. The aim of this study was to assess the quality of life in patients with Sheehan syndrome and to determine its associated factors.
Methods
A cross-sectional study including women with Sheehan syndrome was conducted in the department of endocrinology, La Rabta hospital. Clinical and paraclinical data were collected. Quality of life was assessed using the Short Form Survey-36 (SF-36). Predefined thresholds were used to categorize patients' quality of life: SF-36 overall score < 30: poor quality of life, 30-60: average quality of life, and > 60: good quality of life.
Results
Forty-two women with Sheehan syndrome were enrolled in this study. Their mean age was 61.9 ± 9.6 years. The mean duration and the mean delay in diagnosis of Sheehan syndrome were 31.5 ± 10.2 and 11.8 ± 9.3 years, respectively. All participants had corticotroph, thyrotropin, gonadotropin, and prolactin deficiencies. The overall quality of life score was 50.9 ± 15.2. The averages of role limitation due to physical health, vitality, emotional well-being, bodily pain, and general health scores were below 50. The quality of life was good in 11 patients (26%), average in 27 patients (64%), and poor in 4 patients (10%). Role limitation due to physical health score was negatively correlated with age ($r = -0.326$, $P = 0.04$) and the disease duration ($r = -0.423$, $P = 0.006$). General health

score ($r=0.354$, $P=0.027$) and vitality score ($r=0.365$, $P=0.022$) were correlated with the daily dose of hydrocortisone.
Conclusion
The majority of women with Sheehan syndrome had average to poor quality of life. The most affected dimensions were role limitation due to physical health, vitality, emotional well-being, bodily pain, and general health. Age, disease duration, and the daily dose of hydrocortisone may affect the quality of life in women with Sheehan syndrome.

In-hospital hyponatremia is associated with loss of independence at discharge among older patients

Tanu Hans[1], Navjot Singh[1] & Jubbin Jagan Jacob[2]
[1]Christian Medical College & Hospital, Department of Medicine, Ludhiana, India; [2]Christian Medical College & Hospital, Department of Endocrinology, Ludhiana, India

Context
Hyponatremia is a hormonal disorder of water metabolism encountered in 2% of community dwelling adults in America and in over 15-20% of hospitalized adults.[1,2] Hyponatremia leads to increase in risk of falls, cognitive deficits, gait disturbances, loss of independence, prolongation of hospital stay and mortality among older patients admitted to hospitals.[3]
Objective
To determine in-hospital mortality among older patients admitted to the hospital with concomitant hyponatremia and to assess length of hospital stay and degree of independence at discharge from hospital
Methods
This was an observational cohort recruited from the medical and allied wards of a tertiary care teaching hospital in India. Older patients ($\geq$60 years) with documented hyponatremia (Serum Sodium $<$ 135 mEq/l) who provided informed consent were included. Patients with suspected pseudohyponatremia and those with functional impairments prior to hospitalization were excluded. A similar number of age and gender matched older patients without hyponatremia during hospital stay were recruited as a control group. Demographic and clinical data was noted from the patients' records. Primary outcome measured was in-hospital mortality. Other outcomes included length of hospital stay (LOHS) and loss of independence recorded on the day of discharge by assessment of Katz index of independence (KII) in daily living.[4] A lower score indicates loss of independence.
Results
Hundred and twenty-five patients with hyponatremia and an equal number of controls were consented. Mean age (68.8$\pm$7.7 vs.68.2$\pm$6.5 years P-value$=$0.8) and male gender (57.6% vs.56.8% P-value$=$0.8) were comparable and mean serum sodium were 127.1$\pm$5.5 vs 137.9$\pm$2.5 mEq/l respectively among cases vs. controls (P-value$<$0.0001). In-hospital mortality was higher among patients with hyponatremia (20(16%) vs. 11(8.8%), P-value$=$0.08) but not statistically significant. LOHS was longer (8.4$\pm$5.7 vs. 5.0$\pm$2.8 days, P-value$<$0.0001) and KII scores were lower (3.9$\pm$1.9 vs. 4.8$\pm$1.5, P-value$=$0.0003) among cases. Severe functional impairment at discharge (KII $<$2) was significantly higher among cases (29.5% vs. 13.1%, P-value$=$0.006). Significant positive correlation was seen between serum sodium and KII scores (correlation coefficient -0.28, P value$=$0.003) suggesting increasing loss of independence at discharge with lower sodium values.
Conclsions
Older patients with hyponatremia during hospitalization were less likely to survive the hospital stay and spend longer time in hospital. Loss of independence was significantly associated with both presence of hyponatremia and co-related with the severity of hyponatremia.

3P syndrome: pheochromocytoma, paraganglioma, pituitary adenoma

Barbora Havlinova[1], Filip Gabalec[1], Miroslav Solař[2], Jiri Horacek[1] & Jan Cap[1]
[1]University Hospital Hradec Kralove and Charles University, Faculty of Medicine in Hradec Kralove, 4th Department of Internal Medicine - Hematology, Hradec Králové, Czech Republic; [2]University Hospital Hradec Kralove and Charles University, Faculty of Medicine in Hradec Kralove, 1st Department of Internal Medicine – Cardioangiology, Hradec Králové, Czech Republic

Neuroendocrine tumours, especially pheochromocytomas, paragangliomas and pituitary adenomas, are more common in younger patients in 3rd–5th decade of life. PitNETs are the most common intracranial tumours, while PHEO and PGL are rare. The hormonal activity, signs and symptoms of NET are variable. PGL, PHEO and PitNET in one patient remains an exceptional association. 72 cases of concomitant pituitary adenoma and PGL have been reported to date. The first record of a patient with acromegaly and PHEO dates back to 1952. We present a case of a 39-year-old man with non-specific symptoms including high blood pressure, headache, sweating and specific apparent acromegalic features on the face and hands. Screening CT scan found vascularized expansion (up to 6.5 cm) with cystic necrosis in the area of both adrenal glands. Initial measurement showed high plasma levels of catecholamines and their metabolites, prolactin, growth hormone and IGF-I. Then MRI examination of the brain was indicated and found intrasellar expansion (2 cm x 2.3 cm x 2 cm) prominent into the sphenoid cavity. Genetic analysis was performed due to endocrine syndromic comorbidities in a young patient which revealed a germline mutation in the gene MAX. Treatment included bilateral adrenalectomy of PHEO and neurosurgical intervention. Because acromegaly was not adequately controlled after surgery, somatostatin analogue was introduced. In up to 25 % of cases, especially in younger people, pheochromocytomas may be caused by an inherited mutation of various genes (SDHB, SDHD, SDHC, VHL, MAX, RET). Mutation frequencies in the MAX gene are uncommon. They lead to incorrect regulation of the MYC-MAX-MXD1 path, which is coupled to the mTOR path. So far, the most effective treatment is the surgical removal of the neuroendocrine tumours. Performing genetic analysis is not a routine, but for related individuals, it's a possibility to detect a malignant form of the disease earlier.

Long-term Tolvaptan therapy in the treatment of SIAD in Elderly- A case report with challenging cytochrome P 450 drug interactions

Keerthi Madhurya Kethireddi & Sathish Babu Parthasarathy
Princess Royal Hospital, Endocrinology & Diabetes, Haywards Heath, United Kingdom

Background
Chronic SIAD with its disabling impact is challenging to manage in elderly patients as fluid restriction or demeclocycline often has a limited success. Tolvaptan is a novel selective antagonist of vasopressin receptor (V2R) which is safely used in patients with SIAD and other conditions with hypervolemia. We report a case of longest Tolvaptan use with significant challenges amongst our case series which we had previously published
Method
A Case Report of SIAD managed with long term Tolvaptan therapy with significant cytochrome P450 drug interactions. A 78-year-old male presented with recurrent falls and reduced mobility in April 2017. He had multiple falls prior and was being investigated for cavitating lung lesion in Right Upper lobe. He was found to have severe euvolemic hyponatremia (serum sodium of 104 nmol/l) with a paired serum (228 mOsm/kg) and Urine Osmolalities (419 mOsm/kg), a normal Cortisol of 666 nmol/l and a normal Thyroid function test. His prior baseline sodium was around 130 mmol/l. SIAD was confirmed which failed to respond to fluid restriction (19 days) and demeclocycline (10days). A clinical diagnosis of Aspergillosis was made and oral Itraconazole was started. We commenced Tolvaptan 7.5 mg once daily dose (smaller dose) given drug interaction between Itraconazole (CYP3A4 Inhibitor) and Tolvaptan. Hyponatraemia improved back to baseline within 48 h and patient was discharged on Tolvaptan (7.5 mg OD). Trials of stopping Tolvaptan therapy were unsuccessful (2017, 2019). Patient presented with increased fatigue and low basal cortisol (9 nmol/l) in 2018 despite normal serum electrolytes. Diagnosis of Secondary adrenal Insufficiency was made (250 microgram Short Synacthen test - Cortisol 0 Minutes- 73 nmol/l, 30 minutes- 131 nmol/l, Serum ACTH $<$ 3 ng/l). This is due to known interaction of potent CYP3A4 inhibitor (Itraconazole) with Seretide Inhaler therapy (Fluticasone dipropionate) in our patient. Steroid replacement therapy with Hydrocortisone was commenced. Tolvaptan dose frequency was gradually reduced to 7.5 mg twice weekly (since 2020). There were only 15 endocrine clinic

appointments over 246 weeks with no adverse effects and no further admissions since 2017.
Conclsion
We present our experience of longest use of Tolvaptan in an elderly patient with no adverse events. Clinicians must be aware of potential Cytochrome *P*450 drug interactions to avoid complications. Long term Tolvaptan use in chronic refractory SIAD appears to be safe, feasible and cost effective. More prospective studies are needed for guidance in using vasopressin receptor antagonists in chronic disabling SIAD.

RNA profiling of human growth hormone-secreting and non-functioning pituitary adenomas reveals novel and differentially expressed immune related genes

Emma Jayne Spiteri[1,2], Robert Formosa[3,4], Jean Paul Ebejer[2], Nikolai Paul Pace[2], Mark Gruppetta[3,5], David Saliba[1,2] & Josanne Vassallo[3,5]
[1]Department of Applied Biomedical Science, Faculty of Health Science, University of Malta, Msida, Malta; [2]Centre for Molecular Medicine and Biobanking, University of Malta, Msida, Malta; [3]Division of Endocrinology, Department of Medicine, Faculty of Medicine and Surgery, Mater Dei Hospital, University of Malta, Msida, Malta; [4]Queen Mary University London, Campus Malta, Victoria, Gozo, Malta; [5]Neuroendocrine Clinic, Department of Medicine, Mater Dei Hospital, Msida, Malta

Pituitary neuroendocrine tumours (PitNETs) are broadly classified as non-functioning pituitary adenomas (NFPAs) and functional pituitary adenomas (FPAs) which include growth hormone secreting adenomas (GHPAs). Since the role of the immune system in PitNET pathogenesis is still poorly understood, we employed RNA-sequencing technology to unravel differentially expressed genes in GHPAs and NFPAs. Here we present an RNA-sequencing workflow of GHPAs ($n=3$) and NFPAs ($n=7$) which revealed a total of 7945 differentially expressed genes. Reactome, Gene Ontology and KEGG pathway analysis further revealed 57 genes involved in immune regulation. These genes fell into functional categories of chemokines, cytokines, interleukins, signal transduction and adhesion molecules. 6 immune genes including *GATA3, CCL3,* and *CXCL9* were selected for further validation by qRT-PCR in 14 additional PitNET samples. A number of possible pathways implicated in PitNET functioning were also highlighted. The most significant were 'T_H1 and T_H2 cell differentiation', 'cytokine-cytokine receptor pathway', and 'chemokine receptors bind chemokines'. Through our findings, we highlight distinct gene expression profiles in NFPAs and GHPAs and suggest that some of these genes could be considered as novel PitNET diagnostic markers for these two subtypes. We are currently validating these novel markers by immunohistochemistry in an array of PitNET subtypes.

Background
Subtle symptoms such as fatigue, weight gain and depression are commonly present for years in patients with pituitary adenoma (PA) before the diagnosis is made. A delayed diagnosis with risk of increased morbidity and mortality may be due to differences between patient-reported symptoms and symptoms reported in the patient's medical record.
Aim
To estimate diagnostic delay and investigate the concordance between patient-reported symptoms and the medical record documentation in patients with PA.
Method
Patients with PA attending seven University Hospitals in Sweden participated. Age at first symptoms, age at diagnosis, experience of first symptoms, symptoms at diagnosis, and first healthcare contact were collected from the medical records, the Swedish Pituitary Register and patient questionnaires. The concordance between patient reports and medical record documentation was assessed using kappa statistics.
Results
657 patients (322 women) were included (non-functioning PA (NFPA) $n=314$, prolactinoma $n=118$, acromegaly $n=164$, Cushing's Disease (CD) $n=58$. Median age at inclusion was 61 yrs (19-92) for men and 52 yrs (18-91) for women. A significant difference in duration of onset of symptoms to final diagnosis between men and woman was reported; median 1 yr (0-31) for men and 2 yrs (0-44) for women ($P<0.001$). Patients with acromegaly had the longest diagnostic delay; median 4 yrs (0-32), significantly longer than for NFPA; median 1 yr (0-20), ($P<0.001$). Among NFPA the most frequent patient-reported symptoms were headache, visual deficit and tiredness; for prolactinomas menstrual irregularities, headache, tiredness; for acromegaly change in appearance, snoring, headache and for CD weight gain, tiredness and weakness. Substantial agreement between patient report and medical record was found in visual deficit in NFPA and prolactinomas (Cohen's kappa >0.6) and in menstrual irregularities in prolactinomas (Cohen's kappa >0.7). In prolactinomas we found poor agreement for galactorrhea, and in acromegaly for weakness and tiredness. In CD we found no agreement at all in weakness and dizziness. The first healthcare contact was endocrinologists for NFPA and general practitioners for prolactinomas, acromegaly and CD.
Conclusion
We report a substantial and highly variable diagnostic delay in patients with PA, most pronounced in women. Visual deficit and menstrual irregularities showed substantial agreement between the endocrinologists' documentation and patient reported data, whereas weakness, tiredness and dizziness showed poor agreement. The most frequent entry to diagnosis was general practitioners. An increased awareness of symptoms from pituitary adenomas through increased information to the general population and directed education of health professionals may contribute to earlier diagnosis.

During the spring of 2020, a national lockdown was adopted in Italy to prevent COVID-19 pandemic spread. Restrictive measures have been associated with impaired psychological outcome in the general population. As patients with Cushing's Syndrome (CS), including Cushing's disease (CD), adrenal CS (ACS), and ectopic CS (ECS), are reportedly associated with a higher prevalence of anxiety, stress susceptibility, depression, and maniac episodes, during both active disease and remission, a higher psychological vulnerability during lockdowns cannot be excluded. The aim of the current study was to evaluate the presence of psychological impairment in CS patients associated with the Italian national lockdown due to COVID-19 pandemic, as compared with healthy subjects. The study enrolled 156 CS patients (134 CD, 18 ACS, 4 ECS; 118 F, 38 M; age: 21-70 yrs) and 156 age-, sex-, and education level-matched healthy subjects. General Anxiety Disorder-7 (GAD-7), Perceived Stress Scale (PSS) and Patient Health Questionnaire-9 (PHQ-9) were telematically and anonymously administered to study participants during the last three weeks of Italian national lockdown. Higher scores of GAD-7, PSS and PHQ-9 indicated higher anxiety, perceived stress and depression. Demographic, social, and clinical information were also collected for a correlation with the psychological status. Comparing CS patients and healthy subjects, no significant differences were observed neither in the questionnaires scores nor in the prevalence of general anxiety, high perceived stress, and depression. In CS patients, higher GAD-7, PSS, and PHQ9 scores were contemporary observed in females ($P \leq 0.01$), higher GAD-7 and PSS scores were contemporary observed in patients <50 yrs ($P<0.05$), whereas isolated higher PSS scores were observed in patients with lower educational levels ($P \leq 0.02$), currently under glucocorticoid (GC) replacement therapy ($P=0.017$), and going out from home less than once a week during national lockdown ($P \leq 0.03$). Considering CS patients currently treated with medical therapy, isolated higher GAD-7 scores were observed in patients currently treated with pituitary-directed drugs ($P=0.005$ *vs* adrenal-directed drugs). In conclusion, although CS patients did not suffer increased psychological morbidity, namely general anxiety, stress perception and depressive status, compared to healthy subjects during Italian national lockdown, an increased psychological morbidity may be observed in CS patients with some specific clinical characteristics, namely female sex, age $<$ 50 yrs, lower educational levels, with strict adherence to restrictive measures, as well as in CS patients currently under GC replacement treatment or pituitary-directed drugs. Therefore, an empowered, focused psychological follow-up may be required in these CS patients during national lockdowns.

Acromegaly and aging: a double hit against quality of life?

Irene Gagliardi[1], Sabrina Chiloiro[2], Maria Vallillo[2], Marta Bondanelli[1], Stefano Volpato[1], Antonella Giampietro[2], Antonio Bianchi[2], Laura De Marinis[2], Maria Chiara Zatelli[1] & Maria Rosaria Ambrosio[1]
[1]Section of Endocrinology, Geriatrics & Internal, Dept of Medical Sciences, University of Ferrara, Italy; [2]UOC Endocrinology and Diabetology, Department of Translational Medicine and Surgery, Fondazione A Gemelli, IRCCS, Universitaà Cattolica del Sacro Cuore, Italy

Introduction
Acromegaly patients (ACRO) show increased morbidity that affects health and quality of life (QoL). Elderly ACRO are going to increase in the next few years, but evidence regarding their management is lacking.
Aim
To evaluate physical, functional and cognitive performances of elderly ACRO and the relationship with QoL.
Methods
Multicenter case-control study conducted on 42 older ACRO ($\geq$ 65 years) compared to an age- and gender-matched control group (CTR). Each patient underwent a multidimensional geriatric evaluation. QoL was tested with SF-36 questionnaire.
Results
Mean age in both groups was 73 $\pm$ 6 years and female gender was most represented (69%). 13 ACRO were in remission and 29 had active disease controlled by medical therapy except for one patient. ACRO showed worse mobility skills, poorer functional status assessment and lower cognitive evaluation scores than CTR ($P<0.05$). Age negatively correlated with mobility skills, instrumental and basic daily activities execution (IADL and BADL) and cognitive performance in ACRO ($P<0.05$). ACRO presented less satisfactory scores in 5 out of 8 SF-36 questionnaire domains as compared to CTR: physical activity (PA), physical pain (PP), general health (GH), vitality (V), social activities (SA) ($P<0.05$). PA, V and SA scores worsened with the increasing number of drugs and comorbidities ($P<0.01$). Increasing BMI positively correlated with better PA scores, but no associations were found between BMI and mobility skills. In ACRO, better mobility, IADL, BADL and cognitive performances correlated with more satisfactory PA, PP, GH, V and SA scores ($P<0.01$). Mobility skills, BADL, IADL and cognitive evaluation strongly correlated with all 8 SF-36 domains in ACRO ($P<0.01$). Conversely, no correlations were found in CTR. All comorbidities were more frequent in ACRO than CTR. Musculoskeletal and bone diseases were more frequent in ACRO than in CTR (52% vs. 12%; 64% vs. 10%; $P<$ 0.05) and independently associated with geriatric outcomes in ACRO.
Conclusions
Elderly ACRO show worse performance in mobility skills, functional and cognitive status as compared to no acromegaly patients, supporting increased frailty worsening with aging. Poorer geriatric outcomes directly affect many aspects of QoL and health self-perception. A major prevalence of comorbidities in ACRO group might explain these discrepancies. Our data support the inclusion of a multidimensional geriatric evaluation in routine clinical practice to improve elderly ACRO management and, consequently, ACRO QoL. Further studies are needed to identify the most appropriate geriatric tools.

A systematic literature review to evaluate extended dosing intervals in the pharmacological management of acromegaly

Maria Fleseriu[1], Zhaoyun Zhang[2], Kate Hanman[3], Keval Haria[3], Aude Houchard[4], Sheila Khawaja[5], Antonio Ribeiro-Oliveira[6] & Monica Gadelha[7]
[1]Pituitary Center at Oregon Health & Science University, Portland, United States; [2]Fudan University, Shanghai, China; [3]Costello Medical, London, United Kingdom; [4]Ipsen, Boulogne-Billancourt, France; [5]World Alliance of Pituitary Organizations, Zeeland, Netherlands; [6]Ipsen, Cambridge, United States; [7]Universidade Federal de Rio de Janeiro, Rio de Janeiro, Brazil

Background
Acromegaly is a rare disorder characterized by excess growth hormone (GH) and insulin-like growth factor 1 (IGF-1). Extended dosing intervals (EDIs) of pharmacological treatments may reduce patient burden and costs compared with standard dosing. This systematic literature review (SLR) investigated treatment of acromegaly at EDIs.
Methods
MEDLINE/Embase/the Cochrane Library (2001–June 2021) and key congresses (2018–2021) were searched for relevant literature with a dual reviewer process; identified SLR bibliographies were also reviewed. Included publications reported efficacy/effectiveness, safety, humanistic, and economic outcomes in longitudinal/cross-sectional studies in adult patients with acromegaly. Interventions included EDIs of lanreotide autogel (LAN), octreotide long-acting release (OCT), and pasireotide (all administered less often than every four weeks), oral octreotide (less than twice daily), pegvisomant (PEG; less than once daily), and cabergoline (less than twice weekly), with no comparator required. PROSPERO 2021: CRD42021278922.
Results
In total, 35 publications reported on 27 studies: 14 PEG, 9 LAN, and 4 OCT (monotherapies/combination therapies) at EDIs. No identified studies assessed oral octreotide, pasireotide, or cabergoline EDIs. Baseline characteristics differed across studies. As compared with Baseline, treatment at EDIs resulted in reduced IGF-1 levels in 12/16 studies assessing LAN, OCT, or PEG (7–104 patients treated at EDIs) and GH levels in 5/6 studies (LAN/OCT; 15–32 patients). Normalized IGF-1 and/or GH was achieved/maintained in 70%–100% of patients in 12/13 studies (LAN/OCT/PEG; 15–124 patients). Proportions of patients experiencing adverse events ($n=4$ studies reporting overall events; LAN/OCT/-PEG; 8–96 patients) and discontinuing treatment ($n=9$; LAN/OCT/PEG; 7–124

patients) were similar across EDI and standard regimens. Health-related quality of life (HRQoL) improvement from Baseline was reported in 9/10 studies (LAN/OCT/PEG; 7–109 patients) and did not deteriorate with EDIs vs standard regimens. Patients preferred EDIs (2/2 studies; LAN/OCT; 8–112 patients), and satisfaction with EDIs was high (2/2 studies; LAN/OCT; 13–109 patients). Reduced costs were observed with EDIs vs standard regimens in 3/3 studies (9–23 patients) with LAN (120 mg every 6 vs 4 weeks), OCT (20–30 mg every 6–12 vs 4 weeks), and PEG (40–160 mg weekly vs 15–60 mg daily, both with LAN/OCT).
Conclusion
Clinical, safety, and HRQoL outcomes in patients with acromegaly were similar and costs lower with EDIs vs standard regimens. Satisfaction was high with EDIs. Variation in endpoints and small, heterogenous patient populations precluded conducting meta-analyses. Physicians should consider EDIs where appropriate.

Gene therapy of growth hormone resistant dwarfism in the laron mouse model – comparison of two doses

Kian Chuan Sia[1], Shu Uin Gan[1], Siti Humairah Mohd Rodhi[1], John J. Kopchick[2], Michael J. Waters[3] & Kok Onn Lee[1]
[1]National University of Singapore, Singapore, Singapore; [2]Ohio University, United States; [3]The University of Queensland, Australia

Growth hormone receptor (GHR) defective Laron Syndrome (LS) has been treated with daily subcutaneous recombinant insulin-like-growth factor 1 (IGF1) injections lasting many years. We have reported the results of treatment of 4-5 week old Laron dwarf mice (GHR-/-) with a single injection of an adeno-associated virus vector with a murine GHR (AAV-GHR) and a liver specific promoter at a dose of 4×10^{10} vector genome per mouse (Sia *et al*, Gene Therapy 2022).
Methods
In the present study, we report the results of increasing the dose to four times our earlier reported dose: 16 X 10^{10} vector genome per mouse. In both groups of mice, low dose (previous 4 X 10^{10}) and high dose were injected at the same age of 4-5 weeks. Mice injected with the same doses of AAV-Luciferase were used as controls. The mice were monitored for a total of 20 weeks, after which they were euthanized. The organs were harvested and weighed. Serum was obtained for analyses.
Results
The serum growth hormone (GH) levels decreased, and IGF1, IGF binding protein 3 (IGFBP3) and acid labile subunit (ALS) increased compared to the respective controls. There was a significant increase in body weight and length with both doses, but the difference between the two doses was not statistically significant. All the major organs increased in weight and size, but there was no significant difference between the 2 doses.
Conclusion
Surprisingly, increasing the single dose by four times did not result in a significant increase in the response.

Recovery of pituitary dysfunction following surgery and radiotherapy in non-functioning pituitary macroadenomas

Ziad Hussein[1,2], Hani J Marcus[3], Joan Grieve[3], Neil Dorward[3], Peirre Bouloux[1] & Stephanie Baldeweg[1,4]
[1]University College London, United Kingdom; [2]Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom; [3]National Hospital for Neurology and Neurosurgery, United Kingdom; [4]University College London Hospitals Nhs Foundation Trust, United Kingdom

Background
Hypopituitarism is often part of the presenting clinical manifestation for patients with non-functioning pituitary macroadenomas (NFPMs). Rate of recovery of hypothalamic-pituitary endocrine axes following therapy is uncertain with no clear predictive factors.
Aims
The aim of this study was to assess the degree of hypopituitarism recovery following surgery and radiotherapy in patients with NFPMs.
Methods
All patients treated with surgery and radiotherapy for NFPMs between 1987 and 2018 with more than 6 months follow-up were identified. A retrospective case note review was performed.
Results
In total, 383 patients were identified, 256 patients (256/383; 67%) were men. The median age was 57 years (IQR 48-67) with median follow-up of 5 years (IQR 2-9). At diagnosis, growth hormone deficiency occurred in 115 patients (115/273; 31%), hypogonadotropic hypogonadism in 160 patients (160/375; 43%), 132 patients (132/375; 36%) recorded to have adrenal insufficiency and 157 patients (157/375; 42%) developed secondary hypothyroidism. Panhypopituitarism was reported in 100 patients (100/377; 26%). Surgery only was performed in 318 patients (318/383; 83%) while 65 patients (65/383; 17%) needed surgery and radiotherapy to control tumour relapse. The degree of pituitary insufficiency recovery after NFPMs therapy is shown in the table. The combination of surgery and radiotherapy was associated with less likelihood of improvement in the case gonadotropins and TSH deficiencies as well as anterior hypopituitarism to patients who underwent surgery only. Notably, none of TSH deficient patients regained normal thyroid function post irradiation. Younger age was associated with a higher rate of improvement in gonadotroph deficiency ($P=0.004$), secondary hypocortisolism ($P=0.01$) and anterior hypopituitarism ($P=0.006$). Gender and extent of resection of NFPA on postoperative MRI scan was not related to pituitary recovery.

Table 1

	Total	Surgery	Surgery and radiotherapy	*P* value
GH	28/115 (24%)	27/99 (27%)	1/16 (6%)	0.1
FSH/LH	36/160 (23%)	35/137 (26%)	1/23 (4%)	0.02
ACTH	41/132 (31%)	38/113 (33%)	3/19 (21%)	0.2
TSH	20/157 (13%)	20/130 (15%)	0/27 (0%)	0.03
Panhypopituitarism	32/100 (32%)	31/87 (36%)	1/13 (8%)	0.06

Conclsion
Recovery of pituitary hormone deficit may occur post NFPMs therapy. Factors associated with higher probability of reversal of pituitary hypofunction remain not fully understood. Patients should have regular endocrine evaluation post treatment to assess improvement in pituitary hypofunction and the need for long term replacement therapy.

Liver steatosis in an *in vivo* model of hyponatremia secondary to SIAD

Giada Marroncini[1], Laura Naldi[1], Cecilia Ancheschi[1], Benedetta Fibbi[2] & Alessandro Peri[1]
[1]University of Florence, Experimental and Clinical Biomedical Sciences "Mario Serio", Firenze, Italy; [2]Careggi University Hospital, Endocrinology, Firenze, Italy

Hyponatremia is the most frequent electrolytic disorder in clinical practice. It is estimated that in about 50% of cases hyponatremia is secondary to the syndrome of inappropriate antidiuresis (SIAD). Hyponatremia is associated with a worse outcome and with increased mortality in several diseases, including cancer. *In vitro* and *in vivo* evidence shows that low [Na^+] is associated with neurological and extra-neurological alterations, which include for instance bone demineralization, leading to osteoporosis. In order to better elucidate tissue alterations associated with reduced [Na^+], we developed and characterized an *in vivo* model of hyponatremia secondary to SIAD, induced in a total of 38 Fox $^{nu/nu}$ mice by subcutaneous infusion of the vasopressin analogue 1-deamino [8-D-arginine] vasopressin (dDAVP) via osmotic minipumps for a total of 14 days. Mice were randomly divided into three experimental groups and sacrificed at different times: two groups were infused with 0.3 and 0.5 ng/h dDAVP, respectively (A and B, $n=11$ for each group) and one control group was infused with isotonic saline solution (0.9% NaCl) (C, $n=16$). After the initiation of dDAVP infusion, mice gained weight, urinary volume was reduced and urine osmolarity increased. Starting from a baseline serum [Na^+] of 151 $\pm$ 1.57 mEq/l (mean + SE), a serum

[Na^+] of 131.01 ± 5.76 mEq/l and 116.7 mEq/l ± 5.19 mEq/l was achieved in group A and B, respectively, at the end of dDAVP administration. The day of sacrifice different organs were collected, fixed and processed for histological analysis. In particular, we focused on liver, because evident morphological alterations were observed in hyponatremic mice. Specifically, peripheric steatosis was observed, with accumulation of lipid droplets into hepatocytes and collagen fibers. Western blot analysis of proteins involved in hepatic lipid metabolism confirmed the increased lipogenic status associated with the progressive reduction of serum [Na^+]. The expression of the heme oxigenase-1 (HMOX1) gene, which we had previously found to be upregulated in low [Na^+], significantly increased both in hepatic stellate cells and in Kupffer cells, as confirmed by serial immunohistochemical analysis for α-Smooth Muscle Actin, F480 and HMOX-1. In view of these original findings, we hypothesize that hyponatremia might be consider a trigger for liver steatosis. This observation has a potential impact on clinical grounds, also because liver steatosis is known to possibly evolve into cirrhosis and ultimately into cancer.

Growth hormone-releasing hormone (GHRH) promotes survival and proliferation of neural stem cells and reduces amyloid-β-induced toxicity

Francesca Pedrolli[1], Dana Banfi[1], Iacopo Gesmundo[1], Michela Guglielmotto[2,3], Elena Tamagno[2,3], Andrew V. Schally[4], Ezio Ghigo[1] & Riccarda Granata[1]
[1]Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; [2]Department of Neuroscience, University of Turin, Italy; [3]Neuroscience Institute Cavalieri Ottolenghi Foundation (NICO), University of Turin, Italy; [4]Division of Endocrinology, Department of Medicine, University of Miami Miller School of Medicine, Florida, Miami, United States

Neurogenesis, the process by which new neurons are generated from precursors, persists in discrete regions of the adult hippocampus. The hippocampus is critical for learning and memory and is the main target of Alzheimer's Disease (AD), which causes massive neuronal death, reduction in neurogenesis, and impairment in cognitive functions. Therefore, preventing neuronal loss or increasing the production of new neurons may represent a potential therapeutic strategy to reduce the AD-induced cognitive decline. Growth hormone-releasing hormone (GHRH) and its agonistic analogs, apart from promoting growth hormone (GH) secretion from the pituitary, exert many peripheral functions, including stimulation of cell survival, cardioprotection and neuroprotection. Furthermore, expression of GHRH, as well as GHRH-receptor (GHRH-R) and its splice variants (SVs), has been demonstrated in different brain regions, including the cerebral cortex, cerebellum, hippocampus, and brain stem cells. To date, however, the role of GHRH on neurogenesis and neuroprotection is still unknown. Thus, we aimed to investigate the role of GHRH on survival, proliferation, apoptosis, and differentiation of rat hippocampal neural stem cells (NSCs), in stress conditions such as growth factor deprivation and amyloid-β peptide 1-42 ($A\beta_{1-42}$)-induced toxicity, and to define the underlying mechanisms. We found the expression of both mRNA and protein for pituitary GHRH-R in NSCs. GHRH dose-dependently increased cell survival and proliferation, while reducing apoptosis in NSCs cultured under both growth factor deprivation and exposure to $A\beta_{1-42}$. These effects were blocked by the GHRH-R antagonist JV-1-36. The underlying mechanisms involved $G_{\alpha s}$/cAMP/PKA/CREB signaling, as demonstrated using specific inhibitors, and phosphorylation of ERK1/2, PI3K/Akt, and GSK-3β but not mTOR/p70S6K. Furthermore, GHRH counteracted the $A\beta_{1-42}$-induced phosphorylation of Tau protein and the inhibition of GSK-3β phosphorylation. GHRH also blocked the effect of $A\beta_{1-42}$ on elevation of the proapoptotic protein BAX and on inhibition of the antiapoptotic protein Bcl-2. In addition, our preliminary results suggest an antinflammatory role of GHRH, via inhibition in the mRNA levels of inflammatory cytokines (IL-6, TNF-α, INF-γ) and ROS activity. Finally, the role of GHRH was investigated on the differentiation of NSCs into neuronal lineages, such as neurons, astrocytes, and oligodendrocytes. Interestingly, GHRH increased the mRNA and protein levels of the neuronal marker *Tuj1*/NeuN and the astrocytes marker *GFAP* while showing no effect on the oligodendrocyte marker *Ripk1*. Collectively, these results indicate a role for GHRH in preventing neuronal loss and promoting neurogenesis, suggesting therapeutic potential for its agonistic analogs in neurodegenerative diseases, such as AD.

The screening and management of diabetes mellitus type 2 in patients with acromegaly- a tertiary centre service evaluation

Harry Gray & Justyna Witczak
Cardiff University, Cardiff, United Kingdom

Introduction
Acromegaly is the result of chronic growth hormone (GH) excess, which leads to decreased insulin sensitivity and increased glucose production, to the extent that the impaired blood glucose regulation (IGR) can be recognised as Type 2 Diabetes Mellitus (T2DM). This project looked to identify whether patients were adequately screened or identified as having T2DM on diagnosis of acromegaly. The secondary aim was to determine whether acromegaly treatment affected glycaemic control in our cohort of patients.
Methods
We included ninety-five patients treated for acromegaly in University Hospital Wales, UK, between 1999 and 2020. Screening IGF-1 and nadir growth hormone following a 75g oral glucose tolerance test (OGTT) results were taken as evidence of diagnosis of acromegaly. HbA1c at the time of acromegaly diagnosis (Pre), post acromegaly treatment (Post) and most recent recording (Latest) were taken as a representation of glycaemic control. Analysis of this data and the graphs produced was done using Rstudio version 4.1.0, a statistical software.
Results
Nineteen patients were diagnosed and treated for diabetes mellitus before the diagnosis of acromegaly was made. Six patients were newly identified to have a blood glucose within diabetic range at OGTT (2 h plasma glucose $>=11.1$ mmol/l) and 5 of them underwent subsequent HbA1c testing. However, this was not the case for those with an impaired glucose regulation (IGR) (two-h glucose = 7.8 -11.1 mmol/l and/or fasting glucose = 6.1-6.9 mmol/l) with only 2 out of 16 having a HbA1c result recorded. From the sub-cohort of 26 patients who were identified as having a raised blood glucose measurement on OGTT and a HbA1c reading at acromegaly diagnosis, 15 (58%) had HbA1c reading done 3-6 months after surgical treatment. The results showed a decrease in mean HbA1c post treatment (mean Pre HbA1c = 63.5 mmol/mol, mean Post HbA1c = 45.7 mmol/mol, $P<0.005$). 22 out of 26 patients (85%) who had "Pre", "Post" and "Latest" HbA1c readings were analysed to determine if acromegaly treatment has a long-term effect on glycaemic control. This showed significant decrease between Pre HbA1c and Post HbA1c ($P=0.0210$). There was no significant difference between Post HbA1c and Latest HbA1c ($P=1.00$).
Conclsion
IGR is a risk factor for diabetes mellitus and cardiovascular disease. Our data showed that improvements could be made in the care of patients with IGR detected in the diagnostic OGTT for acromegaly and in the follow up HbA1c monitoring for those with established diabetes mellitus or IGR who underwent acromegaly treatment.

Thinking horses, finding zebras: a rare case report of a giant cell tumor of the skull in a pediatric patient

Viviana Popa[2], Alexandru Florescu & Cristina Preda
"Sfantul Spiridon" Hospital, Iasi, Romania; [2]Saint Spiridon County Hospital, Endocrinology, Iaşi, Romania

Giant cell tumors are rare, benign but aggressive and locally invasive tumors that usually affect the long bones in the limbs, typically presenting during the 3rd or 4th decade of life. Giant cell tumors of the skull are exceedingly rare, and less than 150 cases have been reported to date, of which less than 10 were described in the pediatric population. Here, we present the case of a 14 year old female that progressively developed severe headaches, blurry vision and diplopia over approximately 4 months. She was initially directed to the Neurosurgery service, where imaging studies revealed a mass, initially presumed to be a craniopharyngioma, on the left cavernous sinus topography, that extended into the sella turcica and compressed the pituitary. Complete resection was impossible due to the close proximity of the mass with the internal carotid artery, so endoscopic transnasal partial resection and a biopsy were performed instead. Histopathological examination along with immunohistochemical staining suggested that the mass was a pituitary adenoma. Endocrinological examination revealed partial corticotroph and tireotroph insufficiency, and substitution treatment with hydrocortisone and levothyroxine was initiated, but the patient was non-adherent. Over the next 6 months, the patient's symptoms worsened, and she was readmitted to the Neurosurgery service, where imaging studies showed the remaining mass had grown to 3 centimeters maximum diameter. A second

endoscopic transnasal partial resection and biopsy were performed. Second biopsy results suggested a giant cell tumor, but recommended determining PTH levels to rule out a brown tumor. Subsequent endocrinological examination revealed moderately elevated PTH levels (*124 pg/ml),* and vitamin D deficiency (serum vitamin D = 10.32 ng/ml). PTH levels normalized (*64.9 pg/ml*) after 6 months of vitamind D treatment (2000 IU daily). Giant cell tumors of the skull bones are exceedingly rare, especially in the pediatric population, but should still be considered in the differential diagnosis of sellar and parasellar masses. This case report is an opportunity to go over the impact of this type of tumor on quality of life, the differential diagnosis process, as well as the therapeutic options and their indications and contraindications in the adult and pediatric population.

Predicting hypogonadotropic hypogonadism persistence in male macroprolactinoma

Yaron Rudman[1,2], Hadar Duskin-Bitan[1,2], Hiba Masri-Iraqi[1,2], Amit Akirov[1,2] & Ilan Shimon[1,2]
[1]Beilinson Hospital, Rabin Medical Center, Institute of Endocrinology, Petah-Tikva, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Objective
To study the baseline characteristics predicting hypogonadotropic hypogonadism (HH) persistence in men with macroprolactinoma following medical treatment with cabergoline.
Design
Retrospective cohort study conducted in a tertiary pituitary center.
Methods
Male patients diagnosed with macroprolactinoma and HH that received cabergoline treatment with subsequent prolactin normalization were included: men that achieved eugonadism, and men that remained hypogonadal. Patient's demographic, clinical and biochemical parameters, sellar magnetic resonance imaging (MRI) and visual fields tests were obtained. Univariate analyses and multivariate logistic regression models for HH persistence were developed to investigate the relative contribution of the predicting factors.
Results
Fifty-eight male patients (age, 49.2 ± 12.6 years) with a median baseline prolactin of 1154 ng/ml (IQR, 478-2763 ng/ml) and adenoma (maximal) diameter of 25.9 ± 14.8 mm were followed for a median of 5.6 years (IQR, 3.0-10.7). All men achieved normoprolactinemia with cabergoline treatment. 12 men (21%) suffered from HH persistence at the end of follow-up, and 46 men achieved eugonadism. Baseline testosterone (1.6 ± 0.7 vs 0.7 ± 0.6 ng/ml; $P < 0.01$), luteinizing-hormone (1.8 ± 1.5 vs 0.4 ± 0.2 mIU/ml; $P < 0.01$) and follicle stimulating-hormone (3.4 ± 2.9 vs 0.9 ± 0.7 mIU/ml; $P < 0.01$) were lower, and prolactinoma diameter (23.7 ± 12.8 vs 34.6 ± 18.9 mm; $P = 0.02$) was larger in men with HH persistence. In addition, suprasellar tumor invasion (RR = 6.6; 95% CI 1.6–27.8), visual field defect (RR = 3.8; 95% CI 1.5–9.3) and hypopituitarism (RR = 6.3; 95% CI 2.6–14.8) were associated with HH persistence. 42 out of 46 men (91%) accomplished eugonadism within the first year following prolactin normalization. In a multivariate logistic regression model, the presence of either VFD and/or hypopituitarism (OR = 11.5; 95% CI 1.88–71.32) and baseline testosterone levels (OR = 0.12; 95% CI 0.02–0.64) remained independent predictors of HH persistence. Adenoma maximal diameter (OR 1.02; 95% CI 0.96–1.07) did not predict HH persistence.
Conclusion
In our cohort of men with macroprolactinoma that reached prolactin normalization with cabergoline treatment, 21% had HH persistence. Low baseline testosterone levels, visual field defect and pituitary hormone deficiency were independently associated with HH persistence. 91% of men accomplished eugonadism within the first year following prolactin normalization. These findings support informed clinical decisions regarding testosterone replacement initiation in men with macroprolactinomas.

Pre and post-surgical pituitary dysfunction increase the risk of mortality in patients with non-functioning pituitary tumors: A long-term cohort study

Arturo Beyhart[1,2], Karla Mariaca[2], Valeria Salva-Crespi[1], Daniela Díaz Catalán[1], Iban Aldecoa[3], Maria L Olondo[4], Bernardo Sanchez-Dalmau[5], Isam Alobid[6], Irene Halperin[2], Mireia Mora[1,2], Joaquim Enseñat[7] & Felicia Alexandra Hanzu[1,2]
[1]IDIBAPS, Group of Endocrine Disorders, Barcelona, Spain; [2]Hospital Clinic, Endocrinology and Metabolism, Barcelona, Spain; [3]Hospital Clinic, Pathological Anatomy Centre, Barcelona, Spain; [4]Hospital Clinic, Image Diagnostic Centre, Barcelona, Spain; [5]Hospital Clinic, Ophthalmology Department, Barcelona, Spain; [6]Hospital Clinic, Otorhinolaryngology, Barcelona, Spain; [7]Hospital Clinic, Surgery Department, Barcelona, Spain

Background
Long-term studies evaluating mortality in patients with non-functioning (NF) pituitary tumors (PitNets) are limited, although standardized mortality ratios (SMR) in these patients are reported to be higher than that of general population. There is also no agreement on predictive factors associated to the increased mortality apart from age at diagnosis and glucocorticoid substitution therapy dose.
Objective
To assess long-term mortality and associated predictive factors in a single-surgeon cohort of patients with NF PitNets.
Methods
Patients < 80 years at diagnosis with a NF PitNet surgically intervened between 2005 and 2015 in the Hospital Clínic Barcelona Spain ($n = 90$, 51 females) were followed until censored date (01 December 2021) exitus or loss of follow up. Standardized mortality ratios (SMRs) were calculated using Catalan death rates from included years. Proportional hazards of mortality predictors were assessed by cox regression models. All-cause mortality survival rates were assessed by Kaplan-Meier curves. All analyses were adjusted by age and sex.
Results
Median follow-up was 7 years (range: 1 month–13 years) with a total patient-years of 808. Fifteen patients (16.6%) (5 females) died during the study period at a mean age of 74 ± 11 years. At half of study follow up (93 months), survival rate was 93% for females and 76% for males ($P = 0.083$). Main causes of death were associated to infections, malignancy, and cardiovascular diseases. Gender, age at diagnosis, corticotroph deficiency at diagnosis, tumor extension to the sphenoid sinus, tumor contact with the optical chiasm and tirotroph affection due to surgery were associated to exitus in univariate analysis ($P < 0.03$). However, only corticotroph deficiency at diagnosis and tirotroph affection due to surgery remained independently associated in multivariate cox regression analysis with a hazard ratio of 2.96 (95% CI, 1.32-7.91) and 3.99 (95% CI, 1.87-18.23) respectively. Kaplan-Meir log rank factor comparison showed that corticotroph deficiency at diagnosis was also associated with a younger death age (73.3 vs 81.9 years, $P = 0.021$). Overall SMR adjusted by age and sex was 3.92 in the whole cohort with respect to Catalan population ($P < 0.001$) and higher SMR for patients with tirotroph affection due to surgery was found (9.02 ($P < 0.001$)).
Conclsion
Although NF PitNets have a benign behavior, patients maintain substantially higher mortality rates than general population. Affections of pituitary hormonal axes either due to the mass effect of the tumor or because of neurosurgery are key risk factors associated to increased and earlier mortality.

Congenital combined pituitary hormone deficiency associated with primary ovarian insufficiency: a case report

Ameni terzi, Nadia Khessairi, yasmine mouelhi, Fatma Chaker & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Congenital combined pituitary hormone deficiency (CCPHD) is a rare disorder characterized by an impaired production of two or more hormones of the anterior pituitary gland. It is linked to different genetic mutations and requires an early diagnosis to prevent burdensome developmental consequences. Primary ovarian insufficiency, disparately is the depletion of ovarian function with loss of functional primordial follicles before the age of 40 years due to multiple etiologies including genetic causes. The association between CCPHD and primary ovarian insufficiency has rarely been documented representing thus an uncommon and unexpected condition that merits case report herein.
Case presentation
A 14-year-old female was referred to our department for delayed growth. Born at term with no history of perinatal insult, she was diagnosed with central congenital hypothyroidism in a pediatric unit and L-thyroxine replacement therapy was started. Within the next few years, the patient presented a decrease in growth velocity. Short stature and delayed development were observed. The anthropometric measurements showed weight 28 kgs (between -3SDS and -2SDS) and

height 121 cms (-4SDS) with height genetic target of 175 cm. Her secondary sexual characters rated S1, P1 and A0 according to Tanner's classification. There were no dysmorphic features. She had delayed bone age in relation to chronological age (bone age according to Greulich and Pyle method: 9 years and 6 months). The evaluation of growth hormone (GH) secretion revealed GH deficiency (GH peak response to insulin: inferior to 0.25 mUI/l; GH peak response to glucagon: 0.51 mUI/l). The insulin tolerance test disclosed corticotropin deficiency. ACTH, Prolactin levels were respectively 21.6 pg/ml, 11µg/l. The further investigation of the pituitary gland via magnetic resonance imaging demonstrated congenital pituitary hypoplasia. The patient started consequently GH and glucocorticoid-supplementary therapy. When she was 16-years old, she had primary amenorrhea associated to absence of secondary sexual characters development. Gonadotropin levels were elevated: FSH was 72.9 UI/l and LH was 26.34 UI/l. Pelvic ultrasound showed uterine hypoplasia. The karyotype was 46 XX. Primary ovarian insufficiency was then diagnosed.
Conclusion
This report outlines an unprecedented coexistence of CCPHD (thyrotropin, somatotropin, corticotropin deficiencies in our sample) and primary ovarian insufficiency. A further genetic analysis is essential although the cause remains unidentified in the majority of cases. Early recognition of these disorders is paramount as delay in replacement therapy can have devastating consequences.

Insulin resistance, glucose and lipid metabolism in patients with PROP 1 mutation –single center, long term observation

Łukasz Kluczyński[1], Bartosz Partyński[1], Damian Rogoziński[1], Anna Bogusławska[1], Agata Zygmunt-Górska[2], Małgorzata Wójcik[2], Jerzy Starzyk[2], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Chair and Department of Endocrinology, Faculty of Medicine, Jagiellonian University Medical College, Krakow, Poland; [2]Department of Pediatric and Adolescent Endocrinology, Chair of Pediatrics, Pediatric Institute, Jagiellonian University, Medical College, Krakow, Poland

Introduction
A mutation in the PROP-1 gene is a rare cause of childhood-onset hypopituitarism. Patients with the disorder usually present with multiple pituitary hormone deficits. The pattern of development and the course of insufficiencies of individual axes remain unclear and affect patients metabolic status. Growth hormone therapy and substitution of other hormones may influence on glucose and lipid metabolism as well.
Aim
To characterize the carbohydrate and lipid metabolism of patients with childhood onset of hypopituitarism caused by PROP-1 mutation on the basis of long term observation in the pediatric/adult endocrinology departments of our university. The mean time of follow-up was 38.3 years (SD 12.8) with the longest observation lasting 62 years.
Methods
A retrospective analysis of metabolic data of 21 patients (12W/9 M) with confirmed PROP-1 mutation was performed. The mean age at the diagnosis was 7.3 years (SD 3.5). All patients present with thyroid, gonadal and somatotropic axes insufficiencies, while secondary hypoadrenalism was diagnosed in 19 cases (in 2 patients – transient).
Results
Body mass index (BMI) was elevated in 11/21 of patients (6/21 – overweight, 5/21 – obesity). At least one lipid abnormality - increased level of total cholesterol (in 9/21, 42.8% of cases, mean value 5.6 mmol/l), low-density lipoprotein (LDL – in 13/21, 61.9% of cases, mean value 3.8 mmol/l) or triglycerides (in 5/21, 23.8% of cases, mean value 1.7) mmol/l or decreased concentration of high-density lipoprotein (HDL - in 7/21, 33.3% of cases, mean value 1.4 mmol/l) was detected in majority of cases (16/21, 76% of patients). All patients had correct levels of fasting glucose (mean value 4.6 mmol/l) and glycolyzed hemoglobin (HbA1c; mean value 5.3%). In one patient oral glucose tolerance test (complete data available for 17/21 of cases) revealed impaired glucose tolerance. Mean values of fasting insulin and C-peptide were 6.92 uU/ml (min. 1.76, max. 19.0), and 1.85 ng/ml (min. 0.73, max. 6.58), respectively. HOMA IR was elevated (>2) in 5 patients. BMI was positively correlated ($P<0.05$, calculated for 17/21 of cases) with level of triglycerides, fasting insulin, HOMA-IR and insulin area under curve (AUC) in OGTT as well as negatively associated with HDL values. Age was corelated positively with HbA1c and glucose AUC in OGTT. Moreover, a significant positive correlation was documented for insulin and TC, LDL as well as triglycerides.
Conclusions
Patients with PROP-1 mutation-induced hypopituitarism characterize with multiple metabolic disturbances. The specific group of patients requires multidisciplinary medical care.

Ectopic lipid deposition and insulin resistance in patients with GH disorders before and after treatment

Mai C. Arlien-Søborg[1,2], Michael Alle Madsen[1], Jakob Dal[1], Thomas Krusenstjerna-Hafstrøm[1], Steffen Ringgaard[3], Nickolaj Skou[4], Morten Lyng Høgild[1] & Jens Otto Jorgensen[1,2]
[1]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark; [2]Aarhus University Hospital, Medical Research Laboratory, Department of Clinical Medicine, Aarhus N, Denmark; [3]Aarhus University Hospital, Department of Clinical Medicine - The MR Research Centre, Aarhus N, Denmark; [4]Aarhus University Hospital, Department of Radiology, Aarhus N, Denmark

Background
Insulin resistance as part of the metabolic syndrome is associated with ectopic lipid deposition. Growth hormone (GH) status also modulates ectopic lipid accumulation but how this associates with insulin resistance in patients with GH disorders is not well established.
Aim
To study body composition, ectopic lipid deposition and insulin sensitivity in acromegaly and adult GH-deficiency before and after treatment.
Subjects and Methods
Twenty-one patients newly diagnosed with acromegaly and twelve patients with adult GH deficiency (GHD) were studied at diagnosis and after treatment. A reference group of twelve subjects was studied on a single occasion. Each study day comprised assessment of body composition with dual-energy X-ray absorptiometry, ectopic lipid deposition in the liver and skeletal muscle by MR spectroscopy, and Homeostatic Model Assessment for Insulin Resistance (HOMA-IR).
Results
Disease control of acromegaly decreased lean body mass (LBM) ($P< 0.000$) and increased the percentage of total body fat (TBF) ($P< 0.000$). GH replacement increased LBM in the GHD patients ($P=0.007$) and decreased the percentage of TBF ($P=0.010$). The intrahepatic lipid content (IHL) increased after disease control in acromegaly ($P=0.004$) to levels resembling a reference group ($P=0.28$), whereas IHL did not change significantly after GH replacement in GHD ($P=0.34$). Insulin resistance (HOMA-IR) improved after disease control of acromegaly ($P<0.000$) and remained unaltered after GH replacement in the GHD patients ($P=0.829$). IHL and HOMA-IR correlated positively in the reference group ($r=0.75$, $P=0.005$) and in GHD patients before ($r=061$, $P=0.038$) and after ($r=0.66$, $P=0.020$) GH replacement, whereas in acromegaly the correlation only manifested after disease control ($r=0.52$, $P=0.038$).
Conclsions
1) GH status is a significant modulator of body composition and insulin sensitivity.
2) GH excess reduces total fat mass and intrahepatic lipid content together with induction of insulin resistance.

The data support the notion that GH-induced insulin resistance is unassociated with hepatic lipid accumulation.

The diagnosis of recurrence during postoperative follow-up of Cushing's disease

Mattia Barbot, Alessandro Mondin, Filippo Ceccato, Pierluigi Mazzeo, Martina Lazzara, Daniela Regazzo & Carla Scaroni
University Hospital of Padova, Endocrinology Unit, Department of Medicine-DIMED, Padova, Italy

Introduction
Transsphenoidal surgery (TSS) is the first-choice treatment in Cushing's disease (CD) with an immediate success rate of 70-80%. Unfortunately, due to the high rate of post-operative recurrences, CD patients require life-long surveillance.

However, there is no consensus on how to follow these patients after TSS to early diagnose relapses. The aim of the study was to find reliable predictors of recurrence after neurosurgery in CD.
Material and methods
Fifty-five CD patients (f/m = 43/12, median age 39, IQR 32-49 years) in remission after TSS (median 100, range 36–146 months) were included. Remission was defined by the presence of at least 2 of the following criteria: i) low-undetectable postoperative serum cortisol; ii) prolonged glucocorticoid replacement therapy; iii) normal urinary free cortisol (UFC) and late-night salivary cortisol (LNSC) for at least 12 months after surgery; iv) serum cortisol <50 nmol/l after 1 mg-DST. All patients were submitted to desmopressin (DDAVP) test in the diagnostic phase and were re-tested, at least once, 6-12 month after surgery.
Results
Thirteen patients (24%) recurred after a median time of 43 months (IQR 18-65). There were no differences in age and disease severity at time of diagnosis between patients who recurred and those in long-term remission, whereas macroadenomas were more frequently found in recurrent patients ($P=0.003$). No differences in histological features were recorded. Early post-operative serum cortisol was markedly lower in patients who remained in remission [55.5 (32.3-97) vs 120 (57-250), $P=0.024$], even though there was some degree of overlap between groups. A threshold of 63 nmol/l for serum cortisol was able to identify patient at high risk of relapse with sensitivity (SE) of 77% and specificity (SP) of 69%. Patients with recurrence displayed a greater ACTH and cortisol response to DDAVP test compared to those in prolonged remission ($P<0.0001$). An absolute increase in ACTH >7.6 ng/l was identified (AUC = 0.8796; 95%CI:75–100) as the best predictor of recurrence, with SE of 85% and SP of 83%. At 6 and 12 months from TSS, no differences in UFC and LNSC were observed between groups.
Conclusions
The presence of corticotroph macroadenoma is a risk factor for CD relapse. Early post-operative serum cortisol level is a reliable indicator of surgical outcome but DDAVP test is far more accurate to predict future recurrence. The re-appearance of a positive response to this test precedes the increase in LNSC and UFC by several months, thus patients displaying such alteration should be closely monitored.

Evaluation of copeptin levels during glucagon stimulation test in children with suspected growth hormone deficiency

Emanuele Ferrante[1], Federico Giacchetti[1], Rita Indirli[1,2], Eriselda Profka[1], Giulia Rodari[1], Claudia Giavoli[1,1], Giovanna Mantovani[1,2] & Maura Arosio[1,1]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Italy

Introduction
Glucagon stimulation test is one of the recommended growth hormone provocation tests for diagnosing growth hormone deficiency in children. In adult patients, recent data showed that glucagon administration is able to stimulate the release of copeptin, the stable C-terminal glycopeptide of the AVP prohormone whose evaluation during hypertonic saline infusion represents the gold standard for the differential diagnosis of polyuria/polydipsia. However, similar data on pediatric population are still lacking. Aim of this study was to evaluate copeptin levels during glucagon test in children with suspected GH deficiency and to correlate its secretion with that of glucose, GH and cortisol.
Methods
Twenty-one children (10 females, mean age 10.3 ± 2.9 years) with suspected growth hormone deficiency were studied during glucagon stimulation test (30 μg/Kg, maximum 1 mg intramuscolarly). Of these, 20 patients had normal posterior pituitary function, and one patient had well-established central diabetes insipidus. Blood samples for measurement of glucose, GH, cortisol and copeptin were taken at baseline and 60, 90 120, 150 and 180 minutes after glucagon administration.
Results
Median basal copeptin levels in 20 patients without diabetes insipidus were 4.1 pmol/l (interquartile range: 3.3-6.7). During glucagon test, a significant increase of copeptin was recorded 120, 150 and 180 minutes after stimulation (median: 8.1, 10.6 and 8.9 pmol/l, respectively, for all $P<0.01$ vs basal) with a peak after 150 minutes (median: 10.6 pmol/l, interquartile range: 5.4-17.9).
Correlation study for repeated measures showed that copeptin was directly associated with cortisol ($r=0.39$, $P<0.001$) and GH ($r=0.42$, $P<0.001$), and inversely associated with glucose ($r=-0.36$, $P<0.001$). In a multilevel mixed-effects regression model, copeptin was associated with cortisol ($\beta=0.375$, $P=0.01$) and time ($\beta=0.005$, $P<0.001$) but not with GH and glucose. No difference in median copeptin levels at any time point between patients with negative and positive response to glucagon test was found. The only patient with central diabetes insipidus showed low basal and stimulated copeptin levels (basal: 1.5 pmol/l, peak: 2.0 pmol/l)
Conclusion
glucagon administration represents a nonosmotic stimulus of the posterior pituitary also in children, as indicated by increased copeptin levels during the test. Copeptin peak is reached after 150 minutes and its trend seems to be related to cortisol secretion. Further studies are needed in order to clarify the mechanism behind the copeptin stimulation and to confirm the usefulness of this test for the assessment of posterior pituitary function.

Soluble alpha klotho in adult patients with growth hormone deficiency

Junia Ribeiro de Oliveira Longo Schweizer[1,2], Katharina Schilbach[1], Michael Haenelt[1], Anica Gagliardo[1], Sylvere Störmann[3], Jochen Schopohl[3] & Martin Bidlingmaier[1]
[1]LMU Klinikum; Med. Klinik und Poliklinik IV/Endokrinologie, Munich, Germany, Endokrinologie, Endokrinologisches Labor, München, Germany; [2]LMU Klinikum; Med. Klinik und Poliklinik IV/Endokrinologie, Munich, Germany, München,; [3]LMU Klinikum; Med. Klinik und Poliklinik IV/Endokrinologie, Munich, Germany, München, Germany

Background
We recently have shown a close association of high concentrations of soluble alpha klotho (sαKL) to disease activity in acromegaly. Small pilot studies suggested that sαKL concentrations might be reduced in GH deficiency (GHD) and increase after recombinant human GH (rhGH) therapy. Our aim was to evaluate the potential of sαKL as a biomarker in GHD.
Methods
We evaluated sαKL in comparison to the classical biomarkers GH, IGF-I and IGFBP 3 in different cross-sectional cohorts: adult patients with GHD (AGHD) without ($n=80$; A) or with rhGH ($n=57$; B), patients without GHD having either NFPA ($n=20$; C) or prolactinoma ($n=30$; D), and in healthy subjects ($n=199$; E). Furthermore, 22 patients were evaluated longitudinally, before and during rhGH therapy.
Results
As expected, GH, IGF-I and IGFBP 3 were lower in AGHD without rhGH (A) compared to the non-AGHD groups (C, D and E), and increased with rhGH therapy (B) ($P<0.05$ for all comparisons). SαKL concentrations in the cohorts were as follows (median (interquartile ranges); all pg/ml: A: 612 (468-785), B: 668 (468-801), C: 853 (687-3-962), D: 1036 (827-1399) and E: 869 (720-1122). sαKL was significantly lower in AGHD without rhGH (A) compared to NFPAs (C), prolactinomas (D) and healthy subjects (E) ($P<0.05$ for all comparisons) but was not higher in AGHD patients with rhGH therapy (A vs. B, $P>0.99$). Instead, sαKL concentrations in AGHD patients with rhGH remained lower compared to patients with prolactinoma and healthy controls (B vs. D and E, $P<0.0001$), and tended to remain lower compared to NFPAs (B vs. C, $P=0.09$). However, in the longitudinal cohort, sαKL increased with rhGH (599 (469-762) vs. 728 (605-926)) as did IGF-I (μg/l): 48.5 (38.7-62.2) vs. 142 (108-162), and IGFBP 3 (μg/l): 2681 (1840-3524) vs. 3270 (2541-4257), $P<0.001$ for all).
Conclusion
Our study suggests that sαKL is lower in AGHD than in patients with prolactinoma, NFPA and healthy subjects. During longitudinal assessment in the same patients, a significant increase in sαKL is seen in GHD subjects treated with rhGH. However, in contrast to situations of GH excess, where sαKL is greatly elevated, in GHD before and after treatment with rhGH, it remains within the normal range also seen in normal subjects and patients with pituitary disorders without GHD.

Metyrapone vs osilodrostat in the short-term therapy of endogenous Cushing's syndrome: results from a retrospective single center analysis

Mario Detomas[1], Barbara Altieri[1], Timo Deutschbein[1,2], Martin Fassnacht[1] & Ulrich Dischinger[1]
[1]University Hospital Würzburg, Würzburg, Germany; [2]MEDICOVER Oldenburg MVZ, Oldenburg, Germany

Background
Although surgery is considered the first-line treatment for patients with endogenous Cushing's syndrome (CS), medical therapy is often required to control severe hypercortisolism. Metyrapone and osilodrostat are inhibitors of 11β-hydroxylase that have not been directly compared yet.
Methods
Retrospective analysis of patients with adrenocorticotropin (ACTH)-dependent and ACTH-independent CS treated with metyrapone or osilodrostat (as monotherapy) for at least one month. Serum cortisol and 24h-urinary free cortisol (24h-UFC) were analyzed at baseline (T0), after 2 weeks (T1), 1 month (T2) and 3 months (T3) of therapy. Furthermore, serum potassium and blood pressure were evaluated.
Results
16 patients with CS (8 under metyrapone and 8 under osilodrostat) were identified. Despite heterogeneity, both groups showed comparable mean 24h-UFC levels at T0 (757.8 µg/24h under metyrapone vs 816.9 µg/24h under osilodrostat; n.s.). From T0 to T1, the decrease of 24h-UFC was less pronounced under metyrapone than osilodrostat (-21.3% vs -68.4%; median drug dose: 1000 mg vs 4 mg). This tendency persisted at T2 (-37.3% vs -50.1%; median drug dose: 1250 mg vs 6 mg). A substantial difference in potassium levels at T3 was identified (-10.9% under metyrapone vs +14.5% under osilodrostat from T0). Furthermore, a more prolonged QTc-interval was observed under osilodrostat than under metyrapone (455.3 ms vs 432.5 ms). From T0 to T2, the number of antihypertensive drugs decreased under osilodrostat.
Conclsion
Although both of the drugs are efficient in reducing cortisol levels, osilodrostat seems to induce a faster reduction of cortisol levels and a faster control of blood pressure.

Inferior petrosal sinus sampling for pituitary neuroendocrine tumors localization in cushing's disease

Paloma Moreno-Moreno, M[a] Rosa Alhambra Expósito, Ángel Rebollo-Román, Aura D. Herrera-Martínez & María Ángeles Gálvez-Moreno
Reina Sofia University Hospital, Endocrinology and Nutrition, Córdoba, Spain

Objective
Cushing's disease (CD) is the most common cause of hypercortisolism after iatrogenic origin, it represents approximately 70% of patients with endogenous Cushing's syndrome (CS) and ectopic ACTH secretion (10%). CD is caused by a corticotropin-secreting pituitary neuroendocrine tumor (ACTH-secreting Pit-NETs), 95% of cases as a microadenoma. In ACTH-dependent CS, differential diagnosis between CD and ectopic CS must be established. 40% of CD cases, any tumor is observed in the contrast-enhanced pituitary magnetic resonance imaging (MRI), and among the detected lesions, 85-87% are microadenomas Objective: to evaluate the usefulness of inferior petrosal sinus catheterization in the diagnosis of Cushing's disease, the intrahypophyseal location of the ACTH-secreting Pit-NETs.
Patients and methods
A retrospective observational study was performed in all patients with CS that underwent bilateral inferior petrosal sinus catheterization (BIPSS) in a single center. Statistical analysis: Chi square test with Yate's correction s and Cohen's coefficient k were used as a measure of agreement between the exploratory techniques. Sensitivity, specificity, positive and negative predictive value, and positive and negative probability coefficient were also calculated. Chi-squared test was used to compare categorical data. Statistical analyses were performed using SPSS® statistical software version 20.
Results
BIPSS was performed in 33 patients, 75.8% women, age 41.79 ± 14.60 years. BIPSS achieved a sensitivity of 96.67 %, IC 95% (0.80 − 0.99) and a specificity 100%, IC 95% (0.31 − 0.96). Positive predictive value was 100%, IC 95% (0.85 − 0.99) and the negative predictive value was 75%, IC 95% (0.21 − 0.98). The global value or efficiency of the procedure 96.97% IC 95% (0.82 − 0.99). An intersinus gradient ≥ 1.4 was observed in 25 patients. In those who underwent surgery, tumor localization during surgery coincided with BIPSS results in 80% of cases; Kappa index was 0.658 (P 0.000), so there is good agreement between the lateralization result of the BIPSS and the location by surgery for the location of the ACTH-producing adenoma. No complications were recorded after BIPSS.
Conclusions
BIPSS plays a key role in the diagnosis of CD, and its results in the location of the tumor must be taken into account, since it shows good precision when compared with the surgical location of the tumor.

GH-secreting pituitary adenoma: dura mater invasion is not a predictor of acromegaly persistence after trans-sphenoidal surgery

Nunzia Prencipe[1], Giuseppe Diperna[2], ALESSANDRO MARIA BERTON[1], Bianca Baldassarre[2], Chiara Bona[1], Raffaele De Marco[2], Fabio Bioletto[1], Silvia Grottoli[1] & Francesco Zenga[2]
[1]University of Turin, Department of Medical Sciences, Turin, Italy; [2]Neurosurgery, University of Turin, Department of Neuroscience, Turin, Italy

Background
Despite the benign nature of pituitary adenomas, microscopic examination of surgical specimens showed that dural invasion occurs in about 42-85% of cases. No studies about dura mater invasion were conducted specifically in acromegaly, so the aim of the present study was to evaluate the relationship between histologically verified dural invasion and the "aggressiveness" features of GH-secreting adenomas.
Methods
A prospective study included all consecutive acromegaly patients that underwent neurosurgery (NS) at the Division of Neurosurgery of the University of Turin, between 2017 and 2020. All patients were operated with a 3DHD endoscope using an endoscopic endonasal approach by a single skilled neurosurgeon. For each patient the fallowing data were collected: 1) clinical, biochemical and morphological data at diagnosis, three months and one year after NS; 2) pathological features (dura mater invasion, immunohistochemical analyses, proliferation index Ki67 and p53, granulation pattern; 3) radiological findings at RMI scan, in particular intensity on T2-wighted images.
Results
35 acromegaly patients enrolled. Eleven patients had dura invasion (31%), while 24 did not have (69%). No significant differences were found in gender and age at diagnosis between INV+ and INV-. No difference was found in IGF-1 levels (INV+: 752 ng/ml, [548-987] ng/ml vs INV-: 664 ng/ml, [394-894] ng/ml) and IGF-1/ULN (2.5, [2.3-3.3] vs 2.4, [1.68 - 3.1]). GH levels at diagnosis were higher in INV+ (84.5 ng/ml, [29-153] ng/ml vs 17.2 ng/ml, [4.4-36] ng/ml, $P=0.02$). ROC curve analysis for GH levels at diagnosis showed that GH > 27 ng/ml was able to distinguish patients with dura mater invasion (AUC 0.760;$P=0.006$, sensitivity 80% and specificity 73%) and patients with GH > 27 ng/ml at diagnosis had a 10 times higher risk of dura invasion (Odds ratio 10.7; IC 95% 1.74-65.27). No difference was found in morphological, radiological and pathological features. We also analysed predictive parameters of healing. IGF-1 levels at diagnosis (625.5 ng/ml; [391.5 -867.5] ng/ml vs 872 ng/ml; [812 − 1011.5]ng/ml, $P=0.03$) and proliferation activity (Ki-67≥3%) were significantly lower in cured patients (16% vs 67%, $P=0.03$), while disease remission rate at three months was greater (100% vs 44%, $P=0.002$) compared to persistent disease patients.
Conclusion
The only parameter significantly associated with the dura mater invasion is GH levels at diagnosis. The dura mater invasion does not affect the possibility of recovery from acromegaly at 12 months. We confirmed that lower IGF-1 levels at diagnosis and lower Ki-67 are significantly associated with healing after surgery.

Over the last two years, COVID-19 outbreak and lockdown have exerted a remarkable psychological burden in the general population. Such an impact is supposed to be even worse in acromegaly, known to induce a severe psychological impairment due to its somatic disfigurements and systemic comorbidities. The current observational study aimed at investigating the impact of COVID-19 outbreak and lockdown on psychological health in acromegalic patients as compared to non-acromegalic healthy control population. During the last three weeks of lockdown, 246 patients (110 males, 136 females, age 51.4 $\pm$ 11.7 years) with history of acromegaly or active acromegaly under treatment from 9 Italian acromegaly referral centers and 246 age, gender, and marital status-matched controls were telematically administered several psychological questionnaires, aiming at evaluating the spectrum of anxiety (GAD-7) and depression (PHQ-9), and perceived stress (PSS). For all questionnaires, higher score indicated greater psychological impairment. A questionnaire evaluating quality of life in acromegaly, AcroQol, for which the higher score indicates a better quality of life, was administered exclusively to patients. Compared to controls, patients showed a significantly higher prevalence of moderate ($P=0.046$) and severe depression ($P=0.015$), and severe anxiety ($P=0.024$). Both in patient and controls, females showed higher scores in the entire series of psychological tests performed compared to males ($P<0.001$). Moreover, male patients showed significantly higher anxiety ($P=0.001$), and depression ($P<0.001$) scores, whereas female patients showed higher anxiety ($P=0.003$) and perceived stress ($P=0.037$) scores compared to respective controls. Glucocorticoid replacement (GR) therapy was significantly associated with higher scores of anxiety ($P=0.01$), depression ($P=0.037$), and perceived stress ($P=0.003$), and lower score of AcroQol ($P=0.038$). Patients with anxiety, depression, and perceived stress were mostly females ($P<0.05$), and patients with anxiety and perceived stress were also associated with low-grade instruction ($P<0.01$) and GR therapy ($P<0.01$). In conclusions, patients who experienced acromegaly had a greater risk of depressive and anxiety disorders as well as perceived stress compared to controls during COVID-19 outbreak and lockdown, thus suggesting the importance of a strict psychological monitoring.

Long-term follow up after remission of Cushing's disease - experience of a single centre

Bojana Popovic[1], Sanja Ognjanovic[1], Dusan Ilic[1], Valentina Elezovic[1], Milica Opalic[1], Lena Radic[2], Mihailo Milicevic[2] & Djuro P. Macut[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Clinic for Neurosurgery, University Clinical Centre of Serbia, Centre for Neurooncology, Belgrade, Serbia

Introduction
Chronic endogenous hypercortisolism in Cushing's syndrome imposes a great clinical burden of comorbidities, some of which might persist even after disease remission. Our aim was to analyze factors that predict long-term comorbidities after surgical remission of Cushing's disease (CD).
Subjects and methods
We retrospectively analyzed 37 patents (91.9% females) aged 39.5 $\pm$ 13.9 years (10-70) with diagnosed CD, treated in our institutions, and followed up during 15 years. Each patient was evaluated for presence of comorbidities [overweight/-obesity, impaired glucose metabolism (impaired fasting glucose, IFG/impaired glucose tolerance, IGT/diabetes, DM), hypertension (HTA), dyslipidemia, osteoporosis, depression], at the time of diagnosis and during follow up of clinical remission. Spearman's rank correlation coefficient was used to test associations between comorbidities and age, BMI, biochemical parameters and hormonal levels (basal cortisol and ACTH level, midnight cortisol level). Multiple regression analysis was used to test predictors of long-term comorbidities after CD remission. Statistical analysis was performed by SPSS software.
Results
At diagnosis, dyslipidemia, HTA, overweight/obesity, osteopenia/osteoporosis, IFG/IGT/DM and depression were present in these patients with frequences of 86.5%, 73.0%, 64.9%, 59.5%, 51.4% and 21.6%, respectively. Aside of 4 patients (10.8%), all the other had 2 or more comorbidities. The number of comorbidities positively correlated with age ($P=0.009$), BMI ($P=0.003$), glycemia ($P=0.018$), and triglyceride levels ($P=0.032$), and negatively with HDL ($P=0.009$); there were no significant correlations wih hormonal levels ($P>0.05$). Majority of patients (81.8%) had pituitary microadenoma. Transsphenoidal surgery (TS) was performed in 34 patients (91.9%), with median of 3 $\pm$ 4 months after diagnosis. After initial surgical success rate of 82.4% (28 patients), 20 patients (58.8%) kept long-term remission. Remission was achieved by bilateral adrenalectomy in 2 additional patients (22 overall, 59.5%), with follow up of 76.9 $\pm$ 60.6 months (1-192). Clinical remission was associated with significant decrease in frequency of overweight/obesity ($P=0.006$), depression ($P=0.004$), and HTA ($P=0.051$) while no significant decrease in frequency of dyslipidemia, IFG/IGT/DM and osteoporosis ($P>0.05$) was observed. A number of comorbidites remained positively associated with age ($P=0.016$), BMI ($P=0.042$), glycemia ($P=0.048$), and level of triglycerides ($P=0.048$), and negatively with HDL ($P=0.019$). In sepwise linear regression analysis the strongest predictors of long-term morbidity were age (B=0.068, $P=0.019$, 95% CI 0.013-0.124) and HDL level (B=-1.218, $P=0.005$, 95% CI -2.434–0.001) at diagnosis of CD.
Conclusion
Cushing's disease is the most prevalent cause of endogenous hypercortisolism, causing significant morbidity in these patients that remains so even after long-term remission. Life-long follow up of cardiovascular outcomes is needed in these patients.

Inferior petrosal sinus sampling in differential diagnosis of adreno-corticotropic hormone (ACTH)-dependent cushing's syndrome: a tertiary centre experience

Cátia Araújo[1], Mafalda Martins Ferreira[1], Joana Reis Guiomar[1], Carolina Moreno[1], patrícia oliveira[1], Carla Baptista[1], Leonor Gomes[1,2], dírcea rodrigues[1] & Isabel Paiva[1]
[1]Centro Hospitalar Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal

Introduction
Inferior petrosal sinus sampling (IPSS) has been considered to be the gold standard for differential diagnosis of Cushing's Disease (CD) and ectopic ACTH secretion (EAS).
Aim
To describe the experience of our centre in performing IPSS, its safety and efficacy; assess remission rates from transphenoidal surgery and clinical course; approach to the difficulty in the etiological diagnosis of ACTH-dependent Cushing's Syndrome.

Methods
In this single centre retrospective study we included 14 patients diagnosed with ACTH-dependent Cushing's Syndrome which IPSS were performed between 2011-2021. The diagnosis of CD was made when the basal central/peripheral ACTH ratio was > 2 and/or the rate after CRH/desmopressin stimulation was > 3. With the inter-sinus ratio > 1.3, lateralization was determined.
Results
2 patients whose IPSS failed due to anatomical variation and vasovagal syncope were excluded. In 12 patients, 7 were female patients. Median age: 48.9 ±11.9 years. Sellar magnetic resonance imaging (MRI) demonstrated pituitary microadenoma in 10 cases. IPSS results were conclusive for diagnosis of CD in 83% of patients (10) and none of them indicated EAS. Lateralization by IPSS and MRI was concordant in 9 out of 10 cases with CD and microadenoma. Inconclusive results in 2 IPSS: 1) blood sample collection into non-EDTA tube; 2) absence of measurement of prolactin and impossibility of assessing correct sampling in the absence of basal central/peripheral ACTH ratio. In 10 of 12 patients whose IPSS showed CD diagnosis, correct lateralization was confirmed by the operation in one patient only. Pathology specimens did not show pituitary adenoma in the other 5 cases. The rate of remission after transsphenoidal surgery was 2 out 6 patients.
Conclusions
IPSS is a safe procedure and an effective test in the differential diagnosis of ACTH-dependent Cushing's Syndrome. In our study, the sensibility of IPSS assessed was 83%, similar to what is described in the previous studies. DDaVP stimulation was equivalent to CRH stimulation. We emphasize the possibility of procedural failures that must be identified. It should be noted that regardless of whether or not there is a pituitary adenoma image on an MRI, IPSS proved to be useful to confirm CD and suggest a lateralization of ACTH secretion.

Pituitary adenoma in multiple endocrine neoplasia type 1 (MEN1) syndrome: a single-center study

Roberta Modica, Alessia Liccardi, Roberto Minotta, Giuseppe Cannavale, Elio Benevento & Annamaria Colao
University of Naples Federico II, Department of Clinical Medicine and Surgery, Endocrinology Unit, Naples, Italy

Background
Multiple endocrine neoplasia type 1 (MEN1), is an autosomal dominant inherited disorder with high penentrance, characterized by the onset of multiple tumors, mainly in parathyroid, pituitary gland and gastroenteropancreatic tract. During the course of the disease pituitary adenomas (PA) occur in 20-65%, rarely as first clinical manifestation, and are often described as larger, more aggressive, and more resistant to conventional therapy than their sporadic counterpart. The aim of this study is to analyse clinical characteristics of PA in a monocentric series of MEN1 patients.
Aim
The clinical charts of all patients with MEN1, referred to the Endocrinology Unit at the Federico II University of Naples from January 2000 to June 2021, were retrospectively evaluated, analyzing epidemiological and clinical data.
Results
We identified 91 MEN1 patients (F/M = 50/41). The prevalence of PA was 49.5% (45 patients) with a slight female preponderance (F/M = 1.36). PA was diagnosed in 92.2% of cases after the diagnosis of MEN1. The mean age at diagnosis of PA was 44.6y (13-75y), this was much lower when PA was identified as the first MEN1 manifestation (28y). PA were microadenoma in 60% (27 patients), and macroadenoma in 40% (18 patients). PA were non-secreting in 44.4% (20 patients), PRL-secreting in 42.2% (19 patients), GH-secreting in 2.2% (1 patients), PRL-GH secreting in 8.8% (4 patients), and ACTH-secreting in 2.2% (1 patients). Symptoms of hormonal hypersecretion and/or compression of adjacent structures were detected in 53.4% (24 patients). Among patients with prolactinomas the M:F ratio was 1/1.11 (11/12 patients), and all 12 affected females had associated symptoms (menstrual irregularities, galactorrhea); while only 2/11 male patients had hyperprolactinemia-related disorders (decreased libido, impotence). With regard to therapeutic treatment, cabergoline was used in 40% (18 patients) of PA, while octreotide was used only in 2.22% (1 patient). Transphenoidal surgery was performed in cases of refractoriness or macro-adenoma-related symptoms in 15.5% of cases (7 patients), and radiotherapy subsequently was necessary in 2.22% of cases (1 patient).
Conclusion
PA within MEN1, are more common in women and are rarely the first clinical manifestation of the syndrome. Importantly, our data suggest that PA do not seem to be more aggressive than sporadic forms and show good response to medical and surgical therapy. A multidisciplinary approach in specialized centers may improve the clinical history of these patients allowing early diagnosis.

Ultrasound of the median nerve in acromegalic patients :changes at 1 year follow up

Ivana Ságová[1,2], Dušan Pávai[1], Marián Mokáň[2] & Peter Vaňuga[1]
[1]National Institute of Endocrinology and Diabetology, Department of Endocrinology, L'ubochňa, Slovakia; [2]Comenius University Jessenius Faculty of Medicine, 1st Department of Internal Medicine, University Hospital Martin, Martin, Slovakia

Background
The aim of our study was to asses changes in the cross sectional area (CSA) of the median nerve by ultrasound in newly diagnosed acromegalic patients 1 year after treatment of acromegaly (transsphenoidal surgery, somatostatine analogues).
Patients and methods
The study included 30 newly diagnosed acromegalic patients (18 females and 12 males) and 30 healthy controls (18 females and 12 males) matched for age, gender and body mass index. Clinical history, physical examinations, laboratory examinations and ultrasound evaluations were performed at baseline and 1 year after treatment of acromegaly.
Results
The CSA of the median nerve was increased in acromegalic patients compared with controls (13.3 ± 2.2 mm^2 vs. 7.6 ± 1.8 mm^2 $P < 0.001$). 1 year after the treatment of acromegaly a significant decrease of growth hormone (GH) and insulin-like growth factor I (IGF-I) levels were achieved. The CSA of the median nerve was significantly reduced 1 year after treatment to 11.7 ±1.8 mm^2 ($P < 0.001$). Positive correlation was found between the levels of IGF- I and CSA of the median nerve in acromegalic patients before treatment ($r = 0.492$, $P = 0.006$).
Conclusion
This study demonstrates reduction in median nerve CSA 1 year after treatment of acromegaly. This changes are closely associated with the reduction of IGF- I levels. Biochemical control of acromegaly is important factor for normalization of the median nerve size.
Keywords
acromegaly, cross sectional area of the median nerve, growth hormone, insulin-like growth factor I, ultrasound

From silent to carcinoma: the genomic alterations landscape of whole spectrum macroadenoma corticotrope pituitary tumors and carcinoma

Keiko Taniguchi[1], Sergio Andonegui-Elguera[1], Gloria Elena Silva Román[1], Eduardo Peña-Martinez[1], Sandra Vela Patiño[1], Ilan Remba-Shapiro[1], Moises Mercado[1] & Daniel Marrero-Rodríguez[2]
[1]Hospital de Especialidades, Centro Medico Nacional Siglo XXI, Instituto Mexicano del Seguro Social., Unidad de Investigación Medica en Enfermedades Endocrinas, Mexico City, Mexico; [2]Hospital de Especialidades, Centro Medico Nacional Siglo XXI, Instituto Mexicano del Seguro Social., Unidad de Investigación Medica en Enfermedades Endocrinas, Mexico City, Mexico

Corticotrope cells give arise to utmost aggressive and to very rare pituitary neoplasias, including pituitary carcinomas, Crooke's cell adenomas (CCA), clinically non-functioning silent corticotrope adenomas (SCA) and the Cushing-provoking pituitary adenomas (CD). The molecular etiopathogenesis of these tumors are still poorly understood. Therefore, we carried out whole exome sequencing to better understand the full genomic landscape single nucleotide variants and copy number variations of the pituitary macroadenoma tumors from corticotrope lineage. Carcinomas show SNV in USP8, TP53, AURKA, EGFR, HSD3B1 and CDKN1A. Whereas in CCA SNV in HSD3B1 and CDKN1A where

common however TP53 and AURKA were present in one each. HSD3B1 and CDKN1A SNV were present in all SCA, followed by EGFR and AURKA. They did not show USP8 SNV. As for the CD only one show USP8 SNV, corresponding to an Nelson syndrome tumor. All CD show TP53 and HSD3B1 SNV. None of the corticotrope tumors showed USP48, BRAF, BRG1 nor CABLES1 SNV. Functioning tumors including carcinoma and CD showed more CNV gains than the non-functioning tumors, carcinoma shares 10q11.22 amplification with benign adenomas, whereas 17q12 characterizes only benign adenomas. The theoretical evolutive development of the corticotrope carcinoma starting from the silent adenomas, if that's the case, shows two main clades, the first and smallest, contain two SCA (2/3) and two CD (2/5), these four adenomas shared SNV profile, potentially indicating the genes needed to be altered to make a transition from silent to overt tumors. ATF7IP characterize this clade. The second and largest clade harbors the CCA (1/1), the carcinoma (1/1), one SCA (1/3) and three CD (3/5). Interestingly, in this clade the carcinoma showed a close relation to CCA and to a CD. This clade could represent the molecular alterations required to make the transition from overt adenoma to a carcinoma, or at least to a more aggressive tumor. In this clade there was clustered a Nelson syndrome CD and the carcinoma, which are very aggressive entities. MSH3 gene characterize this clade. Overall, pituitary carcinoma and CD showed more SNV and CNV genomic alterations compared against CCA and SCA.

Targeting invasive pituitary adenomas: in vitro studies and *in vivo* investigations in a murine model of invasive pituitary tumors obtained by orthotopic pituitary GC cells injection

Fanny Chasseloup[1], Etienne Lefevre[1], Alexandre Dormoy[1], Nataly Ladurelle[1], Tiphaine Mignot[1], Clément Janot[1], Mirella Hage[1], Say Viengchareun[1], Philippe Zizzari[2], Philippe Chanson[1,3], Michael Buchfelder[4] & Peter Kamenicky[1,3]
[1]Université Paris-Saclay, INSERM U1185 ≪ Physiologie et Physiopathologie Endocriniennes ≫, France; [2]Université de Bordeaux, INSERM U1215, Neurocentre Magendie, France; [3]AP-HP, Hôpital de Bicêtre, Service d'Endocrinologie et des Maladies de la Reproduction, Centre de Référence des Maladies Rares de l'Hypophyse, France; [4]Universitätsklinikum Erlangen, Department of Neurosurgery, Germany

Context
Surgical removal is the primary treatment option for pituitary adenomas. However, pituitary surgery is frequently incomplete because of invasion of extrasellar cerebral structures, notably, of the cavernous sinus. Our objective was to study the molecular basis of the cavernous sinus invasion by pituitary adenomas.
Methods
We analyzed a tissue collection of 19 invasive pituitary adenomas with a sample from the intrasellar portion and a sample from the portion invading the cavernous sinus of each adenoma. We used RNA-sequencing to compare gene expression patterns of the invading and intrasellar portions. The implication of one differentially expressed candidate gene in the invasive behavior was first analyzed *in vitro* in lactosomatotroph GH3 and gonadotroph LbT2 cells. We used Transwell Assay to analyze the impact of pharmacologic inhibition of the candidate gene on cell migration and invasion. To study the role of this gene on tumor growth and behavior *in vivo,* we elaborated a model of invasive pituitary adenomas by stereotactic injection of murine somatotroph GC cells into the pituitary gland of female Wistar Furth rats. Twelve adult rats received 20.000 GC cells in each pituitary lobe. Tumor development was assessed fortnightly by 7Tesla MRI. Six of the 12 rats were treated with the pharmacological inhibitor of the candidate gene. Rats were sacrificed 7 weeks after cell injection.
Results
RNA-sequencing identified 159 up-regulated genes and 11 down-regulated genes in the invasive adenoma portions. *In vitro* pharmacological inhibition of the selected candidate gene decreased cell migration and invasion in GH3 cells ($P=0.0205$ and$P=0.0038$) and LbT2 cell ($P=0.0345$ and$P=0.0131$). Amongst the 12 injected rats, 11 (92%) developed invasive pituitary tumors. Tumor growth was rapid, causing death from intracranial hypertensions before the end of the protocol in 7 animals. Pharmacological inhibition tended to slow tumor growth from 30.3 mm^3 /week to 7.8 mm^3 /week ($P=0.12$) and decreased cumulative mortality (83% in untreated animals *vs* 33% in treated animals, $P=0.08$).
Conclusion
We described the molecular signature associated with the invasive behavior of pituitary adenomas and identified a therapeutic target, which is related to pituitary cells migration and invasion in functional *in vitro*studies. Pharmacologic inhibition of this target tended to decrease tumor growth and mortality *in vivo*, however larger numbers of animals are necessary to confirm this pilot observation. Our original approach of orthotopic cell injection into rat pituitaries resulting in tumor development provides a new tool for molecular studies of pituitary tumorigenesis and for pharmacological screening.

The role of HIF-1α and vegfa polymorphism (G634C) in the development of the aggressive pituitary adenomas

Zamira Khalimova[1] & Ozoda Azimova[2]
[1]Republican Specialized Scientific Medical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Medical Center of Endocrinology, Neuroendocrinology, Tashkent, Uzbekistan

Introduction
Although pituitary adenomas are considered benign, some have invasive growth, which is one indicator of aggressiveness. Early prognostic markers of aggressiveness may influence the quality of life improvement in patients with aggressive pituitary adenomas
Objectives
To study the clinical-immunological, molecular-genetic aspects of aggressive pituitary adenomas and to develop new approaches to early diagnosis and treatment.
Materials and methods
83 patients diagnosed with pituitary adenoma were examined. All patients underwent clinical examination and magnetic resonance imaging (MRI), to determine the degree of adenoma invasion by Knops classification. Polymorphism of regions of studied genes in the VEGFA gene of position G634C (rs2010963 locus), the gene HIF-1α C/T (rs11549465 locus) and G-197A in the gene IL-17A, made by the allele method - determined by the PCR method.
Results
Genetic analysis of VEGFA polymorphism showed that heterozygote (G/C) mutation in patients with invasive adenomas was found to be twice as high as 32.7% ($n=17.2$) compared to a control group of 15.7% ($n=13$). Moreover, the C/C homozygote mutation is also observed more in the 7.7% invasive adenoma patient group ($n=4$), which supports the evidence that mechanistic progression of invasive adenomas contributes to angiogenesis mutation through the VEGFA pathway. A heterozygous C/T mutation of the HIF-1A gene was found to be significantly higher ($P=0.02$) in patients with invasive adenomas compared to controls, with 25% ($n=13$) and 9.8% ($n=8$), respectively. While in non-invasive adenomas, this mutation was observed about three times lower. Our results clearly support the argument for the regulatory role of HIF-1A within VEGFA in the development of aggressive pituitary adenoma flow.
Conclusions
Thus, genetic analysis can become a predictor of aggressive behavior of pituitary adenomas and the use of genetic markers in clinical practice will contribute to the prevention of complications of aggressive adenomas.

Transition in endocrinology: predictors of drop-out in a heterogeneous population during long-term follow-up

Martina Romanisio[1], Sara Brasili[1], Tommaso Daffara[1], Alice Ferrero[1], Davide Vimercati[1], Francesca Pizzolitto[1], Rosa Pitino[1], Edoardo Luigi Maria Mollero[1], Marco Zavattaro[1], Simonetta Bellone[2], Marina Caputo[1,3], Gianluca Aimaretti[1] & Flavia Prodam[1,3]
[1]Endocrinology, Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy; [2]Division of Pediatrics, Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy; [3]Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy, Novara, Italy

Aim
To evaluate: 1) clinical and epidemiological characteristics of outpatients transitioned from Pediatrics Endocrine (PED) to Adult Endocrine Department (AED) in a tertiary Centre; 2) transition process characteristics, and predictive factors of drop-out.
Patients and methods
Demographic, clinical, and transition features of 170 consecutive patients with paediatric onset of chronic endocrine or metabolic disease (excluded type 1 diabetes) who transitioned from PED to AED (2007-2020) were retrospectively evaluated.
Results
The age at transition was 18.4 ± 4 years (F:M = 1.2: 1). 93.6% of patients were affected by endocrinopathies (19.4% on a genetic basis), while 6.4% were in follow-up only in a cancer-survivor surveillance protocol. 69.4% of patients had one endocrine disease, 20.0% had 2, and 4.2% of them had 3 or more. 40.0% of subjects suffered also from non-endocrine diseases. The total comorbidity burden was high: 37.1%, 20.6%, and 11.1% of patients had 2, 3, 4, or more diseases. The number of treatments progressively increased and was associated with the number of visits (r 0.349, $P < 0.0001$), and the age at the last visit (r 0.184, $P < 0.0.1$). The number of visits was positively associated with the number of endocrine diseases and the etiology (mainly in hypergonadotropic hypogonadism, hypopituitarism). Patients with obesity had the low number of visits ($\chi2 = 13.850$, $P < 0.05$). 64.7% of patients were adherent to the follow-up, mainly if they had a high number of comorbidities ($\chi2 = 14.473$, $P < 0.01$) or thyroid disorders ($\chi2 = 3.618$, $P < 0.04$). Having performed one visit only was predictive of drop-out ($\chi2 = 18.624$, $P < 0.009$), regardless of pathology. Among cancer survivors, patients treated for central nervous system tumors had the highest adherence.
Conclusions
This is the first study that analyzed a specific transition plan for chronic endocrine diseases on long-term follow-up. The proposed "*one size fits all model*" is not adequate in responding to the different needs of patients. A structured transition plan is an emerging cornerstone. The first visit is crucial in building a trusting relationship between patients and healthcare providers and plays an important role in a successful therapeutic intervention.

Validation of a clinicopathological classification for the prediction of pituitary adenomas: a retrospective cohort study in a PTCOE from 2013 to 2020

Thalía Argüello Gordillo, José Miguel Castro García, Lucía Martinez Gauffin, Artem Kuptsov, Dolores Tejedo-Flors, María Eugenia Torregrosa-Quesada, Javier Abarca Olivas, Luis Concepción, Ignacio Aranda & Antonio Pico
General University Hospital of Alicantet, Alacant, Spain

Introduction
Because of the increase of brain image explorations, the prevalence of pituitary tumours has increased a lot. Although most of them have an indolent behaviour, some behave aggressively, demanding a lot of resources for their management. Therefore, it is very important to identify them as soon as possible. The recent WHO 2017 classification of pituitary tumours gives insights into improving their identification using the immunostaining (IS) of transcription factors (TF) but does not include severity indexes. Therefore, a clinicalpathological classification is necessary. In 2013, Trouillas *et al* proposed a clinical-pathological classification that considered pituitary tumour subtypes along with radiological characteristics of the tumours. However, the identification of the pituitary tumour subtypes was based on the IS of pituitary hormones that gives an inacceptable percentage of Null Cell and unusual plurihormonal tumours. The aim of the present study is to classify a series of pituitary tumours coming from a PTCOE, identified according to WHO 2017 recommendations, and using the clinicopathological classification proposed by Trouillas *et al* 2013.
Methods
A retrospective cohort study including 180 patients with pituitary tumors surgically treated (NES) in a PTCOE from 2013 to 2020. We collected the following information from the electronic medical records: function, IS features (pituitary hormones, Transcription Factors, MIB15 and p-53 IS and mitotic count), and MRI tumour characteristics: size, sinus invasion, optic chiasma displacement and T2 value. We have defined aggressiveness based on the presence of tumour invasiveness defined by pre-operative MRI/endoscopic intraoperative examination plus a Ki67 index $\geq$ 3%. We have analyzed the relative risk and adjusted RR for all variables through the Chi-squared test and logistic regression, respectively.
Results
From the 180 recruited patients we have excluded 64 patients due to lack of adequate MRI follow-up. Age 59 } 16 years, 52% males. Of the 116 patients included for analyses, 75% were non-functioning tumors and 35% were functioning. Of functioning tumors, 7.5% were CTs, 13.9% STs, 5.5% PRLs and 1% TTs. Of NFP tumors: 34.3% were silent gonadotroph tumors (SGT), 8% silent corticotroph tumors (SCT), 1% silent somatotroph tumors (SST), 1% silent lactotroph tumors (SLT) and 1.5% silent tirotroph tumors (STT). Recurrence rate in non-functioning and functioning pituitary tumors were 17.9% and 9.7% respectively. A higher risk of post-surgical recurrence was found in tumors with sinus invasion (RR 2.13 (IC95%: 1.6-2.7; $P < 0.001$)), a T2 ratio higher than 2 (RR 2.7 (IC95% 1.7-4.4, $P < 0.001$)). No statistical significance ($P > 0.05$) was found for Ki-67 index >3%, however when combine this last one with sinus invasion (Trouillas IIb) in multivariant analyses a higher degree of recurrence was found (RR 42 (IC95%: 3.0-586); $P < 0.05$). Regarding non-functioning invasive silent CT and GT, 60% and 15.2% showed recurrence, with relative risk of 4 (IC 95% 1.2-13.2) and 1.5 (IC 95% 1.2-1.9), respectively. ($P > 0.05$).
Conclusions
As expected tumors with high proliferation indexes and sinus invasion show worse behaviors and therefore should be managed more frequently and carefully. Therefore, the clinical pathological classification of pituitary tumors proposed by Trouillas *et al* is an important tool which should be used by all PTCOEs. As expected, SCT behaved more aggressively than SGT, highlighting the importance of a correct typification of the different pituitary tumors subtypes, using whenever is possible the IS of TF.

Central diabetes insipidus following immunization with BNT162b2 mRNA Covid-19 vaccine

Bruno Bouça[1], Marisa Roldão[2], Paula Bogalho[1], Luís Cerqueira[3] & Jose Silva-Nunes[1]
[1]Centro Hospitalar Universitário de Lisboa Central, Department of Endocrinology, Diabetes and Metabolism, Lisbon, Portugal; [2]Centro Hospitalar do Médio Tejo, Department of Nephrology, Abrantes, Portugal; [3]Centro Hospitalar Universitário de Lisboa Central, Department of Neuroradiology, Lisbon, Portugal

Introduction
The endocrine complications of COVID-19 remain largely unknown. Cases of central diabetes insipidus (CDI) have been reported after COVID-19, with hypophysitis being the most likely cause. COVID-19 vaccines potential adverse effects may mimetize some of these complications. We present a case of a woman who developed CDI one week after the 2 nd dose of BNT162b2 mRNA COVID-19 vaccine.

Case Report
Female patient, 37 years old, with rheumatoid arthritis under a well tolerated therapy with adalimumab (40 mg twice a month) since December 2018. In October 2021, she reported intense thirst and polyuria starting 4 months earlier (7 days after second dose of BNT162b2 mRNA COVID-19 vaccine). She denied polyphagia, weight loss, foamy urine, macroscopic hematuria, peripheral or periorbital edema. Blood analysis: creatinine 0.7 mg/dl, glucose 95 mg/dl, Na+ 141 mEq/l, K+ 3.9 mEq/l, TSH 3.8 mcUI/l (0.38-5.33), FT4 0.9 ng/dl (0.6-1.1), cortisol 215.4 nmol/l (185-624), ACTH 21.9 pg/ml (6-48), osmolality 298.2 mOs/lg (250-325); Urine analysis: volume 10 200 mL/24h, osmolality 75 mOs/kg (300-900), density 1.002. She was admitted to the ward to perform a water restriction test: 0' − Serum osmolality 308.8 mOsm/kg vs. urine osmolality 61.0 mOsm/Kg; 60' - urine osmolality 102 mOsm/Kg; urine osmolality 1 h after desmopressine was 511 mOsm/kg. MRI of the pituitary gland revealed no abnormal signs consistent with hypophysitis except for the loss of the posterior pituitary bright spot on T1 weighted imaging. Diagnosis of CDI was assumed, and started therapy with desmopressine. Although pituitary biopsy was not conducted, other probable causes of CDI were ruled out. A report of potential adverse effect from BNT162b2 mRNA COVID-19 vaccine was addressed to national health authorities. On the last appointment (December 2021), she was under desmopressin 0.06 mg tid, had no polydipsia or polyuria, BP 110/80 mmHg, and analytical results showed: Serum osmolality 297.2 mOsm/kg, Urine osmolality 148.0 mOsm/kg, FSH 4.76 UI/l, LH 5.62 UI/l, estradiol 323 pmol/l, IGF1 74.8 ng/ml (88-209), PRL 24.7 mg/l (3.3-26.7). Desmopressin was titrated to 0.12 mg bid.
Conclusion
In hypophysitis MRI often shows loss of posterior pituitary bright spot on T1 weighted imaging, pituitary enlargement or stalk thickening but those findings were not present in this patient. However, the same lack of abnormal signs consistent with hypophysitis in MRI has also been reported in 2 cases of CDI following COVID-19 infection. To the best of our knowledge, CDI has never been reported following administration of a COVID-19 vaccine.

Pheochromocytoma/paraganglioma metastatic potential prediction

Ewelina Rzepka[1], Anna Kurzyńska[1], Anna Grochowska[2], Magdalena Ulatowska-Białas[3], Anna Skalniak[4], Martyna Lech[3], Marta Opalinska[5], Anna Bogusławska[1], Elwira Przybylik-Mazurek[1], Anna Sowa-Staszczak[6], Aleksandra Gilis-Januszewska[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University, University Hospital, Endocrinology, Kraków, Poland; [2]Jagiellonian University, University Hospital, Radiology, Kraków, Poland; [3]Jagiellonian University, University Hospital, Pathomorphology, Kraków, Poland; [4]Jagiellonian University, University Hospital, Genetics, Kraków, Poland; [5]University Hospital in Krakow, Department of Endocrinology, Oncological Endocrinology and Nuclear Medicine, Kraków, Poland; [6]Jagiellonian University, University Hospital, Nuclear Medicine, Kraków, Poland

Pheochromocytoma and paraganglioma (PPGL) are rare neuroendocrine tumours, which derive from the chromaffin cells of the adrenal medulla or extra-adrenal sympathetic and parasympathetic ganglia. About 15-20% of those neoplasms could present malignant course. Prediction of PPGL metastatic potential still remains a great clinical challenge, since the sensitivity and specificity of proposed prediction systems are not satisfactory. We performed a retrospective database search for pheochromocytoma and paraganglioma patients, diagnosed and treated in Endocrinology Department, University Hospital in Cracow from 2005 to 2021. 206 patients with pheochromocytoma and 27 patients with paraganglioma were included to the analysis. The mean follow-up period was 59 months (range: 2-396 months). In the whole group, 5 metastatic pheochromocytomas and 2 metastatic paragangliomas have been found. Our objective was to investigate clinicopathological characteristics of the patients with malignant PPGLs in the light of current metastatic potential predictors. The group of patients with disseminated disease comprise 2 men and 5 women. Median patient age was 51 years (range 19-72). In two patients metastatic disease was observed at the moment of diagnosis, in remaining cases metastases developed 5 to 84 months after the diagnosis (median time 32 months). The most common localizations of metastases were lymph nodes and bones (71.4% for each). The leading symptom of metastatic disease was fatigue (86%). The median size of the primary tumour was 7.7 cm. Hormonal assessment revealed significantly elevated 24-h urinary fractionated metanephrines in 6 patients. The dominant catecholamine profile was adrenergic (57%). In all patients concentration of 3- metoxytyramine was elevated. In one patient with paraganglioma it was the only elevated metabolite in 24-h urine collection. Moreover, chromogranin A level was substantially increased in all cases (minimum 4.8- fold the normal upper limit) and it was positively correlated with the progression of the disease. PASS score was known in three patients with pheochromocytoma, in all cases it was higher than 6. In patients with PPGL, detailed analysis of histopathological, clinical, hormonal and imaging results is essential to properly predict the possible course of the disease. In our patients, the most commonly observed metastatic potential predictors were PASS score more than 6, tumour size more than 6 cm, elevation of dopamine metabolite level. A repetitive assessment of chromogranin A concentration during follow-up may have additional value in monitoring of the disease. Due to rarity of the PPGL, the establishment of a new predictive system is difficult and requires multicentre, long-term studies.

Adrenal haemorrhage in a pheochromocytoma - a rare, life-threatening and challenging complication

Ewelina Rzepka[1], Joanna Kokoszka[1], Anna Grochowska[2], Magdalena Ulatowska-Białas[3], Martyna Lech[3], Marta Opalińska[1,4], Magdalena Godlewska[1], Elwira Przybylik-Mazurek[1], Aleksandra Gilis-Januszewska[1] & Alicja Hubalewska-Dydejczyk[1,4]
[1]Jagiellonian University, University Hospital, Endocrinology, Kraków, Poland; [2]Jagiellonian University, University Hospital, Radiology, Kraków, Poland; [3]Jagiellonian University, University Hospital, Pathomorphology, Kraków, Poland; [4]Jagiellonian University, University Hospital, Nuclear Medicine, Kraków, Poland

Adrenal haemorrhage is a rare, usually life-threating complication, most commonly connected with primary or metastatic adrenal tumour. Among them pheochromocytoma is the most common cause of spontaneous adrenal bleeding and accounts for nearly 50% of cases. We performed a database search for pheochromocytoma patients, diagnosed and treated in Endocrinology Department, University Hospital in Cracow from 2005 to 2021. 206 patients with pheochromocytoma were identified. Subsequently, 23 cases were excluded due to incomplete medical data necessary to rule out potential adrenal bleeding. Of the remaining 183 patients with histologically confirmed pheochromocytoma, 7 cases with adrenal bleeding were found (3.8% of cases). The group of patients comprise 4 men and 3 women. Median patient's age was 49 years (range: 36-78 years). The most common manifestation of adrenal bleeding was acute abdominal pain (71.4%). Two patients (28.6%) developed shock, in one case resulted in multiple organ failure (MOF). Hormonal assessment concerning pheochromocytoma were performed in five patients (71.4%). 24- h urinary fractionated metanephrines were significantly elevated in all of them. Most patients (85.7%) have had symptoms suggestive of pheochromocytoma before haemorrhage − most commonly paroxysmal hypertension (57.1%). Nevertheless, In four patients diagnosis of pheochromocytoma was made at the time of adrenal haemorrhage, based on severe clinical manifestation, hormonal status and imaging. One patient died, before the diagnosis of adrenal bleeding was made. In two patients pheochromocytoma was suspected before the episode of haemorrhage: two months and sixteen months, respectively. Six out of seven patients have diagnostic imaging performed: median largest diameter of the lesions was 7.4 cm (range: 5-11 cm). Five patients had elective surgery, preceded by two- week pharmacological treatment with alpha- receptor blockers. In one case, four-day alpha-receptor blockage was administered, followed by the urgent surgery. In all cases the diagnosis of pheochromocytoma was confirmed in postoperative histopathology or in autopsy. PASS score was defined in 5 patients - in three cases it was no higher than 3, in two cases it exceeded 3. In two another cases, because of massive haemorrhagic changes, it couldn't be determined. The perioperative survival rate was 85.7%. Adrenal bleeding is a rare complication of pheochromocytoma, which constitutes a diagnostic and therapeutic challenge. It might remain unrecognized with lethal consequences. Physicians should be aware of such diagnosis in patients with adrenal bleeding, especially with accompanying abdominal pain, hemodynamic shock and previous history of pheochromocytoma-associated symptoms.

Treatment of cushing's disease (CD) after primary failure of pituitary surgery or recurrence: evaluation of long-term control by medical treatment

Adel Ghalawinji[1], Justine Cristante[1], Virginie Lefournier[2], Philippe Chaffanjon[3], Marie muller[1], Emmanuel Gay[4] & Chabre Olivier[1]
[1]Université Grenoble Alpes, Endocrinologie CHU Grenoble Alpes, GRENOBLE, France; [2]Clinique du Mail, Neuroradiologie, Grenoble, France; [3]Université Grenoble Alpes, Chirurgie Endocrine CHU Grenoble Alpes, GRENOBLE, France; [4]Université Grenoble Alpes, Neurochirurgie CHU Grenoble Alpes, GRENOBLE, France

Introduction
Pituitary surgery is the first line treatment for most patients with Cushing's disease (CD) but after failure or recurrence after surgery 3 main strategies can be proposed: medical treatment (MT), a 2 nd pituitary surgery, bilateral adrenalectomy (BA). Pituitary radiotherapy is a 4th strategy, generally combined with one of the 3 others. Medical treatment (MT) emerges as an attractive strategy but there are little data on long-term control after failure of pituitary surgery or recurrence.
Objective
To evaluate long term control of CD with MT after failure of pituitary surgery or recurrence.
Methods
Monocentric retrospective study of all 119 patients who had pituitary surgery for CD between 2001 and 2020 in our institution, with 36 patients candidates for a second line therapy, including 19 with pituitary failures (19/119 =16%, surgical remission rate 84%) and 17 with recurrences (17/100=17%)
Results
The second line treatment was medical treatment (MT) in 28/36 patients (78%) 2nd pituitary surgery in 5/36 patients (14%) and BA in 3/36 patients (8%). The long-term control was achieved by MT in 11/36 patients (30%), 2nd pituitary surgery in 8/36 patients (22%) and BA in 14 patients (39%), while 3/36 patients (8%) remained uncontrolled. During the whole follow-up 29 patients received at least one drug and 67 introductions of drug treatment were performed (average 29/67=1.7/patient), using inhibitors of steroidogenesis: ketoconazole (27), metyrapone (15), osilodrostat (8), mitotane (3) or inhibitors of ACTH secretion: cabergoline(11), pasireotide (3). On long term 11/29 (38%) patients were maintained on MT (group A, duration of treatment 49.6 months) while 18/29 (62%) patients abandoned MT (group B duration of treatment 20.8 months,) for lack of long-term efficiency (66%), intolerance and/or lack of compliance (34%). A normal Urinary Free Cortisol (UFC) was obtained at least one time during 38/67 introductions of treatment (57%), including 36/53 (68%) with steroidogenesis inhibitors and 2/14 (14%) with inhibitors of ACTH secretion. The last treatment used in group A was osilodrostat (6); ketoconazole (3) ketoconazole + metyrapone (1) metyrapone (1). Group A patients had a higher age (55.9 vs 47.9P=0.04), and a tendency toward more different treatments (2.5 vs 1.7P=0.06) but were no different regarding sex and initial UFC. All female patients under 35 years ended in-group B. In conclusion, in this study MT was a long-term solution for 38% of the patients who experienced failure or recurrence after pituitary surgery for CD. Steroidogenesis inhibitors appeared more efficient.

Efficacy, safety and metabolic impact of long-term pegvisomant therapy in acromegaly: results from a 10-year single center experience

Rosa Pirchio[1], Renata Simona Auriemma[1], Maria Elena Montini[1], Alice Vergura[1], Rosario Pivonello[1,2] & Annamaria Colao[1,2]
[1]Università "Federico II" di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Unesco Chair for Health Education and Sustainable Development, "Federico II" University, Naples, Italy

Pegvisomant (PEG) is effective in acromegaly control and exerts a positive impact on glucose metabolism. The current study aimed at investigating the effects of 10-years PEG treatment on disease control, pituitary adenoma size, and metabolic profile in patients with acromegaly resistant to somatostatin analogues (SRLs). Twenty-two patients (9 men,13 women, age 45.54 ± 12.83 years) treated with PEG for 10 years, in monotherapy or in combination with SRLs, were included in the current study. In the whole patient cohort, anthropometric (BMI, systolic and diastolic blood pressure), hormonal (GH, IGF-I), biochemical (fasting glucose and insulin, lipid profile) parameters, and maximal tumour diameter were evaluated before and after 10-years of PEG treatment. After10-years PEG therapy, IGF-I levels persisted significantly decreased in all the patients (P<0.0001) compared to baseline, with full normalization in 91%. No significant change in dose of either PEG or SRLs was required. Tumour maximal diameter slightly decreased in the whole cohort. Fasting glucose (FG) was significantly increased (P=0.035), whereas HbA1c and diabetes prevalence remained stable. Fasting insulin (FI) and HOMA-IR decreased, HOMA-β was significantly reduced (P=0.013), whereas $ISI_{0,}$ was increased. A significant decrease in total- (P=0.03) and LDL- (P=0.05) cholesterol, and a slight increase in triglycerides were found. At baseline, GH and IGF-I levels significantly correlated with systolic blood pressure (SBP), FI, HOMA-IR, HOMA-β, and ISI_0. Baseline IGF-I correlated with percent change after 10 years (Δ) of FI (r=-0.354, P=0.015), and HDL (r=0.045, P=0.045). PEG dose was directly correlated to BMI (r=0.509, P=0.016), and triglycerides (r=0.554, P=0.007), and inversely to age (r=-0.455, P=0.030). Disease duration before PEG was directly related to BMI (r=0.446, P=0.037), and inversely to 10-years HOMA-IR (r=-0.563, P=0.029), HDL (r=-0.424, P=0.049), ΔFG (r=-0.462, P=0.03), ΔFI (r=-0.546, P=0.05), and ΔTG (r=-0.445, P=0.034). Long-term PEG therapy is effective and safe, without requiring an increase in dose to maintain disease control even after a decade of therapy. PEG beneficial impact on both insulin and lipid metabolism persists after prolonged therapy**.** PEG treatment should be started as soon as possible in patients resistant to SRLs as the extent of the metabolic improvement is inversely correlated to disease duration before PEG introduction.

DOI: 10.1530/endoabs.81.P679

Long-term pasireotide therapy: real life experience of a single referral center

Rosa Pirchio[1], Alice Vergura[1], Maria Elena Montini[1], Renata Simona Auriemma[1], Rosario Pivonello[1,2] & Annamaria Colao[1,2]
[1]Università "Federico II" di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Unesco Chair for Health Education and Sustainable Development, "Federico II" University, Naples, Italy

Pasireotide is a second-line therapy for acromegaly, that allows to obtain disease control in patients previously uncontrolled. However, pasireotide-induced hyperglycemia is of major concern. Currently, few data concerning prolonged use of pasireotide are available. The current retrospective study aimed at investigating the efficacy and safety of long-term pasireotide therapy. Sixteen consecutive patients (5 males, 11 females, age 47 ± 11 years) undergoing pasireotide for a minimal period of 36 months, were considered for the current study. In these patients, hormonal (GH, IGF-I), biochemical (fasting glucose and HbA1c), and radiological parameters (tumour maximal diameter and volume) have been considered at baseline and at 6, 12, 36 months, and last follow-up (LFU), during pasireotide therapy. At baseline, GH levels were 4.56 ± 3.82 ng/ml, IGF-I levels were 1.74 ± 0.72 x ULN, resulting 13 patients (81.25%) uncontrolled. Diabetes mellitus (DM) was present in 7 (43.75%), and 4 patients (25%) showed an impaired fasting glucose (IFG). After 6 months of pasireotide, GH and IGF-I levels were significantly reduced compared to baseline (P=0.017 and$P$=0.001, respectively). At 12 months, all patients achieved disease control (P<0.0001), tumour maximal diameter and volume were significantly reduced (P=0.003 and$P$=0.019, respectively). Disease control was maintained at 36 months evaluation, being tumour volume significantly further reduced compared to 12 months (P=0.010). Twelve patients (75%) were treated with pasireotide for a longer period (range 42-66 months); all these patients were controlled with a stable size adenoma at LFU. At 6 months, an increase in dose was recorded in 4 patients (25%, P=0.046), no further dose variation have been required. Pasireotide starting dose was significantly inversely correlated to IGF-I at 36 months (r=-0.614, P=0.011). Fasting glucose (FG) significantly increased in the first year of pasireotide therapy, particularly in the first 6 months (P=0.005); without a consistent increase in HbA1c (P=0.303) and DM (P=0.285). FG at 6 months was significantly correlated to age (r=0.692, P=0.003), rather than pasireotide dose (r=0.417, P=0.108). After 6 months, 75% IFG patients developed DM. At 36 months, 80% euglycemic patients at baseline were diabetic, and 20% showed IFG. As consequence, a significant increase in DM (P=0.023), and in the number of

antidiabetic drugs used ($P=0.005$) were observed. Pasireotide therapy is effective in determining disease control, and tumour shrinkage, even after a long period of treatment. Change in FG mainly occur in the first period, depending on age and glycemic status before pasireotide starting.

The burden of adult growth hormone deficiency diagnostic tests: results of a patient experience survey in the UK

Harry Lewis[1], Joanne Mumford[1], Pat McBride[2], Pauline Whittingham[2], Glenn Darley[3] & Nacima Chernai[3]
[1]Initiate Consultancy, Towcester, United Kingdom; [2]The Pituitary Foundation, United Kingdom; [3]Consilient Health, United Kingdom

Objectives
To collect qualitative and quantitative information on the burden of adult growth hormone deficiency (AGHD) diagnostic tests for the patient.
Methods
A survey was published on The Pituitary Foundation's website and social media pages; respondents completed it online using SmartSurvey over period of two months (October-November 2021). 105 respondents took the survey, with 9 screened out after the first question because they had never taken an AGHD diagnostic test.
Results
Of the 96 respondents who completed the survey, 66 answered questions about the insulin tolerance test (ITT), 23 about the glucagon test, and 7 about the GHRH-arginine test. The ITT, whose mechanism of action depends on induced hypoglycaemia, presented both the widest variety of symptoms and, according to scores given by respondents, the most severe, with 9 of the 13 prompted symptoms experienced by the majority of patients who answered questions about it. When ITT patients were asked to rate the severity of the side effects they experienced on a scale of 1-5 (with 5 being the most severe), 5 symptoms − sweating, shakiness, fatigue, feeling dizzy, and feeling weak − had an average score of 3 or above ('moderate' or 'severe'). Although the glucagon test and GHRH-arginine test were overall less burdensome, they still caused some prompted symptoms to be experienced by the majority of patients who underwent them. Only 44% of patients felt well-prepared for their test, and 34.4% did not think the information they received beforehand was thorough. The majority indicated that their test had impacted their daily life in the days following. Due to the difficulty of correctly managing hypoglycaemia and the level of training and experience required by the clinicians assigned to oversee the test, some patients experienced adverse events such as blood sugars taking longer than usual returning to normal, an unexpectedly strong reaction to the administration of insulin, and adrenal crisis. In some cases, patients needed to have their test repeated.
Conclusions
Taking any AGHD diagnostic test can be a very unpleasant experience for the patient, and adverse events are common; this is particularly true for the ITT, which is the most used test in the UK and the international 'gold standard'. Due to the complexity and length of the test procedures, clinicians do not always appear to be confident when administering them. There is variability in patients' understanding of these facts pre-test, as well as in clinical responses to any complications that occur.

Berlin questionnaire and epworth sleepiness scale as screening tools of sleep apnea risk in patients with acromegaly: comparison of 144 patients and an age-and gender-matched health cohort

Rosa Pirchio[1], Raffaele Addato[1], Maria Elena Montini[1], Corina Valentina De Santis Ciacci[1], Alice Vergura[1], Renata Simona Auriemma[1], Rosario Pivonello[1,2] & Annamaria Colao[1,2]
[1]Università "Federico II" di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Unesco Chair for Health Education and Sustainable Development, "Federico II" University, Naples, Italy

Sleep apnea (SA) is a common acromegaly comorbidity, influencing patients' quality of life and mortality risk. Despite its importance, SA frequently remains undiagnosed, and its real prevalence seems to be underestimated. The current observational study aimed at investigating the role of Berlin questionnaire (BQ) and Epworth sleepiness scale (ESS) in assessing the risk of SA in this high-risk population, and to compare the results with an age-and gender-matched health cohort. One hundred and forty-four patients with acromegaly (63 men, 81 women, age 56.37 $\pm$ 12.94 years), and an equal number of age-and gender-matched health controls were included in the present study. All the subjects had no previous diagnosis of SA. For BQ and ESS, higher score indicated greater SA risk. A questionnaire evaluating quality of life in acromegaly, AcroQol, for which the higher score indicates a better quality of life, was administered only to patients. Patients showed a significantly higher BMI than controls ($P<0.001$), whereas there was no difference about hypertension prevalence ($P=1$). Comparing patients and controls, no significant difference was found in ESS score ($P=0.761$), and prevalence of high SA risk estimated by BQ ($P=0.623$). Furthermore, questionnaire results were analyzed in acromegalic patients related to gender, BMI, and disease control. ESS score and the prevalence of high SA risk based on BQ were similar between men and women. No significant differences were found for both ESS and BQ score among patients according to the BMI categories. Patients with uncontrolled disease had no differences in questionnaires' score compared to controlled patients. Patient's therapy did not influence ESS and BQ results. Acromegaly patients defined at high risk of SA according to BQ presented a significantly higher prevalence of hypertension ($P=0.002$), and number of antihypertensive drugs used ($P<0.001$), and lower AcroQol ($P=0.019$), compared to those at low risk. No differences concerning anthropometric parameters, GH and IGF-I levels, age at diagnosis, and disease duration were found between this two groups. AcroQol was inversely correlated to ESS ($r=$-0.326, $P=0.012$) and BQ ($r=$-0.310, $P=0.018$) scores. No correlation was found with age both in patients and controls. ESS and BQ are scores validated for SA risk assessment in the general population. The results of this study show that these tools seem to be not suitable for assessing SA risk in patients with acromegaly. Probably acromegalic patients, at higher risk of developing this comorbidity compared to the general population, requires a proper questionnaire.

Pallister-hall syndrome diagnosed in a young man after an acute adrenal crisis

Anis Grassa, Meriem Yazidi, Bel Hadj Sliman Chayma, Nadia Khessairi, Ibtissem Oueslati & Melika Chihaoui
Hospital Rabta, Endocrinology, Tunis, Tunisia

Introduction
Pallister-Hall syndrome (PHS) is a very rare congenital syndrome, and its exact prevalence is still unknown. The clinical diagnosis is usually made when a hypothalamic hamartoma is associated with polydactyly. Endocrine manifestations consist of hypopituitarism, hypopituitarism, which can affect one or more pituitary axes, and precocious puberty. Here, we report the case of an 18-year-old young man in whom the diagnosis of PHS was delayed until his hospitalization in the endocrinology department for acute adrenal insufficiency.
Observation
The patient was an 18 years old young man who presented to the emergency room with clinical and biological features of an adrenal crisis. The medical history revealed several surgeries: a corrective one for polydactyly, a surgery for testicular ectopia and for a hypothalamic tumour diagnosed at the age of three years complicated with hypopituitarism. He would have received growth hormone for two years from the age of twelve. He was on hormone replacement therapy for hypothyroidism and adrenal insufficiency, and he stopped his treatment for a week. He had no medical follow-up for several years. The patient's family history was unknown as he was an adopted child. Physical examination showed a height of 157 cm (-3SD), a weight of 68 kg and a BMI of 27.5 kg /m^2. We noted an inequality of the two lower limbs. External genitalia's examination revealed a micropenis and hypoplastic testes. PHS was suspected and further investigations were then performed. An otolaryngology examination showed bifid epiglottis and laryngeal cleft. X-rays of the left hand revealed a surgically corrected postaxial type A polydactyly. Pelvic x-ray showed bone demineralisation and Risser stage was 4. Ultrasounds of heart, abdomen and kidneys were normal. The pelvic ultrasound showed hypoplastic testes. Brain MRI revealed a sellar and suprasellar mass measuring 28x25x24 mm corresponding to hypothalamic hamartoma. On biochemical evaluation, the

renal and hepatic functions, blood count, serum calcium and serum phosphorus results were normal. The pituitary assessment showed a thyrotropin and gonadotropin deficiencies
Conclusion
This patient's presentation shows that PHS may be misdiagnosed given its extremely low prevalence. Practitioners who may see patients with PHS at the young age (pediatricians, surgeons) should be familiar with this disease to avoid late diagnosis which may compromise patient prognosis.

Pituitary macroadenoma revealed by symptoms mimicking Hakim Adams triad

Anis Grassa, Meriem Yazidi, Youssef Gharbi, Ibtissem Oueslati, Fatma Chaker & Melika Chihaoui
Hospital Rabta, Endocrinology, Tunis, Tunisia

Introduction
The clinical presentation of a secretory pituitary macroadenoma usually consists of a tumor syndrome accompanied by visual disturbances with signs of pituitary insufficiency and/or hormonal hypersecretion. Herein we describe an unusual presentation of a mixed secretory adenoma.
Observation
A 69-year-old was referred to our department for the management of a pituitary macroadenoma revealed by a symptomatology mimicking the Hakim Adams triad with gait disorders, sphincter disorders and a dementia syndrome, as well as a right monocular blindness. His past medical history included type 2 diabetes mellitus and hypertension. Physical examination noted a dysmorphic syndrome suggestive of acromegaly. Hormonal investigations revealed a hyperprolactinemia at 4755 ng/ml, a baseline GH of 7.8 ng/ml (>1) with elevated IGF1 levels. Baseline cortisol was at 8.9 µg/dl (nr:5-18) with an ACTH at 36.16 pg/ml (nr:7.22-63.3). TSH and FT4 were at 0.143 mIU/l (nr:0.1- 4.5) and 0.67 ng/dl (0.7-1.5) respectively. FSH and LH were at 2.94 IU/l (nr:1-12) and 1.34 IU/l (nr:2-12) respectively. Brain MRI showed a 5 cm pituitary macroadenoma with supra sellar extension pushing back the optic chiasm and leading to lateral ventricles dilatation upstream and an invasion of the right cavernous sinus. Ophthalmological examination showed pallor and bilateral papillary atrophy. Visual acuity was very low. Visual field showed right monocular blindness and was agonic on the left. The patient was put under Cabergoline at the dose of 1.5 mg per week. The evolution after one week was spectacular with disappearance of the walking, sphincter, and memory disorders with visual improvement, being reduced to a right lateral homonymous hemianopia.
Conclsion
Symptoms mimicking Adams Hakim's triad are exceptionally in relation with a pituitary adenoma. In case of prolactinoma, medical treatment with dopaminergic agonists may be associated with resolution of those neurological symptoms.

Immunotherapy-induced endocrinopathies: a case report

Radvilė Dobrovolskytė, Lina Panceraite, Karolina Prielaidaite, Kristina Semeniene & Birute Zilaitiene
Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania

Endocrinopathies are one of the most common side effects induced by immunotherapy. The side effects result from the activation of immune system, which affects not only cancerous but also healthy body cells. In most cases, only one endocrinopathy occurs, but in our presented case we describe multiple endocrinopathies that occurred to a one person. 53-years-old male patient was referred to the Emergency department due to severe hyperglycemia (37.13 mmol/l) and the following symptoms: frequent urination, thirst, general weakness. New-onset diabetes was diagnosed and the patient was admitted to the Department of Endocrinology. After clarification of past medical history oncological disease emerged. In 2013, metastatic right kidney cancer was diagnosed (the tumor was spread to the lungs), the right nephrectomy was performed. Histopathological analysis confirmed clear cell renal cell carcinoma (ccRCC, pT3aG3). Systemic therapy with Sunitinib has been initiated. During the course of treatment, in 2016, hypothyroidism appeared, LT4 treatment was necessary. In 2020, for the reason of disease progression, immunotherapy with nivolumab, as a second line treatment, was initiated and stereotactic radiotherapy for paraaortic lymph nodes was applied. In the Department of Endocrinology, for the treatment of newly diagnosed diabetes mellitus intensive insulin therapy was chosen (HbA1c 18.7%, anti-IA2 1.0k U/l, n 0-7.5k U/l, anti-GAD 0.57k U/l, n 0-5; suspected immunotherapy-induced autoimmune diabetes mellitus). Depending on the patient medical history, was decided to consider other possible immunotherapy-induced endocrinopathies. After additional investigation hypopituitarism, secondary adrenal insufficiency was confirmed (ACTH 0.4 pmol/l, n 1.63-14.15, morning cortisol 47.1 nmol/l, n 147-726). Hydrocortisone replacement therapywas started immediately. Repeated blood tests revealed low levels of testosterone (T 2.22 → 3.23, n 9.08-30.1). The patient completed an international index of erectile function (IIEF) questionnaire and was diagnosed with mild to moderate erectile dysfunction. Mixed hypogonadism was confirmed (hypogonadism due to hypothalamic/pituitary and testicular dysfunction; LH 4.0 IU/I n 1.7-11.2, FSH 10.2 IU/I n 2.1-18.6), testosterone replacement therapy was prescribed. During inpatient treatment, headache and visual disturbances appeared. In assessing the course of the disease, tests results, despite the fact that no changes in the pituitary gland were seen after MRI, hypohysitis was diagnosed. The patient was discussed at multidisciplinary team meeting and it was decided that after adjusting the patient's condition, immunotherapy can be resumed, continuing the active follow up at the Department of Endocrinology.
It is very important to monitor patients throughout and after the treatment of immunotherapy for possible side effects that can lead to serious, life-threatening complications if not diagnosed in time.

Ruptured rathke's cleft cyst (RCC) with irritation of optic apparatus and rapidly evolving panhypopituitarism

Annalisa Montebello[1], Joan Grieve[2], Hani J Marcus[2], Katherine Miszkiel[3], Fernanda Valerio[4] & William Martyn Drake[1]
[1]St. Bartholomew's Hospital, Endocrinology, London, United Kingdom; [2]University College London Hospital, Neurosurgery, London, United Kingdom; [3]University College London Hospital, QS Diagnostic & Support Services, London, United Kingdom; [4]University College London Hospital, Department of Clinical and Movement Neurosciences, London, United Kingdom

Background
Rathke's cleft cysts (RCC) are benign intrasellar cysts that originate from the remnants of Rathke's pouch and contain mucoid material. Most are asymptomatic, but some may compress adjacent structures leading to visual disturbances and endocrinopathies.
Case Report
A 20-year-old gentleman had an MRI Head in view of headaches. This showed a 17.7 mm peripherally enhancing suprasellar lesion with no intrinsic T1 high signal pre- contrast. He presented acutely three weeks later with headaches, blurred vision, sudden onset polyuria, polydipsia, and lethargy. An MR Pituitary showed a 23 mm, lobulated, peripherally enhancing sellar/suprasellar mass with elevation of the optic chiasm. The right optic tract showed inflammatory changes. The normal pituitary tissue was displaced. Blood investigations showed a random cortisol of 93 nmol/l, TSH 0.5 mU/l, T4 8.6 pmol/l, FSH <1 unit/l, LH <1 unit/l, Testosterone <0.5 nmol/l and central diabetes insipidus with a serum sodium of 139 mmol/l, serum osmolality 295 mmol/kg and urine osmolality of 121 mmol/kg. Pituitary replacement therapy was initiated with hydrocortisone, thyroxine and desmopressin and he underwent urgent transsphenoidal debulking of the lesion. Histology revealed a cystic pituitary lesion with focal xanthogranulomatous inflammation in keeping with cyst rupture. His vision improved post operatively. An ophthalmic review showed 6/3.8 acuity in the right eye and 6/4.8 acuity in the left, mild loss of sensitivity in the temporal hemifield of the right but intact visual fields in the left eye. Repeat imaging in November 2021 showed a residual 16 mm sellar/suprasellar cyst with ongoing distortion of the anterior visual pathways, contact with the intracranial optic nerves and distortion of the optic chiasm. He represented in January 2022 with sudden onset blurred vision. Ophthalmic review showed 6/9 visual acuity in the left and 6/6 in the right eye, a new left relative afferent pupillary defect, and new bitemporal hemianopia.

An MR Pituitary showed enlargement of the residual cystic lesion and further encroachment of the optic tract. He underwent urgent redo transsphenoidal endoscopic drainage of the cyst. His vision improved significantly post operatively. Visual fields were normal to confrontation. Histology showed a fragment of pituitary gland containing granulation tissue and stratified epithelium compatible with elements of a residual RCC.
Conclusion
In most RCCs the development of pituitary dysfunction and neuro-ophthalmic deficit are chronic. We present a rare case of a ruptured RCC causing acute visual problems and panhypopituitarism which recurred within a short period after decompression. The patient will remain under close clinical and radiological follow-up.

Plurihormonal pituitary macroadenoma, co −secreting TSH/GH/and prolactin: a clinical challenge

Ismene Bilbao Garay[1], Nerea Egaña[1], Maite Perez De Ciriza[2], Laura Chinchurreta[2], Cristina Elias[1], Inmaculada Venegas[1], Ane Amilibia[1], Cristina Garcia[1], Jorge Rojo[1] & Alfredo Yoldi[1]
[1]Donostia Unibertsitate Ospitalea, Donostia, Spain; [2]Zumarragako Ospitalea, Zumarraga, Spain

Background
Co secreting Thyrotropin/growth hormone pituitary adenomas are rare, and their clinical presentation and long term management may be challenging. Clinically, the majority of plurihormonal pituitary adenomas are silent and diagnosis almost always relies on immunohistochemical analysis of the tumor tissue. Early detection is key to optimize patient mamagement. We report a case of pituitary plurihormonal macroadenoma with overt clinical hyperthyroidism and minimal GH excess symptoms.
Case Report
A 68-year-old female patient was admitted to our university hospital for transesphenoidal surgery due to a Thyrotropinoma diagnosed by one of our colleagues in another hospital. She underwent a thyroidectomy 15 years prior to diagnosis due to multiple bilateral thyroid nodules and she was taking levothyroxine replacement, noting that she presented discordance TSH/T4 levels. On review of previous test she consistently had elevated TSH and free T4 levels, and there was no family history of thyroid disease. Slightly high prolactin, IGF-I and elevated pituitary glycoprotein αSubunit were found during investigation and magnetic resonance Imaging(MRI) showed a sellar mass consisting of a pituitary macroadenoma that measured 31x21x29 mm(trxAPXCC) invading both cavernus sinuses and causing compression and superior displacement on the optic chiasm. She underwent successful transphenoidal adenomectomy and histopathology displayed a negative p53, a low KI67 of 1% and positivity for prolactin, GH and TSH in immunostaining. The patient was rendered euthyroid on levothyroxine, with GH <0.1 and normal age-sex adjusted IGFI levels and she is being followed without any recurrence of pituitary tumor or thyrotoxicosis.
Conclusion
Co-secreting occurs in 30% of Thyrotropinomas, requiring diligent inmunohistochemical analyses of all pituitary hormones to make the correct diagnosis and to alert the clinicians to ensure the right follow up.

I Parhon"National Institute of Endocrinoloy, Radiology and Medical Imaging, Bucharest, Romania

Introduction
Somatotroph pituitary adenomas (PAs) represent 10-15% of all resected PAs, exhibiting immunohistochemical (IHC) positivity for GH (growth hormone) and PIT-1 transcription factor (TF). The histopathological (HP) and IHC variability of each PA influences the phenotype, radiological features, and therapy response.
Materials and methods
The study included 33 patients with acromegaly, with men: women ratio of 17:16. The HP-IHC characteristics were correlated with the clinical, imaging and laboratory data. Tumour specimens were assessed for anterior pituitary hormones, PIT-1, TPIT and SF-1 TF, Ki-67 labelling index, vimentin and reticulin.
Results
Of all cases, 30 had GH hypersecretion, while 3 had GH and PRL co-secretion. The symptomatology at diagnosis was dominated by the increase in size of extremities, associated with facial changes. Regarding the complications, they were identified right from the diagnosis, almost 50% of patients being hypertensive. Over 90% were macroadenomas. The maximum tumour diameter at diagnosis was positively correlated with suprasellar extension (P 0.001), the latter being also correlated with tumour invasion ($P<0.0001$). The postoperative tumour size was positively correlated with the postoperative value of random GH (P 0.01), the postoperative control of the residual secretion having a negative correlation with the maximum initial diameter. Regarding the biochemical evaluation, a statistically significant correlation was observed between the initial diagnostic values of IGF-1 and nadir GH in OGTT (P 0.02), respectively random GH (P 0.01), correlation maintained postoperatively (P 0.004 and <0.001, respectively). Most PAs were acidophilic, all had a positive IHC expression for GH. As expected, 93.93% had positive expression for PIT-1. PAs with IHC expression positive exclusively for GH accounted for 36.36%, while 13 cases (39.39%) showed a positive expression also for PRL. The expression of the other adenohypophyseal hormones was 12.12% for TSH, 3.03% for ACTH, and 9.09% for LH, respectively. Four cases were plurihormonal PIT-1 positive PAs, all with positive expression for PIT-1. Four cases had unusual IHC hormonal combinations. A particular feature of these PAs was the positive expression of the transcription factor SF-1 in a fairly large number of patients (39.39%). Most had a Ki-67 value below 3%.
Conclusions
The IHC classification of PAs, as stated by the WHO 2017 classification criteria, associated with the radiological dimensions and extent influence disease control, and are, probably, the most accurate prognostic factors. The 4 plurihormonal PIT-1 positive PAs associated a good cell differentiation and strongly acidophilic tinctoriality, advocating for a well-differentiated, mature tumour variant.

Peculiar presentation of a TSH-secreting pituitary adenoma: a possible new multiple endocrine syndrome?

Giovanni Goggi[1,2], Irene Campi[2], Elisa Delle Donne[1,2], Mirella Moro[2], Fabiana Guizzardi[2], Marco Bonomi[1,2] & Luca Persani[1,2]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Department of Endocrine and Metabolic Medicine and Lab of Endocrine and Metabolic Research, Milan, Italy

Introduction
TSH-secreting pituitary adenomas (TSHomas) are a rare cause of central hyperthyroidism, accounting for less than 1% of all pituitary adenomas, with a prevalence in the general population of 1-2 cases per million.
Case Presentation
A 45-year-old female patient presented in 2009 with hypertension and tachycardia: blood tests revealed an inappropriately normal TSH with high fT3/fT4 levels and primary hyperaldosteronism. She declined further investigations and was started on nebivolol and hydrochlorothiazide by her GP. In November 2021, aged 58 years, she came to our observation for a compressive multinodular goiter with intrathoracic extension requiring surgery. In spite of a persistent biochemical picture of central hyperthyroidism, she did not complain symptoms of thyrotoxicosis. We ruled out possible interferences in the thyroid function tests and started the appropriate workup.

Diagnostic Investigations
We found an absent TSH response to exogenous TRH stimulation, suggestive for a TSHoma with a MRI showing a 12 mm pituitary macroadenoma. The remaining pituitary function was normal. Moreover, a primary hyperaldosteronism and a mild normocalcemic hyperparathyroidism despite cholecalciferol supplementation were found. No hyperplastic parathyroid glands were found at US scan, while the abdomen CT scan showed a slightly enlarged left adrenal gland. Due to the co-occurrence of a TSH-secreting pituitary adenoma, hyperparathyroidism and adrenal hyperplasia, suggestive of MEN1-4, we performed molecular analysis, by a targeted-NGS sequencing custom panel. We did not find variants in the *CDNK1B* or *MEN1* gene, while a heterozygous variant in the glial-cell-line-derived neurotrophic factor (*GDNF*) gene, previously reported in Hirschsprung disease, substituting an Isoleucine with a Methionine (p.I211 M) was found.
Discussion and Conclusion
GDNF is a plausible candidate gene for multiple endocrine syndromes, as GDNF family members bind to the GDNF-family-receptor alphas (GFRαs), leading to RET dimerization. In addition, it is expressed in normal pituitary and parathyroid glands and in pituitary/parathyroid adenomas. Furthermore, somatic mutations have been reported in parathyroid adenomas/hyperplasia. Nevertheless, the impact of p.I211 M variant in the pathogenesis of this case remains unclear. Previous studies showed that this *GDNF* variant retained its ability to induce RET tyrosine phosphorylation. These results suggest that the p.I211 M variant might act as a disease modifier in conjunction with other genetic lesions (Eketjall, 2002) still not identified in our patient. The curious association of central hyperthyroidism with primary hyperaldosteronism and hyperparathyroidism is suggestive of a novel MEN syndrome variant.

Clinical characteristics at diagnosis and diagnostic delay among newly-diagnosed patients with acromegaly- single-center, pilot study

Magdalena Godlewska, Anna Bogusławska, Łukasz Kluczyński, Ewelina Rzepka, Alicja Hubalewska-Dydejczyk & Aleksandra Gilis-Januszewska
Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland

Introduction
Diagnostic delay remains significant among the patients with acromegaly, even though the disease awareness has improved over the years.
Aim
The aim was to investigate the diagnostic delay and symptoms present at diagnosis of acromegaly among the newly-diagnosed patients.
Material and methods
72 consecutive patients diagnosed with acromegaly between 01.2014 and 12.2021 were evaluated. Division into groups based on: gender, age upon diagnosis ($\leq$30 and $>$30 years of age) and age at the retrospectively estimated onset of symptoms ($\leq$30 and $>$30 years of age) was made. Clinical and biochemical data at diagnosis were analyzed with IBM SPSS Statistics ver. 27. The study was approved by local Bioethics Committee.
Results
63 patients (56.6% females, mean age 41.13+/- 14.03 years) were included in the study. Pituitary tumor was accidentally discovered in 24.2%, the median diagnostic delay was 4 years (IQR 4.0-7.0). There were no statistically significant differences in diagnostic delay, accidental diagnosis between genders and age groups. Acral enlargement was the most frequently reported symptom (90.3% of patients). Headaches, reported by 45.2% patients, were more frequent in females (42.86%) than in males (29.63%)($P=0.031$). Snoring was more common among patients with onset $>$30 years of age than in early onset (28.13% vs 0%, $P=0.018$). 25.85% patients had visual field impairment due to optic chiasm compression. Menstrual abnormalities were present in 37.14% females; 25.92% males reported decreased libido, with no statistical differences. Those symptoms were more common among patients with onset of symptoms $\leq$ 30 years of age than in those with later onset (50% vs 21.88%, $P=0.041$). Hypogonadotropic hypogonadism was more common in males (74.1%) than in females (16.7%)($P<0.001$). 42.8% of females and 29.6% of males suffered from hyperprolactinemia. Secondary hypothyroidism was present in 14.28% of women and 18.5% men. Adrenal axis insufficiency was discovered in only 2 males (7.4%). Nobody was diagnosed with diabetes insipidus. There was no statistically significant relationship between the diagnostic delay and any of the symptoms or any of the pituitary axis insufficiency.
Conclusions
In our study, males tend to underreport the symptoms of hypogonadotropic hypogonadism. Menstrual irregularities or decreased libido are more frequently reported in younger age, while headaches are more common in females. Diagnostic delay did not statistically depend on presence of any of the symptoms nor pituitary insufficiency.

Very-low-calorie-ketogenic-diet (VLCKD) approach to manage obesity in craniopharingioma patients

Oana Ruxandra Cotta[1], Ylenia Alessi[1], Rosaria Certo[1], Alessandra Piccione[1], Rosalinda Casablanca[1], Giuseppe Paola[1], Martina Buda[2], Monica Scaramuzzo[1], Francesco Ferrau'[1,2] & Salvatore Cannavo'[1,2]
[1]University of Messina, Unit of Endocrinology, Messina, Italy; [2]University of Messina, Department of Human Pathology of Adulthood and Childhood "G. Barresi", Italy

Background
Craniopharingioma patients frequently experience severe obesity, unresponsive to caloric restriction or lifestyle modifications. Recently very-low-ketogenic-diets (VLCKD) proved to be a promising lifestyle intervention for obesity management, but no data are available regarding their effect on hypothalamic obesity (HO).
Introduction
We present the outcome of VLCKD protocol applied in young patients with HO following neurosurgery for craniopharingioma.
Methods
Three patients who developed HO after surgery for craniopharingioma (1 male, mean weight 125±2.8 kg, mean BMI 43.9±3.9 kg/m^2) were treated with VLCKD protocol. All patients had previously undergone largely unsuccessful dietary interventions. BMI, weight, waist circumference changes and adverse effects were assessed during a follow-up period of 7.5±7.3 months (range 3-16 months).
Results
The two female patients presented panhypopituitarism and diabetes insipidus, while the male had multiple pituitary deficiencies (central hypothyroidism, hypogonadotropic hypogonadism and growth hormone deficiency); all patients were on adequate replacement therapy. Both female patients presented visual field impairment. All patients showed non-alcoholic steatoepatitis, hyperinsulinism but not diabetes mellitus, while the male patient also presented hyperuricemia. VLCKD resulted in a significant weight loss (125±2.8 kg vs 112.4±3.6 kg, *P*0.008) as well as waist circumference reduction (111.7±3.8 vs 102.3±3.0, *P*0.029). At last follow-up, BMI (43.9±3.9 kg/m^2 vs 39.4±2.8 kg/m^2 *P*0.17) and HOMA Index (9.66±2.6 vs 5.12±3.5, *P*0.14) remarkably decreased, although not significantly. The only side effect registered was persistent hyponatriemia in one female patient, normalising after VLCKD suspension, corticosteroid and desmopressin replacement treatment adjusting.
Conclusions
The use of VLCKD protocol is a promising, safe and effective treatment option for HO in craniopharingioma patients. Frequent control of electrolytes is mandatory.

Analysis of the frequency of relapses according to the national registry cushing' s syndrome in Republic of Uzbekistan

Umida A. Mirsaidova & Zamira Khalimova
Republican Specialized Scientific Practical Medical Center of Endocrinology of Republic of Uzbekistan named by Ya.Kh.Turakulov, Tashkent, Uzbekistan

Transsphenoidal pituitary surgery is the method of choice in the treatment of ACTH-DCS, although to date, according to a number of researchers, the method is not ideal. Despite the achievement of immediate postoperative remission in 69-

98% of cases, with an increase in the duration of follow-up after TSS from 5 to 10 years, an increase in the frequency of relapses from 15 to 66% is observed. In this regard, we analyzed cases of ACTH DCS subjected to TSS for 2003-2021, included in the national register. Thus, according to the registry data, over a 18-year period, 222 patients with ACTH DCS were under dynamic observation, of which 128(57.6%). The remaining 94(42.4%) patients were on medication - 54 cases (24.4%), adrenalectomy - 36 (16.2%), including 3 patients (1.3%) in combination with RT, on radiation therapy -4 patients (1.8%). Every year, there are 2-3 cases of relapse, which aggravate both the course and outcome of the disease. In view of this, the this stage of our research was the search and analysis of possible causes of the development of relapses of the disease in ACTH-DCS. The analysis revealed that a total of 53 (41.4%) patients out of 128 treated with TSS developed a relapse in the period 2003-2021. Of these women, the overwhelming majority - 48 (90%) and 5 men (10%). The mean age of the patients was 34.3 ± 0.26 years. The average duration of the remission period was 3.25 ± 0.04 years. Due to the development of recurrence and failure to achieve in 33 cases (62.3%), repeated TSS was performed in 11 patients, radiation therapy in 5 and adrenalectomy in 15 patients, which caused the development of pituitary complications in the form of diabetes insipidus in 2 (3.7 %) and panhypopituitarism in 2 (3.7%). Thus, in a cohort of 53 (42.9%) patients with ACTH-DCS, who developed a relapse of the disease after TSS, they were aged 34.3 ± 0.16, consisted mainly of females (90%), were characterized by microadenomas (88.6%), insufficient decrease in ACTH and cortisol levels in the early postoperative period (by 1.5 and 1.7 times, respectively), persistence of arterial hypertension (26.4%), impaired BMD (63.4%), 26.3%), the presence of central diabetes insipidus (3.7%) and panhypopituitarism (3.7%). As the results of the analysis show, the very state of remission in patients with ACTH-DCS is unstable and, for various reasons, they may develop a relapse, the frequency of which increases with an increase in the observation period.

Multimodal treatment including temozolomide (TMZ) and pasireotide for aggressive, giant silent corticotroph PiTNET in a young patient

Anna Bogusławska, Łukasz Kluczyński, Magdalena Godlewska, Ewelina Rzepka, Alicja Hubalewska-Dydejczyk & Aleksandra Gilis-Januszewska
Department of Endocrinology, Endocrine Oncology and Nuclear Medicine, Jagiellonian University Medical College, Cracow, Poland

Silent corticotroph pituitary neuroendocrine tumours (PiTNETs) are a subtype of nonfunctioning PiTNETs, that present positive immunostaining for adrenocorticotropin (ACTH) and/or show the expression of the transcription factor T-PIT without clinical signs of hypercortisolemia. They constitute 20% of all corticotroph PitNETs and manifest in most cases as macroadenoma with suprasellar extension and a higher tendency to apoplexy. We present a 33-year-old male with aggressive course of silent corticotroph PitNET. The patient was admitted to Emergency Department due to severe headaches and vomiting. Headaches (8-9/10 using numbering rating score (NRS)) and worsening vision loss were present one year before the surgery. In computer tomography, a sellar tumour mass (39x33x55 mm) was found with extrasellar extension, causing pressure on the cerebral aqueduct of the third ventricle, involving left sphenoid sinus. Additionally, features of cerebral edema were described. The patient was transferred to Neurosurgery Department and, external ventricular drainage was performed due to obstructive hydrocephalus. Two days later, debulking transsphenoidal surgery (TSS) was performed. Histopathology results showed silent adenoma subtype 1 (densely granulated), Ki67 $< 1\%$. Genetic testing was negative for *AIP* and *MEN1* mutations. However, 3 months later, magnetic resonance imaging (MRI) showed progression of PitNET (40x39x30 mm) with increasing hydrocephalus. Subsequently, second TSS was performed, complicated with cerebrospinal fluid leak. Biochemically, persistent multiple pituitary hormone deficiencies and diabetes insipidus were diagnosed. Clinically, severe headaches (9-10/10 using NRS) without improvement after analgesic and worsening vision loss were observed. The patient was consulted by multidisciplinary pituitary tumour board and radiotherapy was planned. Pasireotide (10 mg) monthly and 0.5 mg of cabergoline weekly were scheduled, however, due to rapid progression of the tumour and the compression of optic chiasm, emergency TSS (05.2021) with the decompression of the optic nerves was performed. After surgery, chemotherapy with temozolomide (starting dose of 150 mg/m^2) for 5 days was introduced. After first cycles, adjuvant stereotactic fractionated radiotherapy (total dose 50.4 Gy in 28 cycles) was performed. Temozolomide at the dose of 200 mg/m^2 for 5 days every 4 weeks was continued. Severe headaches (9-10/10 using NRS) without improvement after analgesic were still present. Pasireotide (increasing dose from 10 to 40 mg/month) was reimplemented, decrease of headaches from (initially 9-10 to none /10 using NRS) has been observed. In last MRI, after 5 cycles of temozolomide, and during pasireotide and cabergoline treatment, regression of the pituitary tumour (current measurements: 20x30x29 mm) was observed. Additionally, patients is in a very good general condition, reports no headaches.

Radiological classification of craniopharyngioma based on its origin

Tanja Skoric Polovina[1], David Ozretic[2], Mirsala Solak[1], Ivana Kraljevic[1], Tina Dusek[1], Annemarie Balasko[1], Karin Zibar Tomšić[1] & Darko Kastelan[1]
[1]Clinical Hospital Center Zagreb, Dpt of Endocrinology, ZAGREB, Croatia; [2]Clinical Hospital Center Zagreb, Dpt of Neuroradiology, Zagreb, Croatia

Recognizing the site of origin of craniopharyngioma (CP) along the hypothalamus-pituitary axis according to pre-operative MR is helpful to understand its growth pattern in relation to hypothalamus, which is critical in the prediction of hypothalamic injury and planning of treatment. We retrospectively classified 29 CP according to MR pre-operative image study using modified classification of Tang *et al*. (Nature, 8:10215, 2018). According to its relation to pituitary stalk, CP were classified into two types: central and peripheral. Peripheral type was further subdivided into three subtypes: hypothalamic stalk, suprasellar stalk and intrasellar stalk. Central type and hypothalamic stalk peripheral subtype CP were considered to be of hypothalamic origin. We compared types of CP with the development of cognitive dysfunction and obesity after the treatment as markers of hypothalamic injury. Of the 29 CP examined in this study, five were classified as central type, and 24 as peripheral type. Twelve of peripheral type were subclassified as hypothalamic stalk CP, four as suprasellar stalk CP, and eight as intrasellar stalk CP. Cognitive dysfunction was found significantly more often in patients with central CP and hypothalamic stalk CP (3/5 and 4/12, respectively) in comparison to patients with suprasellar and intrasellar stalk CP who did not developed cognitive impairment ($P = 0.012$). Obesity developed in 3 of 5 patients with central CP, 4 of 12 with hypothalamic stalk CP, 1 of 4 with suprasellar stalk CP, and 1 of 8 with intrasellar stalk CP, with no statistical difference between CP types. Our results showed that cognitive impairment as a marker of hypothalamic damage was found only in CPs of hypothalamic origin (classified as central and hypothalamic stalk CP). We conclude that this classification, based on preoperative MR findings, can predict hypothalamic damage. Suprasellar and intrasellar stalk CP may not involve the hypothalamus and therefore can be safely resected with no hypothalamic damage.

Background
EuRRECa (eurreca.net) is a web-based project that supports professional networks such as European Reference Networks (ERNs) in capturing standardised clinical information. The project includes an e-reporting registry (e-REC), which can be used to perform regular surveillance of specific events. Since 2018, e-REC has been used by the ERN for rare endocrine conditions (Endo-ERN) to understand the number of new clinical encounters at centres within this network.
Methods
Electronic reporting cards were issued through a simple bespoke reporting platform on a monthly basis to clinicians who had registered to participate in e-REC from July 2018 to June 2021. Clinicians were asked to report any newly encountered cases of any of the conditions that have been included in Endo-ERN.
Results
The number of centres reporting on e-REC has increased over a 3 year period from July 2018 to June 2021 when, a total of 60 centres from 22 countries had reported cases. Over this period, a median of 24 (range 10, 37) paediatric centres and 24 (12, 38) adult centres had reported cases on a monthly basis. A total of 7.860 and 3.771 new cases were reported in adults and children, respectively. Amongst paediatric cases, conditions within the sex development condition group were most commonly reported, comprising 44% of all reported conditions, with a trend towards more cases being reported on an annual basis. Overall, the median number of cases reported per centre was 30 (10, 137) and transgender (male to female) cases comprised the most commonly reported condition (58% of cases). Amongst adults, pituitary and thyroid conditions were most commonly reported, comprising 45% and 20% of all conditions, respectively. An increasing number of pituitary cases were reported over the 3 year period; a median of 79 (6, 255) pituitary cases were reported per centre. The reporting of thyroid cases remained constant; a median of 43 (5, 75) thyroid cases were reported per centre. Amongst conditions within the pituitary and thyroid groups, pituitary adenomas and non-metastatic thyroid carcinomas were the most commonly reported conditions, comprising 69% and 97% of cases, respectively.
Conclusion
There is increasing acceptability of the e-REC platform which can be used to capture brief and simple information to improve our understanding regarding new encounters of rare endocrine conditions. The platform can be adapted to serve the needs of several networks that are interested in understanding the occurrence of rare conditions.

Hormonal treatment modification during the long term follow-up of transwomen and transmen individuals: a retrospective observational Italian study

Marta Cacciani[1,2], Giorgia Spaggiari[1], Antonio R. M. Granata[1], Manuela Simoni[1,2] & Daniele Santi[1,2]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy

Background
Persons with assigned either male (AMAB) or female (AFAB) sex at birth might wish to obtain feminization or masculinization, respectively. To this purpose, hormonal treatment with sex hormones must be tailored to each subject. Several studies and the European Society of Endocrinology guidelines tried to identify the optimal hormonal treatment in both AMAB and AFAB subjects. However, the clinical management in the long term follow-up remains challenging. Many treatment adjustments and/or shifts are clinically performed to reach the therapeutic goal, i.e. phenotypic characteristics of the perceived gender, minimizing adverse events.
Aim of the study
To evaluate treatment modifications/shifts required in the long term follow-up of AMAB and AFAB subjects treated with guideline-based hormone therapy adjusted according to biochemical results.
Methods
A retrospective, longitudinal, observational clinical study was carried out at the Andrology Unit of Modena (Italy). All AMAB and AFAB subjects evaluated since 2006 were considered eligible. All clinical consultations performed until January 2022 were collected, including data regarding previous medical history, comorbidities, physical examination, blood examinations, hormonal assessment, and therapeutic choice.
Results
A total of 120 subjects were enrolled, 69 AMAB (57%) and 51 AFAB (43%). AFAB subjects were significantly older (41.1+9.1 *vs* 33.9+8.8 years, $P<0.001$) and followed-up for longer time (36.8+42.0 *vs*23.4+31.2 months, $P<0.001$) than AMAB.
In AFAB subjects, treatment modifications were performed 60 times (26.5%) during the follow-up and the dropout rate was 2.0% (1 subject). Mean testosterone serum levels during follow-up were 6.7+6.4 ng/ml. Therapy modifications were neither predicted by testosterone serum levels, nor comorbidities number, nor drug number (Cox logistic regression: 0.384, $P=0.061$). In AMAB group, hormonal treatment was modified 164 times (45.1%) during follow-up, with a dropout rate of 24.6% (17 subjects). Mean oestradiol serum levels at follow-up were 49.8+45.1 pg/ml. While therapy changes were not predicted by oestradiol serum levels (Cox logistic regression: 0.778, $P=0.194$), they resulted directly related with the number of comorbidities (Cox logistic regression: 0.585, $P=0.025$).
Conclusion
Our retrospective long term analysis on AFAB and AMAB subjects highlighted a comprehensive maintenance of sex hormones levels within therapeutic ranges burdened by frequent therapy modifications. These drug adjustments resulted more evident in AMAB subjects, in which treatment changes seemed related to the presence of comorbidities. Considering also the higher dropout rate compared to AFAB, AMAB subjects seem to require a more stringent clinical management during follow-up.

Background
Few studies to date have attempted to measure serum anti-Müllerian hormone (AMH) levels in adult men, and solid references ranges have not yet been defined on a large cohort.
Objective
In this study, we aimed to first establish the reference ranges for serum AMH and AMH-to-total testosterone ratio (AMH/tT) in adult males. Secondly, we investigated the relationship between serum AMH and both reproductive hormones and semen parameters.
Methods
This single-center retrospective study included 578 normozoospermic adult men. Serum AMH concentrations were determined with an automated sandwich chemiluminescent immunoassay.
Results
The median serum AMH was 43.5 pmol/l. The 2.5th and 97.5th percentile values for serum AMH and AMH/tT were 16.4 pmol/l − 90.3 pmol/l, and 0.45 − 3.43, respectively. AMH was positively correlated with inhibin B and sperm concentration, and negatively correlated with age, FSH and progressive sperm motility. Interestingly, using immunofluorescence, we documented for the first time that AMH type-II receptor (AMH-R2) is expressed in ejaculated human spermatozoa and gonadotrophic cells in postmortem pituitaries.
Conclusions
A new age-specific reference range for serum AMH and AMH/tT was established. Moreover, AMH-R2 expression in human spermatozoa and gonadotrophic cells, together with the relationship between serum AMH levels and sperm motility or mean FSH levels, highlight new potential functions of AMH in regulating sperm motility or FSH secretion in adult men.

Intranasal kisspeptin administration stimulates reproductive hormone secretion in healthy volunteers and patients with hypogonadism

Edouard Mills[1], Magda Swedrowska[2], Layla Thurston[1], Maria Phylactou[1], Bijal Patel[1], Lisa Yang[1], Sophie Clarke[1], Beatrice Muzi[1], Emma Alexander[1], Muhammad Choudhury[1], Paul Bech[1], Ali Abbara[1], Ben Forbes[2], Alexander Comninos[1] & Waljit Dhillo[1]
[1]Imperial College London, Hammersmith Campus, Section of Endocrinology and Investigative Medicine, London, United Kingdom; [2]King's College London, Institute of Pharmaceutical Science, London, United Kingdom

Background
Kisspeptin is a critical activator of hypothalamic gonadotrophin releasing hormone (GnRH) neurons and has significant potential to treat common reproductive disorders. To date, kisspeptin has solely been administered to humans via the intravenous or subcutaneous routes, however intranasal administration could offer a novel non-invasive delivery route. We therefore sought to determine the effects of intranasal kisspeptin on reproductive hormone release in humans for the first time.
Methods
Randomised, double-blinded, placebo-controlled, cross-over study in 12 healthy men (mean ± SEM age 28.3 ± 1.7 years; BMI 24.5 ± 0.7 kg/m^2). After monitored self-administration of intranasal kisspeptin-54 (3.2, 6.4, 12.8 and 25.6 nmol/kg) or 0.9% saline, serum reproductive hormone levels were measured every 15 minutes for four h. Subsequently, four women (mean age 29.8 ± 3.7 years; BMI 21.2 ± 1.1 kg/m^2) with hypothalamic amenorrhoea (HA) attended for the same protocol comparing intranasal kisspeptin-54 (12.8 nmol/kg) and 0.9% saline. Mean ± SEM was presented. Time profiles of hormone levels were compared using two-way ANOVA, and multiple means using one-way ANOVA.
Results
In healthy men, intranasal kisspeptin dose-dependently increased mean luteinising hormone (LH) levels at doses between 3.2-12.8 nmol/kg ($P = 0.008$ and < 0.0001 for 6.4 and 12.8 nmol/kg vs saline, respectively), with the maximal rises occurring 30-45 minutes post-administration. The maximal LH change from baseline was significantly elevated following all kisspeptin doses vs saline (*saline:* 1.54 ± 0.30 IU/l; *3.2 nmol/kg:* 2.46 ± 0.30 IU/l [p = 0.01]; *6.4 nmol/kg:* 3.08 ± 0.48 IU/l [p = 0.04]; *12.8 nmol/kg:* 4.45 ± 0.59 IU/l [p = 0.002]; *25.6 nmol/kg:* 4.07 ± 0.66 IU/l [p = 0.003]). Follicle stimulating hormone (FSH) levels followed a similar trajectory to LH. Kisspeptin at 12.8 nmol/kg increased serum testosterone from 120 minutes onwards ($P = 0.02$), with a maximal change from baseline of 4.9 ± 0.7 nmol/l ($P = 0.03$). In women with HA, intranasal kisspeptin increased mean LH ($P = 0.002$ vs saline), with the peak levels occurring 30-45 minutes post-administration. The maximal LH change from baseline was 4.06 ± 0.89 IU/l, compared with 0.20 ± 0.38 IU/l for saline ($P = 0.03$). Intranasal kisspeptin increased mean FSH ($P = 0.01$ vs saline). No significant changes in downstream serum oestradiol or progesterone were observed during the acute four-h study.
Conclusion
We report the first investigation of the effects of intranasal kisspeptin delivery on reproductive hormone release. Our results demonstrate that intranasal kisspeptin robustly and dose-dependently stimulates reproductive hormone release in healthy men and in a patient-group of women with hypogonadism. Given the ongoing development of kisspeptin therapeutics, intranasal kisspeptin offers a novel, safe, effective and non-invasive route of administration for the management of reproductive disorders that would be preferred by patients and clinicians alike.

Effects of testosterone therapy on bone turnover markers and bone mineral density in obese males with type 2 diabetes and functional hypogonadism

Kristina Groti Antonic
Ljubljana, Endocrinology, Ljubljana, Slovenia

Aims
Both functional hypogonadism (FH) and type 2 diabetes (T2D) negatively affect bone mineral density (BMD). We aimed to evaluate changes on bone turnover markers (BTMs) and BMD in obese males with FH and T2D due to testosterone therapy (TTh).
Research Design and Methods
55 obese males with FH and T2D participated in a two-year (first year double-blind, placebo-controlled study, second year follow-up) clinical trial. Participants were randomized into two groups. Group T ($n = 28$) received 1000 mg testosterone undecanoate (TU) both years of the study while group P ($n = 27$) received placebo first year and TU second year. BTMs C-telopeptide of type I collagen (CTX) and procollagen I N-terminal propeptide (PINP), estradiol, 25-hydroxyvitamin D, total, calculated free and calculated bioavailable testosterone levels were assessed at baseline, 12 and 24 months. BMD changes were evaluated at baseline and after 24 months using dual-energy x-ray absorptiometry (DXA).
Results
Results show decrease in median CTX from baseline of 1055 (676 to 1344) pmol/l to 911 (556 to 1152) pmol/l after one year of placebo ($P = .012$), then to 453 (365 to 665) pmol/l after one year of TTh ($P < .001$) in group P and from 887 (648 to 1496) pmol/l to 504 (262 to 804) pmol/l after first year of TTh ($P < .001$), then to 372 (165 to 599) after second year of TRT ($P < .001$) in group T. Median PINP did not change from 31.4 (27.1 to 40.3) µg/l baseline at statistically significant level after one year of placebo ($P = .469$) in group *P*but decreased to 28.0 (23.6 to 32.0) µg/l after one year of TTh ($P = .009$); in group T a decrease from 30.9 (21.9 to 35.3) µg/l to 26.2 (18.6 to 32.1) µg/l was observed after first year of TTh ($P = .005$), then to 20.1 (17.8 to 26.5) µg/l after second year of TRT ($P < .001$). DXA showed no changes in femoral neck BMD in 32 patients from both groups *P* ($n = 16$) or T ($n = 16$) while a statistically significant increase in lumbar spine BMD by.075 ± .114 g/cm^2 (95% CI:.014 to.136; $P = .019$) has been observed in group T following two years of TTh.
Conclsions
BTMs decreased significantly after TU and improvement of lumbar spine BMD was observed after two years of TTh in obese males with FH and T2D.

Management of 46, XY 17 alpha-hydroxylase deficiency: a case report

Bruno Bouça[1], Mariana Cascão[2], Pedro Fiúza[3], Sara Amaral[1], Paula Bogalho[1] & Jose Silva-Nunes[1]

[1]Centro Hospitalar Universitário de Lisboa Central, Department of Endocrinology, Diabetes and Metabolism, Lisbon, Portugal; [2]Centro Hospitalar Universitário de Lisboa Central, Intensive Care Unit, Lisbon, Portugal; [3]Centro Hospitalar Universitário de Lisboa Central, Department of Internal Medicine, Lisbon, Portugal

Introduction

17 alpha-hydroxylase deficiency (17OHD) is a rare autosomal recessive disease caused by mutations in the CYP17A gene, representing 1% of cases of Congenital Adrenal Hyperplasia (CAH). The accumulation of mineralocorticoids and the glucocorticoid effect of corticosterone induce high blood pressure (HBP) and hypokalemia.

Clinical Case

A 44 year-old female reporting HBP since the age of 20 years and without chronic medication, presented at the emergency department (ED) complaining of generalized asthenia and polyarthralgia for about two weeks. On examination, she was hypertensive (174/100 mmHg); blood analysis revealed severe hypokalemia − K^+ 1.2 mEq/l (3.5-5.1). In the ED, she had an episode of ventricular tachycardia evolving to asystole. After resuscitation, she was transferred to the Intensive Care Unit with rapid clinical improvement under antihypertensive therapy and hydrocortisone. Further laboratory evaluation showed: cortisol <0.4 mg/dl (3.7-19.4), ACTH 213 pg/ml (<46), aldosterone (decubitus) 27.4 ng/dl (1-16), renin <1.8 mcUI/ml (2.8-39.9). Due to these findings, she was transferred to the Endocrinology ward. On examination, she had an uncharacteristic morphotype, BMI 16.7 kg/m^2 (175 cm; 51.2 kg), cutaneous hyperpigmentation and Tanner stage M1P1. Hormonal evaluation showed: LH 64 mIU/ml (follicular phase 1.8-11.8), FSH 97 mIU/ml (3.03-8.08), estradiol 17 pg/ml (21-251), progesterone 5.2 ng/ml (0.1-0.3), 17-OHP 0.19 ng/ml (0.21-1.45), total testosterone 0.03 ng/ml (0.11-0.56). CT scan revealed bilateral adrenal hyperplasia (right width 11.5 mm; left width 12.9 mm) and absence of female internal genitalia (explaining primary amenorrhea referred by the patient). Genetic diagnosis was confirmed by the identification of the c.3G>A p.(Met1?) variant in homozygosity in the CYP17A1 gene. Karyotype analysis was compatible with 46 XY. At the last appointment, the patient was normotensive under dexamethasone 0.5 mg id, spironolactone 50 mg id, olmesartan 40 mg id, nifedipine 60 mg bid and nebivolol 5 mg id; blood analysis showed K+ 4.7 mEq/l and aldosterone 20.4 ng/dl.

Conclusion

The association of severe hypokalemia, hypertension, hypocortisolism, oligo/amenorrhea and the absence of secondary sexual characteristics favored the diagnosis of 17OHD, confirmed by genetic testing. As in other published cases, diagnosis outside pediatric age is not rare and should be considered in cases of severe hypokalaemia in hypertensive adults and lack of secondary sexual development.

Glycaemic and metabolic effects of testosterone replacement in hypogonadal men with uncontrolled type 2 diabetes − a randomised double blinded placebo controlled trial − stride study

Preethi Mohan Rao[1,2], Daniel M Kelly[2,3] & T. Hugh Jones[1,2]

[1]Barnsley Hospital NHS Foundation Trust, Robert Hague Centre for Diabetes and Endocrinology, United Kingdom; [2]The University of Sheffield, Human Metabolism and Oncology, United Kingdom; [3]Sheffield Hallam University, Biomolecular Research Centre, United Kingdom

The objective of the study was to assess the effect of intra-muscular testosterone on glycemic control, metabolic parameters and hypogonadal symptoms in men with hypogonadism and poorly controlled type 2 diabetes. This is a randomised double-blinded placebo-controlled add-on trial of intramuscular-testosterone undecanoate(Nebido®) administered every 12 weeks in 65 hypogonadal men with poorly-controlled diabetes. Phase-1 patients were randomly assigned to either treatment or placebo arm for 6 months of TRT. Phase-2 was an open-labelled phase for 6 months and patients on placebo moved on to the treatment group wherein patients in the treatment group continued. Anthropometric measurements, questionnaires and biochemical parameters were assessed at baseline and every three months for a year. Mean age of the cohort was 59 ± 8.98 years(mean $\pm$ SD). Mean duration since diagnosis of diabetes was 8.6 years. 17(26%) were on insulin. Baseline cohorts were comparable. There was no improvement in mean HbA1c or fasting plasma glucose(FBG) between the active and placebo groups after 6 months of TRT. No difference was found in HbA1c or FBG at 12 months compared to baseline in the active group either. Our study also showed a significant decrease in serum triglycerides(-0.497 ± 0.213 mmol/l, $P=0.023$) and improvement in left hand grip strength($P=0.025$) at 6 months post treatment in the active group compared to placebo group. There was no significant difference in the mean weight, BMI, WC, WHR, fat mass, fat percentage or fat free mass between the groups. Our study is the first ever RCT to show a significant improvement in total AMS(aging male symptom)scores from baseline after 6 months of TU treatment compared to placebo group($P<0.05$) in a cohort with poorly-controlled type 2 diabetes and hypogonadism. Another key finding is that the proportion of patients with severe symptoms moving to a less severe category(low/mild/moderate severity) was 46% in the active vs only 28% in placebo($P=0.0024$). Our study concludes that TRT did not have a significant improvement in glycaemic control at 6 months between the active/placebo groups and at 12 months within the active group and may need longer duration to see the positive effects especially in cohort of people who have had long duration of diabetes. There was a significant reduction in triglyceride levels and increase muscular-strength after 6 months of TRT. STRIDE study is the first ever RCT to show a significant improvement in clinical symptoms and symptom severity following testosterone treatment in patients with hypogonadism and type 2 diabetes after 6 months of TRT.

Overall impact of gender affirming hormone therapy: the portuguese experience

Miguel Saraiva[1], Rafael Santos[2], Zélia Figueiredo[3], Carolina Lemos[4] & Isabel Palma[1]

[1]Centro Hospitalar Universitário do Porto - Hospital de Santo António, Endocrinology, Diabetes and Metabolism, Porto,; [2]Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto; [3]Hospital de Magalhães Lemos; [4]i3S-Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto

Introduction

The prevalence of Transgender individuals seeking gender affirming hormone therapy (GAHT) has been increasing. This therapy has been known to be highly effective in the treatment of gender dysphoria and enhancing mental health in this population.

Aim

To evaluate the overall impact of GAHT on self-esteem, well-being and social/familial relations in the Portuguese adult transgender population

Methods

Cross-sectional study conducted in March 2021. Data collected through an *online* questionnaire that was delivered to adult transgender people living in Portugal who had been under GAHT for at least one year. To answer some of the items on the questionnaire, an ordinal scale ranging from 0 (worst result) to 6 (best result) was used.

Results

A total of 142 individuals (Group T) answered the questionnaire: 101 under masculinizing GAHT (Group M) and 41 under feminizing GAHT (Group F), with a median age of 25.0(21.0−33.0) years. The overall satisfaction with GAHT was evaluated with a median of 5.0 (5.0-6.0) points, with no differences between subgroups ($P=0.681$).

Discussion

This study reinforces that transgender people report high grades of satisfaction with both the physical and psychological effects of GAHT. This therapy seems to significantly enhance self-esteem, body wellbeing and social/familial relations and to reduce suicidal ideation, having an overall great impact on the quality of life of transgender people.

The effect of testosterone on quality of life, constitutional symptoms, sexual function and memory − randomised placebo-controlled study in hypogonadal men with uncontrolled type 2 diabetes − stride study

Preethi Mohan Rao[1,2] & T. Hugh Jones[1,2]
[1]Barnsley Hospital NHS Foundation Trust, Robert Hague Centre for Diabetes and Endocrinology, Barnsley, United Kingdom; [2]The University of Sheffield, Human Metabolism and Oncology, Sheffield, United Kingdom

The objective of the study was to assess the effect of intra-muscular testosterone on constitutional symptoms, sexual symptoms, memory and in men with hypogonadism and poorly-controlled type-2 diabetes. This is a randomised double-blinded placebo-controlled add-on trial of intramuscular testosterone undecanoate(Nebido®) administered every 12 weeks in 65 hypogonadal men with poorly-controlled diabetes. Phase-1 patients were randomly assigned to either treatment or placebo arm for 6 months of TRT. Phase-2 was an open-labelled phase for 6 months and patients on placebo moved on to the treatment group wherein patients in the treatment group continued. Outcomes(AMS, SF-36, IIEF-5 questionnaires, MMSE, Barnsley and NERI questionnaires) were assessed at baseline and every 3 months. Mean age of the cohort was 59 ± 8.98 years(mean ± SD). Baseline characteristics were comparable between active/placebo groups. Our study is the first ever RCT to show a significant reduction in the mean total AMS score from baseline of 48.34 ± 13.13 to score of 37.72 ± 12.25 at 6 months after testosterone treatment vs from 48.34 ± 12.69 to score of 42.78 ± 13.48 in the placebo group($P < 0.05$) in a cohort with type 2 diabetes and hypogonadism. Our study also showed that the proportion of patients with severe symptoms moving to a less severe category(low/mild/moderate severity) was 46% in the active vs only 28% in placebo group($P = 0.0024$). There was no significant difference in either the SF-36 scores, MMSE scores, BDHQ, NERI or IIEF scores or its domains at baseline and after 6 months of TRT. In phase-2 of the trial, there was a statistically significant reduction in the AMS total score all its subscales before and after TRT in the active arm at 12 months. A significant improvement in libido was also demonstrated. There was a significant reduction in the BDHQ total score($P = 0.07$) and two of its sub-domains − Sexual-wellbeing and Emotional-wellbeing($P = 0.002$ and$P = 0.011$ respectively) within the active arm before and after treatment of testosterone at baseline(0), 3,6,9 and 12 months post treatment. There was significant improvement in the mean scores of physical health domain and health change in over 1-year domain of SF-36 questionnaire($P = 0.019$, $P = 0.019$ respectively) and significant improvement in the mean scores of delayed verbal recall domain of MMSE which was highly significant($P = 0.0004$) before and after treatment in the active arm at baseline(0), 3,6,9 and 12 months post treatment. Our trial is the first RCT to show a significant improvement in constitutional symptoms, sexual symptoms, libido, symptom severity, and delayed verbal recall with TRT in a cohort with poorly-controlled type-2 diabetes and hypogonadism

Our previous study showed that polycystic ovary syndrome (PCOS)-like reproductive and metabolic phenotypes induced by maternal dihydrotestosterone (DHT)-exposure, can be passed on in mice from mothers (F_0) to daughters (F_1),

granddaughters (F_2), and even to great-granddaughters (F_3). The female transmission is independent of diet-induced obesity and is mediated by transcriptional and mitochondrial perturbations of oocytes accompany. How maternal DHT-exposure and obesity affect their male progeny across generations is less known. Based on two clinical studies: a Swedish nationwide register and a Chilean case-control study, we found that sons of mothers with PCOS are more obese and have dyslipidemia. Next, we investigated whether diet-induced maternal obesity and/or prenatal DHT-exposure in mice, mimicking both the lean and the obese PCOS phenotype, result in transgenerational transmission of a PCOS-like phenotype in male offspring via male germline. We find a transmission of reproductive and metabolic dysfunction in F_1 and F_3 male offspring in both androgenized and obese lineages, respectively, but with stronger phenotype in the obese lineage. Small non-coding RNAs (sncRNAs) sequencing of sperm from F_1 and F_3 male offspring revealed common differential expressed sncRNAs (DEsncRNAs) across generations in androgenized, obese, and obese and androgenized lineages, with distinct regulatory patterns among lineages. Three of the predicted targets of PIWI-interacting RNA and micro RNAs were also differentially expressed in serum from sons of PCOS mothers. Our results reveal a previously unknown risk of reproductive and metabolic dysfunction in male progeny of PCOS mothers, which is likely caused by epigenetic germline changes by sncRNAs.

The role of B cells in immune cell activation in polycystic ovary syndrome

Angelo Ascani[1], Sara Torstensson[2], Sanjiv Risal[2], Haojiang Lu[2], Sabrina Teschl[1], Gustaw Eriksson[2], Congru Li[2], Joana Menezes[2], Katalin Sandor[2], Camilla Svensson[2], Martin Stradner[1], Barbara Obermayer-Pietsch[1] & Elisabet Stener-Victorin[2]
[1]Medical University of Graz, Department of Internal Medicine, Graz, Austria; [2]Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden

Objective
Age-associated double negative (DN) B memory cells lacking surface expression of CD27 and immunoglobulin D (IgD) are associated with proinflammatory characteristics and higher disease activity in autoimmune diseases. We first characterized B cells phenotypes in women with and without polycystic ovary syndrome (PCOS). We then took an *in vivo* approach, transferring purified IgG extracted from serum of hyperandrogenic women with PCOS to mice to establish whether self-reactive B cells have a causal effect on the development of a PCOS-like phenotype.
Methods
We initially characterized major B cell lineages in serum of hyperandrogenic women with PCOS and of women without PCOS (controls). We purified IgG from the serum of women with PCOS (PCOS IgG) and controls which was injected intraperitoneally into immunocompetent wild type (WT) female mice and thereafter into age paired mice lacking both B and T cells (RAG1-/-). Reproductive function was tested by measuring anogenital distance and estrous cyclicity. Body composition and metabolic functions were assessed combining EchoMRI, metabolic cages and oral glucose tolerance test. Serum was collected for analysis of sex steroids by liquid chromatography mass spectrometry. Comprehensive flow cytometric analysis of lymphocytes and myeloid cells was applied in whole blood, spleen, lymph node, ovary, endometrium, visceral adipose tissue.
Results
Immunophenotypic analyses showed a significant remodeling of B cell repertoire in women with PCOS compared with controls: higher frequencies of DN B memory cells were found in PCOS patients ($P=0.002$), with declined IgD^+ B memory cells ($P=0.011$). Total testosterone was an independent predicting variable for IgM variability ($P=0.01$). Transfer of human PCOS IgG into female WT mice resulted in PCOS-like phenotype with higher circulating estrogens and trend of increased androgens, as well as higher body weight ($P<0.05$). Preliminary results from immune profiling showed an overall increase of DN B cells in mice receiving PCOS IgG, particularly DN2 subsets with a $CD21^-$ phenotype, with increased frequencies of active naïve cells and neutrophils in ovary.
Conclsions
Women with PCOS display an increased peripheral expansion of DN B cells. Exposing mice with IgG from women with PCOS rapidly induced an altered immune cell profile with increased body weight and circulating sex steroids. PCOS may represent a state of inflammatory-cell hypersensitivity and chronic inflammation, resulting in remodeling of the lymphocytes. The ongoing transfer of purified B cells from prepubertal hyperandrogenic mouse model into mice B cell deficient mice (muMt-) will define the overall impact of androgen exposure on B cell phenotypes.

FSH and bone: comparison between males with central vs primary hypogonadism

Luca Giovanelli[1,2,3], Biagio Cangiano[1,2], Stefano Colombo[4], Luca Persani[1,2], Richard Quinton[3,5], Marco Bonomi[1,2] & Iacopo Chiodini[1,2]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]Istituto Auxologico Italiano, Department of Endocrine and Metabolic Medicine, Milan, Italy; [3]Newcastle-upon-Tyne Hospitals, Department of Endocrinology, Diabetes & Metabolism, Newcastle upon Tyne, United Kingdom; [4]University of Milan, Milan, Italy; [5]University of Newcastle-upon-Tyne, Translational & Clinical Research Institute, Newcastle upon Tyne, United Kingdom

Background
Recent data suggest a direct effect of follicle stimulating hormone (FSH) on the skeletal metabolism. Particularly, it can encourage bone resorption and also inhibit osteoblast differentiation. High FSH levels have been found to correlate with impaired bone health in females, whilst evidence in males remains somewhat poor and conflicting. Intriguingly, men with primary and central hypogonadism might represent a novel study model in this context.
Aims
To investigate the possible association of FSH excess with male osteoporosis.
Patients and Methods
119 men, consecutively referred to Istituto Auxologico Italiano and Newcastle upon Tyne Hospitals, were enrolled in this prospective cross-sectional observational study at the time of the first diagnosis of hypogonadism. All participants had spontaneous pubertal development. Regarding those with hypergonadotropic hypogonadism (Hyper Hypo), patients with a pre-pubertal onset form (PPO) (i.e., Klinefelter syndrome) were distinguished from the ones with an adult-onset form (AO) based on the onset of FSH elevation. Bone mineral density (BMD) at both lumbar spine (LS) and femoral neck (FN) was measured using dual-energy X-ray absorptiometry. The prevalence of morphometric vertebral fractures (VFx) was evaluated by performing spinal radiographs.
Results
Across the whole cohort, LS and FN BMD were directly associated with age at diagnosis and body mass index (BMI), respectively. After adjusting for potential confounders (age at diagnosis, BMI, smoking habits, calculated free testosterone (cfT) and 25OH vitamin D levels) by means of General Linear Model analysis, AO-Hyper Hypo patients showed significantly lower LS BMD and tended to show lower FN BMD values, as compared to those with hypogonadotropic hypogonadism (Hypo Hypo). In men with PPO-Hyper Hypo LS BMD was significantly lower than in AO-Hyper Hypo ones. No significant differences in the prevalence of VFx were found between the groups.
Conclusions
This is the first prospective study comparing men with primary and central hypogonadism in order to better delineate the putative role of FSH on the male bone health. These findings indicate a potential negative effect of FSH excess on the male bone mass, especially at spine. The duration of high FSH levels may also play a part in this setting. Longitudinal studies, involving hypogonadal men on testosterone replacement therapy, are required. Indeed, it would be crucial to identify new risk factors and mediators of male bone

fragility, with a view to ultimately reducing the huge public health burden related to fractures.

Introduction
Polycystic Ovary Syndrome (PCOS) is the most common endocrinopathy in women. Studies exploring the experiences of people with PCOS reveal inadequate patient access to information and limited insight into healthcare professionals' (HCP) attitudes regarding the condition. Simulation via Instant Messaging-Birmingham Advance (SIMBA) is a virtual simulation platform proven to increase learners' confidence in their approach to simulated cases with a high acceptance rate and reproducibility. However, participation in previous SIMBA sessions has been limited to HCPs.
Objectives
To assess the effectiveness of SIMBA in improving HCPs' knowledge on diagnosis and management of health conditions related to PCOS and recognise areas of disparity in knowledge and clinical expectations between HCPs and patients with PCOS.
Methods
Anonymised transcripts based on real-life cases were prepared with expert input and used to train moderators. The transcripts were used to deliver WhatsApp-based simulation to HCPs and parallel Zoom-based workshops to people with PCOS. HCPs were guided through the cases by moderators to elicit history, propose diagnoses, and management plans. People with PCOS discussed the same cases and reflected upon case management based on personal experiences. Patients and HCPs convened for a Q&A discussion at the end of the session where cases were discussed by experts and patient reflections were shared. Participants filled in pre and post SIMBA surveys.
Results
25 HCPs and 15 patients participated in the session. HCPs reported a 41% and 40% increase in confidence in the management of simulated cases (skin, weight, fertility and menstrual periods related issues in PCOS; $P<0.001$) and non-simulated cases (metabolic outcomes, menopause, mental health and endometrial cancer; $P<0.001$), respectively. HCPs reported that SIMBA improved their professionalism (28%) and communication skills (40%) and had a positive personal (84%) and professional (92%) impact. Patients reported a 17.7% increase in confidence regarding HCPs' awareness of management options for all cases following the session ($P=0.0002$). Thematic analysis of patient feedback revealed that 83.3% found the session engaging, organised and insightful. 90% of HCPs agreed that the session improved patients' understanding of the diagnosis and management of PCOS and 100% believed that the session improved their own understanding of patient experiences.
Conclusion
SIMBA is proven to be an effective educational tool that reduces discrepancies in clinical expectations between HCPs and patients and improves HCPs' confidence in managing simulated cases. It promotes transparent discussion of clinical practice and patient experiences, thereby strengthening doctor-patient relationships.

Efficacy of very low calorie ketogenic diet in obese PCOS: a randomized controlled study

Srdjan Pandurevic[1], Paola Dionese[1], Ilaria Mancini[2], Dmitri Mitselman[1], Matteo Magagnoli[1], Rita Teglia[1], Domenica Gazineo[3], Lea Godino[3], Flaminia Fanelli[1], Maria Cristina Meriggiola[2], Uberto Pagotto[1] & Alessandra Gambineri[1]

[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Division of Endocrinology and Diabetes Prevention and Care, Bologna, Italy; [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Unit of Gynecology and Obstetrics, Bologna, Italy; [3]S. Orsola Teaching Hospital, Bologna, Italy

Background
Very low-calorie ketogenic diet (VLCKD) was shown to be effective in reducing weight and insulin resistance (IR) in obese patients. Considering that IR is very common in women with polycystic ovary syndrome (PCOS), and that IR worsens hyperandrogenism, ovulatory disfunction, and body fat accumulation, conceivably VLCKD could alleviate PCOS manifestations in the obese phenotype.
Objective
This study compared the effects of a commercial VLCKD ("PnK® method") and the control low calorie standard diet (LCD) on body weight and composition, insulin resistance, ovulation and hyperandrogenism in a population of obese PCOS.
Methods
This is an open-label, monocentric, randomized controlled trial (NCT04801173), supported by Pronokal Health group S.L. Women aged 18-45 years with PCOS diagnosed using the NIH criteria were randomized into the VLCKD or LCD group (15 vs 15). VLCKD group followed the VLCKD for 8 weeks, switching to the LCD for 8 weeks more, while the LCD group followed the LCD for 16 weeks. Ovulation monitoring by progesterone measurement and pelvic ultrasound was done at baseline and at the end of the study (week 16), while a clinical exam, bioelectrical impedance analysis (BIA) anthropometry, and biochemical analyses were performed at baseline, at week 8, and at week 16 of the study. Androgens were measured by tandem liquid chromatography-mass spectrometry. Free testosterone (freeT) was calculated using the Vermeulen formula. Repeated measures general linear model was used to evaluate within- and between-group differences for continuous variables.
Results
2 dropouts occurred in the VLCKD group, 1 in the LCD group. Body weight decreased significantly in both groups, but more so in the VLCKD group – average difference 12.4 kg (-13.6%) vs 4.7 kg (-5.3%) ($P<0.001$). Significant differences between the VLCKD and LCD groups were also seen in waist circumference (-8.1% vs -2.2%), BIA-measured body fat (-15.1% vs -8.5%), and freeT (-30.3% vs +10.6%), over the course of the study ($P=0.004$, $P=0.02$, and$P=0.002$, respectively). HOMA-IR index also decreased more in the VLCKD group during the first 8 weeks (-36.1% vs -26.1%, $P=0.02$). At baseline, 5/13 (38.5%) participants in the VLCKD group and 2/14 (14.3%) participants in the LCD group had ovulatory cycles, which differentially increased to 11/13 (84.6%) and 5/14 (35.7%) at post-intervention monitoring, respectively (McNemar, $P=0.031$).

Conclusion
This data shows that VLCKD is a valid method for reducing body fat and rapidly ameliorating hyperandrogenism and ovulatory dysfunction in obese PCOS women.

The effect of dihydrotestosterone on the immune profile in a mouse model of Polycystic Ovary Syndrome

Sara Torstensson[1], Angelo Ascani[2], Haojiang Lu[1], Sanjiv Risal[1], Gustaw Eriksson[1], Congru Li[1], Anna Benrick[3], Barbara Obermayer-Pietsch[2] & Elisabet Stener-Victorin[1]
[1]Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden; [2]Medical University of Graz, Department of Internal Medicine, Austria; [3]University of Gothenburg, Department of Physiology, Sweden

Polycystic Ovary Syndrome (PCOS) is an endocrine disorder affecting 10-15% of women worldwide, characterized by high androgen levels, anovulation and/or polycystic ovarian morphology. Chronic low-grade inflammation is associated with the disorder as well as many of its comorbidities, such as obesity and type-2 diabetes. To determine the role of the immune system in the pathophysiology of PCOS, we characterized the immune profile of the dihydrotestosterone (DHT)-induced PCOS-like mouse model. Prepubertal female mice implanted with a DHT-pellet displayed reproductive dysfunction, with a disrupted estrous cyclicity and increased anogenital distance, and a metabolic phenotype similar to the comorbidities seen in women with PCOS, with increased body weight and fat mass (EchoMRI), higher fasting glucose and impaired glucose uptake following oral glucose tolerance test. The immune profiles of reproductive, immunological, and metabolic tissues were analyzed by flowcytometry. The number of eosinophils in endometrium was decreased in the DHT-induced PCOS model compared to control, whereas infiltration of peripheral NK cells was increased. Moreover, an overall shift towards a pro-inflammatory M1 phenotype was seen among macrophages in endometrium of DHT exposed mice, indicated by a higher proportion of macrophages expressing MHC-II, and a trend suggested an increased total number of macrophages. The same effect on eosinophils was seen in visceral adipose tissue (VAT), with no effect on circulating eosinophils. Macrophage immune-phenotype and number followed the same pattern in VAT as in endometrium. Next, an increased number of NK cells was found in the spleen as in endometrium, while there was no difference in number of NK cells in blood in DHT-exposed mice. Strikingly, these mice had a clear reduction in CD8+ cytotoxic T cells in the spleen and in blood, as well as an overall reduction in the CD3+ lymphocyte population in blood. Interestingly, there was no difference in the number of CD4+ T helper cells, neither in blood nor spleen. The altered T cell populations could be due to androgen receptor activation on thymic epithelial cells as androgens suppress thymopoiesis in male mice. This hypothesis is supported by the decreased thymic weight in the DHT-induced PCOS model. In summary, we show that the prepubertal PCOS-like model displays an altered immune profile in a wide range of tissues. Whether these alterations are a result of androgen receptor activation and/or a result of metabolic dysfunctions remains to be elucidated, and it remains to define what impact these immune alterations have on reproductive and metabolic function.

Effects of octamethylcyclotetrasiloxane and decamethylcyclopentasiloxane on female reproductive systems in rat

Jimin Lee, KangMin Kim, Minsu Lee, YongIn Kim & Eui-Bae Jeung
Chungbuk National University, College of Veterinary Medicine, Cheongju-si, Chungcheongbuk-do, Rep. of South Korea

In our daily life, humans are exposed to lots of chemicals. Among those chemicals, octamethylcyclotetrasiloxane (D4) and decamethylcyclopentasiloxane (D5) have been widely used in cosmetics for their functions such as softening, wetting, and viscosity control. However, the effect of these chemicals on the female reproductive systems has not been clearly elucidated. In the case of D4, it was recently recognized as an endocrine disrupting chemical (EDC), but the effect of D5 has been unknown. *In vitro* study, the human uterus epithelial-like Ishikawa cells, were treated with D4 and D5 to measure cell viability. In both D4 and D5 showed, decreased in cell viability at the 10^{-4} M. It means both chemicals are toxic in uterus. *In vivo* study, female Sprague Dawley rats were exposed to D4 and D5 diluted in corn oil for 2 weeks. At this time corn oil (Vehicle), 60 mg/kg/day (D4), and 100 mg/kg/day (D5) were administrated by using oral injection. Result shows there was no significant difference in uterine epithelial and stromal marker gene expression. On the other hand, ovary folliculogenesis and steroidogenesis gene expression were varied. HE staining results showed that increased uterine glands and ovary follicles number. Therefore, this study suggests that D4 and D5 aggravated female reproductivity such as miscarriage and implantation failure.

Functional analysis of anti-mullerian hormone variants in patients with polycystic ovary syndrome

Li Meng, Anke McLuskey & Jenny Visser
Erasmus MC, University Medical Center Rotterdam, Department. of Internal Medicine, Rotterdam, Netherlands

Objective
Recently rare heterozogous AMH genetic variants have been identified in women with polycystic ovary syndrome (PCOS) that result in reduced AMH signaling. However, the exact functional mechanism remains unknown. Therefore, we have performed functional analyses to analyze the processing, secretion and signaling of these PCOS-specific AMH rare variants.
Methods
Six PCOS-specific AMH variants containing mutations (V12G, P151S, P270S, P352S, P362S, H506Q) were selected based on previous findings. The variants were introduced in an AMH expression vector containing either a wild type (AMH-RAQR) or optimized cleavage site (AMH-RARR) and co-expressed with the BRE-Luc reporter in the mouse granulosa cell line KK-1. The AMH expression vectors were stably expressed in HEK293 cells for Western Blot analysis and ELISA.
Results
Expression of AMH-P151S and AMH-H506Q decreased AMH signaling by ~90% ($P<0.001$), depending on the presence of a RAQR or RARR cleavage site. Signaling of the other four variants was comparable to wild-type (wt)-AMH. Coexpression of the variants with wt-AMH at equal amounts confirmed that AMH-P151S and AMH-H506Q significantly inhibited the signaling activity of wt-AMH by ~30% ($P<0.001$). Transfection of increasing amounts of these two variants resulted in a further inhibition, which was independent of the cleavage site. To explain this dominant negative effect, we next analyzed the impact of AMH cleavage on AMH signaling. Cells were transfected with an AMH construct containing an inactive cleavage site (AMH-RAGA) in combination with exogenous AMH treatment. We observed that exogenous AMH-induced signaling was suppressed by 30% ($P<0.01$) in the presence of AMH-RAGA. In contrast, exogenous AMH-induced signaling was not affected when AMH-P151S or AMH-H506Q was transfected. Indeed, Western blot analysis showed that AMH-P151S and AMH-H506Q proteins were only detected in the cell lysate but not in the supernatant, even in the presence of RARR cleavage site. In contrast, wt-AMH and the P352S and P362S variant were detected in both the cell lysate and the supernatant. Further supporting these results, confocal image analysis showed that cells expressing AMH-P151S and AMH-H506Q retained significantly higher cellular AMH protein levels with a highly abnormal

subcellular localization in the ER compared to the cells expressing wt-AMH and AMH-P352S.
Conclusions
Our results show that the PCOS-specific AMH variants P151S and H506Q disrupt normal processing and secretion of AMH. Our results further suggest that these AMH variants hamper secretion of wt-AMH, explaining the dominant negative effect of these variants on AMH signaling.

Objective
This study investigated the association between ethnicity, birthplace and emotional and psychosexual wellbeing in women with Polycystic Ovary Syndrome (PCOS) in the community.
Design
International cross-sectional study.
Methods
Women with a self-reported PCOS diagnosis by a healthcare professional were invited to complete an online Blue Morpho questionnaire between September-October 2020 (UK) and May-June 2021 (India). Four validated questionnaires were included: Hospital Anxiety and Depression Scale (HADS) to examine anxiety and depression; Body Image Concern Inventory (BICI) to assess dysmorphic appearance concerns; Beliefs About Obese Persons Scale (BAOP) to investigate beliefs about causes of obesity; and Female Sexual Function Index (FSFI) to assess domains of sexual function (desire, arousal, lubrication, orgasm, satisfaction and pain). Adjusted linear and logistic regression models were used to evaluate the relationship between ethnicity (White vs Non-white) and country of birth (UK vs India), and questionnaires scores and outcomes (Anxiety and/or Depression [HADS $\geq$11]) and Body Dysmorphic Disorder [BDD; BICI $\geq$72]). Adjustments were made for age category, level of education, marital status and parity.
Results
1008 women with PCOS completed the questionnaire. 44.8% were in the 26-35 age category, 44.9% had an undergraduate degree, 53.9% were single and 84.1% did not have children. The prevalence of anxiety and depression was 60.6% and 24.3%, respectively. Women of non-white ethnicity (60.7%; $n=611$) reported higher prevalence of depression (OR 1.96 [95% CI 1.41-2.73]) but lower BDD (OR 0.57 [95% CI 0.41-0.79]) prevalence compared to white ethnic women (38.9%; $n=392$). Similarly, women born in India (44.9%; $n=453$) had higher prevalence of anxiety (OR 1.57 [95% CI 1.00-2.46]) and depression (OR 2.20 [95% CI 1.52-3.18]) but lower BDD prevalence (OR 0.42 [95% CI 0.29-0.61]) compared to women born in the UK (43.0%; $n=433$). Both groups of white ethnic women and women born in the UK reported higher psychological illbeing; higher BICI and BAOP scores. However, overall sexual wellbeing and all FSFI sexual domains, excluding desire, were significantly impaired for both groups of non-white ethnic women and women born in India.
Conclusion
This study reveals the significant influence of ethnicity and birthplace on emotional and psychosexual wellbeing among women with PCOS, focusing on poor body image, weight stigma and sexual dysfunction. This highlights the importance of providing an individualised, holistic multidisciplinary approach alongside clinical care for women with PCOS and improving awareness of the significant influence of ethnicity and birthplace on PCOS related outcomes amongst primary healthcare providers to improve patient care.

Is N-terminal prohormone of B-type natriuretic peptide (NT-proBNP) disturbed in polycystic ovary syndrome?

Małgorzata Kałużna[1], Pola Kompf[1], Katarzyna Ziemnicka[1], Krauze Tomasz[2], Katarzyna Wachowiak-Ochmańska[3], Andrzej Wykrętowicz[2], Przemyslaw Guzik[2] & Marek Ruchala[1]
[1]Poznan Univeristy of Medical Sciences, Department of Endocrinology, Metabolism and Internal Diseases; [2]Poznan Univeristy of Medical Sciences, Department of Cardiology - Intensive Therapy, Poland; [3]Heliodor Swiecicki University Hospital, Endocrinology, Metabolism and Internal Diseases Ward, Poland

Introduction
Polycystic ovary syndrome (PCOS) patients present with or without biochemical hyperandrogenism (HAPCOS or non-HAPCOS, respectively). Although cardiometabolic and hormonal abnormalities have been reported in women with PCOS, particularly those with hypertension, direct comparisons between normotensive (blood pressure (BP) $<$140/90 mmHg) patients with HAPCOS and non-HAPCOS are scarce. Data on N-terminal prohormone of B-type natriuretic peptide (NT-proBNP) in PCOS are inconclusive.
Methods/design
We compared various cardiovascular (CV), anthropometric, metabolic, and hormonal features of normotensive PCOS patients and healthy women. This case-control observational study involved 249 normotensive PCOS and 85 healthy eumenorrheic women. Based on blood androgen concentrations, PCOS patients were divided into HAPCOS ($n=69$) or non-HAPCOS ($n=180$) groups. NT-proBNP was measured using Cobas 6000 Analyzer with electrochemiluminescence sandwich immunoassays (Roche Diagnostics GmbH, Germany).
Results
HAPCOS patients had significantly ($P<0.05$) lower NT-proBNP concentration than non-HAPCOS women (34.57 vs. 39.77 pg/ml;$P=0.021$) and controls (41.58 pg/ml;$P=0.01$). NT-proBNP levels were comparable between non-HAPCOS and controls. HAPCOS patients had also significantly higher peripheral and central systolic BP and pulse pressure (PP), C-reactive protein, low-density lipoprotein cholesterol, triglycerides, glucose, and insulin than non-HAPCOS and healthy women. Still, these results were within normal ranges. However, body mass index (BMI) of HAPCOS subjects was over 4 kg/m^2 higher than in non-HAPCOS patients and nearly 6 kg/m^2 higher than in controls. Except for BMI, statistical differences in the cardiometabolic profile were of little clinical relevance. Higher amounts of adipose tissue in HAPCOS patients may be an explanation for the coexistence of higher BP and lower NT-proBNP concentration. A negative correlation between parameters of biochemical hyperandrogenism (free testosterone, dehydroepiandrosterone sulfate, androstenedione, dihydrotestosterone), and NT-proBNP was observed, suggesting a role of androgens in influencing NT-proBNP levels. It is likely that a combination of several abnormalities in HAPCOS women, like: excess fat tissue, hyperandrogenism, hyperinsulinemia, and insulin resistance, may be responsible for the relatively lower NT-proBNP levels and higher systolic BP and PP among this patient population.
Conclusions
Normotensive women with HAPCOS have a worse cardiometabolic profile but a lower NT-proBNP concentration than non-HAPCOS patients. Features of this profile in both PCOS groups are within normal ranges typical for healthy women. Increased BMI may be the only clinically relevant parameter differentiating hyperandrogenic from non-hyperandrogenic PCOS patients and healthy women.

Central precocious puberty developed after treatment of leydig cell tumor: case report

Bouguerra Hadjer[1], Khellaf Amina[1], Amel Adimi[2] & Zakia Arbouche[1]
[1]Department of Endocrinology, Beni Messous UHC, Algiers, Algeria;
[2]Department of Endocrinology, Bab El Oued UHC, Algiers, Algeria

Background
Leydig cell tumors (LCTs) are the most prevalent hormone-secreting testicular tumors, but overall, a rare testicular tumor subtype. Surgery is the main therapy with a favorable prognosis. Nevertheless, the development of central precocious puberty after surgery of the tumor has been observed on rare occasions.
Case Report
An 8.5-year-old boy presented with symptoms of sexual precocity dating back to 4 years. He had pubic hair (P4), enlarged left testis (G3: right testis 4 cc, left testis 10 cc with a palpable nodule), and stature advance. The hormonal evaluation revealed high levels of testosterone and estradiol and low levels of FSH and LH. Ultrasound of the testis showed an inhomogeneous hypoechoic tumor of the left testis. An inguinal radical orchiectomy managed this mass. The pathological diagnosis was a benign LCT. Three months after surgery, the patient presented persistent physical signs of sexual precocity, enlarged right testis, and stature gain of 8.5 cm. His hormonal values confirmed central precocious puberty: the testosterone level stayed high at 2.57 ng/ml facing LH and FSH levels at 3.26 UI/l and 4.55 UI/l respectively. Ultrasonography ruled out testicular tumor recurrence and brain magnetic resonance imaging excluded a tumor of the hypothalamus or pituitary gland. We started treatment with triptorelin (GnRH analog). After 3 months of treatment, we observed clinical regression of physical signs and stabilized growth velocity. After 6 months, hormonal assessment showed testosterone returned to prepuberal range (0.15 ng/ml), FSH and LH levels were 0.11 UI/l and 0.43 UI/l respectively. At the last follow-up (1 year from the beginning of triptorelin), we note a stature gain of 2 cm and a stabilization of the bone age with no adverse effects.
Discussion and conclusion
Eleven other cases of gonadotropin-dependent precocious puberty after successful treatment of LCTs have been reported in the litterature[1,2,3]. The mechanism is unknown but is hypothesized due to the rebound secretion of LH after surgery of LCTs and subsequent reduction in androgens, which suppressed the adenohypophysis. The true incidence of central precocious puberty remains unclear because long-term follow-up of children with LCTs is not available. GnRH analog therapy appears to be the most effective medical treatment in such cases.
Keyboards
LCTs, central precocious puberty, GnRH analog.

Coexistence of 46, XX testicular disorder of sex development and 11β-hydroxylase deficiency: *In Vivo* and *In Vitro* Studies

Bang Sun, Xi Wang, Jiangfeng Mao, Xueyan Wu & Min Nie
Peking Union Medical College Hospital, Beijing, China

Background
46, XX testicular disorder of sex development (DSD) and 11β-hydroxylase deficiency (11β-OHD) are two extremely rare types of disorder of sex development. No coexistence has been reported yet.
Case Description
Here we reported the first patient diagnosed as the coexistence of 11β-OHD and 46, XX testicular DSD basing on clinical, biochemical, molecular, cytogenetic, and functional experiment findings. A 22-year-old male showed small testes and gynecomastia for 2 years. At the age of 3, he was diagnosed as congenital adrenal hyperplasia (CAH). Adrenal ultrasound suggested the bilateral adrenal hyperplasia (both length*width = 2.4*0.9 cm) and X ray showed accelerated bone age (12.5 years old). Irregular cortisone acetate 6.25 mg per day was administrated since then. At the age of 18, he was sent to emergency for aortic aneurysm rupture and heart failure, and diagnosed as 11β-OHD. Sanger sequencing revealed that he carried compound heterozygous variants in *CYP11B1* gene: NM_000497.4: c.905_907delinsTT and NM_000497.4: c.954 + 7C > T, which were respectively inherited from his father and mother. According to American College of Medical Genetics and Genomics (ACMG) guideline, c.905_907delinsTT was identified as pathogenic variant, and c.954 + 7C > T, the novel one, was defined as variant of unknown significance. Pathogenicity of c.954 + 7C > T were further verified in COS7, CHO, and 273T cell lines by minigene methods, which turned out to cause the gain of a cryptic one at the 5bp downstream of the original one. The patient was treated by neoplasty of thoracic aortic aneurysm and added anti-hypertension drugs in addition to glucocorticoid after surgery. Unexpectedly, small testes and gynecomastia came into notice recently. Laboratory tests revealed hypergonadotropic hypogonadism and azoospermia. Scrotum ultrasound showed bilateral testicular dysplasia. To figure out these unexplainable results, whole exome sequencing was performed and revealed two copy number variants: duplication of Xp22.33-q28 spanning 151.32 Mb and deletion of Yp11.2-q11.23 spanning 23.34 Mb. Karyotype test by culturing blood lymphocytes showed 46, XX (100/100). Another disease, 46, XX testicular DSD, was diagnosed. Fluorescence *in situ* hybridization (FISH) revealed the presence of *SRY*gene translocating into the short arm of X chromosome. Under the coaction of two diseases, testosterone level was in male normal range, and replacement was unnecessary. Assisted reproduction was advised to start early.
Conclusion
To our knowledge, this is the first report of the coexistence of 46, XX testicular DSD and 11β-OHD in the same individual. The case illustrates the complexity that might be encountered in the diagnosis of DSD when different genetic defects affecting sex development exist.

Cardiometabolic risk factors and diabetes mellitus are related with the severity of menopausal symptoms in middle-aged women

Elena Armeni[1], Stylianos Kopanos[1,2], Eleni Verykouki[3], Areti Augoulea[1], Stavroula A. Paschou[1], Demetrios Rizos[4], George Kaparos[5], Makarios Eleftheriades[1], Anna-Bettina Haidich[3], Dimitrios Goulis[2], Nikolaos Vlahos[1] & Irene Lambrinoudaki[1]
[1]National and Kapodistrian University of Athens, 2 nd Department of Obstetrics and Gynecology, Aretaieio Hospital, Athens, Greece; [2]Unit of Reproductive Endocrinology, Medical School, Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece; [3]Faculty of Health Sciences, School of Medicine, Aristotle University of Thessaloniki, University Campus, Department of Hygiene, Social-Preventive Medicine and Medical Statistics, Thessaloniki, Greece; [4]National and Kapodistrian University of Athens, Hormonal Laboratory, Aretaieion Hospital, Athens, Greece; [5]National and Kapodistrian University of Athens, Aretaieion Hospital, Biochemical Laboratory, Athens, Greece

Background
Both surgical and spontaneous menopause are associated with increased cardiovascular disease (CVD) risk. Recent evidence reported that clusters of menopausal symptoms are associated with accumulation of cardiometabolic risk factors. Climacteric symptoms are also known to be affected by lifestyle parameters, ethnicity, the geographical location as well as by the overall health status at the time of the menopausal transition.
Aim
This study aimed to evaluate the association between menopausal symptoms, and lifestyle as well as cardiometabolic risk factors, in a cohort of apparently healthy middle-aged women.
Methods
This study consisted of 2.793 peri- and postmenopausal women (menopausal-age $\leq$ 15 years), not on menopausal hormone therapy, retrieved from the outpatient Menopause Clinic of the 2nd Department of Obstetrics and Gynecology, National and Kapodistrian University of Athens, Greece. We assessed demographic and athropometric parameters (including body mass index, BMI), and obtained fasting blood samples for evaluation of biochemical/hormonal data. The severity of menopausal symptoms was evaluated by the Greene Climacteric scale (GCS).
Results
Mixed effect models showed that the total GCS-score associated with BMI (b = 0.12, 95%CI: 0.04 to 0.20), diagnosis of type 2 diabetes (T2DM, b = 2.10, 95%CI: 0.06 to 4.15), older age at menopause (menopausal age > 7 years vs 2 to 7 years, b = -1.24.95% CI: -2.17 to -0.33). Physical GCS score associated with BMI (b = 0.06, 95%CI: 0.03 to 0.09), central obesity (b = 0.18, 95%CI: 0.02 to 0.34), menopausal status (2 to 7 years vs > 7 years after the final menstrual period *vs.* perimenopause, b = -0.36, 95%CI: -0.59 to -0.13 and b = -0.65, 95%CI: -0.97 to -0.34, respectively). Psychological GCS-score associated with values of BMI (b = 0.06, 95% CI: 0.00 to 0.11). All previous GCS-scores associated negatively with age. Vasomotor GCS-score associated negatively with menopause-age > 7 years vs younger menopausal age. Poisson mixed models showed that GCS-sexual

score associated with a younger menopausal age (menopause age 2 to 7 years vs > 7 years, incidence rate ratio (IRR) = 1.53, 95%CI: 1.21 to 1.94), central obesity (IRR = 1.18, 95%CI: 1.00 to 1.39), smoking, diastolic blood pressure, age.
Conclusions
The results of this study indicate that the severity of menopausal symptoms is associated with obesity, smoking and T2DM, in a large sample of peri- and postmenopausal women.

Usefulness of routine assessment of free testosterone for the diagnosis of functional male hypogonadism

Paolo Facondo[1], Elena Di Lodovico[1], Letizia Chiara Pezzaioli[1], Carlo Cappelli[1], Alberto Ferlin[2] & Andrea Delbarba[3]
[1]University of Brescia (Italy), Department of Clinical and Experimental Sciences; [2]Unit of Andrology and Reproductive Medicine, University of Padova, Padova, Italy, Department of Medicine; [3]Unit of Endocrinology and Metabolism, ASST Spedali Civili, Brescia, Italy

Objective
To investigate whether routine assessment of free testosterone improves the diagnostic accuracy of functional male hypogonadism.
Methods
Total and free testosterone (calculated through SHBG assessment) were determined in 372 male patients (median age 44) referring to our department for sexual symptoms symptoms (188 patients) or infertility (184 men). Low total and free testosterone were defined as < 2.31 ng/ml and <63 pg/ml, respectively.
Results
Hypogonadism, as calculated free testosterone <63 pg/ml, was found in 47/188 (25.0%) patients with sexual symptoms and in 21/184 (11.4%) with infertility. Total testosterone determination misdiagnosed hypogonadism in 8.4% (12/143) of men with sexual symptoms and in 2% (3/152) with infertility. In subjects with borderline total testosterone (between 2.31 and 3.5 ng/ml), only 24.7% (19/77) had hypogonadism confirmed by free testosterone levels. No subjects had known conditions altering SHBG. Free testosterone levels significantly correlated with age, haematocrit, gonadotropins, gynecomastia, BMI, and number of co-morbidities, whereas total testosterone associated only with the latter two. Moreover age, haematocrit, erectile dysfunction, BMI, and low libido were significantly different between men with normal and low free testosterone, whereas only BMI and low libido were significantly different between patients with normal and low total testosterone.
Conclusion
This is the first study evaluating the impact of FT assessment to diagnose functional hypogonadism in men with hypogonadal symptoms or infertility. Routine assessment of free testosterone allows a more accurate diagnosis of functional hypogonadism, especially in men with sexual symptoms. Free testosterone levels associate with clinical and biochemical parameters of androgen deficiency better than total testosterone levels. A first-line assessment of SHBG and calculated free testosterone levels should be performed in all men with symptoms of male hypogonadism, to improve our diagnostic performance.

Energy deficit as a cause of transient male hypogonadotropic hypogonadism: a successful resolution of a primary infertility

Vânia Benido Silva[1], Maria Teresa Pereira[1], Nuno Rossano Louro[2] & Márcia Barreiro[3]
[1]Centro Hospitalar Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar Universitário do Porto, Urology, Porto, Portugal; [3]Centro Hospitalar Universitário do Porto, Gynecology/Medically Assisted Procreation Center, Porto, Portugal

Introduction
Caloric restriction combined with overtraining can result in a total body energy deficit, which in turn is associated with multiple deleterious endocrine consequences, including hypogonadotropic hypogonadism. This can be a reversible cause of primary infertility, but its occurrence in men is still poorly recognized.
Case Report
We report a case of a 39-year-old male evaluated in an urology appointment for primary infertility. He had a history of psoriasis, previous parotitis with no documented testicular involvement and obesity 4 years earlier (weight:110 kg, height: 1.79 m, Body mass index[BMI]:34.3 kg/m^2). For that reason, he made lifestyle changes, performing a restricted calories and carbohydrates diet combined with 2 h daily intense physical exercise, with significant and rapid weight loss (currently, weight: 71 kg, BMI 22.2 kg/m^2). For at least 1 year, he had a marked decrease in libido, rare sexual intercourses, vaginal anejaculation since the beginning of attempts at procreation, and significant asthenia, which he associated with work stress and physical activity. No changes in erection were valued. Objectively, he presented hairy distribution according to age and sex, absence of gynecomastia. The vas deferens were bilaterally palpable, the testes were of normal volume, with no apparent lesions and no varicocele, and the penis was without alterations. From further investigation, the analytical study proved hypogonadotropic hypogonadism (Total Testosterone [TT] 2.21 ng/ml [Reference Range (RR): 2.8-8.0]; LH 1.4 mIU/ml[RR:1.6-8.6], SHBG 41.7 nmol/l [RR:13-71]). Prolactin (7.5 ng/ml [RR:4.04-15.2]) and TSH (2.11 µIU/ml [RR: 0.30 - 3.18]) were normal. The spermogram showed asthenoteratozoospermia and the scrotal ultrasound showed no changes. The pituitary MRI was normal. The study carried out with the female element did not identify any changes. The hypothesis of hypogonadotropic hypogonadism secondary to caloric restriction and concomitant excessive daily energy expenditure was raised and the patient progressively increased the dietary intake of carbohydrates while maintaining the same frequency and intensity of physical exercise. After 3 months of this modification, the patient reported more energy, complete resolution of libido complaints and greater frequency of sexual intercourse. Analytically, testosterone and gonadotropin levels normalized (TT 2.90 ng/ml[RR:2.8-8.0]; FSH 4.6 mIU/ml[1.5-12.4], LH 1.6 mIU/ml[RR:1.6-8.6]) and a pregnancy spontaneously occurred.
Conclusion
The male reproductive axis is very sensitive to caloric deprivation, with clinical and analytical repercussions. This case alerts to this male cause of hypogonadotropic hypogonadism, often overlooked in the investigation of primary infertility. Given its functional nature, this condition is reversible and treated with increased energy intake.

Y-chromosome disomy and sexual ambiguity

Yosra Hasni[1,2], Oumayma Zarrouk[1], Samia Tilouche[2,3], Hamza Elfekih[1,2], Hayfa Farid[1], Amel Maaroufi[1,2], Maha Kacem[1,2], Molka Chadli Chaieb[1,2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia; [3]Farhat-Hached University Hospital, Pediatrics department, Sousse, Tunisia

Introduction
Chromosomal abnormality 47, XYY, despite being present in approximately 1 in 1000 newborn boys, remains less known phenotypically and more than 85% of men are never diagnosed. Males with 47, XYY syndrome are described to be phenotypically normal. They present often a developmental delay, behavioral difficulties and learning disabilities that may be associated with accelerated growth rate and taller stature in adulthood. Endocrine disorders, especially pubertal delay, are rarely described in patients with this karyotype. We report the case of a boy who had at birth sexual ambiguity revealing a 47, XYY karyotype.
Observation
A 13-year-old boy was found at birth to have sexual ambiguity with a 1.5 cm micropenis and empty scrotum. Imaging ruled out the presence of female external genitalia and concluded to bilateral cryptorchidism. 17-OH Progesterone was normal at 0.5 ng/ml ruling out 21-hydroxylase deficiency. Testosterone, DHT, delta 4-androstenedione and DHEA-sulfate were normal with a testosterone/DHT ratio < 20. Genetic analysis revealed 47, XYY karyotype. He received βHCG injections and had a surgery for the micropenis and bilateral cryptorchidism. The child does not have psychomotor or growth disorders. He is still prepubescent (Tanner staging: P1/G1) with a penis size of 4.5 cm. Hormonal exploration revealed FSH = 0.9 mUI/ml, LH = 0.4 mUI/ml with testosterone < 0.1 ng/ml and a bone age less than 13 years, requiring monitoring to detect early a possible pubertal delay.
Discussion
47, XYY karyotype is a rare anomaly in which gonadal function is generally intact. However, a higher incidence of infertility was noted in men who carry this genetic abnormality. The association of this karyotype with micropenis and

pubertal delay was also described in the literature as a possible cause of this chromosomal anomaly.

Use of selective venous vein sampling in postmenopausal women with hyperandrogenism of unclear aetiology

Ana Romero Gregori[1], Olga Giménez[1], Ismael Capel[1], David Subías[1], Saad Marcouchi[1], Laura Costa[2], Juan Perendreu[3], Eugenio Berlanga[4] & Mercedes Rigla[1]
[1]Hospital Parc Taulí de Sabadell, Endocrinology, Sabadell, Spain; [2]Hospital Parc Taulí de Sabadell, Obstetrics and Gynecology, Sabadell, Spain; [3]Hospital Parc Taulí de Sabadell, Interventional Radiology, Sabadell, Spain; [4]Hospital Parc Taulí de Sabadell, Laboratory, Sabadell, Spain

Background
Hyperandrogenism is infrequent in menopause, being the most common cause benign pathologies. However, it can also be produced by an ovarian or adrenal tumour. Correct diagnosis and location can be challenging because small lesions may not be visible with modern imaging studies. We report a case of ovarian stromal hyperplasia where selective venous catheterization and hormonal sampling were performed to find the origin of excessive androgen production.
Case report
A 74-year-old woman was referred to our hospital with high serum testosterone level and hirsutism. Her medical history included obesity (IMC 34 kg/m^2), type 2 diabetes, dyslipidaemia and OSAS. Her symptoms had begun five years previously with 8 kg weight gain, frontal alopecia and hirsutism on her chest, arms and abdomen. Ferriman-Gallwey scored 21. Laboratory examination revealed severe hyperandrogenism with a total testosterone of 2.27 ng/ml (normal range 0.03-0.41 ng/ml) and free testosterone of 5.1 pg/ml (normal range 0-3.7 ng/ml). Dehydroepiandrosterone sulfate, androstenedione, 17-hydroxyprogesterone, prolactin, IGF-1 and thyroid hormones were all within normal range. Urinary free cortisol was normal in two determinations. An overnight 1 mg dexamethasone suppression test showed normal suppression of serum cortisol. Transvaginal ultrasonography showed that both ovaries were of normal size with no detectable masses. Adrenal computed tomography did not detect enlargement or tumour formation in either adrenal gland. Pelvic magnetic resonance did not show any remarkable findings. An ovarian androgen production was suspected. Selective vein catheterization and hormonal sampling from both ovarian and adrenal veins were performed before and after stimulation with 250 mg $ACTH_{1-24}$. Serum testosterone levels from left and right ovarian vein were remarkably higher than in the other veins, 387 ng/dl and 52.80 ng/dl respectively. Right ovarian vein sampling was uncertain because of anatomic difficulties. Owing to the fact the patient was menopausal, she underwent a laparoscopic bilateral oophorectomy. Final pathology demonstrated ovarian stromal hyperplasia. Postoperatively, her total testosterone levels decreased to 0.10 ng/ml. Four months after the surgery there was a clear improvement in hirsutism and frontal alopecia.
Conclsion
Selective ovarian and adrenal venous sampling is useful to localize the androgen producing source when imaging technique findings are inconclusive. In our case, an ovarian origin was confirmed. Due to the fact that the patient was menopausal and the right ovarian vein sampling was uncertain, a bilateral oophorectomy was preferred. However, selective venous sampling is especially important in women on reproductive age to avoid bilateral oophorectomy.

Kisspeptin improves sexual brain processing in women with low sexual desire

Layla Thurston[1], Tia Hunjan[1], Natalie Ertl[1,2], Matt B Wall[1,2], Edouard Mills[1], Sofiya Suladze[1], Bijal Patel[1], Emma Alexander[1], Beatrice Muzi[1], Eugenii A Rabiner[2], Paul Bech[1], David Goldmeier[3], Ali Abbara[1], Alexander Comninos[1,4] & Waljit Dhillo[1,4]
[1]Imperial College London, Endocrinology and Investigative Medicine, London, United Kingdom; [2]Invicro, London, United Kingdom; [3]Imperial College Healthcare NHS Trust, Sexual Medicine, London, United Kingdom; [4]Imperial College Healthcare NHS Trust, Endocrinology, London, United Kingdom

Introduction
Sexual desire is a key component of the sexual response model. Absence or deficiency of sexual desire can lead to marked distress or interpersonal difficulty, termed 'hypoactive sexual desire disorder' (HSDD). HSDD is the most common female sexual health complaint worldwide, affecting up to 10% of women. Despite its detrimental impact on psychological well-being and quality of life, treatment options are currently limited. The hormone kisspeptin is a key endogenous activator of the hypothalamic-pituitary-gonadal axis, with emerging roles in sexual and emotional behaviour, and thus could serve as a novel treatment option in women with HSDD.
Methods
We performed a randomized, double-blind, two-way crossover, placebo-controlled study in 32 premenopausal women with HSDD. We used psychometric, functional neuroimaging, and hormonal analyses to investigate the effects of kisspeptin administration on brain activity, in response to erotic stimuli (erotic videos) and facial attraction (images of faces of varying attractiveness).
Results
Kisspeptin administration resulted in an increase in self-reported ratings of feeling 'sexy', compared to placebo, measured using the Sexual Arousal and Desire Inventory ($t[32]=2.27$, $P=0.03$). On functional MRI, kisspeptin administration deactivated the left inferior frontal gyrus and activated the postcentral and supramarginal gyrus in response to erotic videos ($Z=2.3$, $P<0.05$). Kisspeptin administration deactivated the secondary somatosensory cortex ($Z=2.3$, $P<0.05$) and enhanced activation in the posterior cingulate cortex on viewing male faces, which correlated with a reduction in self-reported sexual aversion ($r=0.476$, $P=0.005$). Kisspeptin resulted in a mean increase in LH of 2.75 iU/l ($F(1, 62)=6.084$, $P=0.02$) and FSH of 0.37 iU/l ($F(1, 62)=4.030$, $P=0.05$) across the 75-minute duration of the study as expected, with no effect observed on downstream circulating estradiol, progesterone or testosterone levels.
Discussion
Our results demonstrate that kisspeptin administration to women with HSDD increases their self-reported ratings of feeling 'sexy'. Our brain activity changes provide mechanistic insight for this, with deactivation of the left inferior frontal gyrus, likely serving to reduce internal monologue and response inhibition. Furthermore, kisspeptin's deactivation of the secondary somatosensory cortex can reduce a woman's focus on herself, her body image, and related negative thoughts, thus augmenting her judgement of male facial attractiveness. Finally, kisspeptin's actions in the posterior cingulate cortex can serve to increase feelings of romantic love and reward processing, thereby reducing sexual aversion and increasing sexual desire. These behavioural and mechanistic findings in women with HSDD lay the foundations for clinical applications for kisspeptin in psychosexual disorders.

The effect of gastric sleeve resection on menstrual pattern and ovulation in premenopausal women with class III-IV obesity

Tetiana Tatarchuk[1], Ivan Todurov[2], Panagiotis Anagnostis[3], Tetiana Tutchenko[1], Natalia Pedachenko[4], Marina Glamazda[1], Natalia Koseii[1] & Svetlana Regeda[1]
[1]Institute of Pediatrics, Obstetrics and Gynecology of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine; [2]Center for Innovative Medical Technologies, Academy of Sciences of Ukraine, Kiev, Ukraine; [3]Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Thessaloniki, Greece; [4]Department of Obstetrics, Gynecology and Perinatology, P.L. Shupik National Healthcare University of Ukraine

Purpose
Bariatric surgery is very efficacious in treating severe obesity. However, its effect of menstruation and ovulation is currently unknown. The purpose of this study was to assess the effect of gastric sleeve resection (GSR) on menstrual pattern in women with stage III-IV obesity and ovulatory dysfunction compared with conventional management.
Methods
This was a prospective, multicentre, non-randomized trial, in premenopausal women, who fulfilled the criteria for gastric sleeve resection (GSR). Both women with and without polycystic ovary syndrome (PCOS) were evaluated at three, six, nine, 12 and 15 months post-surgery.
Results
Menstrual cycle irregularities were identified in 122 severely obese women (60 with PCOS; 62 non-PCOS). The % total weight loss was greater with GSR than

with conventional management (33.4% *vs*. 3.6% in PCOS; 24.8% *vs*. 3.6% in non-PCOS, respectively). Intermenstrual interval was shortened towards normal length ($\leq$35 days) both in PCOS and non-PCOS GSR groups, by the 6th and 12th post-surgical month, respectively. Furthermore, ovulation at six months was achieved in 63.6% of PCOS and 45% of non-PCOS subjects post-GSR, which was higher than in controls (11.1% and 13.6%, respectively; $P<0.05$). This percentage rose to 75.7% and 81.8% at 12 and 15 months in PCOS, respectively, but not in the non-PCOS group (55% and 52.5%, respectively; $P<0.05$).
Conclusions
Weight reduction after GSR improved menstrual irregularity towards normality in women with severe obesity. Ovulation dysfunction was also resumed in more than half of these patients at 6-15 months. These effects were more evident in women with PCOS.

Interplay between estrogen signaling and notch pathway in rodent Sertoli cells

Sylwia Lustofin, Alicja Kamińska, Małgorzata Brzoskwinia, Joanna Cyran, Barbara Bilińska & Anna Hejmej
Jagiellonian University, Institute of Zoology and Biomedical Research, Department of Endocrinology, Krakow, Poland

Somatic cells of the seminiferous epithelium, called Sertoli cells, play a key role in germ cell development and maintenance of proper course of spermatogenesis. Although androgens are considered the main regulators of Sertoli cell activity, recent studies indicate that their metabolites, estrogens, also influence Sertoli cell function. Estrogens, act mainly through nuclear estrogen receptors α and β (ERα, ERβ), however non-classical signaling *via* membrane G protein-coupled estrogen receptor 1 (GPER) was also confirmed. It is well established that direct interactions between the cells in the seminiferous epithelium, including the Notch pathway, are essential for undisrupted spermatogenesis. Notch pathway is activated by binding membranous ligands Delta-like (DLL) or Jagged (JAG) of one cell to surface Notch receptors of the neighboring cell. The aim of this study was to explore the role of estrogens and their receptors in the control of the expression of Notch pathway ligands in Sertoli cells. Experiments were performed on primary Sertoli cells cultures isolated from rat testis (PSC) and mouse Sertoli cell line (TM4). First, the effect of estrogenic stimulation or estrogen action inhibition were examined using 17β-estradiol or estrogen receptor antagonists (ICI 182.780; G-15), respectively. Next, to determine the precise role of each receptor, siRNA silencing was conducted to knockdown the expression of ERα, ERβ, or GPER. qRT-PCR, western blot and immunofluorescence were employed to analyze the expression of DLL1, DLL4 and JAG1. The expression of all studied ligands was increased after stimulation by 17β-estradiol. The increase of either JAG1 or DLL1 expression in estrogen-stimulated cells was inhibited only by ICI 182.780. Knockdown experiments revealed that ERα silencing entirely abolished the effect of 17β-estradiol on both JAG1 and DLL1 expression. Exposure to ICI 182.780 and G-15 decreased DLL4 protein expression in 17β-estradiol-stimulated Sertoli cells. Silencing experiments demonstrated that ERβ and GPER knockdown effectively blocked estrogen influence on DLL4 protein expression. In summary, our results indicate that the expression of Notch pathway ligands in Sertoli cells is regulated by estrogens. JAG1 and DLL1 expression is controlled mainly *via* ERα, while DLL4 expression is dependent on ERβ and GPER signaling. Thus, the cooperation between classical and non-classical estrogen signaling pathways may be important for the communication within the seminiferous epithelium *via* Notch signaling, and thereby for proper spermatogenesis. This study was supported by a grant N18/MNW/000022 (Jagiellonian University, Faculty of Biology). Finasteride inhibits epinephrine synthesis in humans: implication for sexual dysfunction

Silvia Giatti[1], Silvia Diviccaro[1], Alessandro Di Domizio[2], Lucia Cioffi[1], Eva Falvo[1], Donatella Caruso[1], Alessandro Contini[3] & Roberto Cosimo Melcangi[1]
[1]Università degli Studi di Milano, Department of Pharmacological and Biomolecular Sciences, Milano, Italy; [2]Spillo Project, Paderno Dugnano, Italy; [3]Università degli Studi di Milano, DISFARM, Milano, Italy

Finasteride is a 5alpha-reductase (5α-R) inhibitor used in clinics to treat androgen-dependent conditions, such as benign prostate hyperplasia and androgenetic alopecia (AGA). Its use has been associated with several adverse effects, including sexual complaints. However, to date, no hypothesis to explain such adverse effects has been proposed. This is a consequence of the still incomplete knowledge of the intricate network of motivational, psychological, and molecular inputs that are involved in sexual behavior. In this work, a multidisciplinary approach has been used to evaluate whether finasteride may interact with targets different from 5α-R (i.e., off-target proteins − OTPs). *In silico* analysis (SPILLO-PBBS software and docking/molecular dynamics) indicated that the enzyme phenylethanolamine N-methyltransferase (PNMT), the limiting enzyme in epinephrine production, might be a finasteride OTP. This is interesting, since epinephrine and norepinephrine are involved in erection (Becker *et al*., 2000, J Urol), and alterations in their levels has been observed in patient with erectile dysfunction (Becker *et al*., 2002, Urology). An inhibitory assay developed *in vitro* confirmed that finasteride blocks the human PNMT. Finally, to verify the *in vivo* interaction, adult male rats were treated with finasteride (1 mg/rat/day s.c. daily for 20 days). *Ex vivo* analysis indicated that epinephrine levels were decreased by finasteride treatment in adrenal glands, while those of norepinephrine were increased. This, together with no variation in PNMT protein levels, confirmed the hypothesis of a block in epinephrine synthesis. Therefore, we explored if corpora cavernosa (CC) of finasteride-treated rats presented molecular alterations. A decreased protein level of estrogen receptor beta was observed in CC of finasteride-treated rats, in line with evidence in aging and diabetic rats with erectile dysfunction (Shirai *et al*., 2004, Urology). Moreover, the levels of dopamine, which improve the penis relaxation, were significant decreased in CC tissue after finasteride administration. Overall, the data here presented indicate that finasteride affects epinephrine synthesis by blocking PNMT enzymatic activity in humans. This block can have an impact in sexual behavior, as suggested in an animal model treated with finasteride. In addition, the alterations observed in CC indicate possible impairment of erectile function. Our results suggest possible mechanisms for the sexual dysfunction observed after finasteride treatment in humans and add a piece of knowledge on the mechanisms controlling sexual function in mammals.

Global impact of PCOS awareness month: challenges and opportunities

Kashish Malhotra[1], Carina Synn Cuen Pan[2], Meri Davitadze[3], Konstantinos Manolopoulos[4], Michael O'Reilly[5], Wiebke Arlt[6,7] & Punith Kempegowda[6,7]
[1]Dayanand Medical College and Hospital, Ludhiana, Punjab, India; [2]College of Medical and Dental Sciences, University of Birmingham, United Kingdom; [3]Georgian-American Family Medicine Clinic 'Medical House', Georgia; [4]Henry Dunant Hospital Center, Athens, Greece; [5]Royal College of Surgeons in Ireland (RCSI) University of Medicine and Health Sciences, Department of Medicine, Ireland; [6]University Hospitals Birmingham NHS Foundation Trust, United Kingdom; [7]Institute of Metabolism and Systems Research, University of Birmingham, United Kingdom

Background
September is celebrated as PCOS awareness month worldwide and is aimed at improving the lives of those with PCOS, promoting research, and strengthening advocacy efforts. While significant financial and human resources are invested in promotions during this month, to the best of our knowledge, there is no evidence to show the impact of this initiative. In our study, we evaluated the global digital impact of PCOS Awareness Month, tracking commonly used hashtags as surrogate markers, patterns of associated emotions and identifying key players, collaborations and trending topics associated with PCOS Awareness Month.
Methods
We utilised several online tools (Symplur, SocioViz.net, Sprout Social, Sentiment Viz, and Google trends) to study the global impact of PCOS Awareness Month using #PCOS, #PCOSawareness, #PCOSawarenessmonth, and a corresponding search query. Network and sentiment analysis was done on the last day of PCOS awareness month to identify common themes and associated topics with the tweets. Google Trends was used to study the web and news search popularity globally to get an overall idea of the internet search trends beyond social media platforms.

Results
While we found a growing trend for #PCOS and related hashtags from 2014 to 2020, we noticed a decline in 2021. In each of these years, the largest spike of both impressions and users for #PCOS was seen at the start of September with a declining trend for the rest of the month. Verified users, who have notably more influence, have shown consistently increasing support for the PCOS Awareness Month from 2014 to 2021. On network analysis, the most commonly associated hashtags with the #PCOS were #endometriosis, #fertility, #womenshealth, #pcossupport, and #infertility. Sentiment analysis revealed most of the tweets were linked to subdued but pleasant emotions. 76% of top influencers collaborated with at least one other person during PCOS Awareness Month activities. Geographically, we noted limited engagement in African, Asian, and non-English speaking European countries
Conclsions
PCOS Awareness Month is an effective strategy to raise awareness with social media playing a crucial role in amplifying the message especially with the usage of hashtags. Further gains can be made by enhancing collaborations between like-minded individuals and organisations to make concerted efforts during PCOS Awareness Month. Our findings also provide an opportunity to understand the current perceptions and expectations amongst the public, which can influence future healthcare investment and research.

Influence of polycystic ovary syndrome on in vitro fertilization and relationship with the Asn680Ser polymorphism in FSHR gene

Inês Vieira[1], Ana Filipa Ferreira[2], Alexandra Carvalho[2], Conceição Dias[2], Silvana Fernandes[2], Dírcea Rodrigues[1], Paulo Cortesão[2], Teresa Almeida Santos[2] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, Endocrinology, Diabetes and Metabolism; [2]Coimbra Hospital and University Center, Gynecology, Obstetrics, Reproduction and Neonatology

Introduction
Polycystic ovary syndrome (PCOS) is a frequent cause of infertility. Its influence on the results of in vitro fertilization (IVF) is controversial, and generally not isolated from the effect of obesity. A relationship between the FSH receptor (*FSHR*) polymorphism *Asn680Ser* and the risk and phenotype of PCOS has been studied with conflicting results.
Objectives
To analyze the influence of obesity and PCOS on the gonadal axis and IVF results. To assess the influence of *Asn680Ser* on the risk of PCOS and IVF.
Material and Methods
Retrospective analysis of patients with PCOS by Rotterdam criteria with and without obesity and controls with tubal infertility, undergoing 1st IVF after a short ovarian stimulation cycle with GnRH antagonist.
Results
Sample with 212 patients: 72 without obesity, with PCOS (group A); 75 without obesity or PCOS (B); 36 with obesity and PCOS (C); 29 with obesity, without PCOS (D). Mean age 33.5 ± 3.7 years with homogeneous distribution between groups ($P=0.207$) and similar body mass index in the non-obese (A 23.8 ± 2.9 vs B 23.3 ± 2.7 kg/m2, $P=0.203$) and in the obese groups (C 33.9 ± 3.0 *vs* D 33.1 ± 2.1 kg/m2, $P=0.305$). The PCOS groups had: higher gonadotropins, LH/FSH ratio, testosterone, antral follicle count and anti-Mullerian hormone; lower luteal phase estradiol and progesterone ($P<0.001$ for all analyses). In the IVF results, the differences were more pronounced in the groups with *vs* without obesity, C and D (*vs* A and B) had: fewer mature oocytes (6.3 ± 5.3 and 5.7 ± 2.9 *vs* 9,1 ± 6.8 and 6.7 ± 5.2, $P=0.035$), less blastocysts (1.1 ± 1.6 and 0.5 ± 0.8 *vs* 1.7 ± 2.3 and 1.6 ± 2.2$P=0.031$) and lower embryo transfer rate (45.7 and 41.4 *vs* 68.8% and 69.3, $P=0.007$). In those who transferred embryos, the probability of pregnancy did not differ ($P=0.197$). In multivariate analysis, only obesity had an individual contribution to the transfer probability ($P=0.001$). The *Asn680Ser*polymorphism (analyzed in 113 cases) was present at a similar rate in patients with and without PCOS (65.7 *vs*54.4%, $P=0.225$) and was not associated with the likelihood of embryo transfer or pregnancy ($P=0.452$ and 0.174, respectively).
Discussion
Differences in IVF results were particularly related to obesity, suggesting that, although the hormonal changes associated with PCOS can be overcome by controlled ovarian stimulation, addressing obesity is essential for the success of IVF. In this population, *Asn680Ser*was not associated with the risk of PCOS or IVF outcomes.

Association between basal androgen concentrations and number of follicles on the day of triggering final oocyte maturation in poor responders undergoing IVF - a prospective study

Julia Bosdou[1], Panagiotis Anagnostis[2], Despoina Savvaidou[1], Leonidas Zepiridis[1], Dimitrios Goulis[2], Grigorios Grimbizis[1] & Efstratios Kolibianakis[1]
[1]Aristotle University of Thessaloniki, Medical School, 1st Department of Obstetrics and Gynecology, Unit for Human Reproduction, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Medical School, 1st Department of Obstetrics and Gynecology, Unit of Reproductive Endocrinology, Thessaloniki, Greece

Purpose
Androgens promote early follicular development and granulosa cell proliferation by augmenting follicle-stimulating hormone (FSH) receptor expression in granulosa cells. Several retrospective studies have evaluated the association between basal androgen concentrations and follicular development in women undergoing ovarian stimulation for in vitro fertilization (IVF) with conflicting results. The aim of this study was to investigate whether basal androgen concentrations are associated with the number of follicles on the day of triggering final oocyte maturation in poor responders undergoing IVF.
Methods
This prospective study was performed between 02/2020 and 01/2022 in 103 poor responders according to the Bologna criteria. Androgens, including total testosterone, sex hormone-binding globulin (SHBG), dehydroepiandrosterone sulfate (DHEAS), Δ4-androstenedione and 17-OH progesterone (17-OHP), were measured at the initiation of ovarian stimulation. Ovarian stimulation was performed using a fixed dose of 300 IU of recombinant gonadotrophins and gonadotrophin releasing hormone (GnRH) analogues. Triggering of final oocyte maturation was performed in the presence of three follicles of ≥ 17 mm. Primary outcome measure was the number of follicles ≥ 11 mm on the day of triggering final oocyte maturation. The association between androgen concentrations and the number of follicles ≥ 11 mm on the day of triggering was evaluated using generalized estimating equations, accounting for female age and body mass index (BMI). Values were expressed as a coefficient (coef) or mean (95% confidence interval).
Results
Female age was 41.9 (41.2-42.6) years, while BMI was 26.1 (24.9-27.3) kg/m^2. The number of follicles ≥11 mm on the day of triggering final oocyte maturation was 6.1 (5.3-7.0). The number of COCs retrieved was 3.9 (3.2-4.6), the number of MII oocytes was 3.4 (2.8-3.9) and the number of 2pn oocytes was 2.5 (2.1-2.8). No significant association was found between basal testosterone (coef: -0.008, -0.019 to +0.003, $P=0.17$), 17-OHP (coef: -0.044, -0.391 to +0.303, $P=0.80$), SHBG (coef: -0.002, -0.007 to +0.002, $P=0.25$), Δ4-androstenedione (coef: -0.101, -0.306 to +0.104, $P=0.33$) concentrations and the number of follicles ≥11 mm. In contrast, a significant negative association was found between basal DHEAS (coef: -0.011, -0.019 to -0.003, $P=0.007$) concentrations and the number of follicles ≥11 mm on the day of triggering final oocyte maturation.
Conclusions
Higher DHEAS concentrations were associated with the development of fewer follicles ≥ 11 mm. Given the significant negative association between DHEAS concentrations and the number of follicles on the day of triggering final oocyte maturation, future studies on DHEA supplementation should consider basal DHEAS concentrations.

A need for transgender care education among polish endocrinologists

Katarzyna Matwiej[1], Karolina Zawadzka[1], Grzegorz Sokolowski[2], Alicja Hubalewska-Dydejczyk[2] & Malgorzata Trofimiuk-Muldner[2]
[1]Jagiellonian University Medical College, Students' Scientific Group at the Department of Endocrinology, Kraków, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Background
A significant body of research indicates that transgender and gender-nonconforming persons represent an underserved population susceptible to health care disparities. The attitudes and knowledge of medical doctors toward transgender people have important implications for the future quality of healthcare for transgender patients.

Specific Aim
The aim of this study was an assessment of coverage of transgender care issues in training curricula of endocrinologists in Poland, including educational and practical experience while providing health care to transgender persons.
Methods
An anonymous survey was sent via electronic mail to the members of the Polish Society of Endocrinology. Survey questions were designed to assess the transgender health issues coverage during training, personal experience with transgender patients and attitudes toward gender-affirming interventions.
Results
A total of 110 endocrinologists responded to the online survey, 74 fully answered questionnaires (67.27%) were analysed. The majority of respondents were between the age of 35-54 ($n=50$; 67.57%) with minimal 10 years seniority. Years in practice were not associated with the level of transgender care training. Among respondents, 21 doctors (28.28%) provided hormonal gender-affirming interventions for transgender patients. The vast majority of endocrinologists did not receive during residency any training on the care of transgender patients, including communication skills ($n=54$; 72.97%) and therapeutic recommendations ($n=37$; 50.00%). Assessment of willingness to provide health care to transgender persons revealed that 22 respondents (29.73%) have concerns in this area. In this group, most doctors ($n=15$; 68.18%) did not have any previous experience with transgender patients. The main indicated obstacle was lack of experience and competence ($n=19$; 82.61%). Endocrinologists, who provide hormonal gender-affirming interventions represent a higher level of participation in training on the care of transgender patients (OR = 4.0, $P<0.003$) and acceptance of hormone interventions as well as surgical procedures (OR = 6.6, $P<0.002$).
Conclusion
Medical school and residency curricula are lacking in the content of transgender care. As a result, personal and professional comfort levels while providing medical care to transgender and gender non-conforming persons could be inadequate. Efforts should be made to provide the proper education on health care issues related to gender incongruence.

Crosstalk between androgen-ZIP9 signalling and key regulators of mitochondrial dynamics in rodent leydig cells

Małgorzata Brzoskwinia, Alicja Kamińska, Sylwia Lustofin, Anna Hejmej & Barbara Bilińska
Jagiellonian University, Institute of Zoology and Biomedical Research, Department of Endocrinology, Krakow, Poland

Androgen signalling plays a central role in the regulation of male reproduction. Androgens act predominantly by activating the classical intracellular androgen receptor (AR). In addition, alternative pathways may account for rapid effects of androgens via cytoplasmic or membrane-localized androgen receptor − ZIP9. In the testis, the main source of androgens, in particular testosterone, are Leydig cells. The proper synthesis of testosterone depends on the structural condition of Leydig cells, and any disturbance in the biosynthesis and availability of steroids may affect the secretory activity of these cells. The initial steps of steroidogenesis occur in the Leydig cells mitochondria, which need to be fully functional. It should be noted that the dynamic changes in the mitochondria (their fission and fusion) are associated with the steroidogenic activity of Leydig cells. Therefore, the aim of this study was to test whether the disruption of androgen signalling may have an effect on the expression of mitochondrial dynamics-involved proteins Drp1, Mfn2 and Tom20 in rodent Leydig cells. Experiments were performed using rat primary Leydig cells and mouse TM3 Leydig cell line. To determine the role of AR signalling in the mitochondria dynamics, pharmacological antagonists − hydroxyflutamide (HF) and bicalutamide (BIC) were used to inhibit activation of AR, and ZIP9 (i) or/and siRNA was used to knockdown the expression of these receptors (ii). Immunofluorescence, western blot, qRT-PCR were used for detection Drp1, Mfn2, and Tom20 expression. We found that testosterone increased the expression of Mfn2 and Drp1, whereas the expression of Tom20 decreased in both primary Leydig cells and TM3 cells. HF, BIC, and both androgen receptors silencing partly blocked testosterone effect on Mfn2 expression, which indicates that Mfn2 is controlled by both receptors. The increase of Drp1 expression was inhibited only by BIC and ZIP9 silencing, which suggests that in Leydig cells Drp1 expression is regulated by ZIP9. In contrast, only HF and AR silencing blocked the effect of testosterone on Tom20 expression demonstrating that this protein is dependent on AR signalling. The above findings were confirmed by the results of immunofluorescence analysis. Collectively, our results indicate a crosstalk between androgen and mitochondrial protein expression in Leydig cells and point to cooperation of classical and non-classical androgen signalling pathways in controlling Leydig cell function. This study was supported by a research Grant OPUS 12 2016/23/B/NZ4/01788 from the National Science Centre. The conference attendance was supported by "Jagiellonian Interdisciplinary PhD Programme" (POWR.03.05.00-00-Z309/17-00) funded by the European Union.

Different grade of obesity influences the association between 25-hydroxyvitamin and Testosterone levels: A cross-sectional study in young Spanish men with Obesity

Hatim Boughanem[1,2], Miguel Damas-Fuentes[1,2], Maria Molina Vega[1,2], Francisco José Tinahones Madueño[1,2], Jose Carlos Fernandez Garcia[1] & Manuel Macias[1,2]
[1]Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition, Málaga, Spain; [2]Biomedical Research Institute of Malaga (IBIMA), Cellular and Molecular Endocrinology, Malaga, Spain

Backgrounds
One of the most observations in subjects with obesity, is a high prevalence of vitamin D deficiency, which, in turn, it has been implicated with decreased testosterone levels and an increased hypogonadism risk. Testosterone deficiency is a very common feature in males with obesity. However, only few studies have investigated the effect of vitamin D on testosterone in the context of obesity, and controversial results has been found.
Hypothesis
We hypothesized that a low serum 25-hydroxyvitamin D (25(OH)D) levels may be associated with a decreased testosterone levels in males with obesity. In addition, we also hypothesized that 25(OH)D levels may differ notably according to the different grade of obesity, as a result/consequence of variations in the body mass index (BMI).
Objectives
The aim of the present study was to investigate the relationship between serum 25(OH)D and testosterone levels in young Spanish men with different grade of obesity.
Methods
The study cohort consisted of 269 healthy young men with obesity Men (BMI $\geq$ 30 kg/m^2) aged between 18 and 49 years old, and recruited in Málaga (Spain), between June 2013 to June 2015. Participants were divided under the 50th percentile of serum 25(OH)D levels (134 subjects with vitamin D sufficiency and 135 with vitamin D deficiency). We have measured serum 25(OH)D and sex-related hormones. The associations between 25(OH)D and reproductive hormones and hypogonadism were analyzed using linear regression and binary logistic regression analyses, respectively.
Results
The 25(OH)D deficiency group had significantly decreased both serum total and free testosterone levels and increased serum androstenedione levels when compared to the 25(OH)D sufficiency group ($P<0.05$). Using multivariable lineal regression analyses, 25(OH)D was correlated with the majority of sex-related hormones. However, this significant association disappeared when we adjusted this model by BMI. Further, we analyzed the effect that BMI exerted on the association between 25(OH)D and testosterone, analyzing different grade of obesity. We found that subjects with obesity type III, and adjusted by age, smoking status and BMI, showed that both total testosterone and SHBG were significantly and positively associated with 25(OH)D. Using a mediation analysis, we observed a partial effect of BMI on the association between 25(OH)D and total testosterone levels, indicating that 25(OH)D influence total testosterone levels, and BMI partially mediated this association.
Conclusions
Serum 25(OH)D is associated with total testosterone levels in those subjects with morbid obesity.

[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]University of Modena and Reggio Emilia, International PhD School in Clinical and Experimental Medicine (CEM), Modena, Italy; [3]University of Modena and Reggio Emilia, Center for Genomic Research, Modena, Italy; [4]Azienda Ospedaliero-Universitaria di Modena, Department of Medicine, Endocrinology, Metabolism and Geriatrics, Modena, Italy

Introduction
Follicle-stimulating hormone (FSH) is a glycoprotein that support reproduction by regulating ovarian follicular growth and development. Recent studies demonstrated that proliferative signals mediating folliculogenesis are mediated by the G protein-coupled estrogen receptor (GPER) expressed in ovarian tissues throughout the follicular phase. In granulosa cells, GPER forms heteromers with FSHR, reprogramming cAMP-induced death signals to AKT-dependent, anti-apoptotic/-proliferative events, fundamental to sustain oocyte survival. Since GPER is mainly located in the endoplasmic reticulum, we may hypothesize it modulates FSH signals *via* heteromerization and retention of FSHR in the cytoplasm.
Aim
In this study, we analysed FSHR/GPER heteromers trafficking through early and late endosomes and its impact on FSH-mediated signalling from endocytic compartments.
Methods
HEK293 cells were transfected with FSHR- and GPER-coding plasmids and treated by 10 nM FSH, in the presence or absence of receptor internalization blockade by Dynasore. cAMP production and FSHR interaction with specific endosomal markers, i.e. Ras-related proteins (Rab) 5, 7 and 11, were evaluated at different time-points (0-20 min) by bioluminescence resonance energy transfer (BRET). Results were compared by Kruskal-Wallis test and Dunn's post-hoc test ($P<0.05$; $n=5$) and showed as means $\pm$ SEM.
Results
FSH treatment of FSHR only-expressing cells resulted in the receptor internalization mediated by β-arrestins, and in FSHR localization into Rab7-positive endosomes, addressing it to lysosomes. No FSH-induced compartmentalization of the receptor into early- and recycling-endosomes (Rab5 and Rab11 markers) was found. Conversely, FSHR/GPER co-expression reduces the basal FSHR trafficking through Rab5 and Rab11-marked endosomes, prevents FSH-induced FSHR-Rab7 interaction and drives FSHR internalization mainly through β-arrestin recruitment (FSHR- *vs* FSHR/GPER-expressing cells; $P<0.05$). This event might be essential for FSH-induced signalling modulation. Indeed, as previously described, the FSH treatment of FSHR-expressing cells induces intracellular cAMP increase, while it does not in FSHR/GPER co-expressing cells (AUC FSHR $=85.51\pm8.4$ *vs* AUC FSHR+GPER $=30.6\pm7.4$; $P<0.05$). Interestingly, in FSHR/GPER co-expressing cells where internalization was inhibited by Dynasore, FSH induces a cAMP response, oppositely to what demonstrated in Dynasore-untreated cells (AUC Dynasore-treated FSHR+GPER $=101.1\pm16.11$; $P<0.05$) and suggesting the requirement of the heteromer internalization to inhibit cAMP production.
Conclusion
In conclusion, these results suggest that GPER blocks FSHR-mediated cAMP production *via* compartmentalization of receptors into specific endosomes. These data strengthen the existence of FSHR membrane partners modulating its mode of action, possibly impacting ovarian physiology.

Common and unique transcriptional regulation in target tissues and oocytes across polycystic ovary syndrome-like mouse models

Qiaolin Deng[1], Yu Pei[1,2], Sanjiv Risal[1], Hong Jiang[1] & Elisabet Stener-Victorin[4]
[1]Karolinska Institutet, Physiology and Pharmacology, Stockholm, Sweden; [2]Center for Molecular Medicine, Karolinksa University Hospital, Stockholm, Sweden

Yu Pei and Sanjiv Risal are joint first authors. Elisabet Stener-Victorin and Qiaolin Deng are joint corresponding authors. Polycystic ovary syndrome (PCOS) affects around 15% of women of reproductive age and the key feature of the syndrome is hyperandrogenism. To understand the complex pathophysiology of PCOS, more than 30 PCOS-like animal models have been developed to mimic certain pathophysiological features. So far, not much is known about the common and unique molecular and cellular features among the most used PCOS-like mouse models. The overall aim of this study is to compare three hyperandrogenic PCOS-like mice models that are commonly used to understand the molecular pathology across inflicted tissues: hypothalamus, subcutaneous adipose tissue, ovary, and metaphase II (MII) oocytes among the prenatal androgenized (PNA) model (F1 offspring), the prepubertal androgenized (PPA) model, and the theca-cell specific nerve growth factor overexpressing mouse model (17 NF). We performed bulk RNA sequencing of tissues and single-cell RNA sequencing of MII oocytes across the models and identified differential expressed genes (DEGs) in each tissue and model. The greatest number of DEGs was found in the ovary, followed by adipose tissue whereas hypothalamus is least affected in all models. In addition, ovary and adipose tissue were most affected in PPA model compared to other models. We found several common DEGs were involved in lipid metabolism and steroid hormone biogenies among ovary, adipose tissue and hypothalamus in all models. Moreover, we conducted weighted gene correlation network analysis (WGCNA) method to identify functional correlated gene modules across all models and revealed common biological pathways for hub genes including gonadal development, cell-cell communication, hormonal metabolism and lipid metabolism in ovary and adipose tissue. Notably, greatest transcriptional alteration was also observed in MII oocytes in the PNA model, with DEGs in gonad development and germ cell development, likely due to fetal programming effects. Currently, we are investigating crosstalk between tissues and oocytes and comparing these finding with relevant human tissues.

Background
Polycystic ovarian syndrome (PCOS) is a common endocrine disorder, with an estimated prevalence of 10-15% worldwide. PCOS can have adverse consequences on the emotional wellbeing of the patient. However, evidence exploring the relationship between PCOS and psychosexual wellbeing, specifically sexual function, and dysmorphic appearance concerns, is largely inconclusive.
Aim
A systematic review and meta-analysis were undertaken to assess differences in sexual function and dysmorphic appearance concerns among people with and without PCOS.
Methods
Electronic databases (MEDLINE, EMBASE, APA PsycInfo, PUBMED, Web-of-Science Core Collection, and CENTRAL) were searched through August 2021. Observational studies (cross-sectional, case-control, cohort) and Randomised Control Trials (RCTs) were included. Outcome measures included validated questionnaires or Visual Analogue Scales (VAS) reporting on sexual function or dysmorphic appearance concerns. Methodological quality was assessed by adaptation to the Newcastle-Ottawa Quality Assessment Scale (NOS). The inverse variance method, based on a random- or fixed-effects model (Review Manager, Version 5) was used to perform meta-analyses.
Results
The search yielded 5964 publications and 53 full-text articles were included, of which 38 (71.7%) assessed sexual function outcomes, and 15 (39.5%) assessed dysmorphic appearance concerns using validated scales, in people with PCOS.
27 studies used the Female Sexual Function Index (FSFI) to assess domains of sexual function (desire, arousal, lubrication, orgasm, satisfaction, and pain). Meta-analysis of 11 comparative cohort studies (793 PCOS women and 1507 controls) revealed no significant differences between PCOS and controls in sexual desire ($P=0.11$); satisfaction ($P=0.05$); pain ($P=0.56$); arousal ($P=0.05$) and total

FSFI score ($P=0.27$). PCOS women scored significantly lower on lubrication (SMD $=-0.16$; $P=0.001$) and orgasm (SMD $=-0.16$; $P=0.02$), indicating impaired sexual function. Included studies used 13 different validated scales to assess dysmorphic appearance concerns among people with PCOS. Meta-analysis of 3 comparative cohort studies (406 PCOS women and 394 controls) using the Multidimensional Body-Self Relations Questionnaire Appearance Scales (MBSRQ-AS) to assess appearance concerns was performed. PCOS women scored significantly lower on the appearance evaluation (SMD $=-0.78$; $P<0.00001$) and significantly higher on appearance orientation (SMD $=0.22$; $P=0.0004$), indicating higher overall dissatisfaction with physical appearance.
Conclusions
People with PCOS experience a greater degree of sexual dysfunction and body image concerns implying psychosexual wellbeing needs to feature in clinical assessment of people with PCOS. Further studies are needed to identify ways to minimise this impact.

Andrological effects of SARS-Cov2 infection: a systematic review and meta-analysis

Walter Vena[1], Giovanni Corona[2], Alessandro Pizzocaro[1], Francesco Pallotti[3], Donatella Paoli[3], Giulia Rastrelli[4], Elisabetta Baldi[4], Nicola Cilloni[5], Federico Semeraro[5], Andrea Salonia[6], Suks Minhas[7], Rosario Pivonello[8], Alessandra Sforza[2], Linda Vignozzi[4], Andrea Marcello Isidori[3], Andrea Lenzi[3], Mario Maggi[9] & Francesco Lombardo[3]
[1]Humanitas Research Hospital, Endocrinology, Diabetology and Andrology Unit, Rozzano (MI), Italy; [2]Azienda Usl, Maggiore-Bellaria Hospital, Endocrinology Unit, Medical Department, Bologna, Italy; [3]Sapienza University of Rome, Department of Experimental Medicine, Roma, Italy; [4]University of Florence, Department of Experimental and Clinical Biomedical Science - Andrology, Women's Endocrinology and Gender Incongruence Unit, Florence, Italy; [5]Maggiore Bellaria Hospital, Department of Anaesthesia, Intensive Care and EMS, Bologna, Italy; [6]University Vita-Salute San Raffaele, Department of Urology, Milan, Italy; [7]Imperial Healthcare NHS Trust, Department of Urology, Charing Cross Hospital, London, United Kingdom; [8]Federico II University of Naples, Staff of UNESCO Chair for Health Education and Sustainable Development, Naples, Italy; [9]University of Florence, Endocrinology Unit, "Mario Serio" Department of Experimental and Clinical Biomedical Sciences, Florence, Italy

Background
Since the preliminary epidemiological data concerning the coronavirus disease 2019 (COVID-19) has been availabe, clear sex disparity has been evident, with males, although not more frequently affected, often experiencing worse outcomes when compared to women. The short and long term andrological effects of coronavirus disease 2019 (COVID-19) have not been clarified. The aim of the present study is to systematically review and meta-analyze all available data regarding possible short- and long-term andrological effects of COVID-19. In addition, information regarding the safety of the COVID-19 vaccines on sperm quality was investigated.
Methods
All prospective and retrospective observational studies reporting information on severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) mRNA semen and male genitalia tract detection, as well as those reporting data on semen analysis and hormonal parameters in infected/recovered patients without any arbitrary restriction were included.
Results
Out of 204 retrieved articles, 35 were considered, including 2.092 patients and 1.138 controls with a mean age of 44.1 ± 12.6 years, and mean follow up 24.3 ± 18.9 days. SARS-CoV-2 mRNA can be localized in male genitalia tracts during the acute phase of the disease; mean crude detection rate (DR) was 8[5;12]%. Meta-regression analysis showed that DR was not influenced by patient age or by disease severity or associated morbidities. DR was significantly higher in those studies assessing the viral mRNA presence in the semen less than 11 days after the diagnosis ($P=0.02$). When all studies were considered, COVID-19 was associated with a significant reduction of total sperm count, sperm concentration and total sperm motility, whereas no difference in sperm morphology or progressive motility was observed. Moreover, SARS-CoV2 infected patients were characterized by reduced total T levels, whereas no difference in either LH or FSH levels was observed. Sensitivity analyses confirmed the negative effects of SARS-CoV2 infection on T levels only for those studies that included patients in the acute phase (mean difference in total T levels -2.19 [-7.08;-1.20] nmol/l;$P=0.01$).
Conclusions
COVID-19 can result in short-term impaired sperm and T production. Available data cannot clarify long-term andrological effects. Low T observed in the acute phase of the disease is associated with an increased risk of being admitted to the Intensive Care Unit or death. The use of mRNA COVID-19 vaccines does not seem to affect sperm quality.

Comparison of three different AMH assays with AMH levels and follicle count in women with polycystic ovary syndrome

Loes Moolhuijsen[1], Yvonne Louwers[2], Joop Laven[2] & Jenny Visser[1]
[1]Erasmus MC, Department of Internal Medicine, Rotterdam, Netherlands; [2]Erasmus MC, Div. of Reproductive Endocrinology and Infertility, Department of Obstetrics and Gynaecology, Rotterdam, Netherlands

Anti-Müllerian hormone (AMH) levels strongly correlate with the number of antral follicles in the ovary. In women with polycystic ovary syndrome (PCOS), this is reflected by significantly increased serum AMH levels. AMH levels are therefore suggested as a proxy for polycystic ovary morphology (PCOM) in PCOS diagnosis. Different assays are available to measure serum AMH levels. However, lack of a golden standard and the use of different antibodies to detect AMH, have led to inter-assay variability. Little is known about inter-assay correlation in women with increased AMH levels, especially in PCOS. Hence, our aim was to investigate the correlation of AMH values between different AMH assays and with total follicle count (TFC) in a large cohort of PCOS patients. Serum AMH levels were measured in 1660 PCOS patients, diagnosed using the Rotterdam criteria. AMH levels were measured by three different AMH assays: (1) Gen II ELISA [Beckman Coulter]; (2) picoAMH assay [AnshLabs]; and (3) Automated Elecsys assay [Roche]. Patients were divided in subgroups based on the reported AMH cutoff values for PCOM: low AMH (<2.80 ng/ml), mid AMH ($2.80-7.04$ ng/ml) and high AMH level (>7.04 ng/ml). Passing Bablok regression was used for the comparison between assay methods. Spearman's correlation rank was used to assess the correlation between AMH levels and TFC. The inter-assay correlations over the total range of AMH levels were: Gen II vs Elecsys: 0.81; picoAMH vs Gen II: 0.81; picoAMH vs Elecsys: 0.94. Stratification in three AMH subgroups revealed an AMH level dependent inter-assay correlation. A strong inter-assay correlation was present in both low and high AMH subgroups, ranging from $0.62-0.86$. The correlation in the mid AMH level subgroup was only moderate, with correlation coefficients ranging between $0.28-0.56$. A positive correlation was present over the total range of AMH levels and TFC, with correlation values ranging from $0.57-0.62$. However, subgroup analysis showed that independently of assay method used, the correlation decreased in all three AMH subgroups and became moderate at best with coefficients ranging between $0.11-0.45$. In conclusion, in our cohort of PCOS patients both inter-assay correlation and correlation between AMH level and follicle count depend on the range of serum AMH level. While a high AMH level may reflect the presence of PCOM, our results suggest that it does not accurately reflect the total number of follicles in PCOS. This once more emphasizes the need of a standardization of AMH measurement.

Clinical/biochemical characteristics of functioning gonadotroph adenomas in women presenting with ovarian hyperstimulation

Nikoleta Papanikolaou[1], Amy Coulden[2], Nina Parker[1], Sit Lee[3], Chris Kelly[4], Richard Anderson[5], Aled Rees[6], Jeremy Cox[1], Waljit Dhillo[1], Karim Meeran[1], Maya Al-Memar[1], Niki Karavitaki[2] & Channa Jayasena[1]
[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; [4]NHS Forth Valley, United Kingdom; [5]University of Edinburgh Medical School, United Kingdom; [6]Cardiff University, Cardiff, United Kingdom

Background
Functioning gonadotroph adenomas (FGA) are rare benign pituitary tumours. Several case reports suggest that FGA may present with features of ovarian hyperstimulation in women. However, a lack of aggregated clinical experience of FGA precludes the meaningful guidance of management in affected women.

Methods
Case series of 7 women presenting at different UK sites with FGA induced ovarian hyperstimulation syndrome (OHSS).
Results
Mean age was 31.6 years (range: 16-48) at diagnosis. 3/7 women underwent ovarian surgery prior to diagnosis of FGA. Two of those presented acutely unwell with abdominal pain, distention and palpable mass requiring oophorectomy for torted ovary/ruptured cyst. OHSS was classified as mild or moderate in all other cases. Abdominal pain, irregular periods, headache, visual disturbances, were also reported at presentation by 100%, 71%, 57%, 43% of women, respectively. Visual field defects were present in 6/7 women. Median follicle stimulating hormone (FSH) levels were 26.1 U/l (range:8.3-33), but luteinizing hormone (LH) was <2.5 U/l in all cases. Estradiol (E2) far exceeded the reference range in 5/7 women (2990 to >18000 pmol/L); E2 was at the upper limit of reference range in the remaining 2/7 women (960-1450 pmol/L). Hyperprolactinemia and deficiencies of other pituitary hormones were noted in 6/7 and 4/7 women, respectively. One woman had elevated thyroid stimulating hormone (TSH) and free thyroid hormones; histopathology subsequently confirmed a plurihormonal adenoma expressing TSH and FSH**.** Two patients were given lanreotide prior to surgical management but neither FSH, E2 nor tumour size responded to treatment. Duration of treatment was 6 and 12 weeks. Transsphenoidal surgery was performed in 6/7 women; resection was incomplete but OHSS symptoms and biochemistry improved post-operatively in all cases. The case with longest follow-up period had five transsphenoidal surgeries and radiotherapy twice over a period of 24 years.
Conclusion
This is the largest series of FGA in women. Transsphenoidal surgery remains the only effective treatment improving clinical and biochemical features of OHSS with FGA. Long-term clinical follow-up is required owing risk of adenoma recurrence. The long-term prognosis remains unclear for fertility in women diagnosed with FGA.

The biochemical investigation of PCOS: a UK wide survey of laboratory practice

James M Hawley[1], Rachel Marrington[2], Finlay MacKenzie[2], Jo Adaway[1], Angela Taylor[3], Wiebke Arlt[3] & Brian Keevil[1]
[1]Wythenshawe Hospital, Biochemistry, Wythenshawe, United Kingdom; [2]Birmingham Quality UK NEQAS, Birmingham, United Kingdom; [3]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

Background
Polycystic ovary syndrome (PCOS) is a heterogenous condition that affects approximately 12% of females. The diagnosis can be complex and biochemistry tests are routinely relied upon to help identify hyperandrogenaemia and to exclude other conditions. However, although national and international guidelines advocate the use biochemistry tests, little information is provided as to which tests should be used and which other endocrinopathies should be excluded.
Objectives
To gather information about what tests UK laboratories routinely use to investigate PCOS, what reference ranges are applied, and which other conditions are routinely excluded.
Design
A national survey consisting of 32 questions was compiled by clinical scientists and clinicians. This was circulated to NHS clinical laboratories via UK NEQAS and The British Endocrine Society with online access available between June – December 2021. Supplementary to the survey, UK NEQAS distributed three cases for interpretation to complement their steroid hormone scheme.
Results
The survey attracted responses from 81 participants. Of these, 90% identified that testosterone would be included in an initial screen with only 50% using it in combination with SHBG to provide a free androgen index. Of the conditions that are not routinely excluded; 74% would not add TSH to investigate hypothyroidism and 84% would not consider adding 17OHP to exclude late onset CAH. Testosterone analysis is commonly performed by immunoassay in the UK with only 12% of respondents using LC-MS/MS. Reference ranges for testosterone varied with the most commonly used being a manufacturer derived <1.7 nmol/l and the highest reported being a luteal upper limit of 6.0 nmol/L. Several participants (64%) identified that they would send high testosterones to an LC-MS/MS laboratory for confirmation, the concentration at which this occurred ranged from >1.2 nmol/l to >5 nmol/l. Androstenedione was only included by 16% of participants in the initial screen with the majority using LC-MS/MS for its measurement and the upper limit of normal ranging from 4.6 to 14.3 nmol/l. The results from the clinical interpretation provided varied responses.
Conclusions
There is significant variation across the UK in the investigation of PCOS. This is apparent in which tests are offered by biochemistry laboratories, what reference ranges are used and, as a direct consequence of these, what interpretation is applied. This potentially further complicates the investigation and diagnosis of PCOS and represents an inequality across the healthcare system. There is a requirement for clear guidance on what tests should be used to investigate PCOS.

Cyproterone associated meningioma in a polycystic ovarian syndrome patient- a rare occurrence in our cohort

Ali Al Jumaah[1,2], Narendra Reddy[1,2], Miles J Levy[1,2], Ragini Bhake[1] & Shailesh Gohil[1,2]
[1]Department of Endocrinology, Leicester Royal Infirmary, Leicester, United Kingdom; [2]University of Leicester, Leicester, United Kingdom

Introduction
Meningiomas are the most common brain tumours and they express progesterone receptors. Cyproterone acetate (CPA) is a synthetic progestogen approved for use as an anti-androgen in Polycystic Ovarian Syndrome (PCOS). We report a case of meningioma probably resulting from long-term CPA treatment and a review of our PCOS cohort for further cases.
Case report
A 47-year-old lady with PCOS was treated with CPA 100 mg once daily for hirsutism and androgenic alopecia for 15 years (cumulative dose-exposure = 193g). She developed reduced vision in left eye; an MRI brain revealed a 6-cm left supra-orbital meningioma alongside 2 small separate lesions (0.8 cm & 0.3 cm). CPA was stopped and large mass was resected; histology confirmed Grade 2 meningioma. Smaller lesions were conservatively managed.
Quality Improvement project
To identify further cases of meningioma, a retrospective electronic records' review of consecutive PCOS patients who were on either CPA or Dianette (CPA 2 mg + Ethinyl Estradiol 35 mg) in University Hospitals of Leicester from 1980 to 2021 was undertaken. $n=1302$ patients received either CPA or Dianette as current or past treatment (CPA = 508; Dianette = 794) with a cumulative dose-exposure of 56g/patient. 78/508 CPA patients are currently under active follow-up; 20 are currently on CPA (100 mg = 14; 50 mg = 6). CPA was stopped in rest due to lack of efficacy, tolerability, compliance, and/or lost to follow-up. Up-to-date imaging & records review of 508 CPA-cohort detected one meningioma occurrence which is described above. No meningioma cases were noted in the Dianette cohort.
Discussion
First described in 2008 and confirmed in a recent French study, there is a 11-fold higher dose-dependent risk of meningioma with 36g to 60g cumulative CPA dose-exposure compared to <3g. In June 2020, Medicines and Healthcare products Regulatory Agency (MHRA) issued guidance to minimise risk of meningioma, limiting high dose (50-100 mg) license for only prostate cancer and male hypersexuality. It is plausible that meningioma is co-incidental in our patient as incidence is 6-10 in 100.000 background population. However, recognised association, potent progestogenic effect and high-dose exposure may potentially incriminate CPA. Given solitary incidence in our cohort, remaining 19 CPA patients are closely monitored, MHRA guidance explained with an option offered to swap to alternate treatment.
Learning points
1) To be aware of meningioma side effect risk in high dose CPA (>50 mg/day) treated patients and consider cessation/swapping to alternate treatment.
2) CPA should be stopped in high risk patients such as PMH of meningioma, radiotherapy or Neurofibromatosis-2 genetic mutation.

Polycystic ovary syndrome (PCOS) is the most common endocrine and metabolic disorder affecting women in reproductive age. Women with PCOS exhibit 2-3x higher levels of circulating Anti-Müllerian Hormone (AMH) as compared to healthy women and it is unclear if the elevation of AMH is a bystander effect or is driving the condition. Moreover, PCOS has a strong heritable component, however the etiopathology of the disease and the mechanisms underlying its transmission remain to be elucidated. Therefore, it is crucial to unravel contributions of intrauterine environmental factors that might induce epigenetic changes leading to increased susceptibility to PCOS later in life. We have previously measured AMH levels in a cohort of pregnant women with PCOS and control women revealing that AMH is significantly more elevated in the former group vs the latter. Pregnant mice were treated with AMH to model our clinical findings and investigate the neuroendocrine phenotype of their female progeny across multiple generations. Using this new preclinical PCOS model showed that fetal exposure to excess AMH drives a transgenerational transmission of the major reproductive and metabolic PCOS alterations across multiple generations via altered landscapes of DNA methylation. Furthermore, these findings revealed the existence of common epigenetic signature in a cohort of mothers and their daughters suffering from PCOS as well as in PCOS-like mice, which could serve as markers for early diagnosis of the syndrome. Furthermore, the efficiency of an epigenetic-based therapy used in this preclinical model of PCOS, offers a promising therapeutic avenue to improve the management of PCOS patients. Collectively, our results challenge the concept of PCOS originating *in utero* and appear to consolidate the role of AMH as a trigger of the pathogenesis. This work further points to PCOS-like mouse model as an excellent preclinical tool to investigate both neuroendocrine disturbances of PCOS and how developmental programming effects are transmitted, while offering a therapeutic avenue for the treatment of the disease.
Key words: PCOS, Fetal programming, AMH, GnRH, Transgenerational Transmission

Evolution of congenital hypothyroidism with *in situ* thyroid gland in children and adolescents

Luisa Pignata, Brunella Bagattini, Lucia Montanelli, Patrizia Agretti, Giuseppina De Marco, Eleonora Ferrarini, Francesca Orsolini & Massimo Tonacchera
University of Pisa, Department of Endocrinology and Metabolism, Pisa, Italy

Background
In recent years, increasing cases of congenital hypothyroidism (CH) with *in situ* thyroid gland are identified. Outcome of children affected from CH with normally sited thyroid of normal size is still unknown. The objective of our study is to describe the natural history of this specific form of CH. Patients and methods: We retrospectively evaluated clinical, biochemical and instrumental data of 74 patients with diagnosis of CH with *in situ* thyroid gland, referred to our center after positive neonatal screening. After 3 years of age, 48 patients performed a clinical reassessment after withdrawal of levothyroxine (L-T4) therapy, through biochemical evaluation with thyroid function profile, imaging evaluation with neck ultrasound and, in most cases, a scintiscan with 123-I and perchlorate discharge test. We evaluated the need for L-T4 therapy at retesting and during follow-up.
Results
48 patients performed clinical reassessment: 10 had overt hypothyroidism (20.8%), 20 showed hyperthyrotropinemia (41.7%) and 18 were euthyroid (37.5%) after L-T4 withdrawal for 4 weeks. 32 patients performed a scintiscan with 123-I and perchlorate discharge test: 6 patients presented a partial iodine organification defect, while 4 patients had a total defect. 28 children (58.3%) resumed therapy immediately after clinical reassessment, while 20 (41.7%) suspended it. Follow-up data after retesting (median duration of 10) were available in 44 patients. Between children who had suspended therapy at retesting, 4 resumed therapy during follow-up, while in the group of children who had resumed therapy at retesting, 9 suspended it. At the end of follow-up, 22 patients (50%) were untreated and 22 (50%) were still taking therapy. We observed no statistical differences between CH children who suspended or continued L-T4 in first serum TSH levels, sex ratio, or birth weight. Serum TSH at clinical reassessment showed a significant difference between two groups.
Conclusions
over a third of patients had a normal thyroid function off L-T4 therapy when retested after 3 years of age. During subsequent follow-up, half of our patients underwent to suspension of L-T4. Therefore, a clinical reassessment after 3 years of age should be performed to evaluate the need of L-T4 substitution and avoid unnecessary prolonged treatment. However, it is not possible to predict whether these subjects will need therapy again, so long-term follow-up studies are needed.

Non-alcoholic fatty liver disease prevalence in Klinefelter syndrome

Lucia Digitale Selvaggio, Rosa Di Fraia, Francesca Allosso, Aldo Marrone & Daniela Pasquali
University of Campania L. Vanvitelli, Advanced Medical and Surgical Sciences, Napoli, Italy

Non-alcoholic fatty liver disease (NAFLD) is becoming more common over the world. Its predisposition for evolving to cirrhosis and hepatocellular cancer, as well as its link to extrahepatic symptoms, puts patients and clinicians under a double burden. Several studies have found a link between NAFLD and many endocrinopathies, demonstrating a substantial bi-directional link between NAFLD and hypogonadism, in both men and women. In man with T2DM, NAFLD is linked to reduced total testosterone, however this is owing to a common soil of insulin resistance/obesity rather than the degree of liver necroinflammation or fibrosis. No data are available regarding Klinefelter syndrome (KS), the most common chromosomal condition associated with hypogonadism and NAFLD.
Methods
Thirty-five KS on Testosterone (T) replacement treatment were recruited. All patients underwent physical examination, full liver function tests, fasting glucose, triglycerides, cholesterol, blood cell counts, viral markers (HBV, HCV, HIV) and liver ultrasonography. The presence of autoimmune liver disease was assessed. The body mass index (BMI: kg/m2) was recorded for all patients. Insulin resistance index (HOMA-IR), and renal function were calculated. Conventional ultrasonography was performed to assess liver dimension, hyper echogenicity as compared to the right kidney parenchyma, distal attenuation, and the presence of areas of focal sparing. Prevalence of steatosis, using non-invasive methods in relation to anthropometric, biochemical, virological and ultrasound was estimated.
Results
Prevalence of steatosis in KS was 51%. BMI was 28.4 ± 1.3 and HOMA-IR 3.8 ± 1.0(Mean ± SEM). T, 393.3 ± 22 ng/dl, and SHBG, 31 ± 2 nmol/l, serum levels were in the normal range. AMA, ANA and ASMA were negative. AST, ALT, and gamma GT were slightly increased in 11.1%, 44.4% and 31.1%, respectively. No patient shows signs of advanced liver disease. Total and LDL cholesterol were normal (174 ± 9 and 112 ± 7, Mean ± SEM, respectively). Serologic markers for HBV, HCV, HAV infection were negative.
Conclusions
The prevalence of NAFLD increases by up to 80-90% in cohorts of individuals with dysmetabolic conditions such as overweight/obesity, T2DM, and metabolic syndrome, underscoring the primary role of metabolic factors in its development. These data are consistent with our preliminary findings in KS patients in whom the prevalence of steatosis was relevant in 51% of cases. The presence of autoimmune liver disease was excluded, and viral markers were negative, while KS were overweight and exhibited insulin resistance, despite normal T levels. However, the main pathophysiological mechanisms linking hypogonadism to NAFLD are complex and still under investigation, and more data are needed to better understand this condition.

Early changes in androgen hormones in individuals with spinal cord injury: a longitudinal study

Oche Adam Itodo[1,2,3], Peter Francis Raguindin[2,3,4], Gion Frankl[4,5], Jens Wöllner[6], Inge Eriks-Hoogland[6], Xavier Jordan[7], Margret Hund-Georgiadis[8], Taulant Muka[2], Jürgen Pannek[6], Jivko Stoyanov[4] & Marija Glisic[2,4]
[1]Swiss Paraplegic Research, Spinal Cord Injury Biobanking and Translational Medicince, Nottwil, Switzerland; [2]Institute of Social and Preventive Medicine (ISPM), Bern, Switzerland; [3]Graduate School for Health Sciences, Bern, Switzerland; [4]Swiss Paraplegic Research, Nottwil, Switzerland; [5]Graduate School for Cellular and Biomedical Sciences, Bern, Switzerland; [6]Swiss Paraplegic Centre, Nottwil, Switzerland; [7]Clinique romande de réadaptation, Sion, Switzerland; [8]REHAB Basel, Basel, Switzerland

Background
Individuals with spinal cord injury (SCI) are in increased risk of hypothalamic−pituitary−gonadal axis disruption. We aimed to explore changes in androgen hormones during first impatient rehabilitation and identify factors associated with their levels among participants from the Swiss Spinal Cord Injury Cohort (SwiSCI) cohort.
Methods
We measured sex hormones using Enyzyme Linked Immunosorbent Assay in persons with a newly aquired SCI that participated in the SwiSCI study. We used univariable linear regression analysis to explore the association between clinical and injury characteristics and androgen hormones (total testosterone (TT), free testosterone (FT), sex hormone-binding globulin (SHBG), dehydroepiandrosterone (DHEA), and dehydroepiandrosterone sulfate (DHEAS))) at baseline. Longitudinal changes were explored using linear mixed models adjusted for age, body anthropometrics, injury characteristics, and medication use. Analyses were stratified by sex.
Results
We analyzed paired samples of 86 individuals with SCI [70 males (81%), 16 females (19%)] with median age of 51 years (IQR 36-64) and median rehabilitation duration of 5.6 months (IQR 4.2-7.5). At baseline, increasing age and longer time since injury in men were associated with lower FT, SHBG, DHEA, and DHEAS and higher SHBG respectively. Increased upper extremity spasticity was linked with lower TT, DHEA and DHEAs and higher handgrip strength was associated with higher FT. TT in males in the beginning of the rehabilitation was in low normal range. At the end of rehabilitation, TT and DHEAS increased in males. We found no differences in hormone levels among individuals with different injury etiology, body composition, nor total spinal cord independence measure (SCIM). Due to limited number of women, female-specific findings should be interpreted with caution (**Table 1**).
Conclusions
We observed gradual increase in androgen hormones over a period of rehabilitation which was linked with improved functional recovery. Future studies to explore whether testosterone and DHEA supplementation may improve neurological and functional recovery as well as metabolic parameters during first inpatient rehabilitation.

Intracranial idiopathic hypertension in a maletranssexual patient after testosterone overdosing

Francisco Javier Martinez Martin, Alba Hernandez-Lazaro, Ricardo de Leon-Durango, Agnieszka Kuzior, Paula Gonzalez-Diaz, Esperanza Perdomo-Herrera, Alba Lucia Tocino-Hernandez, Claudia Arnas-Leon, Carmen Acosta-Calero & Maria del Pino Perez-Garcia
Hospital Universitario de Gran Canaria Dr. Negrin, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain

Introduction
Intracranial Idiopathic Hypertension (IIH) is a rare complication of testosterone therapy. It is usually benign, but may result and permanent blindness. Its diagnosis is based on a high CSF (> 25 cm H_2O) pressure, in the absence of specific causes. The androgen receptor is expressed in the human choroid plexus, and may enhance the activity of Na+/K+-ATPase, and therefore CSF secretion.
Methods
Review of the patient's clinical record.
Results
A 24-year old female-to-male transsexual patient had been treated for 4 years with 60 mg of testosterone gel daily, using a dispenser which supplied 20 mg/pulse. He was satisfied with the treatment, his secondary male sexual characters were well developed, his hormonal levels and hematocrit were adequate and he had not suffered any adverse effects except mild acne. The availability of the testosterone dispenser was interrupted and the patient was changed to a different testosterone gel formulation but due to a dispensation error the total daily dose of testosterone was increased to 200 mg. After 2 months the patient was admitted in the Neurology Ward for the workup of an excruciating holocranial headache, poorly responding to common analgesics, which severely limited his daily activities. Tinnitus or visual disturbances were not reported. An intracranial tumor was suspected but the cranial CT scan and MNR were negative and funduscopy did not show significant oedema. Two lumbar punctures revealed CSF pressures on 36 and 29 cm H2O, but otherwise were normal. Total plasma testosterone levels were above the measurable range (> 34.6 ng/ml, normal 2.8 - 10.7 ng/ml) and hematocrit was mildly elevated (52.7%). Testosterone was withdrawn and acetazolamide 500 mg BID was prescribed for a week. The patient was asymptomatic at discharge. One month after the discharge, transdermal testosterone was reinstated, with a daily dose of 50 mg, with no adverse effects, recovery of the target hormonal levels and normal hematocrit.
Conclusions
IIH is a rare complication of testosterone therapy, which we had not previously found in our extensive experience with testosterone treated transsexual patients. In our patient it was related to accidental overdosing, but it has occasionally been reported with standard treatment. It is a potentially severe complication, which may impair the patient's daily activities and in the worst case scenario cause permanent blindness. The risk of IIH must be considered in male transexual patients but only very rarely may result in a contraindication for gender-affirming therapy.

Lessons from a patient with the 48XXXY karyotype: Not just another case of Klinefelter's syndrome

Agnieszka Kuzior[1,2], Alba Hernandez-Lazaro[1], Ricardo de Leon-Durango[1], Carlos Ríos-Gomez[1], Claudia Arnas-Leon[1], Carmen Acosta-Calero[3], Paula Maria Fernandez-Trujillo-Comenge[1], Ana Delia Santana-Suarez[1], Paula Gonzalez-Diaz[4] & Francisco Javier Martinez Martin[1,2]
[1]University Hospital of Gran Canaria Dr. Negrin, Endocrinology and Nutrition Clinic, Las Palmas de Gran Canaria, Spain; [2]Hospitales Universitarios San Roque | Las Palmas de G.C., Endocrinology and Nutrition Clinic, Las Palmas de Gran Canaria, Spain; [3]University Hospital of Gran Canaria Dr. Negrin, Cardiology Clinic, Las Palmas de Gran Canaria, Spain; [4]University Hospital of Gran Canaria Dr. Negrin, Emergency Dpt., Las Palmas de Gran Canaria, Spain

Introduction
The 48XXXY karyotype is an infrequent (incidence about 1/50000 male births) sporadic aneuploidy of the sex chromosomes, classically considered as a variant of the Klinefelter syndrome (47XXY). Although many of their characteristics are shared, patients with the 48XXXY karyotype suffer from additional endocrinological and neuropsychological disturbances which are not part of the classic Klinefelter syndrome. Hereby we present a clinical case.
Methods
Review of the patient's clinical records and of the relevant literature.
Case Presentation
A male, 27 year old patient, previously diagnosed of left renal agenesis, hypertriglyceridemia and cognitive impairment of unknown etiology with a 66% legal disability was referred to our Endocrinology Clinic from the Urology Dept, for workup of testosterone deficiency. He had undergone a standard vasectomy, but his testicles were reported as partially atrophic and his total testosterone was 0.96 ng/ml (normal range 2.8 - 10.7 ng/ml). The anamnesis disclosed cognitive impairment since childhood, with speech development at the age of 4 years and enuresis until 12 years. Growth was normal, having reached target adult height, and the development of secondary sexual characters was normal except for absence of facial hair. The patient had normal erections and maintained regular sexual activity. The physical examination disclosed dysmorphic facial features, bilateral gynecomastia, penis of normal size, testicular volume of 10-12 mL, scarce pubic and axillary hair, gynecoid fat distribution, short trunk with long limbs and bilateral cubitus valgus. Lab tests were compatible with hypergonadotropic hypogonadism, with total testosterone 0.82 ng/ml, FSH 36 mU/ml and LH 24 mU/ml. The workup was completed by the karyotype 48XXXY.
Conclusions
Some of the peculiarities of our patient, such as cognitive impairment, genital hypoplasia and dysmorphic features are characteristic of the 48XXXY syndrome,

while others such as unilateral renal agenesis are less often associated with it. Other developmental abnormalities involving the cardiac, neurological and genitourinary systems may be present. This case underscores the heterogeneity of the syndrome. The early diagnosis of the 48XXXY syndrome is highly desirable because it is significantly more complex than the classic Klinefelter syndrome (47XXY) with additional somatic and cognitive disturbances, and usually requires multidisciplinary care and follow-up.

Infertility is a growing concern in Western countries. Several factors, including lifestyle habits and increased prevalence of chronic disorders associated with hormonal alterations, increased chronic inflammation and systemic oxidative stress (such as obesity and diabetes mellitus), are contributing to the reduction of reproductive potential among males in modern societies. Evidence suggests these factors negatively impact human sperm quality resulting in a combination of alterations in specific sperm features, namely in its motility. Asthenozoospermia is a common cause of fertility reduction and is characterized by a reduction in sperm motility (sperm total motility $<40\%$). Sperm lipid metabolism is crucial for sperm motility and morphology as well as for sperm-oocyte interactions, although the relevance of lipid content of human spermatozoa is poorly understood. In this work, we aimed to compare sperm lipidome from asthenozoospermic and normozoospermic men and to identify lipid metabolites that correlate with sperm motility. Sperm samples from the male partner of couples seeking fertility counselling ($n=57$) were collected and sperm parameters were assessed accordingly to WHO guidelines. Sperm polar lipid content from asthenozoospermic ($n=17$) and normozoospermic ($n=39$) men was analysed by liquid chromatography-mass spectrometry. A total of 245 lipid molecular species were identified and quantified in sperm samples from both groups. Using a PCA model, we found a distinct lipid profile between asthenozoospermic and normozoospermic men. Sperm lipid analysis showed an increase in the lysophospholipid (LPL) content in asthenozoospermic men, whereas the phosphatidylethanolamine (PE) content was increased in normozoospermic men. The levels of several lipids, including lysophosphatidylcholine (LPC) 18:0, 18:1, 20:1, O(16:1) and O(18:2), and lysophosphatidylethanolamine (LPE) 20:1 and O(20:2) negatively correlated with sperm total motility. Contrarily, some PE lipids, including PE-P(36:4), PE-O(38:6), PE-O(38:7), PE-O(40:9), and PE(38:6), as well as acyl-carnitine (26:6) and fatty acid (20:3);3O showed a positive correlation with total sperm motility. Overall, our data show a different lipidomic profile in sperm from asthenozoospermic men. Asthenozoospermic sperm content in LPLs suggests altered lipid metabolism in these men, which might be associated with alterations in sperm membrane fluidity and consequent decrease in sperm motility. Moreover, LPL levels suggest that increased inflammation and oxidative status might be in the aetiology of asthenozoospermia. Our results suggest that alterations in lipid metabolism might be a potential cause for chronic disorders-related decreased sperm motility and male infertility.

The role of hypothalamic markers in the development of POI following COVID-19

Nilufar Baqoyeva[1] & Feruza Xaydarova[2]
[1]Y.X.Turakulov Republican Specialized Scientific and Practical Medical Center of Endocrinology, Polyclinic, Tashkent, Uzbekistan; [2]Y.X.Turakulov Republican Specialized Scientific and Practical Medical Center of Endocrinology, Administration, Tashkent, Uzbekistan

Introduction
Premature ovarian insufficiency (POI) is a pathological condition, which accompanying with loss of ovarian function in women under the age of 40. This is manifested by hypergonadotropic amenorrhea, infertility and estrogen deficiency. POI affects 1% of women. The specific causes can be genetic disorders, autoimmune, infectious-toxic and iatrogenic factors, but the exact mechanism is unclear yet. According to different authors, the idiopathic form accounts for 50 to 90% of cases. Increased cases of menstrual irregularities (amenorrhea), following infection with COVID-19. This abstract review the study conducted on the role of hypothalamic peptides such as kisspeptin and BDNF in the pathogenesis of premature ovarian insufficiency as a consequence of COVID-19. The pandemic has significantly impacted the mental health of women, and it can affect women's reproductive health. This is due to stress during the pandemic. It is very important to identify markers of menstrual disorders after covid-19. The aim of the study was to study the concentrations of kisspeptin and BDNF in blood plasma in patients with POI following coronavirus disease.
Methods and results
The study included 2 groups: 44 women with diagnosed POI following COVID-19 (age 30 $\pm$ 2 years) and 15 women with regular menstrual cycle as control group (age 33 $\pm$ 3). The KISS1 and BDNF levels were measured using enzyme linked immunosorbent assay kit (ELISA KIT). In control group tests were performed in follicular phase (days 3-5). In the group with POI the level of kisspeptin was lower (268.35 $\pm$ 16.7 pg/ml) than in control group (312.95 $\pm$ 31.84 pg/ml, $P<0.005$) The concentration of BDNF was also lower in group with POI (215.48 $\pm$ 37.67 pg/ml) than in control group (402.91 $\pm$ 34.12 pg/ml). The kisspeptin and BDNF plasma levels are correlated negatively with period of amenorrhea. Decreased levels of kisspeptin and BDNF in the blood correlated with the occurrence of premature ovarian insufficiency and were as risk factor for its occurrence. It showed that patients with POI were more likely to have deficiency of kisspeptin and BDNF and higher levels of FSH.
Conclusion
This study confirms the relationship between kisspeptin, BDNF and the occurrence of POI in women following COVID-19. This study provides important potential opportunities for understanding the pathology of POI.

The medical treatment of polycystic ovary syndrome: effects of inositol isomers and metformin on clinical, metabolic and hormonal profile

Nunzia Verde[1], Bianca Pellegrini[1], Lucia Auriemma[1], Alessia Baratto[1], Cristina De Angelis[1], Francesco Garifalos[1], Davide Menafra[1], Michele Castoro[1], Chiara Simeoli[1], Annamaria Colao[1,2], Rosario Pivonello[1,2] & Renata Simona Auriemma[1]
[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Unità di Andrologia e Medicina della Riproduzione e della Sessualità Maschile e Femminile (FERTISEX-CARES), Naples, Italy; [2]Federico II University of Naples, Unesco Chair for Health Education and Sustainable Development, Naples, Italy

Polycystic ovary syndrome (PCOS) is characterized by menstrual irregularities and clinical and biochemical hyperandrogenism, and is associated with insulin resistance, visceral obesity and metabolic disorders. The aim of the current study was to compare the effects of inositol isomers (INO) and metformin (MET) on the clinical, metabolic and hormonal aspects of PCOS. In 94 PCOS women, clinical (weight, BMI, waist circumference - WC, menstrual intervals, Ferriman-Gallway score - FGS), metabolic (fasting glucose and insulin, HOMA-IR, HOMA-beta, lipid profile) and hormonal [FSH, LH, estradiol (E2), androstenedione (A), testosterone (T)] parameters were retrospectively investigated before (T0) and after 6 months (T6) of treatment with INO (Group 1, $n=36$) or MET (Group 2, $n=58$). INO was administered in the 3 following formulations (F): F1, myo-inositol 1000 mg + D-chiro-inositol 200 mg; F2, myo-inositol 1100 mg + D-chiro-inositol 27.6 mg; F3, myo-inositol 1000 mg + alpha-lipoic acid 800 mg. At T0, FGS and hormonal profile were similar between Group 1 and Group 2, except for HDL ($P=0.002$) and FSH ($P=0.02$), which were higher in Group 1, whereas weight ($P<0.0001$), BMI ($P<0.0001$), WC ($P<0.0001$), menstrual intervals ($P=0.011$), fasting insulin ($P=0.001$), HOMA-IR ($P=0.001$), HOMA-beta ($P=0.001$) and triglycerides ($P=0.001$) were higher in Group 2. At T6, in Group 1, menstrual intervals ($P=0.005$), FGS ($P<0.0001$) and testosterone ($P=0.021$) were significantly reduced compared to baseline, with a trend to a decrease for weight, BMI, A, HOMA-IR and triglycerides. The effects of INO

formulations were similar, except for percent increase in E2, which was significantly higher ($P=0.027$) in F1, compared to F3. At T6, in Group 2, weight ($P<0.0001$), BMI ($P<0.0001$), WC ($P<0.0001$), menstrual intervals ($P<0.0001$), FGS ($P<0.0001$), HOMA-IR ($P=0.002$), total cholesterol ($P=0.001$), LDL ($P<0.0001$), triglycerides ($P<0.0001$), A ($P=0.003$) and T ($P=0.005$) were significantly reduced, whereas HDL ($P<0.0001$) and HOMA-beta ($P<0.0001$) were significantly increased, compared to baseline. Noteworthy, percent decrease in weight ($P<0.0001$), BMI ($P<0.0001$) WC ($P=0.018$), HOMA-IR ($P<0.0001$), total cholesterol ($P=0.046$), LDL ($P=0.015$) and triglycerides ($P=0.041$), and percent increase in HDL ($P=0.012$), were significantly higher in Group 2, compared to Group 1. In conclusion, INO and MET are effective treatments for menstrual irregularities and clinical and biochemical hyperandrogenism in women with PCOS, with different formulations of INO displaying similar efficacy, and MET displaying an apparent greater efficacy over INO on insulin resistance, lipid metabolism, and visceral obesity.

Serum testosterone mirrors inflammation parameteres in females admitted with covid-19 disease

Maria Francesca Birtolo[1], Walter Vena[1], Alessandro Pizzocaro[1], Simona Jaafar[1], Antea Ciafardini[1], Alessandro Brunetti[1], Stella Pigni[1], Gherardo Mazziotti[1,2] & Andrea Lania[1,2]
[1]IRCCS Humanitas Research Hospital, Endocrinology, Diabetology and Andrology Unit, Rozzano, Italy; [2]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy

Background
Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection is showing a rapid and continuous evolution in terms of new waves, the spread of variants and the evidence of reinfections. The growing heterogeneity of clinical presentation requires the identification of underlying pathogenic mechanisms to allow a better risk stratification. Previous studies analysed the role of sex hormones in disease severity demonstrating in male patients the association of low testosterone (T) levels with unfavorable outcome of COVID-19. Conversely, data concerning the role of T in women with SARS CoV-2 infection are scant and limited to small cohorts.
Purpose
To investigate the relationship between serum T values and clinical presentation and outcome of SARS-CoV2-related pneumonia in a population of adult females admitted to hospital due to coronavirus-disease 19 (COVID-19).
Methods
All adult females hospitalized for COVID-19 in our Institution during the period between November 1st 2020 and February 28th 2021 were evaluated for arterial partial pressure oxygen (PaO2)/fraction of inspired oxygen (Fio2) ratio, serum T and inflammatory parameters (IL-6 and procalcitonin) at study entry, need of ventilation during hospital stay and in-hospital mortality. Berlin criteria were used to define acute respiratory insufficiency (ARI).
Results
The study included 101 women (mean age 76.8 $\pm$ 13.8 years, mean BMI 27.3 $\pm$ 6.3 kg/m^2 and mean T 1.333 $\pm$ 1.3 nmol/l). A significant correlation was observed between serum T levels and IL-6 ($P<0.044$) and procalcitonin ($P<0.001$). At hospital admission 55% ($n=56$) of subjects were diagnosed with ARI. No significant association was found between serum T levels and ARI ($P=0.227$) . Mean duration for hospital stay was 14.2 $\pm$ 9.9 days, and mortality was 23% ($n=25$). Subjects who died had significantly higher age (83.7 $\pm$ 10, 5 vs 74.6 $\pm$ 14.1; $P=0.033$), IL-6 (89.3 $\pm$ 95.3 vs 35.9 $\pm$ 39.2;$P=0.021$) and procalcitonin levels (1.7 $\pm$ 4.0 vs 0.3 $\pm$ 1.7; $P=0.001$) as well as significantly lower fT3 levels (2.89 $\pm$ 0.55 vs 3.70 $\pm$ 0.80;$P=0.007$) as compared to survivors. No significant difference was observed in serum T levels among the two groups ($P=0.604$).
Conclusion
Oppositely to what observed in male subjects, this study provides a first preliminary evidence about the role of higher serum T levels in female as a mirror of higher inflammatory phenotype and worse COVID-19 disease course, possibly reflecting a massive adrenal cortex activation in response to systemic inflammation.

Age- and body mass index-adjusted association between insulin sensitivity and risk factors for cardiovascular disease in polycystic ovary syndrome

Małgorzata Kałużna[1], Tomasz Krauze[2], Pola Kompf[1], Katarzyna Ziemnicka[1], Wykretowicz Andrzej[2], Marek Ruchala[1] & Przemyslaw Guzik[2]
[1]Poznan Univeristy of Medical Sciences, Department of Endocrinology, Metabolism and Internal Diseases, Poznan, Poland; [2]Poznan Univeristy of Medical Sciences, Department of Cardiology - Intensive Therapy, Poznan, Poland

Introduction
Impaired insulin sensitivity accompanies polycystic ovary syndrome (PCOS). Women with PCOS are usually at risk of premature cardiovascular disease, which increases with age and body weight. We studied the link between insulin sensitivity measured by the Matsuda Insulin Sensitivity Index (MISI) adjusted to body mass index (BMI) and age in otherwise healthy PCOS women.
Methods
250 adult women with PCOS of reproductive age (18-43 years old) underwent measurements of MISI, lipid profile, resting heart rate, peripheral and central systolic and diastolic blood pressure. Patients were divided into tertiles of MISI (T1 (<4.74), T2 (4.74-8.35) and T3 (>8.35), respectively). Their data were compared by the Analysis of Covariance (ANCOVA) adjusted for patients' BMI and age. Only the results with a P-value <0.05 are shown as Estimated Marginal Means +/- Standard Error in the following order: T1, T2 and T3.
Results
Better insulin sensitivity (patients with higher MISI values) was associated with lower plasma concentration of total cholesterol (188.2+/-3.8, 175.3+/-3.5 and 176.2+/-3.6 mg/dl), low-density lipoprotein cholesterol (106.0+/-3.4, 93.6+/-3.1 and 91.8+/-3.2 mg/dl), triglycerides (96.3+/-5.3, 77.5+/-4.8 and 76.2+/-5.0 mg/dl), and resting heart rate (76.9+/-1.5, 73.1+/-1.4 and 70.0+/-1.4 beats/minute) independent of age and BMI. Similar associations were not found for high-density lipoprotein cholesterol, peripheral and central systolic and diastolic blood pressure.
Conclusions
A less atherogenic lipid profile and lower heart rate, regardless of the effects of age and BMI, are observed in PCOS women with better insulin sensitivity. The clinical meaning of these findings requires further studies.

Demographic trends and morbidity in the basque country transgender population (2009-2020)

Pedro González Fernández[1,2], María del Carmen Fernández López[1], Susana Ponce de León Sáenz de Navarrete[1], María Gema Grau Bolado[1,2], María Luisa Guadilla Fernández[1] & Itxaso Rica Echevarría[1,2]
[1]Hospital Universitario Cruces, Barakaldo, Spain; [2]Biocruces Bizkaia Health Research Institute, Barakaldo, Spain

Introduction
The number of transgender men and women who seek gender-affirming therapy is rapidly increasing worldwide. It is still a population at high risk for several morbidities. The Basque Country Gender Identity Clinic was created in 2009 to centralize their medical care in the region.
Aim
To determine the proportion of transgender individuals in the Basque Country, the prevalence of several morbidities in this transgender population, their evolution, and their trends since 2009.
Methods
Cross-sectional study. We selected all transgender men and women who requested therapy at our clinic and registered their demographic and clinical data. We compared the population who was first attended in the years 2009-2014 vs those first attended in 2015-2020. We compared the prevalence of several diseases between the transgender population and the Basque general population as recorded in public registries.
Results
The proportion of transgender people in the Basque Country is 2.4 per 10.000. Transgender men consume more psychoactive drugs than the general male population (9.9% vs 5.0%, $P=0.001$), while transgender women have a higher prevalence of smoking (31.5% vs 21.3%, $P=0.001$), a higher prevalence of HIV infection (3.4% vs 0.003%, $P=0.001$) and lower bone mass density (lumbar Z-score -0.87 SD, femoral neck Z-score -0.44 SD) than the general female

population. Transgender individuals first attended between 2015-2020 were younger (28 vs 17 years, $P=0.001$), had a higher academic level (secondary education or higher in 85.5% vs 37.5%, $P=0.001$) and consume less anxiolytics than those first attended the precedent years (2009-2014).
Conclusions
The proportion of transgender people in the Basque Country is 2.4 per 10.000. Transgender population in the Basque Country is at risk for several morbidities. Individuals who have sought gender-affirming therapy between 2015-2020 have a better profile at baseline (younger age, higher academic level, and less psychoactive drugs use) than those first attended between 2009-2014, which likely reflects the positive changes that have taken place in our area regarding integration and improved medical care to this population.

Phenotypic and genotypic heterogeneity of sexual development disorders 46, XY in the Tunisian population

Faten Haj Kacem Akid[1], Mohamed Abdellahi Mohamed Ahmed[1], Dhieb Nessrine[1], Benrhouma B[2], Kammoun T[3], Hachicha M[3], Kallel N[4], Belguith N[2], Mouna Mnif[1] & Mohamed Abid[1]
[1]Department of Endocrinology and Diabetology CHU Hedi Chaker, Sfax, Tunisia; [2]Human Genetics Department, CHU Hedi Chaker, Sfax, Tunisia; [3]Pediatric Department, CHU Hedi Chaker Sfax, Tunisia; [4]Department of Internal Medicine, Gabes, Tunisia

Introduction
Sexual disorders 46 XY DSD are responsible for a range of phenotypic disorders, ranging from an ambiguous phenotype to a complete female phenotype. In this context, we report a cohort of 22 46 XY patients with a female phenotype in order to establish a phenotype-genotype correlation.
Results
The average age at diagnosis was 15.5 years (E: 7 days-33 years). The reason for consultation was primary amenorrhea in 16 cases (72.7%), sexual ambiguity in 5 cases and inguinal hernia in 1 case. The standard karyotype showed a homogeneous chromosomal formula compatible with a male genetic sex, i.e. 46 XY, in 95% of cases and a mosaic formula, i.e. 46, XY/45, X in two cases. The diagnosis of gonadal dysgenesis was chosen in 4 patients (18.18%) in front of a completely female phenotype with ectopic gonads and frankly low levels of testosterone and HMA compared to age contrasting with increased FSH. Full LH resistance was retained in 3 patients with a female complete phenotype and low testosterone levels contrasting with high LH levels with histological Leydig cell agenesis, the biomolecular study of LH resistance confirmed the presence of a nonsense mutation Q525X in the second extracellular loop. A testicular steroidogenesis abnormality affecting the conversion of Δ4-androstenedione to testosterone was reported in 8 patients with a TESTO/Δ4-A <0.8 ratio after HCG, a molecular abnormality of the 17â-HSD3 gene was confirmed as homozygous in (c618C $>$ A) in 4 patients and as heterozygous composite (Pc206X/Pg133R) in 4 others. A biomolecular abnormality of androgen resistance with the presence of a homozygous mutation of exon 5 (R753X) was identified in 5 patients with an evocative phenotype associated with high levels of testosterone and LH. Finally, a biomolecular abnormality of the 5° reductase gene was mentioned in 2 patients with an ambiguous phenotype associated with a base-increased Testo/DHT ratio and after HCG. A homozygous mutation of exon 4 (pC222T) was confirmed in a single patient.
Conclusion
The abnormalities of sexual differentiation cover a wide spectrum of phenotypic and genotypic abnormalities and pose a real problem of etiological diagnosis. To be sure, advances in molecular biology are of great value in understanding the etiopathological links between clinical aspects and the cascade of sexual differentiation.

Molecular and functional studies of novel genetic variants of TP63 an SAMD11 genes unravel their potential role in the pathogenesis of primary ovarian insufficiency

Raffaella Rossetti[1], Silvia Moleri[1], Fabiana Guizzardi[1,2], Marco Bonomi[1,3], Anna Marozzi[3], Francesco Brancati[4,5] & Luca Persani[1,3]
[1]IRCCS Istituto Auxologico Italiano, Department of Endocrine and Metabolic Diseases and Lab of Endocrine and Metabolic Research, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Molecular Biology Laboratory, Cusano Milanino, Italy; [3]University of Milan, Department of Medical Biotechnologies and Translational Medicine, Milan, Italy; [4]University of L'Aquila, Medical Genetics, Department of Life, Health and Environmental Sciences, L'Aquila, Italy; [5]IRCCS San Raffaele Pisana, Human Functional Genomics, Rome, Italy

Primary ovarian insufficiency (POI) is one of the major causes of female infertility, affecting about 3.7% of women before the age of 40. POI is associated with the premature loss of ovarian function and can manifest with primary amenorrhea (PA) or post-pubertal secondary amenorrhea (SA), with elevated gonadotropins and hypoestrogenism. Several evidence established a clear genetic component to POI, albeit heterogeneous. In search of novel causative genes, we screened 64 POI patients through a customized next generation sequencing panel, which includes known and novel candidate genes potentially involved in POI pathogenesis. Among the novel rare variants identified in genes belonging to pathways relevant in ovarian physiology, we focused our functional studies on a nonsense variant (c.1927C $>$ T) in *TP63* gene, that was identified in two sisters with PA, and a frameshift insertion (c.682_683insT) in *SAMD11* gene, that was identified in 6 unrelated SA patients. The longest isoform of *TP63* gene, TAp63α, is almost exclusively expressed in the nucleus of oocytes after meiotic double-stranded DNA break repair and protect germ line fidelity during meiosis. We investigated the contribution to POI of the *TP63* variant through luciferase reporter assays in Saos-2 cell line using the firefly luciferase gene under the control of three different human promoters, direct targets of p63: *BAX*, involved in cell cycle and apoptosis; *K14*, regulating differentiation; and *IRF6*, required for cell cycle exit and tissue development. *TP63* variant falls in the transactivation inhibitory domain, which inhibits the transactivation domain of the protein. The presence of this variant showed an increment of transcriptional activity on both *K14* and *IRF6* promoters but a slight reduction on *BAX*, which is partially recovered in presence of the wild-type counterpart. The pathogenic consequences of this variant could be the overexpression of dosage-sensible genes involved in differentiation and development of the ovarian follicle and the haploinsufficiency of *TP63* in cell cycle regulation. *SAMD11*gene encodes for a transcriptional modulator that might slightly promote cell proliferation. We observed an enrichment of the frequency of *SAMD11*variant in the POI cohort with respect to the female population worldwide. We observed by immunoblotting that the frameshift generates a truncated protein which can still be produced and possibly further degraded. Moreover, proliferation assay in HEK293T showed a reduced cell growth both at homo- and heterozygous state. *SAMD11*has never been associated to ovarian phenotypes, however, our results suggest this variation might be considered as a POI predisposing factor.

Serum concentrations of 17-hydroxyprogesterone and dehydroepiandrosterone sulfate in women with polycystic ovary syndrome and their relation to the parameters of glucose metabolism

Ewa Stogowska[1], Anna Krentowska[1], Agnieszka Adamska[2], Agnieszka Lebkowska[1] & Irina Kowalska[1]
[1]Medical University of Białystok, Department of Internal Medicine and Metabolic Diseases, Poland; [2]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Poland

Introduction
Polycystic ovary syndrome (PCOS) is characterized by menstrual disorders, hyperandrogenism and polycystic ovaries on ultrasonography. This hormonal disorder is also strongly associated with insulin resistance. The diagnosis of PCOS can be established after the exclusion of other causes of mentioned symptoms, such as non-classic congenital adrenal hyperplasia (NCAH). To date, several studies suggest the increased serum concentration of 17-hydroxyprogesterone (17-OHP) in PCOS, even in the absence of NCAH; however, its impact on glucose metabolism has not been discussed widely in the literature.
Aim of the study
The aim of the study was the evaluation of serum 17-OHP and dehydroepiandrosterone sulfate (DHEA-S) concentrations in women with PCOS and the assessment of their relation to the parameters of glucose metabolism.
Materials and methods
We analyzed 35 PCOS women and 19 control subjects, matched for BMI (24.87 ± 4.51 kg/m2) and age (25.35 ± 4.56 y.o.). In women with PCOS, NCAH was excluded by the ACTH stimulation test. The participants were reviewed for

anthropometric measurements, the clinical signs of hyperandrogenism, complex hormonal profile, oral glucose tolerance test (OGTT) and ovarian ultrasound parameters. The increase in 17-OHP concentrations in the ACTH-stimulation test (17-OHP delta value), the homeostasis model assessment of insulin resistance (HOMA-IR), Matsuda index and free androgen index (FAI) were calculated.
Results
The women with PCOS were distinguished by statistically higher baseline concentration of 17-OHP, FAI, the level of DHEA-S, serum glucose concentrations at 60 min and 120 min of OGTT, as well as insulin concentration at 120 min of OGTT (all $P<0.01$) and higher testosterone level ($P=0.014$) in comparison to the control group. In PCOS-affected women, we found the correlation between the 17-OHP delta value and Matsuda index ($r=$-0.77, $P=0.002$), as well as testosterone and insulin at 60 min of OGTT ($r=0.5$, $P=0.042$). Moreover, we observed that FAI correlated with fasting insulin concentration ($r=0.76$, $P<0.001$), as well as HOMA-IR ($r=0.67$, $P=0.005$). Additionally, in a whole study group, we observed the correlation between glucose concentration at 60 min of OGTT and baseline level of 17-OHP ($r=0.39$, $P=0.006$), 17-OHP delta value ($r=0.44$, $P=0.017$), testosterone ($r=0.29$, $P=0.048$), FAI ($r=0.4$, $P=0.016$) and DHEA-S ($r=0.34$, $P=0.049$). We also found the relationship between DHEA-S and insulin concentration at 120 min of OGTT ($r=0.34$, $P=0.049$), as well as the baseline level of 17-OHP ($r=0.48$, $P=0.004$) in a whole study group.
Conclusion
Serum 17-OHP and DHEA-S concentrations are elevated in PCOS-affected women and their levels might be related to the parameters of glucose metabolism.

Early career clinicians' knowledge about lifestyle management of PCOS and the current practices of implementing it in clinical practice - does more need to be done?

Nawal Zia[1], Jameela Sheikh[1], Halimah Khalil[1], Alisha Narendran[2], Meghnaa Hebbar[1], Saskia Wicks[3], Sindoora Jayaprakash[4], Punith Kempegowda[5] & Pcos SEva Team[6]
[1]Birmingham, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Birmingham, King Edward VI High School for Girls, Birmingham, United Kingdom; [3]Barts Health NHS Foundation Trust, London, United Kingdom; [4]The Dudley Group NHS Foundation Trust, Dudley, United Kingdom; [5]Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [6]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, United Kingdom

Objective
Polycystic Ovary Syndrome (PCOS) is one of the most common endocrine conditions affecting women of reproductive age. Current estimates place the condition as more common than Type 2 Diabetes Mellitus (T2DM). Recent studies have shown several long term comorbidities associated with PCOS, thus making it essential that all physicians, regardless of training and speciality, understand and empower women with PCOS to adopt evidence-based behavioural changes. This study set out to establish an understanding of evidence-based lifestyle management of PCOS and the current practices of implementing it in clinical practice amongst final year medical students and newly graduated healthcare professionals.
Design
A survey was constructed using evidence-based recommendations in the international guidelines for PCOS.
Method
We invited final year medical students and non-specialist junior doctors in the UK to complete an online survey between September 2020 and January 2021. The findings were reported as frequency and proportion.
Results
A total 67 participants took part in the survey (41 female and 25 male; medical students (21%), foundation doctors (64%) and senior house officers (15%); 34% from London deanery and 27% from the West Midlands deanery). 54% ($n=36$) knew the correct prevalence of PCOS. Although 70% ($n=47$) knew biochemical androgen excess is a sign of PCOS, only 43% ($n=28$) and 1% ($n=1$) knew free testosterone and free androgen index respectively, were the tests of choice to diagnose this. Instead, androstenedione (52% ($n=35$) and DHEAS (43% ($n=29$) were the most common biochemical tests of choice by this cohort. Interestingly, 55% (n37) said they would use AMH as a test to diagnose PCOS. Although most of the participants knew that BMI 94% ($n=63$) and waist circumference 95% ($n=64$) required routine monitoring between 6-12 months for PCOS, only 6% ($n=4$) were aware of the national recommendations for exercise. 36% ($n=26$) identified obesity and T2DM as the most common long term effects of PCOS.
Conclusion
Effective evidence-based lifestyle advice and patient empowerment are crucial for enhanced clinical outcomes in people with PCOS. Our study highlights that physicians and medical students have a limited understanding of the international evidence-based recommendations for PCOS. Our future work will focus on understanding the current educational opportunities for medical students and junior doctors about lifestyle advice and patient empowerment. With this information, we will work with all involved stakeholders to improve access to these programmes for medical students and early career clinicians.

Thyroid dysfunction related to SARS-CoV-2 vaccination: the experience of a single center in Milan

Ilaria Muller[1,2], Francesco Di Marco[3], Maura Arosio[1,2] & Mario Salvi[2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan,; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Endocrinology, Milan,; [3]University of Milan, Milan, Italy

Background
The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic disease (Covid-19) has caused millions of deaths worldwide, thus a massive SARS-CoV-2 vaccination campaign has been launched since the end of 2020. Viruses and vaccines can induce adverse thyroid effects; SARS-CoV-2 infection and vaccines have been associated with several thyroid disorders, especially subacute thyroiditis (SAT) and Graves' disease (GD). We aimed to study the occurrence of thyroid diseases following SARS-CoV-2 vaccination in our Centre.
Methods
From February 2020 onwards we have recorded all consecutive cases of SAT of any cause, noting if occurred shortly after SARS-CoV-2 infection or vaccines. We have also retrospectively extended this analysis to GD and Graves' orbitopathy (GO). Our patients underwent blood tests for thyroid function, inflammatory markers, anti-SARS-CoV-2 antibodies and thyroid ultrasound scan.
Results
Up to December 2021 we have registered 15 patients with thyroid dysfunction occurring shortly after SARS-CoV-2 vaccination: 8 SAT and 7 GD, of which 3/7 (43%) also developed GO and 1/7 (14%) associated autoimmune acute hepatitis. Importantly, we observed an increased number of SAT diagnoses from June 2021 onwards, when the vaccination campaign was extended to the Italian general population. Patients' mean age was 53 years (range 23-83 years) and females were 9/15 (60%). 3/15 (20%) patients had a previous history of thyroid disease (one subclinical hypothyroidism, one transient gestational hypothyroidism and one Hashimoto's thyroiditis) and 10/15 (67%) patients had a positive family history of thyroid disorders. Patients received all SARS-CoV-2 vaccination types (8 Pfizer, 5 AstraZeneca, 1 Johnson&Johnson, 1 Moderna); symptoms were developed following the first dose (mean +15 days) in 10/15 (67%), the second (mean +6 days) in 4/15 (27%) and the third (mean +14 days) in 1/15 (7%) patients. A previous documented SARS-CoV-2 infection occurred in 4/15 (27%) patients several months before the vaccination.
Conclusions
SARS-CoV-2 vaccines seem to be associated with the onset of SAT or GD. Possible mechanisms involve the interaction of the spike protein with the ACE-II receptor expressed in thyroid tissue, a cross-reactivity of the spike protein with thyroid self-proteins or an immune reaction induced by adjuvants (ASIA syndrome). The majority of patients had a positive family history for thyroid disorders, thus a genetic predisposition is likely involved. Until more safety data about SARS-CoV-2 vaccines will be available, caution and strict monitoring of individuals predisposed to thyroid disorders or autoimmunity is suggested, especially those with low risk factors for Covid-19 disease.

Indications and extended follow-up of radiofrequency ablation for treatment of hyperthyroidism caused by solitary autonomous functioning thyroid nodules

Manon van der Meeren[1,2], Frank Joosten[2], Hans de Boer[1], Laura Deden[2] & Wim J.G. Oyen[2]
[1]Rijnstate Hospital, Internal Medicine, Arnhem, Netherlands; [2] Rijnstate Hospital, Radiology and Nuclear Medicine, Arnhem, Netherlands

Background
Hyperthyroidism caused by autonomous functioning thyroid nodules (ATN) is usually treated with I-131. Recently, radiofrequency ablation (RFA) has emerged as a promising alternative but it is not yet incorporated in guidelines.
Aims
Assessment of efficacy of RFA treatment in patients with hyperthyroidism caused by ATN and factors that may affect treatment success.
Methods
Retrospective analysis of patients treated for hyperthyroidism caused by ATN with RFA, when follow-up of at least one year was available. Results of patients with a single toxic adenoma (STA) are compared with patients with a toxic multinodular goitre (TMG) and a dominant hyperactive nodule on scintigraphy and ultrasound. Proportions were compared by the chi-squared test. Cure was defined as thyroid medication-free biochemical euthyroidism.
Results
48 patients (36 STA, 12 TMG) were included, 85% were female, mean age was 55 (range 27-80). The median nodule volume was 12 ml at baseline. Median energy delivered during RFA was 0.6 kCal/ml. One year post RFA 29 patients (60.4%) were cured after a median of 3.2 months (range 0.1-11). Median volume reduction was 68% (range 21-99). One patient, with a history of hemithyroidectomy, developed hypothyroidism. 18 patients (37.5%) were hyperthyroid one year post RFA. Baseline and RFA parameters were similar for STA and TMG patients. The one-year cure rate was higher among STA patients compared to TMG: 72% vs 25% ($P<0.05$), respectively. 13 patients with persistent hyperthyroidism received re-RFA. 9 (69%) of them were cured at last follow-up (median 12 months post re-RFA). Extended follow-up was available for 31 patients (25 STA and 6 TMG). 3 STA and 1 TMG patients developed late recurrent hyperthyroidism between 24-37 months post-RFA. Of all 48 patients, cure was achieved in 86% of STA patients and in 33% of TMG patients after 1 or 2 RFA sessions at last available follow-up after first intervention (median 20 months after first intervention).
Conclusion and discussion
The efficacy of single session RFA session was nearly 3 times higher in STA patients compared to TMG. These data confirm that RFA is an effective treatment for STA. Further analysis is required to assess the role of RFA in TMG. Follow-up after RFA should be at least 2 years since late recurrences are observed.

Deiodinase Type I regulation in fatty liver disease

Nuria López Alcántara[1], Cathleen Geißler[2], Alison-Michelle Naujack[2], Yingfu Chen[3], Natalie Taege[2], Jan H. Britsemmer[2], Leonardo Vinicius Monteiro De Assis[4], Henrik Oster[4], Joachim Spranger[3], Eva Wirth[3], Rubén Nogueiras[5], Henriette Kirchner[2] & Jens Mittag[1]
[1]University of Lubeck, Center of Brain, Behavior and Metabolism (CBBM), Institute of Endocrinology, Lübeck, Germany; [2] University of Lubeck, Center of Brain, Behavior and Metabolism (CBBM), Institute of Human genetics. Section Epigenetics and Metabolism, Lübeck, Germany; [3]Charité - Universitätsmedizin Berlin, Center for Cardiovascular Research, Berlin, Germany; [4]University of Lubeck, Center of Brain, Behavior and Metabolism (CBBM), Institute of Neurobiology, Lübeck, Germany; [5]University of Santiago de Compostela, Molecular Metabolism, Santiago de Compostela, Spain

Background and Aim
Hepatic thyroid hormone (TH) signalling plays an important role in onset and progression of liver diseases. Patients with altered thyroid hormone regulation in the liver, leading to a local hypothyroid, are at higher risk of developing non-alcoholic fatty liver disease (NAFLD). Treatment with thyroid hormones proved to be a promising therapy for these patients, slowing the progression of NAFLD to non-alcoholic steatohepatitis (NASH), a more advanced stage of the disease characterized by inflammation and occasional fibrosis. The action of thyroid hormone in the liver is regulated by TH transporters, deiodinases, and receptors. Among these, deiodinase type 1 (*Dio1*) is a major player, converting the prohormone thyroxine (T4) directly to the bioactive form T3 in the hepatocytes. However, the exact regulation of *Dio1* in liver disease is not yet fully understood.
Methods
We studied *Dio1* expression in several hepatic disease models, including male C57BL/6 mice fed with high-fat diet (HFD) during 18 weeks and treated with metformin for the last two weeks of treatment, male C57BL/6 mice fed with methionine-choline-deficient HFD for 2 weeks, male C57BL/6 mice fed with choline-deficient HFD for 4 and 8 weeks at thermoneutrality, and finally male C57BL/6 mice treated with carbon tetrachloride to induce liver failure.
Results
Expression of *Dio1* was rapidly increased in animals fed with HFD and remained elevated throughout the treatment without changes induced by metformin treatment. Remarkably, some of the other conditions did not resulted in an increase in *Dio1*, although lipid deposition in the liver was similar.
Conclusion
Our results show that *Dio1* is rapidly induced by HFD, an effect that seems to be independent of insulin sensitivity, as it was not reversed by metformin treatment. However, *Dio1* induction was restrained in other animal models with similar degree of hepatic lipid deposition, suggesting that other factors such as liver inflammation may prevent the HFD induced *Dio1* induction.

Transoral endoscopic thyroidectomy (TOETVA) in thyroid cancer, our view as endocrinologists

Susana Mallea-Gil[1,1], Yamila Sanchez[1], Bibiana Coca[1], Maria de los Angeles Sosa[1], Adriana Palazzo[1], Javier Rossi[2], Maria Marta Aparicio[1], Silvina Sankowicz[1], Samanta Estevez[3] & Carolina Ballarino[1]
[1]Hospital Militar Central, Endocrinology, Buenos Aires, Argentina; [2] Hospital Militar Central, Surgery, Buenos Aires, Argentina; [3] Hospital Militar Central, Pathology, Buenos Aires, Argentina

Recent progress in surgical technology has resulted in new techniques as transoral endoscopic thyroidectomy (TOETVA) that is an option for patients' cosmetic requests. We evaluated patients with thyroid cancer who underwent thyroidectomy by TOETVA approach and their follow-up. Retrospective study, 5 patients were included, Bethesda classification in FNAC resulted: 2 patients with VI category (CAT), 2: V CAT and 1: III CAT. All patients were operated by TOETVA between 2020-2021. Median age: 48 years (36-64). Median nodules size was: 13.5 mm (7.7-23). No patients presented adenopathies. Total thyroidectomy was performed by TOETVA in 4 patients, one patient required conversion to open thyroidectomy. Hemithyroidectomy was performed in the patient with III CAT, the pathology report resulted in follicular carcinoma and she was later operated by conventional approach. Median size of malignant tumors was 14.7 mm (12-21). Of the 2 patients with VI CAT: 1 had a classical papillary carcinoma, the other one had a follicular variant of papillary carcinoma. Of the two patients with V CAT, 1 had a classical follicular carcinoma and the other one had a nodular goiter; the patient with III CAT had a clear cell variant of follicular carcinoma. In 3 patients the thyroid capsule was absent in some areas, predominantly in the posterior margin. In 4 patients we observed electrocautery effects and tissue attrition. Postoperative complications were: inferior lip insensitivity (5/5), hypogeusia (4/5), mild to soft pain and hematoma in the neck (5/5), suffocating hematoma (1/5), hypoparathyroidism (3/5); all complications were transient. Four patients underwent I-131 therapy; post-therapeutic WBS showed higher and nodular uptake in the neck compared with the patients with conventional thyroidectomy. Stimulated thyroglobulin (TG) was normal in 3 patients and 1 had elevated TG. In the follow-up, only the patient with clear cell variant of follicular carcinoma had increased TG and presented recurrence in the neck, so she was operated again and later received radiotherapy. The remaining patients had normal ultrasonography and TG below 1.
Conclusions
patient selection is very important in TOETVA approach. The cosmetic objective of TOETVA was reached; the complications were different, probably related to the learning curve required for surgeons. Except the patient with the aggressive follicular carcinoma, the patients' follow-up was satisfactory. However, we need more patients and longer follow-ups to determine if the higher and different RAI uptake in the neck scan and the histological findings have an impact in the long follow-up of these patients.

Thyrotoxicosis due to African herbal supplements: does iodine contamination play a role?

Eugénie Van Mieghem[1], Bernaerts Kim[2] & Verhelst Johan[2]
[1]Antwerp University Hospital, Department of Internal Medicine, Edegem, Belgium; [2] ZNA Middelheim, Department of Endocrinology, Antwerpen, Belgium

Introduction
In thyrotoxicosis, the clinical syndrome of excess circulating thyroid hormones, differentiation must be made between thyrotoxicosis with increased or decreased radio-iodine tracer uptake on thyroid scintigraphy. A cause of thyrotoxicosis with decreased radio-iodine uptake is iodine excess. In patients not taking any medication and without any history of recent radiological imaging studies, the confirmation of iodine excess as the cause of the thyrotoxicosis is difficult. Especially in patients with a penchant for traditional medicine and natural supplements, a thorough inquiry about supplement use is key to establishing a correct diagnosis.
Case Presentation
In our endocrinology outpatient clinic, in the period between September 2017 and October 2021, six patients, originally from Western Africa, were referred due to abnormal thyroid function tests with suppressed TSH and elevated fT3 and/or fT4. In all patients thyroid antibodies were negative. No fever, painful swelling of the thyroid or recent URTI were reported. The patients hadn't used any medication containing iodine nor had recently underwent a radiological study. On thyroid scintigraphy, in all patients a reduced to absent radio-iodine uptake could be seen. Ultimately, it came to light that all six patients had been taking African natural supplements. In one patient a complete 24-h urinary iodine excretion was performed, which was significantly elevated with a value of 1115.8 µg iodine per 24 hours (783 µg/l), confirming iodine excess. After discontinuation of the supplements, in all patients a normalization of the thyroid function tests could be seen.
Discussion/conclusion
Some herbal remedies used in traditional African medicine seem to cause hyperthyroidism. Characteristics of this kind of hyperthyroidism are reduced to absent radio-iodine uptake on thyroid scintigraphy, absent thyroid autoimmunity, a normal thyroid ultrasound and a spontaneous restoration of euthyroid state with discontinuation of the supplements. Our hypothesis is that this type of thyrotoxicosis is caused by an increased iodine exposure due to use of natural supplements used in traditional African medicine. We suspect that the African supplements, imported from Western Africa to Europe, are treated with iodine-containing compounds to improve the preservability. Iodine-induced hyperthyroidism, or the Jod-Basedow syndrome, is therefore a cause of thyrotoxicosis that therefore must certainly be kept in mind in certain ethnic groups. If a thorough questioning of the supplement use doesn't reveal the intake of natural remedies, then an urinary iodine excretion can sometimes provide a conclusive answer if iodine excess is suspectedly involved in the thyrotoxicosis.

Association between thyroid autoimmunity and gestational diabetes mellitus in euthyroid women

Georgiana Sitoris[1], Kris Poppe[1], Flora Veltri[1], Malika Ichiche[1], Pierre Kleynen[1], Jean-Philippe Praet[2] & Serge Rozenberg[3]
[1]Centre Hospitalier Universitaire Saint-Pierre, Université Libre de Bruxelles (ULB), Endocrine Unit, Bruxelles, Belgium; [2] Centre Hospitalier Universitaire Saint-Pierre, Université Libre de Bruxelles (ULB), Departement of Internal Medicine, Bruxelles, Belgium; [3] Centre Hospitalier Universitaire Saint-Pierre, Université Libre de Bruxelles (ULB), Departement of Gynecology and Obstetrics, Bruxelles, Belgium

Objective
Pregnant women with autoimmune (subclinical) hypothyroidism have an increased risk of developing gestational diabetes mellitus (GDM). However, this association remains controversial in euthyroid women with thyroid autoimmunity (TAI). Therefore, the aim of the study was to determine the association between TAI and GDM in euthyroid women in a logistic regression analysis with adjustments for baseline/demographic parameters.
Methods
Cross-sectional study in 1447 euthyroid women who performed their entire clinical/biological work-up and oral glucose tolerance test (OGTT) in our center. At median 13 (11-17) weeks of gestation, TSH, free T4 and thyroid peroxidase antibodies (TPOAb) were measured, baseline characteristics recorded and an OGTT was performed between 24-28 weeks of pregnancy. Exclusion criteria were pre-pregnancy diabetes, assisted pregnancies, and women with (treated) thyroid dysfunction before or after screening. The diagnosis of GDM was based on 2013 WHO criteria.
Results
Two hundred eighty women were diagnosed with GDM (19.4%), 26.1% in women with TAI and 18.9% in women without TAI ($P=0.096$). TAI was associated with GDM (adjusted odds ratio (aOR) 1.69 (95% CI, 1.01-2.82); $P=0.046$). Maternal age >30 years, pre-pregnancy BMI ≥ 30 kg/m^2 and another than Caucasian background were also associated with GDM; aOR 1.93 (95% CI, 1.46-2.56); $P<0.001$, 2.03 (95% CI, 1.46-2.81); $P<0.001$ and 1.46 (95% CI, 1.03-2.06);$P=0.034$, respectively.
Conclusions
In our cohort, the presence of TAI in euthyroid pregnant women was associated with gestational diabetes. In line with literature data, higher age and obesity were associated too. Future studies should focus on treatment options that might decrease the development of GDM in euthyroid women with TAI.

Discordance between fT4 and TSH concentrations during levothyroxine treatment

Heleen Jansen[1], Marijn Bult[1], Peter H. Bisschop[2], Anita Boelen[1], Annemieke C Heijboer[1] & Jacquelien Hillebrand[1]
[1]Amsterdam UMC, Vrije Universiteit Amsterdam and University of Amsterdam, Amsterdam Gastroenterology Endocrinology & Metabolism, Department of Clinical Chemistry, Endocrine Laboratory, Amsterdam, Netherlands; [2] Amsterdam UMC, University of Amsterdam, Department of Endocrinology and Metabolism, Amsterdam, Netherlands

Introduction
Physicians in our hospital notified the laboratory staff of a number of patients at the outpatient clinic with increased free T4 (fT4) concentrations without (complete) suppression of thyroid stimulating hormone (TSH). This phenomenon appeared to occur more frequently following implementation of a new automated fT4 immunoassay. The discordance between fT4 and TSH concentrations may be explained by analytical issues (not further explained here), incorrect reference intervals, or patient-related factors (e.g. medication, population). We aimed to establish the contribution of the possible factors involved.
Methods
First, reference intervals of the current Cobas (Roche) and former Delfia (Perkin Elmer) fT4 immunoassay were re-evaluated using blood samples of healthy volunteers. Second, TSH (Cobas, Roche) and fT4 requests and the frequency of discordant pairings (i.e. fT4 above the upper limit of normal and TSH 0.02 − 5.0 mU/l) of patients from Amsterdam UMC were retrospectively analysed using a Delfia fT4 and Cobas fT4 cohort. Third, we performed a literature search to assess whether time of blood draw and time of levothyroxine (L-T4) ingestion may contribute to higher fT4 concentrations in L-T4 users.
Results
The original reference intervals belonging to the Delfia and Cobas assay were confirmed. The Delfia ($n=176$, 5.5%) and Cobas cohort ($n=295$, 8.6%) showed comparable frequencies of discordance. Interestingly, approximately 80% of the discordant results belonged to L-T4 users. Review of the literature showed that fT4 concentrations may vary depending on time of blood draw and, therefore, time of L-T4 intake. Besides, fT3/fT4 ratios are different in L-T4 users vs healthy controls and indicate an adapted regulation of the thyroid axis in those patients.
Conclusion
Discordance between fT4 and TSH concentrations was not related to the introduction of a new fT4 immunoassay. The increased fT4 concentrations with discordant TSH could not be explained by analytical issues or incorrect reference intervals, but may be explained by L-T4 intake. Physicians and laboratory specialists should be aware that patients treated with L-T4 may have fT4 concentrations above the reference interval with normal or slightly decreased TSH concentrations, to avoid questioning the assay's performance, or worse, adapting L-T4 dose in patients.

Thyroid autoimmunity observed in a local center hospital of northeast Japan − Association with the nuclear power plant accidents

Takao Kunori & Hiroshi Yoshida
Iwaki-City Medical Center, Surgery, Iwaki, Japan

Background
Our hospital is located 40 km from the nuclear power plants(Tokyo Electric Daiichi; NPP) exploded in northern east Japan disaster (2010.3). After the explosion, yearly radiation dose reached to 1-10 mSV in our city and 10-50 mSV in most poluted areas (next to our city). In former ESE congress, we reported cytological analysis of nodular goiter (NOD). In the present study, patients' thyroid autoimmunity was analyzed whether there is any difference between pre- and post-NPP accidents. Patients and methods: 1.625 new patients (pts; 6.242 exams; 2007-2021). Ultra-sonogram (US) and hormonal assay for anti-thyroglobulin (aTg), thyroid peroxidase antibody (TPO), anti-TSH receptor antibody (TSH-R) and, in case of HY, thyroid stimulating antibody (TS), were performed at their visits. Fine needle aspiration cytology (FNA) was, if necessary, performed for NOD. Clinical diagnosis: Hyperthytroidism (HY), 420 pts (26%, 1.592 exams). chronic thyroiditis (HA), 160 (10%, 642), NOD 1.045 (65%:solid 27%, cyst 12%, multiple 15%). Data was compared between pre-NPP (A, 2007-2009) and post-NPP period(B1-B3, 2010- 2021). Significance was determined by Kai2 or student-t test (significance $P<0.05$).
Results
1) Age: A, 55 ± 18 years ($n=1.295$); B1(2010-2013), 55 ± 16 ($n=1.796$); B2 (2014-2017) 59 ± 16 ($n=1.495$); B3 (2018-2021) 57 ± 17. (B2B3>A, $P=0.01$). 2) Gender: female(%), A 21.4%; B1 29.6%; B2 23.6%; B3 5.1%(B>A, $P<0.0001$).3)Autoimmunity(%) : a) All periods; TP(aTg+ TPO+) 10%, Tp(aTg+ TPO-) 3.9%, tP(aTg- TPO+) 3.8%, tp(aTg- TPO-) 25%.b) Period A-B (new pts): TP(aTg+ TPO+); A 18%; B1 18%;B2 29%;B3 25%. (B>A, $P=0.0001$). 4) TSH-R positive(%): A 34%($n=206$), B1 27%($n=232$), B2 21%($n=151$), B2 22% +21%($n=196$). (A>B, <0.0001). 5) NOD: Antibody positive(%): Solid, 41%, cyst 52% a) aTg+: A 12%($n=162$), B1 42%($n=246$), B2 13%($n=230$), B3 44%($n=298$). (A<B1B3, $P<0.0001$). b)TSH-R+: A 5.5%($n=162$), B1 4%($n=246$), B2 14%($n=230$), B3 9.1%($n=296$). (A<B, $P<0.0001$).
Discussion
There was a slight increase of aTg+ TPO+ pts and decrease of TSH-R+ pts. This phenomenon is similar to the results of Chernobyl inhabitants' analysis. However, there are various factors influencing autoimmunity, aging, gendar, residence or some others.
Conclusions
No apparent effect of NPP accidents was observed in thyroid immunity. To confirm the radiation effects, more elaborated environmental study is needed.

Estimating incidence and case fatality of thyroid storm in Germany between 2007 and 2017: A claims data analysis

Arulmani Thiyagarajan[1], Katharina Platzbecker[1], Till Ittermann[2], Henry Völzke[2] & Ulrike Haug[1,3]
[1]Leibniz Institute for Prevention Research and Epidemiology-BIPS, Department of Clinical Epidemiology, Bremen, Germany; [2] University Medicine Greifswald, Institute for Community Medicine, Greifswald, Germany; [3] University of Bremen, Faculty of Human and Health Sciences, Bremen, Germany

Background
Given the general lack of descriptive epidemiological studies on thyroid storm, we aimed to estimate the incidence rate and case fatality of thyroid storm in Germany based on a large claims database.
Methods
Using the German Pharmacoepidemiological Research Database (GePaRD) we identified patients with at least one inpatient discharge diagnosis of thyroid storm (International Statistical Classification of Diseases and Related Health Problems, 10th revision, German modification; ICD-10-GM E05.5) between 2007 and 2017 and calculated age-standardized and age-specific incidence rates in males and females. We defined deaths occurring within 30 days of the diagnosis as thyroid storm-associated and determined case fatality by sex and age group.
Results
Overall, we identified 1.690 patients with an incident diagnosis of thyroid storm (72% females). Mean age was 60 years (standard deviation: 18.6 years). The age-standardized incidence rate per 100.000 persons per year was 1.4 (95% confidence interval [CI] 1.2 to 1.7) in females and 0.7 (95% CI 0.5 to 0.9) in males. In females ≤60 and >60 years of age, the incidence rate was 0.9 (males 0.4) and 2.7 (males 1.7), respectively. The case fatality of thyroid storm was 1.0% in males ≤60 years (females: 1.4%) and 16.7% in males >60 years of age (females: 10.9%).
Conclusion
Incidence rates of thyroid storm were markedly higher in females than in males and were three times higher in persons >60 years compared to younger age groups. Case fatality was below 2% in persons aged ≤60 years and markedly higher in older persons (males: 17 times, females: 8 times).

Background
This is the first study, that aimed: a) to compare immune response, namely the kinetics of neutralizing antibodies (Nabs), after vaccination with BNT162b2 mRNA vaccine between patients with autoimmune thyroiditis and controls, and b) to investigate changes in thyroid function in healthy subjects with no history of thyroid dysfunction before and after vaccination.
Methods
The entire study consisted of two sub-studies. In the first sub-study, NAbs levels after BNT162b2 mRNA vaccination were compared between 56 patients with autoimmune thyroiditis and 56 age and gender-matched healthy controls from the day of the first vaccination until a period of up to three months after the second vaccination. In the second sub-study, thyroid hormones (T3, T4, TSH) and thyroid auto-antibodies levels (anti-TG, anti-TPO) of 72 healthy subjects with no history of thyroid disease were examined before (D1) and one month after completion of the second vaccination (D50).
Results
Among patients with autoimmune thyroiditis, the median neutralizing inhibition on D22, immediately before second vaccination, was 62.5%. One month later (D50), values increased to 96.7%, while three months after the second vaccination NAbs titers remained almost the same (94.5%). In the healthy group, median NAbs levels at D22 were 53.6%. On D50 the median inhibition values increased to 95.1%, while after three months they were 89.2%. The statistical analysis did not show significant differences between two groups (P-values 0.164, 0.390, 0.105 for D22, D50 and three months). Regarding changes in thyroid function, the mean value for T4 before vaccination was 89.797 nmol/l and one month after the second vaccination was 89.11 nmol/l (P-value=0.649). On D1 the mean T3 value was 1.464 nmol/l, which dropped to 1.389 nmol/l on D50 (P-value=0.004). For TSH, mean levels were 2.064 mIU/ml on D1 and fell to 1.840 mIU/ml one month after the second vaccination (P-value=0.037). Despite decrease, all thyroid hormone levels remained within the normal range. No changes were found for anti-TPO or anti-TG.
Conclsions
This study provided evidence that patients with autoimmune thyroiditis present similar immunological response to COVID-19 BNT162b2 mRNA vaccination with healthy subjects, while vaccination may affect thyroid function.

[1]OSI Bilbao-Basurto. Basurto University Hospital, Endocrinology, Bilbao, Spain; [2] Basque Country University (UPV-EHU), Medicine, Spain; [3] OSI Bilbao-Basurto. Basurto University Hospital, Endocrinology, Bilbao, Spain; [4] OSI Bilbao-Basurto. Basurto University Hospital, Endocrine Surgery, Bilbao, Spain

Despite being the most successful definitive treatment for GD and offering the best response in terms of quality of life, thyroidectomy is rarely performed worldwide. Few studies evaluate its complication rate and potential prognostic factors for complications. We report our last ten years' experience. Incidence of temporary and permanent hypoparathyroidism, temporary and permanent recurrent laryngeal nerve (RLN) injury and incidental malignancy were recorded, looking for predictors of their occurrence. Biochemical trends of TSI and TSH levels after surgery were also examined. From 1798 thyroid surgeries, 162 patients undergoing total thyroidectomy for GD were collected. Median age was 44.4 years and 78.4% were female. Thirty percent of the patients needed calcitriol at discharge, and one year later this rate was 5.2%. Twelve percent of patients had injury to one RLN following surgery, with permanent damage in 1.9%. Active Graves' orbitopathy (GO) was the second leading reason for surgery (26 cases). GO activity improved in 50% but worsened after thyroidectomy in 6 cases. Mean thyroid weight was 41.4 g and 13 glands showed incidental malignancy, all but one PTC. Prior to surgery, 94.8% of patients had measurable TSI titres (ELISA) and these were persistent 6 and 12 months after surgery in 86% and 62%, with lower titres. Median time to halve TSI titres was four months. One month after surgery, previously suppressed TSH was detectable in 75.2% of patients. There were no recurrences of hyperthyroidism. Univariate analysis showed that glandular weight, lower postoperative calcium, higher preoperative alkaline phosphatase, and parathyroid tissue in the surgical specimen were associated with immediate postoperative hypoparathyroidism, whereas higher TSI titres were associated with a higher incidence of RLN damage. Incidental carcinomas were associated with the presence of severe OG. In multivariate logistic regression, only perioperative PTH and calcium dynamics predicted the need for calcitriol, whereas preoperative [TSI] maintained the predictive value of RLN damage (OR per 1 IU/l: 1.07). OG lost predictive value for the detection of incidental cancers. Neither the finding of incidental malignancy nor the presence of parathyroid glands, nodular disease or germinal centres in histological specimen were associated with increased complication rates. Underused thyroidectomy is a safe alternative to radioiodine in GD, with a low rate of complications. It discloses occult carcinoma in 8% of GD. Surgical hypoparathyroidism is associated with perioperative calcium and PTH dynamics and this study finds a novel association between preoperative TSI level and transient LNR damage.

SARS-CoV-2 Vaccine-Associated Subacute Thyroiditis: Insights from a Systematic Review

Silvia Ippolito[1], Daniela Gallo[1], Alessandro Rossini[2], Bohdan Patera[3], Nicola Lanzo[3], Gaia Francesca Maria Fazzino[1,3], Eliana Piantanida[1,3] & Maria Laura Tanda[1,3]
[1]ASST Sette Laghi, Endocrine Unit, Varese, Italy; [2] ASST Papa Giovanni XXIII, Endocrine Unit, Bergamo, Italy; [3] University of Insubria, Medicine and Surgery, Varese, Italy

Introduction
subacute thyroiditis (SAT) is an inflammatory disease of the thyroid gland causing transient thyrotoxicosis, characterized by neck pain and symptoms of thyroid hormones excess. Viral infections are considered the main trigger of SAT. SAT has also been described after vaccination against H1 N1 vaccine, seasonal influenza virus vaccine, Human Papillomavirus vaccine, and hepatitis B vaccination; more recently, a rising number of cases of SAT following SARS-CoV-2 vaccination has also been reported.
Purpose
perform a systematic review on published cases of subacute thyroiditis secondary to SARS-CoV-2 vaccination, to highlight main features and increase the awareness of this condition.
Methods
original reports of SAT developed after SARS-CoV-2 vaccination (mRNA, viral vector, or inactivated virus vaccines) were retrieved from a search of electronic databases. Individual patient data on demographics, medical history, type of vaccine, workup and therapies were collected. Wilcoxon rank-sum, Kruskal-Wallis and chi-squared tests were employed for comparisons.
Results
29 articles including 48 reports were retrieved, 3 additional cases evaluated by the Authors were described and included for analysis. Of the 51 patients, 38 (74.5%) were women, median age was 39.5 years (IQR 34-47). Patients developed SAT after a median of 10 days (IQR 4-14) after the vaccine shot. Baseline thyroid exams revealed thyrotoxicosis in 88.2% of patients, decreasing at 31.6% at follow-up. Corticosteroids were used in 56.4% of treated patients. Patients undergoing non-mRNA vaccines were most frequently Asian ($P=0.019$) and reported more frequently weight loss ($P=0.021$). All patients with a previous diagnosis of thyroid disease belonged to the mRNA vaccine group.
Conclusions
SARS-CoV-2 vaccine-associated SAT is a novel entity, that should be acknowledged by physicians. Previous history of thyroid disease may predispose to develop SAT after mRNA vaccines, but further studies and larger cohorts are needed to verify this suggestion. SARS-CoV-2 vaccine-associated SAT is usually of mild/moderate severity and could be easily treated in most cases, thus it should not raise any concern regarding the need to be vaccinated.

Identifying the use of clinical and radiological parameters to assess moderate-severe Graves' Orbitopathy − a multi-centre analysis of the characteristics of patients with Graves' Orbitopathy

Nicole George[1], Vickie Lee[2], Claire Feeney[2], Kunwar Bhatia[2] & Amina Ali[1]
[1]Imperial College London, School of Medicine, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, United Kingdom

Background
Early diagnosis and surveillance of Graves' Orbitopathy (GO) is essential to prevent severe, sight-threatening complications and long-term disability; therefore, it is highly desirable to identify risk factors and early predictors of severe disease. GO is clinically assessed using the Clinical Activity Score (CAS) and the EUGOGO Severity Scale (ESS), which are subjective, qualitative tests that are used to evaluate the activity and severity at the anterior orbit. However, we propose the use of radiological characteristics, such as specific muscle enlargement, to predict the progression to severe disease. Therefore, we evaluated the clinical and radiological features of GO in patients presenting to multi-centre multidisciplinary teams in London and identified factors predictive of severe disease.
Method
A retrospective patient-cohort study of 356 patients referred to three multi-disciplinary (MDT) clinics in London between 2012 and 2021 was investigated. Patient characteristics were statistically analysed to investigate group-wise differences and correlations to help predict subsequent disease activity. From this analysis, odds ratios were produced for both clinical and radiological parameters.
Results
Median age was 46.0 years (interquartile range: 36-55), 79.2% female, 41.2% Asian. Out of 356 patients, 43.0% had moderate-severe or sight-threatening disease. On odds ratio analysis, clinical parameters of older age (OR 1.96 (1.07-3.59)), male gender (OR 2.03 (1.19-3.45)), hyperthyroidism (OR 3.64 (2.08-6.38)) were associated with more severe disease. On analysis of radiological parameters, superior rectus-levator complex muscle involvement was also associated with more severe disease (OR 1.90 (1.03-3.50)).
Conclusion
These results suggest that cases of higher severity disease were more prevalent in the older demographic and the male population. The presence of radiological superior rectus-levator muscle involvement was associated with a higher incidence of moderate-to-severe disease. This provides an additional significant radiological criterion for diagnosing moderate-to-severe disease and providing all-important early intervention for these patients. This highlights the merit of both clinical and radiological assessment for the diagnosis and surveillance of Graves' Ophthalmology.

Tuberculosis and myxedema coma − clinical case

Miguel Saraiva, Ariana Maia, Guilherme Assunção, Cláudia Amaral, Cláudia Freitas & André Couto de Carvalho

Centro Hospitalar Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Myxedema coma is the ultimate stage of severe long-standing hypothyroidism, representing a true endocrinological emergency. Many precipitating factors have been identified, including the initiation of certain drugs.
Case report
An 89-year-old woman was admitted to our emergency department due to an inaugural seizure. There was a history of progressive functional deterioration in the last 7 weeks, short after being diagnosed with lymph node tuberculosis (8 weeks before). There was no known history of previous thyroid disease. She suffered from atrial fibrillation, under chronic treatment with amiodarone, and she had undergone scalp radiotherapy for *tinea capitis* during her childhood. The patient presented with marked psychomotor lentification, hypothermia (33.4º C), hypotension (75/25 mmHg) and hypoglycemia (41 mg/dl). Her blood sample revealed normocytic normochromic anemia (9.5 g/dl), mild hyponatremia (133 mmol/l), marked rhabdomyolysis (creatine kinase 610.6 U/l; myoglobin 789.0 µg/L) and primary hypothyroidism (TSH 288.0 µUI/ml; fT4 0.23 ng/dl) with negative antithyroid antibodies titer. There was no evidence of respiratory failure, ongoing acute infection or ischemic event. The brain CT revealed signs of chronic ischemic leukoencephalopathy. Confirming the diagnosis and its severity, the patient scored a total of 95 points in the Diagnostic Scoring System for Myxedema Coma. It is likely that the patient's hypothyroidism was due to a *Wolf-Chaikoff* effect to amiodarone but the precipitating factor myxedema coma seemed to be the initiation of the antitubercular medication, namely rifampicin, which is a known inducer of CYP450 with a potential effect by increasing thyroid hormones' metabolism. During hospitalization, the patient responded well to levothyroxine supplementation, gradually resolving every organic disfunction and was discharged under oral levothyroxine, 36 days after admission.
Discussion
Myxedema coma is a serious clinical condition with high morbidity and mortality. When introducing medications that may alter the metabolism of thyroid hormones, namely CYP450 inducers or inhibitors, it is important to monitor thyroid function. This case highlights that this should be a routine procedure not only for patients with known hypothyroidism but also for those with risk factors for thyroid dysfunction.

Severe refractory active thyroid eye disease: an unmet clinical need in Europe

Ploutarchos Tzoulis[1,2] & Chrysoula Dosiou[3]
[1]IASO General Clinic, Department of Endocrinology, Marousi, Greece; [2] University College London, Department of Experimental and Translational Medicine, London, United Kingdom; [3] Stanford University School of Medicine, Division of Endocrinology, Stanford CA, United States

Introduction
Moderate to severe thyroid eye disease (TED) has a significant impact on quality of life. In some cases, TED is resistant to systemic glucocorticoids, the mainstay of treatment since the 1950s, requiring alternative therapies. We describe here a patient with active severe TED who is refractory to various treatments.
Case presentation
A 48-year-old non-smoker male, with a long history of psoriasis, vitiligo and atrophic gastritis, presented in May 2019 with Graves' thyrotoxicosis and was treated with methimazole. In July 2020, following 14 months of euthyroidism, he started experiencing eye pain, proptosis, and diplopia, with a clinical activity score (CAS) of 6/7. TSI (thyroid stimulated immunoglobulin) levels were 16.2 IU/l (normal range $<$ 1.75 IU/l). He was treated with oral methylprednisolone for 3 months, showing a small response in eyelid swelling, but developed a 15 kg weight gain, proximal myopathy, peripheral edema, restlessness, and insomnia. In November 2020, he underwent total thyroidectomy. After a brief period of hypothyroidism, which was corrected with levothyroxine, he had TED improvement (CAS 4/7) and TSI normalization. In March 2021, a few weeks after COVID vaccination, his TED deteriorated significantly (CAS 6/7), while TSI rose to 4.45 IU/l. Administration of a total dose of 4.5 gr methylprednisolone in 12 weekly intravenous infusions resulted in slight reduction of eyelid swelling, some pain relief, and TSI normalization. Throughout this period, he received artificial tears and oral selenium, while he remained euthyroid. However, he gradually developed worsening diplopia and several side effects, including a 7 kg weight gain, irritability, and insomnia. Tocilizumab, a monoclonal antibody against interleukin-6 (IL-6) receptor, was started intravenously (8 mg/kg). After three monthly infusions, there was significant improvement in eyelid swelling and pain, but no effect on proptosis and diplopia (CAS 5/7). Severe arthralgias and intractable pruritus necessitated discontinuation of treatment.
Conclusion
This case illustrates the therapeutic challenges around severe refractory active TED. Glucocorticoids and tocilizumab improved soft-tissue inflammation, but had minimal impact on proptosis and diplopia. There is an unmet clinical need in Europe for therapies with efficacy against proptosis and diplopia, such as teprotumumab, a monoclonal antibody against the insulin-like growth factor-I receptor. Teprotumumab, approved in 2020 by the US Food and Drug Administration for TED, is still not routinely available in Europe. In a rapidly evolving treatment landscape of TED, it is essential to ensure patient access to therapeutic advances targeting the underlying pathogenetic mechanisms in order to improve patient outcomes.

Is there a familial predisposition to severe amiodarone-induced thyrotoxicosis? Report of two cases

Blanca Bernaldo Madrid[1], Sara Mera Carreiro[1], Xavier Pérez Candel[1], Celia Lopez Nevado[1], Patricia Espinosa De Los Monteros[1], Fernando Hernández Olmeda[1], Santiago Ochagavia Camara[1], Isabel Runkle[1], Jorge Gabriel Ruiz Sánchez[2] & Mario Pazos Guerra[1]
[1]Hospital Clinico Universitario San Carlos, Madrid, Spain; [2] Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Introduction
Amiodarone-induced thyrotoxicosis (AIT) occurs in up to 6% of patients taking this medication in iodine sufficient areas and in up to 10% of patients in iodine deficient areas and has a high rate of mortality, that can reach 50% in untreated severe forms. There are two main types (1 and 2) described, although usually we find mixed types, with both components. Below, we describe the cases of two brothers that developed severe mixed forms of amiodarone-induced thyrotoxicosis.
Case-Report
The first case was a 61-year-old male with ischemic cardiomyopathy and atrial fibrillation which was successfully ablated in 2017 and was treated with amiodarone until September 2018. In April 2019, he was admitted to hospital because of a severe mixed AIT with initially good response to medication, which enabled discharge home with continued medical management. However, he was immediately re-admitted to the hospital due to worsening symptoms and increasing levels of thyroid hormones and required amiodarone continuous infusion and urgent total thyroidectomy. The second case was a 60-year-old male with recurrence of atrial fibrillation successfully ablated a few years prior and also treated with amiodarone until December 2020. In August 2021 he began to experience palpitations and independently decided to start amiodarone for 2 weeks. Two months later he was admitted with severe AIT, despite medical treatment. He was treated with amiodarone continuous infusion and two sessions of plasmapheresis before total thyroidectomy.
Discussion
We report two cases in the same family with severe mixed AIT. They both needed urgent thyroidectomy and amiodarone continuous infusion, useful four days before surgery to rapidly block conversion between T4 and T3, decreasing the active form of the hormone. Furthermore, in one of the cases plasmapheresis was used, being a procedure that decreases blood levels of thyroid hormone up to 40-50%.
Although both cases could be explained by underlying thyroid autonomy or iodine deficiency and a Job-Basedow phenomenon, we can't rule out the existence of familiar predisposition to AIT. There is not literature describing genetic alterations potentially involved in increasing production of thyroid hormones secondary to amiodarone administration. For that reason, it would be useful to report those familiar cases of AIT, from now on, so that we can investigate which factors are involved.

Keep calm and call the surgeon: a case series of urgent thyroidectomy in thyrotoxicosis

Tanja Rezic[1], Tomislav Novosel[2], Mirjana Kardum-Pejic[1], Ivan Oreski[1], Drago Boscic[2], Srecko Marusic[1] & Vlatka Pandzic Jaksic[1]

[1]Clinical Hospital Dubrava, Endocrinology, Diabetes and Clinical Pharmacology, Zagreb, Croatia; [2] Clinical Hospital Dubrava, Zagreb, Croatia

Introduction
The standard management of Graves' disease includes initial use of antithyroid drugs, while radioactive iodine ablation or thyroid surgery are later definitive treatment options. Management of thyrotoxicosis secondary to the use of amiodarone can be challenging as patients may not promptly respond to antithyroid or corticosteroid therapy, and thyrotoxicosis may be more harmful in those patients owing to the underlying cardiac disease. In rare thyrotoxicosis cases, conventional treatment fails, and urgent thyroidectomy is the way to restore euthyroid state. Case series: We report three patients with thyrotoxicosis who underwent successful urgent thyroidectomy with rapid preoperative preparation. Two patients with Graves' disease were treated with methimazole which led to severe agranulocytosis in the first, and severe cholestatic hepatotoxicity in the second patient. In addition to propranolol and corticosteroids, potassium iodine (Lugol's solution) was used to render these patients euthyroid before thyroidectomy. Finally, third patient with severe cardiomyopathy requiring cardiac transplantation presented with type II amiodarone-induced thyrotoxicosis. Plasma exchange was performed to reduce thyroid hormones and to allow stabilisation of this patient prior to urgent thyroid surgery.
Conclusion
Urgent thyroidectomy is the only option for treatment of thyrotoxicosis in selected patients and careful preoperative preparation is essential to optimise surgical outcomes.

Background
Cytology is the gold standard method for the differential diagnosis of thyroid nodules, though 25−30% of them are classified as indeterminate and, in some cases, surgery is required for a definitive diagnosis.
Aim
In order to reduce unnecessary thyroid surgeries, we set up a 'thyroid risk score' (TRS) to increase the diagnostic accuracy in a large series of patients with indeterminate cytology and to apply it to a validation series.
Methods
The pre-surgical TRS derived from the sum of the scores assigned at cytology, namely EU-TIRADS classification, nodule measurement, and molecular characterization (24 different genetic alterations, including point mutations and gene fusions, analysed by our customized assay PTC-MA assay until recently and, currently, from a Next-Generation Sequencing-NGS panel). We prospectively tested 136 indeterminate thyroid nodules for the model evaluation, while further 50 patients have been enrolled to date for the model validation.
Results
66/136 analyzed nodules underwent surgery and 20/66 (30.3%) were malignant. The risk of malignancy (ROM) increased paralleling the score: in the category >4 and ≤ 6 (low suspicion), $>6 \leq 8$ (intermediate suspicion), and >8 (high suspicion) ROM was 10, 47 and 100%, respectively. ROC curves selected the score >6.5 as the best threshold to differentiate between malignant and benign nodules ($P< 0.001$). The TRS $>$ 6.5 had a better performance than the single parameters evaluated separately, with an accuracy of 77% and 82% upon inclusion of noninvasive follicular thyroid neoplasm with papillary-like nuclear features among malignant or benign cases, respectively. In the new series, 12/50 nodules with TRS $>$ 6 will undergo surgery in order to confirm TRS cut-off.
Conclusions
In conclusion, for the first time, we generated and applied a score combining a cost-effective molecular assay with already validated tools, harboring different specificities and sensitivities. The combination of different parameters reduced the number of false negatives inherent to each classification system. The TRS $>$ 6.5 was highly suggestive for malignancy and retained a high accuracy in the identification of patients to be submitted to surgery. A proper role of the TRS can be also predicted in the evaluation of large nodules routed to surgery in most cases. Indeed, in the era of mini-invasive procedures, a low TRS could favor the possibility to submit older patients and cases with co-morbidities to these techniques. The validation series will give more insights into the accuracy of our present TRS cut-off.

Results of radioiodine remnant ablation with 30 mci dose in low-risk differentiated thyroid carcinoma (dtc)

Irene De Lara-Rodriguez[1], Suset Dueñas Disotuar[1], Ana R. Romero Lluch[1], Juan Luis Tirado-Hospital[2], Ana Piñar Gutiérrez[1] & Elena Navarro[1]
[1]Virgen del Rocío University Hospital, Endocrinology, Sevilla, Spain; [2]Virgen del Rocío University Hospital, Nuclear Medicine, Sevilla, Spain

Background
The indication of ablation with I131 in low-risk DTC is controversial. The exact dose needed for thyroid remnant ablation is still a matter of debate in low-risk DTC patients. However, low dose has been found to be equally effective as high dose in terms of recurrence rate in recent studies. Taking this into account the current trend is to administer lower doses, although some studies describe a higher rate of retreatment.
Aims
1. To examine whether there is difference in the response to treatment with 30 vs $>$30 mCi dose in patients with low-risk DTC.
2. To study if there are predictor variables for needing a second I131 dose in low-risk DTC

Material and method
This is a cohort study of pre-ablation low-risk DTC patients undergoing treatment with 30 mCi vs $>$ 30 mCi of 131I between 2017 and 2020. Tumor variables, biochemical characteristics, response after ablation (at one year), and need for a second 131I dose were analyzed. Qualitative variables are expressed as n(%) and quantitative variables as median [IQR]. We used Chi-square and the Kruskal-Wallis test for independent samples to compare both groups.
Results
Both groups are comparable. There were no differences in the type of response and the need for a second dose between groups. However, pre-ablation Tg, stimulated Tg, and pre-ablation AbTg were significantly higher in patients requiring a second dose (P 0.01, P 0.001, and P 0.04, respectively).

		30 mCi	>30 mCi
Median dose (mCi)		30[30-30]	80[80-80]
N		74	62
Women		64(86.5%)	50(80.6%)
Age (years)		55[42-64]	54[45-66]
Tumor type	Papillary	73(98.6%)	58(93.5%)
	Follicular	1(1.4%)	3(4.6%)
Tumor size	T1	34(46%)	23(37%)
	T2	33(44.5%)	30(48.3%)
Excellent response		53(71.7%)	48(77.4%)
Second dose		16(21.6%)	9(14.5%)

Second dose	pre-ablation Tg (ng/ml)	stimulated Tg (ng/ml)	pre-ablation AbTg (UI/ml)
No	0.20 [0.04-0.79]	0.55 [0.06-1.70]	10[10-11.7]
Yes	0.44[0.22-1.54]	2.30[0.79-5.53]	10.35[10-196]

Conclusions
In low-risk DTC patients, the response to treatment with 30 mCi is like that with higher doses. High pre-ablation Tg and AbTg should guide us to use higher doses of I131.

Utility of liquid biopsy in indeterminate thyroid nodules

Soham Tarafdar, Susmita Dutta, Pradip Mukhopadhyay, Nitai P. Bhattacharyya & Sujoy Ghosh
IPGME&R and SSKM Hospital, Dept of Endocrinology and Metabolism, Kolkata, India

Background
Indeterminate thyroid nodules pose a diagnostic dilemma and the patients often undergo unnecessary surgeries or repeat surgery. Currently different molecular methods for detection of driver mutations are being used for better characterisation of these nodules. These methods are costly and not widely available all over the world. Currently use of liquid biopsy by measurement of cell-free DNA (cfDNA) levels from plasma has been useful in diagnosis and follow up of cancers of other organs/tissues. We have analysed cfDNA levels in patients with thyroid nodules to explore the possibility of establishing a cut-off for identification of malignancy and its application in the indeterminate category of nodules.
Methods
Patients underwent ultrasonography (USG) and USG-guided fine needle aspiration as well as surgery, where indicated. CfDNA was extracted from plasma by using a commercially available kit. Quantification and purity of the isolated cfDNA was measured by determining absorbance at 260 nm and 280 nm in duplicate using a Nano Drop Spectrophotometer. Surgical biopsy and histopathology were taken as gold standard for diagnosis. In initial analysis (determination of cut-off), cfDNA levels were compared between Bethesda 2 and Bethesda 5 &6 to establish a cut-off value that could differentiate malignant from benign nodules. In the subsequent analysis, the aforementioned cut-off was applied (validation of cut-off) to those with indeterminate nodules to check ability to predict malignancy.
Results
Fine needle aspiration ($n=207$) yielded patients with Bethesda 2 ($n=112$) Bethesda 5 & 6 ($n=34$) who underwent histopathological confirmation. Cell-free DNA levels in these 2 groups were 23.09 $\pm$ 8.47 and 90.26 $\pm$ 9.00 (ng/ml) respectively. A cfDNA cut-off of 64.05 ng/ml, with area under the curve of 0.993 (95% CI, 0.98-1.0) with 100% sensitivity and 96.4% specificity was established to identify malignant lesions. Indeterminate group (Bethesda 3 & 4 $n=61$) underwent surgery (malignant $n=33$), (benign $n=28$), and using the previously identified cut-off for cfDNA, we were able to identify malignant lesions with a sensitivity of 100% and specificity of 96.43%. There was a very strong agreement between cfDNA-based classification with histopathology-based classification of benign and malignant nodules (Cohen's kappa 0.96; $P < 0.001$).
Conclusion
Liquid biopsy by using plasma cfDNA could be a useful test in differentiating benign and malignant nodules in indeterminate category and help in better management.

Alpelisib-induced thyroiditis in a patient with metastatic breast carcinoma

Anusha Prem Kumar[1], Calvin Flynn[2], Michaela J Higgins[2], Rachel K Crowley[1], Donal O'Shea[1] & Aoife Garrahy[1]
[1]St. Vincent's University Hospital, Department of Endocrinology, Ireland; [2]St. Vincent's University Hospital, Department of Oncology, Ireland

Background
Alpelisib is a novel phosphotidylinositol 3-kinase (PI3K) inhibitor which, in combination with fulvestrant, has been shown to increase progression-free survival in patients with HR+/HER2-/*PI3KCA* mutated advanced breast cancer[1]. Hyperglycaemia, including alpelisib-induced diabetic ketoacidosis is a known adverse effect, along with rash, diarrhoea and stomatitis. No other associated endocrinopathy has been reported to date. Case presentation: We present the case of a 50-year-old woman with metastatic breast cancer was referred from the Oncology service with a two-week history of fatigue, tremors, palpitations, sweats and myalgia, associated with raised free T4 and free T3, and suppressed TSH. Two months prior, she had been commenced on the novel Phosphotidylinositol 3-kinase (PI3K) inhibitor, alpelisib, combined with fulvestrant, due to progression of her disease on first and second-line therapies. Alpelisib was held once abnormal thyroid function was noted. On examination the patient was tachycardic and tremulous. The thyroid was tender to palpation without a discernible goitre. TSH <0.02 mIU/l(0.27-4.20), FT4 62.4 pmol/l (12.0-22.0), FT3 25.1 pmol/l (3.1-6.8). Anti-TSH receptor and anti-thyroid peroxidase antibodies were undetectable. She was commenced on propanolol for symptom relief. Ultrasound thyroid showed a diffusely heterogenous gland without increased vascularity. Technetium 99 m radionuclide uptake scan showed diffusely reduced radiotracer uptake, consistent with thyroiditis. Although her hyperthyroidism initially improved with cessation of alpelisib, it deteriorated again with recommencement. The patient was commenced on prednisolone 30 mg once daily. This was weaned as her thyroid function improved, allowing for recommencement of alpelisib treatment. She currently remains euthyroid. Summary: This is the first reported case of alpelisib-induced thyroiditis in a patient treated for metastatic breast carcinoma. We have demonstrated efficacy in treatment with steroid therapy, allowing for continued treatment with this agent. Activation of the PI3K pathway has been shown to inhibit sodium-iodide symporter expression and function within thyroid follicular cells[2]. However, the pathophysiology of alpelisib-induced thyroiditis remains to be elucidated.

Levothyroxine absorption test results in patients with resistant hypothyroidism

Anis Grassa, Ibtissem Oueslati, Elyes Kamoun, Meriem Yazidi & Melika Chihaoui
La Rabta University hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Hypothyroidism is a very common condition, and its treatment is relatively easy with levothyroxine (LT4). However, cases of resistant hypothyroidism were reported despite high doses of levothyroxine. The aim of this study was to evaluate the usefulness of the levothyroxine absorption test to confirm or exclude a disorder of thyroid hormone absorption.
Methods
This was a retrospective study including patients who were admitted to our department between January 2018 and December 2021 for resistant hypothyroidism under high-dose of levothyroxine ($\geq$ 2.7µg/kg/day). Levothyroxine absorption test was performed on all patients. The percentage of levothyroxine absorption was calculated using the following formula: % LT4 absorption = [(peak ΔT4 $\times$ volume distribution) / administered dose of LT4 (µg)] $\times$ 100 (Volume distribution (dL)=4.42 $\times$ body mass index). Normal absorption was defied by a % LT4 absorption > 60 %.
Results
Seven patients (5 women and 2 men) were enrolled in this study. Their mean age was of 39 $\pm$ 11.3 years [27-62]. Their mean body weight was 85.4 kg [72-98] with a mean body mass index of 30.3 kg/m^2 [25.4-36]. The average duration of hypothyroidism was 10 years [2-20]. The mean dose of levothyroxine was 5.3 µg/kg/day. At baseline (T0), the mean TSH level was 278.8 mIU/l (nr: 0.35- 4.95) and the mean FT4 level was 0.59 ng/dl (nr: 0.7-1.5). During the levothyroxine absorption test, the mean peak of FT4 was 0.80 ng/dl. The average % LT4 absorption was 4.5%. It was < 60% in all patients consistent with the diagnosis of malabsorption. Etiological investigations showed negative celiac disease serology for all patients and a helicobacter pylori gastritis in six patients.
Conclusion
Our results illustrate the interest of the levothyroxine absorption test to confirm the diagnosis of malabsorption and avoid diagnosing wrongly a pseudo-malabsorption.

Risk factors for acute kidney injury in patiens with severe hypothyroidism

Adnan Batman[1], M. Masum Canat[2], Emre Sedar Saygili[3], Ender Besler[4], Duygu Yildiz[5], Feyza Yener Ozturk[2] & Yuksel Altuntas[2]
[1]Koc University, Endocrinology and Metabolism, Istanbul, Turkey; [2]University of Health Sciences Turkey, Sisli Etfal Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [3]Canakkale 18 Mart University, Endocrinology and Metabolism, Istanbul, Turkey; [4]University of Health Sciences Turkey, Sisli Etfal Training and Research Hospital, Department of Internal Medicine, Istanbul, Turkey; [5]Siirt Training and Research Hospital, Endocrinology and Metabolism, Siirt, Turkey

Objective
This study aims to investigate the factors affecting development of acute kidney injury (AKI) due to severe hypothyroidism.
Methods
This retrospective observational study involved patients with primary hypothyroidism and thyroid stimulating hormone (TSH) levels of more than 50 mIU/l at their review in the endocrinology outpatient clinic, between January 2015 and April 2021. Factors affecting the development of AKI were examined by logistic regression analysis.
Results
A total of 100 patients, 20 (11 male (M), 9 female (F)) in the AKI (case) group and 80 (23 M, 57 F) patients in control group, were included in our study. The median age of the case group (56 years, interquartile range (IQR) 44.3−68.5) was significantly higher than the control group (49 years, IQR 32.3−60; $P=0.027$), and the ratio of males to females was significantly higher in the case group ($P=0.001$). Multivariate logistic regression analyses showed that hypothyroidism diagnosed after the age of 60 years (odds ratio (OR) 59.674, 95% confidence intervals (CI) 5.955−598.031; $P=0.001$), free triiodothyronine (FT3) $<$ 1.3 pg/ml (OR 17.151, 95% CI 2.491−118.089; $P=0.004$) and creatine kinase (CK) $>$ 1000 U/l (OR 1.522, 95% CI 1.602−82.848; $P=0.015$) were predictors for the development of AKI due to severe hypothyroidism (Table 1).
Conclusion
We recommend close follow-up and monitoring of patients with AKI caused by severe hypothyroidism if aged $>$ 60 years, CK $>$ 1000 U/l or FT3 $<$ 1.3 pg/ml.

Assessment of the Quality of life in patients with well-controlled primary hypothyroidism: is there a relationship between quality of life and the TSH level?

Chayma Belhadj Slimane, Ibtissem Oueslati, Amani Terzi, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Poorly controlled hypothyroidism is a chronic disease frequently associated with an impaired quality of life (QoL). However, persistent symptoms may be observed in well-controlled hypothyroid patients, impacting their QoL. The aim of our study was to assess the QoL in patients with well-controlled primary hypothyroidism and to evaluate the relationship between the TSH level and the QoL.
Methods
A cross-sectional study was conducted in the outpatient clinic of our department in December 2021. Patients with well-controlled primary hypothyroidism (TSH level between 0.35-4.94 mIU/l), and aged less than 65 years were enrolled in this study. Clinical and paraclinical data were collected from medical records. QoL was assessed using the SF36 questionnaire.
Results
Seventy patients (65 women and 5 men) were enrolled in this study. Their mean age was of 51.2 ± 9.6 years. The mean duration of hypothyroidism was of 8.4 ± 6.7 years. Primary hypothyroidism was secondary to Hashimoto's thyroiditis, thyroidectomy, and radioactive iodine therapy in 58%, 23%, and 14% of cases, respectively. The average dose of levothyroxine was of 97.32µg/day (25-225). Mental health score ($r=$-0.24, $P=0.045$) and social role functioning score ($r=$-0.257, $P=0.032$) were negatively correlated with the TSH level. The QoL was good in 52% of patients and moderate to poor in 48% of patients. The mean TSH level was significantly lower in patients with good QoL than in those with moderate to poor QoL ($P=0.024$). On the other hand, role limitation due to emotional problems score and the SF36 total score were significantly higher in patients with TSH level $<$ 2.5 mIU/l than in those with a TSH level $\geq$2.5 mIU/l. A TSH level $<$ 2.5 mIU/l was significantly associated with a better QoL (Odds Ratio=2.83, $P=0.035$, 95% CI: 1.06-7.58).
Conclusion
In patients with well-controlled primary hypothyroidism, mental health and social role functioning scores were negatively correlated with TSH level. A TSH level $<$ 2.5 mIU/l was positively associated with a better QoL. However, many other factors may impact the QoL of patients with hypothyroidism. Therefore, further studies involving larger sample sizes would be useful to confirm our findings.

Diagnosis of subacute thyroiditis (SAT) in 2021, during COVID-19 vaccination: observation in a single private secondary endocrine centre in the Savona district, Liguria, Italy

Massimo Giusti & Marilena Sidoti
Endocrine Unit, Priamar Clinical and Diagnostic Centre, Savona, Italy

SAT due to viral infections is a cause of thyrotoxicosis, neck pain and tenderness on palpation. In the COVID-19 era, SAT seems to be a manifestation of the disease which occurs during SARS-CoV-2 infection. In 2021, some SAT cases were reported after COVID-19 vaccination. We reviewed the incidence of SAT from 2000 to 2021. In the Savona district vaccination of the general population started in February 2021 and progressively involved fragile, healthy elderly, adult and young-adult subjects. By the end of 2021, about 80% of adults in the Savona district had received at least two doses of COVID-19 vaccines. Electronic records from June to December in each year from 2000 to 2020 were searched. From 8115 medical files, 51 diagnoses of SAT were retrieved (35 females). In the corresponding period in 2021, SAT was diagnosed in 7 females after COVID-19 vaccination. From 2020 to 2021, 0.6% of patients in our centre had SAT and SAT occurred at the median age of 45 years (IQR 38-52) with an incidence of 2 cases/year (1-3). The long-term evolution of the disease was known in

Table 1 Univariate and multivariate binary logistic regression analysis

	Univariate binary logistic regression				Multivariate binary logistic regression			
		95% CI				95% CI

CK $>$ 1000 U/l	0.246	0.082	0.739	0.012*	11.522	1.602	82.848	0.015*
FT3 $<$ 1.3 pg/ml	0.080	0.019	0.345	0.001*	17.151	2.491	118.089	0.004*
FT4 $<$ 0.2 ng/dl	0.241	0.083	0.700	0.009*				
Statin use	0.120	0.026	0.557	0.007*				

*OR: odds ratio; CI: confidence interval; DM: diabetes mellitus; HT: hypertension; CK: creatine kinase; FT4: free thyroxine; FT3: free triiodothyronine. *Statistically significant ($P<$ 0.05).*

25 cases and full thyroid recovery or chronic thyroiditis/hypothyroidism were observed in 72% and 28% of cases, respectively. From June to December 2021, the percentage of SAT in files was 1.5%. SAT diagnoses increased ($P=0.03$) in 2021 in comparison with the 2000-2020 period. The median age of SAT patients in 2021 (54 years; 50-61) was higher ($P=0.05$) than in the 2000-2020 period. To date, 6 women have been followed up for 2-4 months. In 2 women, a decrease in thyroid volume was noted, while in 4, TSH was suppressed or increased; in the remaining 2, L-T4 was ongoing. Pain, palpitation, fatigue and sweating disappeared after prednisone/NSAIDs discontinuation. To date, 19 cases (91% females; median age 40 years) of SAT after COVID-19 vaccinations have been described in the literature, with sub-clinical, normal or increased thyroid function in about 29%, 53% and 12% of cases, respectively, during follow-up. Our findings and the literature data indicate that SAT after COVID-19 vaccination is more frequent in females and at greater age than that occurs in other virus-related SAT cases. In our experience, thyroid function remains undefined after 2-4 months. Our observation of a local increase in SAT during the 2021 COVID-19 vaccination campaign indicates that physicians should be aware of this infrequent side effect, which must be considered and monitored after COVID-19 vaccination.

Comparison in lipid parameters before and after L-thyroxine treatment in subclinical hypothyroidism according to the presence of thyroid peroxidase antibodies

Valentina Velkoska Nakova[1], Brankica Krstevska[2], Katerina Cheshlaroska Markushoska[3], Sasha Jovanovska Mishevska[4] & Tatjana Milenkovic[4]
[1]Clinical Hospital, Faculty of Medical Science, University Goce Delcev, Internal Medicine, Stip, Macedonia; [2] Internal Medical Center "Srce", Skopje, Macedonia; [3] General Hospital "Borka Taleski", Internal Medicine, Prilep, Macedonia; [4] University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia

Objective
Subclinical hypothyroidism (ScH) is a common condition and may be associated with dyslipidemia. We investigated the effect of levothyroxine therapy (L-T4) on lipid parameters in patients with a mild form of subclinical hypothyroidism according to the presence of thyroid peroxidase antibodies (anti-TPO antibodies).
Material and methods
Fifty-seven patients with newly diagnosed ScH (TSH levels between upper reference value and 10 mIU/l with normal FT4 and FT3 values) with indications for L-T4 therapy were included in the study. Lipid parameters and presence of anti-TPO antibodies were evaluated at the moment of diagnosis and after 6 months euthyroid stage.
Results
Average value of TSH was 8.1 $\pm$1.9 mIU/l. Thyroid substitution therapy significantly decreased total cholesterol and LDL-C, and increased HDL-C (5.6$\pm$ 0.9 vs. 5.3$\pm$1.1; 3.4$\pm$1.0 vs. 3.2$\pm$1.1; 1.5$\pm$0.5 vs. 1.6$\pm$0.5 mmol/l, $P<0.05$ respectively). Statistically significant decrease in total cholesterol, total cholesterol/HDL-C, and, LDL-C/HDL-C were observed in patients with positive anti-TPO antibodies after 6 months euthyroid state (5.5$\pm$1.1 vs 5.3$\pm$ 0.9 mmol/l; 3.9$\pm$1.5 vs. 3.5$\pm$1.0; 2.5$\pm$1.2 vs. 2.2$\pm$0.8, $P<0.5$ respectively). There was not statistically significant differences in lipid profile in patients with negative anti-TPO antibodies before and after L-T4 treatment.
Conclusion
The effect of the thyroid substitution therapy on lipid parameters was more pronounced in patients with mild ScH and positive thyroid antibodies. Patients with mild ScH and positive anti-TPO antibodies may benefit of L-T4 treatment even in the lower TSH values.
Key words: subclinical hypothyroidism, thyroid peroxidase antibodies, levothyroxine therapy

HDAC inhibition as a therapy approach in autoimmune thyroid disease

Pablo Sacristán-Gómez[1], Ana Serrano-Somavilla[2], Miguel Sampedro-Nuñez[3], Monica Marazuela[3] & Rebeca Martínez-Hernández[2]
[1]IIS Princesa, Endocrinology, Madrid, Spain; [2] IIS Princesa, Universidad Autónoma de Madrid, Endocrinology, Madrid, Spain; [3] Hospital Universitario la Princesa, IIS Princesa, UAM, Endocrinology, Madrid, Spain

Introduction
Autoimmune Thyroid Diseases (AITD) are one of the most prevalent autoimmune diseases in industrialized countries (5% of population). The two main phenotypes of AITD, Hashimoto thyroiditis (HT) and Graves' disease (GD), are both characterized by the presence of circulating thyroid antibodies and infiltration by autoreactive lymphocytes in the thyroid gland and sometimes the orbit. One of the most studied mechanisms underlying AITD is the imbalance between immune activation and immune homeostasis of CD4+CD25- cells or T effector cells (Teff) and CD4+CD25+FOXP3+ regulatory T cells (Treg). Histone deacetylases (HDACs) are enzymes that exert postranslational modifications at protein level. HDAC9 interacts with FOXP3, the master regulator of Tregs, leading to an imbalance in Treg function. We have recently reported an increase expression of HDAC9 in Treg cells from AITD patients.
Objective
To investigate the in vitro effects of HDAC inhibitors (trichostatin A (TsA) a pan-inhibitor, TMP-269 a class IIa inhibitor and the FDA approved pan-inhibitor, suberanilohydroxamic acid (SAHA/Vorinostat)) on human freshly isolated CD4+CD25- T effector cells from AITD patients.
Methods
Toxicity assays were evaluated using LIVE/DEAD Viability-Cytotoxicity Kit on T cell proliferation by each inhibitor. Treg suppression assays were carried out in healthy controls and AITD patients. CD4+CD25+ Tregs were isolated from fresh PBMC using CD4+CD25+ Regulatory T Cell Isolation Kit (Miltenyi Biotec). To evaluate proliferation Teff cells were CFSE-labeled, and added to wells in serial dilutions giving Treg/Teff ratios of 0:1, 1:1, 1:2; 1:4 and 1:8 and in the presence or absence of differing concentrations of HDACi and using DMSO as control.
Results
Toxicity assays revealed us that TMP269 and SAHA demonstrate the same number and viability as control cells. On the contrary, TsA decreased significantly the viability at the minimal concentration used, discarding this inhibitor from our assays. Suppression assays using the TMP269 inhibitor did not showed significantly effects on the proliferation of CD25- T cells. However, SAHA caused a mild to moderate impairment of CD25- division.
Conclusions
Among all the inhibitors assessed, SAHA did not exert a toxic effect in cells and had a significantly decrease on Teff proliferation compared to TMP269. Our study also showed that the impaired proliferation of CD4+CD25-Teff cells by SAHA, was not only by a specific Treg mediated effect, but also by the decrease in the CD4+CD25- cell division rate. These findings suggest that HDAC inhibition by SAHA may serve as a possible treatment of inflammation in AITD.

Thyrotoxicosis-associated anemia at baseline and after methimazole treatment

Laura Naglabeala[1], Dan Alexandru Niculescu[1,2], Anda Vladescu[3] & Catalina Poiana[1,2]
[1]C. I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2] Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [3] C. I. Parhon National Institute of Endocrinology, Hematology, Bucharest, Romania

Background
Overt newly diagnosed hyperthyroidism is frequently associated with mild anemia. However, there are limited data on long term evolution under methimazole treatment. Our aim was to study the baseline characteristics and evolution of anemia in the hyperthyroidism setting.
Methods
We retrospectively assessed 58 consecutive patients [46 (79.3%) women] presenting with newly diagnosed overt thyrotoxicosis (43 Graves disease, 9 toxic nodular goiters, 4 toxic adenomas and 2 drug induced hyperthyroidism) in our practice. Of these, 30 were reassessed after 4-6 months of methimazole treatment. No patient had treatment for anemia. We measured thyroid-stimulating hormone, free thyroxine, hemoglobin (Hb), hematocrit, red blood cells, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration at both baseline and 4-6 months assessments. Anemia was defined by a Hb value <12 g/dl in women and <14 g/dl in men.
Results
At baseline, 19 patients (32.76%) had normochromic normocytic anemia, of whom 14 (73.63%) were women. Mean Hb was 11.5$\pm$0.25 g/dl and 12.4$\pm$0.97

g/dl in women and men respectively. FreeT4 (39.53±20.2 pmol/l) inversely correlated with Hb in women ($r=0.45$, $P=0.05$), but not in men. All patients (25 women, 5 men) that were assessed after 4-6 months of methimazole treatment had normal Hb levels (including 7 women and 1 man with anemia at baseline).
Conclusion
Our study demonstrated that hyperthyroidism is frequently associated with mild normochromic normocytic anemia. 4-6 months of methimazole treatment leads to resolution of anemia.

When patients with DTC can be discharged to primary care

Nicolas Amich, Estefanía Chumbiauca & Juan Carlos Galofré
University of Navarra, Endocrinology, Pamplona, Spain

Purpose
To evaluate if patients with low- or intermediate-risk differentiated thyroid cancer (DTC) can be discharged to primary care.
Material and Methods
The clinical records and evolution of 346 patients with DTC who had undergone surgery between 1995 and 2020 with a follow-up after a mean of 7.6 ± 6.1 years were retrospectively reviewed. All had a low or intermediate risk of recurrence as defined under the 2015 ATA risk stratification system and a minimum follow-up of one year. Biochemical (thyroglobulin) and structural (imaging findings) yearly evaluations were used to dynamically classify patients based on their response to treatment as *excellent*, *indeterminate*, *biochemically incomplete* or *structurally incomplete*. Primary outcome was the assessment of disease recurrence (biochemical or structural) as defined under the 2015 ATA guidelines.
Results
Throughout follow-up, 14.7% ($n=51$) patients presented disease recurrence. When classified by initial risk of recurrence (low or intermediate) it was seen that 4.53% (11/243) of low-risk patients and 39.81% (41/103) of intermediate-risk patients presented recurrence. This difference was statistically significant ($P<0.0001$) with no statistically significant difference in follow-up times between the two groups ($P=0.34$). Moreover, when examined in terms of response to treatment, it was seen that only 1% (2/193) of low-risk patients with an excellent response to treatment presented recurrence. The majority of patients presented disease recurrence in the first five years of follow-up, 98% (50/51), the mean time to recurrence being 9.38 ± 18.68 months.
Conclusions
Low- and intermediate-risk DTC patients exhibiting an excellent response to treatment have a minimal recurrence risk that could offer the possibility of discharge to primary care follow-up after a five-, or a more cautious ten-year, follow-up period. The 2015 ATA risk stratification system proves to be an accurate and useful tool for the prediction of recurrence both postoperatively as well as at specific points during follow-up.

An innovative synthetic support for cytological and immunocytochemical assessment in cytologically indeterminate thyroid nodules. Feasibility study

Silvia Taccogna[1], Roberto Novizio[2], Martina D'angelo[1], Luca Turrini[1], Agnese Persichetti[3], Alfredo Pontecorvi[2], Enrico Papini[4] & Rinaldo Guglielmi[4]
[1]Regina Apostolorum Hospital, Pathology, Albano Laziale, Italy; [2] Fondazione Universitaria Policlinico A. Gemelli, Catholic University of the Sacred Heart, Endocrinology and Metabolism, Rome, Italy; [3] IRCCS-Regina Elena National Cancer Institute, Service of Pharmacovigilance, Rome, Italy; [4] Regina Apostolorum Hospital, Endocrinology and Metabolism, Albano Laziale, Italy

Background
Fine needle aspiration (FNA) is the diagnostic procedure of choice in the evaluation of thyroid nodules. Nodules with indeterminate cytological categories, Tir3A and Tir3B according to Italian cytological classification, pose diagnostic challenges in clinical practice and are frequently submitted to diagnostic surgery. CytoFoam Core (CF) (Diapath, Martinengo, Italy) uses an absorbent foam device inserted into the needle hub to collect the cytological sample aspirated during FNA. The specimen is formalin-fixed and paraffin-embedded similarly to the microhistological material obtained with core-needle biopsy.
Aim of the study
To assess diagnostic efficacy of CytoFoam core, compared to traditional cytology, in re-evaluating thyroid nodules classified as Tir3A. Post-surgical histology was used as reference standard.
Method
Retrospective study on 89 patients with a first indeterminate cytological report who were referred to the Department of Endocrinology of Regina Apostolorum Hospital (Albano L. Rome, Italy) for a second FNA. FNA was performed after at least one month under ultrasound guidance with a 23G needle according to the established procedure. During the second procedure, both traditional cytological (TC) smears and a single-pass CF specimen were obtained for each patient. On CF samples immunocytochemical staining for Galectin-3, HBME-1, and CK-19 was also performed. Forty-five patients eventually underwent surgery, and their histological diagnoses were compared to the TC and CF reports. Four parameters were blindly and independently compared by two cytopathologists with specific thyroid expertise: inadequacy rate, rate of persistent indeterminate (Tir3A and Tir3B) reports, rate of malignancy in persistently indeterminate nodules, and rate of cancer in lesions cytologically classified as malignant.
Results
Non-diagnostic samples were 8/45 (17.7%) in TC vs 5/45 (11.1%) in CF samples ($P=0.4$). Persistent indeterminate samples were 27/45 (60%) in TC vs 16/45 (35.5%) in CF samples ($P<0.005$). The rate of malignancy in persistently indeterminate nodules was 8/16 (50%) in CF group vs 9/27 (33.3%) in TC group ($P=0.4$). Five/45 (11.0%) samples were classified as benign by TC vs 16/45 (35.0%) samples by CF ($P<0.005$). All these nodules resulted benign at post-surgical evaluation. Five/45 (11.0%) samples were classified as suspicious for malignancy/malignant in TC group against 8/45 (18.0%) samples in CF ($P=0.4$). Post-surgical evaluation confirmed malignancy in all these cases.
Conclsion
CytoFoam core demonstrated greater diagnostic accuracy than TC in repeat FNA assessment of cytologically indeterminate nodules. CF increased the conclusive diagnosis rate and decreased the number of cytologically indeterminate cases. A large prospective study is needed to confirm this pilot study results.

Development of a new ultrasound score to predict thyroid nodule malignancy

Ibtissem Oueslati[1], Hiba-Allah Chatti[1], Aymen Azaiez[2], Jihene Marrakchi[2], Seif Boukriba[3], Slim Haouet[4], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2] La Rabta University Hospital, Department of Oto-Rhino-Laryngology, Tunis, Tunisia; [3] La Rabta University Hospital, Department of Radiology, Tunis, Tunisia; [4] La Rabta University Hospital, Department of Pathology, Tunis, Tunisia

Introduction
Thyroid cancer remains a relatively rare entity. Radiological scoring systems aim to stratify the risk of malignancy based on morphological criteria.The objective of this study was to develop a new score based on ultrasound criteria to predict thyroid nodule malignancy risk.
Patients and methods
This was a retrospective study including 200 thyroid nodules (100 malignant nodules and 100 benign nodules). The report of the thyroid ultrasound and the result of the final histological examination were collected for each nodule. Odds ratios (OR) of ultrasound criteria were calculated. The new score represents the sum of the ORs of the ultrasound criteria for each nodule.
Results
Ultrasound criteria associated with nodule malignancy risk were: solid composition (OR=7.81; $P<10-3$), very hypoechoic character (OR=12.49; $P<10-3$), moderately hypoechoic character (OR=6.2: $P<10-3$), irregular contours (OR=7.47; $P<10-3$), taller-than-wide shape (OR=3.58;$P=0.02$), microcalcifications (OR=3.02;$P=0.006$) and the presence of cervical lymph nodes (OR=5.5; $P<10-3$). The mean ultrasound score was 16.7 ± 7.5 for malignant nodules vs 5.65 ± 6.5 for benign nodules ($P<10-3$). A score ≥ 10

was significantly associated with malignancy (OR = 17.9; $P < 10\text{-}3$). The threshold of 10 had a sensitivity of 85% and a specificity of 76%. A score $\geq$ 25 was predictive of malignancy in 100% of cases. The area under the ROC curve was 0.85 for this new score, 0.81 for the EU-TIRADS classification, and 0.82 for the ACR-TIRADS classification.

Conclusion

Our new ultrasound score seems to be effective in predicting thyroid nodule malignancy risk. However, it needs to be validated by prospective multicenter studies.

Congestive heart failure as a first-time presentation of thyrotoxicosis in COVID-19 positive patient

Ellen McKay[1,2], Kalthoom Elhilo Mousa[1], Muhammad Abrar Ul Haq[1,3], Karen Kelly[4], Mohamad Shafi Rummun[4], Sean Fleming[4] & Ma Pyeh Kyithar[1]

[1]Midland Regional Hospital Portlaoise, Diabetes & Endocrinology, Ireland; [2] University College Dublin Intern Network, Ireland; [3] The College of Physicians and Surgeons Pakistan, Pakistan; [4] Midland Regional Hospital Portlaoise, Cardiology, Ireland

Background

The clinical manifestations of thyrotoxicosis do not always correlate with the extent of thyroid biochemical abnormalities. Here, we report the case of a COVID-19 positive patient who presented with congestive heart failure as a first-time presentation of thyrotoxicosis.

Case report

A 40-year-old female presented to Emergency Department with two days history of lower limb oedema and abdominal distension. She denied dyspnoea, chest pain, palpitations, weight loss or heat intolerance. She had history of cervical cancer 3 years prior, treated with oophorectomy and hysterectomy and 10 pack-year smoking. On clinical examination, diffusedly enlarged thyroid gland, irregularly irregular pulse and signs of congestive cardiac failure (raised JVP, gallop rhythm, reduced air entry in lower zones of the lungs, pitting oedema up to hips bilaterally) were observed. ECG showed atrial fibrillation with atrial flutter; chest X-ray showed bilateral moderate pleural effusion. Laboratory work-up revealed deranged liver biochemistry (bilirubin 38 umol/l, ALT 13 U/l, GGT 120 U/l, alkaline phosphatase 339 U/l), normal troponin, elevated d-dimer (1340 ng/ml), markedly elevated pro-BNP (7421 pg/ml), markedly elevated free T4 73 pmol/l (range 8.3-19 pmol/l), free T3 27 pmol/l (range 3.8-6 pmol/l) and suppressed TSH $<$0.01 mIU/l (range 0.38-5.33 mIU/l). She had positive SARS-CoV-2 PCR on surveillance testing but no symptoms of COVID-19 infection. Transthoracic echocardiogram demonstrated left ventricular dysfunction (ejection fraction 35%), impaired right ventricular systolic function, dilated left and right atria. CT pulmonary angiogram/abdomen/pelvis showed no evidence of pulmonary embolism but demonstrated moderate to large bilateral pleural effusion with extensive free intra-abdominal fluid, an enlarged thyroid gland and heterogeneous liver parenchymal enhancement. She was treated with IV metoprolol, IV furosemide and anticoagulation on admission, later commenced on oral carbimazole 20 mg bd, propranolol and IV furosemide infusion (180 mg/24hr) for further diuresis. Heart failure medications were adjusted as per cardiology team. Metolazone, spironolactone, bumetanide, ramipril and dapagliflozin were commenced. TPO and anti-TSH receptor antibodies returned positive, consistent with Graves' hyperthyroidism. She was discharged home 8 days after admission with close follow-ups with Endocrinology and Cardiology teams. Upon discharge, she was euvolaemic (14 kg weight loss) with improved thyroid function (free T4 34.6 pmol/l, free T3 9.9 pmol/l, TSH 0.01 mIU/l) and pro-BNP (2176 pg/ml).

Discussion

Our case highlights that thyrotoxicosis can present with congestive cardiac failure without classical symptoms of hyperthyroidism. Thyrotoxicosis should be considered in cases with a new presentation of heart failure. There is evidence that COVID-19 may be associated with high risk of thyrotoxicosis. It remains unclear if COVID-19 infection was coincidental or precipitated thyrotoxicosis with heart failure in our case.

Levothyroxine Replacement Therapy overuse. Factors suggesting treatment discontinuation

Sarantis Livadas[1], Christina Bothou[2], Rodis Paparodis[3], Ioannis Androulakis[1], Nicholas Angelopoulos[1], Anastasios Boniakos[1], Panagiotis Anagnostis[4] & Leonidas Duntas[5]

[1]Athens Medical Centre, Athens, Greece; [2] University Hospital of Zurich, Department of Endocrinology, Diabetology and Clinical Nutrition, Zürich, Switzerland; [3] Center for Diabetes and Endocrine Research, University of Toledo College of Medicine, Toledo, United States; [4] Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [5]Evgenidion Hospital, Endocrine Unit, Athens, Greece

Background

Levothyroxine (LT4-Rx) is one of the most prescribed drugs worldwide and the vast majority of patients receive long-term treatment. However, in a recent study of 291 subjects we found that 60% of this cohort were euthyroid two months after LT4-Rx discontinuation[1].

Aim of the study

A prospective clinical cohort follow-up study was carried out. In 688 subjects (82% females) aged 48.01 $\pm$ 15.96 (range 17-84years) with 8.59 $\pm$ 6.98 years on LT4Rx without a solid diagnosis of hypothyroidism, the treatment was abruptly interrupted. The treatment indications and corresponding percentage for LT4-Rx were classified as nodule(s) (33%), indefinite (27%), post-partum (7%) and Hashimoto's (33%). Follow up for a short period of time occurred in 54% of subjects ($\leq$ 4 months, Group A) and long-term follow-up was achieved in the remaining (up to 60 months, Group B). The studied subjects were evaluated at the time LT4-Rx was discontinued, 2-4 months later and at the end of follow-up. At each time point, estimation of TSH, FT4 levels and thyroid ultrasound was performed. A TSH value of $\geq$4.5 IU/ml was considered as underlying hypothyroidism.

Results

Among the entire cohort, $n = 158$ subjects became hypothyroid, while the remaining $n = 530$ remained euthyroid off LT4-Rx (23 vs. 77%, $P < 0.001$). On subgroup analysis, 40% of subjects comprising Group A became hypothyroid, whereas the corresponding value for Group B was 3%. In Group A, the reason for LT4-Rx, LT4 dose, LT4 dose/BMI, TSH levels and the existence of thyroid autoantibodies (ATA) were significantly different in those who became hypothyroid. No difference among any parameter evaluated was disclosed in Group B. Subjects with diagnosis of Hashimoto's, positive ATA, higher TSH values and higher LT4 dose had significantly higher probability to became hypothyroid. Furthermore, in Group A, 15.4% became hypothyroid with baseline TSH $>$ 3 IU/ml vs. 5.4% with baseline TSH $<$ 3 IU/ml ($P < 0.001$); the corresponding values for Group B were 44.4% vs. 10.0%, ($P < 0.001$), respectively.

Conclusions

These findings suggest considerable overuse of thyroxine administration. In cases of uncertainty, the existence of nodules, a low-normal TSH value, a relative small T4 dose and the absence of ATA are strong indicators of euthyroid patients on LT4Rx and accordingly treatment discontinuation is strongly advised. Furthermore, in the case that a subject does not became hypothyroid 2-4 months post treatment discontinuation, then the likelihood to develop hypothyroidism long term is insignificant.

A case of severe hypothyroidism causing reversible chronic kidney disease

Veshalee Vernugopan[1] & Nida Chammas[2]

[1]School of Medicine, University of Glasgow, United Kingdom; [2] Cromwell Hospital, United Kingdom

Introduction

Despite hypothyroidism being seen in patients with kidney disease, it is rarely the underlying cause. We present a rare case of chronic kidney disease (CKD) secondary to severe hypothyroidism that was totally reversed on commencement of Levothyroxine. The mechanism is multifactorial, and importantly involves the pre-renal and direct renal effects of thyroid hormones.

Case report

A 37-year-old Caucasian male presented to the endocrine clinic in March 2020 after a GP friend mentioned that he did not look well. The patient did not feel unwell himself, however on direct questioning complained of cold intolerance, fatigue, puffy eyelids, and weight gain over the preceding years. Most notable to the patient was hair loss on the body and scalp which had left him bald. The

patient's history was only significant for gout. Blood tests showed TSH 548.7 (0.27-4.2) and Free T4 undetectable <4 (12-22). The thyroid antibodies were within normal range. He was 89.95 kg with a BMI in the obesity range (31.12). Additionally, the patient had asymptomatic CKD seen by metabolic abnormalities in the blood test: normocytic anaemia with haemoglobin 87 (130-175), urea 9.3 (2.1-8.5), creatinine 150 (65-119) and GFR 46 (>90). On examination, he had puffy eyelids, but no evidence of goitre. Systemic cardiovascular, respiratory, and abdominal examinations were unremarkable. A thyroid ultrasound showed a small thyroid gland with benign changes suggestive of chronic thyroiditis. He was diagnosed with primary hypothyroidism and commenced on 150μg Levothyroxine once daily. Within two months of starting Levothyroxine, kidney function improved to a GFR of 88. At present, patient is taking 100μg of Levothyroxine once a day, with normal thyroid function tests and normal kidney function. The patient has marked regrowth of scalp hair and has had a significant weight loss of 15.75 kg.

Conclsion

Despite being commonly encountered and well understood individually, hypothyroidism is an underappreciated reversible cause of renal impairment and the interaction between thyroid hormones and the kidneys are rarely remembered. Patients can be asymptomatic even with severe hypothyroidism and CKD; the treatment is sufficient replacement with Levothyroxine which can show profound kidney improvement — as with our patient this can happen within only two months. Hence, clinicians should ensure that renal function tests be performed on initial diagnosis of hypothyroidism to ensure that this reversible complication can be adequately managed with Levothyroxine.

Subacute thyroiditis following mRNA anti-SARS-CoV-2 vaccination in a patient with solitary kidney- a case report

Dimitrios Askitis
Private Practice for Endocrinology, Alexandroupolis, Greece

Introduction

Massive anti-SARS-CoV-2 vaccination campaigns have been established as the cornerstone of confronting the current COVID-19 pandemic. Subacute thyroiditis (SAT) comprises an inflammatory process in the thyroid gland, mostly due to viral infections of the upper respiratory tract, although it may rarely occur after vaccine administration. To date, a few cases of SAT related to anti-SARS-CoV-2 vaccines have been reported globally. Hereby, we present the case of a patient with solitary kidney who developed SAT, mild thyroid autoimmunity activation and subsequent permanent hypothyroidism after mRNA-based anti-COVID-19 vaccination.

Case report

A 79-year old male patient with solitary kidney due to nephrectomy after drug-induced acute renal failure presented for evaluation in terms of newly detected subclinical hyperthyroidism and neck pain starting 20 days ago. The patient had a known history of mild subclinical hypothyroidism diagnosed 2 years ago without laboratory-confirmed autoimmune etiology (negative thyroid-related autoantibodies) and without levothyroxine supplementation. Neck pain and tenderness as well as low grade fever with intermittent episodes of hypothermia had an onset 10 days after the first dose of the mRNA vaccine Comirnaty and continued after administration of the second dose 2 weeks before the patient's visit. The neck ultrasound revealed a pattern typical of subacute thyroiditis with bilateral volume growth and diffuse hetero-echogenicity and inhomogeneity accompanied by reduced blood flow; the adjunctive laboratory evaluation showed elevation of the inflammatory markers (CRP, ESR) with first documentation of slightly elevated TPO-autoantibodies. As the patient reported remission of his symptoms no anti-inflammatory medication was initiated. One month later the patient reported no SAT-related symptoms but the laboratory evaluation revealed overt hypothyroidism. He was started on levothyroxine 88 μg daily and remained euthyroid under supplementation. Neck ultrasound 4 months after the first visit showed a remission of the inflammatory process with reduction of both the thyroid volume and the hypoechoic inflammatory zones.

Conclusion

The above case presentation comprises the first official report of subacute thyroiditis in adjunction with mRNA COVID-19 vaccination in northern Greece. SAT is a self-limiting process and is rarely reported as a mild complication of the anti-SARS-Cov-2 vaccination with only few documented cases related to all types of available vaccines. Therefore, clinicians should be aware of this rare post-vaccination adverse event. Despite the development of permanent hypothyroidism in the present case the definitive benefits of the anti-COVID-19 vaccination outweigh the rare and mostly mild and transient side-effects which shall not comprise an inhibitory factor against vaccination.

Long term prognosis of severe tricuspide regurgitation induced by hypothroidism

Ikram Chamtouri, Asma Ben Abdallah & Faouzi Maatouk
Hôpital Fattouma Bourguiba, Cardiology B, Monastir, Tunisia

Background

Hypothyroidism is associated with multiple heart diseases such as tricuspid regurgitation (TR). We aimed to investigate in the prognosis of TR induced by hypothyroidism.

Methods

We conducted a cohort study included all patients with severe primary TR. Long term prognosis of TR induced by hypothyroidism was compared to the prognosis of other severe primary TR causes.

Results

Among 43 patients with severe primary TR, 19 patients presented hypothroism considered as the only cause of severe TR. Thirteen females patients had hypothyroidism. Hypothyroidism was associated with significantly higher renal failure with no difference in hypertension, diabetes and atrial fibrillation or flutter. At two-years evluation, there were a sgnificantly higher prevalence rehospitalization and mortality a in patients with hypothyroidisme despite the treatment of hypothroidism.

Conclusion

Despite adequat hypothroidism treatment, severe TR induced by hypothyroidism had a long term poor prognosis.

Thyrotoxic periodic paralysis: a case report

Abdul Aziz, Dania Ali & Sarah Nadeem
The Aga Khan University Hospital (AKUH), Karachi, Pakistan

A rare complication of thyrotoxicosis among Asians is Thyrotoxic Periodic Paralysis (TPP), with an incidence of approximately 2% in patients with thyrotoxicosis from any cause. TPP is characterized by sudden onset of hypokalemia and muscle paralysis. Hypokalemia in TPP results from an intracellular shift of potassium induced by the thyroid hormone sensitization of Na^+/K^+ −ATPase rather than depletion of total body potassium. Treatment of TPP includes correcting the underlying hyperthyroid state, prevention of potassium shift by using non-selective beta-blockade, and replacing potassium. TPP is curable once a euthyroid state is achieved. We describe here a rare case of TPP in a young Chinese man who presented with sudden bilateral lower limb weakness. A 23-year-old gentleman of Chinese origin, presented to the outpatient department with complain of bilateral lower limb weakness for one day. Motor examination revealed normal bulk and reflexes bilaterally but power was 2/5 in both the lower limbs. His initial electrolytes showed severe hypokalemia of 1.3 mmol/l (Range: 3.5-5.1 mmol/l). Hypokalemia was rapidly corrected with IV potassium. His symptoms subsequently improved and patient was discharged. At discharge his potassium level was 4.1 mmol/l. Follow up was advised but patient was lost to follow up. Three weeks after the initial presentation, patient again presented to the emergency department with complaints of sudden onset of bilateral lower limb weakness. Motor examination of the lower limb revealed decreased tone and power was 1/5 bilaterally. No goiter, lid lag and lid retraction noted. Rest of the systemic examination was unremarkable. Laboratory findings were significant for a potassium of 1.3 mmol/l). Potassium (K) was replaced intravenously (IV) and when rechecked, the potassium level was 5.2 mmol/l. Patient lower limb weakness also improved clinically. Endocrinology was consulted as laboratory workup revealed a suppressed TSH (<0.010 uIU/ml). We advised checking FT3, FT4 and thyroid receptor antibodies (TRAB). FT4 was markedly elevated at 4.24 ng/dl (Range: 0.89-1.76 ng/dl) and TRAB was positive 8.85 IU/l (Range : 0-1.75 IU/l). Endocrine team recommended initiating anti-thyroid medication, Neomarcazole 15 mg two times a day. He was discharged as soon as K levels normalized. Potassium on discharge was 4.9 mmol/l. It is important to consider TPP as a differential in a patient presenting with low

potassium levels and neurological symptoms as management initially with propranolol and of the underlying thyrotoxicosis is essential in definitive treatment of the recurrent periodic paralysis.

A case of the uncommon Marine-Lenhart syndrome

Maria Mathiopoulou[1] & Ivette Engel-Bicik[2]
[1]University Hospital of Zurich, Thyroid Center, Nuclear Medicine, Zurich, Switzerland; [2] University Hospital of Zurich, Nuclear Medicine, Zurich, Switzerland

Background
The combination of a toxic adenoma and Graves' disease compose the Marine-Lenhart syndrome. This condition is estimated to occur in 0.8-2.7% of Graves' disease patients and only few cases are reported in the literature.
Patient findings
A 29-year-old female patient was referred to our outpatient clinic due to subclinical hyperthyroidism and a newly discovered thyroid nodule on the right thyroid lobe. She had no thyreotoxic symptoms and the clinical examination was unremarkable. Her initial blood tests were: TSH 0.01 mU/l (reference 0.16-4.25 mU/l), fT3 8.3 pmol/l, (reference 3.6-6.4 pmol/l), fT4 15.6 pmol/l (reference 12.3-20.2 pmol/l) and TSH-Receptor-Ab titers $<$ 0.30 U/l (reference $<$ 1.75 U/l). The thyroid ultrasound and scintigraphy revealed a toxic adenoma in a right sided goiter. Following a radioiodine ablation with 200 MBq 131-I was performed. follow-up ultrasound after six months revealed a 70% volume reduction of the formerly toxic adenoma of (2.6 ml, pre-therapy 8.7 ml). Two months later at the regular after-therapy follow-up, a manifest hyperthyroidism was revealed [TSH 0.004 mU/l, (reference 0.10-4.00 mU/l), fT3 28.1 pmol/l (reference 3.0-9.5 pmol/l) and fT4 21.4 pmol/l (reference 10.0-28.0 pmol/l)] and the TSH-Receptor-Ab titers were elevated [1.85 U/l (reference $<$ 1.75 U/l)]. The patient was still completely asymptomatic. The thyroid scintigraphy was repeated and showed a symmetrical, elevated radionuclide uptake, leading to the diagnosis of Graves' disease. A thyrostatic therapy with carbimazole was initiated and continued for 8 months, until the thyroid function markers in the blood were normalised.
Conclusion
The existence of both a toxic adenoma and a Graves' disease in the same patient has been termed as Marine-Lenhart syndrome. This coexistence may be observed simultaneously or in different stages, according to the bibliography. In cases where radioiodine treatment of a toxic adenoma is indicated, attention is required, because it may trigger the Graves' disease, as shown in this case. Every new presentation of hyperthyroidism should be investigated as a new pathology, as it may reveal a new underlying condition indicating the need for different therapeutical pathways.

The use of body composition measured by CUN-BAE as a simple tool to predict the LT4 titration after total thyroidectomy in patients with benign and malignant thyroid disease

Ana María Díaz Abram[1], Estefanía Chumbiauca[2] & Juan Carlos Galofré[2]
[1]Facultad de Medicina, Endocrnología, Pamplona, Spain; [2] Clínica Universidad de Navarra, Endocrinología, Pamplona, Spain

Background
Patients who require levothyroxine (LT4) supplementation after total thyroidectomy often have difficulty achieving target TSH levels. Several studies have attempted to develop a dosing schedule considering different factors such as age, gender, weight, or body mass index (BMI) as potential determinants of the correct dose of LT4. The objective of this study is to determine if a scheme that uses the percentage of body fat (%BF) measured by CUN-BAE is more accurate to correctly predict levothyroxine dose requirements.
Methods
Data from 143 patients who underwent total thyroidectomy for benign and malignant disease at our institution between 1993 and 2021 were retrospectively reviewed. Two new dosing formulas, CUN-BAE Model 1 and CUN-BAE Model 2, were designed using Poisson's regression. These dosing models were applied to our cohort and

compared with other dosing schemes proposed in the literature. The accuracy of each model was established by determining the proportion of correct estimates.
Results
CUN-BAE-1 and CUN-BAE-2 accurately estimated 61.5% and 62.9% of LT4 doses, respectively. These results slightly improve the precision of previous methods such as the Poisson regression proposed by Zaborek *et al* based in several factors including BMI (estimated 60.1%) and the weight-based model (estimated 55.9%) of correct doses.
Conclusion
− The use of %BF calculated by the CUN-BAE formula to adjust the dose of LT4 after total thyroidectomy is a simple and accurate method that improves current formulas based on weight or BMI.

Frequency of autoimmune thyroid disease in polycystic ovary syndrome: case-control study

Sawsen Essayeh[1], Radhouan Gharbi[1], Hiba-Allah Chatti[1], Chedi Mhadhbi[1], Sawsen Mnajja[1], Sana Abdelali[2], Hajer Kandara[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technology of Tunis, Endocrinology, Tunis, Tunisia; [2] National Institute of Nutrition and Food Technology of Tunis, Biochemistry, Tunis, Tunisia

Introduction
Polycystic ovary syndrome (PCOS) is a common endocrine pathology in women with a high prevalence varying between 5 and 20%. Autoimmune thyroid diseases (AITD) are the most prevalent organ-specific autoimmune diseases, particularly in young women. The purpose of our study was to determine the prevalence of AITD in a group of patients with PCOS compared to a control group.
Patients and Methods
103 women were recruited into the study, aged between 18 and 46 years. They were divided into two groups matched for age and body mass index. The first group included 51 women with PCOS and the second group included 52 healthy volunteer women. Serum-free thyroxin (FT4), thyroid-stimulating hormone (TSH), anti-thyroid peroxidase antibody (anti-TPO) levels were evaluated. The diagnosis of Hashimoto's thyroiditis was made when the participant had hypothyroidism coupled with high level of anti-TPO.
Results
The age and the body mass index were comparable between the two groups (29.6± 6.5 vs 29.2 ±6.1 years, $P=0.81$; 30.3±6.5 vs 29.3±8.9 Kg/m^2; $P=0.19$). The TSH, FT4 and ant anti-TPO levels were similar in both groups ($P=0.41$, $P=0.35$, $P=0.41$, respectively). The frequency of Hashimoto's thyroiditis was significantly higher in the PCOS group (21% vs 4%, $P=0.01$). In patients with PCOS and controls, the percentages of positive anti-TPO, subclinical hypothyroidism were similar ($P=0.21$, $P=0.27$, respectively). Graves'disease and subclinical hyperthyroidism were not found in the two groups.
Conclusion
Hashimoto's thyroiditis is a frequent condition in PCOS patients. Therefore, the assessment of TSH and anti-TPO should be considered in patients with PCOS during follow-up even in the absence of overt symptoms.

Introduction
Overt thyroid dysfunction in pregnancy without an early diagnosis and treatment may lead to an increased risk of adverse maternal and fetal outcomes. In this study, our goal was to assess the results of the development of a laboratory alerting system for the diagnosis of thyroid dysfunction in the first trimester of pregnancy.
Material and methods
Observational retrospective study evaluating clinical and biochemical data from pregnant women with overt thyroid dysfunction diagnosed in the first trimester of pregnancy through a laboratory alerting system between October 2020 and August 2021. Overt thyroid dysfunction was defined by overt hypothyroidism (TSH < 4 mcU/ml and low FT4) or overt hyperthyroidism (TSH < 0.1 mcU/ml and high FT4/FT3) in the first trimester of pregnancy. Laboratory alerts were received weekly via e-mail notification and assessed by an Endocrinologist.
Results
A total of 60 laboratory alerts were received. 12 of them did not fulfill the aforementioned criteria and were not considered. Thus, the remaining 48 laboratory alerts from women in the first trimester were evaluated (30.8 ± 7.1 years old, 20.8% presented family history of thyroid disease and 14.5% presented personal history of thyroid disease (6.2% hypothyroidism, 8.3% hyperthyroidism). Considering the 13 laboratory alerts related with overt hypothyroidism, 5 patients presented increased levels of thyroperoxidase antibodies (38.4%), median TSH 7.3 (4.38-617; normal value 0.4-4 μUI/ml), median FT4 10.4 pmol/l (1.98-10.94; normal value: 11-22 pmol/L). 7 women (53.8%) started levothyroxine (median TSH 13.4 μUI/ml), 1 patient was not contacted, and 5 patients presented analytical interferences (normal TSH and slightly decreased FT4) and were not treated. With regard to the 35 laboratory alerts due to overt hyperthyroidism, 3 patients (8.5%) had personal history of transient hyperthyroidism of early pregnancy; 17 (48.6%) presented nausea/vomiting, 1 (2.9%) twin pregnancy and 1 (2.9%) ectopic pregnancy. Positive autoimmunity (TSI) was detected in 5 patients (14-3%), median FT4 22.6 pmol/l (ranging from 22.04 to 55.79), median FT3 7.73 pmol/l (6.88-30.8; normal value 3.1-6.8). 10 patients (28.5%) started treatment with antithyroid drugs, whereas in the rest, the transitory suspension of the iodine supplement was enough for the normalization of biochemical parameters.
Conclsions
A laboratory alerting system for the diagnosis of thyroid dysfunction during pregnancy permitted an early diagnosis and treatment of this pathology in 28.8 % of the received laboratory alerts.

Compare the effects of levothyroxine therapy vs liothyronine/levothyroxine combination therapy on cardiac biomarkers in 364 patients with hypothyroidism

Vishal Gupta[1] & Vaishali Teli[2]
[1]VG-ADVANTAGE Diabetes Thyroid and Endocrine Centre, Endocrinology, Mumbai, India; [2] VG-ADVANTAGE Diabetes Thyroid and Endocrine Center, Mumbai, India

Methodology
Between Jan'20 to Jan'21, 364 patients on thyroid replacement therapy were included in the study and analysed retrospectively. They were divided in 2 groups. T4 group (189 on levothyroxine therapy {T4} therapy) & T3 group (175 on levothyroxine/liothyronine combination therapy {T3/T4}. Hypothyroidism was defined as TSH >4.2 mIU/ml on > 2 occasions > 2 weeks apart irrespective of their thyroid antibody (anti-TPO Ab) status or TSH > 4.2 if symptomatic or positive Anti-TPO Ab. Patients were evaluated every 2-3 months for 6 months for CV markers [body mass index-kg/m^2 (BMI), systolic (S) BP, diastolic (D) BP {mm in Hg}, Lipid profile mg/dl (TC, LDL, TG, HDL), Hs-CRP {mg/l}]. Baseline characteristics were analysed using descriptive statistics. Data was analysed using SPSS 26 and represented as mean ± standard error & independent sample t-test was used. P value <0.05 was considered significant (S).
Results
Baseline characters were well matched in both groups except, DBP (mean±SD) (T4 77.72±9.601 Vs T3/T4 81.69±10.87, P-0.00) & LDL (T4 105.121±33.689 Vs T3/T4 114.687±33.9196, P-0.02). T4 group (baseline to 6 months): there was a S reduction in SBP (3.323±0.941, P-0.01), TSH (4.4522±0.7602, P-0.00), TC (14.04274±3.24371, P-0.00), LDL (11.42795±3.03657, P-0.00), TG (16.15090±3.73617, P-0.00). T3/T4 group (baseline to 6 mths): there was S reduction in BMI (0.5160±0.1213, P-0.00), TSH (6.1134406±1.4832301, P-0.00), TC (12.75764±2.80435, P-0.00), LDL (11.63343±2.72702, P-0.00), TG (8.45775±4.38677, P-0.05). Difference between T4 & T3/T4 at 6 mths: There was no difference in hs-CRP mg/l {T4 0.2947±0.3071 vs T3/T4 0.9844±

0.3602, *P*-0.677}, BMI kg/m^2 {T4 0.2361 ± 0.1892 vs T3/T4 0.5160 ± 0.1213, *P*-0.222}, Lipid parameters, SBP & DBP between both groups.
Conclusion
Both T3/T4 combination therapy & T4 are effective in improving lipid parameters. Both T4 & T3/T4 do not impact either hs-CRP or BP.

Dyslipidemia in subclinical hypothyroidism : a case control study

Leila Ahmed Ali[1] & Nora Soumaya Fedala[2]
[1]Bab El Oued Universitary Hospital, Department of Endocrinology and Metabolic Diseases, ALGIERS, Algeria; [2] Bab El Oued Universitary Hospital, Department of Endocrinology and Metabolic Diseases, Algiers, Algeria

Subclinical hypothyroidism (SCH) represents a mild or compensated form of primary hypothyroidism. Although the relationship between SH and lipid profile have been reported in several studies, the results are conflicting. The objective of the present study is to assess dyslipidemia among patients with SCH. Our study included 107 patients vs 108 sex matched controls. Clinical information and medical history were obtained through a questionnary from all SCH patients and normal control subjects. Blood samples were collected and analyzed for thyroid-stimulating hormone (TSH), free thyroxine (FT4), total cholesterol (T-Chol), serum triglycerides (STG), low-density lipoprotein-cholesterol (LDL-C), and high-density lipoprotein-cholesterol (HDL-C). Results: average CT and LDL-C were significantly higher in patients respectively: 1.91 ± 0.385 vs 1.77 ± 0.294 (IC 95% 1.84$P = 0.02$), and 1.19-0.341 vs 1.09 -0.258 ($P = 0.01$). The average value of TG was higher in patients 1.23 ± 0.69 Vs 1.14 ± 0.527 (IC 95% 1.10)but the difference was not significant$P = 0.28$. No correlation was found between TSH and lipidic parameters. Our study concluded that SCH is associated with elevated CT and LDL −CT. Therefore the assessment of lipidic parameters is highly recommended in theses patients

Resistant Graves' thyrotoxicosis with adverse cardiovascular effects

Scott Williams, Helmine Kejem, Jael Nizza & Upendram Srinivas Shankar
Arrowe Park Hospital, Upton, United Kingdom

A 61-year-old lady presented to her general practitioner in July 2018 with weight loss, loose stools, hair loss, increased anxiety and dry eyes over several weeks. Blood tests revealed Graves' thyrotoxicosis (TSH < 0.10 mU/l, (RR) 0.30-5.50 mU/l; Free T4 (fT4) 26.1 pmol/l, RR 11.5−22.7 pmol/l; Free T3 (fT3) 11.8 pmol/l, RR 0.0-7.0 pmol/l, thyroid receptor antibodies >40.0U/l, RR 0.0-1.8 U/l; thyroid peroxidase antibodies 173.0 iu/ml, RR 0.0-33.9 iu/ml). There was also evidence of mild Grave's orbitopathy. She was commenced on carbimazole 15 mg once daily (od) and propranolol 20 mg three times daily. As thyrotoxicosis worsened, the dose of carbimazole was gradually increased to 60 mg od (December 2019-January 2020). Thyrotoxicosis did not improve (fT4 45.1 pmol/l, fT3 19.2 pmol/l), thus, a month later, aqueous iodine 1 drop three times a day (5 mg) was added first, followed by 1-month course of prednisolone 20 mg per day. No treatment response occurred, so the patient was referred for radioiodine treatment (RAI), that was delayed by the COVID-19 pandemic. In April 2020, the patient suffered an acute inferior ST elevation myocardial infarction (STEMI). This was treated with primary percutaneous coronary intervention, complicated by recurrent stent thrombosis and cardiac arrest. The patient received a 2-day course of Amiodarone to control the ventricular arrhythmias, which interestingly normalised her fT4 and fT3. The patient remained on carbimazole 60 mg od. A surgical thyroidectomy was considered a high operative risk due to the recent STEMI. A month later, the patient was re-admitted with severe congestive cardiac failure. At that time, there was evidence of new hypothyroid (fT4 4.4 pmol/l, TSH 8.10 mU/l). Thus, the dose of carbimazole was reduced to 5 mg once daily. In July 2020, a recurrence of thyrotoxicosis occurred. RAI was administered in July 2020 with 2 weeks of 30 mg per day prednisolone cover for Grave's orbitopathy. Recurrence of thyrotoxicosis occurred as soon as the carbimazole was stopped. Carbimazole 60 mg was restarted and tapered down over the following year, until the carbimazole requirement plateaued at 15 mg/10 mg alternate days. A second radioiodine dose was administered in July 2021 and the carbimazole stopped a month later. By September 2021, the patient had developed profound hypothyroidism (TSH 76.70 mU/l, low fT4 3.8 pmol/l, fT3 < 3.0 pmol/l) and levothyroxine replacement was initiated. This represents a case of Grave's disease which was resistant to treatment with carbimazole, iodine and first dose RAI. Thyrotoxicosis contributed to cardiac complications (STEMI and heart failure). Additionally, the temporary thyroid function suppression following the amiodarone clearly illustrates the Wolff-Chaikoff phenomenon.

A case of severe thyrotoxicosis in acute setting presenting with hypercalcemia and deranged liver function test

Kirtanya Ramachandran[1], Gideon Mlawa[2], Hassan Rehmani[3], Writaja Halder[3] & Prateek Prasannan[3]
[1]Queens Hospital, Romford, United Kingdom; [2] Queens Hospital, Acute Medicine, Romford, United Kingdom; [3] Queen's Hospital, London, United Kingdom

Background
Thyroid hormones may affect bone calcium metabolism either by a direct action on osteoclasts or by acting on osteoblasts which mediate osteoclastic bone resorption. Hyperthyroidism induces an accelerated bone loss, causing hypercalcemia and may thereby increase the risk of low energy fractures. Increased IL-6 levels and hyperadrenergic state due to thyrotoxicosis, are also implicated in hypercalcemia.
Case
A 33 year old who is a known case of Graves' thyrotoxicosis presented to the accident and emergency because of poor control of her thyrotoxicosis symptoms and previous history of asthma, for which she is on Propranalol (40 mg BD) and Carbimazole (10 mg OD). Thyroid examination revealed nodular goitre more enlarged on the right side and fine tremors were present in both hands, bilateral pedal oedema. Bloods revealed deranged thyroid and function test and liver function: TSH: <0.01 mU/l, FT4: >100 pmol/l, FT3: 49.4 pmol/l, calcium: 2.84 mmol/l, ALT 36.3 IU/l.
Patient suffered with constant nausea, poor appetite, weakness, myalgia, mood changes and many other symptoms indicative of poor control. So her Carbimazole dosage was stepped up to 30 mg OD and she was put on a short course of Prednisolone to counteract the impending thyroid storm. Her blood tests 6 weeks after this showed: TSH: <0.01 mU/l, FT4: 26.6 pmol/l, FT3: 9.5 pmol/l, with normal calcium: 2.53 mmol/l and normal ALT 17 IU/l.
Discussion
It has been reported that hyperthyroidism is associated with mild to moderate hypercalcemia in approximately 20% of total patients. The serum calcium levels are often increased by mild to moderate range and it rarely exceeds 3.0 mmol/l in hyperthyroidism associated hypercalcemia. The case presented here demonstrates the importance of timely control of calcium level by adequate anti thyroid treatment which was critical. A follow up appointment has also been arranged for her prior to which certain blood tests like Serum PTH and Vitamin D have also been requested in addition to the routine blood tests. However the quick normalisation of calcium level in her blood following optimisation of her anti thyroid treatment points towards thyrotoxicosis as the cause.
Conclusion
Though this is a rare case, clinicians should be aware of the association of hypercalcemia with hyperthyroidism because timely treatment can save the lives of patients and it should not be ignored after ruling out the other causes of hypercalcemia.

COVID-19 outbreak and de-escalation of thyroid cancer diagnosis and treatment

Giorgio Grani[1], Valeria Del Gatto[1], Laura Ciotti[1], Teresa Montesano[1], Marco Biffoni[2], Laura Giacomelli[2], Mariaiuisa Sponziello[1], Valeria Pecce[1], Antonella Verrienti[1] & Cosimo Durante[1]

[1]Sapienza University of Rome, Department. of Translational and Precision Medicine, Rome, Italy; [2] Sapienza University of Rome, Department. of Surgical Sciences, Rome, Italy

Background

The COVID-19 outbreak in Italy forced the health system to cancel all non-urgent outpatient activities, to avoid further spreading of the disease inside the healthcare facilities. At our institution, for cancer patients the hospital allowed treatments and consultations: the medical team, however, identified patients whose procedures could be postponed. Even after May 2020, the capacity for non-urgent thyroid surgeries was reduced. These events enhanced our efforts to reduce overdiagnosis and overtreatment of non-threatening thyroid cancers, as was already suggested by current practice guidelines. The aim of this analysis was to describe the features of patients submitted to thyroid surgery with a final diagnosis of cancer before and after the Italian lockdown.

Methods

Single-center, subgroup analysis of a prospective observational study (NCT04031339), approved by the institutional review board. The records on all patients being followed up in our center were analyzed. The cohort was split in two groups: the first one, before the COVID-19 lockdown (March 2019-February 2020, group A), and the second one during and after the lockdown (March 2020-February 2021, group B). The early response to treatment was assessed 6 to 12 months after initial treatment, according to the American Thyroid Association guidelines.

Results

Group A consisted of 58 patients, while group B of 38 patients, due to a reduction of the number of thyroid surgeries. There were no difference in age (group A: 48 years, 36-61; group B: 52 years, 33-61;$P=0.9$), gender distributions (females 74.1% and 65.8%, respectively), and known risk factors (i.e., family history of thyroid cancer, previous neck irradiation). Also, the histotype distribution was similar in the two cohorts ($P=0.46$). However, in the cohort of patients submitted to surgery after COVID-19 outbreak, the median tumor size was higher: 14 mm (IQR 10-25 mm) vs 9 mm (IQR 6-20 mm;$P=0.01$), and the rate of microcarcinomas was lower (12 [31.6%] vs 33 [56.9%], $P=0.02$). Furthermore, the ATA risk stratification distribution was different ($P=0.036$), with less low-risk and more high-risk cancers (19.4% vs 5.5%). This is consistent with a reduction in overtreatment of low-risk diseases. However, the early response to treatment was not affected ($P=0.73$) , as the vast majority of patients had no evidence of persistent disease after treatment (A, 51.7% and B, 57.9%).

Conclsions

The "forced" reduction of thyroid surgeries due to COVID-19 outbreak improved the adherence to international practice guidelines, with decreased overtreatment: the short-term outcomes were not negatively impacted.

Staying cool in the heat − the role of thyroid hormone receptor α in thermoregulation

Sarah Sentis, Riccardo Dore & Jens Mittag

Center of Brain, Behavior and Metabolism (CBBM), Institute for Endocrinology and Diabetes, University of Luebeck, Luebeck, Germany

A normal thyroid status is crucial for normal tissue and organ functioning, including temperature homeostasis. The tissue-specific actions of TH on body temperature regulation and thermogenesis are largely modulated via thyroid hormone receptor TRα. Consequently, mice expressing a mutant TRα display bradycardia and a reduced body temperature at 22°C ambient temperature due to excessive heat loss via the tail. To test whether this peripheral heat loss is the sole reason for the hypothermia, we housed TRα-mutants at 30°C, where tail heat loss is minimized. Using infrared thermography, we revealed that the heat loss effect via the tail could be reversed; however, body temperature surprisingly still remains lower during the inactive phase in TRα-mutants. The observed lack of a compensatory brown fat activation suggests that the central regulation of temperature homeostasis may be impaired in TRα-mutants indicating a lower central body temperature set-point, also at 30°C. Whether the expression of mutant TRα in the brain can indeed lower the central body temperature set-point will be tested in future experiments.

Thymic hyperplasia associated with Graves' Disease: lessons from the resolution of six individual cases

Lorenzo Scappaticcio[1], Pierpaolo Trimboli[2], Sergio Iorio[1], Alfredo Clemente[3], Francesco Caiazzo[1], Rosa Di Fraia[1], Lucia Digitale Selvaggio[1], Concetta Di Lorenzo[4], Claudia Varro[4], Giuseppe Bellastella[1], Mariaida Maiorino[1] & Katherine Esposito[1]

[1]University of Campania "L. Vanvitelli", Division of Endocrinology and Metabolic Diseases, University Hospital "Luigi Vanvitelli", Naples, Italy; [2] Faculty of Biomedical Sciences, Università della Svizzera Italiana (USI), Lugano, Switzerland, Clinic for Endocrinology and Diabetology, Lugano Regional Hospital, Ente Ospedaliero Cantonale, Lugano, Switzerland; [3] University of Campania "L. Vanvitelli", Naples, Italy, Radiology and Radiotherapy Unit, Department of Precision Medicine, University of Campania "L. Vanvitelli", Naples, Italy; [4] University of Campania "L. Vanvitelli", Naples, Italy

Objective

Since the relationship between thymic hyperplasia (TH) and Graves' Disease (GD) is of paramount importance for diagnostic and therapeutic choices, a wider knowledge of this association is required for endocrinologists in routine clinical practice. Our aim was to assess the prevalence, the clinical features, and the response to treatment of GD-related TH in an Academic referral centre.

Methods

All consecutive cases of GD-related TH at University Hospital "L. Vanvitelli" between January 2019 to December 2021 were retrospectively reviewed. Cases could be included whether: a) TH was initially suspected by symptoms or neck ultrasound (nUS) but confirmed and followed-up also by neck and chest (nc) computed tomography (CT)/magnetic resonance (RM); b) the imaging follow-up time was at least of six months; c) we had complete data at diagnosis of GD and after therapy (i.e., demographic, clinical, laboratory and imaging details).

Results

Among 144 newly diagnosed GD patients, TH was detected in six patients (6/144, 4.2%). Patients with GD-related TH were female with mean age 34.7 years (age range 23-48 years). Typical cardiovascular and neurological symptoms of thyrotoxicosis were the reasons for the consultation, and mild ocular involvement was present in three patients. No other pathologies affected our patients but multiple sclerosis was previously diagnosed in one case. At nUS mean thyroid volume was 25.2 ml (range 14-36 mL). Mean laboratory values were: fT3 12.5 pmol/l (range 11-18 pmol/l), fT4 32.2 pmol/l (range 28-40 pmol/l), thyrotropin receptor antibodies (TRAb) 9 IU/l (range 5-16 IU/l, positive $\geq$ 1.5 IU/l). In all the six cases TH was asymptomatic and initially identified by nUS as a hypoechoic (relative to thyroid tissue) trapezoidal mass with smooth margins and a reticulated pattern located at jugular notch with partial extension in superior mediastinum. In all the six cases confirmation of TH was obtained by the ncRM, which displayed at T2 images a homogeneous well-defined and lobulated soft tissue mass in the mediastinal prevascular space dislocating epiaortic vessels with a mean maximum diameter of 50 mm (range 44-56 mm) that disappeared after therapy. The average time for TH disappearance was nine months (range 6-14 months), and this was obtained after euthyroidism restoration (i.e. two cases by methimazole, three cases by radioiodine and one case by surgery).

Conclusion

Based on our experience, thymic hyperplasia was not infrequent in the GD setting and it was incidentally detected at nUS. TH regressed with the treatment of GD along with euthyroidism restoration.

The effect of over- and undertreatment of hypothyroidism on hospitalization outcomes of patients with decompensated heart failure

Dana Kagansky[1], Karen Or[2], Matan Elkan[1], Shlomit Koren[3,4] & Ronit Koren[4,5]

[1]Shamir Medical Center, Department of Internal Medicine A, Israel; [2]Shamir Medical Center, Department of Internal Medicine D, Israel; [3]Shamir Medical Center, Endocrine Institute, Israel; [4]Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel.; [5]Shamir Medical Center, Department of Internal Medicine A, Israel

Background

Hypothyroidism has profound effects on cardiac function, however, the effect of over- and undertreatment of hypothyroidism on hospitalization outcomes of patients with acute exacerbation of heart failure (HF) has not been evaluated yet.

Methods

We conducted retrospective cohort analyses of outcomes among 231 consecutive patients with treated hypothyroidism who were admitted to the internal medicine departments of Shamir Medical Center with HF from 2011 to 2019. Patients were divided into three groups according to their TSH levels – normal (TSH 0.4-4 mIU/l), over-treated groupTSH $<$ 0.4 mIU/l, and undertreated group (TSH $>$ 4 mIU/l). The main outcomes were functional deterioration, in-hospital mortality, and recurrent hospitalization within three months.

Results

Among 231 patients, 106 were euthyroid, 14 were overtreated, and 111 were undertreated. Patients' mean age was 79.8 $\pm$ 9.4 years. Heart failure with reduced ejection fraction was found in 41.1%, hypertension in 91.3%, and COPD in 26.8% of patients. The most common triggers to HF decompensation were anemia, infection, and low compliance for treatment. In-hospital mortality occurred in 4.7% in euthyroid patients, 14.3% in the overtreated group, and 10.7% in the undertreated group ($P = 0.183$). Differences in 30- and 90-days mortality were not significantly different as well. Functional deterioration during hospitalization was found in 9.4% in the euthyroid patients, non in the overtreated group, and 6.3% in the undertreated group ($P = 0.288$). There was no significant difference in recurrent hospitalization within 3 months between the three groups ($P = 0.438$). However, when evaluating patients with extreme values of TSH ($<$ 0.4 mIU/l or $>$ 10 mIU/l), we found higher 90 days mortality (30.4% vs 15.1%, $P = 0.016$), as compared to patients with normal or mildly increased TSH (0.4-10 mIU/l).

Conclsion

Our results show that mild under- or overtreatment of hypothyroidism did not have a significant detrimental effect on mortality, functional deterioration, or rehospitalization of patients with acute decompensated HF. However, significant over- and undertreatment do cause adverse hospitalization outcomes. Larger cohorts are needed to establish the relationship between treatment targets and hospitalization outcomes of patients who are at risk for hospitalization for HF.

Impact of COVID-19 vaccination on incidence of graves' disease

Luigi Di Filippo, Fanny Valsecchi, Stefano Frara, Francesca Perticone, Laura Castellino & Andrea Giustina

Institute of Endocrine and Metabolic Sciences, Università Vita-Salute San Raffaele and IRCCS Ospedale San Raffaele, Milan, Italy

Several reports of Graves' disease (GD) onset after COVID-19 vaccination were recently published. The mechanism underlying GD occurrence in these cases could be related to the autoimmune syndrome induced by adjuvants (ASIA), a condition triggered by several vaccine adjuvants and excipients leading to dysfunctional immune response causing different conditions and endocrinopathies in genetically predisposed subjects. In Italy, population campaign for COVID-19 vaccination started in December 2020 and by the end of December 2021 more than 80% of citizens were vaccinated. The aim of our study was to evaluate for the first time the impact of COVID-19 vaccine on incidence of GD in 2021. Of the 33 first-diagnosis of GD in our Center in 2021, in 16 (48.5%) patients, 2 males (12.5%) and 14 (87.5%) females, GD temporally occurred before the vaccination and in 17 patients (51.5%), 5 males (29%) and 12 females (71%), after the first or second vaccine dose. In 14 (83%) patients, GD occurred in the first four weeks after vaccination, in 1 (6%) after 8 weeks and in 2 (11%) after 12 weeks. All 5 male patients with GD after vaccine injection presented symptoms and signs onset and subsequent GD diagnosis in the first four weeks after vaccination. All 33 patients started anti-thyroid treatment. After three months of therapy, TSH was normalized in 7 out of 14 (50%) patients in whom GD occurs after vaccine administration, whereas fT4 and fT3 levels were available in 13 and 12 and within the normal reference range in 11 and 11 patients (85% and 92%), respectively. Anti TSH-receptor antibodies were negative in 2 out of 6 patients (33.3%) with post-vaccine GD. Possibly COVID-19 vaccine-related GD (within 4 weeks after vaccine administration) accounted for more than 50% of the cases observed in our 2021 monocentric experience. Moreover, since one third of post-vaccine GD were males, our observation strengthens the hypothesis of a causal vaccine-GD relationship since males are usually less affected by GD. In conclusion, for the first time we report a remarkable impact of COVID-19 vaccination in GD diagnosis in a single-center experience. Our report can improve awareness of thyrotoxicosis diagnosis by primary-care physicians and endocrinologists, particularly in patients with marked and persistent symptoms, such as fever, palpitations and asthenia, occurring after vaccination.

Management of suspicious neck lymph nodes in patients with differentiated thyroid carcinoma

Simone de Leo[1], Matteo Trevisan[2], Carla Colombo[3], Luca Persani[2], Leonardo Vicentini[4] & Laura Fugazzola[3]

[1]Istituto Auxologico Italiano, Division of Endocrine and Metabolic Diseases, Milano, Italy; [2]University of Milan, Department of Medical Biotechnology and Translational Medicine, Italy; [3]University of Milan, Department of Pathophysiology and Transplantation, Italy; [4]Istituto Auxologico Italiano, Endocrine Surgery Unit, Italy

The management of loco-regional metastases in patients with differentiated thyroid carcinoma is still debated. Current American Thyroid Association guidelines state that in this context the main goal is to differentiate between low-volume metastatic disease that will progress and that remaining stable over time. Aim of our study was to evaluate the behavior of suspicious or cytologically confirmed lymph node metastases, detected after initial treatment (i.e. thyroidectomy with or without cervical lymphadenectomy and radioiodine treatment), in patients with differentiated thyroid carcinoma. Secondary endpoints were the analysis of predictive factors useful to precociously recognize the lesions with a more aggressive behavior. We retrospectively evaluated 95 patients, who were followed-up with serum tumor biomarker evaluation and neck ultrasound every 6-12 months, who had a persistent finding of suspicious neck lymph nodes and a minimum follow-up of 12 months. The lymph-nodal disease was considered aggressive when (a) there was a growth of at least 5 mm in the longest diameter at ultrasound, (b) appearance of at least one new suspicious lymph node, (c) at least one lymph-node was PET-FDG avid. After a mean follow-up of 9 years, 75/95 (79%) patients had a stable disease, while 20/95 (21%) had progressive loco-regional disease. Patients with a more aggressive disease were more frequently male (50% vs 25.3%, $P = 0.03$), older (mean age was 54.3 vs 38 years old, $P = 0.0003$), and with a larger primary tumor (31.8 vs 20 mm, $P = 0.005$). We did not find significant differences regarding TNM, histology, papillary thyroid cancer variant, extrathyroidal extension, ablative radioiodine dose, stimulated thyroglobulin at first radioactive iodine, positive thyroglobulin antibodies after initial treatment, finding of distant metastases at the end of follow-up. At the end of follow-up, 16/20 patients with progressive loco-regional disease had a structural disease despite further treatments (i.e. lymphadenectomy, external beam radiotherapy, radioiodine treatment, tyrosine kinase inhibitors). Our study reports that a high majority of patients with cervical lymph node metastases can be safely followed-up with serial neck ultrasound and serum tumor biomarker evaluation. In case of suspicion, a PET-FDG scan may be necessary. The remaining 20% of patients, in particular male, older patients, and with a larger tumor size at surgery, may have lymph node metastases with an aggressive behavior requiring additional treatments.

Steroid treatment in the management of destructive thyrotoxicosis induced by PD1 blockade

Alessandro Brancatella[1], Laura Pierotti[1], Isabella Lupi[1], Lucia Montanelli[1], Nicola Viola[1], Daniele Sgrò[1], Chiara Sardella[1], Lucia Antonangeli[1], Sandra Brogioni[1], Chiara Cremolini[1], Claudio Marcocci[1], Ferruccio Santini[1] & Francesco Latrofa[2]

[1]Endocrinology Unit, Department of Clinical and Experimental Medicine, University Hospital of Pisa, Pisa, Italy; [2]Oncology Unit, Oncology Unit, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Objective
Destructive thyroiditis is the most common endocrine immune related adverse event (iRAEs) in patients treated with anti-PD1/PD-L1 agents. Given its self-limited course, current guidelines recommend no treatment for this iRAE. Nevertheless in patients with enlarged thyroid volume and a poor performance status, thyrotoxicosis may be particularly severe and harmful. Aim of the study is to evaluate if steroid treatment might be useful in improving thyrotoxicosis in subjects with a poor performance status.
Methods
We conducted a case-control study, comparing the course of thyrotoxicosis of 6 patients treated with oral prednisone at the dosage of 25 mg/d (tapered to discontinuation in three weeks) and an enlarged thyroid volume to that of 12 patients with similar thyroid volume who were left untreated.
Results
The levels of thyroid hormones were lower in subjects treated with prednisone compared to those untreated at time 7, 14, 21, 28, 35, 42, 60 and 90 days ($P<0.05$ at each time). The median time to remission of thyrotoxicosis was 24 days in patients treated with steroids and 92 days in untreated patients ($P<0.001$). At 6 months, the rate of evolution to hypothyroidism was similar in the 2 groups (5/6 in steroid group vs 9/12 in untreated group, $P=0.74$) and no difference was found in tumor progression ($P=0.89$).
Conclsions
A short period of prednisone therapy is useful to restore more quickly euthyroidism in patients with a poor performance status and a severe destructive thyrotoxicosis induced by PD-1 blockade. This treatment does not impair the efficacy of immunotherapy.

Change in body fat distribution after total thyroidectomy in euthyroid patients and its relationship with serum adiponectin and leptin levels

Mustafa Unal[1], Nese Cinar[2], Iffet Dağdelen Duran[3] & Duygu Yazgan Aksoy[4]
[1]Istanbul Haseki State Hospital, Department of Endocrinology and Metabolism, Istanbul, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolism, MUĞLA, Turkey; [3]Denizli State Hospital, Department of Endocrinology and Metabolism, Turkey; [4]Acıbadem University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective
Euthyroid patients undergoing thyroidectomy were reported to gain weight than their matched counterparts. The etiology is still unknown. Serum adiponectin and leptin levels are related to fat mass and thyroid hormones. We aimed to evaluate the influence of thyroidectomy on body composition, serum adiponectin, leptin levels in euthyroid obese and non-obese patients who underwent total thyroidectomy for goiter.
Methods
We conducted a prospective observational study in a training hospital. Twenty-one euthyroid normal-weight patients (16F/5 M, mean age 43.5 ± 8.4 y), 19 obese patients (17F/2 M, mean age 44.3 ± 8.7 y) and 22 healthy controls (21F/1 M mean age 40.4 ± 10.2) were included in the study. Main anthropometric measures, body fat distribution by bioelectrical impedance analysis, preperitoneal fat thickness, plasma glucose (FPG), insulin, lipids, thyroid hormones, leptin, and adiponectin levels were evaluated before and after surgery. L-thyroxine treatment was started immediately. All patients were maintained in a euthyroid status throughout the study, and patients were re-evaluated three months after the achievement of euthyroidism.
Results
At baseline, obese patients had significantly higher BMI, waist circumference (WC), total fat mass, lean body mass, and SC fat thickness than normal-weight subjects and healthy controls ($P<0.001$ for all). Obese patients had higher visceral fat mass than normal-weight patients at a *P*level of 0.051 ($11.0\pm4.5\%$ vs. $8.4\pm3.9\%$). Serum fasting insulin and leptin levels and HOMA-IR values were significantly higher in obese patients ($P<0.05$ for all). In contrast, all groups had comparable FPG and adiponectin levels ($P>0.05$ for both). Mean TSH and free T4 levels were also similar. Although BMI and WC remain unchanged ($P>0.05$), the visceral fat mass increased significantly after surgery (8.4 ± 3.9 vs. 10.0 ± 4.1 in normal-weight; 11.0 ± 4.5 vs. 15.5 ± 6.0 in obese; $P<0.05$). Despite a significant increase in TSH levels, the values remained normal in both groups. Both groups did not show any significant change in serum FPG, insulin, leptin, and adiponectin levels ($P>0.05$ for all).
Conclusions
Total thyroidectomy caused increased visceral fat mass despite no change in clinical anthropometric measures in patients who had a thyroidectomy due to goitre. This change was unrelated to serum adiponectin and leptin levels.

Predictive factors of success of radiometabolic therapy in Graves' disease

Daniela Gallo[1,2], Anna Mercuriali[1], Fabio Tanzi[3], Giovanni Veronesi[4], Adriana Lai[1], Silvia Ippolito[1], Jessica Sabatino[1], Bohdan Patera[1], Silvia Lepanto[1], Nicola Lanzo[1], Gaia Fazzino[1], Federica Bianchi[1], Ilaria Clementi[1], Francesca Manzella[1], Maria Laura Tanda[1,5] & Eliana Piantanida[1,5]
[1]ASST Sette Laghi, Endocrine Unit, Varese, Italy; [1] ASST Sette Laghi, Endocrine Unit, Varese, Italy; [3]ASST Sette Laghi, Health Physics Service, Varese, Italy; [4]University of Insubria, EPIMED Centre, Varese, Italy; [5]University of Insubria, Medicine and Surgery, Varese, Italy

Aim of the study
recurrence or persistence of hyperthyroidism occur in 15-25% of cases after radioiodine therapy (RAI) in Graves' disease (GD). Our study aimed to establish prognostic factors affecting RAI outcome and to investigate if a tailored dosimetric approach based on the application of the "effective biological dose" (BED) offered a higher chance of success.
Materials and methods
our cohort comprised 365 GD patients (280 women and 85 men; age 49 ±14 years) treated with RAI in the period 2001-2021. Patients were allocated into two groups: "failure group" in case of persistence of hyperthyroidism for more than six months post-RAI or hyperthyroidism relapse; "success group" in case persistent euthyroidism or hypothyroidism were achieved after treatment. A multivariate analysis was performed to construct a predictive model of success; a BED threshold value was derived using a ROC curve.
Results
success was achieved in 80% of cases. No significant differences emerged between the two groups when analyzing demographic data (age, sex), smoking habit, GD duration and ongoing medical therapies, presence/severity of orbitopathy, RAI uptake and the applied formula for dosimetry calculation. Negative predictive factors for success were higher thyroid volume, nodules (presence and volume) and disease severity at diagnosis, and a higher effective half-life of radioiodine. The success group had higher FT4 levels immediately before the caption curve (within/slightly above the upper limit of the normal range), a higher difference between the administered activity and the calculated one, a higher BED. Thyroid volume was the most predictive variable in the multivariate analysis, but no single factor was able to predict the outcome. A BED of 369 Gy emerged in the ROC curve as a cut-off value (AUC 0.60, $P=0.01$).
Conclusions
Our study suggests that the outcome of RAI is influenced by clinical, biochemical, ultrasound and dosimetric factors, which interact with each other in a complex way. It is a delicate balance, in which no factor, considering individually, can predict the treatment approach. A multidisciplinary approach is necessary, to better understand the different interactions and confounding factors.

Vitamin D levels in patients with graves orbitopathy

Georgios Boutzios, Sofia Chatzi, Areti Mina, Eleni Koukoulioti & Athanasios Tzioufas
School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Introduction
Graves' disease (GD) is an autoimmune thyroiditis frequently associated with development of Graves' orbitopathy (GO). GD patients have lower vitamin D

levels compared to the general population. Whether low vitamin D levels are associated with GO is still controversial. The aim of our study was to assess the vitamin D levels in patients with GO and the clinical outcome.
Methods
This is a single-center observational study in an outpatient clinic of autoimmune endocrinopathies at a Tertiary, General, University Hospital. Patients with GO and increased levels of thyroid-stimulating immunoglobulin (*TSI > 1.75 IU/l)* were included in the study. Clinical activity score (CAS) was evaluated according to the European Consensus Report. Patients were divided in two groups according to CAS (inactive CAS <3 and active CAS $\geq$ 3). Laboratory tests for TSH, T3, FT4, TSI, TgAbs, TPOAbs, complete blood count, liver enzymes and 25OHvitamin D levels were performed in all patients.
Results
A total of 78 patients (71.8 % females) with a mean age of 53.9 ± 13.33 years were analyzed. The mean follow-up was 3 ± 9.04 years. The median TSI levels were 5.65 IU/l and the mean CAS was 3 ± 1.42. 47% (37/67) and 26.9% (21/70) of the patients had positive anti-TPO and anti-Tg antibodies, respectively. 23.1% (18/78) of the patients had undergone total thyroidectomy, 10.3% (8/78) had thyroid cancer, 29.5% (23/78) had other autoimmunities, and 69.2% (54/78) had smoking history. Overall, mean 25OHVitamin D levels were 21.98 ± 1.38 ng/ml. When analyzed based on disease activity, mean 25OHVitamin D levels were 21.05 ± 7.8 ng/ml in patients with inactive GO (CAS <3) and 22.51 $\pm$ 10.72 ng/ml in patients with active GO (CAS ≥ 3). Overall, CAS was significantly associated with TSI levels, diplopia and years of the disease ($P=0.011$, $P=0.025$ and$P=0.035$, respectively). 25OHvitamin D levels were significantly associated with anti-TPO and the disease duration in patients with active GO ($P=0.05$).
Conclsion
In our study, we found a correlation of vitamin D levels with anti-TPO and disease duration in patients with active GO. However, further prospective studies are needed to confirm whether there is a correlation between GO activity and vitamin D levels.

From hyper to hypothyroidism: pitfalls in graves' disease following DRESS syndrome

Maria Inês Alexandre[1], Catarina Queirós[2] & Ana Gomes[1]
[1]Hospital de Santa Maria, Endocrinology, Diabetes and Metabolism Department, Lisboa, Portugal; [2]Hospital Santa Maria, Dermatology Department, Lisboa, Portugal

Background
Drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome is an uncommon severe systemic hypersensitivity drug reaction. Several studies have described the occurrence of newly developed endocrine autoimmune diseases following DRESS syndrome resolution. However, little attention has been paid by endocrinologists to this disorder. Here, we report a case of a patient with Graves' disease following DRESS syndrome.
Clinical case
A 70-year-old man with urinary tract infection was treated with co-trimoxazole. Two weeks later, he presented to the dermatology outpatient clinic with a pruritic dermatosis, fever and peripheral lymphadenopathy. Physical examination revealed erythematous maculopapular lesions affecting his trunk and limbs and laboratory tests showed leukocytosis, eosinophilia and thrombocytopenia. Diagnosis of DRESS syndrome was made by the dermatologist, and treatment with glucocorticoids was initiated and allowed a gradual recovery. One year later, he presented is his follow-up appointment with fatigue, heat intolerance and palpitations. The blood tests revealed a Graves' hyperthyroidism with suppressed TSH (<0.01 uU/ml), elevated free T4 (2.07 ng/dl; N:0.85-1.7 ng/dl) and positive TSH receptor antibodies (TRAbs) (137 U/l; N: <1.22). He was referred to the endocrinology outpatient clinic, with a suspected newly onset Graves' disease succeeding DRESS syndrome resolution. By the time of his first endocrinology appointment, two months later, the laboratory evaluation revealed hypothyroidism (TSH 33.1 uU/ml; free T4 0.67 ng/dl) with persistent positive TRAbs (128 U/l). The patient started levothyroxine and, to this date, he remains euthyroid under 100 mg per day.
Discussion
There are several reports of newly developed Hashimoto's thyroiditis as sequelae of DRESS syndrome. What is original about this case is the association between Graves' disease and DRESS syndrome, a more uncommon association, and also the coexistence of stimulating and inhibiting TRAbs, leading to a rapid shift from hyperthyroidism to hypothyroidism, a rare condition in Graves' disease. We believe that endocrinologists should be aware of this association and that involvement of endocrine glands should be monitored in patients with a history of DRESS syndrome.

Graves' disease and polymorphisms in proinflammatory cytokines genes

Celestino Neves[1,2,3], Joao Sergio Neves[1,4], Juliana Gonçalves[1], Paula Soares[2,3,5], José Luís Medina[2] & Davide Carvalho[1,2,3]
[1]Department of Endocrinology, Diabetes and Metabolism, São João University Hospital Center, Porto, Portugal; [2]Faculty of Medicine of University of Porto, Porto, Portugal; [3]Institute for Research and Innovation in Health (i3S), University of Porto, Porto, Portugal; [4]Department of Surgery and Physiology, Faculty of Medicine of University of Porto, Porto, Portugal; [5]IPATIMUP-Instituto de Patologia e Imunologia Molecular da Universidade do Porto, Porto, Portugal

Background
Graves' Disease (GD) is one of the most common organ specific autoimmune disorders, being characterized by an abnormal production of stimulating autoantibodies to the thyrotropin receptor (TSHR). Some studies demonstrated that genetic polymorphisms in certain cytokines, namely interleukin-6 (IL-6), tumor necrosis factor-α (TNF-α), interleukin-1β (IL-1β), are associated with a greater susceptibility of developing GD. Our aim was to evaluate if these single nucleotide polymorphisms (SNP) also contribute to metabolic disturbances in GD patients.
Methods
Glycemic and lipid profiles were assessed in a case-control study comprising 97 Graves' disease patients. Genetic variants in IL6-174 G/C (rs1800795), TNFA-308 G/A (rs1800629), IL1B-511 C/T (rs16944), and IFNGR1-56 T/C (rs2234711) were discriminated by real-time PCR using TaqMan SNP genotyping assays. To evaluate the associations of SNP genotypes with glycemic and lipid profiles we used independent t test and Kruskal-Wallis test. We also performed linear and logistic regression models adjusted for age and sex.
Results
Within our sample of 97 patients with GD, 91.8% (89 subjects) were females, with a mean age of 44.4 ± 15.1 years. The mean TSH level of our population was 0.4 (0.0-1.3) µUI/l, while the mean levels of FT3 and FT4 were 3.0 (2.6-3.5) ng/ml and 1.1 (0.9-1.4) µg/ml, respectively. The allele T in IL1B-511 C/T was significantly associated with a higher prevalence of diabetes ($P=0.029$). The A allele in TNFA-308 G/A was associated with significant lower levels of HDL cholesterol ($P=0.037$), and with higher levels of fasting insulin ($P=0.042$) along with HOMA-β higher levels in both analyses ($P=0.027$;$P=0.020$). The T allele in IFNGR1-56 T/C polymorphism was associated with significantly higher mean values of fasting glucose in the adjusted analysis ($P=0.047$), as well as higher levels of C peptide ($P=0.026$). In addition, the analysis of the insulin-resistance indexes showed that HOMA-IR was significantly higher in the T allele group ($P=0.035$), while the QUICKI's mean was lower when the T allele was present ($P=0.035$).
Conclusions
Our study demonstrated that SNP in some pro-inflammatory cytokines may affect lipid and glycemic profiles in GD patients. TNF-α-308 A allele might be responsible for lower levels of HDL cholesterol along with increased beta cell function in patients with GD. IL1β-511 T allele may be linked with a higher prevalence of diabetes among GD patients, and IFNGR1-56 T allele is associated with insulin resistance. More studies are needed to evaluate the clinical relevance of these findings.

McCune-Albright syndrome diagnosed in adulthood with GNAS mutation-related hyperthyroidism and elevated anti-TPO antibodies. Case report.

Katerina Zajickova, Vlasta Sykorova, Karolina Mastnikova & Josef Vcelak
Institute of Endocrinology, Prague, Czech Republic

McCune-Albright syndrome (MAS) is a rare mosaic disorder caused by a postzygotic activating mutation in the GNAS gene encoding the G protein alpha subunit. Although clinical manifestations may be heterogeneous, MAS is often

characterized by the triad of fibrous dysplasia, café-au-lait skin pigmentations and hyperfunctioning endocrinopathy. We report here a 58-year old woman who presented for evaluation of hyperthyroidism, associated with nodular thyroid disease and elevated anti-TPO antibodies. She had been treated with a small dose of methimazole for 16 years but the remission of hyperthyroidism had not been attained. Neck ultrasound revealed a thyroid gland of normal volume with nodules in both lobes. The largest nodules (both hypervascularized and with microcalcifications) were evaluated by fine needle aspiration biopsy (FNAB) and were found to be benign. TSH-receptor antibodies (TRAb) were not elevated. The presence of anti-TPO antibodies led to a misdiagnosis of TRAb negative Graves' disease. Over the course of her disease, and since childhood, the patient exhibited skeletal deformities and fragility fractures that were erroneously diagnosed as atypical osteogenesis imperfecta or familial expansile osteolysis. The presence of skin pigmentation on her right arm raised the suspicion of MAS. The GNAS activating mutation R201H was found in DNA derived from the thyroid nodule by FNAB. Furthermore, the R201H variant was also found in breast cancer tissue of the patient who had recently undergone right mastectomy. Hyperthyroidism is the second most common endocrinopathy in MAS after precocious puberty. The presumption of autoimmune thyroid disease and the incorrect skeletal diagnosis delayed the recognition of MAS in a patient with a classical combination of polyostotic fibrous dysplasia, hyperthyroidism and café-au-lait skin pigmentations. The GNAS genetic testing finally confirmed the diagnosis. Moreover, identification of the R201H mutation in the breast cancer specimen supports the oncogenic role of activating GNAS mutations in multiple tissues. Supported by MH CZ - DRO (Institute of Endocrinology - EÚ, 00023761) and AZV NU21-01-00448.

Hyperpigmentation in Graves' disease

Wiem Saafi[1], Hamza Elfekih[1,2], Asma Ben Abdelkarim[1,2], Sinda Allegue[1], Yosra Hasni[1,2], Amel Maaroufi[1,2], Maha Kacem[1,2], Molka Chadli Chaieb[1,2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia

Introduction
Hyperpigmentation is a clinical sign that can be associated with different endocrine disorders. It is commonly seen in Addison's disease and has rarely been reported in Graves' disease. The exact physio pathological mechanism of this sign is not well established in hyperthyroidism. We describe two cases of Graves' disease accompanied by diffuse hyperpigmentation.
Case report
Case 1 was a 63-year-old female admitted to the endocrinology department for the management of a thyroid crisis. The physical examination didn't find signs of thyroid eye disease or goiter, we instead noted diffuse hyperpigmentation. Laboratory investigations confirmed the diagnosis of hyperthyroidism showing a 6-fold elevation of FT4 (7.7; normal: 0.9-1.7 ng/dl) and low serum thyroid-stimulating hormone (TSH <0.001 mIU/l) with positive anti-TSH receptor antibodies. Hepatic function tests revealed cytolysis and cholestasis. Addison's disease and autoimmune hepatic diseases were eliminated. The patient received radioiodine treatment after preparation with antithyroid drugs. She regained euthyroidism with normalization of her liver function tests, but hyperpigmentation persisted.
Case 2 is a 52-year-old male patient who presented to our department with Graves' disease. He had clinical signs of hyperthyroidism a few months before admission with a concomitant change of his skin color. On physical exam, we noted irregular tachycardia with goiter. The patient had diffuse hyperpigmentation. Hyperthyroidism was biologically confirmed; high serum free T4 (10.3 ng/dl) with low serum thyroid-stimulating hormone (TSH <0.001 mIU/l). Anti-TSH receptor antibodies were positive. The rest of the explorations revealed cholestasis with normal transaminase levels. The patient was treated with radioiodine with clinical and biological amelioration. However, hyperpigmentation remained.
Discussion
Hyperpigmentation is rarely described as a clinical sign of hyperthyroidism. Its physiopathological mechanism is not well elucidated. It has been hypostasized that thyrotoxicosis is associated with an increased ACTH release causing overproduction of melanin and that melanocytes express TSH receptors resulting in their proliferation when stimulated with TRAb**.** More studies are needed to understand the relationship between skin color modification and thyroid function status.

Cervical lymph nodes metastases in differentiated thyroid cancer: impact on clinical outcome

Carla Gambale, Antonio Matrone, Lea Contartese, Alessandro Prete, David Viola, Laura Agate, Eleonora Molinaro & Rossella Elisei
Endocrine Unit, Department of Clinical and Experimental Medicine, University Hospital of Pisa, Pisa, Italy

Background
Cervical lymph node metastases at histology are common findings in differentiated thyroid cancer (DTC); however, their impact on clinical outcome is debated.
Material and method
1332 DTC patients, performed the first ^{131}I treatment between January 2010 and September 2012 and were divided into 2 groups: absence (Nx/N0) or presence (N1) of lymph node metastases at histology. The latter group was further split in central compartment (N1a) or latero-cervical compartment (N1b) metastases. Clinical outcome, according to 2015 ATA guidelines, was defined at: post-operative and post-^{131}I (median time from surgery: 6 months), first evaluation after ^{131}I (median time from ^{131}I: 8 months) and at last evaluation (median time since ^{131}I: 83 months).
Results
1064 (79.9%) patients were in the Nx/N0 group and 268 (20.1%) in the N1 group. N1 patients were more frequently males (35.8 vs 27.3%, $P<0.01$) and younger (median age 40 vs 47, $P<0.01$). Several pathological features were prevalent ($P<0.01$) in the N1 group: multifocality (63.4 vs 46.8%), mETE (67.9 vs 24.6%), vascular invasion (28 vs 8.9%) and intermediate ATA risk (94.8 vs 36.5%). The incomplete structural response rate was higher in N1 group, in all times of follow-up ($P<0.01$), despite N1 patients significantly experienced higher ^{131}I activities and more neck re-operation. N1b ($n=142$, 53%) patients, compared to N1a ($n=126$, 47%), had higher prevalence of mETE (74.6 vs 59.5%, $P<0.01$) and vascular invasion (33.1 vs 22.2%, $P<0.05$) and lower histological thyroiditis (21.1% vs 35.7, $P<0.01$). Regarding treatment, N1b patients experienced higher ^{131}I activities and more neck re-operation. Structural incomplete response rate was significantly higher at post-operative (16.2% vs 6.3%), post-^{131}I (26.1 vs 8.7%) and at first assessment after ^{131}I (24.3% vs 9.6%). Conversely, at the last evaluation, significance was not reached (17.9% vs 10.4%, $P=0.09$).
Conclusions
Cervical lymph node metastases at histology are associated with more aggressive features in DTC. Despite the higher activity of the ^{131}I administered and the more frequent surgery on neck, the N1 patients showed a higher structural incomplete response rate at each time of the follow-up. N1b patients, compared to N1a, experienced more frequent and aggressive treatments during the follow-up with higher incomplete structural response rate.

Comparison of serum calcitonin and neck ultrasound sensitivities in identifying medullary thyroid carcinoma

Antonio Matrone, Carla Gambale, Alessandro Prete, Virginia Cappagli, Loredana Lorusso, Valeria Bottici, Paolo Vitti & Rossella Elisei
Endocrine Unit, Department of Clinical and Experimental Medicine, University Hospital of Pisa, Pisa, Italy

Background
Serum calcitonin (CT) is a very sensitive test for the diagnosis of medullary thyroid carcinoma (MTC). However, its routine dosage in patients with nodular thyroid disease is not recommended by all scientific societies. In addition, to optimize costs, it is only suggested in the case of suspicious nodules on ultrasound, indeterminate nodules at cytology or nodular goiter before surgery. The aim of the study is to evaluate the serum CT in a series of consecutive MTC divided according to the pre-operative ultrasound risk.
Materials
We evaluated the pre-operative features of 152 consecutive patients surgically treated for MTC (2014-2020). Based on the EU-TIRADS, ATA, AACE/ACE-

AME, ACR-TIRADS, and K-TIRADS ultrasound risk stratification systems, we defined 2 groups: Group A (72 pts - 47.4%) with high ultrasound suspicion and Group B (80 pts - 52.6 %) with intermediate-low ultrasound suspicion of malignancy.
Results
The 2 groups did not differ in any epidemiological and clinical features. Pre-operative CT was significantly higher in Group A [369.5 pg/ml (IQR: 84-1718.8)] than Group B [115.5 pg/ml (IQR: 41.5-555)] ($P=0.01$). Despite this difference CT values were suggestive of MTC in both groups. Moreover, CT values directly correlated with nodule size in both groups. To note, in microcarcinomas, also if not clearly diagnostic of MTC, CT value was above the normal range. FNAC was suggestive for MTC only in 43.3% of Group A and 56.5% of Group B, without significant differences.
Conclusions
Increased pre-operative CT values are confirmed to be highly suggestive of MTC, regardless of the ultrasound suspicion of malignancy, the size of the nodule, and the cytological result.

Potential risk factors for post-treatment recurrence in patients with intermediate-risk differentiated thyroid carcinoma

Mattia Rossi[1], Chiara Mele[2], Ruth Rossetto Giaccherino[1], Denise Brero[3], Giulia Marsan[4], Gianluca Aimaretti[2], Ezio Ghigo[1] & Loredana Pagano[1]
[1]Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; [2]Endocrinology, Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy; [3]University of Turin, Turin, Italy; [4]Università del Piemonte Orientale, Novara, Italy

Introduction
The recurrence rate of intermediate-risk differentiated thyroid carcinoma (DTC) ranges between 5% and 20% and the therapeutic strategy requires further evaluations.
Aim
We therefore investigated the potential risk factors for post-treatment recurrence of intermediate-risk DTC at 1 and 3 years from diagnosis.
Methods
This retrospective observational study included 121 patients who underwent thyroidectomy for intermediate-risk DTC between January 2017 and December 2020 in two Italian centres (Endocrinology, Diabetology and Metabolism - Department of Medical Sciences, Turin and Endocrinology - Department of Translational Medicine, Novara). For each patient, demographic, biochemical and histopathological features of DTC were evaluated. Moreover, data about radioiodine (RAI) treatment were recorded and rate of tumour recurrence at 1 and 3 years from diagnosis was assessed. Multivariate logistic regression models were used to identify risk factors for tumour recurrence.
Results
Most of patients were females (M/F:1/3) with an age at diagnosis >55 years in 69.4% of cases. Overall, 92 patients (76.0%) underwent RAI treatment. This subgroup had a higher prevalence of microscopic extrathyroidal extension (mETE) of the tumour (53.3% vs 31.0%, $P=0.03$) and clinical lymph node metastasis at diagnosis (74.4% vs 45.0%, $P=0.01$), as well as higher number (5.5 $\pm$ 4.5 vs 1.8 $\pm$ 0.7, $P=0.02$) and dimensions (12.2 $\pm$ 8.4 vs 0.6 $\pm$ 0.7, $P=0.01$) of metastatic lymph nodes than patients who did not undergo RAI. Tumour relapse was observed in 18.1% and 20.7% of cases at 1 and 3 years from diagnosis, respectively, without significant differences between subgroups. Multivariate logistic regression analysis did not show any significant association between the presence of tumour relapse and DTC histopathological phenotype. The presence of clinical lymph node metastasis and radioiodine dose, a higher stimulated Tg levels in patients undergoing RAI (OR = 1.02, 95%CI 1.00-1.03, $P=0.04$) and a lower age at diagnosis (OR = 0.93, 95%CI 0.87-0.99, $P=0.03$) emerged as the only independent risk factors for 1 year-tumour relapse. Instead, the 3-year-tumour relapse was independently predicted only by the presence of 1 year-tumour relapse (OR = 15.41, 95%CI 1.12-212.10, $P=0.04$).
Discussion
In our study, mETE and clinical lymph node metastasis represent the main indicators for referring patients to RAI. Stimulated thyroglobulin levels in patients undergoing RAI, and the age at diagnosis are the only factors that independently influence the risk of recurrences in patients with intermediate-risk DTC.

Repeating thyroid FNAC: inter-observer agreement among high- and low-volume thyroid services in Naples metropolitan area and correlation with the EU-TIRADS

Lorenzo Scappaticcio[1], Pierpaolo Trimboli[2], Sergio Iorio[4], Stefania Arena[5], Nicole Di Martino[5], Annarita Palmieri[5], Katherine Esposito[4] & Giuseppe Bellastella[4]
[1]University of Campania "L. Vanvitelli", Division of Endocrinology and Metabolic Diseases, University Hospital "Luigi Vanvitelli", Naples, Italy; [2]Faculty of Biomedical Sciences, Università della Svizzera Italiana (USI), Clinic for Endocrinology and Diabetology, Lugano Regional Hospital, Ente Ospedaliero Cantonale, Lugano, Switzerland; [4]University of Campania "L. Vanvitelli", Division of Endocrinology and Metabolic Diseases, University Hospital "Luigi Vanvitelli", Naples, Italy; [5]University of Campania "L. Vanvitelli", Naples, Italy

Objective
Our institution (University Hospital "L. Vanvitelli" - Naples, Italy) is a high-volume (HV) center in Naples metropolitan area and many patients are referred there to repeat thyroid fine-needle aspiration cytology (FNAC) after initial FNAC performed in low-volume institutions (LV). The aims of the study were to 1) to examine the inter-observer agreement between HV and LV institutions according to the Italian thyroid cytology system, and 2) explore how the discordant FNAC reports were distributed among the European Thyroid Imaging and Reporting Data System (EU-TIRADS) categories.
Methods
All consecutive cases of repeated FNAC performed at University Hospital "L. Vanvitelli" from January 2016 to December 2021 were retrospectively reviewed. Cases could be included whether: a) the second FNAC diagnosis was achieved by HV cytologists blind of the previous LV report; b) HV FNAC sample was independently evaluated by two observers; c) nodule could be classified according to the EU-TIRADS by two endocrinologists reviewing ultrasound (US) blind of FNAC reports. Fleiss' kappa (κ) was used to assess the inter-observer agreement, and categorical variables were compared by chi-square testing. $P < 0.05$ was considered statistically significant.
Results
A total of 124 nodules from 124 adults (mean age 49 years; mean maximum diameter 19 mm) were evaluated. Initial FNAC reports at LV were: 4 (3.2%) TIR1c, 64 (51.6%) TIR2, 48 (38.7%) TIR3A, 8 (6.5%) TIR3B, 0 TIR4, 0 TIR5. At repeated FNAC, cytological diagnosis was unchanged in 64 (51.6%) cases including TIR2 and TIR3A results. A downgraded FNAC diagnosis (i.e., TIR2 vs TIR3A, TIR2 vs TIR3B) was observed in 36 (29%) nodules. An upgraded FNAC diagnosis (i.e., TIR3B vs TIR2, TIR3B vs TIR3A, TIR4 vs TIR3A, TIR5 vs TIR2) was recorded in 24 (19.4%) nodules. The overall FNAC reports were significantly different between the LV and HV institutions. The inter-observer agreement between LV and HV institutions was poor ($\kappa=0.13$). Changed FNAC results were significantly ($P=0.0023$) more frequent in nodules at intermediate/high-risk (i.e., EU-TIRADS 4/5) than in those at no/low risk (EU-TIRADS 2/3) [i.e., 32/48 (66.7%) and 28/76 (36.8%), respectively]. Downgraded FNAC results were significantly more frequent in EU-TIRADS 2/3 ($P=0.001$) while upgraded FNAC were present only in EU-TIRADS 4/5 (24/24, 100.0%).
Conclusion
The inter-observer agreement among LV and HV thyroid services was poor. The EU-TIRADS 4 and 5 categories included all the nodules with FNA results reclassified as higher risk (i.e., TIR3B-TIR4-TIR5) by the high-volume cytology service.

Levothyroxine dose adjustment after total thyroidectomy using an artificial intelligence methodology

Hadi Tabesh[1] & Hamid Bazrafshan[2]
[1]Department of Life Science Engineering, Faculty of New Sciences and Technologies, University of Tehran, Tehran, Iran; [2]LMU Klinikum, Ludwig Maximilian University of Munich, Munich, Germany

Introduction
Finding the optimal levothyroxine (LT4) dose regime to ameliorate the abnormally low levels of natural thyroid hormones, especially for thyroidectomized patients, is still challenging. Many researchers have studied various LT4 dosage regimen clinically; and ultimately, they proposed multiple variables affecting LT4 requirements including age, gender, body weight, body mass index (BMI), and body surface area (BSA). However, prescribing the most appropriate LT4 dose regime for different patients remains ambiguous.

Method
We attempt to adjust an appropriate LT4 dose regime for a total thyroidectomized virtual-patient by means of fuzzy logic system (FLS) methodology, an applicable artificial intelligence technique. THYROSIM 3.0© a free web application developed by UCLA Biocybernetics Laboratory, was utilized as a model of feedback control of hypothalamus-pituitary-thyroid axis. In order to evaluate patient responses to LT4 monotherapy, we simulated our total thyroidectomized virtual-patient by setting T3 and T4 secretion parameters at 1% while receiving dynamic oral LT4 dosages post-surgery. In addition, with an assumption that no supplement was administrated, the absorption rate of oral LT4 was set to 88%. Fuzzy logic controller was developed using MATLAB software ver. 2019. The discrepancies of TSH value at day n and one-step time back TSH value (at day n-1) in regard with the TSH set point were considered as the controlled variables while LT4 daily dosage was considered as the manipulated variable.
Results
According to our proposed algorithm, our developed FLS recommends a LT4 monotherapy dose regime for the assumed total thyroidectomized virtual-patient on a daily basis as presented in the following table. The resulting doses provided by FLS are indicated as "Precise FLS LT4 dose" while available doses are presented by rounding the precise dose considering 25 μg intervals in respect with the smallest increment between LT4 dosing strengths.
Conclusion
The FLS method could precisely predict the appropriate LT4 daily doses for our total thyroidectomized virtual-patient. This proposed method would dramatically declines the numbers of days in which our virtual-patient experiences thyroid hormone levels out of normal ranges while eliminating the rigorous fluctuations of the plasma levels of thyroid hormones.

Day	Recommended FLS LT4 dose (μg)	Available LT4 dose (at 25 μg intervals)	TSH error (mU/l) (calculated by FLS)
1	377.87	375	50.05
2	307.86	300	20.82
3	241.83	250	12.35
4	207.31	200	8.29
5	180.45	175	5.81
6	166.31	175	4.30

The effects of aging on thyroid C-cells in male rats

Branko Filipović[1], Vladimir Ajdžanović[2], Jasmina Živanović[1], Milica Manojlović-Stojanoski[1], Svetlana Trifunovć[1], Nataša Nestorović[1] & Branka Šošić-Jurjević[1]
[1]Institute for Biological Research "Siniša Stanković" - National Institute of Republic of Serbia, University of Belgrade, Citology, Beograd, Serbia;
[2]Institute for Biological Research "Siniša Stanković" - National Institute of Republic of Serbia, University of Belgrade, Citology, Beograd, Serbia

Thyroid C-cells, as a second type of endocrine cell population within thyroid, produce and secrete peptide hormone calcitonin (CT). This hypocalcemic hormone acts as an inhibitor of bone resorption. The aging is a complex process that alters various cellular functions. Therefore, the aim of this study was to examine the aging-related changes in the structure and function of CT-producing thyroid C-cells in male Wistar rats, using histomorphometric, ultrastructural and biochemical analysis. The investigation was performed on three groups of male rats: adult (3-months old), middle-aged (16-months old) and old (24-months old). The peroxidase-antiperoxidase method was applied for localization of CT in the C-cells. Stereological analysis was performed using Olimpus microscope (BX-51), equipped with a microcator, a motorised stage and a CCD video camera, and controlled by the newCAST stereological software package. Blood serum samples were analyzed for determination of CT, testosterone (T), calcium (Ca^{2+}) and phosphorus (P) concentrations. We found a significant increase in the volume density (Vv) of thyroid C-cells in both middle-aged and old rats, all compared to adult animals. The percentage of smaller volume range C-cells (<500 μm^3) increases, while the proportion of greater volume rang C-cells (both 500-1000 μm^3 and >1000 μm^3) markedly decreases with aging. By ultrastructural analysis we found that the average number of secretory granules *per* C-cell was significantly increased in both middle-aged and aged rats, all compared to adults. Unlike the C-cells of adult rats, these granules in older, especially in old animals, had a content of fairly low density. By the biochemical analysis, we detected a significant increase in serum CT levels, while serum T was markedly reduced in both middle aged and old rats, all in comparison with adults. Serum Ca^{2+} concentration significantly decreased in middle-aged rats compared to adults, while concentration of serum *P* was lower in both middle-aged and old rats, all related to adult group. Our findings show that aging process increases the Vv of thyroid C-cells, with a simultaneous change in percentage of cells with larger and smaller volume rang, and an increase in the number of both cell types. These changes, accompanied by modulation of the cellular ultrastructure and an increase in serum CT levels, reflect the structure and function of CT-producing thyroid C-cells in our aging model.

Thyroid nodules and glucose metabolism derangements: does sex matter?

Irene Gagliardi[1], Alberto Gobbo[1], ROBERTA ROSSI[2], Martina Rossi[2], Maria Rosaria Ambrosio[1] & Maria Chiara Zatelli[1]
[1]University of Ferrara, Dept of Medical Sciences, FERRARA, Italy;
[2]Endocrine Unit, Department of Oncology & Specialty Medicines, Ferrara, Italy

Background
Glucose metabolism derangements (GMD) and thyroid nodules (TN) are the most frequent endocrine disorders. A relationship between these conditions has been suggested, but data are still controversial and no evidence was reported regarding sex differences.
Aim
To evaluate the distribution of impaired fasting glucose (IFG), normal glucose tolerance (NGT), impaired glucose tolerance (IGT), type 2 diabetes (T2DM) and TN according to sex.
Methods
Retrospective analysis of 342 patients who underwent both an oral glucose tolerance test and a thyroid ultrasound at our Institution. Only patients with normal TSH levels, with or without replacement therapy (RT), were included.
Results
Most patients were females (78%) and were ≥50 years old. No mean age differences were found among sexes in the whole group and among the different GMD categories. IGT/T2DM rate was higher among patients ≥ 50 years old as compared to younger patients in both sexes (males 66.7% vs. 34.5%, $P<0.01$; females 43.2% vs. 20.8%, $P<0.001$). Males presented IGT/T2DM more frequently than females (54% vs. 33%, $P< 0.01$) even when considering only the 193 patients ≥50 years old (67% vs. 43%, $P< 0.01$). No differences between sexes were found concerning IFG nor insulin resistance. Total TN prevalence was 61%, with no differences between the sexes. TN prevalence assessed in GMD classes did not show any significant difference. However, within the female group, TN prevalence was significantly higher in ≥ 50 years old subjects as compared to younger females (72% vs. 51%, $P<0.01$) and in IFG group as compared to no-IFG group (79% vs. 57%, $P<0.01$). When considering only ≥50 years old females, we confirmed that TN prevalence was higher in the IFG group as compared to no-IFG group (87% vs. 63%, $P<0.01$). Median thyroid volume (TV) was found significantly higher in males as compared to females (13 vs. 10 ml, $P<0.01$) in the whole group and among the different GMD categories, except for the IFG group.
Conclusions
Age was confirmed as a risk factor for TN occurrence and GMD. In males, IGT/T2DM prevalence is higher, but no relationship was found with TN occurrence. Furthermore, they showed higher TV in most of GMD categories. Older females present more frequently TNs that occurred more often in patients with IFG. More studies are needed to further explore the relationship between TN and glucose metabolism disorders in order to identify higher-risk population sub-groups.

Role of irisin as modulator of antioxidants in two models of non-thyroidal illness syndrome

Carmine Bruno[1], Edoardo Vergani[1], Emmanuele Capobianco[1], Maria Anna Nicolazzi[4], Angela Maria Rita Favuzzi[2], Andrea Silvestrini[3], Elisabeta Meucci[3], Nicola Panocchia[1] & Antonio Mancini[1]

[1]Università Cattolica del Sacro Cuore, Medicina e Chirurgia Traslazionale, Rome, Italy; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Scienze Cardiovascolari, Rome, Italy; [3]Università Cattolica del Sacro Cuore, Scienze Biotecnologiche di Base, Cliniche Intensivologiche e Perioperatorie, Rome, Italy

Non-thyroidal-illness syndrome (NTIS) is present in chronic diseases and considered an adaptive mechanism. However oxidative stress is linked to NTIS in a vicious circle, due to deiodinases alteration and negative effects of low T3 on antioxidant levels or activity. Moreover there is a tissue-specific thyroid hormone transport, receptor binding and hormone metabolism. Muscle is one of the main targets of thyroid hormone; on the other hand, Irisin is a novel discovered myokine firstly identified for its ability to induce browning of white adipose tissue, increase energy expenditure and finally protect against insulin resistance. Unconclusive data have been reported about the role of Irisin in chronic diseases such as chronic heart and renal failure; moreover, no correlation between Irisin and antioxidant status has been investigated. Therefore, we performed a case-control study with the primary end-point to evaluate Irisin levels in two models of NTIS, such as chronic heart failure and chronic kidney disease during haemodialytic treatment; the secondary end-point was the correlation with total antioxidant capacity in order to establish a possible role of Irisin in the modulation of antioxidant systems. Two groups of patients were selected. Group A included Chronic heart failure patients ($n=18$; Aged 70.22 $\pm$ 2.78 ys; BMI $\pm$ 27.75 $\pm$ 1.28 Kg/m^2); Group B included Chronic Kideny Disease patients ($n=29$; Aged 67.03 $\pm$ 2.64; BMI 24.53 $\pm$ 1.01); Finally, 11 normal subjects have been assumed as controls. Irisin has been evaluated by ELISA method and Total Antioxidant (TAC) capacity by spectrophotometric method. Irisin was significantly higher in Group B vs A and controls (Mean $\pm$ SEM: 20.18 $\pm$ 0.61 ng/ml vs 2.77 $\pm$ 0.77 and 13.06 $\pm$ 0.56, respectively; $P<0.05$); a significant correlation between Irisin and TAC was observed only in group B.
These preliminary data suggest a possible role of Irisin in modulation of antioxidant systems in two chronic syndromes characterized by low T3 syndrome, but with differential pattern in the two models studied. Further studies are needed to confirm these preliminary observations. That can be the basis for a longitudinal investigation, to assess a prognostic role of Irisin evaluation and possible therapeutical implications

Radioactive iodine treatment in thyrotoxicosis- audit, Southampton general hospital

Mohammed Salloum, Ma'en Al-Mrayat, Francis Sundram, Jana Bujonova, Ziauddin Saad, Nemia Pilobello, Diane Bray, Alicja Knysak & Philip Newland-Jones
University Hospital Southampton, Department of Endocrinology and Department of Nuclear Medicine, Southampton, United Kingdom

Hyperthyroidism is common and in iodine-sufficient parts of the world the prevalence of overt hyperthyroidism is estimated to be 0.2% to 1.3%. The treatment options include antithyroid medication (ATD), thyroid surgery, or Radioactive iodine (RAI). The latter is increasingly used as a first line definitive treatment for hyperthyroidism. We reviewed the outcomes of patients who received RAI at our tertiary nuclear medicine department over a 4-year period (May 2015 to Dec 2019) and who are under the care of our unit to ensure we have relevant follow up data. We identified 146 Patients who received RAI: 119 Female (82%), 27 Male (18%) with a mean age of 51.3 years. 45.9 % of patients had Grave's Disease, 11.7% had single toxic adenoma (STA), 40.4% had Toxic Multinodular Goitre (MNG) and 2% had mixed disease (MNG & Graves). Outcome post-RAI: 129 patients (88.3%) achieved remission from thyrotoxicosis after a single dose. 7.5% (5 patients with Graves' disease -GD, and 6 patients with MNG) needed 2 doses of RAI to achieve remission. 5 patients (3.4%; 3 with MNG, one patient with mixed disease, and one with GD) did not respond after 2 doses of RAI and were still on ATD. The remission rates after the first dose per diagnosis were: 91 % for GD, 83 % for MNG, 66% for mixed disease, and 100% for STA. 74.6% of the treated patients developed permanent hypothyroidism after responding to RAI. The risk of developing hypothyroidism was higher in GD patients who responded to treatment, of who 95.5% developed hypothyroidism, followed by patients who had STA (82.3%) with only 47.5 % of patients with MNG developing subsequent hypothyroidism. The average time to develop hypothyroidism after RAI was 3.6 months, however, this tended to be longer with patients who had MNG. In conclusion, RAI is an effective treatment for thyrotoxicosis, which is associated with a high rate of hypothyroidism and a small rate of failure. Our Patients were closely followed up post-treatment as per standard recommendations.

Unexpected alterations in thyroid status: a case of alemtuzumab-induced Graves' disease with fluctuating course

Bárbara Filipa Araújo[1], Mariana Lavrador[1], Cátia Araújo[1], Ana Ribeiro[1], Sandra Paiva[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Coimbra, Portugal

Introduction
Alemtuzumab is a humanized anti-CD52 monoclonal antibody approved for the treatment of relapsing−remitting multiple sclerosis (RRMS). Through an immune reconstitution mechanism, it leads to thyroid autoimmunity in 35% of cases, with Graves' disease (GD) being the most common presentation. Alemtuzumab-induced GD exhibits distinctive clinical and immunological features, with rarely reported cases of fluctuating thyroid status with documented both blocking (TBAb) and stimulating (TSAb) TRAb.
Case description
A 48-year-old woman, diagnosed with RRMS at the age of 33, underwent the first and second cycle of alemtuzumab in 2019 and 2020, respectively. Neither the patient nor her relatives had history of thyroid disease. Clinical and medication history were otherwise unremarkable. Almost 12 months after treatment, she complained about exacerbated fatigue, and was referred to the endocrinology appointment for altered function tests. Clinical examination revealed a non-pulsatile goiter, with no evident signs of orbitopathy (Clinical Activity Score 0). Laboratory workup showed TSH 0.004 mUI/ml (0.4-4), fT4 2.2 ng/dl (0.7-1.5), fT3 5.1 pg/ml (1.8-4.2), TRAb 110 U/l (<1.0) TSAb 40 U/l (<0.1) and anti-TPO 916 UI/ml (<5.6). Thyroid ultrasound excluded nodules. She started treatment with methimazole (MMI) 5 mg/day. Two months after, analytical follow-up revealed TSH 0.29 mUI/ml, fT3 2.1 pg/ml, fT4 0.60 ng/dl and was told to stop MMI. The patient was reevaluated in 2 months, under no therapy, with worsening of fatigue and palpebral oedema, with TSH 93 mUI/ml, fT4 <0.40 ng/dl, fT3 $<$ 1.0 pg/ml, TRAb 98 U/l, TSAb 7.3 U/l. At this point she started levothyroxine (LT4) with progressive doses up to 75 micrograms/day. Six months later, TSH was <0.004 mUI/ml, fT4 1.4 ng/ml, TRAbs 3.1 U/l, TSAb 2.7 U/l and LT4 was stopped. Thereafter, thyroid function kept switching unexpectedly between hyper and hypothyroidism, and was finally proposed to treatment with radioiodine (RAI). Six weeks after RAI, with no other therapy, TSH was 68 mUI/ml, fT4 $<$ 0.40 ng/dl, TRAbs 10 U/l, TSAb 7.3 U/l, and LT4 was re-started in progressive doses.
Conclusion
We present a case of alemtuzumab-induced GD with unexpected fluctuations from hyperthyroidism to hypothyroidism, not explained by omission or changes in therapy. There was evidence of periods were TRAb level were rising but TSAb levels were decreasing, which may be explained by the presence of TBAb in circulation. Our case report emphasizes the need for close monitoring of thyroid function in patients with alemtuzumab-induced GD, as maintaining euthyroidism in these patients may represent a challenge.

Thyroid incidentalomas: which features in internal medicine?

Asma Tekaya, Asma Kefi, Khaoula Ben Abdelghani, Mounira El Euch, Cyrine Sassi, Sami Turki & Ezzedine Abderrahim
Charles Nicolle Hospital, Department of Internal Medicine A, Tunis, Tunisia

Background
Thyroid nodules (TN) are common. Their prevalence increases with age. A thyroid incidentaloma (TI) is defined as a non-palpable TN detected fortuitously during a radiological investigation performed for reasons unrelated to the thyroid gland. Although they are mostly benign, the risk of malignancy is estimated from 7% to 15% of nodules. The objective of this study is to investigate the characteristics of TI in a cohort of patients admitted in an internal medicine department.

Methods
A descriptive retrospective study identifying 48 records of TN in patients hospitalized in an internal medicine department between 2016 and 2021. Then we studied cases of TI.
Results
Among the 48 cases of TN, 50% were incidentalomas. There was a clear female predominance (gender ratio: 0.17). The mean age was 50.8 years old (ranging between 29 and 73). The patients had a medical history of chronic renal failure in 6 cases, Systemic Lupus in 4 cases, Sjögren syndrome in 3 cases, Crohn disease in 1 case, sarcoidosis in 1 case, myelodysplasic syndrome in 1 case and AL amyloidosis in 1 case. TI were mostly detected by neck ultrasound. Only 12.5% were discovered by chest CT scan. These investigations were performed in order to examine lymph nodes (45.83%), parathyroid glands (33.33%) lung parenchyma (12.5%) or parotid glands (8.33%). Ultrasonography, performed in all patients, showed: a solitary nodule (41.7%), a multinodular goiter (29.2%) and lymphadenopathy (14.6%). According to the European Thyroid Imaging Reporting and Data System (EU-TIRADS), TN were classified as EU-TIRADS 2 (4.17%), EU-TIRADS 3 (75%), EU-TIRADS 4 (12.5%), and EU-TIRADS 5 (8.33%). Thyroid function test was abnormal in 5 cases: 3 cases of hypothyroidism and 2 cases of hyperthyroidism. Fine needle aspiration biopsy, performed in 6 patients, revealed: benign cytology in 3 cases, atypia of undetermined significance (oncocytic tumor) in 1 case, cytology suspicious for malignancy in 1 case, and was unsatisfactory in 1 case. Thyroidectomy was conducted in 9 cases, revealing a malignant origin in 2 patients (papillary carcinoma in both cases). Therapeutic modalities were surgery (29.2%), radioactive iodine (14.6%) and monitoring (54.2%).
Conclsion
In our study, incidentalomas were discovered in 50% of TN cases. Among them, 2 cases were malignant (8.33%). Thus, screening for thyroid nodules, by cervical ultrasound, seems necessary for internal medicine patients, so as not to miss thyroid cancer, mainly at a subclinical stage.

Thyroid dysfunction in patients presenting metabolic syndrome

Ajay Sinha[1], Rajeev Ranjan[2] & R K Jha[3]
[1]NMCH, Medicine, PATNA, India; [2]Chest Clinic, Chapra, India; [3]DMCH, Medicine, Darbhanga, India

Introduction
Metabolic syndrome (MetS) consists of a constellation of metabolic abnormalities which include central obesity, hyperglycemia plus insulin resistance, high triglycerides plus low high-density lipoprotein (HDL) cholesterol and hypertension. A developing collection of proof proposes that metabolic condition is related to endocrine problems including thyroid brokenness. Thyroid brokenness in metabolic condition patients might additionally add to cardiovascular illness hazard subsequently expanding mortality. This study was done to survey thyroid capacity in metabolic disorder patients and assess its relationship with the parts of metabolic condition.
Methods
This cross-sectional study was carried out among metabolic syndrome patients at selected hospital in Bihar from June 2020 to March 2021. We selected 346 patients who satisfied National Cholesterol Education Program-Adult treatment Panel III models. Anthropometric estimations (height, weight, waist circumference) and circulatory strain were taken. Fasting blood tests were analysed to gauge glucose, triglyceride (TG), high thickness lipoprotein (HDL) cholesterol and thyroid chemicals. Patients were supposed to be euthyroid assuming all thyroid chemical levels fell inside the reference range [TSH: 0.47-5.0 mIU/l; FT4: 0.71-1.85 ng/dl]. Subclinical hypothyroidism (SCH) was thought of if TSH $>$5.0 mIU/l. Free T4 is inside ordinary reference esteem (0.71-1.85 ng/dl). Unmistakable hypothyroidism was characterized as TSH $>$ 5.0 mIU/l and free T4 $<$ 0.71 ng/dl.
Results
The study population contained 79 males and 267 females, with a mean period of 42.61 $\pm$ 9.13 years. The normal weight file was 26.37 $\pm$ 3.78 kg/m2. The vast majority of the female members were fat, and introduced focal weight. Thyroid brokenness was seen among 162 subjects with a metabolic disorder. The significant thyroid brokenness i.e., subclinical hypothyroidism which was trailed by clear hypothyroidism. Thyroid brokenness was normal among females when contrasted with males however was not measurably critical. HDL cholesterol had uncovered a negative connection with TSH level. Fatty substances uncovered a huge negative relationship with free T4 and a positive connection with TSH levels.
Conclusion
The prevalence of the metabolic condition is expanding everywhere. Thyroid brokenness, unmistakably subclinical hypothyroidism has been noticed more regularly in metabolic condition patients than the general population. The current review distinguishes thyroid brokenness in metabolic condition patients. Subclinical hypothyroidism was the commonest followed by obvious hypothyroidism. Also, thyroid capacity is related to certain parts of metabolic disorder (high thickness lipoprotein cholesterol and triglycerides). Further review is expected to assess the system of this relationship.

Assessing cognitive functions among elderly patients with subclinical hypothyroidism

Anand Shankar[1], Shaibal Guha[2], Amit Kr Das[3] & Subhash Kumar[4]
[1]Shankar Diabetes Care And Research, Diabetes, PATNA, India; [2]Positive Health Center, Patna, India; [3]SHMC Muzaffarpur, Muzaffarpur, India; [4]Diabetes and Obesity Care Center, Diabetes, Patna, India

Background
The consequences of overt hypothyroidism on the central nervous system are well known. Interestingly, there is less proof in regards to the impacts of subclinical hypothyroidism (SCH) on the cognitive functions among elderly subjects. Studies from various countries including India have shown a variable association between SCH and cognitive dysfunction. This study planned to survey the event of cognitive impairment among the older Indian subjects who were introducing subclinical hypothyroidism.
Methods
The participants were 126 elderly subjects (age $>$ 60) with SCH and a similar number of age-matched euthyroid controls. Subclinical hypothyroidism was defined as a serum TSH level of more than 4.0 mIU/l with normal FT3 and FT4. Members were met by a solitary onlooker. Cognitive capacity was evaluated by Mini-Mental State Examination (MMSE) and clock drawing test (CDT). MMSE has the most extreme score of 30 and scores $\leq$ 24 are demonstrative of cognitive impairment. For CDT a score of 3 addresses a cognitive shortfall, while a score of 1 or 2 is viewed as typical. Information was dissected by utilizing SPSS and *P*worth of $<$ 0.05 was huge.
Results
The mean age of the patients' group was 66.3 years and BMI 27.0 kg/m^2 which were tantamount to controls who had a mean time of 68.1 years (*P*-0.17) and mean BMI 26.0 kg/m^2 (*P*-0.24). Any remaining benchmark factors including sex proportion, co-morbidities, family background of dementia, smoking, liquor use, schooling and exercise were likewise similar in both the groups. The mean TSH was 7.7 in the understanding group and 2.8 in the control bunch (*P*-$<$0.06). The mean MMSE score was 26.4 in the understanding group and 27.7 in controls (*P*-0.35). The patients had a mean CDT of 2.31 and control 2.41 (*P*-0.67). Cognitive impairment by MMSE (score $\leq$ 23) was seen in 28.2% of patients and 26.55% of controls (*P*-0.65), additionally the cognitive impairment by CDT (score of 3) was available in 31.3% of patients and 29.8% of controls (*P*-0.48).
Conclusion
Hypothyroidism is known to cause a decrease in cognitive capacities. Studies have tended to the relationship of cognitive impairment with subclinical hypothyroidism with variable outcomes exceptionally in old subjects. In the current review, we have observed that the commonness of cognitive impairment in old subjects with SCH is like the age-matched controls. Subsequently, the expected advantage of LT4 treatment, whenever involved with a point of working on cognitive capacities in this vulnerable group, becomes suspicious.

Thyroid pyramidal lobe detection by ultrasound in 500 consecutive patients

Emin Mammadov
Reteaua de Sanatate Regina Maria, Outpatient, Bucharest, Romania

Background
The thyroid pyramidal lobe (TPL) represents a normal anatomical variation of the thyroid gland. Intraoperative TPL identification is of paramount significance, taking into account that the remnant TPL leads to higher thyroglobulin, could contain thyroid carcinoma foci and lead to recurrence.
Methods
We conducted a prospective single-center, single-operator study to identify TPL in 500 consecutive patients undergoing thyroid ultrasound for any indication. We extended the standard technique to actively search for TPL. The findings reported

were presence and site of the TPL (right vs left), presence of incidentally discovered nodules in TPL and thyroglossal duct cysts (TGDC). We excluded patients who underwent thyroid surgery or radioiodine therapy.
Results
Of the 500 consecutive patients, TPL was identified in 113 (22.6%), 4 had TGDC, 2 had hemiagenesis of the left thyroid lobe. Fourty-nine patients (43.4%) presented with left-sided TPL, 64 (56.6%) with right-sided. In 4 patients (3.5%), we identified incidental asymptomatic nodular lesions within TPL.
Conclsions
We suggest to routinely screen for thyroglossal duct remnants (TPL or TGDC) during thyroid ultrasound. This may reduce the rate of postoperative remnant TPL, obtain lower postoperative thyroglobulin levels and potentially lead to less frequent radioiodine therapy indication. Incidental discovery of thyroid nodules within TPL could also play important role in patient management. We observed a higher prevalence of the right-sided TPL in our study, which differs from previous reports stating more frequently left-sided TPL.

Resistance to methimazole in a patient with Graves' disease

Joao Roque[1], Cristiana Costa[1], Pedro Marques[1] & Dinis Reis[1,2]
[1]Hospital de Santa Maria - Centro Hospitalar Universitário Lisboa Norte, Endocrinology, Diabetes and Metabolism, Lisbon, Portugal; [2]Universidade de Lisboa, Faculty of Medicine, Lisbon, Portugal

Introduction
Graves' disease (GD) is caused by TSH receptor antibodies (TRAbs) which stimulate thyroid activity. Initial treatment usually relies on antithyroid drugs (ATDs), mainly methimazole, carbimazole or propylthiouracil (PTU). These drugs inhibit the enzyme thyroperoxidase, blocking the synthesis of T3 and T4. Definitive therapeutic options include radioactive iodine and total thyroidectomy which are usually reserved for patients who do not tolerate or respond to ATDs, or for those who relapse or do not achieve remission after a course of ATDs. Here, we present a GD patient who suffered from remarkable resistance to ATDs requiring an early definitive therapy in order to solve her thyrotoxicosis.
Clinical case
A 57-year-old female presented with a 1-year history of palpitations, increased sweating, anxiety, insomnia and weight loss. Laboratory work-up confirmed hyperthyroidism: TSH $<$ 0.01 mIU/l, FT4 2.33 ng/dl (0.7-1.9). The titration of TRAbs was 8.55 IU/l ($<$ 2.13) confirming the diagnosis of GD. Methimazole was commenced and progressively titrated up to 70 mg/day (i.e. fourteen 5 mg-tablets) , which the patient has reassured us to be fully compliant with. Nevertheless, she remained in hyperthyroidism, and under methimazole 70 mg/day her thyroid function tests were: TSH $<$ 0.005 mIU/l, FT4 2.56 ng/dl and FT3 9.76 pg/ml (2.0-4.4). This prompted us to consider an early definitive therapy, and the patient was then proposed for total thyroidectomy. Lugol's solution was added to her ATD therapy, and her thyroid function has improved over the following two weeks, with FT4 and FT3 serum levels dropping from 2.00 and 9.76 down to 1.57 and 4.39 ng/dl, respectively. After controlling her thyrotoxicosis, she underwent an uneventful total thyroidectomy.
Discussion
This case highlights the uncommon, but possible, scenario of resistance to high-dose ATD therapy in patients with GD. In these cases, poor compliance to therapy should always be suspect, but other possible explanations include: i) decreased intestinal absorption; ii) impaired thyroid uptake; iii) greater metabolism and excretion of ATDs. High dietary intake of iodine can also impair the action of ATDs, and may further contribute to resistance to high-dose ATDs. Lugol's solution inhibits thyroperoxidase through Wolff-Chaikoff effect, thus blocking the synthesis and release of T4 and T3, as well as it reduces the vascularization of the thyroid gland. Hence, Lugol's solution must be used in GD patients prior to thyroidectomy, particularly in patients unresponsive to ATDs, as illustrated here.

Pazopanib-induced hypothyroidism in a patient with adrenal metastasis of renal cell carcinoma

Cristiana Gomes da Costa, João Roque & Dinis Reis
Hospital Santa Maria, Endocrinology, Lisbon, Portugal

Introduction
Pazopanib is a tyrosine kinase inhibitor (TKI) considered to be a first-line treatment in adult patients with metastatic clear cell renal cell carcinoma (ccRCC). Thyroid dysfunction, namely hypothyroidism, is now recognized as being an important but potentially manageable side effect induced by such therapy. With this case we aimed to recall an endocrinological complication that can emerge during treatment with TKIs and highlight the importance of a thorough follow-up.
Case report
A 51-year-old man, whose past history and family history were irrelevant, was diagnosed with stage 1 ccRCC in 2001. A left radical nephrectomy was performed. In 2013 a lesion with 24 mm in diameter was first recognized in his right adrenal. In 2015 he was referred to the endocrinology outpatient clinic due to an increase in the lesion diameter to 51 mm, the CT scan showed a density of $+30.9$ Hounsfield Units. Laboratory findings excluded autonomous hormone secretion. Due to suspicious radiological findings and rapid tumor growth without evidence of hormonal hypersecretion, a biopsy of the adrenal mass was performed, revealing a ccRCC metastasis. The patient was submitted to a right adrenalectomy and started pazopanib 800 mg daily as adjuvant therapy, along with hydrocortisone and fludrocortisone as substitution therapy. He developed primary hypothyroidism 16 months after he started pazopanib. Anti-thyroid antibodies were normal, and the hypothyroidism was interpreted in relation to pazopanib. Furthermore, due to progressive disease pazopanib was substituted by another drug, however the hypothyroidism did not remit, and the patient remains under levothyroxine substitution therapy at the dose of 50 mg daily for 5 years now.
Conclsion
- √ This case highlights the tendency of ccRCC for adrenal metastases. These metastases may appear several years after the initial diagnosis, in our patient 12 years after the initial diagnosis.
- √ Hypothyroidism is a known adverse effect of pazopanib and therefore periodic surveillance of thyroid function is required. Pazopanib-induced hypothyroidism was recorded in most series in less than 12% of renal cell carcinoma patients.
- √ Pazopanib-induced hypothyroidism in this patient seems to be permanent.
- √ Many mechanisms have been appointed as possibly responsible for the hypothyroidism in relation to TKIs, such as thyroid cell atrophy due to the inhibition of vascularization, drug-induced thyroiditis, thyroid atrophy, deficient hormone production due to anti-thyroperoxidase activity, interference in iodine caption or modification in the RET2 gene. More studies are needed to characterize these mechanisms.

Autoimmune thyroiditis, quality of life and underlying symptomatology

Miguel Pereira[1], Celestino Neves[1,2,3], Joao Sergio Neves[1,4], Juliana Gonçalves[1,2] & Davide Carvalho[1,2,3]
[1]Department of Endocrinology, Diabetes and Metabolism, São João University Hospital Center, Porto, Portugal; [2]Faculty of Medicine of University of Porto, Porto, Portugal; [3]Institute for Research and Innovation in Health (i3S), University of Porto, Porto, Portugal; [4]Department of Surgery and Physiology, Faculty of Medicine of University of Porto, Porto, Portugal

Introduction
Hypothyroidism caused by autoimmune thyroiditis (AIT) is a disease that can originate physical, psychological and behavioral symptoms. Quality of life (QoL) and psychopathologial symptoms in thyroid diseases and its relation with thyroid function remains unclear. In hypothyroidism there is a discussion about the normal range of TSH and Free T4 values and in which way its fluctuation influences the patient in its daily activities.
Objective
To analyze the QoL and physical and psychological symptomatology of patients with AIT.
Methods
We analyzed a sample of 145 patients with AIT with a mean age of 54.4 $\pm$ 15.3 years, 89.7 % were female and 63.4 % were married. We assessed thyroid function tests, thyroid antibodies, lipid profile, high-sensitivity C-reactive protein, B12vitamin, folic acid and applied several questionnaires, namely: the Thyroid Dependent Quality of Life questionnaire (ThyDQoL), the Thyroid Symptom Rating Questionnaire (ThySRQ), the Thyroid Treatment Satisfaction Questionnaire (ThyTSQ) and the Brief Symptom Inventory (BSI). Statistical analysis was performed with the One-way ANOVA test and Pearson's correlation test. P values $\leq$ 0.05 were considered as statistically significant.
Results
In this sample we found that patients had a mean BMI of 28.4 $\pm$ 5.2 Kg/m^2 and TSH 2.69 $\pm$ 8.48 µUl/ml, FT4 1.15 $\pm$ 0.40 ng/dl. Patients reported a mean QoL

value of -2.11 points (range from -9 to 1). In regard to the ThySRQ, 46.2 % of patients have noticed at least moderately memory problems, 50.4% of patients reported at least being moderately tired and 62.7 % showed some kind of depressed feelings. In concern with ThyTSQ, 83.5 % demonstrated being satisfied with treatment and 82 % believes that treatment is working well. In terms of correlations, we found positive correlations between TSH and weight gain ($r=0.19$;$P=0.02$) and loss of appetite ($r=0.27$;$P=0.001$). Free T3 correlated negatively with depression ($r=-0.22$;$P=0.009$), skin problems ($r=-0.19$;$P=0.01$) and loss of appetite ($r=-0.22$;$P=0.007$). Antithyroglobulin antibodies were negatively correlated with colder body sensation ($r=-0.17$;$P=0.04$) and antiperoxidase antibodies correlate itself with voice problems ($r=-0.22$;$P=0.01$).

Conclusions

In this study we can clearly see that despite the normal range of the TSH this disease negatively influences the QoL in AIT patients. We also noticed that there are certain symptoms that suffer a more direct influence of thyroid function. Further studies are needed to analyze the symptomatology that contributes to worsening of the QoL in these patients.

cGMP is not involved in thyroid cancer cell death

Sara D'Alessandro[1,2], Elia Paradiso[1], Clara Lazzaretti[1], Samantha Sperduti[1,3], Lara Baschieri[1,2], Elisa Mascolo[1], Neena Roy[1], Claudia Anzivino[1,3], Sara Righi[1], Daniele Santi[1,4], Giulia Brigante[1,4], Manuela Simoni[1,3,4] & Livio Casarini[1,3]

[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]International PhD School in Clinical and Experimental Medicine (CEM), University of Modena and Reggio Emilia, Modena, Italy; [3]Center for Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; [4]Department of Medical Specialties, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy

Introduction

Type 5 phosphodiesterase (PDE5) inhibitors (PDE5i) lead to intracellular cyclic-guanosine monophosphate (cGMP) increase and are used for clinical treatment of erectile dysfunction. Studies found that cGMP may up/downregulate the growth of certain endocrine tumor cells, suggesting that the use of PDE5i could impact the risk of certain tumors, such as colorectal cancer.

Aim

We evaluated if PDE5i may impact thyroid cancer cell growth *in vitro*.

Materials and methods

We investigated caspase 3 activation by bioluminescence resonance energy transfer (BRET), in malignant (K1) and benign (Nthy-ori 3-1) thyroid cell lines, expressing a specific biosensor. Cells were treated with the PDE5i vardenafil or the cGMP analog 8-br-cGMP (nM-μM range) and reactions stopped at different time-points (0-24 h). The efficacy of vardenafil and 8-br-cGMP in inducing intracellular cGMP increase was evaluated by BRET, using a specific biosensor. The COS7 cell line served as a reference. Cleavage of caspase 3 was further evaluated by Western blotting, as well as phosphorylation of the proliferation-associated extracellularly regulated kinases 1 and 2 (ERK1/2), while nuclear fragmentation was evaluated by DAPI staining. Cell viability was investigated using 3-(4.5-dimethylthiazol-2-yl)-2.5-diphenyltetrazolium bromide (MTT) assay. Positive controls for cell death were set by treating cells with thapsigargin. Experiments were performed in triplicates and results analyzed by Kruskal-Wallis test ($P<0.05$ significance level).

Results

BRET experiments revealed that both vardenafil and 8-br-cGMP effectively induced dose-dependent intracellular cGMP increase ($P<0.05$) in both the K1 and Nthy-ori 3-1 cell lines, as well as in reference COS7 cells. However, no caspase 3 activation occurred between PDE5i-treated vs -untreated cells, at all concentrations and time-points tested ($P\geq0.05$), in contrast to the results obtained using thapsigargin ($P<0.05$). These results match those obtained upon cell treatment with 8-br-cGMP, which failed in inducing caspase 3 clevage in all the cell lines ($P\geq0.05$). Moreover, they reflect the lack of caspase 3 cleavage, evaluated by Western blotting, as well as missing nuclear fragmentation. Interestingly, the modulation of intracellular cGMP levels with vardenafil or the analog did not impact cell viability of both malignant and benign thyroid tumor cell lines, nor the phosphorylation of ERK1/2 ($P\geq0.05$)
.

Conclusions

This study demonstrated that cGMP-mediated signals are not linked to cell viability and death in K1 and Nthy-ori 3-1 cell lines, suggesting that the use of PDE5i could not impact the growth of thyroid cancer cells.

Novel central actions of thyroid hormone in the control of body temperature

Julia Maier[1], Mehdi Pedaran[1], Anna Lena Cremer[2], Heiko Backes[2] & Jens Mittag[1]

[1]University of Lübeck, CBBM, Molecular Endocrinology, Lübeck, Germany; [2]Max-Planck-Institute for Metabolism Research, Multimodal Imaging of Brain Metabolism, Köln, Germany

The ability of thyroid hormones to regulate body temperature is well established. While the active hormone T3 can act peripherally to induce thermogenesis in fat and muscle, it also acts centrally in the brain to increase body temperature through the sympathetic nervous system. Most remarkably, recent studies show that T3 treatment in mice causes an elevated body temperature even at 10°C, far below thermoneutrality, suggesting that the T3 effect constitutes pyrexia rather than hyperthermia. Therefore, mice with induced hyperthyroidism seem to have an altered temperature set point in the brain; however, the precise neuroanatomical substrate has remained unknown. The goal of this research project is to identify the brain region where T3 acts to regulate the body temperature setpoint. Using PET/CT scans of mice treated with T3, several candidate regions have been identified. Among these, the Zona Incerta (ZI), has been associated with the control of body temperature previously. To test whether this region constitutes the missing link between the central T3 effect and pyrexia, we studied the ZI using well-established mouse models. Preliminary data show no difference in cell number of dopaminergic neurons in the ZI when comparing offspring of wild-type mice to those of mice with a mutation in thyroid hormone receptor α1, indicating no developmental effect of thyroid hormones on ZI dopaminergic neurons. However, further studies will be needed to illuminate the acute actions of T3 in this enigmatic brain region.

Serum neopterin levels in graves' disease

Goknur Yorulmaz[1], Sinem Gurcu[2], Evin Kocaturk[3], Hatice Hamarat[4], Melisa Sahin Tekin[5] & Ozkan Alatas[3]

[1]Eskisehir Osmangazi University, Endocrinology, Turkey; [2]Eskisehir City Hospital, Pharmacy, Turkey; [3]Eskisehir Osmangazi University, Biochemistry, Turkey; [4]Eskisehir City Hospital, Internal Medicine, Turkey; [5]Eskisehir Osmangazi University, Internal Medicine, Turkey

Aim

Neopterin has been found to be associated with disease activity in various infectious, inflammatory, and autoimmune diseases. It is an indicator of immune response as it is released after activation of monocytes and macrophages by IFN-γ. It was aimed to measure neopterin levels in Graves' disease, which is a T cell-mediated autoimmune disease of the thyroid gland.

Materials and Methods

Twelve healthy individuals (6 women, 6 men), 13 Graves' disease patients (7 women, 6 men) who applied to the endocrinology outpatient clinic and followed up were included in the study. Serum neopterin concentrations were analyzed with commercial enzyme-linked immunosorbent assay (ELISA) kits (Human Neopterin Assay Kit, Bioassay Techonology Laboratory, China) according to manufacturer's instructions.

Results

The mean age of healthy individuals was 42.17 ± 11.52 years, and the mean age of Graves' patients was 41.31 ± 9.85 years. TSH levels were found to be lower and free T3 and free T4 levels were found to be higher in Graves' patients compared to controls ($P<0.05$). Likewise, serum neopterin levels were high (9.299 ± 6.271 nmol/l: Graves', 1.432 ± 1.304 nmol/l: control, $P<0.05$, respectively).

Conclusion

In our study, serum neopterin levels of Graves' disease patients were found higher than the control group. There is generally a significant relationship between neopterin and IFN-γ concentrations. It has been observed that neopterin increases

in body fluids, especially during the activation periods of diseases in which cellular immunity plays a major role in the pathogenesis. The most potent stimulator of neopterin synthesis is IFN-γ, which is a Th1 cytokine, and it has been suggested that serum neopterin levels are a sensitive marker of endogenous IFN-γ release. In our study, a similar result with the literature was found, such as the detection of high neopterin levels in immune system-related diseases.

Simulation of the plasma level of thyroid hormones for a total thyroidectomized virtual-patient treated by BMI and BSA-based LT4 monotherapy dose regimen

Hadi Tabesh[1], Mostafa Hemmati[1] & Hamid Bazrafshan[2]
[1]Department of Life Science Engineering, Faculty of New Sciences and Technologies, University of Tehran, Tehran, Iran; [2]LMU Klinikum, Ludwig Maximilian University of Munich, Munich, Germany

Introduction
Several levothyroxine (LT4) monotherapy dose regimen have been already proposed by different medical scientists which may result in various daily LT4 doses. Comparing the consequences of such dose regimen are rather difficult since they have to be applied on either the same patient or a large study groups. Therefore, a straight forward method would be to simulate the plasma level of thyroid hormones of virtual-patients treated by various dose regimen.
Method
In this study, the resulting plasma levels of thyroid hormones were compared for a total thyroidectomized virtual-patient treated by BMI and BSA-based LT4 monotherapy dose regimen adopted from Elfenbein *et al*., 2016 and Al-Dhahri *et al*., 2019 respectively. Our virtual-patient was considered as a 37 years old male with 72 kg weight and 170 cm height. The BMI of this patient would be 24.9 kg/m^2 while the calculated BSA based on DuBois & DuBois method is 1.83 m^2. In order to evaluate patient responses to LT4 monotherapy dose regimen, we simulated our total thyroidectomized virtual-patient by setting T3 and T4 secretion parameters at 1% using THYROSIM 3.0 while receiving static oral LT4 dosages post-surgery. In addition, with an assumption that no supplement was administrated, the absorption rate of oral LT4 was set to 88%.
Results
Considering the proposed dose regimen by BMI and BSA our virtual-patient should receive static LT4 dose of 1.9 and 1.4 μ g/kg respectively. Parameters to compare these two dose regimen for a period of 30-days are presented in the following table.
Conclusion
the BMI dose regime shows some superiority over BSA method especially in terms of lower time to reach normal TSH level and the discrepancy between TSH at day 30 and normal TSH. At the end of 30-days treatment period our virtual patient experiences a plasma T4 level of 86.56 and 68.26 μg/l if administering LT4 doses based on BMI and BSA methods.

Parameter	BMI	BSA
Time to reach normal TSH level (days)	15	30
Time to reach normal T3 level (days)	3	4
Time to reach normal T4 level (days)	4	5
TSH out of normal range (days)	14	30
T3 out of normal range (days)	2	3
T4 out of normal range (days)	3	4
Discrepancy between TSH at day 30 and normal TSH (=1.93)	1.93	7.11
Discrepancy between T3 at day 30 and normal T3 (=1.35)	-0.51	-0.59
Discrepancy between T4 at day 30 and normal T4 (=78.21)	8.35	-9.95

Rare presentation of thyrotoxicosis post CoVID-19 vaccination in acute setting

Megha Mohan[1], Bashir Mahamud[2], Janessa Bell[2], Khash Nikookam[2], Belayet Hossain[2], Hassan Rehmani[2] & Gideon Mlawa[2]
[1]Queen's Hospital, Acute Medicine, London, United Kingdom; [2]Queen's Hospital, London, United Kingdom

Coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome coronavirus 2 has led to unparalleled burden on national and global healthcare systems. Vaccines were viewed as way of combating Covid 19 pandemic. This led to development and implementation of vaccination programmes worldwide. Several vaccines have been approved for use in worldwide including Pfizer-BioNTech, Oxford-AstraZeneca vaccine and Moderna vaccine. Disturbingly, the speed at which these vaccines been approved suggest limited studies regarding their efficacy and possible side effects were carried out. Following their widespread use in general public, a problematic trend of post Covid-19 vaccine manifestations are become more apparent and are being reported with increasing frequency. One such manifestation of post Covid -19 vaccination is new onset of autoimmune diseases such as immune thrombotic thrombocytopenia, IgA nephropathy, rheumatoid arthritis and rarely thyroid dysfunction.
Case series
1- A 49-year-old male presented with shortness of breath and palpitations 2 weeks after AstraZeneca vaccine. The patient also reported significant weight loss. On examination, the patient was tachycardic and palpable thyroid nodules. Blood test results can be seen in table 1. Ultrasounds scan of thyroid gland which demonstrated bilateral thyroid nodules with peripheral vasculature. The patient was subsequently diagnosed with Graves' disease and started on treatment with iv hydrocortisone, propranolol, carbimazole. With endocrine team follow up scheduled. 2- A 53-year-old female referred by her GP with deranged thyroid function tests. Patient reported significant weight loss, lethargy, hair loss and ongoing spikes in temperature at night with associated night sweats. The patient indicated her symptoms started 2 weeks after administration of AstraZeneca vaccine. On examination she was found to be tachycardic and visible anterior neck swelling suggestive of goitre. Further to this she underwent Ultrasound scan of Thyroid gland which demonstrated atrophic thyroid gland with right thyroid nodule. The patient was treated with steroids, propranolol, carbimazole.
Discussion/Conclusion
Thyroid dysfunction after vaccination is a rare phenomenon. However, clinicians should be aware that thyroiditis might be an underreported adverse effect of COVID-19 vaccines. Further research is needed to investigate the prevalence and the mechanisms of thyroiditis after COVID-19 vaccination. Based on the finding of these cases we recommend performing Thyroid function test post Covid-19 vaccination to monitor for thyroid dysfunction.

Female papillary thyroid cancer survivors are at increased risk of hyperproliferative pathology of the reproductive system

Tetiana Tatarchuk[1], Mykola Tronko[2], Panagiotis Anagnostis[3], Liudmyla Kalugina[1], Natalia Pedachenko[4], Anna Danylova[4] & Tetiana Kuchmenko[2]
[1]State Institution "Institute of Pediatrics, Obstetrics and Gynecology of NAMS of Ukraine", Kiev, Greece; [2]State Institution "V.P. Komisarenko Institute of Endocrinology and Metabolism", Kiev, Ukraine; [3]Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece; [4]Shupik National Healthcare University of Ukraine, Obstetrics, Gynecology and Gynecology Department, Kiev, Ukraine

Purpose
Thyroid cancer (TC) is the most common endocrine cancer worldwide, affecting mainly women of the reproductive age. However, no data exist with regard to its association with endometrial or uterine disorders. The aim of this study was to assess the risk of hyperproliferative pathology of the reproductive system in female TC survivors.
Methods
This was a cross-sectional study in female patients, aged 20-45 years, diagnosed with papillary TC (PTC) during the period 1994-2018. Age-matched females with normal thyroid structure served as controls.
Results
One-hundred and sixteen patients (mean age 36.7 ± 61 years) and 90 age-matched controls were included. PTC survivors demonstrated an increased risk for adenomyosis [odds ratio (OR) 2.5, 95% confidence interval (CI) 1.3-4.8] and endometrial hyperplasia (OR 3.9, 95% CI 1.1-14.3), compared with controls. The risk for adenomyosis was higher after the ten post-operative years (OR 5.3, 95% CI 2.29- 12.05) than during the first 5-10 years (OR 2.3, 95% CI 1.02-5.10) and increased with the number of RAI courses and the degree of TSH suppression. The risk of endometrial hyperplasia was most evident during the first five years post-thyroidectomy (OR 6.0, 95% CI 1.4-25.5), especially in patients with TSH <0.1 mU/l (OR 6.8, 95% CI 1.4-33.28) No difference in uterine leiomyomas or endometrial polyps was found between PTC survivors and controls.
Conclusions
Female PTC survivors are at increased risk of endometrial hyperplasia and adenomyosis compared with those with normal thyroid structure.

A rare case of a non-secretory medullary thyroid carcinoma

Ana Rita Elvas, Joana Couto, Raquel G. Martins, Jacinta Santos, Teresa Martins & Fernando Rodrigues
Portuguese Oncology Institute of Coimbra, Department of Endocrinology, Coimbra, Portugal

Introduction
Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor (1-2% of all thyroid carcinomas), which arises from calcitonin-producing C cells. Calcitonin (CT) and carcinoembryonic antigen (CEA) are used as tumor markers in the follow-up of patients with MTC. Non-secretory forms of MTC are very rare, accounting for less than 1% of the cases.
Case Report
A 53-year-old man underwent left thyroid lobectomy for a 1.1 cm thyroid nodule subjected to fine-needle aspiration twice, which cytology revealed a "follicular lesion of undetermined significance. Histological examination showed a multifocal MTC (1.2 cm and 0.4 cm) and C-cell hyperplasia. Immunohistochemistry revealed cytoplasmic positivity for CT, chromogranin and synaptophysin, and nuclear positivity for TTF1. Totalization of thyroidectomy and lymph node dissection of the central compartment were performed. Histopathological analysis revealed C-cell hyperplasia and absence of lymph node metastasis in 26 lymph nodes. Preoperatively, there was no elevation of CT or CEA [CT 2.84 pg/ml (NR: 0.40-18.90) and CEA 2.4 ng/ml (NR: <5.0)]. A dilution test for CT was performed and showed no evidence of interference caused by heterophile antibodies. The measurement of fractionated 24-h urinary metanephrines and phospho-calcium metabolism did not show any changes. The search for mutations in the RET gene was negative. In the postoperative study, CT and CEA measurements remained within the normal range. 18F-DOPA positron emission tomography (PET) was requested, which revealed a moderate uptake located in the topography of the duodenal arch. The patient was referred to the Gastroenterology outpatient clinic. He underwent endoscopic ultrasound and abdominal computerized-tomography scan. No duodenal or locoregional lesions were observed. The patient is currently under surveillance, with no clinical, analytical or imaging evidence of recurrent disease.
Conclusion
The reported cases of non-secretory MTC are rare and present a heterogeneous clinical course, which makes it difficult to predict its behavior. It is not clear what is the best way to monitor these patients, as the use of tumor markers is limited. Alternative methods for monitoring are needed to optimize the follow-up of these patients.

Outcomes of low-risk differentiated thyroid cancer submitted to radioactive iodine ablation - a comparative analysis in a single tertiary centre

Catarina Ivo[1], Sara Amaral[2], Nuno Raposo[3], Joana Maciel[4], Joana Simões Pereira[4], Helena Vilar[4] & Valeriano Leite[4]
[1]Armed Forces Hospital, Endocrinology Department, Lisboa, Portugal; [2]Centro Hospitalar Lisboa Central, Endocrinology, Diabetes and Metabolism department, Lisbon, Portugal; [3]Hospital Cuf, Endocrinology Department, Lisboa, Portugal; [4]Instituto Português Oncologia de Lisboa Francisco Gentil - IPOLFG, Endocrinology Department, Lisboa, Portugal

Introduction
The update of 2015 American Thyroid Association (ATA) guidelines recommend that radioactive iodine (RAI) ablation therapy should be used in line with patients' risk stratification. However, there is no consensus on benefits of post-operative RAI ablation in patients with low risk differentiated thyroid cancer (DTC). The aim of this study is to compare the outcomes of patients with low risk DCT submitted to RAI ablation with those who were not.
Methods
This is a retrospective study of patients with low risk DTC followed in a tertiary cancer centre between 2016-2019. Clinicopathological features were collected. Clinical outcomes of patients submitted to RAI ablation were compared to a group control. The risk factors considered for recurrence were: multifocality, minimal extrathyroidal extension (ETE), N1 micrometastases (≤ 5 nodes with $<$ 0.2 cm in largest dimension), suspicious or non-specific findings on post-operative ultrasound (US), positive non-stimulated serum thyroglobulin (Tg) and positive Tg antibodies (ATG) levels. Remission was defined as no evidence of disease /indeterminate response and disease recurrence as biochemical or structural evidence of disease, at last follow-up, based on ATA criteria.
Results
739 patients were included (77.9% female) with a mean age of 53.7 ± 15.9 years-old and a mean follow-up of 3.6 ± 1.2 years. RAI ablation was performed in 45%($n=331$). Recurrence was observed in 4.2% ($n=14$) of the patients submitted to RAI ablation and in 2.9% ($n=12$) of the cases that underwent surveillance ($P=0.342$). Multivariate analysis showed that only post-op Tg - Tg >1 ng/ml [$P<0.001$; hazard ratio (HR): 9.5; 95% confidence interval (95%CI):3.0-30.0), Tg between 0.2-1 ng/ml ($P=0.008$;HR: 5.3; 95%CI: 1.6-18.1)- and suspicious findings on post-op US ($P<0.001$;HR: 8.7; 95%CI: 2.8-27.8) were independent risk factors for recurrence.
Conclusions
Our results demonstrated no differences in clinical outcomes between RAI ablation and surveillance after surgery in low-risk DTC patients, reinforcing that these patients do not benefit from RAI ablation. Positive non-stimulated serum Tg levels and suspicious findings on post-operative ultrasound were the only factors associated with recurrence.

Impact of 2015 ATA guidelines in 131I prescription in low-risk DTC

Sara Amaral[1], Catarina Ivo[2], Nuno Cordeiro Raposo[3], Joana Maciel[4], Joana Simões-Pereira[4], Helena Vilar[4] & Valeriano Leite[4]
[1]Centro Hospitalar Universitário Lisboa Central, Endocrinology, Diabetes and Metabolism Department, Lisboa, Portugal; [2]Armed Forces Hospital Lisbon, Endocrinology Department, Lisbon, Portugal; [3]Hospital CUF, Lisbon, Lisbon, Portugal; [4]Instituto Português de Oncologia de Lisboa Francisco Gentil, Endocrinology Department, Lisbon, Portugal

Background
To minimize potential harm from overtreatment of low-risk thyroid cancers, the 2015 American Thyroid Association (ATA) Guidelines recommend that radioactive iodine (RAI) ablation should not be routinely used in low-risk differentiated thyroid carcinoma (DTC). The present study aims to evaluate trends in RAI therapy in a tertiary center after the update of these Guidelines.
Methods
Data from patients followed in a tertiary center with low-risk DTC between 2016 e 2019 were analyzed. Risk stratification was based on 2015 ATA stating criteria. Multifocality, minimal extrathyroidal extension, ≤ 5 pathologic N1 micrometastases (<0.2 cm in largest dimension), non-specific findings or suspicious lymph nodes on post-operative ultrasound (US), non-stimulated serum thyroglobulin (Tg) >1 ng/ml and positive anti-Tg were considered potential risk factors for recurrence.

Results
A total of 739 low-risk DTC patients were included (77.9% female) with a mean age of 53.7±15.9 years-old. All patients underwent RAI therapy after recombinant human TSH. The number of RAI therapies in low-risk DTC reduced from 53.9% (2016) to 27.8% (2019). All risk factors for recurrence were significant for RAI ablation decision: multifocality (59.5%; $P<0.001$); non-specific findings on post-op US (35.6%; $P<0.001$); minimal extrathyroidal extension (23.1%; $P<0.001$); non-stimulated serum Tg >1 ng/ml (20.8%;$P=0.002$); suspicious lymph nodes on post-op US (11.5%; $P<0.001$); N1 micro-metastases (5.1%; $P<0.001$) and positive anti-Tg (4.8%;$P=0.008$). RAI activity on overall years was 52.7±32.0 mCi and a decrease was observed between 2016 and 2109 (52.8±31.4 to 40.6±24.1 mCi). Higher activities of RAI were observed in patients with N1 micro-metastases ($P=0.004$) and extrathyroidal extension ($P=0.054$).
Conclsions
Our data demonstrates that the number of RAI treatments of low-risk DTC decreased substantially since the update of ATA recommendations. All considered risk factors were significant for RAI treatment decision. The presence of micro-metastases and extrathyroidal extension were associated with higher activities of RAI.

Tocilizumab: an effective and low-cost treatment for recent-onset active moderate to severe graves orbitopathy. a case report

Georgios Boutzios[1], Sofia Chatzi[1], Athina Karampela[1], Andreas Goules[1], Gerasimos Tsourouflis[2] & Athanasios Tzioufas[1]
[1]School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]School of Medicine, National and Kapodistrian University of Athens, Second Department of Propedeutic Surgery, Athens, Greece

Introduction
Graves orbitopathy (GO) is an inflammatory condition of the orbital fat and muscles and affect 30-50% of patients with Graves' disease. The first-line treatment of moderate to severe GO according to EUGOGO is intravenous glucocorticoids, but 20-30% of the cases appear to be corticosteroid resistant or refractory. Promising results have been described with Tocilizumab (TCZ) as a second-line moderate to severe GO treatment.
Case presentation
We report a case of a 33-year-old female presented in our hospital with severe bilateral proptosis and spontaneous retrobulbar pain, lower eyelid retraction, periorbital edema, chemosis without diplopia. She was a former smoker, diagnosed with GO one year before and treated with intravenous methylprednisolone (cumulative dose 4.5gr) with only partial response. After glucocorticoid cessation, the disease relapsed with clinical signs of dysthyroid optic neuropathy and the patient underwent orbital radiotherapy (20Gy). At presentation patient was in thyrotoxic state with TSH=<0.008μIU/ml (n.v.: 0.27-4.2), T3=7.2 nmol/l (n.v.: 0.9-2.8), T4=265 nmol/l (n.v.: 58-140) and markedly increased TSI=19.30 IU/l (n.v <1.75). She was treated with methimazole. CAS score was calculated at 5/7, and protrusion was measured with Hertel exophthalmometer at 30 mm for the right and 31 mm for the left eye, respectively. Upon ophthalmologic evaluation, she was diagnosed with severe keratopathy due to cornel exposure. Orbital MRI was performed, which revealed inflammation of all orbital muscles, predominantly the inferior, medial and lateral rectus binocular. Due to the severity and the progression of the disease despite the corticosteroid treatment and radiotherapy, the patient initiates therapy with TCZ (RoActemra), a monoclonal antibody that inhibits the IL-6 receptor. She received 4 intravenous doses (8 mg/kg) every 28 days, according to Perez-Moreiras RCT. On follow up, symptoms were improved impressively, and CAS score regressed to 1/7. On exophthalmometry, proptosis was 21 for the right, 22 for the left eye, and TSI were within normal values. Moreover, a significant radiological improvement on MRI was established, with decreased size of all affected muscles.
Conclsion
We present this case to raise awareness for the effectiveness of the IL-6 receptor inhibitor (Tocilizumab), to the management of moderate to severe, corticosteroid resistant or refractory GO, of recent-onset, with lower cost compared to other novel therapies such as teprotumumab.

Variation of anti-TSH receptor antibodies after iodine-131 therapy

Inês Vieira[1], Martim Monteiro[2], Paula Soeiro[3], Dírcea Rodrigues[1], Gracinda Costa[2] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, Endocrinology, Diabetes and Metabolism, Portugal; [2]Coimbra Hospital and University Center, Nuclear Medicine, Portugal; [3]São João Universitary Hospital Center, Nuclear Medicine, Portugal

Introduction
Graves' disease (GD) is a systemic autoimmune disease characterized by lymphocyte activation and synthesis of anti-TSH receptor antibodies (TRABs). Higher values of TRABs are associated with a higher risk of Graves' ophthalmopathy and dermatopathy. Iodine-131 therapy (RAI) is one of the well-established options in GD, but it can cause a transient increase in TRABs.
Objectives
To evaluate the evolution of TRABs after RAI; to identify factors associated with a more marked increase in TRABs.
Material and methods
Retrospective analysis of a sample of patients with GD undergoing RAI. Information on demographic data, antithyroid drug therapy (ATD), TRAB values over time (pre-RAI and at 1, 3, 6 and 12 months after RAI) and response to RAI were collected.
Results
We analyzed 86 episodes of RAI, involving 75 patients, mostly female (80.0%), 84.9% corresponded to 1st therapies and 15.1% to subsequent therapies. Age at RAI administration was 40.9±17.2 years, mean 3.0±3.0 years after diagnosis, and 82.6% were under ATDs. The pre-therapeutic TRABs had a median value of 8.0±17.5 U/l (reference range < 1U/l) and, compared to the post-therapeutic TRABs: no statistically significant difference was found at 1 M (8.3±18; $P=0.910$), statistically significant increase was found at 3 M (14.5±28, $P=0.000$) and 6 M (17.0±29.0, $P=0.001$); no statistically significant difference was found at 1 year ($P=0.335$). A doubling of TRABs in relation to the median pre-therapy value, at some point in the 1st year post-therapy, occurred in 54.7%. These patients had a longer diagnostic-therapeutic interval (3.0±3.0 vs 1.0±2.0 years, $P=0.020$), higher estimated glandular mass (57.5±32.7 vs 43.0±25, 0 g, $P=0.024$) and were more frequently of the female gender (60.8 vs 29.4%, $P=0.029$). There was no significant difference in administered dose (11.0±4.6 vs 10.0±4 mCi, $P=0.384$). In multivariate analysis, female gender and the estimated glandular mass maintained a statistically significant relationship with the probability of duplication of the TRABs ($P=0.015$ and$P=0.017$, respectively).
Discussion
Most patients registered an elevation of the TRABs post-RAI. Female patients with larger glandular mass may be especially at risk for higher elevations. These data may have implications for the extrathyroidal manifestations of Graves' disease.

Immune check point inhibitors- induced thyroid disorders -would you recognise them?

Jegadeshwaran Gandhi[1], Bashir Mahamud[1], Janessa Bell[1], Ghada Ahmed[1], Suhier Elshowaya[1], Hassan Rehmani[1], Khash Nikookam[1] & Gideon Mlawa[2]
[1]Queen's Hospital, London, United Kingdom; [2]Queen's Hospital, Diabetes and Endocrinology/Acute Medicine, London, United Kingdom

Introduction
Development and progression of cancers is multifactorial encompassing several mechanisms that aid its proliferation. One of the hallmarks of cancer progression is inhibition of the immune system. Cancer cells can activate different immune checkpoint are pathways that harbour inhibitory or stimulatory mechanisms that enabled self-tolerance and assist with immune response. Through activation of immune checkpoint pathways cancers can suppress immune response against it. Monoclonal antibodies that target immune checkpoints have garnered immense interest in management of solid tumours. The mechanism of action immune checkpoint inhibitors is that they block inhibitory molecules on T-Cells. However, they also downregulate immunological tolerance to self-antigens, inducing immune related adverse events (IrAES). IrAES have been reported in several organs including the endocrine glands including the thyroid and pituitary glands. Here we present cases of two patients which developed hypothyroidism following immune checkpoint inhibitor therapy for their metastatic carcinoma.
Case presentations
Case-1. An 80-year-old gentleman with a background his of metastatic squamous cell carcinoma of the lung was given pembrolizumab(anti-PD-1) treatment. He subsequently developed transient hyperthyroidism (characterised by TSH -69.10

mU/l, FT4 -0.5 *P*mol/l). Five months post therapy he became hypothyroid, (elevated TSH and low FT4). He was subsequently started on levothyroxine and became euthyroid.

Case-2. A 63-Year-old male with history of metastatic cancer of the colon was started on atezolizumab (anti-PD-L1). Post therapy the patient developed severe hypothyroidism characterised by myopathy and myosititis. Before immunotherapy the patient was euthyroid with normal levels of TSH and FT4. Subsequent blood test post treatment showed high levels of TSH >150 mU/l and FT4 6 *P*mol/l. He was treated with high dose of levothyroxine to get him back to his baseline.

Discussion/Conclusion

Thyroid toxicity post immune checkpoint inhibitor therapy is being reported with increasing frequency, based on literature this complication irreversible with patients requiring continuous therapeutic management and follow up which can put increased pressure on patients, who are often under increased mental strain in dealing with their cancer treatment. Based on the case reported here we recommend baseline thyroid function test should be done at initiation of therapy, periodically after immunotherapy and during each cycle of infusion.

Introduction

The SARS-CoV-2 virus has severely affected humanity. The disease causes pneumonia which may be severe. In many cases, patients, especially if there are comorbidities, may have a fatal outcome. The disease affects all organs and the variability of its manifestations has attracted intense scientific interest.

Aim

The aim of the study was to describe the case of a patient who developed subacute thyroiditis after infection with the SARS-CoV-2 virus.

Case description

A patient, female, aged 52 years, developed signs of respiratory infection with a mild clinical picture and fatigue. Hospitalization was not necessary. Sixty days later, she developed signs of subacute thyroiditis with pain in the area of the thyroid gland radiating to the ears, hyperidrosis, tachycardia and intense fatigue. Laboratory investigations revealed IgG Ab COVID-19 31.9 (normal values <1) (ELISA), IgM Ab COVID-19 0.6 (normal values <1) (ELISA), CRP 4.27 mg/dl (normal values <0.5 mg/dl), ESR 85 mm/h and TSH 0.03 μIU/ml. A thyroid ultrasonogram was performed which revealed hypoechoic areas. Non-steroidal-anti-inflammatory drugs were administered which led to pain relief. A month later the patient presented with tachycardia, pain in the area of the thyroid and fatigue. Methylprednisolone was administered 16 mgx2 daily and propranolol 20 mgx2 daily and the patient improved. However, a month later the patient presented with disease relapse. Methylprednisolone 16 mgx2 was administered and the patient improved and is now asymptomatic.

Conclusions

The disease caused by the SARS-CoV-2 virus affects all organ systems. The virus enters cells by attaching to the ACE2 (angiotensin converting enzyme 2) which acts as a receptor for the virus. It has been observed that thyroid cells express the ACE2. It appears that the SARS-CoV-2 virus infects thyroid cells via the ACE2. Cases of subacute thyroiditis, a post-inflammatory disease, have been described mainly in female patients after SARS-CoV-2 infection. In conclusion, it appears that the SARS-CoV-2 virus may affect the thyroid gland.

Comparing non-diagnostic FNA results in thyroid nodules

A K Chandra[1], Vijay Kumar[2], Manish Kumar[3] & R K Jha[4]
[4]Kurji Holy Family Hospital, Medicine, Patna, India; [2]Diabetes Clinic, Patna, India; [3]Chikitsa Clinic, Patna, India [4] DMCH, Medicine, Darbhanga, India

Introduction

Multiple specialities teach and perform ultrasound-guided fine-needle aspiration biopsy (USG-FNA) of thyroid nodules, including Radiology, Endocrinology, and Pathology. Contrasts in cytopathology results might connect with various USG-FNA procedures just as contrasts in the knobs assessed. This study planned to play out a nitty-gritty investigation of USG-FNA results among these different showing administrations at a solitary scholarly clinical focus.

Methods

We performed a review outline survey of patients who went through USG-FNA of a thyroid knob at a solitary scholarly clinical focus from 2015-to 2017, barring patients with hyperthyroidism. Cytopathology results were arranged by the Bethesda framework and separated by the performing strength (Radiology, Endocrinology, and Pathology). Segment, clinical, and ultrasound factors were likewise analysed to additionally research contrasts between the performing specialities.

Results

Of the 356 total thyroid nodules examined by USG-FNA, 167 nodules were biopsied by Radiology, 119 by Endocrinology, and 70 by Pathology. Onsite cytopathology assessment was accessible to Radiology and Pathology, but not to Endocrinology during this period. The appropriation of Bethesda results was different between the three performing administrations ($P < 0.05$). The pace of a Bethesda I (non-indicative) cytopathology result was 3.6% for Radiology, 10.1% for Endocrinology, and 11.4% for Pathology ($P < 0.05$). Contrasts between the pace of harmless (Bethesda II), uncertain (Bethesda III-IV), or high-hazard (Bethesda V-VI) results were not measurably critical. The Radiology-performed USG-FNA group included 58.9% knobs found unexpectedly contrasted with 43.9% and 32.8% for Endocrinology and Pathology, separately ($P^1/_4 0.001$). A larger part of knobs was somewhat or dominatingly cystic in the Radiology (53.4%) and Pathology (55.5%) gatherings, however not in the Endocrinology group (34.6%), which just arrived at a measurable pattern ($P^1/_4 0.07$). No other huge contrasts

Antenatal thyroid hormone therapy and antithyroid drug use in Norway from 2004 to 2018

Kjersti Bakken[1], Kristina Nermo[2], Bjørn Gunnar Nedrebø[3], Tim IM Korevaar[4] & Tor A. Strand[5]
[1]Innlandet Hospital, Women's Clinic, Lillehammer, Norway; [2]Innlandet Hospital, Department of Microbiology, Lillehammer, Norway; [3]Haugesund Hospital, Department of Medicine, Haugesund, Norway; [4]Erasmus University Medical Center, Academic Center for Thyroid Diseases, Rotterdam, Netherlands; [5]Innlandet Hospital, Department of Research, Lillehammer, Norway

Thyroid disease during pregnancy is associated with adverse pregnancy outcomes and suboptimal fetal development. During the last decades, guidelines for diagnosing thyroid disease during pregnancy have changed considerably, and there has been increased awareness. This study aimed to describe the prevalence of thyroid disease treatment over time among pregnant women in Norway. We combined historical data from the Medical Birth Registry of Norway and the Norwegian Prescription Database, identifying pregnant women using thyroid therapy before, during and after pregnancy from 2004 to 2018. A total of 855.067 pregnancies were included in the analyses. The proportion of women using thyroid hormone replacement therapy during pregnancy increased from 1.46% ($n=800$) in 2004 to 3.57% ($n=1940$) in 2018. The proportion of women using antithyroid medications also increased from 0.04% ($n=20$) in 2004 to 0.10% ($n=56$). During these 15 years, the mean maternal age increased by 0.9 years. When adjusting for age, the risk for being on thyroid hormone replacement therapy during pregnancy increased by an average of 5% per year (odds ratio 1.05, 95% confidence interval 1.05−1.05). The reasons behind the increased use of thyroid therapy could be many. Firstly, an enhanced focus on better diagnostics lead to an increased prevalence of thyroid disease, which is evident by the results of a repeated population-based cross-sectional study in Norway. However, one of the key clinical issues in this field is the definition of gestational thyroid disease. A second reason could be the increase in inadequate iodine intake among the pregnant population. Recent study from Norway found that pregnant and postpartum women with mild-to moderate iodine deficiency had altered thyroid. Furthermore, experimental and epidemiological studies have shown that a wide spectrum of environmental contaminants have the potential to adversely affect the hypothalamic-pituitary-thyroid axis, resulting in reduced maternal thyroid hormone synthesis affecting fetal neurodevelopment. Another possible contributor to the increased use of thyroid therapy could be that euthyroid women, with thyroid autoantibodies, use thyroid hormone treatment. The proportion of

babies born after assisted reproductive therapy has increased by 2.2% during the studied period. During the recent 15 years, there has been a substantial increase in the use of thyroid hormone therapy in Norwegian pregnant women. We speculate that this could be due to an increased awareness in combination with overdiagnosis because of inappropriate diagnostic criteria. To truly understand the possible causes and consequences of this development, further research is warranted.

DOI: 10.1530/endoabs.81.P716

DICER1 mutations in pediatric thyroid nodules

Karolina Mastnikova[1], Barbora Pekova[1], Vlasta Sykorova[1], Jitka Moravcova[1], Eliska Vaclavikova[1], Petr Vlcek[2], Rami Katra[3], Daniela Kodetova[4], Josef Vcelak[1] & Bela Bendlova[1]
[1]Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic; [2]2 nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Department of Nuclear Medicine and Endocrinology, Prague 5, Czech Republic; [3]2 nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Department of Ear, Nose and Throat, Prague 5, Czech Republic; [4]2 nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Department of Pathology and Molecular Medicine, Prague 5, Czech Republic

Objectives
Mutations in the *DICER1* gene represent driver events in development of pediatric thyroid nodules, malignant as well as benign. The occurrence of these mutations has been reported in differentiated thyroid carcinomas, poorly differentiated thyroid carcinomas, non-invasive follicular thyroid neoplasms with papillary-like nuclear features (NIFTPs), multinodular goiters and follicular adenomas. The aim of this study was to detect mutations in *DICER1* gene in a large cohort of pediatric thyroid nodules and correlate found mutations with clinicopathological data with a focus on prognosis of disease in patients with papillary thyroid carcinoma (PTC).
Methods
The study consisted of 132 thyroid nodule samples from 124 pediatric patients (age 6-20 years). The cohort included 110 PTCs, 2 NIFTPs and 20 benign nodules. DNA was isolated from fresh frozen thyroid tissues using the Allprep DNA/RNA/miRNA Universal kit and the QIAcube Connect Extraction System (Qiagen, Germany). DNA was used for next-generation sequencing on MiSeq sequencer (Illumina, USA) using the Nextera XT DNA Library Prep Kit (Illumina). Mutations in the *DICER1* gene were visualized in Integrative Genomics Viewer (Broad Institute, USA) and evaluated by VarSome platform (Saphetor SA, Switzerland).
Results
Pathogenic *DICER1* hotspot mutations (E1705K, D1709 N, E1813D) in 7 of 132 (5.3 %) pediatric thyroid samples were detected. Six of them were PTCs (follicular variant), from which 5 were encapsulated. Five PTC patients received only one dose (100 mCi) of radioiodine treatment and are in remission. Only in one case, the patient received three doses of radioiodine (2× 100 mCi, 1× 120 mCi). This patient had a 60-mm carcinoma and angioinvasion was described only in this patient. The *DICER1* alteration was also found in one NIFTP case. All *DICER1*-mutated tumors did not possess other driver mutations (in the *BRAF* gene, *RAS* genes, fusion genes).
Conclusion
In summary, *DICER1* mutations are important molecular markers in pediatric thyroid nodules. Almost all our *DICER1*-mutated carcinomas represented low-risk malignancies and patients had an excellent response to the treatment. However, one patient had an incomplete response to treatment due to the advanced stage at the time of diagnosis. In conclusion, *DICER1*-mutated tumors appear to be indolent, but should not be underestimated.
Supported by AZV NU21-01-00448 and MH CR RVO 00023761.

P718

Clinical presentation and significance of thyroid dysfunctions secondary to PD-1/PD-L1 blockade cancer immunotherapy

Giulia Di Dalmazi[1], Sofia Elena Sorbo[1], Andrea Dudiez[1], Beatrice Ciappini[1], Ilaria Cipolloni[1], Gianluca Russo[2], Dimitri Luisi[2], Giorgio Napolitano[1] & Ines Bucci[1]
[1]University "G.d'Annunzio" of Chieti-Pescara, Department of Medicine and Aging Sciences, Chieti, Italy; [2]Pescara General Hospital, Medical Oncology Unit, Pescara, Italy

Background
Thyroid dysfunctions are among the most common immune-related adverse events (irAEs) following the administration of immune checkpoint inhibitors (ICIs) for malignancies. The pathogenesis of thyroid irAEs remains unclear and the clinical course can be multifaceted.
Aim
Aims of this study were a) to describe the incidence and the clinical course of thyroid irAEs b) to determine the association between thyroid irAEs and overall survival (OS).
Methods
We performed a single-center retrospective study of cancer patients treated with anti-PD-1/PD-L1 from January 2018 to December 2020. Demographic data, thyroid function tests (serum thyrotropin, TSH; free thyroxine FT4; free triiodothyronine, FT3) and thyroid ultrasonographic findings (if available) were retrieved at baseline and at regular intervals after starting ICIs. Patients were excluded if a) they had abnormal thyroid function at baseline b) were on anti-thyroid drugs or levothyroxine (LT4) replacement c) had missing data.
Results
One hundred sixty-six cancer patients were considered for potential enrollment, and after assessment of inclusion and exclusion criteria, 112 were enrolled. The mean age was 67.9 (10.6) years, and 82 patients (73.2%) were males. Lung cancer accounted for 65.8% of all cancers, followed by melanoma (16.2%), squamous cell carcinoma (9.9%), genitourinary cancers (6.3%) and other cancers (1.8%). Among all patients, 97 (86.6%) were treated with a PD-1 blockade, whereas 15 (14.4 %) received a PD-L1 inhibitor. Previous treatments had been performed in 72 patients (79.1%). During the study period, 25 patients (22.3%) developed thyroid irAEs with a median time to onset of 5.1 months (iqr 6.7). Two of them (8%) initially presented with thyrotoxicosis and 23 (92%) with hypothyroidism. Patients with thyrotoxicosis had an earlier median time to onset compared to those who had hypothyroidism (1.3 vs 5.2 months, $P=0.045$). Overall, 19 patients (76%) required LT4 replacement. Systemic steroids were not required in all cases. Thyroid ultrasonography, performed in 19 patients at thyroid irAEs onset, revealed a slightly increased thyroid volume in patients with thyrotoxicosis and a reduced volume in hypothyroid patients (18.1 vs 8.4 mL, $P=0.01$). Multivariable Cox regression analysis revealed that the occurrence of thyroid irAEs was independently associated with better OS (H.R. 0.3, CI 95% 0.1- 0.7, $P=0.006$).
Conclsion
This study confirms that thyroid irAEs occur with a high frequency in routine clinical practice and with heterogenous clinical presentation. It also supports that thyroid irAEs may represent a predictive biomarker of better response to ICIs.

DOI: 10.1530/endoabs.81.P718

P719

Serum FT3 levels and FT3/FT4 ratio as predictors for poor prognosis in hospitalized COVID-19 patients

Marica Milo[1], Giulia Di Dalmazi[1], Fabrizio Febo[2], Sara Coluzzi[2], Federica Carrieri[1], Marco Terrenzio[1], Giovanna Ferrandu[3], Antonella Spacone[4], Giorgio Napolitano[1] & Giustino Parruti[5]
[1]University "G.d'Annunzio" of Chieti-Pescara, Department of Medicine and Aging Sciences, Chieti, Italy; [2]Pescara General Hospital, Endocrinology and Metabolism Unit, Pescara, Italy; [3]Pescara General Hospital, Internal Medicine Unit, Pescara, Italy; [4]Pescara General Hospital, Respiratory Medicine Unit, Pescara, Italy; [5]Pescara General Hospital, Infectious Diseases Unit, Pescara, Italy

Background
The coronavirus disease 2019 (COVID-19) can involve multiple organs and systems, including the endocrine system. In particular, thyroid dysfunctions are frequently seen in COVID-19 patients. The aim of this study was to evaluate thyroid function in hospitalized COVID-19 patients and to correlate thyroid function with inflammatory status, blood count parameters and mortality.
Materials and methods
Data of COVID-19 patients admitted to the hospital of Pescara between October 2020 and March 2021 were retrospectively evaluated. Serum thyrotropin (TSH), free thyroxine (FT4), free triiodothyronine (FT3), FT3/FT4 ratio, thyroid antibodies (TgAb, TPOAb), inflammatory and blood count parameters (C-reactive protein, CRP; interleukin-6, IL-6; red blood cell, RBC; white blood cells, WBC; platelets, PLT; neutrophil to lymphocytic ratio, NLR) were analyzed and compared between survivors and non-survivors.

Results
Three hundred thirty-four adult COVID-19 patients were considered for potential enrollment, and after assessment of inclusion and exclusion criteria, 264 were enrolled. The median age was 74.4 (20.6) years, and 167 patients (63.5%) were males. The average hospital stay was 9 days. Of the 264 enrolled patients, 101 (38.2 %) died of COVID-19 complications. The characteristics of survivors and non-survivors are shown in table 1. Serum FT3 levels and FT3/FT4 ratio were significantly lower in non-survivors compared to survivors. Instead, inflammatory and blood count parameters, except for RBC, were significantly higher in survivors. Notably, FT3 levels and FT3/FT4 ratio negatively correlated with CRP and NLR (r=-0.2, $P<0.05$). In Kaplan-Meier and Cox regression analyses, low FT3 levels (FT3 less than 2.5 pg/ml) were independently associated with mortality (H.R. 1.7, CI 95 % 1.01- 2.96, $P=0.042$).
Conclusions
FT3 levels and FT3/FT4 ratio correlate negatively with inflammatory markers and may be predictive for poor prognosis in hospitalized COVID-19 patients.

Diagnostic accuracy of ultrasonographic features in detecting thyroid cancer in the transition age: a meta-analysis from the TALENT group

Alessia Cozzolino[1], Tiziana Filardi[1], Ilaria Simonelli[2,3], Giorgio Grani[4], Camilla Virili[3], Ilaria Stramazzo[5], Maria Giulia Santaguida[5], Pietro Locantore[6], Massimo Maurici[3], Daniele Gianfrilli[1], Andrea M Isidori[1], Cosimo Durante[4] & Carlotta Pozza[1]
[1]Sapienza University of Rome, Experimental Medicine, Rome, Italy; [2]Service of Medical Statistics and Information Technology, Fatebenefratelli Foundation for Health Research and Education, Rome, Italy, Rome, Italy; [3]Università degli Studi di Roma "Tor Vergata", Biomedicina e Prevenzione, Rome, Italy; [4]Sapienza University of Rome, Translational and Precision Medicine, Italy; [5]"Sapienza" University of Rome, Latina, Medico-Surgical Sciences and Biotechnologies, Italy; [6]Università Cattolica del Sacro Cuore, Rome, Endocrinology Unit, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Italy

Context
Significant uncertainty exists about the diagnostic accuracy of ultrasonographic (US) features used to predict the risk of thyroid cancer in the pediatric population. Moreover, there are not specific indications for thyroid nodule evaluation in patients during the transition age.
Objective
The meta-analysis aimed to address the following question: which thyroid nodule US features have the highest accuracy in predicting malignancy in the transition age.
Methods
We performed a meta-analysis of observational/cohort/diagnostic accuracy studies dealing with thyroid nodule sonography, reporting US features, and using histology as reference standard for the diagnosis of malignancy and histology or cytology for the diagnosis of benignity in the transition age (mean/median age 12-21 years).
Results
The inclusion criteria were met by 14 studies, published between 2009 and 2020, including 1306 thyroid nodules (mean size 17.9 mm). The frequency of thyroid cancer was 36.6%. The US features with the highest diagnostic odds ratio for malignancy were the presence of suspicious lymph nodes [DOR: 56.0 (95% CI: 26.0-119.0)], a "taller than wide" shape of the nodule [6.0 (95% CI: 2.0-16.0)], the presence of microcalcifications [13.0 (95% CI: 6.0-29.0)] and irregular margins [9.0 (95% CI: 5.0-17.0)]. Heterogeneity among the studies was substantial.
Conclusions
Following the diagnosis of a thyroid nodule in transition age, a thorough US examination of the neck is warranted. The detection of suspicious lymph nodes and/or thyroid nodules with a "taller than wide" shape, microcalcifications and irregular margins is associated with the highest risk of malignancy in the selection of nodules candidates to biopsy.

Does the risk of new metabolic changes among thyroid cancer survivors depend upon thyroid function?

Elena Izkhakov[1,2], Yacov Shacham[2,3], Tomer Ziv-Baran[4], Iris Yaish[1,2], Gilad Horowitz[2,5], Anton Warshavsky[2,5], Nidal Muhanna[2,5], Narin Nard Carmel-Neidermann[2,5], Karen Tordjman[1,2] & Yona Greenman[1,2]
[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Diabetes, Metabolism and Hypertension, Tel Aviv-Yafo, Israel; [2]Tel Aviv University, Tel Aviv-Yafo, Israel; [3]Tel Aviv Sourasky Medical Center, Department of Cardiology, Tel Aviv-Yafo, Israel; [4]Tel Aviv University, School of Public Health, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel; [5]Tel Aviv Sourasky Medical Center, Department of Otolaryngology, Head & Neck and Maxillofacial Surgery, Tel Aviv-Yafo, Israel

Background
Various components of metabolic syndrome (MS) significantly increase the risk of thyroid cancer (TC). Moreover, thyroid cancer survivors (TCS) are at increased risk of new components of MS (MSC). The role of thyroid function in this context has not yet been determined. We investigated changes in selected MSC and their association with thyroid function during a two-year follow-up among TCS.
Materials and Methods
This retrospective, nested case-control study used data from a single academic hospital. The one-hundred and fifteen participants had undergone total thyroidectomy, radioactive iodine treatment and thyroid-stimulating hormone-suppressive L-thyroxine therapy for two years due to differentiated TC.
Results
The numbers of MSC in the entire cohort at baseline compared to those after a two-year follow-up were as follows: none in 58.3% patients vs 30.4% patients, respectively, 1 in 20.9% vs 35.7%; 2 in 11.3% vs 16.5%; 3 in 7.8% vs 13.9%; 4 in 1.7% vs 1.7%; and 5 in 0% vs 1.7%. The incidence of MSC increased during the two-year follow-up period in 51 TCS (cases), while none of the 64 TCS (controls) developed any new MSC. The multivariable logistic regression analysis showed that TCS with a FT3/FT4 ratio greater than 0.22 (lower tertile) had a significantly increased risk of a new MSC (odds ratio 2.73, 95% confidence interval 1.14−6.57, $P=0.025$).
Conclusions
Our study demonstrated that an FT3/FT4 ratio greater than 0.22 is correlated with detrimental metabolic changes among TCS.

Clinicopathological characteristics and response to therapy in patients with tall cell variant papillary thyroiid carcinoma in an institution: analysis of 109 cases

Hernan Tala[1], Josefina Razmilic[1] & Jeannie Slater[2]
[1]Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana/Universidad del Desarrollo, Internal Medicine (Endocrinology Unit), Chile; [2]Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana/Universidad del Desarrollo, Pathology Department, Chile

Objectives
1.-Characterization of patients with tall cell variant papillary thyroid carcinoma (TCV-PTC) at diagnosis (Dx) compared to patients with classic papillary thyroid carcinoma (c-PTC);

2.-Evaluation of response to therapy (RT) in the (TCV-PTC) cohort
Experimental design: Retrospective observational study
Materials and methods
Patients submitted to surgery for PTC in our institution since 2010 were evaluated. Clinicopathological characteristics at dx. were compared between TCV-PTC y c-PTC. Subsequently, the RT in the TCV-PTC cohort was evaluated. Continuous variables (v) are described with median and range and categorical variables as proportions. ANOVA was used to compare continuous variables and chi square or Fisher in categorical variable. Logistic regression was used for multivariate analysis.
Results
From 1475 patients with PTC, 1040 (70%) correspond to c-PTC and 109 (7%) to TCV-PTC. Table 1 compares the clinicopathological characteristics most relevant at Dg. In multivariate analysis, TCV-PTC was independently associated with a higher probability of ETE and LNF-Inv in the pathology report. RAI was given to 86% of patients. Of the 68 patients in whom it was possible to evaluate RT (median follow-up 21 months), 66% presented excellent RT, 16% indeterminate RT and 7% structural incomplete RT. RT was significantly better in patients with tumors $\leq$2 cm without lymph node metastases (LNM) at Dg (Table2).

Table 1 Clinicopathological characteristics at diagnosis

	TCV-PTC	c-PTC	p
	n=109	*n*=1040	
Age (Median, range)	46 (19-77)	42 (6-86)	< 0.05
Female	83%	76%	0.10
Tumoral size ≥10 mm	43%	29%	< 0.05
Extra-thyroidal extensión (ETE+)	47%	23%	< 0.05
Linfovascular invasión (LNF-Inv) (+)	46%	23%	< 0.05
Necrosis (+)	5%	1.4%	< 0.05
pT (AJCC 2017)			
pT1a	55%	70%	*P*< 0.05
pT1b	28%	21%	
pT2	5%	7%	
pT3a	0	0.4%	
pT3b	8%	0.9%	
pT4	4%	0.7%	
pN0/Nx	67%	66%	0.7
pN1a	24%	22%	
pN1b	9%	12%	

Table 2: RT according to AJCC-2017

	pT1a/pT1b-N0/Nx	Otros	P
Excelent RT	31/38 (82%)	14/30 (46%)	< 0.05
Indeterminate RT	7/38 (18%)	9/30 (30%)	
Structural incomplete RT	0	7/30 (23%)	

Conclusions
At diagnosis, TCV-PTC has a higher probability of ETE, LNF-Inv, necrosis and larger tumor size. Despite that, RT seems to be good in patients with tumors $\leq$2 cm without LNM. Studies with longer follow-up and larger number of patients are needed to confirm these observations.

Metastatic papillary thyroid carcinoma without identifiable primary tumor in a patient with IgG4-related thyroiditis: challenging diagnosis and management of a rare case

Kasiani Papadimitriou, Melpomeni′ Moustaki, Anastasios Tsitsimpis, Nektaria Papanikola, Alexandros Dermentzoglou, Loukia Spanou & Andromahi Vryonidou

Red Cross Hospital, Endocrinology, Diabetes, and Metabolism Department, Athens, Greece

Introduction
IgG4-related thyroiditis (IgG4-RTD) is a rare fibroinflammatory disorder. It is characterized by dense lymphocyte infiltration (mainly IgG4+ plasma cells), enlargement and dysfunction of the thyroid gland. IgG4-RTD includes mostly cases of Hashimoto's (HT) but also of Riedel's and Graves' thyroiditis. Diagnosis is set according to imaging and histopathological criteria. Papillary thyroid carcinoma (PTC) is the most common form of thyroid cancer (~90%). Co-occurrence of HT and PTC is found in 23-30% and the presence of HT is considered a favorable prognostic factor. The association between PTC and IgG4-RTD remains unclear. Metastatic PTC without an identifiable primary tumor is also a very rare phenomenon.
Case presentation
A 48-year-old woman attended our outpatient clinic presenting with progressive painless cervical enlargement and HT. The patient was euthyroid under levothyroxine treatment. Clinical examination revealed a diffusely enlarged, moderately hard thyroid and palpable, painless, mobile cervical lymph nodes. Neck ultrasonography showed diffuse thyroid enlargement with inhomogeneous, hypoechoic, hypovascular echostructure and several enlarged lymph nodes of the central and lateral cervical compartment. Cytological examination after fine needle aspiration of two suspicious nodes of the central compartment was suggestive of non-specific reactive lymphadenitis. Later, the patient presented further thyroid enlargement with marked stiffness, dysphagia and hoarseness. Thyroid core needle biopsy provided findings of the fibrosing variant of HT and IgG4-RTD. Serum IgG4 levels were also elevated. Computed tomography of chest, abdomen and retroperitoneum returned no findings of systemic IgG4-related disease. She was treated with methylprednisolone 16 mg/d and presented progressive clinical and imaging improvement. After surgical review, total thyroidectomy was carried out. Pathology report revealed HT with extended fibrosis at thyroid specimens and metastatic infiltration of follicular variant of PTC in two cervical lymph nodes. Post-op the patient received 50 mCi of I-131 for remnant ablation. Negative post-ablation whole body scan in conjunction with undetectable thyroglobulin levels and negative anti-thyroglobulin antibodies title were compatible with disease remission.
Discussion
IgG4-RTD, though an unusual clinical entity, should be considered in the differential diagnosis of thyroid enlargement. The management of a patient with IgG4-RTD and metastatic thyroid carcinoma without an identifiable primary tumor is rather challenging, as the impact of IgG4-RTD on cancer prognosis is still ambiguous. Failure in identifying primary tumor may be attributed to the small size (<3 mm) and/or the extended fibrosis of thyroid.

Congenital central hypothyroidism diagnosed in-utero

Michal Yacobi Bach[1,2], Yonit Marcus[1] & Yona Greenman[1]
[1]Tel Aviv Medical Center, Endocrinology Institute, Tel Aviv, Israel; [2]Tel Aviv Medical Center, Genetics Institute, Tel Aviv, Israel

Introduction
Congenital central hypothyroidism (CH), is characterized by low levels of thyroid hormones and TSH. It is not possible to diagnose this condition by neonatal screening programs based on TSH measurements, hence it is often missed. The assumption that CH is usually a mild condition has been refuted, and more than 50% of all newborns with CH have moderate to severe disease. Early diagnosis and treatment lead to better neurodevelopmental outcomes. Isolated CH is a rare condition with an estimated prevalence of 1:13000. More than 90% of cases are due to pathogenic mutations in five known genes: *thyroid releasing hormone receptor* (*TRHR*), *thyroid stimulating hormone beta subunit* (*TSHB*), *immunoglobulin superfamily member 1* (*IGSF1*), *transducin (beta)-like 1X-linked* (*TBL1X*) and in *insulin receptor substrate 4* (*IRS4*) genes. Mutations in both *IGSF1* and *TBL1X* can lead to X-linked isolated CH. *IGSF*1 mutations are also associated with low PRL, variable GH deficiency, metabolic syndrome, and postpubertal macroorchidism.
Case description
A 40-year-old pregnant woman with a past medical history of hemithyroidectomy due to goiter, was diagnosed with CH at the age of 20 years. Prolactin levels were low, adrenal function was preserved and pituitary imaging was normal. She reported having had lactation problems after her first pregnancy. The family history was unremarkable and there is no known consanguinity. Genetic evaluation: A prenatal CMA (chromosomal microarray) revealed a normal

male karyotype 46XY with a 250kb deletion on chromosome X :arr (hg19) Xq26.1- Xq26.2 (130.181.100-130.431.733)*0. This deletion encompasses two omim genes*: ARHGAP36, IGSF1 and* was later confirmed to be inherited from the patient. Central congenital hypothyroidism was diagnosed clinically in the newborn baby, and treatment with thyroid hormone replacement was initiated, there was no need for steroid replacement therapy.
Discussion
X linked *IGSF1* deficiency syndrome is the main etiology for Congenital CH. As far as we know, this is the first described case of a molecular diagnosis made in utero. Such early diagnosis enables focused surveillance of the fetus, regarding thyroid size, bone age and heart rate. Hypocortisolism was described in 20% of neonates with CH. Prenatal diagnosis enables early treatment with thyroid hormones and steroids if needed, and reduces the risk of neurodevelopmental problems.

TIRADS system: what does clinical practice tell us?

Catarina Ivo, Vitória Duarte, David Veríssimo, Ana Cláudia Martins, João Silva, Luís Lopes, Dolores Passos, João Jácome Castro & Mafalda Marcelino
Armed Forces Hospital - Lisbon, Endocrinology Department, Lisboa, Portugal

Introduction
Thyroid nodules have a high prevalence in the adult population (20-76%). In 2018, the American College of Radiology proposed an ultrasound classification score of thyroid nodules - Thyroid Imaging Reporting and Data System-TIRADS, with 88% of sensitivity and 49% of specificity to predict malignancy. Since then, several studies report sensitivity values of 70.6-97% and specificity of 30-98%. We pretend to compared TIRADS score with cytologic results based on Bethesda classification.
Methods
This is a retrospective study of patients with thyroid nodules submitted to fine-needle aspiration (FNA) in an endocrinology department, during 16 months. Cytologic results (Bethesda classification) and TIRADS score (TR) were evaluated. TR score was calculated at the time ultrasound-guided FNA was performed. All Bethesda I (non-diagnostic) results were excluded.
Results
A total of 143 FNA of thyroid nodules were analysed, from 123 patients (57.7 % female) with a mean age of 64 $\pm$ 14.3 years-old. The nodules' mean dimension was 24.6 $\pm$9 mm. 61.5% of nodules were classified as TR 4, 27% TR3, 7% TR5, 2.1% TR1 and 1.4% TR2. 90.2% of FNA were Bethesda II (benign) and 9.8% were Bethesda III (follicular lesion of undetermined significance). No results of Bethesda IV-VI were diagnosed (malignancy). Analysing all TR1 and TR2 nodules, 80% were Bethesda II and 20% were Bethesda III. From nodules of TR3 to TR5, Bethesda II results were obtained in 92.3% of TR3, in 92% of TR4 and 72.7% of TR5, and Bethesda III were obtained in 7.7% of TR3, 8% of TR4 and 27.3% of TR5. No statistically significant difference was verified between categories ($P=0.392$). A 91.9% specificity was achieved for TIRADS score to identify benign thyroid nodules.
Conclusion
Our data demonstrated an elevated TIRADs score specificity that is in line with that reported in the published literature. Our results showed that TIRADs score seems to be particularly useful in identifying benign thyroid nodules. Higher risk TIRADS categories did not reflect higher risk for malignancy in cytologic diagnosis. More studies with greater samples are needed.

Graves' eye disease associated with SARS-CoV2 infection

Jane Noble[1], Brian Carthy[1] & Siobhan McQuaid[1,2]
[1]Mater Misericordiae University Hospital (MMUH), Endocrinology Department, Dublin 7, Ireland; [2]University College Dublin, Dublin 4, Ireland

Introduction
SARS-CoV2 infection or vaccination against SARS-CoV2 has been linked to the onset or recurrence of Autoimmune and subacute thyroiditis resulting in thyroid dysfunction.
Case
We describe a case of Thyroid eye disease temporally associated with SARS-CoV 2 infection in a 48 year old female with a one-year history of subclinical hypothyroidism without interval thyroid hormone replacement or SARS-CoV2 vaccination. Two months following PCR confirmed SARS-CoV 2 infection, the patient presented with eye irritation and oedema. Direct ophthalmological assessment led to a diagnosis of thyroid eye disease. CT orbit confirmed bilateral proptosis with increased intraorbital fat. TSH was 0.01 mIU/l (0.27-4.2) and FT4 18 pmol/l (12-20). Carbimazole 10 mg BD was commenced as she complained of palpitations, heat intolerance and tremor. TFTs three months later indicated T3-thyrotoxicosis (TSH <0.01 mIU/l (0.35-4.94), FT4 14.3 pmol/l (9.0-20.0) Free T3 6.3 pmol/l (2.6-4.9)) with elevated TSH Receptor Antibody 3.5 U/l (0-0.4) in keeping with a diagnosis of Grave's Disease. The patient was referred to Endocrinology for clinical assessment. At that assessment, nine months following eye symptom onset, the patient was clinically and biochemically euthyroid on Carbimazole 5 mg BD (TSH 3.24 mIU/l (0.35-4.94), FT4 11.8 pmol/l (9.0-20.0), Free T3 3.9 pmol/l (2.6-4.9), Anti TPO 108.1 IU/ml (<5.6)). She was an ex-smoker of 2 years with no family history of autoimmunity. Of note the patient reported L-thyroxine replacement until 4 years prior to presentation. Review of available TFTs one year prior, off L-thyroxine, showed TSH 8.7 mIU (0.27-4.2), T4 13.4 pmol/l (12-22), thyroid antibodies unavailable. Mild non-tender goitre was evident on exam with palpebral oedema and conjunctival injection without exophthalmos or lid retraction. Carbimazole was stopped. Although still troubled by eye irritation the patient remains clinically and biochemically euthyroid on review 12 months following onset of eye symptoms (TSH 2.85 mIU/l (0.35-4.94), FT4 12.8 pmol/l (9.0-20.0), Free T3 4.5 pmol/l (2.6-4.9) with reducing titres of TSH Receptor Antibody 1.2 U/l ((0-0.4)).
Conclusion
There have been numerous published cases of new or recurrent Graves' disease and Subacute thyroiditis following SARS-CoV2 infection. In our case, the rapid response to antithyroidal medications and predominant ophthalmic symptoms perhaps point to a dual diagnosis of acute thyroiditis and Graves' Eye Disease. The case is also interesting in that she had a history of sub-clinical hypothyroidism. Should she become hyperthyroid again, thyroid scintigraphy would be beneficial. Clinicians should remain cognisant of the effect of SARS-CoV2 infection on thyroid dysfunction.

Alemtuzumab induced thyroid disease: a Danish cohort study

Juliana Frohnert Hansen[1], Melinda Magyari[2], Åse Krogh Rasmussen[3], Finn Sellebjerg[2] & Ulla Feldt-Rasmussen[3]
[1]Amager Hospital, Department of Internal Medicine, Copenhagen S, Denmark; [2]Copenhagen University Hospital, Rigshospitalet, Glostrup, Danish Multiple Sclerosis Center, Department of Neurology, Copenhagen, Denmark; [3]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinology, Copenhagen, Denmark

Objectives
Alemtuzumab, a monoclonal antibody against CD52, is used in the treatment of multiple sclerosis. A side effect to the treatment is development of autoimmune thyroid disease. The aim was to evaluate the rate, type and course of thyroid disease in Danish patients with multiple sclerosis (MS) previously treated with Alemtuzumab.
Methods
The study was a retrospective cohort study of patients treated with first series of alemtuzumab for multiple sclerosis (MS) in the Capital and Zealand regions (population: 2.6 million) of Denmark between 2014 and 2018 ($n=60$). The following data was collected from patient records: known previous thyroid disease, date of first series of alemtuzumab, onset date of thyroid dysfunction, blood sample result of thyroid hormones and thyroid antibodies and thyroid scintigraphy and ultrasound to determine type of thyroid disease, type of treatment, duration and course of thyroid dysfunction.
Results
The follow-up period was median 58.5 months (31-83, range). Thyroid disease occurred in 24 of the 60 patients (40 %), with a median onset at 24 months after the first alemtuzumab treatment (1-63, range). Graves' disease (GD) occurred in 18 of 60 patients (30 %) and three of these also had silent or postpartum thyroiditis with undetectable thyroid receptor antibodies (TRAB) before onset or after remission of GD. Isolated silent or subacute thyroiditis occurred in two of 60 patients (3 %), unclassified hyperthyroidism (due to lack of information) in two of 60 patients (3%) and toxic multinodular goitre also in two of 60 patients (3%).
An unusual or unpredictable course of GD was observed in 12 patients, with a rapid change in serum hormone concentrations unrelated to changes in

medication, e.g. sudden changes from hyperthyroidism to hypothyroidism, being the most common. Some of these patients were treated with antithyroid hormone or thyroxine titration regimen, while others were switched to block and replace treatment. Full remission of GD, defined as undetectable TRAB, was at the time of data collection only seen in four patients.
Conclusion
Data from this Danish population was in accordance with recent published studies and supports previous observations of both unusual, long-lasting and unpredictable courses of GD in a subgroup of patients. Hypothetically, some of these may benefit from block and replace treatment, to stabilize an otherwise clinically inappropriate fluctuating GD.

A rare etiology for thyrotoxicosis − case report

Teodor Dumitras[1], Gheorghita Patriciu Zubascu[1], Marius Lucian Mitrache[1], Adrian Miron[2,5], Cornelia Nitipir[2,4], Dana Terzea[5] & Simona Fica[1,2]
[1]Elias University Emergency Hospital, Endocrinology, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [3]Elias University Emergency Hospital, General Surgery, Bucharest, Romania; [4]Elias University Emergency Hospital, Oncology, Bucharest, Romania; [5]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Introduction
Hyperthyroidism and thyrotoxicosis can have multiple etiologies, varying from the most frequent described in clinical practice (Graves disease, toxic nodular goiter, thyroiditis) to very rare causes such as anaplastic thyroid cancer, thyroid lymphoma, amyloidosis or even secondary malignancy of the thyroid gland.
Case report
A 53 year old man presented to our department for progressive goiter enlargement in the last two months which was accompanied by dysphagia and dysphonia. The patient had a history of smoking for almost 40 years and also mentioned that in the last two weeks he lost in weight approximately 3 kg. The clinical exam was in normal limits, with the exception of multiple laterocervical adenopathies and the enlarged, firm thyroid gland which was painful and presented local inflammatory signs. The paraclinical investigations showed an acute inflammatory syndrome (ESR 42 mm/h, CRP 85.2 mg/l, Fibrinogen 606 mg/dl) with thyrotoxicosis (TSH - 0.01 mIU/ml, freeT4 - 4.13 ng/dl and total T3 - 278 ng/dl) and negative autoimmunity. The thyroid ultrasound showed a pseudonodular heterogenous aspect with decreased blood flow and multiple non-inflammatory laterocervical adenopathies, largest one being almost 2 cm. In addition, thyroid scintigraphy showed no hyperfunctioning areas while the computed tomography of the neck and thorax discovered a right apical pulmonary nodule of 35/36/46 mm. During his hospital stay he received anti-inflammatory treatment with dexamethasone and ibuprofen. His largest right laterocervical adenopathy was surgically removed and sent to the anatomical pathology department who described a ganglionar metastasis of pulmonary carcinoma with clear large cells. The patient underwent total thyroidectomy and the result confirmed a thyroid metastasis of pulmonary carcinoma. He received replacement therapy with levothyroxine and oncologic treatment with pembrolizumab, pemetrexed and carboplatin. During his last examination, after eight months of treatment, the patient was stable, presenting euthyroidism while the right apical pulmonary nodule had a dimensional regression. Unfortunately, he presented multiple cervical adenopathies for which he will undergo palliative radiotherapy.
Conclusions
This was a rare case of thyrotoxicosis which required a proffesional multidisciplinary team in order to offer an appropriate diagnosis and treatment. Secondary malignancy of the thyroid gland is quite rare, and especially in the form of thyrotoxicosis which probably was caused by a destructive invasion of thyroid tissue with malignant cells, similar to a "thyroiditis".
Key words: thyrotoxicosis, secondary malignancy, pulmonary carcinoma

Hyperthyroidism and ischemic stroke in a young adult

Yosra Hasni[1,2], Hamza Elfekih[1,2], Ghada SAAD[1,2], Wiem Saafi[1], Oumayma Zarrouk[1], Amel Maaroufi[1,2], Maha Kacem[1,2], Molka Chadli Chaieb[1,2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia

Introduction
Moyamoya disease is a rare angiopathy characterized by a progressive stenosis of the intracranial internal carotid arteries (ICA). First described in 1957, its pathophysiological mechanisms are still not well understood. Its association with various systemic diseases is termed moyamoya syndrome
Observation
A 21-year-old female patient, with a family history of hypothyroidism, was admitted initially with stroke. The clinical examination revealed hemiparesis of the right hemisphere and dysarthria, in addition to a moderate goiter and tachycardia. Cerebral CT scan with contrast showed bilateral stenosis of the intracranial ICA with 78% in the left and 30% in the right ICA, confirming the diagnosis of moyamoya angiopathy. Biological analysis on admission and prior to the imaging procedure revealed suppressed TSH level and 10-fold increase in serum FT4. The diagnosis of Graves' disease was made upon the presence of anti-TSH receptor antibodies: 5 IU/l (< 2 IU/l) and high thyroidal technetium-99 m pertechnetate uptake. Thyroid peroxidase antibodies were also positive and 32-fold elevated (1600 IU/ml). The patient received 30 mg qd of thiamazole in addition to rehabilitative management with improvement of its poststroke hemiparesis.
Discussion
Moyamoya syndrome represents one-third of moyamoya angiopathy and is associated with well-recognized conditions like neurofibromatosis type 1, Down syndrome, sickle cell disease but also autoimmune diseases. Autoimmune thyroiditis are increasingly reported in the literature in patients with moyamoya angiopathy suggesting a possible role of the immune process in the pathogenesis of this disease.

Effect of levothyroxine replacement therapy on testosterone, LH, FSH levels in men with overt hypothyroidism

Abhishek Shrivastav[1] & Bharat Saboo[2]
[1]R&R hormone clinic, endocrinology, jabalpur, India; [2]Prayas Diabetes Centre, Diabetes, Indore, India

Introduction
The prevalence of hypothyroidism overtly ranges from 5% to 11%. Though Hypothyroidism is less common in males as compared to females but deficiency of thyroid hormone affects almost all metabolic organs of the body, which includes changes in growth hormone, steroid metabolism, sexual function, antioxidative function.
Aim
− The aim of our study was to assess the levels of total testosterone LH, FSH levels in males with overt hypothyroidism pre and post levothyroxine therapy. In our study we included 51 patients with overt hypothyroidism, with mean age 40.2 years(32-56 years). 50% of patients had low testosterone level at baseline, low testosterone level associated with hypothyroidism has not been well documented in several studies with varying prevalances. In our study only 5 patients had low LH level at baseline while FSH level of all the patients was normal at baseline, semen analysis could not be done due to non consent of patients. In our study after attainment of euthyroidism or after 4 months of replacement of levothyroxine therapy 70% of hypogonadic patients had their testosterone level normal, more than 80% of patients with low ADAMS score showed improvement in their parameters.
Conclusion
Thyroid hormone deficiency affects all tissues of the body, including multiple endocrine changes that alter growth hormone, corticotrophin, glucocorticoids, and gonadal function. Primary hypothyroidism is associated with hypogonadotropic hypogonadism, which is reversible with thyroid hormone replacement therapy. The same has been seen in our study also that after levothyroxine replacement there was significant improvement in free testosterone level, significant improvement in ADAMS score, although predominance of hypogondotropic hypogonadism was not that significant but still some degree of relevance was observed. So according to the results we concluded that overt hypothyroidism can induce hypogonadism or low testosterone levels in men that is reversible with thyroxine replacement therapy. Importantly, some of the clinical manifestations of primary hypothyroidism in men may be due in part to a reduction in free testosterone. Further evaluation of this potential clinical interaction would require a controlled trial of androgen replacement in the hypothyroid state. However, hypogonadotrophic hypogonadism with thyroxine replacement is reversible with full restoration of normal thyroid function.

Epidemiological, clinic-pathological, evolutionary profile of differentiated thyroid carcinoma in adolescents and young adults:About 161cases

Hajar Khouchaf[1], nassim essabah haraj[2], Siham El aziz[1] & Asma Chadli[2]
[1]Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco; [2]Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and MetabolicDiseases Department, Casablanca, Morocco

Introduction
Adolescent and young adult differentiated thyroid cancers are frequently under diagnosed forms. They would be characterized by their aggressiveness and the presence of particular histological forms. The aim of the study was to describe the characteristics of thyroid carcinoma in adolescents and young adults by analyzing the clinical, histological, therapeutic and evolutionary characteristics.
Materials and methods
We conducted a retrospective study in Endocrinology and Diabetology department of Ibn Rochd University Hospital of Casablanca between 1986-January 2022, including 161 cases of thyroid cancer in young adults under 30 years among all thyroid differentiated cancers (927 patients). This group of patients was compared to a second one aged between 30 and 45 years (386patients). The statistical analysis was performed by the software SPSS version 25.0
Results
Mean age at diagnosis was 22.7years (10-29), with a clear female predominance (91.3%). Familial thyroid neoplasia was found in 11.8% of patients. Predominant mode of discovery was multinodular goiter suspected in 62.1% of cases and lymph node metastases in 9.3% of cases. All patients underwent total thyroidectomy associated with lymph node dissection in 21.1% of cases. Papillary carcinoma was the predominant histological type in 95% of cases. Recurrences were found in 6.1% of cases: locoregional recurrence (4.3%) and pulmonary metastases (1.8 %). The analytical study had shown that the following prognostic factors including multifocality, capsular invasion and bilaterality were significantly higher in the group of young patients compared to the older one ($P <$ 0.001), and that the occurrence of metastases were earlier
Conclusion
Differentiated cancers of the young subject are becoming more and more frequent and invasive. The precocity and frequency of local and distant metastases reflect particularly aggressive forms as reported in the literature.

Severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) in advanced thyroid cancer (TC) patients; single-center experience

George Simeakis, Stavroula A. Paschou, Maria Alevizaki & Katerina Saltiki
National Kapodistrian University of Athens, Dept of Clinical Therapeutics, Athens, Greece

Objectives
Patients suffering from pulmonary or/and neoplastic disease are at higher risk of developing serious illness from SARS-CoV-2. TC patients with lung metastases are classified as high-risk for severe CoV-2 disease. Aim of this study was to investigate SARS-CoV-2 prevalence and severity in this particular subgroup of patients.
Methods
Out of 28 patients with metastatic Differentiated Thyroid Cancer (**DTC**) and 21 patients with metastatic Medullary Thyroid Cancer (**MTC**) followed-up in our Dept, 12 and 11 respectively, present lung metastases and they are under Tyrosine Kinase Inhibitors (TKIs) treatment. During a follow-up period of 18 months (from April-2020) SARS-CoV-2 infections (PCR-confirmed) as well as clinical course of TC patients with lung metastases were recorded.
Results
$n = 4/12$ (33.3 %) **DTC-**patients were diagnosed with SARS-CoV-2. **Two patients**, a 68-year-old-female and a 50-year-old-male, with mediastinal lymph nodes/lung metastases, partial structural response to, Sorafenib-800 mg and Lenvatinib-14 mg respectively, experienced mild symptoms and further hospitalization was not required for them. The **third patient**, a 63-year-old-female, with mediastinal lymph nodes/lung/bone metastases, disease stabilization under Sorafenib-800 mg, required further hospitalization- for a total period of 20 days -with administration of Dexamethasone and Remdesivir; Sorafenib was discontinued during this period. The **fourth patient**, a 52-year-old-male, with lung/liver/bone metastases and disease progression under third line TKI Cabozantinib, succumbed to the disease during his hospitalization. $n = 3/11$ (27.3 %) **MTC**-patients were diagnosed with SARS-CoV-2. **Two patients**, a 52-year-old-female and a 47-year-old-male, (sporadic MTCs), with lung metastases and disease stabilization under Vandetanib-300 mg, experienced mild symptoms and further hospitalization was not required for them. The **third patient**, a 34-year-old-female, (MEN2B), with lung/liver metastases and disease stabilization under Vandetanib-300 mg, suffering with concomitant Multiple-Sclerosis under immunomodulatory treatment, required further hospitalization- for a total period of 10 days -with administration of Dexamethasone and Remdesivir; Vandetanib discontinuation was not requisite. All six patients, during a follow-up period of at least two months, stay healthy with neither residual symptoms nor progression of the neoplastic disease to have been recorded. All but one (MEN2B patient) had undergone SARS-CoV-2 vaccination(BNT162b2).
Conclusions
TC patients with lung metastases, under TKIs treatment, are at high-risk of severe CoV-2 disease. Disease stabilization under TKIs as well as lower metastatic burden seem to be favourable prognostic factors regarding SARS-CoV-2 clinical course. TKIs discontinuation, when questioned, has to be performed under a multidisciplinary team (MDT) approach, with a cost-effectiveness analysis, balancing possible risks of neoplastic disease progression.

Increased incidence of primary hyperparathyroidism in patients with papillary thyroid cancer. Just a coincidence or a new syndrome. I have problems defining the rationale of the study Why PHP and thyroidectomy were performed at the same time

Nektaria Papadopoulou-Marketou[1,2], George Chrousos[1], Panagiotis Tsiamyrtzis[3] & Evaggelos Karvounis[4]
[1]National Kapodistrian University of Athens, University Research Institute of Maternal and Child Health and Precision Medicine, Athens, Greece; [2]National Kapodistrian University of Athens, Endocrinology Unit, 1st Department of Propaedeutic and Internal Medicine, School of Medicine, Athens, Greece; [3]Department of Mechanical Engineering, Politecnico di Milano, Milan, Italy; [4]Euroclinic Hospital, Department of Endocrine Surgery, Center of Excellence, Greece

Presence of primary hyperparathyroidism (PHPT) in patients with thyroid disease has been previously reported. However, co-existence of PTHPT and papillary thyroid cancer (PTC) has been reported very rarely, mainly in the form of isolated case reports. Since the pathophysiological mechanisms of the two diseases are theoretically quite different, no causal relation between these diseases has been inferred. The aim of this study was to investigate the presence of PHTP in individuals who underwent thyroidectomy for suspected thyroid cancer or large nodular goiter.
Patients and Methods
A retrospective observational study involving 3230 patients (24% men, mean age 49.8 years, and 76% women, mean age 47.7 years) who underwent total thyroidectomy in the Department of Endocrine Surgery, Euroclinic Hospital, Athens, Greece, over a period of 13 years (2005-2018). The patient groups were categorized according to histopathological criteria of the parathyroid and thyroid glands.
Results
1945 patients (64%) had large benign nodular goiter, while 978 (32%) had papillary thyroid carcinoma. Among patients with benign nodules and those with papillary carcinoma respectively 16 (11 women/5 men) and 38 (33 women/5 men) had PHPT. The relative risk for coexistence of PHPT and PTC was 2.0 (95% CI 1.7 to 2.4, $P <$ 0.0001). The age groups between 30 and 60 years were associated with the highest relative incidence (82%) of PHTP, while there was sexual dimorphism, with a ratio of 4.4:1 in women *vs.* men.
Conclusions
Our study found that coexistence of PHPT and PTC is relatively common. As primary hyperparathyroidism is a chronic disease that is associated with many complications and requires early diagnosis and treatment, this co-morbidity should be considered in all patients requiring thyroidectomy for cancer. Further investigation of the possibly shared pathogenetic mechanisms between primary hyperparathyroidism and papillary thyroid carcinoma and is warranted.

Short and long-term efficacy of image-guided laser and radiofrequency ablation therapies: a prospective monocentric and single-operator study

Maria Francesca Birtolo[1], Simone Antonini[1], Tiziana Ierace[2], Giacomo Cristofolini[1], Giulia Maida[1], Gherardo Mazziotti[1,3], Andrea Lania[1,3] & Luigi Solbiati[2,3]
[1]IRCCS Humanitas Research Hospital, Endocrinology, Diabetology and Andrology Unit, Rozzano, Italy; [2]IRCCS Humanitas Research Hospital, Department of Radiology, Rozzano, Italy; [3]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy

Background
In the last decades mini-invasive techniques have been proposed to reduce costs and complications of emithyroidectomy and thyroidectomy, both for benign nodular goiter and thyroid microcarcinoma, and image-guided laser and radiofrequency ablation are the most used.
Purpose
To investigate short and long-term efficacy of image-guided laser and radiofrequency ablation as therapy options for benign nodular goiter.
Methods
For this prospective monocentric, single-operator study 41 consecutive patients who underwent either ultrasound-guided laser (USG-L) (25 cases) or radio-frequency (USG-RF) (16 cases) ablation were enrolled. All patients had large, predominantly solid nodules with previous benign, THY2 cytological diagnosis. Subsequently, they underwent follow-up assessment with B-mode, color-Doppler and contrast-enhanced sonography at 1-2 months (first follow-up) and 1-, 2- and 3 years after ablation, with evaluation of the volume reduction ratio (VRR).
Results
The median volume (MV) of the nodules undergone USG-L was 15.7 ml (range 0.75–91.58 ml). At the first follow-up the MV was 10.08 ml, with a median VRR of 44.06% ($P < 0.05$: 34.17-53.94%), while at the 3-year follow-up the MV was 4.08 ml and the median VRR 88.09% ($P < 0.05$: 80.83-95.36%), with positive correlation between patients' age and 3-year VRR ($\theta = 0.43$, $P = 0.031$). In the cohort treated with USG-RF, the MV of nodules was 28.65 ml (range 9.81-109.89 ml) before ablation, and 13.89 ml at the first follow-up, with median VRR of 46.80% ($P < 0.05$; 38.44-55.17%). At 3-year follow-up the MV was 5.17 ml, and the median VRR 80.84% ($P < 0.05$: 73.60-88.08%). The difference in number of cases and pre-ablation size between the two groups do not allow to perform statistically significant comparisons. No immediate or late complications occurred, apart from a moderate local discomfort immediately at the end of the procedure, lasting 24-48 h, in almost all patients. No nodular regrowth was detected and no replacement therapy had to be administered to any patient during the 3-year follow-up.
Conclusion
In accordance with the literature, our study confirms that both USG-L and USG-RF can safely achieve significant and long-lasting size reduction of large benign thyroid nodules. Further studies are needed to evaluate if specific features, such as nodular volume and shape, can affect the procedure outcomes and to compare the effectiveness of the two modalities of treatment.

Comparison of virtual 3D-modelling assisted teaching vs traditional lecture-based teaching for first-year medical students to understand the anatomy of various endocrine organs during the COVID-19 pandemic

Kashish Goyal[1], Kashish Malhotra[1], Rohin Kansal[1], Shubam Trehan[1], Mahima Marwah[1], Harry Goyal[2] & Sakshi Malhotra[3]
[1]Dayanand Medical College and Hospital, Ludhiana, India; [2]All India Institute of Medical Sciences, New Delhi, India; [3]Pandit BD Sharma PGIMS, Rohtak, India

Background
3D-modelling is a computer-generated simulation technique that allows the users to interact with a three-dimensional environment and provide an immersive experience to understand minuscule details which becomes especially important when understanding the anatomical relations of endocrinology organs. During the COVID-19 pandemic, medical lectures were shifted to online mode which diminished the opportunity of cadaveric-based teaching that is routinely done for first-year medical students. This study aims to assess the effectiveness of virtual 3D-modelling assisted teaching for first-year medical students and its comparability to online one-way teaching.
Methods
Various three-dimensional models of endocrine organs including thyroid, adrenal, pancreas, and pituitary were used and first-year medical students of Punjab, India were invited to our week-long online 3D-modelled training to teach anatomy of endocrinology organs. A pre-session and a post-session test was done using multiple-choice questions and short answer questions to assess the effectiveness of the session. Perspectives of medical students' were ascertained using a five-point Likert scale questionnaire along with open-ended questions. The data was analyzed using SPSS statistics v26.0.
Results
Amongst 38 respondents, a significantly higher improvement ($P < 0.001$) was seen in the post-session scores with the majority of students (84.2%) strongly preferring/preferring teaching via 3D models rather than online one-way teaching. Majority of the students had never learned previously (92.1%) via 3D-modelling and strongly agreed/agreed (73.7%) that 3D-modelling shall be included more routinely in teaching to teach complex anatomical relations.
Conclusion
The results indicate that 3D-modelling assisted teaching may be used as an adjunct/alternate to the current online one-way teaching. Besides using this technology to learn about the fundamental sciences like anatomy, it may also be used to get hands-on experience in performing endocrine surgeries in the future after further advancements.

Thyroid hormones and platelet activation in COVID-19 patients

Elena Colonnello[1], Mariaignazia Curreli[1], Rossella Tozzi[2], Anna Criniti[1], Emiliano Lorusso[1], Lucio Gnessi[1], Orietta Gandini[2] & Carla Lubrano[1]
[1]Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University of Rome, Rome, Italy; [2]Rome, Department of Molecular Medicine, Sapienza University of Rome, Rome, Italy

Background
The relationships between thyroid hormones (TH) and platelets (PLT) have not been fully established. Physiological concentrations of L-thyroxine (T4) activate human PLT resulting in ATP release and aggregation. On the other hand, subclinical hypothyroidism has been frequently associated with hypercoagulability, in particular mean platelet volume (MPV), a marker of platelet activation, has been found higher in patients with subclinical hypothyroidism. A possible prothrombotic action of TSH has also been hypothesized. COVID-19 is a pleiotropic virus known to exert its effects in many endocrine glands, including the thyroid. In fact, both direct and indirect mechanisms of Sars-CoV2 infection can render the thyroid dysfunctional. In COVID-19 patients hyperactivated platelets, with an increased MPV, and a low T3 syndrome have been described.
Aim
The aim of this study is to evaluate the relationships among TSH, FT3, FT4 and FT3/FT4 ratio and the MPV in 104 patients affected by COVID-19 on admission to the emergency room.
Methods
104 patients (46 males, 58 females) with real-time polymerase chain reaction testing-confirmed COVID-19 admitted to the Policlinico Umberto I hospital of Rome were included in the analysis. Patients without a history of thyroid disease who had a thyroid function test at admission, before starting any treatment, were enrolled.
Results
The mean age of the patients was 75.2 $\pm$ 11.6 years. The mean MPV was 9.03 $\pm$ 1.36 fL. The mean levels of TSH, FT3 and FT4 were, respectively 1.69 $\pm$ 1.14 μU/ml; 2.48 $\pm$ 0.64 pg/ml; 1.43 $\pm$ 0.53 ng/ml. FT3 showed a trend of negative correlation with MPV (r =-,1195P = 0.351), not statistically significant. FT4 was positively correlated with MPV (r = .2951, P = 0.019). Both TSH and FT3/FT4 ratio had a statistically significant inverse correlation with MPV (respectively, r =-,3848;P =,001 for TSH, r =-,2437, P =,05 for FT3/FT4). All the linear regression were adjusted for age, sex and BMI.
Discussion
In this cohort of COVID-19 patients the relationship between TSH and MPV showed an opposite behavior with respect to that reported in non-sick subjects, suggesting that different mechanisms of interaction of TH with PLT may exist in the setting of acute COVID-19 infection that may be protective against platelet activation.

Correlation between painful subacute thyroiditis and COVID-19

Tamar Maghradze, Elena Shelestova & Ramaz Kurashvili
National Center for Diabetes Research, Endocrinology, Tbilisi, Georgia

Background
Subacute thyroiditis is an inflammatory condition of the thyroid with characteristic presentations and clinical course. Patients with the classic, painful (DeQuervain′s; Granulomatous) thyroiditis, (PFSAT) typically present with painful swelling of the thyroid. At times, the pain begins and may be confined to the one lobe, but usually spreads rapidly to involve the rest of the gland. Pain may radiate to the jaw or the ears. Malaise, fatigue, myalgia and arthralgia are common. A mild to moderate fever is expected, and at times a high fever of 104°F (40.0°C) may occur. It is suggested that the etiology of the disease is mainly viral, in addition, subacute thyroiditis often develops after infection of the upper respiratory tract, influenza, measles. COVID 19 is a potentially severe, primarily respiratory illness caused by a coronavirus and characterized by fever, coughing, and shortness of breath. In some people, the disease also damages major organs.
Aim
This study attempts to review the correlation of PFSAT and COVID 19
Method
Within months after the onset of the Covid pandemic, the number of patients referring to the National Center for Diabetes Research and diagnosed with of PFSAT has increased dramatically. Anamnesis showed that the vast majority had suffered Covid-19. Observations were made on 12 patients (8 females/4 males, mean age 22–51 years,) who had a history of Csovid-19 within past 2-3 months.
Discussion
The following studies were performed: test for Covid 19 antibodies and thyroid function tests (TSH and elevation of total T4 and T3 levels consistent with the thyrotoxic state). T3 (ng/dl) to T4 (mg/dl) ratio was less than 20. ESR (>50), CRP and thyroglobulin were all elevated; TPO-ab, Tg-ab and TSHR-ab were negative; RAIU/Scan-thyroid gland was "low or not" visible; ultrasound echogeneity was hypoechoic and vascularity was decreased. Classical treatment of subacute thyroiditis was started initially with non-steroidal anti-inflammatory agents, but the majority of patients (91%) required treatment with prednisone (20-40 mg daily). Beta blocking agents were prescribed in the majority of patients (76%). Most patients recovered in 6-8 weeks.
Conclsion
Data of our small research have shown that Covid 19 can cause sub-acute thyroiditis, though its course does not differ from the classical sub-acute thyroiditis. Data of new large-scale studiesare needed. We plan to continue our observations and increase the number of patients involved.

Predictors of associated autoimmune diseases in patients with Hashimoto′s thyroiditis.

Rosaria Ruggeri[1,2], Francesca Trunfio[1,2], Giuseppe Giuffrida[1,3], Francesco Trimarchi[2], Alfredo Campenni[4] & Salvatore Cannavò[1,3]
[1]Endocrine Unit at University Hospital of Messina, Italy; [2]Department of Clinical and Experimental Medicine, University of Messina, Italy; [3]Department of Human Pathology DETEV, University of Messina, Italy; [4]Department of Biomedical and Dental Sciences and Morpho-Functional Images, University of Messina, Italy

Background
Increased rates of autoimmune diseases (ADs) have been reported in association with Hashimoto′s thyroiditis (HT); however, the risk factors for coexisting ADs in HT patients have been poorly investigated.
Objective
To evaluate the prevalence and factors associated with AD comorbidities in patients with HT.
Materials and Methods
We recruited 687 patients (626 F and 61 M, mean age at diagnosis 39 ± 14.06 yr, F: M = 10.2: 1) diagnosed with HT in 2019-2021. Clinical, biochemical and demographic data of subjects with and without concomitant ADs were statistically compared.
Results
Among the 687 patients with TH, comorbid ADs were found in 322 (47%; $n=292$ F, mean age 39.5 ± 14.8 yr), of whom 86 (12.5%) suffered from more than one associated ADs. Rheumatic diseases exhibited the highest frequency ($n=226$, 33%, including in order of frequency fibromyalgia, rheumatoid arthritis, Siogren syndrome, to mention a few,), followed by cutaneous ($n=71$, 10%, including vitiligo, psoriasis, alopecia, ….) and gastroenteric ($n=62$, 9% coeliac disease, atrophic gastritis, IBD, …) disorders. HT patients with and without comorbidities did not differ in gender and age at diagnosis ($P>0.005$). However, stratifying patients by age, the prevalence of comorbidities increased with increasing age. The two groups did not differ regarding exposure to the main environmental factors (including cigarette smoking, residence in urban areas or with high industrial density compared to small towns/countryside, eating habits, iodine nutrition and vitamin D). However, a family history of either thyroid or non-thyroid autoimmune diseases was significantly more frequent ($P<0.0001$) in patients with associated comorbidities than in those without. Logistic regression analyses revealed that female sex (odds ratio [OR] = 2.45, 95% confidence interval [CI] = 1.24-4.82; $P=0.011$), age (OR = 1.61, 95% CI = 1.18-4.27; $P=0.04$) and family history of ADs (OR = 5.18, IC 95% = 2.217–12.105; $P=0.001$) were predictors of associated ADs.
Conclsions
Female HT patients with increasing age and a family history of ADs have increased rates of AD comorbidities. These data suggest a preponderant role of genetic background, of which familiarity can be considered a surrogate marker, in determining the risk of developing autoimmune comorbidities in HT patients.

The impact of insulin resistance on thyroid function in pregnancy

Andrzej Nowak[1], Grzegorz Sokolowski[2], Alicja Hubalewska-Dydejczyk[2] & Malgorzata Trofimiuk-Muldner[2]
[1]Medical University of Warsaw, Department of Gynecological Endocrinology, Warszawa, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Background
The influence of hyperinsulinemia and insulin resistance on thyroid function is debatable. Insulin, as an anabolic hormone, may also play a role in thyroid hypertrophy and nodular goitre development. Some recent reports focus on the possible interplay between thyroid function and glucose status in pregnancy, including gestational diabetes mellitus.
Aim
The study aimed to assess the relationship between insulin resistance indices and thyroid function in pregnancy.
Material and methods
The study included 1069 pregnant women (median age 29 years, IQR-6 years). Serum TSH, FT4, FT3, and aTPO were measured in each patient. Homeostatic Model Assessment of Insulin Resistance (HOMA-IR) index was assessed based on fasting glucose and insulin concentrations. In each pregnant woman, a thyroid ultrasound was also performed.
Results
The study participants were stratified into three groups based on HOMA-IR. Group 1 included 324 women with HOMA-IR <1; group 2 – 570 women with HOMA-IR between 1 and <2.5, and group 3 – 175 women with HOMA-IR <2.5. Group 1 and 2 differed significantly in TSH (1.66 mIU/l vs. 1.84 mIU/l, $P=0.0205$), and FT3 concentrations (5.12 mIU/l vs. 4.76 mIU/l, $P=0.002$). No difference was found in FT4 concentrations (12.91 pmol/l vs. 12.65 pmol/l, $P=0.1153$). Group 1 and 3 differed significantly in TSH (1.66 mIU/l vs. 1.96 mIU/l, $P=0.0023$), FT4 (12.91 pmol/l vs. 11.47 pmol/l, $P=0.0000$), and FT3 concentrations (5.12 pmol/l vs. 4.66 pmol/l, $P=0.0000$). The significant difference between group 2 and 3 was only found for fT4 concentrations ($P=0.000$) (P values for difference in TSH and FT3 concentrations were 0.1958 and 0.2593 respectively). The groups did not differ in aTPO concentrations. aTPO-positivity was not related to HOMA-IR values (mean HOMA-IR in aTPO-positive and aTPO-negative women was 1.63 and 1.80 respectively, $P=0.32$). Fasting insulin >10 mIU/ml was found in 27.53% of pregnant women (286 out of 1039) with thyroid volume <25 mL, in contrast to 36.67% women (11 out of 30) with thyroid volume <25 mL.
Conclusions
our results indicate that insulin resistance may impact thyroid function in pregnancy independently of thyroid autoimmunity, with higher TSH and lower thyroid free hormone concentrations in pregnant women with higher HOMA-IR indices.

DOI: 10.1530/endoabs.81.P739

Sub acute thyroiditis following COVID-19 vaccination – case report and International survey

William Bennet, Aisha Elamin & John Newell-Price
Sheffield Teaching Hospitals, Endocrine Department, Sheffield, United Kingdom

Case report
A 52-year-old woman developed painful anterior neck swelling seven days after receiving the first COVID-19 vaccine AstraZeneca (AZ). Investigations showed TSH 0.14 mIU/l, CRP 34 mg/l and TRAb 0.3 IU/l. A neck Doppler ultrasound scan on day 15 showed features of thyroiditis. On day 21, she was hyperthyroid with TSH <0.02 mIU/l and free T4 70.3 pmol/l. COVID-19 test was negative, and she was advised to start Carbimazole and propranolol but took only the beta-blocker. She felt well seven weeks after vaccination, and her TSH was spontaneously normalised. Later, she remained asymptomatic but was biochemically mildly hypothyroid with TSH 11 mIU/l and free T4 9 pmol/l, and by week 18, her TSH had spontaneously normalised again. The diagnosis was subacute thyroiditis. She had no prior history of thyroid disease; she was otherwise well and took no regular medication. She was concerned that the COVID-19 vaccination had triggered her subacute thyroiditis.
Survey results
In light of this case report, we conducted an email survey via the Society for Endocrinology UK, about subacute thyroiditis arising within 28 days of administration of a COVID-19 vaccine. Seventeen cases were reported to us: seven were from the UK, 14 were from physicians, and three were from patients. Eleven cases followed Pfizer-BioNTech mRNA vaccine, five followed AZ ChAdOx1 S recombinant vaccine, and one occurred after Moderna mRNA vaccine. Nine cases developed after the first dose of vaccine and eight after a second dose, with symptom onset a mean of 14.5 days after vaccination, ranging from self-limiting to a more severe illness requiring glucocorticoid therapy.
Discussion
There was a temporal association between COVID-19 vaccination and the onset of subacute thyroiditis. It appears likely that COVID-19 vaccines can trigger subacute thyroiditis due to an autoimmune/inflammatory (ASIA) syndrome. Case reports and small case series of subacute thyroiditis following COVID-19 vaccination have recently been described. Endocrinologists should be aware of potential vaccine sequalae when managing thyrotoxic patients, including the heightened risk that thyrotoxicosis following COVID-19 vaccination will result from a potentially self-limiting subacute thyroiditis. It has also been reported that Graves′ disease can develop shortly following COVID-19 vaccination. With over 7 billion COVID-19 vaccine doses administered to date, and a background subacute thyroiditis incidence of 4.9 per 100.000, there remains a caveat that the cases reported here may have arisen by chance.

Aim
Dose corrected for thyroid gland size is one of the methods used to determine radioactive iodine (RAI) activity for patients with Graves disease (GD). This study was aimed to investigate the real-world success rate of this method and the predictors of success after first treatment.
Methods
This is a retrospective study of 80 patients with GD treated between 2014 and 2020 in a tertiary referral hospital in Almada, Portugal. The successful group was defined as maintained Eu- or hypothyroid for at least 12 months after RAI therapy. We used SPSS and Excel to analyze the data.
Results
A total of 80 patients (67 females; mean age: 48 years (SD 13)) were selected and enrolled. The mean estimated thyroid gland size was 59.6 (SD 25) g. Out of 80 patients, 63 (79%) were successfully (Group 1) and 17 (21%) were unsuccessfully (Group 2) treated with the first dose of RAI. In Group 1, one year after the first dose of radioactive iodine therapy, 65% of patients were hypothyroid and 14% were euthyroid. The mean overall dose was 11.6 mCi (SD 4). Univariate analysis showed a significant association between shorter disease duration ($P=0.031$), lower T3 levels ($P=0.017$) and treatment success, but no significant association between sex, age, TRAb titres, RAIU, thyroid gland size, and previous anti-thyroid treatment. Multivariate logistic regression analysis failed to demonstrate a single independent factor capable of predicting RAI effectiveness, although some variables showed a tendency toward a statistical significance: shorter disease duration since the diagnosis ($P=0.056$) smaller RAI dose ($P=0.05$), and non-smoking ($P=0.057$). Nevertheless, we must consider these are only preliminary results, based on a relatively small sample. Further studies with larger samples are needed to confirm the results.
Conclusion
First RAI therapy using dose corrected for thyroid gland size had a success rate of 79% in patients with Graves disease, which is in line with previous studies. We found that shorter disease duration and lower T3 levels were strongly associated with treatment efficacy in the univariate analysis.

Curcumin attenuates the pro-inflammatory response induced by hyaluronan oligosaccharides in human thyroid fibroblasts and thyrocytes

Rosaria Ruggeri[1,2], Aurelio Minuti[2,3], Federica Aliquò[3], Alfredo Campennì[3], Angela Avenoso[3], Fiorenza Gianì[4], Roberta Masto[4], Salvatore Cannavò[2,5] & Angela D'Ascola[1]
[1]University of Messina, Dep Clinical and Experimental Medicine, Messina, Italy; [2]Endocrine Unit at University Hospital, Messina, Italy; [3]University of Messina, Department of Biomedical Sciences and Morphological and Functional Images, Messina, Italy; [4]University of Catania, Dept Clinical and Experimental Medicine, Catania, Italy; [5]University of Messina, Dep Human Pathology of Adulthood and Childhood "G. Barresi", Messina, Italy

Background
Lymphocytic infiltration and inflammation in autoimmune thyroid diseases (AITDs) results in accumulation of HA, contributing to the pathogenesis of both thyroidal and extra-thyroidal (ophthalmopathy, pretibial dermopathy and mixedema) manifestations of AITDs. HA fragments, originating from native HA during tissue inflammation and injury, in turn promote the expression of different mediators of oxidative stress and inflammation, by interacting with the Toll-like receptor 2 (TLR-2) and 4 (TLR-4) and CD44, via nuclear factor kappa-B (NF-kB). Curcumin (diferuloylmethane) is a phytochemical with anti-inflammatory properties. It has been reported to have suppressive effect on NF-kB signaling pathway in various cell types. This study was aimed at investigating the effects of curcumin treatment in cultured primary human thyrocytes and fibroblasts after exposure to 6-mer HA oligosaccharides (6-mer HA).
Methods
Cultured cells were treated with increasing concentrations of curcumin (5 and 10 μg/ml), with and without 6-mer HA (50 μg/ml). mRNA and proteins expression for TLR-2, TLR-4, inducible nitric oxide synthases (iNOS), interleukin-1beta (IL-1beta), IL-6, matrix metalloproteinase 9 (MMP-9), and thyroid-specific genes [thyroglobulin (Tg) and sodium iodide symporter (NIS)] were evaluated by real-time PCR and Western Blot, respectively. Protein quantification was assessed by densitometry analysis. NF-kB (p65) activation was determined in nuclear extracts by DNA binding activity assay. The pro-inflammatory cytokines IL-1 beta and IL-6 levels were measured by ELISA. Levels of NO were measured in culture medium by a fluorometric assay.
Results
In both cell lines 6-mer HA treatment induced the increase in mRNA and protein of TLR-2, TLR-4, CD44, as well as the activation of NF-kB, that in turn increased iNOS, IL-1beta, IL-6 and MMP-9 expression and NO levels. The addition of curcumin at increasing concentrations (5 and 10 μg/ml) decreased NF-κB activation and significantly reduced, iNOS, IL-1beta, IL-6, MMP-9, and NO levels in a dose-dependent manner ($P<0.01$ and $P<0.001$ respectively). Furthermore, in thyrocytes curcumin significantly restored the mRNA expression of Tg and NIS, decreased after exposure to 6-mer HA. Curcumin only slightly reduced CD44 expression ($P<0.05$) and did not change TLRs levels, suggesting that its anti-inflammatory effect mainlly depends on the inhibitory effect on NF-kB activation.
Conclusions
Curcumin attenuates the pro-inflammatory effects of HA oligosaccharides in both thyrocytes and fibroblasts. Since HA fragments might contribute to inflammation in both thyroidal and extra-thyroidal (i.e. dermal and orbital) tissues in the course of AITDs, curcumin could be beneficial in these disorders as a suitable adjunct to conventional pharmaceutical therapy.

Concomitant Graves' disease with COVID-19 infection

Raluca Trifanescu[1,2], Iustin-Daniel Toma[2], Maria - Alexandra Mohora[2], Marioara Cristina Corneci[2], Ileana Nitu[2], Nicoleta Baloseanu[2], Suzana Vladoiu[3], Sorina Schipor[3], Anda Dumitrascu[4] & Catalina Poiana[1,2]
[1]"Carol Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]"C.I. Parhon" National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [3]"C.I. Parhon" National Institute of Endocrinology, Scientific Research Laboratory, Bucharest, Romania; [4]"C.I. Parhon" National Institute of Endocrinology, Radiology Department, Bucharest, Romania

Background
Subacute thyroiditis, autoimmune thyroiditis and an atypical form of thyroiditis due to primary injury of the thyroid gland by SARS Cov2 itself are complications of COVID-19. Angiotensin-converting enzyme 2 is also expressed in the thyroid gland. On the other hand, both untreated thyrotoxicosis and COVID-19 affects heart, generating cardiac complications.
Case report
A 36-year-old woman resident in an iodine sufficient area, heavy smoker, presented for palpitations, resting dyspnea, pedal edema, 40 kg weight loss in the past 2 months, tremor and asthenia. She denies cough, sore throat, rhinorrhea, smell or taste loss, myalgias or diarrhea. Physical examination reveals resting dyspnea, SaO2-95-96%, atrial fibrillation with arrhythmic HR = 200/min, severe heart failure with right pleural effusion and pedal edema, small goiter, tremor, low fever, agitation. Biochemical assessment revealed autoimmune thyrotoxicosis (TSH = 0.0007 mIU/l; FT4 = 40.06 pmol/l, total T3 = 309.88 ng/dl, increased TRAb (160 UI/l) and TPO Abs (209.7 IU/ml), anemia, leukopenia (3680/mm3) with lymphopenia. ESR, fibrinogen, C-reactive protein, procalcitonin were normal. Liver enzymes are elevated, hyperbilirubinemia was present (total bilirubin = 2.6 mg/dl, direct bilirubin = 1.9 mg/dl), alkaline phosphatase (180 U/l) and GGT were also increased. From cardiac point of view, D-Dimers were increased (403.925 ng/ml), CK MB was slightly increased (32 UI/l), troponin was normal, but NTproBNP was significantly increased (6112 pg/ml). RT PCR for SARS Cov2 was positive, IgM Abs against SARSCov 2 were slightly elevated, Ig G Abs were negative. A native CT scan confirmed right massive pleural effusion, without significant pulmonary involvement. Thyroid diffuse enlargement and markedly increased color flow Doppler signal with diffuse homogeneous distribution were present on thyroid ultrasound.
Treatment
During the hospitalization, antithyroid drugs were initiated, well tolerated, with significant decrease of FT4 within 3 days from 40.6 pmol/l to 23.64 pmol/l. High dose beta blockers, digoxin, double diuretic medication and anticoagulation with NOAC were administered for controlling heart rate and severe heart failure.
Follow-up
Despite having initially an increased score for thyroid storm (85), this patient with concomitant Graves disease and COVID-19 infection had a significant improvement within 4 weeks: weight gain, atrial fibrillation converted to sinus rhythm, FT4 was low-normal (8.43 pmol/l), NTproBNP significantly decrease (1007 pg/ml). No pleural effusion was described on her chest X-Ray; Her RT-PCR test was still positive for SARS-CoV-2 and Ig G Abs were increased (43IU/ml).
Conclusion
concomitant Graves disease and COVID-19 infection may be a cause of atrial fibrillation and severe heart failure during SARS Cov2 pandemic.

Echocardiogram findings in patients with hyperthyroidism

Wiem Madhi[1], Khaled Ezzaouia[2], Meriem Yazidi[1], Fatma Chaker[1] & Mélika Chihaoui[1]
[1]Rabta Hospital of Tunis, Endocrinology - Diabetology, Tunisia; [2]Rabta Hospital of Tunis, Cardiology, Tunisia

Introduction
Thyroid hormones have an impact on the function and structure of the cardiac muscle.
Aim
Investigate the prevalence and risk factors of structural and functional cardiac complications in patients with hyperthyroidism.
Methods
We conducted a cross-sectional study on 30 patients with uncontrolled hyperthyroidism. Clinical, biological and therapeutic data were collected. A trans-thoracic echocardiography (TTE) and lung ultrasound has been performed to all patients.
Results
Eight patients presented with left heart failure (HF) signs/symptoms, two presented with right HF signs/symptoms. TTE was abnormal in 12 patients (40%) (Table); all of whom presented pulmonary hypertension (PH). Echocardigraphic signs of HF were present in eight patients: seven patients met the definition of HF with preserved ejection fraction and one had HF with reduced ejection fraction. Clinical signs/symptoms of HF, lower TSH levels, elevated LVFP and a higher E/E′ were associated to PH, $P = 0.013$, $P = 0.004$, $P = 0.003$, $P = 0.002$. HF and PH were associated to the presence of tachycardia in the 24-h Rhythmic Holter monitoring$P = 0.039$, $P = 0.011$, they were also associated to a higher number of premature atrial contraction$P = 0.007$, $P = 0.007$.
Conclusion
Hyperthyroidism can modify the cardiovascular hemodynamic leading to congestive heart failure and pulmonary hypertension.

Table 1 Echocardiographic parameters in patients with hyperthyroidism

Echocardiography parameter	
Pulmonary hypertension, *n (%)*	12 (40)
Elevated filling pressure, *n (%)*	8 (27)
Dilated left atria, *n (%)*	7 (23)
Dilated right atria, *n (%)*	4 (13)
Pulmonary B-lines, *n (%)*	3 (10)
Mitral insufficiency, *n (%)*	5 (17)
Mild	4
Moderate	1
Dysfunction the right ventricle, *n (%)*	2 (7)
Right ventricle hypertrophy, *n (%)*	2 (7)
Right ventricle dilation, *n (%)*	2 (7)
Reduced LV ejection fraction (<50%), *n (%)*	1 (3)
E/E′, m ± SD (extremes)	7.84 ± 5.7 (4 – 35)
LV end-diastolic diameter (mm), m ± SD (extremes)	45.3 ± 4.8 (39 – 62)
Cardiac output (l/min), m ± SD (extremes)	6.79 ± 2.29 (2.57 – 11.36)

Myxedema coma of both primary and secondary origin, with non-classic presentation and elevated creatine kinase

Mihai Lucian Pavel[1], Anca Elena Sirbu[1,2], Miruna Maria Popa[1,2], Irina Bargaoanu[1] & Simona Fica[1,2]
[1]University Hospital of Emergency Elias, Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction
Myxedema coma is the end stage of untreated or inadequately treated hypothyroidism. It has an estimated incidence of 0.22 per million per year. The clinical picture is often that of an elderly obese female, presenting in midwinter with increased lethargy, somnolence and confusion. The presentation is one of severe hypothyroidism, with or without coma.
Such cases are predominantly based on a primary thyroid disorder such as Hashimoto's thyroiditis. However, the underlying cause in approximately 5% of myxedema cases is hypothalamic or pituitary disease, where the patient usually lacks multiple anterior pituitary hormones, including thyroid-stimulating hormones (TSH).
Case study
A 69 years old male presents to the ER with dizziness, headache, postural instability, bradylalia and bradypsyhia symptoms that appeared 1 week prior. A stroke diagnosis was suspected and a cerebral CT scan was made showing a 22/21/38 mm pituitary adenoma with suprasellar extension. Laboratory tests showed high creatine kinase (4459 U/l) and LDH (591 U/l) and low natrium (122 mmol/l). He was then transferred to our clinic.
General examination revealed bradylalia, bradypsyhia, dry, coarse skin, hoarse voice, thin scalp and eyebrow hair with little to no body hair. Laboratory tests showed low values for FT4 (<0.3 ng/dl), TT3 (<40 ng/dl) low values for IGF1 (43.92 ng/ml), FSH (0.683 mIU/ml), LH (<0.1 mIU/ml), morning cortisol (1.06 microg/dl), ACTH

not available and high prolactin (1772 ng/ml) but high thyroglobulin antibodies (> 4000 IU/ml), and less than predicted high TSH (41.8 microUI/ml), TPO antibodies not available. The patient had prolonged QT interval on ECG and minimal pericardial effusion and minimal ventricular dyskinesia on cardiac ultrasonography. We started treatment with L-thyroxine, corticotherapy and cabergoline with clinical improvement.
Conclusion
A male patient diagnosed with myxedema coma of both primary (Hashimoto′s thyroiditis) and secondary origin (macroprolactinoma with associated panhypopituarism) with high creatin kinase and non-classical presentation is treated with hormonal replacement therapy and dopamine receptor agonist with favorable evolution.
Key words: myxedema coma, primary and secondary origin, prolactinoma

Lenvatinib-induced hypocalcaemia due to transient hypoparathyroidism: a case-report

Matteo Trevisan[1], Carla Colombo[2], Noemi Giancola[1], Luca Persani[1,3], Laura Fugazzola[2,3] & Simone De Leo[3]
[1]Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [2]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [3]Division of Endocrine and Metabolic Diseases, Istituto Auxologico Italiano IRCCS, Milan, Italy

Radioiodine refractory differentiated thyroid cancer can be effectively treated with multi-tyrosine-kinase inhibitors (mTKI). Due to their pleiotropic mechanism of action, these drugs may cause different side effects. Hypocalcaemia has been reported in up to 35% of patients treated with mTKI, but little is known about its pathophysiology and clinical relevance. We report the case of a 78 years old woman treated for a multifocal papillary thyroid cancer, infiltrating perithyroidal tissues, striated muscles, oesophagus, blood and lymphatic vessels. Due to the tumour extension and infiltration to contiguous structures, the extent of surgery was limited to hemithyroidectomy and radioactive-iodine treatment could not be performed. The patient was therefore started on lenvatinib 10 mg per day. During the first months of treatment, the patient experienced grade I-II anorexia, fatigue, diarrhoea, nausea and hypertension, according to CTCAE, with no significant alteration at blood exams. Serum thyroglobulin (Tg) decreased from 6825 µg/l to a minimum of 49.6 µg/l, with negative anti-Tg antibodies. After four months of therapy, the patient accessed the E.R. for sudden dyspnoea, muscular cramps and spasms in the upper and lower limbs. Blood exams revealed a grade III hypocalcaemia (corrected serum calcium: 6.6 mg/dl), due to primary hypoparathyroidism (serum PTH: 12.6 pg/ml; serum phosphorus: 4.7 mg/dl). The patient was treated with intravenous calcium infusions and oral vitamin D supplementation. After discharge, the oral dose of carbonate calcium was of 6 g per day. Lenvatinib was discontinued for the duration of hospitalization and restarted three days after discharge, when serum calcium levels were effectively stabilized by oral supplementation (corrected serum calcium: 8.8 mg/dl). Calcium intake was titrated according to blood exams performed every 3-5 days. Two weeks after discharge, while taking calcium 3 g per day, the patient complained worsening of anorexia and stupor. Grade II hypercalcemia (serum calcium: 11.7 mg/dl) was demonstrated. She was treated with an intravenous infusion of physiological solution and calcium supplementation was interrupted. During the following follow up, the patient remained and still is eucalcemic without calcium supplementation. Though hypocalcaemia has already been described as potential side effect, this is the first report of a lenvatinib-induced primary hypoparathyroidism. This case is of particular interest since the patient was submitted to hemithyroidectomy and the hypoparathyroidism was thus definitely not-related to surgery. Further studies are needed to clarify pathogenesis and relevance of this life-threatening adverse event.

Outcomes of incidental thyroid nodules identified during imaging for primary hyperparathyroidism: a retrospective observational clinical study

Quratulain Yousuf[1], Paul Wilson[2] & Laks Varadhan[1]
[1]University Hospitals of North Midlands, Diabetes and Endocrine, Stoke on Trent, United Kingdom; [2]University Hospitals of North Midlands, ENT, United Kingdom

Introduction
Pre-operative localization of parathyroid adenoma is generally done by two localization studies: ultrasonography (US) and parathyroid scintigraphy using 99 m-techentium sestamibi SPECT with CT (Tc-MIBI SPECT/CT), which also report on Incidental thyroid nodules. The aim of our retrospective study was to determine the incidence, characteristics and outcomes of these incidental thyroid findings during parathyroid imaging.
Method
A database of all patients who underwent parathyroid surgery over 2 years (2017-2019) was derived from ENT department. As per local clinical practice, all patients had pre-operative localization with US and Tc-MIBI SPECT/CT. Patients with tertiary hyperparathyroidism were excluded. Clinical details including thyroid function status, outcomes of imaging, referral for further investigations such as FNA and their outcomes were collected. Suspicious thyroid nodules were investigated as per standard clinical practice and local thyroid MDT decisions.
Results
A total of 111 patients were included for analysis. The anatomical outcomes were: Normal gland 52, ectopic thyroid gland 2, unclassified nodules including multinodular goitre 14, benign thyroid nodule not requiring further investigation (graded as U2 on US) 31 and nodules requiring further investigation (graded U3 or above on US). FNA of these 12 patients showed: thyroid carcinoma 7(4 papillary and 3 follicular variant), benign intra-thyroid parathyroid adenoma 3, hyperplastic nodule 1 and lymphocytic thyroiditis 1. All patients with thyroid carcinoma proceeded to total thyroidectomy as per MDT outcome.
On the Tc-MIBI SPECT/CT, 8 patients showed heterogeneous or reduced thyroid uptake, including 3 out of 7 thyroid carcinoma patients proceeding for biopsy and 1 lymphocytic thyroiditis all these patients were on thyroxine replacement. One patient with hyperplastic nodule showed persistent intense uptake while rest 102 patients showed homogenous and symmetrical uptake and were biochemically euthyroid.
Conclusion
A significant number of incidental thyroid findings are identified during parathyroid localization imaging. Our study showed 11% that required further investigations with incidental diagnosis of thyroid cancer.

Oncocytic carcinoma of the thyroid: epidemiological, clinical and anatomopathological characteristics

Nezha Raki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC IBN Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Oncocytic thyroid carcinoma is rare. It is an aggressive tumor, with high nodal and distant metastatic potential.
Purpose of the study
to describe the epidemiological, clinical and anatomopathological particularities of oncocytic carcinomas of the thyroid.
Method
Descriptive retrospective study, including patients followed in thyroid carcinoma consultation at the Endocrinology Department of the CHU Ibn Rochd in Casablanca from 1986 to 2021.
Results
we collected 12 cases of oncocytic carcinomas of the thyroid. The average age of the patients was 53.4 years with a female predominance (11women/1 man). The circumstance of discovery was a multiheteronodular goiter in 67% of the cases, a thyroid nodule in 25% and a toxic multinodular goiter in 8% of the cases. In our series, the majority of patients (67%) had nodules on ultrasound classified EU-TIRADS4. Treatment consisted of total thyroidectomy in 100% of patients, associated with cervical lymph node dissection in 17% of patients. The average size on the anatomopathological examination of these carcinomas was 4.4 cm; the multifocal character was objectified in 25% of the cases with an extrathyroid microscopic extension in 41.6% of the cases. All our patients subsequently benefited from radioactive iodine therapy.
Conclusion
Oncocytic carcinomas of the thyroid constituting a particular anatomo-clinical entity. The diagnosis is based on a range of clinical (size of the nodule, age over

50 years) and histological (capsular rupture, multifocality, angioinvasion) arguments. The surgery must be wide in front of the resistance to radioactive iodine therapy.

DOI: 10.1530/endoabs.81.P748

Sonographic and cytological characteristics of non invasive thyroid follicular neoplasm with papillary nuclear features vs papillary carcinomas

Nezha Raki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC IBN Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
NIFTP (non invasive follicular neoplasm of the thyroid with papillary-like nuclear features, formerly noninvasive encapsulated follicular variant of papillary thyroid carcinoma) has been removed from the carcinoma category due to its indolent nature and its good prognosis. The purpose of our study was to identify preoperative ultrasound and cytological differences between NIFTP and papillary thyroid carcinoma (PTC).
Materials and methods
retrospective study including patients followed in the endocrinology department of the CHU Ibn Rochd in Casablanca, from 2017 to 2021, with histological diagnosis of PTC or NIFTP
Results
A total of 113 cases, including 27 NIFTPs, 86 papillary carcinomas, were observed. The 14 NIFTPs involved 24 women and 3 men, with an average age of 51.9 years, 2 patients had a history of familial thyroid carcinoma. The majority of patients ($n=24$) were euthyroid, 3 were hyperthyroid. Preoperative cytological data were available for 11 cases. Compared to papillary carcinomas, nodules corresponding to NIFTPs are more isoechogenic (59.3% vs 8.1%; $P\leq0.001$), have regular contours (85.2% vs 52.3%; $P\leq0.01$) and have a TIRADS score 3 (48.1% vs 8.1%; $P\leq0.001$), TIRADS 4 (40.7% vs 43%) or TIRADS 5 (7.4% vs 48.8%). Cytologically, NIFTPs are preferentially distributed in categories III (18% vs. 3.8%), IV (9% vs. 11.5%) and V (36.3% vs. 38.4%) of the Bethesda classification without significant difference compared to papillary carcinoma ($P\leq 0.9$).
Conclusion
NIFTPs appear mostly non-suspicious on preoperative ultrasound and of indeterminate significance on cytology. These differences compared to papillary carcinomas can make it possible to suspect the diagnosis preoperatively and to better adapt the surgical management.

BRAFV600E, NRAS, TERT promoter mutations and correlations with clinicopathological features and distant metastasis in Turkish patients with papillary thyroid carcinoma

Ezgi Yılmaz[1], Yesim Gaye Guler Tezel[2], Olcay Kurtulan[2], Jale Karkaya[3], Murat Tuncel[4] & Alper Gurlek[5]
[1]Hacettepe University, Internal Medicine, Ankara, Turkey; [2]Hacettepe University, Pathology, Ankara, Turkey; [3]Hacettepe University, Biostatistics, Ankara, Turkey; [4]Hacettepe University, Nuclear Medicine, Ankara, Turkey; [5]Hacettepe University, Endocrinology and Metabolism, Ankara, Turkey

Background
Various molecular mechanisms play a role in the pathogenesis of papillary thyroid cancer(PTC). Understanding the underlying pathogenesis and genetic changes is needed to improve clinical outcomes in PTC. In this study, it was aimed to determine the frequency of, *BRAF* ^{V600E} *TERT promoter* and *NRAS* mutations in Turkish patients with papillary thyroid cancer, the relationship of mutations between clinicopathological features and distant metastasis and the prognostic and predictive value of mutations.
Methods
In the study, mutations were detected by PCR and direct sequencing method from the paraffin-embedded tumor tissues of 42 PTC patients over 18 years of age who were followed up in Hacettepe University Hospital and archived in the Department of Pathology between 2004-2021, with 16 distant metastasis and 26 without distant metastasis patients and their relationship with clinicopathological features was determined. Pearson′s, chi-square and Mann-Whitney U tests were used for statistical analysis. A value of $P<0.005$ was considered statistically significant.
Results
The overall frequency of *BRAF* ^{V600E} mutation was 64.3% (27/42), *BRAF* positivity was found in %22.2 (6/15) of patients with distant metastasis and 77.8% (21/25) in those without ($P=0.006$). There was no statistically significant difference between *BRAF*^{V600E} mutation and age at diagnosis, gender, tumor size, histological variant, extrathyroidal invasion, multifocality, lymphovascular invasion, capsule invasion, lymph node metastasis, recurrens and distant metastasis. The survival rate was found to be lower in *BRAF*^{V600E} positive cases (3.7%) than in negative cases (96.3%) ($P=0.03$). The frequency of *TERT promoter* mutation was found to be 9.5% (4/42). These mutations were all mutations at position C228T. No statistically significant difference between *TERT promoter* mutation and age at diagnosis, gender, tumor size, histological variant, extrathyroidal invasion, multifocality, lymphovascular invasion, capsule invasion, lymph node metastasis, recurrens and distant metastasis. There was no statistically significant difference for clinicopathological features and distant metastasis in cases with *BRAF* ^{V600E} and *TERT promoter* mutations and in cases with both.
Conclusions
In contrast with the observations in other populations, *BRAF* ^{V600E} was found to be higher in Turkish PTC cases without distant metastasis compared to ones with distant metastasis. The combination of *BRAF* ^{V600E} and TERT promoter mutations in PTC is not prognostic or predicitive for distant metastasis.

Postoperative thyroglobulin (Tg) as a predictor of long-term recurrence in differentiated thyroid carcinoma (DTC)

Nerea Utrilla Uriarte[1], Miren Badiola Molinuevo[1], Virginia Urquijo Mateos[1], Pedro Gonzalez Fernandez[1], José Genollá Subirats[2] & Javier Santamaría Sandi[1]
[1]Cruces University Hospital, Endocrinology, Spain; [2]Cruces University Hospital, Nuclear Medicine, Spain

Introduction
To determine the risk of recurrence in DTC, different clinical factors have been used (presence of adenopathies, extrathyroid extension, histology...). The objective was to examine whether the value of early postoperative Tg concentration may also predict long-term recurrence of DTC.
Material and Methods
The study included 249 consecutive patients (78.3% women, mean age 50.72 $\pm$ 14.26 years) with DTC who were initially treated by total thyroidectomy $\pm$ lymphadenectomy between 2000 and 2016. Serum Tg level was measured 6-8 weeks after surgery using the Immulite 2000 Siemens method, with a sensitivity of 0.5 ng/ml. The patients have been followed-up for a minimum of 5 years (mean 7.27 $\pm$ 2.7 years) or until recurrence was detected. At the end of follow-up, their clinical situation was analyzed according to dynamic risk stratification. Patients with positive anti-Tg antibodies were excluded.
Results
The results obtained are shown in Table 1.

Tg:	$n=249$	Disease recurrence	Excellent response*
<0.5 ng/ml	175	6 (3.4%)	152 (86.9%)
0.5-2 ng/ml	41	6 (14.6%)	25 (61%)
>2 ng/ml	33	17 (51.5%)	12 (36.4%)

*Excellent response was defined as Tg<0.2 ng/ml and no structural disease in neck sonogram.The mean time to recurrence was 35.9 months in patients with Tg<2 ng/dl and 26.4 months in those with Tg<2 ng/ml ($P=$ ns).

Conclsions
Postoperative Tg helps to predict the risk of DTC recurrence, so it should be used routinely in the postoperative evaluation of these patients. 2. In our series, Tg >2 ng/ml predicts a high risk of long-term recurrence, so therapeutic measures and surveillance should be intensified.

Thyroid Cystic Papillary Carcinomas - What's visible is not always seen

Catarina Roque, Ricardo Fonseca & Ana Sofia Osório
Hospital Professor Doutor Fernando Fonseca, Endocrinology, Lisbon, Portugal

The vast majority of thyroid cancers are solid. Predominantly cystic tumors occur in <3% cases. Guidelines report as US characteristics consistently associated with a higher risk of malignancy eccentric position of the solid component, acute angle interface and microcalcifications and as less robustly associated lobulated margins and increased vascularity of the solid portion. We reviewed the US characteristics of predominantly cystic papillary carcinomas confirmed on histological analysis diagnosed at our institution in 2021. The patients had no identifiable clinical risk factor for malignancy. Ultrasound evaluation: Patient 1, 49 y.o. female: predominantly cystic 15 mm nodule with a 5 mm eccentric mixed isoechoic and hypoechoic solid component with irregular margins and hyperechogenic foci, on the isthmus. Histology confirmed 12 mm PTC, pT1b(s)NxMx. Patient 2, 30 y.o. male: predominantly cystic nodule with 61 mm on the right lobe, with an isoechoic solid component with irregular margins and an area of thick wall with hyperechoic foci. Histology confirmed the rare macrofollicular encapsulated variant of the PTC with 50 mm, pT3 NxMx. Patient 3, 42 y.o. male: A solid hypoechoic nodule with lobulated margins and hyperechoic foci with 29 mm on the isthmus and a predominantly cystic nodule with a solid lobulated hypoechoic component with hyperechoic foci that showed increased sign on color-doppler on left lobe. Histology confirmed a 25 mm PTC, pT2(s)N1aR2. All patients had a single mixed supra-centimetric nodule. Margin irregularity or lobulation, microcalcifications and eccentric position of the solid component were present in all three. In all cases the nodules had more than one suspicious feature on US, but not all were described in the US report. US image review is crucial in thyroid nodule evaluation as it alerts the clinician and enables identification of at risk patients to be selected for timely and proper treatments.

Somatostatin analog therapy in advanced sporadic medullary thyroid carcinoma: a case report

Roxana Dumitriu[1,2], Calin Cristiana[1,2], Iulia Florentina Burcea[1,2], Anda Dumitrascu[2] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Endocrinology, Bucharest, Romania; [2]C. I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania

Introduction
Medullary thyroid carcinoma (MTC) is an aggressive neuroendocrine tumor derived from C cells that is responsible for approximately 5% of the gland malignancies, most of them occuring sporadically. Lymph node metastasis may occur early in disease pathogenesis and is one of the most important negative prognostic factor. Surgery is the only curative therapy while other chemotherapeutic options are limited. Neuroendocrine differentiated C cells may express somatostatin receptors (SSTR) and somatostatin analogs have been used with variable therapeutic success in cases of advanced MTC.
Case description
We present the case of a 56-year-old male patient who underwent total thyroidectomy for MTC. He was admitted in our clinic for a anterior neck mass. Thyroid ultrasonographic examination demonstrated a hypoechogenic 25/23/37.5 mm sized nodule invading the left thyroid lobe with microcalcifications. Laboratory work-up revealed an elevated calcitonin, greater than 2000 pg/ml (normal range < 14.3), carcinoembryonic antigen (CEA) of 139.79 ng/ml (normal range: 0-2.5) and normal thyroid function. Our patient underwent a total thyroidectomy with total neck disection. Histological and immunohistochemical studies diagnosed the presence of multifocal MTC (pT2 mN1b) and papillary thyroid microcarcinoma (pT1aN0). The lymph nodes specimen showed metastases from the first lesion (six lymph nodes). The Ki-67 index was <1% and at the investigation for multiple endocrine neoplasia (MEN), RET protooncogene mutation was negative. Since CEA and calcitonin levels were high during follow-up period, neck ultrasonography was performed, with no evidence of pathologic lymphadenopathy, Cervical CT scan revealed a paratracheal left mass. Immunohistochemistry showed positive expression of somatostatin receptors (SSTR) 2 and 5 and the therapy with Octreotide LAR 30 mg every 4 weeks was initiated. An octreotide scan was performed with no detection of metastatic lesions. Six months later, under therapy with octreotide, calcitonins, CEA, serotonin, neuron specific enolase were within the normal range. The therapy was well tolerated with no side-effects recorded.
Conclusions
MTC can be a rare source of carcinoid syndrome. Some studies have shown that long-term octreotide and octreotide-LAR treatment offer a subjective and biological partial remission in one third and in one fourth of the MTC patients, respectively, but it does not improve the natural course of the tumor.

Graves' disease and neutropenia: Diagnostic trap

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Hematologic abnormalities are frequently observed during hyperthyroidism and are related to complex multifactorial pathogenic mechanisms that are still poorly understood and may affect the three hematopoietic lineages in isolation or in combination. These abnormalities are exceptionally revealing and are usually subclinical. For the endocrinologist, they raise the problem of the risk of their aggravation under the hematotoxic effect of synthetic antithyroid drugs (ATS). However, certain abnormalities such as leuko-neutropenia are sometimes simply the expression of a physiological phenomenon of margination of white blood cells which falsely underestimates the count of this lineage and which must be detected.
Observation
Patient aged 45 years, followed for hyperthyroidism on Graves' disease initially put on CTC 60 mg with adjuvant treatment, presented a cardiac complication such as of an AFib put on Sintrom and b-blockers, with a past history of angina put, diabetic since 5 years on insulin, at the clinical examination, patient in good general condition, FC: 89 bpm, homogeneous grade 2 goiter without palpable nodul with bilateral inactive exophthalmos, the biological test objectified a TSHus: 0. 001 µIU/ml, T4L: 48.4 pg/ml (6-12), T3L: 13.2 pg/ml (2.6-5.7), TRAK: 19. 8 IU/l, associated with haematological disturbances such as neutropenia controlled on several occasions: WBC: 5320/mm3, PNN: 850/mm3, before the start of the antithyroid treatment, a control of the blood count formula after 2 h of physical activity, objectified a re-ascension to normal PNN levels at 2780/mm3. This was in fact a physiological margination of the PNN on the blood vessel wall, which was unmasked by the effort, a situation aggravated by the hyperthyroidism but which did not contraindicate the introduction of synthetic antithyroid.
Conclusion
Faced with the coexistence of hyperthyroidism and leukocyte lineage disturbances, a simple stress test should be rapidly performed to unmask false neutropenia, thus avoiding unnecessary transfer to the hospital.

Graves' disease and unilateral gynecomastia - An uncommon initial presentation of a common disease

Daniela Dias, Ana Carolina Neves & Inês Sapinho
Hospital CUF Descobertas, Endocrinology, Lisbon, Portugal

Most cases of gynecomastia are idiopathic. Among the most frequently identified etiologies are: persistent pubertal gynecomastia, hypogonadism, anabolic steroids and other pharmaceutical drugs use. In the literature, ginecomastia is a well-recognized manifestation of thyrotoxicosis in male patients (in the range of 10% to 40%). However, it is extremely rare in clinical practice as the initial presentation of thyrotoxicosis. The two main factors that contribute to gynecomastia in thyrotoxicosis are: increase of SHBG production in the liver

(which leads to a reduction in free testosterone); and increased peripheral aromatization of androgens. We report a case of a 41-year-old white male who applied to our clinic with a 2 weeks history of right-sided breast enlargement. He did not report reduced libido. No past medical history or drug intake were reported. On examination he was normotensive and had normal-weight. Glandular tissue could be palpated on the right breast, underneath the nipple area. Galactorrhoea was not observed. Cervical palpation was normal. The testicles had a normal size and no palpable abnormalities were found. Laboratory data showed testosterone level of 1116 ng/dl (241-827), free testosterone level of 24 pg/ml (8.69-54.69), estradiol level of 51 pg/ml (<32), SHBG of 107 nmol/l (10-57), LH 7.46 mUI/ml (1.5-9.3), FSH 7.68 mUI/ml (1.4-18), TSH <0.01 mUI/l (0.35–5.5), free T4 (FT4) 2.16 ng/dl (0.8–1.76) and free T3 (FT3) 7.52 pg/ml (2.3-4.2). Anti-TSH receptor antibodies values were 2.47 UI/l (<1). Levels of prolactin, alpha-fetoprotein, human chorionic gonadotropin, dehydroepiandrosterone sulfate were normal. An ultrasound examination revealed a thyroid gland diffusely heterogeneous, without nodularity. The diagnosis of Graves' disease was made. He was treated with thiamazole 15 mg daily. After 1 month from the start of treatment, gynecomastia had resolved. The monthly follow-up laboratory findings showed normalization of FT3 and FT4. SHBG and total testosterone levels decreased significantly after 2 months and free testosterone increased. GD may present with atypical symptoms and the classic symptoms of thyrotoxicosis may not always be in the foreground. In case of gynecomastia, thyrotoxicosis should be kept in mind. An attentive diagnosis may identify a potentially treatable cause of gynecomastia.

Radiofrequency and ethanol ablation for benign thyroid nodules: case series

Pedro Jimenez Torrecilla, Paloma González Lázaro, Antonio Moreno Tirado, Cristina Montalban Méndez, Maria Zhao Montero Benítez, Florentino del Val Zaballos & Ines Gomez García
Hospital General La Mancha Centro, Alcázar de San Juan, Spain

Introduction
Thyroid nodule is a frequent condition, being diagnosed in up to 70% of subjects who had undergone thyroid ultrasound. Around 90-95% of them became being benign and, if the do not cause compressive symptoms or esthetical problems, they do not need specific therapy, only clinical follow up. Traditionally, thyroidectomy has been the main therapeutic option in these cases. Radiofrequency and ethanol ablations are recently introduced non-invasive therapies that permit avoid surgery and its related possible complications. Many studies have already evaluated the effectiveness of radiofrequency and ethanol ablation therapies in the reduction of benign thyroid nodule volume. The aim of this study has been to evaluate its efficacy in reducing the volume of benign thyroid nodules.
Material and Methods
This study is a series of 5 patients with a benign thyroid nodule, verified by FNA. All of them were woman between x and x years old, three radiofrequency ablation and two ethanol ablations. We have determinate the hormonal levels and the measures of the nodule before the ablation, 1 month, 2 months and 6 months after of the intervention. We also asked patients about their initial symptoms and the degree of satisfaction with this procedure.
Results
5 subjects (100% woman) were analysed with an average age of 53.2 ± 12 years old with diagnosis of benign thyroid nodule. Initially, measures average was 20.4 x 24.20 x 33 cm (APxTxS), thyroid function was normal in all the patients, and 80% of the cases noticed compressive symptoms. One month after the intervention, nodules size decreased to 14x19x27.3 cm on average and compressive symptomatology disappeared total or partially. Even six months later nodules continued decreasing to 11.2 x 11.7 x 20.6 cm. Along this time, thyroid hormones were at range. All the patients are so satisfied and would repeat it if were necessary.
Conclusions
As we have found (and many other studies), radiofrequency and ethanol ablations permit reduce nodules size and solve compressive symptoms caused by them. Both techniques have few complications and patients feel so satisfied. Considering all this points, they are demonstrating being excellent alternatives to hemithyroidectomy in the treatment of benign thyroid nodules.

Clinical presentation of patients with primary hypothyroidism in rural India

Aniket Inamdar
Samarpan Clinic, Internal Medicine, Omerga, India

Background
Hypothyroidism is a clinical state resulting from underproduction of the thyroid hormones thyroxine (T4) and triiodothyronine (T3). Most cases are due to primary hypothyroidism, a failure of the thyroid gland to produce thyroid hormones. Primary hypothyroidism is defined as thyroid-stimulating hormone (TSH) concentrations above the reference range and free thyroxine concentrations below the reference range. Patients with hypothyroidism usually present with puffy eyes, cold intolerance, coarse hair, constipation, poor memory, slow thinking, muscle cramps, weak muscles, depression, dry skin, and hypersomnolence.
Aim
To study the clinical presentation of patients with primary hypothyroidism in rural India.
Materials and methods
This cross-sectional study was conducted in a hospital in rural India from March 2021 to December 2021. TSH, free T3 and free T4 levels were measured using venous blood in all patients with presented with signs-symptoms of hypothyroidism. Patients having biochemically confirmed primary hypothyroidism (elevated TSH, low free T3 and low free T4) were selected for the study. Proper history was taken from patients and their relatives to obtain the demographic and clinical data including hypothyroidism symptoms.
Results
87 patients with primary hypothyroidism were included in the study among whom 75% were female, 45% aged between 25 to 50 years, 90% lived in rural and suburban areas. Hypertension was the most common (45%) co-morbid condition followed by obesity (29%), diabetes (23%), obstructive sleep apnoea (19%) and ischemic heart disease (15%). 31% patients presented with TSH more than 100. Puffiness of face was most common (65%) symptom followed by dry skin (52%), cold intolerance (42%), constipation (29%), muscle cramps (23%) and hypersomnolence (19%).
Conclusions
Primary hypothyroidism is one of most common and easily treatable endocrine disorder. Despite being potentially manageable, primary hypothyroidism is often undiagnosed and untreated. Timely diagnosis of primary hypothyroidism is utmost important. The medical and family history can be very helpful in identifying patients in whom thyroid dysfunction should be assessed. Gender, age, family or personal history of thyroid diseases, recent pregnancy, presence of autoimmune diseases, medications and radiation history should all be noted. Hypothyroidism is far more common in women, and the prevalence of mild hypothyroidism increases in the elderly. Patient education regarding signs and symptoms of hypothyroidism, regular screening with TSH, free T3 and free T4 are very crucial to diagnose this easily manageable endocrine disorder.

Prevalence and factors associated with arrythmia in patients with hyperthyroidism

Wiem Madhi[1], Khaled Ezzaouia[2], Meriem Yazidi[1], Ibtissem Oueslati[1] & Mélika Chihaoui[1]
[1]Rabta Hospital of Tunis, Endocrinology - Diabetology, Tunisia; [2]Rabta Hospital of Tunis, Cardiology, Tunisia

Introduction
Thyroid hormones represent a biomarker of heart rhythm disorders and pathophysiological origins remain unknown. Some of these disorders like atrial fibrillation (AF) are major issues particularly in asymptomatic patients with in Hyperthyroidism and cause of thromboembolic complications.
Aim
Taking into account the uncertainty of prevalence of cardiac rhythm disorders, we aimed to investigate the prevalence of rhythmic cardiac complications and its risk factors in patients with hyperthyroidism.
Methods
We conducted a cross-sectional study on 30 patients with uncontrolled hyperthyroidism. Clinical, biological and therapeutic data were collected. A 24-h Rhythmic Holter monitoring has been performed to all patients.
Results
The patients were seven male and 23 female, mean age was 44.8 ± 14.4 years. Twenty three patients (77%) had palpitation. The mean heart rate was 95 ± 14

(66 – 124) and 16 patients (53%) had tachycardia. Electrocardiogram showed ventricular premature complexes in one patient (3%). Atrial fibrillation was present in two patients (7%). The 24-h Rhythmic Holter monitoring revealed tachycardia in 16 patients (53%), supra-ventricular premature contraction in 16 patients (53%). Thirteen patients (43%) had ventricular premature complexes. Atrial fibrillation was present in three patients (10%), it was permanent in one patient (3%) and paroxysmal in two (7%). The study of risk factors showed that age > 50 years, the presence of nodules (palpable and on ultrasound) and negativity of TSH receptor antibodies were associated to atrial fibrillation$P=0.041$, $P=0.020$, $P=0.029$, $P=0.008$. Toxic nodular goiter was associated to atrial fibrillation$P=0.004$.

Conclusion

Hyperthyroidism increases heart rate and may cause arrhythmia, mainly atrial fibrillation. This complication is more frequent in older patients with toxic nodular goiter.

Autoimmune polyglandular syndrome Type 2 presenting with autoimmune thyroid disease, diabetes mellitus Type 1 and addison's disease

Angelie Rose Barjose, Jerome Barrera, Daniel Mark Yumol & Ivan Rommel Caluscusin
Zamboanga City Medical Center, Internal Medicine, Zamboanga, Philippines

A. Background/Significance

Autoimmune polyglandular syndrome Type II (APS-II) is a rare polyendocrinopathy with a prevalence of 1 to 2 in 100.000, instigated by immune-mediated destruction of several organs. Knowledge of APS-II is crucial, especially in the early detection of polyglandular disorder among patients with endocrine autoimmunity.

B. Case

This case is of a 40-year-old male who initially presented with Grave′s disease after showing signs and symptoms of hyperthyroidism, as supported by low thyrotropin (< 0.05 uIU/ml; nv: 0.35-4.94) and high free thyroxine levels (2.05 ng/dl, nv: 0.71-1.85). He was maintained on methimazole. Five months following diagnosis, he developed symptoms of Diabetes Mellitus Type 1 (T1DM) as confirmed by high capillary blood glucose, undetectable C-peptide, and positive anti-Glutamic acid decarboxylase. Insulin and rosuvastatin were added on his maintenance medications. Ten months later, he discontinued methimazole and became lost to follow-up. One month after discontinuation, he sought consult again after experiencing symptoms of fatigue, muscle cramps, cold intolerance, forgetfulness, abdominal pain, diarrhea, and episodes of hypoglycemia at home. On examination, he was noted to have hypotension of 80/60 mmHg and skin hyperpigmentation. His random blood sugar was 408 mg/dl. High thyrotropin (57.8777 uIU/ml, nv: 0.35-4.94), low free thyroxine (0.57 ng/dl, nv: 0.71-1.85), and positive antithyroid peroxidase antibody levels revealed Hashimoto′s thyroiditis. Low fasting 8 am serum cortisol (81 nmol/l, nv: 138-635) and low serum cortisol 30 mins (403.85 nmol/l) and 1 h (542.31 nmol/l, normal response: >550 nmol/l) after adrenocorticotropic hormone stimulation test in addition to the clinical manifestations, supported the diagnosis of Addison′s disease. With the combination of Addison′s disease, Autoimmune thyroid disease, and T1DM, a diagnosis of APS Type II was made. Management included insulin, prednisone, and levothyroxine. These resulted in significant improvement in the patient′s symptoms. He is now clinically well and compliant to regular follow-up.

C. Learning Points/Conclusion

It is crucial in APS-II management to identify and manage the associated autoimmune disorders to prevent significant morbidity and mortality. Therefore, in the presence of any autoimmune disorder, a high index of suspicion for APS-II is essential. There should be regular follow-up and observation of patients with autoimmune endocrine disorders to ensure early detection of APS-II. Patient health education must include identifying symptoms of the disorders for which they are at high risk.

Introduction
Graves orbitopathy is the major extrathyroidal manifestation of Graves Disease (GD). The approach depends on its clinical activity and severity. Treatment and referral to specialized centers, with Endocrinology and Ophthalmology, has a strong impact on the prognosis of Graves' Disease (GD) and GO.
Cases report
We report four cases of DG with OG. Their characteristics and clinical evolution are shown in Table 1.
Conclusion
In these four cases a definitive therapy (surgery) was needed to treat GD, suggesting the presence of a more severe disease. GO can progress into severe forms and this evolution is often unpredictable. These 4 clinical reports are illustrative of the importance of a multidisciplinary approach (Endocrinology and Ophthalmology) in specialized centers for patients with GD and GO.

Role of corticosteroids in the treatment of refractory hypothyroidism : a case report

Yousra Settai, Nassim Essabah Haraj, Siham El Aziz & Asma CHADLI
UHC IBN ROCHD, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Refractory hypothyroidism is known as the persistence of clinical and biological signs of hypothyroidism after 6 weeks of treatment or therapeutic adjustment, despite a dose exceeding 1.9µg/Kg/d of Levothyroxine. Several etiologies may be incriminated.
Observation
A 36-year-old patient, followed for Gougerot-sjogren syndrome, having benefited from a thyroidectomy in 2015 in a context of biological hyperthyroidism, on Levothyroxine (LT4) 200µg/d and Liothyronine sodium (LT3) 25µg/d with persistence of refractory hypothyroidism. The clinical examination revealed a slightly slowed down patient, presenting a mucocutaneous infiltration, a hoarse voice, a bilateral galactorrhea evolving since 1 year, and a chronic constipation. All this in a context of generalized asthenia. At the workup, TSHus was 500µUI/l, free T4 $<$0.4 ng/dl (0.7-1.5), hypertriglyceridemia at 12.9g/l put on fenofibrate 160 mg/d. Brain MRI showed a pituitary bulge with no other detectable abnormality. After elimination of poor compliance and possible drug interactions, the diagnosis of refractory hypothyroidism was retained. Parasitological examinations of the stools showed Giardiasis and the patient was put on metronidazole. The Helicobacter Pylori serology came back positive with a pangastritis aspect at the oeso-gastro-duodenal fibroscopy, put under eradication treatment. As hypothyroidism persisted, the patient was put on Dexamethasone 1 mg/d for one week, then tapered to 0.5 mg/d, reduction of levothyroxine dose to 175µg/d and maintenance of Liothyronine sodium at 25µg/d, with clinical improvement of hypothyroidism signs. The thyroid check-up showed a TSHus of 4.63µUI/ml, and a free T4 of 19.86 pmol/l (10.6-19.4)
Conclusion
High-dose glucocorticoids may be considered in some cases of hypothyroidism, especially in patients requiring high doses of thyroid hormones when even the LT4 + LT3 combination is insufficient to achieve euthyroidism.

Recalculating renin and aldosterone to improve specificity in the diagnosis of primary aldosteronism

Luc Doyle[1], Julie Okiro[1], Aysha Sarwani[1], Michael Troy[2], Yousef Ansari[1], Darragh O'Donoghue[1], David Lappin[3], John Mcevoy[4], Paula O'Shea[2,5], John Ferguson[6] & Michael Conall Dennedy[7]
[1]University Hospital Galway, Centre for Diabetes, Endocrinology and Metabolism, Galway, Ireland; [2]School of Medicine, National University of Ireland Galway (NUIG); [3]University Hospital Galway, Department of Nephrology, Galway, Ireland; [4]National University of Ireland Galway (NUIG), School of Medicine, Galway, Ireland; [5]University Hospital Galway, Department of Clinical Biochemistry, Saolta University Health Care Group (SUHCG), Galway, Ireland; [6]National University of Ireland Galway (NUIG), Biostatistics Unit, HRB Clinical Research Facility, NUI Galway, Galway, Ireland; [7]National University of Ireland Galway (NUIG), Discipline of Pharmacology and Therapeutics, Lambe Institute for Translational Research, NUI Galway, Galway, Ireland

Rationale
The Aldosterone:Renin ratio (ARR) is commonly used for patients fulfilling screening criteria for primary hyperaldosteronism (PA), followed by confirmatory testing. Reference intervals for interpretation of the ARR vary in accordance with local population and assay 1. While ARR provides high sensitivity for PA, this is compromised by low specificity, further compounded by medication interference. However, additional variables may improve the specificity of ARR as a diagnostic test, potentially mitigating the need for confirmatory testing in all patients. In the current study, we investigated the relationship between aldosterone and renin as single diagnostic measure for PA.
Methodology
A population-based study of individuals attending a specialist hypertension clinic was performed. PA was screened using the ARR, and confirmed using the saline infusion test. 82 patients with matched ARR and Saline Infusion Tests were investigated. Logistic Regression was used to estimate the relationships between renin, aldosterone, ARR, clinical variables and the probability of a diagnosis of PA. Predictive capacity of each model was measured using Area Under the Curve using "*leave one out*" cross validation to avoid overfitting.
Results
The AUC for the model using ARR on its own was estimated to be 0.68. The model, excluding ARR, but including renin, aldosterone and their interaction on the log-scale: log(Renin) + log(Aldosterone) + log(Renin)*log(Aldosterone), improved the AUC to 0.73. Using this log-structure, as opposed to including aldosterone and renin as linear effects in a logistic model, makes sense since the model involving ARR alone is nested within the log-structure model, which would not be true under the linear model. Covariates including eGFR, serum potassium and the presence of an adrenal nodule were then individually tested for statistical significance, conditional on the choice of this log-scale interactive model. The model Log(Renin) + log(Aldosterone) + log(Renin)*log(Aldosterone) + Adrenal_Nodule provided the highest performance with an AUC of 0.782. For the ARR and the log-model, at a sensitivity of 80%, specificity was 37.5% and 64% respectively, and for a sensitivity of 98%, specificity was 12.5% and 24% respectively.
Conclusion
This log model incorporating the adrenal nodule as a variable improved the AUC from 0.68 (model with ARR alone) to 0.782. This study highlights the importance of statistically re-visiting well-established calculations to better inform clinical practice. Ongoing validation of our findings is proceeding in other clinical samples.

Pituitary -adrenal axis insufficiency among hemodialysis patients

Anat Bel-Ange[1], Daniel Fux[1], Dana Zelnik Yovel[1], Ronit Koren[1], Ilia Beberashvili[1], Carlos Benbassat[1] & Shlomit Koren[1,2]
[1]Shamir Medical Center (Assaf Harofeh), Be'er Ya'akov, Israel; [2]Tel Aviv University, Tel Aviv-Yafo, Israel

Background
The diagnosis of hypocortisolism is challenging in hemodialysis (HD) patients due to shared clinical features between renal failure and cortisol deficiency. We hypothesize that in a significant percentage of HD patients we miss cortisol deficiency.
Methods
A prospective cohort of 56 end stage kidney disease patients on maintenance HD treatment (mean age 65.3$\pm$13.1, females 80 %) was studied. Low dose (1 mg) adrenocorticotropic hormone (ACTH) test was performed on all patients and blood tests for cortisol, ACTH, insulin like growth factor 1 (IGF-1), triiodothyronine (TSH), free thyroxine (FT4), renin and aldosterone, were obtained before hemodialysis session. Adrenal insufficiency was defined as a peak serum cortisol level of $<$500 nmol/l at 30 or 60 min after stimulation.
Results
14 patients (25%) out of the study population had an abnormal low dose ACTH test. Mean systolic blood pressure in the group with abnormal ACTH test was 135.2$\pm$22.0 mm Hg with no difference in blood pressure in multivariable models between the groups of HD patients with abnormal and normal ACTH test. Neither differences were observed in electrolyte levels, nor in renin/aldosterone levels between these groups. Baseline ACTH level predicted an abnormal ACTH test in the study population in both, univariate and multivariate analyses. For each pg/ml increase in baseline ACTH concentration the odds for abnormal ACTH test was

1.15 (95% CI: 1.03 to 1.29). In addition, IGF-SDS (standard deviation score) higher than -0.04 significantly decreased odds for hypocortisolism (OR 0.14, 95% CI: 0.02 to 0.81) in multivariable logistic regression models.
Conclusions
We offer routine testing of hypophyseal-adrenal axis function to detect adrenal insufficiency in HD patients even in the absence of markers characteristic of hypocortisolism.

Long-term mortality and excess mortality after hip fracture in the main urban area of Romania

Ramona Dobre, Ioana Ruzandra Poiana, Dan Alexandru Niculescu, Catalin Cirstoiu, Gheorghe Popescu & Catalina Poiana
Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Background
Excess mortality after hip fracture remains a problem of public health concern. Until present, for Romania no data is available regarding long term mortality rate and excess mortality after hip fracture. We aimed to evaluate the mortality rate 3 years after hip fracture and also standardized mortality rates of osteoporotic hip fracture in the capital city of Romania and suburban area.
Methods
we collected data from over 98 % of fractures admitted during 12 months (09/01/2017 - 08/31/2018) in Orthopedic Surgery Departments in the area of interest. Patients were selected using the hip fracture codes (S72.0, 1, 2, 3, 7, 8, 9), age >40 years old and low-trauma mechanism (fall from a standing height or less). We used the 2018 estimations for stable population in the area selected. We calculated the mortality rate (MR) 3 years after the event and standardized mortality rates (SMR) of hip fracture.
Results
we included a total of 1977 patients with fragility hip fracture (86.5% in the capital city and 13.5 % in the suburban area). MR after 3 years was 46.42% in all patients with a mean age of 81 years old, 69% women. Almost a quarter of patients were not surgically treated. Advanced age, male sex, extracapsular fracture and especially conservative management were associated with increased mortality. SMR after 1st 2nd and 3rd year and cumulative for the whole 3-year period in all patients were 13.69, 5.45, 5.94 and 26.06 respectively. As expected, SMR decreased with advancing age, but remained higher even in patients >85 years old (2.79 for 1st year, 2.34 for 3-year period). Notable differences were observed in SMR between sexes, 29.18 for women and 19.6 for men, 3 years after the fracture.
Conclusion
this is the first study to describe the long-term mortality rate and excess mortality after osteoporotic hip fracture in Romania. Hip fracture has the highest impact on short-time mortality, the risk in the 2nd and 3rd year being significantly smaller compared to 1st year. Even after 3 years, excess mortality for hip fracture patients can be still observed.

The differences between normocalcemic and hypercalcemic primary hyperparathyroidism: a tertiary center's experience

Nikolaos Kalogeris, Nektaria Papanikola, Eleni Herolidi, Eleni Palioura, Vasiliki Papanikolaou, Vasiliki Loi & Andromahi Vryonidou
General Hospital Korgialenio-Benakio, Hellenic Red Cross, Department of Endocrinology & Metabolism – Diabetes Center, Athens, Greece

Introduction
Normocalcemic Primary Hyperparathyroidism is today considered a variant of Primary Hyperparathyroidism. It is characterized by persistently normal calcium levels and increased levels of parathyroid hormone, after the exclusion of other causes of secondary hyperparathyroidism. We aimed to compare clinical, biochemical and imaging data from patients with normocalcemic and hypercalcemic primary hyperparathyroidism.
Methods
This is a retrospective study from the archives of our Department that included 161 patients (38 men and 123 women), who were monitored from 2010 to 2021, 68 with Normocalcemic Primary Hyperparathyroidism (NPHPT) and 93 with Hypercalcemic Primary Hyperparathyroidism (HPHT). The biochemical tests included calcium, total and adjusted for albumin, phosphorus, magnesium, parathyroid hormone and 25OHD3 levels and 24-h urinary calcium. The imaging tests included thyroid ultrasound, scintigraphy with Tc99 m Sestamibi, kidney ultrasound and bone density measurement. We also, accessed the eligibility for surgical treatment of the disease, according to the criteria of the Fourth International Workshop for the Management of Asymptomatic Primary Hyperparathyroidism.
Results
No differences between the two groups were found regarding, age of diagnosis, body mass index (BMI), serum magnesium and 25OHD3 levels and 24-h urine calcium concentration ($P>0.05$). Patients with HPHPT had significantly higher levels of corrected calcium (11.3 ± 0.57 vs 9.8 ± 0.44 mg/dl, $P<0.001$) and PTH (219.2 ± 209.8 vs 111.8 ± 35.5 pg/ml, $P<0.001$) and lower phosphorus levels (2.7 ± 0.54 vs 2.9 ± 0.43 mg/dl, $P<0.01$) compared to patients with NPHPT. No differences were found in the prevalence of osteopenia/osteoporosis, fragility fractures and the need to receive anti-osteoporotic treatment ($P>0.05$). Patients with HPHPT had significantly higher prevalence of nephrolithiasis clinically (history of renal colic: 40.3% vs 25.8%, $P<0.05$) and discovered by imaging (renal ultrasound: 54.3% vs 34.7%, $P<0.03$). Patients with HPHPT more often met the criteria for surgical treatment (54.3% vs 34.7%, $P<0.001$).
Conclusions
Patients with NPHPT often have disease complications, especially osteoporosis, fragility fractures and nephrolithiasis both clinically and through imaging. Until more data on the pathophysiology and natural course of NPHPT are provided, patients with this form of primary hyperparathyroidism should be managed as patients with HPHPT.

Glycogen hepatopathy - a case series

Bhavna Sharma, Rohit Baslas, Amar Sharif & Elaine Hui
Northwick Park Hospital, United Kingdom

Glycogen Hepatopathy (GH) was initially described in 1930 by Pierre Mauriac. 90 years later, GH remains underrecognized in adults. The clinical or radiological characterization of GH is difficult, further compounded by lack of widespread literature. We present two cases of GH characterized by recurrent lactatemia and transient liver function and radiological abnormalities.

- 19 years old male with Type 1 diabetes admitted with nausea and vomiting. pH 6.9, glucose 33 mmols/l and lactate 7.7 mmol/l (normal 0.5-2 mmol/l). He was started on intravenous (IV) fixed rate insulin. Lactate initially improved however was noted to be rising 8 h into being started on insulin peaking at 9.2 mmol/l. On admission, bilirubin 10 umol/l (normal range 0-21 umol/l), ALP 80 IU/l (normal range 0-390 IU/l) ALT 162 IU/l (normal 10-50 IU/l) Albumin 44 gm/l (normal 35-50 gm/l). ALT worsened during admission peaking at 790 IU/l corresponding to lactate. Liver screen including hepatitis, HIV, EBV, CMV, alpha 1 antitrypsin, caeruloplasmin, anti-smooth muscle antibodies, anti-liver kidney microsomal antibodies and ANA were negative. Liver ultrasound revealed smooth gross hepatomegaly with increased liver reflectivity. Liver function started resolving at Day 5 and ALT came down to 442 IU/l on Day 8. Repeat liver function 2 months later was normal. MRI liver three months later revealed normal sized liver with no abnormal enhancement with a smooth surface and no fatty infiltration or cirrhosis.
- 21 years old female, first presentation of Type 1 diabetes with diabetic ketoacidosis (DKA). pH 7.2 on admission, glucose 20 mmol/l and lactate 7 mmol/l. Lactate initially improved with fluids however at 24 h peaked at 8.6 mmol/l. Liver ultrasound showed echogenic enlarged liver. Liver function on admission was normal (ALT 31 IU/l) but worsened after starting IV insulin to 578 IU/l and peaked to 752 IU/l at Day 4. Liver function normalized after 3 months. GH was first reported when short acting insulin was introduced. Supraphysiologic rapid acting insulin dosages during DKA management may be a potential cause to drive glycogen storage in rapid hypo- and hyper-glycaemia cycle. A dual peak of lactate may signify a change from Type 1 (impaired perfusion) to Type 2 lactatemia (impaired gluconeogenesis). Further work is needed to characterize patients at risk of GH in re-attendances and potential plans to give lower dose of rapid acting and higher dose of long-acting insulin in acute phase may be explored.

Metabolic parameters in type 2 diabetic patients with positive Candida cultures

Danijela Radojkovic[1], Saša Radenković[1], Vojislav Ćirić[1], Milan Radojkovic[2], Jana Pesic Stankovic[3], Sanja Curkovic[1] & Sonja Kostic[1]

[1]University Clinical Center Nis, Clinic of Endocrinology, Diabetes and Metabolic Disorders, Nis, Serbia; [2]University Clinical Center Nis, Surgical Clinic, Nis, Serbia; [3]Institute of Public Health, Nis, Serbia

Introduction
The gut microbiota plays an important role in host metabolism, immunity, digestibility and even a behavior. *Candida spec*. is common resident of the gastrointestinal tract and integral part of the microbiota. Number of 10^1 to 10^3 fungal cells per g stool are considered as normal range. However, when mucosal surface is disrupted or host immunity is compromised, life-threatening invasive infection can ensue.
Objective
The aim of the study was to evaluate if positive *Candida* cultures in the stool, influence metabolic parameters in type 2DM patients.
Patients and methods
The study included 46 patients with type 2 DM (20 women and 26 men), 30 -77 years old, with oral antidiabetic treatment (metformin and glimepiride or gliclazide). Beside medical history and clinical examination, all patients were tested for coproculture, fasting glycaemia (FPG), HbA1C, total cholesterol (Hol) triglycerides (Tg), high density lipoproteins (HDL) and low density lipoproteins (LDL).
Results
All patients were divided into following groups: study group (S = 18 patients with positive *Candida sp*. cultures in stool; 39.13%) and control group (C = remaining 28 patients; 60.87%). Comparing the average age in S and C group (68.21 ± 10.4 vs. 66.97 ± 9.7 years), no statistical significance was obtained. Study group patients had a higher BMI compared to the control group (31.41 ± 5.29 vs. 25.18 ± 3.58; $P < 0.001$). Higher values of Tg (2.03 ± 1.13 vs 1.80 ± 0.58), Hol (5.23 ± 1.23 vs 4.73 ± 0.92), LDL (3.27 ± 0.75 vs 2.86 ± 0.83) and HDL (1.63 ± 0.25 vs 1.08 ± 0.44) were verified in study group, compared to the control group, but without statistical significance. HbA1C values were significantly higher in study group patients (9.8 % ± 1.74 vs 6.9% ± 1.89; $P < 0.05$) as well as FPG (10.87 ± 1.35 vs 7.47 ± 1.03; $P < 0.01$).
Conclsion
Type 2DM patients with positive *Candida sp*. have higher FPG, HbA1C and BMI. Uncontroled glycoregulation is one of the host condition which favors candida colonization and subsequent infection. This may be related to the decrease in commensal bacteria-probably the result of yeast-bacterial competition. On the other hand, we have to keep in mind, that a significantly increased number of *Candida* colonies can affect the rate of digestion and absorption of carbohydrates and consequently increase the level of glycaemia in patients with diabetes.

Polyglandular autoimmune syndrome in the elderly: a case report

Sindhuja Suresh[1], Felicity Kaplan[1] & Alastair Cruickshank[2]
[1]East & North Hertfordshire NHS Trust, United Kingdom; [2]Regal Chambers Surgery, United Kingdom

Polyglandular autoimmune syndrome (PAS) is characterised by the coexistence of two or more autoimmune mediated disorders. While the pathophysiology remains poorly understood, environmental triggers and genetic susceptibility are thought to contribute to the dysregulated immune response. PAS has been classified into three main subgroups: Type 1 is seen in the paediatric population while types 2 and 3 are found in adults with autoimmune thyroid disease and insulin-requiring diabetes, are differentiated by the presence or absence of Addison′s disease, and most commonly present in the third decade. There are very few studies looking at the presentation of type 3 PAS in the elderly. Thyroid dysfunction commonly presents in the elderly, but newly diagnosed antibody positive type 1 diabetes is rare in this group. Coeliac disease is prevalent in nearly a quarter of patients with thyroid disease and 10% of those with type 1 diabetes but also rarely presents late in life. We present a rare case of a 76 year old female with features of type 3 PAS. She had a history of hypertension and dyslipidaemia but no personal or family history of autoimmune conditions. The patient was referred to the endocrinology department for further investigation of diabetes and mild hypercalcaemia in the context of weight loss and thirst. Given her age and mildly elevated HbA1c, she had been diagnosed with type 2 diabetes but on further investigation, was found to be GAD and IA-2 antibody positive and started on treatment for type 1 diabetes. Further evaluation also identified TPO antibody positive hypothyroidism and anti -TTG positive coeliac disease. She had normal vitamin B12 levels showing no evidence of pernicious anaemia, no history of vitiligo and normal cortisol, antinuclear antibody and serum angiotensin converting enzyme levels. She is currently under investigation for probable hyperparathyroidism. This is a unique case of type 3 PAS presenting atypically in an elderly patient. Not only is the age of presentation unexpected, but the lack of pernicious anaemia and other autoimmune features typically seen in type 3 PAS make this very distinctive. It highlights the need for further epidemiological research into this presentation, particularly in the elderly, to allow for early detection of a possible autoimmune syndrome. With an ageing population, further understanding is needed on how to manage these complex autoimmune conditions in this vulnerable group.

Immunotherapy induced hypopituitarism including hypogonadism in patient with previous PCOS: call for early detection and endocrine work-up

Gesa Tiemeier, Bhavna Sharma, Mushtaqur Rahman, Asjid Qureshi & Ranjna Garg
Northwick Park Hospital, United Kingdom

Background
Immune checkpoint inhibitors are now commonly used in melanoma, renal cell carcinoma and non-small cell lung cancers. Patients on immune check point inhibitors experience at least one type of immune related adverse event(irAEs) which can occur even after discontinuation of therapy. Endocrine toxicities are commonly reported irAE′s and tend to be irreversible. The most frequently recognized endocrine complications include thyroid dysfunction (30%) hypophysitis (5.6-11%), type-1diabetes (0.2-2%) and adrenal insufficiency (0.7%) Literature is limited on potential impact on gonadal axis.
Case presentation
We report a 50-year-old Caucasian female with metastatic renal cell carcinoma, who was treated with a nephrectomy followed by immune checkpoint blockade with ipilimumab plus nivolumab. After 4 months of treatment she presented with fatigue, generalized pains and being emotional. She was switched to single agent nivolumab, however her symptoms persisted. Investigations revealed hypocortisolism(cortisol 50 nmol/l [range 160-550 nmol/l], hypogonadism(testosterone < 0.7 nmol/l [range 0-2.8 nmol/l], estradiol 280 pmol/l [range 45-1461 pmol/l], FSH10.9 IU/l [normal 25.8-134.8 IU/l]) and hypothyroidism (TSH 0.15 mIU/l [0.27-4.20 mIU/l]), IGF-1 levels were noted to be 20.7 nmol/l (range7.5-35 nmol/l). Patient had been started on prednisolone 10 mg/day, prior to referral to endocrine therefore ACTH was uninterpretable. She was switched to physiological dose hydrocortisone(10 mg/5 mg/5 mg) Retrospective evaluation revealed a background of previous hyperandrogenism related to polycystic ovarian syndrome one year prior to starting immunomodulators. However gradual drop in testosterone was noted from 4.8 nmol/l to undetectable levels (rangel 0-2.8 nmol/l) after starting immunotherapy. Prolactin was also noted to fall from normal values (158 mIU/l) pre-immunotherapy to undetectable level(< 20 mIU/l)(range 102-496 mIU/l). PET Scan did not reveal any abnormalities in pituitary/adrenal gland.
Conclusion
Our case demonstrates gradual onset hypopituitarismwith recognition of only cortisol deficiency. Hypogonaidsm was not identified.
Discussion
Thyroid function and Cortisol are commonly checked hormones. All components of the endocrine axis should be assessed and considerations for correcting each part of pituitary-target axis is needed. Further research is needed on potential impacts on sexual function, fertility in both males and females and bone health. Sexual dysfunction are not reported early on or be taken as part of ongoing treatment or underlying disease, being aware of endocrine dysfunction can improve patients well being as weel as timely counselling of the patinets. Most European guidelines emphasize that hypophysitis is not a contraindication for immunotherapy, we therefore recommend that all patients undergoing immunotherapy with nivolumab and ipilimumab should have a pre-treatment endocrine profile with periodical monitoring and timely endocrinology input to ensure early recognition and appropriate treatment of endocrine dyscrasias.

[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Switzerland; [2]University Hospital Basel, Department of Clinical Research, Switzerland; [3]Royal Victoria Hospital, Regional Centre for Endocrinology and Diabetes, Ireland; [4]Queen's University Belfast, Patrick G Johnston Centre for Cancer Research, Ireland; [5]Churchill Hospital, Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom; [6]Administrator and Patient Advocate for the Facebook Group: Got Diabetes Insipidus?, United States; [7]University Hospitals of Leicester, Department of Endocrinology, United Kingdom; [8]Royal College of Surgeons in Ireland, Ireland; [9]Beaumont Hospital Dublin, Department of Endocrinology, Ireland; [10]Georgetown University Medical Center, United States; [11]University of Birmingham, Institute of Metabolism and Systems Research, United Kingdom; [12]Birmingham Health Partners, Centre for Endocrinology, Diabetes and Metabolism, United Kingdom; [13]University of Sheffield, Deptartment of Oncology and Metabolism, United Kingdom

Background
Central diabetes insipidus (cDI), a rare neuroendocrine condition affecting 1 in 25.000, is characterized by deficiency of arginine vasopressin. Data about treatment-related side effects, psychological co-morbidities, and incidence of wrong management due to confusion with *diabetes mellitus* are scarce and limited to small studies or case series. Furthermore, increasing interest has arisen on a potential need for re-naming the condition.
Methods
A web-based anonymous survey was developed by an international team of endocrinologists and patient representatives covering issues from management of the condition and quality-of-life to lack of awareness amongst medical professionals. Patients were provided with the link to the online survey either via their physician during routine check-ups or the homepages of the *UK Pituitary Foundation*, *Pituitary World News*, *Facebook* group *Got Diabetes Insipidus?*, and *Pituitary Society*.
Results
Worldwide, 1034 patients with cDI, 47%($n=488$) with isolated posterior and 53%($n=546$) with combined anterior/posterior pituitary dysfunction, participated. Median[IQR] age was 42[32, 53], 77%($n=794$) were female. Duration of cDI was 9.0[3.0, 19.0] years and its aetiologies were idiopathic 30%($n=315$), pituitary tumors/cysts (pre-surgical 21%($n=217$), post-surgical 25%($n=254$)), inflammatory/autoimmune 6%($n=61$), infiltrative diseases 6%($n=59$), genetic/familial 4%($n=44$), head trauma 3%($n=34$), and other causes 5%($n=50$). Ninety-six percent ($n=994$) were on desmopressin therapy - oral tablets 56%($n=575$), nasal spray 23%($n=233$), and sub-lingual tablets 12%($n=126$). Among these patients, 26%($n=273$) experienced hyponatremia (self-reported) at least once whilst on desmopressin. Patients who routinely omitted desmopressin (up to several times a week) to allow aquaresis had significantly lower risk of hyponatremia compared to those who did not follow this approach (OR 0.4, 95%CI 0.3-0.7, $P<0.01$). Sixty-four percent($n=660$) reported low quality of life indicated with 6[IQR 4-7] out of 10 points. Thirty-six percent($n=369$, equally prevalent in isolated posterior and combined pituitary dysfunction) experienced psychological problems after the diagnosis, of whom 70%($n=258$) reported higher anxiety levels, 71%($n=263$) sleep disturbances, and 65%($n=239$) depressed mood. Eighty percent($n=823$) encountered a situation where medical professionals, friends or family members confused the diagnosis with "diabetes mellitus", of these 88%($n=637$) indicated that this confusion affected the management of their cDI. In total, 85%($n=884$) would prefer a re-naming of the condition; amongst those, the most common suggestion was "vasopressin deficiency".
Conclusion
This is the so far largest survey conducted in patients with cDI using a web-based method and patient involvement in the survey development. We show a high percentage of treatment-related hyponatremia, a high prevalence of psychological co-morbidities and a clear need for re-naming of the condition from patients' perspective.

Facial phenotype changes and its impact in Quality of Life of acromegaly patients

Laura Ferrer[1], Maria Antonia Martínez-Momblán[2], Montse Marqués-Pamies[1,3], Federico vazquez[1], Berta Soldevila[1], Raquel Ciriza[4], Elena Valassi[1] & Manel Puig-Domingo[1]
[1]Germans Trias i Pujol Hospital, Badalona, Spain; [2]Universitat Autònoma de Barcelona, Bellaterra, Spain; [3]Hospital Municipal Badalona, Badalona, Spain; [4]Spanish Association of Acromegaly People

Acromegaly is a rare disease usually diagnosed late in disease evolution. It implies for skeletal changes of most flat bones including those of the skull. Consequently, a progressive facial disfiguration occurs at slow velocity of irreversible nature. Even after curation most of these changes stay for the whole life of the patient.
Aim
to study the potential relationship between disfiguring facial modifications and psychosocial and Quality of Life (QoL) impact in a group of acromegaly patients.
Patients and methods
Thirty patients accepted to participate in this study (13 women and 17 men); mean age was 61.1 ± 15.8 and 56.3 ± 12.4 years, respectively. Variables studied included: a) Anxiety level, measured through the State-Trait Anxiety Questionnaire (STAI); b) Quality of life evaluation by AcroQoL; c) Self-esteem status through the Rosemberg Self-Esteem Scale and d) Facial acromegaly phenotypic changes evaluated from face photographs and scored by 8 trained endocrinologists. Results: There were gender differences in anxiety levels, with higher values in women than in men (trait: 6.1±2.2 and 5.0±2.0 ($P=0.025$); state: 8.2±1.1 and 3.1±2.1 ($P=0.004$), respectively. Also, there were differences in the Global AcroQoL score: 69.3 ± 17.7 for males and 51.1 ± 21.8 for females ($P=0.004$) and this was reflected in all dimensions. Self-esteem was similar in both groups. There were lower scoring values for the face appearance in women at pre-diagnostic phase compoared to men (3.4±1.3 vs. 4.75±1.5). A negative correlation between self-esteem and changes in facial scores at the pre-diagnostic and diagnostic periods ($r_s=-0.559$, $P=0.074$) was found, consistent with a high impact of facial changes in the psychologic status of the patients. Conclusion: acromegaly facial changes negatively impact the psychosocial condition of these patients with maximal deleterious effects at the time of diagnosis; these disturbances persist over time despite cure or hormonal control and are of higher intensity in women.

Cushing syndrome in older women: age-related differences in disease origin and clinical manifestations

Amit Akirov[1,2], Ilan Shimon[1,2], Manisterski Yosi[3], Nirit Aviran-Barak[3], Varda Nadler[4], Sandra Alboim[4], Gloria Tsvetov[1,2,3] & Dania Hirsch[1,2,3]
[1]Tel Aviv University, Sackler School of Medicine, Tel Aviv-Yafo, Israel; [2]Beilinson Medical Center, Petah Tikva, Israel; [3]Maccabi Health Services, Tel Aviv-Yafo, Israel; [4]Maccabi Healthcare Services, Rehovot, Israel

Background
Adrenocorticotropic hormone (ACTH)-producing pituitary adenoma is the most common cause of endogenous Cushing syndrome (CS), but the relative proportion of adrenal causes of CS is rising. Limited data are available on the clinical manifestations and cause of CS in older women.
Objective
Determine the clinical presentation, biochemical profile, and cause of CS in women 65 years of age and older, compared with younger patients with CS.
Methods
Retrospective charts review of women with pituitary or adrenal CS, treated at Rabin Medical Center between 2000 and 2017, or at Maccabi Healthcare Services in Israel between 2005 and 2017. Patients were classified into 3 groups, according to age at diagnosis: ≤45 (young), 46-64 (middle-age), or <65 (elderly) years.
Results
The cohort included 142 women (mean age, 46.0 ± 15.1 years), including 81 (57.0%) with ACTH-producing pituitary adenoma, and 61 patients (43.0%) with adrenal CS: 68 young, 55 middle-aged, and 19 elderly women. Pituitary source for CS was more common among young patients (48 patients, 70.6%), compared with middle-aged (27 patients, 49.1%) or elderly women (6 patients, 31.6%) ($P<0.05$). Weight gain was evident in 57.4% of young women (60.0% pituitary, 56.3% adrenal), compared with 15.8% of elderly women (50% pituitary, 0% adrenal) ($P=0.011$). Cushingoid features were more common among young vs. elderly patients, but the difference was not significant (40.0% vs. 22.1%, respectively; $P=0.15$). Among patients with adrenal CS, diagnosis of hypercortisolism was established following an incidental finding of an adrenal mass in 3 of 20 (15.0%) young women vs. 7 of 13 (53.8%) elderly women ($P<0.001$). Mean urinary free cortisol levels were highest for young women (5.03±3.6xULN), followed by middle-aged (4.80±6.0xULN) and elderly (3.5±2.6xULN) women ($P<0.001$), while no difference was recorded for serum cortisol levels following low-dose dexamethasone. Adrenal or pituitary tumor size was not different between groups. While in young patients with CS, urinary free cortisol levels were higher for those with adrenal vs. pituitary CS (6.61±3.2xULN vs. 4.36±3.6xULN), in middle aged (3.42±3.4xULN vs. 6.24±7.7xULN) and elderly (2.62±1.9xULN vs. 5.33±2.9xULN) patients, pituitary CS was associated with higher urinary free cortisol levels than adrenal CS.

Conclusions
Older patients with CS have distinct disease cause and presentation, as pituitary source is less common than adrenal CS, the latter is associated with milder hypercortisoluria and is frequently diagnosed incidentally. Weight gain was prevalent in young women, and uncommon in older women.

Hobnail variant of papillary thyroid carcinoma, a systematic review and meta-analysis

Ariadni Spyroglou[1], George Kostopoulos[2], Konstantinos Bramis[1], Sofia Tseleni[3], Konstantinos Toulis[2], George Mastorakos[1], Manousos Konstadoulakis[1], Kyriakos Vamvakidis[4] & Krystallenia Alexandraki[1]
[1]National and Kapodistrian University of Athens, 2 nd Department of Surgery, Aretaieion Hospital, Athens, Greece; [2]424 General Military Hospital, Department of Endocrinology, Thessaloniki, Greece; [3]National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece; [4]"Henry Dunant" Hospital Center, Department of Endocrine Surgery, Athens, Greece

Background
Although papillary thyroid carcinoma (PTC) is considered to have an excellent prognosis, some more aggressive variants have been identified that show reduced overall survival rates. Besides from the diffuse sclerosing, tall cell, columnar cell, and solid variant, the hobnail variant was newly recognized as one of these aggressive forms, affecting recurrence, metastasis, and overall survival rates.
Methods
We performed a systematic review and meta-analysis of studies including cases or case series with patients with hobnail variant of PTC. Furthermore, we included our own case series consisting of six patients.
Results
The pooled mortality rate in the cohort consisting of 191 patients was 3.43 (95% CI 1.72-6.82) per 1000 person/months. No sex differences could be observed concerning mortality ($P=0.52$) but older age and tumor size significantly affected mortality ($P=0.03$ and$P=0.02$, respectively). The percentage of hobnail variant did not affect mortality ($P=0.29$), neither did the presence of BRAF mutations. Classical characteristics as the presence of extrathyroidal extension ($P=0.001$), distant metastases ($P<0.001$) and lymph node metastases ($P<0.001$) all had a significant impact on mortality.
Conclusions
Hobnail variant correlates with worse overall survival and all PTC cases should be carefully assessed for this variant.

Retrospective assessment of malignant thyroid nodules in a group of children and adolescents according to BTA U classification and ACR TI-RADS ultrasound-based risk stratification system in combination with elastography

Artur Bossowski, Hanna Borysewicz-Sanczyk, Beata Sawicka, Filip Bossowski, Agata Karny, Aleksandra Rusak & Janusz Dzieciol
Medical University in Bialystok, Dep of Pediatric Endocrinology and Diabetes, with a Cardiology Division., Białystok, Poland

The risk of malignancy in thyroid nodules correlates with the presence of ultrasound features. In adults, ultrasound risk-classification systems have been proposed to indicate the need for further invasive diagnosis. Furthermore, elastography has been shown to support differential diagnosis of thyroid nodules. The purpose of our study was to assess the application of the American Thyroid Association (ATA) and British Thyroid Association (BTA) ultrasound risk-classification systems as well as strain elastography in the management of thyroid nodules in children and adolescents. Seventeen nodules with Bethesda III, IV, V and VI were selected from 165 focal lesions in children. All patients underwent ultrasonography and elastography followed by fine needle aspiration biopsy. Ultrasound the ATA and BTA stratification systems were assessed retrospectively. The strain ratio in the group of thyroid nodules diagnosed as malignant was significantly higher than in benign nodules (6.07 vs. 3.09, $P=0.036$). According to the ATA guidelines, 100% of malignant nodules were classified as high suspicion and 73% of benign nodules were assessed as low suspicion. Using the BTA U-score classification, 80% of malignant nodules were classified as cancerous (U5) and 20% as suspicious for malignancy (U4). Among benign nodules, 82% were classified as indeterminate or equivocal (U3) and 9% as benign (U2). Our results suggest that application of the ATA or BTA stratification system together with elastography may improve differential diagnosis and help make a clinical decision about the need for further invasive diagnosis of thyroid nodules in children.

Discordant thyroid function tests following Ibrutinib therapy

Alwyn Yung Zhuang Choo & Jayamalee Jayaweera
West Suffolk Hospital, Endocrinology and Diabetes, Bury St. Edmunds, United Kingdom

Background
Tyrosine kinase inhibitors (TKI) are a chemotherapeutic group which include drugs known to cause thyroid dysfunction such as axitinib, imatinib, pazopanib, sorafenib, and sunitinib. However, reports of TKI-Ibrutinib causing thyroid dysfunction are scarce. Although several hypotheses have been proposed to explain TKI-associated thyroid dysfunction there is no clear guidance on how to manage this situation.
Case
86-year-old lady was referred to the endocrinology clinic for evaluation of abnormal thyroid function tests. Her relevant medical histories included stage IV mantle cell lymphoma, hypothyroidism, stage III chronic kidney disease, hypertension, and diverticular disease. She was diagnosed with hypothyroidism in 2003 and has been on Levothyroxine dose of 100 mg and 75 mg on alternate days for many years. She was diagnosed with stage IV mantle cell lymphoma and was commenced on Ibrutinib in June 2020. Her first recorded thyroid function test in 2012 showed hypothyroidism, following that remained relatively stable with the same dose of Levothyroxine. Following introduction of Ibrutinib in June 2020, there was a concurrent rise in thyroid-stimulating hormone (TSH) and free thyroxine (FT4) with mildly decreased free triiodothyronine (FT3). She was fully compliant with Levothyroxine and confirmed taking the tablet well apart from her meals and other tablets. Other relevant blood tests showed stable chronic kidney disease, normal liver function test. Assay interference results were unremarkable. Serial thyroid functions showed rise in TSH (9.4;11.4;8.34;4.39;5.91;11.1) with concurrent rise in FT4 (19.5;23;26;26.9;23;23.1) and low FT3 levels (2.4;2.2;2.5) following Ibrutinib. Thyroxine dose was increased to 100 mg daily as TSH had risen to 11.1 and she complained of excessive tiredness.
Discussion
Suggested mechanism for this pattern is the induction of type 3 deiodinase (D3) pathway which converts FT4 to rT3 and inhibition of type 2 deiodinase (D2) which converts FT4 to FT3, with the balance towards D2 inhibition. Thyroid-binding globulin was not elevated hence it could not account for the raised TT4. Non thyroidal illness causing this picture is unlikely given raised TSH. Induction of uridine diphosphate-glucuronosyltransferases is a plausible cause, which enhances clearance of T4 and T3 (as suggested for another TKI-Imatinib) resulting in hypothyroidism in patients receiving Levothyroxine replacement, however T4 levels were not reduced.
Conclsion
This case highlights the importance of thyroid function testing prior to starting Ibrutinib and the value of close monitoring of thyroid status throughout. Clinicians who prescribe Ibrutinib should be aware of this potential thyroid function dysfunction, and to seek endocrinology advice as appropriate.

Salivary free cortisol and serum DHEA-sulfate measurements with cosyntropin stimulation improve accuracy of secondary adrenal insufficiency diagnosis in pregnancy

Ashley B Humrickhouse & Maya Y Peltsverger
Novant Health New Hanover Regional Medical Center, Wilmington, United States

Background
Diagnosis of secondary adrenal insufficiency (SAI) during pregnancy is challenging due to physiological adaptations and progressive increase of cortisol level throughout the pregnancy (1). The 250-mg standard ACTH stimulation test

(CST) is recommended for evaluation of adrenal hypofunction in pregnancy however, measurement of serum cortisol (SC) maybe misleading in patients with partial SAI. Furthermore, utility of salivary free cortisol (SaFC) (2) and serum DHEA-sulfate (DHEA-S) measurements has been proposed to improve the accuracy of SAI diagnosis (3).

Case

We report the case of a 33-year old female with history of hypopituitarism secondary to Langerhans cell histiocytosis treated with pituitary irradiation during pre-teen years subsequently leading to Diabetes Insipidus, hypogonadism, and growth hormone deficiency. Prior to pregnancy, her thyroid function and ACTH stimulation tests were normal. She presented at 25 weeks of gestation with complaints of profound fatigue and weight loss. Pregnancy was conceived via in vitro fertilization. Morning serum ACTH and SC were 14.9 pg/ml (7.2-63.3 pg/ml) and 14.95 mg/dl (6.2-19.4 mg/dl), respectively. Serum DHEA-S was 39.5 mg/dl (84.8-378.0 mg/dl). During pregnancy SC levels increase 2-to-3-folds higher than in non-pregnant women and DHEA-S levels usually increase by 2nd trimester (4). Thus, secondary adrenal insufficiency was suspected. Patient underwent 250-mg ACTH stimulation test with measurements of SC, DHEA-S, and SaFC concentration before, 30, and 60 min after cosyntropin stimulation. SC increased from 14.76 mg/dl to 25.67 mg/dl and 29.69 mg/dl at 30 and 60 min, respectively. Baseline SaFC was 0.128 mg/dl (0.36 +/-0.17 mg/dl) and minimally increased to 0.276 mg/dl and 0.412 mg/dl at 30 and 60 min, respectively. Baseline DHEA-S was 17.1 mg/dl and minimally increased to 19.1 mg/dl and 21 mg/dl at 30 and 60 min, respectively.

Discussion

Previous studies have reported that SaFC and serum DHEA-S measurements can improve the accuracy of SAI diagnosis. Suri *et al*. proposed that SaFC is superior for assessing adrenal response to ACTH stimulation with cutoff for second trimester being 0.36 +/-0.17 mg/dl at baseline and 2.37+/-0.99 mg/dl after cosyntropin stimulation. Patient in this case report had normal SC peak response to CST however, SaFC levels did not reach expected range after stimulation. Serum DHEA-S is a sensitive indicator of impaired ACTH secretion in patients with SAI (5). Patient in this report had DHEA-S levels that were low throughout the pregnancy. Collectively, the patient′s findings reported here suggest SAI. Initiation of hydrocortisone therapy significantly improve patient′s symptoms.

Adrenal incidentaloma, single center clinical experience

Beril Turan Erdogan[1], Berna Evranos Ogmen[2], Caglar Keskin[1], Sevgul FAKI[1], Cevdet Aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]

[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Backgorund

Adrenal incidentalomas (AI) are lesions discovered incidentally on imaging without clinical symptoms or examination findings. AI can produce hormones in 5-30% of cases. Autonomic cortisol secretion (ACS) is the most common of these. Although ACS is asymptomatic, it increases the risk of metabolic disorders.

Methods

Patients aged < 18 years with adrenal adenoma and upper abdominal MRI who presented and were examined in the endocrinology outpatient clinic, had their data retrospectively documented. Comorbidities, examinations and hormonal tests and results of these patients were evaluated. Those who failed dexamethasone suppression tests (cortisol > 1.8 g/dl) and did not have Cushing's syndrome were classified as ACS.

Results

Among the 223 patients, 138 (61.9%) were women with a median age of 56 (18-80). Of the patients, 26.9% had diabetes mellitus (DM), 54.3% had hypertension (HT), 17.9% had hyperlipidemia (HL), 12.1% had coronary artery disease (CAD), 1.3% had heart failure (HF). Hormone testing revealed that 6 (2.6%) of the patients had primary aldosteronism, 5 (2.2%) had pheochromocytoma, and 35 (15.6%) had ACS. Patients with and without ACS were compared for the presence of other additional diseases and adenoma size (Table-1). DM, HT and HL were higher in the ACS group ($P < 0.05$, for each). Adenoma size was larger in the ACS group ($P < 0.05$). Both groups had comparable age and sex distribution ($P > 0.05$).

Conclusion

İndividuals with large adenomas are more likely to have ACS. Large adrenal adenomas should be monitored for ACS and associated cardiometabolic risks, as well as necessary treatments.

Table 1 Comparison of patient characteristics with and without autonomic cortisol secretion

Autonomic cortisol secretion	Yes	No	P
Sex, Woman/Man	2.18	1.54	0.45
Age (years), median (min-max)	59 (36-80)	55 (18-74)	0.071
Size of adenoma (mm)	25 (10-54)	18 (10-60)	0.001
T2DM	17 (48.6%)	43 (22.9%)	0.002
HT	25 (71.4%)	96 (51.1%)	0.028
HL	13 (37.1%)	27 (14.4%)	0.003
CAD	7 (20%)	20 (10.6%)	0.154
HF	1 (2.9%)	2 (1.1%)	0.402
Osteoporosis or osteopenia	6 (30%)	13 (56.5%)	0.125

Primary hyperparathyroidism, familial hypocalciuric hypercalcaemia or both?

Ashutosh Kapoor[1], Bhavna Sharma[1], Danujan Sriranganathan[1], Neil Tolley[2], Aimee Dimarco[2] & Mushtaqur Rahman[1]

[1]London North West University Healthcare NHS Trust, United Kingdom; [2]Imperial College Healthcare NHS Trust, United Kingdom

Introduction

Primary hyperparathyroidism (PHPT) is an endocrine condition in which autonomous excessive secretion of parathyroid hormone (PTH) results in hypercalcaemia. In approximately 80% of cases the aetiology is due to a single parathyroid adenoma, the remainder are due to hyperplasia of more than one gland. Familial Hypocalciuric Hypercalcaemia (FHH) is an autosomal dominant, inactivating mutation of the calcium-sensing receptor, causing a right-shift in the concentration-response curve, and producing biochemistry similar to PHPT.[1] Although usually benign, it can cause pancreatitis. More than 75% of cases are due to the following genotypes, in descending order of incidence, CASR, AP2S1, GNA11: FHH 1, 3, and 2, respectively.

Case details

We report the case of a 53-year South Asian male, referred with hypercalcaemia. Serum adjusted calcium was 2.71 mmol/l, PTH 4.5 pmol/l, FE_{Ca} 0.014, and 24h urine calcium 6.08 mmol; a previous 24h urine calcium was 8.76 mmol (normal 2.5-7.5). The patient had a history of renal stones, enough to cause hydro-ureteronephrosis. Therefore, despite the equivocal biochemistry, it was felt that this was in keeping with PHPT. Dual-modality imaging did not reveal a discrete adenoma and so 4-gland exploration was undertaken with the removal of three glands, which had features of hyperplasia and was in keeping with the negative results of imaging; peak pre-operative PTH was 13.2, dropping to 4.4 pomol/l after surgery. Due to recurrence of hypercalcaemia and the equivocal FE_{Ca}, genetic testing was undertaken and showed the patient to be heterozygote FHH2 (GNA11).

Discussion

PHPT and FHH occurring in the same patient is rare, but has been reported.[2] A FE_{Ca} < 0.02 should prompt consideration of FHH, but this patient presented with renal stone disease, more in keeping with primary hyperparathyroidism. Therefore, an operative approach was valid and there may have been reduced penetrance of the pathological variant of FHH. Where these conditions co-exist, surgery can reduce the level of hypercalcaemia and treatment choice should be based on presence of end-organ effects[2]; an alternative approach is to use cinacalcet, a calcimetic agent.[1]

Initial results and patient satisfaction with the new oral formulation of semaglutide

Francisco Javier Martinez Martin[1,2], Agnieszka Kuzior[1,2], Claudia Arnas-Leon[1,2], Paula Fernandez-Trujillo-Comenge[1], Sara Quintana-Arroyo[3], Carmen Acosta-Calero[4], Ana Delia Santana-Suarez[1], Paula Gonzalez-Diaz[5], Alba Hernandez-Lazaro[1] & Ricardo de Leon-Durango[1]
[1]University Hospital of Gran Canaria Dr. Negrin, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]Hospital Insular de Gran Canaria, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [4]University Hospital of Gran Canaria Dr. Negrin, Cardiology, Las Palmas de Gran Canaria, Spain; [5]University Hospital of Gran Canaria Dr. Negrin, Emergency, Las Palmas de Gran Canaria, Spain

Introduction
Oral semaglutide has been available in the Spanish market since November 2021. This new formulation has broken the self-injection barrier, and may enhance patient satisfaction.
Methods
Retrospective review of the patients′ records and presential or telephonic interviews. All patients expressed their consent for the anonymous processing of their data. Numeric data are given as mean + s.d; paired t-test was used for comparison. Satisfaction was categorically expressed as very poor, poor, fair, good or very good.
Results
36 obese patients with type 2 diabetes who had taken at least one pill of oral semaglutide were included. Their age was 56 + 12 years; 58% were female; diabetes duration was 6 + 2 years. Of them 34 remain on treatment, 1 withdrew due to gastric intolerance and 1 due to difficulty to schedule the medication intake. 9 are still on the lowest dose (3 mg/day), 11 on the medium dose (7 mg/day) and 14 on the full dose (14 mg/day), 5 of which started on this dose because they were transferred from previous parenteral GLP-1RA therapy. 24 patients have a HbA1C measurement after at least 2 months on oral semaglutide and the difference with the previous is -1.2 + 0.5%. ($P=0.013$). 26 patients have a weight measurement after at least 2 months and the difference is -3.2 + 1.3 kg ($P=0.032$). Mild gastrointestinal disturbances were reported by 8 of the patients (22%), and only persist in 3 of them (8%) but in one case epigastric pain, nausea and vomiting caused withdrawal. No severe hypoglycemia has been reported. Five patients were on previous levothyroxine treatment and their dose was maintained but the intake hour was rescheduled; no dosing changes have been required so far. Seven of the patients were diagnosed with non-proliferative diabetic retinopathy but none were in active treatment; no worsening has been reported. One patient (3%) reported very poor satisfaction, 1 (3%) poor, 4 (11%) fair, 11 (31%) good and 19 (53%) very good. All 5 patients who were transferred from parenteral GLP-1AR reported very good satisfaction.
Conclsions
Our initial experience with oral semaglutide is quite satisfactory, with the expected gastrointestinal disturbances which were mild and non-persistent in the large majority of the patients. No additional clinical problems emerged. Glycemic control was significantly improved without serious hypoglycemia, and body weight was significantly decreased. Satisfaction was good or very good in 5 out of 6 patients.

Insights into the early use of oral semaglutide in routine clinical practice

Bharat Saboo
Prayas Diabetes Center, Indore, India

Introduction
Oral semaglutide (Rybelsus; Novo Nordisk) is the first glucagon-like peptide-1 receptor agonist (GLP-1 RA) developed for oral administration for the treatment of type 2 diabetes (T2D), and it has been approved by the US Food and Drug Administration and the European Medicines Agency. The efficacy and safety of oral semaglutide were assessed in the (PIONEER) program.
Aim
The purpose of this study was to investigate the initial patterns of routine clinical use of oral semaglutide, as well as the clinical features and glycemic control, and weight of patients.
Method
a retrospective, observational cohort study utilizing retrieved electronic medical records involved database search of 28 patients for the demographic parameters at the index date, as well as baseline co-morbidities, antidiabetic drugs, and HbA1c. Baseline and after 1-month, weight and FBS levels were determined for patients with relevant data. For inclusion, adult patients (aged < 18 years) required a diagnosis of T2D and at least one prescription for oral semaglutide. Patients with type 1 diabetes or gestational diabetes were excluded. The results were analyzed using MS Excel.
Result
Although the medical instructions recommend raising the dose to 7 mg after 30 days, 64.3 percent of patients obtained a prescription solely for the initial 3 mg dose. The mean body mass index was 36.2 kg/m^2 n, and the mean HbA1c level was 9.1%. The mean change in FBS from baseline to about one month after initiating oral semaglutide was 6.3%, with more significant reductions in those with higher baseline FBS. The average weight loss was 2.3 kg, significantly more significant in patients with a higher baseline BMI.
Discussion
Our data demonstrates early trends in the use of oral semaglutide in routine clinical practice. Oral semaglutide initiators have a high prevalence of obesity and other co-morbidities, a varied treatment history, and improved glycemic control following therapy initiation. The relatively high number of patients allocated 3 mg as their maximum dose shows that, in patients who tolerate oral semaglutide well, dose escalation to 7 and 14 mg, as indicated, may result in even more significant glycemic control improvements. These findings emphasize the critical nature of bridging existing treatment and knowledge gaps in order to maximize the potential of oral GLP-1 RA therapy. Further examination of real-world data will give more information on the translation, uptake, and impact of such breakthroughs in standard treatment.

In Individuals with obesity, resting energy expenditure does not decrease after weight loss with GLP-1 agonist liraglutide

Mostafa Mohseni[1,2], Mila Welling[1,2], Renate E.H. Meeusen[1,2], Wietske G.C.L.M. Broeders[1,2], Eline van der Valk[1,2] & Elisabeth van Rossum[1,2]
[1]Erasmus MC, University Medical Center Rotterdam, Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [2]Erasmus MC, University Medical Center Rotterdam, Obesity Center CGG, Division of Endocrinology, Rotterdam, Netherlands

Background
Obesity (BMI < 30 kg/m^2) is a chronic and progressive disease, that is associated with many co-morbidities such as cardiovascular and psychiatric diseases, cancer, and arthritis. Lifestyle interventions are the cornerstone of obesity treatment, but when ineffective, anti-obesity pharmacotherapy could be added. In recent years, several anti-obesity agents have been approved, such as the glucagon-like peptide-1 (GLP-1) analogue liraglutide. Liraglutide induces weight loss, presumably by suppressing appetite and improving satiety. It is however unclear whether liraglutide also induces weight loss by alterations of the resting energy expenditure (REE).
Methods
In this observational longitudinal study, we evaluated individuals with obesity who were treated with liraglutide 3.0 mg at the Obesity Center CGG, Erasmus MC Rotterdam, The Netherlands. We included 24 individuals (18 women), of whom four had a confirmed genetic obesity, thirteen had clinical features suspective of genetic obesity, and seven had common obesity. At baseline and after 16 weeks of treatment, which included dose escalation over a period of 4 weeks, we measured anthropometric parameters, body composition using bio-electrical impedance (Inbody S10, BioSpace, Seoul, Korea), and REE using indirect calorimetry (Q-NRG®, Cosmed, Roma, Italy). Predicted REE was calculated using the Harris-Benedict formula.
Results
At baseline, mean weight and BMI were 124.1 kg (± 24.1) and 42.7 kg/m^2 (± 7.5), respectively. Their weight decreased significantly (-5.7%, $n=23$) after 12 weeks of treatment. Fat mass and fat-free mass (FFM) decreased significantly (-5.2 kg and -2.7 kg, respectively; $n=18$) and percentage of fat mass decreased from 47.6% to 46.5% ($P=0.096$). REE increased from 1879 kcal/day to 1956 kcal/day ($P=0.150$), and REE per kg FFM increased from 29.7 kcal/kg/day to 32.3 kcal/kg/day ($P=0.023$). Lastly, REE as a percentage of predicted REE increased from 94% to 98% ($P=0.204$).
Conclsion
In patients with obesity, treatment with GLP-1 analogue liraglutide effectively induces weight loss, with improved body composition. Furthermore, despite decreases in fat free mass, of which muscle mass is a major component, resting energy expenditure did not decrease. Our findings suggest that weight loss induced

by liraglutide may not only be facilitated by decreases in caloric intake through the anorexigenic effects of GLP-1 analogues, but also by increasing the resting energy expenditure per kg fat-free mass.

Neuroprotective properties of GLP-1 receptor agonists and SGLT-2 inhibitors in experimental stroke

Anna Simanenkova[1,2], Natalya Timkina[1,2], Tatiana Karonova[1,2], Polina Tikhomirova[2], Alexandr Gagiev[2], Fedor Radugin[1] & Timur Vlasov[2]
[1]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation; [2]Pavlov First Saint-Petersburg State Medical University, Saint-Petersburg, Russian Federation

Background and aims
The most outstanding cardioprotective potential has been demonstrated for GLP-1 receptor agonists (GLP-1RA) and SGLT-2 inhibitors (SGLT-2i). But only long-acting GLP-1RA dulaglutide (DULA) and semaglutide decrease stroke incidence, while data concerning the influence of any drug on stroke severity are lack. At the same time, ischemic stroke remains one of the leading causes of death in type 2 diabetes mellitus (DM2). The aim of our study was to investigate neuroprotective actions of liraglutide (LIRA), DULA and empagliflozin (EMPA), in comparison with metformin (MET) in acute rat brain ischemia. We have chosen two GLP-1RA with different action duration to evaluate drug- or class-effect.
Materials and methods
male Wistar rats 200-255 g were treated for 7 days with LIRA 1 mg/kg s.c. once daily ("LIRA", $n=12$), DULA 0.12 mg/kg s.c. every 72 h ("DULA", $n=10$), EMPA 2 mg/kg per os once daily ("EMPA", $n=9$), MET 200 mg/kg kg per os once daily ("MET", $n=8$) or 0.9% NaCl s.c. once daily ("Control", $n=12$). Then all animals were subjected to 30-min filament middle cerebral artery occlusion (MCAO). 48 h after MCAO neurological deficit was evaluated by Garcia scores – healthy animals have 18 points, maximal neurological deficit is characterized by 3 points. Then rats were euthanized, brain slices were incubated with 1% 2,3,5-triphenyltetrazolium chloride for necrosis measurement. Blood glucose level (BGL) was studied every second day.
Results
Brain infarct volume was significantly smaller in "LIRA" and "DULA" (5.50(3.97;5.50)% and 6.65(4.1;11.0)%) comparing with "Control" (16.56(13.33;24.65)% of total brain volume). Stroke volume in "EMPA" (4.91(2.67;14.49)%) was also smaller than in "Control". There was no difference among "LIRA", "DULA" and "EMPA" groups. Treatment with MET also led to brain damage volume decrease (8.67(5.39;30.07)%), comparing with control, but it was larger than in other treatment groups. Rats in groups "LIRA" and "DULA" had less prominent neurological deficit and more points according to Garcia score (14.0(11.5;15.5) and 13.5(8.5;15.0)) comparing with "Control" (12.0(9.0;14.0)), with no difference between LIRA and DULA. Neither EMPA (12.0(9.5;14.0)), nor MET (12.0(6.5;12.5) points) diminished neurological deficit, comparing with "Control". BGL was normal in all groups.
Conclusions
GLP-1RA, SGLT-2i and MET are neuroprotective in rat transient brain ischemia and this effect is not connected with glucose metabolism. Infart-limiting effect of LIRA, DULA and EMPA is similar and is more prominent than that of MET. Only GLP-1RA diminish neurological deficit. Neuroprotective property of GLP-1RA with different action duration is similar, being most probably a class-effect.

Suppressor of cytokine signaling-3 in pregnant females with or without hypertension: a case-control study

Huma Ali[1], Mubeen Ali[1], Sabah Farhat[2] & Syeda Sadia Fatima[3]
[1]Aga Khan University, Medical College, Karachi, Pakistan; [2]Aga Khan University, Department of Biological and Biomedical Sciences, Karachi, Pakistan; [2]Aga Khan University, Department of Biological and Biomedical Sciences, Karachi, Pakistan

Suppression of Cytokine Signalling-3 (SOCS-3) modulates the inflammatory pathways responsible for vascular stability by playing a role in inflammatory pathway. It acts by inhibiting the activation of Janus kinase-signal transducer and activating of transcription (JAK-STAT) pathway to transmit their information into the cell nucleus. Therefore, this study aimed to estimate SOCS-3 levels in 2 nd trimester pregnant females and correlate it with blood pressure. A case control study recruiting ($n=111$) females was conducted at the Aga Khan University Hospital, Karachi from January 2017 till February 2018. Pregnant females in their 2 nd trimester (13 to 27 weeks) between the ages of 20-35 years were included in the study. Females with any comorbid such as gestational diabetes, twin pregnancies, chronic cardio metabolic illness or infectious diseases such as HIV, HBV, HCV or females on anti-inflammatory medication, were excluded from the study. Furthermore, females with pre-existing hypertension, and complicated cases were excluded from this study. Recruited females were then classified as pregnancy-induced hypertensives or normotensive as per American College of Obstetricians and Gynecologists Guidelines. Weight, body mass index, lipid profile and blood glucose were recorded while SOCS-3 was measured by ELISA. Results showed that higher SOCS-3 levels were seen in hypertensive group (30 pg/ml) vs normotensive (16 pg/ml). Both systolic & diastolic blood pressure ($r=0.520$; $P<0.001$) ($r=0.490$; $P<0.001$) showed an independent significant positive correlation with SOCS-3 level. Although hypertensive pregnant females were obese and had a higher BMI compared to normotensive females ($P<0.05$), no difference in the lipid profile levels was observed, suggesting that SOCs-3 may act as an independent marker for blood pressure in pregnancy. Higher SOCS-3 levels were seen in hypertensive group (30 pg/ml) vs normotensive (16 pg/ml). Thus, it is safe to suggest that SOCS-3 has an association of causing high blood pressure. However, more research needs to be conducted to establish a mechanism and chronological order to these events in a pregnant female.

Silent acromegaly- a case report

Hanaan Ashraf[1] & Idrees Mubarik[2]
[1]Aster DM Healthcare, Internal Medicine, Dubai, United Arab Emirates; [2]Aster DM Healthcare, Endocrinology, Dubai, United Arab Emirates

Background
Mammosomatotroph cell adenoma is rare, accounting for fewer than 2% of all pituitary adenomas and about 8% of tumors associated with acromegaly. A variety of adenomas may present with clinical signs and symptoms of GH hypersecretion including pure GH cell adenomas, mixed GH and prolactin cell adenomas, and monomorphous adenomas with primitive cells able to secrete GH and prolactin including the acidophilic stem cell adenoma and the mammosomatotroph cell adenoma. Here we present a patient with pituitary macroadenoma discovered three years ago with elevated Insulin Growth Factor-1 (IGF-1) but no clinical features of acromegaly.
Clinical presentation
A 35-year-old Caucasian nulliparous woman, known case of pituitary macroadenoma with a recent onset of hypertension presented to the clinic for routine check-up. Her initial presentation was of irregular menstruation, labs revealed high PRL and MRI confirmed pituitary macroadenoma in the year 2019. MRI′s at the time of diagnosis and further follow-ups were compared, despite the use of cabergoline the tumor size did not reduce; Hence she was evaluated for NFPA. Endocrinological workup for our patient revealed Ft4 1.10(1-2 ng/dl), prolactin 18(6 - 29.9 ng/ml), cortisol 10.3(3.7-19.4 mg/dl), OGTT values were 114/144, Hba1c 5.5, serum IGF-1 levels of 721(63.4-223.0 ng/ml), Growth hormone suppression test revealed 1 h GH of 12 ng/ml. Over the three years pituitary MRI′s were done each year and size in first, second and third MRI are 1.2X1.3X1.2 cm,1.2X1.3X 1.1 cm and 1.2X1.1X0.95 cm respectively. There was no reduction in tumor size over the past 3 years. Her serum IGF-1 levels were 3 times the normal upper limit. GH suppression test confirmed somatotroph adenoma with no symptoms of acromegaly. With these results, cabergoline was stopped, patient was advised for pituitary surgery.
Conclusion
In conclusion, the clinical spectrum of acromegaly varies from florid to subtle/no features and the diagnosis may be missed in some patients who are presumed to have clinically nonfunctioning pituitary tumors or no pituitary disorder. IGF-1 and GH should be checked in all patients of pituitary macroadenomas irrespective of initial symptoms as clinical features may take time to evolve. This recognition expands the therapeutic options to include pharmacological treatment and also provides a tumor marker to monitor the efficacy of treatment.

Changes in acromegaly presentation and treatment over a three-decade period

Charlotte Aagaard[1], Amanda S Christophersen[1], Susanne Finnerup[1], Christian Rosendal[1], Peter Vestergaard[1,2], Jesper Karmisholt[1], Eigil H Nielsen[1] & Jakob Dal[1]
[1]Aalborg University Hospital, Endocrinology, Aalborg, Denmark; [2]Steno Diabetes Center, North Jutland, Aalborg, Denmark

Objective
To study time-dependent changes in the prevalence and patient characteristics of acromegaly, as well as to access the impact of changes in treatment on disease control.
Methods
A total of 107 patients with acromegaly were identified by healthcare registries and subsequently validated by patient chart review over a three-decade period (1992-2021).
Results
The prevalence of acromegaly significantly increased throughout the study period ($R^2 = 0.94$, $P < 0.001$) and was 122 cases/10^6 in 2021 whereas the annual incidence was constant 4.6 cases/10^6. The age at the first sign of acromegaly and the age at diagnosis significantly increased during the study period, whereas GH and IGF-I decreased. Incidentalomas constituted 32% of all cases diagnosed with acromegaly in the last decade. Primary surgery was used in 93% of all cases, and reoperations decreased from 24% to 10% during the three decades. The use of somatostatin analogues (SSA, 21%-48%) and second-line medical treatment (4%-20%) increased with a concomitant improvement of biochemical disease control (58%-91%).
Conclusion
The prevalence of acromegaly is higher than previously reported and the clinical presentation has shifted towards a milder phenotype. Modern treatment of acromegaly enables individualized treatment and disease control in the majority of patients.

The first reported pregnancy and birth by a patient affected by Alström Syndrome: a case report

Luca Marozio[1], Gianluca Bertschy[1], Emilie M. Canuto[1], Pietro Maffei[2], Gabriella Milan[2], Francesca Dassie[2], Stefano Cosma[1] & Chiara Benedetto[1]
[1]Department of Obstetrics and Gynecology, University of Turin, Turin, Italy; [2]Department of Medicine, University of Padua, Padua, Italy

Background
Alström Syndrome (ALMS, OMIM 203800) is an ultra-rare disease caused by autosomal recessive mutations of the *ALMS1* gene (2p13). ALMS is characterized by double sensory impairment and systemic comorbidities, including hyperandrogenism in female patients. Fertility issue and conception have not been systematically studied.
Case
This case report describes the pregnancy and birth by an ALMS patient with mild phenotype, characterized by late onset visual impairment, hypertension and mild cardiac fibrosis at MRI. Patient had no history of hyperphagia, metabolic, hepatic, nephrological comorbidities and auditory disorders. From a gynecological point of view, menarche occured at the age of twelve years and the following menses was regular, she had a Tanner stage of 5 for breast development and 3 for pubic hair representation. The year before her pregnancy her hormonal evaluation on follicular phase showed normal levels of gonadotropin, prolactin, oestradiol, progesterone, testosterone, dehydroepiandrosterone-sulfate, SHBG, TSH, insulin, fasting glucose and increased levels of Dihydrotestosterone (1.33 nmol/l normal values 0.08-1.26) and androstanediol glucuronide (7.70 mg/l normal values 0.34-7.53). She had conceived spontaneously in January 2020. A rigorous clinical follow-up of maternal and fetal conditions was carried out. A weight gain of 10 kg during pregnancy was recorded. The course of pregnancy was normal up to 34 weeks gestation when preeclampsia developed. She was treated with corticosteroid as prophylaxis for respiratory distress syndrome, nifedipine, ursodeoxycholic acid, Alfametildopa and Labetalol. Due to patient's preeclampsia and elevated blood pressure, a cesarean section was performed at 35 weeks plus 3 days of gestation. A healthy male weighing 1.950 g was born. Histological examination of the placenta showed partial signs of flow obstruction, limited abruption areas, congested fetal vessels and villi, and a small single infarcted area.
Conclusion
The present case demonstrates that, although hyperandrogenism and comorbidities, conceiving is possible for ALMS patients. A particular attention can be observed for management of systemic comorbidities.

Superior vena cava syndrome associated with graves' disease

Himmet Durmaz[1], Unzile Arifoglu[2], Mustafa Ömer Yazıcıoglu[3], Muhammed Sacıkara[2], Narin Nasıroglu İmga[2], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ankara Bilkent City Hospital, Ankara, Turkey; [3]Department of General Surgery, Ankara Bilkent City Hospital, Ankara, Turkey

Introduction
Goiter means that the thyroid gland is larger than the normal size for the patient's age and gender. Some of the causes of goiter are iodine deficiency, thyroid nodules, Graves' disease(GD). Goiter, hyperthyroidism, ophthalmopathy and dermopathy can be seen in GD. Compression symptoms due to goiter (dyspnea, dysphagia, superior vena cava syndrome) are also seen. Here, we will present a case of GD with superior vena cava syndrome.
Case
A 50-year-old male patient, who had been using methimazole for 6 years due to hyperthyroidism, applied to our outpatient clinic with swelling in the neck. The patient was taking methimazole 10 mg/day. On physical examination, he had goiter, bilateral venous collaterals in the neck, and inactive Graves' ophthalmopathy. Pemberton's sign was positive. In laboratory tests, TSH, fT4, fT3, antiTPO, antiTG, TSH receptor antibody were: <0.008 mU/l, 1.01 ng/dl, 10.6 ng/l, >13000 U/l(<60 negative), 724 IU/ml (<1.3 negative), 34.3 U/l (≤ 1 negative), respectively. In the thyroid ultrasound, the dimensions of the right lobe were 33.9x33.4x73.4 mm, the dimensions of the left lobe were 35.3x50x78.5 mm, the dimension of the isthmus was 20 mm, no thyroid nodule was observed. The thyroid gland showed retrosternal extension. Thyroid scintigraphy was consistent with GD. Computed tomography of the neck and thorax was performed to evaluate the differential diagnosis and cervical region: The dimensions of both thyroid lobes have increased considerably, extending to the paraesophageal, paratracheal, and intrathoracic retrosternal areas, and significant extrinsic compression of the larynx and esophagus was observed. In addition, bilateral subclavian veins were pressed by the thyroid gland, and diffuse dilated venous structures were observed in the skin-subcutaneous part of the anterior of the thyroid. Varicose dilated veins were observed in the anterior mediastinum. (Secondary to subclavian vein compression?). No pathological finding was detected in the lung parenchyma. Bilateral total thyroidectomy was performed. Its pathology was reported as diffuse toxic hyperplasic thyroid gland. Venous collaterals in the neck of the patient disappeared in the postoperative period. Clinical improvement was observed.
Conclusion
The most common cause of hyperthyroidism is GD. Compression symptoms due to diffuse hyperplasia of the thyroid gland may be seen. In particular, the retrosternal extending goiter may cause superior vena cava syndrome by compressing the vascular structures. The most common cause of superior vena cava syndrome is malignancy. GD should also be considered in the differential diagnosis of superior vena cava syndrome. Improvement in this situation is expected with thyroidectomy.

Parathormone washout in cytology of Suspicious for Follicular Neoplasm

Himmet Durmaz[1], Burçak Cavnar Helvacı[2], Nagihan Beştepe[2], Ayşegül Aksoy Altınboğa[3], Ahmet Dirikoc[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ankara Bilkent City Hospital, Ankara, Turkey; [3]Department of Medical Pathology, Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey

Introduction
The risk of malignancy in thyroid nodules is reported by the Bethesda system by performing fine needle aspiration biopsy (FNAB). Atypia of undetermined significance(AUS) or follicular lesion of undetermined significance(FLUS)(Bethesda 3) and suspicious for a follicular neoplasm (Bethesda 4) create uncertainty about treatment and follow-up. Molecular tests, ultrasonographic features of the nodules, and calcitonin level help us for this uncertainty. Here, we will present a patient whose FNAB cytology was Bethesda 3 and Bethesda 4.

Case
A 53-year-old female patient was admitted to our outpatient clinic after detecting a thyroid in neck ultrasound. She had familial Mediterranean fever, osteoporosis, and renal transplantation (5 years ago). In addition, the patient stated that she had been operated on the parathyroid gland while she was receiving dialysis treatment. There was no document related to parathyroid surgery. In laboratory tests, thyroid function tests, calcitonin, calcium levels were normal. 25-OH vitamin D, parathormone level, creatinine, eGFR were 14 ng/ml, 152 pg/ml, 1.51 mg/dl, 39 ml/minute respectively. Secondary hyperparathyroidism due to vitamin D deficiency was considered. On thyroid ultrasound, a hypoechoic nodule that containing cystic degeneration areas was observed adjacent to inferior carotid artery in the right lobe. The dimensions of nodüle were 9.7x11.4x13.7 mm. FNAB was reported as Bethesda 3. The second FNAB cytology was also reported as Bethesda 4. Molecular testing could not be performed in our hospital. The microscopy of FNAB revealed "some of the cells were small, round, monotonous nuclei with pale cyanophilic cytoplasm with unclear borders". No uptake suggestive of parathyroid lesion was observed in parathyroid scintigraphy. Third FNAB cytology was nondiagnostic; Parathormone washout was 525 pg/ml. Due to the high suspicion of parathyroid lesion, fourth FNAB and diluted PTH washout were performed. Fourth FNAB cytology was Bethesda 3, diluted parathormone level was 103871 pg/ml. The lesion was evaluated as intrathyroidal lesion (adenoma or parathyroid seeding due to surgery). Follow-up was planned for the patient.
Conclusion
In parathyroid lesions evaluated as thyroid nodules, FNAB cytology and microscopy give us an idea in terms of intrathyroidal parathyroid lesion. Parathyroid scintigraphy also does not always show uptake. In this situation, PTH washout can be done. If the ultrason features, FNAB microscopy and PTH washout are inconsistent, diluted PTH washout may provide accurate results due to possible hook effect. In addition, intrathyroidal parathyroid seeding should also be kept in mind in patients who have undergone parathyroid surgery for tertiary hyperparathyroidism.

Myxedema coma: case report and literature review

Renata Cassitas Mendonça[1], Laura Vilas Boas[2], Thielsen Cardoso da Silva[2], Laura Maranho Ribas[1], Tamila Sohn Fagundes[1], Taciane Elizabeth Cesca[2] & Mirnaluci Paulino Ribeiro Gama[1]
[1]Hospital Universitário Evangélico Mackenzie, Brazil; [2]Evangelical Mackenzie Faculty of Parana, Brazil

Introduction
Myxedematous coma is a rare endocrine emergency that settles in the absence of appropriate treatment for hypothyroidism for a long period. The severe and chronic reduction of serum thyroid hormones culminates in the insufficiency of compensatory mechanisms that maintain the physiological homeostasis of the organism. The clinical condition is severe, commonly associated with hypoxemia, hypercapnia, hypothermia, reduced cardiac output, and altered mental status.
Case report
A 60 years old female patient with a previous history of thyroidectomy, was admitted at the Hospital hemodynamically unstable, with bradycardia, hypothermia, sedated with midazolam 10 mL/hr, and fentanyl 10 mL/hr, RASS scale – 2 (Richmond Agitation Sedation Score), and miotic pupils. Blood pressure 115x80 mmHg with noradrenaline 10 mL/hr, heart rate 52 bpm, and oxygen saturation 94% on mechanical ventilation. Due to high suspicion of myxedematous coma, was administered an attack dose of levothyroxine (500 mg/day) via a nasogastric probe in the first three days with hydrocortisone 100 mg every 8 h. Levothyroxine dose was maintained at 250 mg/day by a nasogastric probe, and hydrocortisone 50 mg intravenous every 8 h. Laboratory: amylase (160 UI/l) and lipase (250 UI/k), TSH 26 (0.3 and 4.0 mU/l) and free T4 <0.017 (0.9 to 1.8 ng/dl). Chest tomography: massive pericardial and pleural effusion, as well as parenchymal opacities in the outstanding portions and septal thickening inferring pulmonary edema. X-ray: increase cardiothoracic ratio caused by pericardial effusion. Abdominal computerized tomography: ascites, more evident in the upper abdominal (peri-hepatic) and liquid infiltration of intra and extraperitoneal fat by generalized anasarca. She was unstable during the hospitalization period, presented with progressive hypoxemia and hemodynamic instability. Thus, due to suspicion of pulmonary thromboembolism, in addition to the adjustment of vasoactive drugs, full dose enoxaparin was initiated. Meantime, due to the severe condition of refractory hypotension the measures instituted, the patient progresses to death on his twenty-second day of hospitalization.
Conclusion
Although myxedematous coma has an arduous prognosis, there are still gaps regarding the best medication management. It emphasizes the need for studies for the development of a scientific basis that standardizes the most appropriate pharmacological treatment to be instituted. Since there is no consensus on the best form of monotherapy - T4 or in combination with T3. Furthermore, there is a lack of data in the literature to corroborate the effective dose of levothyroxine orally in a myxedematous coma in places where there is no IV medication, such as the situation of this clinical case.

Do polymorphisms of the glucocorticoid and mineralocorticoid receptors play a role in adrenal crises?

Irina Chifu, Freytag Janik, Sabine Herterich, Weber Heike & Stefanie Hahner
University Hospital Würzburg, Würzburg, Germany

Introduction
Polymorphisms of the glucocorticoid (NR3C1) and mineralocorticoid receptor (NR3C2) have been linked to the regulation of HPA-axis and to glucocorticoid sensitivity. We investigated whether NR3C1 and NR3C2 polymorphisms correlate with the occurence of adrenal crises (AC) in patients with primary adrenal insufficiency (PAI).
Material and methods
We investigated 100 patients with PAI (70% women, mean age 51 ± 15 years). DNA was extracted from whole-blood and NR3C1 and NR3C2 polymorphisms were genotyped by PCR and MALDI-TOFF mass spectrometry. Results were correlated with history of AC (number of events since first diagnosis and number of events per patient years), replacement therapy, HbA1c and 24-h blood pressure profile.
Results
Three NR3C1 polymorphisms (rs6198, rs17100289, rs4912911) and one NR3C2 (rs5522) polymorphism were significantly associated with a higher prevalence of AC. For NR3C1 rs6198, AC occured more often in C allele carriers (66% CC/CT vs 44% TT, $P=0.04$, OR 2.5 95% CI 1.0-6.0). For NR3C1 rs17100289, patients with AA genotype experienced more frequent AC (61% AA vs 40% TT/TA, $P=003$, OR 2.4 95% CI 1.0-5.5) and exhibited lower HbA1c levels (5.3 (4.8-8.2) AA vs 5.7 (4.6-8.1) TT/TA, $P=0.03$) and higher degrees of noctural blood pressure dipping (-14% (-26, -5) AA vs -8% (-19, 7) TT/TA, $P=0.02$). For NR3C1 rs4912911, AC occured more often within AA genotype (61% AA vs 38% GA/GG, $P=0.021$, OR 2.6 95% CI 1.1-5.8). For NR3C2 rs5522, AC occured more often in C allele carriers (74% TC/CC vs 44% TT, $P=0.02$, OR 3.5 95%CI 1.2-10.6).
Conclusion
We identified several NR3C1 and NR3C2 polymorphisms that are associated with a higher incidence of AC. The identified NR3C1 polymorphisms have been shown to decrease glucocorticoid sensitivity, whereas NR3C2 rs5522 seems to interfere with the glucocorticoid stress response. Our preliminary data suggests that inter-individual differences in glucocorticoid sensitivity may contribute to increased susceptibility to AC.

Actions taken for prevention of adrenal insufficiency in adult patients who are at risk - audit report

Jayamalee Jayaweera, Sara Sheikh, Rakitha Higgoda, Karthayani Kundrapu, Bilal Jajah & Anupam Brahma
West Suffolk Hospital, Bury St Edmunds, United Kingdom

Background
Adrenal insufficiency (AI) is can be often under recognised condition in the clinical practise which can potentially result in adrenal crisis or even death if not treated properly. Identification of patients who are at risk of developing AI is important in order to take appropriate steps in minimising unwanted incidents.
Objectives
Study aims to assess whether we identify patients who are at risk of AI and take recommended precautions.
Method
We performed a single centred retrospective audit at West Suffolk hospital in the United Kingdom using electronic health records to identify 57 adult patients who were on long term steroid therapy. This included oral, inhaled or injected steroids

for a period exceeding 4 weeks, being prescribed by different specialties (respiratory, rheumatology, haematology, renal gastroenterology) and patients who already had the diagnosis of hypopituitarism and Addison′s disease. The records were then searched from 2016 to 2022 and data was collected on demographics, whether appropriate advice had been given and whether they were managed appropriately during inpatient stays.
Results
Over two thirds (64.3%) of patients had no alert on their record to state they were at risk of AI. Only one patient had documentation of having received a steroid emergency card. Just 22.8% of patients were documented as having an emergency intramuscular hydrocortisone pen. Documented 'sick day rules′ advice was not given to almost two thirds of patients (67.9%). In contrast we noted 100% of patients who had the diagnosis of hypopituitarism and being followed up at endocrine clinics had been given sick day rules. Nearly one fifth of our study population comprised patients with a former diagnosis of hypopituitarism and Addison′s disease. Just less than a half of patients who had surgery or invasive procedure had been appropriately managed with pre-operative steroids. Finally, 17.5% of patients had been admitted to hospital in adrenal crisis at least once.
Conclusion
This audit report highlights the importance of raising awareness of AI among clinicians across different subspecialties and making relevant recommendations to prevent any undesired events.

Hypertension in Pheochromocytoma and paraganglioma : Characteristics, treatment and outcomes

Nada Derkaoui[1], Achwak ALLA[1], Rania El Amel[1], Rami Imane[1], Siham ROUF[1] & Hanane Latrech[1]
[1]Mohamed VI University Hospital Center Oujda - Faculty of Medicine and Pharmacy Oujda, Endocrinology Diabetology and Nutrition Department, Oujda, Morocco

Introduction
Pheochromocytomas and paraganglioma are neuroendocrine tumors that arise from the chromaffin cells of the adrenal medulla or originate from the autonomic nerve ganglia. Hypertension in patients with PPGL is the most frequent symptom and can be responsible of lethal cardiovascular complications. The aim of our work is to describe the clinical characteristics of hypertension in PPGL, the treatment and the outcomes after surgical treatment.
Materials and methods
Our study is retrospective descriptive, involving 34 patients (29 patients with pheochromocytoma and 5 patients with functional paraganglioma) followed in our Endocrinology-Diabetology and Nutrition Department of Mohammed VI University Hospital Center in Oujda, Morrocco.
Results
The mean age of our patients was 47 ± 17.9 years (15-81) with a sex ratio H/F of 0.4. History of hypertension was present in 58.8% of cases of which (55%) had uncontrolled treated hypertension, and (45%) had well controlled hypertension under antihypertensive medication. Hypertension was diagnosed at the same time as the tumor in 14.3% of cases. Half of our patients (47%) had permanent hypertension, 11.7% had paroxysmal hypertension and 11.7% experienced orthostatic hypertension. 24-h urinary metanephrine level was elevated in 76% of the cases, and 24 h urinary normetanephrine level was elevated in 84% of the cases. Imaging revealed unilateral abdominal PPGL in 73% of cases, bilateral pheochromocytoma in 11.7% of cases and cervical PGL in 6% of cases. The mean size of the tumor was 51.4 mm $\pm$ 29.4. Before surgery, all of our hypertensive patients received α1blockers preparation 15 days before surgery. Peroperatively, only 12% of patients presented hypertensive peaks without further complications. Good blood pressure control was achieved postoperatively and antihypertensive medication was reduced in all of our hypertensive patients with good clinical and biological outcomes.
Discussion–Conclusion
Although rare, PPGL can be dangerous due to the excess of catecholalmines and cardiovascular complications. Treatment of hypertension before, during and after the removal of the tumor is mandatory to avoid complications. The preoperative management of hypertension usually includes treatment with α1blockers at least 10 to 14 days before surgery, with the addition of beta blockers when necessary. Surgical removal of functional PPGL is the main treatment.
PPGL : Pheochromocytoma and paraganglioma

Multiple vertebral fractures following ibrutinib therapy in a patient with B-cell chronic lymphocytic leukemia

Jelena Andric[1], Marija Ivic[2], Özren Jaksic[2], Renata Huzjan Korunic[3], Darko Perovic[4] & Vlatka Pandzic Jaksic[1]
[1]Dubrava University Hospital, Department of Endocrinology, Zagreb, Croatia; [2]Dubrava University Hospital, Department of Hematology, Zagreb, Croatia; [3]Dubrava University Hospital, Department of Radiology, Croatia; [4]Dubrava University Hospital, Department od Orthopaedics and Traumatology, Croatia

Some hematologic malignancies might increase the risk of fractures due to intrinsic factors of the disease but also because of the treatment with steroids or chemotherapy. The direct impact of novel targeted agents on the development of osteoporosis in these patients has not been recognized yet. A 64-years old female patient with B-cell chronic lymphocytic leukemia (B-CLL) has been followed for four years with no other comorbidities. In order to measure the burden of the disease consecutive CT scans were performed. Two years ago, she underwent endocrinological evaluation because of incidental adrenal adenoma. Hypercortisolism and other endocrine disorders were excluded. She has never experienced a bone fracture before and no radiographic vertebral fractures were present. According to Fracture Risk Assessment Tool her 10 years probability of fractures with bone mineral density and adjusted for trabecular bone score was 5.2% for major osteoporotic fracture and 0.7% for hip fracture. Her B-CLL progressed with lymph nodes enlargement and first line therapy with ibrutinib – bruton tyrosine kinase (Btk) inhibitor was started. Three months later the patient presented with severe lumbar pain that occurred suddenly without clear precipitating factor. Radiologic examinations were performed and multiple osteoporotic lumbar vertebral fractures were found (Genant′s grade 2 in L2 vertebra and grade 1 in L1, L3 and L4 vertebrae). We repeated endocrinological investigation. Vitamin D was reduced (44 nmol/l) but no evident secondary causes of osteoporosis were revealed. Her bone mineral density was significantly deteriorated. We deferred vertebroplasty and the treatment with teriparatide and cholecalciferol was introduced. Increased risk of axial fractures was already observed in B-CLL patients and infiltration of bone marrow with leukemic cells has been recently shown to impair osteoblastogenesis and promote osteoclastogenesis. Ibrutinib up to now has not been labeled as a drug that could significantly impair bone health. Early experimental studies suggested that it could even inhibit osteoclast differentiation and function. However, recent observations recorded signals of potential increase of fractures with ibrutinib therapy. Although no cause and effect could be claimed, the occurrence of multiple osteoporotic vertebral fractures shortly after the ibrutinib therapy was introduced, suggests that this might play a role in bone damage and warrants further studies.

Diagnostic process in a lipodystrophic syndrome suspition, a clinical case

Pablo Ferreira[1], Paula Martínez de la Cruz[2], Ane Miren Azkutia Uribe Echevarría[1], Amir Shabaka Fernández[3], Pablo Lois Chicharro[1], Sandra Carolina Doejo Marciales[1], Solange Fabiola Barra Malig[1], Cristina Garmendia Fernández[2], Francica Almodóvar Ruiz[1] & Juan José Gorgojo Martínez[1]
[1]Hospital Universitario Fundación Alcorcón, Endocrinology, Metabolism and Nutrition, Alcorcón, Spain; [2]Hospital Universitario Fundación Alcorcón, Internal Medicine, Alcorcón, Spain; [3]Hospital Universitario Fundación Alcorcón, Nephrology, Alcorcón, Spain

The lipodystrophic syndromes are a heterogeneous group of congenital or acquired disorders characterized by either complete or partial lack of adipose tissue with the apparent accumulation of fat in other regions of the body. Their prevalence is low and ranges from 1:200000/500000 and they usually suffer metabolic abnormalities associated with the abnormal distributition of fat such as severe insulin resistance with acantosis and diabetes, progressive liver disease along with muscle hipertrophy, internal megaly, hirsutism, developmental delay or proteinuric renal dammage. The diagnosis of these síndromes is thus very complex and demmand multiple studies. We report a case of suspected lipodistrophy that we follow in our center in Alcorcon (Madrid) in the year 2022.
Case Report
36 year old woman, born in Colombia, with unique background of diabetes mellitus cataloged as type 2, diagnosed at age 18 with no familiar history and

treated with insulin along with severe acantosis nigricans and PCOS. Admitted under episode of hyperosmolar hyperglucemic síndrome secondary to poor acces to treatment, extended folliculitis and urinary infection due to K. pneumoniae. Good progress under emergent insulin and antibiotic treatment. We detect a particular phenotype consisting of prominent muscularity and low peripheric adipose tissue, severe acantosis nigricans plates, rough facial traits and hirsutism. There was therefore a suspition of a syndrome that could include all the manifestations depicted, specifically lipodystrophic síndrome. We deepened in the study of diabetes with a 12% HbA1c determination but normal C-Peptide, pancreatic autoinmunity and pancreatic imaging with abdominal tomography that on the other hand revealed several dermic thickening, low subcutaneous celular tissue, gastric and renal lypomas. Greater find of difuse adenopathies in all the abdominal cavity though normal proteinogram without monoclonal pike and normal urine inmunofixation. 24-h urianalsys demonstrated nefrotic proteinuria in context of diabetic nephropaty in a renal biopsy. Negative HIV study. Due to clinical stability the patient is discharged, with presumptive diagnosis of adquired generalized vs partial congenital lipodystrophy, only remaining the leptin determination.
Conclusion
The lipodystrophic syndromes though rare entities, must be suspected when several metabolic disorders combine with phenotipic features i.e lack of peripheral adipose tissue. The proper study of the etiology and the secondary alterations is crutial to assure the good treatmente and prognosis of these patients.

Correlation of adiponectin and resistin with atherogenic markers in insulin resistant and non-insulin resistant adolescent women with polycystic ovary syndrome

Aleksandra Atanasova Boshku & Daniela Ivanova Panova
University Clinic of Gynecology and Obstetrics, Faculty of Medicine, Ss. Cyril and Methodius University Skopje, Skopje, North Macedonia

Aim
To evaluate adiponectin and resistin levels and their relationship with various biochemical and metabolic and atherogenic parameters markers, as well as their correlation, and to investigate its contribution in pathogenesis of insulin resistance in cohort women with PCOS and of insulin resistance as well as in non-insulin resistant women with PCOS. Methods: This study was designed as a cross-sectional and involves 80 premenopausal women. Of these patients, 63 females have met the criteria for PCOS (59 insulin resistant, 28 non-insulin resistant). We assessed anthropometric indices of obesity –waist and hip circumference, waist to hip ratio, serum glucose, insulin, total cholesterol, HDL-cholesterol, triglycerides, FSH, LH, E2, testosterone, adiponectin and resistin. Body mass index, waist to hip ratio, HOMA-IR, LDL-cholesterol, and adiponectin to resistin ratio were calculated. Results: Insulin resistant PCOS woman had significantly lower levels of adiponectin compared to non-insulin resistant PCOS women, and controls. Resistin levels were higher in IR-PCOS, but without statistical significance. Adiponectin showed significant positive correlation with LH, HDL-C, and negative correlation with BMI, insulin, HOMA-IR and triglycerides. Resistin correlated positively with BMI and WC. A/R was significantly higher in insulin resistant PCOS women compared to non-insulin resistant and control women. Conclusions: These results suggest that PCOS women were at higher metabolic and atherogenic risk as compared to the healthy women, and also more pronounced in the insulin-resistant group. Correlations of adipokines with insulin resistance suggest their involvement of adipokines in modulation of insulin action in PCOS women.

Insulin-Like Growth Factor-I might be a predictor for severe nonalcoholic fatty liver disease in morbidly obese patients

Seda Turgut[1], Didem Acarer Bugün[1], Hakan Seyit[2], Naim Pamuk[1], Hamide Pişkinpaşa[1], Evin Bozkur[1], Mehmet Karabulut[2] & İlkay Çakır[1]
[1]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]University of Health Science Bakırköy Dr. Sadi Konuk Training and Research Hospital, General Surgery, Istanbul, Turkey

Aim
To compare the IGF-1, metabolic and clinical parameters among the ultrasonographically classified NAFLD groups, to examine the effect of weight loss on metabolic parameters and determine the factors that may predict the NAFLD severity in morbidly obese patients who underwent bariatric surgery.
Method
This descriptive cross-sectional study was conducted in 316 morbidly obese patients (250 females, 66 males). The data of patients before and 1st year after bariatric surgery were included in the study. According to the NAFLD assessment, patients were classified as normal (Group 1, $n=57$), mild and moderate (Group 2, $n=219$), or severe (Group 3, $n=40$). IGF-1 standard deviation score (SDS) levels were calculated according to age and gender. Preoperative and postop 1st-year clinical and metabolic parameters and factors that could predict the presence and severity of NAFLD were evaluated in all groups.
Results
IGF-1 levels were significantly associated with severe NAFLD compared with the normal group, and the significance remained between the same groups when IGF-1 levels were standardized as SDSIGF1. Moreover, liver diameter explained 50% of severe NAFLD than the normal group and %13 of severe NFLAD compared to mild-moderate NAFLD. FPG, ALT, AST, and GGT were also significant predictors for severe NAFLD compared to the normal and mild-moderate NAFLD groups.
Conclusion
Together with liver diameter, FPG, AST, ALT, and GGT, IGF-1 is among important predictors of NAFLD in bariatric surgery candidate morbidly obese patients. Further studies are needed to validate the clinical utility of IGF-1 in the presence and staging in NAFLD patients.

Coexistence of hypopituitarism caused by Sheehan′s syndrome and Hashimoto′s thyroiditis. A case report, review of literature.

Marjeta Kermaj[1], Irsa Zaimi[2], Mirjeta Guni[3], Adela Shkurti[4,5], Thanas Fureraj[1] & Agron Ylli[6]
[1]UHC "Mother Tereza", Endocrinology, Tirana, Albania; [2]Fier Regional Hospital, Endocrinology, Fier, Albania; [3]American3 Hospital, Endocrinology, Tirana, Albania; [4]Vila Maria, Endocrinology, Tirana, Albania; [4]Vila Maria, Endocrinology, Tirana, Albania; [1] UHC "Mother Tereza", Endocrinology, Tirana, Albania

Introduction
Hypopituitarism due to Sheehan′s syndrome is a rare complication and its diagnosis is often overlooked. The vast majority of people with hypothyroidism have primary hypothyroidism, often due to Hashimoto's thyroiditis. Coexistence of hypopituitarism and primary hypothyroidism, may accelerate clinical manifestations, mainly those associated with hypothyroidism. Hashimoto′s Thyroiditis with concomitant hypopituitarism is rare but has been described previously, but there are no reports of Hashimoto′s Thyroiditis occurring with Sheehan′s syndrome.
Case report
In this case study, we report a patient with Hashimoto′s Thyroiditis associated with Sheehan′s syndrome. Our case is a 38 –year-old female patient, presented with generalized fatigue, weakness, pain in the muscles of the lower extremities and other nonspecific complaints which were aggravated in recent months. She was consulted with various doctors but with the medication she received, there was no improvement until she presented in poor condition in emergency unit. She gave birth 7 years ago; after delivery she had a history of prolonged bleeding, amenorrhea and inability to lactate. Her physical examination revealed pale, dry, cold, rough skin, sluggish speech and thick voice, decreased body hair. Her laboratory evaluation showed, low levels of free thyroxin (FT4) and free triiodothyronine (FT3), high normal level of thyrotropin stimulating hormone (TSH). Thyroid antibodies were high level. She had hypogonadotropic hypogonadism, hypoprolactinemia, hypocortizolism with low level of adrenocorticotropic hormone and growth hormone deficiency, normochromic normocytic anemia, high level of LDL-cholesterol. Her magnetic resonance imaging was empty sella. Her thyroid ultrasonography revealed aspect of chronic thyroiditis. Our diagnosis was Hypopituitarism due to Sheehan′s syndrome co-existing with Hashimoto′s Thyroiditis. She was treated with hormone replacement and she was in a good condition 2 months later.
Conclusion
A high index of suspicion is crucial for the early diagnosis of the coexistence of hypopituitarism due to Sheehan′s syndrome and Hashimoto′s thyroiditis that is a rare condition in clinical practice, to prevent long-term morbidity.

A patient with acromegalic heart disease

Mehdi Houssein[1], Kubra Turan[1], Ahmet Temizhan[2], Belma Tural Balsak[1], Abbas Ali Tam[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara City Hospital, Department of Endocrine and Metabolic Diseases, Ankara, Turkey; [2]Ankara City Hospital, Department of Cardiology, Ankara, Turkey

A 36 years of old patient was admitted to the intensive care unit of cardiology when he experienced palpitations and orthopnea. The patient's complaints started about 2 years ago as syncope and sudden shortness of breath. Thorax CT showed pleural effusion and increased cardiothoracic index. Findings on ECHO were : Ejection fraction 35%, severe mitral regurgitation and global hypokinesia. Coronary angiogram showed a fibrocalcific plaque noted in in the distal LAD. The patient was started on Furossemide, spironolactone, isosorbide mononitrate. Despite the treatment, the patient's complaints gradually increased and over the course of the next 24 months, the patient was repeatedly hospitalised due to heart failure, and his medication was adjusted several times. Two years later, the patient was admitted to our center with the diagnosis of acute heart failure. A decrease in ejection fraction was detected in the new echocardiography (%10), and no further clinical improvement was seen, the decision was then taken to initiate treatment with levosimendan and noroadrenaline. Dilated cardiomyopathy was observed with cardiac MRI. He was consulted to the endocrine departement because of suspected acromegaly. When he was evaluated, he complained of shortness of breath, arthralgia and increasing shoe size. Physical examination was positive for acral growth, nose widening, and prognathism. GH and IGF-1 levels were increased at diagnosis (table 1), the baseline and peak GH concentrations were 8.74 and 34.4 ng/ml during 75-g OGTT, showing paradoxical increases in GH (table 2). Pituitary MRI showed a non-invasive, intrasellar, macroadenoma (fig1). The diagnosis made was: Acromegaly due to growth hormone secreting pituitary macroadenoma leading to dilated cardiomyopathy. His family history was negative, but due to his young age and aggressive clinical course, the patient was screened for AIP gene mutation; a germline AIP mutation was not identified. TSS was scheduled, and primary medical treatment with sandostatin lar 20 to improve the patient's condition. However, the patient developed cardiogenic shock and unfortunately before surgery and before assessment of response to therapy.

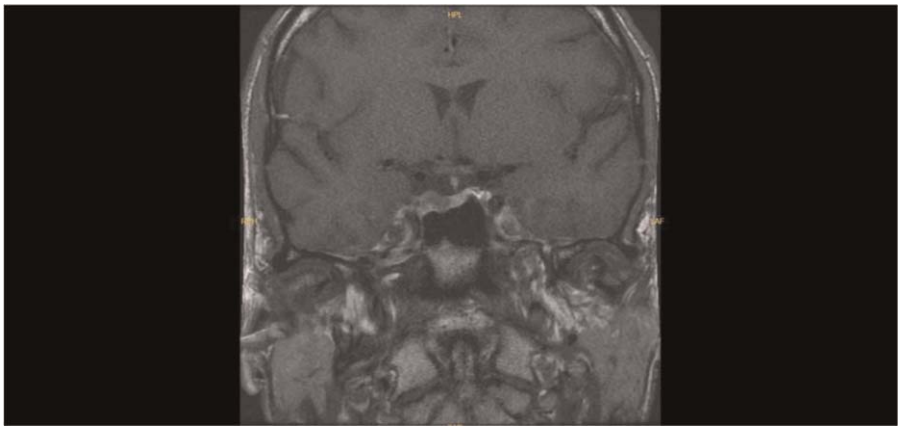
SRSF6 (Serine/arginine-Rich Splicing Factor 6) is a novel factor regulating androgen receptor signalling in prostate cancer cells

Antonio J. Montero-Hidalgo[1,2,3,4], Juan Manuel Jimenez-Vacas[1,2,3,4], Ana de la Salud De la Rosa-Herencia[1,2,3,4], Vicente Herrero-Aguayo[1,2,3,4], Enrique Gómez-Gómez[1,3,4,5], Antonio Carlos Fuentes-Fayos[1,2,3,4], Manuel David Gahete-Ortiz[1,2,3,4] & Raul Miguel Luque-Huertas[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [2]University of Cordoba, Department of Cell Biology, Physiology and Immunology, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Reina Sofia University Hospital (HURS), Urology service, Cordoba, Spain

Prostate cancer (PCa) represents the most diagnosed tumour pathology in developed countries among men population. The main pharmacological approach to treat this pathology is based on the blockade of the androgen receptor signalling pathway, commonly known as androgen-deprivation therapy. However, some of the patients does no longer respond to this therapy, therefore developing castration-resistant prostate cancer (CRPC), the most aggressive phenotype of this pathology, which remains lethal nowadays. Therefore, new molecular targets with potential to identify more effective therapeutic strategies are extremely needed. In this sense, alteration of RNA-splicing process has raised as a new hallmark of cancer. Herein, we studied the presence and pathophysiological role of SRSF6, a splicing factor that has been reported to have an oncogenic potential in other tumor-types (e.g., ovarian, lung and colon). To that aim, SRSF6 levels were interrogated by quantitative real-time PCR (mRNA levels) and immunohistochemistry (protein levels), in two well-characterized cohorts: 1) fresh PCa ($n=42$) and control ($n=9$) samples, and 2) formalin-fixed, paraffin-embedded PCa ($n=84$) and non-tumour adjacent tissue ($n=84$) samples. Additionally, functional and mechanistic assays were performed in different cell models [PCa cells (LNCaP, 22Rv1, DU145, and PC-3) and non-tumour prostate cells (PNT2)] in response to SRSF6 silencing (using a specific siRNA). Moreover, the effect of SRSF6 *in vivo* silencing was also tested using a xenograft mouse model. Finally, we also analysed *in vitro* the putative relationship between the expression levels of SRSF6 with the androgen signalling and the resistance to androgen-deprivation therapy. Our results revealed that SRSF6 is upregulated (at mRNA and protein levels) in PCa samples and its levels are directly associated to key clinical and molecular parameters of PCa aggressiveness [e.g., Gleason grade, androgen-receptor (AR) signalling pathway]. Furthermore, the silencing of SRSF6 significantly decreased critical functional aggressiveness parameters in PCa cells (i.e. proliferation and migration rates and tumorsphere formation). Mechanistically, SRSF6 silencing altered the splicing process of AR, by reducing specifically the oncogenic splicing variant AR-V7. Consistently, a preclinical approach showed that the treatment with SRSF6 siRNA reduced the size of 22Rv1-derived tumours, impacting key molecular pathways (e.g., AR signalling). Taken together, our results suggest that SRSF6 impact AR signalling by



dysregulating AR-V7 splicing and that its targeting could represent a novel and promising therapeutic strategy for the treatment of advanced PCa.

Thionamides-induced agranulocytosis in a patient with previous hematological disease: a case report

Tamila Sohn Fagundes[1], Laura Vilas Boas[2], Thielsen Cardoso da Silva[2], Laura Maranho Ribas[1], Renata Cassitas Mendonça[1], Letícia Peon Train Nicoluzzi[2], Maria Roberta Bianchini Fernandes[2] & Mirnaluci Paulino Ribeiro Gama[1]
[1]Hospital Universitário Evangélico Mackenzie, Brazil; [2]Evangelical Mackenzie Faculty of Parana, Brazil

Introduction
The treatment of thyroid diseases with thionamides can cause agranulocytosis a potentially fatal side effect. The manifestations resulting from such a condition include, in most cases, infections that, if not treated immediately, have a high risk of septicemia. Therefore, the clinical presentation includes fever of unknown origin and infections such as pneumonia, tonsillitis, and abscesses. Most patients who do not receive immediate medical intervention progress to septicemia, a fact that shows the relevance of early diagnosis and adequate management
Case report
A 38-year-old female patient had Chronic Myeloid Leukemia without follow-up and treatment. She developed severe neutropenia induced by thionamide used to control hyperthyroidism. Laboratory tests performed on admission at the Hospital showed Hb 8.6 g/dl, pancytopenia with worsening leucopenia: leukocytes 720/mm3, absolute segmented count 9 mm3, 0/mm3 (zero) basophils, 0 /mm3 (zero) blasts, and 670/mm3 lymphocytes, TSH 0.029 mU/l (normal 0.4-4.5 mU/l) and free T4 4.93 ng/dl (normal 0.7-1.8 ng/dl). Autoantibodies against TSH receptor (TRAb) were negative The absence of evidence of transformation into accelerated and blastic phases of Chronic Myeloid Leukemia, positive clinical response, resolution of neutropenia 8 days after the suspension of thionamides, and the presence of a 5/1 Myeloid: Erythroid ratio in bone marrow biopsy, suggested the previous destruction of neutrophils, with recovery after drug discontinuation.
Conclusion
The state of severe neutropenia is attributable to drugs in 70 to 90% of cases. The absence of evidence of transformation for the accelerated and blast phases of Chronic Myeloid Leukemia, positive clinical response associated with resolution of neutropenia after thionamide withdrawal and the presence of a 5/1 Myeloid: Erythroid ratio in bone marrow biopsy, suggesting the previous destruction of neutrophils, with recovery after discontinuation of the drug evidence the differential diagnosis of thionamide-induced agranulocytosis overlying the underlying diagnosis of hematological disease. The manifestations resulting from such a condition include, in most cases, infections that have a high risk of progressing to septicemia. After resolution of the condition, which occurs between 3-14 days after the drug is discontinued, definitive treatment for hyperthyroidism should be considered, usually with radioactive iodine or surgery.

Thyroglobulin antibodies in women with recurrent pregnancy loss: a systematic review and meta-analysis

Perrine Huisman[1], Jesper Krogh[1], Claus Henrik Nielsen[2], Henriette Svarre Nielsen[3], Ulla Feldt-Rasmussen[1] & Sofie Bliddal[1]
[1]Copenhagen University Hospital, Medical Endocrinology and Metabolism, København, Denmark; [2]Rigshospitalet, Institute for Inflammation Research, Center for Rheumatology and Spine Diseases, København, Denmark; [3]Copenhagen University Hospital (Rigshospitalet), Recurrent Pregnancy Loss Unit, Fertility Clinic 4071, København, Denmark

Background
Thyroid autoimmunity is the most prevalent autoimmune disorder among women of reproductive age and has been linked to pregnancy loss. In recurrent pregnancy loss (RPL), couples suffer several consecutive losses resulting in physical as well as psychological strains. Thyroid autoimmunity has been suggested as a risk factor in RPL, but most studies have focused on thyroid peroxidase antibodies (TPOAbs), not taking into account the presence of thyroglobulin antibodies (TgAbs). The aim of this study was to systematically assess the prevalence of TgAbs in women suffering from RPL, and whether TgAb-presence was associated with a lower live birth rate in the next pregnancy.
Methods
A systematic literature search for studies reporting on TgAbs in women with recurrent pregnancy loss was performed. The primary outcome was TgAb-positivity in RPL women compared to healthy controls, with a secondary outcome of association between TgAb-positivity and live birth in the next pregnancy. Pooled effect estimates were expressed as odd ratios (OR) with 95% confidence intervals (95% CI) using a random-effects approach. Heterogeneity was reported as I^2 statistic. The study was registered with PROSPERO and adhered to PRISMA guidelines.
Results
A total of 518 studies were screened, sixteen of which included a total of 3869 women. The prevalence of TgAb-positivity in women with RPL ranged from 3.6 to 27% compared to 2.3 to 29% in healthy controls. The OR for women with RPL being TgAb-positive was 2.21 (95% CI: 1.54-3.12; $I^2 = 36\%$) compared to healthy controls, while the OR for women with RPL being positive for TgAbs and/or TPOAbs was 2.23 (95% CI: 1.45 to 3.44; $I^2 = 61\%$). Two studies reported on the outcome of the next pregnancy after referral in TgAb-positive women compared to TgAb-negative women and yielded highly heterogenous results. One study reported an almost equal risk of pregnancy loss (OR 0.96), while the other reported an OR of 10.0 for pregnancy loss in women being TgAb-positive. Consequently, a meta-analysis could not be performed.
Conclusion
Women suffering from RPL were significantly more often TgAb-positive than healthy controls - independent of TPOAb-positivity. No conclusion could be drawn on the association of TgAbs and subsequent live birth rate in women with RPL because of high heterogeneity and an overall lack of prospective studies on the topic. Such studies are necessary in order to firmly determine the role of thyroid autoimmunity in RPL.

Regulatory B cells involvement in autoimmune phenomena occurring in pediatric graves' disease patients.

Artur Bossowski[1], Kamil Grubczak[2], Aleksandra Starosz[2], Karolina Stożek[3], Filip Bossowski[4] & Marcin Moniuszko[5]
[1]Medical University in Bialystok., Department.of Pediatric Endocrinology and Diabetes, with a Cardiology Unit, Bialystok, Poland; [2]Medical University in Bialystok, Department of Regenerative Medicine and Immune Regulation, Bialystok, Poland; [3]Medical University in Bialystok, Dep. Of Pediatric Endocrinology and Diabetes, with a Cardiology Unit, Bialystok, Poland; [4]Medical University in Bialystok, Dep of Pediatric, Endocrinology and Diabete, with a Cardiology Unit, Bialystok, Poland; [2]Medical University in Bialystok, Department of Regenerative Medicine and Immune Regulation, Bialystok, Poland

Graves's disease is the most common type of autoimmune hyperthyroidism. Numerous studies indicate different factors contributing to the onset of the disease. Despite years of research, the exact pathomechanism of Graves' disease still remains unresolved, especially in the context of immune response. B cells can play a dual role in autoimmune reactions, on the one hand, as a source of autoantibody mainly targeted in the thyroid hormone receptor (TSHR) and, on the other, by suppressing the activity of proinflammatory cells (as regulatory B cells). To date, data on the contribution of Bregs in Graves' pathomechanism, especially in children, are scarce. Here, we investigated the frequencies of Bregs before and during a methimazole therapy approach. We reported higher Foxp3+ and IL-10+ Breg levels with CD38- phenotype and reduced numbers of CD38 + Foxp3 + IL-10+ in pediatric Graves' patients. In addition, selected Breg subsets were found to correlate with TSH and TRAb levels significantly. Noteworthy, certain subpopulations of Bregs were demonstrated as prognostic factors for methimazole therapy outcome. Our data demonstrate the crucial role of Bregs and their potential use as a biomarker in Graves' disease management.

Fatty acid binding protein 4 mediates atherosclerosis by disrupting gut microbiota and immunity

Lingling Shu[1,2], Xiaoping Wu[1,3], Leigang Jin[1,2], Laiyee Cheong[1,2], Boya Liao[1,3], Zixuan Zhang[1,3], Ruby L C Hoo[1,3] & Aimin Xu[1,2,3]
[1]The University of Hong Kong, HKU State Key Laboratory of Pharmaceutical Biotechnology, Hong Kong; [2]The University of Hong Kong, Department of Medicine, Hong Kong; [3]The University of Hong Kong, Department of Pharmacology & Pharmacy, Hong Kong.

Introduction
Atherosclerosis is a chronic inflammatory arterial disease and is currently one of the most common causes of cardiovascular morbidity and mortality worldwide. Therefore, there is an urgent need to discover new therapeutic targets for treatment of this fatal chronic disease. Fatty acid binding protein 4 (FABP4), a pro-inflammatory adipokine that links obesity with its related metabolic diseases, has been implicated in the development of atherosclerosis. This study aims to investigate whether FABP4 potentiates atherosclerosis by mediating the crosstalk between gut microbiota and immunity and to explore whether targeting FABP4 is therapeutically effective for treatment of this disease.
Method
$FABP4^{+/+}ApoE^{-/-}$ and $FABP4^{-/-}ApoE^{-/-}$ mice were generated for the study and fed with high fat and high cholesterol diet (HFHC) for 12 weeks. Biochemical, immunological, flow cytometry and denaturing gradient gel electrophoresis (DGGE) analysis were conducted to determine the pathophysiological roles of FABP4 in potentiating diet-induced atherosclerosis by altering gut microbiota and immunity. Fecal microbiota transplantation (FMT) were performed to further investigate the role of FABP4 in atherosclerosis mediated through microbiota. The FABP4 chemical inhibitor BMS309403 was used to evaluate the effects of FABP4 inhibition in alleviating atherosclerosis.
Result
The aortic trees stained with Oil Red exhibited significantly reduced atherosclerosis in $FABP4^{-/-}ApoE^{-/-}$ mice comparing to $FABP4^{+/+}ApoE^{-/-}$ littermates. Likewise, FMT of $FABP4^{-/-}$ feces to $FABP4^{+/+}$ mice significantly attenuated the development of atherosclerosis. DGGE analysis of fecal DNA showed that the pattern of bacterial phyla was obviously changed in $FABP4^{-/-}$ mice comparing to $FABP4^{+/+}$ littermates. These changes in $FABP4^{-/-}$ mice were accompanied by significantly increased expression of zona occuldens protein-1 (ZO-1) and occludin in intestinal villa, suggesting that FABP4 may enhance the intestinal permeability in mice in response to HFHC diet. Furthermore, FABP4 promoted macrophage infiltration and the polarization of macrophage from M0 to pro-inflammatory M1 subtype in the intestine of mice. Treatment with the FABP4 inhibitor BMS309403 dramatically alleviated the inflammatory response in the gut and atherosclerotic plaque formation, and elevated the intestinal expression of ZO1 and occludin in $FABP4^{+/+}$ mice.
Conclusion
FABP4, which is elevated during obesity, alters the composition of gut microbiota and intestinal permeability by creating a pro-inflammatory microenvironment, leading to endotoxinemia and subsequently contributing to the development of atherosclerosis. Targeting FABP4 with small-molecule inhibitors such as BMS303409 is a promising therapeutic strategy for treatment and prevention of atherosclerosis by modulating gut microbiota and intestinal immunity.

Limb-girdle muscular dystrophy type 2J: case report

Fatima Zahra Outtaleb[1], Amal Tazzite[2], Bouchaib Gazzaz[2,3] & Hind Dehbi[1,2]
[1]Ibn Rochd University Hospital, Laboratory of Medical Genetics, Casablanca, Morocco; [2]Faculty of Medicine and Pharmacy. Hassan II University, Cellular and Molecular Pathology Laboratory, Casablanca, Morocco; [3]Royal Gendarmerie, Genetics Analysis Institute, Rabat, Morocco.

Limb-girdle muscular dystrophies are a heterogeneous group of disorders regarding both their phenotypes and their underlying genetic causes. One of these defects is limb-girdle muscular dystrophy type 2J (LGMD2J), which has an unknown prevalence. Our aim is to describe clinical features an evolution of a novel case of this rare condition. Our patient is female, aged 29 from a non-consanguine family bearing features of limb-girdle muscular dystrophy. The first signs of this affection appeared around age 13 and gradually worsened, leading this patient to be unable to walk 10 years after onset. Her brother actually displayed a similar symptomatology and her father presented with lower limb muscular weakness that begun at age 30. Genetic analysis revealed the presence of a compound heterozygous *TTN* mutation c.4261C>T and c.65672C>T winch confirms diagnoses of LGMD2J. Family members will be tested for these two mutations in order to confirm the father's diagnosis of tibial muscular dystrophy and to provide appropriate genetic counselling to this family. Disorders caused by pathogenic *TTN* variants are a large and heterogeneous group of muscular dystrophies. Among these are both LGMD2J and tibial muscular dystrophy. Furthermore, *TTN* gene, that codes for protein titin, is one of the main genes involves in dilated cardiomyopathies, which have a prevalence of 17%. Considering that physiopathology of these disorders remains unknown, it seems therefore very important to report such disorders so as to improve their diagnosis and to obtain a better genotype phenotype correlation regarding *TTN* variants.

Impact of adrenocortical carcinoma and associated adrenal insufficiency on patient wellbeing – a systematic review

Phillip Yeoh[1], Wladyslawa Czuber-Dochan[2], Simon Aylwin[3] & Jackie Sturt[1]
[1]KING'S COLLEGE LONDON, Florence Nightingale Faculty of Nursing, Midwifery & Palliative Care, London, United Kingdom; [2]King's College London Waterloo Campus, United Kingdom; [3]KING'S COLLEGE HOSPITAL, Endocrinology & Diabetes Dept, United Kingdom.

Context
Adrenocortical carcinoma is a rare cancer with an annual incidence of 0.7-2 cases per million population and 5-year survival of 31.2%. Adrenal insufficiency is a common and life shortening complication of ACC and little is understood about how it impacts on patients.
Objective
To understand patients' experience of the condition, its treatment, care process, impact of AI on ACC wellbeing, self-care needs and support.
Design
Systematic review of MEDLINE, EMBASES, CINAHL, PsycINFO and Open Grey for studies published until February 2021. All research designs were included. The findings underwent a thematic analysis and narrative synthesis. Studies quality was assessed using mixed method assessment tools.
Results
A total of 2837 citations were identified; 15 titles with cohort, cross sectional, case series and case report study designs met the inclusion criteria involving 479 participants with adrenal insufficiency secondary to adrenocortical carcinoma. Quantitative research identified impacts of disease and treatment on survivorship, the burden of living with AI/ACC, toxicity of therapies, supporting self-care and AI management. These impact factors included adjuvant therapies involved and their toxicities, caregivers/family supports, healthcare and structure support in place, specialist skill and knowledge provided by healthcare professional on ACC management. No qualitative patient experiences evidence was identified.
Conclusion
ACC appears to have high impact on patients' wellbeing including the challenges with self-care and managing AI. Evidence is needed to understand patient experience from a qualitative perspective.

Clinical-laboratory and morphological predictors of pheochromocytoma progression

Anna Motrenko[1], Timur Britvin[2], Irena Ilovayskaya[1] & Larisa Gurevch[3]
[1]Moscow Regional Research and Clinical Institute (MONIKI), Neuroendocrine Unit, Department of Endocrinology, Moscow, Russian Federation; [2]Moscow Regional Research and Clinical Institute (MONIKI), Department of Endocrine Surgery; [3]Moscow Regional Research and Clinical Institute (MONIKI), Department of Pathology, Russian Federation.

According to the 4th edition of the WHO classification of endocrine organ tumors (2017), all pheochromocytomas are classified as malignant tumors (ICD-O code 8700/3). However, in the literature there are no unambiguous data on the significance of clinical and laboratory predictors of the aggressiveness of pheochromocytoma. The aim of the study was to verify possible predictors of pheo-progression using clinical data, the results of laboratory and instrumental

examination (including PASS and GAPP scales) of patients with a verified diagnosis of pheochromocytoma.
Material and methods
According to the data of this pilot retrospective study, data were analyzed from 27 patients with pheochromocytoma (16 women, 11 men) aged 22–73 years (median 51 years), who were operated on for the period from 2016 to 2021. 24-hour urine analysis for free metanephrines was determined by high performance liquid chromatography with tandem mass spectrometry with the addition of a preservative. The location and size of the pheochromocytoma was assessed by CT data with the determination of the native HU density. An immunohistochemical study was performed with antibodies to chromogranin A, synaptophysin, Ki-67, followed by an assessment of the potential for malignancy using the PASS and GAPP scales.
Results
There was a strong positive correlation between the PASS and GAPP scales ($r=0.720$), which is statistically significant ($P<0.01$). Both scales have a statistically significant positive correlation of mean strength with tumor size (PASS: $r=0.382$ / $P=0.049$; GAPP: $r=0.403$ / $P=0.037$). Correlation of these scales with the gender and age of patients, as well as the secretory activity of the tumor, was not revealed. A direct correlation was established between the PASS and GAPP scales and the size of the tumor.
Conclusion
According to our data, tumor size should be considered as a clinical predictor of metastatic potential of pheo, however gender, age, and functional activity of the tumor were not useful.
Keywords: pheochromocytoma; immunohistochemistry; PASS; GAPP.

Adrenal incidentalomas in geriatric patients: Prevalence, radiological features, and hormonal profile

Faten Haj Kacem Akid[1], Abdelmouhaymen Missaoui[1], Mariem Belhoul[2], Wafa Belabed[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1,1], Mouna Elleuch[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Departement of Family Medicine, Sfax, Tunisia.

Background and Aims
The incidence of adrenal incidentaloma(AI) has been rising sharply due to the increased use of radiologic imaging. It shows evident variation with age, with the majority of the cases presenting in the 5th to 7th decade of life. This study aims to assess the prevalence of AI and its radiological features and hormonal profiles in the geriatric population.
Patients and Method
We conducted a retrospective descriptive study including 177 patients diagnosed with AI, referred to the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia during 2011–2020. All patients have undergone clinical examination, adrenal CT, and biochemical workup for hormonal secretion.
Results
Among the 177 patients diagnosed with AI, 38.9% were 65 years and older. We focused our investigation on the geriatric population sample($n=69$). The mean age at diagnosis was 71.4 ± 4.2 years, with a female predominance(57.5%). At the time of diagnosis, older adults reported various unspecific "aging-related symptoms" such as asthenia(50%), weight loss(40%), and paresthesia(37.5%). Hypertension(67.5%), diabetes(42.5%), and dyslipidemia(30%) were the leading comorbidities in geriatric patients bearing AI. Ninety-five percent of AI were detected on CT scans performed mainly for nephritic colitis(42.5%) or abdominal pain(17.5%). Complementary centered adrenal CT featured adrenal adenomas in 90%, less frequently bilateral adrenal hyperplasia (7.5%), and macronodular adrenal hyperplasia(2.5%). AI was unilateral in 61%, mainly left-sided(54.5%), and bilateral in 39%. The mean size of AI was 24.1 ± 12.8 mm. 10% of aged patients were harboring AI larger than 40 mm. Non-contrast CT density was $<$ 10UH in 82.5%. As for the remaining patients(17.5%), enhanced CT showed an absolute washout $>$ 60% in 42.9% of cases. Based on the hormonal workup, 70% of elderly patients had non-secreting lesions. The functioning incidentalomas displayed autonomous cortisol secretion(32.5%), primary hyperaldosteronism(25%), or secondary hyperaldosteronism(21.8%). Only one senior had a secreting pheochromocytoma. AI with mixed hormonal secretion was recorded in 12.5%.
Conclusion
AI often affects the geriatric population, with an incidence reaching 10% after 70 years compared to 1–4% in younger adults. The vast majority of the AIs are non-functioning adenomas. Less common, some hormonal secretions, especially autonomous cortisol secretion and primary hyperaldosteronism, may be individualized in elderly patients bearing AI, although the hormonal excess often remains subclinical. Due to frailty and comorbidities frequently associated with advanced age, surgical management should be discussed on a case by case basis and proposed for seniors harboring lesions suspected of malignancy or overt hormonal secreting tumors: pheochromocytoma, cortisol secreting adenoma, etc

Application of machine learning techniques in a qualification for a surgical treatment of adrenal tumors

Marta Wielogórska[1], Marcin Adamski[2], Vitalii Ulychnyi[1], Beata Podgórska[1], Katarzyna Siewko[1], Anna Popławska-Kita[1], Małgorzata Szelachowska[1], Adam Krętowski[1,3] & Agnieszka Adamska[1]
[1]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Białystok, Poland; [2]Bialystok University of Technology, Faculty of Computer Science, Poland; [3]Medical University of Bialystok, Clinical Research Centre, Poland.

Background
The gradual increase in the detection rate of adrenal incidentalomas makes them a common clinical problem. The vast majority of them are benign adrenocortical adenomas. Nevertheless every patient with adrenal incidentaloma requires performing number of tests to exclude pheochromocytoma, autonomous cortisol secretion, adrenal carcinoma and primary hyperaldosteronism. Evaluation of whether adrenal incidentalomas are malignant or functional and continuing patient follow-up to assess the necessity for surgery assumed important place in endocrinology practice.
Objective
The aim of the study was to compare several machine learning techniques in a qualification for a surgical treatment of adrenal tumors and choose the most accurate algorithm as a valuable adjunct tool for decision-making.
Methods
A retrospective, single-center study was performed on hospitalized patients with adrenal incidentaloma between 2017 and 2019. From a database comprising 264 patients with adrenal incidentaloma, clinical data for 30 patients who underwent adrenalectomy due to suspicion of primary aldosteronism, pheochromocytoma, Cushing's syndrome, or adrenal cancer were extracted. All included patients underwent the endocrine work-up aimed to study the hormonal status of adrenal incidentalomas and every adrenal lesion was assessed with CT scan. On the basis of postoperative histopathological examinations, proper qualifications were confirmed in 20 out of 30 selected patients. Several machine learning algorithms, including Support Vector Machine, Multilayer Neural Network, C4.5 Decision Tree, Random Forest, k-Nearest Neighbours, Naïve Bayes, Zero R, One Rule, Logistic Regression, were trained to qualify the patients for an adrenalectomy. Finally, attribute selection technique was used to assess their usefulness in classification.
Results
The highest average accuracy was obtained for Support Vector Machine with linear kernel and soft margin – 90% of properly classified subjects. The Neural Network gave the second best result and was able to classify with an accuracy of 86%. Statistical evaluation using Pair-T Student modified for dependent samples was significantly better in comparison to baseline approach Zero-R ($P<0.05$). The most commonly selected by classifiers attributes were tumor homogeneity (100%), maximum diameter of the tumor (100%) and obesity (98%). Nevertheless prior attribute selection did not improve accuracy of trained algorithms.
Conclusions
Presented results show that application of machine learning methods in qualifying patients for an adrenalectomy may improve the decision process. The new training machine learning-based methods might be used to simplify making therapeutic decisions in adrenal incidentaloma patients and reduce the time from the initial identification of adrenal incidentaloma to the final decision about surgery.

Background and objective
Children with chronic kidney disease (CKD) have impaired growth that leads to short stature in adulthood and treatment with recombinant human growth hormone (rhGH) is associated with improved growth. This study aimed to evaluate the efficacy and safety of daily rhGH (Jintropin®) in children in China with growth failure caused by CKD prior to transplantation.
Methods
Prepubertal patients (2–13 years old) with CKD-related short stature were enrolled in this multicenter, randomized, open-label, negative-controlled study (NCT03535415). Eligible patients were randomized 1:1 to receive daily rhGH 0.05 mg/kg/day administered subcutaneously or control (no rhGH given, only relevant examinations were performed) for up to 52 weeks. The primary endpoint was improvement in (Δ) height standard deviation score (HT SDS). Secondary endpoints included improvements in height velocity (HV), bone maturation (bone age [BA]/chronological age [CA]), insulin-like growth factor 1 standard deviation score (IGF-1 SDS), IGF-1/IGF binding protein-3 (IGFBP-3) molar ratio, and safety.
Results
A total of 68 patients were randomized to either treatment or control; 11 patients (treatment: 7; control: 4) dropped out, 8 (treatment: 5; control: 3) of whom due to transplantation. At week 52, ΔHT SDS from baseline was 0.747 ± 0.579 ($P < 0.001$) and 0.173 ± 0.470 ($P = 0.039$) in the treatment and control groups, respectively (intergroup $P < 0.001$). Least-squares mean difference between both groups was 0.582 (95% confidence interval 0.323–0.842). Statistically significant improvements were also observed in those who received treatment compared with those in the control group for ΔHV (7.021 ± 3.795 cm/year vs 2.566 ± 3.577 cm/year; intergroup $P < 0.001$), ΔIGF-1 SDS (1.697 ± 2.098 vs -0.171 ± 1.506; intergroup $P < 0.001$), ΔIGF-1/IGFBP-3 molar ratio (0.046 ± 0.073 vs 0.001 ± 0.041; intergroup $P < 0.001$), and Δheight (9.87 ± 2.89 cm vs 6.43 ± 2.72 cm; intergroup $P < 0.001$). Δ(BA/CA) was 0.041 ± 0.074 and 0.008 ± 0.079 in the treatment and control groups, respectively (intergroup $P = 0.118$). Most treatment-emergent adverse events (TEAEs) were mild to moderate; 19 patients (treatment: 10; control: 9) experienced serious adverse events, and 5 in the treatment group temporarily discontinued rhGH due to TEAEs. 7 reported drug-related TEAEs, which included elevated blood insulin, scoliosis, glycosuria, musculoskeletal discomfort, hyperinsulinemia, and abnormal liver function.
Conclusion
Daily rhGH 0.05 mg/kg per day for 52 weeks was effective and well tolerated in children with short stature caused by CKD. At the end of the study, significant improvements in ΔHT SDS, ΔHV, ΔIGF-1 SDS, ΔIGF-1/IGFBP-3 molar ratio, and Δheight were observed with treatment.

The spectrum of CYP21A2 copy number variations and gene mutations by MLPA in a pediatric Romanian population with 21-hydroxylase deficiency

Sorina Schipor[1], Ioana Nedelcu[1], Camelia Procopiuc[1], Elena Braha[1], Madalina Boboc[1], Andreea Brehar[1], Andrei Muresan[1], Alina Dumitrica[1], Oana-Monica Popa[1], Andra Caragheorgheopol[1], Dana Manda[1], Susana Vladoiu[1] & Iuliana Gherlan[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Research Department, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Objective
The analysis of the copy number variation of *CYP21A2* gene in a cohort of 21-hydroxylase deficiency (21-OHD) pediatric patients in a tertiary referral center from Romania.
Methods
A total of 24 patients (21 female and 3 male, 7:1 female to male sex ratio) with previously biochemically and clinically diagnosed 21-OHD were enrolled in this study from October 2020 to October 2021. The age at the diagnosis was 4.6 ± 4.8 years (mean ± S.D.). All clinical and biochemical data were collected. Genomic DNA was extracted from peripheral blood leukocytes, and copy number variations along with several point mutations of *CYP21A2* gene were detected by multiple ligation-dependent probe amplification (MLPA) using MRC-Holland SALSA MLPA P050-C1 kit and Coffalyser.net software. The study has been approved by Ethical Committee of the Institute.
Results
Clinical and biochemical phenotype revealed 13 patients (54.17%) with classic and 11 patients (45.83%) with non-classic form of 21-OHD. Salt-wasting phenotype was diagnosed in 8 patients in whom MLPA analysis results were: large deletion/rearrangement in *CYP21A2* (2 patients with homozygous *CYP21A2* deletion and 2 patients with fused *CYP21A1P/CYP21A2* gene (chimeras)); 2 patients with heterozygous g.655A/C > G (I2G) mutation, 1 patient compound heterozygous for P31L/I172N and one patient heterozygous for I172N mutation. In 5 patients with classic simple virilizing 21-OHD MLPA analysis showed: *CYP21A1P* deletion (2 patients), *CYP21A1P* duplication (1 patient), I2G/I172N (2 patients). The MLPA analysis in the remaining 11 patients with non-classic form of 21-OHD indicated: heterozygous gene deletion and I172N mutation (2 patients), partial *CYP21A1P* deletion (1 patient), *CYP21A2* duplication (1 patient), *CYP21A1P* duplication (1 patient), homozygous mutation I172N and a heterozygous P31L mutation (1 patient), with a normal profile in 5 patients.
Conclusions
Copy number variation analysis is a very useful tool in 21-OHD molecular diagnosis, especially in classic salt-wasting patients but a complete precise diagnosis should be complemented by *CYP21A2* sequencing analysis.

Pheochromocytoma during pregnancy: diagnosis and treatment challenges

Imen Halloul, Ach Taieb, Ben Abdelkerim Asma, Saad Ghada, El Fekih Hamza, Hasni Yosra, Maaroufi Amel, Kacem Maha, Chaieb Molka & Ach Koussay
Farhat Hached University Hospital, Department of Endocrinology and Diabetes, Sousse, Tunisia.

Introduction
Pheochromocytoma in pregnancy is rare with an incidence of 0.007%. A timely diagnosis is essential since fetal and maternal mortality depends on the early treatment. Our object is to report a pheochromocytoma diagnosed in a patient at the beginning of the pregnancy and to highlight the particularity in the therapeutic care.
Case presentation
A 32-year-old female patient was admitted to our endocrinology department for exploration of palpitation associated with headache and sweats. She had a family history of diabetes and hypertension and no history of pituitary adenoma or hyperparathyroidism. The symptoms were concomitant to food intake, and evolving for 02 years. The patient decreased her diet to avoid the symptoms, therefore, losing 09 kg. Clinically, her systolic blood pressure was ranging between 140 and 170, and diastolic between 80–90 mmHg. Pheochromocytoma was suspected and confirmed with increased plasma normetanephrine and metanephrine levels (10* the normal range). Abdominal CT scan showed a heterogenous mass of the left adrenal gland (5*4 cm) with spontaneous density of 40UH. Shortly after, the patient discovered she was 9 weeks pregnant. We started

treatment with doxazosin, and blood pressure values were normalized. At 18 weeks of menstrual age, laparoscopic adrenalectomy of the left adrenal gland was performed without any complications during or after surgery. The tumor was confirmed to be a 7-cm pheochromocytoma in histological exam. After surgery, blood pressure was normal without treatment and post-operative measurements of serum normetanephrines and metanephrines were normal. At 30 weeks of menstrual age, the fetus was healthy.

Conclusion

Maternal and fetal mortality du to pheochromocytoma decreases to less than 15% if the diagnosis was made antepartum. Symptoms in pregnant patients do not differ from symptoms in non-pregnant patients. However, they may worsen with advancing pregnancy due to an increased pressure on the tumor by the abdominal distension, fetal movements and uterine contractions. When the diagnosis is made within the first 24 weeks of pregnancy and adequate α-blockade can be established, tumor removal is recommended in the second trimester via laparoscopic surgery. Decisions for those patients should be made by an experienced multidisciplinary team.

A case of ChAdOx1 vaccine-induced thrombocytopaenia and thrombosis syndrome leading to bilateral adrenal haemorrhage and adrenal insufficiency

Agathoklis Efthymiadis[1], Dalia Khan[2], Sue Pavord[2] & Aparna Pal[1]
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.

Introduction

Vaccine-induced thrombosis and thrombocytopenia (VITT) after vaccination against SARS-CoV-2 with the adenoviral vector-based vaccines ChAdOx1 and Ad26.COV2.S has been associated with adrenal pathology, such as bilateral adrenal vein thrombosis, adrenal cortex haemorrhage and adrenal insufficiency in six percent of patients[1].

Case report

We report the case of a 23-year-old healthy woman who presented at eight days after ChAdOx1 vaccination with a low platelet count of 43×10^9/l, raised D Dimers $>100\,000$ ng/ml and multiple lobar and segmental pulmonary emboli. Anti-platelet factor 4 antibodies were detected confirming definite VITT in accordance with the UK diagnostic criteria. At sixteen days post-vaccine, further imaging showed bilateral adrenal haemorrhage, non-occlusive splenic vein thrombosis and right ventricular thrombosis. Her cortisol level was <25 nmol/l. She was treated with anticoagulation, plasmapheresis, immunosuppression and steroid replacement. She had high anti-spike titre and positive anti-nucleocapsid titres for SARS-CoV-2. She developed seizures secondary to posterior reversible encephalopathy, requiring intensive care. After 4 weeks in hospital, she was discharged on warfarin, hydrocortisone and fludrocortisone replacement. Short synacthen tests three and nine months later showed no recovery of adrenal function, although magnetic-resonance-imaging of the adrenal glands showed resolving adrenal haemorrhage.

Discussion and conclusions

Adrenal insufficiency secondary to bilateral adrenal vein thrombosis and adrenal cortex haemorrhage should be suspected in patients with vaccine-induced thrombosis and thrombocytopenia (VITT) and treated promptly. Adrenal haemorrhage can occur as the initial presentation of VITT or days to weeks after the development of thrombosis in other sites. Completion of vaccination schedule against SARS-CoV-2 post VITT using an mRNA-based vaccine should be recommended to patients post-VITT, as mRNA-based vaccines have not been associated with VITT. There is paucity of data regarding the potential for recovery of adrenal function after bilateral adrenal haemorrhage in the context of VITT and thus more studies are needed to inform clinical practice. The need for disease registries for rare conditions, such as VITT, is crucial as direct cooperation and sharing of information by clinicians might enable quicker identification of disease patterns than would have been possible via established reporting tools of adverse events.

The concentration of metanephrine and normetanephrine in the most common indications for biochemical monitoring

Romana Marušić[1,2] & Tatjana Bačun[1,3]
[1]Faculty of Medicine Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia, Osijek, Croatia; [2]National Memorial Hospital Vukovar, Department of Internal Medicine, Vukovar, Croatia; [3]Clinical Hospital Centre Osijek, Department of Internal Medicine, Osijek, Croatia.

Objectives

Pheochromocytomas are rare neuroendocrine tumors that originate in chromaffin cells of the adrenal medulla and excessively secrete catecholamines, which leads to a multitude of different symptoms. The most common symptoms include headaches, palpitations and sweating. Because of a diverse clinical picture, they pose a major challenge in diagnostics and often go unidentified. The diagnosis is confirmed by measuring plasma and 24-hour urinary metanephrine and normetanephrine. The aim is to determine the most common indications for biochemical testing by sex and age and the association between the concentrations of metanephrine and normetanephrine and indications, sex, and age.

Study design

Cross-sectional study with historical data.

Participans and methods

The study was conducted on subjects in whom the concentration of metanephrine and normetanephrine in plasma was determined in 2019. A list of patients was collected from the Clinical Institute for Laboratory Diagnostics at the Osijek Clinical Hospital by accessing the laboratory information system. Data (indication for biochemical testing, sex, age) was collected from the Department of Nephrology for each patient by accessing the hospital information system.

Results

The study was conducted on 224 respondents (42.9% men and 57.1% women). The most common indication for biochemical testing is adrenal incidentaloma (61.6%) and symptoms of pheochromocytoma (18.3%). There is no significant difference in the distribution of patients according to gender. The median age of participants with adrenal incidentaloma and participants with previously treated pheochromocytoma is higher compared to subjects with hereditary risk for pheochromocytoma and hypertension before they turned 20 years old. There is no significant association between the values of metanephrine and normetanephrine and the indication for biochemical testing. Metanephrine values are significantly lower in women. There is no significant association between age and metanephrine values, while the association between age and normetanephrine values is positive and significant, but very weak.

Conclusion

Higher values of metanephrine are associated with males and higher values of normetanephrine are associated with older age. Adrenal incidentalomas and pheochromocytoma-indicating symptoms are very common in the general population, while the incidence of pheochromocytoma is extremely rare. Given the risk of missing a diagnosis, it is important to know the indications for biochemical testing to make a timely diagnosis and prevent complications.

QTc interval in patients with pheochromocytoma and paraganglioma

Dina Rebrova[1], Elisey Fedorov[1], Igor Chinchuk[1], Vladimir Rusakov[1], Leonid Krasnov[1], Ilya Sleptsov[1], Roman Chernikov[1], Ilya Sablin[1], Natalya Vorokhobina[2], Sergei Fogt[2], Ilya Shcherbakov[1], Shamil Shihmagomedov[1], Ekaterina Zgoda[1] & Arseny Semenov[1,3]
[1]Saint Petersburg State University, Saint Petersburg State University Hospital, St. Petersburg, Russian Federation; [2]North-Western State Medical University n.a. I.I. Mechnikov, Department of Endocrinology, St. Petersburg, Russian Federation; [3]Saint Petersburg State University, Medical Faculty, Saint-Petersburg, Russian Federation.

Introduction

Prolonged QTc interval is a known risk factor for developing ventricular tachyarrhythmias. QTc prolongation is often reported in patients with pheochromocytoma, however the literature data on this issue are rather heterogeneous. Here we report the results of QTc measurement in patients with pheochromocytoma and paraganglioma (PPGL) in comparison to hormonally inactive benign adrenal tumors.

Methods
The test group included 204 patients with pheochromocytoma and 2 with paraganglioma. 27 people with hormonally inactive benign adrenal tumors (HIBAT) served as a control group. QT interval was measured during standard 12-lead ECG before surgical intervention for the disease, and then corrected with Bazett formula (QTcB). The interval was categorized into gender-specific categories. For women, the cutoff points were $\leq$450 ms (normal), 451 to 470 ms (borderline), and $>$470 ms (prolonged), and for men $\leq$430 ms (normal), 431 to 450 ms (borderline), $>$450 ms (prolonged). The pattern of arterial hypertension (i.e. paroxysmal, sustained or mixed type) was evaluated according to complaints, anamnesis and clinical examination results. Numerical data are presented
Results
Medians of QTcB were similar and reached 416 [392, 436] ms in patients with PPGLs and 413 [398, 435] ms in patients with HIBAT ($P=0.975$, Mann–Whitney U test). The intervals were categorized in test group and control group as normal in 169 (82.04%) and 21 (77.77%), borderline in 22 (10.68%) and 5 (18.52%), prolonged in 15 (7.28%), and 1 (3.70%) patient respectively. The hypothesis that the clinical course type of PPGL may influence QTcB was tested. Patients who had sustained or mixed type of tumor-induced arterial hypertension, which may indicate continuous catecholamine exposure, were compared to those with paroxysmal hypertension or asymptomatic disease. In the first subgroup QTcB counted 413 [389, 432] ms, in second it was 428 [400, 451] ms ($P=0.011$, Mann–Whitney U test). The number of patients with borderline or prolonged QTcB was 21 (13.55%) in first subgroup and 16 (31.37%) in second ($P=0.007$, Yates's chi-squared test, odds ratio 2.9 [95%CI: 1.4, 6.2]).
Conclusion
Our data suggest that pheochromocytoma and paraganglioma may be associated with increased QTc, however this effect is limited to certain risk groups. Patients with sustained tumor-induced hypertension, which probably means prolonged catecholamine exposure, are at risk of prolonged QTc.

A challenging case of hypertension: an ACTH-secreting pheochromocytoma

Nicola Lanzo[1], Gaia Francesca Maria Fazzino[1], Francesca Manzella La Barbera[1], Bohdan Patera[1], Silvia Lepanto[1], Federica Martina Bianchi[1], Ilaria Clementi[1], Eliana Piantanida[1,2] & Maria Laura Tanda[1,2]
[1]Insubria University, Department of Medicine and Surgery, Varese, Italy; [2]Ospedale di Circolo e Fondazione Macchi - ASST Sette Laghi, Endocrine Unit, Varese, Italy.

Pheochromocytoma is a rare catecholamine-secreting tumour arising from chromaffin cells in the adrenal medulla and one of the main causes of endocrine hypertension. We here report the case of a 48-year old man admitted to the Internal Medicine Department for evaluation of resistant hypertension. The patient presented with headache, sweating, palpitations, pitting edema, hypertension and hypokalemia both resistant to conventional polytherapy. He was therefore investigated for endocrine causes of hypertension with evidence of urinary metanephrines above the upper reference limit. Besides, an abdominal CT scan showed a left adrenal mass highly suspicious for pheochromocytoma. Calcitonin and PTH levels were within the normal range. Further investigations showed high ACTH and blood cortisol levels. The latter remained unsuppressed after low-dose and high-dose dexamethasone suppression tests (1289 µg/l and 1302 µg/l, respectively). To rule out Cushing's disease, a pituitary MRI was performed, without evidence of sellar abnormalities. All other anterior pituitary hormone levels were within the normal range, except for biochemical central hypothyroidism. The severe Cushing syndrome associated with hypokalemia along with the very high ACTH level (319 ng/l, normal values 7–63 ng/l) supported an ectopic source of ACTH. A total body CT scan confirmed only the previously known left adrenal mass lesion. The right adrenal gland was of normal appearance. The mass showed only selective enhancement in its caudal portion with 123I-MIBG scintigraphy, so a somatostatin receptor scintigraphy was performed which resulted positive. Treatment with metyrapone 250 mg every six hours and thyroxine replacement were initiated to control hypercortisolism and restore euthyroidism before surgery. After proper alfa- and beta-adrenoreceptor blockade treatment, a left adrenalectomy was performed. Hydrocortisone was given before and immediately after the operation, while cortisone acetate was employed afterwards. At two months follow-up, normalization of ACTH levels (24 ng/l) and urinary metanephrines was observed. Histopathology confirmed an ACTH-secreting pheochromocytoma associated with adrenal hyperplasia, with prevalence of the *pars intermedia*, with no signs of angio- or neuroinvasion nor necrosis, low mitotic index, no expression of SDHB and immunostaining positive for ACTH, synaptophysin, chromogranin A, GATA 3. Ectopic ACTH-production is most often related to small cell lung carcinomas or, rarely, to neuroendocrine carcinoids. Few cases of sporadic ACTH-producing adrenal-medullary tumours have been described. Despite its rarity, in those cases where hypertension is burdened by severe hypokalemia and hyperglycemia, an ACTH-secreting pheochromocytoma may be suspected. This condition should be excluded for its high mortality rate and since proper pre-operative management is essential.

Adrenal sarcomas – Exceptionally rare or more common than thought? Prevalence in adrenalectomy specimens over 12 months period and presenting features.

Nur Azman[1], James Lawrence[2], Matthew Hayes[3], James Douglas[3] & Jana Bujanova[11]
[1]University Hospital Southampton NHS Foundation Trust, Endocrinology Department, Southampton General Hospital, Southampton, United Kingdom; [2]Salisbury District Hospital, Endocrinology Department, Salisbury, United Kingdom; [3]University Hospital Southampton NHS Foundation Trust, Urology Department, Southampton General Hospital, Southampton, United Kingdom.

Adrenal/periadrenal sarcomas are very rare entity of adrenal tumours. An epidemiological analysis of primary adrenal cancers found prevalence of adrenal sarcoma of 1.3% compared to adrenocortical carcinoma (ACC) 43.8%, neuroblastoma 39.7%, pheochromocytoma 10.9% and non-Hodgkin's lymphoma 4.3% (1). In 2021, 26 adrenalectomies in adults were performed in our institution. 12/26 had malignant histology. 9/26 lesions were $>$ 6 cm. 7/9 lesions $>$ 6 cm were malignant (2 adrenal sarcomas, 2 ACC, 2 infiltrative renal cancer, 1 metastatic melanoma). Adrenal sarcoma was detected in 2/26 adrenalectomized specimens. We present two cases of adrenal sarcoma detected over 12-month period in University Hospital Southampton, United Kingdom. Case 1: 35-year-old woman presented with right abdominal pain for over one year. Ultrasound showed right suprarenal mass. CT CAP and adrenal MRI confirmed large tumour 4.9$\times$6.1$\times$5.7 cm adjacent to or arising from right adrenal gland and indents IVC. No metastases. Urine metanephrines, aldosterone, renin, 1 mg ODST were normal. Working diagnosis was non-functioning ACC. Patient underwent open adrenalectomy and post-operatively her pain resolved. Histology revealed high grade leiomyosarcoma (pT2 N0 G3) adjacent to adrenal with narrow excision margin. Patient opted against adjuvant chemotherapy and remains under surveillance. Imaging 8 months post-op showed no evidence of recurrence. Case 2: 70-year-old man presented with two months history of left flank and back pain, weight loss, and elevated CRP (159 mg/l). CT detected suspicious 7.8 cm heterogenous left adrenal mass extending to splenic hilum. Metanephrines, lymphoma screen- normal, 1 mg ODST-raised (72 nmol/l). Patient underwent open adrenalectomy, splenectomy and wedge excision of the liver due to intraoperative findings of liver metastases. Histology confirmed high grade epithelioid angiosarcoma. Restaging CT post-op showed lung, liver metastases and local recurrence in resection bed. He commenced palliative paclitaxel chemotherapy, with good radiological response. Adrenal sarcomas should be considered in any age in differential diagnosis of indeterminate adrenal masses especially when $>$ 6 cm, associated with ipsilateral pain and raised CRP. 1 mg ODST can be raised due to raised metabolic rate associated with high-grade malignancy. The duration of symptoms could range from few weeks to 12 months. In our second case with metastatic disease, surgical debulking of primary tumour provided significant pain relief and increased patient's quality of live and prognosis. Both patients are alive at the time of writing.

Don't break my heart: sparing the knife in SDHB mutated cardiac paraganglioma treated with cabozantinib

Lindsay Carafone, William Archibald, Adrienne Victor & Inga Harbuz-Miller
University of Rochester, Rochester, United States.

Introduction
Cardiac paragangliomas are rare endocrine neoplasms. Surgical resection is first line treatment. Here, we describe a case of cardiac paraganglioma where surgical resection was aborted due to involvement of important cardiac structures. Systemic therapy was instead pursued with tyrosine kinase inhibitor cabozantinib.
Case
A 64-year-old man with a past medical history significant for tobacco use and poorly controlled type 2 diabetes mellitus presented with chest pain, several months of progressive fatigue and 15 pound unintentional weight loss. Echocardiogram revealed a 6.9×5.8×4.9 cm right-sided cardiac mass. Biopsy was performed demonstrating cytopathology consistent with paraganglioma. Laboratory studies revealed chromogranin A 1,038 ng/ml (normal <93 ng/ml), plasma normetanephrine 1.87 nmol/l (0–0.89 nmol/l) and plasma metanephrine 0.14 nmol/l (0–0.49 nmol/l). Ga-68 DOTATATE Positron Emission Tomography/Computed Tomography (PET/CT) scan revealed DOTATATE avidity within the region of the cardiac mass. No additional lesions or metastatic foci were identified. Next-generation sequencing performed on the tissue biopsy demonstrated an SDHB mutation (H244D) at a variant allele frequency of 62.2%. Surgical resection was attempted and aborted due to the paraganglioma encasing the right coronary artery and the tricuspid valve. Systemic therapy was initiated with tyrosine kinase inhibitor cabozantinib. Dose reduction was required due to development of palmar-plantar erythrodysesthesia. Subsequent surveillance Ga-68 DOTATATE PET/CT scan revealed partial response to treatment at two months with increasing central photopenia of the cardiac mass from 94 standardized uptake value (SUV) to 54 SUV. The patient had biochemical response with decreasing chromogranin A and norepinephrine levels.
Conclusion
Treatment of cardiac paraganglioma ideally consists of local resection, however this is not always possible due to involvement of critical structures of the heart. Systemic therapy for paragangliomas is largely based on small, retrospective studies. Our case illustrates an unresectable cardiac paraganglioma with response to cabozantinib as evidenced by radiologic and biochemical data. Radionucleotide therapy is a potential future treatment option for this patient.

Optimization of familial hypercholesterolemia diagnosis through LDL cholesterol correction formula for lipoprotein(a) levels

Rosana Urdaniz Borque[1], Sergio Roman Gimeno[1], Elena Pérez Galende[11], Gema Gonzalez Fernandez[11], Borja Sanz Martín[2] & José Antonio Gimeno Orna[1]
[1]Lozano Blesa University Clinical Hospital, Endocrinology, Zaragoza, Spain; [2]Reina Sofía Hospital of Tudela, Tudela, Spain.

Introduction
For the clinical diagnosis of heterozygous familial hypercholesterolemia (HeFH) validated algorithms are used, with the Dutch Lipid Clinic Network (DLCN) Criteria being the most recommended in our environment. One of the items that scores for the system proposed by the DLCN is the value of LDL cholesterol. However, LDLc levels can be distorted by lipoprotein a (Lpa(a)) levels.
Objective
To analyze the change in the validity of the DLCN criteria for the diagnosis of HeFH with pathogenic mutation confirmed when using the LDLc.
Methods
Observational, retrospective, cross-sectional, and analytical study in a cohort of 91 patients with clinical diagnostic criteria for probable or defined familial hypercholesterolemia according to the DLCN criteria, followed in our Lipid Unit at Lozano Blesa University Clinical Hospital, from 1 May 2019 to 31 December 2020. The DLCN criteria have been calculated based on LDLc values, and LDLc corrected for Lp(a) [according to the corrected LDLc formula = LDLc – 0.30*Lp(a)]. In all the statistical test performed, significant values of $P<0.05$ were considered. Several ROC (Receiver Operating Characteristic) curves have been generated between the initial LDLc and that LDLc corrected by Lp(a) values to predict the presence of genetic mutation. Corresponding cross tables have been made between LDLc (initial and corrected) and genetic mutation; as well as between the DLCN score (obtained with uncorrected LDLc) and genetic mutation.
Results
We included 91 patients (51.65% women, mean age at diagnosis 48.80±12.96 years). 43.95% of them did not present mutation in the genetic study for HeFH. Lp(a) in subjects with no known mutation was 24.70 ± 86.10 mg/dl compared to 22.50 ± 60.3 mg/dl in patients with known mutation. The area under the ROC curve of the LDLc variable and the presence of mutation in the genetic test was higher in the case of LDLc corrected by Lp(a) (AUC=0.639,$P=0.038$) than in the uncorrected LDLc (AUC=0.623,$P=0.065$). This improves the specificity of the LDLc variable to predict genetic mutation if used corrected by Lp(a): 70% versus 62.74% if used uncorrected. When using the LDLc corrected by Lp(a) for the calculation of the DLCN score, 66.66% of the patients were reclassified from probable diagnostic group to a possible diagnosis, without presenting 56.26% of them a known genetic mutation.
Conclusions
The use of adjustment of LDL cholesterol levels according to Lp(a) levels in the diagnosis of HeFH facilitates a more specific diagnosis than with the use of unadjusted LDLc.

Associated factors with metabolic syndrome in elderly patients harboring adrenal incidentaloma: A comparative study

Faten Haj Kacem Akid[1], Abdelmouhaymen Missaoui[1], Mariem Belhoul[2], Wafa Belabed[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nadia Charfi[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Department of Family Medicine, Sfax, Tunisia.

Background and Aims
Numerous studies have suggested that metabolic syndrome (MetS) is related to adrenal incidentaloma (AI) in young adults. Limited data about MetS in geriatric patients diagnosed with AI are available, despite the high incidence of this adrenal disease in the elderly. This study aims to assess the prevalence of MetS and its associated factors in aged patients harboring AI.
Patients and Method
We conducted a retrospective, comparative, and analytical study including 69 patients aged 65 years and above diagnosed with AI. All patients have undergone clinical examination, adrenal CT, and biochemical workup at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia, from 2011 to 2020. MetS was diagnosed based on the National Cholesterol Education Program's Adult Treatment Panel III (ATP III) criteria. We compared two groups:
[MetS+]: elderly subjects with MetS ($n=17$)
[MetS-]: elderly subjects without MetS ($n=52$)
Results
There was no significant age diffrence between both groups ([MetS+]:72.1 vs [MetS=] 71.0 years old; $P=0.82$). Female gender was significatly associated with MetS ([MetS+] 82.4% vs [MetS-] 39.1%; $P=0.006$). Patients bearing bilateral AI were significantly more affected by MetS ([MetS+] 58.8% vs [MetS-]: 4.3%; $P=0.000$) compared to those having unilateral AI. Smaller incidentaloma size seems to aggravate substabtially the risk of developping MetS in the elderly (incidentaloma size in [MetS+] 21.0 vs [MetS-]:26.7 mm; $P=0.009$). Both groups had similar electrolyte profile except higher phosphatemia which was statistically linked to the prescence of MetS ([MetS+] 1.30 vs [MetS-]: 0.96 mmol/l; $P=0.018$). We noted no significant correlation between hormonal hypersecretion and MetS in older adults, since there was a comparable distribution of functioning ([MetS+] 46.7% vs [MetS-] 40.0%) and nonfunctioning AI([MetS+] 53.3% vs [MetS-] 60%; $P=0.693$) in the two groups.
Conclusion
AI is associated with a higher cardiometabolic risk. This risk seems to increase in advanced age. Metabolic abnormalities are classically attributed to hormonal hypersecretion, especially in Cushing's syndrome. However, several studies have recently proven that insulin resistance and metabolic dysregulation also occur in nonfunctioning AI. Our results suggest that bilateral and smaller AI may worsen the risk of metabolic disturbances in geriatric patients, regardless of their secreting profile. Further research is needed to elucidate this hypothesis.

Cardiovascular risk factors in mild adrenal autonomous cortisol secretion in a Caucasian population

Agnieszka Adamska[1], Vitalii Ulychnyi[1], Katarzyna Siewko[1], Anna Popławska-Kita[1], Małgorzata Szelachowska[1], Marcin Adamski[2], Angelika Buczyńska[3] & Adam Krętowski[1,3]
[1]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Poland; [2]Bialystok University of Technology, Faculty of Computer Science, Poland; [3]Medical University of Białystok, Clinical Research Centre, Poland.

Background
Cardiovascular (CVS) risk factors could be present in patients with mild adrenal autonomous cortisol secretion (MACS), which could account for up to 50% of patients with adrenal adenomas. However, the most frequent CVS risk factors in MACS have not been established.
Objective
The aim of the present study was to analyse the difference in CVS risk factors in patients with MACS in comparison to those with non-functioning adrenal tumour (NFAT).
Materials and Methods
A total of 295 patients with adrenal incidentaloma who were hospitalised in the single-center between 2017 and 2019 were included in this retrospective study. All patients underwent a 1 mg overnight dexamethasone suppression test (DST). We divided our group into those who showed suppression in the DST (NFAT) and those who did not show suppression in the DST (MACS). In the studied groups, we analysed the presence of CVS risk factors, such as obesity, prediabetes (PD), type 2 diabetes mellitus (T2DM), hypertension, hyperlipidaemia, and chronic kidney disease.
Results
In our study, 18.9% of patients were defined as MACS, and the remaining 80.1% of patients were defined as NFAT. In the group with MACS, we observed obesity in 33.9%, whereas in NFAT, the prevalence of obesity was 34.7% ($P=0.9$). Hypertension was diagnosed in 78.5% of MACS vs. 69.5% of NFAT ($P=0.2$), whereas chronic kidney disease was observed in 32.1% of MACS vs. 28.5% of NFAT ($P=0.7$). Accordingly, we did not find differences in the diagnosis of prediabetes in MACS vs. NFAT (26.8% vs. 34.3% ($P=0.35$)). Importantly, T2DM was diagnosed in 41% of MACS vs. 23% of NFAT ($P<0.01$). Interestingly, we observed a higher frequency of occurrence of hyperlipidaemia in NFAT (72.4%) vs. MACS (53.6%) ($P=0.01$). Accordingly, in patients without T2DM, MACS was observed in 15.2%, in comparison to 29.5% in patients with T2DM ($P<0.01$).
Conclusions
In our retrospective analyses, we found that T2DM is more prevalent in MACS than in NFAT, whereas hyperlipidaemia is more prevalent in NFAT. Accordingly, no differences were observed in the incidence of obesity, hypertension, prediabetes, or kidney damage in NFAT and MACS patients. This could suggest that mild hypercortisolaemia is not associated with a higher CVS risk in comparison to NFAT.

Niemann-Pick disease type B and bilateral adrenal incidentalomas

Hamza Elfekih[1,2], Sinda Allegue[1], Monia Zaier[2,3], Oumayma Zarrouk[11], Hayfa Farid[1], Amel Maaroufi[1,2], Maha Kacem[1,2], Molka Chadli Chaieb[1,2], Yosra Hasni[1,2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia; [3]Farhat-Hached University Hospital, Department of Clinical Hematology, Sousse, Tunisia.

Introduction
Niemann Pick disease is a rare autosomal recessive lysosomal storage disorder caused by a deficiency in acid sphingomyelinase. Usually discovered in childhood, it can affect liver, spleen and pulmonary function. Here, we report the case of a Niemann Pick type B disease in an adult associated with bilateral adrenal incidentalomas.
Observation
A 45-year-old male patient was found to have bilateral adrenal incidentalomas associated with hepatomegaly and multinodular splenomegaly, discovered by an abdominal CT scan that was requested during his follow-up for inguinal and umbilical hernia. MRI and CT scan with contrast showed bilateral adrenal hyperplasia and a 26 mm non-adenoma in the medial arm of the right adrenal gland. The patient's clinical examination and biological workup were normal. Short synacthen test ruled out adrenal insufficiency. Plasma metanephrines and low-dose dexamethasone suppression test excluded adrenal hypersecretion. During etiological workup of the splenomegaly, the patient underwent a bone marrow biopsy revealing sea-blue histiocytosis. In addition, a serum acid sphingomyelinase activity assay revealed a deficiency (<0.3 µmol/l per hour) confirming the Niemann-Pick disease type B.
Discussion
The prevalence of adrenal incidentalomas is approximately 5% in the general population and they are bilateral in 7.8 to 15% of cases. Systematic etiological investigation of bilateral adrenal lesions is necessary to exclude malignancies and hypersecretions. Niemann-Pick diseases are characterized notably by hepatosplenomegaly and gradual deterioration in pulmonary function. Its association with bilateral adrenal hyperplasia, adrenal masses and sea-blue histiocytosis has not been previously reported in the literature.

Adrenal hemangioma with subclinical cushing's syndrome

Ould Kablia Samia[1], Mouna Benfiala[1], Benabdelatif Katia[1], Reda Kassa[2] & Amira Bouchenna[1]
[1]Central Hospital of the Army, Endocrinology, Algiers, Algeria; [2]Douira Hospital, Histopathology, Algiers, Algeria.

Introduction
Adrenal cavernous hemangioma is a rare tumor with few cases reported in the world. Usually this adrenal masses are incidentally discovered and non functional.
Case report
We describe the case of a 63 year old male patient with a history of hypertension and treated prostate. He was referred to our endocrinology department with complaints of his left lower back. At the admission the BMI was 21 kg/m^2, his blood pressure was 160/90 mmHg and the heart rate was 84 beats /mn. In the clinical examination there were no clinical signs of hypercortisolism or catecholamine or mineralocorticoid excess. The abdominal enhanced C T showed a left large heterogeneous adrenal tumor of 50 mm with hemorrhage, necrosis and calcification, the C T value of solid part was 30 UH. The laboratory evaluation revealed a morning cortisol level of 179 nmol/l after a 1 mg overnight dexamethasone suppression test and a low ACTH concentration. The plasma metanephrine, normetanephrine, aldosterone level and renine activity were normal. All these features make it difficult to distinguish from a primary adrenal cortical carcinoma and then required operative management. An adrenalectomy was performed and the tumor was safely completely resected with no evidence for local invasion. The results of pathological examinations were in favor of a cavernous hemangioma of the left adrenal gland.
Conclusion
Adrenal cavernous hemangioma is a rare tumor that can have a very large size, and it is difficult to differentiate from adrenal cortical carcinoma clinically or radiologically.

Metabolic and cardiovascular consequences of hormone replacement by hydrocortisone in adrenal insufficiency

Ines Charrada, Alaya Wafa, Boubaker Fadia, Najoua Lassoued, Zantour Baha, Berrich Olfa & Sfar Mohamed Habib
Endocrinology-Diabetology and Internal Medicine Service CHU Tahar Sfar Mahdia Tunisia, Mahdia, Tunisia.

Introduction
During adrenal insufficiency (AI), glucocorticoid treatment is supposed to be neutral on the metabolic parameters of patients. However, recent data from the literature report that this corticosteroid replacement therapy increases the metabolic risk. The aim of our work was to determine the metabolic and cardiovascular impact of hydrocortisone (HC) replacement therapy during peripheral AI.
Patients and methods
This was a descriptive and analytical study involving 77 patients with peripheral AI (66 women and 11 men), all treated with HC. For each patient, we determined the length of the disease, the duration of the follow-up, the daily and cumulative dose of HC, the evolution of metabolic parameters (weight, blood pressure, glycemia, lipid parameters), and the Framingham score under HC.
Results
The mean age was 40.5 years (range: 22-63 years). The mean duration of evolution was 7.7 years. The study of metabolic and cardiovascular parameters after treatment with hydrocortisone showed weight gain in 96.1% of patients (overweight: 46.75% and obese: 40.25%). We noted that 41.5% of patients had developed hypertension, 54.54% had pre-diabetes, 37.66% had diabetes mellitus, 52% had dyslipidemia. We noted a significant positive relationship between daily HC dose and the development of obesity ($P<10^{-4}$), hypertension (P: 0.003), diabetes mellitus (PP: 0.025) and dyslipidemia (P: 0.004), respectively. We found a significantly positive relationship between, on the one hand, disease duration, cumulative HC dose and, on the other hand, obesity (P:0.05/P:0.029), hypertension ($P<10^{-4}$/$P<10^{-4}$), and glycemic homeostasis disorders

(*P*: 0.03/*P*: 0.02), respectively. For cardiovascular risk, we noted an elevation of the Framingham score after HC treatment (>20% in 6 patients), with a positive correlation between this score and, respectively, disease duration (*P*: 0.036), cumulative HC dose (*P*: 0.022), female sex (*P*: 0.001) and menopause (*P*: 0.044). In the same setting, four patients had experienced a cardiovascular event, and were all on a HC dose ≧30 mg/d.
Conclusion
The metabolic and cardiovascular risk of corticosteroid replacement therapy with HC during AI appears to be real. It increases with the duration of the disease and the cumulative dose of HC. Regular monitoring of metabolic and cardiovascular parameters is therefore essential with constant re-evaluation of the dose of this drug in these patients.

Adrenal ganglioneuroma: presentation of two cases

Athanasia Michou, Zoi Efstathiadou, Paraskevi Komzia, Apostolos Gogakos, Efstathios Divaris, Georgia Kourkouta & Marina Kita "Hippokration" General Hospital of Thessaloniki, Endocrinology, Thessaloniki, Greece.

Introduction
Adrenal ganglioneuroma (AGN) is a rare (about 470 described cases), benign tumor arising from the neural crest tissue. These tumors are usually asymptomatic and incidentally detected. They have variable radiological features that often raise suspicion of malignancy. AGN are diagnosed at a mean age of 50 years, have no gender preference and are rarely associated with genetic syndromes.
Aim
The presentation of two male patients, 24 and 53 years old with adrenal incidentalomas and a final diagnosis of AGN.
Case 1
A 24-year-old male patient, with a history of asthma, was referred for evaluation of a left adrenal tumor incidentally discovered on a chest CT performed due to an exacerbation of his respiratory symptoms. The tumor, measuring 1.4 cm, had smooth borders but showed increased density (30 HU). On MRI, the tumor showed mild signal enhancement in T2 sequences and poor enhancement with delayed uptake of paramagnetic substance. Clinical and laboratory workup of the patient were normal. The patient was normotensive and testing for cortisol, metanephrines and adrenal androgens (DHEAS, 17OHPRG), no functionality was detected. The patient underwent a laparoscopic adrenalectomy, the histological examination of which showed morphological features of AGN.
Case 2
A 53-year-old male patient with no previous comorbidities was diagnosed with a large incidentaloma on the right adrenal gland, during a diagnostic work up for fever of unknown etiology. On CT, the incidentaloma had a size of 11×7.5×6.5 cm, high density (>30 HU) and very low absolute and relative contrast media washout. Clinical examination of the patient revealed no signs of hypercortisolism or other pathological findings. Haematological and biochemical tests were normal. Similarly, hormonal workup exclude hypersecretion (normal circadian cortisol rhythm (morning 9.8 μg/dl, evening 1.6 μg/dl), normal 24-hour metanephrines fractions [normetanephrine =261 μg/24 h (<780), metanephrines =41 μg/24 h (<375)] and normal adrenal androgens DHEAS and 17OHPRG. Due to the size of the tumor and the imaging characteristics, which were not compatible with an adrenal adenoma, a retroperitoneal endoscopic right adrenalectomy was performed. Histological examination revealed an AGN with scattered microcalcifications without evidence of necrosis and atypia. The patient, after 4 years of follow-up, remains disease free.
Conclusion
AGNs usually have a benign course. Nevertheless, their imaging features guide patients to their surgical removal to establish a definitive diagnosis and determine prognosis. Age of diagnosis ultimately may not play a decisive role in the differential diagnosis of AGN.

DOI: 10.1530/endoabs.81.EP22

EP23

Determination of 18-hydroxycortisol, 18-oxocortisol by HPLC–MS/MS in the differential diagnosis of various forms of primary aldosteronism

Natalia Romanova, Nadezhda Platonova & Ekaterina Troshina The National Medical Research Centre for Endocrinology, Therapeutic Endocrinology Department, Moscow, Russian Federation.

Introduction
Aldosterone synthase participates in the key reactions of aldosterone synthesis – 11-hydroxylation, 18-hydroxylation and, finally, 18-oxidation. In recent works devoted to evaluating the effectiveness of hybrid steroids in the differential diagnosis of subtypes of primary aldosteronism (PA), it is worth emphasizing the experience of using high-performance liquid chromatography – tandem mass spectrometry (HPLC-MS/MS), which allows detecting even very low concentrations in peripheral plasma (the lower limit for 18-oxocortisol is 0.25 ng/dl).
Objective
To evaluate differences in the synthesis of steroid end products by HPLC-MS/MS at PA.
Material and methods
Retrospective evaluation of blood serum samples from 136 patients with a verified diagnosis of primary aldosteronism. In accordance with standard protocols, the parameters of steroidogenesis were evaluated – aldosterone, 18-oxocortisol, 18-hydroxycortisol, 18-hydroxycorticosterone, 20b-dihydrocortisone, cortisone, cortisol, testosterone, 21-deoxycortisol, corticosterone, 11-deoxycortisol, androstenedione, 11-deoxycorticosterone, DHEA, 17-OH progesterone, 17-OH pregnenolone, progesterone, pregnenolone, androstenedione, adrenosterone, 11-hydroxyandrostendione by HPLC–MS/MS.
Results
As part of the study, in 136 patients with aldosterone-producing adenoma (APA) ($n=56$), idiopathic hyperaldosteronism (IHA) ($n=24$) and 56 with hormonally inactive tumors (HIT), a study of steroidogenesis was conducted, including the determination of the end products of steroid synthesis – 18-hydroxycortisol, 18-oxocortisol by HPLC–MS/MS. Thus in patients with APA, the levels of 18-oxocortisol, 18-hydroxycortisol, 18-hydroxycorticosterone, pregnenolone, determined by HPLC–MS/MS, were statistically significantly increased compared to the study of those in patients with hormonally inactive tumors (18-Oxocortisol Me(PA) 0.75 [0.13; 1.98] ng/dl, Me(HIT) 0.1 [0.06; 0.14] ng/dl, $P<0.05$; 18-Hydroxycortisol Me(PA) 5 [2.52; 10.95] ng/dl, Me(HIT) 2.4 [2; 3.44] ng/dl, $P<0.05$; 18-Hydroxycorticosterone Me(PA) 3.48 [1.97; 7.02] ng/dl, Me(HIT) 1.76 [1.25; 2.52] ng/dl, $P<0.05$; Pregnenolone Me(PA) 2.22 [1.4; 3.07] ng/dl, Me(HIT) 1.38 [0.98; 2.19] ng/dl, $P<0.05$).
Conclusions
Thus, the expediency of determining 18-oxocortisol and 18-hydroxycortisol by HPLC–MS/MS in the differential diagnosis of various forms of PA has been proved.

Complex adjuvant treatment of patients with two-component adrenocortical cancer (clinical case)

Alexey Krivosheev[1], Timur Britvin[2], Anna Motrenko[3], Larisa Gurevch[4] & Irena Ilovayskaya[5]
[1]Moscow Regional Research and Clinical Institute (MONIKI), Department of Endocrine Surgery, Russian Federation; [1]Moscow Regional Research and Clinical Institute (MONIKI), Department of Endocrine Surgery; [3]Moscow Regional Research and Clinical Institute (MONIKI), Neuroendocrine Unit, Department of Endocrinology, Moscow, Russian Federation; [4]Moscow Regional Research and Clinical Institute (MONIKI), Department of Pathology, Russian Federation.

Adrenocortical cancer (ACC) is a tumor of the adrenal cortex, clinical manifestations, recurrence, and progression potential are determined by its biological characteristics. Morphological diagnosis of tumors of the adrenal glands in some cases presents significant difficulties. According to the WHO classification of tumors of the endocrine organs (4th revision, 2017), in addition to the classical one, myxoid, sarcomatoid and oncocytic histological variants of ACC are distinguished. According to a number of studies, the oncocytic variant is characterized by a less aggressive clinical course. In our work, we present a clinical case of combined treatment of two-component hormonally active (hypercorticism and virilization) adrenocortical carcinoma. After radical surgical treatment, histological examination was verified a polyclonal adrenocortical carcinoma, represented by two components different in cellular composition and architecture. Most of the tumor is of classical structure (Weiss score 4), the second component is an oncocytic variant of ACC (2 major and 2 minor Lin-Weiss-Bisciglia criteria). An immunohistochemical (IHC) study of the oncocytic component of tumor revealed expression of subtype somatostatin 2 receptors (SSTR2), KI67 index was 21%. There was no expression SSTR2 in classical component, the Ki67 proliferation index was 10%. Chromogranin A expression was absent in both tumor components. Invasion of periadrenal adipose tissue, Ki67 10% or more in both tumor components, positive expression of SSTR2 served as the basis for starting adjuvant drug treatment with mitotane in combination with long-acting somatostatin analogs. There was no progression of

the disease during 30 months of patient monitoring. To date, mitotane remains the only drug for the treatment of ACC with proven efficacy. A number of targeted drugs interacting with specific tumor receptors have been proposed, but their use is limited a low efficiency. Recently, reports have been published on the expression of SSTR in tumor tissue, as well as on the effect of synthetic somatostatin analogs on the growth of ACC cell lines. A feature of this clinical case is the development of polyclonal adrenocortical carcinoma, with different functional activity, histostructure, proliferation index and receptor status of its components, which suggests a different malignant potential of tumor components and emphasizes the need for accurate morphological verification of adrenocortical tumors for individualization of treatment. The progression-free period more than 30 months after radical surgical treatment gives grounds for the use of somatostatin analogs in the drug treatment of ACC, but its effectiveness requires further study and evaluation.

Acute adrenal crisis following COVID-19 in a patient with 11β-hydroxylase deficiency

Hamza Elfekih[1,2], Manel Dridi[1], Asma Ben Abdelkarim[1,2], Siwar Kahloun[1], Yosra Hasni[1,2], Amel Maaroufi[1,2], Maha Kacem[1,2], Molka Chadli Chaieb[1,2] & Koussay Ach[1,2]
[1]Farhat-Hached University Hospital, Endocrinology-Diabetology Department, Sousse, Tunisia; [2]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia.

Introduction
11-Beta-hydroxylase deficiency (11β-OHD) is the second most common cause of congenital adrenal hyperplasia. It leads to the accumulation of steroids precursors prior to the enzyme defect, notably 11-deoxycorticosterone (DOC), leading therefore to low renin hypertension and hypokalemia. Hence, patients with 11β-OHD are reportedly protected from adrenal crisis. Here, we report a case of a male with 11β-OHD presenting with acute adrenal insufficiency.
Observation
A 40-year-old male, following in our department for congenital adrenal hyperplasia due to 11β-OHD, was admitted for abdominal pain and vomiting. He had also headaches, chills without shortness of breath, that started one day before his admission leading to the diagnosis of Covid-19 infection. The patient was receiving glucocorticoid replacement therapy (hydrocortisone 30 mg b.i.d.) with good compliance. On examination, he had a blood pressure of 120/70 mmHg despite discontinuation of antihypertensive treatments (Calcium channel blocker, Beta-blocker and spironolactone). His heart rate was 114 bpm and his blood oxygen saturation rate was 95%. Laboratory analysis showed normal serum potassium level of 4.2 mmol/l, functional acute kidney failure and elevated C-reactive protein of 49 mg/l. The patient received hydrocortisone hemisuccinate 200 mg the first day with an improvement of his symptoms.
Discussion
Acute adrenal crisis is exceptional in patients with 11β-OHD. The diagnosis in our case was based on abdominal pain, vomiting, the abnormally normal blood pressure and serum potassium level, and the favorable progression after hydrocortisone hemisuccinate. It was hypothesized that regular treatment with hydrocortisone in these patients will suppress ACTH secretion and leads to a reduced accumulation of steroids precursors that may expose them to the risk of developing acute adrenal crisis in case of hydrocortisone therapy interruption or in the absence of doses adjustment in stressful conditions.

A rare cause of a surrenal mass

Coskun Ates, Erhan Hocaoglu, Ensar Aydemir, Filiz Mercan Saridas, Özen Öz Gül, Soner Cander, Canan Ersoy & Erdinc Erturk
Uludag University Faculty of Medicine, Endocrinology and Metabolic Diseases, Bursa, Turkey.

Introduction
Myxoid adrenocortical adenoma was described by Brown et al. in 2000 (1). Myxoid adrenal cortical adenoma with pseudo glandular structure is a particular histological variant and is extremely rare. Accurate diagnosis is based on the combined evaluation of clinical features, adrenal imaging, and pathological features. Immunohistochemical studies (cytokeratin, melan-A, USP10, chromogranin, vimentin) can distinguish adrenocortical adenoma from other retroperitoneal myxoid tumors (2).
Case
A 43-year-old male patient uses a bi-level positive airway pressure device for known obstructive sleep apnea syndrome. The patient described occasional high blood pressure had left flank pain in the last 15 days. No pathology was detected in the urinalysis performed by the urology and in the abdominal X-ray. Contrast-enhanced upper abdomen computed tomography was then performed on the patient. In his report, it was seen that there was a 29×27 mm mass lesion in the left adrenal gland with intense contrast enhancement in the arterial and venous phases. In the 1 mg dexamethasone suppression test performed by us, aldosterone, renin, adrenaline, noradrenaline, dopamine, metanephrine and normetanephrine levels were within the normal range. Doxazosin treatment was given to the patient who described occasional blood pressure attacks. The patient underwent laparoscopic left adrenalectomy two weeks later. No complications developed. Histopathological study showed that the mass was a myxoid adrenocortical adenoma with a pseudo glandular pattern. Immunohistochemically, vimentin, CD56, melan-A, CK8 were diffusely positive, while inhibin was focally positive. No immunoreactivity was found in cytokeratin 7, S-100, calretinin, synaptophysin, chromogranin A, TTF1, CK7, napsin, mesolthelin, WT-1, PanCK, CD99. The patient has been followed for 15 months after laparoscopic adrenalectomy. No pathology was detected in the control adrenal hormone profile and control computed tomography. Blood pressure is regulated.
Conclusion
Myxoid adrenocortical adenoma with pseudo glandular pattern may suggest adrenocortical metastasis or pheochromistoma by adrenal imaging method. Immunohistochemical markers are very useful in differential diagnosis.

Impact on quality of life and sleep of hydrocortisone hormone replacement in adrenal insufficiency.

Ines Charrada, Alaya Wafa, Boubaker Fadia, Houcem Mrabet, Zantour Baha, Berrich Olfa & Sfar Mohamed Habib
Endocrinology-Diabetology and Internal Medicine Service CHU Tahar Sfar Mahdia Tunisia, Mahdia, Tunisia.

Introduction
Hydrocortisone (HC) is the most widely used replacement molecule in the treatment of adrenal insufficiency (AI). This substitution treatment is far from ideal especially as it is impossible to reproduce the nycthemeral cycle of cortisol with its current galenic form which has a short half-life. The aim of our work was to determine the impact of HC treatment of peripheral AI on the long-term quality of life and sleep.
Patients and methods
This is a descriptive and analytical study involving 77 patients with peripheral AI (66 women and 11 men), all treated with HC. For each patient, we determined the duration of the disease, the daily and cumulative dose of HC, the number of times HC was taken, the SF-36 quality of life score and the Pittsburgh sleep quality score in 58 patients.
Results
The mean age was 40.5 years (range: 22–63 years). The mean duration of progression was 7.7 years. We found that the percentage of patients with impaired quality of life was higher than in the healthy Tunisian adult population (79.31% vs. 51%), with a lower mean SF-36 global score (54.9 vs. 69.4). We noted a better quality of life in case of three HC intakes compared to two (*P*: 0.006). Regarding sleep quality, we found that 24% of patients had a sleep disorder of the type insomnia of the second part of the night with early awakening, without any correlation with the HC dose. This prevalence was higher than in the general adult population (24% vs. 9.7%). This quality of sleep seems to be better in case of three intakes of HC (morning, noon and afternoon).
Conclusion
Our results agree with those of the literature, since it appears that a 3-dose schedule was more beneficial for quality of life and long-term sleep. However, even with these HC dosing regimens, we remain far from the physiological rhythm of cortisol, and new modified-release HC preparations (DuoCort/Chronocort) could allow to better mimic the nycthemeral cycle of cortisol in patients suffering from AI.

Addison disease masquerading as hyperemesis gravidarum and good fetal outcome.

Stela Vudu[1], Ina Dusa[1], Veronica Gonta[2], Neonila Tofan[2], Aristia Seremet[1] & Lorina Vudu[1]
[1]State University of Medicine and Pharmacy "Nicolae Testemitanu", Endocrinology, Chisinau, Moldova; [2]Republican Clinical Hospital, Endocrinology, Chisinau, Moldova.

Here we report the case of a woman with first presentation of Addison disease in pregnancy that went undiagnosed until postpartum period. She gave birth to a healthy child by vaginal delivery at 40 weeks of pregnancy. Our patient is a 31 years pregnant woman with unremarkable medical or familial history. At 8 weeks of pregnancy she was complaining of nausea, vomiting, loss of appetite and fatigue, leading to hospitalization. The physical examination revealed a blood pressure of 80/50 mmHg, a check-up that included blood and urine analyses did not reveal any abnormalities. She received treatment with saline and glucose perfusion, vitamin B and was discharged after one week, with persistent symptoms attributed to hyperemesis gravidarum. At 16 weeks of gestation the patient noticed a bronze appearance of the skin. Her condition was deteriorating, with accentuation of fatigue and 9 kg weight loss, leading to another 2 hospitalizations due to presumed hyperemesis gravidarum. Neverthless at 40 weeks of gestation she gave birth to a healthy child by vaginal delivery. 2 months later she was hospitalized in the endocrinology department due to extreme fatigue and persistent gastrointestinal symptoms. At admission the patient's blood pressure was 85/55 mmHg, pulse – 88 beats/minute and respiratory rate – 20 breaths/minute. She had tanned skin and hyperpigmented spots on gums, tongue and mucosa of cheeks. Laboratory data showed: ACTH 1006 (0–46 pmol/l), cortisol 2.41 (69–690 nmol/l). A diagnosis of primary adrenal insufficiency was established and intravenous hydrocortisone hemisuccinate was initiated. Thereafter, the patient was transferred to oral cortisone, and discharged on the 5th day. Currently the patient is in good condition, taking tablets of Cortisone 25 mg at 0800 h and 12.5 mg at 1200 h, and is breastfeeding.

Discussion

Addison disease (AD) is a rare condition, usually due to autoimmune destruction of the adrenal cortex. Addison disease complicating pregnancy is even rarer, about 100 pregnancies being reported worldwide. Untreated Addison disease during pregnancy leads to increased maternal mortality and fetal growth retardation. Nausea and vomiting due to adrenal insufficiency may be confused with typical symptoms of pregnancy. Generalized hyperpigmentation – a hallmark of Addison disease may be seen in normal pregnancy, but dark spots on lips and mouth mucosa should prompt adrenal insufficiency evaluation.

Conclusion

First diagnosis of Addison disease during pregnancy may be challenging due to misleading symptoms attributed to normal pregnancy. Differential diagnosis of severe and prolonged hyperemesis gravidarum should include adrenal insufficiency.

Pheochromocytoma in the elderly: treatment challenges

Imen Halloul, Ach Taieb, Saad Ghada, Ben Abdelkerim Asma, El Fekih Hamza, Hasni Yosra, Maaroufi Amel, Kacem Maha, Chaieb Molka & Ach Koussay
Farhat Hached University Hospital, Department of Endocrinology and Diabetes, Sousse, Tunisia.

Introduction

Pheochromocytoma is a rare neuroendocrine tumor with a prevalence ranging from 0.05% to 0.1%. Those tumors are usually diagnosed in young adults. However, they can also affect children and the elderly, with sporadic cases being more common in older patients. Giving the recent increases in life expectancy and improvements in imaging techniques, there has been an increase in the number of pheochromocytoma in the elderly.

Case presentation

An 85-year-old female patient was admitted to our endocrinology department for exploration of adrenal incidentaloma. She was followed for hypothyroidism and hypertension for 10 years now. The mass was discovered at an abdominal CT scan when the patient developed vomiting and abdominal pain. The mass was a heterogeneous 65 mm tumor of the left adrenal gland, with a spontaneous density of 55 UH and was in contact to the left renal vein. Biological explorations confirmed the presence of a pheochromocytoma with an elevated level of metanephrines and normetanephrines (5* the normal range). Treatment with doxazosin was administered for 2 weeks in preparation for surgery. A left adrenalectomy was performed without incidents. Histologically, the tumor was confirmed to be a benign pheochromocytoma. The follow-up showed a complete remission with a normal blood pressure and a normal level of plasmatic metanephrine.

Conclusion

Management of pheochromocytoma is delicate in the elderly population, giving the comorbidities associated. Thus, surgical removal should be made by an experienced multidisciplinary team to avoid post-operative complications. Meticulous preparation for surgery is crucial with a particular attention on maintaining balance between the adrenal disease and comorbidities.

Rare case of SIADH related hyponatremia in sarcoidosis

Bhavna Sharma & Mushtaqur Rahman
Northwick Park Hospital, United Kingdom.

Disorders of sodium metabolism in sarcoidosis are predominated by diabetes insipidus; SIADH is extremely rare, restricted to sporadic case reports. We present the case of a 68 year old South Asian female presenting with a 3 year history of chronic, mild hyponatraemia, which was asymptomatic apart from mild lightheadedness. She had a history of stable sarcoidosis that was not requiring treatment, based on lung pathology. Despite fluid restriction, serum sodium remained around 128 mmol/l; serum osmolality was 263 mOsm/kg, urine osmolality 296 mOsm/kg, and urine sodium 76 mmol/l. TSH was normal, 3.52 mIU/l. A Short synacthen test was normal: baseline serum cortisol of 497 nmol/l, rising at 30 mins to 809 and at 60 mins to 1002. IGF-1 and HbA1c were normal. Serum ACE was raised, 82U/L.A CT Chest/Abdomen/Pelvis revealed two calcified paratracheal lymph nodes and stable apical thickening in both lungs, with slightly more marked subpleural reticulation in right upper lobe of lung. An MRI scan of the brain showed no gross pituitary pathology. The patient was managed with oral slow-sodium 2 tabs bd and furosemide 20 mg od. In light of the hyponatremia, active management of the sarcoidosis was reconsidered in case of neurosarcoidosis and for this, an MRI scan of the brain with the use of gadolinium needs to be undertaken first

Spontaneous haemorrhage of an adrenal angiomyolipoma: case report

Paloma González Lázaro, Maria Zhao Montero Benitez, Cristina Montalban Méndez, Pedro Jimenez Torrecilla, Amparo Lomas Meneses & Ines Gomez García
La Mancha Centro Hospital Center, Endocrinology, Alcázar de San Juan, Spain.

Introduction

Angiomyolipomas are rare mesenchymal tumours arising from the perivascular epithelioid cells. They are benign endocrinologically inactive tumours with a histological structure consisting of variable amounts of adipose, thick-walled blood vessels and smooth muscle cells. Commonly, angiomyolipomas occur in the kidney with few extra renal case reports in adrenals.

Case Report

We report the case of a 76-year-old-man with personal history of hypertension and hypercholesterolemia, who presents as an incidental finding on ultrasound performed by urology due to an episode of acute urine retention, a 91 mm right adrenal mass, which on scan is suggestive of adenoma. The hormonal study (cortisoluria, metanephrines and aldosterone) was negative for functionality and, DHEA sulfate revealed normal results. Due to the large size, the patient underwent an open right adrenalectomy and was discharged home just over 1 week post-operatively without incidences. Histology showed a soft tissue tumour composed of mature adipose tissue, proliferating thick-walled vessels and in a smaller quantity proliferation of smooth muscle, with focal spindle and epithelioid cells Immunostains for Melan-A (Fig. 4) and HMB-45 were focally positive. Desmin and smooth muscle actin were also focally positive, confirming the presence of smooth muscle in the tumour, also there were present cystic areas occupied by devitalized tissue and fibrino-hematic material. These histological features are consistent with an spontaneous adrenal hematoma of an angiomyolipoma.

Discussion

This case report describes spontaneous haemorrhage of an adrenal angiomyolipoma picked up incidentally on imaging. A review of the literature revealed 18

previously reported cases of adrenal angiomyolipoma. Of these, 15 were sporadic and 3 were reported in patients with tuberous sclerosis or lymphangioleiomyomatosis]. There were 2 reported cases of spontaneous haemorrhage. Management of these lesions has been guided by the limited number of case reports in the literature. It is general consensus that smaller lesions detected incidentally should be managed non-surgically and their size should be kept under surveillance. Surgical management has been proposed for lesions which are either symptomatic and/or greater than 5 cm. Laparoscopic adrenalectomy has successfully been used, but larger lesions are best removed using open adrenalectomy

Conclusion

Adrenal angiomyolipomas are rare benign tumours that have the ability to reach a large size and potential to bleed. Here we report the 3er case reported on literature of spontaneous haemorrhage in an adrenal angiomyolipoma, which was successfully treated with open adrenalectomy.

Interference in aldosterone assay revealed by hemolysis.

Martine Deckers[1], Tamira Klooker[2], Jacquelien Hillebrand[3], Sjoerd van den Berg[4] & Prim de Bie[1]
[1]OLVG lab BV, Clinical Chemistry, Amsterdam, Netherlands; [2]Flevoziekenhuis, Internal Medicine, Almere, Netherlands; [3]Amsterdam UMC, Clinical Chemistry, Laboratory of Endocrinology, Amsterdam, Netherlands; [4]Erasmus MC, Internal Medicine, Rotterdam, Netherlands.

We report an interference in an immunoassay for aldosterone, which potentially could have led to a wrongful diagnosis and unnecessary surgery. The interference was serendipitously recognized due to a preanalytical error. A 59-year-old female patient with hypertension was referred to the department of endocrinology after an adrenal incidentaloma was detected. Because of her hypertensive history, screening for primary hyperaldosteronism was performed. An elevated aldosterone and a raised aldosterone/renin ratio was measured. To confirm the diagnosis of primary hyperaldosteronism a saline infusion test was performed. However, Aldosterone could not be reliably measured by our own immunoassay (Liaison XL) due to hemolysis in the sample taken after 2L saline infusion. This sample, together with the sample before infusion, was sent to our referral laboratory, where aldosterone was measured by LC–MS/MS. Low concentrations of aldosterone were measured by LC–MS/MS in both samples, rejecting the diagnosis hyperaldosteronism. Strikingly, the basal aldosterone concentration as measured by LC–MS/MS was much lower comparted to the concentration as measured by the Liaison XL immunoassay, raising suspicion of an assay interference. Confirmative testing with a repeat sample, using an additional immunoassay (Lumipulse 2100) and a dilution experiment all pointed towards a method specific interference in our own immunoassay. These results showed that the patient did not have primary hyperaldosteronism and that her incidentaloma was hormonally inactive. In retrospect, based on these results dynamic testing would not have been necessary. Surgical intervention was not performed and the patient was treated with antihypertensive drugs. Since in most laboratories aldosteron results from both screening and confirmative tests are derived from the same method, analytical interference in an immunoassay is difficult to detect. This especially holds true if there is a high clinical probability for primary hyperaldosteronism as in this case due to presence of hypertension and the finding of an adrenal incidentaloma. This may also explain the low number of publications on this type of interference in the literature.

Large adrenal tumor in paucisymptomatic ACTH – independent Cushing syndrome's patient – a clinical case

Maria-Alexandra Mohora[1], Raluca Trifanescu[1,2], Caragheorgheopol Andra[3], Iordachescu Carmen[3], Hortopan Dan[3] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania; [3]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania.

Background

Cushing's syndrome is represented by the cummulation of signs and symptoms of excess glucocorticoids and has many potential causes. Approximately 20 percent of all cases are represented by ACTH-independent adrenal tumors – with a majority of these being represented by cortisol secreting adrenal adenomas. Generally, a large adrenal tumor has over 5 cm in diameter and the risk of it being malignant raises proportionately with the dimensions. Large adrenal tumors are rare and the management and surgical indication is patient-specific.

Case report

A 20 years old female presented for weight gain (30 kg in the last 3 years), bradimenorrhea, hirsutism and treatment-resistant acne, referred by a dermatologist. Clinical exam revealed general obesity with little central redistribution, facial and shoulders pustular acne, vessel fragility (bruises and hematomas), purple axillary striae and hirsutism (Ferriman score = 29). Blood pressure was normal upon multiple examinations. The patient had upper-normal 0800 h cortisol values (19.19 μg/dl) with suppressed 0800 h plasma ACTH (1.05 pg/ml), with loss of circadian secretion rhythm (late-night serum cortisol – 15.8 μg/dl) and lack of cortisol suppression both after 1 mg overnight dexamethasone (17.8 μg/dl) and after 2 mg × 2 days dexamethasone suppression test (19.7 μg/dl). She also had increased free urinary cortisol levels (324 μg/24 h) and late-night salivary cortisol (19.1 nmol/l). She also had increased androgens (testosterone and androstenedione), with a FAI of 14, with upper-normal values of DHEA-S, without suppression after the dexamethasone dynamic tests. Glucose metabolism was normal, with normal HOMA-IR score. Abdominal MRI was performed, revealing a large left adrenal tumor 6.7/5.6/6.3 cm and a hypo-plastic right adrenal gland. **The diagnosis was** ACTH-independent Cushing syndrome due to adrenal tumor secreting cortisol and androgens, with radical-surgery indication.

Treatment

Taking into account the potential malignancy, the patient underwent open surgery. The histopathological examination revealed an 8/7/7 cm cortical adrenal adenoma, without any malignancy characteristics. The immunohistochemistry analysis is pending.

Follow-up

Postoperatively, the patient showed adrenal insufficiency. Five months later, the basal cortisol value was low (0.97 μg/dl) with a slighly raised value of ACTH (56.64 pg/ml). The MRI confirmed total removal of the left adrenal tumor and a slightly smaller right adrenal gland.

Conclusion

Despite having a large adrenal tumor, our young patient had a paucisymptomtic ACTH – independent Cushing syndrome. Morning cortisol values aren't enough to exclude hypercortisolism especially in young patients.

EP34

Single centre experience of assessment of adrenal incidentalomas – it's time for a change

Thin Kyi Phyu Naing, Husay Janebdar, Neetha Jose, Janak Saada, Mark Rochester, Khin Swe Myint & Rupa Ahluwalia
Norfolk & Norwich University Hospital, United Kingdom.

Background

Adrenal incidentalomas (AIs) refer to adrenal masses discovered on imaging performed for conditions unrelated to suspected adrenal diseases. In an ageing population with improving radiological modalities, the detection of AIs has increased. While most are benign, non-functioning adenomas, some may represent functioning and/or malignant disease including adrenal carcinoma. Investigating AIs can be time-consuming and anxiety-inducing for patients, while under-investigation can result in missing life-threatening diagnoses. Thus, AI investigation pathways should be streamlined to achieve both efficiency and cost-effectiveness.

Method

A review of management of AIs was conducted in a large, tertiary centre within the United Kingdom. The size and laterality of lesions including attenuation, functional status and multidisciplinary team (MDT) meeting outcomes were assessed. This is an ongoing audit and the full data analysis will be available at the time of presentation.

Results

A total of 182 patients with AIs were referred between 2019 and 2022. 91 patients were seen in 2021, the data for which is presented below.

Discussion

Under current hospital guidelines, (based on the European Society of Endocrinology's 2016 recommendations), all patients with AIs undergo biochemical testing and clinical assessment followed by discussion at the adrenal MDT meeting. Similar to published evidence, our data demonstrates that the majority of AIs are benign and non-functioning (84%). Thus, the investigation pathway should be remodelled to avoid unnecessary clinic appointments. For those with benign, non-functional adenomas, a nurse-led or virtual consultation could be offered. Face-to-face appointments for further examination and treatment should be reserved for those with functioning and/or malignant lesions.

Given the low risk of malignancy or functional lesions amongst AIs and the expected rise in incidence of reported AIs, it's imperative to optimise current practice and avoid further strain on clinical services.

Carbohydrate metabolism disorders in patients with Addison's disease

Dhoha Ben Salah, Khouloud Boujelben, Asma Zargni, Mouna Elleuch, Maalej Souhir, Mouna Mnif, Mnif Fatma, Nadia Charfi, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Diabetology and Endocrinology Department, Sfax, Tunisia.

Introduction
In adults with Addison disease, over glucocorticoid replacement therapy is associated with an increased morbidity and decreased life expectancy, related to low bone mineral density and cardiometabolic outcomes. The aim of our study was to assess the prevalence of carbohydrate metabolism disorders in patients with Addison disease and identify its predictive factors.
Patients and methods
A cross sectional study including 50 patients diagnosed with Addison disease with a mean duration of glucocorticoid replacement of 13.9 years. Biochemical markers of glucose metabolism were evaluated.The prevalence of type 2 diabetes and its complications were analyzed. Patients presenting type 1 diabetes were excluded from our study.
Results
The mean age of patients was 49.5 ± 13.9 years (18–78 years) with significant female predominance and a sex ratio of 0.25.High blood pressure (52%) and diabetes mellitus (52%) were the most common family histories. Mean fasting blood glucose at the diagnosis of Addison disease was 4.6 ± 0.6 mmol/l (3.6–5.4 mmol/l). Mean glycated hemoglobin (HbA1c) was 4.6 ± 0.7%(3.8–5.5%).No patient had prediabetes nor diabetes at the diagnosis. At the time of our study, disorder of carbohydrate metabolism was found in over a third of patients (38%) after a mean duration of Addison disease of 17.5 ± 5.4 years (4–35 years).Among those patients, 31.6% had type 2 diabetes. Diabetic retinopathy occurred in 2 patients and one patient complained of diabetic neuropathy. Daily and cumulative dose were higher in patients with diabetes compared to those with normal blood sugar level (27,5 ± 5 mg/day versus 25.6 ± 6.9 mg/day; 506.2 ± 277.2 mg versus 355.4 ± 282.9 mg) without significant difference. As well, longer Addison disease duration was found in patients presenting diabetes compared to those with a normoglycemia (19.8 ± 9.9 versus 13.2 ± 8.4 years; $P = 0.1$).
Conclusion
At the present time, despite of the worldwide availability of replacement therapy in Addison disease, exposure to supraphysiological dose of corticosteroids leads to altered insulin secretion and decreased hepatic and muscular insulin sensitivity, that result in risk exacerbation of carbohydrate metabolism disorders.

Evaluation of the efficacy of osilodrostat in five patients with Cushing's syndrome: A single-center study

Naoko Hashimoto[1], Satomi Kono[2], Takashi Kono[1], Shimatsu Akira[3], Alberto Pedroncelli[4] & Tomoaki Tanaka[2]
[1]Chiba University, Department of Molecular Diagnosis, Graduate School of Medicine, Chiba, Japan; [1]Chiba University, Department of Molecular Diagnosis, Graduate School of Medicine, Chiba, Japan; [3]Omi Medical Center, Kusatsu, Japan; [4]Recordati AG, Basel, Switzerland.

Context
Osilodrostat (Osi), a potent inhibitor of 11β-hydroxylase, blocks the conversion of 11-deoxycortisol to cortisol and improves hypercortisolism in patients with Cushing's syndrome (CS). Here, we report a study evaluating the efficacy of Osi in five non-Cushing's disease (CD) CS patients treated with Osi in Japan.
Subjects and Results
Five patients with non-CD CS were treated with Osi at Chiba University [primary disease breakdown: 4/5 patients with adrenal Cushing's syndrome (cortisol-producing adenoma (CPA): 3, primary macronodular adrenal hyperplasia (PMAH): 1) and 1 with an adrenocorticotropic hormone (ACTH)-producing tumor originating from the thymus]. The mean age was 38.4 years, the male to female ratio was 1:4, and the mean duration of treatment was 3.4 months for the 3 patients who underwent CPA surgery after receiving Osi, 15 months for the patient with an ACTH-producing tumor and 18 months for the patient with PMAH. The maximum dose of Osi ranged from 4 mg/day to 10 mg/day. Three patients had been treated with metyrapone before Osi was administered. The maximum dose of metyrapone ranged from 1000 mg/day to 5000 mg/day. Osi was administered after approximately one-month wash-out period. The mean urinary free cortisol level before administration was 2162 μg/day (251-5420), which decreased markedly to a mean of 13 μg/day (8.3-20.6) after treatment, all of which were normalized. Laparoscopic surgeries were performed safely. The major adverse events were related to the Osi mechanism of action, such as adrenal insufficiency/hypofunction and fatigue, and no grade 4 adverse events were observed. The three patients with CPA were cured by surgery after preoperative Osi administration. None of the patients discontinued Osi because of safety.
Conclusion
Osi efficiently normalized symptoms and rapidly and persistently lowered urinary cortisol levels in patients with CS due to adrenal or ectopic ACTH. Our findings show that Osi is an effective treatment option and contributes to safely undergoing surgery for CPA patients.

Clinical sexual dimorphism in patients with nonfunctioning adrenal incidentaloma

Antoan Stefan Sojat[1], Miomira Ivovic[2], Ljiljana Marina[2], Bogdan Dugic[3], Milina Tancic-Gajic[2], Zorana Arizanovic[1], Dunja-Simona Petkovic[4], Kristina Saravinovska[4], Tijana Petkovic[1], Natalija Antic[1], Aleksandra Kendereski[2] & Svetlana Vujovic[2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Obesity, Metabolic and Reproductive Disorders, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Department for Obesity, Metabolic and Reproductive Disorders, Belgrade, Serbia; [3]School of Electrical Engineering, University of Belgrade; [4]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
The incidence of adrenal incidentaloma (AI) increases with age. According to epidemiological studies they are more frequent in women than in men.
Aim
The aim was to determine the possible clinical sexual dimorphism in patients with nonfunctional adrenal incidentaloma (NAI).
Patients and methods
This was an observational, cross-sectional study of 381 patients with AI that were functionally assessed in our Clinic. After exclusion of patients with overt adrenal hyperfunction, malignancy, cysts and patients with (possible) autonomous cortisol secretion the studied group consisted of 195 patients with NAI: 129 female and 66 males. Based on average menopause age of 51, we stratified women in two groups: < 51 and $\geqq 51$. For the sake of comparison, we age-matched the male group, and evaluated differences in body mass index (BMI), adrenal tumor size (ATS), localization, ACTH, 24 h cortisol, 1 mg dexamethasone suppression cortisol (1 mg DST), and prevalence of hypertension (HTA) and type 2 diabetes mellitus (T2DM).
Results
Female sex was predominant in the whole NAI cohort (F/M %: 66.1/33.8) as well as in both age groups (< 51, 44 patients – F/M %: 61.3/38.6 and $\geqq 51$, 151 patients – F/M %: 67.5/32.4) with no difference in gender frequency between younger and older patients. There was no difference in age, BMI, ATS, localization, ACTH, 24 h cortisol, 1 mg DST cortisol, HTA and T2DM prevalence between female and male patients. Upon stratification by age, older female patients had significantly higher BMI ($P=0.002$), higher 24 h cortisol ($P=0.017$) and more prevalent T2DM ($P=0.003$) than younger female patients, while HTA was equally prevalent in both female groups. In a linear regression, BMI was the most significant predictor of HTA in premenopausal female patients ($B=0.552$, 95%CI $B=0.006$–0.102, $P=0.028$).
Conclusion
Despite younger age and significantly lower BMI in premenopausal women with NAI, the frequency of HTA was the same as in the menopausal group with BMI being the most significant predictor. Our results add to the body of evidence that female gender plays a role as a cardiometabolic risk factor in NAI patients indicating the existence of clinical sexual dimorphism in patients with NAI.

Endocrine emergencies during Ramadan

Yousra Settai, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC IBN ROCHD, Endocrinology and Metabolic Disorders, Casablanca, Morocco.

Introduction
Ramadan, the holy month of fasting, is a stressful period that exposes to endocrine disturbances, which may decompensate some endocrinopathies or precipitate their revelation.
Objectives
To evaluate the incidence of endocrine emergencies during the month of Ramadan, and thus the risk of endocrine decompensation related to fasting.
Materials and methods
This is a prospective study conducted in the department of endocrinology and diabetology, including 47 patients who consulted for endocrine emergencies during Ramadan, in the period from April 13 to May 12, 2021. Data analysis was performed using SPSS version 25 software.
Results
The average age of our patients was 39 years (18–70 years), with a sex ratio of 3:1. Young people represented 78.7%. Before the month of fasting, 68% of the patients were known to have endocrinopathy (hyperthyroidism, hyperparathyroidism, adrenal insufficiency), 43% of whom admitted poor compliance with their treatment during Ramadan. Hyperthyroidism predominated in 48.9%, with 25.5% of acute adrenal insufficiency, 21.2% of acute hypocalcemia, and 4.2% of acute hypercalcemia. In 63.9% of the patients, no decompensation factor other than fasting was identified. Other causes were mainly pancreatitis (34%), underlying heart disease (16%), urinary tract infections (11%), and other causes (cholecystitis, tuboovarian abscess, pneumocystis, Guillain-Barré syndrome).
Conclusion
Ramadan fasting is a sacred ritual for Muslims, but it is not without risks since it exposes to hormonal disturbances that can reveal or decompensate certain endocrinopathies. Hence the need for a pre-Ramadan consultation to adapt the treatment and to discuss the possibility of fasting, with close follow-up during the holy month, to avoid the risk of complications.

Hypertension during pregnancy: A diagnosis that should not be overlooked.

Wiem Saafi, Taieb Ach, Asma Ben Abdelkarim, Ghada Saad, Hamza Elfekih, Yosra Hasni, Maha Kacem, Molka Chaieb, Amel Maaroufi & Koussay Ach
Farhat Hached University Hospital, Endocrinolgy, Sousse, Tunisia.

Introduction
Hypertension disorders during pregnancy constitute a significant cause of maternal and perinatal mortality worldwide. Paragangliomas represent a rare cause of hypertension in gestation. The management of these endocrine tumors can be challenging, especially when diagnosed during pregnancy. We describe a case of a paraganglioma discovered in a pregnant woman.
Case report
We report the case of a twenty-seven-year-old female patient who presented to our endocrinology department with gestational diabetes when she was 27 weeks pregnant. At 20 weeks of gestation, she was explored for high blood pressure, and the diagnosis of gestational hypertension was retained and treated with calcium inhibitors. The patient continued to have elevated blood pressure with typical signs of the Menard triad. A pheochromocytoma was then suspected. Plasma metanephrine levels were twelve times above the normal range. Since the patient was pregnant, MIBG scintigraphy could not be practiced. Thoracic and abdominal MRI showed a retroperitoneal and right latero-aortic mass of 3.5 cm. The diagnosis of paraganglioma was established, we treated the patient with alpha-blockers. As for her diabetes, she required insulin therapy. Surgical treatment was postponed. She had regular control of her hypertension and diabetes. The obstetrical ultrasound did not show any abnormalities during control. The patient had cesarean delivery at 38 weeks of gestation with a positive outcome.
Conclusion
Paraganglioma represents a rare cause of hypertension during pregnancy. The association between hypertension and diabetes should be alarming, especially during the first weeks of gestation. The early diagnosis of this situation can make its management less complicated.

Pheochromocytoma with subclinical and adrenocorticotropic hormone-independent Cushing Syndrome

Elyes Kamoun[1,2], Ibtissem Ben Nacef[1,2], Sabrine Mekni[1,2], Youssef Lakhoua[1], Nadia Mchirgui[1,2], Imen Rojbi[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia.

Introduction
Adrenal incidentaloma prevalence is rising with the advancement of imaging techniques. The hormonal work-up should always include free metanephrines for the diagnosis of a pheochromocytoma and 1 mg overnight dexamethasone suppression test for the diagnosis of autonomous cortisol secretion. These tumors have two distinct embryologic origin and don't usually coexist, and when they do, it occurs in case of an ectopic adrenocorticotropic hormone (ACTH) production by the pheochromocytoma. We herein describe a pheochromocytoma with an ACTH-independent possible autonomous secretion of cortisol.

Observation
We report the case of a 57 years old woman, with a history of an insulin-treated type 2 diabetes mellitus, high blood pressure treated with captopril and amlodipine, atrial fibrillation treated with beta-blockers and vitamin K antagonists, referred to our department for an adrenal incidentaloma. It was a left adrenal mass measuring 28*23*32 mm with a spontaneous density of 28HU, an absolute washout of 71% and relative washout of 40%. She didn't have any clinical sign of pheochromocytoma or Cushing syndrome. On laboratory investigation, she had a glycated hemoglobin of 8,7%, a low potassium level at 3.4 mmol/l and TSH levels at 1.38 µUI/ml. Adrenal hormonal work-up found urinary fractionated metanephrines levels at 364 nmol/creatinine (3*normal) and urinary fractionated normetanephrines levels at 463 nmol/creatinine (1.65*normal) confirming the diagnosis of pheochromocytoma. Cortisol levels after 1 mg overnight dexamethasone suppression test were at 87 nmol/l, confirming a possible autonomous secretion of cortisol with ACTH levels inferior to 5 pg/ml excluding an ectopic secretion of ACTH. Aldosterone and renin levels were assessed and a secondary hyperaldosteronism was discovered with aldosterone levels at 740 pmol/l, renin levels at 53 pg/ml and aldosterone/renin ratio at eight. Sex hormones and steroid precursors were normal. The diagnosis of a corticomedullary mixed tumor of the adrenal gland is suspected in our patient. Complementary work up didn't find osteoporosis, calcitonin and calcium levels were normal, transthoracic echocardiography concluded to a concentric hypertrophy of the left ventricule. The patient was put under alpha blockers and was referred to surgery.
Conclusion
This case illustrates the presentation of a corticomedullary mixed tumor, which is a rare adrenal tumor presenting as a pheochromocytoma with an ACTH-independent cortisol production. The pre and peri operative management includes the management of a pheochromocytoma and an autonomous cortisol secretion. Confirmation of this diagnosis relies on histology and immunohistochemistry.

Papillary stasis edema revealing arterial hypertension in the context of an 11beta-hydroxylase deficiency

Rekik Mona[1], Kammoun Sonda[1], Ayedi Omar[1], Faten Haj Kacem Akid[2], Ben Amor Saloua[1] & Trigui Amira[1]
[1]Habib Bourguiba Hospital, Department of Ophthalmology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia.

Introduction
11-Hydroxylase deficiency is a rare form of congenital adrenal hyperplasia characterized by glucocorticoid deficiency, hypertension, hypokalemia and virilization in females. We report a case of congenital adrenal hyperplasia due to 11beta-hydroxylase deficiency revealed by bilateral papilledema in the context of arterial hypertension.
Case report
A 13-year-old patient, with no medical history, presented with complains of headache, vomiting and bilateral visual blurring. Visual acuity was 10/10 in both eyes. The fundus examination showed bilateral papilledema. Brain magnetic resonance imaging was normal. The blood pressure was at 17/10. Holter monitoring of blood pressure revealed high blood pressure levels. The patient also presented with hirsutism. The etiological assessments concluded with an adrenal enzymatic block caused by 11-hydroxylase deficiency. The patient was successfully treated with glucocorticoids.
Discussion
11beta-hydroxylase deficiency is the second cause after 21-hydroxylase deficiency of congenital adrenal hyperplasia, and accounts for about 5 to 8% of cases. 11beta-hydroxylase deficiency is clinically manifested by a syndrome of hyperandrogenism associated with arterial hypertension found in two out of three patients with this anomaly. In this case, the condition was revealed by bilateral stasis papilledema associated with arterial hypertension. Indeed, papilledema is the clinical expression of various conditions in children. Its management is urgent because vital and visual prognoses can be engaged. Stasis edemas are caused by general conditions, the leader of which is intracranial hypertension, whatever its etiology. A second cause that should not be overlooked is represented by malignant hypertension.
Conclusion
Papilledema in children poses many problems, including diagnostic ones. Its management is urgent because vital and visual prognoses can be engaged. The diagnosis and the treatment can be multidisciplinary involving ophthalmologist, radiologist and neuropediatrician and endocrinologist.

Giant non-functioning adrenocortical carcinoma – the elephant in the room

Sing Yang Sim[1], Jana Bujanova[2], Matthew Hayes[2], Charles Tilley[2], Simon Crabb[2] & Lorena Arnez[1]
[1]St Mary Hospital, Diabetes and Endocrinology, Isle of Wight, United Kingdom; [2]University Hospital Southampton, Southampton, United Kingdom.

Adrenocortical carcinoma (ACC) is a rare malignancy with an incidence of 0.7–2.0 cases/million habitants/year, often with a dismal prognosis. Patients present with abdominal symptoms or symptoms of hormone excess. However, 15% are diagnosed incidentally. (1) A 59y male was referred with progressive lethargy, weight loss, dyspepsia and abdominal distension over the past 2 years. He was dismissive of 'the elephant in the room' and in denial. He was pushed to seek medical attention by his family when abdominal mass and cachexia could no longer be ignored. His weight was 63 kg, BMI 20.2 kg/m^2. He looked emaciated with no Cushing's stigmata.There was a large firm mass on the entire left half of his abdomen extending midline. CT chest/abdomen/pelvis showed 23 cm mass arising from the left adrenal gland, heterogenous with punctate calcification and central necrosis. Mass was hormonally non-functional apart from incomplete cortisol suppression on 1 mg overnight dexamethasone suppression test – 86 nmol/l ($<$50).
Results
Normetanephrine 1.67 µmol/24 h (0–3), Urine metanephrine 0.49 µmol/24 h (0–1.40), Urine 3-methoxytyramine 0.75 µmol/24 h (0.57–2.39), DHEA 12.9 µmol/l (1.3–9.8), testosterone 4.8 nmol/l, androstenedione 12.2 nmol/l (2.8–10.5), SHBG 30.9 nmol/l (15–48), FAI 13.9 (34–106), 17OHP 2.2 nmol/l, aldosterone renin ratio 30 pmol/mIU.
FDG PET CT showed a large avid necrotic left upper abdominal mass with SUV max 7 inseparable from the left adrenal gland. He underwent an open adrenalectomy. 6 kg organised mass with central necrosis was fully excised measuring 37$\times$21$\times$21 cm. Post-operative period was complicated by hyponatraemia despite Hydrocortisone cover. Histology showed positive staining for calretinin, inhibin and melan-A. Staining for PAX8, S100, chromogranin was negative. The appearances were consistent with ACC, Weiss Score 5 and ki-67-5.9%, T1, N0, M0, R0. Post-operatively he was very well, off steroids and back at work part-time. He was offered adjuvant mitotane but decided not to receive it. His circumstances were borderline-he did not meet ESMO guidelines for mitotane, although the ESE guidelines would suggest, that it could be considered 'on a case-by-case basis'.
Conclusion
To our knowledge, this is the largest and the second heaviest ACC ever reported. This case highlights a very wide heterogenicity in ACC behaviour from a very aggressive to indolent disease. A combination of patient psychological factors leading to delayed presentation and indolent behaviour of this ACC allowed it to reach colossal proportions, something we are unlikely to see again.

Clinical case: adrenal cortical carcinoma

Vita Lizdeniene[1], Saule Cyrolyte[2], Ieva Meskinyte[2], Darius Pranys[3] & Raimonda Klimaitę[4]
[1]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Department of Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Hospital of Lithuanian University of Health Sciences, Kauno klinikos, Department of Pathology, Kaunas, Lithuania; [4]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Adrenal cortical carcinoma (ACC) is a rare and aggressive malignancy. Most patients (80%) are asymptomatic at the time of diagnosis. ACC generally has a poor prognosis with a 5-year survival rate of 20–25%.
Case
A 37-year-old man came to the Hospital of Lithuanian University of Health Sciences Kaunas Clinics for general weakness, fatigue, intermittent abdominal pain, and weight loss ($\sim$ 10 kg in 9 months). During the abdominal US, the mass in the right adrenal gland was found. Physical examination: no clinical signs of hypercortisolemia and no changes in other endocrine systems were observed.

Laboratory tests
Diagnosis of pheochromocytoma and primary hyperaldosteronism excluded. 26.10.20 – 1 mg of Dexamethasone test – no suppression of cortisol was detected, low-dose and high dose Dexamethasone suppression tests – pathologic (Table 1).
Abdominal CT
In the right adrenal gland – ∼ 4.6×4.1 cm mass, non-homogeneous with microcalcifications, unevenly accumulates contrast. Laparoscopic right adrenalectomy was performed.
Macroscopic examination
Right adrenal gland 7.5×5×4 cm, in incisions yellowish 5×4.5×3.1 cm mass.
Microscopic examination
About 50% of the tumor consists of cells, which layout in lobular and alveolar structures. Cells are medium-sized with round, chromatic nuclei and a moderately abundant, mildly eosinophilic cytoplasm. Another component of the tumor takes up to 3.0 cm of the tumor itself and is formed by polymorphic medium-sized and large atypical cells with highly accentuated, polymorphic, and chromatic nuclei. The cells have mildly eosinophilic cytoplasm of varying abundance. Part of the tumor cells is monstrous. Narrow areas of tumor necrosis and wide inclusions of fibrous tissue were found. No overgrowth of the fibrous adrenal capsule was found.
Conclusion:
adrenal cortical carcinoma against the background of cortical adenoma pT1 Nx Mx LVI R0.
Chest and abdominal CT
Right adrenal gland is removed, no signs of metastases were observed, left-without changes.
DXA
Osteopenia. MEN1, Beckwith-Wiedemann, and Lynch syndromes were ruled out by genetic tests. Post-operative treatment included Hydrocortisone 20–30 mg/d replacement therapy. Renin, aldosterone, cortisol (in the background of Hydrocortisone use), ACTH, electrolytes – all in the normal range (Table 1).
Conclusion
Non-functioning adrenal carcinoma and its nonspecific clinic may be a challenge in the diagnosis of the disease and require careful clinical examination. Nonspecific clinics of adrenal cortical carcinoma can often lead to a late diagnosis, leading to local and systemic progression of the disease.

Lipid profile in patients with Addison disease

Dhoha Ben Salah, Khouloud Boujelben, Abdelmouhaymen Missaoui, Faten Haj Kacem Akid, Mouna Mnif, Mnif Fatma, Nadia Charfi, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Sfax-Tunisia, Department of Endocrinology, Diabetology.

Introduction
Long-term glucocorticoid replacement therapy in patients with Addison disease has been linked to an increased cardiovascular risk and consequent mortality. Our objective was to determine the frequency of dyslipidemia in patients with Addison disease and its potential predictive factors.
Patients and methods
This was a cross-sectional study, performed in the department of endocrinology in Hedi Chaker hospital –Sfax –Tunisia. Fifty patients with Addison disease were recruited between March 2020 and July 2021.Lipid profile at time of disease diagnosis and after glucocorticoid replacement was analyzed.
Results
The mean age of our patients was 49.5 ± 13.9 years (18–78 years).The female sex was the most affected with a sex ratio of 4. The disease duration was 13.9 ± 8.7 years on average with extremes between 5 and 35 years. Lipid profile at time of Addison disease diagnosis was normal in 81.5% of patients. For those presenting disturbed lipid balance, there were isolated hypercholesterolemia in two patients, hypertriglyceridemia in one patient and mixed dyslipidemia in 2 patients. At the time of our study, the prevalence of hyperlipidemia was 16% (8 patients), occurring after a mean duration of glucocorticoid replacement therapy of 13.6 years. The alterations in the lipid balance observed were mixed dyslipidemia in 5 patients, isolated hypercholesterolemia in one patient, hypertriglyceridemia in 2 patients and low HDL-cholesterol level in 5 patients. Among those patients, five patients were treated with statins and 2 patients with fibrates. One patient was on healthy diet. All lipid parameters increased at the time of the study compared to lipid profile at time of disease diagnosis: Total cholesterol level:4.3 ± 0.9 mmol/l vs 3.7 ± 1 mmol/l;Triglyceride level: 1.6 ± 1 mmol/l vs 1.2 ± 0.7 mmol/l;HDL-cholesterol level:1.4 ± 0.3 mmol/l vs 1.1 ± 0.5 mmol/l;LDL-cholesterol level:2.4 ± 0.6 vs 2 ± 0.6 mmol/l. There were no significant correlation between hyperlipidemia and cumulative hydrocortisone dose nor duration of glucocorticoid replacement therapy.
Conclusion
Our findings highlight the importance of controlling lipid status in patients with Addison disease. Identifing patients at risk of lipid metabolism disorders at the preclinical phase seems imperative to reduce cardiovascular complications of long-term glucocorticoid replacement therapy.

Metabolic syndrome in patients with Addison disease

Dhoha Ben Salah, Khouloud Boujelben, Abdelmouhaymen Missaoui, Mouna Elleuch, Mnif Fatma, Mouna Mnif, Nadia Charfi, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Department of Endocrinology, Diabetology, Sfax, Tunisia.

Introduction
Inadequate glucocorticoid replacement therapy in Addison disease leads to an increased risk of both cardiovascular disease and metabolic syndrome. The metabolic effects of long-life corticosteroid exposure are due to physiological mechanisms that are associated with carbohydrate metabolism disorder, dyslipidemia and insulin resistance. In this study, we aimed to determine the prevalence and predictive factors of metabolic syndrome in patients with Addison disease.
Patients and methods
A cross sectional study performed between March 2020 and July 2021, including 50 patients with Addison disease. Metabolic syndrome was assessed by referring to the National Cholesterol Education Program-Adult Treatment Panel III.
Results
Mean age was 49.5 ± 13.9 years (40 females versus 10 males). Average duration of the disease was 13.9 ± 8.7 years (5–35 years). All patients were on hydrocortisone replacement, taking daily 27.4 ± 6.7 mg (15–42.1 mg). The average weight was 72.5 kg (62–107 kg).Progressive weight gain was observed in 70% of patients. This gain was more pronounced during the first year of follow-up and estimated at 7.4 kg on average. Mean Body Mass Index (BMI) was 28.1 kg/m^2 (21,2–45,8 kg/m^2).Twenty four (48%) patients were obese. Mean waist circumference was 107 ± 11.8 cm (65–121 cm) for woman and 105.1 ± 9.6 cm (64–119 cm) for men. Android fat distribution was found in 60% of patients versus 12% at time of diagnosis. Glucose intolerance was found in over a third of patients (38%).Among those patients, 31,6% had type 2 diabetes. Hypertriglyceridemia was found in 2 patients. Five patients had low HDL-cholesterol level. Metabolic syndrome was found in 24% of patients versus only one patient at time of diagnosis. No significant correlation was identified between Addison disease duration and the occurrence of metabolic syndrome. Daily hydrocortisone dose was significantly higher among patients having metabolic syndrome ($P = 0.04$).As well, cumulative hydrocortisone dose was higher among those patients but without significant difference ($P = 0.5$).
Conclusion
Similarly, to anti-inflammatory corticotherapy, a broad range of metabolic effects including insulin resistance and profound alterations in carbohydrate and lipid metabolism impedes glucocorticoid replacement therapy.

Ovarian cyst in woman treated with mitotane, side effects not to be ignored

Mouna Mezoued, Bessaid Khadidja & Malha Azzouz
Bologhine Hospital, Endocrinology, Alger, Algeria.

Introduction
Mitotane is an adrenolytic drug that is used as an adjuvant to treat adrenocortical carcinoma, The side effects of lysodren are numerous, but some of them are less known. We report a case of ovarian cyst in a woman of childbearing age. It is a 26 years old patient treated with Lysodren® for a locoregional recurrence of an adrenal cacinoma stage II of the ENSAT. After 9 months of treatment, the patient presented an amenorrhea, with the appearance of a large ovarian cyst of 50 mm, detected on the follow-up CT scan, which initially led to the suggestion of a recurrence. At presentation, FSH, luteinizing hormone (LH), were within the normal range, The levels of marker CA-125, occasionally controlled, remained normal. The cyst spontaneously disappeared 6 months after having stopped the treatment, and the patient became spontaneously pregnant having an uncomplicated delivery 2 years later.

Conclusion
Therapeutic concentrations of mitotane could be associated with the presence of benign ovarian cysts and amenorrhea, up to 50% of women. It is of clinical importance to be aware of this unwanted effect of mitotane, because finding a growing ovarian mass induces anxiety and may conduce to a misdiagnosis of ACC progression.

Morning cortisol and circulating inflammatory cytokine levels: a mendelian randomisation study

Skanda Rajasundaram[1,2], Rezbieara Rahman[3], Benjamin Woolf[4], Steven Zhao[5] & Dipender Gill[3,6,7]
[1]Kellogg College, University of Oxford, Oxford, United Kingdom; [2]Imperial College London, Faculty of Medicine, London, United Kingdom; [3]St George's, University of London,, Clinical Pharmacology and Therapeutics Section, Institute for Infection and Immunity, London, United Kingdom; [4]University of Bristol, Medical Research Council (MRC) Integrative Epidemiology Unit, Bristol, United Kingdom; [5]The University of Manchester, Manchester Academic Health Science Centre, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Science, Manchester, United Kingdom; [6]Imperial College London, Department of Epidemiology and Biostatistics, London, United Kingdom; [7]Novo Nordisk Research Centre Oxford, Old Road Campus, Oxford, United Kingdom.

Background
Cortisol is an essential steroid hormone released from the adrenal gland. Plasma cortisol levels follow a circadian rhythm under the control of the Hypothalamic–Pituitary–Adrenal axis, reaching peak levels in the morning. Cortisol has long been known to exert immunosuppressive effects and accordingly, glucocorticoids are central in treating inflammatory disease. Cortisol's propensity to downregulate certain pro-inflammatory cytokines and upregulate other anti-inflammatory cytokines is well-established. However, there remain gaps in our mechanistic understanding of how cortisol modulates various cytokines. Historically, studies have focussed on a small number of relatively well-established cytokines yet the effect of cortisol on many other cytokines remains uncertain.
Methods
Leveraging data from the CORtisol NETwork ($N=25\,314$) and FINRISK ($N=8293$) genome-wide association studies, we used two-sample Mendelian Randomisation (MR) to investigate the causal effect of genetically proxied increased morning cortisol levels on 42 circulating cytokines. MR utilises genetic variants in an instrumental variable framework to make causal inferences. By virtue of Mendel's Law of Segregation and Law of Independent Assortment, the inheritance of genetic variants is random. Furthermore, germline genetic variation corresponding to levels of morning cortisol and circulating cytokines is non-modifiable by the environment and temporally precedes the onset of clinically detectable changes in circulating cytokine levels. Thus, under specific assumptions, MR offers a method of investigating the causal effect of a morning cortisol on a comprehensive range of cytokines that is less vulnerable to confounding and reverse causation biases in comparison to traditional observational studies.
Results
Increased genetically proxied morning cortisol levels were associated with reduced levels of Interleukin 8 (IL-8) and increased levels of Macrophage Migratory Inhibitory Factor (MIF). A 1 s.d. increase in genetically proxied morning cortisol levels corresponded to a 0.767 normalised SD-unit decrease in IL-8 ($P=1.14\times10^{-4}$, 95% CI $=-1.157$ to -0.378) and a 0.806 normalised SD-unit decrease in MIF ($P=3.68\times10^{-5}$, 95% CI $=-1.189$ to -0.423). These findings remained statistically significant after applying the Bonferroni correction for multiplicity.
Conclusions
These results provide mechanistic insight into the immunomodulatory effects of cortisol. Clinically, our findings underline the therapeutic importance of steroids in inflammatory conditions where IL-8 and MIF play central roles in the pathophysiology of disease, e.g. Inflammatory Bowel Disease, Rheumatoid Arthritis and Systemic Lupus Erythematosus. Moreover, IL-8 and MIF may represent alternative therapeutic targets in these conditions, which could avoid some of the adverse effects of long-term glucocorticoid therapy.

Fibrin clot properties and fibrinolysis in Cushing's syndrome

Christina Berr[1], Ewa Warchoł-Celińska[2], Julia Fazel[3], Anetta Undas[4,5,6] & Aleksander Prejbisz[2]
[1]Department of Endocrinology, I. Medical Clinic, University Hospital, University of Augsburg, Augsburg, Germany; [2]Department of Hypertension, National Institute of Cardiology, Warsaw, Poland; [3]Medizinische Klinik und Poliklinik IV, Klinikum der Ludwig-Maximilians-Universität München, München, Germany; [4]Innovative Laboratory Diagnostic Centre, John Paul II Hospital, Cracow, Poland; [5]Cracow Centre for Medical Research and Technologies, John Paul II Hospital, Cracow, Poland; [6]Department of Invasive Cardiology and Angiology, National Institute of Cardiology, Warsaw, Poland.

Background
Cushing's syndrome (CS) and hypertension (HT) are associated with alterations of coagulation. This is the first study that compares parameters of fibrin clot and fibrinolysis in CS with patients with essential hypertension (EHT) and healthy normotensive controls (HC).
Methods
The patients were recruited at the university hospital of Ludwig-Maximilians-Universität München (Germany) and the Department of Hypertension, Institute of Cardiology, Warsaw (Poland). We analyzed 31 patients (mean age: 42.9 ± 13.2 years, 25 females, 86% HT) with active CS (n = 25) and subclinical CS ($n=6$). They were compared with 31 age, sex and BMI matched patients with EHT (mean age: 44.3 ± 12.7 years, 25 females) and 31 age and sex matched HC (mean age: 43.8 ± 12.8 years, 25 females). The following variables were assessed: plasma fibrin clot permeability (Darcy's constant, Ks), clot lysis time (CLT) and a kinetics profile of thrombin generation i.a. the endogenous thrombin potential (ETP) with the use of a calibrated automated thrombogram. Immunoenzymatic and chromogenic assays were used to determine plasminogen activator inhibitor-1 (PAI-1) and plasma-activated thrombin-activatable fibrinolysis inhibitor antigen (TAFI).
Results
Fibrin clot structure in patients with CS is less dense in comparison to EHT, but comparable to HC (median Ks in CS 6.98 [5.53–8.91] vs. EHT 4.68 [3.96–6.11] 10^{-9} cm^2, $P<0.001$; CS 6.98 [5.53–8.91] vs. HC 7.89 [7.19–8.36] 10^{-9} cm^2, $P=0.09$). Higher density is generally found in patients with higher cardiovascular risk. Fibrin clot structure was most resistant to lysis in EHT (median CLT CS 97.10 [90.0–113.6] vs. EHT 110.5 [95.8–126.3] vs. HC 93.8 [79.2–104.0] min, CS vs. EHT $P<0.039$). Furthermore, CS patients present with a higher ETP as compared to healthy controls, but in EHT this is even more pronounced (median ETP in CS 1753.3 [1370.2–1881.4] vs. EHT 2087.6 [1946.0–2394.4], nM*min, $P<0.001$; CS 1753.3 [1370.2–1881.4] vs. HC 1132.6 [1048.1–1256.6] nM*min, $P<0.001$). Proteins inhibiting fibrinolysis such as PAI-1 and TAFI are significantly higher in CS than in EHT (mean PAI-1: CS 49.22 ± 26.43 vs. EHT 24.44 ± 23.79 ng/ml, $P<0.001$; mean TAFI: CS 131.25 ± 13.86 vs. EHT 95.03 ± 26.59 AG %, $P<0.001$).
Conclusion
Despite an overlap of hypertension in CS and EHT, we observe significant differences in fibrin clot structure and fibrinolysis in both entities. Fibrin clot density, CLT and ETP are more altered in EHT than in CS, whereas proteins inhibiting fibrinolysis are higher in CS.

The different contribution of IGF1R and IR in mediating insulin-like growth factor 2 (IGF2) effects in adrenocortical carcinomas

Rosa Catalano[1], Emma Nozza[1], Emanuela Esposito[1], Anna Maria Barbieri[1], Giusy Marra[1], Donatella Treppiedi[1], Federica Mangili[1], Genesio Di Muro[1], Federico Arlati[1], Valentina Morelli[2], Maura Arosio[1,3], Giovanna Mantovani[1,3] & Erika Peverelli[1]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Istituto Auxologico Italiano, IRCCS, Unit for Bone Metabolism Diseases and Diabetes, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy.

Adrenocortical carcinomas (ACCs) are rare endocrine tumors with poor prognosis. They overexpress the insulin-like growth factor 2 (IGF2), that drives a proliferative autocrine loop by binding to IGF1R and IR. The majority of studies focused on IGF1R as mediator of IGF2 biological effects, but recently a high expression of IR, in particular of the isoform A, was observed in most ACCs, suggesting a potential role of this receptor in modulating IGF2 effects in adrenocortical tumorigenesis. However, the relative contribution of IGF1R and

IR to the biological effects of IGF2 in ACC is still unknown. Aim of this study was to investigate the specific roles of IGF1R and IR in mediating IGF2 tumorigenic effects in ACC. To this purpose we performed genetic silencing of both IGF1R and IR by transfecting H295R, MUC1 and primary ACC cells with specific siRNAs directed against IGF1R and IR. We found that the IGF2 anti-apoptotic effects were enhanced in H295R and ACC primary cultured cells silenced for both IGF1R ($-15.16\pm3.27\%$, $P<0.01$ and -45%, $P<0.05$, of caspase 3/7 activity, respectively) and IR ($-23.62\pm16.03\%$, $P<0.05$ and -32.4%, $P<0.001$, respectively). In addition, we demonstrated that IGF2 was still able to promote ERK and AKT phosphorylation after IGF1R and IR silencing in H295R and ACC primary cultured cells. Moreover, both IGF1R and IR silencing did not affect the IGF2-mediated proliferation in H295R. In MUC1 cells, IGF1R silencing did not alter IGF2-induced cell apoptosis and proliferation. Heterogeneous results were obtained in primary cultured cells obtained from 2 different ACC. In one of them IGF1R silencing decreased IGF2-induced cell proliferation, underlining the importance of this receptor in mediating IGF2-mitogenic effects. In the other one IGF2-mediated cell proliferation was reduced after IR, but not IGF1R, silencing. IGF1R, but not IR, knockdown reduced the antiproliferative effects of IGF1R/IR inhibitor Linsitinib in H295R and ACC primary cultured cells ($-32.76\pm20.81\%$ in control cells, $P<0.05$ and $-18.36\pm11\%$ in IGF1R silenced H295R cells, $P<0.05$), suggesting a main role of IGF1R in the response to Linsitinib. In conclusion, our data demonstrated a differential involvement of IGF1R and IR in mediating IGF2 tumorigenic effects in adrenocortical cancer cells.

Urine steroid profiling as a tool for the treatment evaluation assessment in patients with adrenocortical carcinoma

Ludmila Iosifovna Velikanova[1], Natalia Vladimirovna Vorokhobina[2], Zulfia Rifgatovna Shafigullina[2], Valentina Victorovna Kalugina[2], Ekaterina Valerievna Malevanaya[1], Vagan Yurikovich Bohyan[3], Ivan Socratovich Stilidi[3] & Nikolai Evgenievich Kushlinskii[3]
[1]North-Western State Medical University named after I.I. Mechnikov, Chromatography Laboratory, Saint Petersburg, Russian Federation; [2]North-Western State Medical University named after I.I. Mechnikov, Endocrinology department, Saint Petersburg, Russian Federation; [3]Federal State Budgetary Institution "N.N. Blokhin National Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation.

Background
The aim of the study was to evaluate urine steroid profiles by gas chromatography–mass spectrometry (GC–MS) in patients with adrenocortical carcinoma (ACC) to assess therapy efficacy.
Patients and Methods
39 ACC patients were examined before and after treatment. The median age was 47 years (41–60). The Weiss score was no less than 4 points. 10 patients were disease-free in the early postoperative period (up to 12 months after surgery). Metastases were detected 1–5 years after the surgery in 29 patients. The control group consisted of 25 patients with adrenocortical adenoma (ACA) without malignant features defined by the histologic analysis. The median age was 52 (47–61) years. We studied urine steroid profile using gas chromatograph–mass spectrometer SHIMADZU GCMS – TQ 8050. Statistical data was processed with software STATISTICA for WINDOWS (Version 10). Results comparison was made using Mann–Whitney test.
Results
ACC's main biomarkers urinary excretion rates [dehydroepiandrosterone (DHEA), etiocholanolone (Et), pregnanediol (P2), pregnanetriol (P3), pregnenediol (dP2), pregnenetriol (dP3)] did not differ between the disease-free postoperative ACC patients and the control group ($P>0.05$). The 3β,16,20-dP3 urinary excretion rate and the 3α16,20-dP3/3β,16,20-dP3 ratio were identified as the most discriminating markers in differentiating disease-free postoperative patients from preoperative ACC patients (receiver-operating characteristics (ROC) analysis revealed sensitivity = 100%, specificity = 96%, AUC = 0.99, cut-off < 194 μg/24 h and sensitivity = 85.7%, specificity = 92%, AUC = 0.87, cut-off > 3.4, respectively). Patients after surgery and chemotherapy had decreased urinary excretion rates of 3β,16,20-dP3 (cut-off < 100 μg/24 h sensitivity = specificity = 100%, AUC = 1,0) and the increase of 3α16,20-dP3/3β,16,20-dP3 ratio (cut-off > 2.7 sensitivity = 75%, specificity = 88%, AUC = 0.81) in comparison with the same patients' preoperative steroid profiles. Patients with recurrent ACC (in the postoperative period before the chemotherapy initiation or with the relapse occurrence after the completion of chemotherapy) had the similar excretion rates of ACC biomarkers as in the preoperative period.
Conclusion
Urine steroid profiling is a promising tool for the evaluation of treatment efficacy in ACC patients.

Is there a difference in symptoms, catecholamine release and tumor size in pheochromocytomas diagnosed due to initially symptoms or incidenthalomas

Ingrid Nermoen[1,2,3] & Marte Henriksen Korneliussen[1]
[1]University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [2]; [3]Akershus University Hospital, Norway.

Background
Pheochromocytoma is a rare adrenal tumor that can present with a variety of different symptoms. The cardinal symptoms are paroxysmal palpitations, headaches and sweating together with paroxysmal or persistent hypertension. Increasing use of CT scan contribute to the discovery of more adrenal incidentalomas and therefore more pheochromocytomas due to the workup of the incidentalomas. We intended to investigate if the presentation of the pheochromocytoma was different in the incidentaloma group, if so, what symptoms the tumor presented with, and if the tumors was different in size and metanephrine release.
Methods
Twenty-nine cases with pheochromocytomas examined and treated at Akershus University Hospital, Norway, during the last 20 years were reviewed. Age, year diagnosed, tumor characteristics, biochemistry, radiology, medical treatment before surgery, complications during surgery, and blood pressure measurement before, during and after the operation were registered.
Results
Of the 29 cases included, 70.4% presented as incidentalomas and 26.6% was discovered based on clinical symptoms and none due to genetic screening. The mean ($\pm$S.D.) age of the incidentalomas (58.0 ± 12.3) years was significantly higher than the patients diagnosed because of clinical suspicion (42.0 ± 9.9) years. Females were overrepresented in both groups and was in total 65.6%. There was no significant difference in blood pressure between the two groups (incidenthaloma vs clinical group), systolic 142.0 ($\pm$21.9) vs 154.2 ($\pm$18.8) mmHg, tumor size 4.9 ($\pm$3.0) vs 4.2 ($\pm$1.0) cm or normetanephrine median (range) 2.7 (0.7–26.2) vs 5.7 (3.1–44.0) nmol/l nor the excretion of metanephrine 1.5 (0.3–12.6) vs 1.4 (0.3–6.1) nmol/l. Out of the 19 incidentalomas 72.2% were retrospectively symptomatic and the most common symptoms were sweating, palpitations and headaches, followed by palpitations and tremor but these symptoms were rarely present at the same time. The last 10 years from 2010 to 2020, 15 incidenthalomas made up the 20 pheochromocytomas vs 4 of 7 from 2000 to 2010.
Conclusion
Our hospital diagnosed more pheochromocytomas the last years due to increasing discovery of incidentalomas on CT imaging and 72.2% of these incidenthalomas were retrospectively symptomatic. This points out the importance of investigating all incidentalomas biochemically and making a good medical history for symptoms as undiagnosed pheochromocytomas can be life-threatening.

Prevalence and clinical manifestations of neurogenic bladder dysfunction in type 2 diabetes: a population-based survey

Faten Haj Kacem Akid[1], Abdel Mouhaymen Missaoui[1], Mariem Belhoul[2], Wafa Belabed[1], Cyrine Chahaider[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Departement of Family Medicine, Sfax, Tunisia.

Background and aims
Lower urinary tract (LUT) symptoms are one of the most common complications related to autonomous diabetic neuropathy. It is responsible for several dysfunctions due to distended bladder with a high risk of contracting retention.

The current survey aims to assess the clinical manifestations of neurogenic bladder dysfunction (NBD) and determine its prevalence in patients with type 2 diabetes (T2DM).
Patients and method
We conducted a cross-sectional descriptive study that included 200 patients with T2DM consulting at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia, from April 2019 to December 2019. We administrated the Urinary Symptom Profile (USP) questionnaire to all patients to assess clinical manifestations of NBD.
Results
The mean age was 59.3±10.6 years, with a female predominance (55.5%). Dyslipidemia (57%) and hypertension (49.7%) were the most common comorbidities. The duration of the evolution of diabetes was 11.0±7.9 years. Oral antidiabetic agents (OAD) and insulin therapy were prescribed in 40% and 13.6%, respectively. Most of the patients were receiving a mixed insulin-OAD treatment (44.2%). A glycemic imbalance was noted in 79.7%. Stress urinary incontinence prevailed in 22.5%. the discomfort linked to this dysfunction was mild or moderate in 53.3% and 42.2%, respectively. An overactive bladder was recorded in 70.5% and caused severe or extreme discomfort for 24.1% and 16.3% of patients, respectively. Near one-half of investigated patients (51.5%) reported dysuria. The latter disorder was responsible for serious distress for 26.2% of patients. In total, the prevalence of LUT dysfunction was as high as 79.5% of patients with T2DM.
Conclusion
NBD is a cluster of lower urinary tract disorders such as stress urinary incontinence, dysuria, and overactive bladder. NBD is considered a chronic diabetic complication [1]. The prevalence of NBD varies from 25% to 87% in different studies. Urodynamic studies remain the gold standard diagnostic tool. However, the USP questionnaire represents a simple and very sensitive questionnaire for screening of NBD in patients with diabetes in clinical practice [2]. Due to its frequency, NBD should be screened for in patients with diabetes suffering from LUT dysfunctions.

Syncope: an unusual presentation of a rare disease
Uzair Akbar Ali[1], Muhammad Sajjad Sadiq[2] & Elizabeth Ann Brosnan[2]
[1]St. Luke’s General Hospital, Kilkenny, Ireland; [2]Mayo University Hospital, Castlebar, Ireland.

Background
Syncope is common in healthy adolescents and young adults. It can happen due to hypotension secondary to orthostasis. Primary adrenal insufficiency is infrequently reported in patients presenting with syncope and dizziness caused by loss of vasopressor effect of catecholamines and volume depletion.
Clinical Case
A 17-year-old boy with a past medical history of learning disability and asthma presented to our health facility with an episode of syncope. He felt dizzy on standing and had transient loss of consciousness at the General Practitioner (GP) Surgery. He was feeling unwell and nauseous for past several days. His physical examination revealed darkening of skin (pigmentation) but rest of the examination was unremarkable. Initial baseline investigations including blood glucose were normal except mild hyponatremia with sodium levels of 134 mmol/l (135–145). CT scan of thorax, abdomen and pelvis was unremarkable. He was referred to the endocrinologist with a clinical impression of primary adrenal insufficiency. Further investigations including serum ceruloplasmin and iron studies were normal. Short synacthen test revealed cortisol levels of 46 nmol/l and 40 nmol/l at 30 and 60 minutes respectively. Adrenal antibodies were weak positive. He was treated as auto-immune adrenal insufficiency or Addison’s disease and given mineralocorticoid (fludrocortisone) and corticosteroids (hydrocortisone) regimen. Careful history taken with his mother revealed that he had vitiligo in the past but denied any significant family or drug history. His previous investigations showed high levels of TSH at different times ranging from 2.69 to 45.18 mIU/l (0.51–4.30). Anti TPO antibodies were tested and found significantly raised with a value of 220 IU/ml (0–40). The patient was given the diagnosis of autoimmune polyendocrine syndrome type 2 (APS-2). He was advised screening for antibodies against IA-2, insulin, GAD65 to test for type 1 diabetes predisposition and tissue transglutaminase autoantibodies to screen for coeliac disease. His family was finding it difficult to absorb all these information and asked for some time before proceeding to further tests. He was advised endocrine clinic follow ups.
Conclusion
This case report highlights the importance of arriving at the right diagnosis as signs and symptoms can be vague and mimic other conditions. Appropriate investigations, treatment and follow up can improve quality of life.
Key words: syncope, adrenal insufficiency, auto-immune.

False positive metanephrines secondary to sinemet-diagnostic dilemmas in interpretation
Bhavna Sharma[1], Asjid Qureshi[1], Florian Wernig[2] & Shivashankar Seechurn[1]
[1]Northwick Park Hospital, United Kingdom; [2]Imperial College London, United Kingdom.

A 50 year-old lady was referred to the endocrine service for evaluation of significantly elevated 3-methoxytyramine (3-MT) levels. Past medical history included well controlled HIV and hypertension controlled by a single agent only (amlodipine). On one occasion, she was noted to have an elevated systolic blood pressure of 189 mmHg in clinic and therefore 24 h urinary metanephrines were requested. She did not have any other symptoms to suggest excess catecholamines. Systems review was unremarkable. There was no family history of endocrinopathies. She had recently been diagnosed with multiple system atrophy. A Dopamine Active Transporter scan revealed reduced uptake at the basal ganglia. She had been started on Sinemet 125 mg TDS by the neurologist and her symptoms, which include postural hypotension, greatly improved. In the endocrine clinic, her systolic blood pressure was 128 mmHg. The history was revisited and it transpired that on the day her blood pressure had been elevated, she had omitted her amlodipine. Physical examination did not reveal any obvious stigmata of an endocrinopathy. Blood tests showed normal electrolyte, renal function, bone profile and thyroid function. However, repeat 24 h urinary metanephrines were a follows: Metanephrine 488 nmol/ 24 h (NR 0-2000), normetanephrines 1139 nmol/24 h (NR 0-4400) and 3-MT 20 424 nmol/24 h (NR 0-2500). This confirmed a previous 24 urine collection result. It was thought that the isolated markedly raised 3-MT, a dopamine metabolite, was secondary to Sinemet which is a combination of carbidopa and levodopa. Sinemet could not be discontinued as it significantly improved her symptoms. A differential diagnosis of a dopamine secreting neuroendocrine tumour was a considered. Chromogranin A & B were evaluated and were normal. Her case was discussed at the regional adrenal MDT meeting. The MDT concluded that the markedly raised 3-MT were secondary to Sinemet and no further investigations such as functional imaging would be required. Interpreting biochemical markers in the presence of influencing factors and drugs can often be challenging. Abnormal results can trigger unnecessary investigations which can be distressing to the patient. This case highlights the importance of MDT discussions in such scenarios.

The asymmetric adrenal in mice and men: Sexual dimorphism and potential hormonal consequences
Nicole Bechmann[1,2], Mats Leif Moskopp[3], Deepika Watts[4], Charlotte Steenblock[2], Waldemar Kanczkowski[2], Ben Wielockx[4], Stefan R Bornstein[2], Mirko Peitzsch[4] & Graeme Eisenhofer[2,4]
[1]Institute of Clinical Chemistry and Laboratory Medicine, University Hospital Carl Gustav Carus, Medical Faculty Carl Gustav Carus, Technische Universität Dresden, Germany; [2]Department of Internal Medicine III, University Hospital Carl Gustav Carus, Technische Universität Dresden, Germany; [3]Department of Neurosurgery, Vivantes Friedrichshain Hospital, Charité Academic Teaching Hospital, Germany; [4]Institute of Clinical Chemistry and Laboratory Medicine, University Hospital Carl Gustav Carus, Medical Faculty Carl Gustav Carus, Technische Universität Dresden, Germany.

Evidence indicates that the adrenals are sexually dimorphic and asymmetric. These differences may have implications for the prevalence and progression of adrenal diseases, which also show asymmetry and sexual dimorphism. The present study aims to characterize the morphological and metabolic differences associated with adrenal sex and asymmetry in mice and humans. Adrenals were compared bilaterally in male and female C57B/6NRj mice with regard to

morphological and hormonal characteristics. Female adrenals were consistently larger than male adrenals (330.2 ± 14.7 vs. 215.4 ± 15.8 µg protein/adrenal, $P < 0.001$). Although males had smaller adrenals, total contents of catecholamines were higher in males than in females (mean both adrenals: 3.8 ± 0.3 vs. 3.5 ± 0.2 µg catecholamines/adrenal). In contrast, adrenal contents of the two main adrenal steroids, corticosterone and aldosterone, were significantly higher in females than males. In females, the right adrenal was significantly smaller than the left adrenal (295.3 ± 19.0 vs. 365.2 ± 12.9 µg protein/adrenal, $P = 0.03$), whereas no clear differences were observed in males. In both sexes, total tissue catecholamines as well as corticosterone and aldosterone were higher in the left than the right adrenal. We confirmed these findings in three additional mouse strains (C57BL/6J, CD6 and Tie2 GFP/FVB). Furthermore, we performed a systematic review of adrenal imaging data in humans. Unlike in mice, women have smaller adrenals than men, but also in humans the left adrenal gland is larger than the right adrenal. Using adrenal vein samples and human adrenal tissue data, we will further characterize hormonal differences in patients. Characterization of differences between sexes and of adrenal asymmetry in mice and humans may have implications for prediction and diagnosis of adrenal disease, and it may also allow improved translation of results from experimental murine models to the clinic.

Cushing disease in patient with chronic renal failure treated by hemodialysis: a case report

Ameni Terzi, Nadia Khessairi, Yasmine Mouelhi, Meriem Yazidi & Melika Chihaoui
Rabta hospital, Endocrinology, Tunis, Tunisia.

Introduction
The occurrence of Cushing's syndrome in individuals with chronic renal failure is notably rare. It represents a challenging diagnosis in the context of pre-existing chronic kidney disease due to commonly associated alterations in the hypothalamic–pituitary–adrenal axis function. Consequently, the interpretation of standard tests used to detect hypercortisolism can be peculiarly difficult and reveal concrete particularities in comparison to patients with normal renal function. We here present the case of a chronic hemodialysis patient who was diagnosed with Cushing syndrome disclosed by an adrenal incidentaloma.
Case presentation
In December 2021, a 67-year-old female was admitted to our department for exploration of a 23 mm left-sided adrenal nodule incidentally detected on a computed tomography (CT) performed about 6 months ago for suspicion of an arteriovenous fistula stenosis. Indeed, the patient started hemodialysis 3 times a week since 2014 for end-stage renal disease caused by tubulointerstitial nephritis. In addition, she underwent subtotal parathyroidectomy associated to right loboisthmectomy for tertiary hyperparathyroidism and multinodular goiter in 2015. Clinically, she didn't have hypercortisolism features except slender lower limbs and a recently diagnosed hypertension. Her body mass index was 28.75 kg/m^2. Biologically, she had hypertriglyceridemia and glucose intolerance. Subsequent endocrinological testing revealed negative plasma fractionated metanephrines and resistance to suppression of low dose (1 mg), 4 mg and high dose (8 mg) of dexamethasone: the early morning cortisol level was respectively 7.1 µg/dl, 2.6 µg/dl and 2.3 µg/dl. The plasma ACTH level performed twicely was 55 pg/ml and 31 pg/ml. It led to the practice of a brain MRI that was normal. A latterly conducted CT scan detected a left adrenal adenoma with a diameter of 31 mm, spontaneous density of 20 UH, relative washout of 49% and absolute wash out of 64%. The patient didn't have obstructive sleep apnea. Based on these findings, Cushing's syndrome secondary to a left adrenal tumor was diagnosed and the patient was presented for left adrenalectomy.
Conclusion
This is the first documented report outlining the coexistence of Cushing syndrome and tertiary hyperparathyroidism in an individual with end stage renal disease and the fourth known case of Cushing disease occurring in a long-term hemodialysis patient. This observation emphasizes the cortisol dynamics alterations broadly associated with renal failure. These pituitary adrenocortical function disturbances are mainly characterized by increased cortisol levels, heightened plasma ACTH levels and resistance to low dose dexamethasone suppression testing highlighting thereby the delicate diagnosis of Cushing disease in this context.

EP57

Monitoring for the long-term metabolic complications in patients with subclinical cushing's syndrome: service evaluation

Jessica Yau[1] & Justyna Witczak[2]
[1]Cardiff University, School of Medicine, Cardiff, United Kingdom; [2]University Hospital of Wales, Centre for Endocrine and Diabetes Sciences, Cardiff, United Kingdom.

Introduction
Patients with subclinical Cushing's syndrome (SCS) are thought to have excess cortisol from an adrenal adenoma, secreting ACTH-independent cortisol that is not fully suppressed by the pituitary feedback system. High cortisol levels may be linked to metabolic complications. There are no specific guidelines on the surgical management of SCS.
Objective
To evaluate if patients with SCS are monitored and managed for metabolic complications due to cortisol excess.
Method
A retrospective service evaluation study on patients diagnosed with SCS from 2016 to 2019 at the University Hospital of Wales, United Kingdom. We identified 114 patients with a non-suppressed response to the overnight dexamethasone test (ODST), qualified as a 0900 h cortisol > 50 nmol/l. 48/114 were excluded either due to a further negative dexamethasone suppression test or no adrenal adenoma present on imaging. Data of 66 patients were collected on the monitoring and management for metabolic complications in July 2021.
Results
66 patients showed a mean age of 66 ± 12.74 s.d., a male to female ratio of 2:1. 89% (59) had a single adenoma, 11% (7) had bilateral adenomas, and the mean lesion size was 2.82 cm ± 1.34 s.d.. 70% (46) of patients had at least one known metabolic complication present. The four metabolic complications present were hypertension (65%), diabetes mellitus (21%), dyslipidaemia (15%), and osteoporosis/osteopenia (27%). 21% (14) of patients had a history of cardiovascular disease (CVD). The majority had one to three metabolic risk factors (RF) screened; four patients had all four RF tests done; positive results for HbA1c (7/22), lipid profile (11/33), blood pressure (24/43), and DEXA scan (18/21). 28 (42%) patients had been discharged, 12 (18%) were deceased. Surgery was discussed in 26 patients (39%); 10/26 were offered and ultimately 8 underwent the surgery. The criteria to be offered surgery were only clear in 4/8 (50.0%) patients, as they had a lesion > 4 cm. 6/8 surgical patients had at least one metabolic complication, and 5/8 had a minimum of one positive RF result. All the adrenal adenomas removed were shown to be benign in the histopathology studies.
Conclusion
SCS is linked with other metabolic complications; improvement in monitoring of these complications will help the patient receive the required treatment earlier to reduce their CVD risk. More defined surgical criteria could aid clinicians in decision-making. Non-surgical patients may benefit from continued monitoring of metabolic risk factors/complications even after discharge.

Inadequate peroxisomes activity – a rare cause of Adrenal Insufficiency

Nicoleta Chelaru[1], Laura-Mihaela Trandafir[2,3], Christina-Maria Ungureanu[1,3], Otilia-Elena Frasinariu[2,3] & Ioana Vasiliu[2,3]
[1]Saint Spiridon County Hospital, Iaşi, Romania; [2]Saint Mary Emergency Children Hospital, Iasi, Romania; [3]"Grigore T. Popa" University of Medicine and Pharmacy of Iaşi, Iasi, Romania.

Introduction
Zellweger Spectrum Disorders, one of the two groups of Peroxisome Biogenesis Disorders (PBD-ZSD) are rare, complex autosomal recessive genetic anomalies characterised by mutations in any of the PEX genes which are responsible for defective peroxisomes activity. The peroxisomes are organelles that play a primary role mainly in the lipid metabolism of almost all the cells of the body, hence their defective biosynthesis, assembly or biochemical functions turn PBD-ZSD into a multi-organ disease. The disease progression is variable, with a wide spectrum of clinical phenotypes and may include the onset of adrenal insufficiency.
Case report
We report the case of a 2 year-old girl who was previously diagnosed with a malfunctioning PEX6 protein as a result of biallelic pathogenic variants in PEX6 gene. The medical history work-up draws attention to the overall developmental delay, psychomotor retardation, partial vision and hearing loss and seizures under treatment with antiepileptic drugs. Among the clinical features we emphasize the

small size, craniofacial dysmorphism, dysphagia, poor feeding and hepatomegaly. Laboratory data revealed elevated liver functions, abnormal coagulation profile and modified adrenal tests: elevated adrenocorticotropic hormone (ACTH) with normal morning cortisol level. The diagnosis of subclinical adrenal insufficiency was confirmed by the impaired plasma cortisol response following the Synacthen test. Hydrocortisone supplementation was recommended during stressful situations and intercurrent illness.
Discussion
Our patient's clinical picture fits with an intermediate PBD-ZSD. Given the complexity of the disease, the management of PBD-ZSD is multidisciplinary and it focuses mostly on symptomatic or supportive treatment. These patients need close monitoring for adrenal insufficiency onset, which may by life-threatening if the diagnosis is delayed. Experts recommend yearly endocrinological check-ups by measuring serum morning cortisol and ACTH. Also, the endocrinological management may include vitamin D supplementation and bisphoshonates treatment, as patients with PBD-ZSD are at risk for osteopenia over time.

Screening of primary aldosteronism among egyptian hypertensive population

Marwa Fathy[1], Mona Mansour[2], Ahmed Rabie[2], Fatma Abd Elhafiz[3], Randa Salam[1] & Abeer Awad[2]
[1]Faculty of Medicine-Cairo University, Internal Medicine-Endocrinology Unit, Cairo, Egypt; [2]Faculty of Medicine-Cairo University, Cairo, Egypt; [3]Faculty of Medicine-Cairo University, Clinical Pathology, Cairo, Egypt.

Background
Hypertension is a common condition that affects many people all over the world. It could be associated with several complications especially in cases of resistant hypertension. Many clinical practice guidelines recommend screening for primary aldosteronism especially in persons with resistant hypertension owing to the worse prognosis when compared with blood pressure-matched essential hypertension.
Objective
The study aimed to screen for primary aldosteronism in high-risk hypertensive Egyptian patients, and to determine the challenges faced in the diagnosis.
Material and Methods
50 high-risk hypertensive patients were recruited from the Outpatient Endocrinology Clinic out of 200 hypertensive patients in the period from February 2019 and April 2021. Creatinine, Glycosylated hemoglobin (HBA1c), lipid profile, potassium level, sodium level, plasma aldosterone concentration (PAC), active renin concentration (ARC), and aldosterone/ renin ratio (ARR) were assessed in all patients.
Results
A series of 50 hypertensive patients screened for PA (26 females and 24 males) with a mean age of 41.88 ± 11.91 s.d.. We found that 41 (82%) patients were receiving antihypertensive medications and 9 (18%) patients didn't receive treatment for hypertension previously. 9 (18%) patients kept on no treatment, 6 (12%) patients were kept on the same anti-hypertensive medications, and 35 (70%) of them were shifted to other anti-hypertensive drugs. 4 patients out of total 50 patients had a positive ARR (>46), while 13 (26%) patients out of total 50 hypertensive patients had low renin levels. There was a statistically significant relation between serum aldosterone/ renin ratio (ARR) and serum potassium (K) with P-value $=0.001$ (Figure 4), also a statistically significant relation between serum aldosterone/ renin ratio (ARR) and (systolic blood pressure, diastolic blood pressure) with P-value $=0.001$ was found.
Conclusion
we recommend routine screening for PA in high-risk hypertensive patients that could offer targeted treatment before adverse cardiovascular consequences develop.

Adrenal incidentaloma: clinical and metabolic characteristics and follow-up results, a 10-year experience

Yasin Araç[1], Guzin Yaylali[2] & Senay Topsakal[2]
[1]Meric Town Public Hospital, Edirne, Turkey; [2]Pamukkale University, Department of Endocrinology and Metabolic Diseases, Denizli, Turkey.

Objective
In this retrospective study we investigated the clinical and radiological characteristics, hormonal status and metabolic components of the patients with adrenal incidentaloma(AI). Additionally, we investigated whether tumor size or hormonal status changes during long-term follow-up and the effect of these on metabolic parameters.
Methods
The data of 384 patients who were followed up with the diagnosis of AI between 2010 and 2020 were retrospectively analyzed. All patients underwent radiological, hormonal and metabolic evaluation and prospective follow-up.
Results
374 patients (248 female (%64)) enrolled to this study. 348(%90.6) of them were reported as adenomas and 31(%8.07) of them as non-adenomas and 4(%1.04) of them were indeterminate. The mean adenoma diameter was approximately 2 centimeters and was mostly detected on the left (%48.9). %13,81 of the subjects(n = 53) were functioning and among functional adenomas 9 subjects(%2.34) have autonomous cortisol secretion(ACS), 7 subjects(%1.82) have primary hyperaldosteronism, 4 subjects(%1.04) have pheochromocytomas, and 39 subjects(%10.1) have possible autonomous cortisol secretion. In patients with bilateral incidentalomas, the mean diameter of adenomas was higher than unilateral incidentalomas with a diameter of 24.22 mm in comparison to 20.36 mm. Similarly, in patients with bilateral incidentalomas, systolic and diastolic blood pressure was higher than unilateral incidentalomas (135.83 ± 20.27,130.02 ± 18.84% and 79.25 ± 11.56, 78.52 ± 10.11, respectively). Moreover, our study revealed that the frequency of diabetes, hypertension and hyperlipidemia in patients with possible autonomous cortisol secretion was %37, %63, %22.2, respectively. Of 384 patients, 9.11% ($n = 35$) underwent surgery. The most common pathological finding was adrenocortical adenoma ($n = 19$, %54). The median follow-up duration of patients was 48.91 months. Of 384 patients, %44.7 ($n = 172$) were followed up regularly with CT/MRI. During the follow-ups, the diameter of adenomas (%11.6) has increased by more than 10 mm. Of 384 subjects, %56.7 ($n = 218$) were followed with hormonal evaluation and 6 patients have developed possible autonomous cortisol secretion and 3 patients have developed autonomous cortisol secretion. Moreover, 1 subject has been developed primary hyperaldosteronism.
Conclusions
The main findings of the present study are that there was no relevant tumor growth after 5 years of follow-up and that the conversion rate to subclinical or clinical hypercortisolism was low and there were no new cases of pheochromocytoma. Only one subject has shown the development of primary hyperaldosteronism. Our study revealed a significantly increased risk of developing DM, HT and HL in patients with possible autonomous cortisol secretion.

Prevalence, clinical and biochemical peculiarities of metabolic syndrome in aged patients bearing adrenal incidentaloma

Faten Haj Kacem Akid[1], Abdelmouhaymen Missaoui[1], Mariem Belhoul[2], Wafa Belabed[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Department of Family Medicine, Tunisia.

Background and Aims
Growing scientific evidence supports the hypothesis of an increased cardiometabolic risk in patients harboring adrenal incidentalomas (AI). This risk would be higher in aging populations and patients with functioning adenomas. The current study aims to determine the clinical and biochemical characteristics of metabloic syndrome(MetS) and assess its prevalence in older patients with AI.
Patients and Method
We conducted a retrospective descriptive study including 69 patients aged 65 years and above diagnosed with AI. All patients have undergone clinical examination, adrenal CT, and biochemical workup at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia, from 2011 to 2020. MetS was diagnosed based on the National Cholesterol Education Program's Adult Treatment Panel III (ATP III) criteria.
Results
The mean age at diagnosis was 71.4 ± 4.2 years, with a female predominance (57.5%). Seventy percent of elderly patients had non-secreting AI. The functioning incidentalomas displayed autonomous cortisol secretion (32.5%), primary hyperaldosteronism (25%), or secondary hyperaldosteronism (21.8%). One senior had a secreting pheochromocytoma. Hypertension was the most

common metabolic disorder encountered in 77.5% of aged patients. The mean Body mass index was 28.5 ± 5.4 kg/m^2. Our elderly population was frequently overweight (32.5%) or obese (40%). Abdominal obesity affected remarkably the female gender (87% in females versus 35.3% in males) with a mean waist circumference of 106 cm in females and 99 cm in males. We noticed a glucose metabolism disorder in 70%: mainly diabetes mellitus in 60%, impaired fasting glucose in 7.5%, and impaired glucose tolerance in 2.5%. Most senior patients had disturbed lipid profiles. HypoHDLemia prevailed in 45.7%, while hypertriglyceridemia and hypercholesterolemia were found in 17.5% and 28.2%, respectively. The prevalence of MetS in our sample of geriatric patients carrying AI was 24.6%.

Conclusion

Recent scientific data has concluded that AI defines a novel risk factor of MetS [1]. We could hypothesize that AI (despite its hormonal profile) may be associated with a subtle excessive cortisol secretion, hardly labeled clinically and biochemically, which could cause an acquired condition of insulin resistance [2]. Along with multiple age-related mechanisms, this condition would be clinically manifest and result in overt MetS in the geriatric population.

Synchronous adrenal gland masses in a patient: clinical case

Mafalda Martins Ferreira, Mariana Lavrador, Cátia Araújo, Joana Reis Guiomar, Carolina Moreno, Patrícia Oliveira & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal.

We describe the case of a 69-year-old woman with bilateral adrenal incidentalomas identified in CT-scan: on the right, a 57 mm heterogeneous mass with < 10 Hounsfield units(HU) with absolute washout of 16%; on the left a 13 mm mass with 35UH, intense contrast enhancement but washout of 66%. She had a recent onset of diabetes, hypertension, androgenic alopecia and facial hair. The systolic blood pressure remained persistently > 160 mmHg despite receiving four antihypertensive drugs. She referred multiple episodes of syncope in the orthostatic position without palpitations, facial flushing or diaphoresis. She had no malignancy history nor had any apparent syndromic physical features. Her BMI was 32.3 kg/m^2, waist circunference of 110 cm with thin members and she presented with androgenic alopecia, submental hair lacking other Cushing features. Hormonal tests showed elevation of plasmatic metanephrines: metanephine 79.9 pg/ml (< 60), normetanephrine 214.6 pg/ml (< 120); 3-metoxityramin of 12.7 pg/ml (< 14); 1 mg dexamethasone suppression test of 4.7 µg/dl with supressed ACTH < 5 pg/ml; and elevation of total-testosterone 1.2 ng/ml (< 0.90), DHEA-SO4 1.54 µg/ml (0.15–0.8) and androstenedione 6.7 ng/ml (0.5–3.4). 17-hydroxyprogesterone: 0.67 ng/ml (0.1–2.3). 18 F-FDOPA PET confirmed a pheochromocytoma on the left adrenal gland without metastatic lesions. She began treatment with phenoxybenzamine. Gadolinium MRI suggested a adrenocortical carcinoma on the right. Urology proposed right adenomectomy and total adrenalectomy of the left adrenal gland, then converted to total adrenalectomy of the right gland and parcial adrenalectomy of the left because the pheochromocytoma was macroscopically hard to find even with patient mobilization. Histopathology was consistent with a pheochromocytoma on the left adrenal gland (PASS-score 4/20) and adenoma on the right. After surgery there was normalization of the levels of metanephrines and androgens. Synacthen showed a 60 minute cortisol of 10 µg/dl. She was discharged with 10 mg hydrocortisone once a day. The genetic study is in process.

Discussion

There are few reports on bilateral adrenal masses since they are uncommon, especially if from different etiologies. This patient had simultaneously a pheochromocytoma and a cortisol plus androgen-producing adenoma confirmed by normalization of hormones after its resection – androgen-hypersecretion by benign tumors is also unusual since is more typical of carcinomas. The surgeon was faced with the need to decide the type of surgical approach at the last minute: there are few recommendations on adrenal surgery but there is general consensus to perform total adrenelectomy on pheochromocytoma-affected glands. However, complete normalization of metanephrines and eventual future adrenocortical-hormone sufficiency are good outcome predictors.

Malignant pheochromocytoma with bone, pulmonary and brain metastases

Cátia Araújo, Mafalda Martins Ferreira, Mariana Lavrador, Carolina Moreno, Patrícia Oliveira, Carla Baptista & Isabel Paiva
Centro Hospitalar Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal.

Introduction

Pheochromocytomas are rare neuroendocrine tumors whose malignancy is defined by the presence of metastases that may appear several years later. The appropriate follow-up time remains uncertain.

Clinical Case

We present the case of a woman with a history of pheochromocytoma who underwent complete resection at 48 years old. The genetic evaluation was negative for mutations on RET, VHL, SDHB or SDHD genes. At 66 years old, a thoracic vertebral metastasis appeared on MIBG-I123 scintigraphy. The biopsy of the lesion was consistent with neuroendocrine tumor metastasis. The patient was submitted to radiotherapy, radioisotope therapy and kyphoplasty. The radioisotope therapy with MIBG-I123 proved to be ineffective. Therapy with an antagonist of the alpha-adrenergic receptors (phenoxybenzamine) was initiated. In the next eleven years, the MIBG-I123 scans and lombar CT showed progression of bone metastases and doubt about the possibility of liver lesions. Over these years, plasma metanephrine and 3-methoxytyramine remained normal but normetanephrine showed marginal and progressive elevations. At 77 years, the patient underwent a second radioisotope treatment with MIBG-I123, once again ineffective. 3 months later, the patient was admitted with fatigue, respiratory failure and gait imbalance. Chest CT showed miliary pulmonary spread. Bronchoalveolar lavage immunocytochemistry was compatible with NET metastases. 18F-DOPA PET/CT confirmed pulmonary and massive liver metastases and new bone lesions. Cranial CT scan showed cerebellar, lenticular, frontal and hypothalamic–pituitary involvement suggestive of secondary lesions. Despite the pituitary involvement, there was no hormonal deficiency. Plasma normetanephrine increased. The clinical condition worsened and the patient ended up dying 2 months later.

Conclusions

Metastases typically involve bone, liver and lung – cerebral metastases are rare. MIBG-I123 scintigraphy can detect metastases susceptible to radioisotope therapy, but about a third of patients do not respond. Even in the absence of obvious high-risk characteristics, malignancy can occur and it is not easy to predict. This case illustrates the importance of life-long follow-up in these tumors and the unpredictability of occurrence of metastatic lesions.

Pheochromocytoma experience

Zafer Pekkolay
Dicle University Faculty of Medicine, Endocrinology, Diyarbakır, Turkey.

Aim

This study aims to evaluate patients with a diagnosis of pheochromocytoma.

Method

This retrospective case–control study includes data from a tertiary endocrine center from January 1, 2010, to December 31, 2020. Demographic, laboratory, operation/pathology data of patients with pheochromocytoma were recorded.

Results

A total of 38 patients (20 patients (52.6%) were male) were included in the study. Median age 48 years (17–81) IQR:18. Tumor localization (right/left/bilateral: 23/9/6) was most common on the right at a rate of 60.5%. Six patients had bilateral tumors. Five patients (three from the same family) had MEN 2A syndrome, and one patient had MEN 2B syndrome. All MEN syndromes had medullary thyroid cancer. One patient had pheochromocytoma, medullary thyroid cancer, and parathyroid adenoma. Neurofibromatosis was detected in one patient. Median tumor size was 6,5 cm (1.6-24) IQR: 3.3 Metanephrine level median: 666(18-23115) IQR:2793(52–341 µg/day) Normetanephrine level median: 3342(187-18900) IQR: 3378(88–444 µg/day) All patients had a normal aldosterone/renin ratio. There was no response to dexamethasone suppression in 10.5 percent of the patients. Mean calcitonin level in patients with medullary thyroid cancer: 2306.5. Normetanephrine was elevated in 92% of patients. Metanephrine elevated in 65% of patients. Normetanephrine and metanephrine were found to be elevated at the same time in 80% of those with bilateral masses.

Conclusion

Pheochromocytoma is seen equally in both gender. It is mainly localized in the right adrenal. It often secretes norepinephrine. Epinephrine/norepinephrine is

often increased in bilateral disease. MEN syndrome is common in bilateral disease.

False positive metanephrines in high risk patient for pheochromocytoma

Ricardo Fonseca, Catarina Roque & Ana Sofia Osório
Hospital Fernando Fonseca, Amadora, Portugal.

Background
False positive results are common in the screening of pheochromocytoma. Even in high risk patients with disorders related to multiple endocrine neoplasia it's crucial to exclude possible interferences with analytical methods.
Clinical case
A 69 year-old man was submitted to total thyroidectomy, due to a 11 mm hypoechogenic nodule suspicious of papillary carcinoma (FNA). Histology confirmed medullary carcinoma pT1b. The surgery department ordered the screening for primary hyperparathyroidism and pheochromocytoma and sent the case to Endocrinology. Initial 24 h urinary metanephrines (HPLC) were increased [861 µg/24 h (<302)], but urine was collected shortly after surgery. The patient didn't have paroxistic symptoms and the abdominal CT showed normal adrenal glands. The tests were repeated one month later without known interferences (taking tamsulosin, atorvastatin, omeprazole and levothyroxine): metanephrines were normal in plasma and urine [plasmatic 38 pg/ml (<65), urinary 132 µg/24 h (<302)], but the urinary normetanephrines were elevated 4 fold [2005 µg/24 h (<527) while plasmatic remained normal [110 pg/ml (<196)]. RET gene study didn't show mutations. Given the discrepancy of the results, the metanephrines and normetanephrines were repeated after tamsulosin withdrawal for 15 days, which resulted in normal plasmatic and urinary levels [24 h urinary metanephrines 158 µg/24 h (<302), normetanephrines 213 µg/24 h (<527); plasmatic metanephrines 45 pg/ml (<65), normetanephrines 35 pg/ml (<196)].
Discussion
There are many interferences with nor/metanephrine tests. Anesthetics and some analgesics are known interferences, but there is a comprehensive list of possible medications associated with false positive results. In this case, the first metanephrines were interpreted as interference caused by surgery and anesthetics given that metanephrine levels normalized later. After hospital discharge normetanephrines increased in spite of low risk of disease (RET gene negative for mutations, normal adrenal glands in abdominal CT). Tamsulosin is an alpha-adrenergic blocker with local prostatic action, unexpected to have significant changes in normetanephrines, but only after 15 days of drug discontinuation the results were normal.

Effects of cumulative doses of corticosteroids on the recovery of patients with COVID-19

Mitra Kazemijahromi[1], HamidReza Samimagham[2], Reza Reza Farrokh Seresht[2] & Soroosh Soroosh Jaber Ansari[2]
[1]Endocrinology and Metabolism Research Center, Hormozgan University of Medical Sciences, Bandar Abbas, Iran; [2]Clinical Research Development Center,Shahid Mohammadi Hospital, Hormozgan University of Medical Sciences, Bandar Abbas, Iran.

Background
Corticosteroids suppress the immune system and have been proposed as a treatment for the severe form of (COVID-19) due to their potential ability to inhibit the COVID-19-induced cytokine storm. We aimed to evaluate the effects of cumulative doses of corticosteroids on the recovery of COVID-19 patients.
Methods
In this descriptive cross-sectional study, we retrospectively evaluated patients with COVID-19 (confirmed by [PCR]) receiving corticosteroids at Shahid Mohammadi Hospital, Bandar Abbas, Iran during June-October 2020. All patients had been admitted to the general wards and not the intensive care unit. COVID-19 was not severe in any of the patients. Beside corticosteroids, all patients had received similar standard COVID-19 treatment according to the National COVID-19 Committee protocols. In addition to the demographic features of the patients including age and gender, COVID-19 symptoms, respiratory rate (RR), lactate dehydrogenase (LDH) level, C-reactive protein (CRP) level, oxygen saturation (SpO2), lymphocyte percentage and count on admission and at the last evaluation before discharge were extracted from the patients' medical files.
Results
A total of 200 patients with confirmed COVID-19 were included in this study. The mean age of the patients was 51.65 ± 9.35 years and 117 (58.5%) were male. The administered corticosteroid was dexamethasone in 55%, methylprednisolone in 32.5%, and prednisolone in 12.5%. The mean administered cumulative corticosteroid dose was equal to 82.69 ± 59.40 mg prednisolone. All COVID-19 symptoms, including fever, cough, dyspnea, headache, body ache, and anosmia decreased in the patients. However, there was no significant difference between patients using < 65 mg of corticosteroids and those using ≧ 65 mg of the medicine regarding the final status of symptoms. The increase in SpO2 was significantly higher in patients using < 65 mg of corticosteroids ($P = 0.008$). Moreover, the proportion of patients with negative final CRP was significantly higher in this group ($P < 0.001$). On the contrary, hospital length of stay was significantly shorter in patients using ≧ 65 mg of corticosteroids ($P = 0.034$). The two groups had no significant differences in terms of LDH levels, lymphocyte percentage and count, RR, and the final status of lung infiltration ($P > 0.05$).
Conclusions
While the cumulative dose of corticosteroids equal to < 65 mg of prednisolone is associated with increased SpO2 and decreased CRP in COVID-19 patients, it leads to prolonged hospital stay compared to the ≧ 65 mg dose of corticosteroids.

Arterial hypertension in elderly patients carrying adrenal incidentaloma: epidemiological,clinical and therapeutic features

Faten Haj Kacem Akid[1], Abdelmouhaymen Missaoui[1], Mariem Belhoul[2], Wafa Belabed[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Depatment of Family Medicine, Tunisia.

Background and Aims
Arterial hypertension (AH) is one of the most common comorbidities in the elderly. The association of adrenal incidentaloma (AI) with AH in older patients may influence the clinical and therapeutic outcomes of the latter condition. In the current study, we aimed to assess the prevalence of AH and its clinical and therapeutic features in geriatric patients bearing AI.
Patients and Method
We conducted a retrospective descriptive study including 69 patients aged 65 years and above diagnosed with AI. All patients have undergone clinical examination, adrenal CT, and biochemical workup at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia, from 2011 to 2020.
Results
The mean age at diagnosis was 71.4 ± 4.2 years, with a female predominance (57.5%). Hypertension was the most common metabolic disorder encountered in 77.5% of aged patients carrying AI. The mean systolic blood pressure was 132 mmHg (extremes = 100–180). The mean diastolic blood pressure was 75 mmHg (extremes = 50–120). AH was newly diagnosed in 10% of cases thanks to a 24-hour ambulatory blood pressure monitoring during the AI clinical assessment. For the patients already diagnosed with AH, the average duration of hypertension was 8.9 ± 7.2 years. Most elderly patients with AI had stage I high blood pressure (87.1%) at diagnosis. Stage II (9.7%) and stage III (3.2%) AH were less frequently encountered. Antihypertensive monotherapy was proposed for 51.9% of patients. Antihypertensive bitherapy (29.6%) or tritherapy (11.1%), quadritherapy (3.7%) were less prescribed. Target organ damage related to AH was observed in 37%, mainly renal (29.4%) and neurological (22.2%) complications. Primary hypertension was the most common form in 70% of cases. Secondary AH was diagnosed in 30% of aged patients having AI due to autonomous cortisol secretion (32.5%), primary hyperaldosteronism (25%), or secondary hyperaldosteronism (21.8%). One senior had a secreting pheochromocytoma. Bilateral AI (92.3%) is subsequently more associated with AH in aged patients than unilateral AI (57.7%) ($P = 0.027$). We did not establish any significant correlation between the AI size and the severity of AH.
Conclusion
Although the prevalence of AH increases with aging, secondary hypertension must be excluded in hypertensive aged patients with AI, mainly autonomous cortisol hypersecretion and pheochromocytoma. The studied population shared the same clinical and therapeutic features as the general hypertensive population. Despite its hormonal profile, bilateral AI is a significant predictive factor of the onset of AH in the elderly.

Clinical sexual dimorphism in patients with adrenal incidentaloma and (possible) autonomous cortisol secretion

Ljiljana Marina[1], Miomira Ivovic[2], Antoan Stefan Sojat[1], Bogdan Dugic[3], Milina Tancic-Gajic[2], Zorana Arizanovic[1], Kristina Saravinovska[4], Dunja-Simona Petkovic[4], Tijana Petkovic[1], Natalija Antic[1], Aleksandra Kendereski[2] & Svetlana Vujovic[2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Obesity, Metabolic and Reproductive Disorders, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Department for Obesity, Metabolic and Reproductive Disorders, Belgrade, Serbia; [3]School of Electrical Engineering, University of Belgrade, Belgrade, Serbia; [4]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Many diseases of the adrenal cortex show a higher prevalence in women than men with incidence increasing with age in both genders.
Aim
The aim was to determine the possible sexual dimorphism in patients with adrenal incidentaloma (AI) and (possible) autonomous cortisol secretion ((P)ACS).
Methods
This was an observational, cross-sectional study of 381 patients with AI that were functionally assessed in our Clinic. After exclusion of patients with overt adrenal hyperfunction, malignancy, cysts and nonfunctional AI, the studied group consisted of 186 patients with (P)ACS: 138 female and 48 males. Based on average menopause age of 51, we stratified women in two groups: < 51 and $\geqq 51$. For the sake of comparison, we age-matched the male group, and evaluated differences in body mass index (BMI), adrenal tumor size (ATS), localization, ACTH, 24 h cortisol, 1 mg dexamethasone suppression cortisol (1 mg DST), and prevalence of hypertension (HTA) and type 2 diabetes mellitus (T2DM).
Results
Female sex was predominant in the whole cohort (F/M % 74.2/25.8) and in both age groups (< 51 years, 33 patients – F/M % 87.8/12.2 and $\geqq 51$ years, 153 patients – F/M % 71.2/28.8), with a higher frequency in younger group when compared to males ($P=0.048$). There was no difference in age, BMI, ATS, localization, ACTH, 24 h cortisol, 1 mg DST cortisol, HTA and T2DM prevalence between female and male patients. Older male patients had a higher prevalence of T2DM ($P=0.035$) than younger males with 24 h cortisol level being the most significant predictor of T2DM ($P=0.047$). There was no difference in prevalence of HTA, nor other significant differences between younger and older male patients. In the female group, there was no difference in HTA and T2DM prevalence between younger and older patients. In older female patients ATS was the most significant predictor of T2DM ($B=0.247$, 95% CI $B=0.002$–0.018, $P=0.011$) while BMI was the most significant predictor of HTA ($B=0.301$, 95% CI $B=0.009$–0.031, $P=0.002$), whereas there were no detectable significant predictors in younger females for both T2DM and HTA.
Conclusion
Female gender is a predisposing factor for subtle cortisol hypersecretion in patients with AI, while also being a predisposing factor for cardiometabolic comorbidities in women younger than 51 years of age, thus pointing to a relevant clinical sexual dimorphism that could aid in providing a decision-making process and tailored treatment.

Epidemiological and clinical data and factors of poor blood pressure control in known hypertensive patients in the Sfax region

Fatma Mkaouar[1], Fatma Mnif[2], Khouloud Boujelben[2], Jihen Jdidi[3] & Mohamed Abid[2]
[1]Hedi Chaker, Medecine Interne, Sfax, Tunisia; [2]Hedi Chaker, Endocrinologie, Sfax, Tunisia; [3]Hedi Chaker, Medecine Communautaire et Preventive, Sfax, Tunisia.

Introduction
Hypertension is a very common chronic disease worldwide. Its imbalance is one of the main causes of cardiovascular and neurodegenerative complications.
Patients and Methods
We collected data from hypertensive patients who voluntarily presented for screening on both diabetes and hypertension screening days.Poor blood pressure control was defined as systolic blood pressure (SBP) greater than or equal to 140 mmHg and/or diastolic blood pressure (DBP) greater than or equal to 90 mmHg. The Student t test and the Chi-squared test were used.A threshold of statistical significance was set at 5% for the different tests used.
Results
These were 389 patients who were known to be hypertensive among 2012 patients who were collected at the diabetes and hypertension screening days (19.3%). The median age of the known hypertensives was higher than that of the nonknown (60 years versus 50 years). Men were significantly more affected by hypertension than women (60.7% versus 39.3%) ($P<0.001$).Most of the known hypertensives had a family history of hypertension with a frequency of 64.5% ($P<0.001$). One hundred and fifty known hypertensive patients were diabetic (38.6%) versus 238 who were diabetic without associated hypertension (15.2%) with a $P<0.001$. Smoking was found in 23.1% of known hypertensive patients versus 28.7% of those without hypertension ($P=0.02$). Alcohol consumption was found in 8.2% of the known hypertensive subjects versus 11.7% of the non-known hypertensive subjects ($P=0.05$). A minority was on diet (11.2%). The majority were on monotherapy (58.4%). The use of two hypotensive drugs was for 58 subjects (17.6%). The remaining 42 subjects were on triple therapy (12.8%).The mean SBP was 138.2 mmHg with extremes ranging from 98 mmHg to 215 mmHg and the mean DBP was 82.5 mmHg with extremes ranging from 50 mmHg to 120 mmHg. It was noted that 58.6% of hypertensive patients were poorly balanced.Almost half of the women were well balanced (50.3%) whereas only 35.6% of the men had a good balance of their BP ($P=0.004$). For both subjects with a family history of hypertension and those without, the frequency of well-controlled BP was almost the same (41%). Known diabetics had a balanced BP in 44.3% of cases, whereas this balance was achieved in only 39.6% of the non-diabetics ($P=0.35$).
Conclusion
The management of hypertension is part of the management of all cardiovascular risk factors, which also indicate the therapeutic attitude and target blood pressure values.

Adverse events associated with supraphysiological glucocorticoid dosing in congenital adrenal hyperplasia (CAH): results of a structured literature review

Vijay Sharma[1], Helen Coope[2], Kamran Maskin[2], Lotta Parviainen[2], John Porter[2], Michael Withe[2] & Anne-Marie Barnes[1]
[1]BresMed Health Solutions Ltd, United Kingdom; [2]Diurnal, United Kingdom.

Objectives
Congenital adrenal hyperplasia (CAH) is a rare condition caused by enzyme deficiency in cortisol biosynthesis. Patients with CAH require lifelong therapy, with the aim of replacing deficient hormones (cortisol +/− aldosterone) and reducing excess androgen production. Guidelines state that the lowest effective glucocorticoid (GC dose) should be used; however, current GC therapy is suboptimal, and supraphysiological GC doses are used to reduce excess androgens. This study aimed to evaluate the published evidence on long-term adverse events (AEs) associated with GC dosing in CAH.
Methods
A structured, comprehensive literature review was conducted to identify evidence for the link between supraphysiological GCs dosing and long-term AEs of interest to the CAH population: such as cardiovascular disease (CVD), osteoporosis/bone health, obesity, diabetes, reduced growth, and poor fertility.
Results
In total, 4,874 records were identified, and 53 studies were included. There is a lack of prospective randomised controlled trials comparing standard GC regimens. Available literature report heterogeneity of patient populations, treatment regimens and study duration. Studies show that complex and multiple dose GC regimens are used in CAH, and both over- and underdosing are associated with AEs. The relationship between GC dosing and bone health was most widely reported with 17 papers reporting a link between excess GC dosing and poor bone health. Fracture risk was shown to increase in older patients. Sixteen articles reported a link between GC dosing and obesity and associated metabolic syndrome including fat mass and lean body weight. These studies reported that higher GC dosing was associated with higher BMI. Thirteen articles reported a link between GC dosing and height / growth in CAH patients providing evidence for an important link between GC dosing and growth period, with high doses of GC during adolescence being associated with lower final height. Four articles linked diabetes markers, such as HbA1c levels, glucose metabolism, and insulin resistance, with GC dosing. Other relationships supported by the literature were the links between GC dosing and patients' health related quality of life, and CVD/associated risk factors.

Conclusion
This literature review identified a wealth of evidence to support relationships between supraphysiological GCs dosing and long-term AEs in CAH. There is an unmet need for a treatment for CAH that provides optimal cortisol replacement at a physiological dose, thereby reducing AEs associated with excess GC dosing.

Adrenal incidentaloma rate during coronavirus disease 2019 (COVID-19) pandemic

Ozge Telci Caklili[1], Arzu Poyanli[2], Esin Duvek[2], Eda Canipek[2], Alpay Medetalibeyoglu[3], Hulya Hacisahinogullari[1], Ozlem Soyluk Selcukbiricik[1], Nurdan Gul[1] & Ayse Kubat Uzum[1]
[1]Istanbul University, Faculty of Medicine, Endocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University, Faculty of Medicine, Radiology, Istanbul, Turkey; [3]Istanbul University, Faculty of Medicine, Internal Medicine, istanbul, Turkey.

Background
Adrenal incidentaloma (AI) is described as an adrenal mass detected on imaging not performed for adrenal disease. In coronavirus disease 2019 (COVID-19) pandemic, chest CT evaluation was performed for all ages in adults. In this study, we aimed to detect adrenal adenoma(s) which were identified with chest CT, during COVID-19 diagnostic work-up to find AI prevalence in our population.
Methods
All patients who underwent chest CT examination for COVID-19 at Istanbul University Faculty of Medicine between March 15, 2020 and June 15, 2020, were screened. Patients' demographic characteristics were recorded from their medical records. Patients with a history of malignancy were excluded. Images were assessed by two radiologists and consulted with an experienced senior radiologist.
Results
A total of 4449 patients' CT images were screened. There were 4108 patients with no lesion (control group) and 248 (5%) patients with at least one lesion (adrenal group). The mean age of the control group was 46.67 ± 17.07 and the adrenal group was 60.65 ± 16.83 years ($P < 0.001$). In 248 patients, there were 134 patients with at least one adrenal nodule (3% among all screened CT images). The mean age of the patients was 58.70 ± 15.09 years. Thirty-four patients had a right nodule, 78 patients had a left nodule and 22 had bilateral nodules. When nodule size and Hounsfield unit (HU) were compared there was no statistically significant difference between the left adrenal gland and right adrenal gland ($P = 0.57$ and $P = 0.97$, respectively).
Conclusion
Our data showed an AI rate of 3% and the majority of nodules were in the left adrenal gland.

Bone impact of hydrocortisone hormone replacement in adrenal insufficiency.

Ines Charrada, Alaya Wafa, Najoua Lassoued, Boubaker Fadia, Zantour Baha, Berrich Olfa & Sfar Mohamed Habib
Endocrinology-Diabetology and Internal Medicine Service CHU Tahar Sfar Mahdia Tunisia, Mahdia, Tunisia.

Introduction
The treatment of adrenal insufficiency (AI) is based on long-term glucocorticoid substitution. Hydrocortisone (HC) is the most commonly used substitution molecule. The aim of our work was to determine the long-term bone impact of patients with peripheral AI.
Patients and methods
This is a descriptive and analytical study involving 77 patients with peripheral IS (66 women and 11 men), all treated with HC. For each patient, we determined the duration of the disease and the daily and cumulative dose of HC, and performed a phosphocalcic assessment, an alkaline phosphatase (ALP) determination, and a bone densitometry (BMD) performed in 30 patients.
Results
The mean age was 40.5 years (range: 22–63 years). The mean duration of evolution was 7.7 years. We found that among the patients who had a BMD, 75% had bone demineralization at the time of the study, which was more marked in the cancellous bone (spinous site). This prevalence was high compared to the Tunisian adult population (75% vs 45.7%). This demineralization was positively correlated with the cumulative dose of HC (mean cumulative dose (g) $= 60 \pm 80.4$ in patients with normal BMD vs 132 ± 86.4 in patients with bone demineralization; $P = 0.042$), and was more frequent but not significantly so in postmenopausal women. However, we did not find any correlation between bone demineralization and daily HC dose and disease duration, respectively. Biologically, at the time of the study, ALP was elevated and hypocalcemia was present in 15% and 26.7% of patients, respectively. However, we did not find any correlation between these two biological abnormalities and the daily dose of HC, the cumulative dose and the duration of the disease respectively.
Conclusion
Hormone replacement therapy of peripheral AI with HC seems to be a risk factor for bone demineralization, especially with the higher cumulative dose of this corticoid. Further studies are needed to better define the cumulative dose threshold at which bone densitometry monitoring is indicated.

A rare cause of Cushing's syndrome

Vittoria Favero[1], Carmen Aresta[2], Chiara Parazzoli[1], Valentina Morelli[2] & Iacopo Chiodini[1,2]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Department of Endocrine and Metabolic Diseases, Milan, Italy.

Introduction
Aggressive ACTH-independent Cushing's syndrome is rare and frequently related to malignant adrenocortical tumor. However, in exceptional situations, ectopic steroids secretion has been described.
Case report
We report the case of an 87 years-old woman referred to our clinic in September 2020 after a low trauma sacral fracture. Her recent medical history revealed the onset, in the previous months, of severe hypokalemia, uncontrolled type 2 diabetes (glycated hemoglobin 9.2%), worsening of arterial hypertension and spontaneous bruising. Because of the medical history, a Cushing's syndrome (CS) was suspected and after exclusion of exogenous glucocorticoid use, specific tests were carried out. Laboratory findings confirmed the diagnosis of CS: 24-hour urine free cortisol $> 4 \times$ ULN, cortisol after 1-mg overnight dexamethasone suppression test of 58.8 µg/dl, undetectable adrenocorticotropic hormone (ACTH) levels, and hypokalemia. The subsequent abdominal CT scan revealed normal adrenal glands, but showed a suspicious 8-cm pelvic mass, which was suggestive of malignancy. Unfortunately, given the old age and the severe clinical picture, no further investigations were feasible and a medical therapy with metyrapone was initiated. After few weeks of therapy, we observed an improvement of glucose and pressure control and the restoration of normal potassium levels, even though the clinical picture remained severe. After six months a clinical improvement was observed, and the patient could undergo an abdomen MRI for better characterizing the pelvic mass. This second radiologic evaluation showed a significant increase of the pelvic mass diameter, which had doubled, reaching the diameter of 17 centimeters. Because of the rapid tumor growth and the presence of ACTH independent hypercortisolism, the patients could be suspected to be affected by an ectopic cortisol secreting adrenocortical carcinoma. Histological confirmation would be necessary, but surgical options or other invasive procedures are not feasible.
Discussion
Ectopic adrenal carcinomas may result from adrenal embryonic remnants. Adrenocortical neoplasms arising in ectopic locations are extremely rare, and cortisol-secreting ones are even rarer, with only a few cases reported in the literature. The treatment of ectopic adrenocortical carcinoma does not differ from that of eutopic tumors. However, ectopic adrenocortical carcinomas are, in general, aggressive and poorly differentiated and they are, therefore, associated with a high mortality rate.

Magnetic iron oxide nanoparticles for the delivery of thermal therapy for the treatment of primary aldosteronism

Anna Sorushanova[1], Padraig Donlon[1], Obdulia Covarrubias-Zambrano[2], Jose Covarrubias[2], Sunitha Varghese[2], Peter Owens[3], Martin O'Halloran[44], Punit Prakash[5], Stefan Bossmann[2] & Michael Conall Dennedy[1]
[1]National University of Ireland Galway, Clinical Pharmacology, Ireland; [2]The University of Kansas Medical Center, Department of Cancer Biology,

United States; [3]National University of Ireland Galway, Centre for Microscopy & Imaging, Ireland; [4]National University of Ireland Galway, Translational Medical Device Lab, Ireland; [5]Kansas State University, Department of Electrical and Computer Engineering, United States.

To minimise damage to surrounding tissues, targeted delivery of therapeutics to the tumour is highly desirable, and the development of nanotechnology has shown promising results. Magnetic iron oxide nanoparticles (MIONPs) have been gaining traction over the years for applications such as drug delivery, molecular imaging and delivering hyperthermia for treatment of various cancers (1). MIONPs have great therapeutic potential as they can be produced in various sizes and shapes, with the ability to modify the surface by coating the nanoparticles. MIONPs have the ability to be activated by external magnetic field to generate heat and to cause hyperthermia (2). Translationally, the delivery of thermal therapy offers an option for minimally invasive definitive treatment of primary aldosteronism, an endocrinopathy of aldosterone excess/dysregulation which represents the commonest secondary form of hypertension. In this study, MIONPs have been used at different concentrations to evaluate nanoparticle uptake and rate of uptake by adrenal cortical and endothelial cells, as well as gain understanding of the location of nanoparticles within the cell. Magnetic iron oxide nanoparticles (MIONPs) were provided by The University of Kansas. Adrenal Cortical cell-lines (MUC1, H295R and HAC15) and Endothelial cell-line (HUVEC) were used in this study. MIONPs were added at concentrations of 0.5, 5, 10, 20 and 50 μg/ml to the cells and incubated overnight. MIONP up-take efficiency, rate of uptake and cytotoxicity was assessed by Flow Cytometry. Confocal Microscopy was used to image the cells following MIONP incubation. Cellular proliferation was assessed by Xcelligence system and ala-marBlue. Cellular respiration was assessed by "Seahorse" technology. MIONP location within the cells was assessed by transmission electron microscopy (TEM). Following overnight incubation with MIONPs, Flow Cytometry showed significant uptake by MUC1, HAC15 and HUVEC cells at 10 μg/ml MIONP concentration. Confocal and TEM images revealed MIONPs in the cytoplasm and in the vesicles for all cell types (Fig. 1 and 2). Live Confocal imaging showed MIONP phagocytosis specific uptake by the HAC15 cells.

Introduction

The performance of medical imaging leads to the incidental discovery of many silent and ignored tumor lesions. The term "adrenal incidentaloma" (AI) is a neologism for an adrenal mass discovered incidentally during an abdominal imaging examination, not motivated by the exploration of adrenal pathology, most of the time asymptomatic. Several authors hypothesize that adrenal adenomas could be a manifestation of the metabolic syndrome and that the prevalence of insulin resistance indicators (diabetes, hypertension, obesity) is high in patients with an adrenal incidentaloma. The aim of this work is to research among our patients with non-secreting adrenal adenoma, abnormalities of markers of metabolic syndrome in order to identify patients at high metabolic and vascular risk, which may prompt us to reconsider the management of these non-functioning tumors.

Material and methods

A prospective and descriptive study of 50 cases of adrenal incidentalomas, including 24 cases of non-secreting adenomas, collected in the endocrinology, Diabetology and Nutrition department of the CHU Mohamed VI of Oujda. The data were collected from the medical records and processed by SPSS V21 software

Results

Non-secreting adenoma represents 48% of AI. The mean age of our patients with non-functional adenoma was 62.4 ± 10.5 years with female predominance (70.8%). Among 24 patients, eight had a BMI >30 kg/m2, a mean waist circumference of 103.8 mm in women and 108.5 mm in men, 11 patients were hypertensive and 6 were diabetic (25%). Fourteen patients had low HDL cholesterol including 5 male and 9 female patients. Moreover, nine patients had elevated triglycerides. Sixty-six percent of patients satisfied the definition of metabolic syndrome according to the IDF 2005 criteria (International Diabetes Federation), including 10 women and 6 men. Regarding cardiovascular risk, according to the recommendations of the European Society of Cardiology, 70.8% of patients were classified at very high risk and 29.2% at high cardiovascular risk.

Discussion/Conclusion

Non-functional adrenal adenomas are often associated with metabolic syndrome which is a major risk factor for cardiovascular or thromboembolic events, hence the need to consider cardiovascular risk in patients with non-secretory adrenal adenoma for optimal management.

Pulmonary thromboembolism as the initial presentation of ACTH-independent Cushing's Syndrome

Daniela Dias[1], Ines Damasio[2], Helder Simões[1], Filipa Serra[1], Luisa Fontes[3], Carlos Leichsenring[4], Nuno Pinheiro[4] & Inês Sapinho[1]
[1]Hospital CUF Descobertas, Endocrinology, Lisbon, Portugal; [2]Oncology Institute Francisco Gentil, Endocrinology, Lisboa, Portugal; [3]Hospital CUF Descobertas, Internal Medicine, Lisbon, Portugal; [4]Hospital CUF Descobertas, Surgery, Lisboa, Portugal.

Cushing's syndrome (CS) is associated with a considerable risk of complications including thromboembolic events (TE). They occur mostly within the first 2–3 months postoperatively. When present before surgery, CS has high rates of perioperative mortality and morbidity. The benefit of steroidogenesis inhibitors after TE is not fully known. Furthermore, little guidance is available regarding TE assessment/management in CS. We report a case of a 34-year-old male admitted in our emergency department for a presyncope episode during minimum physical activity. He described severe fatigue that had progressively worsened over 3 months. He experienced progressive weight gain of 10 kg and the appearance of extensive purple trunk striae in the last year. His past medical history included hypertension, obesity and obstructive sleep apnea. His blood pressure was 100/78 mmHg, his heart rate 150 bpm and oxygen saturation was 99%. Laboratory tests revealed: hemoglobin 15 g/dl, leukocytosis 13,200/mm3, AST 259 U/L (15–37), ALT 653 U/L (16–63), indirect hyperbilirubinemia 1.20 mg/dl, D-dimer 70.370 ng/ml (<500), NT-proBNP 125 pg/ml, troponin T 663 ng/l. CT scan pulmonary angiography found extensive pulmonary embolism involving the right and left pulmonary arteries with extension to lobar arteries, also revealed a 35 mm solid tumor on his left adrenal gland. Lower limb color doppler ultrasound demonstrated deep venous thrombosis in the right popliteal vein. Anticoagulant therapy was initiated. The patient was hospitalized for treatment and further investigation. Elevated urinary free-cortisol(UFC) levels were noted (936 μg/24 h;1389 μg/24 h;28–213), ACTH level was undetectable (<5 pg/ml), salivary cortisol showed loss of circadian rhythm (32.8 nmol/l- 0800 h; 32.5 nmol/l-0011 h), and low dose dexa 1 mg plasma cortisol result was 26.4 μg/dl and low DHEA-S of 76 μg/dl (80–560). These results were compatible with ACTH-independent CS. He started on metyrapone to control the hypercortisolaemia (maximum 1500 mg 8–8 h). Ketoconazol was not an option given the elevated liver enzymes. There was an initial reduction in 24 hours UFC within a few weeks of initiation of metyrapone. However, the UFC level failed to normalize, after 7 months of medical therapy alone(UFC 706 μg/24 h).An uneventful laparoscopic left adrenalectomy was subsequently performed, with hydrocortisone started for empiric treatment of secondary adrenal insufficiency. Postoperative histopathology confirmed an adrenal adenoma. He completed 3 months of rivaroxabane. Presently, 5 months after surgery, he remains on hydrocortisone. Studies on medical therapy directed to lower cortisol values and their effects in TE risk are sparse. Additional studies are needed to reinforce well defined guidelines regarding CS and its thrombotic complications.

Adrenocortical carcinoma: experience of a tertiary center

Ana Rita Elvas, Joana Couto, Raquel G Martins, Jacinta Santos, Teresa Martins & Fernando Rodrigues
Portuguese Oncology Institute of Coimbra, Department of Endocrinology, Coimbra, Portugal.

Introduction
Adrenocortical carcinoma (ACC) is a rare endocrine malignancy with poor prognosis. Objective: The aim of this study is to characterize patients with ACC followed at a tertiary center. Material and Methods: Retrospective analysis of clinical records of patients with histopathological diagnosis of ACC followed in our clinic. Results and conclusions: We reviewed 11 patients. The average age at diagnosis was 57.3 ± 15.2 years and 63.6% were females. Seven patients had a functioning adrenal carcinoma. At diagnosis, 72.7% of the patients presented weight loss, 36.4% back pain and 27.3% referred asthenia. Two patients presented Cushing's syndrome, one hirsutism and three arterial hypertension and hypokalaemia. Regarding imaging data, the tumour was detected almost exclusively through abdominal computed tomography (CT); dimensions ranged from 3.8 to 20 cm with a median size of 10 cm; 54.5% were located on the left adrenal gland; 28.6% had signs of necrosis; 27.3% presented local invasion and 36.4% distant metastasis. Prognostic stratification based on ENSAT tumour stage was used; two (18.2%) patients were in stage I, four (36.4%) in stage II, one (9.1%) in stage III and four (36.4%) in stage IV. Ten patients (90.9%) underwent adrenalectomy, 70% through laparotomy. Presence of residual tumour could not be assessed(Rx) in 50% of the patients; total resection was reported in 10%; microscopic (R1) or macroscopic (R2) res ection margins were observed in 30% and 10%, respectively. The Weiss Score ranged from 3 to 6 (median of 3) and the Ki67 proliferative index ranged from 2 to 20 (median of 7). Postoperatively, 4 (36.3%) patients received only mitotane treatment and 3 (27.3%) patients were given systemic chemotherapy combined treatment with mitotane. Adjuvant radiotherapy was applied in two patients; and other two required palliative radiotherapy. One patient who received mitotane did not report any drug side effects. The symptoms reported were mostly gastrointestinal disturbances (81.4%, $n=5$); one patient presented neurotoxicity and other reported skin lesions and mucositis. Two patients even had to discontinue treatment du e to intolerance. Disease specific mortality was 85.7%. The mean overall survival was 62.1 ± 14.7 months for stages I + II (ranging from 33.3 to 90.9 months) and 8.8 ± 2.9 months for stages III + IV (ranging from 3.1 to 14.5 months), $P=0.005$. ENSAT staging at diagnosis was the major prognostic factor in our series.

Subthreshold cortisol deficiency-another ray in the spectrum?

Foteini Adamidou, Paraskevi Komzia & Marina Kita
Ippokration General Hospital, Department of Endocrinology, Thessaloniki, Greece.

Introduction
In Endocrinology, subclinical disorders meet certain diagnostic laboratory thresholds, but are by definition asymptomatic. Subthreshold disorders in Endocrinology have not been defined. We describe two cases of cortisol deficiency, primary and secondary, with normal baseline cortisol, which were by presentation clinical, but could be characterized as subthreshold by biochemical cut-off criteria.
Case 1
A 47-year-old woman was referred for assessment of adrenal reserve, one year after a complicated admission following a road accident. Her past medical history was remarkable for Hashimoto's thyroiditis on thyroxine. During her hospitalization with multiple injuries and subdural hematoma, she developed multiple complications, including bilateral adrenal hemorrhage. On examination the patient complained of fatigue; she was hemodynamically stable, but skin and mucosal hyperpigmentation was noted. Multiple measurements of am serum ACTH revealed values between 428–800 pg/ml (10–60) with preservation of circadian rhythm and of cortisol between 10 and 20 ng/ml (6–22). Other relevant labs were: TSH 3.67 mIU/ml, DHEAS 75 μg/dl (150–475), plasma renin activity 13.88 ng/ml/h (0.48–4.88), aldosterone 13.7 ng/dl (4–30). Response to 250 μg tetracosactrin stimulation was borderline at 60' (17.8 μg/dl). Pituitary MRI was normal. Adrenal CT showed normal/small adrenal glands, with complete resolution of hemorrhage. Antibodies to 21-hydroxylase were negative. Serum cortisol-binding protein was 3.8 mg/dl (1.7–3.1) while on oral contraceptives. She was started on hydrocortisone 10–0–5 mg with resolution of symptoms. Four years following the initial presentation, the patient had an am cortisol of 11.89 ng/ml, ACTH 24.5 pg/ml, DHEAS 21 μg/dl and normal response to tetracosactrin stimulation (0' 16.2 μg/dl, 30' 20.16 μg/dl, 60' 21.77 μg/dl), indicating full delayed recovery of the axis.
Case 2
A 87-year-old woman was hospitalized because of severe fatigue, nausea and associated hyponatremia at 125 mmol/l. Her past medical history was significant for hypertension treated with carvedilol 6.25 bid. Her am serum ACTH and cortisol on repeated measurements were 13.6 pg/ml (10–60) and 11.8 μg/dl respectively. Response to 250 μg tetracosactrin stimulation was borderline at 60' (17.9 μg/dl). Prolactin was 1.89 ng/ml, TSH 0.255 mIU/l, FT4 0.61 ng/dl (0.6–1.49) and FSH 1.79 mIU/ml. Pituitary MRI was normal. The cause of hypopituitarism remained unknown. She was started on hydrocortisone 10-0-5 mg and thyroxine 25 μg/d, with resolution of symptoms and electrolyte normalization. A challenge trial of cortisol discontinuation led to symptomatic relapse.
Conclusions
Clinical cortisol deficiency with normal baseline serum cortisol can be defined as subthreshold condition. Concurrent ACTH measurements and stimulation tests are necessary to unmask the problem. The definition should not contest current diagnostic cut-offs or the principle of quaternary prevention.

A multidisciplinary team for diagnosis and management of primary hyperaldosteronism

Meir Frankel[1], Gabriel Munter[1], Sophia Magen[2] & Anthony Verstandig[1]
[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]Laboratory Division, Shaare Zedek Medical Center, affiliated to Faculty of Medicine, Hebrew University, Jerusalem, Israel.

Background
Primary hyperaldosteronism (PH) is a syndrome caused by excess aldosterone secretion, which leads to hypertension and hypokalemia and increased risk for target organ damage. The overproduction of aldosterone at the adrenal gland can be unilateral or bilateral. For unilateral disease the best treatment is unilateral adrenalectomy. According to international guidelines, most of the patients should have adrenal venous sampling (AVS) to distinguish between bilateral and unilateral disease. At 2018 we established a multidisciplinary team for diagnosis and management of primary hyperaldosteronism. The aim of this study was to investigate all cases of PH treated in our institute since establishment, including advantages and pitfalls of AVS procedure.
Methods
A retrospective study was performed on a cohort including all patients that were diagnosed and treated at Shaare Zedek Medical Center during 2018–2021. All patients had adrenal imaging (CT or MRI) followed by AVS as needed. Data collection included demographic, clinical and biochemical information, detailed results of AVS procedures and follow up after. AVS protocol and interpretation of the results were done according to International clinical practice guidelines.
Results
During the described period, 22 patients were diagnosed with PH. Mean age 51.6 ± 10, 19/22 (86%) males. All patients had hypertension and 18/22 (82%) had hypokalemia. 21 of them had an AVS. All AVS procedures were done by one invasive radiology specialist. In 17/21 (81%) the AVS results were fully successful, with improvement during time, from 70% at the first ten patients to 90% at the last ten patients. In 4/21 (19%) there was difficulty to locate the right adrenal vein; even though, in 3/4 patients there was evidence for lateralization according to indirect interpretation of the results, overall 20/21 (95%) had a conclusive lateralization result. In 8/21 (38%) adrenal imaging wasn't accurate in confirming lateralization side. No significant complications of the AVS were observed. 11/16 patients with unilateral disease had unilateral adrenalectomy, all of them became normotensive with less medications or no medical treatment for hypertension.
Conclusion
Establishment of a multidisciplinary team can improve management and treatment for patients with primary hyperaldosteronism. Learning curve for AVS can be achieved after 10 cases. With the limitation of adrenal imaging to locate the hyperaldosteronism source, AVS is a critical step in the diagnosis of primary hyperaldosteronism, and with a good implementation process it is a safe and efficient procedure.

Adrenal insufficiency presenting as hypercalcemia and acute kidney injury

Nauman Jadoon
Queen Elizabeth University Hospital, United Kingdom.

Introduction
Hypercalcemia is uncommon in patients with adrenal insufficiency. It is common in patients with primary hyperparathyroidism and malignancy.
Case
This is a case of primary adrenal insufficiency presenting as acute kidney injury and hypercalcemia. The patient was referred with 10 days history of vomiting, decreased appetite, lethargy and abdominal pain. A week before admission, she developed pleuritic chest pain worsening with inspiration. Her admission bloods showed acute kidney injury (eGFR 38 ml/min), hyponatremia (121 mmol/l), hyperkalaemia (5.7 mmol/l), and hypercalcemia (3.11 mmol/l). Workup for primary hyperparathyroidism and screening for malignancy were negative. Basal cortisol was undetectable (<30 nmol/l) and adrenocorticotrophic hormone level was raised (1030 ng/l). Administration of hydrocortisone and intravenous fluids resulted in dramatic resolution of hypercalcemia and electrolyte abnormalities within 48 h.
Conclusion
This case shows that adrenal insufficiency can may present with hypercalcemia and acute kidney injury and should be considered while evaluating cause of hypercalcemia in patient especially if investigations for common causes are negative.

Percutaneous ethanol ablation of large adrenal tumor

Inmaculada Venegas Nebreda, Nerea Egaña Zunzunegui, Cristina Elías Ortega, Ane Amilibia Achucarro & Alfredo Yoldi Arrieta
Hospital Universitario de Donostia, San Sebastian, Spain.

Introduction
Percutaneous ablation has been used over the years for the minimally invasive treatment of liver, kidney, thyroid and, although less frequent, adrenal cysts. We describe the case of a young patient with a large adrenal cyst treated with ethanol ablation, avoiding adrenalectomy.
Clinical case
We present a 32-year-old woman who is referred to Endocrinology due to a 10 cm adrenal incidental finding in an MRI performed due to disc herniation. As her personal history, she presented gestational Diabetes (DM) in both her pregnancies with subsequent type 2 DM and hypertension. Her treatment includes Metformin and Enalapril. She does not have a Cushingoid phenotype. She reports mild abdominal discomfort, occasional headaches and palpitations. Her blood analysis show HbA1c 6.1% with fasting glucose of 153 mg/dl, with metanephrines, Nugent test and urinary free cortisol in the normal range. The CT scan reveals a thin-walled cystic image of 10 cm in diameter, with no apparent interior content and with a probable diagnosis of a right adrenal cyst. After discussing the case in the endocrine tumor committee, we present the patient with the two available alternatives: adrenalectomy or percutaneous ablation with ethanol. After explaining both options to the patient, she chooses sclerosis because it is less aggressive. Under local anaesthesia, 500 ml of yellow liquid are evacuated with the subsequent introduction of 100 ml of ethanol. After 1 hour, another 100 ml of fluid are evacuated to sclerosize the lesion. Upon examination, no adrenal cells are identified in the sample. The patient is discharged the same day. One month after the ablation, the patient undergoes a control ultrasound where a 90% reduction in cyst volume is observed. In another control at 4 months the cyst remains stable in size.
Discussion
Adrenal cysts are rare lesions which may sometimes reach a considerable size. They may result in complications such as infection, haemorrhage, rupture or compression of adjacent structures. Percutaneous ethanol ablation may be a valid alternative to adrenalectomy in patients with large or recurrent cysts.

Glucocorticoids and androgen secreting adrenocortical adenoma: A case report and literature review

Ali Alqahtani, Mohammed Almehthel & Mohammed Almohaya
King Fahad Medical City, Obesity, Endocrinology and Metabolism Center, Riyadh, Saudi Arabia.

Background
The presence of Adrenocorticotropic hormone (ACTH)-independent Cushing syndrome that is associated with androgen hypersecretion is extremely rare in benign adrenal tumors. Precise recognition and management of this association will have a great impact on the management of such patient.
Clinical case
We describe a case of a 35-year-old lady who presented with 2 years history of difficult-to-control hypertension, symptoms of androgen excess along with Cushing features. Further workup revealed lack of serum cortisol suppression after overnight 1-mg dexamethasone suppression test [493 nmol/l (17.8 μg/dl)] along with 24-h urine free cortisol of 1020 μg/24 h (reference range: 21–292 μg/24 h) and Adrenocorticotropic hormone (ACTH) level of 1.18 pmol/l (reference range: 1.03–10.70 pmol/l). Androgens profile was consistent with high Dehydroepiandrosterone (DHEA) level [22 umol/l (reference range: 2–11.1 umol/l)] and serum testosterone level was 2.18 nmol/l (reference range: 0.38–1.97 nmol/l). There was no biochemical evidence of hyperaldosteronism or pheochromocytoma. Subsequent imaging confirmed the presence of large heterogeneous left adrenal mass ($4.4\times7\times4.6$ cm) with enhancing solid and cystic/necrotic components and small round calcifications. A left robotic adrenalectomy was performed uneventfully. The histopathologic findings were consistent with the diagnosis of an adrenocortical adenoma as there were no features of malignancy seen as per modified Weis criteria. Postoperatively, the patient had undetectable cortisol level with marked improvement in her blood pressure.
Conclusion
An unusual case of adrenocortical adenoma that is associated with plurihormonal hypersecretion is described. Clinicians should be aware of such rare association when evaluating a patient with a similar context.

Giant pheochromocytoma: wich management?

Sara Ijdda, Rafi Sana, Ghizlane El Mghari & El Ansari Nawal
University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, MARRAKECH, Morocco.

Introduction
Malignant pheochromocytomas present a real challenge for practitioners. This entity of tumors is rare, with complex characterization, and heterogenocity in their evolution and prognosis. Given the rarity of this tumor group, there is no consensus on the therapeutic management. The management must be in a multidisciplinary framework. Through this illustrative case, we propose a literature review of this rare entity with discussion of the different therapeutic options in a metastatic situation.
Observation
A 23-year-old patient, with no pathological history, admitted for etiological assessment of a right adrenal mass revealed by isolated right low back pain evolving 5 years previously. An ultrasound was carried out having objectified two tissue masses of the liver of secondary appearance, then a complement by an adrenal scan objectified a voluminous tumoral process at the right adrenal, very vascularized seat of a zone of necrosis with liver metastases. Methoxylates were negative, urinary free cortisol was normal, and dexamethasone suppression test was positive. The patient underwent a right adrenal-nephrectomy complicated by renal failure due to tubular necrosis. The anatomopathological study was in favor of a pheochromocytoma. Bone scintigraphy revealed humeral metastases. As part of a multidisciplinary decision, chemotherapy (CVD), metabolic radiotherapy and treatment with iodine 131 MIBG were proposed. The patient is currently being monitored in France, since she was admitted there for doctoral studies. The 1-year follow-up after surgery showed a reduction in the volume of hepatic metastases, as well as an improvement in renal function with clinical and radiological monitoring as a therapeutic option.
Discussion/Conclusion
Malignant pheochroocytomas represent 10 to 15%. They are defined by the presence of metastases at sites devoid of chromaffin. In the absence of curative treatment and the presence of long survivors, monitoring may be a therapeutic option. The treatment is justified by the presence of a large tumor volume, the presence of an uncontrollable hormonal syndrome and radiological progression.

Cytoreductive surgery should reduce symptoms and improve response to other treatments.For slowly progressive metastatic pheochromocytomas, treatment with 131I-MIBG has been recommended as first-line treatment, with 177Lu-DOTATOC being a potential alternative for those with positive somatostatin receptor metastases; chemotherapy combining Dacarbazine, Vincristine and Cyclophosphamide, may be considered for progressive disease. Prospective trials, in terms of targeted therapies, are necessary for a better characterization of these tumors in order to identify the appropriate treatment. The prognosis of theses tumors remains unfortunate.

The primary aldosteronism rollercoaster: hypoaldosteronism as a potential postoperative complication

August Palma[1], Lihua Hu[1], Heok Cheow[1], Iosif Mendichovszky[1], Vasilis Kosmoliaptsis[1], Alison Marker[1], Waiel Bashari[1,2], Russell Senanayake[1,2] & Mark Gurnell[1,2]
[1]Wellcome Trust-MRC Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge Biomedical Campus, Cambridge, United Kingdom; [2]University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom.

Introduction
Primary aldosteronism (PA) is a common and potentially reversible cause of secondary hypertension, characterised by resistance to standard antihypertensive therapy and possible hypokalaemia. Lateralisation investigations, including adrenal vein sampling (AVS), are required to distinguish between unilateral or bilateral disease, with unilateral disease representing a potentially surgically curable form of PA. The majority of patients proceeding to adrenalectomy remain well postoperatively, with complete resolution of hypokalaemia. Rarely, patients can develop hypoaldosteronism postoperatively, due to prolonged suppression of the contralateral zona glomerulosa. There remains a lack of guidance on how to predict and monitor hypoaldosteronism in PA patients undergoing adrenalectomy. We will illustrate these challenges within two cases.
Cases
Case 1: A 58-year-old fit and otherwise healthy female was referred with a 20-year history of hypertension (on three antihypertensive agents) and unprovoked hypokalaemia (K = 2.9 mmol/l). Following diagnosis of PA, lateralisation studies confirmed unilateral left adrenal disease. She underwent an uncomplicated left adrenalectomy. At her 1-month postoperative review, she reported symptoms of postural hypotension with fatigue. A short synacthen test (SST) was normal. However, serum electrolytes revealed hyperkalaemia (K = 6.1 mmol/l), hyponatraemia (Na = 129 mmol/l) and renal impairment (creatinine = 129 μmol/l). Additional biochemical testing revealed plasma renin concentration (PRC) 62 mU/L and plasma aldosterone concentration (PAC) 104 pmol/l. Following commencement of fludrocortisone, there was significant clinical and biochemical improvement (serum K = 4.9 mmol/l, Na = 135 mmol/l, creatinine = 84 μmol/l). A subsequent attempt to withdraw fludrocortisone therapy was associated with recurrence of hypoaldosteronism. *Case 2*: A 55-year-old male was referred with a 10-year history of hypokalaemia and resistant hypertension (average BP 170/11 mmHg on four antihypertensive agents). He had a history of mild renal impairment (baseline creatinine 107 μmol/l). Following diagnosis of PA, he was commenced on Eplerenone which successfully achieved a normotensive state. Lateralisation studies confirmed unilateral left adrenal disease, and the patient proceeded to left adrenalectomy without complication. At his 1-month post-operative review, he was found to be hyperkalaemic with renal impairment (creatinine 176 μmol/l). His PAC was undetectable (< 70 pmol/l); SST was normal. Following commencement of fludrocortisone, there was a rapid improvement in his biochemistry (K = 5.1 mmol/l, Na = 141 mmol/, creatinine 113 μmol/l).
Conclusion
Although considered to be a relatively rare (~5%) complication in patients with PA undergoing unilateral adrenalectomy, hypoaldosteronism is a potentially serious manifestation. Factors that may predict its development include severity of PA (e.g. presence of hypokalaemia). Our cases highlight the importance of attempting to identify those patients who are at higher risk of postoperative hypoaldosteronism, ensuring that there is a strategy for close biochemical surveillance postoperatively in these patients.

Assessment of glucolipid metabolism in patients with Cushing's syndrome caused by adrenal adenoma

Jie Li[1], Jiaxin Zhang[1], Guimei Yang[1], Xintong Hou[1], Dan Yang[1], Jing Yang[1], Yi Zhang[2] & Yunfeng Liu[1]
[1]First Hospital of Shanxi Medical University, Department of Endocrinology, Taiyuan, China; [2]Shanxi Medical University, Department of Pharmacology, Taiyuan, China.

Backgrounds
Based on anthropometry and blood biochemical tests, this study aims to analyze the variation of glucose and lipid metabolism in Cushing's syndrome (CS) patients caused by adrenal adenoma combining with flash glucose monitoring system (FGMS) and dual-energy X-ray absorptiometry (DEXA).
Methods
According to the strict diagnostic and exclusion criteria, seven healthy controls (HCs) and seven CS patients were collected in this study. First, the anthropometric parameters and blood biochemical indexes of all subjects were collected. Subsequently, their body composition of the whole body were measured by DEXA. Finally, all were equipped with a sensor of FGMS, and the blood glucose levels were recorded. According to the data of FGMS, the related indexes of blood glucose variation were calculated. The data between HCs and the CS group were analyzed by T-test or Mann–Whitney test.
Results
(1) Anthropometric parameters: compared with HCs, the CS group showed the higher waist circumference and waist-to-hip ratio (all $P < 0.005$); (2) Blood biochemical indexes: the levels of HbA1c%, TG, TC and LDL-C in the CS group were higher than those in HCs (all $P < 0.005$), while FBG and FINS were generally unaffected in the CS group than in HCs; (3) Data related FGMS: compared with HCs, the changes of general blood glucose alterations, within-day and day-to-day glucose variability, and the percentage of blood glucose above the standard range (PT3) were significantly higher, and the percentage of blood glucose within the standard range (PT2) was significantly lower (all $P < 0.005$); (4) Data related DEXA: a significantly increased fat ratio in Android area (represent for midsection fat) was found in the CS group (all $P < 0.005$), but no increase or decrease in fat or lean tissue of other areas were observed; (5) Fast insulin, HOMA-β index and HOMA-IR index of CS group tend to be higher than HCs, but there are no significant difference.
Conclusion
The homeostasis of glucolipid metabolism in the CS group was significantly destroyed, but impaired islet β-cell function and IR were not observed. A limitation of our study is its relatively small sample size due to the rare occurrence of CS.

Head and neck paraganglioma: exploring the metastasizing potential. Case report

Laura Teodoriu[1,2], Andreea Boboc[3], Ana-Maria Patrascu[44], Stefana Bilha[1], Letitia Leustean[1], Maria-Christina Ungureanu[1], Cipriana Stefanescu[5] & Cristina Preda[1]
[1]University of Medicine and Pharmacy Gr. T Popa, Endocrinology, Iasi, Romania; [2]Regional Institute of Oncology, Endocrinology, Iasi, Romania; [3]Regional Institute of Oncology, Surgery, Iasi, Romania; [4]Regional Institute of Oncology, Pathology, Iasi, Romania; [5]University of Medicine and Pharmacy Gr. T Popa, Nuclear Medicine, Iasi, Romania.

Introduction
Paragangliomas (PGLs) are tumors originating from neural crest-derived cells situated in the region of the autonomic nervous system ganglia. Head-and-neck PGLs (HNPGLs) originate from the sympathetic and parasympathetic paraganglia, most frequently from the carotid bodies and jugular, tympanic and vagal paraganglia, and are usually non-catecholamine secreting.
Case report
We present the case of a 60 years old male patient, which was admitted at Endocrinology Department for differential diagnosis of bilateral cervical lymph nodes, which occurred over past 10 years, with a clinical exacerbation in the last year. His thyroid ultrasound results were suggestive only for a Hashimoto's thyroiditis, with hormonal tests implying hypothyroid status. In the context of bilateral lymph nodes, with MRI that indicated a potential haemalogical malignancy, the left lateral cervical formation has been biopsied and the histopathological result concluded: head and neck paraganglioma. Immunohistochemical result indicates that our HNPGL might have malignancy potential: increased tumor dimensions (over 10 cm identified on MRI exam), Ki 67 positive

in 3% of the tumor cells, sustentacular cells and low expression of S100 in those cells. Other immunohistochemical staining highlighted positive synaptophysin, chromogranin and GATA3. Our patient was not expressing catecholamine secretion clinical features but we recommend complete hormonal exploration: normetanephrine, 3-methoxytyramine and neuron-specific enolase (NSE), tests in working progress. We will recommend full exploration of adrenal glands also, to exclude synchronous affection.
Conclusion
His case will be reviewed by multidisciplinary committee to conclude proper therapeutic management: surgery, radiotherapy or somatostatin analogs and potential PRRT after specific functional imaging. With integral neuroendocrine tumor markers and functional imaging results we'll be able to determine if this paraganglioma is malignant or not.

Managing Immune checkpoint inhibitors and adrenal insufficiency in acute setting

Mahamud Bashir, Kirtanya Ramachandran, Rebecca Volmy, Alexanderia Williams, Akunna Elonu, Gloria Elekwa, Lamis Fahal, Hassan Rehmani, Homagni Roy & Gideon Mlawa
Queens Hospital, London, United Kingdom.

The introduction of immune checkpoint inhibitors (ICIs) in clinical management of cancer has had an undeniable impact in management of cancer patients. Currently there are several ICIs are used across Europe including but not limited to, pembrolizumab, atezolizumab, and ipilimumab. Even though their clinical efficacy is reputable, they have the potential of causing serious immunotherapy-related adverse events' (irADRs) in several organ systems including endocrine organs. With the ever-growing use of ICIs, case reports are emerging with increasing frequency of rare yet life-threatening endocrine dysfunctions, particularly involving the pituitary, thyroid and less frequently adrenals.
Case presentations
Case 1)A 64 y/o patient was admitted under medical team with features of adrenal insufficiency. He had background of metastatic poorly differentiated adenocarcinoma of lung(T4N3M1c), for which he was treated with pembrolizumab (from October 2019 – May 2020), cisplatin, premetrexed, simvastatin 20 mg OD, ezetimibe 10 mg OD and analgesia. She presented with general fatigue, loss of appetite and mouth ulcers since ICI therapy. He was given iv hydrocortisone and the patient improved clinically. On physical examination, the patient's looked tired and his HR was 116 bpm. Blood test showed his cortisol to be 8 nmol/l, TSH: 4.39 mU/L. He was discharged on prednisolone 10 mg OD which was reduced to 7.5 mg. 2)A 59 years with a background of right eye choroidal melanoma for which she underwent primary enucleation in January 2019 and was subsequently started on Pembrolozumab. She also has other comorbidities like T2DM, HTN, IHD for which she is being medically managed. She was admitted with general fatigue, vomiting and she was hypotensive and her lab findings showed her cortisol to be very low at 28 nmol/l. She was also in in fast AF and AKI. The oncology team reviewed her, and she was started on IV methyl prednisolone and IV fluids following which her AKI resolved. She was discharged on hydrocortisone 10 mg BD.
Discussion/ conclusion
Adrenal insufficiency (AI) is a rare irADRs of ICI therapy. If left untreated AI is life-threatening and unlike other autoimmune complication of ICI use AI is irreversible with patients often require long term steroid therapy. Baseline endocrinology tests like TFT, glucose(HbA1C), cortisol need to be done at initiation of treatment and monitored regularly. Based on our findings from this case we believe that it is important that the patients are educated regarding risk of AI and follow up monitoring for signs of AI be put in place post therapy with ICI.

Management of primary hyperaldosteronism and the role of adrenal venous sampling; a single-center experience

Carlien De Herdt[1], Philipse Eva[2], D'Archambeau Olivier[3], Ysebaert Dirk[4], Snoeckx Annemiek[3], Peeters Bart[5] & Christophe De Block[2]
[1]Antwerp University Hospital, Endocrinology-Diabetology-Metabolism, Edegem, Belgium; [2]Antwerp University Hospital, Endocrinology-Diabetology-Metabolism, Edegem, Belgium; [3]Antwerp University Hospital, Radiology, Edegem, Belgium; [4]Antwerp University Hospital, Endocrine and Transplantation Surgery, Edegem, Belgium; [5]Antwerp University Hospital, Clinical Biology, Edegem, Belgium.

Background
Primary hyperaldosteronism (PA) is a prevalent, but underdiagnosed syndrome. Diagnosis and treatment have been relatively constant since the development of the latest Endocrine Society guidelines in 2016.
Study objective
Baseline characteristics, treatment and follow-up of subjects with PA referred for adrenal venous sampling (AVS) in a tertiary hospital since 2009 are presented.
Results
Thirty five subjects (M/F: 17/18, mean age 49 ± 10 years) underwent AVS. Reasons for screening were; therapy-resistant hypertension (46%), sustained blood pressure > 150/100 mmHg (20%), hypertension and an incidental mass (3%), hypertension with hypokalaemia (28%). One subject without hypertension had a positive screening for PA in the work-up of an adrenal incidentaloma. Echocardiogram showed left ventricular hypertrophy in 19 subjects (54%). Plasma aldosterone/ renin ratio (ARR) was above the threshold of 24 (pg/ml) /(μu/ml) in most (94%) subjects. With a mean plasma aldosterone (PAC) of 306 pg/ml, 88% had a PAC > 150 pg/ml. A combination of an elevated PAC and ARR was seen in 81%. Saline infusion test was still performed in 60% of subjects of which 81% had a PAC above 100 μg/ml and 19% between 50 and 100 μg/ml. AVS showed unilateral aldosterone hypersecretion in 12 and bilateral hypersecretion in 11 subjects. In 9 subjects the right adrenal vein was not reachable and in 3 subjects there were analytical problems. Discrepancy in lateralization between CT adrenals and AVS was seen in 57%; normal CT vs AVS with lateralization (2 subjects), normal CT vs AVS with bilateral hypersecretion (4 subjects), adrenal adenoma on CT with lateralization on the contrary adrenal (2 subjects), adrenal adenoma on CT without lateralization on AVS (5 subjects). Of the 12 subjects with lateralization, 9 underwent unilateral adrenalectomy of which 3 could stop all antihypertensive drugs, but all could reduce medication from 5 to 2, average. Of the 12 subjects with a non-diagnostic AVS, 6 underwent unilateral adrenalectomy with the histological confirmation of an aldosterone producing adenoma and antihypertensive drugs could be stopped postoperatively in 3 subjects.
Conclusion
Since 2009 only 35 subjects were referred to undergo AVS which suggests the underdiagnosis of PA. Hypertension and hypokaliëmie are not mandatory characteristics of PA but were present in 97% and 57%, respectively. The number of patients with unilateral vs bilateral aldosterone hypersecretion was similar. 57% had a discrepancy in lateralization between AVS and CT adrenals. Antihypertensive drugs could be stopped in 40% of subjects who underwent unilateral adrenalectomy.

Alternative treatment in Bilateral Macronodular Adrenal Hyperplasia with possible adrenal hypersensitivity to Angiotensin II

Aurora Calisi, Enrichetta Gigante, Raffaele Pepe, Valeria Creato & Francesco Cipollone
SS Annunziata, UOC Clinica Medica, Chieti, Italy.

Bilateral Macronodular Adrenal Hyperplasia (BMAH) is an uncommon cause (< 2%) of endogenous Cushing's syndrome, characterized by enlarged adrenal glands Althought the exact pathogenetic mechanism remains unclear, recently, it has been reported that aberrant expression of ectopic receptors, such as AVP, GIP, angiotensin II (AT1 receptor) catecholamine, LH, 5HT4 agonists, and leptin, evoked cortisol secretion, which escapes from cortisol-mediated feedback in BMAH. Here we report a case of BMAH that suggested an aberrant response to angiotensin II via AT1 receptor in cortisol hypersecretion. A 66-yr-old man was admitted to a hospital for stroke,medically treated since beyond the established thrombolytic window. On admission he presented severe hypertension (BP 230/140 mmHg). On the hypothesis of secondary hypertension we performed in−depth analysis. Laboratory test documented undetectable plasma ACTH level (1,6 pg/ml) and high level of 24−h urinary free cortisol (983 mg/die). Plasma cortisol was not suppressed (12,8 μg/dl) after the administration of 1 mg dexamethasone overnight. Abdominal Magnetic Resonance Imaging demostrated nodular enlargement of bilateral adrenal glands. Moreover, renine and aldosterone levels were high (respectively 83 mU/ml and 74 ng/dl) and Angio-CT revealed right renal artery stenosis. These results indicated a diagnosis of Cushing's syndrome due to BMAH with suspected adrenal hypersensitivity to angiotensin II. Therefore, Renal Artery Stenosis Angioplasty (PTA) was performed and the patient underwent a revised assessment which revelead

normal level of plasma ACTH, urinary free cortisol and renine and aldosterone. Although it is well known that angiotensin II stimulates aldosterone secretion mainly through angiotensin II receptor (AT1), there has been no evidence, to our knowledge, that angiotensin II affects cortisol secretion in vivo. In our case, PTA blocked the aberrantly increase of plasma cortisol level. Therefore, it is possible that the adrenal hypersensitivity to angiotensin II is involved in the pathogenesis of BMAH and that angiotensin II aberrantly stimulated cortisol secretion via AT1 receptor. A similar case report described a case of BMAH with adrenal hypersensitivity to angiotensin II, treated with bilateral adrenalectomy [1]. In summary, we have reported a case of BMAH with possible hypersensitivity to angiotensin II. Further investigations are required to clarify the significance of abnormal adrenal response to angiotensin II.

Tumor enlargement in adrenal incidentaloma is related to glaucoma and statin treatment: are there two new prognostic features?

Alice Ferrero[1], Tommaso Daffara[2], Chiara Mele[2], Marco Zavattaro[3], Martina Romanisio[2], Beatrice Cavigiolo[3], Samuele Costelli[2], Marina Caputo[3,4], Paolo Marzullo[3], Flavia Prodam[3,4] & Gianluca Aimaretti[3]
[1]Endocrinology, Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]Endocrinology, Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]Endocrinology, Università del Piemonte Orientale, Novara, Italy., Department of Translational Medicine, Novara, Italy; [4]Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy.

Aim
The uncertainty on the management of small adrenal incidentalomas (AIs) in guidelines still represents a challenge in real clinical practice. The aim of the study was to identify risk factors for morphological or functional changes during follow-up by using clinical, radiological, and pathological features.
Methods
We retrospectively evaluated demographic (gender and age at diagnosis), clinical (weight, height, body mass index, smoking habit, comorbidities), radiological characteristics (localization, diameter, HU for CT scan; T1 and T2, and the loss of intensity at chemical shift for MRI) and biochemical parameters of adrenal hypersecretion of 177 AIs (2007-2021). To detected risk factors for tumor enlargement or hypersecretion, diseases associated with AIs were included if the prevalence was higher than 2%. Patients were divided into two groups according to dimension during follow-up (group A: radiological stability; group B: tumor enlargement at radiological scans).
Results
90.4% of patients belongs to group A, while 9.6% to group B. Chronic obstructive pulmonary disease (COPD), neoplasms, and glaucoma were the most frequent associated diseases. Group B showed larger diameter at diagnosis ($P=0.09$), higher aldosterone ($P<0.001$), DHEAS ($P=0.007$), ARR ($P=0.01$), lower DRC ($P<0.04$) levels and higher weight than group A. Open laparotomy was chosen most frequently in group B ($P<0.004$). AI diameter was negatively correlated with age ($r -0.159$, $P<0.04$), 17-OHP levels ($r -0.461$, $P=0.05$), statin treatment inversely to the drug potency ($r -0.193$, $P<0.02$), and positively with ACTH ($r 0.198$, $P=0.06$) and urinary normetanephrine levels ($r 0.248$, $P<0.01$). Analyzing AIs changing over time, an enlargement occurred within 36 months of follow-up and only glaucoma was an independent predictor of it ($B=3.370$, exβ $=29.077$; $P<0.005$). Considering concomitant treatments, at 36 months of follow-up, 100% of subjects showing an enlargement were not taking statins, compared to 45.2% of subjects with stable disease ($P=0.06$). Subjects suffering from glaucoma, atrial fibrillation, impaired glucose metabolism (T2DM or IGT), COPD (in males only) had a lower dimensional change-free survival than non-affected.
Conclusions
The presence of glaucoma and treatment with statins seems to be a risk and a protective factor, respectively, for an AI enlargement. Further prospective studies of validation are needed. If subtle undetectable cortisol hypersecretion and proliferation cellular mechanisms have a role are two topics for further research.

EP91

Silent clinical presentation of a rare genetic disorder

Diandra Carmen Giuca[1], Dan Hortopan[2], Suzana Vladoiu[1], Adriana Padure[1], Andra Caragheorgheopol[1], Andreea Kremer[1] & Iuliana Gherlan[1,3]
[1]"C.I.Parhon" National Institute of Endocrinology, Bucharest, Romania; [2]Gral Medical Center, Bucharest, Romania; [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Carney complex is a rare autosomal dominant genetic disorder which develops secondary to mutation in the PRKAR1A gene located in the 17q22-24 region. It is commonly characterised by the association between spotty skin pigmentation, cardiac myxoma and secretory endocrine tumors.
Case presentation
A 15.8-year-old boy known with PRKAR1A mutation diagnosed based on his personal history – cutaneous papiloma of the neck resected at the age of 6 years, bilateral testicular microlitiasis, right testicular teratoma resected at the age of 9 years, embolic stroke secondary to left atrial myxoma resected at the age of 10 years was adressed for tall stature. His family history is negative. Clinical examination reveals a height of +2.03 S.D. (+1.54 DS compared to his familial target height), a height growth velocity of 6 cm per year (+3.86 S.D.), BMI 19 kg/sm; no other specific findings are met. Thyroid function and neck ultrasound are normal. Prolactin, hypophiseal-gonadal axis and androgens are within the normal range. Testicular ultrasound reveals the presence of persistent bilateral microlitiasis, but tumor markers (BhCG and alfa-fetoprotein) are negative. IGF1 (468.5 ng/ml, +1.65 SDS), IGFBP3 (5401 ng/ml) have normal values, with a supressed growth hormone of 1.28 ng/ml after oral glucose dynamic testing. Bone age is comparable to the chronological age (16.5 years old). Serum ACTH (1 pg/ml) and 0800 h cortisol (10.78 μg/dl) levels and free urinary cortisol (240.87 μg/24 h) raise the susspicion of ACTH-independent hypercorticism. Liddle test shows paradoxal stimulation of both serum and free urinary cortisol after dexamethasone intake (baseline, day 2 and 6 serum cortisol of 4.46, 9 and 18.43 μg/dl, respectively; baseline, day 3 and 6 free urinary cortisol of 39.26, 81.85 and 903.15 μg/dl, respectively), thus confirming the diagnosis of adrenal hypercorticism. Abdominal MRI shows no pathological changes of the adrenal glands. The most probable diagnosis in this case is primary pigmented adrenal hyperplasia which often accompanies PRKAR1A mutation.
Discussion
The therapeutic approach is bilateral adrenalectomy, but given the absence of clinical glucocorticoid changes, patient's family decision is to follow-up. He remains in observation for his height, but for the moment growth hormone excess can be excluded. This case particularities consists in the large range of clinical features of the Carney complex at an early age; still, one of the important feature of the syndrome –hypercorticism– was present in a subtle, subclinical manner and it was identified in a proactive evaluation.

EP92

Very high urinary free cortisol levels in patients treated with tuberculostatics

Catarina Roque, Ana Sofia Osório & Ricardo Fonseca
Hospital Professor Doutor Fernando Fonseca, Endocrinology, Lisbon, Portugal.

Introduction
Pharmacologically induced false positive results in urinary free cortisol levels (UFCL) have been ascribed to 11βHSD-2 inhibition or direct interference on HPLC. Few drugs have been implicated by mechanisms not yet confirmed.
Case Reports
We report 3 patients with active pulmonary tuberculosis (TB) and very high UFCL, 2-6× above the upper limit of reference [mean levels 3411 μg/24 h (RR 167-827)]. The 2 males and the woman aged 31 to 60 y.o. had hypertension, one had diabetes mellitus and the other HIV. None had stigmata of Cushing syndrome. Known causes of falsely elevated UFCL were not found (eg. polyuria, synthetic steroid use). Acute disease could justify hypercortisolism but we kept the patients under observation to confirm UFCL normalization. On the first out-patient appointment the UFCL remained very high (mean 2431 μg/24 h) 1, 5 and 6 months after hospital discharge. On the second out-patient appointment, after completion of the anti-TB (HRZE) treatment, all patients had normal UFCL (mean 477 μg/24 h). We reviewed the files for active diseases, comorbidities and treatments: the one common situation was active TB and though acute disease could justify hypercortisolism initially, we considered it less likely to justify the more than 2 fold UFCL elevation in the clinically stable patient after hospital

discharge. The drugs used by the 3 patients during hospitalization, continued after the first and discontinued before the second out-patient appointments were Isoniazid and Rifampicin, which we suspect to cause this previously undescribed pharmacological interference. Rifampicin has been implicated in false positive dexamethasone suppression tests.

Conclusions

We report the association of very high UFCL in patients without stigmata of Cushing syndrome treated with anti-TB regimens containing Isoniazid and Rifampicin. Hopefully in the future we will confirm the underlying mechanism and appraise the impact of this finding on the exclusion criteria for adrenal insufficiency in these specific group of patients.

Detection of late-onset adrenal hyperplasia in girls with peripubertal virilisation, a case stady

Bessaid Khadidja[1] & Mouna Mezoued[1,2]
[1]Public Hospital Establishment of Bologhine, Algiers, Algeria; [2]Bologhine Hospital, Endocrinology, Algiers, Algeria.

Introduction

Non-classical congenital adrenal hyperplasia (NCCAH) is considered to be a common monogenic inherited disease, with an incidence range from 1:500 to 1:100 births worldwide. NCCAH is often peri or post pubertal pauci or even asymptomatic. We report the case of a young girl with severe hirsutism and sexual ambiguity, despite late disclosure.

Observation

This is the case of a 16-year-old girl, with a history of menarche at the age of 14, presenting since puberty a spaniomenorrhea with rapidly worsening hirsutism. The clinical examination finds a normal height at 160 cm, a BMI at 21 kg/m^2, severe hirsutism scored at 33 according to Ferriman and Galway with signs of virilization and defeminization associating alopecia of the frontal gulfs, muscle hypertrophy, hoarseness tract, significant clitoral hypertrophy and breast atrophy. The biological assessment found elevated testosterone at 2.83 ng/ml, baseline 17OHP at 5.98 ng/ml, and 47.6 ng/ml after synacthen, normal plasma cortisol at 543 nmol/l, ACTH at 162 pg/ml. The abdominopelvic ultrasound objectified an aspect of micro polycystic ovaries. CT of the adrenal glands and pelvic MRI are without abnormalities. The diagnosis of NCCAH was retained. The patient was treated with cyproterone acetate and valerate of estradiol.

Discussion

Despite the high incidence, there is a low genotype-phenotype correlation, which explains why NCCAH diagnosis is usually delayed or even never carried out, since many patients remain asymptomatic or are misdiagnosed as suffering from other hyperandrogenic disorders.

The burden of illness associated with adolescent and adult congenital adrenal hyperplasia: results of a structured literature review

Uzmah Sabar[1], Helen Coope[2], Kamran Maskin[2], Lotta Parviainen[2], John Porter[2], Mike Withe[2] & Matthew Woods[1]
[1]BresMed Health Solutions Ltd, Sheffield, United Kingdom; [2]Diurnal Limited, Cardiff, United Kingdom.

Objectives

Congenital adrenal hyperplasia (CAH) is a rare condition caused by enzyme deficiency in cortisol biosynthesis. The aim of this study was to evaluate the burden of illness associated with child/adolescent and adult CAH.

Methods

A structured, comprehensive literature review was conducted to identify articles describing the burden and treatment landscape of CAH. Literature databases (MEDLINE, Embase, the Cochrane Library and EconLit), websites and conference proceedings were searched. Searches were performed in 2016 and updated in June 2020; eligible articles presented evidence for child/adolescent (aged $\leq$18 years where reported) or adult CAH, for $\geqq$1 topic of interest (natural history; risk factors; epidemiology; clinical characteristics; humanistic, caregiver and economic burden; treatment options; or clinical guidelines). The evidence presented here focusses on the humanistic, caregiver and economic burden of child/adolescent and adult CAH.

Results

A total of 3,711 citations were identified and 338 were included. A total of 89 (adults) and 86 (adolescents) references were identified that reported humanistic, caregiver or economic burden data respectively. Compared to the general population, patients with CAH (irrespective of age) were found to be significantly shorter and experienced poor bone health, increased occurrences of cardiometabolic events (including obesity, hypertension and insulin resistance), were at risk of developing adrenal crises (which contributed to excess mortality), and in adolescent/adult CAH, had impaired male and female fertility (with adolescents commonly experiencing precocious puberty). Both adolescent and adult patients with CAH were also at risk of developing psychosocial health issues compared to the general population, with adult patients experiencing emotional trauma related to their condition and subsequently finding it difficult to speak about their illness. The reported generic HRQL (no CAH specific instruments were identified) in CAH was varied, with increased impairment observed in more severe forms of CAH and in general, HRQL frequently more impaired in women compared with men. Although the literature was sparse, it did indicate that CAH is associated with a substantial caregiver burden; parents of children/adolescents with CAH reported high levels of anxiety, depression and worry for their loved one. Furthermore, CAH was also associated with a notable economic burden, with significantly higher annual healthcare costs compared to matched controls ($P=0.007$ for patients aged 18–40 years; $P<0.001$ for patients aged $\geqq$40 years).

Conclusions

Our review highlights that CAH is a complex and debilitating disease which is associated with significant humanistic, caregiver and economic burden in both child/adolescent and adult CAH patients.

Congenital adrenal hyperplasia due to 21-hydroxylase deficiency and hypertension: a case report

Chayma Besrour, Rojbi Imen, Mekni Sabrine, Majdoub Marwa, Lakhoua Youssef, Ben Nacef Ibtissem & Khiari Karima
Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia.

Introduction

Congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency is the most common of the CAH, it is also the most common of the autosomal recessive diseases. Hypertension is generally absent, and its presence should lead to an investigation of another cause.

Observation

We report the case of a 26-year-old young man, descendant from a second-degree consanguineous marriage with a family history of the death of a brother at the age of 25 days of severe dehydration, who is followed in our department for HCS with HTA. The diagnosis of CAH was suspected at the age of 9 days due to dehydration with electrolyte disorders. Hormonal assays confirmed the diagnosis in front of a high level of 17-OH progesterone. At the age of 3 years old, he was operated for right testicular ectopia and at the age of 8 years old, we discovered a hypertension. The etiological assessment concluded to a secondary hyperaldosteronism.

Discussion

The 21-hydroxylase deficiency is generally not associated with hypertension, taking into consideration the hypocortisolism and the aldosterone deficiency depending on the level of the block. Hyperaldosteronism associated with 21hydroxylase deficiency constitutes a new entity recently reported by a few studies, but its pathophysiological mechanism remains unclear.

Ectopic Cushing's syndrome

Guranda Maisuradze & Salome Kalandadze
New Hospitals, Tbilisi, Georgia.

Introduction

Ectopic Cushing's syndrome (ECS) is a condition caused by an ACTH-secreting tumor outside the pituitary or adrenal glands. Most cases are caused by neuroendocrine tumors of the lung, pancreas, thymus or medullary carcinoma of the thyroid. Small-cell carcinomas of the lung are probably the most common cause of biochemical hypercortisolism. About 15% of Cushing's syndrome cases are due to ECS.

Case description
A 27-year-old male patient presented to the clinic with a 4-months history of weakness, swelling, moon face, purple striae on the skin of the abdomen and thighs, hypertension, and hyperglycemia. On examination: BMI – 30.8 kg/m^2, T/A – 160/100 mmHg. Investigations: 0800 h Cortisol-474.0 ng/ml (64.1–209.4), ACTH-201 ng/l (12–62), FPG-168 mg/dl, HbA1c-4.6%, ALT-79($<$ 41), electrolytes-N; 1600 h Cortisol-383.93 (30–160); urinary free Cortisol-153 µg/24 hours (3.5–45). After hypercortisolism was confirmed, further tests were done to determine the cause. MRI scans of the brain, abdomen and pelvic with no pathology. Next we performed MRI scan chest – 11 $\times$ 14 mm solid pulmonary nodule appeared in the left lower lobe. ECS was diagnosed. Diet, regimen and Metformin were recommended. Patient was referred to the thoracic surgeon.
Conclusion
The best treatment for ECS is surgical removal of the tumor. This is usually possible when the tumor is benign. However, many tumors are malignant, and have metastasized before cortisol excess has been diagnosed. Surgical removal is not possible in these situations, and drugs to suppress cortisol secretion may be given. Surgical removal of the tumor may lead to full recovery, but there is a chance of the tumor coming back. Survival for people with ectopic tumors depends upon the outcome associated with the particular tumor type.

Adrenal insufficiency revealed during a septic shock
Rym Belaid, Anissa Ben Bouzid, Nada Ban Abdelaziz, Naourez Abid & Raja Amri
Mohamed Tahar's Maamouri Hospital, Internal Medecine Department, Nabeul, Tunisia.

Introduction
Acute adrenal insufficiency (AAI) is a rare but life-threatening condition. It may occur in 50 to 60% of septic shocks (SS). Its diagnosis can be difficult as symptoms are sometimes nonspecific. Herein, we report the case of a female patient with an AAI revealed during SS.
Abstract
A 30-year-old woman with a history of celiac disease since the age of 25 on a gluten-free diet, presented to the emergency department with abdominal pain, vomiting, fever and profound asthenia evolving for five days. Physical examination revealed an increased pulse rate of 120 beats per minute, a rapid respiratory frequency of 40 cycles per minute, fever (38.8) and low arterial hypotension of 60/40 mmHg. The abdomen was diffusely painful. Blood investigations showed leukocytosis (14000), mildly increased C-reactive protein (CRP) (84 mg/l), hypoglycemia (0.5 g/l), severe hyperkalemia (7.22 mmol/l) and hyponatremia (122 mmol/l). Arterial blood gas test noted a metabolic acidosis. A Computed Tomography (CT) scan of the lungs, abdomen and pelvis was normal. The urine culture was positive. The diagnosis of septic shock due to urinary tract infection was then initially retained. The patient was treated with vasoactive drugs and appropriate antibiotic therapy. The evolution was marked by the persistence of abdominal pain, arterial hypotension, hypoglycemia and hydro electrolytic disorders. The diagnosis of acute adrenal insufficiency was therefore suspected and then confirmed by a low serum cortisol level of 1.6 µg/dl (6.–18). The patient received intravenous hydrocortisone hemisuccinate and parenteral rehydration.- Clinical and biological improvement was noticed in few days.
Conclusion
Our case illustrates the difficulty of the diagnosis of an AAI during SS. Thus, acute adrenal insufficiency must be suspected in the context of SS especially in patients with hyperpigmentation; hyponatremia and/or hyperkalemia, a medical history of autoimmune disease or an increased vasopressor dependency. Parenteral rehydration and intravenous hydrocortisone hemisuccinate should be initiated immediately, even before laboratory confirmation of the diagnosis.

Adrenal crisis revealing factitious hypoglycaemia in a pregnant woman
Anis Grassa, Nadia Khessairi, Yezza Hajer, Fatma Chaker, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia.

Introduction
Factitious hypoglycaemia in adults is usually due to exogenous intake of insulin or hypoglycaemia sulfonamides. This occult intake is most often voluntary and the diagnosis is not always obvious.
Observation
We report the case of a 37-year-old pregnant woman at 15 weeks of amenorrhoea, followed for addisson's disease since 3 years and not diabetic, was referred to our department for acute adrenal insufficiency following the discontinuation of her replacement therapy for more than 3 months. The main symptoms were asthenia, vomiting, abdominal pain and recurrent hypoglycaemia. She was treated with intravenous high-dose hydrocortisone, with improvement of the symptoms except for randomly scheduled hypoglycaemia resistant to correction.She denied taking any medication other than those given by the nurses and the hypoglycemia continued. Investigations such as plasma measurements of insulinemia, C-peptide, hypoglycaemia sulfonamides were done concomitantly as a venous glycemia at 0.4 g/l and were respectively 87.81 µIU/ml (normal: 2.6–24.9), 8.59 ng/ml (normal: 1.1–4.4) and 135 µg/ml. The diagnosis of factitious hypoglycemia by taking sulfonamides was confirmed. The day before and during hospitalization, the patient had admitted to sneaking glibenclamide tablets and the drug was seized.
Conclusion
Factitious hypoglycaemia represents a challenge for the clinician, on the one hand the patient tries to hide certain proofs on the other hand it remains an elimination diagnosis, especially if an organic cause is preexisting as it is in our observation.

Geant myolipoma adrenal: report of two cases and literature review
Benabdelatif Katia, Mouna Benfiala, Bensalah Meriem, Lachkhem Aicha & Ould Kablia Samia
Central Military Hospital, Algiers, Algeria.

Introduction
Adrenal myelolipoma is a rare, benign and nonfunctional tumor composed of mature adipose and hematopoietic cells. It is often of incidental finding (8%) and the diagnosis is based on radiological imaging. We report two cases of giant adrenal myelolipoma and discuss the diagnostic and therapeutic aspects of this pathology.
Observation
Patient D.K 40 years old, hospitalized for adrenal mass revealed by right back pain radiating to the right hypochondrium, without signs of endocrine hypersecretion. Clinical examination showed sensitivity of the right lumbar fossa. 24-hours urinary methoxyl derivatives and dexamethasone suppression test were correct. The patient underwent the removal of the abdominal masse and anatomo-pathological examination showed adrenal myelolipoma. Patient A.M, 51 years old, with a personal history of simple mammary and renal cysts, consulted for an adrenal incidentaloma of 65 cm discovered on pelvic MRI during exploration of myxomatous uterus. Clinically, the patient did not present signs of endocrine hypersecretion or abdominal pain. Hormone levels returned normal. Abdominal scan revealed a large left adrenal mass with spontaneous density of – 45 HU, heterogeneous, 60*18*78 mm, without any sign of vascular invasion or neighbouring organs. The patient underwent a left adrenalectomy. Anatomo-pathological study showed adrenal myolipoma.
Conclusion
Unlike other adrenal incidentalomas, adrenal myelolipoma is a rare, benign tumor that is often asymptomatic with special radiological features. Management is based on clinical and radiological follow up of asymptomatic forms. Surgical treatment is reserved for large, symptomatic or complicated adrenal myelolipomas.

Management of pituitary apoplexy

Ajay Sinha
NMCH, Medicine, Patna, India.

Introduction
Pituitary apoplexy is a rare clinical emergency with an incidence of 2–7% in pituitary adenomas. There does not exist any evidence-based standards of optimum care for the patients. A key controversy in management is related to the functioning of acute neurosurgical intervention. The nature of clinical presentation precludes robust randomised controlled trials. Practical guidelines are derived from high-quality observational studies. On this background, we report the management of pituitary apoplexy in a large cohort of patients treated at a single tertiary referral centre.
Methods
This retrospective study evaluates the clinical presentation, management and clinical outcomes presenting with pituitary apoplexy during 2020–2021.
Results
80 patients with 34 females were included. Among these patients, 10 patients had been previously diagnosed with a pituitary tumour. The common symptoms were visual disturbance, headache, diplopia and cranial nerve involvement. 32 patients had undergone surgery, while 48 patients were conservatively managed. All 32 patients had visual disturbances, while 59% of them had recovered fully. Among these patients, 76% made full recovery while 33 had visual disturbances. In the surgical group, 84% required hydrocortisone, 15% withdrew treatment, 69% required thyroxine, 34% required sex steroids, 9% started growth hormone. In the conservatively managed patients, 79% started hydrocortisone, 13% stopped doing so, 60% required thyroxine, 46% started sex steroids, 19% started growth hormones.
Conclusion
This data represents the largest case series from a single centre. We propose that patients with acute apoplexy who have mild or stable symptoms/signs can be managed conservatively with careful monitoring; only rarely is there a need to change from conservative to surgical management in these patients.

Visfatin as a potential serum marker of adrenal gland cancers

Nadia Sawicka-Gutaj, Hanna Komarowska, Aleksandra Derwich, Elżbieta Wrotkowska & Marek Ruchala
Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland.

Introduction
There are not many studies specifying the role and contribution of adipocytokines in biology of adrenal gland cancer. Many research show correlation between increased level of serum visfatin and malignant potential, stage progression and prognosis. *Visfatin/ NAMPT* overexpression has been found in a various type of malignances. So far, to the best of knowledge, this is the first research studying the role of visfatin in diagnosis of adrenal cortical carcinoma.
Patients and methods
This was a prospective observational study with a consecutive enrollment. Twenty two patients with adrenal gland cancers and 34 patients with benign adrenal tumors were recruited.
Results
Patients with adrenal gland cancers have higher serum visfatin concentrations as compared to controls (Me 7.7 ng/ml vs 5.9 ng/ml, $P=0.0017$). Also, ROC curve analysis detected visfatin concentrations higher than 7.1 ng/ml as a biomarker of adrenal cancers ($P=0.0007$; sensitivity 59.1%, specificity 85.3%). Visfatin serum concentrations in patients with adrenal cancers did not differ between men and women. In the whole group, visfatin positively correlated with the tumor size ($P=0.0193$, $r=0.318$).
Conclusion
Visfatin is a potential serum marker of adrenal gland cancers.

Factors associated with metabolic syndrome in tunisian psychiatric patients

Abdel Mouhaymen Missaoui[1], Salem Jdira[2], Oumeyma Trimeche[1], Houda Hsine[2], Wafa Abbes[2] & Ines Khochtali[1]
[1]Fattouma Bourguiba University Hospital, Endocrinology Departement, Monastir, Tunisia; [2]Gabes Regional Hospital, Departement of psychiatry, Gabes, Tunisia.

Introduction
Metabolic Syndrome (MetS) is a bunch of metabolic disturbances related to insulin resistance and is considered a global public health problem. The screening and management of MetS is particularly challenging in psychiatric practice.
Objectives
We aim to identify clinical and therapeutic factors associated with MetS in a Tunisian psychiatric population.
Methods
We conducted a descriptive and analytical cross-sectional study involving 126 patients who attended the psychiatry department at Gabes regional hospital, Tunisia, from 2019 to 2020. MetS was diagnosed based on the 2005-IDF criteria. We compared two subgroups:
* [MetS+]: Patients with MetS ($n=32$)
* [MetS−]: Patients without MetS ($n=94$)
Results
[MetS+] patients were significantly older ([MetS+]:52.1 ± 10.5 versus [MetS−]:43.3 ± 12.7 years; $P=0.001$). The onset of psychiatric symptoms was significantly earlier in [MetS−] ([MetS+]:36.0 ± 14.1 versus [MetS−]:26.8 ± 11.0 years; $P=0.004$). No significant gender nor addictive behaviours diffrences were reported in both subgroups. The two shared an unprivileged educational and socioeconomic backgrounds. Married patients were more affected by MetS ([MetS+]: 65.6% versus [MetS−]:43.6%; $P=0.006$). Schizophernia and psychotic disorders(50%), and mood disorders(18.8%) were more recorded in [MetS+] unlike anxiety disorder (18.1%) which was more prevalent in [MetS−], without any statistic significance. Mental patients are more likely to develop MetS when prescribed anxiolytics (OR = 3.4; $P=0.034$; 95% CI[1.7–10.8]) or atypical antipsychotics (OR = 9.3; $P=0.001$; 95% CI[2.4–36.2]).
Conclusions
Screening psychiatric patients for comorbid MetS is recommended both before and during treatment. The initial drug selection should take into consideration specific metabolic profiles. The opportune identification of MetS can facilitate early lifestyle interventions and treatment to reduce the cardiometabolic risk in this vulnerable population.

Metastatic adrenal carcinoma? When not everything is what it seems...

Daniel Medina Rivero[1], Isabel Mateo Gavira[2] & Francisco Javier Vílchez López[2]
[1]San Fernando, San Fernando, Spain; [2]Hospital Universitario Puerta del Mar, Cádiz, Spain.

69-year-old male, with a history of bipolar disorder under treatment, smoker and high blood pressure. He is referred for left adrenal injury detected incidentally by secondary hypertension study. Abdominal CT shows a mass of 67.7 × 51.8 × 52.3 mm in the left adrenal area, with radiological characteristics of malignancy and aggressive behavior, contacting the left renal pole and upper splenic pole, compatible with adrenal carcinoma vs. metastasis. The functional study is negative. In the extension study, a 10.2-mm right apical pulmonary nodule with nonspecific characteristics and a high-density lesion in the spinal canal at the level of the 9th costal arch compatible with a tumor lesion were detected. The PET-CT does not rule out the malignancy of both lesions. To differentiate whether the adrenal lesion is a primary or metastatic lesion, it was decided to perform FNA, which was inconclusive on 2 occasions. Finally, surgical intervention of the mass was chosen, with an initial approach of en bloc removal of the left adrenal gland, spleen and left kidney, although it was finally possible to perform an isolated left adrenalectomy as no invasion of neighboring organs was observed during the surgical act. The definitive pathological anatomy is compatible with anastomosing hemangioma, an exceptional variant of adrenal tumor, difficult to differentiate radiologically from adrenal carcinoma but that presents benign behavior, which completely changes management and prognosis.

EP104

Establishment of humanized mouse humoral immunity evaluation system using the pregnancy immune system

Atsushi Yasuda[1], Toshiro Seki[1], Natsumi Kitajima[1], Masami Seki[2] & Yoshie Kametani[1]
[1]Tokai University School of Medicine, Japan; [2]Seirei Numazu Hospital, Japan.

(Aims) Regulation of humoral immunity is important to develop vaccines for infectious disease and cancer. However, human and mouse humoral immune systems contain different molecular mechanisms, and the evaluation of efficacy is difficult in the pre-clinical investigation. Humanized mice with reconstructed human immune system are useful for drug discovery of molecular-targeted drugs related to the immune system, and evaluation of antibody production by vaccines. The development of a good model for evaluating the antibody-producing ability has been awaited. However, it was difficult to develop antigen-specific IgGs in the mice, because the maintenance of fully developed T cells and B cells was not successful. We focused on the fact that the mother during pregnancy accepts the other, the foetation, while maintaining the production of specific antibodies, and attempted to produce humanized mice based on the expression of pregnancy-related protein interleukin-4 (IL-4). As we found that the mice can secrete antigen-specific antibodies, futher experiments were performed. (Materials and Methods) We immunized the 20mer HER2 peptide CH401MAP, which we developed as a breast cancer vaccine model, into NOG-hIL-4-Tg mice transplanted with healthy donor's peripheral blood mononuclear cells (PBMCs). Then, the subsets and activation level of T cells was confirmed by flow cytometry. Glucocorticoid receptor (GR) was quantified by realtime-RT-PCR. Moreover, the antibody production performance was confirmed by ELISA/LC-MS. (Results and Discussion) As a result, in the presence of high concentration of IL-4, antigen-specific IgG antibody production was detected in the plasma of PBMC-transplanted NOG-hIL-4 mice. Because glucocorticoid suppresses not only humoral immunity but also innate and cellular immunity, we analyzed the relationship among GR expression levels, the profile of human lymphocyte subsets and the humoral immunity status of PBMC-transplanted NOG-hIL-4 mice. The results showed that NOG-hIL-4-Tg splenocytes had significantly lower human GR mRNA levels than conventional NOG splenocytes after immunization. Moreover, B-cell proportion and antigen-specific IgG concentration in plasma showed strong negative correlations with the GR mRNA level. It was considered that IL-4 decreased GR expression to increase the viability of B cells and to induce the proliferation and class switching of clones producing specific antibodies. This system may help mother's immunity to protect their body from the infectious diseases and cancer. Moreover, it may help producing and sending pathogen-specific IgGs to their fetus.

Serum cortisol immunoassay performance in the overnight dexamethasone suppression test.

Jonathan Atkins[1], Laura Owen[2,3], Jonathan Clayton[4], James M Hawley[1], Jonathan Scargill[4] & Brian Keevil[1]
[1]Wythenshawe Hospital, Manchester University NHS Foundation Trust, Manchester, UK; [2]Salford Royal Hospital, Northern Care Alliance NHS Foundation Trust, Manchester, UK; [3]The University of Manchester, Manchester, UK; [4]Royal Oldham Hospital, Northern Care Alliance NHS Foundation Trust, Greater Manchester, UK.

Background
The 1 mg overnight dexamethasone suppression test (ONDST) is recommended for the differential diagnosis of Cushing's syndrome and the investigation of adrenal incidentalomas. However, diagnostic performance of the test relies on accurate methods to quantitate cortisol in serum. Although the variable performance of serum cortisol immunoassays has been well-documented, little has been published on their performance following the ONDST.
Aims
Assess the performance of three common immunoassay platforms (Roche Elecsys II, Abbott Alinity & Siemens Centaur) when compared to a liquid chromatography tandem mass spectrometry (LC–MS/MS) method.
Methods
Samples ($n=77$) sent to the laboratory as part of an ONDST were retrieved prior to disposal and stored at −80°C until commencement of the study. Samples were pseudononymised, aliquoted and frozen prior to distribution to participating laboratories for immunoassay analysis. Samples with cortisol >250 nmol/l and samples with cortisol lower than the limit of quantitation for each assay were excluded. Immunoassay results were compared to a routine LC–MS/MS serum cortisol method that is metrologically traceable to a candidate reference measurement procedure. Statistical analysis was done, for total results and split into male and female cohorts, through Passing-Bablok regression and Bland-Altman plots.
Results
The Roche gen II compared well, with a mean bias of −2.4 nmol/l and a Passing-Bablok regression fit of $y=-1.332+0.9857x$. This bias was not affected by sex. The worst comparison was observed with the Abbott immunoassay. The mean bias here was −17.7 nmol/l, with a Passing-Bablok regression fit of $y=-5.565+0.8362x$. This negative bias was exacerbated in the samples taken from female patients (−20.9 nmol/l) vs male patients (−15.0 nmol/l). The Siemens assay had a mean bias of 3.2 nmol/l and a Passing-Bablok regression fit of $y=0.9035+1.044x$. This positive bias was worse in male patients (6.7 nmol/l) vs female patients (0.01 nmol/l).
Conclusions
Method-dependent variation exists in the analysis of serum cortisol as a part of ONDSTs. Of the immunoassays, Roche gen II and Siemens more closely aligned with LC–MS/MS. Use of the Abbott immunoassays may result in the underestimation of cortisol and a reduction in ONDST diagnostic sensitivity, particularly in female patients. Clinicians should be aware of the performance of their local assay and on the basis of this data there is evidence to support assay-specific cut-offs for the ONDST.

11-deoxycorticosterone producing adrenal hyperplasia as a very unusual cause of endocrine hypertension: case report and systematic review of the literature

Queralt Asla Roca[1,2,3], Helena Sardà Simó[1,2,4], Enrique Lerma Puertas[2,4,5], FELICIA ALEXANDRA HANZU[6,7,8], Eulàlia Urgell Rull[2,9], José Ignacio Pérez García[2,10], Susan Webb Youdale[1,2,4,11] & ANA AULINAS MASO[1,2,3,11]
[1]Hospital de la Santa Creu i Sant Pau, Endocrinology and Nutrition, Barcelona, Spain; [2]Institut de Recerca – Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]University of Vic, Medicine, Vic, Spain; [4]Universitat Autònoma de Barcelona, Medicine, Bellaterra, Spain; [5]Hospital de la Santa Creu i Sant Pau, Pathological Anatomy, Barcelona, Spain; [6]Hospital Clínic, Endocrinology and Nutrition, Barcelona, Spain; [7]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [8]Universitat de Barcelona, Medicine and Health Sciences, Barcelona, Spain; [9]Hospital de la Santa Creu i Sant Pau, Biochemistry, Barcelona, Spain; [10]Hospital de la Santa Creu i Sant Pau, General and Digestive Surgery, Barcelona, Spain; [11]Carlos III Health Institute, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unit 747), Madrid, Spain.

11-deoxycorticosterone (DOC) is an aldosterone precursor synthesized from progesterone and converted to corticosterone in the adrenal cortex. DOC overproduction due to an adrenal lesion is a very rare cause of mineralocorticoid-induced hypertension. The objective of this study is to provide the most relevant clinical features that clinicians dealing with patients presenting with the hallmarks of hypertension due to DOC-producing adrenal lesions should be aware of. We report a case of a patient with a DOC producing adrenal hyperplasia and provide a systematic review of all published cases (PubMed, Web of Science) until 2021. A 53-year-old woman without any previous history of hypertension consulted to the Emergency Department for high blood pressure (BP), muscle aches and stiffness. Blood test showed serum potassium of 1.73 mmol/l. After being admitted to the Intensive Care Unit and the hospitalization ward, she was diagnosed of a left functional adrenal mass due to non-aldosterone dependent mineralocorticoid secretion (aldosterone: 81.94 pmol/l; reference range 187–930 and plasma renin activity: undetectable), namely excessive DOC production (35.8 ng/dl; reference range 2–15). A left adrenalectomy was performed. Macroscopy revealed a cortical adenomatous hyperplasia and microscopy excluded atypia, mitosis or necrosis, with a Ki67 index positive in <1% of cells. After surgery, her potassium levels normalized and BP and DOC levels significantly improved. The systematic review of the literature identified 44 cases (including ours). Most cases (30, 68%) affected women with a mean age of 42.8±15.6 years and presented with high BP and hypokalaemia (average: 2.65±0.61 mmol/l). Median (interquartile range) time from onset of first suggestive symptoms to diagnosis was 24 (56) months. DOC levels were a median of 15.8 (18.9) times above the upper limit of the normal reference range reported in each article and overproduction of more than one hormone was seen in 29 (66%) cases. Carcinoma was the most common histological type (48.8%). Median tumour size was 64 (67.5) mm. Reduced 11β-hydroxylase and 17α-hydroxylase enzyme activities were the most frequent immunohistochemical findings. Malignant compared to benign lesions were

larger (97 vs 40 mm, $P=0.0001$), had higher DOC levels (20.3 vs 6.2 times above the upper limit of normal, $P=0.041$) and shorter time of evolution (11 vs 42 months, $P=0.029$). In conclusion, DOC-producing adrenal lesions are very rare, affecting mostly middle-aged women with a primary aldosteronism-like clinical presentation and carcinoma is the most frequent diagnosis. Measuring DOC levels when low aldosterone levels are present in hypertensive patients is advisable.

Cushing's syndrome due to primary bilateral macronodular adrenal hyperplasia in medical treatment. A case report

Susana Bacete Cebrián[1], Vanessa Triviño[1], Beatriz Ugalde Abiega[2], Javier Modamio[1], Mikaela Zubillaga[1], Olalla Meizoso-Pita[1], Isabel Huguet[1], Inmaculada Moreno-Ruiz[1], Iciar Martin Timon[1] & Cristina Sevillano-Collantes[1]
[1]Hospital Universitario Infanta Leonor, Endocrinología y Nutrición, Madrid, Spain; [2]Hospital Ramón y Cajal, Madrid, Spain.

Background
Primary bilateral bilateral macronodular adrenal hyperplasia is a cause of Cushing's syndrome. It is characterised by a large enlargement of the adrenal glands at the expense of multiple non-pigmented nodules. There is inefficient steroidogenesis.
Summary of the case
A 58-year-old woman with a history of extreme obesity, type 2 diabetes mellitus, hypertension and dyslipidaemia was admitted to our hospital for cellulitis and anaemia secondary to a post-traumatic haematoma. The endocrinology department was consulted for hyperglycaemia. Clinical examinations revealed a Cushing's phenotype. Blood hormone analysis revealed hypercortisolism, confirmed by elevated urinary cortisol. The primary origin was confirmed by the absence of basal cortisol suppression after dexamethasone 1 mg. An abdominal CT scan revealed enlargement of both adrenal glands consisting of multiple nodular hypodense lesions with low attenuation values. Associated hyperproduction of catecholamines, aldosterone and androgens, and 21-hydroxylase deficiency were ruled out. A 131-iodine-cholesterol scan was requested, which showed intense early bilateral uptake of both adrenals with a final diagnosis of bilateral adrenal hyperplasia scan. Genetic study detected the probably pathogenic variant c.394dup p.(Ala132Glyfs*55) in heterozygosis in the ARMC5 gene.Our patient was diagnosed with long-standing primary Cushing's syndrome due to bilateral macronodular adrenal hyperplasia caused by a heterozygous mutation in the ARMC5 gene; associated with secondary complications: extreme obesity with severe functional limitation, arterial hypertension, type 2 diabetes mellitus, dyslipidaemia, chronic hypokalaemia and metabolic alkalosis, recurrent spontaneous haematomas and depressive syndrome. Surgical treatment was proposed, but was ruled out due to the maximum surgical risk due to her comorbidities. We therefore started medical treatment with ketoconazole, titrating the dose up to 800 mg per day, achieving disease control, after normalisation of hypercortisolism. During admission, functional limitation of the lower limbs was added, and an X-ray of the lumbar spine was performed, awaiting bone densitometry, which revealed vertebral crushing, and zolendronic acid was started. At present, our patient has been hospitalised for a year as a social problem. She remains functionally and cognitively limited due to persistent depression.
Conclusion
Primary bilateral macronodular adrenal hyperplasia as a cause of Cushing's syndrome is rare. The initial management of this pathology is surgical, but there are patients with extensive comorbidity in whom this is not possible, and we have to opt for medical treatment. It is important to address all associated comorbidity as it is a pathology with a slow clinical course, but which greatly impairs the quality of life of patients.

Assessing health-related quality of life in patients with Addison disease

Dhoha Ben Salah, Khouloud Boujelben, Abdelmouhaymen MISSAOUI, Faten Haj Kacem Akid, Mnif Fatma, Mouna Mnif, Nadia Charfi, NABILA REKIK MAJDOUB, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Department of Endocrinology, Diabetology, Sfa, Tunisia.

Introduction
Conventional glucocorticoid replacement therapy has been suggested to increase morbidity in patients with Addison disease and fail to restore their quality of life (QOL). The aim of our study was to assess QOL in patients with Addison disease and to identify factors that determine their QOL.
Patients and methods
This cross-sectional study was carried out at the department of Endocrinology in HediChaker hospital-Sfax –Tunisia, from March 2020 to July 2021.Fifty patients with Addison disease were recruited both outpatient and hospitalization departments. Healthrelated quality of life was measured using the 36-item Short-Form Health Survey (SF-36).The questionnaire contained eight domains:physical functioning (PF), role physical (RP), bodily pain (BP) general health (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH). An overall mean score of less than 66.7 means impaired quality of life.
Results
Mean age of patients and duration of Addison disease was $49,5 \pm 13,9$ years and $13,9 \pm 8,7$ years.The female sex was the most affected with a sex ratio of 4. The majority of patients (72%) were unemployed.Approximately half of patients were overweight (BMI $\geq$ 25) (48%) and had a sedentary lifestyle (66%). All patients were on hydrocortisone replacement, taking daily $27,4 \pm 6,7$ mg (15–42,1 mg). Mean cumulative hydrocortisone dose was $374,636 \pm 283,821$ mg (60–1184, 94 mg). Overall SF-36 scores were on average $65,7 \pm 4,1$.QOL was impaired in 65% of patients. Both daily and cumulative hydrocortisone doses were higher in patients having an impaired QOL but without significant difference. No correlation was identified between QOL and duration of glucocorticoid replacement therapy.
Conclusion
Patients with Addison disease experience significant impairment in their health QOL, which is linked particularly to metabolic and bone consequences of long-term glucocorticoid replacement therapy. The assessment of QOL in patients with Addison disease may help to ameliorate patient's wellbeing.

Primary adrenal insufficiency due to bilateral adrenal hemorrhage-adrenal infarction in a patient with systemic lupus erythematosus and antiphospholipid syndrome

Katerina Bouki[1], Vasiliki Venetsanaki[1], Maria Chrysoulaki[1], Aikaterini Pateromichelaki[2], George Bertsias[2], VASILIKI DARAKI[1], Konstantinos Spanakis[3], Grigoria Betsi[1], Nikolaos Sbyrakis[4], Maria Sfakiotaki[1], Kalliopi Kontolaimaki[1], Eleni-Konstantina Syntzanaki[1], Rodanthi Vamvoukaki[1], Panagiotis-Nikolaos Tsakalomatis[1], Prodromos Sidiropoulos[2] & PARASKEVI XEKOUKI[4]
[1]University General Hospital of Heraklion, Endocrinology and Diabetes Clinic, HERAKLION, CRETE, Greece; [2]University General Hospital of Heraklion, Rheumatology and Clinical Immunology Clinic, HERAKLION, CRETE, Greece; [3]University General Hospital of Heraklion, Radiology Department, Department of Medical Imaging, HERAKLION, CRETE, Greece; [4]University General Hospital of Heraklion, Emergency Department, HERAKLION, CRETE, Greece.

Background
Systemic lupus erythematosus (SLE) is an autoimmune disease with multisystem involvement and varied presentation but its association with adrenal insufficiency is rarely reported.
Case presentation
A 30-year-old female presented to the emergency department with fever, lethargy and syncopal episodes during the last 48 h. She complained of general weakness, abdominal pain, nausea, vomiting, weight loss and anorexia for five months. Symptoms deteriorated progressively but were attributed to cholelithiasis for which she underwent a cholecystectomy one month prior, without symptom resolution. She had been hospitalized two years ago due to acute myocarditis and pulmonary embolism and was diagnosed with systematic lupus erythematosus (SLE) and secondary antiphospholipid syndrome (APS). Treatment included hydroxychloroquine, mycophenolic acid (MMF), tinzaparin and periodical corticosteroid treatment. At presentation, physical examination revealed severe hypovolemia, anuria, abdominal tenderness and skin and mucosal hyperpigmentation. Laboratory evaluation revealed anemia, hyperkalemia, hyponatremia, hypercalcemia, troponinemia, prolonged clotting time tests, acute renal insufficiency (serum creatinine:6,5 mg/dl) and pyuria. Primary adrenal insufficiency was suspected and was later confirmed by a low plasma cortisol level (1 μg/dl). She was initially admitted to the Intensive Care Unit (ICU) and treated with fluid resuscitation, continuous hydrocortisone infusion, inotropic agents, antiarrhythmics, anticoagulants, antibiotics and blood transfusions with a good

clinical response. Low levels of C3, C4 combined with high titres of SLE-related autoantibodies, lupus anticoagulant and a positive direct Coombs test were suggestive of clinically active SLE. Anti-adrenal antibodies were negative. Adrenal computed tomography performed on the seventh day revealed high density bilateral adrenal enlargement with fluid stranding of the adjacent fat probably due to recent bilateral adrenal haemorrhage. The patient remained in the ICU for three days and was then transferred to the Endocrine and subsequently to Rheumatology Clinic for further treatment. She was discharged 18 days later, on corticosteroids, hydroxychloroquine, MMF, bisoprolol, acenocoumarol and instructions about stress steroid dosing.
Discussion
Bilateral adrenal involvement in our patient was probably a manifestation of a hypercoagulable state due to APS, which can cause adrenal vein thrombosis, followed by adrenal haemorrhagic infarction, although haemorrhage due to tinzaparin therapy cannot be excluded. Addison disease is rare in patients with SLE however, adrenal failure in the presence of elevated antiphospholipid antibodies has been reported. High index of clinical suspicion is required in patients with lupus or APS presenting with unexplained symptoms and adrenal insufficiency should be included in the differential diagnosis.

Tertiary adrenal insufficiency revealing Gayet-Wernicke encephalopathy

Kaoutar Rifai, Loubna Guissi, Farah Kamel, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco.

Introduction
Gayet-Wernicke encephalopathy (WE) is a rare neurological disorder, caused by thiamine (vitamin B1) deficiency. We report a case of tertiary adrenal insufficiency revealing Gayet-Wernicke encephalopathy.
Case presentation
A 45-year-old women was admitted with abdominal pain, vomiting and weakness. Her medical history was significant for a long-term self-medication with corticosteroids and chronic vomiting. Clinical examination revealed a cushingoid appearance (discrete facial erythrosis, protuberant abdomen, skin fragility). The Laboratory results revealed a natraemia of 136 mmol/l, a kalaemia of 4 mmol/l, and an 0800 h serum cortisol level of 50 ng/ml. The diagnosis of tertiary adrenal insufficiency was made and treatment with parenteral hydrocortisone hemisuccinate was started. The evolution was characterized by the development of nystagmus, confusional state and flaccid tetraparesis. Brain MRI was consistent with Gayet-Wernicke encephalopathy. Parenteral vitamin B1 was initiated. As a result the symptoms of nystagmus and confusion subsided, but the patient retained motor sequelae.
Discussion
Wernicke encephalopathy (WE) is an acute neurological condition resulting from thiamine deficiency, most often secondary to chronic alcoholism, but can also occur in the context of chronic vomiting. WE is characterized by a clinical triad of ophthalmoparesis with nystagmus, ataxia and confusion. Brain MRI may reveal hyperintense signaling in the periventricular thalamus, mammillary bodies and periaqueductal gray matter. Early and adequate treatment with thiamine is necessary to avoid death or progression to permanent brain damage.
Conclusion
Our case illustrates the seriousness of self-medication with corticosteroids ranging from a simple tertiary adrenal insufficiency to a serious pathology such as Gayet-Wernicke encephalopathy.

The "RESCUE" Trial: 11β-Hydroxysteroid Dehydrogenase Type 1 (HSD-1) Inhibition for ACTH-Dependent Cushing's Syndrome

Frank Czerwiec[1], Jeffrey Drajesk[2], Sarah Hooper[1], Kimberly Hunsicker[3], Robert Jacks[5], Jamie MacPherson[4], Tonya Marmon[5] & David Katz[3]
[1]Sparrow Pharmaceuticals, Inc., Clinical Development, Portland, OR, United States; [2]Sparrow Pharmaceuticals, Inc., Program Management, Portland, OR, United States; [3]Sparrow Pharmaceuticals, Inc., Executive Management, Portland, OR, United States; [4]Sparrow Pharmaceuticals, Inc., Regulatory Affairs, Portland, OR, United States; [5]Sparrow Pharmaceuticals, Inc., Consultant Statistician, Portland, OR, United States.

Background
HSD-1, an intracellular enzyme, converts cortisone to cortisol in tissues where cortisol excess is associated with morbidity including liver, adipose, bone, brain, muscle, skin, and eye. SPI-62 is a potent and specific HSD-1 inhibitor in development for treatment of Cushing's syndrome and autonomous cortisol secretion, and as adjunctive therapy to prednisolone in polymyalgia rheumatica. In Phase 1 clinical trials SPI-62 was generally well tolerated and associated with maximal liver and brain HSD-1 inhibition. SPI-62 decreased urinary cortisol metabolites indicating a similar decrease of hepatocellular cortisol in this important target tissue. After a corresponding transient decrease, circulating cortisol homeostasis was restored by ACTH increase which also resulted in a moderate adrenal androgen increase. SPI-62's effects on androgens did not result in adverse effects. Urinary free cortisol was unaffected. The RESCUE trial will assess SPI-62 safety and efficacy in patients with a dysregulated HPA axis, ie., ACTH-dependent Cushing's syndrome.
Methods
In this randomized, placebo-controlled, crossover, multinational, Phase 2 clinical trial, adult patients ($n=26$) with ACTH-dependent Cushing's syndrome with active and consistently elevated urinary free cortisol (UFC) will be randomized to receive SPI-62 and placebo for 12 weeks each. A diagnosis of an inadequately treated pituitary adenoma (Cushing's disease) or ectopic ACTH or CRH producing tumor based on established criteria is required. Evidence of Cushing's associated morbidities including at least 2 of A) insulin-resistance/type-2 diabetes mellitus, B) dyslipidemia, C) hypertension, or D) osteopenia is required. Subjects must not have had recent Cushing's surgical, radiation other approved or experimental medical therapies for cortisol excess. Medical conditions or treatments likely to interfere with study assessments or subject safety are also excluded. The primary outcome is pharmacological suppression of the urinary ratio of hepatic 5- and 3-steroid reductase metabolites of cortisol and cortisone (tetrahydrocortisol + allotetrahydrocortisol)/tetrahydrocortisone). Safety is assessed by adverse events, vital signs, ECG, and clinical laboratory analyses including effects on HPA/HPG axis biomarkers. Efficacy is assessed by reduction of Cushing's features and morbidities of hyperglycemia, dyslipidemia, adiposity, hepatic steatosis, hypertension, glaucoma, osteopenia, muscle strength, cognition, sleep, and mood. Assessments include tumor-imaging by MRI, ocular tonometry, timed up-and-go and hand-grip strength tests, dual-energy x-ray absorptiometry, oral glucose tolerance, continuous glucose monitoring, and ambulatory blood pressure monitoring.
Results
This trial is ongoing; results are pending.
Discussion
This Phase 2 explores SPI-62 safety, HSD-1 inhibition, effects on HPA/HPG axes, and clinical effects in patients with ACTH-dependent Cushing's syndrome.

The ACSPIRE trial: 11β-hydroxysteroid dehydrogenase type 1 (HSD-1) inhibition for autonomous cortisol secretion and adrenal cushing's syndrome

Frank Czerwiec[1], Jeffrey Drajesk[2], Sarah Hooper[1], Kimberly Hunsicker[1], Robert Jacks[5], Jamie MacPherson[4], Tonya Marmon[5] & David Katz[3]
[1]Sparrow Pharmaceuticals, Inc., Clinical Development, Portland, OR, United States; [2]Sparrow Pharmaceuticals, Inc., Program Management, Portland, OR, United States; [3]Sparrow Pharmaceuticals, Inc., Executive Management, Portland, OR, United States; [4]Sparrow Pharmaceuticals, Inc., Regulatory Affairs, Portland, OR, United States; [5]Sparrow Pharmaceuticals, Inc., Consultant Statistician, Portland, OR, United States.

Background
HSD-1, an intracellular enzyme, converts cortisone to cortisol in tissues where cortisol excess is associated with morbidity including liver, adipose, bone, brain, muscle, skin, and eye. SPI-62 is a potent and specific HSD-1 inhibitor in development for treatment of autonomous cortisol secretion (ACS) and Cushing's syndrome, and as adjunctive therapy to prednisolone in polymyalgia rheumatica. In Phase 1 clinical trials SPI-62 was generally well tolerated and associated with maximal liver and brain HSD-1 inhibition. Single and multiple SPI-62 doses decreased urinary cortisol metabolites indicating a similar decrease of hepatocellular cortisol in this important target tissue. After a corresponding

transient decrease, circulating cortisol homeostasis was restored rapidly by ACTH increase which also resulted in a moderate adrenal androgen increase. SPI-62's effects on ACTH and androgens did not result in adverse effects. Urinary free cortisol was not affected. The ACSPIRE trial will assess SPI-62 safety and efficacy in patients with dysregulated cortisol production due to ACS or adrenal Cushing's syndrome (aCs) for the first time.
Methods
In this randomized, placebo-controlled, multinational, Phase 2 clinical trial, adult patients with ACS or aCs with otherwise benign adrenal adenomas, persistently elevated morning cortisol after verifiably adequate dexamethasone suppression, and at least two morbidities associated with hypercortisolism [A) insulin-resistance/type-2 diabetes mellitus, B) dyslipidemia, C) hypertension, or D) osteopenia] will be randomized to receive SPI-62 or placebo for 12 weeks. Subjects must have declined, delayed, or been deemed ineligible for adrenalectomy and not recently taken approved or experimental medical therapies for cortisol excess. Medical conditions or treatments likely to interfere with study assessments or subject safety are also excluded. Efficacy at 12-weeks is assessed by reduction of cortisol-associated morbidities of hyperglycemia and dyslipidemia while also examining, adiposity, hepatic steatosis, hypertension, inflammatory cytokines, osteopenia, muscle strength, cognition, sleep, and mood. Safety is assessed by adverse events, vital signs, ECGs, clinical laboratory analyses. Pharmacology is assessed by effects on HPA/HPG axis biomarkers and suppression of the urinary ratio of hepatic 5- and 3-steroid reductase metabolites of cortisol and cortisone (tetrahydrocortisol + allotetrahydrocortisol)/tetrahydrocortisone). Assessments include timed up-and-go and hand-grip strength tests, dual-energy x-ray absorptiometry, oral glucose tolerance test, continuous glucose monitoring, and 24-hour ambulatory blood pressure monitoring.
Results
This trial is ongoing; results are pending.
Discussion
This Phase 2 explores SPI-62 safety, HSD-1 inhibition, effects on HPA/HPG axes, and clinical effects in patients with ACS and aCs.

Adrenal venous sampling in patients with hyperaldosteronism

Ángel Rebollo-Román[1], M[a] del Carmen Serrano Laguna[1], María-Eugenia Pérez-Montilla[2], Paloma Moreno-Moreno[1] & MARIA ANGELES GALVEZ MORENO[2]
[1]Hospital Universitario Reina Sofía, UGC Endocrinología y Nutrición, Córdoba, Spain; [2]Hospital Universitario Reina Sofía, UGC Radiodiagnóstico y Cáncer de Mama, Córdoba, Spain.

Objective
Adrenal venous sampling (AVP) is a reliable procedure to differentiate if in patients with primary aldosteronism (PA) aldosterone production is unilateral or bilateral and guide the treatment of these patients. Our objective was to describe their characteristics and the outcomes of the AVPs.
Methods and patients
Observational longitudinal clinical study between July 2020 and September 2021 in patients who underwent AVP in our Hospital.
Results
10 patients included. Mean age: 50.9 ± 14.67 years. 60% women. IMC: 26.64 ± 4.05 kg/m^2. 80% patients with an adenoma in the CT: 20% in the right gland, 50% in the left and 10% in both. 20% of patients without adenoma in CT. Reason of PA screening: 40% resistant high blood pressure (HBP), 20% HBP and adrenal adenoma and 40% HPA and hypokalemia. All patients received HBP treatment. 70% of patients took potassium supplementation. In 90% of patients catheterization of both adrenal glands was successful. 66.7% of them showed a left lateralization. 33.3% with no lateralization. Among the 5 patients with successful AVS and adenoma in CT, in 4 of them AVS lateralization matched the image. In 1 patient AVS lateralized to the opposite side. In 1 patient AVS showed left lateralization although no adenoma was seen in CT.All patients with successful catheterization underwent surgery according to the AVS result. 71.4% of them could stop HBP medication.
Conclusion
– In spite of the limited number of AVS performed in our center, AVS is successful in most of the patients (90%) in our series.
– In most patients (80%) AVS lateralization results matched the side of the adenoma in the CT image if it was present. In one patient there was lateralization although no image was seen in CT.
– After surgery most patients in our series can stop their HBP medication.

Late diagnosis of adrenoleukodystrophy in an adult patient with tetraparesis and addisonian crisis.

Apostolos Gogakos[1], Aliki Aggelaki[2], Apostolos Dougalis[2], Georgia Kourkouta[1], Marina Kita[1] & Zoi Efstathiadou[1]
[1]"Hippokration" General Hospital of Thessaloniki, Greece; [2]Fourth Department of Internal Medicine, "Hippokration" General Hospital of Thessaloniki, Greece.

Introduction
Adrenoleukodystrophy (ALD) is a rare, X-linked inherited, genetic disease, characterized by a disorder of peroxisome metabolism, leading to the accumulation of very long-chain fatty acids (VLCFAs) mainly at the central nervous system and the adrenal glands. It usually occurs in childhood, but there are types of the disease that manifest later in life.
Case
A 57-year-old man with a history of progressive spastic paresis, starting at the age of 25, was admitted due to weakness and hypotension, nausea, abdominal pain, and blurred vision. Fever and severe hyponatremia (Na 108 mmol/lt) were present. Due to the clinical-laboratory picture and reported episodes of hypoglycemia, basal cortisol and ACTH levels were determined, which were indicative of primary adrenal insufficiency [cortisol 2.5 μg/dl, ACTH 360 pg/ml (7–64)]. The diagnosis was confirmed by a short synacthen test (250 μg tetracosactide) with a maximum cortisol response of 1.43 μg/dl. The patient was discharged fever-free and electrolytically stable on hydrocortisone and fluorohydrocortisone replacement therapy. Considering the neurological history and the newly diagnosed Addison's disease, the possible diagnosis of adrenoleukodystrophy was suspected. The new MRI imaging of the brain showed no typical focal lesions while cervical spinal cord atrophy was reported, a typical finding of adrenomyeloneuropathy, one of the most common forms of the disease in adult patients. He underwent a long-chain fatty acid test that confirmed the diagnosis.
Conclusion
The patient suffered spastic tetraparesis without an identified neurological diagnosis for many years. The diagnosis of coexisting primary adrenal insufficiency led to the diagnosis of adrenoleukodystrophy. Adrenomyeloneuropathy is a less severe form of adrenoleukodystrophy, with the onset of symptoms in adolescence or adulthood. This form of the disease does not involve brain damage and should be included in the differential diagnosis of men with adrenal insufficiency or neurological motility disorders of unknown causes.

Paraneoplastic Cushing's syndrome in metastatic poorly differentiated carcinoma of the kidney

Sandra Ghenoiu[1], Teodor Constantin[2], Costel Daniel Serban[3], Cristina Capatina[1,4] & Catalina Poiana[1,4]
[1,]"C.I.Parhon" National Institute of Endocrinology, VI, Bucharest, Romania; [2,]"C.I.Parhon" National Institute of Endocrinology, Bucharest, Romania; [3]Emergency Clinical Hospital "Dr. Bagdasar-Arseni", II, Bucharest, Romania; [4,]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Paraneoplastic Cushing's syndrome is attributed to ectopic ACTH release from a non-pituitary tumor. The lung is frequently the primary site of the underlying neoplasm but sometimes, in cases of advanced metastatic disease, determining the origin may be challenging.
Case presentation
A70-year-old man was reffered to our centre for generalised bone pain, lethargy, and important weight loss in the last six months. Before admission, a contrast-enhanced CT scan of thorax and abdomen revealed multiple lung nodules, mediastinal lymphadenopathy, spinal bone lesions suggestive of metastases (with considerable size and extension in the spinal canal), bilateral adrenal masses (with washout percentage >55%) and a large heterogeneous renal mass. The patient presented poor general condition, immobilisation (mainly due to intense bone pain), pale skin and maleolar petechiae; classical clinical features of hypercortisolism were not present. Moderate hypercalcemia, high inflammatory markers, severe ACTH dependent Cushing's syndrome and low PTH level were noticed. Spine MRI confirmed the osteolytic lesions and also the spinal cord

compression due to important tumoral processes affecting thoracic vertebrae. A percutaneous biopsy of a vertebral metastasis revealed a highly anaplastic tumoral process with renal orgin. Mifepristone and analgesic treatment were initiated with biochemical control of Cushing's syndrome, but the patient died within 6 weeks from diagnosis.
Conclusions
ACTH-dependent hypercortisolism source is difficult to identify in a patient presenting with multi-organ masses. Although rare, the renal origin of ectopic Cushing's syndrome should not be disregarded.

Metyrapone treatment in bilateral macronodular adrenal hyperplasia: a report of two cases

Vittoria Favero[1], Carmen Aresta[2], Chiara Parazzoli[1], Iacopo Chiodini[1,2] & Valentina Morelli[2]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Department of Endocrine and Metabolic Diseases, Milan, Italy.

Introduction
Primary bilateral macronodular adrenal hyperplasia (PBMAH) is potentially responsible for variable degree of cortisol excess. In patients with PBMAH the complete remission of cortisol hypersecretion can be achieved only by performing bilateral adrenalectomy, leading to a persistent hypocortisolism and to a consequent need of a lifelong glucocorticoid replacement therapy. Therefore, bilateral adrenalectomy is worth doing only in patients with severe hypercortisolism, while a medical treatment could be a valid alternative for patients with mild Cushing's syndrome (mCS), particularly in the presence of possibly related clinical conditions (i.e. diabetes, hypertension and bone fragility). In this scenario, steroid synthesis inhibitors, such as metyrapone, have been proposed as possible therapeutic options. We report two cases of PBMAH with mCS treated with low doses of metyrapone (mean dose of 500 mg). Before and after 6 months of therapy, an assessment of clinical consequences of mCS was performed with a 24-hour ambulatory blood pressure monitoring (ABPM) and an oral glucose tolerance test (OGTT).
Case reports
Case 1. A 68 years old male with history of scarcely controlled arterial hypertension. The basal OGTT was consistent with a diabetes diagnosis (fasting glucose levels 128 mg/dl, 2-hour OGTT glucose levels 202 mg/dl). After 6 months of treatment, he achieved: i) the remission of diabetes (fasting glucose levels 97 mg/dl. 2-hour OGTT glucose levels 122 mg/dl) with no changes in anti-diabetic therapies; ii) the ABPM documented improvement in mean blood pressure values (147/80 mmHg and 121/63 mmHg, respectively before and 6 months after treatment). Case 2. A 79 years old female with a history of osteoporosis with 4 clinical vertebral fractures, arterial hypertension and depressive disorder. Before starting the therapy, she had an impaired fasting glucose (104 mg/dl) with a normal response to the glucose load (post-OGTT glucose levels 96 mg/dl). After six months of therapy, we observed: i) the normalization of basal glucose levels (90 mg/dl) and the persistence of a normal OGTT response (132 mg/dl); ii) the important reduction of anti-hypertensive medications with ABPM documented stable mean blood pressure values (119/68 mmHg); iii) the striking amelioration of the depressive disorder and cognitive function. In both patients metyrapone was well tolerated without signs or symptoms of hypocortisolism. In the first patient, potassium levels decreased during the treatment period but remaining within the normal range.
Discussion
Our observations suggest that low doses of metyrapone are well-tolerated and can improve blood pressure and glycemic control in PBMAH and mCS

EP117

Unusual case of adrenal insufficiency

Ana Matijaca
Clinical Hospital Dubrava, Department of Endocrinology, Diabetes and Metabolic Diseases, Zagreb, Croatia.

33-year old obese but otherwise considered 'healthy' patient was admitted to department of surgery due to wet gangrene of left foot. Lower leg amputation was done. As patient was obese with ITM 44 kg/m^2 endocrinologist was consulted. In overnight 1 mg dexamethason supression test cortisol was 72 nmol/l, HbA1c was 5.7%, TSH was 8 mIU/l, level of 25-OH D vitamin below lower range and arterial blod pressure was normal (130/80 mmHg). Patient had central obesity with muscle wasting and gynecomastia, but did not have any purple stirae, bruises, fat pads or hypertension. During stay worsening of clinical condition with respiratory insufficiency due to sepsis occured and patient was transfered to Critical care unit. Debridemenet and re-amputation were needed so few surgical procedures were done and dexmedetomidine for sedation was repeatedly given during few days. After stabilisation of clinical state polyuria was noticed and although patient was normotensive and sodium and potassium level as plasma osmolality were normal, level of cortisol was checked and found to be below level of detection ($<$ 11 nmol/l). Level of pituitary hormones was normal: TSH 2,7 mIU/l, FSH 18,54 IU/l and slightly elevated LH 15,19 and prolactin 646 mIU/l together with ACTH 10,7 pmol/l. Level of peripheral thyroid hormons and testosteron was normal (FT4 12,44 pmol/l, testosterone 9,39 nmol/l) as were SHBG 57,1 nmol/l. CT radiography of adrenal glands showed no signs of necrosis or haemorrhage of the adrenals which morphology was normal. Short test with 250 ug Synacthen iv. was done and showed no adequate adrenal response, cortisol was 100 nmol/l after 30' and 107 nmol/l 60' after stimulation. After one week of supstitution with hydrocortison (20 + 10 mg per os daily) as surgical treatment was over and discharge was planned, afternoon dose of hydrocortisone was omitted and level of cortisol on 0800 h was 83 nmol/l. We concluded that partial recovery of adrenal gland happened but patient was recommended to continue with low dose hydrocortison supplementation (10 + 5 mg tbl). Control work –up in Outpatient clinic was scheduled. Aim of this case presentation is to remind of possible causes of adrenal failure, not only due to sepsis but also malnutrition, drugs – in this particular case dexmedetomidine and to recall other possible mechanisms of adrenal failure in severe or critically ill patients, even in those who might first seem to have Cushing syndrome as was the case with this patient.

Virilizing adrenal oncocytoma: about 2 cases report

Mouna Mezoued, Bessaid Khadidja & Malha Azzouz
Bologhine Hospital, Endocrinology, Alger, Algeria.

Introduction
Oncocytomas of adrenal glands are extremely rare and usually present as incidentally detected masses. The aim of this presentation is to report tow cases of a virilizing androgen-secreting adrenal oncocytoma.
Case description
Case 1: A 27-year-old female was admitted to our clinic with a 116 mm left adrenal incidentaloma. The patient's main symptom was hirsutism. Upon investigation, elevated values of testosterone, and DHEA-S were found. Contrast-enhanced abdominal CT and MRI scans revealed a heterogenous large left mass (diameter 116 $\times$ 95 mm) with necrotic areas, and a clear distinction from the adjacent structures. The patient underwent a surgical adrenalectomy. The histological examination of the tumor revealed a borderline adrenocortical oncocytoma. Case 2: A 25 years-old woman, presenting a recent and progressive virilization syndrome. Hormonal evaluation showed elevated serum testosterone and delta-4-androstenedione levels, normal urinary free cortisol level and incomplete suppression of cortisol at the 1 mg dexamethasone suppression test. CT scan of the abdomen revealed a 60$\times$50 mm right adrenal mass. The patient benefited from an adrenelectomy. The histological examination of the tumor revealed a benign adrenocortical oncocytoma

A case of autoimmune polyglandular syndrome type 2

Nino Zavrashvili, Ketevan Chanturishvili, Natia Margvelashvili, Ketevan Gvazava & Natia Shonia
Tbilisi Institute of Medicine, Endocrinology Department, Tbilisi, Georgia.

Autoimmune polyglandular syndromes (APS) are a group of immune-endocrine syndromes that cause autoimmune destruction of multiple endocrine organs. The most common in this group is APS type 2, which frequently presents with primary

adrenal insufficiency with autoimmune thyroid disease and/ or type 1 diabetes mellitus. We present a case of 46 year old male, with no significant medical history who presented in our clinic with: weakness, fatigue and weight loss for the preceding last 3 months. On the examination he was found to have hypotension, tachycardia, hyper pigmentation of the skin and vitiligo. Based on the lab reports and physical exam findings diagnosis primary adrenal insufficiency, Graves Hyperthyroidism and vitiligo was made corresponding with the Autoimmune Polyglandular Syndrome type 2. Treatment with Hydrcortisone, Fludrocortisone and Thionamides was started in our patient resulting in significant improvement in patient's symptoms. After achieving euthyroidism, the thionamide dose was gradually decreased and later discontinued after a year of treatment. Patient remains euthyroid to present day and continues only adrenal hormone replacement therapy with both glucocorticoid and mineralocorticoid. Patient is on regular follow up and is clinically well. He is given the instructions of "sick day rules" to change the hydrocortisone dose appropriately. Patient consent for publication is obtained. The Case report will be accompanied with the corresponding pictures depicting pre and post treatment appearance of the patient.

COVID-19 pandemic and alternative options to classical pathways: real life experience

Benedetta Zampetti, Iuliana Pauna[2], Sara Andreani[2], Emanuela Isabella Carioni[1], Daniela Dallabonzana[1], Roberto Attanasio[3], Marco Boniardi[2] & Renato Cozzi[3]
ASST Grande Ospedale Metropolitano Niguarda, Endocrinology Department, Milano, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, General Oncologic and Mini-invasive Surgery Department, Milano, Italy; [3]Scientific Committee Associazione Medici Endocrinologi, International Chapter of Clinical Endocrinology, Italy.

COVID-19 pandemic obliged physicians to find out alternative options to classical pathways, to lower viral spread and related dangers as well as to cope with redeployment of personnel and resources. We describe here two cases in whom surgery for adrenal Cushing's syndrome (CS) and pheochromocytoma (PHEO) was deferred due to the unavailability of surgical facilities.
Case no 1: A 69-yo woman was evaluated for CS. Type 2 diabetes mellitus was diagnosed some years before and a 35-mm right adrenal mass incidentally found at US; no endocrine work-up was performed. Progressively clinical picture worsened and physical examination suggested ACTH-independent hypercortisolism, confirmed by endocrine work-up performed in January 2020. The whole picture was so severe that she was not considered suitable for surgery that became anyway inaccessible due to pandemic. Ketoconazole was given up to 400 mg/day with a progressive reduction in CLU values. Due to the occurrence of symptomatic hypoadrenalism, a block-and-replace therapy with cortisone acetate was started, obtaining a progressive and persistent improvement in clinical/biochemical picture. Due to the persistence of pandemic and the unavailability of surgical facilities for not urgent surgeries, patient is still waiting surgery. Case no 2: In an 83-yo woman, abdominal plastic surgery was complicated by hypertensive crisis, acute pulmonary edema, cardiogenic shock, acute renal failure; multiple stenoses were disclosed at coronary-angiography, reverse Takotsubo at ventriculography. Abdominal CT disclosed a 45×31 mm left-adrenal lesion consistent with PHEO, confirmed by Endocrine-workup. Recovery of systolic function and pressure control were obtained with doxazosin (in addition to ongoing lowering blood pressure treatment. The planning of adrenal resection was postponed due to an adrenal hematoma developed while on LMWE treatment; the subsequent CT showed hematoma reabsorption but in the meanwhile there was the outbreak of the pandemic. The patient was monitored throughout subsequent months with telemedicine controls, confirming optimal pressure control; she underwent laparoscopic-adrenalectomy without any perioperative complications. A post-op CT and hormonal evaluation did not disclose any tumor remnant/relapse and the patient has an optimal pressure without any anti-hypertensive treatment.
Conclusion
This change of the mainstay of treatment for adrenal hypersecreting lesions due to pandemic could offer a new therapeutic paradigm of these diseases in cases when surgery is contraindicated for severe comorbidities.

EP121

Primary hyperaldosteronism and graves 'disease, a rare combination

Randa Salam
Cairo University, Internal Medicine, Endocrinology, Cairo, Egypt.

Introduction
Primary hyperaldosteronism is a known cause for secondary hypertension. In addition to its effect on blood pressure, aldosterone exhibits proinflammatory actions and plays a role in immunomodulation of autoimmunity. Autoimmune hyperthyroidism (Graves' disease) and primary hyperaldosteronism rarely coexist but underlying mechanisms associating the two are still unclear.
Case report
A 32-year-old female referred to endocrine unit for further evaluation and management of hypertension and hypokalemia. She was on three antihypertensive medications at the time of presentation but had poor blood pressure control. She also had nonspecific body aches and intermittent muscle cramps palpitation and sweating with associated heat intolerance, recent weight loss, for the past 2 months. She did not have any virilizing features. She was not on diuretics or any long-term medications except three antihypertensive medications. None of her family had hypertension, strokes, or sudden deaths at younger age. Examination, pulse: 110 /minute, blood pressure: 140/100 mmHg while on antihypertensive therapy BMI: 23 kg/m2. There was a small diffusely enlarged goiter without any tenderness. Bilateral mild exophthalmos normal eye movements and vision. Investigations:potassium, 2.1 mmol/l (3.5–5) Patient with hypertension, hypokalemia, possibility of primary hyperaldosteronism was considered. Aldosterone: renin ratio (ARR) was measured after correcting the potassium value and adjusting the interfering medications ARR was 198 [ng/dl]/[ng/ml/hr] ($n: < 20$) A contrast enhanced computed tomography (CT) of abdomen showed a right-sided homogenously dense (density of 9.5 Hounsfield Units {HU}) adrenal lesion measuring $2.0 \times 1.5 \times 0.8$ cm Evaluation of the thyroid status revealed evidence of hyperthyroidism: TSH $<$ 0.08 μIU/ml (0.27–4.0), free T4—4.60 ng/dl (0.7–1.9), and free T3—7.36 pg/ml (2–4.4). Ultrasound scan of the thyroid showed diffusely enlarged gland with increased echo pattern and vascularity on Doppler studies, compatible with Graves' disease Thyrotoxicosis was managed with antithyroid drugs (Carbimazole)30 mg/day titration till she was on 10 mg/day and once patient rendered euthyroid, laparoscopic right adrenalectomy was performed. Antithyroid medications were discontinued after 12 months after which patient achieved remission of Graves' disease.
Conclusion
Primary hyperaldosteronism (PA) is a leading endocrine cause for secondary hypertension, particularly in resistant hypertension Recent studies have demonstrated role of aldosterone on immunomodulation together with its effects on adaptive immune system, suggesting the possible rare link with development of autoimmune disorders

Malignant pheochromocytoma: a case report

Ghita Khamel, Kamel Farah, Kaoutar Rifai, Hind Iraqi & Mohamed Hassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco.

Introduction
Pheochromocytoma (PHEO) is an adrenal medulla tumor secreting catecholamines. Malignancy is defined by the presence of metastases in non-chromaffin tissue. Its optimal management requires experienced multidisciplinary teams.We report the case of a patient followed for malignant pheochromocytoma
Comment
58-year-old patient operated for a pheochromocytoma in 2016, then lost sight of. The evolution was marked 6 years later by the installation of right lumbar pain associated with a Menard triad evolving in a context of weight loss not figure. Clinical examination found right lumbar contact with tenderness on palpation, associated with swelling next to the left scapula. The dosage of urinary methoxylated derivatives shows a normetanephrine level twice the normal. The adrenal CT shows a right interhepato-renal lesional process invading the hepatic parenchyma measuring: 8.4×10.5 cm. As part of the extension assessment, a CTAP CT scan was performed showing an inter hepatorenal tissue mass invading the liver and the thoracic wall in favor of tumor recurrence with secondary pancreatic and bone localizations at the level of the femoral head, and lysis scapular bone. MIBG scintigraphy and PET FDG are not available The file was

staffed in mulidisciplinary meeting, the therapeutic decision was to complete with palliative chemotherapy with VP 16 cisplatine A genetic study is requested in search of a mutation of the SDHB gene
Discussion
The prevalence of metastatic pheochromocytomas varies between 5 and 26%. Only the presence of lymph node or distant metastases affirms malignancy; histological examination does not provide certain information Secondary localizations are most often pulmonary, hepatic and bone.The diagnosis of recurrence can be made through MIBG scintigraphy despite a normal hormonal balance. Surgery is rarely curative, but tumor reduction or resection of metastases particularly reduces cardiovascular risk. Treatment with 131I-MIBG is an interesting alternative in the management of malignant pheochromocytomas when chemotherapy is indicated as first-line treatment in the event of an inoperable tumor or failure of metabolic radiotherapy.
Conclusion
Our case illustrates the importance of clinical, biological and even morphological monitoring of all patients operated for pheochromocytoma, which must be continued for a long time (15 years) given the possibility of late revelation of metastases. In spontaneous evolution, the 5-year survival is generally less than 50%. Due to the current absence of an effective treatment for malignant tumors, several palliative therapies allow tumor reduction and improved survival.

The Adrenal that inCYSTS on causing pain

Christopher Horne[1], Charles Tilley[2], Martin Smith[3] & C Richard W Lockyer[4]
[1]University Hospital Southampton, Endocrinology, Southampton, UK; [2]University Hospital Southampton, Pathology, Southampton, UK; [3]Salisbury District Hospital, Endocrinology, Salisbury, UK; [4]University Hospital Southampton, Urology, Southampton, UK.

Adrenal lymphangiomatous cysts are rare, often found incidentally, but can also present in association with abdominal/loin pain or hypertension.[1] They have occasionally been reported in association with hormone over secretion of either aldosterone, cortisol or catecholamines. We present a case of a 40-year-old serving soldier who was suddenly awoken with severe left sided abdominal and flank pain. Over the course of several months, he was forced to take time off work, required opiate analgesia and experienced significant psychological burden because of the severity of symptoms. His initial work up involved a cystoscopy (due to dipstick haematuria) which was normal and a CT of the abdomen which showed a left sided 3.5 cm cystic, partially calcified adrenal lesion. Full endocrinological workup revealed the lesion to be non-functioning. He was normotensive. The size of the adrenal cyst was not thought to correlate with the severity of his pain (and a follow up CT showed no growth or intracyst haemorrhage), but in the absence of an alternative explanation, the patient chose to proceed to a laparoscopic left adrenalectomy. His pain immediately resolved postoperatively, he discontinued all analgesia and returned to work. Histology showed multiloculated cyst lined by flattened endothelial-like cells. Immunohistochemistry confirmed expression of D2-40, CD31 and CD34 consistent with cystic adrenal lymphangioma. Whilst most small adrenal cysts are asymptomatic, adrenal cystic lymphangiomas have been associated with back/abdominal/loin pain in 48% and hypertension in 14% cases.[1,2] This suggests that these endothelial cysts are more likely to cause symptoms regardless of their size. The possible mechanisms of pain in relatively small cysts with no evidence of prior bleed could include retroperitoneal irritation, local cytokine release, abnormal lymphatic drainage, but what exactly causes this phenomenon, especially if pain is severe, remains a mystery. Management of the adrenal cyst and decision on whether to proceed to surgery remains dependent on the size and clinical imperative. However, this case provides an example of small adrenal cyst having life changing implications, had it not been removed. Recognition that small adrenal cystic lymphangiomas can cause such symptoms may help inform future clinical decision making.

A case report of 24 years old female with stage IV adrenocortical carcinoma in vilnius university santaros clinics.

Modesta Alekniene[1,2], Greta Kazakeviciute[1,2], Karolina Charciunaite[1], Gintare Naskauskiene[1,2] & Zydrune Visockiene[1,2]
[1]Vilnius University Hospital Santaros Klinikos, Center of Endocrinology, Vilnius, Lithuania; [2]Vilnius University Faculty of Medicine, Clinic of Internal Diseases, Family Medicine and Oncology, Vilnius, Lithuania.

Introduction
Adrenocortical carcinomas (ACC) are rare and frequently aggressive tumors that may be functional (hormone-secreting) – causing Cushing's syndrome and/or virilization, or nonfunctional – presenting as an abdominal mass or as an incidental finding. We describe a rare case of stage IV adrenocortical carcinoma which first manifested as treatment resistant Cushing's syndrome**.**
Case report
In september of 2021**,** a 24-year-old female came with a complaint of acne and weight gain. During the process of anamnesis collection other symptoms characteristic to hypercortisolism were identified – rounding and flushing of the face, widening of the neck, abdominal weight gain, limb weakening and thinning, increase in blood pressure and thirst. In initial blood test results biochemical parameters testosterone and plasma metanephrines were within normal limits. Serum cortisol was elevated (1049,9 nmol/l), also secondary hypothyroidism was found. Low-dose dexamethasone test was performed and no suppression was observed, cortisol after suppression test remained high – 797 nmol/l. We confirmed autonomous cortisol secretion after disturbed circadian cortisol rhythm, high levels of the 24-hour urinary free cortisol, suppressed adrenocorticotropic hormone were found. Following that, chest, abdominal, pelvis computed tomography (CT) scan was performed and right adrenal mass was identified (90 × 62 × 127 mm), with metastases in the liver and in nearby lymph nodes. Interdisciplinary team decided on a treatment plan consisting of radical surgery followed by a postoperative chemotherapy treatment with mitotane. 2021-10-15 radical surgery was performed and she started the rehabilitation process. After surgery she felt better, she lost weight, her blood pressure became normal. 2021-10-28 histological test results came and adrenocortical carcinoma with metastases in liver was confirmed. 2021-11-29 treatment with doxorubicin, cisplatin and etoposide has begun, but after the first 3 days of treatment – chemotherapy induced cardiotoxicity appeared. She was hospitalized 2021-12-02. 2021-12-06 Abdominal CT scan showed tumor recurrence and progression. Due to hypokalemia, hypercortisolism – etomidate therapy was given, starting from 40 mg a day, through 8 h intravenously. 2021-12-22 mitotane was given, starting from 2000 mg per day. One more cycle of chemotherapy was tried, but her condition rapidly deteriorated and on 2022-01-05 she died.
Conclusion
Our case showed that despite the rarity of the tumor and young patient's age it is important to perform further clinical evaluation in any patient with unexplained symptoms characteristic to hypercortisolism.

EP125

A case of Cushing's disease caused by pituitary macroadenoma

Guranda Maisuradze[1] & Salome Kalandadze[2]
[1]New Hospitals, Endocrinology, Diabetes and Metabolism, Tbilisi, Georgia; [2]New Hospitals, Tbilisi, Georgia.

Introduction: Cushing's disease (CD) accounts for approximately 80% of cases of Cushing's syndrome. Almost all patients with CD have a pituitary adenoma. The tumors are usually microadenomas, only approximately 5 to 10 percent are macroadenomas. Pituitary adenomas arise from epithelial pituitary cells and account for 10–15% of all intracranial tumors. Pituitary imaging is important in confirming the diagnosis of pituitary macroadenoma and also for determining the differential diagnoses of other sellar lesions. Case report: A 27-year-old woman was referred with a 2-week history of headache, blurred vision, edema, amenorrhoea, acne and 14 kg weight gain. Three months previously, her gynecologist had diagnosed hyperprolactinemia (PRL-1053 U/ml) and had started treatment with Cabergoline ¼ tab. 2 times per week. She stopped the treatment without doctor's permission. On examination, there was no galactorrhoea and no purple stretch marks, BMI-19 kg/m^2, BP-110/70 mmHg, P-76', regular. Investigations: MR scan of brain – *chiasm-compressing* adenoma with suprasellar extension 1.2x2.0x1.5 cm, CT scan – *without adrenal hyperplasia,* PRL-1053 U/ml (102-496), TSH-0.696 mIU/ml (0.27-4.2), FT4-10.76 pmol/l (12-22), FT3-3.09 pmol/l (3.1-6.8), LH < 0.100 mIU/ml (2.4-12.6),

FSH-0.954 mIU/ml (3.5-12.5). Serum ACTH and Cortisol were not performed properly, the patient couldn't menaged collecting 24 h urine as well. All other investigations were in normal range. She was diagnosed with macroadenoma pituitary, hyperprolactinemia, central hypothyroidism, secondary hypogonadism. We prescribed Dopamine agonist and Levothyroxine. 2 weeks later she presented new Lab results: 08:00 ACTH-25.03 pg/ml (7.2-63.3), Cortisol-1271 nmol/l (172-497). The high-dose dexamethasone test was performed; proper fall of cortisol was not achieved. CD was diagnosed and she was referred for adenomectomy to neurosurgeon. Buffalo Hump and purple stretch marks first appeared some days before surgery. Transsphenoidal adenomectomy was performed. After surgery replacement therapy has begun.

Conclusion

Patients with macroadenomas are more likely to have supranormal plasma ACTH concentrations than are those with microadenomas (83 versus 45 percent), and the concentrations are less likely to fall with high doses of dexamethasone, as it was described in our case. The treatment of choice for patients with CD is transsphenoidal surgery and resection of the pituitary tumor.

Disorders of sexual development due to congenital adrenal hyperplasia

Fatima Zahra Outtaleb[1], Amal Tazzite[2] & Hind Dehbi[1,2]
[1]Ibn Rochd University Hospital, Laboratory of Medical Genetics, Casablanca, Morocco; [2]Faculty of Medicine and Pharmacy, Hassan II University, Cellular and Molecular Pathology Laboratory, Casablanca, Morocco.

Disorders of sexual development are defined as any congenital condition, in which the development of the chromosomal, gonadal, or anatomical sex is atypical. Congenital adrenal hyperplasia is one of the most common etiology of those disorders, whiwh may be responsible for acute adrenal insufficiency in the neonatal period. The objectives of this case report are to underline the interest of the diagnosis and the genetic counseling for this pathology characterized by an autosomal recessive transmission. It is a child aged of 3 months at the time of diagnosis, the last of a sibling of nine children, with a history of four deaths in the siblings, and who presented at the age of 2 months with an acute adrenal insufficiency syndrome, revealing congenital adrenal hyperplasia due to 21-hydroxylase deficiency. Clinical examination revealed a sexual ambiguity (hypospadias and cryptorchidism). The rest of the clinical examination did not find any dysmorphism or other associated abnormalities. The inguino-scrotal ultrasound revealed a pelvic structure in the shape of a uterus and the absence of testicles. The karyotype on two different samples confirmed the female chromosomal sex of the child, with a normal formula of 46.XX. Genetic counseling with molecular study are planned. Disorders of sexual development are the result of anomalies that have arisen during the sex differentiation of the individual. The diagnosis of these abnormalities requires in particular cytogenetic and molecular analyses. Prenatal diagnosis is performed in high-risk pregnancies and prenatal treatment with dexamethasone seems effective in preventing genital anomalies in affected female fetus.

EP127

A newly diagnosed Cushing's syndrome after a visit at the Emergency Department

Marina Iliescu[1], Mihaela Tarna[1], Marian Andrei[1], Luminita Nicoleta Cima[1,2], Carmen Sorina Martin[1,2] & Fica Simona[1,2]
[1]Spitalul Universitar de Urgenţă Elias, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania.

Cushing's syndrome results from an excess exposure to glucocorticoids which can result from various causes, divided into ACTH-dependent and ACTH-independent etiologies. An example of ACTH-independent causes are adrenal masses which are either benign adenomas, representing the majority of adrenal mass cases, or by malignant neoplasms. We present the case of a 52 yo woman who presented at the Emergency Department (ER) with thoracic pain and palpitations, for which several cardiac investigations where performed including a thoracic CT scan in order to exclude a pulmonary embolism (PE). The CT scan infirmed the PE, but revealed masses on both adrenal glands. The left adrenal gland showed a heterogeneous, hypodense aspect with a nodule of 1,7 cm and 106 HU. The right adrenal gland showed an homogeneous, hypodense aspect of -13 HU. Therefore the patient was transfered to the Endocrinology Department. Physical examination revealed an obese patient with central fat distribuition, lean proximal parts of the limbs, buffalo hump, hirsutism and kyphotic attitude of the spine. The patient was known with a history of arterial hypertension grade 3, uncontrolled despite treatment with 4 antihypertensive drugs and she complained of mechanical back pain. The routine blood tests were normal, except a mixted dyslipidemia. We excluded pheochromocytoma and primary hyperaldosteronism. Cortisol circadian rhythm was abnormal and basal plasma ACTH low. The cortisol secretion did not suppress after administration of 1 mg overnight of dexamethasone. Severe osteoporosis was diagnosed after DXA evaluation with a vertebral fracture at T4 level. After diagnosing Cushing's syndrome due to primary bilateral macronodular adrenal hyperplasia we decided to perform unilateral adrenalectomy because our patient had moderately increased cortisol production, but with clinical evidence of cortisol excess and the left adrenal was larger on CT scan. Unfortunately, we were not able to screen for aberrant receptors or perform adrenal venous sampling. The particularity of this case is the fact that the patient presented at the ER complaining of nonspecific thoracic pain and the diagnosis of Cushing's syndrome was suspected via an imaging which was not perfomed for evaluation of an adrenal disease.

EP128

Case report of rare adrenocortical oncocytoma with cushing's syndrome and liver hemangiomas

Khatuna Chakvetadze[1], Tamar Shervashidze[2] & Armaz Mariamidze[3]
[1]JSC EVEX – Kutaisi Referral Hospital, Outpatient Diagnostic Department, Kutaisi, Georgia; [2]David Abuladze Georgian-Italian Clinic, Outpatient, Georgia; [3]Pathology Research Center, Georgia.

Introduction

Hormonally active adrenocortical oncocytoma is a very rare neoplasm. Adrenal oncocytomas are mostly considered as non-functioning, benign tumors, with the size of generally >6 cm and lack of pathognomonic features on radiological examinations.

Case Report

A 41-year-old woman was referred to the endocrinologist in April 2021 due to weight gain, resistant arterial hypertension and menstrual irregularities for the last several years. She has been infertile for 10 years, though 5 years ago she delivered a preterm baby girl by the 35th week of pregnancy. Physical examination revealed cushingoid characteristic features: dorsal cervical fat pad, moon facies, fragile skin and thin extremities. Cushing syndrome was confirmed by an overnight 1 mg dexamethasone suppression test, an elevated free cortisol on a 24-hour urine collection, suppressed ACTH level and low DHEA-S level. Primary hyperaldosteronism was excluded by an oral salt loading test. Urinary metanephrines were normal. HBA1C-6.0%. Abdominal CT and MRI revealed left sided adrenal heterogeneous lesion (adenoma) measuring 2.3X2.8X2.2 cm with a calcification focus in the periphery. She was also revealed small liver hemangiomas and NAFL disease. In July 2021 the patient underwent laparoscopic left adrenalectomy. To prevent postoperative adrenal insufficiency, the patient was medicated with hydrocortisone. The operative adrenal gland measured 6x2.5x2.5 cm, with a nodule of 2.5x2.2x2.0 cm of well-defined limits, yellowish. The histological and immunohistochemical analysis revealed the diagnosis of adrenocortical neoplasm with predominance of oncocytic cells in solid-trabecular structures (adrenocortical oncocytoma), having uncertain malignant potential. The doses of hydrocortisone were tapered slowly and stopped 3 months later. 6 months after surgery her cortisol, DHEA-S and electrolyte levels were normal, without any radiologic evidence of recurrence. She is currently in follow up.

Discussion

Adrenocortical oncocytomas are extremely rare tumors with almost 200 published cases, first reported in 1986 by Kakimoto. Although it is by definition, non-functioning, recent data indicate that 17.0-31.5% of adrenal oncocytomas have hormonal activity. By origin oncocytomas are epithelial tumours composed of large eosinophilic cells, due to mitochondria-rich cytoplasm. The frequency of non-functioning oncocytomas is higher in female. The diagnosis of these neoplasms is mostly based on histological and immunohistochemical analysis. The Lin-Weiss-Bisceglia risk system is used to distinguish malignant oncocytic tumors, with major and minor criteria for differentiation. Small oncocytomas are commonly benign tumors, but in our clinical case the hormonally active oncocytoma, with two minor criteria (necrosis and capsular invasion), was classified as having uncertain malignant potential, thus suggesting important prognosis and need for close follow-up.

Altered steroid metabolism in patients following severe trauma: the golden hour study

Conor Bentley[1,2,3], Jon Hazeldine[1,2], Laura Bravo[4], Angela Taylor[5], Lorna Gilligan[5], Fozia Shaheen[5], Animesh Acharjee[2,4,6], Georgios V Gkoutos[2,4,6,7], Mark Foster[1,2,7], Wiebke Arlt[5] & Janet Lord[1,2]
[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, UK; [2]National Institute for Health Research Surgical Reconstruction and Microbiology Research Centre, Queen Elizabeth Hospital Birmingham, Birmingham, UK; [3]School of Sport, Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham, UK; [4]Institute of Cancer and Genomic Sciences, Centre for Computational Biology, University of Birmingham, Birmingham, UK; [5]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, UK; [6]Institute of Translational Medicine, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [7]Royal Centre for Defense Medicine, Birmingham, UK.

Background
Advancements in medical care have significantly improved survival after major traumatic injury and the main risks are now sepsis and multi-organ failure. An understanding of the hormonal, inflammatory and metabolic changes that occur following trauma is still evolving but it is clear that they impact significantly upon patient prognosis. To date, studies that have examined trauma-induced changes in steroid metabolism have analysed samples taken from patients post-hospital admission, culminating in marked variability in the time of first blood sample. Here we investigated the major changes in steroidogenesis following trauma, focusing on the immediate time after injury.
Methods and Results
We recruited 31 male trauma patients (mean age 28.1 years range 19–59) who had an initial blood sample taken within 1-hour of injury, with subsequent samples taken 4–12 and 48–72 h post-injury. Our control cohort was 35 healthy male volunteers (mean 30 years; range 18–50). Sixteen serum steroids were quantified by liquid chromatography tandem mass spectrometry using a Waters Acquity UPLC and a Xevo-XS mass spectrometer;

- precursors; progesterone, 17hydroxyprogesterone,
- glucocorticoids; 11-deoxycortisol, cortisol, cortisone,
- mineralocorticoids; 11-deoxycortocosterone, corticosterone,
- androgen precursors; DHEAS, DHEA, androstenedione,
- androgens; testosterone, DHT,
- 11-oxygenated androgens; 11-hydroxy-androstenedione, 11hydroxy-testosterone, 11keto-androstenedione and 11keto-testosterone.

Eleven of the sixteen steroids were significantly increased 1 h after injury in comparison to healthy controls. Maximum concentrations of these steroids were observed one hour post injury, concentrations then decreased at 4–12 h and reached levels similar (or lower than) healthy controls 48–72 h after injury. The exceptions were cortisone, 11Keto-androstenedione, 11Keto-testosterone, testosterone and DHT. The concentrations of testosterone and DHT decreased one hour post injury when compared to healthy controls, then decreased further at 4–12 and again at 48–72 h post injury. To estimate when trauma-induced steroid metabolism changes occurred we employed generalised additive models (GAMs) to the samples collected within the first hour of injury. GAMs allowed us to estimate the time excretion of each steroid was altered compared to the healthy controls. The modelling estimated injury-induced changes in steroid precursors 9 min post trauma then in a sequential manner reflecting steroidogenesis to active androgens at 35 min, demonstrating rapid disruption of both adrenal and gonadal steroid biosynthesis.
Conclusions
These data show major changes in steroidogenesis following trauma, for the first time focusing on the immediate time after injury. Whether those patients that have ultra-early changes in steroid metabolism are associated with poor patient outcome warrants further investigation.

More than a coincidence? a true risk factor in spontaneous coronary dissection: hypothyroidism

Aymen Noamen, Khalil Bahri, Houssem Ben Ayed, Sarra Chenik, Nadhem Hajlaoui & Wafa Fehri
Military Hospital of Tunis, Cardiology, Tunis, Tunisia.

Introduction
Spontaneous coronary artery dissection (SCAD) is an uncommon cause for acute coronary syndrome (ACS). It has been linked to many conditions such as physical exertion, emotional stress, fibromuscular dysplasia, autoimmune diseases. Recent studies suggest high prevalence of hypothyroidism in unselected consecutive patients with SCAD compared with a control group of ACS patients without SCAD with more distal dissections on curly vessels.
Case report
A 51 years old woman with no particular medical history except for hyperthyroidism diagnosed 5 months prior and treated with anti-thyroid drugs, presented to the emergency department for sudden constrictive chest pain following an unusual physical exertion. The EKG showed a regular sinus rhythm of 75 bpm and ST segment depression in the apico-lateral and inferior leads. Troponin levels were high (>40.000 ng/l) and the rest of the lab tests were unparticular. The patient received anti-ischemic treatment and was transferred to our department. At the admission to the intensive care unit, the patient was pain-free, and the EKG showed a sinus regular rhythm with complete regression of the previous patterns, she was then promptly transferred to the cath lab where coronary angiography was performed and showed a tubular dissection of a tortuous mid left anterior descending artery without flow limitation, concordant with type 2 SCAD. The decision then was to perform angioplasty with a DES covering the length of the diseased segment. The transthoracic echocardiography showed an akinetic apex, a left ventricle ejection fraction of 40% and an apical thrombus. The thyroid hormones dosage revealed a hypothyroidism, which was most likely iatrogenic due to the anti-thyroid drugs; subsequent dose lowering was put into effect for an eventual interruption. The patient was discharged with uneventful clinical course.
Conclusion
SCAD is still a topic of interest with unresolved pathophysiology and multiple factors that have been linked to it like thyroid disorder. More studies are needed in this context, which could potentially help elucidate the mechanisms involved in this phenomenon.

Adrenal insufficiency revealed during a diabetic pregnancy: a case report

Oussama Jaddi, Zineb Ait Si Ali, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
Mohammed VI University Hospital, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco.

Introduction
Adrenal insufficiency is rarely diagnosed during pregnancy. In the absence of treatment it is associated with high maternal-foetal morbidity and mortality. We report the case of a twenty-one years old female patient, diagnosed with adrenal insufficiency during a diabetic pregnancy of 12 weeks of gestation.
Observation
Twenty-one years old female patient, diagnosed with type 1 diabetes since the age of 15, Referred to our department for the follow-up of her diabetes with an unplanned, evolving pregnancy estimated at 12 weeks of gestation. The patient reported multiples episodes of hypoglycemia reaching 0.42 g/l and persistent asthenia. The clinical examination showed a blood pressure of 100/68 mmHg, heart rate of 71 bpm, and BMI of 22.86 kg/m^2. Suspicion of adrenal insufficiency is confirmed by a low baseline cortisol of 13 µg/dl for an average of 25.1 µg/dl according to the term (12 weeks of gestation). The patient initially received hydrocortisone 30 mg/d reduced after to 20 mg/d with a favorable evolution after the replacement therapy. Adrenal insufficiency of autoimmune cause in the context of autoimmune polyendorcrinopathy, is the most likely etiological diagnosis. The results of the etiological investigation are in progress.
Conclusion
Adrenal insufficiency can occur during pregnancy and be life-threatening if not treated appropriately. However with a correctly adapted hormonal substitution during pregnancy the evolution is favorable in most cases. During delivery, the treatment must be increased and administered by injection as during surgery. The diagnosis can sometimes be difficult due to confusion with the signs of pregnancy or in case of association with diabetes which could be responsible for a delayed management.

Association of preoperative therapy by native form vitamin D and hypocalcemia after parathyroidectomy in primary hyperparathyroidism patients

Alina Elfimova[1], Anna Eremkina[1], Olga Rebrova[2,3], Elena Kovaleva[1] & Natalia Mokrysheva[4]
[1]Endocrinology Research Center, Department of Parathyroid Disease, Moscow, Russian Federation; [2]Endocrinology Research Center, Moscow,; [3]Pirogov Russian National Research Medical University, Department of Medical Cybernetics and Informatics, Moscow, Russian Federation; [4]Endocrinology Research Center, Director, Moscow, Russian Federation.

Background
Primary hyperparathyroidism (PHPT) is a common endocrine disorder resulting from oversecretion of parathyroid hormone (PTH) in parathyroid glands. Hypocalcemia can occur in the postoperative period after parathyroidectomy (PTE) and can be challenging to control and requires varying doses of supplementation. Vitamin D deficiency can worsen the severity of PHPT and promote the development of "hungry bone syndrome" due to increased influx of calcium into bone after PTE.
Aim
To estimate the association of preoperative cholecalciferol therapy and development of hypocalcemia in 1–3 days after PTE in patients with PHPT.
Methods
Patients with PHPT, serum 25-hydroxyvitamin D (25(OH)D) <20 ng/ml (vitamin D deficiency), and serum total calcium <3 mmol/l were included. Exclusion criterion was the therapy with drugs affecting calcium-phosphorus metabolism – cinacalcet, denosumab or bisphosphonates (either as monotherapy or as a part of combination therapy). All patients underwent selective PTE at the Endocrinology Research Center in 1993–2010 or 2017–2020. PTH, total calcium, phosphorus were measured on 5 days – 4 years before surgery and before therapy by cholecalciferol (if any). 25(OH)D, alkaline phosphatase (AP), osteocalcin, c-terminal telopeptide of type 1 collagen (CTX-1) and dual-energy X-ray absorptiometry were measured on 4-365 days before surgery.
Results
Among 117 included patients, 110 (94%) were female and 7 (6%) male with median age 58 [49; 65] years. 21 patients took cholecalciferol for 2 weeks–2 months at a dose according to the replenishment of vitamin D deficiency and 96 did not. No significant difference was found in demographical (sex, age at surgery), clinical (severity of bone mass density loss) and laboratory parameters (PTH, total calcium, phosphorus, AP, osteocalcin, CTX-1, 25(OH)D) between these groups of patients. Patients with cholecalciferol therapy had significantly less frequent postoperative hypocalcemia (10% vs 63%, $P<0.001$, χ^2). Cholecalciferol intake is negatively associated with hypocalcemia, RR $=0.15$, 95% CI: 0.03–0.51.
Conclusions
Taking cholecalciferol before PTE for 2 weeks–2 months reduces the risk of postoperative hypocalcemia by 2–33 times in patients with PHPT.

Metabolic parameters in patients with primary hyperparathyroidism before and after parathyroidectomy

Ekaterina Bibik[1], Ekaterina Dobreva[1], Anastasia Miliutina[2], Alina Elfimova[1], Anna Eremkina[1] & Natalia Mokrysheva[3]
[1]Endocrinology Research Centre, Department of Parathyroid Pathology and Mineral disorders, Moscow, Russian Federation; [2]Endocrinology Research Centre, Department of Registries of Endocrinopathies, Moscow, Russian Federation; [3]Endocrinology Research Centre, Moscow, Russian Federation.

Background
Metabolic syndrome may be the nonclassical feature of primary hyperparathyroidism (PHPT) because an increased incidence of various glucose and lipid disorders is often observed in patients with this disease. Earlier we showed PHPT patients had higher serum triglycerides and higher rate of insulin resistance compared to the control group. Dynamics of metabolic parameters after surgery is ambiguous.
The aim
of this study was to compare metabolic parameters in patients with PHPT before and after parathyroidectomy.
Material and Methods
24 patients with PHPT (median age 37 years [33; 41]) underwent biochemical and hormone evaluation, standard oral glucose tolerance test, euglycemic hyperinsulinemic and hyperglycemic clamps, bioelectrical impedance analysis of the body composition before and 1 year after surgery. The exclusion criteria were the GFR $<$ 60 ml/min/1.73 m^2, severe comorbid illness, body mass index (BMI) ≥ 32 kg/m^2, diabetes mellitus, using drugs affecting glucose, lipid and calcium balance. Control group ($n=20$) was sex-, age- and BMI-matched without any endocrine pathology (median serum albumin-adjusted calcium (Ca_{adj}) 2.24 [2.15; 2.28]mmol/l, parathyroid hormone 40.19 [31.10; 51.04]pg/ml).
Results
Except one patient who had glucose intolerance others had normal glucose metabolism according to standard lab tests. 54.2% had normal weight, 41.7% was overweight and just 1 person had obesity I, herewith 45.8% of all had over visceral fat. Insulin resistance (by M-index) was detected in 54.2% cases. PHPT patients had higher serum triglycerides (1.13 [0.94; 1.39] vs 0.79 [0.63; 1.01]mmol/l), lower M-index (5.60 [4.25; 7.45] vs 7.9 [7.0; 10.6]mg/kg*min) and higher C-peptide and insulin levels in both phases of pancreas secretion compared to the control group ($P<0.05$ for all). After radical parathyroidectomy we detected decreased fasting glucose (5.04 [4.63; 5.23] vs 4.69 [4.48; 5.00]mmol/l, p $=0.031$), uric acid (297.7 [246.4; 365.6] vs 261.58 [238.52; 350.37]μmol/l, p $=0.044$) levels and insulin level of second secretion phase (AUC 1150.2 [960.8; 1447.9] vs 982.0 [805.8; 1375.7], p $=0.039$) but any significant changes of lipid profile and M-index as well as body composition weren't revealed. We found negative correlation between Caadj and total cholesterol levels ($r=-0.50$), $P<0.05$ as well as total fat mass and osteocalcin ($r=-0.45$), b-CrossLaps ($r=-0.41$) and magnesium levels ($r=-0.43$), $P<0.05$ in patients before surgery.
Conclusion
Changes of bone and mineral parameters in PHPT can lead to metabolic disorders. Remission of the parathyroid pathology is suspected to improve carbohydrate and purine balance but further studies are required to clarify this statement.

«Hungry bone» syndrome in delay diagnosed primary hyperparathyroidism with fibrocystic osteitis: A case report

Karina Pogosian[1], Lubov Yanevskaya[1], Arina Mikhailova[1], Alisa Semenova[2], Daria Ryzhkova[3], Lidia Belousova[1], Uliana Tsoy[1] & Tatiana Karonova[1]
[1]Almazov National Medical Research Center, Endocrinology, St. Petersburg, Russian Federation; [2]Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation; [3]Almazov National Medical Research Center, Nuclear Medicine and Theranostics, St. Petersburg, Russian Federation.

Background
Fibrocystic osteitis is rare PHPT manifestation. Poor management and delay in diagnosis of fibrocystic osteitis may lead to reduced quality of life and also provoke severe postoperative hypocalcemia – «hungry bone» syndrome.
Clinical case
We present a case of 66-years-old Caucasian woman, with history of urulithiasis/nephrocalcinosis (CKD stage 4), two pathological fractures, and fibrocystic osteitis. In Jan 2021 MRI was performed due to increasing bone and joint pain, unsteady gait and showed multiple vertebral lesions in L3 and L4. Since the diagnosis was not established CT was performed, it revealed bone resorption sites in Th12, L2 – L5, sacrum, and left ileum. These changes were considered to be multiple myeloma signs, but bone marrow trephine biopsy and monoclonal antibody assay did not support this diagnosis. L3 trephine biopsy suggested the giant-cell tumor. Zoledronic acid (4 mg/28 days) therapy was started and undertook whithin 4 months. Later PHPT was suspected. Subsequently iPTH level was 2306.9 pg/ml (15.0–68.3), serum Ca^{++} level – 2.17 mmol/l (1.11–1.29), serum total Ca – 3.86 mmol/l (2.15–2.65), 25(OH)D – 10.80 ng/ml (9.40–59.10). Within the adenoma localization neck ultrasound was performed, although it didn't show any lesions. CT and ^{11}C-methionine PET/CT neck and thorax scans revealed two lesions presumed to be ectopic parathyroid adenomas (3.0x2.1x4.8 cm and 0.8x0.5x0.9 cm). Loop diuretics, rehydration, and cholecalciferol (2000 IU/daily) therapy was started. Parathyroidectomy was performed shortly due to increasing hypercalciemia, both lesions were confirmed to be adenomas. From the third day postoperatively low serum Ca^{++} was detected 0.85 mmol/l in terms of normal iPTH level (45.83 pg/ml), as the patient was having seizures, muscle pain, hallucinations, fatigue, and bradycardia. This condition was evaluated as a «hungry bone» syndrome in terms of prolonged course of fibrocystic osteitis. IV calcium gluconate (16.8 g/daily) and oral calcium carbonate/citrate (5 g/daily), cholecalciferol (4000 IU/daily) and alfacalcidol (4 μg/daily) were used to cope with hypocalcemia. Fourteen-day therapy and replacing alfacalcidol with calcirliol (2 μg/daily) allowed to withdraw IV calcium and reduce oral calcium supplementation.
Conclusion. Delayed diagnosis of long-term hypercalcemia, high iPTH level, unsubstituted 25(OH)D deficiency, and the use of bisphosphonates in high doses

caused development of "hungry bones" syndrome in early postoperative period. Severe hypocalcemia required prescription of active and native forms of vitamin D, oral calcium supplements and IV calcium therapy.

Quality of life improvement as a valuable outcome of parathyroidectomy in patients with symptomatic and asymptomatic primary hyperparathyroidism

Tatiana Nikitina, Dmitry Buzanakov, Inna Gladkova, Vladimir Rusakov, Roman Chernikov, Yulia Karelina, Sergey Efremov & Tatiana Ionova
Saint-Petersburg State University Hospital, Saint Petersburg, Russian Federation.

Background
Comprehensive evaluation of the effect of surgery in patients with primary hyperparathyroidism (PHPT) and monitoring of patient's well-being after treatment including assessment of patient-reported outcomes is worthwhile.
AIM
We aimed to assess changes in quality of life (QoL) and symptoms in patients with symptomatic and asymptomatic PHPT after surgery (parathyroidectomy, PTX).
Materials and methods.
Adult patients with PHPT who were referred for PTX were included in the single-center prospective observational real-world study. Patients filled out generic and specific questionnaires, namely SF-36 and PHPQoL, for QoL assessment and symptom checklist for assessment of presence and severity of their symptoms prior to surgery and 3, 12 months after PTX. Statistical analysis included Student's t-test or Wilcoxon's non-parametric test, the generalized estimating equations (GEE) method, correlation analysis, and $\chi 2$ test.
Results
In total 72 patients (mean age (S.D.) – 52 years (10.4), 97% female) with symptomatic (68%) and asymptomatic (32%) PHPT were enrolled in the study. Moderate/severe hypercalcemia was observed in 34.7% patients. Before PTX patients with PHPT experienced significantly decreased role functioning, physical and social functioning, and vitality as compared to healthy controls ($P<0.05$). Mean PHPQoL score was 53.7 (IQR: 42.2–64.1). Half of the patients experienced moderate-to-severe symptoms such as weakness, fatigue, cognitive impairment, changes in mood, as well as joint and bone pain. In 3 and 12 months after surgery, improvement in both physical and psychological components of QoL in PHPT patients was shown. Significant changes were observed for the total PHPQoL score as well as for role, physical, emotional and social functioning and vitality by SF-36 (GEE, $P<0.05$). Positive QoL changes were demonstrated for patients with both symptomatic and asymptomatic PHPT, but they were more pronounced in the first ones. QoL improvement was not associated with baseline Ca level or type of PHPT (χ^2, $P>0.05$), but correlated with baseline QoL: the lower baseline QoL the higher QoL improvement after PTX ($r=-0.376$, $P<0.05$). Significant decrease in PHPT-associated symptoms such as weakness, fatigue, loss of concentration and mood changes was found within 12 months after PTX (GEE, $P<0.05$); it was more pronounced in symptomatic PHPT.
Conclusion
PTX leads to pronounced positive QoL changes in PHPT patients. The results obtained demonstrate that QoL improvement is a valuable outcome of surgery both in patients with symptomatic and asymptomatic PHPT. Positive effect of PTX from patient's perspective confirms the value of QoL assessment to measure the degree of recovery at long term follow-up.

Glomerular filtration rate 12 months after parathyroidectomy in patients with primary hyperparathyroidism

Alina Elfimova[1], Anna Eremkina[1], Olga Rebrova[1,2], Elena Kovaleva[1], Anastasia Miliutina[3,4] & Natalia Mokrysheva[5]
[1]Endocrinology Research Center, Department of parathyroid disease, Moscow, Russian Federation; [2]Pirogov Russian National Research Medical University, Department of Medical Cybernetics and Informatics, Moscow, Russian Federation; [3]Endocrinology Research Center, Department of Edemiology of Endocrinopathy, Moscow, Russian Federation; [4]Pirogov Russian National Research Medical University, Moscow, Russian Federation; [5]Endocrinology Research Center, Director, Moscow, Russian Federation.

Background
In some patients with primary hyperparathyroidism (PHPT), glomerular filtration rate (GFR) demonstrate decrease after parathyroidectomy (PTE). GFR may decrease immediately after surgery due to general anesthesia, but after a month not all patients restore kidney function; a decreased GFR is also observed after 1–2 years after surgery.
Aim
To find the pre-surgical factors of GFR decrease after PTE.
Methods
Patients with PHPT who underwent selective PTE in 1993–2010 (50% of the patients) or 2017–2020 at the Endocrinology Research Center were included. Twenty-two variables were analysed. PTH, calcium total, phosphorus were measured prior to surgery (5 days – 4 years before surgery) and administration of drugs affecting calcium-phosphorus metabolism – cinacalcet, denosumab or bisphosphonates (either as monotherapy or as a part of combination therapy). 25(OH)D, alkaline phosphatase (AP), osteocalcin, c-terminal telopeptide of type 1 collagen (CTX-1), GFR, urea, triglycerides, uric acid, dual-energy X-ray absorptiometry and clinical characteristics were measured on 4–365 days before surgery. GFR was also estimated at 12 months after surgery.
Results
206 patients were included, aged 57 [47; 62] years, 19 (9%) male and 187 (91%) female. On 12 months after surgery 56 of them (27%) progressed to more severe stage of CKD (group 1), and 150 remained at the same stage of CKD (group 2): in the group 1 there were 25 (45%) patients with CKD C2, 17 (30%) with CKD C3a, 8 (14%) with CKD C3b, 6 (11%) with CKD C4, in the group 2 there were 65 (43%) patients without CKD, 63 (42%) with CKD C2, 13 (9%) with CKD C3a, 7 (5%) with CKD C3b, and 2 (1%) with CKD C5. There were no differences in sex, age, BMI, frequency of renal colic and stones, initial stages of CKD, initial GFR, frequency of bone fractures and osteoporosis between the groups. There were also no differences in phosphorus–calcium metabolism (total calcium, ionized calcium, and phosphorus), lipid metabolism (total cholesterol, LDL and HDL cholesterol, triglycerides), PTH, uric acid, urea, osteocalcin and CTX-1. AP was higher in group 1 (309.0 vs 190.3 IU/l, $P<0.001$, U-test).
Conclusions
Groups with decreased and stable GFR significantly differ by bone remodeling marker AP, but not in clinical manifestations of bone disorder. Moreover, groups were comparable in terms of GFR, uric acid and renal complications (renal colic and stones, CKD).

EP138

A comparison study of sublingual spray versus peroral capsules and oil in vitamin d supplementation

Sintija Sausa[1,2], Marija Aleksejeva[1], Ilva Trapina[3] & Valdis Pirags[1,2]
[1]University of Latvia, Faculty of Medicine, Riga, Latvia; [2]Pauls Stradinš Clinical University Hospital, Internal Medicine, Rīga, Latvia; [3]University of Latvia, Genomics and Bioinformatics, Institute of Biology, RIga, Latvia.

Background
Vitamin D is a vital hormone for calcium metabolism, bone and muscle health, and immune responses. Vitamin D deficiency affects entire Latvian population.
Aim
To compare the effectiveness of different forms of vitamin D.
Materials and methods
In a prospective, open-label, randomized study in the Jaunliepaja Primary Health Care Centre, data from 98 vitamin D deficient volunteers over one month at initiation of substitution with 4000 IU (100 mcg) Colecalciferol was analyzed. The efficacy of the peroral oil, lanolin-derived microemulsion sublingual spray and peroral capsules dissolved in sunflower oil was evaluated by comparing patient data with age, BMI, renal function.
Results
Among 98 volunteers with total 25(OH) D vitamin levels below 30 ng/ml, mean 18.30 ± 7.01 ng/ ml, and BMI below 35 kg/m^2, mean age 39.34 ± 13.01 years, 60.2% were female. After one month of intervention, the increase in vitamin D in all groups was 13.21 ± 11.82 ng/ml (95% CI, $P=5.72\times10^{-6}$). In oil group 14.98 ± 13.58, using capsules 11.06 ± 7.13 and in spray group 9.97 ± 7.73 ng/ml accordingly. In the capsule group, an inversely related – slower increase in vitamin D was observed in the elderly (-0.36, $P=4.53\times10^{-2}$) and in participants with a higher body mass index (BMI) (-0.40, $P=2.30\times10^{-2}$),

but the spray group higher increase in vitamin D levels was in participants with a higher glomerular filtration rate (GFR) (0.37, $P=2.93\times10^{-2}$).
Conclusions
An increase in vitamin D levels was observed in all groups after one month of supplementation, and the formulation did not statistically significantly affect the overall outcome. There was at least one respondent with negative vitamin D dynamics in each group. In the capsule group, the changes in vitamin D were statistically significantly inversely related to the respondent's age and BMI – the younger the person, the more pronounced the increase in vitamin D, similarly, the lower the BMI, the higher the increase in vitamin D. In the spray group, a statistically significant correlation was found between the increase in vitamin D and higher GFR.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

«Physician to physician» telemedicine consultations in parathyroid pathology: experience of quaternary endocrinological medical center

Anna Gorbacheva, Maria Fadeyeva, Anna Eremkina & Natalia Mokrysheva
Endocrinology Research Center, Parathyroid disorders, Moscow, Russian Federation.

Introducton
Telemedicine consultations (TMC) are a useful tool for ensuring communication between medical specialists, especially in a large country and in the era of COVID-19. It is important to study the needs and possibilities of TMC for various diseases, in particular, for the pathology of the parathyroid glands.
Materials and methods
TMC between regional health specialists and Endocrinology Research Centre (Moscow, Russian Federation) were conducted in 2019–2021 via All-Russian Center for Disaster Medicine «Zashchita».
Results
In 2019 1221 TMC were held in our center, 859 (70%) – for adult patients. In 2020 there were 1248 TMC, in 2021 – 3005 TMC, among them there were 1077 (86%) and 1622 (54%) TMC for adults, respectively. A high prevalence of parathyroid disorders in TMC was noticed (Table 1).

Table 1 Parathyroid disorders in nosological structure of "physician to physician" (P2P) TMC.

	2019	2020	2021
Total TMC count	1221	1248	3005
Number of TMC for adults	859	1077	1622
Number of TMC for parathyroid disorders/% regarding the number of consultations for adults	100 (11,6%)	121 (11,2%)	187 (11,5%)
Among them (according to ICD-10):			
E89.2 (Postprocedural hypoparathyroidism)	9	9	26
E21.0 (Primary hyperparathyroidism)	56	75	111
E21.1 (Secondary hyperparathyroidism)	20	13	18
E21.2 (Other hyperparathyroidism)	3	1	8
E21.3 (Hyperparathyroidism, unspecified)	12	21	18
E21.4 (Other specified *disorders of parathyroid gland)	0	0	3
21.5 (Disorder of parathyroid gland, unspecified)	0	2	3
Hospitalization recommended/% regarding the number of consultations for parathyroid disorders	43 (43%)	61 (50,4%)	121 (64,7%)

Conclusion
The relatively high proportion of parathyroid gland pathology in the structure of P2P TMC may indicate a relatively low awareness of doctors in the regions of Russian Federation about these diseases. At the same time, a high percentage of recommended hospitalizations indicates that such patients need high-tech treatment in a specialized center, which leads to their referral to a fourth-level facility. Further analysis is needed to determine the role of P2P TMC in routing of patients with parathyroid disorders.

Practical approach for hypocalcemia in infants: earlier diagnosis, earlier management

Abeer Alassaf
University of Jordan, Pediatric Department, Amman, Jordan.

Background
Hypocalcemia is a serious condition that occurs at any age with various etiologies according to various age groups. Hypocalcemia in infant is an emergency condition and the exact etiology should be identified as early as possible to ensure early appropriate management.
Methods
We are presenting 3 cases for infants who presented with seizures caused by hypocalcemia.
Case 1: A 3-month-old male infant presented with apnea and up rolling of eyes. He was full term with normal birth weight. He had poor weight gain, deep-seated eyes, long philtrum and small hands.
Case 2: An 11-day-old male neonate, presented with left-sided focal seizure. He was full term with normal birth weight. He was breast-fed with no vitamin D supplementation. Physical exam was unremarkable.
Case 3: A 6-day-old female neonate who presented with bilateral upper and lower limb clonic seizure. She was full term with normal birth weight. Her physical exam was normal.
Critical sample was sent at the time of hypocalcemia for the three patients. They received intravenous calcium gluconate during admission then switched to oral calcium.
Results
Laboratory work up for case 1 showed hypocalcemia, hyperphosphatemia and absent parathyroid hormone level in blood. Based on his dysmorphic features and laboratory work up, Sanjad Sakati syndrome was suspected which was confirmed by genetic testing. He is currently on daily oral calcium supplement and alfacalcidiol. For Case 2, patient had hypocalcemia, normal blood phosphorus level and very low vitamin D level. Vitamin D level was done for his mother and it was low. He was discharged on oral calcium and vitamin D. Calcium supplement was stopped after 1 week and he continued on vitamin D till last follow up. Case 3 had hypocalcemia, normal blood phosphorus level, low parathyroid hormone and low magnesium level. She was treated during admission in addition to intravenous calcium gluconate, with intravenous magnesium sulfate. She was discharged on calcium and magnesium supplement which were decreased gradually till stopped after few months. Magnesium deficiency which was the cause of her hypocalcemia was transient with no obvious cause.
Conclusion
Physicians should be aware of the precise approach for investigating the etiology of hypocalcemia in infants, in order to establish an early diagnosis and an early appropriate management, through taking full history and full physical exam and performing the appropriate investigations.

Mediastinal parathyroid lipoadenoma as a cause of primary hyperparathyroidism

Jesus Manuel Cornejo Dominguez, Alvaro Vidal Suarez, Isabel Maria Mateo Gavira, Maria del Mar Roca Rodriguez & Isabel Maria Torres Barea
Hospital Universitario Puerta del Mar, Cádiz, Spain.

Introduction
The parathyroid gland is made up of principal cells and oxyphilic cells, surrounded by stroma, whose main component is adipose tissue, which accounts for 25% of the content of the parathyroid in adults. In parathyroid adenomas, prominent parathyroid cellularity can be observed, with a very marked decrease in

the stroma. Parathyroid lipoadenoma is a rare variant of parathyroid adenoma, characterized by hyperfunctioning parathyroid cells in an abundant fatty stroma. Case reports.
We present a case of a 76-year-old woman with a history of high blood pressure and a previous diagnosis of non-toxic multinodular goiter without follow-up. During an outpatient study due to weakness and incipient cognitive disorders, severe hypercalcemia of 18.3 mg/dl with creatinine of 2.3 mg/dl was detected, for which she was admitted for treatment and study. In previous tests, a progressive increase in calcium was observed that had not been studied, with at least 6 years of evolution, with levels of 15 mg/dl the previous year. During admission, she showed parathyroid hormone (PTH) figures of 2,310.7 pg/ml (NV: 15–68), 25-OH-vitamin D of 12 ng/ml and TSH 0.12 IU/ml, with normal FT4. Cervical ultrasound revealed a multinodular goiter. In the 99mTc-sestamibi SPECT scintigraphy with a heterogeneous uptake of the radiotracer. Cervicothoracic CT revealed a right paratracheal mass with well-defined borders, with solid and fat densities, and dimensions of 5 × 5 × 8 cm, with no other lesions. A biopsy of the mass was performed, obtaining a whitish-brown sample consisting of adipose tissue and tissue with benign characteristics, with a low proliferative index (Ki67 of 1%), confirming its parathyroid origin with immunohistochemical techniques (positivity for the expression of panCK, PAX8 and chromogranin, and negative for PLAP, TTF1 and thyroglobulin). All this compatible with parathyroid lipoadenoma. Before surgical treatment, we started treatment with cinacalcet 30 mg/day, zoledronic acid and fluid therapy. The patient underwent total thyroidectomy and resection of the mediastinal mass. Intraoperative PTH was determined with progressive reduction (basal: 609.8 pg/ml; 5': 240 pg/ml; 10': 155.6 pg/ml; 20': 132.6 pg/ml). The mediastinal surgical specimen, 91 g and 9 × 5 × 3.5 cm, had a nodular appearance with a smooth, yellowish surface, covered by a fibrous capsule. The definitive histological study confirmed nodular thyroid hyperplasia and mediastinal parathyroid lipoadenoma. At hospital discharge, the patient presented calcium 9.34 mg/dl and was undergoing outpatient treatment with LT4 and calcium and vitamin D supplements

Brown Tumors as a first sign of secondary hyperparathyroidism

Maria Boudina, Chrysanthi Zouli, Eleana Zisimopoulou, Aimilia Fotiadou, Mariana Stamati, George Christantoniou, Chrysanthi Balodimou & Alexandra Chrisoulidou
"Theagenio" Cancer Hospital of Thessaloniki, Endocrinology, Thessaloniki, Greece.

Aim
Brown tumors are a very rare and serious complication of sustained undiagnosed secondary hyperparathyroidism. Diagnosis and differential diagnosis are made by combining clinical, biochemical, radiological and pathological findings. We present the case of a male with chronic renal disease and multiple bone damage.
A 58-year-old male was referred to the endocrine clinic because of lower back and pleural pain. He was an obese smoker with a heavy medical history of hypertension, Stage III chronic kidney disease, obstructive pulmonary disease, heart failure and atrial fibrillation. His past medical history included hyperthyroidism and a large retrosternal goiter. The patient underwent a Thorax CT, which revealed extrapulmonary masses infiltrating the thoracic cage and the ribs. The masses were considered at first to be metastatic and the patient underwent further imaging of the abdomen and cerebrum, as for staging. However, no possible primary lesion was illustrated and the patient was referred for a biopsy. The laboratory tests showed total calcium: 9,2 mg/dl (8,4–10,2), albumin: 4,1 mg/dl (3,5–5), phosphorus: 2,38 mg/dl (2,7–4,5), Parathyroid hormone: 1184 pg/ml (15–65), mild Vitamin D deficiency of 17,3 ng/ml and elevated levels of alkaline phosphate: 595 mg/dl (33–122). Histology confirmed the presence of brown tumors. The patient received supplementation with calcium and vitamin D analogs, as well as cinacalcet, and there was a significant improvement in his laboratory results: calcium 8,3 mg/dl, albumin 3,9 mg/dl, PTH 274 pg/ml, ALP 776 mg/dl and vit D 38 ng/ml. A Thorax CT six months after the diagnosis showed a decrease in the multiple bone lesions and further improvement in his laboratory tests.
Conclusions
Secondary hyperparathyroidism is a common complication of end stage renal disease. Rarely, when undiagnosed and left untreated it can lead to the formation of brown tumors, as a result of osteoclastic activity, fibroblast proliferation and bone resorption. Differential diagnosis should be made from giant cell tumors and metastatic disease.

Bilateral neck exploration is comparable to preoperative visualization methods in searching for parathyroid adenomas on the neck

Dmitrii Buzanakov[1,2], Arseny Semenov[1,2], Ilya Sleptsov[1,2], Roman Chernikov[1], Konstantin Novokshonov[1], Yuliya Karelina[1], Anna Uspenskaya[1], Nataliya Gorskaya[1], Svetlana Alekseyeva[1], Nataliya Timofeyeva[1], Igor Chinchuk[1], Elisey Fedorov[1], Yuriy Malyugov[1], Dina Rebrova[1], Shamil Shikhmagomedov[1], Ilya Sablin[1], Timur Dzhumatov[2], Mikhail Lyubimov[1], Alexander Pushkaruk[1], Kseniya Gerasimova[1], Anna Zolotukho[2] & Alexander Bubnov[1]
[1]Saint Petersburg State University Hospital, Saint Petersburg, Russian Federation; [2]Saint Petersburg State University, Faculty of Medicine, Saint Petersburg, Russian Federation.

Background
Undetected multiglandular disease (MGD) is a leading cause of persistent primary hyperparathyroidism after surgical treatment. There is still a number of clinically significant parathyroid adenomas that remain unseen preoperatively.
Materials and methods
A retrospective cohort study was conducted in order to reveal factors associated with risk of MGD. 810 cases of pHPT patients who had received primary surgical treatment at SPBU Hospital in 2017–2018 were included. All the patients had at least one preoperative visualization study (neck ultrasound performed by a surgeon) before the operation. In 537 cases two studies (additional 4D CT or MIBI scan) were performed and 164 cases had all three studies. A surgeon was free to choose whether perform bilateral neck exploration or not. Data analysis was performed in R.
Results. Number of patients with at least one adenoma that was not localized preoperatively with no less than two studies performed was 46 (26 single adenomas and 20 complementary). In 30 cases BNE was performed resulting in finding an unseen adenoma in 27 cases (90%). US, CT and MIBI sensitivity values were found to be 83.5%, 92.3% and 75.1% respectively. MGD rate accounted for 6.17% (50 cases). 43 cases of persistent disease after surgery were reported, 25 of them were caused by MGD. Negative predictive value of MGD for different combinations of studies with concordant results (US + MIBI, US + CT and US + CT + MIBI) did not differ significantly and was 96.95%, 97.4% and 97.7% respectively. Logistic regression model was performed, showing that independent negative US, negative CT or negative MIBI were not statistically significant in predicting risk of MGD, as well as age and body mass index.
Conclusion. Bilateral neck exploration added to a routine parathyroidectomy is helpful for discovering an unsuspected MGD case.

Serum calcium, magnesium and phosphorus levels in patients with coronavirus disease 2019: an analysis of their relationship with poor outcome and mortality

Juan Jose Diez[1], Pedro Iglesias[1], Agustín García[2], Ignacio Martín Casasempere[3] & Francisco A Bernabéu-Andréu[4]
[1]Hospital Universitario Puerta de Hierro Majadahonda, Department of Endocrinology, Majadahonda, Spain; [2]Hospital Universitario Puerta de Hierro Majadahonda, Department of Admission and Clinical Documentation, Majadahonda, Spain; [3]Consejería de Sanidad de la Comunidad de Madrid, Madrid, Spain; [4]Hospital Universitario Puerta de Hierro Majadahonda, Department of Biochemistry, Majadahonda, Spain.

Purpose
To assess the impact of serum corrected calcium (CorrCa), magnesium (Mg) and phosphorus (P) levels at hospital admission on SARS-CoV-2 infection outcome.
Methods
In this retrospective study, all adult patients with laboratory-confirmed COVID-19 hospitalized in Hospital Universitario Puerta de Hierro Madadahonda during 2020 were included. Demographic, clinical and laboratory data were registered and related to the prognosis of the disease. Poor outcome was considered in patients who presented need for mechanical ventilation, intensive care unit (ICU) admission, or in-hospital mortality.

Results
Of a total of 2,473 patients (956 females) aged (mean ± s.d.) 63.4 ± 15.9 years were studied. Median (IQR) hospitalization time was 7(4–13) days. During admission, 169 patients (6.8%) required mechanical ventilation, 205 (8.3%) were admitted to the ICU, and 270 (10.9%) died. Composite variable of poor outcome, defined as need for mechanical ventilation, ICU admission or death, was present in 434 (17.5%) patients. In univariate analysis, the need for mechanical ventilation was positively to related to Mg levels (OR 8.37, confidence interval [CI] 3.62-19.33; $P < 0.0001$). ICU admission was related to CorrCa (OR 0.49, CI 0.25–0.99) and Mg levels (OR 5.81, CI 2.74–12.35; $P < 0.0001$). In-hospital mortality was related to CorrCa (OR 1.73, 95% CI 1.14–2.64; $P = 0.011$) and the composite variable of poor outcome was only related to Mg (OR 2.68, 95% CI 1.54–4.68; $P = 0.001$). However, in multivariate analysis CorrCa was significantly related to the need for mechanical ventilation (OR 0.19, 95% CI 0.05–0.72; $P = 0.014$) and ICU admission (OR 0.25; 95% CI 0.09–0.66; $P = 0.005$), but not with in-hospital mortality or the composite variable of poor outcome. We found no relationship between poor outcome or mortality and serum levels of Mg or P in the multivariate analysis.
Conclusion
These results suggest that CorrCa can be used as a simple and reliable marker of poor outcome in patients with COVID-19, although not to predict the risk of in-hospital mortality.

Autosomal dominant hypocalcaemia type 1 with intact PTH and relative hypocalciuria.

Razan Ali Rashid[1], Richard Quinton[1] & Ashwin Joshi[2]
[1]Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Endocrinology and Diabetes, Newcastle upon Tyne, UK; [2]Sunderland Royal Hospital, South Tyneside and Sunderland NHS Foundation Trust, Department of Endocrinology Diabetes and Metabolic Medicine, Sunderland, UK.

Autosomal Dominant Hypocalcaemia (ADH) type 1 is caused by activating mutations of the calcium-sensing receptor (CaSR) gene. Although a rare condition, the exact prevalence is uncertain as patients are asymptomatic and, historically, were sometimes diagnosed with hypoparathyroidism (HPT) due insensitivity of earlier PTH assays and failure to check urinary calcium. The consequences of an erroneous diagnosis of HPT in patients with ADH can be profound, as treatment with calcium salts or activated vitamin D characteristically result in more severe hypercalciuria and nephrocalcinosis. A 28-year-old female was referred with hypocalcaemia, extreme tiredness and generalised muscle aches that persisted despite correction of hypovitaminosis D. She had no paresthesia symptoms of tetany or muscle spasms, but suffered from intermittent restless legs at night. There was no history of recurrent urinary tract infections or kidney disease. She had a normal childhood with no significant past medical history. There were no significant medical or genetic conditions in the family, except for type II diabetes. She gave birth to a healthy girl 5 years ago with no complications. She had gastric banding for obesity a year ago and recovered well from the surgery with no complications. She is not on regular medications. On examination, she was clinically euthyroid, with positive Chvostek's but negative Trousseau's signs. Other systems were unremarkable. Height was 1.69 m. Her kidney ultrasound showed no renal calculi. Genetic analysis of the patient identified a heterozygous autosomal dominant CASR variant: c.2497G > T (p.Val833Phe) diagnosing her with Autosomal Dominant Hypocalcaemia Type 1 (ADH). This gene variant has not been identified in the gnomAD population database yet. In conclusion, hypocalcaemia needs to be investigated as we now have better assays to detect low normal PTH levels. Misdiagnosing ADH type 1 with hypocalcaemia or HPT increases the risk of nephrocalcinosis and hypercalciuria in those patients.

Laboratory analysis (Table 1):

Parameter	Results	Normal Range
Corrected calcium level	1.92 mmol/l	2.20–2.60 mmol/l
Magnesium	0.81 mmol/l	0.7–1.20 mmol/l
Phosphate	1.45 mmol/l	0.80–1.50 mmol/l
Alkaline phosphatase	81 u/l	30–130 u/l
Potassium	5.1 mmol/l	3.50–5.30 mmol/l
Creatinine	104 umol/l	45–85 umol/l
Vitamin D	57.6 ng/l	
TSH:	1.00 mIU/l	0.30–4.50 mIU/l
Calcium Fractional Excretion	1.38%	
Urinary Calcium/Creatinine	0.22 mmol/umol	
PTH	4.1 pmol	1.10–6.90 pmol
Tissue transglutaminase antibody	Negative

Quality of life in chronic hypoparathyroidism on conventional treatment

Nikolay Gins[1], Alina Elfimova[2], Elena Kovaleva[2], Anna Eremkina[2] & Natalia Mokrysheva[3]
[1]Endocrinology Research Centre, Department of Epidemiology of Endocrinopathy, Moscow, Russian Federation; [2]Endocrinology Research Centre, Department of Parathyroid Disorders, Moscow, Russian Federation; [3]Endocrinology Research Centre, Director, Moscow, Russian Federation.

Introduction
Reduced health-related quality of life (HRQoL) is common in patients with hypoparathyroidism (HypoPT) treated conventionally with calcium and active vitamin D supplements.
Aim
we studied the HRQoL in patients with chronic HypoPT estimated with the 36-Item Short-Form Health Survey (SF-36) and multidimensional fatigue inventory (MFI-20).
Methods
64 patients with chronic HypoPT (women/men – 57/7, median age 47[36;59] years) participated in the study. The median duration of the disease was 4 years [3;9]. SF-36 is a 36-item QOL questionnaire with response alternative scores 1–6 for each item. A scoring algorithm transforms the raw score to a score from 0 to 100, where a high score indicates better HRQoL. MFI-20 has an even proportion of positively and negatively worded items that are rated on a 5-point Likert scale. Subscale scores are calculated as the sum of item ratings and a total fatigue score – as the sum of subscale scores. Higher scores indicate a higher level of fatigue.
Results
we didn't find any associations between the SF-36 and MFI-20 scores of and serum calcium levels. However, HypoPT patients with magnesium (Mg) level under 0,7 mmol/l had significantly higher SF-36 scores such as PF ($P = 0.0131$); BP ($P = 0.0034$); RE ($P = 0.0376$); PH ($P = 0.0042$). We found a negative correlation between the number of tablets and SF-36 PF score ($P = 0.0133$; $r = -0.31$). Median of tablets' number in patients with Mg < 0.7 mmol/l is 6[5;10] vs median of tablets' number 7[5;10] in patients with Mg ≥ 0.7 mmol/l. But the difference isn't significant. Duration of HypoPT had a positive correlation with SF-36 scores VT($P = 0.0083$; $r = 0.33$), MH($P = 0.2594$; $r = 0.04$) and negative correlations with some MFI-20 scores – general fatigue ($P = 0.015$; $r = -0.31$), reduced activity ($P = 0.0336$; $r = -0.27$) and reduced motivation ($P = 0.0088$; $r = -0.33$). These results may be related to the phenomenon of adaptation to chronic diseases such as HypoPT. In general, the presence of HypoPT complications had a positive correlation with SF-36 scores VT($P = 0.0496$; $r = 0.25$), SF($P = 0.0013$; $r = 0.39$) and negative correlation with reduced activity ($P = 0.0204$; $r = -0.29$). These results also can be explained by better examination and thus better awareness in patients with chronic HypoPT, especially if they already have at least one complication.
Conclusion
further studies with better instruments for assessing HRQoL are required. Patients with HypoPT often can use a lot of medications and should follow the strict rules of their taking, which can significantly affect the HRQoL. Of course, doctors want to improve all mineral disturbances, but therapy should be personalized and clearly discussed with the patients.

25-hydroxyvitamin D, parathyroid hormone and bone turnover markers in patients with addison disease

Dhoha Ben Salah, Khouloud Boujelben[1], Abdelmouhaymen MISSAOUI[1], Mouna Elleuch[1], Mnif Fatma[1], Mouna Mnif[1], Nadia Charfi[1], NABILA REKIK MAJDOUB[1], Faten Haj Kacem Akid[1] & Mohamed Abid
Hedi Chaker Hospital, Department of Endocrinology, Diabetology, Sfax, Tunisia.

Introduction
Patients with Addison disease require lifelong glucocorticoid replacement treatment and it is recommended that glucocortiocoid therapy should be monitored in these patients to avoid over replacement and minimize long-term consequences of bone loss. The present study was carried out with the aim of evaluating bone turnover markers in patients with Addison disease.
Patients and methods
A cross sectional study including 50 patients who are followed for Addison disease, at the department of Endocrinology at Hedi Chaker hospital, sfax-Tunisia. Biochemical markers of bone metabolism (calcium, phosphorus, alkaline phosphatases, vitamin D and parathyroid hormone (PTH)) were measured and the average values were retrospectively analyzed.
Results
There were 40 females and 10 males. The average age of patients was 49,5 ± 13,9 years (18–78 years). The majority (70%) were aged between 40 and 50 years old. Average duration of the disease was 13,9 ± 8,7 years (5–35 years). Approximately 42,5% of females were menopausal. Two-thirds (66%) of patients were not physically active. All patients took no calcium oral supplementation nor oestrogen replacement. Only four patients received Vitamin D oral supplementation. Mean serum levels of calcium and phosphorus were 2,29 ± 0,13 mmol/l (1,9–2,55 mmol/l) and 1,10 ± 0,18 mmol/l (0,8–1,66 mmol/l),respectively. Hypocalcemia was observed in 9 (18%) patients after a mean duration of Addison disease of 11,9 ± 7,1 years (4–26 years) and a mean cumulative hydrocortisone dose of 317,7 ± 211,7 mg (75–702 mg). No significant statistically differences were found between hypocalcemia with regard to age, duration of glucocorticoid replacement or glucocorticoid dose. Mean alkaline phosphatase was 77,2 ± 28,5 IU/l (15–190 IU/l). Patients presenting an increased alkaline phosphatase level (18%) received higher cumulative hydrocortisone dose but without statistical difference (413,4 ± 348 mg versus 365,5 ± 271 mg; $P = 0,7$). Mean vitamin D level was 22,28 ± 14,14 ng/ml (5,6–78,6 ng/ml).Hypovitaminosis D was observed in 33 (66%) patients. Mean PTH level was 51,79 ± 23,84 pg/ml (16,36–139 pg/ml).An elevated PTH level was observed in 10 (20%) patients who had all vitamin D deficiency.
Conclusion
Long-term glucocorticoid replacement therapy in patients with Addison disease is associated with an increased risk of fractures and osteoporosis, which is not only identified by bone mineral density. Other markers as bone turnover markers may be useful. Markers of bone resorption seem to be higher in patients with Addison disease, particularly those who present hypovitaminosis D.

DOI: 10.1530/endoabs.81.EP147

EP148

Pregnancy and lactation induced osteoporosis – a social media based survey

Naama Peltz-sinvani[1,2], Sophia Ish-Shalom[3], Iris Vered[1,2] & Liana Tripto-Shkolnik[1,2]
[1]Sheba Medical Center, Division of Endocrinology, Diabetes and Metabolism, Ramat Gan, Israel; [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv-Yafo, Israel; [3]Elisha Hospital, Haifa, Israel.

Background
Pregnancy and lactation induced osteoporosis (PLO) presenting as spinal fractures in late pregnancy or early postpartum period is a rare condition. The risk factors and pathophysiology are still incompletely understood. The impact of the disorder on the young mother's quality of life can be profound, further aggravated by a delay in diagnosis and treatment that often occurs.
Aim
To delineate clinical parameters related to fractures in a group of women with PLO, and to compare risk factors and osteoporosis-related quality of life with a control group.
Methods
Participants of a social media (WhatsApp) group for women with PLO were offered a questionnaire, including a specific osteoporosis-related quality of life section (MINI OQLQ). Mothers of young children in parent WhatsApp groups were approached to serve as a random control.
Results
Twenty-four patients with PLO and 43 healthy controls (36.9 ± 4.8 vs 38.8 ± 4.3 y.o, $P = 0.11$) were included in the study. Fifty percent of patients suffered from fractures of more than 5 vertebrae, 25% of 4 and 25% had 3 or less vertebrae involved, 85.7% of the fractures were a-traumatic. Nineteen percent of the fractures occurred during pregnancy and others, during early postpartum period. Diagnosis was delayed for more than 16 weeks in 41.8% of women. Bone mineral density test was performed in all participants in the PLO group and 62.5% were treated with teriparatide. A significantly lower proportion of women in the PLO group engaged in physical activity over 2 h/week during pregnancy (37.5 vs. 86.3%, $P < 0.05$) and more PLO patients were treated with low-molecular-weight-heparin during pregnancy, although the difference was of borderline significance ($P = 0.06$). No difference was observed in smoking, periods of amenorrhea, lactation, or family history of fractures between the groups. Seventy-one percent of the PLO patients expressed fear of fractures and 58.3% fear of falls compared to none and 2.3%, respectively ($P < 0.01$) of the controls.
Conclusions
PLO-related spinal fractures involve multiple vertebrae in the majority of the affected women, and the diagnosis is delayed in many. Less physical activity might pose a risk. Most of PLO patients in our cohort were treated with teriparatide. PLO patients reported a significant impairment of quality of life. Multidisciplinary effort should be exerted to early identification and treatment of this severe condition.

EP149

Bone mineral density in patients with addison disease versus congenital adrenal hyperplasia

Mariana Lavrador, Bárbara Filipa Araújo, Ana Carreira, Sandra Paiva, Luísa Barros & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinology, Coimbra, Portugal.

Introduction
The treatment of Primary Adrenal Insufficiency involves the chronic use of glucocorticoids. The balance between the dose needed to supply the cortisol deficit and the possible consequences of overtreatment is a challenge. In patients with Addison disease (AD), androgens deficiency is an additional factor for osteoporosis.
Objective
To evaluate if there are differences in bone mineral density (BMD) in patients with Addison's disease versus congenital adrenal hyperplasia (CAH) – classic form.
Methods
We included patients with a diagnosis of Addison's disease or CAH, with follow-up in a tertiary center. Patient's characteristics and cumulative doses of glucocorticoid (in hydrocortisone converted doses) were recorded and calculated by body surface area (HC/BSA). BMD was evaluated by dual-energy X-ray absorptiometry (DXA), at lumbar spine, femoral neck, and distal radius. Excluded patients with secondary causes of osteoporosis.
Results
27 patients were included: 16 with AD and 11 with CAH. Sex and age distribution were similar between groups. Patients with Addison had a lower BMI (26.34 ± 4.17 vs 31.47 ± 6.4, $P = 0.030$), and shorter disease duration (17,75 ± 12.27 vs 31.63 ± 11.47, $P = 0.007$). Daily doses of HC/BSA were similar between groups (15.91 ± 4.48 for AD vs 11.22 ± 4.17, $P = 0.061$), but cumulative yearly doses of HC/BSA were higher in patients with Addison (5672 ± 1621 vs 3480 ± 1885, $P = 0.027$). Lumbar T-score was significantly inferior in patients with Addison (−2.00 ± 1.20, vs −0.69 ± 0.93, $P = 0.022$), with no differences in femoral or radius T-score between groups. There was a non-significant correlation between lumbar T-score and cumulative yearly doses of HC/BSA ($r = -0.321$, $P = 0.208$).
Conclusion
The significantly difference found in lumbar T-score between AD and CAH my be explained by the higher cumulative yearly dose of HC/BSA of the AD group which is associated to high risk of BMD reduction. Also, the AD group had lower BMI, which is known to be a protective factor against bone mineral loss. Androgen deficiency, typical of Addison disease, is also a reasonable explanation for this discrepancy, since androgens are known to increase bone formation markers.

SuperJump training in eumenorrheic women and gut peptides: a randomized controlled study about the mechanism of action on bone and glucose homeostasis

Alessandra Amato[1], Sonya Vasto[2], Patrizia Proia[1] & Sara Baldassano[2,3]
[1]University of Palermo, Department of Psychology, Educational Science and Human Movement, Palermo, Italy; [2]Università degli Studi di Palermo, Department of Biological, Chemical and Pharmaceutical Sciences and Technologies, Palermo, Italy; [3]Edificio 16 – Aula S1, Department of Biological, Chemical and Pharmaceutical Sciences and Technologies, Palermo, Italy.

The role played by physical activity in promoting bone health is now widely recognized. Physical activity limits and slows down the physiological demineralization that occurs over the years and plays an important role in the prevention of osteoporosis. SuperJump, a high-impact training activity performed on a mini-trampoline characterized by alternating between aerobic and anaerobic exercises, has been shown to be able to generate a substantial osteogenic response and increase bone balance and strength in eumenorrheic women. In this study it was analyzed whether gastrointestinal peptides play a role in the regulation of bone metabolism and their impact on glucose homeostasis.

Methods

Using a randomized controlled study design, participants were assigned either to the intervention group performing SuperJump activity for 20 weeks or to the control group, that did not undertake any intervention. Blood samples were collected at baseline and at the end of the study and compared within and between the groups for markers of bone metabolism (CTX, osteocalcin, PTH, Vitamin D, albumin adjusted calcium) gut peptides (GLP-1, GIP, GLP-2, PYY, ghrelin) markers of glucose metabolism (glucose, insulin, insulin resistance, β-cell function, insulin sensitivity).

Results

After 20 weeks of SuperJump activity, CTX and PTH was reduced, GLP-1 and GIP levels were significantly increased while levels of GLP-2, PYY and ghrelin did not change. Moreover, SuperJump activity significantly reduced fasting insulin, glucose, insulin resistance and increased insulin sensitivity but did not affect beta cell function.

Conclusion

The results of the study show that 20 weeks of SuperJump was highly effective in improving bone and glucose homeostasis in eumenorrheic women and suggests that GLP-1, and GIP are involved in the mechanism of action.

Sex differences of the reaction of undercarboxylated osteocalcin to hypoglycaemia

Hana Pospisilova, Michaela Duškova, Lucie Kolátorová, Hana Jandíková & Luboslav Stárka
Institute of Endocrinology, Prague, Czech Republic.

In recent years, there has been increasing evidence for the hypothesis of bones as endocrine organs. Osteocalcin, long considered just a marker of new bone formation, is now seen as the first hormone produced by bones, and seems to be associated with regulating glucose metabolism and reproduction. The aim of this work was to monitor changes of osteocalcin in reaction to hypoglycaemia, and determine if there are differences in such reactions between the sexes. The study included 61 healthy probands with physiological calciophosphate metabolism (30 men and 31 women). We applied to each of them an insulin tolerance test, and then monitored levels of undercarboxylated osteocalcin and reactions to hypoglycaemia at regular time intervals. We found differences in the reaction to hypoglycaemia between the sexes. In men there was a significant decline in undercarboxylated osteocalcin between the 30 and 40 min ($P < 0.0015$), which reflects a reaction to a glycemic decline between 25 and 30 min, followed by reversal. Low undercarboxylated osteocalcin in men lasted up to 90 min, after which they returned to levels before the test. In women we did not find any significant changes in undercarboxylated osteocalcin levels. Changes in undercarboxylated osteocalcin induced by hypoglycaemia indicate a relationship between bones and glucose metabolism. There was an interesting difference between the sexes. However, a definitive conclusion about the role of osteocalcin in human metabolism will require numerous future studies. Teriparatide for hypoparathyroidism after bariatric surgery

Ettore Maggio[1], Cesare Morgante[2], Vittoria Ramunno[2], Andrea Corsello[2], Gianluca Cera[2], Alfredo Pontecorvi[2] & Salvatore Maria Corsello[2,3]
[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS Università Cattolica del Sacro Cuore, Unit of Endocrinology and Diabetes, Rome, Italy; [1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS Università Cattolica del Sacro Cuore, Unit of Endocrinology and Diabetes, Rome, Italy; [3]Saint Camillus International University of Health Sciences, UniCamillus, Rome, Italy.

Background

Hypoparathyroidism is an endocrine disorder characterized by hypocalcemia due to low levels of parathyroid hormone (PTH). Activated vitamin D (calcitriol) and calcium supplementation may be difficult in patients with malabsorption, as calcium requires an acid environment to dissolve. In this setting, subcutaneous administration of PTH analogues may be effective in reducing the dosage of oral calcium and vitamin D supplementation.

Case report

A 36-year-old woman with a history of sleeve gastrectomy and Single Anastomosis Duodeno-Ileal switch was diagnosed with papillary thyroid carcinoma and referred to total thyroidectomy. After surgery, she presented paresthesia, undetectable PTH, calcium 6.5 mg/dl and TSH was normal, so an oral regimen of calcium carbonate 1 gr tid and calcitriol 0.5 mcg tid was started without resolution. She came several times both to our Endocrinology Unit and to the emergency department due to symptomatic hypocalcemia. Therefore, oral treatment was gradually increased up to calcium carbonate 9 gr and calcitriol 4 mcg per day, and then intravenous calcitriol and calcium gluconate infusion was started. However, this did not allow complete resolution of hypocalcemia and the patient experienced some discomfort mainly due to gastrointestinal symptoms. Symptoms began to worsen after several weeks. At this moment, in Italy, RDNA PTH (1–84) is not refunded by the national health service. For that, after patient's consent, treatment with rhPTH (1–34 – teriparatide) analogue 20 mcg/day was started with no adverse reaction. Soon, we were able to significantly reduce the dosage of calcium carbonate to 2 gr and calcitriol 2.5 mcg/day. After fifty days of this treatment calcium was 8.5 mg/dl. Recently the dose of teriparatide was titrated to 40 mcg/day, with further reduction of oral treatment, and the patient has not had any symptoms related to hypocalcemia.

Conclusion

First-line of treatment in hypoparathyroidism is activated calcitriol and calcium supplementation maintain low-normal calcium levels, to prevent hypocalcemia and avoid hypercalcemia and renal calcification. Gastric bypass or duodenal resection can increase the risk of hypocalcemia, as they cause malabsorption. As alternative options intravenous calcium, calcitriol infusion and rhPTH should be considered to maintain normal calcium levels. Even when the patient is stabilized, episodes of hypocalcemia may occur, so careful monitoring is still required. To date, this is the second reported case of the use of a PTH analogue to treat hypoparathyroidism with good calcium control in a patient who underwent bariatric surgery.

The parathyroid carcinoma manifesting during pregnancy

Daria Sazonova[1], Ekaterina Bibik[2], Anna Gorbacheva[2], Anna Eremkina[2] & Natalia Mokrysheva[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Endocrinology Research Centre, Department of Parathyroid Pathology and Mineral Disorders, Moscow, Russian Federation.

Background

Parathyroid carcinoma (PC) is a rare cause of primary hyperparathyroidism (PHPT) and extremely rare endocrine malignancy during pregnancy. Different maternal and fetal/neonatal complications of PHPT occur in 67 and 80% of untreated cases respectively, probably more due to severe hypercalcemia.The diagnostic and therapeutic approaches are limited in pregnant women and require individual risk-benefit assessment.

Aim

We present a case of PC manifested during pregnancy when delayed treatment led to severe complications.

Clinical case

Young woman suffered from urolithiasis since the age of 19. Moreover, she had a history of multiple low-energy bone fractures of limbs. At the age of 35 lab tests showed high PTH (55,51 pmol/l (NR 1,6–6,9)) and hypercalcemia (total calcium 3,28 mmol/l), US detected a tumor of the left inferior parathyroid gland

33x25x18 mm (PG). So, PHPT was diagnosed at 29 week of gestation. Given severe hypercalcemia and gestational age parathyroidectomy was recommended but the patient refused the surgery as well as cinacalcet therapy. Cesarean section was performed at 38 week of pregnancy without any complications. The woman breastfed for 1,5 years. During this period, the patient had low-energy fractures of left humerus that required osteosynthesis. 2 years after delivery exam showed albumin-adjusted calcium 2.9 mmol/l, PTH 1044 pg/ml (15–65), 24-hours urinary calcium 13.3 mmol. US, CT scan, 99mTc-sestamibi scintigraphy confirmed tumor of the left inferior PG. The patient had bilateral nephrolithiasis, significant BMD reduction (Z-score radius −5.9 S.D.), also osteitis fibrosa cystica and vertebrae fractures (Th8-9,12) were verified. The parathyroidectomy was carried out, PTH and total calcium decreased to 50.1 pg/ml and 2.18 mmol/l respectively on the fifth day after surgery, oral calcium supplementation and alfacalcidol were prescribed. Morphological examination revealed PC, pT1NxM0.

Conclusion

Parathyroidectomy is a preferable treatment for patients with symptomatic PHPT in the second trimester of pregnancy. Severe hypercalcemia accompanied with high PTH and large tumor size are suspicious for PC. Mutation of CDC73 should be examined to assess the prognosis in patients with confirmed PC.

Clinical outcomes of COVID-19 infection in rare bone and mineral disorders

Ana Luisa Priego Zurita[1], Jillian Bryce[2], Maria-Luisa Brandi[3], Simona Glasberg[4], Alberto M Pereira[1], Luca Sangiorgi[5], Camilla Schalin-Jantti[6], Erica van den Akker[7], Faisal Ahmed[1,2,8] & Natasha Appelman-Dijkstra[1]

[1]Leiden University Medical Centre, Department of Medicine, Division of Endocrinology, Leiden, Netherlands; [2]University of Glasgow, Office for rare Conditions, Glasgow, UK; [3]Fondazione Italiana Ricerca Sulle Malattie Dell'Osso (F.I.R.M.O. Foundation), Florence, Italy; [4]Hebrew University, Neuroendocrine Unit, Enets Center of Excellence, Department of Endocrinology and Metabolism, Hadassah Medical Organization and Faculty of Medicine, Jerusalem, Israel; [5]Irccs Istituto Ortopedico Rizzoli, Department of Rare Skeletal Disorders, Bologna, Italy; [6]University of Helsinki and Helsinki University Hospital, Division of Endocrinology, Abdominal Center, Helsinki, Finland; [7]Erasmus Mc – Sophia Children's Hospital, University Medical center Rotterdam,, Division of Pediatric Endocrinology, Department 0f Pediatrics, Rotterdam, Netherlands; [8]University of glasgow, Developmental Endocrinology Research Group, Royal Hospital for Children, Glasgow, UK.

Background

The European Registries for Rare Endocrine Conditions and the European Registries for Rare Bone and Mineral Conditions were created in collaboration with the European Reference Networks for Rare Endocrine and Bone Disorders (Endo-ERN and ERN BOND). Following the onset of the COVID-19 pandemic in 2020, the registries, together with the ESE RD Committee, have collected the occurrence of confirmed and suspected cases of COVID-19 in patients with rare endocrine and bone conditions via the electronic reporting system (e-REC), a tool that does not collect personal identifiable information.

Aim

To collect clinical outcome data of patients with rare bone and mineral disorders affected by COVID-19.

Methods

Between May 2020 and May 2021, 11 cases of COVID-19 in patients with a preexisting mineral condition and 8 in patients with a preexisting bone condition were reported. Reporters were invited to complete a secure online questionnaire. The questionnaire was completed in 15/19 cases (79%) from four centres in three countries. Of 19 cases, 18(95%) were confirmed by a test. Vaccination status was reported only for one case of mineral conditions (1/19), who had received the vaccine.

Results

Of 7 mineral cases, 3 had hypophosphatemia (42%), 3 hypoparathyroidism (42%) and 1 primary hyperparathyroidism (14%). The median age at the time of infection was 39 (range 4,52). Of 7 cases 6 were confirmed by a test (86%). The most prevalent symptoms were fever 5/7 (71%), cough 3/7 (43%), fatigue 3/7 (43%), loss of taste and smell 3/7 (43%), muscle pain 3/7 (43%), runny nose 2/7 (28%), headache 2/7 (28%) and shortness of breath 2/7 (28%). One patient was asymptomatic. Comorbidities were reported in 4/7 (57%): hypertension 2/7 (28%), obesity 1/7 (14%), asthma 1/7 (14%). None required hospital admission and complete remission occurred in all cases. Of 8 bone cases 5 had fibrous dysplasia of bone (62%), 2/8 (25%) had a bone dysplasia with increased bone density and 1/7 (13%) had osteogenesis imperfecta. The median age at the time of the COVID-19 infection was 35 (range 16,69). The most prevalent symptoms were cough 6/8 (75%), fever 4/8 (50%), and shortness of breath 2/8 (25%). Two patients were asymptomatic (25%). Comorbidities were reported in 3/8 (38%): obesity 2/7 (25%) and asthma 1/8 (13%). None required hospital admission and complete remission occurred in 100% of cases.

Conclusion

The results of this survey suggest good clinical outcomes in patients with rare bone and mineral disorders experiencing a COVID-19 infection.

EP155

Prevalence of anemia in patients with primary hyperparathyroidism: a single-center observational study

Anna Gorbacheva, Anastasia Miliutina, Alina Elfimova, Anna Eremkina & Natalia Mokrysheva

Endocrinology Research Center, Moscow, Russian Federation.

Background

The combination of primary hyperparathyroidism (PHPT) with anemia was first described in 1931. It remains unclear whether PHPT is the direct cause of anemia, or it develops as a PHPT's complication. The etiology of anemia in PHPT could be multifactorial, including iron deficiency, renal failure as well as bone marrow fibrosis.

Aim

To assess the prevalence of anemia in patients with PHPT admitted to the Department of Parathyroid Glands Pathology of the Endocrinology Research Centre from January 2017 to August 2020.

Materials and Methods

The study included patients with PHPT over 18 years old. A single-center observational one-stage one-sample uncontrolled study was carried out. We analyzed laboratory and instrumental data obtained during inpatient examination in accordance with the standards of medical care. Statistical analysis was performed using Statistica 13 (StatSoft, USA) and SPSS (IBM, USA) software.

Results

The study included 327 patients with PHPT, 28(9%) men and 299(91%) women. The median age was 59 years [51;66]. 26 patients (8%) with anemia were identified. Significant differences between patients with and without anemia were found only in the GFR. Comparison of patients with and without anemia didn't reveal any significant differences in the incidence of PHPT's complications. Significant differences in serum hemoglobin concentration and average hemoglobin concentration in erythrocytes were revealed between patients with and without vertebrae fractures. In the group of patients without compression fractures these parameters were higher ($p < 0.001$ for both). In the subgroup of patients with total calcium >3 mmol/l and iPTH >3 normal values, the incidence of anemia reached 21% (95% CI: 10%;35%). Within this subgroup we revealed tendencies to higher levels of iPTH, ionized calcium and osteocalcin in patients with anemia.

Conclusion

We did not find any correlations between hypercalcemia, iPTH levels and the presence of anemia in the general group. However, in the subgroup of patients with severe hypercalcemia, there was a relationship between the iPTH, ionized calcium and the incidence of anemia. In patients with PHPT and vertebral fractures, significantly lower concentrations of blood hemoglobin and hemoglobin in erythrocytes were observed.

Late diagnosis of life-threatening hypocalcemia in a patient with hypoparathyroidism after hemithyroidectomy: A case report

Sona Maghakyan[1], Anna Vardanyan[1], Ara Ghazaryan[2] & Elena Aghajanova[3,4]

[1]Yerevan State Medical University, Endocrinology, Yerevan, Armenia; [2]Mikaelyan Institute of Surgery, Medical Director, Yerevan, Armenia; [3]Yerevan State Medical University, Head of YSMU Department of Endocrinology; [4]Muratsan University Hospital, Head of Endocrinology Clinic of "Muratsan" University Hospital Complex, Armenia.

Introduction

Hypocalcemia is defined as a decreased level of calcium in the blood. The presentation of hypocalcemia varies widely, from asymptomatic to life-threatening. The most common cause of chronic hypocalcemia is postsurgical hypoparathyroidism. This may occur after removal of all parathyroid tissue

during thyroidectomy and radical neck dissection for malignancies or after inadvertent interruption of the blood supply to the parathyroid glands during head and neck surgery. Here we report the case of an elderly patient with hypoparathyroidism after hemithyroidectomy who developed clinical manifestations of severe hypocalcemia and her life was saved through a tracheostomy.
Case Presentation
A 72-year-old woman was admitted to Mikaelyan University hospital with shortness of breath. She spoke with difficulty, in syllables. The patient's general condition was extremely heavy and she was admitted in ICU department. She had a history of hemithyroidectomy 30 years ago. The patient had a disorder of consciousness, perioral paresthesia and tingling of the fingers during these years. For this, she was started treatment with calcium 1–3 g/daily, vitamin D3 5000U daily for 10 years and L-thyroxin 25 mcg for 5 years. She had a history of acute respiratory infection 1 month before admission. On admission, examination revealed Ps = 122 bpm, BP = 160/85 mmHg, T = 36.5 °C, SpO_2 95% (15 liter/min O_2+), BMI = 27.5 kg/m^2. Trousseau and Chvostek signs were positive. Electrocardiogram revealed a prolonged QTc interval. The patient received first medical aid with oxygen, dexamethasone, euphyllin. After the results of blood chemistry, which showed low serum corrected calcium level (1.80 mmol/l), calcium gluconate 10% 10 ml IV was added to the treatment. Unfortunately, the patient's condition didn't improved on treatment and she even could not be intubated because of laryngospasm, that's why tracheostomy was performed. Endocrine examinations showed: 25(OH)D-39.66 ng/ml (n 30−70), parathormone-6.54 pg/ml (n 15−65), TSH-0.939 uIU/ml (n 0.3−4.5), FT4-15.07 pg/ml (n 8.9−17.2). She was diagnosed with postoperative hypoparathyroidism. She continued treatment with calcium gluconate, dexamethasone, L-thyroxine and started treatment with calcitriol 0.25 mcg. The patient improved on this treatment; the tracheostomy was removed after 2 weeks. She was discharged in good general health condition and was advised to continue L-thyroxine, calcitriol therapy with the same dose, calcium 1 g/daily and check serum corrected calcium level in 1 week.
Conclusion
This case report showed that severe hypoparathyroidism can develop even after hemithyroidectomy and lead to life-threatening hypocalcemia requiring emergency procedures. Screening programs for patients with thyroidectomy could help to prevent these life-threatening complications.

EP157

Vitamin D and bone metabolism in Graves' disease. A prospective study

Selwan Khamisi[1], Martin Lundquist[2], Annica Rasmusson[3], Britt Eden Engstrom[2], F Anders Karlsson[2] & Östen Ljunggren[2]
[1]Uppsala University Hospital, Uppsala, Sweden, Department of Endocrinology and Diabetes, Uppsala, Sweden; [2]Akademiska Sjukhuset, Sweden; [3]Institutionen för Medicinska Vetenskaper, Sweden.

Objective
Vitamin D and osteoporosis in Graves' disease (GD) have previously been examined in cross-sectional studies with partly divergent results. Here, we prospectively studied vitamin D metabolism and bone health in patients with newly diagnosed GD.
Methods
Thirty consecutive patients with *de novo* overt thyrotoxicosis diagnosed with GD were included. None of the patients at diagnosis were treated with vitamin D supplementation or anti osteoporotic drugs. All patients were initially treated with antithyroid drugs. Blood samplings were performed at baseline and at 6 weeks, 3, 6, 12 and 24 months after treatment start. Serum levels of 25OHD3, 1,25OH2D3, calcium, parathyroid hormone (PTH), and C-terminal telopeptides of Type I collagen (CTX-I) were analyzed. Bone mineral density (BMD) was measured at baseline, and after one and two years after treatment initiation.
Results
At diagnosis patients with GD did not have vitamin D deficiency. There were no significant correlations between levels of 25OHD3 and thyrotoxicosis. Upon treatment of the thyrotoxicosis, serum calcium transiently fell, and PTH and 1,25OH2D3 increased. 25OHD3 fell within the normal range and stabilized at 6 months. CTX-I fell over 12 months, BMD increased significantly up to 2 years, $P = 0.002$, < 0.001 and 0.005 in spine, left total hip and left femoral neck respectively.
Conclusion
The present data underline that thyrotoxicosis negatively impacts bone health and demonstrate fine-tuned dynamics in bone and vitamin D metabolism. Upon treatment, bone health improved over a follow-up period of 24 months despite rising PTH. Increased conversion of 25OHD3 to 1,25OH2D3 occur during treatment of GD.

Milk-alkali syndrome in a patient with chronic hypoparathyroidism

Catarina Cidade-Rodrigues, Catarina Chaves, Filipe Cunha, Mariana Martinho & Margarida Almeida
Centro Hospitalar do Tamega e Sousa, Endocrinology, Penafiel, Portugal.

Introduction
Milk-alkali syndrome is defined by the triad hypercalcemia, metabolic alkalosis and renal impairment, due to intake of calcium salts and absorbable alkali. It is the 3rd leading cause of hypercalcemia but often underdiagnosed. Patients with chronic hypoparathyroidism after total thyroidectomy have increased risk for this potentially life-threatening complication and its epidemiology is unclear. We present a case of milk-alkali syndrome in a patient with chronic hypoparathyroidism.
Case report
Female, 60 years-old. Chronic hypoparathyroidism and hypothyroidism after total thyroidectomy due to non-toxic multinodular goiter 2 years ago. Rheumatoid arthritis, chronic kidney disease and inferior limb deep vein thrombosis. Brown-Sequard syndrome 1 year ago due to cervical spine hematoma and submitted to vertebral laminectomy. Medication: levothyroxine 100 ug, calcitriol 0.25 ug id, calcium carbonate/cholecalciferol 1500 mg/400 UI 2id, acenocoumarol, *methotrexate,* and methylprednisolone 4 mg bid. She presented with nausea, vomiting and polydipsia for 4 days. She was dehydrated, BP 139/74 mmHg, HR 78 bpm, SatO2 99% (room air), temperature 36.4°C. Normal cardiopulmonary auscultation. No signs of acute abdomen and no peripheral oedema. Arterial blood gas analysis: pH 7.49, pCO2 59 mmHg, pO2 79 mmHg, HCO3− 38.6 mmol/l, iCa^{2+} 1.70 mmol/l. ECG: 57 bpm. Venous blood analysis: creatinine 2.5 mg/dl, urea 89 mg/dl, sodium 142 mmol/l, potassium 3.1 mmol/l, corrected total calcium 14.4 mg/dl, magnesium 2.3 mg/dl, phosphate 3.7 mg/dl, PTH <4 pg/ml, 25-hidroxicholecalciferol 5 nmol/l, TSH 0.81 uUI/ml, T4L 1.22 ng/dl, CRP 6 mg/dl, leukocyte count 10690/uL. Kidney ultrasound: non-obstructive bilateral echogenic foci. She was diagnosed with milk-alkali syndrome. Calcium and vitamin D supplements were suspended and started treatment with intravenous isotonic saline and potassium chloride, maintaining a good urine output. Calcium and creatinine levels improved progressively. Calcium carbonate/cholecalciferol 1500 mg/400 UI 2id and calcitriol 0.25 ug one every other day were restarted and she was discharged 4 days after. At the follow-up, she was asymptomatic with a corrected total calcium 8.7 mg/dl, phosphate 4.0 mg/dl and creatinine 1.37 mg/dl.
Discussion
In people exposed to large doses of calcium and alkali, normal kidney function and calcitriol suppression help maintain calcium and acid–base balance. However, once hypercalcemia develops, it perpetuates metabolic alkalosis, which itself decreases renal calcium excretion. Risk factors are older-age, chronic kidney disease, pregnancy and medication. Potential triggers are dehydration, volume depletion, infection, diets rich in pH-basic foods and altered medication dose. Our patient had chronic kidney disease, so when exposed to volume depletion and dehydration secondary to vomiting, she was unable to excrete excessive calcium. Additionally, the inability to decrease calcium absorption, due to exogenous calcitriol, in response to increased serum calcium levels might have aggravated hypercalcemia.

Long term treatment with teriparatide in hypoparathyroidism

Antonio Spada, Daniela Bosco & Assunta Santonati
San Giovanni Addolorata Hospital, Endocrinology, Roma, Italy.

Hypoparathyroidism is, in Italy, an orphan disease because the hormonal replacement therapy is possible only with teriparatide (fragment 1–34 of of human parathyroid hormone). Otherwise the patients use oral calcium and calcitriol. This scheme of therapy obtained correct plasmatic calcium and phosphate levels, correct urinary excretion of calcium and phosphate, adequate quality of life – QoL only in a little percentage of patients. Especially kidney stones, intra-renal calcifications, chronic kidney disease are too frequent during this "conventional" therapy. Recently, Italian Agency of drug approved the use of recombinant human parathyroid hormone (rhPTH) for chronic hypoparathyroidism, but only on payment. Long-term studies on rhPTH(1–84) replacement therapy, up to 6 years, demonstrated prolonged efficacy of this drug, with persistent normal plasmatic and urinary levels of calcium and phosphate, reduced renal complications, high QoL. We have given teriparatide at the started dose of 20 mcg twice, to four hypoparathyroid patients (all women, post-surgical, after an unsuccessful period of "conventional" therapy characterized by frequent accesses in emergency for hypolcalcemic crisis notwithstanding high levels of oral calcium and calcitriol) for six (one patient) or eight years (three patients), monitoring

plasmatic and urinary biochemical levels, renal ultrasounds, femoral and lumbar densitometry, questionnarie for QoL. All patients quickly obtained increased plasmatic calcium levels, despite reduction or interruption of calcium and calcitriol supplementation; no one had hypocalcemic crisis: three of them normalized plasmatic calcium levels and one had to stop teriparatide for hypercalcaemia. One patient had persistent low values of serum calcium (even though higher than in conventional therapy), but without hypocalcemic crisis and a persistent well-being feeling. Plasmatic phosphate levels decreased up to normal, as urinary excretion of calcium and phosphate. No other biochemical parameter was significantly modified. No patient developed urinary complications. No-one is in therapy with bone active drugs for osteoporosis. We also administered, at baseline, at 6 and 24 months and at the end of study, the RAND 36-Item Short Form (SF-36) Health Survey, covering eight domains of physical and mental health, to evaluate their perception of QoL before and during therapy with teriparatide. Data showed a significant improvement in the mean scores of all eight domains, especially during the first two years of therapy. We can conclude that the treatment with teriparatide in post-surgical hypoparathyroidism is effective and safe in improving mental and physical health of patients, also in a prolonged period of therapy.

Clinical evidence for the benefits of burosumab therapy in two adult cases of X-Linked Hypophosphatemia

Elisa Dinoi[1], Laura Pierotti[1], Laura Mazoni[1], Simona Borsari[1], Elena Pardi[1], Filomena Cetani[2] & Claudio Marcocci[1]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University Hospital of Pisa, Endocrine 2 Unit, Pisa, Italy.

X-linked hypophosphatemia (XLH), representing about 80% of hypophosphatemic rickets, is an X-linked dominant disease due to inactivating mutations in the *PHEX* gene (located at Xp22.1) resulting in an excessive secretion of the phosphaturic hormone fibroblast growth factor 23 (FGF23). The effects are renal phosphate wasting and reduced active vitamin D synthesis leading to rickets, osteomalacia, bone deformities, odontomalacia, frequent dental abscesses and disproportionate short stature. Conventional therapy, based on phosphate and/or active vitamin D supplementation, heals the active radiological lesions of rickets and improves statural growth but doesn't prevent the clinical manifestations of the disease and is associated to potential side effects such as nephrolithiasis, nephrocalcinosis and hyperparathyroidism. Since 2018 burosumab, a fully humanized monoclonal antibody against FGF-23, has been authorized for patients affected by XLH on the basis of promising results from different clinical trials in adults and children. However, all studies include severely affected patients and very few data on the effects of burosumab in everyday setting are available. We present the response to one-year treatment with burosumab injected subcutaneously at 1 mg/kg every four weeks in two patients belonging to the same family namely patient 1 (mother, aged 54 years) and patient 2 (son, aged 19 years), with a genetically confirmed diagnosis of XLH, due to a splice site mutation in the PHEX gene. Of note, patient 2 was on conventional therapy with oral phosphate and calcitriol which was suspended one week before the beginning of burosumab. Both patients had bone deformities, such as varus knee and scoliosis. Patient 1 had undergone multiple orthopedic interventions during childhood and suffered from limb stiffness and severe arthralgias with functional limitations. Patient 2 was in general good conditions but developed recurrent dental abscesses. In both patients burosumab led to rapid normalization of phosphate levels and increase of tubular reabsorption of phosphate (TRP) and TmP/GFR. Serum PTH and bone alkaline phosphatase (BAP) levels were not significantly modified during treatment. Burosumab was well-tolerated, with overall adverse events of mild severity, such as transient nausea, diarrhea, skin lesions, muscle cramps and arthralgia. In patient 2, only one episode of dental abscess occurred during burosumab treatment. BPI and WOMAC questionnaires, assessing the severity of pain, stiffness and physical functioning respectively, were administrated at each visits showing a great improvement of scores. In conclusion, in our patients burosumab has been proven to be effective and safe allowing a significant improvement in quality of life.

Hypophosphatemia in patients with primary hyperparathyroidism

Alessandro Amodeo[1], Giorgia Dito[2], Gregorio Guabello[3], Matteo Longhi[3] & Sabrina Corbetta[4]
[1]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Department of of Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [2]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [3]Rheumatology Unit, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy.

Osteoporosis management increased determination of serum calcium (Ca) levels, and detection of hypercalcemia in the set of out patients. Serum phosphate (P) levels are less frequently measured in osteometabolic patients. Primary hyperparathyroidism (PHPT) is the most common cause of hypophosphatemia. However, hypophosphatemia receives poor attention during the PHPT diagnostic work up, and also data in literature are scanty. We retrospectively reviewed the clinical records from 3 different series of PHPT patients: a first surgical series (group 1; all patients underwent successful parathyroidectomy), a second series from a Hospital setting with Emergency Department (group 2), and a third series of out-patients referred for osteoporosis management (group 3). In group 1, serum P levels were measured in 74 [13%; 13 males, 61 females; 58.0 (49.0,67.3) years, median (range IQ)] out 567 surgically confirmed PHPT patients, confirming that it is often neglected. Group 2 included 115 PHPT patients, 22 males, 93 females, aged 65.5 (56.0, 74.0) years. Group 3, included 88 PHPT patients, 13 males, 75 females, aged 66.0 (59.0, 75.0) years. Group 1 patients were younger than those in group 2 ($P=0.003$) and group 3 ($P=0.0005$ by ANOVA). Serum phosphate levels were lower in Group 1 patients [2.4 (2.1, 2.8) mg/dl] with respect to levels in Group 2 [2.7 (2.3, 3.0) mg/dl, $P=0.016$] and group 3 [2.7 (2.4, 3.0) mg/dl, $P=009$ by ANOVA] patients. Considering the whole series of 277 patients, hypophosphatemia (<3.0 mg/dl) was detected in 209 (75%) patients. Serum P levels were lower in males than females. Hypophosphatemia was mild (2.1–3.0 mg/dl) in 171 patients (62%), moderate (2.0–1.1 mg/dl) in 37 (13%), while severe hypophosphatemia (<1.0 mg/dl) was not registered in any patients. As expected, hypophosphatemic PHPT patients showed lower serum total calcium, higher PTH levels, than normophosphatemic patients. Any difference in age, serum creatinine levels, ionized calcium levels, serum 25hydroxyvitamin D (25OHD), 24 h urine calcium excretion corrected for body weight, prevalence of kidney stones, bone mineral density at lumbar and femur sites as well as number of fragility fractures could be detected. Indeed, a positive correlation emerged between serum 25OHD and P levels ($r=0.176$, $P=0.015$ by Spearman correlation). In conclusions, our data supported recently published data on hypophosphatemia in PHPT patients, confirming the relationship with a more severe PHPT phenotype. Determination of serum P levels concomitantly with serum calcium, PTH, 25OHD, and creatinine helps clinicians in the diagnosis of PHPT and in estimation of its severity.

Primary hyperparathyroidism: what is the impact on bone ?

Lamiae Zarraa, Soumiya Berrabeh, Yousra Laalaoua, Siham ROUF & Hanane Latrech
Endocrinology-Diabetology and Nutrition Department Chu Mohamed VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Oujda, Morocco.

Key words: Primary hyperparathyroidism-PTH level –osteoporosis-osteolytic bone lesions-brown tumor

Introduction

Primary hyperparathyroidism is a frequent pathology responsible for an alteration of the phosphocalcic metabolism at the origin of numerous complications, in particular osseous. The objective of this work is to evaluate the bone impact of primary hyperparathyroidism in our series.

Matériel et méthodes

Retrospective descriptive and analytical study, including 44 patients followed for primary hyperparathyroidism over a period spanning 6 years from 2015 to 2021. Data were collected from medical records and analyzed by SPSS-V21 software.

Material and methods

The mean age was 55 ± 11 years, with a clear female predominance with a sex ratio M/F = 0.29 which 80% of the women were menopausal. Eighty-one percent of the cases had hypercalcemia with 36% of the cases presenting with malignant hypercalcemia.The assessment of the bone consequences of primary hyperparathyroidism showed osteoporosis in 58.6% of the cases with osteopenia in 24%. A pathological fracture revealed primary hyperparathyroidism in one case or in

2.3% of cases. The bone CT scan showed osteolytic bone lesions in 51.5% of the cases, the most of them were diffuse, brown tumors in 18.2% of the cases, most often of multiple locations, affecting the maxillomandibular region, pelvis (iliac bone and ischium), scapula and femoral neck respectively. Primary hyperpathyroidism was complicated by fibrocystic osteitis in one case, i.e. 2.3% of our series. Vitamin D deficiency was noted in all patients, with a deficiency in 61.4% of cases. six point eight percent of cases in our series ($n=3$) were complicated by Hungry bone syndrome and 3 cases (6.8%) by definitive hypoparathyroidism. The relationship between the level of bio-intact PTH 1–84 and the occurrence of bone complications found: a statically significant association with the occurrence of brown tumor and osteolytic bone lesions and with Hungry bone syndrome, while no statically significant correlation with osteoporosis and bio-intact PTH 1–84 level.
Discussion–conclusion
Although primary hyperparathyroidism is a benign endocrinopathy, it remains a serious condition because of its complications, particularly bone complications, as shown by the results of our work in our series, which is in agreement with the literature. Early and adequate management can improve the prognosis of its complications.

The clinical presentation of primary hyperparathyroidism during the Covid-19 pandemic

Elena Castellano, Giorgio Borretta, Micaela Pellegrino, Francesco Tassone, Andrea Craparo, Claudia Baffoni & Laura Gianotti
Santa Croce and Carle Hospital, Department of Endocrinology, Diabetes and Metabolism, Cuneo, Italy.

Background
In the last decades, the clinical profile of PHPT in Western Countries has changed from a highly symptomatic to a largely asymptomatic disease. However, a substantial stability in its clinical features has been reported in the last two decades. The usual management, including time to diagnosis and treatment, of PHPT during the Covid-19 pandemic has been changed and likely slowed down. Whether further changes in the clinical presentation of PHPT have occurred during the Covid-19 pandemic is currently unknown.
Patients
A retrospective survey was conducted in our series of 150 well-characterized consecutive PHPT patients, who were admitted to our Hospital between January 2012 and December 2021. Patients were initially subdivided according to the date of PHPT diagnosis in 2 consecutive 5-year period ($n=79$ and 71, respectively). The more recent group was then split into 2 subgroups before and after the Covid-19 Pandemic (i.e. 2017–2019, $n=45$; 2020–2021, $n=26$).
Results
In the last five-year period an increased rate of post menopausal women ($P=0.011$) and of patients with osteoporosis at any site ($P=0.007$) was found among PHPT patients compared to those in the previous five-year period. Furthermore a non significant reduction of "mild asymptomatic" patients was observed. After subdividing the last five-year period based on the pandemic, the increased rate of post menopausal women was confirmed in the Covid-19 period compared to the remaining ones ($P=0.022$). In addition, the number of criteria for surgery met by asymptomatic PHPT patients has become statistically higher in the pandemic period than in preceding periods ($P=0.017$).
Conclusions
During the Covid-19 pandemic, when surgery for benign diseases and hospital visits have been restricted, only minor changes in the PHPT clinical presentation have occurred. An increased rate of postmenopausal women with osteoporosis was diagnosed with PHPT.

Reduced bone mineral density in primary adrenal insufficiency: consequences of long-term treatment

Bárbara Filipa Araújo, Mariana Lavrador, Cátia Araújo, Mafalda Ferreira, Luisa Barros, Sandra Paiva & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Portugal.

Introduction
The effects of long-term replacement therapy of primary adrenal insufficiency (PAI) are still a matter of debate. Glucocorticoid (GC) replacement regimens do not completely mimic the endogenous hormonal production and their monitoring is sometimes difficult. Therefore, some patients are exposed to mild GC excess with potential complications, such as hypertension, diabetes, and skeletal fragility. Data on bone mineral density (BMD) in PAI is still scarce and controversial.
Objective
To evaluate the impact of long-term GC treatment on BMD, in patients with PAI.
Methods
We conducted a retrospective cohort study of patients with a diagnosis of PAI, followed-up between 2011 and 2021. Patients with other causes of osteoporosis were excluded. BMD was evaluated by dual-energy X-ray absorptiometry (DXA). Doses of the various glucocorticoids were converted to hydrocortisone (HC) equivalents. We calculated cumulative doses of HC (annual and lifetime), divided by corresponding body area (mg/m2), until the date of DXA.
Results
47 patients with PAI were included, 29 with autoimmune origin (63%), 11 with congenital adrenal hyperplasia (CAH) (23.9%), 4 from tuberculosis (8.7%), 1 from x-ALD and 1 from spontaneous bilateral bleeding (2.2%). Mean age 51.3 ± 14.3 years, 57.5% females, disease duration 24.6 ± 15.5 years. Mean daily HC dose was 16.6 ± 4.3 mg/m^2 and mean cumulative lifetime dose was 154 ± 139 g/m^2. 43 patients were under mineralocorticoid (91.5%). Osteoporosis was present in 35.7% of patients. There was an inverse correlation between cumulative lifetime GC dose and lumbar ($r=-0{,}435$, $P=0{,}030$) or femoral T-scores ($r=-0.437$, $P=0.030$); and between cumulative annual dose and lumbar T-score ($r=-0.458$, $P=0.025$). Patients with osteoporosis (any T-score ≤ -2.5) had a higher cumulative lifetime HC dose ($P=0.027$), and a logistic regression model revealed that this association was independent of sex, PAI etiology, and treatment with mineralocorticoids ($P=0.048$). There was no association between T-score and type of GC replacement. There was a correlation between lumbar T-score and age ($r=-0.460$, $P=0.016$), but there was no relationship between BMD and disease duration.
Conclusion
In this study, there was an inverse linear relationship between glucocorticoid cumulative dose and bone mineral density at lumbar spine, which is in line with the known preferential action of GC on trabecular bone. Mild GC excess for some periods of life may have a greater impact in BMD reduction than disease duration. Our results reinforce the need for close monitoring of GC replacement therapy in patients with PAI.

Endocrinopaties in thalassemia patients

ÖZGE ÖZER[1], Goknur Yorulmaz[1], Müfide Okay Ozgeyik[2], Hava Usküdar Teke[3] & Eren Gunduz[3,3]
[1]Eskisehir Osmangazi University, Department of Endocrinology and Metabolism, Esogu, Turkey; [2]Eskisehir City Hospital, Department of Hematology, Eskisehir, Turkey; [3]Eskisehir Osmangazi University, Department of Hematology, Eskisehir, Turkey.

Objectives
Disorders concerning the endocrine system may be seen in patients with transfusion-dependent thalassemia major.It is thought that iron accumulated in the organs,especially with transfusion,causes this.In our study,we tried to reveal a relationship by comparing the iron parameters of these patients with various endocrine parameters.
Methods
Our study is a retrospective study.The data of 18 thalassemia major patients who applied to Osmangazi University Endocrinology and Hematology departments were collected from medical records.Parametres are sex,age,iron parameters,H-ba1c,fasting glucose,fructosamine,lipid profile,thyroid function tests, anterior pituitary hormone panel, parathormone (PTH), 25-OH vitamin D level.
Results
18 patients with thalassemia major were analyzed. 8(44.4%) were male and 10 (55.6%)were female.The mean age was 36.94 ± 10.86 years and the age range was between 20 and 54 years. All of the patients received blood transfusion once a month and were followed up with iron chelation therapy. The fructosamine levels of 6 patients were also above the normal value. GH and IGF-1 levels of the patients were in the normal range. The 25 OH vitamin D level of 11 patients was below 30 ng/ml. Osteoporosis was detected in 9 patients. Seven of these patients (7/9) were evaluated as secondary osteoporosis. Endocrine parameters of the patients were compared with iron parameters. There was a positive relationship between transferrin saturation and 25-OH vitamin D,a negative relationship between iron and PTH, and a negative relationship between ferritin and FSH,LH. Thyroid function tests were normal in 9 patients (50%), primary hypothyroidism was found in 8 patients (44.4%), and hyperthyroidism with graves diagnosis was

detected in 1 patient. There was no thyromegaly in thyroid USG. Autoimmunity was only present in the patient diagnosed with graves.
Conclusions
Evaluation of endocrinopathies in thalassemia patients should be done regularly to detect and treat endocrine complications. It may be appropriate to screen these patients at least once a year in this respect. The role of pituitary hormones in the routine follow-up of thalassemia patients is still controversial. Larger prospective studies are needed. Collaborative multicenter studies should be considered to reach more precise information.
Keywords
Thalassemia, endocrinopathy, ferritin, iron, transfusion

Classical complications of primary hyperparathyroidism

Lamiae Zarraa, Yousra Laalaoua, Soumiya Berrabeh, Siham ROUF & Hanane Latrech
Endocrinology-Diabetology and Nutrition Department CHU MOHAMED VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Oujda, Morocco.

Key words
Primary hyperparathyroidsm-Bone complications-Renal complications and digestive complications.
Introduction
Primary hyperparathyroidism is a frequent endocrinopathy whose diagnosis is biological and linked to an inappropriate secretion of parathyroid hormone (PTH), wich leads to an altered phosphocalcic metabolism that can be responsible for numerous complications. The aim of this work is to evaluate the classical complications of primary hyperparathyroidism in our series: bone, digestive and renal.
Material and methods
Retrospective descriptive and analytical study including 44 patients followed for primary hyperparathyroidism between 2015 and 2021. Only classical complications (bone, kidney and digestive) were noticed in this work. Data were collected from medical records and analyzed by SPSS-V21 software.
Results
The mean age was 55 ± 11 years, with a clear predominance of women in 77.3% of whom 80% were postmenopausal. 81% of the cases had hypercalcemia, including 36% with malignant hypercalcemia ($n=13$). The diagnosis of primary hyperparathyroidism was revealed by complications in 25% of cases ($n=11$).The impact assessementof hyperparathyroidism showed a remarkable effect on the skeletal system with osteoporosis in 60.7% of the cases, osteolytic bone lesions in 18% ($n=8$), the majority of which were of diffuse localization, and brown tumors in 13.6% of the cases ($n=6$), Fibrocystic osteitis was observed in 2 cases (4.5% of our series) and a pathological fracture in one patient. On the renal level, renal lithiasis complicating primary hyperparathyroidism in 31.8% ($n=14$) which 78.5% of the cases were bilateral ($n=11$) and complicated by nephrocalcinosis in 2 cases or 5.7%. Alteration of renal function was noted in 11.6% ($n=5$ and GFR: 30–60 ml/min). The digestive complications were mainly represented by acute pancreatitis in 3 patients (6.8%) and chronic calcifying pancreatitis in one case. On postoperative, Hungry bone syndrome complicated 6.81% of the cases or 3 cases in our series. On postoperative, Hungry bone syndrome complicated 6.81% of the cases or 3 cases in our series. The relationship between the bio-intact PTH 1–84 level and the occurrence of complications finds: a statically significant association with the occurrence of brown tumor as well as a statically significant correlation with osteolytic bone lesions, while no significant correlation with the occurrence of renal lithiasis, osteoporosis and pancreatitis and PTH level.
Discussion–Conclusion
Primary hyperparathyroidism is an endocrinopathy that is usually benign but remains a serious condition because of its bone, kidney and digestive complications.

Hypercalcemia in sarcoidosis unmasked by treatment with Vitamin D

Helmine Kejem[1], Scott Williams[1,2,2], Emmanuel George[1], Yee Ho Chiu[1] & Upendram Srinivas Shankar[1]
[1]Wirral University Teaching Hospital, St Helens, UK; [2]Wirral University Teaching Hospital NHS Foundation Trust (WUTH), Birkenhead, UK.

We present the case history of a 62 year old male, who was recently diagnosed with sarcoidosis which was confirmed on biopsy of a calf nodule. CT scan revealed pulmonary involvement. Our patient had low vitamin D 12 nmol/l (nr 50–100) and initial adjusted calcium was 2.48 mmol/l (2.13–2.63). DEXA bone density scan revealed osteopenia. He was commenced on loading dose of colecalciferol 40,000 units weekly and received 3 doses. He presented 1 month later with polydipsia, polyuria, bone pains and lethargy. Adjusted calcium went up to 3.69 mmol/l and PTH was low at 0.39 pmol/l (1.1–6.0). At this point vitamin D was 94 nmol/l (50–100) and serum creatinine 156 umol/l (59–104) with baseline creatinine being normal at 76 umol/l. Adjusted calcium remained elevated at 3.5 mmol/l, despite treatment with intravenous pamidronate 60 mg. Our patient received oral prednisolone 40 mg/day and is currently on a tapering dose of prednisolone. The adjusted calcium normalised to 2.35 mmol/l in 15 days.
Discussion
Our case history highlights the importance of replacing vitamin D in patients with sarcoidosis with caution. Alveolar macrophages produces 1-alpha hydroxylase which converts 25-hydroxyvitamin D3 to 1, 25-dihydroxyvitamin D3. Vitamin D replacement results in avidly available, 25-hydroxyvitamin D3 to the macrophages in sarcoid granulomata, leading to excess production of 1,25 dihydroxy vitamin D3, which causes intestinal absorption of calcium and bone resorption leading to raised calcium levels. Another point our case history highlights is the role of corticosteroids in the treatment of hypercalcaemia due to sarcoidosis. Corticosteroids reduce gastrointestinal calcium absorption and inhibit osteoclast function, and are particularly effective in sarcoidosis because of their effects on vitamin D metabolism, as they are potent inhibitors of macrophage 1-alpha hydroxylase.

Introduction
Familial hypocalciuric hypercalcemia (FHH) is a rare mostly asymptomatic genetic disorder affecting the calcium sensing receptor (CaSR) and its associated proteins with autosomal dominant inheritance. Mutation in AP2S1 gene is responsible for FHH3.
Aim
Expand the phenotype of FHH type 3.
Methods
Clinical and biochemical characterization of a patient with *de-novo* FHH3 mutation.
Results
S.Z, A 30-year-old man was hospitalized for recurrent pancreatitis. His medical history included chronic hypercalcemia in the range of 11.7–13.3 mg/dl attributed to his prior clinical diagnosis of FHH. Abdominal imaging and lipid profile were unremarkable. The working diagnosis was of hypercalcemia-related acute pancreatitis. He was treated conservatively with resolution of symptoms and normalization of serum amylase and lipase. A multi-gene panel that was performed (INVITAE) revealed a heterozygous mutation in the *AP2S1* gene-p.Arg15Leu. His parents and two siblings were normocalcemic. A second genetic panel for pancreatitis related genes was negative. DXA bone mineral density revealed Z score of -2.3 at LS and -2.9 at FN and TH – a typical finding in FHH3 patients. Cinacalcet at a dose of 120 mg daily was well tolerated and normalized calcium levels with no episodes of pancreatitis within 26 months of follow-up. His three-year-old son is followed for speech delay and was found to be hypercalcemic; he carries the same AP2S1 mutation.

Conclusions
We describe a family with a de novo mutation in the AP2S1 gene presenting with recurrent pancreatitis, low bone mass and speech delay thus expanding the phenotype of FHH3.

Vitamin D levels in relationship to thrombotic markers in severe Sars-CoV-2 infection

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Sofia Nikolakopoulou[3], Alexandra Konstantinou[3], Olga Mascha[4], Charilaos Samaras[3] & Panagiotis Athanassiou[5]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [3]Asclepeion Hospital, Voula, Covid-19 Department, Athens, Greece; [4]Asclepeion Hospital, Voula, Department of Biochemistry, Athens, Greece; [5]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece.

Introduction
Severe infection from the SARS-CoV-2 virus is associated with various manifestations, including hematological manifestations. Thrombotic events or a tendency to develop thrombotic events also characterize severe COVID-19 disease and may be related to fatalities. Vitamin D is known to have immunomodulating properties and to enhance the body defense system against invading pathogens and to have immunostimulatory properties as far as the innate immune response is concerned.
Aim
The aim of the study was to measure $25(OH)D_3$ levels in patients hospitalized for severe COVID-19 infection and to investigate the relationship between $25(OH)D_3$ levels and ferritin levels and d-dimer levels in this cohort.
Methods. In a cohort of 42 patients hospitalized for severe infection from the SARS-CoV-2 virus 25(OH)D3 levels were measured. In the same cohort ferritin levels and d-dimer levels were also measured. Observations were also performed in a control group.
Results
$25(OH)D_3$ levels were 8.08 ± 1.48 ng/ml (mean $\pm$ S.E.M.) and they were inversely related to ferritin levels, correlation coefficient -0.15, $P=0.001$, linear regression analysis and to d-dimer levels, correlation coefficient -0.34, $P<0.001$, linear regression analysis.
Conclusions
Severe infection from the SARS-CoV-2 virus is related to a tendency for the development of thrombotic events. D-dimer levels are measured and followed in these patients. Ferritin levels are also increased in severe SARS-CoV-2 infection and may be related to adverse outcome. We showed that vitamin D levels are low in hospitalized patients with severe SARS-CoV-2 infection and are inversely related to ferritin and d-dimer levels. It may thus be proposed that vitamin D is an inverse index of severity in the context of SARS-CoV-2 infection.

DOI: 10.1530/endoabs.81.EP170

EP171

A sporadic case of pseudohypoparathyroidism type Ib and fahr's syndrome

Cátia Araújo, Mafalda Martins Ferreira, Bárbara Filipa Araújo, Mariana Lavrador, Carla Baptista, Margarida Bastos & Isabel Paiva
Centro Hospitalar Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal.

Introduction
Pseudohypoparathyroidism is a heterogeneous disease characterized by hypocalcemia, hyperphosphatemia and parathyroid hormone resistance. The distinct pseudohypoparathyroidism types are distinguished by physical features, the coexistence of other hormone resistances and genetic defects. Pseudohypoparathyroidism type Ib is more often associated with sporadic cases, unlike others types.
Clinical Case
Male, born in France, diagnosed with pseudohypoparathyroidism during childhood. There was a history of fatigue, gait disorder and delayed eruption of teeth. Laboratory investigation revealed serum hypocalcemia, hyperphosphatemia and elevated serum PTH levels. No family history of phosphocalcium metabolism disorder. He was treated with oral calcium and cholecalciferol. At the age of 9, he starts living in Portugal. Physical examination showed no features of Albright Hereditary Osteodystrophy. Laboratory results showed normal thyroid function and no evidence of other hormone resistances. He started treatment with calcitriol also in addition to oral calcium and cholecalciferol. Over the years, the goal to an adequate calcium-phosphate level was difficult to obtain in this patient due to poor treatment adherence. At 34 years old, urinary calculi was detected on renal ultrasonography. 7 years later, head computerized tomography revealed extensive calcifications at the level of the cerebellar hemispheres, lenticular nuclei, corona radiata, centra semiovale and subcortical level, suggestive of Fahr's syndrome. He was referred to a geneticist and the molecular genetic result revealed a GNAS gene methylation defect specifically in 20q13.32 region performed by MS-MLPA analysis. STX16 deletion was not detectable. This result confirms the diagnosis of pseudohypoparathyroidism type Ib caused by a paternal uniparental disomy of the long arm of chromosome 20.
Conclusions
The molecular investigation is not essential for the therapeutic approach. In this patient, the identification of a methylation defect in a region of *GNAS* gene was useful for the classification of pseudohypoparathyroidism and allowed us to evaluate this case as a sporadic event, therefore without specific risk for the patient's offspring. The present case also serves to emphasize the importance of treatment adherence that may prevent acute and chronic complications of hypocalcemia.

DOI: 10.1530/endoabs.81.EP171

EP172

Acute hypercalcemic crisis in an elderly with granulomatous disease

Leo Tiu Jr & Maria Leonora Capellan
Makati Medical Center, Section of Endocrinology, Diabetes and Metabolism, Makati City, Philippines.

Background
Tuberculosis rarely leads to clinically significant hypercalcemia. However, elderly patients remain predisposed due to advanced age, multiple comorbidities and polypharmacy.
Clinical Case
An 81-year-old female presented with 1 month history of bilateral weak hand grip and sluggish mastication. She was initially managed as progressive Parkinson's Disease. After 3 weeks, she was now reported to have episodes of fall from imbalance. After few days, there was noted increased sleeping time, decreased verbal output, response lag and slurred speech. There were no pulmonary symptoms or febrile episodes. Her medical history includes hypertension, Diabetes Mellitus, previous CVD infarct, Chronic Kidney Disease, recovered Moderate COVID-19 infection and pulmonary tuberculosis that was diagnosed 30 years ago. Outpatient evaluation revealed severe hypercalcemia (15.36 mg/dl). Upon admission, Calcium (500 mg/day) and Vitamin D (1500 IU/day) supplements were discontinued. She was started on vigorous intravenous hydration and diuresis with Furosemide. Calcitonin nasal spray was administered for 2 days. Cranial CT scan showed absence of acute infarction or intracranial hemorrhage. On the 3rd hospital stay, serum calcium was still elevated (11.99 mg/dl) but decreased from baseline. Other blood tests results showed elevated 25(OH)D 119.72 ng/ml (>30 ng/ml), normal PTH 15.84 pg/dl ($<$ 67.90 pg/dl), magnesium 2.41 mg/dl (1.6–2.6 mg/dl) and phosphorous 3.6 mg/dl (2.29–4.79 mg/dl). Hence, PTH-independent causes were evaluated with high suspicion of Vitamin D intoxication. Chest imaging showed a thick walled cavitary mass with adjacent consolidation and surrounding centrilobular nodule in a tree-in-bud configuration in the right upper lobe suggestive of an infectious process. On the 10th hospital stay, CT guided biopsy of the right upper lung mass was done. Histopathology showed lung tissues with fibrosis, focal necrosis, and chronic inflammation. MTB GeneXpert was positive consistent with Tuberculosis for which she was started on Anti-Koch's medications to be completed for 6 months. An elevated Serum $1,25(OH)_2D$ could have supported extrarenal 1α hydroxylation in granulomatous disease but was not readily available. On the 12th hospital stay, due to persistent hypercalcemia (11.72 mg/dl), she was started on Prednisone 10 mg/day which was up titrated to 20 mg/day after 3 days of initiation then down titrated weekly. She was discharged in a stable condition. Normocalcemia was documented upon follow up with subsequent improvement in the patient's sensorium.
Conclusion
Granulomatous disorders as the etiology of hypercalcemia should be suspected in the setting of hypervitaminosis D and low-normal or low parathyroid hormone level. Hypercalcemic crisis is an infrequent endocrine emergency that portends excellent outcomes with prompt diagnosis and management.

Palovarotene for the treatment of fibrodysplasia ossificans progressiva: methodology of the phase III open-label PIVOINE rollover trial

Alexander Artyomenko[1], Aude Houchard[2] & Azzeddine Zemam[2]
[1]Ipsen, Slough, UK; [2]Ipsen, Boulogne-Billancourt, France.

Objectives
Fibrodysplasia ossificans progressiva (FOP) is an ultra-rare genetic disorder characterized by heterotopic ossification (HO) and progressive restriction of mobility. To date, no approved disease-modifying treatments for FOP exist, but interim phase III trial (NCT03312634) results suggest marked efficacy for palovarotene (PVO).[1] Here, we describe methodology of the PIVOINE trial (NCT05027802) designed to allow treatment continuity and further evaluation of PVO safety and efficacy.
Methods
Patients will receive 5 mg PVO daily, or the parent study completion dose, for a maximum of 3 years; during flare-ups, patients will receive 20 mg daily for 4 weeks, then 10 mg daily for 8 weeks. Enrollment criteria: completion of a parent study (end of study/treatment visit of NCT03312634 or NCT02279095/NCT02979769), ≥14 years old, full skeletal maturity if aged <18 years or deemed to be final adult height. PIVOINE aims to enroll 61 patients; recruitment has not begun. Outcomes are presented in Table.
Summary
Results from PIVOINE, estimated to end in November 2024, will allow further evaluation of PVO in FOP.

McCune Albright syndrome – a clinician's challenge and a multi-disciplinary approach: case report

Mădălina Elena Iftimie[1], Iulia Florentina Burcea[1,2], Mihnea-Nicolae Moise[3], Rareş-Ştefan Deculescu[3], Larisa Budulucă[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania; [3]Elias University Emergency Hospital, Bucureşti, Romania.

Introduction
McCune-Albright syndrome is a rare, heterogenous disorder, consisting of at least two of the following three features: polyostotic fibrous dysplasia, café-au-lait skin pigmentation and autonomous endocrine hyperfunction. We present the case of a patient with an atypical presentation of McCune Albright syndrome (MAS) and severe fibrous dysplasia lesions.
Case report:
An 18-year-old girl diagnosed with MAS (at the age of four) was referred to our clinic for a first endocrine evaluation. She had a history of allergodermia and recurrent wheezing from an early age (8 months and 1.8 years respectively), with the subsequent development of a limp (2.5 years old). She had attained menarche at 3.3 years of age (currently having normal spontaneous menses) and had multiple pathologic fractures during childhood, the first being a proximal femoral shaft fracture (4 years old), for which she underwent 2 surgeries, resulting in shortening of the left leg. Prior X-ray imaging and CT scans showed left coxa vara, tibial bowing, cortical thinning, and multiple sclerotic and lytic lesions suggesting polyostotic fibrous dysplasia (confirmed by left femur biopsy). On physical examination, she had hyperpigmented macules with irregular margins, leg length discrepancy, macrocephaly with clover shaped skull and facial asymmetry. Her height was 165 cm, within her target height range (172.5+/−10 cm). Laboratory data revealed normal calcium, phosphorus and parathyroid hormone levels, vitamin D deficiency, very high alkaline phosphatase levels (15.6×upper limit of normal, ULN) and elevated bone turnover markers. Insulin-like growth factor 1 was within the normal range, but she had unsuppressed growth hormone (GH) levels following 75 g oral glucose load (nadir GH 1.72 ng/ml) and elevated random GH (10.56 ng/ml). Prolactin levels were slightly elevated (1.29×ULN). Pituitary imaging found a sellar mass of 5/7/6.7 mm. Thyroid ultrasonography showed several micronodules, with normal thyroid function. No other endocrinopathies were found. Antiresorptive agents such as bisphosphonates (pamidronate) or anti-RANKL antibody (denosumab) are taken into consideration as therapeutic options.
Conclusion
Diagnosis of MAS is usually established on clinical grounds, but the presenting signs and symptoms are highly variable. Although GH and prolactin excess are common (21%)[1], the clinical expression can be 'whispering', as in our case. As all MAS features have a varied time of presentation, early referral to an endocrinologist and meticulous follow-up and management is essential.

Differences between atypical parathyroid adenomas and parathyroid adenomas in patients with primary hyperparathyroidism

Ensar Aydemir, Coskun Ates, Yasemin Aydoğan Ünsal, Erhan Hocaoglu, Filiz Mercan Saridas, Soner Cander, Ozen OZ GUL, Canan Ersoy & Erdinc Erturk
Uludag University Medical School, Bursa, Turkey.

Background
Atypical parathyroid adenoma (APA) is a rare disease that can be challenging to distinguish from benign parathyroid adenoma. APA shows some laboratory and histopathological features with parathyroid cancer. This study attempts to compare clinical, laboratory, radiologic and histopathological characteristics in APA and parathyroid adenoma (PA).
Methods
This was a retrospective study was based on the database of eighty-two subjects who underwent surgery for primary hyperparathyroidism at a tertiary referral center between 2010 and 2021. Forty-one patients with APA matched by age and gender to controls with PA. Clinical, laboratory, radiologic and characteristics were obtained from the hospital database.
Results
Forty-five (54.8%) of primary hyperparathyroidism (PHPT) patients were symptomatic, 36 (90%) had nephrolithiasis, 6 (15%) had fracture and 3 (7.5%) had hypercalcaemic crisis. APA patients present with significantly inceased serum calcium, parathormone (PTH) and alkalen phosphatase levels ($P<.001$, all). No significant difference was observed in the results of bone mineral density (BMD), T-scores and Z-scores. The size of adenoma was significantly greater in APA group (24 (8.8–70) mm vs. 12 (3.8–32) mm, $P=0.005$).
Conclusion
Our study revealed that increased preoperative serum calcium, parathormone, alkalen phosphatase concentrations and parathyroid adenoma size on ultrasound may have predicted the atypical parathyroid adenoma.

PTH 1–34 delivery via insulin pump in a patient with severe post-operative hypoparathyroidism

Elisa Dinoi[1], Laura Mazoni[1], Laura Pierotti[1], Matteo Apicella[1], Claudio Marcocci[1] & Filomena Cetani[2]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Endocrine 2 Unit, Pisa, Italy.

Hypoparathyroidism (HypoPT) is the only hormone deficiency syndrome whose standard treatment is not based on the replacement of the missing hormone. Although most cases of postsurgical HypoPT can be effectively managed with the conventional use of oral calcium and active vitamin D (SOC therapy), some patients require very high doses and develop complications such as hypercalciuria, renal stones, nephrocalcinosis and ectopic calcifications. In the last few years, recombinant human PTH (rhPTH) has become an appealing option for patients affected by chronic HypoPT who are refractory to SOC therapy. Winer et al have adapted an insulin pump delivery system to treat patients with a continuous infusion of rhPTH (1–34) (teriparatide). We describe the case of a 33-years old woman who was referred to our Clinic for severe chronic HypoPT after total thyroidectomy for multinodular goiter. Despite being on therapy with high doses of oral calcium and active vitamin D, she reported muscle spasms, cramps and perioral paresthesia on a daily basis and was frequently admitted to the Emergency Room to be treated with intravenous calcium infusion. At our evaluation, we confirmed a severe hypocalcemia (7.5 mg/dl), hyperphoshatemia (5.2 mg/dl) and hypercalciuria (388 mg/24 h). The abdomen ultrasound showed the presence of medullary nephrocalcinosis and right microlithiasis. After using teriparatide 20 mcg twice-daily injection without success, we decided to treat the patient with a continuous subcutaneous perfusion of rhPTH (1–34) by using an insulin pump. rhPTH (1–34) (Terrosa®, 20 μg/80 μL) was diluted with distilled water and the patient start continuous administration of subcutaneous rhPTH (1–34) via a Medtronic® pump with a rate of 0.8 UI/h (equivalent to 11 mcg of teriparatide/day). The patient was monitored by daily clinical evaluation (symptoms and Chvostek and Trousseau signs) and assessment of serum calcium and ionized calcium levels. Moreover, we assessed the patient's quality of life by using the SF-36 questionnaire at baseline and at 6 months. The daily dose was progressively uptitrated until 22 mcg/day and the SOC therapy was gradually reduced until discontinuation. At the last evaluation (9 months) serum calcium was 9.5 mg/dl, serum phosphate was 3.3 mg/dl and 24 h urine calcium was 100 mg/24 h. Abdomen ultrasound did not show the nephrolithiasis. The SF-36 test showed a significant improvement of the scores. In conclusion, the continuous infusion of rhPTH (1–34) in our patient was the only treatment option able to restore long-term calcium homeostasis and improve the quality of life.

Identification of GATA3 pathogenic variants in two patients with hypoparathyroidism, deafness and renal dysplasia (HDR) syndrome

Elisa Dinoi[1], Laura Pierotti[1], Laura Mazoni[1], Simona Borsari[1], Matteo Apicella[1], Fulvia Baldinotti[2], Maria Adelaide Caligo[2], Claudio Marcocci[1] & Filomena Cetani[3]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University Hospital of Pisa, Laboratory of Molecular Genetics, Pisa, Italy; [3]University of Pisa, Endocrine 2 Unit, Pisa, Italy.

Hypoparathyroidism, deafness and renal dysplasia (HDR) syndrome, also known as Barakat syndrome, is a rare autosomal dominant disease characterized by the triad of hypoparathyroidism (H), deafness (D) and renal abnormalities (R). Its genetic cause is known to be the haploinsufficiency of the zinc finger transcription factor *GATA3*. This disorder exhibits a great clinical variability and an age-dependent penetrance of each feature. The most frequent manifestation is sensorineural deafness, usually diagnosed during childhood. Symptomatic or asymptomatic hypoparathyroidism affects about 90% of patients. Kidney abnormalities, such as renal cysts, are less common. We report two cases of HDR syndrome due to pathogenic variants in exon 3 of the *GATA3* gene. Subject 1 was a 17-years-old boy who was referred to our Department in 2018 for hypocalcemia incidentally detected at routine blood tests. At physical examination Trousseau and Chvostek signs were positive and laboratory evaluation confirmed a severe hypocalcemia (ionized calcium 0.62 mmol/l, n.v. 1.13–1.32), hyperphosphatemia (8.8 mg/dl) with undetectable PTH levels (< 4 pg/ml, n.v. 8–40). At abdomen ultrasound and magnetic resonance multiple renal cysts were detected. Subject 2 was a 16-years-old boy who was referred to our Department in 2005 for hypocalcemia complicated by epileptic seizure. His past clinical history was remarkable for right nephrectomy at 4 months of age for multicystic renal disease. At our first evaluation physical examination was normal and blood tests showed low ionized calcium (0.99 mmol/l, n.v. 1.13–1.32) with undetectable PTH levels (< 10 pg/ml, n.v. 15–75). Computed tomography displayed multiple cerebral calcifications and the audiometric evaluation revealed the presence of bilateral mild sensorineural hearing loss in both patients. On the basis of clinical and biochemical data, HDR syndrome was suspected and genetic analysis of the *GATA3* gene revealed the presence of a pathogenetic variant in exon 3, c.404dupC in subject 1, but not in his parents and sister, and c.431dupG in subject 2. These frameshift variants produce a premature stop codon resulting in the synthesis of a non-functional truncated protein (p.Ala136GlyfsTer168 and p.His145ProfsTer159, respectively). A good control of H is achieved in both patient by using rhPTH in subject 1 and oral calcium and active vitamin D in subject 2. HDR syndrome, although rare, is one of the genetic causes of H and must be excluded in all patients with idiophatic H, particularly if young. A correct diagnosis is important for the early detection of other features of the syndrome and for genetic counseling.

Sickle cell disease and hyperparathyroidism: case report

Maysam JRIDI, Sabrine Mekni, Adel Meriem, Imen Rojbi, Ibtissem Ben Nacef, Nadia Mchirgui & Karima Khiari
Hospital Charles Nicolle, Tunis, Tunisia.

Introduction
Primary hyperparathyroidism (pHPT) is a common endocrine disorder usually diagnosed by the presence of elevated serum calcium levels with inappropriate normal or increased parathyroid hormone (PTH) serum levels. This condition has been reported in few cases of patients with sickle cell disease (SCD), a multisystem disorder with acute and chronic complications.
Observation
We report a case of a 63-year-old Tunisian woman with a history of homozygous sickle cell disease (SS phenotype), high blood pressure and atrial fibrillation, referred to the emergency department for hypercalcemia 3.68 mmol/l (*n*:2.25–2.6) with electrocardiogram (ECG) abnormalities. After hydration, a decrease of calcium level 2.82 mmol/l and normalized ECG, she was admitted to the endocrinology ward. Physical examination showed a centimetric basal cervical mass. Blood tests showed: hypophosphatemia 0.73 mmol/l (*n*: 0.78–1.52), an elevated parathyroid hormone level 1479 pg/ml (*n*: 26.5–96.5) and a moderate decrease in kidney function (creatinine clearance = 44 ml/min). Urinary cast showed no hypercalciuria. This case was compatible with pHPT. Hypercalcemia was treated with oral route and intravenous hyper hydration along with bisphosphonate perfusions. Ultrasonography of the neck revealed a mass at the left inferior parathyroid lobe of 17 × 14 mm and the Sestamibi scan showed a 15 mm single left parathyroid adenoma. Renal echography revealed no nephrolithiasis albeit an aspect of chronic renal disease. Bone densitometry revealed osteoporosis (T scores of −3.5, −2.5 in lumbar spine and left hip respectively). Then the patient underwent an excision of the parathyroid adenoma. The histological analysis showed pseudo adenomatous parathyroid hyperplasia.
Discussion
Some explanations for the association of SCD with pHPT have been delineated in the literature, such as vitamin D deficiency, high levels of EPO du to chronic hemolysis which could stimulate the parathyroid glands and increased growth factors and fibroblastic growth factor which seem to promote parathyroid cells proliferation
Conclusion
If we consider pHPT to be a complication of SCD, calcium levels should be routinely checked, keeping in mind the fatality of hypercalcemia complication adding to that the threatening complications of SCD. Further research is required to underpin the association of SCD with pHPT.

Primary hyperparathyroidism revealed by a brown tumor: a case report

Gorgi Khaoula, Kamel Farah, Echchad Lamya, Rifai Kaoutar, Iraqi Hinde & Gharbi Mohamed El Hassan
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco.

Introduction
Brown tumors are osteolytic lesions rarely revealing hyperparathyroidism. They result from abnormalities of bone metabolism. They usually occur in the terminal stage of hyperparathyroidism. We report the case of a patient with hyperparathyroidism revealed by a brown tumor.
Case
A 39-year-old female patient with no notable medical history who presented for 1 year a mandibular swelling progressively increasing in size after a dental extraction without other associated signs. A phosphocalcic assessment was requested, coming back in favor of a primary hyperparathyroidism: high level of calcemia at 132 mg/l, a low phosphoremia at 17 mg/l and an elevated parathormonemia 9 times above the normal. A biopsy of the mass was performed, which anatomopathological examination was in favor of a reparative giant cell granuloma, hence the diagnosis of brown tumor. Cervical ultrasound revealed a 3–4 cm parathyroid adenoma and scintigraphy confirmed the parathyroid origin. The patient underwent parathyroidectomy and the histological study was in favor of an atypical parathyroid adenoma. The evolution was marked by a normalization of the phosphocalcic balance.
Discussion and conclusion
Brown tumors are rarely revealing bone manifestations of primary PTH.Their discovery requires exploration of the parathyroid glands, which are most often the site of an adenoma. Excision of the parathyroid adenoma remains the reference treatment for this condition.

Primary hyperparathyroidism revealed by acute pancreatitis: a case report

Gorgi Khaoula, Kamel Farah, Khamel Ghita, Echchad Lamya, Rifai Kaoutar, Iraqi Hinde & Gharbi Mohamed El Hassan
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco.

Introduction
Primary hyperparathyroidism (PPH) can be complicated by pancreatitis. The frequency of association of primary hyperparathyroidism with pancreatitis is rare, varying between 1.5% and 7%. We report the case of a patient with hyperparathyroidism revealed by acute pancreatitis.
Case
A 78-year-old patient, without any particular history, who consulted the emergency room for an acute digestive picture with abdominal pain and bilious vomiting, an abdominal CT scan was ordered showing stage D pancreatitis. After eliminating other classical causes of pancreatitis with a normal triglyceride level. The etiological research revealed a profile of primary hyperparathyroidism: PTH: 392 pg/ml or 9×normal, hypercalcemia: 141 mg/l (85–105), hypophosphatemia 19 mg/l (20–45). Cervical ultrasound and cervico-thoracic MRI confirmed the parathyroid localization by showing a paratrachial formation dte in front of the post edge of the inf pole of the thyroid lobe dte measuring 17×15×23 mm. The workup for hypercalcemia was unremarkable. The patient was rehydrated and given furosemide, and when her blood calcium level did not improve, she was given a bisphosphonate infusion. After the normalization of the calcemia the patient underwent a parathyroidectomy with good clinical and biological evolution.
Discussion and conclusion
The association between HPTP and pancreatitis is rare, however, the pathophysiology of this association is still unknown. Experimental data support a direct or indirect role of hypercalcemia via activation of pancreatic proteases. Acute pancreatitis may be indicative of HPTP, which should be systematically investigated in all acute pancreatitis, in the absence of an obvious cause.

Small and foudroyant parathyroid carcinoma with lung metastasis and no local invasion at diagnosis

Daniel Grigorie, Mircea Ghemigian, Dumitru Ioachim, Cristina Florescu & Alina Sucaliuc
National Institute of Endocrinology, Bucharest, Romania.

Parathyroid carcinoma (PC) rarely presents with metastasis at diagnosis and usually in patients also having gross local invasion.
Case presentation
We report the case of a 51-year-old postmenopausal woman presenting at our institution in June 2019 with symptomatic hypercalcemia (fatigue, polyuria, constipation and bone pain), but with a surprisingly good general condition. She had been treated with bisphosphonates for osteoporosis (DXA: LS T score −4.2 s.d., Z score −3.6 s.d.; FN T score −2.4 s.d., Z score −1.7 s.d.) for 2 years, having a variable hypercalcemia up to 12.6 mg/dl, but undiagnosed for primary hyperparathyroidism (PHPT). She had no family history of parathyroid disease or endocrine neoplasia. Initial laboratory findings revealed marked hypercalcemia (17.5 mg/dl), very high PTH levels (1561 pg/ml) and turnover (CTX 4.58 ng/ml) and normal kidney function, which led to the suspicion of PC. Neck ultrasound showed a hypoechoic tumor with slightly irregular margins, Ø max 1.5 cm, in the position of right superior parathyroid gland. The tumor was surgically removed and three other parathyroids were identified in canonical location and of normal appearance, with no gross invasion. As the preliminary pathology report revealed characteristic features of PC, a total thyroidectomy was performed, and a small normal parathyroid gland was found adjacent to the initial tumor. After tumor removal, her PTH levels decreased by 65%, from 1561 pg/ml to 560 pg/ml (Ca 11.34 mg/dl) and then increased fast, at the the same rate as preoperatively: 39% in 3 weeks preop vs 39% in 1 mo postop; and progressively reached 1684 pg/ml after 3 mo. A MIBI scan including the mediastinum was negative and a FDG−PET CT showed increased metabolic activity in a 10 mm nodule, in the right para aortic mediastinal pleura, the descending colon and skeleton. A bone scan showed homogenous symmetrical uptake throughout the skeleton and X-rays were normal. A CT scan confirmed a mediastinal nodule measuring 11/7/13 mm, tangent to the right antero-lateral face of the ascending aorta and bilateral pulmonary micronodules. Total serum Ca was variably controlled (9.1 mg/dl to 15 mg/dl) with pamidronate and then denosumab (60−120 mg). The surgery performed abroad confirmed that the mediastinal nodule was a metastasis of PC. Eventually, the hypercalcemia became resistant to denosumab (6 mo postop) and the patient died due to a hypercalcemic crisis (20 mg/dl).
Conclusion
This is a rare case of a small and very aggressive parathyroid carcinoma with lung metastasis at diagnosis although with no local invasion.

Aberrant epigenetic features occurring in parathyroid tumors involve DNA methylation, histone methylation, and non-coding RNAs. RASSF1A and APC were frequently downregulated in human cancers. Here, we investigated *RASSF1A* and *APC* methylation status in a series of parathyroid tumors from Italian patients with primary hyperparathyroidism (PAds, $n=80$), confirming *RASSF1A* and *APC* promoter methylation as a hallmark of sporadic parathyroid adenomas. Morever, we extended the analysis in parathyroid carcinomas (PCas, $n=9$), which displayed *RASSF1A* promoter methylation, while *APC* promoter was methylated only in 2 samples. In PAds, *RASSF1A* promoter methylation levels positively correlated with the methylation levels of *APC* promoter, suggesting a common methylation process for both genes. We focused the attention on the oncosuppressor RASSF1A. Our results showed that *RASSF1A* transcripts were significantly reduced in PAds ($n=35$) when compared with normal parathyroid glands (PaNs; $n=3$), though *RASSF1A* mRNA levels and levels of *RASSF1A* promoter methylation did not correlate. At protein level, RASSF1A was detectable by immunohistochemistry in the cytoplasm of cells in PaNs ($n=3$) and in the rim of PaN surrounding parathyroid adenomas, while cells in PAds ($n=11$) showed weakly positive citoplasmic staining. PCas ($n=6$) were definitely negative both at cytoplasmic and nucelar levels. Furthermore, we investigated 2 potential epigenetic modifiers involved in *RASSF1A* promoter methylation: the methylatransferase DNMT1 and the antisense lncRNA *RASSF1-AS1*. DNMT1 methylates both *RASSF1A* and *APC* gene promoters. We found that DNMT activity, investigated in PAds nuclear extracts ($n=16$), was inversely correlated with RASSF1A protein levels ($r^2=0.400$, $P=0.009$), supporting the involvement of deregulated DNMT activity in the aberrant *RASSF1A* promoter methylation. *RASSF1-AS1* (alias *ANRASSF1*) was implicated in a locus-specific mechanism for the *RASSF1A* epigenetic repression, mediated by Polycomb Repressive Complex 2 (PRC2), reinforcing RASSF1A long-term epigenetic silencing. In PAds, *ANRASSF1* levels positively correlated with expression levels of *RASSF1A* ($r=0.788$, $P=0.0001$). Similarly, *RASSF1A* promoter methylation negatively correlated with *ANRASSF1A* mRNA levels ($r=-0.366$, $P=0.031$). These findings exclude *ANRASSF1* in the methylation process of the *RASSF1A* promoter in PAds. Finally, using HEK293A cells transiently transfected with human CASR as experimental model (CASR-HEK293A), we investigated the effects of *RASSF1A* gene silencing on pERK/ERK levels stimulated by the CASR agonist R568. Efficient *RASSF1A* silencing increased basal pERK/ERK levels and blunted the pERK/ERK increase induced by CASR activation, suggesting that loss of RASSF1A may contribute to the parathyroid cell desensitization towards extracellular calcium concentrations observed in parathyroid tumors.
In conclusion, *RASSF1A* and *APC* promoter methylation is a hallmark of parathyroid adenomas.

DOI: 10.1530/endoabs.81.EP182

EP183

Prediction of 25-hydroxy vitamin D status by serum alkaline phosphatase (ALP) value.

Ishara Ranathunga, J P Naveenkumar, Manilka Sumanatilleke & Noel Somasundaram
NHSL, Colombo, Sri Lanka.

Background and Objectives
The low vitamin D status in an individual leads to a compensatory increase in serum parathyroid hormone (PTH) level giving rise to secondary hyperparathyroidism. The elevated PTH will conserve calcium excretion from the kidneys in the expense of excreting phosphate. Thus, serum calcium levels tend to remain normal until the latter stages of vitamin D deficiency. PTH action on the bone to reabsorb more calcium from the bone lead to elevation of bone alkaline phosphatase (ALP) in the serum. Nevertheless, population screening for vitamin D deficiency in asymptomatic individuals is currently not recommended. ALP measurement as a screening test to detect vitamin D deficiency is a relatively inexpensive test that can be performed easily. We have studied the relationship between the ALP, calcium, phosphate and PTH level to the vitamin D status of patients attending the NHSL.
Methods
A descriptive cross sectional study was conducted from March/ 2019 to March/ 2020 at the Endocrinology Unit of the National Hospital of Sri Lanka. Consecutive sampling was done recruiting all patients who have had vitamin D assessment as part of the routine medical care. Interviewer administered questionnaire was used collect data. Vitamin D sufficiency, insufficiency and deficiency was defined on levels of >50 ng/ml, 20–50 ng/ml, <20 ng/ml respectively. Pearson correlation analysis was used to determine the effects of vitamin D status on various blood parameters including serum total calcium, serum phosphate, ALP and PTH level. Receiver operating characteristic (ROC) curves were used to determine the optimal ALP level to predict vitamin D deficiency.
Results
153 subjects who meets the inclusion and exclusion criteria were recruited in to the study over a period of one year. The population mean age was 52.1 (S.D. $\pm$ 14.38) years and ranged from 18 to 89 years. Out of the whole population 58.8% had vitamin D deficiency while 31.4% suffered from vitamin D insufficiency. Only 9.8% had normal vitamin D levels. ALP level was significantly related to vitamin D deficiency ($P<0.05$). At ALP cutoff value of 72.5 U/L the vitamin D deficiency could be predicted with 76% sensitivity and 80% specificity. ALP cutoff 43 U/L predicts vitamin D deficiency at a 100% sensitivity and 20% specificity.
Conclusions
The population screening for vitamin D deficiency is not a cost effective intervention. A more cheaper and feasible ALP assessment at a cutoff value of 72.5 U/L can predict vitamin D deficiency at a significantly higher specificity and sensitivity.

EP184

The short test with active metabolites of vitamin D in differential diagnosis between primary normocalcemic and secondary hyperparathyroidism for inpatient treatment

Elena Karaseva[1], Anna Eremkina[1], Alina Elfimova[1], Anna Gorbacheva[1], Ekaterina Bibik[1], Elena Kovaleva[1] & Natalia Mokrysheva[2]
[1]Endocrinology Research Center, Department of Parathyroid Disease, Moscow, Russian Federation; [2]Endocrinology Research Center, Director, Moscow, Russian Federation.

Objective
Normocalcemic primary hyperparathyroidism (PHPT) is a phenotype of PHPT characterized by normal serum calcium and persistently increased parathyroid hormone (PTH) after exclusion of secondary causes of PTH elevation.
The aim
of this study was to investigate the capability of the short test with active metabolites of vitamin D for differential diagnosis between normocalcemic PHPT and secondary hyperparathyroidism (SHPT) for inpatient treatment.
Material and methods
We included 90 hospitalized patients with normal albumin-adjusted calcium ($Ca_{adj.}$) and elevated PTH levels (84 women, 6 men, median age 60 years). Ca_{adj}, PTH, creatinine, eGFR, daily calciuria were evaluated before and PTH, $Ca_{adj.}$, creatinine, eGFR 3–5 days after taking 1 mcg of alfacalcidol or calcitriol. Data is presented by medians and interquartile ranges (Median, (25;75)).
Results
According to baseline and dynamic biochemical evaluation patients were divided into 3 groups: group 1 ($n=32$) – patients with elevated or within the upper limit PTH ($n=4$) who reached hypercalcemia ($Ca_{adj.}>2.55$ mmol/l); group 2 ($n=14$) – patients with normalization of PTH and normal Ca_{adj}; group 3 ($n=44$) patients with elevated PTH and normal $Ca_{adj.}$. In group 1, baseline $Ca_{adj.}$ was 2.52 mmol/l (2.50; 2.54), PTH 101.1 pg/ml (81.9; 138.0), after short test – 2.61 mmol/l (2.58; 2.64), and 92.3 pg/ml (71.2; 119.5) respectively, regarded as PHPT. Among them 19 patients underwent surgery with histological confirmation of diagnosis, 2 patients are waiting for surgery, 11 patients with asymptomatic form are under dynamic observation. In group 2, baseline $Ca_{adj.}$ was 2.34 mmol/l (2.31; 2.44), PTH 81.1 pg /ml (72.9; 95.7) vs 2.40 mmol/l (2.33; 2.51) and 54.53 pg/ml (40.7; 63.6) respectively after short test regarded as SHPT. Groups with PHPT and SHPT significantly differed from each other in Ca_{adj} and daily calciuria ($P<0.05$) but not in PTH, eGFR. 44 patients from group 3 did not show significant changes thus differential diagnosis was continued on an outpatient basis.
Conclusion
The study showed significant changes in calcium and PTH levels during the short test in 46/90 patients. Stable normocalcemia and normalization of PTH allows confirming SHPT while elevated or within the upper limit PTH levels with hypercalcemia – PHPT.

Evaluation of response to alendronate treatment on osteoporosis using cathepsin K and other biomarkers

Roxana Novac[1], Popescu Costin-Ioan[2] & Cotirlet Valentin-Adrian[3]
[1]Emergency Hospital, Moineşti, Romania; [2]Institute of Biochemistry of the Romanian Academy, Bucureşti, Romania; [3]Vasile Alecsandri University of Bacău – Mărăşeşti Campus, Bacău, Romania.

Background
Osteoporosis has been an excruciating disease for many years now. Although various treatments are available, there is an unmet need for disease prognosis, early disease diagnosis and prediction of treatment efficacy. New biomarkers are crucial for the diagnosis or prognosis of a disease as well as for monitoring treatment efficacy and improve decision making. Cathepsin K is a cysteine protease that cleaves collagen type I, the major type of collagen found in bone, so it is useful to measure to assess the function and number of osteoclasts. The aim of the current study was to evaluate the fluctuation of cathepsin K, phosphorus, 25 HO vitamin D, alkaline phosphatase and PTH before and after 6 and 12 months of treatment with alendronate.
Methods
We conducted a longitudinal study with a cohort of 28 female patients with osteoporosis and 15 healthy controls. All subjects were menopaused, non-diabetic, non-obese, without secondary osteoporosis. All patients were treated with alendronate and calcium and vitamin D supplements. Serum samples were collected longitudinally before treatment, at 6 and 12 months post treatment initiation and the levels of cathepsin K, phosphorus, 25 HO vitamin D, alkaline phosphatase and PTH were measured.. Basal serum cathepsin K levels were also compared to premenopausal women without osteoporosis ($n=15$).
Results
We observed that serum cathepsin K levels were higher in premenopausal women with osteoporosis (9746.07 +/− 1824 RFU/ml) compared with healthy premenopausal women (7747.33 +/− 762.67 RFU/ml; $P<0.01$). Also, serum cathepsin K decreases gradually after alendronate treatment (5.09% at 6 months, and 7,17% at 12 months, $P<0.05$). We also found a positive association of cathepsin K and phosphorus and alkaline phosphatase and a negative association with 25 HO vitamin D.
Conclusion
We conclude that serum cathepsin K may serve as an additional biomarker for bone metabolism and alendronate treatment monitoring besides phosphorus and alkaline phosphatase. The role of Cathepsin K as a risk biomarker marker in premenopausal women without osteoporosis is also discussed.

Bone tissue metabolism in children with dystrophic form of congenital epidermolysis bullosa before and during therapy with cholecalciferol.

Irina Pronina[1], Svetlana Makarova[1], Nikolay Murashkin[2], Elena Semikina[3] & Tamara Chumbadze[1]
[1]National Medical Research Center of Children's Health of the Russian Federation Ministry of Health, Department of Preventive Pediatrics, Moscow, Russian Federation; [2]National Medical Research Center of Children's Health of the Russian Federation Ministry of Health, Department of Dermatology, Moscow, Russian Federation; [3]National Medical Research Center of Children's Health of the Russian Federation Ministry of Health, Clinical Diagnostic Laboratory with a group of express diagnostics, Moscow, Russian Federation.

Introduction
Malnutrition, deficiency of micro- and macronutrients, including calcium and vitamin D are typical for children with dystrophic form of congenital epidermolysis bullosa (DEB). Thereby, there is a slowdown in osteogenesis and in stimulation of osteoclast activity, bone tissue resorption, which leads to increased bone fragility and low-traumatic fractures.
Aim of the study
To evaluate markers of bone tissue metabolism and phosphorus-calcium metabolism in children with DEB before and during therapy with cholecalciferol.
Methods and materials
71 children with DEB were included (39 girls (55%), 32 boys (45%)), the median age was 8.5 years [3.67; 11.92] and 5.75 years [3.13; 10.46]. All patients were examined before the therapy with cholecalciferol, and 6 months after. Dual X-ray absorptiometry was used to assess bone tissue density. Vitamin D, total calcium, phosphorus, N-terminal propeptide of procollagen type I (P1NP), osteocalcin (OS) and carboxyterminal cross-linked telopeptide of collagen type I (CTX) levels were determined.
Results
A high frequency of insufficiency (20–30 ng/ml) – 22.5%, deficiency (10–20 ng/ml) – 31% and deep deficiency (< 10 ng/ml) – 9.9% of vitamin D, as well as hypocalcemia total calcium (< 2.2 mmol/l) – 39.4% was identified. BMD decrease to osteopenia level was identified in 33.8%, osteoporosis – in 19.7% of children. In patients with hypocalcemia (Me total calcium 2.13 mmol/l [2.1; 2.16]), OS and CTX was significantly lower than in patients with normal calcium (Me OS 53.16 ng/ml [32.86; 64.61] vs 73.61 ng/ml [44.43; 111.9], $P=0.001$; Me CTx 1.22 ng/ml ml [0.93; 1.38] vs 1.49 ng/ml [1.2; 1.83], $P=0.015$). P1NP levels did not differ in patients with hypocalcemia and normal calcium ($P=0.617$). In children with hypocalcemia there was a lower BMD ($P=0.004$). The median daily dose of colecalciferol was 1100 IU in boys [1000; 2250] and 2000 IU [1000; 3000] in girls. After 6 months of the therapy normalization of 25(OH)D level in 62% of children. Statistically decreased levels of P1NP (409.15 ng/ml [156.1; 695] after the treatment vs. 436.65 ng/ml [196.1; 864] before the treatment, $P<0.001$), phosphorus (1.51 mmol/ l [1.3; 1.68] vs 1.58 mmol/l [1.45; 1.67], $P=0.012$) were detected. As well as BMD decrease severity (Z-score −1.3SD [−2.3; −0.2] vs −1.5 s.d. [−2.2; −0.4], $P=0.024$), with simultaneous OS growth 70.1 [56.3; 96.04] vs 65.17 [42.86; 85.4], $P<0.001$.
Conclusion
On cholecalciferol supplementation, we observed bone tissue metabolism markers positive dynamics and BMD increase. Further research in this field with the optimal medicine dose is needed.

A special case of type Ib pseudohypoparathyroidism

Kadiri Chaimae & Amhager Samah
Hôpital Cheikh Zayd, Pediatric, Rabat, Morocco.

Introduction
Pseudohypoparathyroidism type Ib are genetic diseases with transmission maternal, defined by a resistance to the action of the parathormone without resistance to the TSH. Clinical manifestations are variable and depend on the severity of hypocalcaemia. We report the case of a patient presenting with type Ib pseudohypoparathyoidia.
Observation
This is a 9-year-old child admitted for care and exploration of a severe hypocalcaemia. The patient has been followed for unlabeled laryngeal stridor since birth. We note childhood obesity. He has episodes of spasm repetitive pedal carpe with vomiting. The clinical examination demonstrates a moon faces with macroglossia. The phosphocalcic balance shows a severe hypocalcaemia at 56 mg/l with elevated phosphoremia and hypocalciuria. The parathormone dosage was high (160.6 pg/ml) with normal TSH (1.27 uIU/ml). Brain CT finds Fahr's syndrome. X-ray of the hands finds a slight brachymetacarpy of the fourth ray. The genetic study highlights evidence of pseudohypoparathyroidism in non-transmissible somatic mosaicism. The patient received vitamin-calcium supplementation with a good clinical and biological evolution.
Discussion
Pseudohypoparathyroidism is a pathology that is sometimes difficult to diagnose, generally evoke in front of any hypocalcaemia with hyperphosphatemia and PTH high. This observation underlines the interest of thinking about pseudohypoparathyroidism in children in front of spasms in order to allow an adapted treatment allowing avoiding the occurrence of severe hypocalcaemia threatening the vital prognosis and the impact on child growth.

EP188

Chronic bone pain revealing a parathyroid adenoma

Kadiri Chaimae & Lachkar Hassan
Hôpital Cheikh Zayd, Endocrinology, Rabat, Morocco.

Introduction
Primary hyperparathyroidism is an endocrinopathy characterized by the excessive secretion of parathyroid hormone, most commonly associated with parathyroid adenoma. The osteoarticular manifestations of hyperparathyroidism are currently exceptional. The diagnosis is most often established at the asymptomatic stage by measuring calcium levels and parathyroid hormone.
Observation
We report the case of a 67-year-old patient with a history of partially calcified right parietal meningioma, and who consulted for diffuse mechanical bone pain. A phosphocalcic balance is carried out objectifying a hypercalcemia corrected to 117 mg/l with a normal phosphoremia at 29 mg/l, a normal vitamin D and a parathyroid hormone elevated to 115 g/l. A subtraction parathyroid scintigraphy with MiBi-99mTc/Pertechnetate revealed a right lower polar parathyroid adenoma measuring 5×4×6 mm, oval, regular, hypoechoic and heterogeneous. Ablation of the parathyroid adenoma was performed in our patient with simple operative consequences and good progress.

Discussion and conclusion
Bone manifestations have become rare in hyperparathyroidism. They are characterized mainly by mechanical polyarthralgia, bone swelling or even pathological fractures. The positive diagnosis is based biologically on confirmed hypercalcemia with elevated PTH and morphologically on parathyroid scintigraphy at TC 99 m which allows visualization of the parathyroid adenoma. The treatment is surgical.

Bilateral pathologic fracture of the femur in brown tumor İnduced parathyroid carcinoma

Filiz Mercan Sarıdaş, Ensar Aydemir, Coskun Ates, Erhan Hocaoğlu, Soner Cander, Ozen Oz Gul, Canan Ersoy & Erdinc Erturk
Bursa Uludag University, Endocrinology and Metabolism, Bursa, Turkey.

Introduction
Brown tumor refers to the skeletal change that develops as one of the complications of hyperparathyroidism, in which cystic and fibrous changes occur in the bone. It occurs in approximately 10−20% of patients with primary hyperparathyroidism. Parathyroid cancer is a rare cause of primary hyperparathyroidism and accounts for approximately 1% of cases. In some cases, hyperparathyroidism may be asymptomatic until it becomes a pathological fracture and may be the first sign of a malignant tumor. Here, we report a case of parathyroid carcinoma presenting with bilateral femoral fracture because of its rarity.
Case
A 56-year-old male patient presented with pain and limitation of movement in both thighs after falling in the bathroom. It was learned that he had difficulty in walking and pain in the legs for 6 months in his history, and he did not have an additional disease or medication. X rays showed the fractures in both femurs and left olecranon and findings consistent with multiple (bilateral femur, tibia, fibula and right radius and ulna) Brown tumors were found in the bones. Blood investigations showed raised levels of serum calcium, with highly raised levels of serum parathyroid hormone (PTH). After neck ultrasonography and parathyroid scintigraphy, an appearance compatible with parathyroid adenoma was found in the inferior of the right thyroid lobe, and parathyroidectomy was performed, but postoperative PTH elevations continued. Thereupon, the patient was evaluated with neck tomography and parathyroid scintigraphy for the second time, and he was reoperated when another focus was detected in the upper mediastinum at the level of the angulus venosus in the isthmus inferior of the thyroid gland. The operative pathology resulted as parathyroid carcinoma. The patient who developed postoperative hungry bone syndrome was operated for bilateral femoral fracture after calcium normalization was achieved.
Conclusion
The main treatment for parathyroid carcinoma is surgery. In the presence of fracture, it is recommended to perform parathyroidectomy first and then orthopedic treatment. In the presence of osteolytic lesion and high serum calcium in patients presenting with pathological fracture, Brown tumor related to parathyroid carcinoma should be kept in mind in the differential diagnosis.
Keywords
Hyperparathyroidism, brown tumor, femur, pathological fracture.

Giant cells and a hungry bone: a diagnostic and therapeutic challenge.

Rashmi Nanjundaswamy[1,2], Sunil Navalgund[1], Govindarajan Mallarajapatna[1], Srimant Srinivas Bindiganavile[1] & Hema Venkataraman[1]
[1]Apollo Hospitals Bangalore, Bengaluru, India; [2]Apollo Sugar Clinics, Bengaluru, India.

Introduction
Brown tumours (BT) are a recognised complication of severe prolonged untreated hyperparathyroidism (HPT). BT can mimic bone metastases and giant cell tumors (GCT). Hungry bone syndrome (HBS) is a severe and prolonged, postoperative hypocalcemia following parathyroidectomy. BT are a risk factor for HBS. We report the case of a young lady with BT masquerading as a GCT,from a tertiary centre in India.
Case study
A 25 year lady presented with pathological fractures of humerus,tibia and inabilty to weight bear. MRI in primary care, showed multiple hyperintense (T2 imaging) expansile lytic lesions over humerus,pelvis and femur with compression fracture of vertebrae. FNAC was suggestive of giant cell tumour. PET-CT confirmed hypermetabolic multifocal expansile bone lesions with fractures and osteoporotic vertebrae with no evidence of primary malignancy, raising a differential diagnosis of brown tumours. Biochemistry revealed elevated calcium (S.Ca 11.9 mg/dl, normal range (NR) 8.8–10.6), Alkaline phosphatase(304 IU/L,(NR 53–141)). Parathyroid hormone(PTH) was elevated: PTH 486 pg/ml (NR 10.0 −65 pg/ml) with severe Vitamin D deficiency: 6.5 ng/ml(NR 30–100 ng/ml),low phosphorous 1.7 mg/dl(NR 2.5–4.5 mg/dl). A diagnosis of primary HPT with brown tumours was made.PETCT, contrast enhanced CT and targeted ultrasound failed to localize a parathyroid adenoma. Sestamibi scan showed faint uptake at the right superior parathyroid. Preoperatively a loading dose of 300,000 units of Intramuscular and 200 units of oral cholecalciferol was given. Consent for targeted parathyroidectomy and possible full neck exploration was taken. Right superior parathyroid gland of 1.6×1.2 cm was excised, which was thin and flat (probably the reason for missing on CT/ultrasound). Significant decrease in intraoperative PTH level (628.1–35.5 pg/ml) was observed. Intra-operative frozen section confirmed parathyroid adenoma.Post procedure she developed HBS (mean calcium 7.9 mg/dl) remaining asymptomatic. She required escalating dose of oral calcium upto 15 g of elemental calcium and 4 mg calcitriol with intermittent intravenous calcium and magnesium supplements. Proton pump inhibitors (PPI) were with-held. Post discharge calcium remained stable around 9 mg/dl with above dose of calcium and calcitriol. Pathological fractures are being managed conservatively.
Conclusion
BT is an important differential diagnosis for lytic expansile bone lesions with giant cell morphology on histology. BT often resolves with HPT treatment. Early diagnosis aviods complex surgical intervention.BT increases risk of post-operative HBS. Pre-operative loading of Vitamin D may have reduced duration and severity of HBS. However more evidence is needed to support this approach. Correction of Hypomagnesemia and withholding PPI aids optimal absorption of oral calcium.

Primary hyperparathyroidism in the setting of previous roux-en-Y gastric bypass: a case report

Lavinia Monte, Dario Tuccinardi, Rocky Strollo, Silvia Briganti, Donatella Rausa, Paolo Pozzilli, Nicola Napoli & Silvia Manfrini
Campus Bio-Medico University of Rome, Unit of Endocrinology and Diabetes Department of Medicine, Rome, Italy.

Introduction
Primary hyperparathyroidism (PHPT) after roux-en-Y gastric bypass (RYGB) is poorly described. The diagnosis can be difficult as secondary hyperparathyroidism(SHPT) commonly occurs in patients after RYGB due to calcium hypoabsorption and vitamin D deficiency.
Observation
We present the case of a 50-year-old female with a history of normocalcemic hyperparathyroidism and nephrolithiasis. In 2005 the patient had undergone RYGB. During the first visit, an iso-hypoechoic nodule below the right inferior pole of the thyroid gland with a maximum size of 47 mm and internal vascularization was detected. Her biochemistry revealed a PTH of 930 pmol/l (18–80 pmol/l), normal levels of total calcium and phosphorus, mild hypoalbuminemia, adjusted calcium of 9.8 mg/dl, hypercalciuria, 25-OH vitamin D levels of 6.4 mcg/l (>30 mcg/l). She was initially treated with 100 000 IU of Vitamin D3 intramuscularly once a month, but calcifediol, a hydroxylated form of vitamin D, was later prescribed due to the patient's discomfort with the intramuscular injection. Further investigations demonstrated decreased bone density at the hip and distal radius and a single image suggestive for parathyroid adenoma detected by SestaMIBI scintigraphy. The patient underwent parathyroidectomy, and she was discharged with calcium carbonate and calcitriol therapy, but a few days later, she accessed our A&E for hypocalcemia. The hungry bone syndrome was excluded due to her normal phosphorus and magnesium. Histology confirmed a parathyroid adenoma with a maximum diameter of 5 cm. The patient was treated with a single 10% calcium gluconate vial, and subsequently, we preferred to start with calcium citrate supplementation, which is absorbed more efficiently than calcium carbonate. Calcitriol and a protein supplement to treat the persistent patient's hypoalbuminemia were added. After that, no more severe hypocalcemia episodes occurred, her serum calcium and vitamin D level remained within normal range, PTH levels dropped until 135 pmol/l, and a gradual reduction of the oral supplementation doses was made.

Conclusion
PHPT after RYGB is a rare condition, and concomitant SHPT can make diagnosis and follow-up difficult and predispose patients to more severe postoperative hypocalcemia.

Fahr Syndrome secondary to pseudohypoparathyroidism.

Tea Shehu, Violeta Hoxha, Dorina Ylli & Agron Ylli
University of Medicine, Mother Teresa Hospital Center, Endocrinology, Tirana, Albania.

Background
Fahr's Syndrome, also known as striopallidodentate calcinosis is a rare form of neurological disorder characterized by abnormal calcified deposits in basal ganglia, cerebellar and cerebral cortex. Its prevalence goes from 2 to 12.5%. Etiology of this disorder is very wide and involves endocrinopathy, mitochondrial myopathies dermatological abnormalities, infectious disease or may be idiopathic. We present a case of a patient with diffuse brain calcifications due to pseudohypoparathyroidism probably type 1b.
Case description
We present a case of a 37 years old man who presented in the Emergency Unit with epileptic generalized tonic-clonic seizure. He was known to suffer from epilepsy since 4 months of age but head CT was performed for the first time during this hospitalisation and difuse bilateral brain calcifications were noticed. The patient has short stature with round face and brachydactyly of 4th metacarp. He also showed intellectual disability.Biochemical analysis showed hypocalcemia (6.1 mg/dl) with low/normal Vit D levels (29.8 ng/ml) and high PTH levels (152.1 ng/l). Hepatic and renal function were normal. Other electrolytes were also normal. Anterior hypophysis hormones were in their normal range. Because of hipocalcemia with high PTH levels and normal vit D, magnesium levels and renal function, diagnosis of pseudohypoparathyroidism was made. Lack of other hormone resistances, and clinical appearance suggests pseudohypoparathyroidism type 1b. The patient was treated with IV calcium and Vit D3 firstly and then with calcitriol 0.25/daily. On follow up levels of serum ionized calcium and 24 h calcinuria were improved.
Conclusions
Fahr's Disease is a rare, neurological complication of chronic pseudohypoparathyroidism. In most cases the diagnose is clinical-radiological with diffuse brain calcifications. It is suggested that PTH plays a protective role against calcifications in the brain. The mechanism is not fully explained but it is emphasized the importance of PTH receptor 2, found in brain cells and mitochondrial superoxides. After confirming pseudohypoparathyroidism, the patients should start treatment with cholecalciferol or ergocalciferol (firstly to fill the depots) and calcium supplements. Because PTH is required for the renal conversion of calcidiol to calcitriol (active metabolite) calcitriol is often the treatment of choice.

Late hypocalcaemia complicating the management of papillary thyroid carcinoma

Ihssane Abidi, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
University Mohammed 5 Rabat, Endocrinologie, Rabat, Morocco.

Introduction
COVID-19 is a pandemic related to SARS-COV-2 virus infection. It is most often manifested by an influenza-like syndrome with other symptoms that are more specific such as loss of smell and taste.
Its severity is highly variable, ranging from asymptomatic to severe or prolonged forms.
We report the case of a 47-year-old female patient, who is being followed for hypoparathyroidism, who developed severe and persistent cramps after the COVID-19 vaccine.
Observation
This is a 47-year-old female patient with a history of high-risk papillary thyroid carcinoma since 2018, operated and irradiated. Her surgery was complicated by supplementary hypoparathyroidism. Her blood calcium was well controlled and she was asymptomatic since her supplementation with Alfacalcidol and calcium. She received the first dose of astrazeneca in July 2021, after 4 h she developed persistent painful cramps in her extremities. Her clinical examination did not reveal any signs of hypocalcaemia and the biological dosage was 84 mg/l. As the cramps persisted, we started her on calcium and magnesium. The clinical evolution was good after 6 h and there was no recurrence.
Discussion
COVID-19 vaccines are as well tolerated in neuromuscular patients as in the general population (1). Hypoparathyroidism is not a neuromuscular disease, but it can be caused by hypocalcaemia, which is the cause of the neuromuscular manifestations. Campesium can be seen with COVID-19 vaccines, and is generally benign and transient. The particularity of our observation is that the cramps were severe and incapacitating with the need for intravenous calcium treatment and monitoring, adding the hypoparathyroid terrain which posed a problem of differential diagnosis.
Conclusion
The vaccine against COVID-19 has become an unavoidable necessity in the face of the pandemic population. It certainly has short and long term side effects. Fragile patients must be monitored to avoid complications, particularly neuromuscular ones.

Vitamin D deficiency in the type 2 diabetic population of Northern Gran Canaria Island: Still highly prevalent but supplementation is on the rise

Alba Hernandez-Lazaro, Ricardo de Leon-Durango, Agnieszka Kuzior, Carmen Acosta-Calero, Claudia Arnas-Leon, Maria del Sol Sanchez-Bacaicoa, Debora Garcia-Alamo, Marta Martin-Perez, Paula Gonzalez-Diaz & Francisco Javier Martinez Martin
Hospital Universitario de Gran Canaria Dr. Negrín, Spain.

Introduction
Vitamin D deficiency is associated with higher risk of severe COVID-19, and type 2 diabetic patients are a vulnerable group**.** We described an alarming rate of vitamin D deficiency (around 80.0% with plasma calcifediol <30 ng/ml) in unsupplemented type 2 diabetes patients during the 2020 spring lockdown and the following winter in Northern Gran Canaria. There is an increasing awareness of this problem, both in family physicians and the general population, and the use of vitamin D supplements is rising.
Objectives
To assess the prevalence of vitamin D deficiency in type 2 diabetic patients from Northern Gran Canaria during the late autumn-early winter period (November 2021 to January 2022), and its relationship with vitamin D supplementation.
Methods
Plasma calcifediol levels were sampled in an unselected type 2 diabetic population, and recorded anonymously along with age, gender and vitamin D supplementation status. All included patients gave their informed consent.
Results
Data were obtained from 217 consecutive patients; only 2 ($<1\%$) were excluded due to lack of consent.129 were female (59.4%), mean age was 58.6 ± 13.9 years. 138 (60.8%) were taking vitamin D supplements. Mean plasma calcifediol was 35.7 ± 14.9 ng/ml; but it was lower than recommended ($<$ 30 ng/ml) in 85 (39.2%) of the patients, deficient ($<$ 20 ng/ml) in 35 (16.1%) and severely deficient (<12 ng/ml) in 8 (3.7%). In vitamin D supplemented patients, mean calcifediol was 43.2 ± 11.6 ng/ml, with 20 patients (14.5%) <30 ng/ml, 6 (4.3%) <20 ng/ml, none $<$ 12 ng/ml and 1 (0.7%) $>$ 80 ng/ml. In unsupplemented patients, mean calcifediol was 22.7 ± 9.3 ng/ml, with 65 (82.2%) $<$ 30 ng/ml, 29 (36.7%) $<$ 20 ng/ml and 8 (10.1%) <12 ng/ml). Plasma calcifediol was significantly higher in supplemented patients (mean difference 20.5 ± 5.9 ng/ml, unpaired t-test, $P < 0.0001$) and the proportions of low, deficient and severely deficient patients were significantly lower (Fisher's exact test, $P < 0.0001$, $P < 0.0001$ and $P = 0.0002$, respectively).
Conclusions
The prevalence of vitamin D deficiency during the late autumn-early winter months in our unsupplemented type 2 diabetic population remains extremely high. However, the use of supplements is increasing, about 60% of our patients at present (45% in our previous survey 1 year ago). In supplemented patients vitamin D status is satisfactory with 4% deficient, none severely deficient and $<$ 1% above the recommended level.

EP195

Management of denosumab discontinuation in a patient with osteonecrosis of the jaw and coexisting primary hyperparathyroidism

Matteo Malagrinò, Elisabetta Belardinelli, Paola Altieri, Uberto Pagotto & Guido Zavatta
Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy.

Context
Patients with primary hyperparathyroidism (PHPT) may be treated with denosumab due to coexisting osteoporosis. Few studies have been conducted in this population.
Case presentation
An 84-year-old woman was seen in the outpatient clinic in March 2018 due to calcium levels at the upper limit of reference range (10,2 mg/dl) associated with elevated levels of PTH (112 pg/ml) and sufficient 25(OH)Vit D (24 ng/ml) levels, findings consistent with mild PHPT. Her past medical history included: osteoporosis with vertebral fractures (T11 and T12 vertebral bodies) since 2009, hystero-annexectomy in 1973, quadrantectomy for breast carcinoma in 2009, bowel resection for adenocarcinoma in 2008, prior ischemic stroke, prior gastric ulcer treated with gastrectomy and current jejunum ulcer. The patient had been on Alendronate 70 mg weekly since 2008 and taking 1100 IU of vitamin D3, and furosemide 25 mg/day. Patient's biochemistries were rechecked after three months: PTH was 61 pg/ml (12–88 pg/ml), serum Ca 11.3 mg/dl, serum phosphate 2.6 mg/dl, CTX 0.809 ng/ml. Due to age and comorbidities, the patient was not a good candidate for parathyroid surgery. Alendronate was stopped and denosumab 60 mg q6m was prescribed, the patient being evaluated every six months. In December 2020, a 2-cm area of active osteonecrosis appeared in the right mandibular region. Denosumab was promptly interrupted. To avoid potential rebound hypercalcemia the patient was immediately switched to cinacalcet at an initial dose of 30 mg per day, then increased at 60 mg per day after a few months, while checking serum calcium levels every 3 to 6 months, with safe control of serum calcium, PTH and overall symptoms.
Discussion
Denosumab is effective in improving BMD, lowering bone turnover and serum calcium in patients with PHPT, nonetheless, because of its mechanism of action, its discontinuation has been associated with rebound clinical fractures. Currently, limited data are available on the best management of patients discontinuing denosumab, although it is recommended to continue anti-osteoporotic treatment with oral or intravenous bisphosphonates. For our patient we could not consider these options due to coexisting active osteonecrosis. The patient had also two previous vertebral fractures. Hypercalcemia was managed with cinacalcet, and the patient has not sustained any fractures as of January 2022.
Conclusion
We suggest prompt cinacalcet use to manage potential rebound hypercalcemia following denosumab discontinuation in patients with PHPT, although these patients will remain at risk of rebound fractures.

Impact of COVID-19 pandemic on waiting time from referral to definitive surgery in primary hyperparathyroidism: a large tertiary centre experience

Razan Ali Rashid[1], Jason Ramsingh[2], Richard Bliss[2], Peter Truran[2] & Yaasir Mamoojee[1]
[1]The Newcastle upon Tyne Hospitals, Department of Endocrinology, Newcastle upon Tyne, UK; [2]The Newcastle upon Tyne Hospitals, Department of Endocrine Surgery, Newcastle upon Tyne, UK.

Background
The COVID-19 pandemic has resulted in widespread disruption to delivery of emergency and elective care in the last 2 years. Nevertheless, healthcare systems have quickly readapted to accelerate use of novel pathways for delivering clinical services. We reviewed the impact of COVID-19 pandemic on our time from community referral to definitive surgery in patients with Primary Hyperparathyroidism (PHPT).
Methods
We retrospectively reviewed the waiting times from General Practice (GP) referral to parathyroid surgery through our pathway which includes initial Endocrinology review before referral for surgical review. Data was collected before COVID19 pandemic (2019) and compared with data during the pandemic (2020–2021). Results are reported as mean for continuous variables. The Mann Whitney U test was used for comparing continuous variables between groups. A P value of <0.05 was considered statistically significant.
Results
28 patients were included in the pandemic cohort and 37 patients were in the pre-pandemic cohort. Time from GP referral to Endocrinology review was 60 days in the pandemic cohort (vs. 91 days in the pre-pandemic cohort, $P=0.03$). Time from first Endocrinology review to referral for surgery was 26 days in the pandemic cohort, compared to 341 days in the pre-pandemic cohort ($P<0.01$). There was no statistical difference in waiting times from surgical referral to surgical clinic review and thence to surgery between the pandemic and pre-pandemic cohort (54 days vs. 73 days and 181 days vs. 156 days, respectively). Overall, time from GP referral to definitive surgery was lower in the pandemic cohort at 314 days compared to 651 days in the pre-pandemic cohort ($P<0.01$), with the most impact on this reduced waiting time being from GP referral to surgical referral by Endocrinology (84 days vs. 422 days, $P<0.01$). There was no difference in our surgical pathway from time of referral for surgery to date of surgery in both cohorts (239 days v.s 229 days, $P=0.85$).
Conclusion
Our waiting times from GP referral to definitive surgery in patients with PHPT are surprisingly lower during the COVID-19 pandemic when compared to pre-pandemic times. These improved waiting times can be attributed to innovative pathways and judicious use of resources by both the Endocrinology and Surgical teams in our tertiary centre.

Correlation between vitamin D levels and severity of COVID 19 disease. Argentine Experience

María Laura García[1], Ana Paula Lisdero[1], Evangelina Giacoia[2], Franco López[3], Mauro Cruceño[2], Valeria Pollini[4], Marcia Esposito[5], Mariana Scarabino[6], Susana Bacigaluppi[7] & Aizhar Giselle Mumbach[7]
[1]Sanatorio Méndez, Endocrinology, Buenos Aires, Argentina; [2]Hospital Posadas, Endocrinology, Argentina; [2]Hospital Posadas, Endocrinology, Argentina; [4]Hospital Morón, Argentina; [5]Sanatorio Anchorena, Argentina; [6]Sanatorio Méndez, Internal Medicine, Argentina; [7]Sanatorio Méndez, Endocrinology, Argentina.

Objective
Vitamin D (VD) plays a role in immune response. Recent data shows that low levels of VD could worsen COVID-19 outcomes. This study aimed to establish an association between VD levels among COVID-19 patients with clinical outcomes and inflammatory markers.
Methods
Prospective multicentric cohort study. Consecutively recruitment. Patients were grouped according admission status and level of VD [sufficient >30 ng/ml (VDS), insufficient 20–30 ng/ml (VDI), deficient <20 ng/ml (VDD)]. The variables evaluated were age, gender, oxygen mask requirement (O2r), mechanical ventilation (MV), pre-existing comorbidities, inflammatory markers, severity of COVID-19 measured by News Score.
Results
363 patients were recruited (age 53 ± 16), 59% male, 88% from total were hospitalized, whose VD levels were significantly lower than ambulatories (19 ± 11 vs. 24.3 ± 14 ng/ml P:0.006). The amount between groups was VDS (15%), VDI (27%), VDD (58%).VD levels correlated negatively with hospitalization days and evolution time (P:0.045-P:0.043). Severity of COVID-19 adjusted by comorbidities was linked to a lower VD status (P: <0.001) Also an association with pronation requirement among patients with lower VD levels (P: 0.008) was observed. O2r risk was elevated among VDI (OR 2.9 95%CI 1.3–7) and VDD (OR 3 95%CI 1.4–6),multiplying the odds in 2.6 and 3.7 in presence of 1 or more comorbidities with a higher need of ICU in VDD groups (OR 4.8 95%CI 1.2–20). A negative relation between VD levels, basal ferritin and LDH was described (P:0.018 and P:0.045).
Conclusion
Among COVID-19 hospitalized VD level was significantly lower than ambulatory patients. There is an association between low VD with a worse course of disease needing more days of hospitalization, thus lengthening the time of sickness. VDI and VDD group had severe forms of COVID-19. VDD presented a higher risk for ICU attention. Further studies are needed to emphasize the importance of adequate levels of VD to improve COVID-19 outcomes.

From chronic hypomagnesemia with secondary hypoparathyroidism to basal ganglia calcification

Irine Lomtadze[1], Maka Mania[2], Tamari Khutsishvili[3] & Nino Eloshvili[4]
[1]Aversi Clinic, Endocrinology, Tbilisi, Georgia; [2]Aversi Clinic, Neurology, Tbilisi, Georgia; [3]Research Institute of Clinical Medicine, Todua Clinic, Endocrinology, Tbilisi, Georgia; [4]New Hospitals, Endocrinology, Tbilisi, Georgia.

As it is known, hypomagnesemia leads to decreased synthesis of Parathyroid hormone (PTH) and can cause PTH resistance. Chronic hypoparathyroidism itself may lead to basal ganglia calcification. We report a 58 years old male, who has suffered from convulsions for over 10 years, with a history of alcohol abuse (more than 25 units of alcohol/week). During this period there have been frequent aware convulsions, resembling to tetany, typical for hypocalcemia. Hypocalcemia and hypomagnesemia had been detected several times. Symptoms usually resolved by administration of Calcium and Magnesium. Patient used to stop taking supplements and continued alcohol abuse as soon as symptoms ameliorated.At the age of 58 patient had 3 tonic-clonic seizures with loss of consciousness, different from previous convulsions. The laboratory investigations showed severe hypocalcemia, hypomagnesemia, very low level of PTH and hyperphosphatemia (ionized Ca_0,60 mmol/l (1.15–1.29), Mg_0.56 mmol/l (0.66–1.07), PTH_2.5 pkg/ml (15–65), Phos_1.54 mmol/l (0.81–1.45), 25(OH)D_24.0 ng/ml. Electroencephalogram showed epileptiform activity (less common to hypocalcemia) and brain CT showed basal ganglia calcification, which may be manifestation of longstanding hypoparathyroidism. According to those findings, patient was diagnosed with structural generalized epilepsy. We believe it is a complication of longstanding hypomagnesemia with secondary hypoparathyroidism. Anticonvulsant (CBZ 200 mg TID) was added to prescription. Main cause of hypomagnesemia seems to be alcohol abuse, but other factors may also exist.
I/v correction of hypocalcemia and hypomagnesemia was followed by oral Magnesium orotate (Mg _ 32.8 mg) two times a day, Calcium Carbonate (Ca _ 500 mg.) three times a day, and Calcitriol 0.5 mcg/daily. Calcitriol was discontinued in several days after Calcium correction. On follow up visit (6–7 weeks later) elevation of PTH level was found _ PTH 10.49 ng/l (12–50), Ca _1.12 mmol/l (1.12–1.32), Mg_ 1.66 mg/dl (1.6–2.6). No more seizures were noted. Non managed chronic hypomagnesemia with secondary longstanding hypoparathyroidism might lead to basal ganglia calcification, followed by development of epilepsy. In our case, it is not till clear, if hypomagnesemia is the only cause of hypoparathyroidism or not, because PTH level still stays below of reference range. However, it is clear, that administration of magnesium increased PTH secretion and decreased severity of hypoparathyroidism. We keep on observing.
Conclusion
Serum Magnesium level (as well as Calcium level) should be measured in all patients with seizures. Early diagnosis and management of hypomagnesemia with secondary hypoparathyroidism may prevent long-term irreversible neurologic complications.

When to expect a positive parathyroid hormone washout in primary hyperparathyroidism – a single center experience

Mirna Mustapic[1], Jelena Andric[1], Ana Majic[1], Ozana Jaksic[2], Lovorka Derek[3], Tajana Stoos Veić[4] & Vlatka Pandzic Jaksic[1]
[1]Dubrava University Hospital, Department of Endocrinology, Zagreb, Croatia; [2]University of Zagreb, School of Medicine, Zagreb, Croatia; [3]Dubrava University Hospital, Department of Laboratory Diagnostics, Zagreb, Croatia; [4]Dubrava University Hospital, Department of Pathology and Clinical Cytology, Zagreb, Croatia.

Parathyroid localization by fine needle aspiration and parathyroid hormone (PTH) washout measurement is not a widely accepted method because of possible alterations in parathyroid histology. However, when performed with technical competence this easily available method has been praised to be an immediate confirmation of enlarged parathyroid glands found on ultrasound. We retrospectively reviewed primary hyperparathyroidism (PHPT) patients with previously performed PTH washout in pathologically confirmed parathyroid adenoma or hyperplasia. Their biochemical and anthropometric data, the size and location of analyzed parathyroid glands and concordant thyroid sonographic features were collected. Among 48 included patients, PTH washout measurement was available for 51 operated glands. In only 5 cases PTH washout level was lower than patient's serum PTH value. In this analysis we applied a stringent criterion: the ratio between the PTH washout level and serum PTH (PTH W/S) ≥ 2 was considered unequivocally positive. The sample was divided in two groups: 39 cases with positive PTH W/S and remaining 12 cases that did not reach this cutoff. In the comparison between investigated groups there was no difference in serum and urine calcium or PTH elevation. Body mass index, the upper or lower location of parathyroid glands and the presence of concomitant thyroid nodules or ultrasound features of diffuse thyroid disease were not different between groups. The volume and the maximal diameter of enlarged parathyroid glands measured by ultrasound were significantly larger in the group with positive PTH W/S ($P < 0.05$), while the minimal parathyroid diameter was not different between groups. For parathyroids that have a volume lower than 0.145 ml the odds ratio for not obtaining positive PTH W/S was 8.75 (CI 1.47–56.67). Adverse events or later surgical and pathological complications related to PTH washout procedure were not reported. While location, concomitant thyroid disease and patient obesity did not show a significant role in obtaining a positive PTH washout, the size of diseased glands remains the biggest challenge in parathyroid localization. It has significant impact on the accuracy of almost all available imaging methods. Considering that small size might be also associated with multigland PHPT, optimal diagnostic steps should be carefully planned. Doubts about the safety of parathyroid fine needle aspiration need to be finally solved with further analysis in large series of histological specimens.

Management of hypocalcemia after thyroidectomy

Ben Arfi Tayssir, El Abed Wed, Akrout Ines & Gnaba Khalil
Ibn El Jazzar Teaching Hospital of Kairouan, ENT Department, Kairaoun, Tunisia.

Introduction
Hypocalcemia is a well-known complication of total thyroidectomy. Usually, it's a reversible and a transitory complication. However, it requires a regular check-up.
Objective
The aim of this study is to determine the epidemiological and the therapeutic characteristics of hypocalcemia after total thyroidectomy.
Methods
This is a retrospective study about 106 cases of total thyroidectomy that operated between the year of 2010 and 2019 in the ENT department in Kairouan.
Results
The average age was 44.11 [22–76 years] with a sex ratio of 0.1. The determination of serum calcium is done systematically at day 2 or 3 after surgery; earlier on if the hypocalcemia was symptomatic.The incident usually occurs 3 days after surgery. Postoperative hypocalcemia was found in 36 patients (33.9%). Symptoms were found in 20 patients (55.5%): 18 of them presented with paresthesia of the extremities (90%). And the other 2 patients presented with tetany (10%). All patients presented with hypocalcemia were given calcium gluconate and vitamin D orally. The IV supplementation was only given in 22.2% of the symptomatic patients.The treatment took about 2 months on average. And only 6 patients developed definitive hypocalcemia. The multinodular goiter was the most found pathology in the cases of postoperative hypocalcemia (72%). In second place comes the Grave's disease (16%). And in third place, cancer. In our study, 6 patients had total thyroidectomy with lymph node dissection. 4 of them, developed postoperative hypocalcemia.
Conclusion
Hypocalcemia is a frequent complication of total thyroidectomy, needing both, clinical and biological surveillance. Temporary oral supplementation usually does the trick.

Chronic asymptomatic hypocalcemia following thyroid surgery

Mohamed Gharbi, Sabrine Mekni, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Tunis, Tunisia

Introduction
Postoperative hypoparathyroidism is a frequent complication of total thyroidectomy that must be detected and treated. The resulting hypocalcemia is quite severe and usually occurs in the first few days or weeks after surgery.Herein, we describe a case of chronic asymptomatic hypocalcemia related to postoperative hypoparathyroidism diagnosed years after total thyroidectomy.
Observation
We report the case of a 61 year old woman, who had a total thyroidectomy in 1997 for papillary carcinoma and was lost to follow up after surgery. She was referred to the endocrinology department (24 years later) to explore asymptomatic hypocalcemia (1.47 mmol/l) discovered incidentally in a biological check-up. She had no family or personal history of autoimmune disease. Physical examination showed no abnormalities but the electrocardiogram suggested prolongation of the Q-T interval. The patient was treated with i.v. infusion of calcium gluconate. Laboratory tests revealed, a controlling serum calcium: 1.65 mmol/l (55 mg/l), phosphate: 2.56 mmol/l (80 mg/l), PTH levels: 12 pg/ml. Further exploration showed long-term complications of hypoparathyroidism: a Fahr's syndrome on the CT scan of the brain, dental anomalies, bilateral sub capsular cataract but no renal calcifications. The diagnosis of chronic hypocalcemia secondary to postoperative hyoparathyroidism was retained. She was put on calcium gluconate and alfacalcidol.
Conclusion
This case present a rare presentation of chronic asymptomatic hypocalcemia diagnosed 24 years after thyroid surgery and probably due to postoperative hypoparathyroidism.

Artificial intelligence technology for the early diagnosis of osteoporosis in cushing syndrome

Margaret McBride
Lancaster University, School of Medicine & Health Sciences, Bailrigg, United Kingdom

In Cushing syndrome (CS), glucocorticoid-induced osteoporosis is suggested to be the main reason for drug-induced osteoporosis. This health condition creates weaknesses in bones which are then easily fractured.Studies estimate that osteoporosis is under diagnosed in the UK by around *50%*, and according to the International Osteoporosis Foundation 2021, osteoporosis is a major healthcare burden in Europe with 4.3 million fragility fractures and healthcare costs more than 56billion euros annually. Primary prevention rates are very low, and most patients only receive a Dual-Energy X-ray Absorptiometry (DEXA), scan following a first or second fracture. Osteoporosis is one of the most common comorbidities in CS patients.A recent Doctor of Philosophy (PhD) survey of CS members of a support group found 30 (*42%*) of the female members and 1 male member (*6.6%*), had been diagnosed with this condition. Only 12 of them initially had a DEXA scan to confirm their osteoporosis, and *23.8%* reported that they had found an improvement in their condition after being prescribed medical therapy.However, the length of waiting time for a DEXA scan was between 8 months to 2 years. Over *70%* of the women and *40%* of the men in the survey reported bone pain, proximal muscle weakness, and mobility disabilities, and this had impacted on their social, personal, and working lives.The findings from recent clinical trials have shown that by using advanced physics modelling and Artificial Intelligence (AI), methods, accurate measure of bone mineral density from standard digital x-ray (DXR), images, example wrist and hip, can be achieved. This means for the first time, patients who undergo skeletal imaging can be opportunistically assessed for osteoporosis.Interestingly, in this PhD study, *33.3%* ($n=24$), of the other members including males, were referred for skeletal x-ray examinations mainly due to fractures which occurred following their CS diagnosis.AI technology could revolutionize the way in which the early onset of osteoporosis is identified and subsequently lead to earlier treatment and improved quality of life. Additional benefits being a reduction in the socioeconomic cost of long-term treatment for fractures and unnecessary radiation doses to patients. The recommendation from the PhD study being, that more research using AI technology is required and could become an integral part of the diagnostic workup for endocrine patients, thus avoiding the wait for a DEXA scan, as DXR equipment is more readily available.

A comparison of bone densitometry and mineral disorders in hemodialysis patients due to diabetics and non diabetics patients

Ramy Ben Tekaya[1], Haifa Hachfi[1], Mouna Brahem[1], Zahra Sfar[1], Olfa Jomaa[1], Zohra Atii[2] & Mouhamed Younes[1]
[1]University Hospital Tahar Sfar, Rheumatology Department, Mahdia, Tunisia; [2]University Hospital Tahar Sfar, Nephrology Department, Mahdia, Tunisia

Introduction
The chronic kidney disease (CKD) is associated to various bone and mineral disorders.Many studies showed that diabetics influence the bone and mineral metabolism
Aim
To investigate the bone disorder in CKD and the effect of diabetes on bone mineral density.
Methods
This is a cross sectional study conducted in rheumatology department of Taher Sfar university hospital in mahdia, Tunisia. The study involved 61 patients with chronic hemodialysis. They were invited to participate and were included after signing informed consent until the calculated sample size was reached. Patients were asked to undergo a hip and lumbar (L2-L4) densitometry by DXA to measure bone mineral density (BMD).
Results
The studied group of 61 patients was 26 females (42,6%) and 35 males (57.4%), there mean age was 53.9 [17-83] years, with mean dialysis duration 6,1 years. The mean onset age of hemodialysis therapy was 44.7+/- 15.4 years. It was diabetic nephropathy in 25 cases (41%) vascular nephropathy in 15 cases and tubulointerstitial nephropathy in 21 cases (34,4). 23 patients (37,7%) had osteoporosis using the WHO criteria (T-score $<$ -2,5), 26 patients (42,6%) had osteopenia and 12 patients had normal BMD. The mean bone mineral density of lumbar in diabetics patients and non-diabetics patients -1,72 vs -1,43 ($P<0{,}005$). The mean bone mineral density of the hip in diabetics patients and non-diabetics patients -1,83 vs -1,21 ($P<0{,}005$).
Conclusion
Our study showed that chronic kidney disease has an important impact on bone and mineral metabolism. Second our study showed that diabetes can worsen patient bone mineral density.

Regional Migratory Osteoporosis- An under-diagnosed entity

Ashutosh Kapoor & Laxmi Manohar Rao Balmuri
Manchester University NHS FT, United Kingdom

Introduction
Regional Migratory Osteoporosis (RMO) is a rare condition, characterised by a self-limiting migratory arthralgia, which generally tends to involve the lower limbs. The arthralgia is usually, not associated with any history of trauma. Radiologically, Magnetic Resonance Imaging (MRI) is the investigation of choice. Bone Marrow Oedema (BMO) with subchondral sparing are the usual findings in patients with RMO. This condition is usually under diagnosed due to the complexity and lack of classical features.
Case details
We report the case of a 59-year-old gentleman, who presented to his General Practitioner (GP) with traumatic Right second toe pain, accompanied by significant deterioration in Quality-of-life (QOL). On X-Ray, there was no evidence of acute fractures. The symptoms at the time, were managed with analgesia and strapping.Subsequently, a year later, he incurred symptoms of pain and stiffness in the Right third and fourth toes, which was not preceded by a history of trauma. On this occasion, there was involvement of the Right hip as well. In total, at this point his QOL was severely impacted over the course of the last 18 months.He was then referred to the Tertiary sports and exercise specialist, for expert input. An MRI scan detected bone and soft tissue oedema centred on the second and third metatarsal heads involving the surrounding muscles,

subcutaneous tissues and proximal and perhaps the middle phalanges. Mild plantar bone marrow oedema seen of the fourth metatarsal head.The appearances were highly suggestive of RMO, which instigated a referral to Metabolic bone services.A battery of investigations showed normal renal functions, Adjusted Calcium levels, Thyroid status and Vitamin D levels. Extended screening for Coeliac disease, Testosterone deficiency, Multiple Myeloma and Hyperparathyroidism were normal.
Management
A discussion in the Metabolic Bone Multi-Disciplinary setting advised repeat MRI and treatment with Bisphosphonates. The repeat MRI confirmed appearances in keeping with Transient BMO syndrome.Treatment with Intravenous Zoledronate alleviated his symptoms significantly and shortened recovery time, with Improvement in QOL.
Discussion
Till this date, the aetiology of RMO remains unclear. The key to diagnosis lies in a thorough clinical history supplemented by radiological findings. The radiology of RMO resembles Transient Osteoporosis of the Hip (TOH) and thus, the history of migratory arthralgia is key in distinguishing between both entities.Treatment options generally involve repletion of Vitamin D and Calcium levels, where appropriate. Bisphosphonates have been shown to improve symptoms and shorten recovery time.

Osteoporosis in patients with Addison's disease: Incidence and predictive factors

Dhoha Ben Salah, Khouloud Boujelben, Asma Zargni, Faten Haj Kacem Akid, Ameni Salah, Mnif Fatma, Mouna Mnif, Nadia Charfi, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Diabetology and Endocrinology Department, Sfax, Tunisia

Introduction
Because of a long-term glucocorticoid replacement over many years, patients with Addison disease may have an increased occurrence of osteoporosis. Furthermore, the prevalence of osteoporosis in patients with Addison disease may also be increased because of premature menopause associated autoimmune endocrinopathies and hypovitaminosis D.The objective of this study is to assess the incidence and risk factors for osteoporosis among patients with Addison disease.
Patients and methods
A cross-sectional study including 50 patients with Addison disease who had been receiving glucocorticoid replacement therapy for at least 5 years.Bone mineral density of the lumbar spine and both femoral necks was measured on osteodensitometry. The incidence of osteoporosis and its potential predictive factors were analyzed.
Results
Our study included 40 females and 10 males with a mean age of 49,5 ± 13,9 years (18-78 years). Average age at diagnosis was 35,5 ± 14,6 years (0-70 years). All patients were on hydrocortisone replacement, taking mean daily dose of 27,4 ± 6,7 mg (15-42,1 mg) corresponding to 0,388 ± 0,128 mg/kg.Mean cumulative hydrocortisone dose was 374,636 ± 283,821 mg (60 – 1184, 94 mg). No patient received antiresorptive therapy (oestrogen substitution therapy, bisphosphonates) .Low bone mineral density was observed in 24 (48%) patients, 12 (24%) of whom had osteoporosis. No osteoporotic fracture was observed.Patients who developed osteoporosis were significantly older than those with normal bone mineral density were ($P = 0{,}018$). Menopause was a significant predictor of incident osteoporosis ($P = 0{,}006$). Furthermore, osteoporosis was significantly more prevalent among females ($P = 0{,}046$).No statistically significant association was found between osteoporosis and Addison disease duration neither the body mass index.Daily and cumulative hydrocortisone dose were higher in patients with osteoporosis than those with normal osteodensitometry (26,5 ± 8,3 mg/day vs 25,6 ± 6,3 mg/day; 462,2 ± 373,2 mg vs 344,6 ± 245,5 mg) but without statistical significance.
Conclusion
Identification of predictive factors of osteoporosis in patients with Addison disease is useful in the management of long –term glucocorticoid therapy's bone impact. Then, further studies are needed to better analyze these factors and control bone mineral density during the course of Addison disease.

EP207

rhPTH(1-84) treatment-induced increased bone turnover in a young woman with postsurgical hypoparathyroidism

Foteini Adamidou[1], Paraskevi Komzia[1], Gesthimani Mintziori[2] & Marina Kita[1]
[1]Ippokration General Hospital, Department of Endocrinology, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, 1st Department of Obstetrics and Endocrinology, Thessaloniki, Greece

Introduction
rhPTH(1-84) replacement is the treatment of choice in adults with hypoparathyroidism not adequately controlled on standard therapy. Although increased bone turnover markers have consistently been reported in trials of safety and efficacy, marked elevations coupled with significant symptoms have been rare. We describe a case of increased treatment-induced bone turnover, necessitating significant therapeutic adjustments and monitoring.
Case report
A 26-year-old female suffered with severe hypoparathyroidism for 10 years, following total thyroidectomy and incidental parathyroidectomy (three glands) for papillary thyroid cancer (pT1N0). Laboratory values on calcium carbonate 4gr daily, alfacalcidol 3 mg daily, magnesium aspartate 60 mg bid and thyroxine 137 mg/d were as follows: TSH 0.33μIU/ml (0.27-4.7), thyroglobulin <0.1ng/ml (<1), anti-TG negative, corrected calcium 6.5 mg/dl (8.4-10.1), phosphate 6.6 mg/dl (2.7-4.5), Mg 1.61 mg/dl (1.6-2.6), Cr 0.7 mg/dl, ALP 55IU/l (23-104), PTH 5.1 pg/ml (15-65), 25(OH)D 34.9 ng/ml (20-50), $1,25(OH)_2D3$ 29 pg/ml (18-80). Kidney ultrasound revealed nephrocalcinosis bilaterally and 24h urinary calcium was 539.7 mg/24h (<250 mg/24h).Following referral, rhPTH(1-84) 50 mg daily was started and titrated to 100 mg daily within 6 months. The patient discontinued alfacalcidol and remained on 500 mg calcium carbonate and 1000IU cholecalciferol daily, with excellent response.Within a week on 100 mg/d the patient reported severe bone pain in the knee joints and back, paralleled with successive increase in serum ALP at 163IU/l, 221IU/l and 611IU/l (range 23-104IU/l) and bone markers: CTx 1.59ng/ml (0.04-0.6ng/ml), P1NP 623ng/ml (15-60 ng/ml) and osteocalcin 157ng/ml (5.4-59.1ng/ml). Liver function tests and liver ultrasound were normal. rhPTH(1-84) was reduced to 50 mg daily with gradual improvement in bone pain, but with immediate relapse of hypoparathyroid symptoms and worsened biochemical control. ALP levels normalized within 10 weeks to the upper normal range [113IU/l (46-116IU/l)]. Subsequently the dose was up titrated to 75 mg/d, together with calcium carbonate 500 mg bid, magnesium 60 mg bid and alfacalcidol 1 mg/d. She has remained stable clinically and biochemically for the past 6 months. ALP values increased again but are maintained within 10%ULN.
Conclusions
Elevation of bone turnover markers are anticipated by rhPTH(1-84) mechanism of action. However, they remain within normal range in the long term. The etiology for marked symptomatic increase in bone turnover in a minority of patients affecting treatment tolerability is unknown.

Patient with mediastinal mass and hypercalcemia

Katarina Mlekus Kozamernik[1,2], Barbara Salobir[1,2], Marko Hočevar[1,3] & Tomaž Kocjan[1,2]
[1]Faculty of Medicine, University of Ljubljana, Slovenia; [2]University Medical Center Ljubljana, Slovenia; [3]Institute of Oncology Ljubljana, Slovenia

Introduction
Hypercalcemia is mostly caused by primary hyperparathyroidism and malignancy. Parathyromatosis is a rare condition characterized by multiple nodules of hyperfunctioning parathyroid tissue scattered throughout the neck and superior mediastinum, which can present a diagnostic and therapeutic challenge.
Case report
A 56-year-old woman visited the ER due to chest pain, left-sided neck edema, and hematoma. The day before, she experienced left-sided neck pain and dysphagia. Her other complaints were recent weight loss and fatigue. Due to chest pain and high D-dimer level, CT pulmonary angiography was ordered, which showed a large heterogeneous soft tissue formation extending from the left side of the neck over the upper thoracic aperture and over the posterior mediastinum to just above

the esophageal hiatus. The patient was admitted to Respiratory Medicine, where hypercalcemia (serum calcium 3.18 mmol/l; ref. 2.1-2.6 mmol/l) was found. At first, it was thought to be paraneoplastic, and an ultrasound-guided fine-needle aspiration biopsy of the mediastinal formation was performed, which was not diagnostic. FDG PET/CT two weeks after admission revealed a significant shrinkage of the mediastinal formation that showed low metabolic activity. Nothing abnormal was detected elsewhere. Finally, the patient was diagnosed with parathyroid hormone-dependent hypercalcemia (PTH 225 ng/l; ref. 10-65 ng/l) and transferred to Endocrinology. After parenteral hydration and introduction of a calcimimetic, serum calcium level fell to 2.68 mmol/l. Marked hypercalciuria (17 mmol (680 mg)/24 h was found, however, nephrocalcinosis or nephrolithiasis on ultrasound were absent. Bone mineral density was in the range of osteoporosis (T-scores: lumbar spine -2.5 SD, femoral neck -2.6 SD, one-third radius -4.5 SD) with increased bone turnover (bone-specific ALP 59.1 µg/l; ref. 5.5-27.1 µg/l, CTX 3.976 µg/l; ref. 0.142-1.351 µg/l, PINP 50.0 µg/l; ref. 27.7 – 127.6 µg/l). 18F-choline PET/CT showed hyperfunctioning parathyroid tissue at the lower part and behind the left thyroid lobe. A metabolically active process around the esophagus extending caudally to Th3 level was also present. Surgery revealed extensive parathyromatosis at the lower part of the left thyroid lobe and in the neck adipose tissue. Histopathology confirmed extensive parathyromatosis. A surgical cure was not possible, and the patient continued treatment of persistent primary hyperparathyroidism with a calcimimetic. Cholecalciferol supplementation and zoledronate were given for osteoporosis.
Conclusion
We present a patient with mediastinal mass and hypercalcemia, which was first thought to be paraneoplastic. Further diagnostic workup revealed a rare case of spontaneous rupture and hemorrhage of a parathyroid adenoma with subsequent surgically incurable parathyromatosis.

Complications of a rare condition, untreated due to difficult living conditions

Lea Slahor & Henzen Christoph
Luzerner Kantonsspital, Division of Endocrinology/Diabetes, Lucerne, Switzerland

Introduction
Pseudohypoparathyroidism is a rare disorder characterized by end-organ resistance to parathyroid hormone, caused by molecular defects of the PTH receptor. Resulting chronic hypocalcemia and hyperphosphatemia require lifelong treatment with active vitamin D metabolites and monitoring, representing a challenge especially in difficult living conditions.
Case report
A 19-year-old woman presented to our clinic with carpopedal spasms and tetany. Living in Switzerland since 5 years as a refugee from Eritrea, she reported having been treated with "pills" because of an undefined condition diagnosed in her early infancy. Her treatment was inevitably stopped when fleeing her native country and medical reports were not available. Clinical examination was unremarkable (61 kg, 164 cm, BMI 22.7 kg/m^2), normal pubertal development and menstrual history. Her parents and the four siblings were asymptomatic. Laboratory tests showed hypocalcemia of 1.59 mmol/l, serum albumin-corrected calcium 1.35 mmol/l [reference range 2.15-2.55], with an elevated parathyroid hormone (PTH) of 389 pg/ml [reference range 15-65], accompanied by hyperphosphatemia of 1.94 mmol/l [reference range 0.87-1.45] and vitamin D deficiency (25-OH-vitamin D3 17 nmol/l [$<$50]). Renal function, magnesium- and TSH-levels were normal. Hypercalciuria was absent. Brain MRI revealed severe calcification of basal ganglia. Molecular genetic analysis showed reduced methylation at the GNAS gene locus, which, in combination with the unremarkable clinical phenotype, pointed to pseudohypoparathyroidism type 1 B. Treatment with calcium carbonate, cholecalciferol and calcitriol was started and symptoms resolved with correction of serum calcium.
Comment and conclusion
Pseudohypoparathyroidism type 1 B is defined by predominantly renal resistance to parathyroid hormone, resulting in hypocalcemia and hyperphosphatemia with elevated PTH, caused by molecular defects (sporadic or inherited) at the GNAS locus of PTH receptor, a G-protein–coupled receptor (Gsα). As various endocrine receptors depend on stimulatory G-protein-coupled transduction, other hormonal resistance (TSH, gonadotropins, GHRH) can result, typically found in different subtypes in the heterogenous group of pseudohypoparathyroidism disorders. The hormone resistance syndromes, in combination with specific somatic features (round facies, heterotrophic subcutaneous ossifications, brachydactyly) and development abnormalities, were first described by F. Albright in 1942, therefore known as Albright hereditary osteodystrophy. Although a rare disease (estimated prevalence: 0.79/100'000), pseudohypoparathyroidism must be suspected in symptomatic hypocalcemia with elevated PTH. Our case report highlights the importance of correct diagnosis, medical treatment and patient information to avoid potentially fatal consequences. Unfortunately, this was delayed for several years in our patient due to difficult living conditions as a refugee and asylum seeker.

Hypercalcaemia induced acute pancreatitis

Mona Abouzaid & Sony Anthony
North Tees and Hartlepool NHS Foundation Trust, Department of Diabetes & Endocrinology, Stockton on Tees, United Kingdom

Introduction
Milk-alkali syndrome (MAS) consists of hypercalcemia, renal failure, and metabolic alkalosis as a result of ingestion of large amounts of calcium and absorbable alkali. Daily elemental calcium intake of no more than 2 g is considered safe. However, even doses lower than 2 g daily may result in hypercalcemia if additional predisposing factors are present. Vulnerable patients because of vomiting, diuretic use, and deviant eating habits. In these susceptible patient groups, supplementing calcium in a form that contains no absorbable alkali is probably a safer.
Case Presentation
We report a case of a 70 -year-old woman presented in September 2021 with sever lower abdominal pain and confusion. She was diagnosed with acute pancreatitis precipitated by hypercalcemia. Her past medical history of hypertension, gastroesophageal reflux disease. Her regular medications are Atorvastatin and Ramipril. Her husband stated that she has been taking over the counter Deflatine tablets "like sweets" for at least 2 years as an antacid (Deflatine or Rennie tablets contain calcium carbonate and magnesium carbonate). On admission she was found to have very high serum adjusted calcium at 4 mmol/l (2.20 – 2.60), acute kidney injury with EGFR of 15 (her base line EGFR prior to admission was 45) and significantly high lipase and amylase. Her parathyroid hormone PTH level was on the low side at 1 pmol/l (1.3 - 7.3). 25 OH total vitamin D level was 42 nmol/l. CT chest, abdomen and pelvis confirmed the diagnosis of acute pancreatitis, there was no evidence of malignancy or gall stones. She recovered very well with hydration and supportive treatment. Her calcium level normalized after stopping of Deflatine tablets and remained normal up to date.
Conclusion
MAS is believed to be the third most common cause of in-hospital hypercalcemia, after hyperparathyroidism and malignant neoplasms. Hypercalcemia can be severe and, in our patient, caused acute pancreatitis. Renal failure is generally reversible, but impairment in renal function may persist in some cases. Treatment is supportive and involves hydration and withdrawal of the offending agents. Physicians and the public need to be aware of the potential adverse effects of ingesting excessive amounts of calcium carbonate.

Acute confusional state as presenting feature in severe para-neoplastic hypercalcemia

Uzair Akbar Ali, Ghazanfar Iqbal Rana & Summan Jannat
St. Luke's General Hospital, Kilkenny, Ireland

Background
Hypercalcemia is a common clinical problem. Severe hypercalcemia or hypercalcemic crisis is an endocrine emergency and can be life threatening if left untreated. The condition has high mortality and requires immediate therapeutic interventions and diagnostics. A rapid rise to the calcium levels can result in the impaired function of organ systems including central nervous system. Hypercalcemia is mainly (more than 90%) caused by primary hyperparathyroidism or malignant conditions.
Clinical case
A 63-year-old man with background history of alcohol abuse presented to our institution with acute confusional state. Collateral history revealed that he was wandering in the streets. He was found pleasantly confused and disorientated by local police who brought him to the hospital. His physical examination revealed a Glasgow coma scale (GCS) score of 13/15 with no obvious localizing signs or

neurological deficit. Initial investigations showed alcohol levels of less than 10 mg/dl, negative toxicology screen, unremarkable CT brain with normal blood glucose and serum amylase levels. He had decreased urinary output of 15-20 ml/hr with normal renal function but raised calcium levels of 3.72 mmol/l (2.20-2.60) and low phosphate levels of 0.77 mmol/l (0.8-1.5).He was treated as hypercalcemic crisis with intravenous fluids and given intravenous bisphosphonate (zolendronic acid 4 mg) in critical care unit. His calcium levels started decreasing with the treatment and his conscious level significantly improved. The diagnostics included low PTH levels with value of 6.7 pg/ml (15-65) and CT of thorax, abdomen and pelvis which revealed a left renal lesion of 15 x 12 cm^2 infiltrating into anterior and posterior perinephric soft tissue.He was referred to urology department for further investigations. Histopathology of renal biopsy specimen showed renal cell carcinoma and graded as advanced renal cancer (Stage IIIc). Unfortunately, due to his baseline status and compliance issues he was not deemed a candidate for surgery or systemic therapy and advised consideration for palliative approach.

Conclusion

The case illustrates the need to carefully review the differentials of hypercalcemia and consider immediate treatment interventions in situations of severe hypercalcemia or hypercalcemic crisis. Renal cell carcinoma should be considered as possible causative in hypercalcemia of unknown underlying pathology.

A rare case of Pseudohypoparathyroidism

Natia Shonia & Nino Zavrashvili
Tbilisi Institute of Medicine, Endocrinology, Tbilisi, Georgia

Background

Pseudohypoparathyroidism includes a genotypically diverse group of syndromes of primary resistance to hormones whose actions are mediated by cyclic adenosine 3': 5'-monophosphate, in most cases caused by mutations and/or epigenetic changes at the complex GNAS locus on chromosome 20q13.3.Renal resistance to PTH leads to impaired formation of 1,25(OH)2D, the fully active form of vitamin D, and reduces expression of sodium-dependent phosphate transporters in the renal tubules, leading to hypocalcemia and hyperphosphatemia, with elevated serum PTH levels.Patients with PTHT clinically manifest with tetany seizures, soft tissue calcifications and many congenital malformations.Early diagnosis and vitamin D3 or calcium treatment seem to be the most important for patient's condition.

Case

We describe a case of possible sporadic pseudohypoparathyroidism type II, confirmed hashimoto thyroiditis, iron deficiency anemia, chronic erosive gastritis. 28 year old Caucasian female visited our clinic with complaints of frequent hospitalizations due to seizures and tetany since December 11, 2021. Patient was hospitalized at least 4 times and required Ca infusions. Patient complained of mild, intermittent and self-limited paresthesias, persistent asthenia, tachycardia, arrhythmia since early years. She had been diagnosed at the age of 6 with hypocalcemia and possible pseudohypaparathyroidism, but diagnosis was not verified by genetic test. Initial lab investigation showed elevated PTH- 334.3 (15-65) pg/ml, hypocalcemia (iCa-0.73 (1.15-1.29) mmol/l) hyperphosphatemia (*P*-2.03 (N0.81-1.45) mmol/l), hypocalciuria (<0,2 mmol/l (N2,5-7,5), decreased bone mineral density on Dexa Scan - T score L2=-2.4. Combined calcium and calcitriol supplementation was commenced, with symptomatic and laboratory improvement. Couple days after initiating Ca supplements and calcitriol, we achieved laboratory and clinical improvement (Ca-1.93 (2.15-2.5) mmol/l, p-1.85 (0.81-1.45) mmol/l (18.01.2022), Mg- 0.65 mmol/l (0.6-1.07)).Molecular identification is ordered and will be presented.

Conclusion

With initiated treatment, we hope for complete resolution of patient's complaints and attaining symptomatic remission. A careful follow-up is needed to avoid complications and recurrence. Once correction of hypocalcemia and hyperphosphatemia is achieved, with no reported complications and recurrence, a good prognosis is anticipated, comparable to the general population.

Primary hyperparathyroidism – experience of a single center

Ana Rita Elvas, Joana Couto, Raquel G. Martins, Jacinta Santos, Teresa Martins & Fernando Rodrigues
Portuguese Oncology Institute of Coimbra, Department of Endocrinology, Coimbra, Portugal

Introduction

Primary hyperparathyroidism (pHPT) is the most common cause of hypercalcemia in the outpatient setting and is a frequent endocrine disorder. Large cohort studies of pHPT patients in the Portuguese population are scarce.

Aim

To characterize patients with pHPT followed at a tertiary center.

Material and Methods

Retrospective analysis of clinical records of patients with pHPT followed in our hospital from 2003 to 2021.

Results

A total of 177 patients were included, 82.5% were female. The mean age was 61±13.6 years. In 79.6% of the cases, hypercalcemia was detected in a routine analysis. Some patients had complaints of muscle and/or bone pain (33.3%), asthenia (27.6%) and polydipsia and polyuria (15.5%). 124 (80%) patients had DXA scan done out of which 37.4% had osteoporosis and 28.5% had osteopenia. History of fragility fractures was seen in 9.4% of the patients; nephrolithiasis was present in 37.5%; hypercalciuria (>400 mg/24h) in 17.1% and renal function impairment in 7.0%. At diagnosis, the mean ionized calcium, total calcium, phosphate, parathormone and 25-OH D levels were 1.44±0.17 mmol/l; 11.52±1.20 mg/dl; 2.71±0,62 mmol/l; 333.90±891.80 pg/ml and 20.61±10.ng/dl, respectively. 14 (7.9%) patients presented normocalcemic pHPT. Neck ultrasound and sestamibi scan detected parathyroid disease in 53.7% and 81.5% of the cases. 111 patients (62.7%) underwent surgical treatment, only two patients with pHPT normocalcemic. Pathological examination revealed a parathyroid adenoma (PT) in 65.5%, atypical adenoma 5.4%, hyperplasia 14.5%, carcinoma 9.0% and no parathyroid tissue in 6.3% of the patients. Right inferior parathyroid gland was the most common site of PT. A >50% decline of PTH 10-15 minutes after gland excision was observed in 80.8% of the patients. Post-operative transient and permanent hypocalcemia was observed in 52.4% and 8.5% of the cases. After PT surgery, the cure rate was 84.8%. Persistence and recurrence disease rates were 9.9% and 3.6% respectively. Hereditary forms of hyperparathyroidism were present in 11 patients: MEN-1 in 4 (2.3%) patients and MEN2A in 7 (4.0%). Somatic CDC73 mutations were found in 3 patients with PT carcinoma.

Conclusion

To the best of our knowledge this is the largest cohort of patients with pHPT in Portugal. Despite the diagnosis being mostly incidental with most patients presenting mild hypercalcemia, some were found to have evidence of skeletal and renal manifestations of the disease.

Risk factors associated with bone loss in patients with Addison disease

Dhoha Ben Salah, Khouloud Boujelben, AbdelMouhaymen Missaoui, Mouna Elleuch, Mnif Fatma, Mouna Mmnif, Nadia Charfi, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Sfax-Tunisia, Department of Endocrinology, Diabetology

Introduction

Even at physiological doses, glucocorticoid replacement therapy may lead to deleterious outcomes on bone mineral density (BMD).The aim of our study was to investigate the BMD in Tunisian patients with Addison disease and to identify the risk factors associated with its decline.

Patients and methods

The study included 50 patients diagnosed with primary adrenal disease (Addison disease). BMD was assessed by the dual -energy -X-ray absopitometry. Predictive factors of reduced BMD were analyzed.

Results

The mean age of patients was 49,5±13,9 years and 40 patients were female;42,5% menopausal. Disease duration was 13,9±8,7 years.). All patients were on hydrocortisone replacement, taking daily 27,4±6,7 mg (15-42,1 mg) corresponding to 0,388±0,128 mg/kg. Hypovitaminosis D was observed in 66% of patients. Twenty percent of patients had a higher than normal level of parathyroid hormone (PTH).The BMD was significantly reduced in 48% of patients. Three patients presenting congenital adrenal hyperplasia had normal

BMD.A significant higher incidence of reduced BMD was observed among menopausal women ($P=0,049$). Moreover, a higher mean PTH level was found in patients with decreased BMD but without statistically significant difference ($56\pm21,8$ pg/ml vs $48,1\pm25,4$ pg/ml;$P=0,1$).A lower mean vitamin D level was also found among those patients ($19\pm10,2$ ng/ml vs $25,2\pm16$ ng/ml).Cumulative hydrocortisone dose was higher among patients with reduced BMD compared to those with normal BMD, without statistical significance ($408,9\pm324$ mg vs $338,9\pm236$ mg;$P=0,7$).No significant correlation was identified between decreased BMD and duration of glucocorticoid substitution.
Conclusion
Bone loss is frequent in patients with Addison disease taking long-term glucocorticoid therapy and related to many factors affecting bone remodeling such as hydrocortisone dose and vitamin D deficiency. It seems imperative to ensure long-term follow-up of changes in BMD in patients with Addison disease.

Pregnancy and lactation-associated osteoporosis

Zvezdana Jemuovic, Marina Nikolic Djurovic, Sandra Pekic Djurdjevic, Dragana Miljic, Marko Stojanovic, Mirjana Doknic, Ana Petakov & Milan Petakov
Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center of Serbia, Department of Neuroendocrinology, Belgrade, Serbia

Introduction
Pregnancy and lactation-associated osteoporosis (PLO) is a rare condition in which women have fragile fractures associated with significant reduction of BMD during pregnancy or postpartum period.
Case report
A 37-year-old female patient was admitted at our Clinic for further investigation of aetiology of osteoporosis in July 2019. Soon after delivery in February 2019 patient had felt left hip and foot pain as well as sharp intensive pain (intensity 9/10) in thoracic spine with propagation anteriorly into intercostal spaces. Pain was increased during body position changes, and was alleviated with ibuprofen intake. She also complained on morning stiffness. MRI of thoracic spine was performed in June and it showed irregularly decreased height of thoracic vertebrae 7 and 8, which seemed as compressive fractures. Osteodensitometry showed osteoporosis with total T-score of spine -2.8 (L3 -3.1), Z-score -2.6(L3 -3.0) and osteopenia of the hip with T-score of neck of the femur -1.1, Z-score -1.1. Trabecular bone score indicated preserved microarchitecture of bones. On admission she complained of malaise, cold hands and feet, tingling in legs and dry mouth with occasional problem swallowing solids and liquids. First menstrual period after the delivery was in July and it is also when she stopped breast-feeding. In the previous years she had a spontaneous miscarriage and 3 tries of insemination. During 1st trimester she was on progesterone therapy. She had an operation of myoma in 2015. Her family history is positive for CVD, DM, and lung carcinoma. Patient is a smoker (did not stop during the pregnancy). Full laboratory workup showed normal calcium and PTH levels, with vitamin D insufficiency. Thyroid hormones, FSH, LH, prolactin, testosterone, and cortisol were within normal reference range as well as electrophoresis of proteins, tumour markers, Bence-Jones protein. Vertebral fracture assessment indicated crush fracture of L4. After all workup, we concluded that this is a case of pregnancy and lactation -associated osteoporosis and we advised vitamin D 2000IU, calcium-carbonate 1000 mg. In December 2019, she received a first dose of zolendronic acid. On a first check-up 6 months later, X-ray of thoracic spine was performed and it showed new pathological fractures of toracic vertebra 9 and 11 so she received 2nd dose of zolendronic acid. Third dose was applied in December 2021. Next osteodensitometry is scheduled for March 2022.
Conclusion
PLO is a rare condition and it should be considered as differential diagnosis in patients with back pain during or after pregnancy.

Association of primary hyperparathyroidism and papillary thyroid Cancer: a case report

Gorgi Khaoula, Mhamdi Zineb, Lamya Echchad, Rifai Kaoutar, Iraqi Hinde & Gharbi Mohamed El Hassan
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Primary hyperparathyroidism is a common pathology. The association of papillary thyroid carcinoma and primary hyperparathyroidism has been reported in 2.3–4.3% of patients operated on for primary hyperparathyroidism.We report the case of a patient with papillary thyroid carcinoma revealed by primary hyperparathyroidism
Observation
53-year-old patient admitted for management of primary hyperparathyroidism. A cervical ultrasound revealed a right subthyroid tissue nodule suggestive of a parathyroid adenoma associated with a multiheteronodular goiter classified as eutirads 3-5. The cervical scan shows 2 lobar nodules, upper and lower right. Thyroid scintigraphy confirmed the upper and lower right parathyroid originthe patient benefited from an upper and lower adenomectomy + total thyroidecto-my.The anatomopathological study was in favor of a parathyroid adenoma associated with a papillary thyroid carcinoma
Discussion &Conclusion
The coexistence of papillary thyroid carcinoma and hyperparathyroidism is thought to be rare. The mechanisms underlying this association have not been established. A possible hypothesis is suggested for this relationship based on shared embryological origin and genes, high parathyroid hormone, low 1,25 hydroxy vitamin D, hypercalcemia resulting in high levels of angiogenic growth factors.The presence of these two diseases can complicate patient management due to untreated hypercalcemia, unrecognized thyroid cancer and need for second surgery if not screened for both diseases carefully

Results of denosumab used in postmenopausal women

Yana Navmenova[1], Elena Makhlina[2], Tamara Moskvicheva[1], Nelli Chernova[1] & Irina Savasteeva[1]
[1]SI «The Republican Research Center for Radiation Medicine and Human Ecology», Gomel, Belarus, Endocrinology, Gomel, Belarus; [2]Gomel State Medical University, Internal Medicine No. 1 with courses in Endocrinology and Hematology, Gomel, Belarus

The aim of the study was to assess the effectiveness of postmenopausal osteoporosis (PMOP) therapy with denosumab.Patients and methods 32 postmenopausal women with established PMOP for a period of 24 months or more received denosumab 60 mg subcutaneously once every 6 months combined with calcium and vitamin D. A quantitative assessment of bone mineral density (BMD) was carried out before treatment, after 12 and 24 months of observation, using dual-energy X-ray absorptiometry of the lumbar spine (LI – IV) and femoral neck (FN) on the right and left. Changes in the severity of pain were assessed using a visual analogue scale (VAS), the severity of the pain syndrome was assessed before treatment, after 12 and 24 months of observation.Statistical processing was carried out using the SPSS 23.0 software package.
Results and Discussion
The average age of women included into the study was 61.76 (59.35; 68.47) years. The average age at the onset of menopause was 47.52 (43.13; 49.83) years, the average duration of menopause at the time of the study was 12.64 (10.10; 21.62) years.The median values of the T-score in LI-IV before, after 12 and 24 months of treatment were, respectively: «-»2,5/«-»2.1/«-»1.85 ($P<0,0001$).The median values of the T-score in the FN on the right before and after 12 months of treatment were "-"1.9/"-"1.7 ($P=0.07$); The median values of the T-score in the FN on the left before and after 12 months of treatment were "-"1.9/"-"1.5 ($P=0.04$).The median values of the T-score in the FN on the right before and after 24 months of treatment were "-"1.9/"-"1.5 ($P=0.012$); The median values of the T-score in the FN on the left before and after 24 months of treatment were "-"1.9/"-"1.4 ($P=0.01$).The median values of pain severity according to VAS before, after 12 and 24 months of treatment were 5.5/4/2 points, respectively ($P<0.0001$).After 24 months of using denosumab, the mineralization indices of all the studied localizations significantly improved in comparison with the initial data.

Conclusions
Therapy with denosumab 60 mg subcutaneously 2 times a year with an interval of 6 months for 24 months in combination with calcium and vitamin D made it possible to significantly increase the BMD of the lumbar spine and significantly reduce the severity of pain syndrome according to VAS.

Is obesity detrimental to postmenopausal bone health?

Radina Dimitrova[1], Mila Boyadzhieva[1], Kiril Hristozov[1] & Yana Bocheva[2]
[1]MU Varna, Second Department of Internal Medicine, Varna, Bulgaria; [2]MU Varna, Department of Clinical Laboratory, Varna, Bulgaria

Introduction
Despite available evidence for a relationship between bone health and obesity, the results of clinical trials remain conflicting. Thus, we conducted a cross-sectional study to analyze possible associations between waist circumference (WC), body mass index (BMI) and body weight (BW) with bone health in postmenopausal women.
Materials and Methods
The study included 84 women from Northeastern Bulgaria. Their mean age was 60.54 ± 7.07 years, and their mean duration of menopause was 11.45 ± 6.62 years. Bone health was assessed by dual-energy X-ray absorptiometry (DEXA), analysis of bone metabolic markers and fracture risk calculation.
Results
According to BMI 31% of the subjects were with normal weight, 50% were overweight and 20% were obese. In 82% of the women WC was over 80 cm. Significant positive correlations of bone mineral density (BMD) with **WC** (L1-L4 $r=0.264$; $P=0.015$, Femoral Neck $r=0.338$; $P=0.002$, Total Neck $r=0.393$; $P < 0.001$), **BMI** (L1-L4 $r=0.295$; $P=0.006$, Femoral Neck $r=0.223$; $P=0.042$, Total Neck $r=0.330$; $P=0.002$) and **BW** (L1-L4 $r=0.446$; P 0.001, Femoral Neck $r=0.409$; P 0.001, Total Neck $r=0.457$; P 0.001) were found. However, after BW adjustment the correlations of BMD with WC and BMI became insignificant. Moreover, a negative association was found between Femoral Neck BMD and BMI after BW adjustment ($r=-0.260$; $P=0.018$). On the other hand, the positive relationship between BMD and BW remained significant after WC and BMI adjustment. In addition, WC was inversely related to osteocalcin ($r=-0.217$; $P=0.048$) and Beta CrossLaps ($r=-0.226$; $P=0.039$). Nevertheless, a positive relationship was found between WC and pyrilinks D/creatinuria ratio ($r=0.277$; $P=0.011$), but it was associated with higher eGFR in obesity. Furthermore, higher BW was noted as a significant negative predictor of the 10-year risk of major osteoporotic fracture (MOF) ($\beta=-0.730$, P0.001) and hip fracture (HF) ($\beta=-0.730$, P0.001), but positive associations were found between BMI and the both fracture risks (for MOF $\beta=0.532$, $P=0.009$; for HF ($\beta=0.441$, $P=0.026$).
Conclusion
We assumed that obesity might be detrimental to postmenopausal bone health, as it was associated with lower BMD, lower bone turnover and higher fracture risks.

Endocrine disorders and osteoporosis: case series

Meriem Adel, Sabrine Mekni, Maysam Jridi, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Homeostasis of calcium and phosphor influence bone metabolism. They depend on several hormones, including parathyroid hormone, thyroid and sexual hormones. Low bone mass seems a common issue in endocrine disorders. The aim of this study is to identify the different endocrine disorders in patients with low bone mass.
Methods
Retrospective study collecting the medical files of patients followed in the endocrinology department of Charles Nicolle Hospital between the years 2018 and 2021. The exclusion criteria are: patients followed for a systemic disease or rheumatic disease and patients who received corticosteroid therapy.
Results
We have studied 50 consecutive patients (14 males, 36 females, sex ratio 0.38, aged 8-88 years). Postmenopausal women represented 56% of the study population.We measured bone mineral density (BMD) at the hip: 70% of patients had osteoporosis (36% males, 64% females) and 30% had osteopenia (12% males, 88% females). The average of T score was -2,78 (min -6; max 0.8) for the spine and -2,09 (min -4,7;max 0,7) for the femur neck with a significant correlation between them. 44% of patients were at a risk of fracture and 2% had a pathological fracture. According to the type of endocrinopathy: 62% of patients had hyperparathyroidism (63,3% osteoporosis; 36.7% osteopenia), 12% had hypogonadotropic hypogonadism (85,7% osteoporosis; 14,3% osteopenia), 10% had hyperthyroidism, 8% had primary ovarian insufficiency (25% osteoporosis; 75% osteopenia) and 2% had hyperadrenocorticism (50% osteoporosis; 50% osteopenia).
Conclusion
Additional studies are needed to further understand the endocrine secondary osteoporosis in order to establish evidence based guidelines about its diagnosis, evaluation, treatment and follow up.

IPN60130 for the treatment of fibrodysplasia ossificans progressiva: methodology of the randomized, double-blind, placebo-controlled phase II FALKON trial

Negar Karimian[1], Christine Powell[2] & Fei Shih[2]
[1]Ipsen, Montreal, Canada; [2]Ipsen, Cambridge, MA, United States

Objectives
Fibrodysplasia ossificans progressiva (FOP) is an ultra-rare genetic disorder caused by activin receptor-like kinase-2/activin A receptor type 1 (*ALK2/ACVR1*) mutation and characterized by heterotopic ossification (HO) inducing progressive restriction of mobility. IPN60130 is a selective ALK2/ACVR1 inhibitor being investigated for the treatment of FOP.[1] Here, we describe methodology of the FALKON trial (NCT05039515) designed to compare efficacy and safety of IPN60130 with placebo in patients with FOP.
Methods
Patients will be randomized to oral placebo, or low or high dose IPN60130 for 12 months; patients receiving placebo will then transition to IPN60130 for 12 months. Enrollment criteria include: ≧5 years old, clinical FOP diagnosis with disease-causing mutation, and either a flare-up, new HO or joint ankylosis, or increase in Cumulative Analogue Joint Involvement Scale (CAJIS) score in the prior year. Recruitment is ongoing to enroll 90 patients. The primary efficacy outcome will be annualized change from Baseline in HO volume to Month 12, assessed by low-dose whole-body computed tomography (CT). Secondary efficacy outcomes are presented in the **Table**. Safety will be assessed via adverse event (AE) and serious AE incidence over 25 months. Patients aged ≧15 years will be eligible for a sub-study assessing HO by [^{18}F]NaF positron emission tomography-CTT.

Table 1 Secondary efficacy outcomes

Timeframe, months[a]	Outcome	Comparison
12	CfB in volume of new HO lesions[b] CfB in number of HO lesions[b] Flare-up rate; number of flare-up days Number of body regions with new HO CfB in pain intensity Proportion of patients with new HO	IPN60130 vs placebo
24	CfB in HO volume[b]	IPN60130 vs placebo and untreated natural history study (NCT02322255) participants

[a]From Baseline up to the month given; [b]Assessed by low-dose whole-body computed tomography. CfB: change from Baseline; HO: heterotopic ossification.

Summary
Results from FALKON, estimated to complete in August 2025, will allow evaluation of the efficacy and safety of IPN60130 in patients with FOP.

Brown tumour of the mandible as the first manifestation of primary hyperparathyroidism: a case report

Ana Majic[1], Maja Cigrovski Berkovic[1], Ivan Zajc[2] & Ivan Salaric[2]
[1]Clinical Hospital Dubrava, Department of Endocrinology, Diabetes, Metabolic Diseases and Clinical Pharmacology, Zagreb, Croatia; [2]Clinical Hospital Dubrava, Department of Oral Surgery, Zagreb, Croatia

Introduction
Brown tumour is a rare, benign, tumour-like lesion of bones.The presence of brown tumour is a rare complication of uncontrolled primary, secondary or tertiary hyperparathyroidism.Brown tumours can be solitary or multifocal and are most commonly located in ribs, clavicles, pelvic girdle, extremities and facial bones (maxilla, mandible, and hard palate).A diagnosis of brown tumour in hyperparathyroidism is established by evaluation of serum calcium, phosphorus and parathyroid hormone levels. Very often a histologic diagnosis of a giant cell tumour is made in case of brown tumour.Treatment of these lesions is often directed to the management of the underlying hyperparathyroidism, which frequently results in regression and resolution of the lesion without surgical intervention. However, surgical treatment may be required in refractory cases or in large symptomatic lesions.
Case presentation
A 67-year-old male was referred to an oral surgeon for a right mandible mass and bleeding that was present for approximately one year. The patient's past medical history was significant for recurrent nephrolithiasis.An incisional biopsy of the mass was performed and histologic examination suggested giant cell granuloma. Despite the histologic diagnosis, the experienced oral surgeon suspected brown tumour in hyperparathyroidism. The patient was referred to an endocrinologist and additional evaluation was performed.A laboratory examination showed hypercalcemia: total calcium level of 2.94 mmol/l (normal range: 2.14 – 2.53), ionized calcium level of 1.61 mmol/l (normal range: 1.18 – 1.32), hypophosphatemia: 0.66 mmol/l (normal range 0.79 – 1.42) and a high PTH level: 44.02 pmol/l (normal range: 1.59 – 7.24).The patient's renal function was normal and kidney ultrasound revealed mild bilateral nephrocalcinosis without nephrolithiasis. Bone density test revealed osteoporosis.Neck ultrasound revealed an enlarged parathyroid gland and Tc-99 m MIBI SPECT/CT imaging of the neck and mediastinum showed pathological radiopharmacology uptake posterior of the left thyroid lobe compatible with a parathyroid adenoma.The patient underwent left inferior parathyroidectomy and the pathological findings confirmed the diagnosis of parathyroid adenoma.After one-year follow-up, serum calcium, phosphorus and PTH levels were normal. The excision of the remaining exophytic mandible mass was carried out by an oral surgeon due to slow bone healing.
Conclusion
Brown tumour can be the first manifestation of uncontrolled primary hyperparathyroidism, often misdiagnosed as a giant cell tumour. It is an important differential diagnosis in the evaluation of patients with osteolytic bone lesions, with serum calcium, phosphorus and parathyroid hormone measurements being helpful and widely available diagnostic tools.

Malignant hypercalcemia showing parathyroid adenoma in a patient with renal impairment

Tizgha Mohamed[1,2]
[1]Faculty of Medicine Mohamed Maherzi, Medicine, Algier, Algeria; [2]El Djazair, Medicine, El Djazair, Algeria

Introduction
hyperparathyroidism is usually diagnosed at a pauci or asymptomatic stage. However, in rare cases, the diagnosis is made at the stage of major threatening hypercalcemia. This diagnostic delay may be responsible for complications such as chronic end stage renal disease (CRRD).
Observation
we report the case of a 64-year-old patient referred to the endocrinology department for primary hyperparathyroidism, with no particular family history and a personal history of type 2 diabetes mellitus known for 14 years, high blood pressure and renal lithiasis performed 14 years ago (without etiologic exploration) . Hyperparathyroidism was discovered following a review commissioned by the nephrologist for the exploration of malignant hypercalcemia. The clinical examination revealed major signs of hypercalcemia and a large cervical nodule. Biology: PTH >560 pg/ml twice with serum calcium >130 mg/l, renal balance: clearance at 24 ml/min. This CKD has long been considered secondary to diabetic nephropathy while it was strongly in favor of interstitial nephropathy due to chronic hypercalcemia due to the absence of diabetic retinopathy. Cervical ultrasonography: 45 mm parathyroid macro-nodule. The patient received hyperhydration and injectable biphosphonates 30 times (Bondronate: the only one listed in the CRI) before referring him to surgery.
Discussion
malignant hypercalcemia is a sign of severity in primary hyperparathyroidism, hence the value of screening for asymptomatic forms to avoid life-threatening complications

A pathological fracture of the femur and multiple pelvic osteolytic lesions mimicking bone metastases as the first presentation of Primary Hyperparathyroidism

Haris Khan[1], Maimoona Nawaz[2], Cuong Dang[1] & Isha Malik[1]
[1]North Manchester General Hospital, Crumpsall, United Kingdom; [2]Fairfield General Hospital, Manchester, United Kingdom

Introduction
Pathological fractures are uncommon in young patients and raise concern about malignancy. Brown tumour (osteitis fibrosa cystica) is a rare benign resorptive bone lesion reported in approximately 3% of patients with primary hyperparathyroidism (PHPT). These have become uncommon in contemporary practice and have the potential to be misdiagnosed because of radiological similarities to other bone diseases especially malignancy.We present a case where the first presentation of PHPT was a fracture of the left femur with multiple pelvic lesions masquerading as a metastatic malignancy.
Case Report
A 47-year-old male patient presented to the emergency department with sudden sharp pain in his left hip. He was unable to weight bear. He had been suffering from chronic hip pain for the last few weeks. On examination, he had no active movement in the left hip. X-ray showed left superior pubic rami fracture. An MRI scan revealed a left neck of femur fracture with multiple osteolytic lesions in the pelvis. A differential diagnosis of metastases was suggested. He was subsequently diagnosed to have PHPT confirmed by high serum calcium, 3.28 mmol/l (2.10-2.60), serum phosphate 0.73 mmol/l (0.8-1.45), PTH 162.7 pmol/l (1.2-6.9), and Vitamin D 26.7 nmol/l (>50). A parathyroid sestamibi scan revealed a large right posterior inferior adenoma measuring $41\times15\times13$ millimeters. His pelvic lesions and fractures were attributed to Brown tumour secondary to PHPT. He had a left intramedullary nail inserted for left hip repair. His parathyroid adenoma was excised following correction of vitamin D levels. He was transferred to the high dependency unit in anticipation of 'hungry bone syndrome' post-surgery. His calcium level dropped to 1.67 mmol/liter. It was treated with intravenous calcium and activated vitamin D (alfacalcidol). He recovered well and subsequent imaging showed good healing of the fractures and mobility returned to normal.
Conclusion
Brown tumours are rare diagnostic findings in developed countries due to routine monitoring of calcium levels and early detection of PHPT.The presentation of pathological fracture as the first presentation of PHPT as in our case is exceedingly rare. It highlights that once a diagnosis of pathological fracture is made, metabolic bone diseases (such as PHPT and osteomalacia) should be investigated. Brown tumours should be in the differentials of patients presenting with bone tumours, to avoid unnecessary invasive investigations.A timely good outcome in this patient was achieved by collaboration between endocrinologists, endocrine and orthopaedic surgeons, and intensive care.

Intrathyroidal parathyroid adenoma: a rare localization

Rihab Laamouri[1,2], Raccolta Niculina[2], Stahl Ninon[1], Lerintiu Felix[2], Caro Lopez Rita[2] & Smagala Agnès[2]
[1]University of Medicine of Strasbourg, Strasbourg, France; [2]Hospital Louis Pasteur, Colmar, France

Primary hyperparathyroidism is a frequent endocrine disorder but intrathyroidal parathyroid adenoma is extremely rare. Combining cervical ultrasound and MIBI scintigraphy allows localizing most parathyroid adenomas. Because intrathyroidal parathyroid adenomas mimic thyroid nodules the diagnosis can be challenging, requiring eventually the realization of a fine-needle cyto-puncture. We report here a case of an intrathyroidal parathyroid adenoma diagnosed via a combination of cervical ultrasound, cyto-puncture and MIBI scintigraphy.A 47-year old female was addressed by her GP for diarrhea and asthenia associated with a 3.3 mmol/l hypercalcemia. Biologic assessment confirmed hypercalcemia associated with hypophosphatemia and elevated PTH, confirming primary hyperparathyroidism. The patient did not present ECG modifications. Abdominal ultrasound did not find renal lithiasis and osteopenia was found on DXA. Hypercalcemia was managed with iv hydration, bisphosphonate iv perfusion and Cinacalcet oral treatment. Cervical ultrasound did not find any parathyroid adenoma but showed a 24x18x15 mm, regular, smooth border, hypoechoic EUTIRADS 4 inferior nodule in the right lobe. Scintigraphy concluded to a MIBI focal uptake behind the lower part of the right thyroid lobe. A cyto-puncture of the thyroid nodule was performed and concluded to the presence of parathyroid tissue. The patient underwent right lobectomy. Pathological analysis confirmed an intrathyroidal parathyroid adenoma.Intrathyroidal parathyroid adenoma remains a rare entity. Different case reports and studies confirm the most common ultrasound features being a solid hypoechoic nodule, smooth and regular shaped, like the adenoma presented by our patient. One feature that is extremely characteristic for the intrathyroidal parathyroid adenoma is the presence of a hyperechoic line on the ventral surface of the adenoma, feature that was not identified for our patient. Nevertheless, as these intrathyroidal adenomas mimic suspicious thyroid nodules, cyto-puncture is frequently performed before any surgery and helps confirm the diagnosis, as in our case.

Osteitis fibrosa cytica as index presentation of severe vitamin D deficiency

Mohammad Jeeyavudeen[1], Anca Oniscu[2], Matthew Hicks[3] & Ganesh Arunagirinathan[1]
[1]Edinburgh Centre for Endocrinology & Diabetes, Western General Hospital, Edinburgh, United Kingdom; [2]Department of Pathology, Royal Infirmary Of Edinburgh, Edinburgh, United Kingdom; [3]Department of General Medicine, Western General Hospital, Edinburgh, United Kingdom

Introduction
Osteitis fibrosa cystica (OFC) or brown tumour is a non-neoplastic fibrocystic expansile lytic bone lesion caused due to excess parathormone (PTH). Brown tumour is classically known to occur in severe primary or secondary hyperparathyroidism due to end-stage renal failure with very high PTH level. OFC presenting as a mass due to nutritional vitamin D deficiency (NVD) is exceedingly rare.
Case presentation
47-year-old Caucasian gentleman presented with symptoms of generalised bone pain, particularly in the back and right knee progressing over two years with declining mobility but denied tingling, numbness or spasm. He is a strict vegetarian by choice with a significant past history of Vitamin B12 deficiency anaemia. Clinical examination revealed profound kyphoscoliosis causing 19 cm height loss and a warm tender 6 cm swelling arising from the lateral aspect of proximal right tibia. He had diffuse tenderness in the pelvis and lumbar spines and exhibited positive Gower's sign. Serum bone profile is shown belowImaging studies confirmed a cavitating lesion in the tibia and several areas of lytic lesion at other bony sites. In view of radiological suspicion of malignancy, biopsy of the tibial lesion was performed which showed extensive bone remodelling with areas of cellular and focally haemorrhagic stroma rich in osteoclast giant cells consistent with brown tumour. He was treated with high dose intramuscular Ergocalciferol and went on to develop hungry bone syndrome, requiring parenteral calcium infusion.

	Patient's value	Normal range
Adjusted calcium	2.24	2.2- 2.6 mmol/l
Phosphate	0.61	0.8-1.4 mmol/l
Alkaline phosphatase	1988	40-125 U/l
PTH	85	1.6-6.9 pmol/l
25(OH) Vitamin D3 $^{\Psi}$	<14	50-170 nmol/l
eGFR*	>60	
Myeloma and coeliac screen	Negative	

Ψ- 25 hydroxy vitamin D3, *-estimated glomerular filtration rate

Discussion
NVD induced brown tumours are extremely rare in the developed world due to fortification of food,. Hence only a handful of cases are reported in high risk individuals with poor dietary intake, malabsorption disorders and poor exposure to sunlight due to dressing habit. This gentleman was house-bound and completely lacked vitamin D containing foods in his diet for several years leading to this unusual presentation. Radiologically, OFC can be challenging to distinguish from primary bone tumor. Bone biopsy remains the gold standard for diagnosis. The mainstay of treatment is medical with correction of vitamin D and calcium supplementation during the acute phase to prevent hungry bone syndrome. Thorough education and long-term maintenance with Vitamin D supplements should be pursued in high risk individuals.

Non-functioning parathyroid cystic tumour: a diagnostic and therapeutic challenge

Moncef Sellami, Wadii Thabet, Malek Mnejja, Bouthaina Hammami, Souha Kallel & Ilhem Charfeddine
Habib Bourguiba Hospital, University of Sfax, Otorhinolaryngology, Tunisia

Introduction
Parathyroid cysts (PCs) are uncommon lesions. They represent less than 0.5% of parathyroid lesions. Cysts are divided into two groups, functional and non-functional, in relation to their hormonal characteristics. Non-functioning ones make up 80 – 90% of PCs.We discussed three cases of non-functioning parathyroid cysts that we surgically excised.
Methods
We report 3 cases of non-functioning PCs treated in our department.
Results
Our series included 1 man and 2 women. The median age was 35 years [22 years – 45 years]. Patients presented a neck lump in the lower anterior neck. Dysphagia was noted in 2 cases. Clinical examination showed a soft, non-tender and well-limited anterior neck mass that move on swallowing. The mass had a median approximate size of 3 cm.Ultrasonography of the neck revealed a cystic lesion behind the left lobe of the thyroid gland in 1 patient and a right cystic thyroid nodule in 2 cases.Fine-needle aspiration (FNA) with detection of parathyroid hormone (PTH) in the cyst fluid was performed in one patient and the intracystic PTH level was high (355 ng/l). Recurrence was noted 1 month after the cyst aspiration. Serum calcium and PTH levels were normal in all patients.All patients underwent surgical treatment: surgical excision of the cystic mass in one case and right lobectomy in 2 cases. Histologic exam confirmed the diagnosis in all cases. PC was intrathyroidal in 2 cases.After median follow-up of 25 months [12 months - 41 months], no recurrence was noted.
Conclusion
Parathyroid cysts are extremely rare lesions. Our cases were nonfunctional parathyroid cystic lesions. FNA with detection of PTH in the cyst fluid (regardless of the level) is an important tool and confirmed the diagnosis in one patient in our study. Three therapeutic options are indicated: cyst aspiration, sclerotherapy and surgery.

Pseudohypoparathyroidism type I-b: a rare entity

Eugénia Silva, Rute Ferreira, Bernardo Marques, Francisco Sousa Santos & João Manuel Sequeira Duarte
Hospital Egas Moniz, Endocrinology, Lisboa, Portugal

Introduction
Pseudohypoparathyroidism (PHP) is a rare disorder characterized by parathormone (PTH) resistance, caused primarily by genetic defects involving the alpha-subunit of the stimulatory G protein. Biochemical and molecular analysis classify pseudohypoparathyroidism into types I-a, I-b, I-c and 2. We report a case of PHP I-b in an adolescent presenting with a neurological disorder.
Case Report
11 years old female patient, with no relevant personal or family history, referred to a Neurology appointment for paroxysmal episodes of dystonia of the feet. She had hypocalcemia (corrected serum calcium 6.4 (8.6-10) mg/dl), hyperphosphatemia (serum phosphate 8.6 (2.5-4.5) mg/dl), elevated parathormone (PTH 438 (15-65)pg/ml); low urinary calcium (<9 mg/24H), normal D vitamin (1,25-diOH-calciferol and 25-OH-calciferol), magnesium and kidney function. Thyroid function showed TSH 7,21, uU/ml (0.4-4.6), free T4 11,1 pmol/l (12-22) and negative thyroid antibodies (TPO, TG). The laboratory results were suggestive of PTH resistance and partial TSH resistance. Supplementation with calcitriol, calcium carbonate and levothyroxine was initiated. No typical features of Albright hereditary osteodystrophy (AHO) were observed. A cerebral computed tomography scan revealed bilateral symmetrical calcifications of the cranial base nuclei involving the lenticular nucleus, globus pallidus, posteroexternal aspect of the thalamus and the cerebellar nuclei, especially dentate nucleus, suggestive of Fahr syndrome. Renal ultrasound revealed nephrolithiasis; thyroid ultrasound showed no alterations. Oftalmologic evaluation excluded cataracts. Genetic study was requested revealing a maternally inherited 3-kb *STX16* deletion, with loss of methylation restricted to the *GNAS* exon A/B, cause of autosomal dominant PHP I-b. Currently, the patient shows little compliance to therapy, despite the risks, and remains with asymptomatic hypocalcemia.
Conclusion
PHP I-b is most often a sporadic disorder, but sex-linked autosomal dominant inheritance has been reported. Patients with PHP I-b show, occasionally, thyroid stimulating hormone (TSH) resistance and typically lack of Albright hereditary osteodystrophy features.

Multifactorial causes of secondary osteoporosis: a case report

Delfina Indira Fortes & Ana Paula Barbosa
Hospital Santa Maria, Endocrinology, Lisboa, Portugal

Introduction
Osteoporosis is a metabolic bone disease, characterized by reduction and changes in the bone mass quantity and quality, leading to an increased risk of fractures. It can be divided in primary (postmenopausal or senile), secondary and idiopathic. In the presence of osteoporotic fractures, particularly in men before the age of 65, it is essential to investigate the presence of secondary causes in order to establish an etiological therapy.
Case Report
A 62-year-old man was referred to an outpatient consultation for fractured osteoporosis after suffering spontaneous rib fractures during a coughing episode. He had history of arterial hypertension, diabetes mellitus, smoking, depressive disorder and an adrenal nodule under surveillance for 9 years. He was chronically medicated with metformin, enalapril, lercanidipine, nebivolol, hydrochlorothiazide, atorvastatin and fluoxetine.Physical examination revealed a mildly Cushingoid phenotype and deformation of the left tibia without local inflammatory signs. The analytical evaluation reveled bone alkaline phosphatase 97.6 ($n<$ 22.9 µg/l), serum cortisol 22.8 µg/dl and after 1 mg of dexamethasone 4.5 µg/dl, urinary cortisol 388 µg/24 h ($n<$ 213.7), ACTH 8.7 (N: 7 – 63 pg/ml), hemoglobin A1c 8.1%, calcium 9.3 mg/dl, phosphorus 3.7 mg/dl, Vitamin D 10 ng/ml and PTHi 117 (N: 12-65 pg/ml).DXA revealed T-scores -1.6 CL and -1.5 CF, while bone scintigraphy showed uptake of 3 right posterior rib arches (C8,9,10) and homogeneous uptake of the proximal two-thirds of the left tibia and distal extremity of the left femur. MRI confirmed the diagnosis of Paget's Bone Disease of the left tibia and femur.Adrenal MRI revealed a dimensional increase (from 12 to 27 mm) of the right adrenal nodule. Treatment with zoledronic acid associated with calcium and vitamin D supplementation was initiated, as well as optimization of antidiabetic therapy with empagliflozin. He underwent laparoscopic right adrenalectomy, and histology revealed nodular hyperplasia of the adrenal cortex.
Discussion and Conclusions
In the reported case, the patient had several risk factors for low bone mass and fragility fractures, namely diabetes mellitus, functional hypercortisolemia, secondary hyperparathyroidism, Paget's bone disease and smoking. A multifactorial therapeutic approach was essential in order to reduce its high fracture risk.

Association between musculoskeletal manifestations in hemodialysis patients and depression

Ramy Ben Tekaya[1], Haifa Hachfi[1], Mouna Brahem[1], Olfa Jomaa[1], Amal Hariz[1], Zohra Atti[2] & Mouhamed Younes[1]
[1]University Hospital Tahar Sfar, Rheumatology Department, Mahdia, Tunisia; [2]University Hospital Tahar Sfar, Nephrology Department, Mahdia, Tunisia

Introduction
Musculoskeletal pain is a major problem for hemodialysis patients. So, we have to control it, to ameliorate their life quality.
Aim
The purpose of this study was to evaluate the prevalence musculoskeletal symptoms and their relation with chronic hemodialysis.
Methods
This is a cross sectional study conducted in rheumatology department of Taher Sfar university hospital in mahdia, Tunisia. The study involved 61 patients with chronic hemodialysis. They were invited to participate and were included after signing informed consent until the calculated sample size was reached. Clinical and demographic characteristics were recorded, as well as years of hemodialysis duration. We asked the patients HAD score, and DN4.
Results
61 patients were included 26 females (42,6%) and 35 males (57.4%). The mean age of the study group was 53.9 [17-83]. The mean age of onset of nephropathy was 44.7+/- 15.4 years, the medium duration of dialysis: 6,1 years. Musculoskeletal manifestation was noted in 49 (80,3%) patients, the bone pain was noted in 32 patients (52,5%) 20 patients (32,8%) had diffuse bone pain, 34 (55,7%) patients had myalgia, 24 patients (39,3%) had muscular weakness, 14,3% had neuropathic pain, 3 patients (4,9%) have jobs, 12 patients (19,7%) are retired, 46 patients (75,4%) are unemployed. The mean HAD score was 17,88 and 33 patients (54,1%) with HAD score over 19. The mean duration of dialysis in symptomatic patients and asymptomatic patients 7,01 years vs 3,24 years ($P<$0,005). The mean HAD score of symptomatic patients and asymptomatic patients 18,81 vs 14,04 ($P<$0,005).
Conclusions
Our study shows the important damage of chronic kidney disease on the musculoskeletal system that can affect patients' quality of life and professional life. That's why mineral and bone disorders in advanced CKD should be well managed.

Association between serum magnesium levels and physical performance tests in patients with primary osteoporosis

Daniela Ioana Iulia Greere[1,2], Gabriela Voicu[3], Dana Alice Manda[4] & Cătălina Poiană[1,2]
[1]"C.I. Parhon" National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Discipline - Endocrinology - National Institute of Endocrinology C.I. Parhon and Clinical Base Carol Davila Central Military Emergency University Hospital, Bucharest, Romania; [3]"C.I. Parhon" National Institute Of Endocrinology, Radiology and Imaging, Bucharest, Romania; [4]"C.I. Parhon" National Institute Of Endocrinology, Research, Bucharest, Romania

Introduction
Osteoporosis is the most frequent metabolic bone disease worldwide affecting primarily the senior population. The associated bone loss in combination with a decline in physical performance lead to increased incidence of falls and fragility fractures. Thus, improving physical performance is key to preventing osteoporotic fractures.

Methods
A total of 140 participants were inrolled in a cross-sectional study. Secondary causes of osteoporosis were excluded. All participants underwent dual x-ray absorptiometry analysis and lateral spine radiography (which resulted in 105 subjects being diagnosed with primary osteoporosis and 35 subjects with osteopenia or normal bone density). Each subject underwent several physical performance tests. Blood samples were obtained to perform biochemical and hormonal assessment.
Results
Statistically significant correlations were found between serum magnesium levels and 4-m Gait Speed values in patients suffering from osteoporosis with or without fragility fracture ($P=0{,}004$, $r=0{,}272$). Linear regression showed a negative statistically significant correlation between serum magnesium levels and Timed Up and Go Test ($P=0{,}034$, $r=-0{,}207$) in the osteoporosis subgroup. None of these correlations applied to subjects with osteopenia or normal bone density. All subjects except one had serum magnesium levels within the reference range.
Conclusion
Serum magnesium levels correlate with pysical performance tests in patients suffering from primary osteoporosis. In the setting of hypomagnesemia being known to be associated with poor physical performance, the results of this study suggest more research is needed to establish whether magnesium supplementation should be an adjunct to osteoporosis therapies.

Hypoparathyroidism: about 61 cases

Mnif Fatma, Asma Zargni, Kawthar El ARBI, Mouna Elleuch, Raida Trigui, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker Hospital, Diabetology and Endocrinology Department, Sfax, Tunisia

Introduction
Hypoparathyroidism (HPT) is an often under-diagnosed condition. It is imperative to diagnose it at an early stage and to initiate prompt treatment given the evolving potential of the disease.The aim of our study is to describe the epidemiological, clinical and paraclinical features of HPT.
Patients and Methods
This is a retrospective study of 61 observations of HPT collected at the endocrinology department during a 12-year period.
Results
The mean age of our patients at the time of diagnosis was 41 years and 6 months (extremes ranging from 13 to 80 years). HPT was more frequent in the age group 21-30 years. A clear female predominance was observed with a sex ratio of 4.5. The circumstances of discovery were mainly paresthesias (65%) and muscle cramps (62%). The majority of our patients (90%) had hypocalcemia with an average blood calcium level of 1.65 mmol/l (normal range 2.2-2.6 mmol/l). Hypophosphatemia was found in 52% of cases, and hypocalciuria in 80%. Low PTH was found in 72% of cases with a mean level of 9.48 pg/ml. Cervical surgery was responsible for a postoperative HPT in 74% of cases. However, 16% of the cases were idiopathic PTH. Autoimmune origin was observed in 3 cases (5%).
Discussion-conclusion
HPT is a rare and often asymptomatic disease, hence the interest of the calcemia analysis in front of even minor clinical signs.

Persistent hypophosphataemia due to gastrointestinal losses

Rahat Tauni[1,2,3], Nida Ali[1] & Amjad Khan[1]
[1]St Albans City Hospital, United Kingdom; [2]Hemel Hempstead General Hospital, United Kingdom; [3]Watford General Hospital, United Kingdom

A 49-year-old lady was referred to the endocrine clinic for hypophosphataemia. Apart from tiredness, she had no other symptoms. Past medical history was significant for bronchiectasis, obstructive sleeps apnoea, caudaequina syndrome, migraine and anxiety. She had frequent hospitalisations due to bronchiectasis exacerbations requiring systemic steroids. Usual medications included azithromycin, gabapentin, omeprazole, antacids, laxatives, carbocisteine, fluoxetine, montelukast, propranolol and inhaled formoterol and budesonide. She drank at least 16 pints of milk every week, did not drink alcohol in excess and stopped smoking two years ago. Examination was unremarkable with negative Chvostek sign, no proximal myopathy and no evidence of endocrine disease. Body mass index was raised in the overweight range. Phosphate levels were persistently low for the last two years, with the lowest recorded at 0.15 mmol/l during hospital admissionrequiring intravenous phosphate replacement. Calcium and other bone biochemistry were normal. 25-hydroxy Vitamin D level was 61 nmol/l and she was commenced on oral cholecalciferol 1000 IU/day. Urine tests did not suggest renal potassium loss. She was maintained on oral phosphate replacement on outpatient basis as she was not keen to stop PPI and antacids. Phosphate is a molecular element critical to normal cellular function. Intestines, kidneys and bones are important in phosphate homoeostasis. Hypophosphataemia is caused by inadequate phosphate intake, reduced intestinal absorption, increased renal excretion, phosphate shift from extracellular to intracellular space or a combination of above mechanisms. In our case, hypophosphataemiawas thought to be caused by PPI and antacids, frequent use of steroids, frequent hospital admissions, and intermittent under-nutrition and feeding (‘fast and feast’). Severe and/or symptomatic cases need intravenous replacement as generalised muscular weakness, rhambdomyolysis and acute kidney injury are potential complications. Mild cases may not present with any symptoms but it is important to explore the cause and replace phosphate orally as prolonged hypophosphatemia can lead to osteoporosis or osteomalacia due to reduced bone mineralisation and there are no contraindications of oral phosphate replacement.

Clinical, biological and evolutionary comparison of postsurgical hypoparathyroidism and non-postsurgical hypoparathyroidism

Siddiqa Soomauroo, Fatma Mnif, Mohamed Abdellahi Mohamed Ahmed, Faten Haj Kacem Akid, Nadia Charfi, Mouna Mnif & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Hypoparathyroidism (HPTH) is an uncommon condition resulting in the production of insufficient amounts of parathyroid hormone (PTH) by the parathyroid glands consequently affecting the calcium phosphate balance. The most frequent etiology of HPTH is the damage to or removal of the parathyroid glands due to a surgery for another condition. Other causes, including autoimmunity and genetic disorders may be responsible for HPTH. Our aim is to compare the different clinical, biological and evolutive aspects of postsurgical HPTH to non-surgical HPTH.
Patients and methods
It is a retrospective study that collected data from 61 patients diagnosed with hypoparathyroidism that were hospitalized in the Department of Endocrinology, Hedi Chaker University Hospital, Sfax over 12 years.
Results
The most common etiology of HPTH was postsurgical HPTH found in 45 cases (74%), including 40 women and 5 men. The mean age of the patients that underwent surgery was 41.5 years. A clear female predominance with a sex ratio (F/M) of 8. The type of intervention was total thyroidectomy in 29 cases, subtotal thyroidectomy in 11 cases and parathyroidectomy in 7 cases. The diagnosis of HPTH was made within the first few days post-intervention. The mean serum calcium level within the first week of surgery was 1.8 mmol/l (extremes: 1.24-2.38 mmol/l). The hypocalcaemia was symptomatic in 29 cases. In 31 cases, the patients required urgent treatment with intravenous calcium salts as well as oral calcium supplementation. Transient HPTH was observed in 3 patients with a mean recovery time of 2.5 months whereas as permanent HPTH was found in 34 patients. Only the presence of clinical signs of hypocalcaemia within the first week post-intervention was significantly correlated as a predictive risk factor for permanent HPTH. More trophic and psychic disorders were found in non-postsurgical HPTH whereas there was no significant difference in serum calcium levels. A more favorable clinical outcome under calcium supplementation therapy in postsurgical HPTH than in non-postsurgical HPTH.
Conclusion
HPTH is a rare affection which results from an absence or reduced secretion of PTH form parathyroid glands resulting in the inability to maintain extracellular calcium homeostasis. One of the most common causes either of transient or permanent HPTH remains post-thyroid surgery. Serum calcium dosage within the first days of thyroid or parathyroid surgery is primordial as well as monitoring the

patients for clinical symptoms so as to detect hypocalcaemia and treat it effectively and accordingly.

Association between primary hyperparathyroidism with severe bone disease and osteomalacia: A case report.

Hager Khiari[1], Imen Rojbi[1], Houaida Smadhi[2], Sabrine Mekni[1], Youssef Lakhoua[1], Ibtissem Ben Nacef[1] & Karima Khiari[1]
[1]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia; [2]Beja Hospital, Endocrinology, Beja, Tunisia

Introduction
Primary hyperparathyroidism is associated with multiple complications: severe bone disease is one of them. Osteomalacia is by definition a metabolic bone disease characterized by a softening of the bones. We herein report a rare case of an association between primary hyperparathyroidism with osteitis fibrosa cystica and osteomalacia caused by a severe vitamin D deficiency.
Observation
A 37-year old woman was referred for investigation of weakness and loss of autonomy. She complained of generalized muscular and bone pain, height and weight loss for 1 year. On physical examination, she had waddling gait and hourglass chest deformity. X-ray examination showed looser zones at the pelvis, osteopenia and an aspect of osteitis fibrosa cystica. Computed tomography showed a brown tumor at the right ilium. The patient was diagnosed with primary hyperparathyroidism based on increased serum calcium 2.7 mmol/l (normal range: 2.20-2.60), increased parathormone concentration 2504 pg/ml (normal range: 15-72) and a low serum phosphate 0,67 mmol/l (normal range:0.80-1.45). The urinary calcium was 0.08 mmol/kg/24h. Renal ultrasonography showed a bilateral nephrolithiasis and BMD showed osteoporosis with a high fracture risk: lumbar T-score -5.3 and Hip T-score -4. The diagnosis of osteomalacia was based on clinical and radiological presentation, low 25-OH vitamin D 3.28 ng/ml and elevated phosphatase alkaline 4590 UI/l (normal range <240). Cervical ultrasonography showed a 25x17 mm hypoechoic mass below the left lobe of the thyroid. Parathyroid scintigraphy confirmed increased uptake in the topography of left inferior parathyroid gland. The patient received vitamin D and calcium supplementation and therefore underwent a left lower parathyroidectomy. Postoperative pathology confirmed the diagnosis of parathyroid adenoma. The intraoperative serum PTH concentration was 106 pg/ml. She had hypocalcemia on the third day after surgery: the serum calcium concentration was 1.9 mmol/l. She recovered well after calcium supplementation and was discharged 1 week after surgery.
Conclusion
This case report illustrates a rare case of a severe bone disease caused by an association of a chronic primary hyperparathyroidism and osteomalacia. Prevention, diagnosis and treatment of vitamin D deficiency and the early diagnosis of primary hyperparathyroidism are very important.

Sporadic multiple-gland disease in primary hyperparathyroidism

Sirine Ayedi[1], Wadii Thabet[1], Mohamed Amine Chaabouni[1], Manel Mallouli[2], Malek Mnejja[1] & Ilhem Charfeddine[1]
[1]Habib Bourguiba Hospital, University of Sfax, Otorhinolaryngology, Tunisia; [2]Habib Bourguiba Hospital, University of Sfax, Pathology, Tunisia

Introduction
In 80–90% of cases, the cause of sporadic primary hyperparathyroidism is adenoma of one parathyroid gland. Multiple-gland disease (MGD) is defined in patients with more than one pathological parathyroid gland. The frequency of occurrence of MGD is from 7% to 33%.Our aim is to report a case of primary hyperparathyroidism with MGD and to describe its diagnostic and therapeutic features.
Case Report
A 55-year-old man presented with 1-year history of bone pain and asthenia. He had history of diabetes and hypertension. He had not been suffering from pathological fractures, nephrolithiasis or gastropathy. No familial history of multiple endocrine neoplasia syndrome was noted. Physical exam showed a 2-cm left anterior neck mass.The laboratory workup revealed: serum calcium level was 3.05 mmol/l, serum phosphate level was 0.99 mmol/l, and serum PTH level was 127 ng/l. Ultrasonography of the neck revealed a 26-mm parathyroid nodule behind the left lobe of the thyroid gland and another one behind the right lobe, measuring 15 mm. A 99 m technetium (99 mTc) sestamibi scan has been performed: it showed an inferior right parathyroid adenoma with doubt on another left adenoma.The patient underwent superior and inferior right parathyroidectomy and left inferior parathyroidectomy. The intra-operative examination suggested parathyroid adenomas. The postoperative course was uneventful. The level of serum PTH (43 ng/l) and serum calcium (2.45 mml/l) were normalized after the surgery. Histological exam confirmed the diagnosis of MGD: adenoma of the right superior parathyroid gland, pseudo adenomatous hyperplasia of the right inferior parathyroid gland and hyperplasia of the left inferior parathyroid gland.No recurrence was noted after 1 year of follow-up.
Conclusion
Identifying preoperatively patients at risk for MGD remains challenging. Intraoperative decisions are important for achieving acceptable cure rates and long-term follow-up is mandatory in such patients. Patients with MGD have an increased risk of complications at surgery and for persistence and recurrence after surgery.

Particularities of primary hyperparathyroidism in multiple endocrine neoplasia type 1: Tunisian data

Mnif Fatma[1], Kawthar El Arbi[1], Yosra Lajmi[2], Asma Zargni[1], Dhoha Ben Salah[1], Oumeyma Trimeche[1], Mouna Elleuch[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Faten Haj Kacem Akid[1], Hassen Kammoun[2], Fatma Abdelhédi[2] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Medical Genetics, Sfax, Tunisia

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is an inherited syndrome characterized mainly by the association of: Primary hyperparathyroidism (PHP), gastro-entero-pancreatic tumors (GEP) and pituitary tumors. The aim of our work is to specify the particularities of PHP in MEN1 among Tunisian population.
Patients & Methods
It is a retrospective descriptive study of 7 cases of MEN1, including 3 familial cases, during a 28-year period.
Results
The mean age at diagnosis of our patients was 36 years with a female predominance (Sex-Ratio = 1.3). PHP was the most frequent initial manifestation in MEN1 (5 cases) and it was present in all cases (7 cases). Four patients were asymptomatic at the time of diagnosis. PHP was complicated by urinary lithiasis in 3 cases and osteoporosis in 3 cases, which was severe in 2 cases. Surgical treatment was considered in six cases. This consisted of parathyroid adenoma removal in 4 cases and subtotal parathyroidectomy in two cases. The anatomopathological study concluded to multiple adenomas in 3 cases. A therapeutic failure with persistent hypercalcemia was observed in 2 cases. The genetic study was done in 4 patients. It showed the presence of a novel mutation, not previously described in the literature, of the MEN1 gene at exon 4 in three cases.
Conclusion
Our work illustrates the particularities of PHP in MEN1 and subsequently confirms the results of the literature.

Primary hyperparathyroidism and rheumatoid arthritis

Lambros Athanassiou[1], Ifigenia Kostoglou-Athanassiou[2], Maria Mavroudi[3], Pavlos Tsakiridis[3], Nikolaos Koukosias[3] & Panagiotis Athanassiou[3]
[1]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [3]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Rheumatoid arthritis is a systemic autoimmune inflammatory disease characterized by severe pain, if left untreated. Primary hyperparathyroidism is a systemic disorder characterized by disordered calcium metabolism leading to increased serum calcium and PTH levels. Primary hyperparathyroidism may be due to the presence of a parathyroid adenoma or parathyroid hyperplasia. The aim was to present a cohort of patients with rheumatoid arthritis who presented with primary hyperparathyroidism.A cohort of patients with rheumatoid arthritis is presented. Three patients with active rheumatoid arthritis are described. Patients were female, aged 58, 65 and 67 years old. They had seropositive rheumatoid arthritis, anti-CCP positive, rheumatoid factor positive and had severe pain on treatment with methotrexate and corticosteroids. During laboratory evaluation increased calcium levels were observed along with increased PTH levels.In further evaluation an ultrasonogram revealed the presence of a parathyroid adenoma adjacent to the thyroid in two of the patients, while in the other scintigraphy with 99 mTc-SESTAMIBI was performed which revealed an adenoma beneath the left lobe of the thyroid gland. Surgical removal of the parathyroid adenomas was planned. For the management of rheumatoid arthritis biologic therapy was introduced.Primary hyperparathyroidism in the context of rheumatoid arthritis is rare. If diagnosed it may require surgical removal of the parathyroid adenoma as increased calcium levels may aggravate pain in the setting of systemic inflammation. The diagnosis of primary hyperparathyroidism in the setting of rheumatoid arthritis may be due to routine screening for calcium levels on biochemical evaluation in modern times.

How we managed malignant hypercalcemia in a hyperparathyroid in heart failure in the emergency room

Ali Halouache, Errahali Yassine, Chakdoufi Sanae, Isouani Jad & Guerboub Anas
Hopital Militaire d'Instruction Mohammed V, Endocrinology, and Metabolic Diseases, Rabat, Morocco

Introduction
We report a case of malignant hypercalcemia complicated by acute pancreatitis, in a patient whose cardiac insufficiency obliged us to use an unconventional therapeutic means: calcimimetics
Case Report
Mrs. Halima, 74 years old, had a history of arterial hypertension complicated by ischemic heart disease at the stage of heart failure. She consulted the emergency room for typical pancreatic pain, the biological workup found a lipasemia at 30 times normal and acute renal failure, the abdominal CT scan was in favor of an acute pancreatitis stage E of Balthazaar.The etiological investigation found malignant hypercalcemia (140 mg/l) secondary to primary hyperparathyroidism (PTH: 679 pg/ml).the patient was put on fasting, with analgesic treatmentFor hypercalcemia, hyperhydration was not possible in the presence of decompensated cardiac insufficiency, and biphosphonates were contraindicated in the presence of kidney failureFaced with the reduced therapeutic choices, our attitude was to prescribe cinacalcet at a progressive dose: 30 mg per day then 60 mg per day, the calcemia went in two days from 140 mg/l to 120 mg/l then to 100 mg/l, as regards the adverse effects; our patient presented only one episode of vomiting the first day.After stabilization, she benefited from a localization check-up which revealed a parathyroid nodule, and the evolution was favorable after surgical removal.
Discussion
Cinacalcet is an oral calcimimetic that mimic the effects of calcium on the calcium receptors of the parathyroid cell. It lowers blood calcium and reduces PTH concentration.[1] Initially used in hyper parathyroid hypercalcemia associated with end-stage renal disease is actually FDA approved to treat secondary HPT in patients with parathyroid carcinoma (2011) [2], and hypercalcemia in patients with primary HPT who are unable to undergo Para thyroidectomy.but its use in malignant hypercalcemia in emergency situations has not been recommended, in some cases, and when the classical treatment of hypercalcemia is not possible, as in our patient's case, calcimimetics, and in particular cinacalcet, can be the most effective therapeutic option to save the patient
Conclusion
we suggest that the use of this therapeutic class may be useful in urgent situations in patients with cardiac or kidney failure when hyper hydration is not possible[1] Wada M., and Nagano N.: Control of parathyroid cell growth by calcimimetics. Nephrol Dial Transplant 2003; 18: pp. iii13-iii17[2] Silverberg S.J. *et al*: Cinacalcet hydrochloride reduces the serum calcium concentration in inoperable parathyroid carcinoma. Post covid 19 vaccine cramps in a patient followed for hypoparathyroidism: who is to charge?

Ihssane Abidi, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
University Mohammed 5 Rabat, Endocrinologie, Rabat, Morocco

Introduction
COVID-19 is a pandemic related to SARS-COV-2 virus infection. It is most often manifested by an influenza-like syndrome with other symptoms that are more specific such as loss of smell and taste.Its severity is highly variable, ranging from asymptomatic to severe or prolonged forms.We report the case of a 47-year-old female patient, who is being followed for hypoparathyroidism, who developed severe and persistent cramps after the COVID-19 vaccine.
Observation
This is a 47-year-old female patient with a history of high-risk papillary thyroid carcinoma since 2018, operated and irradiated. Her surgery was complicated by supplementary hypoparathyroidism. Her blood calcium was well controlled and she was asymptomatic since her supplementation with Alfacalcidol and calcium.She received the first dose of astrazeneca in July 2021, after 4 hours she developed persistent painful cramps in her extremities. Her clinical examination did not reveal any signs of hypocalcaemia and the biological dosage was 84 mg/l.As the cramps persisted, we started her on calcium and magnesium. The clinical evolution was good after 6 hours and there was no recurrence.
Discussion
COVID-19 vaccines are as well tolerated in neuromuscular patients as in the general population (1). Hypoparathyroidism is not a neuromuscular disease, but it can be caused by hypocalcaemia, which is the cause of the neuromuscular manifestations.Campesium can be seen with COVID-19 vaccines, and is generally benign and transient.The particularity of our observation is that the cramps were severe and incapacitating with the need for intravenous calcium treatment and monitoring, adding the hypoparathyroid terrain which posed a problem of differential diagnosis.
Conclusion
The vaccine against COVID-19 has become an unavoidable necessity in the face of the pandemic population. It certainly has short and long term side effects. Fragile patients must be monitored to avoid complications, particularly neuromuscular ones.

EP241

Pseudohypoparathyroidism discovered in adulthood

Chayma Besrour, Rojbi Imen, Mekni Sabrine, Majdoub Marwa, Lakhoua Youssef, Ben Nacef Ibtissem & Khiari Karima
Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia

Introduction
Pseudohypoparathyroidism (PHP) is a part of a very rare heterogeneous group of endocrine disorders. It is caused by alterations in the PTH receptor, which is encoded by the GNAS1 gene inducing target tissue resistance to PTH. Pseudohypoparathyroidism typically gets discovered during early childhood, rare are the cases discovered in adulthood.
Observation
Herein the case of a 35-year-old man, descendant of a non-consanguineous marriage, with a medical history of bilateral cataract surgery at the age of 33 years-old, who consulted the emergency department for an epileptic seizure then he was transferred after discovering a severe hypocalcemia with Fahr's syndrome at the CT-Scan.The patient didn't present neither cramps or paresthesia. Chvostek

and Trousseau signs were negative. He had a short stature (Height 153 cm vs Target height 180 cm), dental hypoplasia and soft tissue calcifications on the dorsal part of the hands confirmed by the X-Ray imaging. The patient was in sinus tachycardia at 115 bpm with a non-prolonged corrected QT interval (353 ms). The biology showed a low corrected calcium level at 1.94 mmol/l, an elevated level of phosphorus (1.89 mmol/l), a high level of PTH (170 pg/ml) and a normal renal function (creatinine 60µmol/l), in favor of the diagnosis of PHP. The patient was treated with the association of calcium (6g/day) and alphacalcidol (2µg/day), and the corrected calcium level when he was discharged was at 2.14 mmol/l.
Conclusion
In PHP the target tissue is resistant to PTH, resulting in hypocalcemia and hyperphosphatemia. Five different types of PHP, each with specific features, have been described. The best-known type of PHP is type 1a, where biochemical disruptions are combined with a phenotype called Albright's hereditary osteodystrophy (AHO), including short stature, round face, brachymetacarpia, and subcutaneous ossifications. But the diagnosis of certainty in our case remains genetic.

EP242

Primary vs tertriary hyperparathyroidism in a patient with medullary nefrocalcinosis and chronic renal failure

Tea Shehu, Violeta Hoxha, Dorina Ylli, Adishah Çerma & Agron Ylli
University of Medicine, Mother Teresa Hospital Center, Endocrinology, Tirana, Albania

Background
Nephrocalcinosis is characterized by the deposition of calcium products in kidney parenchyma and tubules. It may cause acute or chronic kidney injury or be incidentally detected radiographically in a patient with normal kidney function. Most patients with nephrocalcinosis do not progress to end-stage kidney disease, but with certain underlying conditions, may be associated with progressive kidney dysfunction.
Methods
The patient was diagnosed with primary hiperparathyroidism on the basis of blood analysis, biochemical analysis, schintigraphy, calcium levels and parathyroid hormone (PTH).
Case presentation
A 70 year old female patient came to the Emergency Unit with fatigue, diffuse abdominal pain, vomiting, diarrhea and decrease in the amount of urination. Laboratory analysis revealed hyperkalemia, hyponatremia, high azotemia (266 mg/dl) and creatinemia (7.2 mg/dl), high uricemia and phosphatemia. PTH = 832 g/d (high), 25-hidroxyVit D = 8.3 mg/dl (low), total Ca = 9 mg/dl(normal). Cell blood count showed normocromic normocytic anemia. Diuresis was 1 liter/24 - hours (low) and diagnosis of acute renal failure was made. Hemodyalisis was started and after first session dhe patient was hospitalized to nephrology department. The patient was well known for a 20 years of recidivant renal calculosis and has had three interventions of renal calculus, which ended successfully. She suffered from chronic renal failure as well. Levels of calcium and PTH raised progressively from 2016 to 2021. Actual abdominal echography showed calculus and multiple cysts. Parathyroid schintigraphy showed hyperfixation of 99 mTc MIBI 20 mCi that leads to the conclusion of parathyroid adenoma. During hospitalization the patient underwent hemodyalisis. She was planned for three and half gland parathyroidectomy.
Conclusion
Medullary nephrocalcinosis is a well known manifestation of primary hyperparathyroidism. When this happens, hyperplasia of parathyroid gland also occur and if primary hyperparathyroidism wasn't diagnosed, tertiary hyperparathyroidism can develop and differential diagnosis become very difficult. In our case, nephrocalcinosis is a strong evidence of primary hyperparathyroidism and correlates with schintigraphy, but raising values of PTH during years also suggests secondary hyperparathyroidism due to chronic renal failure. In this scenario tertiary hyperparathyroidism can also happen. Treatment of choice is three and a half parathyroidectomy wich is a definitive solution for adenoma (primary vs tertiary), and calcium lowering therapy even in the background of parathyroid hyperplasia.
Keywords
Medullary nephrocalcinosis, primary hyperthyroidism, parathyroid adenoma, calcium, PTH, kidney, parathyroid glands, calcul, chronic renal faiure.

Paralytic sciatica revealing hyperparathyroidism: a case report

M'ballou Camara, Sana Rafi, Ghizlane EL Mghari & Nawal EL Ansari
CHU Mohammed VI, Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introducing
Primary hyperparathyroidism (HPT1) is a frequent endocrinopathy. Diagnosed incidentally or in front of a urinary or bone symptomatology, we report a case of primary hyperparathyroidism in the mode of revelation makes the originality "a paralyzing sciatica".
Observation
The patient was 44 years old and was undergoing neurosurgery for chronic low back pain that was resistant to etiological treatment. In view of the persistent and hyperalgesic nature of the disease, a detailed radiological work-up was carried out: CT scan of the spine with multiple somatic lesions in the lumbosacral region and in the iliac wings. The diagnosis of multiple myeloma was ruled out and on the phosphocalcic workup: primary hyperparathyroidism was diagnosed (with parathyroid hormone (PTH) elevated to 1033 pg/ml, hypercalcemia at 116 mg/l compared to albuminemia at 36 g/l, high calciuria at 392 mg/24h, low phosphorus level at 12 g/l with total protein at 76 g/l);A cervico-thoraco-abdomino-pelvic CT scan showed a left parathyroid nodule measuring 3.6 cm with thyroid nodules classified as TIRADS 2, 3, and 4, the patient benefited from a total thyroidectomy with excision of the parathyroid nodule, on anatomopathological examination: aspect of a parathyroid adenoma subsequently substituted in calcium and vitamin D
Discussion
Primary hyperparathyroidism results from an increased secretion of parathyroid hormone (PTH), associated with hypercalcemia, most often related to a parathyroid adenoma, hyperplasia of the parathyroid glands and parathyroid carcinoma are very exceptional. The classic presentation associating fibrocystic osteitis, chondrocalcinosis, nephrocalcinosis, renal colic, and the digestive and neuropsychic clinical signs of hypercalcemia is less and less frequently encountered in Western countries, but remains frequent in some countries. The diagnosis of severity and the etiological diagnosis allow the indications and the modalities of surgical treatment to be determined; any symptomatic form (bone, kidney or hypercalcemia-related signs) constitutes an indication for surgery. Minimally invasive parathyroidectomy is the first-line treatment for most patients.
Conclusion
The presence of diffuse cervical and lower extremity polyarthralgia may not be due to osteoarthritis alone. This deserves a thorough investigation such as a blood calcium and PTH measurement

DOI: 10.1530/endoabs.81.EP243

Symptoms alleviation of primary hyperparathyroidism intensified by COVID-19 pandemic effects using a balanced diet: a case report

Narges Kashanivahid[1], Hadi Tabesh[1] & Hamid Bazrafshan[2]
[1]Department of Life Science Engineering, Faculty of New Sciences and Technologies, University of Tehran, Tehran, Iran; [2]LMU Klinikum, Ludwig Maximilian University of Munich, Munich, Germany

Introduction
Hyperparathyroidism happens when one or more of parathyroid glands secret excessive parathyroid hormone, causing calcium levels in blood to rise. A diagnosis may be missed or delayed because there are no symptoms or they are vague, like depression, tiredness, losing your appetite in addition to hypercalcaemia symptoms e.g. vomiting, bone and joint pain, dehydration, hypertension, etc. Surgery to remove the parathyroid gland is usually the only way of treating primary hyperparathyroidism. Patients who are unable to have surgery, cinacalcet tablet may help control the condition while being sure to have a healthy and balanced diet.
Method
A 57 years old female patient with 115 kg weight and 160 cm height and a history of osteoarthritis, osteoporosis, joint pain and inability of movement in addition to depression was referred to our endocrinology clinic. Since COVID-19 pandemic, she had to leave her job as a teacher and staying at home. This situation dramatically deteriorated her mental health and intensified weight gain procedure. Considering her history and laboratory examination results, especially high plasma level of calcium, hyperparathyroidism was diagnosed. Nevertheless, no

medicine was prescribed for her. Analyzing her routine nutrition, we found that her daily liquid intake was very low ca. 2 glasses, accompanied by irregular meals with almost no snack. Instead, an intense diet of 1500 kcal per day with high citrate, magnesium and B-complex and low calcium and high liquid consumption was designed in order to change her nutrition style for 6 months. The diet was planned to balance her meals with 3 main meals and 3 snacks in the meantime. She was recommended to consume more citrus and lemons and no spinach to prevent renal calculi formation. Her health condition was monitored every week by our dietitian staff.
Results
After one month of this intense diet, the patient lost 5 kg of her weight. She reported a kind of lightheadedness feeling, amelioration of joint's pain while she could walk 10 minutes at home each day. By 6 months follow up, she reported a remarkable improvement of her QOL and losing 12 kg of the weight, no more joint pains and no renal problem.
Conclusion
Although the effects of COVID-19 pandemic especially staying at home could worsen the symptoms of primary hyperparathyroidism and hypercalcaemia, a healthy and balanced diet seems to highly ameliorate these symptoms without the need of any medicine and prevent the surgery to remove the parathyroid gland.

A recurrent hypercalcemia after subtotal parathyroidectomy revealing a Munchhausen syndrome

Elyes Kamoun[1,2], Ibtissem Ben Nacef[1,2], Sabrine Mekni[1,2], Youssef Lakhoua[1], Nadia Mchirgui[1,2], Imen Rojbi[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia

Introduction
Primary hyperparathyroidism is the most common manifestation of multiple endocrine neoplasia (MEN) type 1, with a frequent involvement of all the parathyroids. In cases where the four glands weren't resected, a close monitoring should be performed for an early diagnosis of recurrence. Elevated calcium levels with elevated parathormone (PTH) levels in this context makes the physician suspect an adenoma or a hyperplasia of the remaining parathyroid. We herein describe the case of a suspected recurrent hyperparathyroidism which revealed a Munchhausen syndrome.
Observation
We report the case of a 34-year-old man carrying a heterozygous missense mutation of the third exon of the MEN1 gene. He didn't have gastric nor intestinal tumors. He had two infracentimetric nodules in the tail of the pancreas, with a negative hormonal screening. He had a two millimeters pituitary nodule with normal prolactin and IGF1 levels. For the adrenal tumors, there was a non-functional micronodular hyperplasia. There was no thymic nor bronchopulmonary tumor. The patient presented four years ago a hypercalcemia at 3 mmol/l with elevated PTH levels at 400 pg/ml, and he was operated on with resection of three parathyroid gland containing each an adenoma; the fourth parathyroid gland wasn't found during surgery. During four years, calcium and PTH levels were normal, with the last normal control respectively at 2,5 mmol/l and 84,5 pg/ml (26,5-96,5), all in favor of a remission. During follow-up, he presented an asthenia and tachycardia with elevated calcium levels at 3,26 mmol/l and PTH at 68,5. In this context, a recurrent hyperparathyroidism was suspected, but cervical ultrasound, computed tomography and parathyroid scintigraphy didn't find any abnormal or functional gland. The lability of the calcemia and the excessive concern for his disease made us suspected a facticious hypercalcemia, confirmed when he presented a severe hypercalcemia at 4,28 mmol/l, low PTH at 3 pg/ml and elevated vitamin D at 267 ng/ml (>60ng/ml) with the presence in his belongings of calcium-containing pills and ampoules and activated vitamin D. After treatment with intravenous saline and glucocorticoids, his calcemia reached 2,64 mmol/l. He was referred for psychiatric management, confirming the Munchhausen syndrome, with a calcemia level controlled at 2,62 mmol/l.
Conclusion
Hypercalcemia was rarely reported in association of Munchhausen syndrome. In our patient, the calcium and active vitamin D used to treat a member of his family for post-operative hypoparathyroidism and his knowledge of his disease allowed him to use hypercalcemia as a self-inflicted symptom.

Association between interleukin-6 and renal function in patients with diabetes mellitus

Volha Vasilkova[1], Tatsiana Mokhort[2], Ivan Pchelin[3] & Yana Borovets[1]
[1]Gomel State Medical University, Endocrinology, Homiel, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Saint Petersburg State University, Saint Petersburg, Russian Federation

Background and Aims
to assess the relationship between level of interleukin-6 (IL-6) and the renal function in patients with diabetes mellitus (DM).
Method
A total of 416 patients with DM, aged 34 to 75 years, were examined. Control group included 60 healthy patients the same age/All patients underwent standard clinical and laboratory examination, with an assessment of the levels of natriuretic peptides (BNP, proBNP) and level of IL-6. Renal function was assessed based on the levels of serum creatinine, cystatin C, eGFR, which was calculated according to the CKD-EPI formula, and albuminuria, which was assessed as albumin/creatinine ratio. Statistical data analysis was performed using smSTATA 14.2 for Mac (2018).
Results
The levels of IL-6 in patients with DM were higher than in control group (3,14 [1,7;9,1] vs. 1,5 [1,5;1,7] mg/ml). The level of IL-6 increased with GFR decreasing from 1.7 [1.5; 1.9] mg/ml in CKD 1 to 11.4 [8.9; 32.1] mg/ml in CKD 5 and significantly different between all groups. At the same time, IL-6 values in patients with CKD 1 were also significantly higher compared to the control group (1.7 [1.5; 1.9] mg/ml vs. 1.5 [1.5; 1.7], at $p<0.001$). IL-6 significantly correlated with cystatin C ($r=0.71$, $p<0.001$). A strong negative correlation was also observed between IL-6 and eGFR ($r=-0.73$, $p<0.001$). Multiple linear regression analysis revealed a significant association of creatinine and IL-6 ($ß=0.29$, $p<0.001$). To find the optimal cut-off threshold for reducing eGFR, a classification analysis using ROC curves was used. At the level of IL-6=2.6 mg/ml, the sensitivity and specificity were 76.7% and 73.9%.
Conclusion
IL-6 might be an independent predictor of decreased renal function in patients with diabetes. Further study of the role of pro-inflammatory cytokines in the development of renal impairments will make it possible to finally decode the mechanisms of their pathogenesis, which will further allow us to understand their complex effect on the body and obtain information for the development of new effective and safe specific medicines.

COVID-19 triggered inborn errors of metabolism in adults: a case report of mitochondrial fatty acid β-oxidation disorder

Viacheslav Serebrennikov[1] & Kseniya Serebrennikova[2]
[1]The Vishnevsky 3rd Central Military Clinic Hospital, Endocrinology department, Krasnogorsk, Russian Federation; [2]A.N. Bach Institute of Biochemistry, Research Center of Biotechnology, Russian Academy of Sciences, Moscow, Russian Federation

Introduction
Autosomal recessively inherited disorders in the metabolism of mitochondrial fatty acid β-oxidation (FAO) constitute a group of rare diseases with different clinical manifestations and prognosis depending on the type of enzyme deficiency. Hypoketotic hypoglycemia is common to all these types of disorders and is associated with increased consumption of glucose and impaired synthesis of ketone bodies from fatty acids during the fasting periods, infection, or prolonged physical exertion. The analysis of acylcarnitines using tandem mass spectrometry is the gold standard diagnosis of FAO disorders; however, it can be supplemented by the determination of acylglycines, organic acids and other metabolites to clarify the type of enzyme deficiency. The study aims to discuss a clinical case of genetic FAO disorder, first diagnosed after coronavirus disease (COVID-19) as a trigger for the development of clinical signs of the disease.
Case report
A previously healthy 18-year-old male patient was admitted to the intensive care unit in a hypoglycemic coma with a blood glucose level of 1.8 mmol/l. Upon examination, COVID-19 with moderate bilateral pneumonia was diagnosed. Biochemical investigations showed the significantly elevated levels of creatine phosphokinase, liver enzymes, creatinine and urea. After clinical stabilization and

resolution of SARS-CoV-2 infection the renal biomarkers, liver enzymes and creatine phosphokinase were normalized, and the patient was transferred to the endocrinology department for further examination. After exclusion of insulin-producing tumors, adrenal insufficiency and other common causes of hypoglycemia, a fasting test was performed. Decreasing the glucose level to 3.4 mmol/l, insulin to 5.5 IU/l and C-peptide to 0.7 ng/ml, accompanied by severe headache, nausea and recurrent vomiting in the patient, led to the decision to stop fasting after 28 hours. In cases of suspected congenital metabolic disorders, the profiles of acylcarnitine in plasma and organic acid in urine during a period of fasting were measured. Elevated levels of plasma acylcarnitines and increased excretion of ethylmalonic, glutaric and isovaleric acids indicated multiple deficiency of acylcoenzyme A dehydrogenase.
Conclusions
Along with the risk of a severe course of COVID-19 in individuals with metabolic dysfunction, COVID-19 can be a trigger for the initial detection of rare inherited metabolic disorders. This study describes for the first time a clinical case of a newly diagnosed multiple deficiency of acylcoenzyme A dehydrogenase in an adult during the development of SARS-CoV-2 infection.

Correlation between pulse wave velocity and cardiovascular risk in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
Diabetes increases the risk of high blood pressure, atherosclerosis, coronary heart disease and stroke. Therefore, People with diabetes have an increased cardiovascular risk. Arterial stiffness is a marker of cardiovascular risk and has been shown to have an independent prognostic effect on cardiovascular disease. The aim of this study was to examine the relationship between cardiovascular risk and arterial stiffness in type 2 diabetes.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications, between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 ± 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years.Our population were divided into two groups; high cardi-vascular risk 27.3% and very high cardio-vascular risk 72.7%.CfPWV $>$ 10 m/s was found in 77.9% of the patients with high cardio-vascular risk and in 95% of the patients with a very high cardio-vascular risk.In the first group, cfPWV was at 11.92 ± 2.08 m/s VS 14.29 ± 2.79 m/s in the second group ($P < 0.001$).
Conclusion
Arterial stiffness is often increased in type 2 diabetics. Moreover, it has been shown that it may predict cardiovascular events in asymptomatic individuals. Therefore, its evaluation in a high-risk population such as the diabetics, must be a routine in our daily practice.

Evaluation of pulse wave velocity in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
Type 2 diabetes is an insidious and progressive disease; accounting for about 90% of all diabetes cases worldwide. Atherosclerosis is a common pathology in diabetes that involves a combination of fatty degeneration (atherosis) and stiffening of the arterial vessels (sclerosis), and the best tool to evaluate the arterial stiffness is the pulse wave velocity. The aim of this study is to evaluate the arterial stiffness in type 2 diabetic patients.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications, between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 ± 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years. The mean body mass index was at 29.31 ± 4.98 kg/m^2 and the prevalence of obesity was at 41%.High blood pressure and dyslipidemia were present in 54.2% and 98.4% of patients. Microangiopathic complications were found in 58.2% of the patients. Only 24.5% of the patients had a controlled diabetes. Arterial stiffness defined as cfPWV $>$ 10 m/s was present in 91.2% of the patients. And the mean cfPWV was at 13.64 ± 2.82 m/s.
Conclusion
Arterial stiffness is often increased in type 2 diabetes. It is currently considered an essential link in the development of atherosclerosis and represents a new marker of cardiovascular risk. Carotid-femoral pulse wave velocity is the "gold-standard" method for assessing arterial stiffness in both populations; diabetics and the general population.

Diabetes Mellitus and COVID-19: Is there a bidirectional relationship?

Ajili Rihab, Mlouki Imen, Ayed Souha, Naimi Arij, Karchoud Syrine, Ouerghi Nawres, Sfar Nouha & El Mhamdi Sana
University Hospital Tahar Sfar Mahdia, Department of Preventive and Community Medicine, Mahdia, Tunisia

Introduction
Diabetes mellitus is a well-known risk factor for worse clinical outcomes in patients with Coronavirus Disease 2019 (COVID-19). However, the relationship between these two entities seems to be bidirectional. The aim of this study was to identify the relationship between diabetes and COVID-19.
Methods
We conducted a prospective study including all patients admitted at the COVID-19 departments of The University Hospital Taher Sfar (Tunisia), between November 2020 and December 2021. We used "The RAPID CORE CASE REPORT FORM" developed by the World Health Organization.
Results
A total of 422 patients were included with a mean age of 59.8 ± 14.7 years (53.2% were females). The type 2 diabetes mellitus (T2DM) was present in 32.5% of cases. During hospitalization, 62.5% patients with T2DM presented a poor glycemic controlwith a mean rate of blood glucose level of 12.7 ± 9 mmol/l and a mean rate of hemoglobin A1c of 8.4 ± 2.5%.Hyperglycemic complications among patients with T2DM included diabetic ketoacidosis and hyperosmolar hyperglycemic syndrome in 48.5% and 12.1% of cases respectively. A quarter of non-diabetic patients affected by COVID-19 was diagnosed with new-onset diabetes.Our survey showed a significantly higher death rate among patients with T2DM ($P = 0.015$).
Discussion and Conclusion
The ongoing pandemic of COVID-19 has significantly affected blood glucose control in patients with T2DM. The results of this effects can be classified into direct effects by the viral infection and indirect effects especially by the use of treatments for the COVID-19 infection like corticosteroids, which affect glucose homeostasis and can also induce diabetes. Furthermore, diabetes is a risk factor for worse outcomes and even death in patients with COVID-19.

Canagliflozin and liraglutide effect on myocardial damage in diabetic rats with experimental myocardial infarction

Natalya Timkina[1,2], Anna Simanenkova[1,2], Anzhelika Shimshilashvili[1], Valeria Timofeeva[1], Alena Chernikova[1], Sarkis Minasian[1,2] & Michael Galagudza[1,2]
[1]National Medical Research Center. VA Almazov, Clinical Endocrinology Laboratory, Sankt-Peterburg, Russian Federation; [2]Pavlov First State Medical University of St. Petersburg, Sankt-Peterburg, Russian Federation

Background
Cardiovascular events are the major cause of mortality among patients with type 2 diabetes mellitus (DM2). Menopause in women additionally increases cardiovascular risk. Despite myocardial infarction (MI) treatment approach in diabetic patients is not specific, some glucose-lowering drugs could have cardioprotective properties. In general, most glucagon-like peptide-1 receptor agonists (GLP-1Ra) and sodium-glucose co-transporter-2 inhibitors (SGLT-2i) have cardiovascular advantages. Particularly, liraglutide (LIRA), semaglutide, empagliflozin, canagliflozin (CANA), dapagliflozin decrease MI incidence. However, SGLT-2i and GLP-1Ra influence on MI manifestations, damage volume and severity in patients with DM2 remains the subject for further investigation. Moreover the cardiotropic properties of these drugs in menopause diabetic subjects undergoing MI is even less studied.
Aim
To evaluate the effect of CANA in comparison with LIRA on myocardial damage area in menopause type 2 diabetic rats in experimental MI.
Materials and methods
Female Wistar rats were subjected to bilateral ovariectomy on order to induce menopause. DM2 was modelled by high-fat diet and streptozotocin 60 mg/kg + nicotinamide 230 mg/kg injection. Rats in control group were fed with standard chow. The following groups were formed: "DM + M" (ovariectomized (menopause) rats with DM2, $n=5$), "DM + M + CANA" (ovariectomized rats with DM2 treated with CANA 25 mg/kg for 8 weeks, $n=5$), "DM + M + LIRA" (ovariectomized rats with DM2 treated with LIRA 0,06 mg/kg for 8 weeks, $n=4$), "CRL" (females without any procedures, $n=5$). After 16 weeks of treatment transient global myocardial 30-min ischemia of isolated heart was modelled in all rats. Myocardium necrosis area was evaluated after 90 min of reperfusion.
Results
Necrosis area was significantly larger in "DM + M" group (42.00 (34.00; 70.00) % of total heart area) in comparison to "CRL" group (33.00 (22.60; 40.00) %, $P=0.003$). Both LIRA and CANA administration led to decrease of myocardial damage area (31.67 (15.50; 46.00) % and 31.75 (24.00; 59.00) %, respectively) in comparison with "DM + M" (42.00 (34.00; 70.00) %) group (significantly for LIRA, $P=0.009$ and statistical tendency for CANA, $P=0.07$). Importantly, there was no significant difference in myocardial damage area between "DM + M + CANA" and "DM + M + LIRA" groups, $P=0.2$. Glucose control was similarly satisfactory in both treatment groups.
Conclusions
Both LIRA and CANA similarly decrease heart necrosis area in menopause diabetic rats with myocardial infarction.

Comparative analysis of characteristics of pregnant women with pathological oral glucose tolerance test vs negative oral glucose tolerance test in a trimester of 2019

Víctor José Simón Frapolli[1], José Ignacio Martínez Montoro[1], María José Picón César[1], Carolina Gutiérrez Repiso[1,2], María Suárez Arana[3], Francisco José Tinahones Madueño[1,2] & María Molina Vega[1]
[1]Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition Clinical Management Unit, Málaga, Spain; [2]CIBER Fisiopatología de la Obesidad y Nutrición-CIBEROBN; [3]Hospital Regional Universitario de Málaga, Gynecology and Obstetrics Clinical Management Unit, Málaga, Spain

Introduction
Gestational diabetes mellitus (GDM) is the metabolic disorder most frequently associated with pregnancy, presenting important maternal and fetal implications. Strict glycemic control through lifestyle measures and/or pharmacotherapy is essential to achieve adequate obstetric-perinatal results. The objective of this study is to compare baseline characteristics and perinatal results in patients diagnosed with GDM after performing oral glucose tolerance test (OGTT) vs patients with negative OGTT, in a trimester of 2019.
Materials and method
Retrospective observational study comparing baseline clinical-laboratory characteristics and obstetric-perinatal results of 258 women referred to our center during the September-October-November trimester of 2019 due to a positive O'Sullivan test to perform the confirmatory test with 100-g OGTT.
Results
Exposed in Table 1. Of the 258 OGTT performed, 217 were negative and 41 were positive (16% positive). Among the most relevant findings, the BMI before pregnancy of the 41 women diagnosed with GDM was 29.08 ± 5.82 kg/m^2 compared to 27.64 ± 7.03 kg/m^2 in the 217 with negative OGTT ($P=0.046$). Weight gain during pregnancy was significantly lower in the group with GDM ($P=0.001$): 6.79 ± 5.3 kg vs 10.33 ± 5.26 kg. Of the 41 women diagnosed with GDM, 11 received treatment with insulin, 1 with metformin and 29 with dietary measures. No differences were found in obstetric or perinatal outcomes in both groups.
Conclusion
Through diagnosis and treatment of GDM, perinatal and obstetric results achieved were similar to those of women without GDM. Although women diagnosed with GDM started with higher BMI values, they presented significantly less weight gain during pregnancy than those with negative OGTT, after undergoing a specific treatment

Table

	Pathological OGTT ($n=41$)	Negative OGTT ($n=217$)	p
Previous BMI (kg/m^2)	29,08 ± 5,82	27,64 ± 7,03	0,046
History of GDM ($n=111$)	4	8	0,142

PSMA6 and KEAP1 genes methylation in patients with type 1 diabetes and diabetic retinopathy

Deimante Kardonaite[1], Rasa Verkauskiene[1], Lina Radzeviciene[1], Laura Daugintyte-Petrusiene[2], Vilma Jurate Balciuniene[3], Jelizaveta Sokolovska[4] & Natalia Paramonova[5]
[1]Institute of Endocrinology, Kaunas, Lithuania; [2], Department of Endocrinology, Kaunas, Lithuania; [3], Department of Ophthalmology,

Kaunas, Lithuania; [4]Faculty of Medicine, Rīga, Latvia; [5]Institute of Biology, Rīga, Latvia

Background
Diabetic retinopathy (DR) is one of the most common complications resulting from uncontrolled diabetes mellitus (DM). DR is the leading cause of blindness and low vision. DR is usually diagnosed at an advanced stage, so despite the individual treatment, it is only possible to slow down the progression of DR. Therefore, new potential biomarkers are needed for an earlier DR prognosis to prevent the development of DR. According to the latest studies, ubiquitin-proteasome system (UPS) dysfunction is associated with an increased risk of developing DR. UPS is the main protein quality control system which is responsible for recognition and degradation of damaged proteins. DNA methylation has been linked to a variety of pathological conditions such as tumorigenesis. However, the role of epigenetic modifications of UPS and UPS related genes in the pathogenesis of DR is poorly understood. The aim of this study was to analyze UPS (*PSMA6)* an UPS related (*KEAP1*) genes methylation levels in samples of DR patients and to identify their association with patients' clinical data.
Materials and methods
120 blood samples, taken from patients with the diagnosis of DM and DR, were analyzed. DNA was extracted by salting out method from peripheral blood tissue leukocytes. *PSMA6* and *KEAP1* genes methylation level was determined by RT–PCR analysis with SYTO 9 fluorescent dye using OneStep qMethyl™ kit. Associations of *PSMA6* and *KEAP1* genes methylation level and the patients' gender, age, duration of DM and the stage of DR were analyzed.
Results
PSMA6 gene methylation levels were higher in the group of patients with non-proliferative DR (NPDR) compared to patients with proliferative DR (PDR) ($P<0.01$). Increased *KEAP1* gene methylation level was observed in the group of patients with DM compared to patients with NPDR and PDR ($P<0.001$). Increased levels of *KEAP1* gene methylation were observed in patients with shorter duration of DM (*P*0.001). In different groups of DR severity, the methylation level of the *KEAP1* gene was the lowest in the group of patients with more advanced stage of DR – PDR, and the highest in the group of patients without DR (*P*0.001).
Conclusions
KEAP1 gene could be used as a prognostic biomarker for determining the severity of DR or as a risk factor for the development of DR.

Effects of semaglutide on glycemic control and weight loss in a patient with Prader-Willi Syndrome: a case report

Elena Sani[1], Giuliana Da Prato[1], Maria Grazia Zenti[1], Andrea Bordugo[2], Maddalena Trombetta[1] & Enzo Bonora[1]
[1]University of Verona and Azienda Ospedaliera Universitaria Integrata of Verona, Division of Endocrinology, Diabetes and Metabolism, Verona, Italy; [2]Azienda Ospedaliera Universitaria Integrata, Verona, Italy, Inherited Metabolic Diseases Unit and Regional Centre for Newborn Screening, Diagnosis and Treatment of Inherited Metabolic Diseases and Congenital Endocrine Diseases, Verona, Italy

Background
Prader-Willi syndrome (PWS) is the most frequent genetic cause of obesity and is often complicated by glucose metabolism alterations. Conventional therapies prescribed in type 2 diabetes mellitus (T2DM), like oral hypoglycemic agents and insulin, frequently failed to achieve adequate glycemic control in patients with PWS. Beneficial effects of the glucagon like peptide-1 receptor agonists (GLP1RAs) exenatide and liraglutide have been reported for the management of T2DM in PWS, but no data are currently available on the use of semaglutide, belonging to the same class of drugs, in this particular population.
Case presentation
We report for the first time the use of semaglutide 1 mg per week in an adult patient with genetically confirmed PWS complicated by poor controlled diabetes and severe obesity. At baseline his HbA1c was 11.1%, body weight 99.5 kg, BMI 37.5 kg/m2. He was on a multi-injection insulin therapy, with a total daily insulin dose of 180 IU, in addition to metformin 3000 mg/day. After 6 months of semaglutide treatment, his weight had fallen to 93.9 kg (-5.6 kg, BMI 39.1 kg/m2) and HbA1c had dropped to 7.7% (-3.4%). After 12 months, his weight had plateaued at 94.3 kg (-5.2 kg, BMI 39.3 kg/m2) and HbA1c further improved until 7.2% (- 3.9%). As assessed by bioimpedentiometry, there was also a notable decrease in fat mass (-4.9 kg), without significant changes in lean mass, and a progressive reduction in insulin requirements up to 140 IU (-40 IU/day). The patient well tolerated the therapy and no adverse events were reported. Interestingly, our patient had previously tried liraglutide therapy in adjunction to metformin and insulin therapy reporting no substantial efficacy.
Conclusions
The beneficial effects of semaglutide on glycemic control and weight reduction provide a promising treatment for diabetes and obesity in PWS. This treatment could also be successfully used in combination with insulin, to reduce the dosage of the latter and to avoid weight gain frequently related to its use, and could be even considered in those patients who have already tried a treatment period with liraglutide or other GLP1RAs with no substantial efficacy. Further studies are required to confirm the efficacy and safety of semaglutide in patients with PWS.

Central nervous system condition in children with diabetes mellitus type I

Nataliia Nikolaeva, Olga Gumeniuk, Yuriy Chernenkov & Nina Bolotova
Saratov State Medical University, Saratov, Russian Federation

Diabetes mellitus is a metabolic disease that is accompanied by brain injury manifested as cognitive, emotional and vascular impairment.
Purpose
To study prevalence and degree of disorders of central nervous system in children with diabetes mellitus type I (TIDM).
Objects and methods
Examination of nervous system in 100 children - age 7-18 yrs [9.0-17.8] with TIDM was provided. The control group consisted of healthy children ($n=30$). The condition of central nervous system was determined on the basis of cognitive and emotional function tests; studying of cerebral circulation was performed using extracranial Doppler study according to standard techniques. The degree of compensation of diabetes was estimated according to criteria ISPAD Consensus Guidelines (2018).
Results
Optimal level (HbA1c $<7.0\%$) of compensation was revealed in 62% of children (group I) and nonoptimal in 38% of children (group II). Decrease of cognitive functions, disturbance of emotional sphere and deterioration of cerebral circulation was established in 12 children (19%) in group I and 16 patients (42%) in group II ($P=0.02$). The performed correlation analysis revealed association of cognitive, emotional dysfunction and cerebral circulation disorders with the $HbA1_c$ level ($r=-0.41$; –0.5 and –0.47 accordingly, *P* 0,001).
Conclusions
Diabetic children with nonoptimal $HbA1_c$ level frequently cognitive, emotional and cerebral circulation disorders (42%). Prevalence of cognitive, emotional and cerebral circulation increased parallel to $HbA1_c$ level.

Association of sarcopenia with peripheral nerve functions in type 2 diabetes mellitus patients in East India: A prospective cross sectional study.

Kishore Behera[1], Subarna Mohapatra[2], Nibedita Priyadarsini[2], Pranati Nanda[2] & Ananda Srinivasan[3]
[1]AIIMS BHUBANESWAR, Endocrinology & Metabolism, Khordha, India; [2]AIIMS BHUBANESWAR, Physiology, Khordha, India; [3]AIIMS BHUBANESWAR, Pharmacology, Khordha, India

Background
Diabetic peripheral neuropathy (DPN) is considered to be the risk factor for the development of sarcopenia. Various previous studies showed the correlation between DPN and muscle disorders, but the study regarding the association between sarcopenia and nerve conduction parameters in diabetic peripheral neuropathy is limited.
Aim
This study was planned to detect the association between sarcopenia with peripheral nerve functions in type 2 diabetes mellitus (T2DM) patients.

Methods
A total of 174 participants aged ≧ 45 years were included in the study. Out of 174, group-1 58, were age and gender matched healthy volunteers (28 males and 30 females); group-2,56 were T2DM without neuropathy (30 males and 26 females); group-3, 60 were T2DM with neuropathy (30 males and 30 females). The mean age of the T2DM subjects was 47.5±7.7(range 42-68 years, mean HbA1c of 7.4%. All the participants underwent peripheral nerve function tests by nerve conduction studies and sarcopenia was evaluated according to the Asian Working Group for Sarcopenia (AWGS) criteria using prediction equation.
Results
According to ASMI cut-off [ALM/height 2: <7.0 kg/m2 (men) <5.4 kg/m2(women)], T2DM with neuropathy had sarcopenia of 67%, T2DM without neuropathy prevalence of sarcopenia was 46%. There was a statistically significant difference in sarcopenia between DM with and without neuropathy ($P<0.002$). All the patients with T2DM with neuropathy are having reduced handgrip strength in contrast to 94% without neuropathy. In addition, there was a significant correlation between ASMI and nerve conduction parameters found in men but in women, significance was found between right common peroneal latency.
Discussion
The prevalence of diabetic neuropathy detected by using nerve conduction studies in our population was 33%. Based on the Sarc-Calf questionnaire score > 11 was about 63% of patients with neuropathy and 29.6% of patients without neuropathy are diagnosed with sarcopenia. Skeletal Muscle mass was compared between the three groups and it was found that there was a statistically significant difference between the groups with ASMI, Handgrip strength, and Sarcopenia calf score (*P*-value <0.05) in males but not in females except for sarcopenic calf score.
Conclusion
The prevalence of sarcopenia in T2DM patients with neuropathy is higher in comparison to those without neuropathy. Therefore, regular screening for skeletal muscle mass and strength may be performed in T2DM patient with DPN.g
Keywords
Diabetic peripheral neuropathy; sarcopenia; Appendicular skeletal muscle mass index(ASMI); Sarc-Calf questionnaire score.

Subclinical left ventricular dysfunction in patients with obesity and chronic obstructive pulmonary disease

Elena Klester, Karolina Klester & Oksana Stefanovskaya
Altai State Medical University, Therapy and Endocrinology, Barnaul, Russian Federation

The purpose of the work
to compare the changes in the global longitudinal strain of the left ventricle in obese patients with and without COPD.
Material and methods of research
group I consisted of obese patients without COPD ($n=50$; 21 - males, mean age - 48.8±9.1 years). Group II – 40 patients with obesity and COPD, comparable in age, gender. Group III – 37 patients with COPD without obesity, comparable in age, gender and risk group of COPD, group A was in 7, group B – in 16, group C – in 5, group D – in 9 patients (GOLD, 2021).
Exclusion criteria
secondary forms of obesity, persons with a BMI <18 kg/m2. BMI, waist circumference, hip circumference, their ratio, visceral obesity index (VAI) and percentage of adipose tissue content according to Deurenberg, cardiometabolic risk on the CMDS scale, fat-free mass index (FFMI) and appendicular skeletal muscle mass index (ASMI) were evaluated. All patients in remission underwent standard echocardiography (EchoCG) with estimated global LV strain in the longitudinal direction (Global Longitudinal strain-GLS) using the "AFI" option.
Results
unlike conventional echocardiographic parameters, speckle-tracking echocardiography revealed a significant deterioration in global LV strain in the II group compared to the I group (-14.4%±2.4% vs. -16.3%±1.8%, $P=0.04$). At the regional level, LV apical septum tension was reduced in I group ($P=0.003$) in the presence of metabolically unhealthy obesity. Patients of group I and III have a deterioration of GLS that correlated with the severity of COPD ($P=0.02$), the visceral obesity index VAI and a decrease in the appendicular lean mass index.After adjustment for clinical and echocardiographic characteristics, MUHO in patients was independently associated with changes in GLS (95% confidence interval was from 0.98 to 2.11, *P*0.001).
Conclusion
the deterioration of global LV longitudinal strain is determined in 66% of patients in the presence of metabolically unhealthy obesity (vs 26% without obesity, p< 0.001). The negative dynamics of GLS is associated with the severity of COPD, visceral obesity and low muscle mass.

Background and aim
Obesity is a chronic disease associated with a positive energy balance leading to lipotoxicity, which contributes to the onset of obesity-associated metabolic disorders such as type 2 diabetes and insulin resistance. It's well known that thermogenesis in brown adipose tissue (BAT) and "browning" of white AT (WAT) increase energy expenditure, thus promoting weight loss and protect against obesity. Recently, the microRNAs (miRNAs) that regulate thermogenesis and browning are acquiring great interest. In addition, several studies have reported that miR-21 regulate adipogenesis and could be associated with obesity. Recently, our group have demonstrated that miR-21 mimic decreases body weight by inducing thermogenesis and browning of WAT in animal model. Thus, the aim of the present study was to associate miR-21 with gold nanoparticle; which could be a good tool to deliver this miRNA to WAT; to evaluate the nanosystem citotoxicity, and to analyze its effect on body weight gain, browning and thermogenesis.
Materials and methods
The cytotoxicity evaluation of nanosystem was carried out by microscopic study and by analyzing the short and long-term effect of miR-21 mimic/Au@ treatment on blood composition of C57BL/6J mice. In addition, the effect of this nanosystem on body weight gain and on thermogenic and browning markers expression was evaluated.
Results
We observed that hematological and biochemical parameters values did not shown any significant differences between control and treated mice groups. Moreover, no tissue damage nor accumulation of nanoparticles in the organs from miR-21-mimic/An@ treated mice. In parallel, this nanosystem significantly decreased body weight gain of obese mice and increased the expression levels of browning and thermogenic markers *Ucp1, Tmem26, Pgc1-a, Prdm16 y Vegf-A* in WAT.
Conclusion
Our results suggest the potential role of mimic-miR-21/Au@ nanosystem as a possible and efficient treatment against obesity and type 2 diabetes.This work was supported by grants from: Instituto de Salud Carlos III (ISCIII)/FEDER-UE (PI18/00785) and Consejería de Transformación Económica, Industria, Conocimiento y Universidades Dirección General de Investigación y Transferencia del Conocimiento (PY20-01274) co-funded by Fondo Europeo de Desarrollo Regional–FEDER.S.L. is a recipient of a post-doctoral grant Plan Andaluz de Investigación, Desarrollo e Innovación (**DOC-01138**) from Consejería de Economía, Conocimiento, Empresas y Universidades.R.E.B. is under a contract from the 'Nicolas Monarde' (C-0030-2016) program from the Servicio Andaluz de Salud, Regional Ministry of Health of the Andalusian Government, Andalusia

The intestinal microbiome and the adipomyokine profile of different phenotypes of obesity

Natalya Volkova[1], Lilia Ganenko[1], Yulia Naboka[1], Alexander Shestopalov[2], Ilya Davidenko[1] & Yuliya Degtyareva[1]
[1]Rostov State Medical University, Department of Internal Diseases No3, Rostov-on-Don, Russian Federation; [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation

Currently, it has been established that obesity is a heterogeneous disease. There are metabolically healthy (MHO) and metabolically unhealthy obesity (MNHO) depending on the presence of cardiometabolic disorders. Potential factors that differentiate obesity into phenotypes include the gut microbiome and endocrine activity of adipose and muscle tissue. Purpose of the study was to compare intestinal microbiome and adipomyokine profile in patients with different obesity phenotypes and in healthy people. A cohort cross-sectional study was performed. The study involved 265 participants (men-44 (16.6%), women-221 (83.4%), average age - 47.1 ± 4.8 years). Formed clinical groups: group 1 ($n = 129$) - healthy people with normal body weight, group 2 - obese patients ($n = 136$). In order to isolate different obesity phenotypes, patients of group 2 were divided into 2 subgroups based on the NCEP-ATP III criteria: subgroup 2a ($n = 40$) - MHO, subgroup 2b ($n = 55$) - MNHO. Quantitative and qualitative assessment of the state of the gut microbiome was performed by metagenomic analysis. Measurement of adipokines and myokines was performed by multiplex ELISA on a Magpix analyzer. Statistical analysis was conducted in the R version of the RStudio program. As a result, in patients with MHO the presence of Lentisphaerae was less often observed and the number of Bacteroidetes was lower, but the amount of Firmicutes was higher compared to MNHO subgroup (P0.05). In obese group, the number of Bacteroidetes, Proteobacteria was increased and the amount of Actinobacteria, Firmicutes, TM7, Fusobacteria was decreased, and the phylotypes of Tenericutes, Planctomycetes and Lentisphaerae were more often verified compared with similar indicators in healthy people (P0.05). When comparing the studied adipokines and myokines in patients with different obesity phenotypes, significant differences were found for adiponectin and leptin ($P < 0,05$). In patients with MHO, the level of adiponectin and leptin was significantly higher compared with the MNHO. In patients with MHO and MNHO, the level of adiponectin was significantly lower, and leptin and asprasin - higher compared with the control group (P0.05). No significant differences in the content of myokines in different obesity phenotypes were found in our study. The obtained results indicate changes in the composition of the intestinal microbiome and adipokine profile in different obesity phenotypes. Further research is required, both to confirm the obtained results and to identify correlations between metabolic parameters with individual phylotypes of the gut microbiome and the profile of adipomyokines.

Maternal weight gain during pregnancy and neonatal birth weight among women with gestational diabetes mellitus

Olfa Lajili, Aroua Temessek, Rim Rachdi, Yosra Htira & Feika Ben Mami
National Institute of Nutrition of Tunis, The Research Unit of GDM (Department C), Tunis, Tunisia

Introduction
Body mass index (BMI) and gestational weight gain are increasing globally. However, the association between gestational weight gain consistent with the Institute of Medicine (IOM) guidelines and neonatal birth weight among women with gestationnel diabetes (GDM) remain unclear.
Objective
The aim of our study was to assess gestational weight gain among tunisian women with GDM and his effect on neonatal birth weight.
Methods
A prospective and longitudinal study including 220 women with GDM followed at the gestational diabetes research unit of department C at the National Institute of nutrition of Tunis. The study was carried out from july 2019 to december 2020 and during the entire period of pregnancy. Height and starting weight and weight at the end of pregnancy were measured. Statistics were performed using SPSS 20.
Results
The mean pre-gestational BMI was 28.8 ± 5.2 kg/m^2. The mean term of discovery of GDM was (24 gestational week + 2day) ± (7 gestational week + 2day). The average weight gain in late pregnancy was 12.2 ± 4.6 kg. More than half of the patients (56.1%) had inadequate weight gain and 44.5% had excessive weight gain in late pregnancy. The mean birth weight was 3368.2 ± 551.2 g [1022g -5000 g]. The main neonatal outcomes were macrosomia (13.5%) and transient respiratory distress (11.4%). Patients with macrosm newborns tended to have higher pre-gestational BMI but with no significant difference between the two groups (29.3 ± 4.8 kg vs 28.5 ± 5.2 kg; $P = 0.4$). Furthermore, there was no correlation between the weight gain in late pregnancy and the birth weight ($P = 0.679$). Similarly, we did not observe an association between the incidence of macrosomia and the weight gain in late pregnancy ($P = 0.559$).
Conclusion
The half of women (65,1%) had inadequate weight gain in late pregnancy. These data point out the interest to follow the recommendations of weight gain during pregnancy in patients with GDM to prevent pregnacy outcomes including macrosomia.

Correlation between pulse wave velocity and microangiopathy in type 2 diabetes

Chayma Besrour[1], Rojbi Imen[1], Ben Ahmed Habib[2], Mekni Sabrine[1], Mchirgui Nadia[1], Ben Nacef Ibtissem[1] & Khiari Karima[1]
[1]Hospital Charles Nicolle, Endocrinology, Tunis, Tunisia; [2]Hospital Charles Nicolle, Cardiology, Tunis, Tunisia

Introduction
Microangiopathy is defined as damage to small blood vessels, and more particularly arterioles and arteriolar capillaries that supply organs. It can occur under different conditions and it represents a complication of diabetes. The aim of this study was to examine the relationship between microangiopathic complications and arterial stiffness in type 2 diabetes.
Methods
We conducted a prospective study including 249 diabetic patients without macroangipathic complications, between July 2020 and May 2021. Using a SphygmoCor®XCEL device, we measured arterial stiffness directly by the carotid to femoral pulse wave velocity (cfPWV).
Results
The mean age of the study population was 57.53 ± 9.34 years (139 women and 110 men). The mean duration of the disease was 10.2 years.Microangiopathic complications were found in 58.2% of the patients.In this group, cfPWV was at 14.41 ± 2.84 m/s VS 12.56 ± 2.42 m/s in patients without microangiopathic complications ($P < 0.001$).Moreover, the presence of arterial stiffness multiples by 4 the risk of microangiopathic complications (Odds Ratio = 4).The ROC curve that we established to find a threshold value of the cfPWV from which this correlation appears, had an area under the curve equal to 0.694. The discriminate threshold value having the best sensitivity/specificity pair was 13.45 m/s.
Conclusion
Arterial stiffness is often increased in type 2 diabetes. Its presence contributes to the development of microangiopathic complications. Which leads us to believe that the early prevention of arterial stiffness may delay microangiopathy.

Evolution of combined impaired fasting glucose and impaired glucose tolerance in 58 β-thalassemia major (β-TM) patients during a mean 7.7 year follow-up

Vincenzo De Sanctis[1], Shahina Daar[2], Ashraf Soliman[3], Ploutarchos Tzoulis[4], Mohamed Yassin[3] & Christos Kattamis[6]
[1]Quisisana Hospital, Ferrara, Italy; [2]College of Medicine, Sultan Qaboos University, Muscat, Oman; [3]Hamad Medical Center, Pediatrics, Doha, Qatar; [4]Department of Diabetes and Endocrinology, Whittington Hospital, London, United Kingdom; [5]Hamad Medical Center, Hematology, Doha, Qatar; [6]National Kapodistrian University of Athens, First Department of Paediatrics, Athens, Greece

Background
In patients with β- thalassemia major (β-TM) glucose dysregulation (GD) develops insidiously, aggravating prognosis and quality of life.
Objectives
The objectives of this study were to retrospectively review the extent to which β-TM patients, having combined impaired fasting glucose (IFG) and impaired

Table Clinical and laboratory parameters reported at the diagnosis of β-TM-RD and at the last visit in the 3 groups of β-TM patients.

Patient's groups	Age (yrs) at diagnosis of IFG + IGT	SF (ng/ml) at diagnosis of IFG + IGT	ALT (U/l) at diagnosis of IFG + IGT	SF peak (ng/ml)	Duration of follow-up (yrs)	SF at last observation (ng/ml)	BMI at last observation
Group A: **From IFG + IGT to β-TM-RD (13 patients)**	**21.0 ± 7.5**	**3467.7 ± 2089.2**	**104.1 ± 82.0**	**4676.5 ± 1758.8**	**4.8 ± 4.1**	**2519.1 ± 1641.6**	**23.9 ± 5.4**
Group B: **From IFG + IGT to NGT (13 patients)**	**21.3 ± 6.4**	**1319.6 ± 608.8**	**59.3 ± 31.7**	**2858.6 ± 1163.8**	**8.6 ± 4.0**	**1219.3 ± 802.7**	**23.1 ± 2.7**
Group C: **From IFG/IGT to PP (32 patients)**	**19.8 ± 5.8**	**2071.8 ± 1646.2**	**54.7 ± 36.6**	**4071.4 ± 1451.2**	**8.8 ± 5.0**	**1251.7 ± 835.5**	**22.5 ± 2.6**

glucose tolerance test (IGT) on oral glucose tolerance test (OGTT), progressed to diabetes (DM) and to analyze the progression to DM or regression to normal glucose tolerance test (NGT).
Method
58 β-TM patients were followed for a mean duration of 7.7 years with annual or biennial OGTT. Glucose and insulin data were analysed.
Results
During the follow-up, FPG and 2-h PG levels after OGTT reverted to NGT in 13 (22.4%), deteriorated to DM in 13 (22.4%) and did not change in 32 (55.2%). A significant correlation was observed between FPG and ALT level (r: 0.3158; P:0.01) and between chronological age and serum ferritin (SF) level (r: -0.321; P:0.014). Both SF and ALT at the baseline and at the time of last observation, were independent predictors of evolution to diabetes mellitus.
Conclusion
The combination IFG/IGT in β-TM patients with severe iron overload constitutes a high-risk state for developing diabetes.

Hormonal-metabolic and functional predictors of unfavorable cardiovascular prognosis in young patients with type 1 diabetes mellitus.

Vengrzhinovskay Oksana[1], Irina Bondarenko[2], Olga Shatskaya[1], Marina Shestakova[2], Victor Kalashnikov[2] & Natalia Mokrysheva[1]
[1]National Medical Research Center for Endocrinology of the Ministry of Health of the Russian Federation, Department of Health, Moscow, Russian Federation; [2]National Medical Research Center for Endocrinology of the Ministry of Health of the Russian Federation, Departament of Health, Moscow, Russian Federation

Background
Patients with type 1 diabetes have a significantly higher risk of coronary events, as well as diseases of the cardiovascular system.Purpose of the study – to show the relationship between metabolic, structural, and functional parameters of the cardiovascular system in young patients with DM1.
Methods
The study included 60 patients without CVD: 40 patients with DM1 and 20 patients without DM1, the groups were comparable in age, sex, AMT, heart rate, blood pressure.. All patients underwent a laboratory examination, which also included an assessment of the levels of adiponectin, resistin, electrocardiography, bioimpedancemetry, ergospirometry.
Results
In the group of patients with DM1, an increased content of adipose tissue ($P=0.036$) was revealed in the absence of a statistical difference with the group without DM in terms of BMI and correlations between the level of maximum power of exercise performance (METs) with the content of muscle tissue $P=0.09$ and with adipose tissue $P=-0.049$. In the control group, correlations were revealed - METs to % of muscle tissue $P=0.004$. The decrease in the functional parameters of the cardiorespiratory system in young patients with DM is noteworthy: the time to reach the anaerobic threshold (AP) ($P=0.008$) and the maximum oxygen consumption (VO2 max) ($P=0.034$), compared with the group of patients without DM1. Correlations were revealed in the group of patients with DM1: METs to VO2 max $P=0.001$ and to AP $P=0.004$. In the control group: METs to VO2max $P=0.001$, to AP $P=0.008$ and VO2max to AP $P=0.003$.It should also be noted an increase in the level of resistin in the group of DM1 patients compared with the group without DM1 ($P=0.044$). When conducting a correlation analysis In the group of patients with DM1, a correlation was found between VO2max and the level of adiponectin $P=0.021$.
Conclusions
Young patients with DM1 have lower functional indicators of the cardiorespiratory system, compared with patients without DM, while maintaining a high tolerance to physical activity. Also, in young patients with DM1 who do not have cardiovascular diseases, there is a significant increase in the level of resistin, which has pro-inflammatory activity and, according to many studies, is associated with an increase in cardiovascular risk.

Association of adherence to the mediterranean diet and body composition in type 1 diabetes mellitus

Enrique Redondo, María Del Carmen Andreo-Lopez, Javier García, Teresa Zarco, Victoria Contreras Bolivar & María Luisa Fernández Soto
Hospital Universitario San Cecilio, Endocrinology and Nutrition, Granada, Spain

Introduction
Body composition is gaining great interest in some pathologies such as Type 1 Diabetes Mellitus (DM1). Adherence to the Mediterranean diet has been shown to be effective in improving the prognosis of cardiovascular disease, which is the main cause of mortality in these patients.
Objectives
To assess whether adherence to the Mediterranean diet in DM1 is associated with improvement in disease control parameters, body composition, anthropometry, dynamometry, and other cardiovascular risk factors.
Patients and methods
Cross-sectional study in 32 patients with DM1. Sociodemographic parameters, variables related to the disease, anthropometrics, dynamometry and body composition were collected using vectorial electrical impedance analysis. In addition, adherence to the Mediterranean Diet was evaluated using the validated 14-point test of the PREDIMED trial. Statistical analysis was performed using the SPSS program (SPSS, inc, v 25.0)

Results
32 DM1 patients under follow-up in the Endocrinology consultation of the HUSC of Granada were selected. Mean age was 41.5±15.2 years, 20 women (62.5%) and 12 men (37.5%). Mean BMI was 26.0±5.1 kg/m2, mean HbA1C was 7.4±1.1%, mean phase angle was 5.9±0.7°. Patients were divided according to their adherence to the Med Diet into high adherence (≧9 points) or low adherence (<9 points) according to the results of the PREDIMED trial test. 19 patients (59%) obtained 9 or more points. There were significant differences between the groups in terms of total insulin dose (37.4±14.1 vs 49.9±15.5, $P=0.024$), insulin/kg (0.53±0.2 vs 0.67±0.15, $P=0.034$) and insulin sensitivity factor (50.6±20.2 vs 37±15.56, $P=0.05$), standardized phase angle (1.2±1.5 vs 0.02±0.84, $P=0.019$) and C-reactive protein (1±0.5 vs 2.4±1.3, $P=0.047$). A tendency to the difference between the groups in terms of HbA1c and lipid profile was found, without finding statistical significance. A statistically significant difference was found between the groups, with those who were less adherent presenting higher levels of the Tg/HDL ratio.
Conclusions
In our sample, type 1 DM patients who presented greater adherence to the Med Diet showed lower insulin needs and greater sensitivity to it with improvement in the inflammatory pattern and better preservation of cell membranes measured indirectly by the angle of phase. Based on these preliminary results, we should reinforce diabetes education programs to increase adherence to the Mediterranean diet in our DM1 patients.

Glycemic variability in pregnant women with gestational diabetes mellitus

Fatima Ushanova, Tatyana Demidova & Mariyam Izmailova
Pirogov Russian National Research Medical University, Moscow, Russian Federation

Introduction
Glycemic variability (GV) is a more accurate parameter for assessing the risk of developing diabetic complications than traditional parameters for assessing compensation. In most cases, diet therapy is used to treat GDM, while the glycemia in a pregnant woman should correspond to the glucose level in healthy pregnant women. The aim of our work is to compare two-week glycemic profiles and GV in pregnant women with GDM on diet therapy and in healthy pregnant women using the FreeStyle Libre flash monitor system.
Materials and methods
Analysis of the glycemic profile of 62 pregnant women aged 33.2±6.1 years. The average gestational age of the women included in the study was 12.6±6.4 weeks of gestation. The pregnant women were divided into 2 groups: 50 pregnant women with GDM and 12 healthy pregnant women. According to the self-monitoring diary using a glucometer, all pregnant women with GDM had target glycemic values. Each group underwent a two-week glucose profile monitoring using the FreeStyle Libre continuous monitoring system. To assess GV, the following parameters were used, reflecting various characteristics of the glycemic curve: SD characterizes the degree of scatter in glycemic values; MAGE is the average amplitude of glycemic fluctuations; MAG - reflects the rate of change in glucose levels; CONGA - duration of glycemic increase; HBGI – hyperglycemia risk index; LBGI – hypoglycemia risk index; ADDR is the average value of risks.
Results
Taking into account the peculiarities of control in GDM, the threshold values of the normal range were changed in accordance with the target values for pregnant women with GDM. Indicators of glycemia and glycemic variability were significantly higher in the group of pregnant women with GDM compared with pregnant women without carbohydrate metabolism disorders, but within the target range. The average level of glycemia in the groups was 4.724±0.37 mmol/l vs 4.24±0.34 mmol/l, respectively ($P<0.0001$). Comparative analysis of GV parameters in groups: SD - 0.8 vs 0.7213 ($P<0.05$); LI- 1.4 vs 0.8 ($P<0.05$); LBGI 5.56 vs 4.6 ($P<0.05$); HBGI- 0.43 vs 0.42 ($P=0.06$); J-index- 9.98 vs 7.9870 ($P<0.001$); MOOD- 0.96 vs 0.79 ($P=0.07$); MAGE- 2.3 vs 1.8 ($P<0.05$); ADDR- 1.02 vs 0.4210 ($P<0.05$); MAG- 3.8 vs 2.6 ($P<0.001$), CONGA index 3.9 vs 3.7 ($P=0.09$), respectively.
Conclusions
Flash glycemic monitoring can be used to obtain more detailed information about the glycemic profile, especially when it is difficult to assess the degree of GDM compensation.

The common genetic polymorphism of KCNJ11 is associated with features of continuous glycemic profile in individuals with type 2 diabetes mellitus receiving vildagliptin monotherapy

Polina Shorokhova, Vitaly Baranov & Natalya Vorokhobina
North-Western State Medical University named after I.I Mechnikov, Department of Endocrinology named after acad. V.G. Baranov, Saint-Petersburg, Russian Federation

Background and aims
The rs5219 variant in the KCNJ11 have been consistently associated with type 2 diabetes (T2D) and therapeutic response to sulfonylureas in type 2 diabetic patients. However, the impact of KCNJ11 genetic polymorphism on the antidiabetic efficacy of vildagliptin has not yet been evaluated. This study was aimed to investigate the association of KCNJ11 rs5219 with vildagliptin glucose lowering ability by monitoring continuous blood glucose profile.
Materials and methods
We included 48 (18 men) drag-naïve patients (mean age 58.5±5.6 years; mean body mass index 31.1±4.5 kg/m^2) with newly diagnosed T2D, who had clinical indications to start vildagliptin therapy. The patients in this data set had mean HbA1c of 7.73%±1.1%. All participants received vildagliptin at an initial dose of 50 mg once a day. KCNJ11 rs5219 (C>T) genetic polymorphism genotyping was performed by real-time polymerase chain reaction. Several parameters, including mean 24-hour blood glucose level, minimum 24-hour blood glucose level, time of relatively low blood glucose, and indices of glucose variability (24-hour standard deviation), were extracted from continuous glucose monitoring (CGM) data obtained using a CGM system iPro2 for a 72-hour period.
Results
The frequencies of the CC, CT and TT genotypes were 41.7%, 37.5% and 20.8% respectively. Minor allele T frequency was 0.39. Genotype distribution followed Hardy-Weinberg equilibrium. All patients receiving 50 mg of vildagliptin per day, were divided into two groups based on rs5219 genotype: CC-genotype carriers ($n=20$) and CT/TT-genotype carriers ($n=28$). The minimum 24-hour blood glucose level was significantly lower in CT/TT- genotype carriers than in CC-genotype carriers: 4.0 [3.5; 5.4] vs 6.0 [5.9; 6.3] mmol/l ($P=0.042$) respectively. Additionally, the mean 24-hour blood glucose level tended to be lower in CT/TT-genotype carriers than in CC-genotype carriers: 6.3 [5.4; 6.8] vs 7.6 [5.9; 6.4] mmol/l and time of relatively low blood glucose tended to be prolonged in patients with rs5219 polymorphism compared to those with wild genotype: 20.0 [0.0; 75.0] vs 0.0 [0.0; 0.0] min; $P=0.075$ and 0.20 respectively. No differences in measures of glycemic variability between the genotype groups were observed: 24-hour standard deviation of CC-genotype carriers was 1.2 [0.9;1.3] mmol/l vs 0.9 [0.8;1.1] mmol/l of CT/TT-genotype carriers ($P>0,05$).
Conclusions
Despite limited sample size, we can conclude that the KCNJ11 rs5219 polymorphism is associated with better response to vildagliptin treatment in medication-naïve patients with newly diagnosed T2D, although patients with the CT/TT- genotypes are more likely to develop mild hypoglycemia than patients with CC-genotype.

GLUCUBE: Usability validation of a non-invasive device for blood glucose measurement.

Mariola Méndez Muros[1], David Naranjo Hernández[2], Javier Reina Tosina[2], Laura María Roa Romero[2], Gerardo Barbarov Rostán[2] & María Asunción Martínez Brocca[1]
[1]Virgen Macarena University Hospital, Endocrinology and Nutrition Department, Seville, Spain; [2]University of Seville, Department of Signal Theory and Communications, Biomedical Engineering Group, Seville, Spain

Introduction
The Biomedical Engineering Group of the University of Seville, the Endocrinology and Nutrition Unit of the Virgen Macarena Hospital (ENU-VMH) and the company Igluco Tech are developing the GLUCUBE device, a new non-invasive sensor for blood glucose measurement.
Objective
First validation of usability and accessibility of the device by patients in a controlled clinical environment.
Material and Methods
General user-centered methodology. Design of questionnaires and semi-structured interviews to collect opinions, requirements and improvements

suggested by users. Selection of subjects for validation based on the heterogeneity of the sample, age, gender, socioeconomic characteristics and digital culture. From a preliminary prototype, iterative development carried out in parallel to the validation incorporating the identified improvements to the user-sensor interfaces.
Results
Study characteristics: 96 people with type I diabetes, 142 type II, 1 LADA, 19 without diabetes; 123 women; 84±19 kg weight (mean ± standard deviation); 54±16 years; 166±13 cm height, 30±7 BMI, assisted in follow-up consultations of ENU-VMH.Age group of people under 50 years old: 72 people with type I diabetes, 12 type II, 6 without diabetes; 43 women, 47 men; 80±21 kg weight; 35±10 years; 169±14 cm height, 27±7 BMI.Age group of people over 50 years old: 24 people with type I diabetes, 130 type II, 1 LADA, 14 without diabetes; 80 women, 89 men; 86±18 kg weight; 65±8 years; 165±12 cm height, 31±6 BMI.The usability and accessibility tests showed that 81% of the volunteers under the age of 50 expressed interest in having the results preferably displayed on the screen of a mobile phone, while 19% indicated the device screen as a preference. On the other hand, in the age group of people over 50 years old, only 13% of the volunteers preferred the screen of a mobile phone compared to 87% who preferred a visual interface on the device. 100% of the users positively valued the non-invasive nature of the proposed prototype and the ease of use. Regarding general aspects of the prototype, 97% of the patients indicated that the device did not need improvements and 2% suggested that voice prompts be included. 20% of users indicated a long battery life as a desirable feature for the device.
Conclusions
The introduction of user usability and accessibility validation in the design, from its early stages, guarantees the ease of use and adherence of the patient to the use of the final device.

Psychological impact of obesity in adult women

Dhoha Ben Salah[1], Hana Charfi[1], Yossra Mejdoub[2], Hanen Maamri[2], mouna elleuch[1], Sourour Yaich[2], Jihen Jdidi[2], Faten Haj Kacem Akid[1] & Mohamed Abid[1]
[1]Hedi Cheker University Hospital, Endocrinology, Sfax, Tunisia; [2]Hedi Cheker University Hospital, Community Medicine, Tunisia

Introduction
Obesity is a global epidemic with a growing prevalence in recent decades. In Tunisia, obesity is a major problem as it is increasing in adults as well as in children and adolescents. It therefore appears important to deepen the knowledge on this pathology and especially on the psychological profile, since studies concerning the mental health of obese subjects remain rare.
Purpose
Study the psychological impact of obesity in adult women
Patients and Methods
Descriptive observational study using the quantitative approach, including 115 obese female adults who consulted the clinics of Sfax. A validated questionnaire was proposed to these patients concerning 6 dimensions: depression and anxiety (HAD scale), social phobia (LSAS score), self-esteem (RSE score), body image (BSQ-8c short version) and eating disorders (BITE scale).
Results
The average age of our population was 47.14 years. Seventy-eight percent of our patients were married. The median body weight was 93,15 +/- 17,6 kg and 54,7% of our population had stage 1 obesity. Stage 2 and 3 were present in 20,7% and 24,7% respertively. Abdominal obesity was present in 94,7% of cases. Fifty-one patients were on a diet that was prescribed mainly by family and friends (41%) and only 8% seaked medical care.Depression was present in 17,4% of our population and anxiety in 76,5%. All our patients had low self-esteem and social phobia, of which 90,4% had very low self-esteem and 40,9% had intense social phobia. Preoccupation with body image was described in 90% of our female patients and 32% had severe body image concerns. Sixty percent of our population suffered from eating disorders, of which 12,2% had bulimia.
Conclusion
Obesity is a growing concern, not only in terms of physical and social health, but also in terms of psychological health, throughout the world.

Should we systematically detect hypothyroidism in obese subjects ?

Dhoha Ben Salah, Alaa Eddine Ben Issa, Mouna Elleuch, El Asmar Khouloud, Fatma Mnif, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Endocrinology, Tunisia

Introduction
Hypothyroidism has always been considered one of the most common endocrine etiologies of obesity. That said, would screening for hypothyroidism be justified in the face of obesity? The purpose of our study was to study the thyroid profile of obese people.
Patients and methods
We conducted a retrospective study which patients with obesity hospitalized in the diabetology endocrinology department, CHU Hédi Chaker of Sfax, between 01/10/2022 and 31/12/2022. for all patients who had consulted for obesity in which a thyroid assessment was requested as part of an etiological survey.
Results
the total number of patients was 70 obese, (12 men and 58 women), aged on average 44.57 years (±15 years). The average BMI of our patients was 38,38±6,09 k/m^2. In our study population, 30% of patients were moderately obese; 34.3% were severely obese and 35.7% were morbidly obese. No subject was known to have a history of dysthyroidism. Among patients, 6.7% ($n=5$) had subclinical hypothyroidism with TSH higher than 4 µmol/l and a normal FT4. In the latter, a thyroid check-up was done after one month returning normal. The rest of the patients ($n=65$) had no abnormalities in their thyroid function. The analytical study did not find a correlation between TSH blood level and the BMI of patients ($P=0.134$).
Conclusion
Our study shows that hypothyroidism remains a secondary cause to look for in the face of obesity with signs of appeal in favor of diagnosis instead of a systematic screening that proves to be unjustified.

A 36-year-old Caucasian male was referred in November 2021 to our clinic, for investigations regarding his recent genetic diagnosis of congenital hyperinsulinism, revealed by genetic testing, performed after the birth of couple's second child presenting with recurrent hypoglycemia.The female newborn diagnosed with fetal macrosomia (birth at 38 weeks, 4.3 kg), required follow-up and further examinations.A massive parallel sequencing on panel of 4867 genes using Roche platform, performed on the entire family, revealed the presence in the heterozygous state of the variant c.4432G>A, p.Gly1478Arg in the ABCC8 gene in the newborn, her father and the couple's first child, born in 2018 (3.6 kg at 36 weeks), which inherited the variant, but had no suspicious event of hypoglycemia.In our patient, the condition is transmitted in the autosomal dominant mode.Each child of a carrier individual has a 50% risk of inheriting the anomaly. However, the expressivity is variable and the penetrance incomplete, therefore the severity of the phenotype cannot be predicted.Venous blood sample showed non-fasting sugar level at 62 mg/dl(3.4 mmol/l) with inappropriate normal value of C-Peptide(0.954 nmol/l) and insulin(92.9 pmol/l).7-day continuous glucose monitoring (CGM) with Dexcom G5® Mobile CGM System, highlighted several hypoglycemic events, confirmed by fingerstick measurement, going as low as 45 mg/dl (2.5 mmol/l) linked mostly to meals, occasional alcohol consumption or after a 5-hour fasting period. Going backward in time, in the light of this new medical information, the patient could relate with his condition several unexplained symptoms that he presented over time, since childhood, as mild headaches and extreme hunger.Regarding the treatment, the simplest strategy is to eat several small low-carbohydrate meals daily. If not sufficient, further treatment is based on Diazoxide, a potassium channel agonist which inhibits insulin secretion in some forms of congenital hyperinsulinism by stimulating the opening of KATP channels leading to hyperpolarization of the β-cell membrane and inhibiting insulin secretion or Octreotide, a somatostatin analog that acts to suppress insulin release downstream of the KATP channel.The patient was placed on a low-carb meal regimen with successful prevention of

hypoglycemic events.The understanding of the genetic basis of familial hyperinsulinism should borne in mind that certain patients with hypoglycemia might present genetic forms with late-onset (or late diagnosis), such as congenital hyperinsulinism.Mild hypoglycemia in an adult can be easily missed, but the underlying cause can be rare with important further implications for the patient and his offspring.

Impact of emotional eating in the weight of woman

Victor Viana[1], Miguel Pereira[1], José Paulo Almeida[1] & Davide Carvalho[2]
[1]Department of Psychology, São João University Hospital Center, Porto, Portugal; [2]Department of Endocrinology, Diabetes and Metabolism, São João University Hospital Center, Porto, Portugal

Introduction
Obesity is nowadays one of the most important challenges in public health and, therefore, the investigation of their causes is most relevant. Among the various behavioral roots of obesity, the emotional over ingestion determined by emotional factors, i.e. emotional eating (EE), is one of them.
Objectives
To study how emotions contribute to obesity in woman.
Methods
We gathered a convenience sample 220 woman in the hospital and community settings, of which, 43 had normal weight, 37 overweight, 19 grade 1 obesity, 35 grade 2 obesity and 86 grade 3 obesity. The mean age was 39.3 ± 10.4 years and BMI was 35.3 ± 9.5 kg/m2. We applied the Emotional Appetite Questionnaire (EMAQ) that evaluates the EE determined by positive and negative emotions and by positive and negative situations. Statistical analysis was performed with the One-way ANOVA with Bonferoni correction test and Pearson's correlation test for variable association. P values $\leq$ 0.05 were considered as statistically significant.
Results
We found a positive correlation among age and BMI ($P<0.001$) and the mean of negative situations ($P<0.001$). We observed a negative correlation among BMI and education ($P<0.005$), the mean positive emotions ($P<0.001$) and positive situations ($P<0.005$). We noticed a significant age difference among normal weight vs grade 2 obesity and grade 3 obesity ($P<0.001$) participants. Normal weight and grade 3 obesity groups had different education levels ($P<0.02$). In terms of EE we observed significant differences between normal weight and grade 3 obesity ($P<0.005$) and between overweight and grade 3 obesity ($P<0.03$). Normal weight and grade 3 obesity participants had significant differences in the positive situations ($P<0.03$).
Conclusions
In this sample older and lower education participants showed a higher BMI. Woman with higher BMI appear to have more EE determined by negative emotional situations. Ingestion originated by positive emotions and situations results in lower BMI. Attending to all groups of weight classes concerning the EE, only the positive emotions distinguish the normal weight of the grade 3 obesity and the overweight. The positive situations distinguish the normal weight and the grade 3 obesity. According with some the literature, this study, corroborates the importance of the positive EE as a differential factor in the woman's weight. Thought, did not confirm the influence of the negative emotions and situations.

Impact of bariatric surgery on cognitive function

Maria-José Barahona[1], Andreu Simó[1], Montse Ibarra[1], Mireia Libran[1], Montse Ramos[1], Veronica Perea[1], Aida Orois[1], Carmen Quirós[1] & Laura Casas[2]
[1]Hospital Universitari Mútua Terrassa, Endocrinology Department, Terrassa, Spain; [2]Hospital Universitari Mútua Terrassa, Neurology Department, Terrassa, Spain

Aim
Obesity was shown to be related to global cognitive decline, being especially altered the executive function and the information processing speed. Bariatric surgery (BS) is an effective means of weight reduction in severely obese patients and correlates with improvements in neurocognition. The mechanisms underlying these improvements are not fully elucidated.
Material and Methods
Prospective, observational study, including consecutive patients that underwent Y-de- Roux gastric bypass at our center. Fat mass (FM %) and appendicular skeletal mass index (ASMI) (kg/m^2) by dual-energy X-ray absorptiometry (DXA) and Neurocognitive Test Battery (NTB) were assesed in all patients 1 month prior BS and 12 months after BS.
Results
From a cohort of 75 patients, 15 were selected as they completed 12 months of follow-up data. Almost all patients were female (87%), mean age (56 ± 8 years), pre-BS BMI 43 ± 5 kg/m^2, % total weight loss 28 ± 5. Eleven patients had diabetes (2 T1D, 9 T2D), 4 of them were treated with insulin and excluded for the calculation of HOMA. FM% (55 ± 5 vs 44 ± 7), ASMI (7.4 ± 1.6 vs 6.7 ± 1.2) and HOMA-IR (9.23 ± 6 vs 2.28 ± 1.4) significantly decreased 12 months after BS ($P<0.005$). Furthermore, patients had better performance (raw score and scaled score) in Free and Cued Selective Reminding Test (25.4 ± 5.4 vs 29.4 ± 5.5; 9.2 ± 2 vs 11.2 ± 2), visual immediate memory (16.6 ± 10.6 vs 21.8 ± 8.4; 9.5 ± 4.5 vs 12 ± 3.4), visual delayed memory (17.6 ± 10 vs 20 ± 8; 10.3 ± 4 vs 11.5 ± 3) and Boston Naming Test (52.9 ± 4.5 vs 54.4 ± 3.7; 11.8 ± 2.3 vs 13 ± 2.2) ($P<0.005$). After regression analysis, the only independent predictor for each post-BS performance test was the performance of those tests in pre-BS, not related to changes in body composition or HOMA-IR.
Conclusions
Our preliminary results suggest improvements on verbal and visual memory and language function after BS. Both memory and language depend on temporal lobe structures. These improvements seem not to be related to body composition or insulin resistance. Larger series are needed in order to confirm these preliminary results.

Serum xanthinoxidase activity (sxo)-glucose homeostasis association in patients with type 2 diabetes mellitus (t2dm)

Oksana Khyzhnyak[1,2], Anna Cherniaieva[1,2,3], Myroslava Mykytyuk[1,2,3] & Iurii Karachentsev[†,3]
[1]V. Danilevsky' Institute of Endocrine Pathology Problems, Clinical Endocrinology, Kharkiv, Ukraine; [2]Kharkiv Medical Academy of Post-graduate Education, Department of Endocrinology, Kharkiv, Ukraine; [3]Institute for Endocrine Pathology Problems, National Academy of Medical Sciences of Ukraine, Ukraine

Introduction
Hyperuricemia is increasingly being considered a potential pathogenic factor for T2DM, metabolic syndrome, and several adverse consequences of vascular disease. It has been suggested that xanthine oxidase may underlie the urine acid-T2DM association. The study aimed to determine the associations between clinical parameters, glucose homeostasis, and SXO activity in patients with T2DM.
Methods
125 patients with T2DM, age (58.9 ± 9.4) years. Determined WC, HC, ratio WC/HC, BMI, FBG, PBG, fasting insulin, serum urine acid (SUA), HOMA_IR, QUICKI, Caro, HOMA_β%, HOMA_S%, and SXO activity.
Results
It was found that in the total group patients with T2DM SUA depends on SXO activity ($r=0.34$; $P=0.007$). The total group established the presence of association SXO activity with fasting insulin ($r=0.45$; $P=0.001$), HOMA_β% ($r=-0.34$; $P=0.021$), HOMA_S% ($r=-0.52$; $P=0.00001$), QUICKI ($r=-0.35$; $P=0.016$), Caro ($r=-0.40$; $P=0.007$). No sexually significant differences have been established according to SUA and SXO activity in groups with different control of glycemia.
Conclusions
The patients with T2DM SUA are linearly associated with SXO activity regardless of the state of the control of glycemia serum for activity and nonlinearly associated with other parameters of glucose homeostasis. The patients with high SXO activity are by character significant higher fasting insulin, faster secretory activity of β-cells, low faster oral insulin sensitivity, and more pronounced manifestations of insulin resistance compared to patients with normal SXO activity. The level of SXO activity in patients with T2DM, regardless of the state of the control of glycemia, is determined by the SUA ($t=2.52$; $P=0.02$) and WC/HC ($t=2.87$; $P=0.007$). In patients with optimal control of glycemia, SXO activity determines fasting insulin ($t=2.68$; $P=0.015$), with suboptimal control and high risk – age ($t=-2.74$; $P=0.015$) and HOMA_IR ($t=2.62$; $P=0.02$).

Liraglutide improves binge-eating and increases ghrelin levels in obese diabetic 2 patients

Fedir Laniush & Alina Urbanovych
Danylo Halytsky Lviv National Medical University, Endocrinology, L'viv, Ukraine

Background and aims
liraglutide belongs to glucagon-like peptide-1 receptor agonists (GLP-1 RA) and is widely used for diabetes type 2 (DT2) management as well as for obesity treatment. GLP-1 RA reduce body weight and suppress eating behavior by delaying gastric emptying and affecting arcuate nucleus in hypothalamus. Binge eating disorder (BED) is the most common eating disorder (ED) in individuals with obesity and DT2. BED is characterized by consuming large amounts of food with an associated sense of loss of control. A well-known appetite-stimulating hormone is ghrelin, secreted within the gastric mucosa. Some studies report about decreased ghrelin levels in obese, diabetic 2 patients as well as in individuals with BED. Our aim was to evaluate the effect of liraglutide on BED and ghrelin level after 3 months of administration in obese diabetic 2 patients.
Materials and methods
75 individuals (mean age – 60.1 ± 6.4 years; BMI - 33.4 ± 3.6 kg/m^2; history of diabetes < 5 years) with DT2 were recruited into the study. After completing Binge eating scale (BES) 18 patients were screened positive for BED. 8 binge-eaters (1st study group) started therapy with metformin and liraglutide 1.8 mg daily. Other 10 participants (2nd study group) used metformin and SGLT-2 inhibitors as glucose-lowering therapy. Ghrelin level was assessed at the 1st and 12th week of the study.
Results
the 1st study group which used dual therapy with liraglutide demonstrated greater weight loss compared to the 2nd group (4.3 ± 1.3 kg vs. 1.7 ± 0.8 kg, $p < 0.05$). BES-scoring improved in the 1st study group and 3 participants (37,5%) were categorized into non-binge-eaters. Baseline ghrelin level in the liraglutide group (18.8 ± 10.3 ng/ml) increased (24.9 ± 10.8 ng/ml) significantly ($P < 0.05$) but not in the 2nd group.
Conclusion
liraglutide is effective and safe for the use in obese diabetic 2 individuals with BED. It reduces body weight and stabilizes eating behavior which makes them potential candidates for the application in diabetic 2 patients with BED. Changes in ghrelin level reflect the recovery of energy homeostasis due to weight loss.

EP275

A potential complication of diabetes: ischemic colitis

Shielah Mauntana[1] & Mahesh Gajendran[2]
[1]Paul L. Foster School of Medicine, El Paso, United States; [2]Long School of Medicine, University of Texas Health Center at San Antonio, Division of Gastroenterology, San Antonio, United States

Background
Ischemic colitis (IC) is a disorder characterized by a decrease in blood flow of the large intestine. Many factors can contribute to decreased blood flow in the arteries supplying the large intestine, such as nonocclusive causes like hypertension and atherosclerosis and occlusive causes like embolism from myocardial infarction. With Ischemic colitis's high mortality rate and its association with many cardiovascular diseases, it's important to understand the comorbidities that might lead to these events. Diabetes is known to cause atherosclerosis and other cardiovascular events. Thus, Diabetes might play a role in the development of ischemic colitis. This study aims to find and assess comorbidities like diabetes associated with admission for ischemic colitis.
Methods
We conducted a cross-sectional study of adults with IC listed as the primary ED diagnosis from 2005 to 2014 using the Nationwide Readmission Database (NRD). The characteristics of the IC-related ED visits were analyzed.
Results
The estimated number of ED visits with a primary diagnosis of IC from 2005-2014 was 541,267 people. Our results showed that the mean age of the cohort was 62 +/- 14 years, suggesting that most patients affected with ischemic colitis are elderly. 101,758 out of 541,267 ischemic colitis patients were found to have uncomplicated diabetes, amounting to 18.8% of the ischemic colitis population.
Conclusions
A notable comorbidity associated with ischemic colitis was uncomplicated Diabetes. Diabetes is marked by hyperglycemia, which can result in atherosclerosis. Atherosclerosis may lead to hypoperfusion of organs and ultimately ischemic colitis. Constipation is not only the most common gastrointestinal symptom of diabetes, but most common precipitating factor of ischemic colitis in the elderly. Most of the patients affected with ischemic colitis are elderly, based on the results. Thus, uncomplicated diabetes may be regarded as a comorbidity associated with ischemic colitis, constipation being the resulting precipitating factor.

Lipoatrophy in type 1 diabetes treated by human insulin: a case report

Manale Azriouil, Loubna Guissi, Farah Kamel, Nawal Moussaid, Kaoutar Rifai, Hinde Iraqi & Mohamed Elhassan Gharbi
Hôpital Universitaire Ibn Sina, Endocrinology, Rabat, Morocco

Introduction
Lipoatrophy is a rare cutaneous complication in diabetes that presents with localized subcutaneous fat atrophy at the insulin injection site. We report a case of a 62-year-old man type 1 diabetic with lipoatrophy lesions on the thighs.
Case report
A 62-year-old male, with clinical history of basedow's disease, He was diagnosed type 1 diabetes (T1D) when he was 19 years old, treated with premixed human insulin for the last 4 years.His weight was 68 kg and his body mass index was 21 kg/m2, he developed subcutaneous lipoatrophy around the insulin injection site at the thighs. The rest of the physical examination was normal.The results of blood testing were: K^+4.1 mEq/l, Na^+139 mEq/l, Hb1Ac 8.9%, cholesterol 157 mg/dl, triglycerides 108 mg/dl, liver and kidney functions were normal.The type of insulin was changed to insulin analogs (aspart and glargine insulin) and the injection site was changed to the abdomen.
Discussion
Lipoatrophy, is clinically characterized by visible cutaneous depression at the injection site. With the arrival of more purified forms of insulin it has become an extremely rare complication of insulin therapy. It is more than a cosmetic problem, because of the variability of insulin absorption of insulin and therefore the glycemic controlLipoatrophy is due to mechanical trauma from repeat injections. Immune etiologies have also been suggested, furthermore, the authors stated that lipoatrophy is found more frequently in patients with other autoimmune diseases, our patient has Basedow's diseaseAvoiding injections in the lipoatrophy sites and changing the insulin needle daily help to resolve lipoatrophy. Local treatment with sodium cromolyn, low- dose oral, or subcutaneous coadministration of corticosteroid are some therapeutic options used in some studies.
Conclusion
Lipoatrophy although rare can still occur even with the use of technologically advanced newer insulin preparations. This complication of insulin therapy may be limited by regularly inspecting and changing the injection sites.

Detection of visceral obesity in children and adolescents based on body composition analysis

Iuliia Samoilova, Mariia Matveeva, Oxana Oleynik, Daria Podchinenova, Venera Mutalimi, Ekaterina Trifonowa & Poina Zaharchuck
Siberian State Medical University, Children Diseases, Tomsk, Russian Federation

Introduction
Visceral obesity is a primary risk factor for metabolic syndrome and is associated with short- and long-term effects on physical and psychosocial health. It is now known that body mass index (BMI), which is used as the main method of diagnosing obesity, does not allow the assessment of body composition and differentiation of visceral adipose tissue.The aim of the study. To investigate the features of body composition that influence metabolic risks in primary school children.
Materials and methods.
Prior to any procedures of the study protocol informed consent was signed by the child's legal representative or self at the age of 15. We examined 519 children aged 8 to 12 years, including anthropometry (height, weight, BMI, SDS BMI). SDS BMI was calculated using Anthroplus WHO software developed by the

World Health Organization for children aged 6 to 19 years. Body composition was assessed in all participants using an Inbody 770 analyser (Inbody Co. Ltd, Korea). Statistical processing of the results was performed using SPSS Statistics 25.0.
Results
Fat mass parameters in girls and boys from the obese and overweight groups were comparable to the SDS BMI values. The 11% of normal weight girls ($n=146$) had increased body fat mass, 32.2% had increased body fat percentage, and 7.5% had visceral obesity (VO). Among all female examinees, 45.9% had decreased muscle mass. Boys with normal body weight ($n=147$) had increased fat mass in 17.7% cases, 34.7% of those examined had increased percentage of fat mass and 2.1% had visceral obesity. Among all boys surveyed, 17.5% had decreased muscle mass. Weight deficient children, irrespective of gender, had no excess fat mass but all had deficit muscle mass.
Conclusions
The results obtained in the survey are probably related to lifestyle aspects of modern children, such as low physical activity and an unbalanced diet. The revealed changes in body composition in children with normal SDS BMI indicate the need for more active diagnostic tactics and the use of additional tools to diagnose these deviations and their correction. The use of bioimpedance measurement will allow early detection of signs of visceral obesity in children, irrespective of BMI.

DOI: 10.1530/endoabs.81.EP277

EP278

Evolution of glucose-insulin homeostasis in children with β -thalassemia major (β -TM): A twenty-year retrospective ICET- A observational analysis from early childhood to young adulthood

Vincenzo De Sanctis[1], Shahina Daar[2], Ashraf Soliman[3], Ploutarchos Tzoulis[4], Mehran Karimi[5] & Christos Kattamis[6]
[1]Quisisana Hospital, Ferrara, Italy; [2]College of Medicine, Sultan Qaboos University, Muscat, Oman; [3]Hamad Medical Center, Doha, Qatar; [4]Department of Diabetes and Endocrinology, Whittington Hospital, London, United Kingdom; [5]Hematology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran; [6]National Kapodistrian University of Athens, Athens, Greece

We studied retrospectively the changes of glucose-insulin homeostasis from early childhood to young adulthood in β-thalassemia major (β -TM) patients with impaired fasting glucose (IFG) vs those with normal OGTT.
Methods
All data entered in the database of β -TM patients' records from September 1983 to September 2021 were included in the study.
Results
The occurrence of dysglycemia (GD) (IFG, IGT and IFG + IGT) after 20 years of follow up was markedly higher in the group with IFG at the beginning of the study compared to the group with normal OGTT. There was no case of diabetes mellitus. In patients who had normal OGTT at baseline, a small proportion developed GD (2/9 at 15 years and only 1/8 at 20 years). On the other hand, 3 out of 9 patients with baseline IFG, had persistent IFG at 5 years. One had persistent isolated IFG and 3 developed IGT 10 years later. 5/9 had IFG after 15 years, and finally 6/8 had GD after 20 years. (table)Indices of insulin secretion and sensitivity (MI, HOMA-IR, oDI) were statistically different ($P=<0.001$) between the two groups. HOMA-IR was higher in patients who had IFG vs (6/9 patients had HOMA-IR > 2.24) vs the group with normal OGTT (2/6 patients had HOMA-IR > 2.24). This suggested a degree of insulin resistance in the etiology of GD.In both groups of patients, no correlation was observed between serum ferritin (SF), ALT and indexes of insulin sensitivity or insulin resistance.
Conclusion
Our data advocates that baseline IFG predicts future development of GD because almost half of patients with IFG at the outset had abnormal glucose handling 15 years later. Understanding the sequence of abnormalities in the progression from normal glucose homeostasis to GD and identifying the risk factors for the glycol-metabolic defects in thalassemia patients might help in the formulation of interventions.

Table Proportions of progressive dysglycemia in BTM patients with normal OGT vs those with IFG.

	BTM -Normal OGTT	BTM- Impaired Fating Glucose
	***n*=9**	***n*=9**
Age yr.	**5.4+/- 0.7**	**5.6+/- 1.7**
After 5 yr.	**1/9 IFG**	**2/9 IFG**
Total Dysglycemia	**1/9**	**2/9**
After 10 yr.	**2/9 IFG and 1 IFG+ IGT**	**3/9 IGT**
Total Dysglycemia	**3/9**	**3/9**
After 15 yr.	**2/9 IGT**	**5/9 IFG**
Total Dysglycemia	**2/9**	**5/9**
After 20 yr.	**1/9 IFG**	**2/9 IFG, 2/9 IGT, 2 IFG+IGT**

Malnutrition risk using morphofunctional evaluation in hematopoietic stem cell transplantation

Concepcion Muñoz Jimenez, Carlos Alzas Teodomiro, Mireia García-Ramírez, Laura Romero, Estefania Garcia, Alfonso Jesús Calañas Continente, Maria José Molina & Aura D. Herrera-Martínez
Hospital Universitario Reina Sofía, Córdoba, Spain

Background
Malnutrition affects 30-50% of patients with hematological malignancies; it is due to the disease itself, the treatment-related catabolic process and chemo-or radio-therapy side effects (nausea, vomiting, diarrhea and mucositis). Patients with poor nutritional status have increased morbidity (treatment complications, infections, mucositis) and mortality.
Aim
To evaluate the nutritional status of all patients that underwent hematopoietic stem cell transplantation (HPSCT) in our center during April-November 2021
Methods
A novel morphofunctionalnutritional evaluation (included electrical bioimpedance, handgrip dynamometry, biochemistry, abdominal adipose ultrasoundand rectus femoris muscle ultrasound) was performed baseline and 24±9 days after HPSCT.
Results
Forty-eight patients were included; mean age 50.2±14.6;62.5% males. Lymphomas was the most common cause of HPSCT (35%), and most patients underwent an autologous transplant (56.3%). At baseline severe and moderate malnutrition (using the GLIM criteria) were observed in 21%and 37.5% of patients respectively, despite only 21% presented with BMI <20 kg/m^2. Patients lost weight during the study period (5.6±3.1%; $p<0.05$), especially fat free mass (16.7±2.3 vs 18.4±6.5; $p<0.05$), serum albumin levels, superficial and deep abdominal adipose tissue, as well as thecircumference of rectus femoris significantly decreased in most patients during follow-up ($P<0.05$).
Conclusions
Malnutrition is observed in more than 50% of patients before theHPSCT despite normal or increased BMI. Significant weight loss during the first days after HPSCT worsens the nutritional status of these patients. The novel morphofunctional nutritional evaluation provides early and additional information that could have prognostic value. Routine nutritional evaluation should be performed in all patients before HPSCT.

C-peptide response to standardized test meal in patients with newly diagnosed type 2 diabetes mellitus

Jelena Stojanovic[1], Marina Andjelic Jelic[1,2], Miljanka Vuksanovic[1,3], Milica Marjanovic Petkovic[1,3], Biljana Jojic[1], Ana Cvetkov Grujanac[1] & Teodora Beljic Zivkovic[1,3]
[1]Zvezdara University Medical Center, Division of Endocrinology, Diabetes and Metabolic Disorders, Belgrade, Serbia; [2]University of Belgrade, Faculty of Dental Medicine, Belgrade, Serbia; [3]University of Belgrade, Medical Faculty, Belgrade, Serbia

Background
Optimal testing of beta-cell dysfunction is still elusive. Oral based solid-food tests could superiorly approximate real-life stimulation by incorporating incretin activation. Increased body fat was recently associated with better preserved beta-cell secretory response, due to gluco-lipotoxicity induced adaptation.

Objective
To assess C-peptide response to standardised test meal (STM) and its dependency on subject characteristics in newly diagnosed type 2 diabetes mellitus (DM2) patients.
Patients and Methods
STM consisted of one 60g white flour bread-roll (24g carbohydrates) and 200 ml 2.8% milk-fat yoghurt (12g carbohydrates), totalling 300 kCal, consumed over 5 minutes after overnight fasting. C-peptide was analysed at baseline and 2h post STM in newly diagnosed DM2 patients ($n=80$; 30-65 years old; 47 males) with initial HbA1c ≧ 9% and BMI 25-40 kg/m^2.
Results
Baseline C-peptide of 2.29±0.14 ng/ml, increased after STM by 1.40±0.20 ng/ml (63.6%±7.7%). In women vs. men, there was non-significantly higher baseline C-peptide (2.48±0.26 ng/ml vs. 2.16±0.15 ng/ml, $P>$ 0,05) with a significantly greater C-peptide increase (ΔCP) in STM: 1.92±0.33 ng/ml vs. 1.04±0.14 ng/ml (P 0,05). Average baseline C-peptide (2.29±0.14 ng/ml) correlated significantly with average BMI (29.7±0.5 kg/m2) ($P<0.01$; Pearson's $r=0.32$). Baseline C-peptide was significantly lower in the normally nourished (1.58±0.22ng/ml) compared to overweight (2.41±0.23ng/ml; $p<0.05$) and obese (2.46±0.22 ng/ml; $p<0.05$). STM-stimulated ΔCP was significantly lower in the normally nourished (0.68±0.21 ng/ml) compared to twice greater in the overweight (1.40±0.20ng/ml; $p<0.05$) and obese (1.71±0.44 ng/ml; $p<0.05$). Average ΔCP in STM (1.40±0.20 ng/ml) correlated significantly with BMI (29.7±0.5 kg/m2) (P 0.05; Pearson's $r=0.23$). ΔCP correlation to age was not significant.
Conclusions
Standardised test meal is a promising simple and naturalistic alternative to asses beta-cell function in-vivo through C-peptide response in patients with newly diagnosed DM2, but interpretation should respect its dependency on gender and BMI. Significant positive correlation of baseline C-peptide and its stimulated response to STM with BMI supports the hypothesis of more preserved or better adapted beta-cell reserve in the obese patients.

Flash glucose monitoring system in a regional hospital in the south area of granada

Sara León Utrero, Victoria Contreras Bolívar, Enrique Redondo Torres, Javier García Sánchez & Pablo José López-Ibarra Lozano
Hospital Universitario San Cecilio, Servicio de Endocrinología y Nutrición, Granada, Spain

Introduction and Objectives
Poor metabolic control in Type 1 Diabetes Mellitus (DM 1) is associated with micro and macrovascular complications. The implementation of interstitial glucose monitoring systems has contributed to improving glycemic control in recent years. Our objective was to know the metabolic control in people with type 1 DM and the Flash system and to establish if there is an association between its use and glycemic control variables.
Material and Methods
Cross-sectional observational study in people with DM 1, carriers of Flash glucose monitoring system, with follow-up in a Regional Hospital (Hospital Santa Ana, Motril-Granada). Downloads were performed for the previous three months and glycemic control variables were analyzed: average glucose (mg/dl), % of time in range (TIR, 70-180 mg/dl), % above target (>180 mg/dl), % below target (< 70 mg/dl), % coefficient of variation, estimated glycosylated hemoglobin (GMI, %) and low glucose events (in no.). Statistical analysis was performed using the SPSS 15.0 program.
Results
179 patients were included, 51.9% women, with a mean age of 42.04±15.3 years. All patients were receiving basal-bolus insulin therapy. The average glucose of the last three months was 176.65±44.54 mg/dl and the estimated GMI was 7.4± 0.84%. The mean number of readings per day was 9.25±6.4. The coefficient of variation was 37.7±8.8%. The mean time within target was 53.28±19.08%, over range was 41.8±20.8% and under range was 4.9±5.4%. Taking 10 or more readings per day was statistically significantly associated with lower mean glucose levels (164.0 vs 184.6, $p<0.01$), lower estimated GMI (7.23 vs 7.55, $p<0.01$), increased time in range (59.10 vs 49.60, $p<0.01$) and decreased time above target (35.06 vs 45.72, $p<0.01$).
Conclusions
Insufficient metabolic control was observed in people with DM 1 under follow-up in a Regional Hospital. 10 or more daily readings was associated with better results in terms of glucometry. Therefore, we could recommend the active and frequent use of the FLASH sensor in people with DM 1 to achieve better metabolic control.

Nurses knowledge in diabetes self-management education in Sfax Tunisia

Mouna Elleuch, Hana Charfi, Dhoha Ben Salah, Ameni Salah, Fatma Mnif, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Cheker University Hospital, Endocrinology, Tunisia

Introduction
Diabetes mellitus is a major public health problem affecting all ages worldwide. In Tunisia, 18% of the population has diabetes mellitus. In fact, it is one of the first ten causes of death in our country.Therefore, self-management education for diabetic patients play an important role in reducing diabetes complications and mortality rate. The education is conducted not only by doctors, but also by nurses.
Purpose
The aim of this study is to determine the nurses' knowledge in diabetes self-management education (DSME)
Methods
We are presenting a descriptive study including 32 nurses, 17 nurses from the endocrinology department of Hédi Chaker hospital, Sfax, Tunisia, and 15 nurses from the healthcare dispensary Mohamed Ali Sfax Tunisia.
Results
The majority of nurses: 62,50% were young, aged between 25 and 40 years old, 78% of them were female and 78,5% were married. We discovered that only 63% of the nurses were involved in nurse-led DSME and did actually have specific training in DSME. The nurses believed that the purpose of DSME is essentially to prevent complications (36%), to lead as normal a life as possible (30%), to obtain a balanced blood sugar (18%) and to improve the patient's life (16%).Only 6,25%of the nurses had real good knowledge in DSME vs 75% and 18,75% having average and poor knowledge respectively.The majority of the female nurses (56,25%) had average knowledge in DSME vs 18,75% in the male group, and only 6,25% of the female nurses knew how to properly educate the diabetes patients vs 0% in the male nurses.Total absence of DSME knowledge was mostly described in the youngest group of nurses (25-40 years old) with an average of 18,75% vs 0% in older nurses (> 40 years old).We noted that nurses having more than 10 years work experience were more efficient in educating the patients than those with less work experience.Finally, we asked the nurses to provide solutions on how to get more information about DSME, 50% of them proposed attending seminars, 44% proposed organizing ongoing training sessions and 6% didn't comment.
Conclusion
In recent years, great emphasis has been placed on the role of non-pharmacological self-management in the care of patients with diabetes. Studies have reported that nurses, compared to other healthcare professionals, are more likely to promote preventive healthcare seeking behaviors.

Pharmacogenomics and efficacy outcome of therapy with glucagon-like peptide-1 receptor agonists in type 2 diabetes

Camille Beniga & Hassan Heshmati
Endocrinology Metabolism Consulting, LLC, Anthem, Arizona, United States

Introduction
Individual variability in drug efficacy and safety due to genetic diversity is a major challenge for clinicians. Pharmacogenetics deals with inherited differences in the efficacy and safety responses to drugs. The incidence of type 2 diabetes (T2D) is increasing worldwide and the disease is reaching pandemic proportions. T2D is treated by oral and/or injectable drugs. The interindividual variability of T2D drug actions may be caused, at least in part, by genetic factors. This review outlines the contribution of pharmacogenomics to the efficacy outcome of glucagon-like peptide-1 receptor agonists (GLP1RAs) therapy in T2D.

Methods
A systematic search of literature was conducted using the search terms pharmacogenomics, type 2 diabetes, glucagon-like peptide-1 receptor agonists, and efficacy.
Results
Pharmacogenomics has identified the relevance of approximately 56 genes in the response to 7 pharmacological classes of antidiabetic drugs. More than 460 million people worldwide have T2D. According to the American Diabetes Association and the European Association for the Study of Diabetes, GLP1RAs are recommended as a second-line treatment in the management of T2D when there is a need for combination therapy. The identified genes influencing the efficacy outcome of GLP1RAs treatment [increased or decreased efficacy based on single nucleotide polymorphisms (SNPs)] include *GLP1R* (increased or decreased efficacy with rs6923761, rs3765467, rs10305420, and rs761386 SNPs), *TCF7L2* (increased efficacy with rs7903146 SNP), *CNR1* (increased efficacy with rs1049353 SNP), *SORCS1* (increased efficacy with rs1416406 SNP), and *WFS1* (decreased efficacy with rs10010131 SNP).
Conclusion
Pharmacogenomics is becoming an important tool in medicine. Education of clinicians is essential for the implementation of genetic testing into clinical practice. The use of genotype-guided dosing can help obtaining better efficacy and safety outcomes with drugs. Potential genomic markers for targeted GLP1RAs therapy have been identified. However, the number of studies is relatively limited and more comprehensive research including larger populations is needed to determine the therapeutic implication of incorporating precision medicine with the utilization of GLP1RAs in T2D.

Factors affecting glycemic outcomes using closed-loop systems in real-world

Lara Albert Fàbregas, David Subias Andujar, Ana Romero Gregori, Maria Florencia Luchtenberg, Albert Cano Palomares, Isabel Mazarico & Mercedes Rigla
Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Endocrinology and Nutrition, Sabadell, Spain

Aims
To evaluate real-world efficacy of closed-loop systems (CLS) (Minimed™ 780G, DBLG1 -Diabeloop- and Control-IQ™ Tandem) as well as to assess those predictive factors related with the achievement of near-normal glycemic control.
Methods
A prospective, longitudinal, and observational study was performed. It included T1D adults who initiated CLS between April and December 2021 in our hospital and provided data for ≧3 months (ninety of 130 CLS users were included). We evaluated the initial and three-months data regarding glycemic outcomes and their baseline characteristics.
Results
Ninety T1D were included (54 female, 45.1 ± 11.5 years, 76.2 ± 16.0 kg weigh, 27.4 ± 4.9 kg/m^2 BMI, baseline HbA1c 7.5 ± 0.9%). 41% were previously under multiple daily injections (MDI), 91% used continuous glucose monitoring (CGM) and 56% used an insulin bolus advisor. Different commercial CLS were used: 54 DBLG1, 18 Control-IQ™ and 18 Minimed™780G.After three months, HbA1c significantly decreased to 6.9% ± 0.7% (-0.6% ± 0.1%, p < 0.001). 58% achieved HbA1c < 7%, 25% HbA1c 7-7.5% and 17% HbA1c > 7.5%. Mean glucose management indicator (GMI) was 7.0% ± 0.4% (45% GMI < 7%, 13% GMI = 7% and 100% GMI ≤ 7.9%). Mean time-in-range (TIR) was 73% ± 10% (67% TIR > 70%) and mean time below range 54-69 mg/dl (TBR) was 1.4% ± 1.0%.Optimal glycemic control was observed among people with higher education level (GMI 6.8% ± 0.3% vs 7.1% ± 0.4%, p < 0,04) and among people under 45 years old (HbA1c 6.7% ± 0.1% vs. 7.1% ± 0.1%, p < 0.04).We observed a positive trend towards better glycemic control in women (TIR > 70% 71% vs. 61%) and in those people who exercise regularly (HbA1c ≤ 7% 75% vs. 54%; TBR < 4% 0% vs. 8%)). Overweight didn't affect glycemic control.Regarding prior treatment, a higher percentage of patients with insulin pump obtained optimal glycemic control compared with MDI (HbA1c ≤ 6.5% 34% vs. 22%). Similarly, the previous use of insulin bolus advisor related to a higher proportion of optimal HbA1c (HbA1c ≤ 6.5% 34% vs 21%).We observed a better glycemic control with the Minimed™780G system (GMI = 6.7% vs. 7.0% DBLG1 and 7.0% Control-IQ™; TIR > 70% 81% vs. 65% DBLG1 and 59% Control-IQ™ (n.s.); better TAR and TBR, but no differences in HbA1c).
Conclusions
In almost all cases the use of a CLS improved glycemic control substantially. Factors that lead to an optimal glycemic control are higher education level, younger age and the CSL system used. Other factors that could influence glycemic outcomes are female sex, previous use of insulin pump and/or insulin bolus advisor and regular exercise.Partially funded by ISCIII (PI18/01118).

Predicting the effectiveness of metformin in patients with type 2 diabetes mellitus from molecular genetic positions

Yulia Sorokina[1], Sergey Sukhanov[2], Olga Zanozina[3,4,4] & Anna Mosina[5]
[1]Privolzhsky Research Medical University, General and Clinical Pharmacology, Nizhny Novgorod, Russian Federation; [2]Privolzhsky Research Medical University, Hospinal Therapy, Nizhny Novgorod, Russian Federation; [3]Privolzhsky Research Medical University, Regional Hospital named after N.A, Semashko, endocrinology, Nizhny Novgorod, Russian Federation; [4]Privolzhsky Research Medical University, Regional Clinical Hospital named after N. A. Semashko, Endcrinology, Nizhny Novgorod, Russian Federation; [5]Privolzhsky Research Medical University, Nizhny Novgorod, Russian Federation

Purpose
to assess the possibility of predicting the effectiveness of pharmacotherapy with metformin in patients with type 2 diabetes mellitus (DM2) depending on the single nucleotide polymorphism of the nitric oxide synthase gene.
Materials and methods
186 patients were examined, referred for planned hospitalization, the duration of DM2 was 6-8 years, the target level of glycated hemoglobin was 7.5%, the actual level was 8.3%. All patients were prescribed metformin. Single nucleotide polymorphism of the gene (SNP) eNOS3 C786T (rs 2070744) was determined by real-time PSR, the level of Klotho protein was determined by ELISA, and the level of glycated hemoglobin was determined by BioRad. According to the results of the genetic study, the patients were divided into three groups: with the CC, TC and TT genotypes (SNP) eNOS3 C786T (rs 2070744).
Results
Patients with genotype CC achieved and maintained glycated hemoglobin levels below the target in 86% of cases when metformin was used at a dose of 1700 mg per day. In the same group, the Klotho protein level was significantly higher than in the other groups ($P < 0,05$).
Conclusions
The use of metformin as monotherapy at a dose of 1700 mg/day may sometimes be sufficient in the presence of the CC genotype. The patients with TC and TT genotypes need to the combined hypoglycemic pharmacotherapy at the start.

Age-related changes in proinsulin processing in non-diabetic individuals

Markéta Vaňková, Daniela Vejražková, Petra Lukášová, Josef Včelák & Běla Bendlová
Institute of Endocrinology, Molecular Endocrinology, Praha, Czech Republic

Introduction
To understand the pathological changes associated with glucose homeostasis in old age, it is necessary to know the natural changes in the processing of proinsulin into mature insulin. Surprisingly, while there is abundant information about insulin function in diabetics, the situation in healthy adults and old humans was rarely examined.
The study aimed
To determine how the proinsulin secretion in individuals with normal glucose tolerance changes during the process of natural aging.
Methods
A total of 761 individuals (539 women, 222 men) with normal glucose tolerance were divided into groups according to age: 1) 18-30 years 355 persons, 2) 30-45 years 234 persons, 3) 45-60 years 103 persons, 4) 60-75 years 58 people, 5) 75-90 years 11 people.Basal blood glucose, proinsulin, insulin, C-peptide levels, HOMA-R, BMI and proinsulin/insulin, proinsulin/C-peptide,

proinsulin/glycemia ratios were monitored.Parameters were compared between age groups, separately for women and men. Statgraphics software (Kruskal-Wallis, Dunn's test, *P*0.05).
Results
Blood glucose levels increased with age. The age categories up to 30 and up to 45 years had the lowest levels and differed from the older groups. The older categories no longer differed. HOMA-R increased with age and matched the development of BMI in the categories. HOMA-R was highest in women in the 60-75 category and men in the 45-60 category.Basal insulin and C-peptide levels depended on gender. For women, the highest levels were in the category of 60-75 years, for men already in the category of 45-60 years. Proinsulin levels were highest in the youngest women under the age of 30, then decreased with age and the differences were no longer significant. In men, proinsulin levels did not differ with age.The proinsulin/insulin ratio was highest in both sexes under 30 years of age. The proinsulin/glycemia ratio was also highest at age 30, but only in women. The insulin/C-peptide ratio did not change with age.
Conclusion
A cross-sectional analysis of basal proinsulin secretion in normoglycemic individuals showed that its levels were surprisingly highest in the 18-30 age group, especially in young women. The proinsulin/insulin ratio was also highest in the youngest, both sexes. All people, including normoglycemic, develop insulin resistance with age. We showed a slight age-dependent increase in insulin and C-peptide secretion, the peak of which was different in men and women. However, in normoglycemic subjects, proinsulin secretion did not increase with age.AZV-NV18-01-00399, MH-CZ-DRO-(EU00023761)

New challenge for endocrinologists–heterozygote familial hypercholesterinemia (part 1)

Ingvars Rasa[1], Ksenija Jenbajeva[2] & Alīna Anufrijeva[2]
[1]Rīga East Clinical University Hospital, Outpatient Clinic, Rīga, Latvia; [2]Rīga Stradiņš University, Faculty of Medicine, Rīga, Latvia

Background
Heterozygote familial hypercholesterolemia (HeFH) is a common genetic disorder resulting in high low–density lipoprotein–cholesterol (LDL–C) levels. It has been established that only 3% of patients (pts) among the Latvian population were diagnosed in 2019. The early HeFH diagnosis and treatment can prevent premature cardiovascular complications and save lives. Aim. The study aimed to determine the incidence of HeFH in a single-centre endocrinologist's clinical practice in Riga East Clinical University Hospital Outpatient Clinic. Methods. We collected three years of data from medical records with HeFH (ICD-10 code E78.01) from January 2019 to December 2021. Based on LDL–C, Apo B, Apolipoprotein index (Apo Index), Lipoprotein (a) (Lp (a)), and using the Dutch Lipid Clinic Network criteria; all pts were divided into two groups: group Nr.1 – definitive FH; group Nr.2 – probable FH. Statistical analysis was conducted using IBM SPSS. Results. Altogether, there were 3720 pts in an endocrinologist's practice, from which 129 (3.47%) pts were included, 39 (30.2%) males and 90 (69.8%) females. The mean age was 49.8±12.3SD years. 58 pts (45.0%) were included in the first group, and 71 pts (55.0%) were included in the second group. Only 18 pts (14%) received lipid-lowering therapy initially. The laboratory findings in the first group before the treatment were: LDL–C 4.49 mmol/l (±1.29SD); Apo B 117.52 mg/dl (±25.11SD); Apo Index 0.79 (±0.20SD); Lp (a) 82.76 mg/dl (±62.06SD). The laboratory findings in the second group before the treatment were: LDL–C 4.12 mmol/l (±0.90SD); Apo B 98.22 mg/dl (±16.51SD); Apo Index 0.64 (±0.12SD); Lp (a) 17.47 (±23.90SD). In the first group, 36 (62.1%) pts received statin therapy, 10 (17.2%) – combination therapy with statins and ezetimibe, 6 (10.3%) pts – fibrates, 1 (1.7%) pt – combination therapy with statins and fibrate, 3 (5.2%) pts refused treatment. However, in the second group, 50 (70.4%) pts received statin therapy, 10 (14.1%) pts – fibrates, 3 (4.2%) pts – combination therapy with statins and fibrates. In both groups, we found out that LDL–C, Apo B, Apo Index decreased at the end of the study ($P=0.272$ and $P=0.499$). Conclusion. Study data suggest that HeFH is much more common than generally thought. The lipid-lowering therapy decreased LDL–C, Apo B, Apo Index. Medication use reflects the extent of underdiagnosis and undertreatment of HeFH in the community and primary and secondary care.

MATSUDA INDEX (MI 0-120)	6.70±2.24	6.38±2.28	17.11±6.7	NS	< **0.001**	< **0.001**
HOMA-IR	1.92±0.53	2.85±0.77	0.72±0.52	< **0.05**	< **0.001**	< **0.001**
Insulinogenic Index (IGI)	0.53±0.29	0.74±0.68	0.75±0.16	NS	NS	NS
Oral disposition Index (oDI)	3.45±2.11	4.01±3.82	12.92±5.11	NS	< **0.001**	< **0.001**

We assessed glycemia and insulin markers in 18 young children with beta thalassemia major (BTM). Insulin markers measured included: the Homeostatic Model Assessment index of insulin resistance (HOMA-IR), Matsuda index (MI), the insulinogenic index (IGI), and the oral disposition index (oDI). 9 had normal fasting glucose (FG) and 9 had impaired fasting glucose (IFG)
Results
HOMA-IR, a marker of IR was significantly higher in children with BTM compared to normal controls. Fasting insulin was significantly higher in children with BTM patients vs normal children. Despite higher fasting insulin compared to controls thalassaemic children (group A) had higher fasting glucose levels. Both findings support an insulin resistance state early in these patients. oDI was significantly lower in children with BTM (with and without IFG) compared to normal controls.
Conclusion
These findings supported the presence of significant insulin resistance in children with BTM on repeated blood transfusion and iron chelation

Obesity in adults with type 1 diabetes mellitus and its relation to their eating habits and physical activity

Dimitra Pappa[1], Eleftheria Barmpa[1], Maria Christou[2], Ioannis Katsaras[1], Stylianos Tigas[2] & Alexandra Bargiota[1]
[1]University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece; [2]University Hospital of Ioannina, Department of Endocrinology and Metabolic Diseases, Ioannina, Greece

Introduction
Obesity is rising worldwide and the number overweight or obese patients with type 1 diabetes mellitus (T1DM) is increased and eating habits (EH) and physical activity (PA) play an important role on glycemic control and weight gain. The aim of the present study was to examine the EH and the exercise level in patients with T1DM and their relation to body weight.
Methods
126 patients with T1DM (55/126 males, 71/126 females) attending our outpatient clinics were studied. Their mean age was 34,53 ± 11,9 years and the mean diabetes duration was 18,09 ± 10,67 years. In all patients at baseline weight, height, BMI, waist circumference (WC) and glycosylated hemoglobin (HbA1c) were measured. Food consumption and EH were assessed by a standardized semi-quantitative food-frequency questionnaire. PA was assessed by the International Physical Activity Questionnaire (IPAQ). Patients were divided in two groups according to their BMI; GroupA = BMI <25 kg/m^2 and GroupB = BMI $\geqq 25$ kg/m^2
Results
The mean BMI was 25,98 ± 5,44 kg/m^2, WC 91,8 ± 12 cm and HbA1c 7,63 ± 1,63%. In GroupA 68/126 patients (53,95%) were included with a mean BMI 22,33 ± 1,90 kg/m^{2,} WC 85,41 ± 7,82 cm, age 32,5 ± 11,72 years and diabetes duration 16,92 ± 10,38 years and in GroupB 58/126 patients (46,03%) with a mean BMI 30,25 ± 5,14 kg/m^2, WC 98,30 ± 12,00 cm, age 36,91 ± 11,76 years and diabetes duration 19,46 ± 10,93 years. GroupA had a significantly lower HbA1c compared to GroupB (7,58 ± 1,77% vs 7,69 ± 1,45%, $P = 0{,}000$).Patients in GroupB had more meals per day compared to GroupA, all patients in both groups had lunch, more patients in Group B skipped breakfast compared to GroupA (17,24% and 13,23% respectively). In GroupB patients were eating out or take away more frequently than those in GroupA. Eating out or take away was related with higher consumption of 'junk type of food'. Food and meal choices in both groups were made by the patients.In GroupA 1,47% had no PA last week, 7,35% had median and 10,29% intense PA three days last week. In GroupB 12,06% had no PA last week, 8,6% had median and 5,17% intense PA three days last week.
Conclusion
Overweight and obesity is increased among patients with T1DM with almost half of them to be overweight or obese. Overweight and obese patients have more meals per day, skip breakfast, eat out or take away more frequently, exercise less and have worse glycemic control than the non-obese ones. Education and early intervention is needed to improve these outcomes.

Glycemic changes in relation to hepatic iron status in patients with non-transfusion dependent (NTD-SCD) and transfusion dependent sickle cell disease (TD- SCD).

Ashraf Soliman[1], Mohamed Yassin[2] & Vincenzo De Sanctis[3]
[1]Hamad Medical Center, Pediatrics, Doha, Qatar; [2]Hamad Medical Center, Hematology, Doha, Qatar; [3]Quisisana Hospital, Ferrara, Italy

Introduction
We evaluated glycemia and the iron status in patients with NT-SCD and 6 patients with TD- SCD by measuring serum ferritin level (SF), liver iron content (LIC), alanine transferase (ALT) and fasting blood glucose (FBG) over 5 years of follow up.
Results
At the initial assessment, 16 adults with (age: 33 ± 14 years), and six of TD-SCD ($n = 6$, age = 25 ± 10 years) were studied. 6/16 of NT-SCD had SF $>$ 500 µg/l, and 5/16 had high LIC ($>$ 36 µmol Fe/kg dry weight). 6/16 had elevated ALT concentrations. 2/16 had impaired fasting glucose (IFG), but none had IGT or diabetes (DM). In the TD-SCD who were receiving top-up RBC transfusion to keep Hb $>$ 10 g/dl, and oral iron chelation (Exjade), all had high LIC and 14/16 had high. ALT was high in 2/6. 1/6 had IFG.Five years later, 3/16 of NTSCD had DM and 2 had IFG. Those who developed DM had had LIC = 13, 75, and 22 mmol/kg 5 years before the development of DM. The 2/16 who developed IFG had had LIC = 27 and 39 mmol/kg DW. In TDSCD, 2/6 developed DM and 1/6 had IFG. Those who developed DM had had LIC = 127 and 20 mmol/kg and normal FBG 5 years before the development of DM. The one with IFG had previously LIC = 22 mmol/kg and normal FBG 5 years back. Echocardiography revealed abnormalities of the left ventricle, dilated left atrium and dyskinesis in 5/22.FBG was correlated significantly with the age of patients ($r = 0.68$, P0.01) but did not correlate with ferritin, LIC or BMI. LIC was correlated significantly with SF ($r = 0.89$, P 0.001)

Table

(A)	Age yr	Hb g/dl	SF ng/ml	FPG mmol/l	LIC mmol/kg d.w.
NTD-SCD	33.0 ± 14*	10.1 ± 1.9	772 ± 1300	4.7 ± 0.7	1.9 ± 1.7
TD-SCD	24.8 ± 10	8.5 ± 0.8	3310 ± 3078*	4.6 ± 0.7	11.1 ± 13.3*
(B)					
NTD-SCD	38.3 ± 14*	9.5 ± 1.2	550 ± 467	6.4 ± 2.0	2.9 ± 0.4
TD-SCD	30.6 ± 10	8.9 ± 0.9	2767 ± 2925*	5.9 ± 1.1	16.1 ± 8.9*

*P: $<$0.05 NTD-SCD vs. TD-SCD

Conclusions
A significant number of our patients with ND-SCD and TDSCD develop dysglycemia (IFG, and DM) that is correlated with age but not correlated with BMI. Glycemic data and iron status in patients with NTD-SCD vs TD SCD at the beginning of the study (A) and after 5 years of follow-up (B) (mean +/- SD)

Description of patients with diabetic foot of neuropathic and vascular cause cared for in a multidisciplinary Diabetic Foot Unit

Ana Piñar Gutiérrez, Noelia Gros-Herguido, Fernando Losada-Viñau, Fatima Farfan-Diaz, Monica Enriquez-Pérez, Carmen Ruiz-Trillo, Felipe Pareja Ciuro, Lucas Mengibar Fuentes & Alfonso Soto-Moreno
Virgen del Rocío University Hospital, Sevilla, Spain

Objective
6% of people with diabetes present with diabetic foot as a complication, which means greater morbidity and mortality compared to those who do not. Its diagnosis and management by multidisciplinary teams including surgeons can improve these patients' care. The objective was to analyze the main characteristics of patients and health results obtained, as well as to evaluate the impact of PAD (peripheral artery disease) existence in patients cared for in our multidisciplinary Diabetic Foot Unit.

Research Design and Methods
Observational prospective study. 273 patients from two different populations (with and without PAD - classified according to the presence of distal pulses-) attended in a 14-month period in the multidisciplinary Diabetic Foot Unit were included. Data on patient's characteristics and outcomes were analyzed in order to compare them. For inference study, a comparison of medians with the non-parametric test for independent samples for the quantitative variables and an X2 test for the comparison of proportions in qualitative variables were performed.
Results
$n=273$

Table

	With pulse	Without pulse
N	135	138
Male	108(80%)	95(69%)
Age*	**60(54-67)**	**64(75-81)**
HbA1c(%)	7,6(6,7-9,5)	6.9(5,6-8,05)
Type 2 Diabetes	118(87%)	128(93%)
Previous ulcers*	**71(52%)**	**37(27%)**
Hypertension*	**88(65%)**	**114(82%)**
Dyslipemia*	**78(60%)**	**107(77%)**
Smoking history	83(61%)	63(46%)
Nephropathy	47(35%)	48(35%)
Retinopathy*	**45(50%)**	**28(32%)**
Coronary disease*	**11(8%)**	**40(29%)**
Cerebrovascular disease*	**9(7%)**	**25(18%)**
Number of consultations* Hospitalization	**3(1-6)** 38(28%)	**1(1-2)** 49(35,5%)
Amputation **Major amputation***	31(23%) **2(1,4%)**	43(31%) **17(12,3%)**
Antibiotherapy* Intravenous antibiotherapy	**87(64,4%)** 38(28%)	**71(51,4%)** 44(32%)
Revascularization		28(20%)

*$p<0.05$

Conclusions
Patients with PAD are older, and presented with a greater macrovascular burden and a history of previous ulcers. However, patients with neuropathic foot presented with more microvascular complications, with similar metabolic control in both groups

Number of gestational diabetes risk factors associates with adverse pregnancy outcomes

Catarina Chaves[1], Catarina Cidade-Rodrigues[1], Anabela Melo[1], Odete Figueiredo[1], Ana Morgado[1], M. Céu Almeida[2], Mariana Martinho[1], Margarida Almeida[1] & Filipe M Cunha[1]
[1]Centro Hospitalar do Tâmega e Sousa, Portugal; [2]Centro Hospitalar e Universitário de Coimbra - Maternidade Dr. Bissaya Barreto, Coimbra, Portugal

Introduction
There are several known risk factors for gestational diabetes mellitus (GDM), a condition associated with worse pregnancy outcomes. Once GDM is established, the association between the presence of GDM risk factors and pregnancy outcomes is less well-known. We studied the association between the number of GDM risk factors and pregnancy outcomes in a population of women with GDM.
Methods
Retrospective study of the Portuguese multicentre GDM registry from 2012 to 2017. We analysed only singleton liveborn pregnancies and excluded women with missing data on variables of interest. GDM risk factors were: first degree family history of type 2 diabetes mellitus (FHT2D), maternal age >40 years, body mass index (BMI) $\geqq 30$ kg/m^2, previous history of GDM, and previous history of a macrosomic infant. Primary endpoints were pregnancy hypertensive disease (PHD) (pregnancy-induced hypertension or preeclampsia), preterm delivery, caesarean section, birth trauma, neonatal hypoglycaemia, and neonatal macrosomia. Women were grouped by number of GDM risk factors (none, 1, 2, 3 or more) and compared. A multivariate logistic regression analysis was built. Variables included were those with different distribution between groups and those known to be associated to the outcome under analysis.
Results and Conclusions
We studied 10 677 women with a mean age of 33 ± 5 years, 529(5.0%) had >40 years, 2924(27.4%) had a BMI$\geqq 30$ kg/m^2, 4795(44.9%) had FHT2M, 1396(13.1%) had previous history of GDM, and 529(5.0%) had history of macrosomic infant. There was 3663 (34.3%) women with 0 GDM risk factors, 4309 (40.4%) with 1, 2106 (19.7%) with 2, and 599 (5.6%) with $\geqq 3$. Women with more risk factors more often gained excessive weight during pregnancy, were diagnosed in the first trimester, had higher HbA1c, and needed insulin more frequently. They more frequently had chronic hypertension, history of abortion, and were more often multiparous. The prevalence of PHD, caesarean section, and neonatal macrosomia increased with increased number of GDM risk factors. There were no differences between groups in preterm delivery, birth trauma or neonatal hypoglycaemia. After multivariate adjustment, women with 1, 2, and $\geqq 3$ risk factors had an OR (95%CI) of PHD compared to those without risk factors of 1.35(1.058-1.68), 1.76(1.37-2.26), and 1.74 (1.20-2.52), respectively. The OR for the association with caesarean section, were 1.19(1.08-1.31), 1.59(1.41-1.79), and 2.05(1.69-2.50), respectively, and for macrosomia 1.42(1.07-1.90), 2.12(1.56-2.90) and 4.58(3.18-6.60), respectively.Women with GDM with increasing number of GDM risk factors have higher risk of PHD, caesarean section, and neonatal macrosomia.

HbA1c response after initiation of flash glucose monitoring in adults with diabetes

Antonio Moreno Tirado, Cristina Montalban Mendez, Maria Zhao Montero Benítez, Pedro Jimenez Torrecilla, Paloma González Lázaro, Florentino Del Val Zaballos, Amparo Lomas Meneses, Francisco Javier Gómez Alfonso, Maria Lopez Iglesias & Inés Gómez García
Hospital General La Mancha Centro, Alcázar de San Juan, Spain

Introduction and Objective
Flash glucose monitoring is a form of interstitial glucose monitoring and it is indicated in patients with diabetes mellitus.The objetive of the study was to assess the effect of introducing flash glucose monitoring in adults with diabetes with respect to change in hemoglobin A1c (HbA1c).
Material and methods
Prospective observational study of adults with diabetes in our center, in whom a prescription for a flash glucose monitoring sensor was collected, started between June and November 2020. Primary outcome was change in HbA1c 12 months after initiation of flash glucose monitoring. Changes in fasting blood glucose 12 months after the start of monitoring were also studied.
Results
77 subjects (55,8% men) were analysed with an average age of 47.3 ± 13 years old with diagnosis of diabetes (71,4% DM1, 26% LADA, 2,6% DM2). The average of month with diagnosis of diabetes of our subjects were 169.8 ± 10.3 months. Only 26% of subjets were well trained in the correct calculation of carbohydrate portions. We observed how the average HbA1c baseline $7.87\pm1.2\%$, and 12 after initiation of flash glucose monitoring was $7.33\pm1.2\%$, this results was statistically significant finding ($P<0,001$). Likewise, statistically significant changes in fasting blood glucose were found, baseline 168.9 ± 74.8 mg/dl and 12 months after initiation of flash glucose monitoring 140.3 ± 48.9 mg/dl. No changes were observed in either weight or insulin dose.
Conclusions
Flash monitoring is associated with significant reduction in HbA1c and fasting blood glucose in people with diabetes. Multiple causes can justify said improvement, and more studies are necessary to demonstrate the reason for these changes.

DOI: 10.1530/endoabs.81.EP293

The melatonin receptor gene polymorphism rs10830963 is not associated with significant differences in sleep patterns and biorhythms.

Daniela Vejrazkova[1], Denisa Chocholova[2], Marketa Vankova[1], Petra Lukasova[1], Josef Vcelak[1], Martin Sladek[3], Alena Sumova[3] & Bela Bendlova[1]
[1]Institute of Endocrinology, Department of Molecular Genetics, Prague, Czech Republic; [2]Faculty of Science, Charles University, Molecular Biology and Biochemistry, Prague, Czech Republic; [3]Institute of Physiology, The Czech Academy of Sciences, Biological Rhythms, Prague, Czech Republic

Introduction
Melatonin is a crucial hormone for controlling sleep rhythms and disruption of its natural secretory rhythmicity is considered to be one of the causes of type 2 diabetes mellitus. The MTNR1B gene encodes the melatonin receptor. Polymorphism rs10830963 in this gene shows an association with fasting blood glucose and impaired glucose tolerance. Current studies suggest that carriers of the minor allele G have a slightly shifted cycle of melatonin secretion toward a later rise in the evening and a slower decline in the morning, which may interact with social pressure on early morning activity and thus adversely affect glucoregulation. The aim of this study was to determine whether the polymorphism is projected into sleep patterns, biorhythms and chronotype evaluated through a questionnaire.
Methods
A total of 268 volunteers completed the MCTQ (Munich chronotype questionnaire) to determine sleep habits and chronotype. The average age did not differ significantly between the compared genotype groups. The ratio of women/men in the groups was also similar. Genotyping was performed on a TaqMan instrument (LC480, Roche), data were evaluated by NCSS/PASS 2020.
Results
Minor variant G was present in a heterozygous constellation in 124 participants (46%) and in a homozygous constellation in 26 (10%) with an allelic frequency of 33%. The remaining 118 individuals (44%) were homozygous in the common variant C. The average length of sleep on weekdays and days off did not differ between the groups, nor did the mid-sleep phase on weekdays and days off. The chronotype calculated from the mid-sleep phase values corrected for sleep debt accumulated during working days was also comparable. The time of subjective maximum daily activity was similar in all three genotype groups, with a median at 11 a.m. The social jat lag resulting from the discrepancy between the natural biorhythm and work/social duties averaged 0.85 ± 0.698 h regardless of genotype. Interestingly, while in the groups with CG and CC genotype there were about 9% of people with very low caffeine consumption, in the group of homozygous GG carriers, individuals with low caffeine requirement were completely absent.
Conclusion
In the sample of the Czech population, we did not observe significant differences in sleep patterns and chronotype between the groups formed depending on the rs10830963 SNP genotype of the MTNR1B gene.Grant support: NU20-01-00308 and MZ CZ RVO EÚ00023761

“ Features of the angiography of the eye bottom in patients with diabetic retinopathy” “

Firuza Urmanova, Fazilyat Bakhritdinova & Guzal Kengilbaeva
Tashkent Medical Academy, Tashkent, Uzbekistan

The purpose of the study is to study the F = features of the angiography of the eye bottom in patients with diabetic retinopathy in patients with type 2 diabetes mellitus (DM2), with different stages of diabetic retinopathy (DR).
Material and research methods
252 people were examined ($n = 504$), of which 168 patients with type 2 type and 84 practically healthy persons. The main group (I; $n = 174$) with DM2, divided into subgroups, depending on the stage of DR: Easy non-proliferative DR (NDR), moderate NDR, severe NDR and PDR. As a comparison group (II; $n = 162$), patients are included without clinical manifestations of others (III; $n = 168$) - the control group was almost healthy faces without significant ophthalm and somatic pathology.All patients conducted a standard and specialized ophthalmological examination. Optical coherent tomography in the angio mode is made using an Optical Cherent Tomograph RevOFC with an angiography module with a 3×3 mm scan area. The level of VEGF in serum was evaluated by solid-phase immunoassy analysis using Quantikine ELISA sets.
Results
Analysis of the blood flow density indicates a significant decrease (P0.05) of this indicator in a subgroup of patients with a type of type 2 without DR and an average NDR on average by 3-5% compared with the control group. While with a moderate NDR - this figure is reduced by 12%, with a severe NDR - by 17%, at DA, by 19%. The area of the phases at DM 2 of the type without OB was higher than the norm by 21%, with a light NDRT 24%, with a moderate NDR - by 28%, with a heavy NDR - by 56%, with a PDR - to 62%.
Conclusions
Detected depletion of the peripheolar vascular drawing among patients without clinical signs of others.

Impact of glucoregulation and duration of diabetes on the incidence of diabetes chronic complications in Republic of Srpska/Bosnia and Herzegovina

Snjezana Popovic Pejicic[1,2], Nina Pejicic[2] & Ljiljana Stanivuk[3]
[1]Medical Faculty, University of Banja Luka, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [3]Institute of Public Health of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina

Background/Aim.
Importance of glucoreglation qality in diabetes complication prevention was proven in numerous clinical studies. Aim of this study is to determine impact of glucoregulation and duration of diabetes on the incidence of chronic complications of diabetes in Republic of Srpska (RS).
Method
Study model included subjects with T1D and T2D who participated in the two-year project in the RS. It was a cross-sectional study with 1088 participants. Specially designed questionnaire included data obtained by objective trial, clinical examination, data on antihyperglycemic treatment, and patient’s record data regarding diabetes and diabetes complications. The quality of glycoregulation was assessed based on glycosylated hemoglobin (HbA1c) values.
Results
Finally, study included 1037 subjects, 4.6% with T1D and 95.4% with T2D, 576 women (55.5%) and 461 (44.5%) men. Poor glycemic control (Hba1c $\geqq$6.5%) was found in 61.1% of subjects ($\chi^2 = 4.874$, df = 1, $P = 0.027$) and percentage of this patients increased with longer diabetes duration. Among patients with diabetes, more than 10 years’ duration, poor glucoregulation (HbA1c $\geqq$ 6.5%) was recorded in 84.6% with T1D and 76.1% with T2D; with less than 5 years’ duration was recorded in 58.30% of patients with T1D and 48.0% with T2D. The most common complication was neuroischemic foot (55.8%), statistically significantly more frequently observed in patients with HbA1c $\geqq$ 6.5% ($\chi^2 = 5.220$, df = 1); microalbuminuria (49.2%) was reported most frequently in diabetes of 5-10 years’ duration. Polyneuropathy (42,5%) and microalbuminuria were more common in T2D ($\chi^2 = 10.217$, df = 1, $P = 0.001$), while retinopathy (25,0%) was more common in T1D. Microvascular complications were statistically significantly more common in patients with unsatisfactory glycoregulation as well as longer duration of diabetes, especially in patients with T2D and disease duration over 10 years.Cardiovascular disease was recorded in 82.0% of T2D patients with HbA1c $\geqq$ 6.5% and in 82.1% of those with HbA1c $\leq$ 6.5%, with no statistically significant difference with regard to glucoregulation quality.
Conclusion
It can be concluded that 3/5 of diabetes patients in RS (61.1%) have poor glucoregulation. Microvascular complications, have higher incidence in patients with poor glucoregulation Longer T2D duration significantly increases incidence of microvascular complications, especially disease duration of 10 years or more. Cardiovascular complications are present in high percentage regardless of quality of glycemic control. These results are similar to results from developing countries and indicate the need for implementation of additional, interventional measures for improving glucoregulation and reducing chronic complications in patients with diabetes in RS.

Cochleo-vestibular disorders in diabetic patients

Mnif Fatma[1], Asma Zargni[1], Hanene Ben Jemaa[2], Boutheina Hammami[2], Kawthar El Arbi[1], Dhoha Ben Salah[1], Mouna Elleuch[1], Nadia Charfi[1], Faten Haj Kacem Akid[1], Ilhem Charfeddine[2] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Diabetology and Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba Hospital, Department of Oto-Rhino-Laryngology, Sfax, Tunisia

Introduction
Cochleovestibular disorders in patients with diabetes is not well known as compared to other complications. The aim of this study was to evaluate the epidemiological, clinical and paraclinical characteristics of cochleovestibular dysfunction in diabetes.
Materials and Methods
This is a retrospective study of 100 diabetic patients. The patients had a clinical otological and vestibular examination as well as a tonal audiometry and a video nystagmography.
Results
The mean age of our patients was 50.97 years with extremes ranging from 17 to 82 years. A female predominance was noted with a sex ratio of 0.66. The mean

duration of diabetes was 10 years with extremes ranging from 5 to 27 years. The diabetes was type 1 in 22 cases and type 2 in 78 cases. Degenerative complications were noted in 20% of cases. These included diabetic retinopathy alone in 7% of cases, diabetic neuropathy in 6% of cases and both complications in 7% of cases. Deafness was noted in 32 cases (32%). It was a sensorineural hearing loss in all cases, more important in the medium to high frequencies. The hearing impairment was more severe in type 1 diabetes. Vestibular involvement (peripheral and/or central) was present in 24 cases (31.5%). An analytical study analyzing epidemiological characteristics, metabolic control, and the presence of degenerative complications did not find statistically predictive factors for cochleovestibular involvement.
Conclusion
In our study, we did not find any predictive factor for vestibular impairment in diabetics. However, this is only preliminary data, because our study did not include non-diabetic controls.

Precipitating factors of diabetic ketoacidosis

Nino Matas[1,1], Anja Barač Nekić[1], Antonela Čović[2], Fran Vrandečić[3], Tatjana Bačun[4], Ivan Feldi[5], Darko Kaštelan[3], Tina Dušek[3], Karin Zibar Tomšić[3] & Anela Novak[2]
[1]Ulica Doktor Roka Mišetića, Internal Medicine, Dubrovnik, Croatia; [2]Spinčićeva Ulica, Split, Croatia; [3]Kišpatićeva Ulica, Zagreb, Croatia; [4]Ul. Bana Jelačića 10, Našice, Croatia; [5]Ulica Josipa Huttlera, Osijek, Croatia

Introduction
Diabetic ketoacidosis (DKA) is one of the most serious acute complications of diabetes mellitus (DM). In some studies, infections have been shown to be a precipitating factor in half of the subjects. On the other hand, several recent studies emphasise that poor treatment adherence is also a common cause of DKA.
Objective
To identify the most common precipitating factors for DKA in the Republic of Croatia.
Patients and Methods
This retrospective, multicentre study included DM type 1 or DM type 2 patients diagnosed with DKA between January 1, 2014, and December 31, 2018, and treated in 5 different DM treatment centres: Dubrovnik, Našice, Split, Zagreb, and Osijek. Only the first episode of DKA was included in the analysis. Patients suffering from steroid DM and DM due to endocrine disorders such as acromegaly and Cushing's syndrome were excluded.
Results
The study included 160 patients (55% men), 68% of whom had DM type 1. The median age of the respondents was 42 years (18-89). The most common cause of DKA was infection (57%), followed by poorly controlled DM (37%) and first presentation of DM (10%), while in 6% of patients DKA was due to other causes such as insulin pump failure, stroke or myocardial infarction. In the group of patients with infections, urinary tract infections (30%), gastrointestinal infections (30%), and respiratory tract infections (19%) were the most common, while 21% of patients had other sources of infection. In 39% of these patients, previously poorly controlled diabetes was present along with the infection, and in 12% of them, DKA caused by the infection was the first manifestation of the disease. In patients with DM type 2, infections were more frequently the cause of DKA than in patients with DM type 1 (P 0.05). In patients with DM type 1, poorly regulated glycemia is obviously more often the cause of DKA (31.2%) than in patients with DM type 2 (17.7%).
Conclusion
The most common precipitating factors for the development of DKA are infections and poor diabetes management, likely due to lack of patient cooperation with insulin treatment and inadequate education about the use of insulin therapy in acute illness.

Is the 2009 CKD-EPI more accurate with or without the race coefficient for black adults from outside the United States?

Carolina Zingano[1], Gustavo Monteiro Escott[1], Bruna Martins Rocha[1], Indianara Franciele Porgere[1], Candice Cristine Moro[1], Pierre Delanaye[2,3] & Sandra Pinho Silveiro[1,4]
[1]Federal University of Rio Grande do Sul, Graduate Program in Medical Sciences: Endocrinology, Porto Alegre, Brazil; [2]ULiège, Department of Nephrology-Dialysis-Transplantation, Liège, Belgium; [3]University Hospital of Nimes, Department of Nephrology-Dialysis-Apheresis, Nîmes, France; [4]Hospital de Clínicas de Porto Alegre, Endocrine Unit, Porto Alegre, Brazil

Introduction
Diabetes is the leading worldwide cause of chronic kidney disease, which is diagnosed by measuring albuminuria and estimating glomerular filtration rate (GFR) with creatinine-based formulas, such as the 2009 CKD-EPI developed in the United States of America (USA). Nonetheless, the race coefficient (RC), present in the 2009 CKD-EPI, may overestimate GFR in other countries.
Aim
The goal of this systematic review and meta-analysis was to assess the accuracy, measured by P30 (percentage of estimated results within 30% of measured GFR), of the 2009 CKD-EPI in estimating GFR with and without the RC in black adults outside the USA.
Methods
A bibliographical search of PubMed and Embase was performed and last updated on December 5th, 2021. Eligible studies included 2009 CKD-EPI P30 accuracy values with or without the RC for black adults outside the USA. Studies which used inadequate measuring methods of GFR were excluded. Our study is registered in PROSPERO (CRD42021236613) and reported according to the PRISMA-DTA guideline. The data was extracted by independent pairs of reviewers and was pooled using a random-effects model.
Results
Our systematic review included 11 studies, with a total of 1834 black adults from Africa, South America and Europe. Eliminating the RC in the 2009 CKD-EPI formula significantly increased P30 accuracy results in these populations (from 61.9% [95% CI, 53% to 70%] to 72.9% [95% CI, 66.7% to 78.3%]; $P = 0.03$).
Conclusion
Outside the USA, the 2009 CKD-EPI should not be used with the RC, even though it is not sufficiently accurate (P30 below 75%). Thus, we endorse KDIGO guidelines to use exogenous filtration markers in black patients outside the USA when a more accurate estimation of GFR may impact clinical conduct.

A patient with aniridia and Type 1 diabetes mellitus

Dimitra Pappa, Eleftheria Barmpa, Maistros Linaras, Panagiotis Tsakos, Nikolaos Zikos & Alexandra Bargiota
University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
Aniridia is a rare congenital condition which is characterized by a complete or partial absence of the iris and fovea and malformations of the lens and anterior chamber. It is usually related to mutations in PAX6, a member of a multigene family of transcription factors, which is important for the development of the nervous system, the eyes and also the endocrine pancreas and it is found to be associated with mild glucose intolerance. Complete loss of insulin secretion is rarely described and here we present such a case.
Presentation
A seventeen years old male, with congenital bilateral aniridia, and no other past medical history, referred to our department due to polydipsia, polyuria, fatigue and weight loss (10 kilograms the last five months) gradually worsening. On clinical examination his BMI was 27,73 kg/m^2, blood pressure 120/70 mmHg, pulses 82/min and he was dehydrated. From his laboratory exams his blood glucose was 391 mg/dl, glycosylated hemoglobin (HbA1c) 9,5%, C-peptide 0,6 ng/ml, Glutamic acid decarboxylase antibodies (Anti-GAD) and Pancreatic Islets antibodies (Anti-ICA) were both positive. On these findings the diagnosis of type 1 diabetes mellitus (T1DM) was made and the patient was started on insulin (basal – bolus regime). His father was fifty two years old and had also congenital aniridia and type 2 diabetes mellitus treated with oral hypoglycemic agents. A genetic test for the PAX6 gene was sent and results are expected.
Conclusion
Aniridia is a rare inherited condition and is mostly related to glucose intolerance and mild diabetes, but complete loss of insulin secretion and T1DM can also be found. Patients with aniridia need a close follow up, so that any disorder of glucose metabolism be detected on time.

Endogenous hyperinsulinism and diabetes remission : A report of 2 cases

Senda Ben Rebai, Ibtissem Ben Nacef, Sabrine Mekni, Chayma Besrour, Youssef Lakhoua, Nadia Mchirgui, Imen Rojbi & Karima Khiari
Hospital of Charles Nicole, Endocrinology Department, Tunis, Tunisia

Introduction
Diabetes is a chronic, progressive disease characterized by elevated levels of blood glucose. In type 1 diabetes, some patients experience a "honeymoon period" shortly after diagnosis, wherein insulin needs decrease significantly and a few studies have demonstrated that drug-free glycemic control can be achieved in type 2 diabetes. We describe 2 unusual cases of endogenous hyperinsulinism and diabetes remission.
Case presentation 1
A 24 year-old female who was admitted to the hospital for hypoglycemia. She was diagnosed with type 1 diabetes at the age of 17 after an episode of Diabetic Ketoacidosis. She was treated with insulin for 6 years. During the last year, she experienced recurrent episodes of hypoglycemia that have persisted regardless of the progressive withdrawal of insulin therapy with no episodes of hyperglycemia. In the first 48 hours of glycemic control in hospital care, a symptomatic hypoglycemia was documented and a blood sample showed that her plasma glucose was 62 mg/dl, insulin level was 3,3 µUI/ml and C-peptid was 1,04 ng/ml. These levels confirmed endogenous hyperinsulinism.
Case presentation 2
A 43 year-old female who was referred to our hospital for evaluation of recurrent episodes of hypoglycemia. She was discovered having diabetes mellitus at the age of 33 and treated with insulin for the last 10 years. During the last year, she continued to have frequent hypoglycemic episodes, despite repeated dose reductions and finally she stopped the insulin therapy. Two months later, her fasting plasma glucose was 2.4 mmol/l. On admission, A blood sample showed that her plasma insulin level was 24.1 µIU/ml, C-peptide was 0.43 ng/ml and cortisol was 49 nmol/l, while glucose level was 33 mg/dl. These levels were consistent with endogenous hyperinsulinism.
Conclusion
These cases highlight the possibility of diabetes remission induced by endogenous hyperinsulinism. Diabetes remission after years of insulin therapy is uncommon and it should be investigated thoroughly.

Effects of glucagon-like peptide 1 analogue on eating behavior in patients with obesity

Oksana Logvinova & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
One of the objectives of weight loss in obesity is to prevent metabolic disorders. An important component in the maintenance of the achieved results is a change of eating behavior.
Goal
To study the effect of liraglutide 3.0 mg on the dynamics of metabolic parameters and eating behavior in patients with obesity.
Materials and methods
The study enrolled 42 obese patients in whom anthropometric parameters, metabolic parameters, and eating behavior were assessed with Dutch Eating Behavior Questionnaire (DEBQ). Patients were divided into 2 groups, one of which received liraglutide 3.0 mg with lifestyle modification for 3 months. The other group was recommended to receive only lifestyle modification. The participants were re-examined after 3 months.
Results of the study
In the liraglutide group in addition to a significant decrease in body weight, BMI and waist circumference, there was a statistical trend toward lower glucose, insulin and HOMA-IR levels. When comparing the dynamics of parameters between the groups, Δ body weight, BMI and glucose in the liraglutide group were significantly superior. In reassessment of eating behavior after 3 months of treatment, no statistically significant differences were found with the initial severity of restrictive, emotional, and/or external types in both groups and, despite a more pronounced decrease in body weight in the liraglutide group, between them.
Conclusions
Three months of isolated lifestyle modification and/or its combination with liraglutide 3.0 mg is not sufficient to make a lasting change in eating behavior. However, considering that obesity is a chronic and relapsing disease, the need for eating behavior correction remains relevant to prevent disease recurrence. This substantiates the need for more long-term intervention in obesity, including drug therapy.

Prevalence of sarcopenia with different DXA indices in a population with high-risk obesity

Elena González Arnáiz, Lucía González Roza, Beatriz Ramos Bachiller, Begoña Pintor de la Maza, David Barajas-Galindo, Isidoro Cano Rodríguez & María Ballesteros-Pomar
Complejo Asistencial Universitario de León, Endocrinology and Nutrition, León, Spain

Background
Sarcopenic obesity(SO) is an entity characterized by excess fat mass(FM) and low muscle mass (LMM) and function. Excess FM itself can lead to loss of muscle

Diagnosis	Variables	Cut-off point	Female ($n = 89$)	Male ($n = 35$)	Total ($n = 124$)
Low muscle function	HGS	Female <16 kg.Male <27 kg	13.5% ($n = 12$)	17.1% ($n = 6$)	14.5% ($n = 18$)
	ASM	Female <15 kg.Male <20 kg	6.7% ($n = 6$)	2.9%($n = 1$)	5.6% ($n = 7$)
	ASMI	Female <5.5 kg/m^2.Male <7 kg/m^2	0%	5.7% ($n = 2$)	1.6% ($n = 2$)
	TSMI	Female <6 kg/m^2.Male <9 kg/m^2	0%	2.9% ($n = 1$)	0.8%($n = 1$)
LLM	LESMI	Female <3.7 kg/m^2, Male <5.1 kg/m^2	0%	5.7% ($n = 2$)	1.6% ($n = 2$)
	ALMI	Female <5.45 kg/m^2.Male <7.26 kg/m^2	0%	2.9% ($n = 1$)	0.8% ($n = 1$)
	SMI	Female $<23.5\%$. Male $<29.9\%$	100%($n = 89$)	100%($n = 35$)	100%($n = 124$)
	ALM/W	Female $<19.4\%$. Male $<25.7\%$	83.1($n = 74$)	97.1%($n = 34$)	87.1%($n = 108$)
Low physical performance	TUG >10 seconds $\rightarrow$ Falling risk 31.4%($n = 11$) 24.2%($n = 30$)	21.4%($n = 19$)			
Severity	Low hand grip strength + Low physical performance	4.5%($n = 4$)	11.4%($n = 4$)	6.5%($n = 8$)	

mass and function at any age. The combination of obesity and sarcopenia is a proven risk factor for frailty, comorbidities and mortality. New diagnostic criteria have been developed for this entity.
Aims
To assess the prevalence and severity of SO with different indices by DXA, in a group of individuals with high-risk obesity(HRO).
Methods
Prospective observational study of individuals with HRO(BMI > 35 kg/m^2) under follow-up by the obesity unit of the Complejo Asistencial Universitario de León. We collected demographic and anthropometric variables, body composition by dual energy X-ray absorptiometry(DXA, A Lunar Idxa; GE Healthcare, USA), hand grip strength(HGS) (Dynex®,DynExgrip) and physical performance with the timed up and go test(TUG). For the diagnosis of LMM with DXA, the equations appendicular skeletal muscle mass (ASM;lean mass arms and legs–bone mass arms and legs), appendicular skeletal muscle mass index (ASMI;ASM/height^2), total skeletal mass index (TSMI; TSM/height^2, TSM:ASMx1.33), lower extremity skeletal muscle mass index (LESMI;LESM/-height^2,LESM: lean mass legs–bone mass legs), appendicular lean mass index (ALMI;ALM/height^2,ALM: lean mass arms + lean mass legs), skeletal muscle mass index (SMI;(ASM/weight) × 100) and appendicular lean mass/weight (ALM/W;(ALM/weight) × 100) were used.
Results
124 subjects were included, 71.8% women, mean age 42.6 (SD 9.0) years, mean BMI 46(SD 5.2 kg/m^2). The cut-off points and percentage of patients diagnosed with low strength, muscle mass and low physical performance are shown in the table below.
Conclusions
The prevalence of low muscle mass with DXA varies according to the parameter and setting used. The adjustment of DXA-derived parameters for muscle mass, should be made according to the investigated cohort in terms of ethnicity, BMI, sex and age range. In this population, if we take into account the two criteria; muscle mass (with SMI) and muscle function (HGS), 13% of women and 17% of men will have sarcopenia, 4.5% and 11.4% severe sarcopenia respectively.

Empagliflozin and arterial stiffness in type 2 diabetic patients: a real clinical practice case-control study

Francesco Tassone[1], Cinzia Ferreri[2], Arianna Rossi[2], Claudia Baffoni[1], Giorgio Borretta[1] & Mauro Feola[2]
[1]A.S.O. Santa Croce & Carle di Cuneo, Division of Endocrinology, Diabetes & Metabolism, Cuneo, Italy; [2]Ospedale Regina Montis Regalis Mondovì, Division of Cardiology, Mondovì, Italy

Background
Sodium-glucose cotransporter-2 (SGLT2) inhibitors demonstrated beneficial effects on cardiovascular and renal events in patients with type 2 diabetes mellitus. The mechanisms underlying these effects are not fully elucidated. Aim of this study was to investigate whether empagliflozin is able to affect arterial stiffness/pulse wave velocity in type 2 diabetic patients.
Methods
Pulse wave velocity and other parameters of arterial stiffness were assessed before and after a 3-month treatment with empagliflozin in 16 consecutive T2DM outpatients; data were compared with 16 T2DM outpatients not treated with SGLT2 inhibitors.
Results
The sex of the patients and the duration of diabetes mellitus did not differ between groups. However age was significantly higher in the empagliflozin group at baseline compared to controls (64.1 ± 8.68 vs 74.45 ± 8.13, $P < 0.05$). Empagliflozin treatment significantly decreased HbA1c after 12 weeks of treatment (7.9 ± 0.78 vs 7.04 ± 1.09% , $P < 0.008$.). After 12 weeks' treatment, empagliflozin significantly improved PWV compared to controls not treated with SGLT2-i (ΔPWVV -0.68 ± 1.1 vs 0.89 ± 1,6 p < 0.004, $P = 0.0065$ with age and HbA1c as covariates). Moreover body weight significantly decreased in the empagliflozin group (86.75 ± 16.16 vs 81.71 ± 16.5 kg, p = 0.001) compared to controls (in whom remained unchanged) as long as BMI (30.48 ± 5.4 versus 28.75 ± 5.66 kg/m^2, $P < 0.002$) compared to controls (in whom remained unchanged). Estimated glomerular filtration rate (eGFR) remained unchanged in the two groups during the study whereas urine Albumin to Creatinine ratio significantly improved with empagliflozin (17.8 ± 46.8 vs 12.2 ± 35.7 mg/mmol, $P = 0.049$).
Discussion
In this 'real clinical practice' study the potential effect of empagliflozin treatment on arterial function in T2DM patients was extensively investigated. Arterial stiffness was significantly decreased in the group treated with the empagliflozin and the difference was significant compared to the control group. Significantly improvement in urine Albumin to Creatinine ratio suggest an improvement of endothelial function in these patients that could be involved in reducing arterial stiffness.

Association of single nucleotide polymorphisms (SNPs) of the intestinal fatty acid-binding protein (FABP2) gene with peripheral atherosclerosis in patients with type 2 diabetes mellitus.

Sergey Sukhanov, Yulia Sorokina, Olga Zanozina & Veronika Lagonskaya
Privolzhsky Research Medical University, Hospital Therapy, Nizhny Novgorod, Russian Federation

Relevance
There is a search for candidate genes that contribute to the progression of atherosclerosis in patients with diabetes mellitus. It has been suggested that the FABP2 Ala54Thr polymorphism may be associated with the risk of atherosclerosis.
Objective
To evaluate the relationship between polymorphism of the intestinal fatty acid-binding protein (FABP2) gene Ala54Thr with peripheral atherosclerosis in patients with type 2 diabetes mellitus.
Materials and methods
We examined 40 patients with type 2 diabetes, who were in the endocrinology department of the Regional Clinical Hospital. N. A. Semashko in September-November 2021 The duration of diabetes mellitus is from 2 to 18 years, glycated hemoglobin is 8.1 ± 0.93%. The patients' age ranged from 43 to 76 years old.. All patients had grade 1-2 obesity, dyslipidemia, 36 patients were diagnosed with arterial hypertension. Patients had micro and macrovascular complications of diabetes mellitus of varying severity. Glycemic indicators (HbA1c, glycemic fluctuations using FreeStyle monitoring), lipid profile, body mass index (BMI), systolic and diastolic blood pressure (SBP and DBP) were determined, ultrasound examination of the vessels of the lower extremities and the brain was performed. Molecular genetic study was carried out on the basis of the Regional Clinical Hospital named after N. A. Semashko. We saw FABP2 (rs1799883) Ala54Thr. DNA samples isolated from whole blood leukocytes using the DNA-Express-Blood-Plus reagent kit were used for analysis, followed by analysis of the isolated DNA by polymerase chain reaction (PCR) on a CFX-96 amplifier (Bio-Rad, USA). Used reagent kits (Litekh, Moscow) in accordance with the instructions
Results
A positive association of Ala54Thr with body mass index, blood pressure level was revealed. In 50% of cases, patients were diagnosed with GG SNP (Ala/Ala), in 28% of cases - GA SNP (Ala/Thr), in 22% - AA SNP (Thr/Thr). Indicators of glycemic control, levels of triglycerides and low density lipoproteins were significantly higher in patients with the AA (Thr/Thr) group. In the same group, a lower ankle-brachial index was noted ($P = 0.04$).
Conclusions
AA SNP genotype (Thr/Thr) is associated with an increased incidence of peripheral atherosclerosis in patients with type 2 diabetes.

Retrospective analysis of association between coronary artery disease and Glycemic Control in South Indian T2DM population

Mahadevan V
Stanley Medical College & Jayam Diabetes & Heart Specialty Clinic, Department of Endocrinology, Chennai, India

Background
Type 2 diabetes mellitus (T2DM) is independently associated with an increased risk for cardiovascular disease caused mainly by early development of vascular changes leading to atherosclerosis. Coronary artery disease (CAD) is one of the common complications However, the exact correlation between glycemic control and the risk of developing CAD remains unclear. This study sought to assess the correlation of glycemic control and risk of developing CAD in South Indian population.
Methods
This retrospective analysis was conducted amongst 1888 patients with type 2 diabetes who visited a diabetes and cardiology care center in Tamil Nadu, India between January 2017 and December 2021. This study assessed glycemic and cardiometabolic parameters including HbA1c, blood pressure, lipid levels, electrocardiogram, and ECHO reports. The statistical analysis was conducted using SPSS software and Chi-square test was used.

Results
The average age in the patient data analyzed was 62 years with an average duration of diabetes of 8.6 years. About 69% of the patients were male, while 31% were female. Among the analyzed patient cohort, 26% went on to be diagnosed with CAD within 24 months of their first visit. The average HbA1C at the time of diagnosis of T2DM was 8.3%, while that at the time of diagnosis of CAD was 9.2%. A positive correlation was found between poor glycemic control and the diagnosis of CAD within 24 months of the visit ($P < 0.01$). The mean blood pressure at the time of diagnosis of T2DM was 130/82 mm of Hg, while that at the time of diagnosis was 152/91 mm of Hg. Echo-cardiography revealed 38.9% had mild LV dysfunction, 16.29% had moderate LV dysfunction and 4% had severe LV dysfunction. Upon analyzing, it was found that 48% of the 491 diagnosed with CAD had triple vessel disease, while 31% had double vessel disease and 5% had total occlusion of coronary artery. The overall mortality in patients diagnosed with CAD was 2% at the time of reporting.
Conclusions
This analysis demonstrated a positive correlation between poor glycemic control and diagnosis of CAD. Tight glycemic control has the potential to prevent progression of cardiovascular disease among people with T2DM.

Predictive factors for distal and symmetric polyneuropathy in diabetic patients

Mouna Elleuch, Maalej Souhir, Hsine Houda, Dhoha Ben Salah, Hamdi Frikha , Faten Haj Kacem Akid & Mohamed Abid
CHU Hedi Chaker, Endocrinology, Sfax, Tunisia

Introduction
Diabetic neuropathy is the most common cause of neuropathy worldwide and is known to affect approximately half of all diabetic patients. It significantly impairs the quality of life of patients.
Aim of the study
To establish the predictive factors of distal symmetric polyneuropathy (DSPN) in diabetic patients.
Methods
This is a descriptive cross-sectional study including 116 patients. The diagnosis of PNDS was established according to the MNSI (Michigan Neuropathy Screening Instrument) and DN4 (Neuropathic Pain Diagnostic Questionnaire) scores. We divided the patients into two groups: group one (G1) patients with DSPN (N = 67) and group two (G2) without DSPN (N = 49). Then, using SPSS software, we were able to perform a multivariate study on independent predictive factors of DSPN as well as a univariate study of factors associated with this complication.
Results
Among the sociodemographic factors, only age was predictive of DPN with $P = 0.005$ (mean age: G1 = 64.85 +/- 12.56 years versus 58.27 +/- 11.88 years for G2). The analysis of the history showed that: nephropathy ($P = 0.002$), retinopathy ($P < 0.001$), myocardial infarction ($P = 0.037$), stroke ($P = 0.020$), hypertension ($P < 0.001$) and dyslipidemia ($P = 0.006$) were associated with DSPN. Symmetrical and peripheral polyneuropathy was found in 64 subjects with a diabetes duration of more than 5 years ($P = 0.015$), in 57 with unbalanced diabetes ($P = 0.024$) and in 34 with a history of hospitalization ($P < 0.001$). Regarding treatments, biguanides ($P = 0.001$), sulfonamides ($P = 0.01$) and insulin ($P < 0.001$) were associated with symmetric and peripheral polyneuropathy. Comparison between the two groups according to biological data showed a significant difference in creatinemia ($P = 0.011$), blood glucose ($P = 0.030$) and a significant increase in HbA1c in the neuropathy group with $P = 0.001$. On multivariate analysis, the independent predictors of DSPN were retinopathy and hypertension.
Conclusion
Age, nephropathy, retinopathy, history of myocardial infarction and stroke, and the presence of other cardiovascular risk factors such as dyslipidemia and hypertension, as well as the length of time the patient has had diabetes, are the main predictive factors for distal and symmetrical polyneuropathy in patients living with diabetes.

DOI: 10.1530/endoabs.81.EP307

EP308

Depression associated factors among Tunisian diabetic patients

Malak Belkhiri[1], Boubaker Fadia[1], Ashraf Khemiri[1], Walid Bouali[2], Houcem Mrabet[1], Alaya Wafa[1], Zantour Baha[1], Sfar Mohamed Habib[1] & Lazhar Zarrouk[2]
[1]Taher Sfar University Hospital, Internal Medicine and Endocrinology Department, Tunisia; [2]Taher Sfar University Hospital, Psychiatry, Tunisia

Introduction
Diabetes mellitus and depression are two major public health problems which can coexist and influence each other. Identification of the predictive and associated factors with depression among diabetics can facilitate the task of clinicians.
Objective
Evaluate the socio-demographic and clinical factors associated with depression among patients having diabetes mellitus (DM).
Materials and methods
A cross sectional study was conducted among 260 diabetic patients followed in the Endocrinology Department at "Taher Sfar University Hospital" in Mahdia, Tunisia. Patients with a psychiatric history were excluded at the outset. Depression was diagnosed according to DSM-V criteria and the severity determined via the Hamilton score scale.
Results
Our patients were aged between 20 and 91 years old, 62.7% of the participants in the study were women. The mean duration of the diabetic disease was of 9 years (from 1 to 50 years). Type 2 diabetes was found among 92.3% of patients. According to DSM-V diagnosis criteria, we found that 15% of our patients suffered from Major Depressive disorder (MDD). Among this group having MDD, 71.8% were female, 31% belonged to the age group 35-45 years and 53.84% were married. Matrimonial status wasn't significantly linked to MDD but correlated with the severity of depression ($P = 0.048$).We also found that the majority of patients with MDD (84.6%), had at least one chronic disease in addition to diabetes and that a good proportion of them (69%) was treated with insulin. Both MDD and severity of depression were significatally linked to chronic complications of DM ($p \leq 0.001$ for both). Distal neuropathy was present among 39% of patients and this complication had a significant relationship with depression ($P = 0.025$).
Conclusion
Our study showed that diabetic patients suffering from MDD are mostly women but since proportion of women was most important in our study, these results should be evaluated. The relationship between depressive symptoms and insulin therapy can be explained by the arduousness of the injections and the increased risk of hypoglycemia causing depressive symptoms in one hand, and in the other by the failure to reach glycemic targets via other medications among depressive patients having poor treatment compliance.The risk of depression seems to be increased in diabetic patients suffering from chronic diabetic complications and screening for depression would be necessary in this case. Other studies should be conducted to determine if early screening of depression could delay insulin therapy or help prevent diabetes complications.

Prevalence and risk factors of diabetic painful distal symmetrical polyneuropathy

Dhoha Ben Salah[1], Mariem Abdelmoula[2], Yosra Mejdoub[3], Nouha Ketata[2], Mouna Elleuch[1], Fatma Mnif[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Faten Haj Kacem Akid[1] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Family Medicine, Sfax, Tunisia; [3]Hedi Chaker Hospital, Department of Epidemiology, Sfax, Tunisia

Introduction
Distal and symmetrical peripheral polyneuropathy is the most frequent type of diabetic neuropathy. Its painful form (PDN) is the most common cause of non-traumatic neuropathic pain and can place a heavy burden on patients' lives. Despite the major impact that it can have on the quality of life, PDN is generally underdiagnosed because of a large interindividual variability of symptoms and in the absence of well-established diagnostic criteria.
Aim
To determine the prevalence of PDN and to identify the different risk factors of its occurrence within Tunisian diabetic patients.
Methods
This was a cross-sectional study conducted in the endocrinology-diabetology department of Hedi Chaker hospital Sfax Tunisia, in which we collected adults with diabetes. The DN4 Questionnaire was used to diagnose PDN.
Results
A total of 185 patients were recruited. The mean age of patients was 54.9 years with a slight female predominance (54.1% Vs 45.9%). Patients with type 2 diabetes represented 82.7% against 17.3% with type 1 diabetes. The mean duration of diabetes' evolution was 12.31 years. The average of HbA1c level was 10.27%. Among diabetes' complications, PDN was the most frequent in our study (48.1%). The mean DN4 score was 3.57. Significant predictors of PDN included advanced age ($P = 0.004$), high waist circumference ($P = 0.01$), long history of diabetes ($P = 0.000017$), insulin therapy in patients with type 2 diabetes ($P =$

0.03), in addition to some comorbidities such as dyslipidemia, sedentary life style, diabetic retinopathy, erectile dysfunction and history of leg ulcer. Some features of foot examination were also found to be risk factors of PDN namely trophic disorders ($P = 0.02$), dry skin ($P = 0.00016$), hyperkeratosis ($P < 0.001$), foot deformity ($P = 0.004$), abolition of patellar and Achilles reflexes ($P < 0.001$) and positive monofilament test ($P < 0.001$)

Conclusion

In conclusion, the present study demonstrated that the prevalence of painful diabetic neuropathy is very high among our population. This emphasizes the need to screen periodically diabetic patients using a simple instrument such as the DN4 questionnaire and to educate regularly at risk patients about predictors of PDN.

Obesity and abdominal adiposity are associated with lower urinary tract symptoms in Tunisian patients with type 2 diabetes : a cross-sectional study

Faten Haj Kacem Akid[1], Abdelmouhaymen Missaoui[1], Mariem Belhoul[2], Wafa Belabed[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Mohamed Abid[1]

[1]Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Departement of Family Medicine, Sfax, Tunisia

Background and Aims

Lower urinary tract (LUT) dysfunctions are highly prevalent, especially in women. Diabetes is a well-established risk factor for developing LUT symptoms. Several studies suggest that a high body mass index (BMI) may worsen the urinary discomfort in patients with type 2 diabetes (T2DM). The current survey aims to investigate the relationship between obesity and LUT dysfunctions in patients with T2DM.

Patients and Method

We conducted a descriptive and analytical cross-sectional study that included 200 patients with T2DM consulting at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia, from April 2019 to December 2019. We administrated the Urinary Symptom Profile (USP) questionnaire to all patients to assess LUT symptoms.

Results

The mean age was 59.3 $\pm$ 10.6 years, with a female predominance (55.5%). Dyslipidemia (57%) and hypertension (49.7%) were the most common comorbidities. The duration of the evolution of diabetes was 11.0 $\pm$ 7.9 years. Oral antidiabetic agents (OAD) and insulin therapy were prescribed in 40% and 13.6%, respectively. Most of the patients were receiving a mixed insulin-OAD treatment (44.2%). A glycemic imbalance was noted in 79.7%. As high as 79.5% of patients with T2DM reported symptoms related to LUT dysfunctions.We compared the body composition in two subgroups

- G1 : patients with LUT dysfunction ($n = 159$).
- G2: patients without LUT dysfunction ($n = 41$).

The mean weight in G1 was significantly more elevated than in G2 (77.5 $\pm$ 13.8 versus 70.3 $\pm$ 11.1 kg; $P = 0.003$). Similarly, G1 displayed a substantially higher BMI than G2 (29.2 $\pm$ 5.8 versus 26.4 $\pm$ 4.2 kg/m^2; $P = 0.03$). The prevalence of obesity (BMI$>$30) was significantly higher in G1 (34.0%) compared to G2 (14.6%) ($P = 0.016$). Abdominal adiposity with significantly associated with LUT symptoms, since the average waist circumference was higher in G1 in comparison with G2 (103.5 versus 95.7 cm; $P = 0.01$).

Conclusion

Diabetes and the female gender are largely linked to the onset of LUT dysfunctions in the general population. Our work highlights an additional risk of urinary dysfunction due to weight gain, high BMI, and visceral adiposity in patients with T2DM. Increasing weight is associated with urinary incontinence and other LUT symptoms, most likely because of elevated pressure on the bladder and straining the muscles that support the urethra. These mechanisms, along with hyperglycemia-related osmotic polyuria and diabetic neuropathy are responsible for a greater prevalence and worsened quality of life in this population.

Difference of serum glucose, sodium and potassium levels in diabetic ketoacidosis

Tatjana Bačun[1,2], Željka Dragila[1], Klara Čosić[1], Dora Rudić[1], Ivan Lekić[1], Krešimir Solić[1,3] & Sran Čaloševič[4]

[1]Faculty of Medicine, Osijek, Croatia;[2]University Hospital Centre Osijek, Division of Endocrinology, Department of Internal Medicine, Osijek, Croatia; [3]Faculty of Electrical Engineering, Computer Science and Information Technology Osijek, Osijek, Croatia; [4]Emergency Medical Center of the Osijek - Baranja County, Osijek, Croatia

Background and aims

Diabetic ketoacidosis is acute complication of diabetes mellitus. Hyperglycemia is one of the diagnostic features of diabetic ketoacidosis. Electrolyte disturbances are common as well. Aim of this study is to examine whether there is a difference in serum glucose, sodium and potassium concentrations with respect to age, gender and severity of diabetic ketoacidosis.

Materials and Methods

Medical records from 1 January 2017 to 31 December 2019 were reviewed and patients with the diagnosis of diabetic ketoacidosis were selected.

Results

The study included 52 patients. Most patients belonged to the younger age group (18-24 years, 37.3%), there were more women (54.9%) and moderate diabetic ketoacidosis dominated (66.7%). The average glucose concentration was 27.10 mmol/l (median). Glucose concentration was significantly higher in the age group of 25 to 44 years and $>$ 65 years compared to the group of 18 to 24 years ($P = 0.02$). No difference in glucose concentration was found with respect to gender. The average sodium concentration was 130.00 mmol/l (median). Sodium concentration was significantly higher in the age group 18 to 24 years and $>$ 65 years compared to groups 25 to 44 and 45 to 65 years ($P = 0.002$). The average potassium concentration was 4.80 mmol/l (median). Women had significantly higher sodium concentrations ($P = 0,002$). Potassium concentration was significantly higher in the age group 25 to 44 years compared to other groups ($P = 0.01$). Men had significantly higher potassium concentrations ($P = 0.01$). The mean pH concentration was 7.19 (median). There was no association of pH levels with regards to age and gender. No significant relationship was found between glucose, sodium and potassium concentrations with regard to severity of diabetic ketoacidosis.

Conclusion

Diabetic ketoacidosis was most common in the age group 18 to 24 years and in women and was most often of moderate severity. The highest average concentrations of glucose and sodium were found in those older than 65 years, whereas potassium was high in the group 25 to 44 years. Women had significantly higher sodium concentration, while men had significantly higher potassium concentration. The severity of diabetic ketoacidosis was not related to glucose, sodium and potassium concentration.

Clinical characteristics and glycemic control in Tunisian patients with type 2 diabetes suffering from lower urinary tract dysfunctions: a comparative population-based survey

Faten Haj Kacem Akid[1], Abdelmouhaymen Missaoui[1], Mariem Behoul[2], Mohamed Abdellahi Mohamed Ahmed[1], Wafa Belabed[1], Dhoha Ben Salah[1], Mnif Fatma[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Mohamed Abid[1]

[1]Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia; [2]Faculty of Medicine of Sfax, Departement of Family Medicine, Sfax, Tunisia

Background and Aims

Several studies have pointed a significant relationship between diabetic complications, glycemic imbalance, and the onset of lower urinary tract dysfunction (LUTD) in this population. The current survey aims to assess the clinical and biochemical characteristics related to glycemic control in patients with type 2 diabetes presenting with symptoms of LUTD.

Patients and Method

We conducted a comparative cross-sectional study that included 200 patients with T2DM consulting at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia, from April 2019 to December 2019. We administrated the Urinary Symptom Profile (USP) questionnaire to all patients to assess LUT symptoms. We compared the clinical and biological factors related to diabetes in two subgroups.

- G1 : patients with LUTD ($n = 159$).
- G2: patients without LUTD ($n = 41$)

Results

The mean age was similar between the two subgroups (G1:59.7$\pm$ 10.3 versus G2:58.0 $\pm$ 11.8 years old; $P = 0.36$). A slight female predominance was noted in

G2 (G1:52.0% versus G2:63.4%; $P = 0.16$). The mean duration of T2DM was significantly longer in G1 (G1:11.9 versus G2: 7.7 years; $P = 0.03$). Insulin-requiring diabetes was substantially more associated with LUTD as insulin therapy was more prescribed for G1 (G1:62.0% versus G2: 42.5%; $P = 0.025$). Unlike diabetic retinopathy ($P = 0.07$), diabetic nephropathy ($P = 0.021$) and nephropathy ($P = 0.000$) were strongly associated with the onset of LUTD. Diabetic macroangiopathy did not seem to be linked to this urinary disorder. A significant glycemic imbalance was noted in G1 with more elevated fasting plasma glucose (G1:10.7$\pm$ 4.4 versus G2:7.5 $\pm$ 1.2 mmol/l; $P = 0.000$) and higher A1C (G1:9.5$\pm$ 2.3% versus G2:8.1 $\pm$ 2.4%; $P = 0.000$). Multivariable regression analysis identified duration of evolution of diabetes (OR=1.1 ; 95%CI [1.0-1.2] ; $P = 0.033$), diabetic neuropathy (OR=6.4 ; 95%CI [2.4-17.3] ; $P = 0.000$), and A1C>7% (OR=0.4 ; 95%CI [0.2-0.6] ; $P = 0.045$) as significant risk factors implicated in the onset of LUTD.

Conclusion

Glycemic imbalance, diabetic microangiopathy, and diabetic neuropathy were found to be significant baseline characteristics associated with the onset of LUTD in the diabetic population. Glycemic control and therapeutic patient education are the most efficient preventive measures to reduce the incidence of LUTD in patients with T2DM. A multidisciplinary approach including a team of diabetologists, urologists, and physiatrists may ensure well-coordinated management of patients presenting with LUTD.

Comparison of admissions for diabetic ketoacidosis in patients older and younger than 25 years of age at San Cecilio Clinical University Hospital in Granada

Javier García, Enrique Redondo , María Del Carmen Andreo-Lopez , Sara León Utrero & Pablo J López-Ibarra Lozano
San Cecilio Clinical University Hospital, Endocrinology and Nutrition, Granada, Spain

Introduction and objectives

Diabetic ketoacidosis (DKA) is a severe acute complication of Diabetes Mellitus (DM) and as such, on a large number of occasions will require hospital admission. As we know, it happens when there is an absolute or relative insulin deficit, although it is true that the characteristics described in the literature of these episodes are very different. Our aim was to compare the characteristics of DKA occurring in patients under 25 years of age with those of patients over 25 years of age in our setting.

Material and Methods

Retrospective observational study comparing patients older than 25 years with DM admitted for DKA at San Cecilio Clinical University Hospital in Granada, Spain with those aged 16-24 years from January 1, 2019 to December 31, 2021. Variables related to the disease (type of DM, time of evolution, associated complications...) and to the episode of DKA (precipitating factor, hospital admission time, ICU stay...) were analyzed. Analyses were carried out with SPSS 15.0.

Results

We included 39 patients older than 25 years and 22 younger than 25 years (49% women in both groups). The time of evolution of DM was significantly shorter in patients younger than 25 years (10.86 vs 19.69 years, $P < 0.05$). As comorbidities, 40.5% of those older than 25 years had alterations in the psychiatric sphere (vs 14.3% of the other group, $P < 0.05$). Regarding previous treatment, those older than 25 years had significantly lower total slow insulin doses (22.48 vs 30.71 IU, $P < 0.05$). There were no significant differences in terms of need for ICU stay (59% in both groups). The most important precipitating factors in both groups were: treatment omission, dietary transgressions and concomitant infections. Metabolic control in terms of HbA1c was worse in the group under 25 years of age (11.74 vs 10.54%, $P < 0.05$). No significant differences were observed in analytical parameters (blood glucose, pH, HCO3 and lactic acid) at admission.

Conclusions

In our work, it was observed that admissions for DKA in our center were more frequent in patients older than 25 years, as well as that these present worse metabolic control in terms of HbA1c and higher insulin needs. On the other hand, there is a tendency for the majority of DKA episodes in patients over 25 years of age to be associated with infections, while the main risk factor in younger patients is the omission of treatment.

Gestational diabetes mellitus : Association between maternal insulin resistance with pregnacy outcomes and maternal characteristics

Olfa Lajili, Aroua Temessek, Rim Rachdi, Yosra Htira & Feika Ben Mami
National Institute of Nutrition of Tunis, The Research Unit of GDM (Department C), Tunisia

Introduction

Gestational diabetes mellitus (GDM) is the most common metabolic disturbance during pregnancy. The prevalence of GDM is rising and correlates with the increase in maternal obesity over recent decades. The aim of our study was to assess the association between maternal insulin resistance with pregnacy outcomes and maternal characteristics among tunisians women with GDM.

Methods

A prospective longitudinal study carried out during the year 2020 at the research unit of GDM of Department C at the National Institute of nutrition of Tunis. The study was conducted among 135 women diagnosed with GDM with 75 g oral glucose tolerance test (OGTT 75) between 24–28 weeks. Insulin resistance was evaluated using the homeostasis model assessment of insulin resistance (HOMA-IR). Patients are followed during pregnancy and until post partum. Statistical analyses were performed using SPSS 20.

Results

The mean age was 32.3 $\pm$ 5.3 years. The mean pre-gestational BMI was 28.31 $\pm$ 4.9 kg/m^2. Two thirds of the patients (72.4%) were overweight and 29.9% were obese. The means of fasting blood glucose and the number of abnormal glycemia values at time of OGTT 75 were respectively 0.96 $\pm$ 0.11 g/l and 1.45 $\pm$ 0.63. The means of fasting blood glucose, HbA1c and total cholesterol were 4.85 $\pm$ 0.69 mmol/l, 5.32 $\pm$0.43% and 5.87 1.25 mmol/l. One third of patients (36.3%) were diagnosed before 24 gestational weeks. The mean HOMA-IR was 3.18 $\pm$ 1.7 and 55.3% of women had insulin resistance. Macrosomia and pregnancy induced-hypertension were noted in 15.8% and 3.8% of cases. The univariable analysis showed an association between the HOMA-IR and the pre-gestational BMI, fasting blood glucose and the number of abnormal glycemia values at the time of OGTT 75, levels of HbA1c, fasting glucose value, C-peptide and total cholesterol and also with an earlier diagnosis of GDM before 24 gestational weeks (respectively $P < 0.01$, $P < 0.01$, $P = 0.004$, $P < 0.01$, $P < 0.01$, $P < 0.01$, $P = 0.049$ and $P = 0.019$). however, there was no association between the HOMA-IR and pregnacy outcomes.

Conclusion

Our study showed that The HOMA-IR was associated with advanced maternal age, higher pre-gestational BMI, higher fasting blood glucose, HbA1c, and C-peptide levels. Women followed for GDM with higher HOMA-IR remain a high risk population and more researchs are necessary to improve outcomes in this group.

Analysis of glycemic control in type 1 diabetes patients using flash glucose monitoring

Miguel Damas-Fuentes[1,2], José Ignacio Martínez Montoro[1], Victor Simón Frapolli[1], Andrea Fernadez Valero[1] & Francisco José Tinahones Madueño[1,2]
[1]Hospital Universitario Virgen de la Victoria, Malaga, Spain; 2Instituto Investigación Biomédica de Málaga (IBIMA), Malaga, Spain

Introduction

Flash glucose monitoring expansion to an increasing number of patients with type 1 diabetes, coupled with its increased accuracy and ease of use, has increased available data on glycemic control in this population and allows detection of improvement areas in diabetes education and treatment.

Objective

To analyze main parameters standardized by ATTD consensus (2019) in our population of patients with type 1 diabetes using flash glucose monitoring.

Material and methods

Cross-sectional study carried out on May 7, 2021. Glucose profile of patients with medical follow-up in Endocrinology service in Virgen de la Victoria Hospital in Malaga were analyzed on Libreview platform. Those patients without download available in previous two weeks were excluded.

Results

1,562 patients were analyzed. 51.2% were male. Average number of readings was 10.98$\pm$8.13 daily readings with 84.11$\pm$20.74% active time. Mean glucose was 165.34$\pm$39.04 mg/dl with a standard deviation (SD) 61.81$\pm$18.80 mg/dl and a coefficient of variation 37.31$\pm$7.52%. time in range (TIR) was 58.96$\pm$18.86%, time above range (TAR) was 35.66$\pm$19.92%, and time below range (TBR) was

5.38 ± 6.25%. 28.83% patients achieved an TIR greater than 70%, 63.5% a TBR less than 5% and 33.74% a TAR less than 25%. Average interquartile range was 88.09 ± 31.14. Mean hypoglycemia number is 0.65 ± 0.54 daily events, with a mean duration of 90.53 ± 54.51 minutes.
Conclusions
Glycemic control in our cohort of patients, although similar to populations with same characteristics, is still far from parameters recommended in ATTD consensus. We must exploit flash glucose monitoring to detect possible areas for improvement both individual and populationally.

Did the COVID-19 pandemic affect the management of gestational diabetes?

Ioannis Ilias, Stefanos Togias, Vassiliki Papadopoulou, Ekaterini Kougioumtzi, Vassiliki Mastrodimou, Ekaterini Michou, Charalampos Milionis, Evangelia Venaki & Eftychia Koukkou
Elena Venizelou Hospital, Athens, Greece

Introduction
Researchers argue that increased morbidity is noted in pregnant women during the current COVID-19 pandemic. Reports indicate that the pandemic has led to disruptions in care of persons with diabetes. Glycated hemoglobin A1c (A1c) is not sufficient in screening for gestational diabetes mellitus (GDM) but may be of use in monitoring glycemia in GDM. To the best of our knowledge no studies honed on late pregnancy glycemia (via A1c), as a surrogate of the access/quality of care for women with GDM, have been put forth.
Aim
To assess whether care for women with GDM during the COVID-19 era (via measurement of A1c in late pregnancy) was compromised, compared to the pre-COVID-19 period.
Subjects & Methods
We accessed the medical records of 90 pregnant women (49 before and 41 during the COVID-19 era; mean age + SD: 34.01 + 5.50 years) with GDM, in whom A1c was measured after the 34th week of pregnancy. We noted the following parameters: age, body weight change (diffBW) during pregnancy, presence of thyroid disease and treatment (nutrition therapy only [NT] or combined with insulin [INS]). Statistical evaluation was done with two way analysis of variance (ANOVA), analysis of covariance (ANCOVA) and with the chi square test.
Results
Fifteen of 49 and 15/49 women in the preCOVID-19 era had thyroid disease and were on INS, respectively, whereas 10/41 and 20/41 in the COVID-19 era had thyroid disease and were on INS, respectively ($P > 0.1$, Chi square). Mean + SD A1c was 5.26% + 0.42% before and 5.37% + 0.58% during the COVID-19 era ($P > 0.10$, ANCOVA), with no significant effect or differences in age, diffBW or presence of thyroid disease ($P > 0.1$ ANCOVA). The only factor that had an effect on A1c was the mode of treatment (NT or INS) both in the pre-COVID-19 era and in the COVID-19 era; women on INS had higher A1c in both time periods ($P = 0.001$, ANOVA).
Discussion
As far as late pregnancy glycemia, via A1c, is concerned, no effect of the COVID-19 era on care for women with GDM was noted. Although we have to acknowledge the non-inclusion of other parameters in our study such as perinatal outcomes, our results are in accordance with studies that show no effect of COVID-19 on adverse outcomes in pregnancy during the COVID-19 era in high-income countries (in contrast to mid/lower income ones).

EP317

Effect of metformin on weight loss and blood pressure in obese hypertensive patients

Oksana Obertynska
National Pirogov Memorial Medical University, Vinnytsya, Ukraine

Obesity is independently associated with poor control of blood pressure (BP) and weight reduction is generally recommended as the first line of treatment. However, the challenge remains to find the appropriate approach for weight reduction to influence BP status. The aim was to investigate the effect of non-pharmacologically and pharmacologically (metformin) induced weight loss on BP in obese hypertensive patients (HP).

Methods
100 HP (mean body mass index (BMI) 32.2 kg/m^2) were included in the study (antihypertensive treatment with a mean of 1,9 ± 1.4 drugs). All followed hypocaloric diet (D) for 3 months, after that 50 patients started on metformin (M) at a mean daily dose of 2.1 ± 0.45 g with D and 50 patients followed on D for 6 months. Anthropometry, metabolic profile, including lipids and oral glucose tolerance test with insulin, uric acid, plasma aldosterone (AS) were performed at baseline and after 3, 9 months. Homeostatic model assessment HOMA-R was calculated for insulin resistance. At baseline and after 6 months HP underwent 24-hour BP measurements.
Results
At baseline was an excellent correlation between BMI and HOMA-R ($r = 0.45$, $P < .01$), AS and HOMA-R ($r = 0.31$, $P < .05$). Also, asymptomatic hyperuricemia was observed in 24.9%, dyslipidemia in 43.1%, impaired glucose tolerance in 21%. 29% of the HP had > 3 metabolic syndrome components. There was a modest no significant reduction in BMI and BP after 3 months of D in whole group. Patients on M experienced greater weight loss (-3.4 ± 2.3 versus -2.3 ± 1.2 kg, $P < .05$) and reduction in BMI (-1.9 ± 1.1 versus -1.0 ± 0.9 kg/m^2, $P < .05$). A 6-month M therapy significantly changed the levels of glucose, insulin, lipids, uric acid, HOMA-R and resulted in significantly reduced AS ($P < .01$). BP decreased more in M-treated patients than in the D group (SBP -6.7 ± 5.1 versus -2.2 ± 4.2 mmHg; DBP. -6.4 ± 3.1 versus -1,9 ± 4.2 mmHg, $P < .05$ for both). By linear regression analysis changes in BP on M was associated with HOMA-R and AS changes (0.362, $P < .05$; 0,423, $P < .05$ respectively).
Conclusions
The diet alone wasn't enough for a reduction in weight and BP in obese hypertensive patients. Weight-loss program with metformin is more effective and shows an additional antihypertensive effect in those individuals. The reduction of BP on metformin is mediated by improvement insulin/glucose homeostasis, it is accompanied by lowering of aldosterone, uric acid and lipid-lowering effects, what results in cardiovascular risk reduction.

Role of incretins, gut microbiota and permeability in the remission of type 2 diabetes mellitus after bariatric surgery

Laura Hernández-Montoliu[1], Rocio Puig[2], Silvia Pellitero[3], Joan Vendrell[4], Sonia Fernández-Veledo[4], Fernando Guerrero[1], Anna Vidal[5] , M. Mar Rodríguez[4], Rosa Montseny[1] & Núria Vilarrasa[1,5]
[1]Bellvitge University Hospital, L'Hospitalet de Llobregat, Spain; [2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Germans Trias i Pujol Hospital, Badalona, Spain; [4]Hospital Universitari de Tarragona Joan XXIII, Tarragona, Spain; 5IDIBELL Institut d'Investigació Biomèdica de Bellvitge, L'Hospitalet de Llobregat, Spain

Introduction
Bariatric surgery is an effective therapy for patients with type 2 diabetes mellitus (T2D). Many mechanisms have been proposed for its metabolic benefits, such as caloric restriction, weight loss, increased secretion of gut hormones like glucagon-like peptide 1 (GLP-1) and 2 (GLP-2), bile acid diversion, decrease of pancreatic and hepatic fat deposits and changes in gut microbiome.
Aims
Evaluate changes after surgery in gut microbiome profile, incretin secretion, intestinal permeability, systemic inflammation and succinate levels. Assess the associations between former variables and determine predictors of metabolic outcomes.
Material and Methods
Prospective single-center, non-blinded randomized controlled trial study, including patients with grades II and III obesity and T2D undergoing metabolic RYGB (mRYGB). At baseline and at one year after surgery we performed anthropometric, body composition, biochemical analysis including fasting IL-6 and zonulin, a standard meal test (SMT) and lipid test (LT) with plasma insulin, C-peptide, plasma GLP-1, GLP-2, succinate, and the study of gut microbiota was performed.
Results
13 patients were evaluated, 9 females and 4 males, mean age 52.6 ± 6.5 years, mean BMI 39.3 ± 1.4 kg/m^2, initial HbA1c of 7.62 ± 1.5% with 69.2% under insulin treatment. Twelve months after surgery a reduction of 33% of total weight loss at the expense of fat mass was observed. Diabetes remission was achieved in 69% of patients. Fasting plasma succinate and zonulin significantly decreased after surgery. After SMT and LT a significant increase in AUC for GLP-1 and GLP-2 and C- peptide was observed after surgery whereas AUC for glucose significantly decreased. Patients achieving T2D remission had higher initial C-peptide but similar proportion of insulin treatment and incretin response. In the

multiple regression analysis only higher initial C-peptide levels predicted better metabolic outcomes. The microbiota analysis showed a significant increase in beta diversity after surgery. Compared to pre-surgical faeces samples, certain families increased after mRYGB including Veillonellaceae, Enterobacteriaceae, Streptococaceae and Prevotellaceae, and were negatively correlated with HbA1c and BMI. On the contrary, some families significantly decreased: Eubacteriaceae, Ruminococcaceae, Clostridiaceae and Erysipelotrichaceae, and showed an inverse correlation with former parameters. Therefore, those families increasing after surgery were associated with a better metabolic profile. No association was found between microbiota families and incretin profile or gut permeability markers.
Conclusions
We showed beneficial changes in multiple aspects following mRYGB, spanning from an enhanced incretin secretion, decreased intestinal permeability and succinate levels to a shift towards a specific healthier metabolic microbiome.

What is the impact of being overweight on the progressive genius of Crohn's disease?

Imen Akkari, Hassine Ameni, Mrabet Soumaya & Ben Jazia Elhem
Farhat Hached Hospital, Gastroenterology, Sousse, Tunisia

Background
Overweight is becoming increasingly more common among patients with inflammatory bowel disease and plays a role in the development and course of the disease especially in Crohn's disease (CD). However, there is currently little data on his impact on the evolutionary genius of CD. The aim of this study was to assess the impact of overweight on the epidemiological, clinical, therapeutic and progressive characteristics of CD.
Patients and Methods
It is a retrospective study of patients with CD hospitalized between 2016 and 2020. Demographic, clinical, therapeutic and evolution data were identified from medical records. Patients were divided into two groups based on the body mass index (BMI) at the time of diagnosis; group 1 (BMI$\geq$ 25), group 2 (BMI $<$25). A comparison of the two groups was performed
Results
A total of 56 patients were collected. The median baseline BMI was 21.59 kg /m^2 [16-29.4]. 85.7% of patients had a BMI $<$25 kg /m^2, 14.3% were overweight (n =8). The comparison of these groups shows no significant difference in terms of age, sex ratio, tobacco consumption, the duration of development of disease, disease phenotype, presence of anoperineal lesions, presence of upper digestive tract, the severity of the initial flare or the degree of initial intestinal damage assessed by the Lemann score. However, a significant association was demonstrated between overweight and a colonic localization of the disease at the time of diagnosis, compared to other localizations (P = 0.02). After a mean follow-up of 36.82 months [6 –52 months], there was no significant difference between the 2 groups concerning the occurrence of complications of CD (P = 0.76), the number of severe relapses (P = 0.21), course of intestinal damage (P = 0.59), use of systemic corticosteroid therapy (P = 0.75), immunosuppressants (P = 0.58), biotherapy (P = 0.34) or surgical treatment (P = 0.37). Extra-digestive manifestations were more frequent in overweight patients compared to patients with a normal BMI but without statistically significant difference (group 1: 37.5% vs group 2: 27.1%, P = 0.41). The possibility of achieving deep remission was similar in the two groups (group 1: 12.5% vs group 2: 8.3%, P = 0.55).
Conclusion
According to these results, being overweight in CD does not significantly alter the long-term course of the disease. Studies on larger scales are therefore necessary.

Incidence of hypoglycemia among patients with type 2 diabetes who fasted during Ramadan

Bayar Qasim[1], Mazyar Ahmed[2] & Ayad Mohammed[3]
[1]College of Medicine, University of Dohuk, Medicine, Duhok, Iraq; 2Kurdistan Board for Medical Specialties, Erbil, Iraq; 3College of Medicine, University of Dohuk, Duhok, Iraq

Background and Objectives
Fasting causes a major change in the dietary habits including the frequency, the timing, and the patterns which will result in a major change in the metabolic response of the body. Physicians should advise the patients about the complications of diabetes mellitus during fasting especially hypoglycemia, the aim of this study is to determine the relation between type 2 diabetes mellitus and hypoglycemia and to evaluate whether this correlation is significant or not.
Patients and Methods
This is a cross-sectional prospective study, which included 304 Muslim patients with type 2 diabetes mellitus who decided to fast Ramadan during 2019 in two cities, 122 patients were from Duhok city and 183 patients from Erbil city, Kurdistan region of Iraq.
Results
Majority of patients fasted the Ramadan and the mean days of fasting were 26.96. Most patients had no attacks of hypoglycemia (85%), 4.6% have a single attack, and 8% had 4 attacks. There was no significant correlation between the hypoglycemic attacks and the variables studied in this article, such as the duration of diabetes, oral hypoglycemic agents, days of fasting, and fasting before Ramadan.
Conclusion
Physicians must warn patients about the possible risk of hypoglycemia during fating and it's the patient's own decision to continue fasting or not, however the high risk group should be advised against fasting. Lastly, the other role of physician is to adjust the dose of anti-diabetic drugs during fasting in order to minimize the risk of hypoglycemia.

The effect of insulin resistance syndrome in obese children on the development of hypertension

Zhanar Nurgaliyeva, Dana Akhatay & Shakhniza Abdrimova
NJSC "Kazakh National Medical University named after S.D.Asfendiyarov", Department of Pediatric Diseases with a Course of Neonatology, Almaty, Kazakhstan

Objective
To investigate the state of blood pressure in children with obesity and insulin resistance.
Materials and Methods
127 obese children, age from 6 to 15 years, average age 11.5 years. Anthropometry, calculation of body mass index (BMI), waist/hip volume ratio, measurement of blood pressure (SBP, DBP), study of the level of immunoreactive insulin, glucose were carried out. Insulin resistance was determined with hyperinsulinemia above 22.0 microns/ml, a high NOMA index.
Results
obesity in the observed children was of varying degrees, the average BMI was 26.9$\pm$2.2, while the predominantly abdominal type of distribution of the subcutaneous fat layer was revealed. Impaired glucose tolerance and fasting glycemia were detected in 14 (11.0%) obese children, type 2 diabetes mellitus in 1 (0.8%) child, hyperinsulinemia was detected in 45 (35.4%) children, while the average insulin level was 56.5$\pm$8.6 μm/ml. An increase in the HOMA index was detected in 64 (50.4%) patients, the average indicator was 12.0$\pm$1.9, which made it possible to verify their insulin resistance syndrome. An increase in blood pressure was detected in 46.5 $\pm$ 4.4% of obese children, in 55.2$\pm$8.1 children with obesity and insulin resistance. The frequency of elevated SBP values in obese children was registered in 39.1%, DBP - in 24.6%. In children with obesity and the presence of insulin resistance, high rates of SBP were recorded in 53.4%, DBP - 39.7%. Also, among children with insulin resistance, there were high values of SBP and pulse pressure, which indicates the indirect influence of insulin resistance syndrome in the formation of increased peripheral vascular resistance and the development of arterial hypertension.
Conclusions
arterial hypertension is a fairly common concomitant pathology in obese children. When burdened with insulin resistance syndrome in obese children, the frequency of arterial hypertension increases and is recorded in every second sick child, which indicates a direct and / or indirect effect of insulin resistance on an increase in blood pressure.

Lipid abnormalities in hospitalized patients with diabetes

Chaima Sdiri, Yosra Htira, Skander Msolly, Maryam Cheikhrouhou , Zohra Hadj Ali, Hedfi Imene, Chaima Jemai & Feika Ben Mami
Institut De Nutrition, Tunis, Tunisia

Introduction
Lipid abnormalities are frequent in type 2 diabetes. They increase the risk of cardiovascular events, morbidity and mortality in these patients. The aim of this study was to determine the lipid profile in patients with diabetes during hospitalization.
Method
We conducted a prospective study in the department of diabetology in the National Institute of Nutrition in Tunis from October 2021 to January 2022. This work was carried out on the medical records of hospitalized patients. Hypercholesterolemia was defined when the total cholesterol >5.2 mmol/l, Hypertriglyceridemia when a triglyceride level >1.7 mmol/l, and Low HDL cholesterol level by an HDL cholesterol level <1 mmol/l and <1.3 mmol/lin men and women respectively.
Results
We included 97 patients with diabetes with a sex ratio (M/F) of 0.6 and a mean age of 51.1 ± 17.5 years. The majority were type 2 diabetics (72%). The mean age of diabetes was 12.2 ± 8.8 years [0;34]. Pre-obesity, class I, class II and class III obesity were found in 28%, 30%, 3% and 3% of patients, respectively. The lipid profile showed hypercholesterolemia in 19% and hypertriglyceridemia in 29% of cases. Hypertriglyceridemia was correlated significantly with diabetes imbalance ($P = 0.005$) and with poor compliance with dietary rules ($P = 0.002$). Then, no significant correlation with obesity was found ($P =$ NS). In addition, Low HDL cholesterol concerned 55% of the patients. LDL cholesterol was ≥ 0.7 g/l in 86% of cases and it was correlated with the presence of coronary artery disease ($P = 0.03$). Statins were prescribed for 54% of diabetics: 49% of patients were on atorvastatin while 3% of diabetics were on simvastatin. Only one patient was on rosuvastatin.
Conclusion
Achieving glycemic control in patients with diabetes is compulsory to improve lipid profile. Lipid-lowering drugs, especially statins are often necessary to prevent cardiovascular diseases.

EP323

Ketogenic diet and Glucagon-like peptide 1 (GLP1) receptor agonists for obesity: our experience

Elisa Pisocri, Manuela Cimorelli & Nadia Cerutti
Asst di Pavia, U.O.S.D Medicina Generale Ad Indirizzo Dietologico, Italy

Background & aims
it is now known that the benefits due to weight loss are therefore attenuated by the recovery of body weight. Two therapeutic options facilitate the maintenance of weight loss at a distance: very low caloric ketogenic diet (VLCKD) and medications; the recent literature also shows how much the recovery of weight loss is significantly lower in subjects treated with medications for obesity than in them who have taken a VLCKD or low calorie diet. The aim of this work is to describe the anthropometric characteristics of two samples of subjects, affected by obesity, treated with a VLCKD or GLP-1 agonists.
Material & Methods
The sample called "ketogenic diet group" (KD) is composed of 19 adult patients; the mean initial weight was 99.8 ± 20.3 kg and the mean initial BMI was 37.8 ± 6.4 kg/m^2. They received a VLCKD with natural foods (10) or with artificial meals (7) or artificial foods mixed with natural foods (2). The sample called "GLP-1 agonists group" (GLP-1) is composed of 19 adult patients; the mean initial weight was 106.1 ± 25.4 kg and the mean initial BMI was 38.7 ± 8.5 kg/m^2. They were treated with liraglutide (4) or semaglutide (12) or exenatide (3).
Results
The mean percentages of weight loss for the KD group and for the GLP-1 group at 2 months were 8.9% and 7.8%, at 3 months were 11% and 6.2% and at 6 months were 13.1% and 11.5%, respectively.
Conclusions
maintaining long-term weight loss is the big challenge for obesity experts. The results of the present work, despite the small number of subjects, have shown a similarity in percentage weight loss in both samples in the short-medium term (6 months). In order to observe the results reported in the most recent literature, the percentage weight loss must be observed after at least 1 year and in bigger samples. However, it is important to underline that a 5-10% weight loss leads to a reduction in the risk of developing diabetes and dyslipidemia, cardiovascular diseases, sleep apnoea, osteoarticular, gynecological and mood disorders.

EP324

Features of the course and outcome of pregnancy in gestational diabetes mellitus in real clinical practice

Fatima Ushanova & Tatyana Demidova
Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background and aims
Published data on the prevalence of GDM and its complications in real clinical practice in Russia are insufficient. To assess the prevalence of GDM among pregnant women in one of the districts of Moscow, the structure of risk factors, the course and outcomes of pregnancy in women with GDM.
Materials and Methods
A retrospective analysis of data from the primary documentation of 510 pregnant women who were diagnosed with GDM during 2019.
Results
GDM was diagnosed in 510 pregnant women out of 5000 observed (10.2%). The mean age of women was 31.9 ± 4.8 (95% CI 31.5-32.3). The diagnosis was made in the 1st trimester of pregnancy - 224 pregnant women (43.9%), in the 2nd trimester - 31.8% (162), in 18.6% (95) in the 3rd trimester. Mean values of venous plasma glucose - 5.43 [5.25; 5.7] mmol/l, HbA1c - 5.19 ± 0.4% (95% CI 5.15-5.24). Treatment with diet therapy - 84.3%, the rest - insulin therapy (in all cases, aspart and detemir were used). The structure of risk factors: burdened hereditary history - 206 (40.4%), GDM in previous pregnancies - 54 (10.6%), macrosomia in history - in 6.3% of cases; antenatal fetal death in history - 3 (0.59%). Obesity was found in 120 (23.5%) women: BMI 30-34.9 kg/m^2 was recorded - 14.3%, BMI 35-39.9 kg/m^2 - in 5.1%, BMI 40 kg/m^2 or more - 4.1%. Pregnancy complications were observed in 123 women (24.1%): in 64 (12.5%) cases - fetoplacental insufficiency; preeclampsia - 54 (10.6%); 1 of the pregnant women - eclampsia; the threat of abortion and the threat of premature birth - 1.56% and 1.96%. In 12 pregnant women (2.35%) - polyhydramnios, in 18 cases (3.52%) - oligohydramnios. Adverse pregnancy outcomes were registered in 153 women with GDM out of 213 analyzed (71.8%): caesarean section in 22.5% of cases; premature rupture of amniotic fluid - in 58 (27.2%); macrosomia - 16.43%; ruptures of the pelvic organs - 41.31%; clavicle fracture - 2 cases; cephalohematoma - 3 cases; distress syndrome - in 6 newborns (2.82%); congenital malformations - in 2 newborns. CNS depression syndrome (7.98%), fetal cerebral ischemia - in 8.92%.
Conclusions
Totally unfavorable pregnancy outcomes were significantly more common in the group with earlier manifestation of GDM (60.7%) compared with the 2nd group (37.7%) ($p<0.001$). A detailed comparison of pregnancy complications in these groups showed no statistically significant difference.

Mitochondrial Diabetes: a case report

Hind Ouakrim, Sara Ijdda, Sana Rafi , Ghizlane El Mghari & Nawal El Ansari
Mohammed VI University Hospital, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Mitochondrial diabetes represents about 1% of diabetes but still very often misunderstood. The most frequent mutation is 3243A $>$G of the mtDNA, which is responsible for the maternally inherited diabetes and deafness syndrome (MIDD). We report an observation of a patient with strong suspicion of mitochondrial diabetes.
Case presentation
43-year-old female patient, with diabetes for 5 years on an Insulin Therapy.Anamnesis:&hypen; Diabetes discovered at the Age of 38 years by an acid ketosis decompensation.- Strong heredity of diabetes: grand-mother, two uncles, two aunts, tree cousins, all on the mother's side.
- Hypoacusis in an uncle and two sisters on the mother's side.
- Blindness in grandmother and diabetic retinopathy in mother
- Diabetic nephropathy in aunt on the mother's side.

Clinical examination is without particularity with BMI at 37.86 kg/m^2. Diabetes typing immunological test is negative

Discussion
Various abnormalities (mutations or deletions) in mtDNA are thus responsible for multi-organ syndromes that include diabetes among other abnormalities. Maternally Inherited Diabetes and Deafness (MIDD) is the most common form of mitochondrial diabetes. The 3243A >G mutation affects the tertiary structure of tRNA. The consequence is a cellular energetic deficit that mainly manifests in very active metabolically organs such as the endocrine pancreas. Mitochondrial diabetes should be suspected in view of the young age of onset of diabetes, maternal transmission, and association with other extra-pancreatic disorders (neurosensory deafness, reticular macular dystrophy, neurological and muscular disorders, cardiomyopathy). The purpose of searching for the mutation is to confirm the clinical diagnostic, to deduce the risk of maternal transmission and to propose a genetic diagnostic to the relatives.
Conclusion
Knowing mitochondrial diabetes is essential for early diagnosis, systematic screening for multi-organ damage, specific and multidisciplinary management, and to offer genetic counseling.

Association of fasting heart rate with fasting and post prandial blood glucose levels in Indians

Aniket Inamdar
Samarpan Clinic, Internal Medicine, Omerga, India

Background
Diabetes mellitus is associated with abnormal autonomic function. Diabetes and impaired fasting glucose are associated with increased mortality, particularly from cardiovascular causes. Several factors, including fast heart rate, have been identified to be associated with an increased likelihood of having diabetes. Heart rate is a crude index of the autonomic nervous system tone, reflecting a balance of sympathetic and parasympathetic inputs, and correlates with muscle sympathetic nerve activity and noradrenaline serum levels. Examining its potential role in diabetes risk could improve our understanding of the pathogenesis of diabetes.
Aim
Aim of our study was to establish correlation between fasting heart rate and fasting and post prandial blood glucose levels.
Materials and Methods
509 patients between age group 25 years to 75 years were studied at different centers in India. Resting heart rate was recorded on finger pulse oximeter before taking fasting blood sample. Fasting and post prandial blood samples were obtained by venepuncture and estimation was done by the hexokinase method. Diabetes mellitus was defined as use of insulin or a hypoglycemic agent, a fasting plasma glucose level of 126 mg/dl or more ($\geq$7.0 mmol/l), or a 2-hour postprandial plasma glucose level of 200 mg/dl or more ($\geq$11.1 mmol/l). Pearsons correlation test was used for statistical analysis.
Results
We found that resting heart rate was significantly higher in patients with higher fasting blood glucose levels compared with patients with normal glucose levels. This difference was statistically significant with $P = 0.002$ (r:0.137). It was also noted that fasting heart rate was also significantly higher in patients with higher post prandial blood glucose levels with P value of 0.002.
Conclusions
Our study strongly supports faster resting heart rate as an independent risk factor for incident diabetes and impaired fasting glucose. Meta-analysis of seven published studies confirmed the positive association between resting heart rate and diabetes risks. A resting heart rate is generally considered as a surrogate marker for autonomic activity, and increased sympathetic nerve system activity is associated with both acute and chronic insulin resistance. One of the most important mechanisms for increased diabetic risk might be that sympathetic activation causes vasoconstriction and decreases skeletal muscle blood flow, resulting in the impairment of glucose uptake into the skeletal muscle. Ultimately, the exact mechanism by which increased heart rate is induced remains to be elucidated; however, our findings suggest that this area of investigation may be relevant for future studies.

Growth Assessment and Metabolic Syndrome (MetS) Criteria in children with steroid-sensitive Nephrotic syndrome (SSNS) and frequent relapses treated with long-term prednisone therapy (LTPT): Comparison between children who developed obesity versus those who did not develop obesity

Mostafa Elbaba[1], Ashraf Soliman[1], Noor Hamed[1], Fawzia Alyafei[1], Maya Itani[2], Fatima Al-Naimi[2], Doaa Al Yousef[2] & Mona Shaat Dalees[2]
[1]Hamad Medical Center, Pediatrics, Doha, Qatar; [2]Hamad Medical Center, Nutrition and Dietitic Department, Doha, Qatar

Introduction
Long term prednisone therapy (LTPT) can be associated with overweight, obesity, and short stature. Both LTPT and obesity are considered risk factor for the occurrence of the different components of the metabolic syndrome (MetS).
Aim
We studied steroid-associated metabolic and clinical adverse events in children with NS and frequent relapses treated with LTPT (obese vs non-obese).
Methods
Data of 30 children with SSNS was analysed retrospectively. 16/30 were obese after LTPT and 14 were not obese. The cumulative dose of steroids over 5 years was calculated for each child. Growth and different components of the metabolic syndrome (MetS) including impaired fasting glucose (IFG), high LDL and cholesterol, lower HD and high blood pressure were studied over this period and compared with the data for 66 age-matched obese non-nephrotic children.
Results
Analysis of data showed that children with NS who developed obesity during therapy were significantly taller than the normal weight group. The obese group had higher cholesterol, TG and LDL level compared to the non-obese group. Both groups had high prevalence of hypertension (40% in the obese group vs 35.7% in

Treatment adherence in patients with type 2 diabetes and its associated factors

Mehrez Achwak, Rahma Khalaf, Imen Sebai, Fatma Boukhayatia, Haifa Abdesslam, Kamilia Ounaissa & Chiraz Amrouche
Institute of Nutrition of Tunis, Tunisia

Introduction
Treatment adherence is fundamental in diabetes control. The aim of our study is to evaluate treatment adherence in patients with type 2 diabetes and to determine its associated factors.
Methods
Cross-sectional study enrolling 80 type 2 diabetes patients followed up in the outpatient department of the national institute of nutrition. The Morisky questionnaire was used to evaluate treatment adherence. Age, gender, body mass index (BMI), diabetes duration and treatment, glycosylated hemoglobin (HbA1c), serum lipid profile, microvascular and macrovascular complications were assessed.
Results
The mean age was 60 $\pm$ 8 years. Of the study population, 60% were females. and 65% were insulin-treated. The mean diabetes duration was 14.9 $\pm$ 7.7 years, mean glycated hemoglobin was 10.4% $\pm$ 1.6 and mean BMI was 30.1 $\pm$ 6.2 Kg/m^2. High adherence was reported in 37% of cases, medium adherence in 28% of cases and low adherence in 35% of cases. Patients with good adherence had higher BMI (31.74 $\pm$ 6.7 Kg/m^2 vs 27.99 $\pm$ 5.55 Kg/m^2;$P = 0.03$) and better serum lipid profile including a lower triglycerides levels (1.94 $\pm$1.11 mmol/l vs 1.3$\pm$ 0.52 mmol/l ;$P = 0.003$). Lower HbA1c levels (10.89%$\pm$ 1.4 vs 10.42% $\pm$1.5 ; $P = 0.25$), lower total cholesterol levels (4.08 mmol/l $\pm$1.06 vs 4.47 mmol/l $\pm$ 1 ; $P = 0.17$) and higher HDL cholesterol levels (1.14 $\pm$0.32 vs 1.02 $\pm$0.2 ;$P = 0.13$) were associated to a better adherence but not significant. The presence of peripheral neuropathy, gastroparesis and genital autonomic neuropathy were significantly associated with low adherence ($P = 0.015$, $P = 0.007$ and $P = 0.02$ respectively). Patients with good adherence had lower prevalence of macrovascular complications including acute coronary syndrome (15.4% vs 35% ;$P = 0.1$), stroke (4.8% vs 7.7% ; $P = 0.6$) and peripheral arterial disease (38.5% vs 52.4% ; $P = 0.2$).
Conclusions
Our study highlights the beneficial impact of good adherence on lipid, and glycemic control. More awareness campaigns and counseling services should be provided by health professionals to improve treatment adherence and diabetes management.

Metreleptin treatment in woman with familial partial lipodystrophy and severe hypertriglyceridemia

Eleftheria Barmpa, Dimitra Pappa & Alexandra Bargiota
University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
Metreleptin, a recombinant analogue of leptin, is the only drug available for the treatment of generalized or partial lipodystrophy. Familial partial lipodystrophy (FPL) is a rare genetic disorder characterized by selective loss of subcutaneous adipose tissue, ectopic fat deposition, decreased leptin levels, and varying metabolic disorders, which in some patients can be quite severe and life-threatening. We present here such a woman with FPL who is treated with metreleptin.
Presentation
A 53-year-old woman diagnosed with FPL (LMNA gene variant) 8 years ago, had the typical phenotypic features of the syndrome, type 2 diabetes mellitus (T2DM) (HbA1c = 8.7%) and severe hypertriglyceridemia (triglycerides = 1113.6 mg/dl) despite maximum treatment and good adherence to it. She also had extensive visceral fat, fatty liver with a marked increase in liver size, ectopic fat disposition with increased fat in the mediastinum and significant increase in pericardial fat, fibrosis of the heart septum and myocardiopathy. The patient commenced treatment with metreleptin 5.8mg per day subcutaneously. Three months after the initiation, she showed improvement in body weight and metabolic parameters (HbA1c = 6.1% and triglycerides = 349 mg/dl). A year on metreleptin treatment, improvement of fatty liver infiltration and a significant reduction of its size (from 25cm to 20 cm) was observed as well as a significant reduction of the fat in the mediastinum and pericardium. Body composition measured by dual energy X-ray absorption (DXA), showed a fat redistribution with an increase in the upper and lower extremities and a decrease in the trunk. At two years on the same dose of metreleptin, she was metabolically stable (HbA1c = 5.7% and triglycerides = 320 mg/dl), with a further reduction of liver size, at 18 cm.
Conclusions
FPL is a rare disease with varying phenotype and a broad spectrum of metabolic disorders which at times can be quite severe and life-threatening. The use of metreleptin in these patients can significantly improve such metabolic aberrations and their potentially fatal consequences.

Study of the effects of long-term therapy DPP4i on the morphofunctional state of pancreatic endocrinocytes in the older age group in the clinic and experiment in conditions of type 2 diabetes.

Taisiia Tuchina & Alina Babenko
Almazov National Medical Research Centre, Saint Petersburg, Russian Federation

Introduction
DDP4i improves the function of β-cells and α-cells. However, there have been short-term follow-up and young subjects in many experimental and clinical studies. The imbalance of pancreatic endocrinocytes increases in adulthood and changes become less reversible. We decided that it would be useful to study the morphofunctional features of pancreatic endocrinocytes while taking iDPP4 in the older age group in the clinic and experimentally.
Materials and methods
Male Wistar rats with streptozotocin-nicotinamide-induced type 2 diabetes (DM type 2) ($n = 20$, age over 12 months) received group therapy for 24 weeks.
1. Control - healthy control group.
2. DM type 2 - DM type 2 without therapy.
3. DPP4i - Vildagliptin 1.5 mg per kg.Pancreatic preparations were made after the end of therapy. Immunohistochemical study was carried out with antibodies to glucagon, insulin.Patients ($n = 36$, over 50 years of age) were divided into groups depending on the therapy.
1. DPP4i for more than a year in combination with Metformin.
2. Metformin + sulfonylurea preparation(SU).

Insulin, glucagon, C-peptide levels were examined before and after a standard breakfast. The HOMA IR and HOMA β indices were calculated.
Results
Experiment. A statistically significant difference in the volume of β-cells (significantly less in the group DM type 2($P < 0.05$)), in the volume of α-cells (significantly more in the group DM type 2 ($P < 0.05$)) was revealed when comparing DM type 2 group with a healthy control group. A statistically significant difference($P < 0.05$) was obtained when comparing the DM type 2 group without therapy and the DPP4i group. The number of β-cells was significantly higher with iDPP4 therapy, and the number of α-cells was significantly lower. There was no statistically significant difference in the number of β- and α-cells ($P > 0.05$) when comparing the DDP4i group with the control group. Clinical part of the study. We obtained a significant difference in fasting glucagon and insulin levels between the Metformin + DPP4i and Metformin + SU groups ($P < 0.05$). More significant hyperglucagonemia and hyperinsulinemia were observed in the group receiving Metformin + SU.Discussion.Long-term use of drugs DPP4i contributed to the normalization of the number of β- and α-cells in the experiment. And also DPP4i reduced the secretory imbalance of insulin and glucagon in a clinical study. Our results show that DPP4i contributes to the normalization of the functional state of pancreatic endocrinocytes, including in older age groups.

Development of complex of biomarkers for screening program for early diagnosis of familial diabetes mellitus

Talat Saatov[1], Kha Karimov[2], Zafar Ibragimov[1], Timur Alimov[2], Nasiba Alimova[3], Anvar Abduvaliev[1], Kodirjon Boboev[2], Elvira Ibragimova[1], Tokhir Ishankhodjaev[1], Zulaykho Shamansurova[1,4] & Abdunabi Tashtemirov[1]

[1]Institute of Biophysics and Biochemistry under Mirzo Ulugbek National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [2]Specialized Scientific-Practical Medical Center of Hematology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan; [3]Ya.Kh. Turakulov Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan; [4]Tashkent Pediatric Medical Institute, Uzbekistan Ministry of Education, Tashkent, Uzbekistan

Diabetes mellitus (DM) is a most significant medical-social worldwide problem. Absence of reliable screening program for identification of persons with the higher risk of DM dictates a necessity of sensitive tests of early DM diagnosis. Following genealogical analysis, two experimental groups were formed; patients with type 1 DM with the familial burden (probands) and those at risk (siblings) were included into the 1st and 2nd groups, respectively. Apparently healthy subjects without carbohydrate metabolism disorders served as the controls. The screening program consisted of determination of immunological and genetic biomarkers, to name presence of specific autoantibodies to β- cells of Langergance islets (ICA) and to decarboxylase glutamic acid (GAD), A49/G polymorphisms of CTLA4 gene and INS gene rs689 in patients with the familial DM burden and persons at high DM risk. The familial DM burden was found in 71.2% of patients with type 1 DM. In the probands, significant increase of mean concentrations of ICA and GAD autoantibodies, as compared to the controls ($P < 0.001$) was found. Among the patients having siblings with DM as the first line relatives, concentrations of the GAD autoantibodies were found almost two times higher than in those with DM but without familial DM burden. Analysis of results of genotyping for CTLA4 gene A49/G polymorphisms and those of INS gene rs689 in patients with genetically determined DM burden demonstrated association of G allele and heterozygous AG genotype of CTL4 gene and T allele and heterozygous AT genotype of INS gene with the risk of DM onset. The findings are the evidence for importance of biomarkers under study for identification of genetically determined DM forms and prognosis for its progression at early preclinical stage.

The impact of the interventions based on mobile apps in physical activity among people with Type 2 diabetes mellitus

Elissavet Lykoudi, Eugenia Vlachou, Eleni Evangelou, Anastasia Ntikoudi, Eleni Dokoutsidou & Nikoletta Margari

University of West Attica, Department of Nursing, Athens, Greece

Introduction

The mobile health (mHealth) technologies use mobiles and also wireless network and devices to offer services for improving health, promoting behavior changes and supporting self-management. The increasing global use of mobile application (app) is widely accepted in managing chronic diseases and especially among people with type 2 diabetes mellitus (T2DM).

Aim

The purpose of this study was to identify the impact of the interventions based on mobile apps in physical activity among people with T2DM which included in randomized controlled trials (RCTs).

Methods

The international bibliography was examined to present the impact of the intervention based on mobile app in physical activity among people with T2DM comparing with usual diabetes care. This study is a narrative review and for this purpose the electronic database of PubMed was searched using keywords such as "Type 2 diabetes", "mobile applications","physical activity" in English and Greek language for studies for the past 5 years. The inclusion criteria were all RCTs associated with a comparison of mobile app-based interventions and with usual diabetes care in adults with T2DM. The exclusion criteria were those not being RCTs or those which were study protocols and pilot studies.

Results

A total number of 26 RCTs were reviewed in this study. By using the search terms and by applying the eligibility criteria 6 RCTs were chosen and screened for developing this study and the non-relevant cases of 20 articles were excluded according to exclusion criteria. In the 6 RCTs that were included in the narrative review, 1.005 people participated with T2DM. Finally, these studies had separated the participants to intervention group based on mobile app and control group with usual diabetes care. The intervention group who received the mobile app with physical activity advices had increased their physical exercise and had decreased their hemoglobin A1c (HbA1c) compared to the control group with the usual diabetes care. Moreover, changes were observed between these two groups to their biomarkers and anthropometry measures such as weight, waist circumference and body mass index (BMI) in favour of the intervention group.

Conclusion

The usage of mobile apps bridges the gap between the people and the self-management of their diabetes. The findings of this review suggest that the mobile apps used by participants can significantly improve physical activity and help to adopt exercise habits. Furthermore, the new digital health care is possible to lead to a successful outcome in HbA1c levels and more over.

Contraception in diabetic women: A review of 100 cases

Fadwa Atfi & Imane El Abbassi

CHU Ibn Rochd , Maternity Department, Casablanca, Morocco

Introduction

Contraception in women with diabetes is difficult. It is the subject of an individualised prescription, which takes into account the metabolic and vascular state as well as the gynaecological tolerance of the patient.

Materials and Methods

This is a prospective survey having concerned 100 diabetic women surveyed in the Maternity ward of the CHU Ibn Rochd of Casablanca, during a five-month period, between April and September 2021.

Results

The average age of the women was 35.2 years. Obesity was noted in 26%, hypertension in 51%, dyslipidaemia in 35% and in 35% and 5% of the women were smokers. Type 1 diabetes accounted for 35% and type 2 for 65%. Diabetes was unbalanced in 91% and complicated in 68%. Hormonal contraception was used in 42%, the intrauterine device in 28%, local methods in 20%, tubal ligation was performed in 9%. The maternal-foetal risks linked to unbalanced diabetes were known in 66%, the need for obstetrical and diabetic pregnancy monitoring in 63%, and the obligation to start insulin in pregnant diabetic women in 47%. Women who used hormonal contraception despite having a contraindication to the pill represented 30%.

Discussion

The problem of contraception must be systematically addressed in a diabetic woman of childbearing age, during each consultation, Oestrogen-progestin treatments should not be excluded from the contraceptive Oestrogen-progestin treatments should not be excluded from the contraceptive regimen in women with diabetes, type 1 or type 2, and under 35 years of age. Potential adverse impacts on blood glucose, lipid profile and micro angiopathy are apparently modest. The effects on macroangiopathy need to be integrated with other cardiovascular risk factors. The evaluation of knowledge concerning contraception will have to be the subject of several more in-depth studies in order to properly define the issue and to propose practical solutions to generalise the information with the aim of reducing the risk of unforeseen consequences on pregnancy in these women who most often have complicated diabetes.

Conclusion

The prescribing practitioner should be the subject of several studies in order to propose practical solutions to improve knowledge and contraceptive practices with the aim of reducing the unforeseen risks of pregnancy in these women.

A Rare Case: Non Ketotic Hyperglycemic Chorea

Filiz Mercan Sarıdaş[1], Mehmet Akif Ötegeçeli[2], Ensar Aydemir[1], Coskun Ates[2], Erhan Hocaoğlu[1], Soner Cander[1], Ozen Oz Gul[2], Canan Ersoy[1] & Erdinc Erturk[2]

[1]Bursa Uludag University, Endocrinology and Metabolism, Bursa, Turkey; [2]Bursa Uludag University, Internal Medicine, Bursa, Turkey

Introduction

Hemichorea-hemiballismus, secondary to hyperglycemia, is a rare but easily treatable condition that is usually associated with poorly controlled type II diabetes mellitus. Diagnosis is based on clinical assessment and imaging. Etiology includes primarily cerebrovascular diseases, metabolic, degenerative,

infectious diseases, space-occupying lesions, basal ganglia damage due to drugs and toxic substances.
Case
Here we report a rare case of a 78-year-old woman presenting with involuntary movements on the left side of her body secondary to long standing and uncontrolled hyperglycemia. The T1-weighted magnetic resonance imaging revealed hyperintensity in the right basal ganglia. She received intensive insuline therapy and haloperidol. During the follow-up, the patient's blood glucose level and HbA1c improved, along with significant improvement in choreiform movements.
Conclusion
In conclusion, when patients with diabetes mellitus present with unilateral movement disorder, non-ketotic hyperglycemic chorea should be considered, and treatment should be started immediately after diagnosis.Key Words: Hemichorea, Hemiballismus, Hyperglycemia, T-1 hyperintensity.

Poor glycemic control is associated with major depression among diabetic patients

Malak Belkhiri, Boubaker Fadia[1], Ashraf Khemiri[1], Houcem Mrabet[1], Walid Bouali[2], Lazhar Zarrouk[2] & Habib Sfar[1]
[1]Taher Sfar Hospital, Endocrinology, Tunisia; [2]Taher Sfar Hospital, Psychiatry, Mahdia, Tunisia

Introduction
Diabetes mellitus (DM) and depression are two frequent health conditions. Their coexistence may represent a medical challenge for clinicians. In addition, early detection of depression can help in better management of diabetes and preventing its complications.
Aim of the study
To assess depression and glycemic control among a group of patients having diabetes.
Methods
A cross sectional study was conducted among diabetic patients followed in the Endocrinology Department of the "Taher Sfar University Hospital" in Mahdia, Tunisia. Depression assessment was made using the DSM-V diagnosis criteria and glycemic control assessment with the last available fasting blood glycemia and HbA1c. The study took place over a one-year period (from October 2019 to October 2020). Patients with a previous psychiatric history were ruled out.
Results
By the end of the study, 260 diabetic patients were included, females represented 62.7%. The mean age of patients was calculated at 57.36 years . The majority of patients had type 2 diabetes (92.3%). The mean of the diabetes duration was of 9 years. Different complications of the diabetic disease were assessed in the time of the study : neuropathy (39%), retinopathy (37%) and nephropathy (24%. A regular physical activity was reported by 58.5% of our patients and a healthy diet pattern by 12.3%. A regular self-blood sugar monitoring was reported by 44.2% of the participants. According to DSM-V diagnosis criteria, the number of participants having Major Depressive disorder(MDD) were of 39 (15%). In this group having MDD, almost all patients (97.4%) had poor glycemic control with a mean of the fasting blood glycemia at 13.45 mmol/l and a mean HbA1c of 10.385%. There was a significant correlation between glycemic control and depression ($P = 0.002$).
Conclusion
Our study showed a worse glycemic control among diabetics having MDD. Clinicians should be attentive to look for depression in case they fail to meet glycemic targets. Depression can predict health-related behaviors problems, and unsatisfactory glycemic control at follow-up which can worsen depressive symptoms. A multidiciplinary approach appears necessary.

Flash glucose monitoring and glycemic control in type 1 diabetes: Real world data

Antonio Ballesteros Martín-Portugués, Marta Iturregui, Lourdes García-García-Doncel, Concepción Cruzado-Begines, Silvia Ponce-Delgado & Maria Gloria Baena-Nieto
Jerez Hospital, Endocrinology Unit, Jerez, Spain

The use of Flash Glucose Monitoring system (FGM) for the management of type 1 diabetes mellitus (T1D) is rapidly increasing. FGM enables people with diabetes to regularly track their glucose levels without needing to perform capillary finger-stick measurements (SMBG). Clinical studies have shown improvement of glycemic control and hypoglycemia reduction, as well as better comfort and quality of life in people with type 1 diabetes (T1D) using this technology. Objectives: to asses the degree of achievement of glycemic targets in T1D patients using the flash sensor properly (>70% of the time) in our center.
Methods
We analysed registry data collected at a tertiary diabetes centre in Spain. People with T1D routinely using FGM to manage their diabetes were included in the analysis. Downloaded LibreView data of patients were collected: data regarding glucose management indicator (GMI), time within range 70-180 mg/dl (TIR), coefficient of variation (CV) and hypoglycemic events.
Results
A total of 712 patients were included in the study. 80 patients did not download any sensor data. The downloaded data were prior to 6 months in 20 patients and sensor use was <70% of the time in 116 patients. We analyzed data from patients who used the sensor appropriately (>70% of the time). Data from 488 patients (68.53%) were analyzed. The percentage of patients with a GMI< 7% was 48%, those with CV<36% were 49,8% and those with TIR>70% were 31,6%. All targets were met only in 22,5% of patients. In addition, 87.9% of patients had a high risk of hypoglycemia and 27,5% had experienced at least 1 daily hypoglycemic event.
Conclusions
There is a high percentage of T1D patients using FGM who do not use it properly. Only 15% of TD1 patients with adequate use of the sensor have good glycemic control. Metabolic control in T1D patients should be improved and strategies for proper use of FGM must be implemented.

The possible biomarkers of the "postCovid-19 syndrome" in patients with type 2 diabetes

Sergey Sukhanov[1], Yulia Sorokina[2], Olga Zanozina[3] & Veronika Lagonskaya[3]
[1]Privolzhsky Research Medical University, Hospital Therapy, Nizhny Novgorod, Russian Federation;[2]Privolzhsky Research Medical University, General and Clinical Pharmacology, Nizhny Novgorod, Russian Federation; [3]Privolzhsky Research Medical University, Regional Hospital named after N.A,Stemashko, Endocrinology, Nizhny Novdorod, Russian Federation

COVID-19 has a significant effect on the patient's well-being even after the norm of laboratory parameters.The patients had cognitive blunting breathlessness, headache, fatigue, myalgia, weakness etc. The symptoms could last 3–12 months, from mild to severe, can lead to death.
Purpose
To determine the significance of some biomarkers characterizing the condition of a patient with diabetes mellitus after undergoing covid.
Materials and Methods
We examined 27 patients with type 2 diabetes who underwent Covid-19 4 months ago. This was the first group. The average age was 62.3 years, the duration of diabetes was 6.8 years. Glycated hemoglobin was 8.1%. The second group consisted of 18 patients without a new coronovirus infection and comparable to the patients of the first group by sex, age, duration of the disease, the level of glycated hemoglobin, complications of diabetes and concomitant diseases. The severity of of dysfunctions was assessed in points. We investigated: glycated hemoglobin (BioRad), haptoglobin, ceruloplasmin, c-reactive protein, D-dimers (ACL TOP 700 Instrumentation Laboratory), Klotho protein (ELISA).
Results
The Klotho protein levels in the first group were significantly lower than in the patients of the second group ($P = 0,024$), while the level of other indicators in these groups did not differ significantly. We noted a significant relationship between the severity of polyfunctional disorders in diabetic patients after a new coronovirus infection and the level of Klotto protein. The Klotto of protein level significantly negatively correlated with the level of glycated hemoglobin ($r = -0.8$, $P = 0.023$) and the level of c reactive protein ($r = -0.72$, $P = 0,039$).
Conclusion
The Klotho protein can be a biomarker of the "postCovid-19 syndrome" in patients with type 2 diabetes who have undergone a new coronavirus infection

Features of some metabolic and instrumental indices in patients with type 2 diabetes mellitus and COVID-19 in oxygen deficiency developed for the first time depending on the initial compensation

Ina Darashkevich[1], Tatjana V Mokhort[2], Alena Kulaha[3] & Nataliya Bahamazava[3]
[1]Grodno State Medical University, Grodno, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Grodno University Clinic, Grodno, Belarus

Patients with type 2 diabetes mellitus (DM) are one of the most vulnerable categories of patients in terms of adverse outcomes of COVID-19 infection.
Aim
To assess the features of laboratory and instrumental data in patients with COVID-19 and type 2 DM (unvaccinated) depending on the value of glycated hemoglobin (HbA1c) at the time of the onset of oxygen deficiency.
Materials and methods
The study involved 78 patients with type 2 DM and COVID 19. All the participants were divided into 2 groups. Group 1 ($n = 47$) included patients with HvA1c$\leq$7.0%, group 2 ($n = 31$) - $\geq$7.0%. The patients underwent computed tomography scan of the lungs (CT), assessment of blood oxygen saturation level (SpO2), HbA1c, C-reactive protein(CRP), ferritin, D-dimer, complete blood count on the 6-9th day of the disease.
Results
Analyzing the obtained results it was revealed that in patients of group 1 the duration of type 2 DM was 7.0 [6.0;7.5] years vs 8.9 [7.0;10.0] years in group 2 ($P = 0.031$). The HbA1 was significantly higher in group 2 -8.5 [8.0;9.8]% vs 7,0 [6.7;7.0]%, ($P = 0.001$). So, in group 1 at the time of hospitalization SpO2 was 91.0 [90.0;93.0]% vs 87.0 [86.0;89.0]% ($P = 0.005$). All the patients had bilateral interstitial pneumonia, the median value of the percentage of lung tissue damage in group 1 was 45.0 [40.0; 55.5]% vs 65.0 [60.0; 70.0]% in group 2 ($P = 0.002$) (CT lungs). In group 2 there is a higher value of CRP 52.5 [37.0; 78.0] mg/l vs 36.0 [27.0;43.0] mg/l ($P = 0.016$), ferritin value 545.0 [480.0; 550.0] ng/ml. vs 433.7 [420.0;580.0] ng/ml ($P = 0.011$). In groups 1 and 2, there were no significant differences in the indicators of erythrocytes and hemoglobin. There was a difference in the value of leukocytes 9.4 [9.0; 9.9]$\times 10^9$/l vs 5,7 [4,7; 8,3] $\times 10^9$/l ($P = 0.023$), stab neutrophils 4.0 [3.0;5.0]% vs 7,0 [6,0; 10,0]% ($P = 0.002$) and lymphocyte count 16.0 [11.0;17.0]% vs 11.0 [10.0; 14.0]% ($P = 0.013$). An increase in HbA1c is associated with a decrease in SpO2 (r =-0.78), an increase in the percentage of lung tissue damage by CTlungs (r =0.66), CRP (r =0.67), ferritin (r =0.79), D-dimers(r =0.60) in group 1. A positive correlation was registered between the HbA1c values and the percentage of lung tissue damage by CT (r =0.87), CRP(r =0.96), D-dimer (r =0.93), ferritin (r = 0.93); and a decrease in SpO2 is associated with an increase in HbA1c (r=-0.98), CTlungs (r =-0.98), CRP(r =-0.92), D-dimers (r =-0.89) in group 2.
Conclusions
Decompensation of diabetes mellitus in patients with COVID 19 is accompanied by an increased degree of damage to the lung tissue, prolonged oxygen therapy, increased values of CRP, D-dimers, ferritin, lymphopenia, and the lowest value of leukocytes.

Impact of COVID-19 pandemic on diabetic patients

Salma Abadlia, Zouaoui Chadia, Bchir Najla, Sarra Raddadi, Annam Benchhida, Chaima Souibgui & Haroun Ouertani
Military Hospital , Endocrinology, Tunis, Tunisia

Introduction
The COVID-19 pandemic had a significant emotional and psychological impact on populations worldwide, especially vulnerable people with chronic diseases such as diabetics. The objective of our study was to assess the quality of life and psychological distress of diabetic patients and to study patients' attitudes towards managing their diabetes.
Methods
We conducted a cross sectional descriptive study involving 60 diabetic patients followed in Endocrinology-Nutrition department of the Military Hospital of Tunis during the period between February and March 2021. We used the short form questionnaire SF-12 to assess quality of life of participants, allowing us to calculate two scores; mental component score (MCS) and physical component score (PCS) with a total score ranging from 0 to 100. A higher score indicates a better health. We also used Kessler psychological distress scale (K10) with a total score ranging from 0 to 40. Low scores indicate low levels of psychological distress while high scores indicate high levels of psychological distress. Mean level of worry was assessed using a scale from 0 to 10.
Results
Our population was predominantly female (sex ratio=0.8). The average age was 52.4 years. Our patients were suffering from two or more chronic diseases in 78.4% of cases. The mean duration of diabetes was 11 years with an average HbA1c of 8.9%. The mean level of worry was 4.8. The mainly subjects of worries concerned "the shortage of anti-diabetic drugs and monitoring equipment" (78.3% and 71.7% respectively), the notion of "high risk population" (75%) and "the potential severity of the infection in diabetics" (73.3%). Patients were more observant for their treatment and in monitoring their glycemia in respectively 45% and 38.3% of cases. Nevertheless, physical activity was reduced in 36.7% and food intake increased in 26.7% of cases. MCS and PCS were 39 $\pm$10.4 and 37.4$\pm$9.3, respectively. The mean K10 score was 12.9$\pm$8.8. In univariate analysis, MCS, PCS and K10 were significantly associated with gender (P = 0.03; 0.009 and 0.005 respectively). PCS was associated with age ($P = 0.025$).
Conclusion
The quality of life of diabetic persons is impaired. This involves the implementation of a monitoring, follow-up and support strategy by the health system for these patients.

COVID-19 pandemic: Impact on follow up care of insulin-requiring diabetic patients

Asma Kardi, Radhouen Gharbi , Ben Salem Maram, Manel Jemel, Hajer Kandara, Marwa Chiboub & Ines Kammoun
Institut De Nutrition, Tunis, Tunisia

Introduction
COVID-19 is a novel pandemic affecting globally. It has led to an unprecedented global health crisis assessing health system's preparedness to deal with health disasters. The aim of our study was to evaluate the impact of COVID-19 on the follow up care of diabetic patients.
Methods
We conducted a retrospective study in 100 insulin-requiring diabetic patients. Data regarding treatment availability, weigh, glycemic control and follow up care during two years before (T1: 2018-2019) and during the pandemic of COVID-19 (T2 : 2020-2021) were collected.
Results
The study population included 60 women and 40 men. The mean age was 58.6 $\pm$ 1.3 years. Among our 100 patients, 30% have type 1 diabetes mellitus and 70% have type 2 diabetes mellitus. Fifty-seven patients were using insulin alone and 43 patients were treated by insulin with metformin. Hypertension and dyslipidemia prevalence was respectively 55% and 56%. Insulin had always been available. However, metformin, anti-hypertensive drugs and anti-dyslipidemic drugs disponibility in public health facilities decreased, with respectively 57%, 36% and 75% of cases before pandemic versus 79%, 59% and 85% in T2 ($P = 0.022$, $P = 0.004$ and $P = 0.332$ respectively). Eight patients missed at least one medical consultation in T1 versus 46 patients in T2 ($P <$ 10-3). Fundoscopy and screening for microalbuminuria were performed respectively in 83% and 89% of patients in T1 and in 41% and 87% in T2 ($P <$ 10-3, $P = 0.839$ respectively). Glycosylated hemoglobin increased in 75% of patients. Its mean raised from 8.9% to 9.3% ($P <$ 10-3). The percentage of patients with well-controlled diabetes decreased from 29% in T1 to 19% in T2 ($P = 0.013$). A weight gain was documented in 57% of patients. The mean of weight increased from 76.9 Kg to 78.3 Kg ($P <$ 10-3). Out of 100 patients, cardiovascular events were documented in one patient in T1 and in five patients in T2 ($P = 0.219$).
Conclusion
A significant impairment in the follow up care of diabetic patients and their glycemic control has been revealed through our study. This can be partially explained by the impact of lockdown on treatment facilities availability, healthy lifestyle habits and by the stressful condition related to this pandemic. However, defective health systems have contributed to worsen this critical situation. Hence, effective preparedness are needed in future so that complications can be minimized.

Diabetes distress and its clinical determinants in Type 2 diabetes patients

Najoua Lassoued, Marwa Majdoub, Mehrez Achwak, Khalil Chadly, Zantour Baha, Alaya Wafa & Sfar Mohamed Habib
Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
Diabetes distress (DD) refers to the emotional burdens and worries, often hidden, that are part of the spectrum of the patient experience when managing a chronic and demanding disease like diabetes. The objective of this work was to determine the prevalence of DD and its clinical determinants in type 2 diabetic patients.
Patients and methods
Cross-sectional study conducted on 92 type 2 diabetic patients who consulted on an outpatient basis between April and June 2021. DD was assessed using the Diabetes Distress Scale (DDS).
Results
The average duration of diabetes was 10.35 years. 69.6% of patients presented with moderate to severe distress related to diabetes. The dimension of lifestyle distress had the highest score among the DDS subscales. There was a correlation between age, level of education, social coverage, rate of follow-up, HbA1c level and DD. HbA1c levels and rate of follow-up were the main predictors of DD.
Discussion and conclusion
The results of this work underscore the importance of identifying DD in type 2 diabetics. High levels of DD have been significantly associated with poor glycemic control, poor diabetes self-management, and poor quality of life. More work is needed to better explore and manage psychological comorbidity in type 2 diabetics.

A diabetic foot case with bilateral charcot arthropathy

Ensar Aydemir, Erhan Hocaoglu[1], Coskun Ates , Filiz Mercan Saridas, Soner Cander , Ozen Oz Gul, Canan Ersoy & Erdinc Erturk
Uludag University Medical School, Bursa, Turkey

Background
Diabetic foot infections are an important cause of morbidity and mortality associated with poor glycemic control, polyneuropathy and micro/macrovascular diseases. The clinical, laboratory, radiological, pharmacological and/or surgical evaluation is required. We report a case of diabetic foot infection with bilaterally charcot joint.
Case
A 52-year-old female patient with type 2 diabetes mellitus (DM), hypertension (HT), coronary artery disease (CAD) and peripheral artery disease (PAD) applied to our endocrine clinic with ulcerated lesion on the sole of the right foot. Eight years previously she had undergone a left first metatarsophalangeal (MTP) joint amputation due to underlying diabetic foot. On examination, she had a bilaterally neuropathic arthropathy (Charcot joint). Her plasma glucose level was 272 mg/dl, HbA1C of%7.8, erythrocyte sedimentation rate (ESR) of 46 mm/h and C-reactive protein (CRP) of 41.2 (normal range, 0-5) mg/l with normal renal and liver function tests in the first laboratory evaluation. Two-sided X-Ray and magnetic resonance imaging (MRI) of the ankle and foot revealed destructive joint disease without osteomyelitis (Figure 1). The diagnosis of diabetic foot infection was made, and treatment with intravenous piperacillin/tazobactam and teicoplanin for two weeks, then the patient improved. After clinical and biochemical improvements, the patient was discharged with oral antibiotics.
Discussion
Uncontrolled diabetes mellitus is the most common cause of non-traumatic amputations. Chronic, progressive and destructive arthropathy may develop in diabetic patients associated with sensory, autonomic and motor neuropathy. Treatment of charcot neuroarthropathy is based on multidiciplinary team management. Inappropriate and late approach of diabetic foot infection often results to amputation of any limb.

Foot risk assessment in diabetic patients

Zeineb Zemni[1], Daii Raja[1], Olfa Lajili[2], Emna Bornaz[3], Amal Salem[4], Salma Abadlia[5], Htira Yosra[1], Hedfi Imene[1], Zohra Hadj Ali[1] & Faika Ben Mami[1]
[1]National Institute of Nutrition Of Tunis, Department C, Tunis, Tunisia; [2]Military Hospital of Instruction of Tunis, Hygiene Service, Tunis, Tunisia; [3]National Institute of Nutrition of Tunis, Department B, Tunis, Tunisia; [4]National Institute of Nutrition of Tunis, Outpatient Department and Functional Explorations, Tunis, Tunisia; [5]Military Hospital of Instruction of Tunis, Endocrinology Departement, Tunis, Tunisia

Background
The management of diabetic foot starts with prevention, mainly based on the early detection of peripheral neuropathy and peripheral arterial disease, called podiatric risk assessment. This risk must be evaluated in all type 2 diabetics since the discovery. The aim of this study was the assessment of diabetic foot ulcer risk according to International Working Group on the Diabetic Foot (IWGDF) and the identification of risk factors for developing foot lesions.
Methods
We conducted a descriptive, cross-sectional study that concerned 60 diabetic patients hospitalized in the Department C of the National Institute of Nutrition between July and September 2021.
Results
Mean age of patients was $59,1 \pm 12,23$ years with sex ratio 0.66. Half patients were hypertensive, 64,4% had a personal history of dyslipidemia and 34% were smokers. All patients had Type 2 diabetes with evolution duration $9,33 \pm 6,26$ years. The majority of patients (91,7%) had uncontrolled diabetes and 66,7% had microangiopathy (retinopathy and nephropathy). Thirteen patients (21%) had a foot at risk. On clinical examination, neuropathy was found in 21% of cases, while lower limb arteriopathy in 14,3%. Patients were classified into four risk groups according to IWGDF criteria as follows: grade 0: 78,3%; grade 1: 13,3%; grade 2: 6,7% and grade 3: 1,7%. There was statistically significant relationship between LDL cholesterol ($P = 0,035$), microangiopathy ($P = 0,003$) and foot risk grade. Patient's sex, BMI, diabetes duration, smoking, and HBA1c did not have significant association with risk of diabetic foot ulcer.
Conclusion
Diabetic foot remains a major health problem and a frequent cause of limb amputation. Podiatric risk assessment represents a key tool to avoid many dreaded complications.

Relationship between kidney function and the level of amylinemia in patients with diabetes mellitus

Nataliia Pashkovska & Iryna Tsaryk
Bukovinian State Medical University, Department of Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background
Chronic kidney disease (CKD) is one of the leading causes of disability and mortality in patients with different types of diabetes mellitus (DM). However, relationships between kidney function and serum amylin levels are still controversial, especially in patients with heterogeneous types of diabetes. The objective of the study was to determine the features of the glomerular filtration rate (GFR) in patients with DM depending on the level of amylinemia.
Methods
89 patients with DM and CKD were examined, as well as 15 representatives of the control group. The patients were divided into three groups by the types of DM (25 patients with classical type 1 diabetes mellitus (T1DM), 36 patients with latent autoimmune diabetes in adults (LADA), 28 patients with type 2 diabetes (T2DM)) and by the GFR stages (G1-21, G2-49, G3a-48, G3b-17, G4-10). GFR was determined by the CKD-EPI formula. Serum amylin levels were measured using the ELISA method.
Results
The level of amylinemia in patients with GFR stages G1 and G2 probably did not differ in comparison with the control and among themselves. In the group of patients with GFR stage G3a, the level of serum amylin was 7.7 times higher than the control, 3.7 times higher than the G1 group, but did not differ from the one in group G2. In patients with GFR of stage G3b, the above indicator was 14.7 times higher relative to the control, 7.2 times higher relative to the group of individuals with GFR of stage G1, 3.5 times higher than the G2 stage and 1.9 times higher

than the G3a stage. The serum level of amylin in the group of patients with GFR stage G4 was significantly higher by 26.0 times compared to the control, 12.7 times – in the group of patients with GFR stage G1, 6.1 times – in the group of patients with GFR of stage G2, 3.4 times – in the group of patients with GFR of stage G3a and has not changed compared to the G3b group. In patients with DM positive correlations were found between the content of amylin and insulin, C-peptide, HOMA-IR index and creatinine ($P<0.05$), in the group of patients with T2DM - between serum amylin and GFR ($P<0.05$).

Conclusion

The level of amylin was increased in proportion to the stages of GFR in patients with T2DM and LADA, which indicates the role of hyperamilinemia in the development of CKD in this category of patients.

Acute pancreatitis revealing major hypertriglyceridemia at 94 g/l!

Kaoutar Rifai, Loubna Guissi, Salma Ahallat, Hind Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction

Hypertriglyceridemia (HTG) is a rare but well-known cause of acute pancreatitis, which can be fatal with an overall mortality rate of 36-50% in the most severe forms.

Case presentation

A 29-year-old patient was admitted to the emergency department with abdominal pain, bilious vomiting and alteration of general condition. Physical examination showed hemodynamic shock with diffuse abdominal tenderness. The Laboratory results showed a serum lipase of 546 U/l (higher than 6 times the upper limit of normal), a severe hypertriglyceridemia at 94 g/l and hypercholesterolemia at 11 g/l. Abdominal ultrasound did not show lithiasis, abdominal CT scan revealed Balthazar grade E pancreatitis and magnetic resonance cholangiopancreatography (MRCP) did not show microlithiasis of the gallbladder and biliary ducts. Pancreatic autoantibodies were negative. The diagnosis of acute pancreatitis due to major hypertriglyceridemia was made. The patient was managed with fasting, intravenous hydration, heparin and fibrate therapy. The evolution was marked by a clinico-biological improvement.

Discussion

The association between acute pancreatitis and HTG is widely recognized. It presents 12-38% of all acute pancreatitis. The symptomatology of this acute pancreatitis is unremarkable. The management of major hypertriglyceridemia is based on symptomatic treatment combining effective analgesia, parenteral nutrition, adequate hydration and lipid-free nutrition. Other therapies have been reported, such as heparin infusion and insulin. Plasma exchange may be useful, although its clinical efficacy has not been proven.

Conclusion

Hypertriglyceridemia is a rare cause of acute pancreatitis. It requires specific treatment to overcome the acute phase and prevent recurrence.

EP346

A new case of hypoglycemia of unrelated etiology.

Daniel Medina Rivero[1], Isabel Mateo Gavira[2] & Esteban Sánchez Toscano[2]
[1]Hospital Universitario Puerta del Mar, San Fernando, Spain; [2]Hospital Universitario Puerta del Mar, Cádiz, Spain

Male, 29 years old. Go to consultations in our center for a second opinion for assessment of hypoglycemia. The patient has reported, for 3 years, symptoms consisting of episodes of dizziness and headache predominantly during the day, which subside after eating food, and which increase in frequency in relation to exercise. He provides capillary glycaemia objectified in family glucometer between 40-70 mg / dl coinciding with the episodes. The patient was initially treated at another center, which after a study (04/2012: glucose 62 mg/dl, insulin 5.89 mcIU/ml, C-peptide 4.5 ng/ml, TSH 1.93 mcIU/ml, HGH 0.09 ng/ml, IGF-1 264 ng/ml, basal cortisol 16.09 mcg/dl) is classified as reactive hypoglycemia and hygienic-dietary measures are prescribed by means of a divided diet and avoiding the intake of rapidly absorbed carbohydrates. We admitted the patient to perform a fasting test (07/2012), which was positive at 30 hours (glycemia 36 mg/dl, insulin 4.46 mcIU/ml, C-peptide 1.51 ng/ml) compatible with hyperinsulinemic hypoglycemia. Treatment with diazoxide 100 mg 1-0-1 was prescribed at discharge. A localization study consisting of an abdominal CT scan was performed, which revealed a doubtful 1.4 cm lesion in the body of the pancreas. It is completed with pancreatic MRI that does not describe the lesion mentioned in the CT. To determine the etiology, the patient was admitted on 09/2012 to perform an arterial calcium stimulation test by selective pancreatic catheterization, which was negative for insulinoma, since only a 21% increase in blood insulin was observed in the splenic artery and no it is observed in the rest (hepatic or superior mesenteric). It is decided in principle management with medical treatment and follow-up with imaging tests. It is performed during the same CT scan of the pancreas every 2 years and 2 echoendoscopies. In the last ultrasound endoscopy performed (10/2017), pancreatic lesions compatible with insulinoma were still not observed. There is talk of diffuse ultrasound changes in pancreatic tissue, to rule out nesidioblastosis. The patient remains relatively controlled with medical treatment and pancreatic surgery is not proposed.

EP347

The efficacy of liraglutide for weight loss in a patient with relapse in obesity after bariatric surgery – case report

Anna Dabrowska[1,2] & Jaroslaw Dudka[1]
[1]Medical University of Lublin, Department of Toxicology, Lublin, Poland; [2]Endocrinology Outpatient Clinic, Lublin, Poland

Introduction

Obesity is a chronic disease which has become a global epidemic. Approximately 7% of deaths per year is associated with obesity, especially because of its complications such as cardiovascular diseases, type 2 diabetes or cancer. Lifestyle interventions are the first line of management but additional pharmacotherapy or bariatric surgery should be considered in more severe cases.

Case report

A 40-year-old woman was referred to Endocrinology Outpatient Clinic because of severe obesity. She underwent laparoscopic sleeve gastrectomy few years ago which led to weight loss. However, a return to unhealthy eating habits as well as an insufficient physical activity, have caused obesity recurrence. The patient has been treated with metformin 1 g because of insulin resistance, perindopril 5 mg due to hypertension and venlafaxine 150 mg because of depression. Despite of metformin implementation, diet and activity interventions, the reduction of weight has not been achieved. At the first endocrinology consultation, the patient had a body weight of 124 kg and a body mass index of 43.97 kg/m^2. Blood pressure was 137/85 mmHg under treatment. The laboratory tests revealed normal liver and renal function. The pituitary function (corticotropic, thyroid, gonadal, and somatotroph axes) was also confirmed as normal. US abdomen examination showed signs of hepatic steatosis and lack of gall bladder which has been removed due to cholelithiasis. Fasting laboratory test results showed: total cholesterol of 183.0 mg/dl, LDL-cholesterol of 110.2 mg/dl, triglycerides of 109.0 mg/dl, HDL-cholesterol of 51 mg/dl. Oral glucose tolerance test at time 0-60-120 min, after a 2-week break in the use of metformin, revealed glucose levels: 100-278-99 mg/dl and insulin levels 10.8-75.9-18.4 μUI/ml, with mild insulin resistance at fasting (HOMA-IR 2.67). Thus, considering severe obesity, unresponsive to diet and lifestyle interventions, complicated by hypertension, impaired fasting glucose, hepatic steatosis and depression, a GLP1-receptor agonist therapy with liraglutide has been proposed, from a starting dose at 0.6 mg up to a final dose at 3.0 mg per day. No side effects have been registered during therapy so far. At the last follow-up visit, four months after introducing liraglutide, the patients' weight was 108 kg (BMI 38.29 kg/m^2), with a total weight loss of 16 kg (-12.9%).

Conclusions

Liraglutide effectively reduces body weight and may be a safe option of treatment in patients with severe obesity. It should be also considered in subjects with obesity recurrence after bariatric surgery, as an alternative management to reoperation.

Assessment of the Podiatric Risk on Diabetics: Cross-Sectional Study in Regard to 200 Patients

El Amri Abir[1], Nadia Ben Amor[1], Rihab Yamoun[2], Faten Mahjoub[2], Sirine Nsir[3], Amany Amorri[3], Ramla Mizouri[1], Rym Ben Othman[1], Olfa Berriche[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Tunisia; [2]Faculty of Medicine Of Tunis, Tunisia; [3]University of Tunis El Manar, Tunisia

Introduction
The diabetic foot is a frequent, serious and costly complication of diabetes. The prevention of diabetic foot involves a systematic podiatric evaluation of diabetic patients to identify the foot at risk. The aim of our study was to determine the podiatric risk in a Tunisian diabetic population according to the classification of the International Working Group on the Diabetic Foot (IWGDF) and the factors associated with podiatric risk.
Methods
It was a prospective cross-sectional, descriptive and analytical study conducted over a three-month period including patients aged 18 years and older with a confirmed diagnosis of type 1 and type 2 diabetes, hospitalized in nutrition department A between 1 August and 31 October 2021. Subjects under 18 years of age or hospitalized for conditions other than diabetes were excluded from the study.
Results
The study enrolled 200 patients and the sex-ratio was 0.72. The average age of the cohort was 53 years. 74.2% of the patients were running type 2 diabetes. Of them, 75% had dyslipidemia and 82% were overweight or obese. High Blood Pressure was found in 51% of cases. The capillary blood glucose and glycated hemoglobin were respectively around 12.26 mmol/l and 10.8%. Prior ulceration and/or amputation were noted in 9% of cases. The gradation of the foot risk according to the International Working Group on the Diabetic Foot (IWGDF) was established as follow: grade 0 (76.3%), grade 1 (12.6%), grade 2 (6.3%), grade 3 (4.8%). Risk factors most associated with foot injury occurrence included diabetic peripheral neuropathy ($P = 0.000$), the absence of pulse perception ($P = 0.000$), chronic peripheral artery occlusive disease (PAOD) ($P = 0.000$), diabetic retinopathy ($P = 0.002$) and diabetic nephropathy ($P = 0.017$).
Conclusion
